About this book

This book describes DB2® for Linux, UNIX, and Windows support for Java™. This support lets you access relational databases from Java application programs.

Who should use this book

This book is for the following users:

• DB2 for Linux, UNIX, and Windows application developers who are familiar with Structured Query Language (SQL) and who know the Java programming language.
• DB2 for Linux, UNIX, and Windows system programmers who are installing JDBC and SQLJ support.
Chapter 1. Java application development for IBM data servers

The DB2 and IBM® Informix® database systems provide driver support for client applications and applets that are written in Java.

You can access data in DB2 and IBM Informix database systems using JDBC, SQL, or pureQuery.

JDBC

JDBC is an application programming interface (API) that Java applications use to access relational databases. IBM data server support for JDBC lets you write Java applications that access local DB2 or IBM Informix data or remote relational data on a server that supports DRDA®.

SQLJ

SQLJ provides support for embedded static SQL in Java applications. SQLJ was initially developed by IBM, Oracle, and Tandem to complement the dynamic SQL JDBC model with a static SQL model.

For connections to DB2, in general, Java applications use JDBC for dynamic SQL and SQLJ for static SQL.

For connections to IBM Informix, SQL statements in JDBC or SQLJ applications run dynamically.

Because SQLJ can inter-operate with JDBC, an application program can use JDBC and SQLJ within the same unit of work.

pureQuery

pureQuery is a high-performance data access platform that makes it easier to develop, optimize, secure, and manage data access. It consists of:

- Application programming interfaces that are built for ease of use and for simplifying the use of best practices
- Development tools, which are delivered in IBM InfoSphere® Optim™ Development Studio, for Java and SQL development
- A runtime, which is delivered in IBM InfoSphere Optim pureQuery Runtime, for optimizing and securing database access and simplifying management tasks

With pureQuery, you can write Java applications that treat relational data as objects, whether that data is in databases or JDBC DataSource objects. Your applications can also treat objects that are stored in in-memory Java collections as though those objects are relational data. To query or update your relational data or Java objects, you use SQL.

For more information on pureQuery, see the Integrated Data Management Information Center.
Supported drivers for JDBC and SQLJ

The DB2 product includes support for two types of JDBC driver architecture.

According to the JDBC specification, there are four types of JDBC driver architectures:

**Type 1**
Drivers that implement the JDBC API as a mapping to another data access API, such as Open Database Connectivity (ODBC). Drivers of this type are generally dependent on a native library, which limits their portability. The DB2 database system does not provide a type 1 driver.

**Type 2**
Drivers that are written partly in the Java programming language and partly in native code. The drivers use a native client library specific to the data source to which they connect. Because of the native code, their portability is limited.

**Type 3**
Drivers that use a pure Java client and communicate with a data server using a data-server-independent protocol. The data server then communicates the client's requests to the data source. The DB2 database system does not provide a type 3 driver.

**Type 4**
Drivers that are pure Java and implement the network protocol for a specific data source. The client connects directly to the data source.

DB2 for Linux, UNIX, and Windows supports the following driver:

<table>
<thead>
<tr>
<th>Driver name</th>
<th>Packaged as</th>
<th>Driver type</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM Data Server Driver for JDBC and SQLJ</td>
<td><em>db2jcc.jar and sqjl.zip for JDBC 3.0 support</em>&lt;br&gt;<em>db2jcc4.jar and sqjl4.zip for support of some JDBC 4.0 or later functions</em></td>
<td>Type 2 and Type 4</td>
</tr>
</tbody>
</table>

**IBM Data Server Driver for JDBC and SQLJ (type 2 and type 4)**

The IBM Data Server Driver for JDBC and SQLJ is a single driver that includes JDBC type 2 and JDBC type 4 behavior. When an application loads the IBM Data Server Driver for JDBC and SQLJ, a single driver instance is loaded for type 2 and type 4 implementations. The application can make type 2 and type 4 connections using this single driver instance. The type 2 and type 4 connections can be made concurrently. IBM Data Server Driver for JDBC and SQLJ type 2 driver behavior is referred to as *IBM Data Server Driver for JDBC and SQLJ type 2 connectivity*. IBM Data Server Driver for JDBC and SQLJ type 4 driver behavior is referred to as *IBM Data Server Driver for JDBC and SQLJ type 4 connectivity*. 
Two versions of the IBM Data Server Driver for JDBC and SQLJ are available. IBM Data Server Driver for JDBC and SQLJ version 3.5x is JDBC 3.0-compliant. IBM Data Server Driver for JDBC and SQLJ version 4.x is compliant with JDBC 4.0 or later.

The IBM Data Server Driver for JDBC and SQLJ supports these JDBC and SQLJ functions:

- Version 3.5x supports all of the methods that are described in the JDBC 3.0 specifications.
- Version 4.x supports all of the methods that are described in the JDBC 4.0 or later specifications.
- SQLJ application programming interfaces, as defined by the SQLJ standards, for simplified data access from Java applications.
- Connections that are enabled for connection pooling. WebSphere® Application Server or another application server does the connection pooling.
- Connections to a data server from Java user-defined functions and stored procedures use IBM Data Server Driver for JDBC and SQLJ type 2 connectivity only. Applications that call user-defined functions or stored procedures can use IBM Data Server Driver for JDBC and SQLJ type 2 connectivity or IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to connect to a data server. The IBM Data Server Driver for JDBC and SQLJ is the default driver for Java routines.
- Support for distributed transaction management. This support implements the Java 2 Platform, Enterprise Edition (J2EE) Java Transaction Service (JTS) and Java Transaction API (JTA) specifications, which conform to the X/Open standard for distributed transactions (Distributed Transaction Processing: The XA Specification, available from http://www.opengroup.org).

**JDBC driver and database version compatibility**

The compatibility of a particular version of the IBM Data Server Driver for JDBC and SQLJ with a database version depends on the type of driver connectivity that you are using and the type of data source to which you are connecting.

**Compatibility for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity**

The IBM Data Server Driver for JDBC and SQLJ is always downward compatible with DB2 databases at the previous release level. For example, IBM Data Server Driver for JDBC and SQLJ type 4 connectivity from the IBM Data Server Driver for JDBC and SQLJ version 3.61, which is shipped with DB2 for Linux, UNIX, and Windows Version 9.7 Fix Pack 3, to a DB2 for Linux, UNIX, and Windows Version 8 database is supported.

The IBM Data Server Driver for JDBC and SQLJ is upward compatible with the next version of a DB2 database if the applications under which the driver runs use no new features. For example, IBM Data Server Driver for JDBC and SQLJ type 4 connectivity from the IBM Data Server Driver for JDBC and SQLJ version 2.x, which is shipped with DB2 for z/OS® Version 8, to a DB2 for z/OS Version 9.1 database is supported, if the applications under which the driver runs contain no DB2 for z/OS Version 9.1 features.

IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to IBM Informix is supported only for IBM Informix Version 11 and later.
Compatibility for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity

In general, IBM Data Server Driver for JDBC and SQLJ type 2 connectivity is intended for connections to the local database system, using the driver version that is shipped with that database version. For example, version 3.6x of the IBM Data Server Driver for JDBC and SQLJ is shipped with DB2 for Linux, UNIX, and Windows Version 9.5 and Version 9.7, and DB2 for z/OS Version 8 and later.

However, for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to a local DB2 for Linux, UNIX, and Windows database, the database version can be one version earlier or one version later than the DB2 for Linux, UNIX, and Windows version with which the driver was shipped. For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to a local DB2 for z/OS subsystem, the subsystem version can be one version later than the DB2 for z/OS version with which the driver was shipped.

If the database version to which your applications are connecting is later than the database version with which the driver was shipped, the applications cannot use features of the later database version.

“Supported drivers for JDBC and SQL” on page 2

DB2 for Linux, UNIX, and Windows and IBM Data Server Driver for JDBC and SQLJ levels

Each version of DB2 for Linux, UNIX, and Windows is shipped with a JDBC 3 version and a JDBC 4 version of the IBM Data Server Driver for JDBC and SQLJ.

The following table lists the DB2 for Linux, UNIX, and Windows versions and corresponding IBM Data Server Driver for JDBC and SQLJ versions. You can use this information to determine the level of DB2 for Linux, UNIX, and Windows or DB2 Connect™ that is associated with the IBM Data Server Driver for JDBC and SQLJ instance under which a client program is running.

Table 1. DB2 for Linux, UNIX, and Windows fix pack levels and versions of the IBM Data Server Driver for JDBC and SQLJ

<table>
<thead>
<tr>
<th>DB2 version and fix pack level</th>
<th>IBM Data Server Driver for JDBC and SQLJ version</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2 Version 10.5</td>
<td>3.66.xx, 4.16.xx</td>

</tbody>
</table>

Note:

1. All driver versions are of the form n.m.xx. n.m stays the same within a GA level or a fix pack level. xx changes when a new version of the IBM Data Server Driver for JDBC and SQLJ is introduced through an APAR fix.

You can find more detailed information about IBM Data Server Driver for JDBC and SQLJ and DB2 for Linux, UNIX, and Windows versions at the following URL:

http://www.ibm.com/support/docview.wss?uid=swg21363866
Chapter 2. Installing the IBM Data Server Driver for JDBC and SQLJ

After you install the IBM Data Server Driver for JDBC and SQLJ, you can prepare and run JDBC or SQLJ applications.

Before you install the IBM Data Server Driver for JDBC and SQLJ, you need the following software.

- An SDK for Java, 1.4.2 or later.
  For all DB2 products except the IBM Data Server Runtime Client and the IBM Data Server Driver Package, the DB2 for Linux, UNIX, and Windows installation process automatically installs the SDK for Java, Version 5.
  If you want to use JDBC 4.0 functions, you need to install an SDK for Java, 6 or later.
  If you want to use JDBC 4.1 functions, you need to install an SDK for Java, 7 or later.
  If you plan to run JDBC or SQLJ applications on your system, but not to prepare them, you need a Java run-time environment only.

  **Important:** Support for the SDK for Java 1.4.2 is deprecated for Java routines, and might be discontinued in a future release.

- JVM native threads support
  Any JVMs that run Java applications that access DB2 databases must include native threads support. You can specify native threads as the default thread support for some JVMs by setting the THREADS_FLAG environment variable to "native". Refer to the documentation for your Java environment for instructions on making native threads the default on your system.

- Unicode support for System i® servers
  If any SQLJ or JDBC programs will use IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to connect to a DB2 for i server, the System i operating system must support the Unicode UTF-8 encoding scheme. The following table lists the System i PTFs that you need for Unicode UTF-8 support:

<table>
<thead>
<tr>
<th>System i version</th>
<th>PTF numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>V5R3 or later</td>
<td>None (support is included)</td>
</tr>
</tbody>
</table>

- Java support for HP-UX clients and servers
  **HP-UX servers:** The IBM Data Server Driver for JDBC and SQLJ does not support databases that are in the HP-UX default character set, Roman8. Therefore, when you create a database on an HP-UX server that you plan to access with the IBM Data Server Driver for JDBC and SQLJ, you need to create the database with a different character set.
  **HP-UX clients and servers:** The Java environment on an HP-UX system requires special setup to run stored procedures under the IBM Data Server Driver for JDBC and SQLJ.

  **Restriction:** If you install the IBM Data Server Driver for JDBC and SQLJ on a Windows 64-bit operating system, you cannot use IBM Data Server Driver for
JDBC and SQLJ type 2 connectivity to connect to a DB2 for Linux, UNIX, and Windows instance from a 32-bit Java application.

Follow these steps to install the IBM Data Server Driver for JDBC and SQLJ.

1. During the DB2 for Linux, UNIX, and Windows installation process, select Java support on UNIX or Linux, or JDBC support on Windows. These selections are defaults. If you have already installed DB2 for Linux, UNIX, and Windows without JDBC support, you can run the installation process in Custom mode to add JDBC support.

   Selection of Java support or JDBC support causes the installation process to perform the following actions:

   a. Installs the IBM Data Server Driver for JDBC and SQLJ class files.

      The files are placed in the sqllib\java directory for Windows systems, or the sqllib/java directory for UNIX or Linux systems.

      The files names are:

      db2jcc.jar or db2jcc4.jar

         Include db2jcc.jar in the CLASSPATH if you plan to use the version of the IBM Data Server Driver for JDBC and SQLJ that includes only JDBC 3.0 or earlier functions.

         Include db2jcc4.jar in the CLASSPATH if you plan to use the version of the IBM Data Server Driver for JDBC and SQLJ that includes JDBC 4.0 or later functions, and JDBC 3.0 or earlier functions.

      sqlj.zip or sqlj4.zip

         Include sqlj.zip in the CLASSPATH if you plan to prepare SQLJ applications that include only JDBC 3.0 or earlier functions.

         Include sqlj4.zip in the CLASSPATH if you plan to prepare SQLJ applications that include JDBC 4.0 or later functions, and JDBC 3.0 or earlier functions.

   b. Modifies the CLASSPATH to include the IBM Data Server Driver for JDBC and SQLJ class files.

      Important: This step is performed automatically only for the db2jcc.jar and sqlj.zip file. If you are using the db2jcc4.jar file or the sqlj4.zip file, you must modify the CLASSPATH manually. Change db2jcc.jar to db2jcc4.jar or sqlj.zip to sqlj4.zip in the CLASSPATH.

      You also need to make this change in every DB2 command line window that you open.

      Important: Include db2jcc.jar or db2jcc4.jar in the CLASSPATH. Do not include both files.

      Important: Include sqlj.zip or sqlj4.zip in the CLASSPATH. Do not include both files. Do not include db2jcc.jar with sqlj4.zip, or db2jcc4.jar with sqlj.zip.

   c. If IBM Data Server Driver for JDBC and SQLJ client license files exist, the installation process installs them and modifies the CLASSPATH to include them.

      The files are placed in the sqllib\java directory for Windows systems, or the sqllib/java directory for UNIX or Linux systems. The file names are:
Table 3. IBM Data Server Driver for JDBC and SQLJ license files

<table>
<thead>
<tr>
<th>License file</th>
<th>Server to which license file permits a connection</th>
<th>Product that includes license file</th>
</tr>
</thead>
</table>
| db2jcc_license_cisuz.jar | DB2 for z/OS  
DB2 for i | All DB2 Connect products |

Client license files are not required for connections to DB2 for Linux, UNIX, and Windows, Cloudscape, or IBM Informix databases from the IBM Data Server Driver for JDBC and SQLJ version 3.50 or later. Client license files are not required for direct connections to DB2 for z/OS if DB2 Connect Unlimited Edition for System z® server license activation is performed.

**Recommendation:** If you connect to DB2 for z/OS data servers directly, rather than through a DB2 Connect gateway, and you use DB2 Connect Unlimited Edition for System z 9.7 Fix Pack 3 or later, you should activate the server license key for DB2 Connect Unlimited Edition for System z. You need to activate the license key on each DB2 for z/OS subsystem or data sharing group to which you will connect. See the DB2 Connect information for details on server license activation.

d. Installs IBM Data Server Driver for JDBC and SQLJ native libraries for support of IBM Data Server Driver for JDBC and SQLJ type 2 connectivity. The files are placed in the sqllib\bin directory for Windows systems, or the sqllib/lib directory for UNIX or Linux systems. The file names are:

- **libdb2jctt2.so**  
  For AIX®, HP-UX on IPF, Linux, and Solaris
- **db2jctt2.dll**  
  For Windows

As an alternative to installing the IBM Data Server Driver for JDBC and SQLJ class files during installation, you can download the class files, and follow the steps above to configure the driver. You cannot download the IBM Data Server Driver for JDBC and SQLJ type 2 connectivity native libraries. To download the IBM Data Server Driver for JDBC and SQLJ class files, follow these steps:

- Under Downloads and fixes, select View IBM Data Server Client Packages...
- In the Refine my fix list window, select Show me more options.
- On the Fix Central page, select Information Management in the Product Group field, IBM Data Server Client Packages in the Product field, the latest version in the Installed Version field, and All in the Platform field.
- On the Identify fixes page, type "Data Server Driver for JDBC" in the Text field.
- On the Select fixes page, select the latest version of the IBM Data Server Driver for JDBC and SQLJ.
- On the Download options page, select the options that are appropriate for you.
- Extract the zip file into an empty directory.

The zip file contains the following files:

Chapter 2. Installing the IBM Data Server Driver for JDBC and SQLJ 9
- db2jcc.jar
- db2jcc4.jar
- sqlj.zip
- sqlj4.zip

- Copy the files to the locations that are specified in step 1a on page 8 above.

After you have downloaded the IBM Data Server Driver for JDBC and SQLJ class files, you need to follow the entire procedure that is described in this topic to install the driver.

2. Customize the driver-wide configuration properties, if any of the defaults are inappropriate.

3. Configure TCP/IP.

Servers must be configured for TCP/IP communication in the following cases:
- JDBC or SQLJ applications that use IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.
- JDBC or SQLJ applications that use IBM Data Server Driver for JDBC and SQLJ type 2 connectivity, and specify server and port in the connection URL.

Ensure that the TCP/IP listener is running. To activate the TCP/IP listener:

a. Set the environment variable DB2COMM to TCPIP:
   ```
   db2set DB2COMM=TCPIP
   ```

b. Update the database manager configuration file with the TCP/IP service name as specified in the services file:
   ```
   db2 update dbm cfg using SVCENAME TCP/IP-service-name
   ```

   The port number used for applets and SQLJ programs needs to be the same as the TCP/IP SVCENAME number used in the database manager configuration file.

c. Execute the db2stop and db2start commands for the service name setting to take effect.

4. On DB2 for Linux, UNIX, and Windows servers on which you plan to run Java stored procedures or user-defined functions, update the database manager configuration to include the path where the SDK for Java is located.

You can do this by entering commands similar to these on the server command line:

- For database systems on UNIX or Linux:
  ```
  db2 update dbm cfg using JDK_PATH /home/db2inst/jdk15
  ```

  `/home/db2inst/jdk15` is the path where the SDK for Java is installed.

- For database systems on Windows:
  ```
  db2 update dbm cfg using JDK_PATH c:\Program Files\jdk15
  ```

  `c:\Program Files\jdk15` is the path where the SDK for Java is installed.

To verify the correct value for the JDK_PATH field in the DB2 database manager configuration, enter the following command on the database server:

```
db2 get dbm cfg
```

You might want to redirect the output to a file for easier viewing. The JDK_PATH field appears near the beginning of the output.
5. If you plan to call SQL procedures that are on DB2 for Linux, UNIX, and Windows servers from Java programs, and the date and time format that is associated with the territory code of the database servers is **not** the USA format, take the following actions:
   
a. Set the `DB2_SQLROUTINE_PREPOPTS` registry variable on the database servers to indicate that the default datetime format is ISO:
      
      ```
db2set DB2_SQLROUTINE_PREPOPTS="DATETIME ISO"
      ```
   
b. Redefine any existing SQL procedures that you plan to call from Java programs.

   These steps are necessary to ensure that the calling application receives date and time values correctly.

6. If you plan to access DB2 for z/OS database servers with your Java applications, follow the instructions in "Special setup for accessing DB2 for z/OS servers from Java programs" in *Developing Java Applications*.

---

**DB2Binder utility**

The DB2Binder utility binds the DB2 packages that are used at the data server by the IBM Data Server Driver for JDBC and SQLJ, and grants EXECUTE authority on the packages to PUBLIC. Optionally, the DB2Binder utility can rebind DB2 packages that are not part of the IBM Data Server Driver for JDBC and SQLJ.

**DB2Binder syntax**

```java
java com.ibm.db2.jcc.DB2Binder -url jdbc://server://database

-user user-ID -password password
-size integer
-action action

-collection collection-name
-tracelevel trace-option
-action action

-blocking all
-blocking unambig
-blocking no

-optprofile profile-name

-owner authorization-ID
-generic

-package package-name
-version version-id
-keepdynamic no
-keepdynamic yes
```
DB2Binder option descriptions

-url
Specifies the data source at which the IBM Data Server Driver for JDBC and SQLJ packages are to be bound. The variable parts of the -url value are:

server
The domain name or IP address of the operating system on which the data server resides.

port
The TCP/IP server port number that is assigned to the data server. The default is 446.

database
The location name for the data server, as defined in the SYSIBM.LOCATIONS catalog table.

-user
Specifies the user ID under which the packages are to be bound. This user must have BIND authority on the packages.

-action
Specifies the action to perform on the packages.

add
Indicates that a package can be created only if it does not already exist. Add is the default.

replace
Indicates that a package can be created even if a package with the same name already exists. The new package replaces the old package.

rebind
Indicates that the existing package should be rebound. This option does not apply to IBM Data Server Driver for JDBC and SQLJ packages. If -action rebind is specified, -generic must also be specified.

drop
Indicates that packages should be dropped:
- For IBM Data Server Driver for JDBC and SQLJ packages, -action drop indicates that some or all IBM Data Server Driver for JDBC and SQLJ packages should be dropped. The number of packages depends on the -size parameter.
- For user packages, -action drop indicates that the specified package should be dropped.

-action drop applies only if the target data server is DB2 for z/OS.

-size
Controls the number of Statement, PreparedStatement, or CallableStatement objects that can be open concurrently, or the number of IBM Data Server Driver for JDBC and SQLJ packages that are dropped.

The meaning of the -size parameter depends on the -action parameter:
If the value of -action is add or replace, the value of -size is an integer that is used to calculate the number of DB2 packages that the IBM Data Server Driver for JDBC and SQLJ binds. If the value of -size is integer, the total number of packages is:

\[
\text{number-of-isolation-levels} \times \text{number-of-holdability-values} \times \text{integer} + \text{number-of-packages-for-static-SQL} = 4 + 2 \times \text{integer} + 1
\]

The default -size value for -action add or -action replace is 3.

In most cases, the default of 3 is adequate. If your applications throw SQLExceptions with -805 SQLCODEs, check that the applications close all unused resources. If they do, increase the -size value.

If the value of -action is replace, and the value of -size results in fewer packages than already exist, no packages are dropped.

If the value of -action is drop, the value of -size is the number of packages that are dropped. If -size is not specified, all IBM Data Server Driver for JDBC and SQLJ packages are dropped.

If the value of -action is rebind, -size is ignored.

- **collection**
  Specifies the collection ID for IBM Data Server Driver for JDBC and SQLJ or user packages. The default is NULLID. DB2Binder translates this value to uppercase.
  
  You can create multiple instances of the IBM Data Server Driver for JDBC and SQLJ packages on a single data server by running `com.ibm.db2.jcc.DB2Binder` multiple times, and specifying a different value for -collection each time. At run time, you select a copy of the IBM Data Server Driver for JDBC and SQLJ by setting the `currentPackageSet` property to a value that matches a -collection value.

- **tracelevel**
  Specifies what to trace while DB2Binder runs.

- **reopt**
  Specifies whether data servers determine access paths at run time. This option is not sent to the data server if it is not specified. In that case, the data server determines the reoptimization behavior.
  
  -reopt applies to connections to DB2 for z/OS Version 8 or later, or DB2 for Linux, UNIX, and Windows Version 9.1 or later.

  - **none** Specifies that access paths are not determined at run time.

  - **always** Specifies that access paths are determined each time a statement is run.

  - **once** Specifies that DB2 determines and caches the access path for a dynamic statement only once at run time. DB2 uses this access path until the prepared statement is invalidated, or until the statement is removed from the dynamic statement cache and needs to be prepared again.

  - **auto** Specifies that access paths are automatically determined by the data server. auto is valid only for connections to DB2 for z/OS data servers.

- **blocking**
  Specifies the type of row blocking for cursors.
ALL For cursors that are specified with the FOR READ ONLY clause or are not specified as FOR UPDATE, blocking occurs.

UNAMBIG
For cursors that are specified with the FOR READ ONLY clause, blocking occurs.

Cursors that are not declared with the FOR READ ONLY or FOR UPDATE clause which are not ambiguous and are read-only will be blocked. Ambiguous cursors will not be blocked.

NO Blocking does not occur for any cursor.

For the definition of a read-only cursor and an ambiguous cursor, refer to "DECLARE CURSOR".

-optprofile
Specifies an optimization profile that is used for optimization of data change statements in the packages. This profile is an XML file that must exist on the target server. If -optprofile is not specified, and the CURRENT OPTIMIZATION PROFILE special register is set, the value of CURRENT OPTIMIZATION PROFILE is used. If -optprofile is not specified, and CURRENT OPTIMIZATION PROFILE is not set, no optimization profile is used.

-optprofile is valid only for connections to DB2 for Linux, UNIX, and Windows data servers.

-owner
Specifies the authorization ID of the owner of the packages. The default value is set by the data server.

-owner applies only to IBM Data Server Driver for JDBC and SQLJ packages.

-sqlid
Specifies a value to which the CURRENT SQLID special register is set before DB2Binder executes GRANT operations on the IBM Data Server Driver for JDBC and SQLJ packages. If the primary authorization ID does not have a sufficient level of authority to grant privileges on the packages, and the primary authorization ID has an associated secondary authorization ID that has those privileges, set -sqlid to the secondary authorization ID.

-sqlid is valid only for connections to DB2 for z/OS data servers.

-generic
Specifies that DB2Binder rebinds a user package instead of the IBM Data Server Driver for JDBC and SQLJ packages. If -generic is specified, -action rebind and -package must also be specified.

-package
Specifies the name of the package that is to be rebound. This option applies only to user packages. If -package is specified, -action rebind and -generic must also be specified.

-version
Specifies the version ID of the package that is to be rebound. If -version is specified, -action rebind, -package, and -generic must also be specified.

-keepdynamic
Specifies whether the data server keeps already prepared dynamic SQL statements in the dynamic statement cache after commit points, so that those prepared statements can be reused. -keepdynamic applies only to connections to DB2 for z/OS. Possible values are:
**no**  The data server does not keep already prepared dynamic SQL statements in the dynamic statement cache after commit points.

**yes**  The data server keeps already prepared dynamic SQL statements in the dynamic statement cache after commit points.

There is no default value for -keepdynamic. If you do not send a value to the data server, the setting at the data server determines whether dynamic statement caching is in effect. Dynamic statement caching occurs only if the EDM dynamic statement cache is enabled on the data server. The CACHEDYN subsystem parameter must be set to YES to enable the dynamic statement cache.

**-release**
Specifies when to release data server resources that a program uses. -release applies only to connections to DB2 for z/OS. Possible values are:

- **deallocate**
  Specifies that resources are released when a program terminates. 
  -release deallocate is the default for DB2 for z/OS Version 10 and later.

- **commit**
  Specifies that resources are released at commit points. -release commit is the default for DB2 for z/OS Version 9 and earlier.

**-bindoptions**
Specifies a string that is enclosed in quotation marks. The contents of that string are one or more parameter and value pairs that represent options for rebinding a user package. All items in the string are delimited with spaces: 

"parm1 value1 parm2 value2 ... parmn valuen"

-bindoptions does not apply to IBM Data Server Driver for JDBC and SQLJ packages.

You can specify the following special parameters:

**bindObjectExistenceRequired**
Specifies whether the data server issues an error and does not rebind the package, if all objects or needed privileges do not exist at rebind time. Possible values are:

- **true**  This option corresponds to the SQLERROR(NOPACKAGE) bind option.
- **false**  This option corresponds to the SQLERROR(CONTINUE) bind option.

**degreeIOParallelism**
Specifies whether to attempt to run static queries using parallel processing to maximize performance. Possible values are:

- **1**  No parallel processing.
  - This option corresponds to the DEGREE(1) bind option.
  -1  Allow parallel processing.
  - This option corresponds to the DEGREE(ANY) bind option.

**packageAuthorizationRules**
Determines the values that apply at run time for the following dynamic SQL attributes:

- The authorization ID that is used to check authorization
• The qualifier that is used for unqualified objects
• The source for application programming options that the data server uses to parse and semantically verify dynamic SQL statements
• Whether dynamic SQL statements can include GRANT, REVOKE, ALTER, CREATE, DROP, and RENAME statements

Possible values are:

0  Use run behavior. This is the default.
   This option corresponds to the DYNAMICRULES(RUN) bind option.

1  Use bind behavior.
   This option corresponds to the DYNAMICRULES(BIND) bind option.

2  When the package is run as or runs under a stored procedure or user-defined function package, the data server processes dynamic SQL statements using invoke behavior. Otherwise, the data server processes dynamic SQL statements using run behavior.
   This option corresponds to the DYNAMICRULES(INVOKERUN) bind option.

3  When the package is run as or runs under a stored procedure or user-defined function package, the data server processes dynamic SQL statements using invoke behavior. Otherwise, the data server processes dynamic SQL statements using bind behavior.
   This option corresponds to the DYNAMICRULES(INVOKEBIND) bind option.

4  When the package is run as or runs under a stored procedure or user-defined function package, the data server processes dynamic SQL statements using define behavior. Otherwise, the data server processes dynamic SQL statements using run behavior.
   This option corresponds to the DYNAMICRULES(DEFINERUN) bind option.

5  When the package is run as or runs under a stored procedure or user-defined function package, the data server processes dynamic SQL statements using define behavior. Otherwise, the data server processes dynamic SQL statements using bind behavior.
   This option corresponds to the DYNAMICRULES(DEFINEBIND) bind option.

packageOwnerIdentifier
   Specifies the authorization ID of the owner of the packages.

isolationLevel
   Specifies how far to isolate an application from the effects of other running applications. Possible values are:

1  Uncommitted read
   This option corresponds to the ISOLATION(UR) bind option.
2 Cursor stability
   This option corresponds to the ISOLATION(CS) bind option.
3 Read stability
   This option corresponds to the ISOLATION(RS) bind option.
4 Repeatable read
   This option corresponds to the ISOLATION(RR) bind option.

releasePackageResourcesAtCommit
   Specifies when to release resources that a program uses at each commit point. Possible values are:
   true   This option corresponds to the RELEASE(COMMIT) bind option.
   false  This option corresponds to the RELEASE(DEALLOCATE) bind option.

If -bindoptions is specified, -generic must also be specified.

-verbose
   Specifies that the DB2Binder utility displays detailed information about the bind process.

-help
   Specifies that the DB2Binder utility describes each of the options that it supports. If any other options are specified with -help, they are ignored.

DB2Binder return codes when the target operating system is not Windows

If the target data source for DB2Binder is not on the Windows operating system, DB2Binder returns one of the following return codes.

### Related tasks:

- Chapter 2, “Installing the IBM Data Server Driver for JDBC and SQLJ,” on page 7

#### DB2LobTableCreator utility

The DB2LobTableCreator utility creates tables on a DB2 for z/OS database server. Those tables are required by JDBC or SQLJ applications that use LOB locators to access data in DBCLOB or CLOB columns.

#### DB2LobTableCreator syntax

```bash
java -jar com.ibm.db2.jcc.DB2LobTableCreator -url jdbc:db2://server:port/database -user user-ID -password password
```

#### DB2LobTableCreator option descriptions

- `-url`
  Specifies the data source at which DB2LobTableCreator is to run. The variable parts of the `-url` value are:
jdbc:db2:
Indicates that the connection is to a server in the DB2 family.

server
The domain name or IP address of the database server.

port
The TCP/IP server port number that is assigned to the database server.
This is an integer between 0 and 65535. The default is 446.

database
A name for the database server.
database is the DB2 location name that is defined during installation. All
characters in this value must be uppercase characters. You can determine
the location name by executing the following SQL statement on the server:
   SELECT CURRENT SERVER FROM SYSIBM.SYSDUMMY1;

-user
Specifies the user ID under which DB2LobTableCreator is to run. This user
must have authority to create tables in the DSNATPDB database.

-password
Specifies the password for the user ID.

-help
Specifies that the DB2LobTableCreator utility describes each of the options that
it supports. If any other options are specified with -help, they are ignored.

Chapter 2, “Installing the IBM Data Server Driver for JDBC and SQLJ,” on page 7

Customization of IBM Data Server Driver for JDBC and SQLJ
configuration properties

The IBM Data Server Driver for JDBC and SQLJ configuration properties let you
set property values that have driver-wide scope. Those settings apply across
applications and DataSource instances. You can change the settings without having
to change application source code or DataSource characteristics.

Each IBM Data Server Driver for JDBC and SQLJ configuration property setting is
of this form:
   property=value

You can set configuration properties in the following ways:

• Set the configuration properties as Java system properties. Configuration
  property values that are set as Java system properties override configuration
  property values that are set in any other ways.
  For stand-alone Java applications, you can set the configuration properties as
  Java system properties by specifying -Dproperty=value for each configuration
  property when you execute the java command.

• Set the configuration properties in a resource whose name you specify in the
db2.jcc.propertiesFile Java system property. For example, you can specify an
  absolute path name for the db2.jcc.propertiesFile value.
  For stand-alone Java applications, you can set the configuration properties by
  specifying the -Ddb2.jcc.propertiesFile=path option when you execute the java
  command.
Set the configuration properties in a resource named DB2JccConfiguration.properties. A standard Java resource search is used to find DB2JccConfiguration.properties. The IBM Data Server Driver for JDBC and SQLJ searches for this resource only if you have not set the db2.jcc.propertiesFile Java system property.

DB2JccConfiguration.properties can be a stand-alone file, or it can be included in a JAR file.

If the DB2JccConfiguration.properties file is in the ISO 8859-1 (Latin-1) encoding scheme, or is in the Latin-1 encoding scheme with some Unicode-encoded (\udddd) characters, you do not need to do character conversion before the IBM Data Server Driver for JDBC and SQLJ can use the file. If the DB2JccConfiguration.properties file is in some other encoding scheme, you need to use the Java native2ascii converter to convert the contents to Latin-1 or Unicode-encoded characters.

If DB2JccConfiguration.properties is a stand-alone file, the path for DB2JccConfiguration.properties must be in the CLASSPATH concatenation.

If DB2JccConfiguration.properties is in a JAR file, the JAR file must be in the CLASSPATH concatenation.

Special setup for accessing DB2 for z/OS servers from Java programs

If you plan to write JDBC or SQLJ applications that access DB2 for z/OS database servers, your IBM Data Server Driver for JDBC and SQLJ installation process requires additional steps.

Follow these steps to allow connectivity to DB2 for z/OS servers:
1. If you plan to connect to any DB2 for z/OS Version 7 or Version 8 database servers, install these PTFs on those database servers.

<table>
<thead>
<tr>
<th>DB2 for z/OS</th>
<th>PTF or APAR numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version 7</td>
<td>UQ72083, UQ93889, UK21848</td>
</tr>
<tr>
<td>Version 8</td>
<td>UQ93890, UK21849</td>
</tr>
<tr>
<td>Version 9</td>
<td>PK44166</td>
</tr>
</tbody>
</table>

2. Run the com.ibm.db2.jcc.DB2Binder utility to bind the DB2 packages that are used at the server by the IBM Data Server Driver for JDBC and SQLJ.

3. On DB2 for z/OS database servers, customize and run job DSNTIJMS.
   DSNTIJMS is located in data set prefix.SDSNSAMP. It performs the following functions:
   - Creates the following stored procedures to support DatabaseMetaData methods, tracing, and error message formatting.
     - SQLCOLPRIVILEGES
     - SQLCOLUMNS
     - SQLFOREIGN KEYS
     - SQLFUNCTIONS
     - SQLFUNCTIONCOLUMNS
     - SQLGETTYPEINFO
     - SQLPRIMARYKEYS
– SQLPROCEDURECOLS
– SQLPROCEDURES
– SQLPSEUDOCOLUMNS (DB2 for z/OS Version 10 or later)
– SQLSPECIALCOLUMN
– SQLSTATISTICS
– SQLTABLEPRIVILEGES
– SQLTABLES
– SQLUDTS
– SQLCAMESSAGE

• Creates the following tables to support efficient storing of data in CLOB or DBCLOB columns and the use of LOB locators for CLOB or DBCLOB retrieval:
  – SYSIBM.SYSDUMMYU
  – SYSIBM.SYSDUMMYA
  – SYSIBM.SYSDUMMYE

An alternative way to create those tables is to run the com.ibm.db2.jcc.DB2LobTableCreator utility on the client, against each of the DB2 for z/OS servers.

4. Enable Unicode support for OS/390® and z/OS servers.

If any SQLJ or JDBC programs will use IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to connect to a DB2 for z/OS Version 7 server, the OS/390 or z/OS operating system must support the Unicode UTF-8 encoding scheme. This support requires OS/390 Version 2 Release 9 with APAR OW44581, or a later release of OS/390 or z/OS, plus the OS/390 R8/R9/R10 Support for Unicode. Information APARs II13048 and II13049 contain additional information.

5. If you plan to use IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to implement distributed transactions against DB2 for z/OS Version 7 servers, run the DB2T4XAIndoubtUtil utility once for each of those DB2 for z/OS Version 7 servers.

Related reference:

“DB2T4XAIndoubtUtil for distributed transactions with DB2 UDB for OS/390 and z/OS Version 7 servers”

“DB2LobTableCreator utility” on page 18

“DB2Binder utility” on page 11

---

**DB2T4XAIndoubtUtil for distributed transactions with DB2 UDB for OS/390 and z/OS Version 7 servers**

If you plan to implement distributed transactions using IBM Data Server Driver for JDBC and SQLJ type 4 connectivity that include DB2 UDB for OS/390 and z/OS Version 7 servers, you need to run the DB2T4XAIndoubtUtil utility against those servers.

DB2T4XAIndoubtUtil allows Version 7 servers, which do not have built-in support for distributed transactions that implement the XA specification, to emulate that support.

DB2T4XAIndoubtUtil performs one or both of the following tasks:

• Creates a table named SYSIBM.INDOUBT and an associated index
• Binds DB2 packages named T4XAIN01, T4XAIN02, T4XAIN03, and T4XAIN04
You should create and drop packages T4XAIN01, T4XAIN02, T4XAIN03, and T4XAIN04 only by running DB2T4XAIndoubtUtil. You can create and drop SYSTEM.INDOUBT and its index manually, but it is recommended that you use the utility. See [DB2T4XAIndoubtUtil usage notes] for instructions on how to create those objects manually.

**DB2T4XAIndoubtUtil authorization**

To run the DB2T4XAIndoubtUtil utility to create SYSTEM.INDOUBT and bind packages T4XAIN01, T4XAIN02, T4XAIN03, and T4XAIN04, you need SYSADM authority.

To run the DB2T4XAIndoubtUtil only to bind packages T4XAIN01, T4XAIN02, T4XAIN03, and T4XAIN04, you need BIND authority on the packages.

**DB2T4XAIndoubtUtil syntax**

```bash
```

**DB2T4XAIndoubtUtil parameter descriptions**

- `-url`
  Specifies the data source at which DB2T4XAIndoubtUtil is to run. The variable parts of the `-url` value are:

  `jdbc:db2:`
  Indicates that the connection is to a server in the DB2 family.

  `server`
  The domain name or IP address of the database server.

  `port`
  The TCP/IP server port number that is assigned to the database server. This is an integer between 0 and 65535. The default is 446.

  `database`
  A name for the database server. `database` is the DB2 location name that is defined during installation. All characters in this value must be uppercase characters. You can determine the location name by executing the following SQL statement on the server:

  ```sql
  SELECT CURRENT SERVER FROM SYSIBM.SYSDUMMY1;
  ```

- `-user`
  Specifies the user ID under which DB2T4XAIndoubtUtil is to run. This user
must have SYSADM authority or must be a member of a RACF group that corresponds to a secondary authorization ID with SYSADM authority.

_password
Provides the password for the user ID.

_owner
Provides a secondary authorization ID that has SYSADM authority. Use the _owner parameter if the -user parameter value does not have SYSADM authority. The -user parameter value must be a member of a RACF group whose name is _owner-ID.

When the -owner parameter is specified, DB2T4XAIndoubtUtil uses _owner-ID as:
• The authorization ID for creating the SYSIBM.INDOUBT table.
• The authorization ID of the owner of the T4XAIN01, T4XAIN02, T4XAIN03, and T4XAIN04 packages. SQL statements in those packages are executed using the authority of _owner-ID.

-help
Provides that the DB2T4XAIndoubtUtil utility describes each of the options that it supports. If any other options are specified with -help, they are ignored.

-delete
Specifies that the DB2T4XAIndoubtUtil utility deletes the objects that were created when DB2T4XAIndoubtUtil was run previously.

-priqty
Specifies the primary space allocation, in kilobytes, for the table space that contains the SYSIBM.INDOUBT table. The default value for -priqty is 1000.

Important: The -priqty value divided by the page size for the table space in which SYSIBM.INDOUBT resides must be greater than the maximum number of indoubt transactions that are allowed at a given time. For example, for a 4 KB page size, the default -priqty value of 1000 allows about 250 concurrent indoubt transactions.

-secqty
Specifies the secondary space allocation, in kilobytes, for the table space that contains the SYSIBM.INDOUBT table. The default value for -secqty is 0.

Recommendation: Always use the default value of 0 for the -secqty value, and specify a -priqty value that is large enough to accommodate the maximum number of concurrent indoubt transactions.

-bindonly
Specifies that the DB2T4XAIndoubtUtil utility binds the T4XAIN01, T4XAIN02, T4XAIN03, and T4XAIN04 packages and grants permission to PUBLIC to execute the packages, but does not create the SYSIBM.INDOUBT table.

-showSQL
Provides that the DB2T4XAIndoubtUtil utility displays the SQL statements that it executes.

-jdbcCollection collection-name | NULLID
Provides the value of the -collection parameter that was used when the IBM Data Server Driver for JDBC and SQLJ packages were bound with the DB2Binder utility. The -jdbcCollection parameter must be specified if the explicitly or implicitly specified value of the -collection parameter was not NULLID.
The default is -jdbcCollection NULLID.

**DB2T4XAIndoubtUtil usage notes**

To create the SYSTEM.INDOUBT table and its index manually, use these SQL statements:

```sql
CREATE TABLESPACE INDBTTS
    USING STOGROUP
    LOCKSIZE ROW
    BUFFERPOOL BP0
    SEGSIZE 32
    CCSID EBCDIC;

CREATE TABLE SYSIBM.INDOUBT(indbtXid VARCHAR(140) FOR BIT DATA NOT NULL,
                              uowId VARCHAR(25) FOR BIT DATA NOT NULL,
                              pSyncLog VARCHAR(150) FOR BIT DATA,
                              cSyncLog VARCHAR(150) FOR BIT DATA)
    IN INDBTTS;

CREATE UNIQUE INDEX INDBTIDX ON SYSIBM.INDOUBT(indbtXid, uowId);
```

**DB2T4XAIndoubtUtil example**

Run the DB2T4XAIndoubtUtil to allow a DB2 for OS/390 and z/OS Version 7 subsystem that has IP address mvs1, port number 446, and DB2 location name SJCEC1 to participate in XA distributed transactions.

```
java com.ibm.db2.jcc.DB2T4XAIndoubtUtil -url jdbc:db2://mvs1:446/SJCEC1 \\
    -user SYSADM -password mypass
```

**Related tasks:**

- Chapter 2, "Installing the IBM Data Server Driver for JDBC and SQLJ," on page 7
Chapter 3. JDBC application programming

Writing a JDBC application has much in common with writing an SQL application in any other language.

In general, you need to do the following things:
- Access the Java packages that contain JDBC methods.
- Declare variables for sending data to or retrieving data from DB2 tables.
- Connect to a data source.
- Execute SQL statements.
- Handle SQL errors and warnings.
- Disconnect from the data source.

Although the tasks that you need to perform are similar to those in other languages, the way that you execute those tasks is somewhat different.

Example of a simple JDBC application

A simple JDBC application demonstrates the basic elements that JDBC applications need to include.

Figure 1. Simple JDBC application

```java
import java.sql.*;

public class EzJava
{
    public static void main(String[] args)
    {
        String urlPrefix = "jdbc:db2:*";
        String url;
        String user;
        String password;
        String empNo;
        Connection con;
        Statement stmt;
        ResultSet rs;

        System.out.println("**** Enter class EzJava");

        // Check the that first argument has the correct form for the portion
        // of the URL that follows jdbc:db2:,
        // as described
        // in the Connecting to a data source using the DriverManager
        // interface with the IBM Data Server Driver for JDBC and SQLJ topic.
        // For example, for IBM Data Server Driver for
        // JDBC and SQLJ type 2 connectivity,
        // args[0] might be MVS1DB2M. For
        // type 4 connectivity, args[0] might
        // be //stlmvs1:10110/MVS1DB2M.

        if (args.length!=3)
        {
            System.err.println("Invalid value. First argument appended to "$ +"jdbc:db2: must specify a valid URL.");
            System.err.println("Second argument must be a valid user ID.");
            System.err.println("Third argument must be the password for the user ID.");
```
System.exit(1);

url = urlPrefix + args[0];
user = args[1];
password = args[2];
try {
    // Load the driver
    Class.forName("com.ibm.db2.jcc.DB2Driver");
    System.out.println("**** Loaded the JDBC driver");

    // Create the connection using the IBM Data Server Driver for JDBC and SQLJ
    con = DriverManager.getConnection(url, user, password);
    // Commit changes manually
    con.setAutoCommit(false);
    System.out.println("**** Created a JDBC connection to the data source");

    // Create the Statement
    stmt = con.createStatement();
    System.out.println("**** Created JDBC Statement object");

    // Execute a query and generate a ResultSet instance
    rs = stmt.executeQuery("SELECT EMPNO FROM EMPLOYEE");
    System.out.println("**** Created JDBC ResultSet object");

    // Print all of the employee numbers to standard output device
    while (rs.next()) {
        empNo = rs.getString(1);
        System.out.println("Employee number = " + empNo);
    }
    System.out.println("**** Fetched all rows from JDBC ResultSet");
    // Close the ResultSet
    rs.close();
    System.out.println("**** Closed JDBC ResultSet");

    // Close the Statement
    stmt.close();
    System.out.println("**** Closed JDBC Statement");

    // Connection must be on a unit-of-work boundary to allow close
    con.commit();
    System.out.println("**** Transaction committed");

    // Close the connection
    con.close();
    System.out.println("**** Disconnected from data source");
    System.out.println("**** JDBC Exit from class EzJava - no errors");
}
catch (ClassNotFoundException e) {
    System.err.println("Could not load JDBC driver");
    System.out.println("Exception: " + e);
    e.printStackTrace();
}
catch(SQLException ex) {
    System.err.println("SQLException information");
    while(ex!=null) {
        System.err.println("Error msg: " + ex.getMessage());
        System.err.println("SQLSTATE: " + ex.getSQLState());
        System.err.println("Error code: " + ex.getErrorCode());
        ex.printStackTrace();
        ex = ex.getNextException(); // For drivers that support chained exceptions

How JDBC applications connect to a data source

Before you can execute SQL statements in any SQL program, you must be connected to a data source.

The IBM Data Server Driver for JDBC and SQLJ supports type 2 and type 4 connectivity. Connections to DB2 databases can use type 2 or type 4 connectivity. Connections to IBM Informix databases can use type 4 connectivity.

The following figure shows how a Java application connects to a data source using IBM Data Server Driver for JDBC and SQLJ type 2 connectivity.
The following figure shows how a Java application connects to a data source using IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

*Java byte code executed under JVM, and native code

Figure 2. Java application flow for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity

The following figure shows how a Java application connects to a data source using IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

*Java byte code executed under JVM

Figure 3. Java application flow for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity
Connecting to a data source using the DriverManager interface with the IBM Data Server Driver for JDBC and SQLJ

A JDBC application can establish a connection to a data source using the JDBC DriverManager interface, which is part of the java.sql package.

The steps for establishing a connection are:

1. Load the JDBC driver by invoking the Class.forName method.
   
   If you are using JDBC 4.0 or later, you do not need to explicitly load the JDBC driver.
   
   For the IBM Data Server Driver for JDBC and SQLJ, you load the driver by invoking the Class.forName method with the following argument:
   
   com.ibm.db2.jcc.DB2Driver
   
   For compatibility with previous JDBC drivers, you can use the following argument instead:
   
   COM.ibm.db2os390.sqlj.jdbc.DB2SQLJDriver
   
   The following code demonstrates loading the IBM Data Server Driver for JDBC and SQLJ:
   
   ```java
   try {
     // Load the IBM Data Server Driver for JDBC and SQLJ with DriverManager
     Class.forName("com.ibm.db2.jcc.DB2Driver");
   } catch (ClassNotFoundException e) {
     e.printStackTrace();
   }
   ```

   The catch block is used to print an error if the driver is not found.

2. Connect to a data source by invoking the DriverManager.getConnection method.

   You can use one of the following forms of getConnection:
   
   ```java
   getConnection(String url);
   getConnection(String url, user, password);
   getConnection(String url, java.util.Properties info);
   ```

   For IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, the getConnection method must specify a user ID and password, through parameters or through property values.

   The url argument represents a data source, and indicates what type of JDBC connectivity you are using.

   The info argument is an object of type java.util.Properties that contains a set of driver properties for the connection. Specifying the info argument is an alternative to specifying property=value; strings in the URL. See "Properties for the IBM Data Server Driver for JDBC and SQLJ" for the properties that you can specify.

   There are several ways to specify a user ID and password for a connection:
   
   • Use the form of the getConnection method that specifies url with property=value; clauses, and include the user and password properties in the URL.
   
   • Use the form of the getConnection method that specifies user and password.
• Use the form of the getConnection method that specifies info, after setting the user and password properties in a java.util.Properties object.

Examples

Example: Establishing a connection and setting the user ID and password in a URL:

```java
String url = "jdbc:db2://myhost:5021/mydb:" +
    "user=dbadm;password=dbadm;";
    // Set URL for data source
Connection con = DriverManager.getConnection(url);
    // Create connection
```

Example: Establishing a connection and setting the user ID and password in user and password parameters:

```java
String url = "jdbc:db2://myhost:5021/mydb;";
String user = "dbadm;";
String password = "dbadm;";
Connection con = DriverManager.getConnection(url, user, password);
    // Create connection
```

Example: Establishing a connection and setting the user ID and password in a java.util.Properties object:

```java
Properties properties = new Properties(); // Create Properties object
properties.put("user", "dbadm"); // Set user ID for connection
properties.put("password", "dbadm"); // Set password for connection
String url = "jdbc:db2://myhost:5021/mydb;";
    // Set URL for data source
Connection con = DriverManager.getConnection(url, properties);
    // Create connection
```

URL format for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity

If you are using type 4 connectivity in your JDBC application, and you are making a connection using the DriverManager interface, you need to specify a URL in the DriverManager.getConnection call that indicates type 4 connectivity.

IBM Data Server Driver for JDBC and SQLJ type 4 connectivity URL syntax

```
jdbc:db2://server-name:port/database-name:connection-options
```

connection-options:

```plaintext
(1)  
property=value;  special-registers
```
special-registers:

- specialRegisters = special-register-name=special-register-value;

Notes:
1. *property=value* pairs and the special-registers string can be specified in any order.

**IBM Data Server Driver for JDBC and SQLJ type 4 connectivity URL option descriptions**

The parts of the URL have the following meanings:

- **jdbc:db2:** or **jdbc:db2j:net:**
  The meanings of the initial portion of the URL are:
  - **jdbc:db2:**
    Indicates that the connection is to a DB2 for z/OS, DB2 for Linux, UNIX, and Windows.
    - **jdbc:db2:** can also be used for a connection to an IBM Informix database, for application portability.
  - **jdbc:db2j:net:**
    Indicates that the connection is to a remote IBM Cloudscape server.

- **jdbc:ids:**
  Indicates that the connection is to an IBM Informix data source.
  **jdbc:informix-sqli:** also indicates that the connection is to an IBM Informix data source, but **jdbc:ids:** should be used.

- **server**
  The domain name or IP address of the data source.

- **port**
  The TCP/IP server port number that is assigned to the data source. This is an integer between 0 and 65535. The default is 446.

- **database**
  A name for the data source.
  - If the connection is to a DB2 for z/OS server, **database** is the DB2 location name that is defined during installation. All characters in the DB2 location name must be uppercase characters. The IBM Data Server Driver for JDBC and SQLJ does not convert lowercase characters in the database value to uppercase for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.
  - You can determine the location name by executing the following SQL statement on the server:
    ```sql
    SELECT CURRENT SERVER FROM SYSIBM.SYSDUMMY1;
    ```
  - If the connection is to a DB2 for z/OS server or a DB2 for i server, all characters in **database** must be uppercase characters.
  - If the connection is to a DB2 for Linux, UNIX, and Windows server, **database** is the database name that is defined during installation.
  - If the connection is to an IBM Informix server, **database** is the database name. The name is case-insensitive. The server converts the name to lowercase.
If the connection is to an IBM Cloudscape server, the database is the fully-qualified name of the file that contains the database. This name must be enclosed in double quotation marks ("). For example:
"c:/databases/testdb"

property=value;
A property and its value for the JDBC connection. You can specify one or more property and value pairs. Each property and value pair, including the last one, must end with a semicolon (;). Do not include spaces or other white space characters anywhere within the list of property and value strings.

Some properties with an int data type have predefined constant field values. You must resolve constant field values to their integer values before you can use those values in the url parameter. For example, you cannot use com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL in a url parameter. However, you can build a URL string that includes com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL, and assign the URL string to a String variable. Then you can use the String variable in the url parameter:

String url =
"jdbc:db2://sysmvs1.stl.ibm.com:5021/STLEC1" +
"user=dbadm;password=dbadm;" +
"traceLevel=" +
(com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL) + ";";
Connection con =
java.sql.DriverManager.getConnection(url);

specialRegisters=special-register-name=special-register-value,...special-
register-name=special-register-value
A list of special register settings for the JDBC connection. You can specify one or more special register name and value pairs. Special register name and value pairs must be delimited by commas (,). The last pair must end with a semicolon (;). For example:

String url =
"jdbc:db2://sysmvs1.stl.ibm.com:5021/STLEC1" +
"user=dbadm;password=dbadm;" +
"specialRegisters=CURRENT_PATH=SYSIBM,CURRENT CLIENT_USERID=test" + ";";
Connection con =
java.sql.DriverManager.getConnection(url);

For special registers that can be set through IBM Data Server Driver for JDBC and SQLJ Connection properties, if you set a special register value in a URL string using specialRegisters, and you also set that value in a java.util.Properties object using the following form of getConnection, the special register is set to the value from the URL string.
getConnection(String url, java.util.Properties info);

You can specify only one value for each special register using the specialRegisters parameter. For special registers that take multiple values, such as CURRENT PATH, CURRENT PACKAGE PATH, CURRENT PACKAGSET, you can specify multiple values for a special register by using the DataSource interface and the DB2DataSource.setSpecialRegisters method.
Related reference:
“DB2DataSource class” on page 510

URL format for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity

If you are using type 2 connectivity in your JDBC application, and you are making a connection using the DriverManager interface, you need to specify a URL in the DriverManager.getConnection call that indicates type 2 connectivity.

IBM Data Server Driver for JDBC and SQLJ type 2 connectivity URL syntax

connection-options:

(1)

property=value; special-registers

special-registers:

specialRegisters = special-register-name=special-register-value;

Notes:
1  property=value pairs and the special-registers string can be specified in any order.

IBM Data Server Driver for JDBC and SQLJ type 2 connectivity URL options descriptions

The parts of the URL have the following meanings:

jdbc:db2: or jdbc:db2os390: or jdbc:db2os390sqlj: or
jdbc:default:connection

The meanings of the initial portion of the URL are:

jdbc:db2: or jdbc:db2os390: or jdbc:db2os390sqlj:
Indicates that the connection is to a DB2 for z/OS or DB2 for Linux, UNIX, and Windows server. jdbc:db2os390: and jdbc:db2os390sqlj: are for compatibility of programs that were written for older drivers, and apply to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for z/OS only.

jdbc:default:connection
Indicates that the URL is for a connection to the local subsystem through a DB2 thread that is controlled by CICS®, IMS®, or the Java stored procedure environment.
**database**
A name for the database server.
- *database* is the database name that is defined during installation, if the value of the serverName connection property is null. If the value of serverName property is not null, *database* is a database alias.

**property=value**
A property and its value for the JDBC connection. You can specify one or more property and value pairs. Each property and value pair, including the last one, must end with a semicolon (;). Do not include spaces or other white space characters anywhere within the list of property and value strings.

Some properties with an int data type have predefined constant field values. You must resolve constant field values to their integer values before you can use those values in the *url* parameter. For example, you cannot use `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL` in a *url* parameter. However, you can build a URL string that includes `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL`, and assign the URL string to a String variable. Then you can use the String variable in the *url* parameter:

```java
String url =
    "jdbc:db2:STLEC1" +
    ":user=dbadm;password=dbadm;" +
    "traceLevel=" +
    (com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL) + ";";
Connection con =
    java.sql.DriverManager.getConnection(url);
```

**specialRegisters=special-register-name=special-register-value,...special-register-name=special-register-value**
A list of special register settings for the JDBC connection. You can specify one or more special register name and value pairs. Special register name and value pairs must be delimited by commas (,). The last pair must end with a semicolon (;). For example:

```java
String url =
    "jdbc:db2:STLEC1" +
    ":user=dbadm;password=dbadm;" +
    "specialRegisters=CURRENT_PATH=SYSIBM,CURRENT_CLIENT_USERID=test" + ";";
Connection con =
    java.sql.DriverManager.getConnection(url);
```

For special registers that can be set through IBM Data Server Driver for JDBC and SQLJ Connection properties, if you set a special register value in a URL string using specialRegisters, and you also set that value in a `java.util.Properties` object using the following form of getConnection, the special register is set to the value from the URL string.

```java
getConnection(String url, java.util.Properties info);
```

If you specify a special register that is supported on the data server, but you specify a value that is not supported on the data server, the IBM Data Server Driver for JDBC and SQLJ returns an error. If you specify a special register that is not supported on the data server, the driver returns a warning.

You can specify only one value for each special register using the `specialRegisters` parameter. For special registers that take multiple values, such as CURRENT PATH, CURRENT PACKAGE PATH, CURRENT PACKAGESET, you can specify multiple values for a special register by using the DataSource interface and the DB2DataSource.setSpecialRegisters method.
Connecting to a data source using the DataSource interface

If your applications need to be portable among data sources, you should use the DataSource interface.

Using DriverManager to connect to a data source reduces portability because the application must identify a specific JDBC driver class name and driver URL. The driver class name and driver URL are specific to a JDBC vendor, driver implementation, and data source.

When you connect to a data source using the DataSource interface, you use a DataSource object.

The simplest way to use a DataSource object is to create and use the object in the same application, as you do with the DriverManager interface. However, this method does not provide portability.

The best way to use a DataSource object is for your system administrator to create and manage it separately, using WebSphere Application Server or some other tool. The program that creates and manages a DataSource object also uses the Java Naming and Directory Interface (JNDI) to assign a logical name to the DataSource object. The JDBC application that uses the DataSource object can then refer to the object by its logical name, and does not need any information about the underlying data source. In addition, your system administrator can modify the data source attributes, and you do not need to change your application program.

To learn more about using WebSphere to deploy DataSource objects, go to this URL on the web:
http://www.ibm.com/software/webservers/appserv/

To learn about deploying DataSource objects yourself, see “Creating and deploying DataSource objects”.

You can use the DataSource interface and the DriverManager interface in the same application, but for maximum portability, it is recommended that you use only the DataSource interface to obtain connections.

To obtain a connection using a DataSource object that the system administrator has already created and assigned a logical name to, follow these steps:

1. From your system administrator, obtain the logical name of the data source to which you need to connect.
2. Create a Context object to use in the next step. The Context interface is part of the Java Naming and Directory Interface (JNDI), not JDBC.
3. In your application program, use JNDI to get the DataSource object that is associated with the logical data source name.
4. Use the DataSource.getConnection method to obtain the connection.
   You can use one of the following forms of the getConnection method:
   ```java
   getConnection();
   getConnection(String user, String password);
   ```
Use the second form if you need to specify a user ID and password for the connection that are different from the ones that were specified when the DataSource was deployed.

Examples

**Example of obtaining a connection using a DataSource object that was created by the system administrator.** In this example, the logical name of the data source that you need to connect to is `jdbc/sampledb`. The numbers to the right of selected statements correspond to the previously-described steps.

```java
import java.sql.*;
import javax.sql.*;
import com.ibm.db2.jcc.*;
...
Context ctx=new InitialContext();
DataSource ds=(DataSource)ctx.lookup("jdbc/sampledb");
Connection con=ds.getConnection();
```

*Figure 4. Obtaining a connection using a DataSource object*

**Example of creating and using a DataSource object in the same application:**

```java
import java.sql.*; // JDBC base
import javax.sql.*; // Additional methods for JDBC
import com.ibm.db2.jcc.*; // IBM Data Server Driver for JDBC and SQLJ

DB2SimpleDataSource dbds=new DB2SimpleDataSource();
dbds.setDatabaseName("dbloc1");
// Assign the location name
dbds.setDescription("Our Sample Database");
// Description for documentation
dbds.setUser("john");
// Assign the user ID
dbds.setPassword("dbadm");
// Assign the password
Connection con=dbds.getConnection();
```

How to determine which type of IBM Data Server Driver for JDBC and SQLJ connectivity to use

The IBM Data Server Driver for JDBC and SQLJ supports two types of connectivity: type 2 connectivity and type 4 connectivity.

For the DriverManager interface, you specify the type of connectivity through the URL in the DriverManager.getConnection method. For the DataSource interface, you specify the type of connectivity through the driverType property.

The following table summarizes the differences between type 2 connectivity and type 4 connectivity:

<table>
<thead>
<tr>
<th>Function</th>
<th>IBM Data Server Driver for JDBC and SQLJ type 2 connectivity support</th>
<th>IBM Data Server Driver for JDBC and SQLJ type 4 connectivity support</th>
</tr>
</thead>
<tbody>

<td>Supported</td>
</tr>
<tr>
<td>J2EE 1.4 compliance</td>
<td>Compliant</td>
<td>Compliant</td>
</tr>
</tbody>
</table>

The following points can help you determine which type of connectivity to use.

Use IBM Data Server Driver for JDBC and SQLJ type 2 connectivity under these circumstances:

- Your JDBC or SQLJ application runs locally most of the time.
  Local applications have better performance with type 2 connectivity.
- You are running a Java stored procedure.
  A stored procedure environment consists of two parts: a client program, from which you call a stored procedure, and a server program, which is the stored procedure. You can call a stored procedure in a JDBC or SQLJ program that uses type 2 or type 4 connectivity, but you must run a Java stored procedure using type 2 connectivity.

Use IBM Data Server Driver for JDBC and SQLJ type 4 connectivity under these circumstances:
Your JDBC or SQLJ application runs remotely most of the time. Remote applications have better performance with type 4 connectivity.

You are using IBM Data Server Driver for JDBC and SQLJ connection concentrator and Sysplex workload balancing support.

**JDBC connection objects**

When you connect to a data source by either connection method, you create a Connection object, which represents the connection to the data source.

You use this Connection object to do the following things:

- Create Statement, PreparedStatement, and CallableStatement objects for executing SQL statements. These are discussed in "Executing SQL statements in JDBC applications".
- Gather information about the data source to which you are connected. This process is discussed in "Learning about a data source using DatabaseMetaData methods".
- Commit or roll back transactions. You can commit transactions manually or automatically. These operations are discussed in "Commit or roll back a JDBC transaction".
- Close the connection to the data source. This operation is discussed in "Disconnecting from data sources in JDBC applications".

**Related concepts:**

"JDBC interfaces for executing SQL" on page 47

**Related tasks:**

"Learning about a data source using DatabaseMetaData methods" on page 40

"Committing or rolling back JDBC transactions" on page 128

"Disconnecting from data sources in JDBC applications" on page 138

**Creating and deploying DataSource objects**

JDBC versions starting with version 2.0 provide the DataSource interface for connecting to a data source. Using the DataSource interface is the preferred way to connect to a data source.

Using the DataSource interface involves two parts:

- Creating and deploying DataSource objects. This is usually done by a system administrator, using a tool such as WebSphere Application Server.
- Using the DataSource objects to create a connection. This is done in the application program.

This topic contains information that you need if you create and deploy the DataSource objects yourself.

The IBM Data Server Driver for JDBC and SQLJ provides the following DataSource implementations:

- com.ibm.db2.jcc.DB2SimpleDataSource, which does not support connection pooling. You can use this implementation with IBM Data Server Driver for JDBC and SQLJ type 2 connectivity or IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.
• com.ibm.db2.jcc.DB2ConnectionPoolDataSource, which supports connection pooling. You can use this implementation with IBM Data Server Driver for JDBC and SQLJ type 2 connectivity or IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

• com.ibm.db2.jcc.DB2XADatasource, which supports connection pooling and distributed transactions. The connection pooling is provided by WebSphere Application Server or another application server. You can use this implementation only with IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

To create and deploy a DataSource object, you need to perform these tasks:
1. Create an instance of the appropriate DataSource implementation.
2. Set the properties of the DataSource object.
3. Register the object with the Java Naming and Directory Interface (JNDI) naming service.

The following example shows how to perform these tasks.

```java
import java.sql.*; // JDBC base
import javax.naming.*; // JNDI Naming Services
import javax.sql.*; // Additional methods for JDBC
import com.ibm.db2.jcc.*; // IBM Data Server Driver for
// JDBC and SQLJ
// implementation of JDBC
// standard extension APIs

DB2SimpleDataSource dbds = new com.ibm.db2.jcc.DB2SimpleDataSource();  // 1
dbds.setDatabaseName("db2loc1");  // 2
dbds.setDescription("Our Sample Database");
dbds.setUser("john");
dbds.setPassword("mypw");
...
Context ctx=new InitialContext();
Ctx.bind("jdbc/sampledb",dbds);  // 4
```

*Figure 6. Example of creating and deploying a DataSource object*

**Java packages for JDBC support**

Before you can invoke JDBC methods, you need to be able to access all or parts of various Java packages that contain those methods.
You can do that either by importing the packages or specific classes, or by using the fully-qualified class names. You might need the following packages or classes for your JDBC program:

**java.sql**
Contains the core JDBC API.

**javax.naming**
Contains classes and interfaces for Java Naming and Directory Interface (JNDI), which is often used for implementing a DataSource.

**javax.sql**
Contains methods for producing server-side applications using Java

**com.ibm.db2.jcc**
Contains the implementation of JDBC for the IBM Data Server Driver for JDBC and SQLJ.

**Related concepts:**
“Example of a simple JDBC application” on page 25

---

**Learning about a data source using DatabaseMetaData methods**

The DatabaseMetaData interface contains methods that retrieve information about a data source. These methods are useful when you write generic applications that can access various data sources.

In generic applications that can access various data sources, you need to test whether a data source can handle various database operations before you execute them. For example, you need to determine whether the driver at a data source is at the JDBC 3.0 level before you invoke JDBC 3.0 methods against that driver.

DatabaseMetaData methods provide the following types of information:
- Features that the data source supports, such as the ANSI SQL level
- Specific information about the JDBC driver, such as the driver level
- Limits, such as the maximum number of columns that an index can have
- Whether the data source supports data definition statements (CREATE, ALTER, DROP, GRANT, REVOKE)
- Lists of objects at the data source, such as tables, indexes, or procedures
- Whether the data source supports various JDBC functions, such as batch updates or scrollable ResultSets
- A list of scalar functions that the driver supports

To invoke DatabaseMetaData methods, you need to perform these basic steps:
1. Create a DatabaseMetaData object by invoking the getMetaData method on the connection.
2. Invoke DatabaseMetaData methods to get information about the data source.
3. If the method returns a ResultSet:
   a. In a loop, position the cursor using the next method, and retrieve data from each column of the current row of the ResultSet object using getXXX methods.
   b. Invoke the close method to close the ResultSet object.

**Examples**

**Example:** The following code demonstrates how to use DatabaseMetaData methods to determine the driver version, to get a list of the stored procedures that are
available at the data source, and to get a list of datetime functions that the driver supports. The numbers to the right of selected statements correspond to the previously-described steps.

**Figure 7. Using DatabaseMetaData methods to get information about a data source**

```java
Connection con;  
DatabaseMetaData dbmtadta;  
ResultSet rs;  
int mtadtaint;  
String procSchema;  
String procName;  
String dtfnList;  
...

dbmtadta = con.getMetaData();  // Create the DatabaseMetaData object  
mtadtaint = dbmtadta.getDriverVersion();  // Check the driver version

System.out.println("Driver version: " + mtadtaint);  
rs = dbmtadta.getProcedures(null, null, ";

while (rs.next()) {  // Position the cursor

procSchema = rs.getString("PROCEDURE_SCHEMA");  // Get procedure schema

procName = rs.getString("PROCEDURE_NAME");  // Get procedure name

System.out.println(procSchema + "." + procName);  // Print the qualified procedure name

}  

dtfnList = dbmtadta.getTimeDateFunctions();  // Get list of supported datetime functions

System.out.println("Supported datetime functions:");  
System.out.println(dtfnList);  // Print the list of datetime functions
 rs.close();  // Close the ResultSet

**DatabaseMetaData methods for identifying the type of data source**

You can use the DatabaseMetaData.getDatabaseProductName and DatabaseMetaData.getProductVersion methods to identify the type and level of the database manager to which you are connected, and the operating system on which the database manager is running.

DatabaseMetaData.getDatabaseProductName returns a string that identifies the database manager and the operating system. The string has one of the following formats:

database-product  
database-product/operating-system

The following table shows examples of values that are returned by DatabaseMetaData.getDatabaseProductName.

<table>
<thead>
<tr>
<th>getDatabaseProductName value</th>
<th>Database product</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2</td>
<td>DB2 for z/OS</td>
</tr>
</tbody>
</table>
Table 8. Examples of DatabaseMetaData.getDatabaseProductName values (continued)

<td>DB2 for Linux, UNIX, and Windows on Linux on x86</td>
</tr>
<tr>
<td>IBM Informix/UNIX64</td>
<td>IBM Informix on UNIX</td>
</tr>
</tbody>
</table>

DatabaseMetaData.getDatabaseVersionName returns a string that contains the database product indicator and the version number, release number, and maintenance level of the data source.

The following table shows examples of values that are returned by DatabaseMetaData.getDatabaseProductVersion.

Table 9. Examples of DatabaseMetaData.getDatabaseProductVersion values

<table>
<thead>

</tbody>
</table>

**DatabaseMetaData extensions for obtaining information about modules**

The com.ibm.db2.jcc.DB2DatabaseMetaData class contains methods that let you retrieve information about procedures, functions, and user-defined types that are in modules.

A *module* is a database object that is a collection of other database objects such as functions, procedures, types, and variables. Modules are similar to Java classes. The primary purpose of modules is to group together object definitions that have a common business purpose or use. Modules are supported by DB2 for Linux, UNIX, and Windows Version 9.7 or later.

The IBM Data Server Driver for JDBC and SQLJ provides the following methods in the DB2DatabaseMetaData interface that let you retrieve information about database objects that are in modules. Each method returns a result set that contains all of the columns in the related java.sql.DatabaseMetaData method, and an extra column that identifies the module in which the database object resides.

<table>
<thead>
<tr>
<th>Method</th>
<th>Related DatabaseMetaData method</th>
<th>Information returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>getDBFunctionColumns</td>
<td>getFunctionColumns</td>
<td>Information about the parameters and return values for user-defined functions or built-in functions that are at a data source.</td>
</tr>
<tr>
<td>getDBFunctions</td>
<td>getFunctions</td>
<td>Information about the user-defined functions or built-in functions that are at a data source.</td>
</tr>
<tr>
<td>getDBProcedureColumns</td>
<td>getProcedureColumns</td>
<td>Information about the parameters and return values for stored procedures that are at a data source.</td>
</tr>
<tr>
<td>Method</td>
<td>Related DatabaseMetaData method</td>
<td>Information returned</td>
</tr>
<tr>
<td>--------------</td>
<td>---------------------------------</td>
<td>---------------------------------------------------------</td>
</tr>
<tr>
<td>getDBProcedures</td>
<td>getProcedures</td>
<td>Information about the stored procedures that are at a data source.</td>
</tr>
<tr>
<td>getDBUDTs</td>
<td>getUDTs</td>
<td>Information about the user-defined types that are at a data source.</td>
</tr>
</tbody>
</table>

If the same stored procedures, functions, or user-defined types are defined in several different modules, and you call one of the DatabaseMetaData methods, those methods return more than one row for the same procedure, function, or user-defined type. Those rows are identical, except for the SPECIFICNAME column. To uniquely identify stored procedures, functions, or user-defined types by module name, use the DB2DatabaseMetaData methods.

**Example**

Suppose that your ID is DB2ADMIN, and you create two modules, named MYMOD1 and MYMOD2:

```java
... 
stmt.executeUpdate("CREATE MODULE MYMOD1");
stmt.executeUpdate("CREATE MODULE MYMOD2");
...
```

Next, you create the same SQL procedure named PROC1 in module MYMOD1 and module MYMOD2:

```java
... 
stmt.executeUpdate("ALTER MODULE MYMOD1 PUBLISH PROCEDURE PROC1 (" +
   "IN PARM1 BOOLEAN, " +
   "INOUT PARM2 INTEGER) " +
   "LANGUAGE SQL " +
   "BEGIN...END");
stmt.executeUpdate("ALTER MODULE MYMOD2 PUBLISH PROCEDURE PROC1 (" +
   "IN PARM1 BOOLEAN, " +
   "INOUT PARM2 INTEGER) " +
   "LANGUAGE SQL " +
   "BEGIN...END");
```

The following example uses the DB2DatabaseMetaData.getDBProcedures method to return information about all procedures named PROC1 in schema DB2ADMIN that are in modules with a name like "MYMOD%".

```java
Connection con;
... // Establish a connection to the data source
DatabaseMetaData dbmd = con.getMetaData(); 
// Create a DatabaseMetaData object
String schemaname="DB2ADMIN";
String modulename="MYMOD%";
String procname="PROC1";
// Indicate that you want information
// about all procedures that meet these
// criteria:
// Schema: DB2ADMIN
// Module: MYMOD%
// Procedure name: PROC1
ResultSet rs =
((com.ibm.db2.jcc.DB2DatabaseMetaData)dbmd).getDBProcedures(null, schemaname,modulename,procname); // Cast the DatabaseMetaData object
```
To a DB2DatabaseMetaData object, and call DB2DatabaseMetaData.getDBProcedures

ResultsetMetaData rsm = rs.getMetaData();

// Retrieve a ResultSetMetaData object from the ResultSet that contains the procedure information, so you know how many columns to retrieve, and the name of each column.

while (rs.next()) {
    System.out.println("----------- Row " + rowcount++ + " -----------");
    // Retrieve each row in the ResultSet
    for (int i = 1; i <= rsm.getColumnCount(); i++) {
        System.out.println(i + ": " + rsm.getColumnName(i) + " = " + rs.getString(i));
    }
}

The values that are returned are similar to these:

----------- Row 1 -----------
1: PROCEDURE_CAT = null
2: PROCEDURE_SCHEM = DBADMIN
3: ROUTINENAME = PROC1
4: NUM_INPUT_PARAMS = 0
5: NUM_OUTPUT_PARAMS = 0
6: RESULT_SETS = 0
7: REMARKS = null
8: PROCEDURE_TYPE = 1
9: SPECIFICNAME = SQL090504144847100
10: MODULENAME = MYMOD1

----------- Row 2 -----------
1: PROCEDURE_CAT = null
2: PROCEDURE_SCHEM = DBADMIN
3: ROUTINENAME = PROC1
4: NUM_INPUT_PARAMS = 0
5: NUM_OUTPUT_PARAMS = 0
6: RESULT_SETS = 0
7: REMARKS = null
8: PROCEDURE_TYPE = 1
9: SPECIFICNAME = SQL090504144847800
10: MODULENAME = MYMOD2

Metadata for columns that are defined in code units

The java.sql.DatabaseMetaData methods provide information about table columns that are defined with code units.

DB2 for Linux, UNIX, and Windows Version 10.5 or later supports character or graphic column definitions that have the OCTETS, CODEUNITS16, or CODEUNITS32 length attribute. That attribute indicates whether the column or parameter length is defined as single bytes, UTF-16 units (two-byte units), or UTF-32 units (four-byte units).

For example, in the following table definition, the length of the first column is in bytes, the length of the second column is in two-byte units, and the length of the third column is in four-byte units:
CREATE TABLE MYTABLE (  
  COL1 CHAR(10 OCTETS),  
  COL2 GRAPHIC(10 CODEUNITS16),  
  COL3 VARCHAR(10 CODEUNITS32));

The standard JDBC java.sql.DatabaseMetaData methods return information about lengths of the columns in bytes and code units. That information is summarized in the following table.

<table>
<thead>
<tr>
<th>Method</th>
<th>Length and code unit information returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.sql.DatabaseMetaData.getColumns</td>
<td>COLUMN_SIZE result set column</td>

“Learning about parameter and ResultSet columns that are defined with code units” on page 56

**Variables in JDBC applications**

As in any other Java application, when you write JDBC applications, you declare variables. In Java applications, those variables are known as Java identifiers.

Some of those identifiers have the same function as host variables in other languages: they hold data that you pass to or retrieve from database tables. Identifier `empNo` in the following code holds data that you retrieve from the EMPNO table column, which has the CHAR data type.

```java
String empNo;
// Execute a query and generate a ResultSet instance
rs = stmt.executeQuery("SELECT EMPNO FROM EMPLOYEE");
```
while (rs.next()) {
    String empNo = rs.getString(1);
    System.out.println("Employee number = " + empNo);
}

Your choice of Java data types can affect performance because DB2 picks better access paths when the data types of your Java variables map closely to the DB2 data types.

“Data types that map to database data types in Java applications” on page 313

Comments in a JDBC application

To document your JDBC program, you need to include comments. You can use Java comments outside of JDBC methods and Java or SQL comments in SQL statement strings.

You can include Java comments outside JDBC methods, wherever the Java language permits them. Within an SQL statement string in a JDBC method call, you can use comments in the following places:

• For connections to DB2 data servers or Informix data servers, comments can be:
  – Anywhere in the SQL statement string, and enclosed in /* and */ pairs. /*
    and */ pairs can be nested.
  – At the end of the SQL statement string, and preceded by two hyphens (--).
• For connections to Informix data servers only, comments can be enclosed in left curly bracket ( { ) and right curly bracket ( } ) pairs.

Restriction: A comment that is enclosed in a { and } pair is not valid if either of the following conditions is true:
  – The SQL statement string is not a stored procedure call, the SQL statement string is preceded and followed by comments that are enclosed in { and } pairs, and the comment at the beginning of the SQL statement string begins with the word call.
  – The SQL statement string is a stored procedure call, and the comment {call} is at the beginning of the escape syntax for the stored procedure call.
  – The comment contains any of the following characters:
    - Single quotation mark ( ’ )
    - Double quotation mark ( “ )
    - Left curly bracket ( { )
    - Right curly bracket ( } )
    - /*
  – The comment can be interpreted as SQL escape syntax. Comments that begin with the following characters can be interpreted as SQL escape syntax:
    - d followed by a space
    - t followed by a space
    - ts followed by a space
    - escape followed by a space
    - j followed by a space
    - fn followed by a space

For example, the following SQL statement strings are not valid:
JDBC interfaces for executing SQL

You execute SQL statements in a traditional SQL program to update data in tables, retrieve data from the tables, or call stored procedures. To perform the same functions in a JDBC program, you invoke methods.

Those methods are defined in the following interfaces:

- The Statement interface supports all SQL statement execution. The following interfaces inherit methods from the Statement interface:
  - The PreparedStatement interface supports any SQL statement containing input parameter markers. Parameter markers represent input variables. The PreparedStatement interface can also be used for SQL statements with no parameter markers.
    With the IBM Data Server Driver for JDBC and SQLJ, the PreparedStatement interface can be used to call stored procedures that have input parameters and no output parameters, and that return no result sets. However, the preferred interface is CallableStatement.
  - The CallableStatement interface supports the invocation of a stored procedure. The CallableStatement interface can be used to call stored procedures with input parameters, output parameters, or input and output parameters, or no parameters. With the IBM Data Server Driver for JDBC and SQLJ, you can also use the Statement interface to call stored procedures, but those stored procedures must have no parameters.

- The ResultSet interface provides access to the results that a query generates. The ResultSet interface has the same purpose as the cursor that is used in SQL applications in other languages.

Related reference:

- “Driver support for JDBC APIs” on page 399

Creating and modifying database objects using the Statement.executeUpdate method

The Statement.executeUpdate is one of the JDBC methods that you can use to update tables and call stored procedures.

You can use the Statement.executeUpdate method to do the following things:

- Execute data definition statements, such as CREATE, ALTER, DROP, GRANT, REVOKE
- Execute INSERT, UPDATE, DELETE, and MERGE statements that do not contain parameter markers.
With the IBM Data Server Driver for JDBC and SQLJ, execute the CALL statement to call stored procedures that have no parameters and that return no result sets.

To execute these SQL statements, you need to perform these steps:
1. Invoke the Connection.createStatement method to create a Statement object.
2. Invoke the Statement.executeUpdate method to perform the SQL operation.
3. Invoke the Statement.close method to close the Statement object.

Suppose that you want to execute this SQL statement:

```
UPDATE EMPLOYEE SET PHONENO='4657' WHERE EMPNO='000010'
```

The following code creates Statement object stmt, executes the UPDATE statement, and returns the number of rows that were updated in numUpd. The numbers to the right of selected statements correspond to the previously-described steps.

```java
Connection con;
Statement stmt;
int numUpd;
...
stmt = con.createStatement(); // Create a Statement object
numUpd = stmt.executeUpdate("UPDATE EMPLOYEE SET PHONENO='4657' WHERE EMPNO='000010'");
// Perform the update
stmt.close(); // Close Statement object
```

`Figure 8. Using Statement.executeUpdate`

Related reference:
”Driver support for JDBC APIs” on page 399

**Updating data in tables using the PreparedStatement.executeUpdate method**

The Statement.executeUpdate method works if you update DB2 tables with constant values. However, updates often need to involve passing values in variables to DB2 tables. To do that, you use the PreparedStatement.executeUpdate method.

With the IBM Data Server Driver for JDBC and SQLJ, you can also use PreparedStatement.executeUpdate to call stored procedures that have input parameters and no output parameters, and that return no result sets.

DB2 for z/OS does not support dynamic execution of the CALL statement. For calls to stored procedures that are on DB2 for z/OS data sources, the parameters can be parameter markers or literals, but not expressions. The following types of literals are supported:

- Integer
- Double
- Decimal
- Character
- Hexadecimal
- Graphic

For calls to stored procedures that are on IBM Informix data sources, the PreparedStatement object can be a CALL statement or an EXECUTE PROCEDURE statement.
When you execute an SQL statement many times, you can get better performance by creating the SQL statement as a PreparedStatement.

For example, the following UPDATE statement lets you update the employee table for only one phone number and one employee number:

```
UPDATE EMPLOYEE SET PHONENO='4657' WHERE EMPNO='000010'
```

Suppose that you want to generalize the operation to update the employee table for any set of phone numbers and employee numbers. You need to replace the constant phone number and employee number with variables:

```
UPDATE EMPLOYEE SET PHONENO=? WHERE EMPNO=?
```

Variables of this form are called parameter markers.

To execute an SQL statement with parameter markers, you need to perform these steps:

1. Invoke the Connection.prepareStatement method to create a PreparedStatement object.
2. Invoke the PreparedStatement.setXXX methods to pass values to the input variables.
   - This step assumes that you use standard parameter markers. Alternatively, if you use named parameter markers, you use IBM Data Server Driver for JDBC and SQLJ-only methods to pass values to the input parameters.
3. Invoke the PreparedStatement.executeUpdate method to update the table with the variable values.
4. Invoke the PreparedStatement.close method to close the PreparedStatement object when you have finished using that object.

The following code performs the previous steps to update the phone number to '4657' for the employee with employee number '000010'. The numbers to the right of selected statements correspond to the previously-described steps.

```java
Connection con;
PreparedStatement pstmt;
int numUpd;
...
pstmt = con.prepareStatement(
    "UPDATE EMPLOYEE SET PHONENO=? WHERE EMPNO=?");
// Create a PreparedStatement object
pstmt.setString(1,"4657"); // Assign first value to first parameter
pstmt.setString(2,"000010"); // Assign first value to second parameter
numUpd = pstmt.executeUpdate(); // Perform first update
pstmt.setString(1,"4658"); // Assign second value to first parameter
pstmt.setString(2,"000020"); // Assign second value to second parameter
numUpd = pstmt.executeUpdate(); // Perform second update
pstmt.close(); // Close the PreparedStatement object
```

*Figure 9. Using PreparedStatement.executeUpdate for an SQL statement with parameter markers*

You can also use the PreparedStatement.executeUpdate method for statements that have no parameter markers. The steps for executing a PreparedStatement object with no parameter markers are similar to executing a PreparedStatement object with parameter markers, except you skip step 2. The following example demonstrates these steps.
JDBC executeUpdate methods against a DB2 for z/OS server

The JDBC standard states that the `executeUpdate` method returns a row count or 0. However, if the `executeUpdate` method is executed against a DB2 for z/OS server, it can return a value of -1.

For `executeUpdate` statements against a DB2 for z/OS server, the value that is returned depends on the type of SQL statement that is being executed:

- For an SQL statement that can have an update count, such as an INSERT, UPDATE, DELETE, or MERGE statement, the returned value is the number of affected rows. It can be:
  - A positive number, if a positive number of rows are affected by the operation, and the operation is not a mass delete on a segmented table space.
  - 0, if no rows are affected by the operation.
  - -1, if the operation is a mass delete on a segmented table space.
- For an SQL CALL statement, a value of -1 is returned, because the data source cannot determine the number of affected rows. Calls to `getUpdateCount` or `getMoreResults` for a CALL statement also return -1.
- For any other SQL statement, a value of -1 is returned.

Making batch updates in JDBC applications

With batch updates, instead of updating rows of a table one at a time, you can direct JDBC to execute a group of updates at the same time. Statements that can be included in the same batch of updates are known as batchable statements.

If a statement has input parameters or host expressions, you can include that statement only in a batch that has other instances of the same statement. This type of batch is known as a homogeneous batch. If a statement has no input parameters, you can include that statement in a batch only if the other statements in the batch have no input parameters or host expressions. This type of batch is known as a heterogeneous batch. Two statements that can be included in the same batch are known as batch compatible.
Use the following Statement methods for creating, executing, and removing a batch of SQL updates:
- addBatch
- executeBatch
- clearBatch

Use the following PreparedStatement and CallableStatement method for creating a batch of parameters so that a single statement can be executed multiple times in a batch, with a different set of parameters for each execution.
- addBatch

Restrictions on executing statements in a batch:
- If you try to execute a SELECT statement in a batch, a BatchUpdateException is thrown.
- A CallableStatement object that you execute in a batch can contain output parameters. However, you cannot retrieve the values of the output parameters. If you try to do so, a BatchUpdateException is thrown.
- You cannot retrieve ResultSet objects from a CallableStatement object that you execute in a batch. A BatchUpdateException is not thrown, but the getResultSet method invocation returns a null value.

To make batch updates, follow one of the following sets of steps.
- To make batch updates using several statements with no input parameters, follow these basic steps:
  1. For each SQL statement that you want to execute in the batch, invoke the addBatch method.
  2. Invoke the executeBatch method to execute the batch of statements.
  3. Check for errors. If no errors occurred:
     a. Get the number of rows that were affect by each SQL statement from the array that the executeBatch invocation returns. This number does not include rows that were affected by triggers or by referential integrity enforcement.
     b. If AutoCommit is disabled for the Connection object, invoke the commit method to commit the changes.
     If AutoCommit is enabled for the Connection object, the IBM Data Server Driver for JDBC and SQLJ adds a commit method at the end of the batch.
- To make batch updates using a single statement with several sets of input parameters, follow these basic steps:
  1. If the batched statement is a searched UPDATE, searched DELETE, or MERGE statement, set the autocommit mode for the connection to false.
  2. Invoke the prepareStatement method to create a PreparedStatement object.
  3. For each set of input parameter values:
     a. Execute setXXX methods to assign values to the input parameters.
     b. Invoke the addBatch method to add the set of input parameters to the batch.
  4. Invoke the executeBatch method to execute the statements with all sets of parameters.
  5. If no errors occurred:
     a. Get the number of rows that were updated by each execution of the SQL statement from the array that the executeBatch invocation returns. The number of affected rows does not include rows that were affected by triggers or by referential integrity enforcement.
If the following conditions are true, the IBM Data Server Driver for JDBC and SQLJ returns `Statement.SUCCESS_NO_INFO` (-2), instead of the number of rows that were affected by each SQL statement:

- The application is connected to a subsystem that is in DB2 for z/OS Version 8 new-function mode, or later.
- The application is using Version 3.1 or later of the IBM Data Server Driver for JDBC and SQLJ.
- The IBM Data Server Driver for JDBC and SQLJ uses multi-row INSERT operations to execute batch updates.

This occurs because with multi-row INSERT, the database server executes the entire batch as a single operation, so it does not return results for individual SQL statements.

b. If `AutoCommit` is disabled for the `Connection` object, invoke the commit method to commit the changes.

If `AutoCommit` is enabled for the `Connection` object, the IBM Data Server Driver for JDBC and SQLJ adds a commit method at the end of the batch.

c. If the `PreparedStatement` object returns automatically generated keys, call `DB2PreparedStatement.getDBGeneratedKeys` to retrieve an array of `ResultSet` objects that contains the automatically generated keys.

Check the length of the returned array. If the length of the returned array is 0, an error occurred during retrieval of the automatically generated keys.

6. If errors occurred, process the `BatchUpdateException`.

In the following code fragment, two sets of parameters are batched. An UPDATE statement that takes two input parameters is then executed twice, once with each set of parameters. The numbers to the right of selected statements correspond to the previously-described steps.

```java
try {
    ...  
    PreparedStatement preps = conn.prepareStatement(
        "UPDATE DEPT SET MGRNO=? WHERE DEPTNO=?");  
    ps.setString(1,mgrnum1);  
    ps.setString(2,deptnum1);  
    ps.addBatch();  
    ps.setString(1,mgrnum2);  
    ps.setString(2,deptnum2);  
    ps.addBatch();  
    int [] numUpdates=ps.executeBatch();  
    for (int i=0; i < numUpdates.length; i++) {
        if (numUpdates[i] == SUCCESS_NO_INFO)  
            System.out.println("Execution "+i +" unknown number of rows updated");  
        else  
            System.out.println("Execution "+i +" successful: " + numUpdates[i] +" rows updated");
    }  
    conn.commit();  
} catch(BatchUpdateException b) {  
    // process BatchUpdateException
}
```

In the following code fragment, a batched INSERT statement returns automatically generated keys.

```java
import java.sql.*;
import com.ibm.db2.jcc.*;
```
Connection conn;  
...  
try {
    ...  
    PreparedStatement ps = conn.prepareStatement("INSERT INTO DEPT (DEPTNO, DEPTNAME, ADMRDEPT) VALUES (?, ?, ?)", Statement.RETURN_GENERATED_KEYS);  
    ps.setString(1, "X01");  
    ps.setString(2, "Finance");  
    ps.setString(3, "A00");  
    ps.addBatch();  
    ps.setString(1, "Y01");  
    ps.setString(2, "Accounting");  
    ps.setString(3, "A00");  
    ps.addBatch();  
    int [] numUpdates=preps.executeBatch();  
    for (int i=0; i < numUpdates.length; i++) {
        if (numUpdates[i] == SUCCESS_NO_INFO)  
            System.out.println("Execution"+i+"unknown number of rows updated");
        else  
            System.out.println("Execution"+i+"successful: " +numUpdates[i] + " rows updated");
    }
    conn.commit();  
    ResultSet [] resultList = ((DB2PreparedStatement)ps).getDBGeneratedKeys();  
    if (resultList.length != 0) {
        for (i = 0; i < resultList.length; i++) {
            while (resultList[i].next()) {
                java.math.BigDecimal idColVar = rs.getBigDecimal(1);  
                // Get automatically generated key  
                // value  
                System.out.println("Automatically generated key value = " + idColVar);
            }
        }
    } else {  
        System.out.println("Error retrieving automatically generated keys");
    }
} catch(BatchUpdateException b) {  
    // process BatchUpdateException
}

In the following code fragment, a batched UPDATE statement returns
automatically generated keys. The code names the DEPTNO column as an
automatically generated key, updates two rows in the DEPT table in a batch, and
retrieves the values of DEPTNO for the updated rows. The numbers to the right of
selected statements correspond to the previously described steps.

import java.sql.*;
import com.ibm.db2.jcc.*;
...
Connection conn;  
...  
String[] agkNames = {"DEPTNO"};
try {
    ...
ps.setString(2, "Planning");
ps.addBatch();
ps.setString(1, "Y01");
ps.setString(2, "Bookkeeping");
ps.addBatch();

int [] numUpdates = ps.executeBatch();

for (int i = 0; i < numUpdates.length; i++) {
    if (numUpdates[i] == SUCCESS_NO_INFO)
        System.out.println("Execution " + i + " unknown number of rows updated");
    else
        System.out.println("Execution " + i + " successful: " + numUpdates[i] + " rows updated");
}

conn.commit();

ResultSet[] resultList = ((DB2PreparedStatement)ps).getDBGeneratedKeys();

if (resultList.length != 0) {
    for (i = 0; i < resultList.length; i++) {
        while (resultList[i].next()) {
            String deptNoKey = rs.getString(1);
            // Get automatically generated key value
            System.out.println("Automatically generated key value = " + deptNoKey);
        }
    }
} else {
    System.out.println("Error retrieving automatically generated keys");
}

} catch (BatchUpdateException b) {
    // process BatchUpdateException
}

Learning about parameters in a PreparedStatement using ParameterMetaData methods

The IBM Data Server Driver for JDBC and SQLJ includes support for the ParameterMetaData interface. The ParameterMetaData interface contains methods that retrieve information about the parameter markers in a PreparedStatement object.

ParameterMetaData methods provide the following types of information:
- The data types of parameters, including the precision and scale of decimal parameters.
- The parameters’ database-specific type names. For parameters that correspond to table columns that are defined with distinct types, these names are the distinct type names.
- Whether parameters are nullable.
- Whether parameters are input or output parameters.
- Whether the values of a numeric parameter can be signed.
The fully-qualified Java class name that PreparedStatement.setObject uses when it sets a parameter value.

To invoke ParameterMetaData methods, you need to perform these basic steps:
1. Invoke the Connection.prepareStatement method to create a PreparedStatement object.
2. Invoke the PreparedStatement.getParameterMetaData method to retrieve a ParameterMetaData object.
3. Invoke ParameterMetaData.getParameterCount to determine the number of parameters in the PreparedStatement.
4. Invoke ParameterMetaData methods on individual parameters.

The following code demonstrates how to use ParameterMetaData methods to determine the number and data types of parameters in an SQL UPDATE statement. The numbers to the right of selected statements correspond to the previously-described steps.

```java
Connection con;
ParameterMetaData pmtadta;
int mtadtacnt;
String sqlType;
...
pstmt = con.prepareStatement("UPDATE EMPLOYEE SET PHONENO=? WHERE EMPNO=?"); // Create a PreparedStatement object
pmtadta = pstmt.getParameterMetaData(); // Create a ParameterMetaData object
mtadtacnt = pmtadta.getParameterCount(); // Determine the number of parameters
System.out.println("Number of statement parameters: " + mtadtacnt);
for (int i = 1; i <= mtadtacnt; i++) {
    sqlType = pmtadta.getParameterTypeName(i); // Get SQL type for each parameter
    System.out.println("SQL type of parameter "+i" is "+sqlType);
}
...
pstmt.close(); // Close the PreparedStatement
```

Figure 11. Using ParameterMetaData methods to get information about a PreparedStatement

Metadata for columns that are defined in code units
The java.sql.DatabaseMetaData methods provide information about table columns that are defined with code units.

DB2 for Linux, UNIX, and Windows Version 10.5 or later supports character or graphic column definitions that have the OCTETS, CODEUNITS16, or CODEUNITS32 length attribute. That attribute indicates whether the column or parameter length is defined as single bytes, UTF-16 units (two-byte units), or UTF-32 units (four-byte units).
For example, in the following table definition, the length of the first column is in bytes, the length of the second column is in two-byte units, and the length of the third column is in four-byte units:

```sql
CREATE TABLE MYTABLE (
  COL1 CHAR(10 OCTETS),
  COL2 GRAPHIC(10 CODEUNITS16),
  COL3 VARCHAR(10 CODEUNITS32));
```

The standard JDBC java.sql.DatabaseMetaData methods return information about lengths of the columns in bytes and code units. That information is summarized in the following table.

<table>
<thead>
<tr>
<th>Method</th>
<th>Length and code unit information returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.sql.DatabaseMetaData.getColumns</td>
<td>COLUMN_SIZE result set column</td>

“Learning about parameter and ResultSet columns that are defined with code units.”

**Learning about parameter and ResultSet columns that are defined with code units**

The IBM Data Server Driver for JDBC and SQLJ provides methods that you can use to determine the number of bits in a code unit for parameters or ResultSet columns that are defined with the OCTETS, CODEUNITS16, or CODEUNITS32 attribute.

The standard JDBC java.sql.ParameterMetaData and java.sql.ResultSetMetaData methods return information about lengths of the parameters or columns only in code units. That information is summarized in the following table.
<table>
<thead>
<tr>
<th>Method</th>
<th>Length and code unit information returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.sql.ParameterMetaData.getPrecision</td>
<td>Returns the parameter length in code units</td>
</tr>
<tr>
<td>java.sql.ResultSetMetaData.getColumnDisplaySize</td>
<td>Returns the column length in code units</td>
</tr>
<tr>
<td>java.sql.ResultSetMetaData.getPrecision</td>
<td>Returns the column length in code units</td>
</tr>
</tbody>
</table>

The IBM Data Server Driver for JDBC and SQLJ provides methods that return the number of bits in a code unit for columns or parameters that are defined in code units. Those methods are:

- com.ibm.db2.jdbc.DB2ParameterMetaData.getMaxStringUnitBits
- com.ibm.db2.jdbc.DB2ResultSetMetaData.getMaxStringUnitBits

To determine the number of bits in a parameter or in a ResultSet column that is defined in code units, follow these steps.

1. Use one of the standard JDBC methods to retrieve the length in code units.
2. Retrieve the number of bits in a code unit with the `DB2ParameterMetaData.getCodeUnitScalingFactor` or `DB2ResultSetMetaData.getCodeUnitScalingFactor` method.
3. Multiply the two values to get the length of the parameter or ResultSet column in bits.

**Examples**

**Example:** Suppose that you want to insert values into a table is defined like this:

```sql
CREATE TABLE MYTABLE (
    CHARCOL CHAR(9 OCTETS),
    VARCHARCOL VARCHAR(9 CODEUNITS32));
```

The following code demonstrates how to determine the length in bits of the parameters that are defined in code units. The numbers to the right of selected statements correspond to the previously described steps.

```java
... PreparedStatement pstmt = 
    con.prepareStatement("INSERT INTO MYTABLE VALUES (?,?)");
ParameterMetaData pmd = pstmt.getParameterMetaData();
int pCount = pmd.getParameterCount();
int pLenInCodeUnits;
int pBitsPerCodeUnit;
for (int j=1;j<=pCount;j++)
{
    System.out.println("Parameter type = " +
        pmd.getParameterTypeName(j));
    pLenInCodeUnits = pmd.getPrecision(j));
    System.out.println("Length in code units = " + pLenInCodeUnits); 1
    pBitsPerCodeUnit =
        (com.ibm.db2.jdbc.DB2ParameterMetaData(pmd).getMaxStringLengthUnitBits();
    System.out.println("Bits per code unit = " + pBitsPerCodeUnit); 2
    System.out.println("Length in bits = " + pLenInCodeUnits*pBitsPerCodeUnit); 3
}
```

The following results are returned:
Data retrieval in JDBC applications

In JDBC applications, you retrieve data using ResultSet objects. A ResultSet represents the result set of a query.

Retrieving data from tables using the Statement.executeQuery method

To retrieve data from a table using a SELECT statement with no parameter markers, you can use the Statement.executeQuery method.

This method returns a result table in a ResultSet object. After you obtain the result table, you need to use ResultSet methods to move through the result table and obtain the individual column values from each row.

With the IBM Data Server Driver for JDBC and SQLJ, you can also use the Statement.executeQuery method to retrieve a result set from a stored procedure call, if that stored procedure returns only one result set. If the stored procedure returns multiple result sets, you need to use the Statement.execute method.

This topic discusses the simplest kind of ResultSet, which is a read-only ResultSet in which you can only move forward, one row at a time. The IBM Data Server Driver for JDBC and SQLJ also supports updatable and scrollable ResultSets.

To retrieve rows from a table using a SELECT statement with no parameter markers, you need to perform these steps:
1. Invoke the Connection.createStatement method to create a Statement object.
2. Invoke the Statement.executeQuery method to obtain the result table from the SELECT statement in a ResultSet object.
3. In a loop, position the cursor using the next method, and retrieve data from each column of the current row of the ResultSet object using getXXX methods. XXX represents a data type.
4. Invoke the ResultSet.close method to close the ResultSet object.
5. Invoke the Statement.close method to close the Statement object when you have finished using that object.

The following code demonstrates how to retrieve all rows from the employee table. The numbers to the right of selected statements correspond to the previously-described steps.
Retrieving data from tables using the
PreparedStatement.executeQuery method

To retrieve data from a table using a SELECT statement with parameter markers, you use the PreparedStatement.executeQuery method.

This method returns a result table in a ResultSet object. After you obtain the result table, you need to use ResultSet methods to move through the result table and obtain the individual column values from each row.

With the IBM Data Server Driver for JDBC and SQLJ, you can also use the PreparedStatement.executeQuery method to retrieve a result set from a stored procedure call, if that stored procedure returns only one result set and has only input parameters. If the stored procedure returns multiple result sets, you need to use the PreparedStatement.executeQuery method.

You can also use the PreparedStatement.executeQuery method for statements that have no parameter markers. When you execute a query many times, you can get better performance by creating the SQL statement as a PreparedStatement.

To retrieve rows from a table using a SELECT statement with parameter markers, you need to perform these steps:

1. Invoke the Connection.prepareStatement method to create a PreparedStatement object.
2. Invoke PreparedStatement.setXXX methods to pass values to the input parameters.
3. Invoke the PreparedStatement.executeQuery method to obtain the result table from the SELECT statement in a ResultSet object.

Restriction: For a PreparedStatement that contains an IN predicate, the expression that is the argument of the IN predicate cannot have more than 32767 parameters if the target data server is a DB2 for Linux, UNIX, and Windows system. Otherwise, the IBM Data Server Driver for JDBC and SQLJ throws an SQLException with error code -4499.

4. In a loop, position the cursor using the ResultSet.next method, and retrieve data from each column of the current row of the ResultSet object using getXXX methods.
5. Invoke the ResultSet.close method to close the ResultSet object.

```java
String empNo;
Connection con;
Statement stmt;
ResultSet rs;
...
stmt = con.createStatement(); // Create a Statement object  
rs = stmt.executeQuery("SELECT EMPNO FROM EMPLOYEE");  
// Get the result table from the query
while (rs.next()) { // Position the cursor
empNo = rs.getString(1); // Retrieve only the first column value
System.out.println("Employee number = " + empNo);  
// Print the column value
}
rs.close(); // Close the ResultSet
stmt.close(); // Close the Statement
```

Figure 13. Using Statement.executeQuery

Related reference:
“Driver support for JDBC APIs” on page 399
6. Invoke the PreparedStatement.close method to close the PreparedStatement object when you have finished using that object.

The following code demonstrates how to retrieve rows from the employee table for a specific employee. The numbers to the right of selected statements correspond to the previously-described steps.

```java
String empnum, phonenum;
Connection con;
PreparedStatement pstmt;
ResultSet rs;
...
pstmt = con.prepareStatement("SELECT EMPNO, PHONENO FROM EMPLOYEE WHERE EMPNO=?");
   // Create a PreparedStatement object
pstmt.setString(1,"000010");   // Assign value to input parameter
rs = pstmt.executeQuery();   // Get the result table from the query
while (rs.next()) {
   emnum = rs.getString(1);   // Retrieve the first column value
   phonenum = rs.getString(2);   // Retrieve the first column value
   System.out.println("Employee number = " + empnum +
      "Phone number = " + phonenum);   // Print the column values
}
rs.close();   // Close the ResultSet
pstmt.close();   // Close the PreparedStatement
```

Figure 14. Example of using PreparedStatement.executeQuery

“Driver support for JDBC APIs” on page 399

Making batch queries in JDBC applications

The IBM Data Server Driver for JDBC and SQLJ provides a IBM Data Server Driver for JDBC and SQLJ-only DB2PreparedStatement interface that lets you perform batch queries on a homogeneous batch.

To make batch queries using a single statement with several sets of input parameters, follow these basic steps:

1. Invoke the prepareStatement method to create a PreparedStatement object for the SQL statement with input parameters.
2. For each set of input parameter values:
   a. Execute PreparedStatement.setXXX methods to assign values to the input parameters.
   b. Invoke the PreparedStatement.addBatch method to add the set of input parameters to the batch.
3. Cast the PreparedStatement object to a DB2PreparedStatement object, and invoke the DB2PreparedStatement.executeDB2QueryBatch method to execute the statement with all sets of parameters.
4. In a loop, retrieve the ResultSet objects:
   a. Retrieve each ResultSet object.
   b. Retrieve all the rows from each ResultSet object.

In the following code fragment, two sets of parameters are batched. A SELECT statement that takes one input parameter is then executed twice, once with each parameter value. The numbers to the right of selected statements correspond to the previously described steps.
java.sql.Connection con = java.sql.DriverManager.getConnection(url, properties);
java.sql.Statement s = con.createStatement();
// Clean up from previous executions
try {
    s.executeUpdate("drop table TestQBatch");
} catch (Exception e) {
}

// Create and populate a test table
s.executeUpdate("create table TestQBatch (col1 int, col2 char(10))");
s.executeUpdate("insert into TestQBatch values (1, 'test1')");
s.executeUpdate("insert into TestQBatch values (2, 'test2')");
s.executeUpdate("insert into TestQBatch values (3, 'test3')");
s.executeUpdate("insert into TestQBatch values (4, 'test4')");
s.executeUpdate("insert into TestQBatch values (1, 'test5')");
s.executeUpdate("insert into TestQBatch values (2, 'test6')");

try {
    PreparedStatement pstmt =
        con.prepareStatement("Select * from TestQBatch where col1 = ?");
pstmt.setInt(1,1);
pstmt.addBatch();
    // Add some more values to the batch
    pstmt.setInt(1,2);
pstmt.addBatch();
pstmt.setInt(1,3);
pstmt.addBatch();
pstmt.setInt(1,4);
pstmt.addBatch();
    ((com.ibm.db2.jcc.DB2PreparedStatement)pstmt).executeDB2QueryBatch();
}

// Related tasks:
"Making batch updates in JDBC applications” on page 50

Learning about a ResultSet using ResultSetMetaData methods
You cannot always know the number of columns and data types of the columns in a table or result set. This is true especially when you are retrieving data from a remote data source.

When you write programs that retrieve unknown ResultSets, you need to use ResultSetMetaData methods to determine the characteristics of the ResultSets before you can retrieve data from them.

ResultSetMetaData methods provide the following types of information:
• The number of columns in a ResultSet
• The qualifier for the underlying table of the ResultSet
After you invoke the executeQuery method to generate a ResultSet for a query on a table, follow these basic steps to determine the contents of the ResultSet:

1. Invoke the getMetaData method on the ResultSet object to create a ResultSetMetaData object.
2. Invoke the getColumnCount method to determine how many columns are in the ResultSet.
3. For each column in the ResultSet, execute ResultSetMetaData methods to determine column characteristics.

The results of ResultSetMetaData.getColumnName call reflects the column name information that is stored in the DB2 catalog for that data source.

The following code demonstrates how to determine the data types of all the columns in the employee table. The numbers to the right of selected statements correspond to the previously-described steps.

```java
String s;
Connection con;
Statement stmt;
ResultSet rs;
ResultSetMetaData rsmtdata;
int colCount;
int mtadtaInt;
int i;
String colName;
String colType;
...
stmt = con.createStatement(); // Create a Statement object
rs = stmt.executeQuery("SELECT * FROM EMPLOYEE"); // Get the ResultSet from the query
rsmtdata = rs.getMetaData(); // Create a ResultSetMetaData object
colCount = rsmtdata.getColumnCount(); // Find number of columns in EMP
for (i=1; i<= colCount; i++) {
    colName = rsmtdata.getColumnName(); // Get column name
    colType = rsmtdata.getColumnTypeName(); // Get column data type
    System.out.println("Column = " + colName + " is data type " + colType); // Print the column value
}
```

Figure 15. Using ResultSetMetaData methods to get information about a ResultSet
Characteristics of a JDBC ResultSet under the IBM Data Server Driver for JDBC and SQLJ
The IBM Data Server Driver for JDBC and SQLJ provides support for scrollable, updatable, and holdable cursors.

In addition to moving forward, one row at a time, through a ResultSet, you might want to do the following things:

- Move backward or go directly to a specific row
- Update, delete, or insert rows in a ResultSet
- Leave the ResultSet open after a COMMIT

The following terms describe characteristics of a ResultSet:

scrollability
Whether the cursor for the ResultSet can move forward only, or forward one or more rows, backward one or more rows, or to a specific row.

If a cursor for a ResultSet is scrollable, it also has a sensitivity attribute, which describes whether the cursor is sensitive to changes to the underlying table.

updatability
Whether the cursor can be used to update or delete rows. This characteristic does not apply to a ResultSet that is returned from a stored procedure, because a stored procedure ResultSet cannot be updated.

holdability
Whether the cursor stays open after a COMMIT.

You set the updatability, scrollability, and holdability characteristics of a ResultSet through parameters in the Connection.prepareStatement or Connection.createStatement methods. The ResultSet settings map to attributes of a cursor in the database. The following table lists the JDBC scrollability, updatability, and holdability settings, and the corresponding cursor attributes.

<table>
<thead>
<tr>
<th>JDBC setting</th>
<th>DB2 cursor setting</th>
<th>IBM Informix cursor setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONCUR_READ_ONLY</td>
<td>FOR READ ONLY</td>
<td>FOR READ ONLY</td>
</tr>
<tr>
<td>CONCUR_UPDATABLE</td>
<td>FOR UPDATE</td>
<td>FOR UPDATE</td>
</tr>
<tr>
<td>HOLD_CURSORS_OVER_COMMIT</td>
<td>WITH HOLD</td>
<td>WITH HOLD</td>
</tr>
<tr>
<td>TYPE_FORWARDONLY</td>
<td>SCROLL not specified</td>
<td>SCROLL not specified</td>
</tr>
<tr>
<td>TYPE_SCROLL_INSENSITIVE</td>
<td>INSENSITIVE SCROLL</td>
<td>SCROLL</td>
</tr>
<tr>
<td>TYPE_SCROLL_SENSITIVE</td>
<td>SENSITIVE STATIC, SENSITIVE DYNAMIC, or ASENSITIVE, depending on the cursorSensitivity Connection and DataSource property</td>
<td>Not supported</td>
</tr>
</tbody>
</table>
If a JDBC ResultSet is static, the size of the result table and the order of the rows in the result table do not change after the cursor is opened. This means that if you insert rows into the underlying table, the result table for a static ResultSet does not change. If you delete a row of a result table, a delete hole occurs. You cannot update or delete a delete hole.

**Specifying updatability, scrollability, and holdability for ResultSets in JDBC applications:**

You use special parameters in the Connection.prepareStatement or Connection.createStatement methods to specify the updatability, scrollability, and holdability of a ResultSet.

If you plan to update ResultSet objects, ensure that the enableExtendedDescribe property is not set, or is set to DB2BaseDataSource.YES (2). Updates of ResultSet objects do not work correctly unless extended describe capability is enabled.

By default, ResultSet objects are not scrollable and not updatable. The default holdability depends on the data source, and can be determined from the DatabaseMetaData.getResultSetHoldability method. These steps change the scrollability, updatability, and holdability attributes for a ResultSet.

1. If the SELECT statement that defines the ResultSet has no input parameters, invoke the createStatement method to create a Statement object. Otherwise, invoke the prepareStatement method to create a PreparedStatement object. You need to specify forms of the createStatement or prepareStatement methods that include the resultSetType, resultSetConcurrency, or resultSetHoldability parameters.

   The form of the createStatement method that supports scrollability and updatability is:
   ```java
   createStatement(int resultSetType, int resultSetConcurrency);
   ```

   The form of the createStatement method that supports scrollability, updatability, and holdability is:
   ```java
   createStatement(int resultSetType, int resultSetConcurrency,  
                  int resultSetHoldability);
   ```

   The form of the prepareStatement method that supports scrollability and updatability is:
   ```java
   prepareStatement(String sql, int resultSetType,  
                   int resultSetConcurrency);
   ```

   The form of the prepareStatement method that supports scrollability, updatability, and holdability is:
   ```java
   prepareStatement(String sql, int resultSetType,  
                   int resultSetConcurrency, int resultSetHoldability);
   ```

**Important:** In a prepareStatement method invocation in which the first parameter is a CALL statement, you cannot specify the scrollability, updatability, or holdability of result sets that are returned from a stored procedure. Those characteristics are determined by the stored procedure code, when it declares the cursors for the result sets that are returned. If you use the prepareStatement method to prepare a CALL statement, and the prepareStatement call includes the scrollability, updatability, or holdability parameters, the IBM Data Server Driver for JDBC and SQLJ does not use those
parameter values. A prepareStatement method with scrollability, updatability, or holdability parameters applies only to preparation of SQL statements other than the CALL statement.

The following table contains a list of valid values for resultSetType and resultSetConcurrency.

**Table 11. Valid combinations of resultSetType and resultSetConcurrency for ResultSets**

<table>
<thead>
<tr>
<th>resultSetType value</th>
<th>resultSetConcurrency value</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE_FORWARD_ONLY</td>
<td>CONCUR_READ_ONLY</td>
</tr>
<tr>
<td>TYPE_FORWARD_ONLY</td>
<td>CONCUR_UPDATABLE</td>
</tr>
<tr>
<td>TYPE_SCROLL_INSENSITIVE</td>
<td>CONCUR_READ_ONLY</td>
</tr>
<tr>
<td>TYPE_SCROLL_SENSITIVE</td>
<td>CONCUR_READ_ONLY</td>
</tr>
<tr>
<td>TYPE_SCROLL_SENSITIVE</td>
<td>CONCUR_UPDATABLE</td>
</tr>
</tbody>
</table>

Note:
1. This value does not apply to connections to IBM Informix.

resultSetHoldability has two possible values: HOLD_CURSORS_OVER_COMMIT and CLOSE_CURSORS_AT_COMMIT. Either of these values can be specified with any valid combination of resultSetConcurrency and resultSetHoldability. The value that you set overrides the default holdability for the connection.

Restriction: If the ResultSet is scrollable, and the ResultSet is used to select columns from a table on a DB2 for Linux, UNIX, and Windows server, the SELECT list of the SELECT statement that defines the ResultSet cannot include columns with the following data types:

- LONG VARCHAR
- LONG VARGRAPHIC
- BLOB
- CLOB
- XML
- A distinct type that is based on any of the previous data types in this list
- A structured type

2. If the SELECT statement has input parameters, invoke setXXX methods to pass values to the input parameters.

3. Invoke the executeQuery method to obtain the result table from the SELECT statement in a ResultSet object.

4. For each row that you want to access:
   a. Position the cursor using one of the methods that are listed in the following table.

   **Restriction:** If resultSetType is TYPE_FORWARD_ONLY, only ResultSet.next is valid.

**Table 12. ResultSet methods for positioning a scrollable cursor**

<table>
<thead>
<tr>
<th>Method</th>
<th>Positions the cursor</th>
</tr>
</thead>
<tbody>
<tr>
<td>first</td>
<td>On the first row of the ResultSet</td>
</tr>
<tr>
<td>last</td>
<td>On the last row of the ResultSet</td>
</tr>
<tr>
<td>next</td>
<td>On the next row of the ResultSet</td>
</tr>
<tr>
<td>previous</td>
<td>On the previous row of the ResultSet</td>
</tr>
</tbody>
</table>
Table 12. ResultSet methods for positioning a scrollable cursor (continued)

<table>
<thead>
<tr>
<th>Method</th>
<th>Positions the cursor</th>
</tr>
</thead>
<tbody>
<tr>
<td>absolute(int $n$)</td>
<td>If $n &gt; 0$, on row $n$ of the ResultSet. If $n &lt; 0$, and $m$ is the number of rows in the ResultSet, on row $m+n+1$ of the ResultSet.</td>
</tr>
<tr>
<td>relative(int $n$)</td>
<td>If $n &gt; 0$, on the row that is $n$ rows after the current row. If $n &lt; 0$, on the row that is $n$ rows before the current row. If $n = 0$, on the current row.</td>
</tr>
<tr>
<td>afterLast</td>
<td>After the last row in the ResultSet</td>
</tr>
<tr>
<td>beforeFirst</td>
<td>Before the first row in the ResultSet</td>
</tr>
</tbody>
</table>

Notes:
1. This method does not apply to connections to IBM Informix.
2. If the cursor is before the first row of the ResultSet, this method positions the cursor on the first row.
3. If the cursor is after the last row of the ResultSet, this method positions the cursor on the last row.
4. If the absolute value of $n$ is greater than the number of rows in the result set, this method positions the cursor after the last row if $n$ is positive, or before the first row if $n$ is negative.
5. The cursor must be on a valid row of the ResultSet before you can use this method. If the cursor is before the first row or after the last row, the method throws an SQLException.
6. Suppose that $m$ is the number of rows in the ResultSet and $x$ is the current row number in the ResultSet. If $n > 0$ and $x + n > m$, the driver positions the cursor after the last row. If $n < 0$ and $x + n < 1$, the driver positions the cursor before the first row.

b. If you need to know the current cursor position, use the getRow, isFirst, isLast, isBeforeFirst, or isAfterLast method to obtain this information.
c. If you specified a resultSetType value of TYPE_SCROLL_SENSITIVE in step 1 on page 64 and you need to see the latest values of the current row, invoke the refreshRow method.

Recommendation: Because refreshing the rows of a ResultSet can have a detrimental effect on the performance of your applications, you should invoke refreshRow only when you need to see the latest data.
d. Perform one or more of the following operations:
   • To retrieve data from each column of the current row of the ResultSet object, use getXXX methods.
   • To update the current row from the underlying table, use updateXXX methods to assign column values to the current row of the ResultSet. Then use updateRow to update the corresponding row of the underlying table. If you decide that you do not want to update the underlying table, invoke the cancelRowUpdates method instead of the updateRow method.
      The resultSetConcurrency value for the ResultSet must be CONCUR_UPDATABLE for you to use these methods.
   • To delete the current row from the underlying table, use the deleteRow method. Invoking deleteRow causes the driver to replace the current row of the ResultSet with a hole.
      The resultSetConcurrency value for the ResultSet must be CONCUR_UPDATABLE for you to use this method.

5. Invoke the close method to close the ResultSet object.
6. Invoke the close method to close the Statement or PreparedStatement object.
The following code demonstrates how to retrieve all rows from the employee table in reverse order, and update the phone number for employee number "000010". The numbers to the right of selected statements correspond to the previously-described steps.

```java
String s;
String stmtsrc;
Connection con;
Statement stmt;
ResultSet rs;
...
stmt = con.createStatement(ResultSet.TYPE_SCROLL_SENSITIVE,
    ResultSet.CONCUR_UPDATABLE); // Create a Statement object
    // for a scrollable, updatable ResultSet
stmtsrc = "SELECT EMPNO, PHONENO FROM EMPLOYEE " +
    "FOR UPDATE OF PHONENO";
rs = stmt.executeQuery(stmtsrc); // Create the ResultSet
rs.afterLast(); // Position the cursor at the end of
    // the ResultSet
while (rs.previous()) {
    s = rs.getString("EMPNO"); // Retrieve the employee number
        // (column 1 in the result table)
    System.out.println("Employee number = " + s); // Print the column value
    if (s.compareTo("000010") == 0) { // Look for employee 000010
        rs.updateString("PHONENO","4657"); // Update their phone number
        rs.updateRow(); // Update the row
    }
}
rs.close(); // Close the ResultSet
stmt.close(); // Close the Statement
```

Multi-row SQL operations in JDBC applications:

The IBM Data Server Driver for JDBC and SQLJ supports multi-row INSERT, UPDATE, and FETCH for connections to data sources that support these operations.

Multi-row INSERT

In JDBC applications, when you execute INSERT or MERGE statements that use parameter markers in a batch, if the data server supports multi-row INSERT, the IBM Data Server Driver for JDBC and SQLJ can transform the batch INSERT or MERGE operations into multi-row INSERT statements. Multi-row INSERT operations can provide better performance in the following ways:

- For local applications, multi-row INSERTs result in fewer accesses of the data server.
- For distributed applications, multi-row INSERTs result in fewer network operations.

You cannot execute a multi-row INSERT operation by including a multi-row INSERT statement in a statement string in your JDBC application.
Multi-row INSERT is used by default. You can use the Connection or DataSource property enableMultiRowInsertSupport to control whether multi-row INSERT is used. Multi-row INSERT cannot be used for INSERT FROM SELECT statements that are executed in a batch.

**Multi-row FETCH**

Multi-row FETCH can provide better performance than retrieving one row with each FETCH statement. For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS, multi-row FETCH can be used for forward-only cursors and scrollable cursors. For IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, multi-row FETCH can be used only for scrollable cursors.

When you retrieve data in your applications, the IBM Data Server Driver for JDBC and SQLJ determines whether to use multi-row FETCH, depending on several factors:

- The setting of the enableRowsetSupport property
- The setting of the useRowsetCursor property, for connections to DB2 for z/OS
- The type of IBM Data Server Driver for JDBC and SQLJ connectivity that is being used
- The version of the IBM Data Server Driver for JDBC and SQLJ

For IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to DB2 for z/OS, one of the following sets of conditions must be true for multi-row FETCH to be used.

- **First set of conditions:**
  - The IBM Data Server Driver for JDBC and SQLJ version is 3.51 or later.
  - The enableRowsetSupport property value is `com.ibm.db2.jcc.DB2BaseDataSource.YES (1)`, or the enableRowsetSupport property value is `com.ibm.db2.jcc.DB2BaseDataSource.NOT_SET (0)` and the useRowsetCursor property value is `true`.
  - The FETCH operation uses a scrollable cursor.
    For forward-only cursors, fetching of multiple rows might occur through DRDA block FETCH. However, this behavior does not utilize the data source's multi-row FETCH capability.

- **Second set of conditions:**
  - The IBM Data Server Driver for JDBC and SQLJ version is 3.1.
  - The useRowsetCursor property value is `com.ibm.db2.jcc.DB2BaseDataSource.YES (1)`,
  - The FETCH operation uses a scrollable cursor.
    For forward-only cursors, fetching of multiple rows might occur through DRDA block FETCH. However, this behavior does not utilize the data source's multi-row FETCH capability.

For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for z/OS the following conditions must be true for multi-row FETCH to be used.

- The IBM Data Server Driver for JDBC and SQLJ version is 3.51 or later.
- The enableRowsetSupport property value is `com.ibm.db2.jcc.DB2BaseDataSource.YES (1)`,
- The FETCH operation uses a scrollable cursor or a forward-only cursor.
For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS, you can control the maximum size of a rowset for each statement by setting the maxRowsetSize property.

**Multi-row positioned UPDATE or DELETE**

The IBM Data Server Driver for JDBC and SQLJ supports a technique for performing positioned update or delete operations that follows the JDBC 1 standard. That technique involves using the ResultSet.getCursorName method to obtain the name of the cursor for the ResultSet, and defining a positioned UPDATE or positioned DELETE statement of the following form:

```sql
UPDATE table SET col1=value1,...coln=valueN WHERE CURRENT OF cursorname
DELETE FROM table WHERE CURRENT OF cursorname
```

**Multi-row UPDATE or DELETE when useRowsetCursor is set to true:** If you use the JDBC 1 technique to update or delete data on a database server that supports multi-row FETCH, and multi-row FETCH is enabled through the useRowsetCursor property, the positioned UPDATE or DELETE statement might update or delete multiple rows, when you expect it to update or delete a single row. To avoid unexpected updates or deletes, you can take one of the following actions:

- Use an updatable ResultSet to retrieve and update one row at a time, as shown in the previous example.
- Set useRowsetCursor to false.

**Multi-row UPDATE or DELETE when enableRowsetSupport is set to com.ibm.db2.jcc.DB2BaseDataSource.YES (1):** The JDBC 1 technique for updating or deleting data is incompatible with multi-row FETCH that is enabled through the enableRowsetSupport property.

**Recommendation:** If your applications use the JDBC 1 technique, update them to use the JDBC 2.0 ResultSet.updateRow or ResultSet.deleteRow methods for positioned update or delete activity.

**Testing whether the current row of a ResultSet is a delete hole or update hole in a JDBC application:**

If a ResultSet has the TYPE_SCROLL_SENSITIVE attribute, and the underlying cursor is SENSITIVE STATIC, you need to test for delete holes or update holes before you attempt to retrieve rows of the ResultSet.

After a SENSITIVE STATIC ResultSet is opened, it does not change size. This means that deleted rows are replaced by placeholders, which are also called holes. If updated rows no longer fit the criteria for the ResultSet, those rows also become holes. You cannot retrieve rows that are holes.

To test whether the current row in a ResultSet is a delete hole or update hole, follow these steps:

1. Call the DatabaseMetaData.deletesAreDetected or DatabaseMetaData.updatesAreDetected method with the TYPE_SCROLL_SENSITIVE argument to determine whether the data source creates holes for a TYPE_SCROLL_SENSITIVE ResultSet.
2. If DatabaseMetaData.deletesAreDetected or DatabaseMetaData.updatesAreDetected returns true, which means that the data source can create holes, call the ResultSet.rowDeleted or ResultSet.rowUpdated methods.
method to determine whether the current row is a delete or update hole. If the method returns true, the current row is a hole.

The following code tests whether the current row is a delete hole.

```java
Statement stmt = con.createStatement(ResultSet.TYPE_SCROLL_SENSITIVE,
                        ResultSet.CONCUR_UPDATABLE);  // Create a Statement object
                        // for a scrollable, updatable
                        // ResultSet
ResultSet rs = stmt.executeQuery("SELECT EMPNO FROM EMPLOYEE FOR UPDATE OF PHONENO");  // Create the ResultSet
DatabaseMetaData dbmd = con.getMetaData();  // Create the DatabaseMetaData object
boolean dbSeesDeletes =
    dbmd.deletesAreDetected(ResultSet.TYPESCROLL_SENSITIVE);  // Can the database see delete holes?
rs.afterLast();  // Position the cursor at the end of
                // the ResultSet
while (rs.previous()) {  // Position the cursor backward
    if (dbSeesDeletes) {  // If delete holes can be detected
        if (!rs.rowDeleted()) {  // If this row is not a delete hole
            s = rs.getString("EMPNO");  // Retrieve the employee number
            System.out.println("Employee number = " + s);  // Print the column value
        }
    }
}
rs.close();  // Close the ResultSet
stmt.close();  // Close the Statement
```

Inserting a row into a ResultSet in a JDBC application:

If a ResultSet has a `resultSetConcurrency` attribute of CONCUR_UPDATABLE, you can insert rows into the ResultSet.

Ensure that the `enableExtendedDescribe` property is not set, or is set to DB2BaseDataSource.YES (2). Insertion of a row into a ResultSet does not work unless extended describe capability is enabled.

1. Perform the following steps for each row that you want to insert.
   a. Call the ResultSet.moveToInsertRow method to create the row that you want to insert. The row is created in a buffer outside the ResultSet. If an insert buffer already exists, all old values are cleared from the buffer.
   b. Call ResultSet.updateXXX methods to assign values to the row that you want to insert.
      You need to assign a value to at least one column in the ResultSet. If you do not do so, an SQLException is thrown when the row is inserted into the ResultSet.
      If you do not assign a value to a column of the ResultSet, when the underlying table is updated, the data source inserts the default value for the associated table column.
      If you assign a null value to a column that is defined as NOT NULL, the JDBC driver throws and SQLException.
   c. Call ResultSet.insertRow to insert the row into the ResultSet.
      After you call ResultSet.insertRow, all values are always cleared from the insert buffer, even if ResultSet.insertRow fails.
2. Reposition the cursor within the ResultSet.
To move the cursor from the insert row to the ResultSet, you can invoke any of the methods that position the cursor at a specific row, such as ResultSet.first, ResultSet.absolute, or ResultSet.relative. Alternatively, you can call ResultSet.moveToCurrentRow to move the cursor to the row in the ResultSet that was the current row before the insert operation occurred.

After you call ResultSet.moveToCurrentRow, all values are cleared from the insert buffer.

The following code illustrates inserting a row into a ResultSet that consists of all rows in the sample DEPARTMENT table. After the row is inserted, the code places the cursor where it was located in the ResultSet before the insert operation. The numbers to the right of selected statements correspond to the previously-described steps.

```java
stmt = con.createStatement(ResultSet.TYPE_SCROLL_SENSITIVE,
                         ResultSet.CONCUR_UPDATABLE);
ResultSet rs = stmt.executeQuery("SELECT * FROM DEPARTMENT");
rs.moveToInsertRow(); // SF5800001a/SF590000
rs.updateString("DEPT_NO", "M13");  // SF5800001b/SF590000
rs.updateString("DEPTNAME", "TECHNICAL SUPPORT");
rs.updateString("MGRNO", "000010");
rs.updateString("ADMREDEPT", "A00");
rs.insertRow();  // SF5800001c/SF590000
rs.moveToCurrentRow(); // SF5800002/SF590000
```

**Testing whether the current row was inserted into a ResultSet in a JDBC application:**

If a ResultSet is dynamic, you can insert rows into it. After you insert rows into a ResultSet you might need to know which rows were inserted.

To test whether the current row in a ResultSet was inserted, follow these steps:

1. Call the DatabaseMetaData.ownInsertsAreVisible and DatabaseMetaData.othersInsertsAreVisible methods to determine whether inserts can be visible to the given type of ResultSet.
2. If inserts can be visible to the ResultSet, call the DatabaseMetaData.insertsAreDetected method to determine whether the given type of ResultSet can detect inserts.
3. If the ResultSet can detect inserts, call the ResultSet.rowInserted method to determine whether the current row was inserted.

**Retrieving rows as byte data in JDBC applications**

You can use the DB2ResultSet.getDBRowDataAsBytes method to retrieve an entire row from a table as raw bytes, and retrieve the column data from the returned rows.

1. Create a Statement or PreparedStatement object.
2. Invoke the Statement.executeQuery method or PreparedStatement.executeQuery method to obtain a ResultSet object.
3. Cast the ResultSet object as a DB2ResultSet object.
4. Repeat the following steps until there are no rows left to retrieve:
   a. Move the cursor to the next row.
   b. Call the DB2ResultSet.getDBRowDataAsBytes method to retrieve an Object array that contains the row data.
   c. Cast the first element of the Object array as a byte array.
This byte array contains the data for each column in the row. See the description of `getDBRowDataAsBytes` in “DB2ResultSet interface” on page 532 for the data format.

d. Cast the second element of the `Object` array as an `int` array.
   Each integer in this array contains the offset into the row data byte array of the beginning of the data for a column.

e. Call the `DB2ResultSet.getDBRowDescriptor` method to retrieve an `int` array that contains the row data.
   This array contains descriptive information about each column in the row. See the description of `getDBRowDescriptor` in “DB2ResultSet interface” on page 532 for the data format.

f. Use the offset value for each column to locate the column data, and retrieve each byte of the column data.

g. Use the information that is returned from `DB2ResultSet.getDBRowDescriptor` to convert the bytes into a value of the column type.

Suppose that table `MYTABLE` is defined like this:

```
CREATE TABLE MYTABLE (  
  INTCOL1 INTEGER NOT NULL,  
  INTCOL2 INTEGER NOT NULL)
```

The following program retrieves rows of data as raw bytes, and retrieves the column values from each returned row. The numbers to the right of statements correspond to the previously described steps.

```java
import java.sql.*;
import com.ibm.db2.jcc.*;

Connection conn;...
String sql1="select INTCOL, CHARCOL FROM MYTABLE";
int colSqltype;
int colCcsid
int colLen;
int colRep;
Object obj[];
byte data[];
int returnedInfo[];
int numberOfColumns;
int j;
int offsets[];
byte b1;
byte b2;
byte b3
byte b4;
int intVal;

try {
  Statement stmt = conn.createStatement ();
  DB2ResultSet rs = (DB2ResultSet)stmt.executeQuery(sql1);
  int rowNum=0;
  while(!rs.isLast())
  {
    rs.next();
    rowNum++;
    obj[] = rs.getDBRowDataAsBytes();
    //********************************************
    // Retrieve the data and offsets.
    // The code for checking the row indicator is
    // not shown. Assume that the row indicator
```
Calling stored procedures in JDBC applications

To call stored procedures, you invoke methods in the CallableStatement or PreparedStatement class.

The basic steps for calling a stored procedures using standard CallableStatement methods are:

1. Invoke the Connection.prepareCall method with the CALL statement as its argument to create a CallableStatement object.

You can represent parameters with standard parameter markers (?), named parameter markers, or named parameters. You can mix named parameters and standard parameter markers in the same CALL statement, but you cannot mix named parameter markers with standard parameter markers or named parameters.

Restriction: The parameter types that are permitted depend on whether the data source supports dynamic execution of the CALL statement. DB2 for z/OS does not support dynamic execution of the CALL statement. For a call to a stored procedure that is on a DB2 for z/OS database server, the parameters can be parameter markers or literals, but not expressions. Even if all parameters are literals, you cannot use Statement methods to execute CALL statements. You
must use PreparedStatement methods or CallableStatement methods. The following table lists the types of literals that are supported, and the JDBC types to which they map.

Table 13. Supported literal types in parameters in DB2 for z/OS stored procedure calls

<table>
<thead>
<tr>
<th>Literal parameter type</th>
<th>JDBC type</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>java.sql.Types.INTEGER</td>
<td>-122, 40022, +27</td>
</tr>
<tr>
<td>Floating-point decimal</td>
<td>java.sql.Types.DOUBLE</td>
<td>23E12, 40022E-4, +2723E+15, 1E+23, 0E0</td>
</tr>
<tr>
<td>Fixed-point decimal</td>
<td>java.sql.Types.DECIMAL</td>
<td>-23.12, 40022.4295, 0.0, +2723.23, 10000000000</td>
</tr>
<tr>
<td>Character</td>
<td>java.sql.Types.VARCHAR</td>
<td>‘Grantham Lutz’, ‘O’Conner’, ‘ABcde?z?’</td>
</tr>
<tr>
<td>Hexadecimal</td>
<td>java.sql.Types.VARBINARY</td>
<td>X'C1C30427', X'00CF18E0'</td>
</tr>
<tr>
<td>Unicode string</td>
<td>java.sql.Types.VARCHAR</td>
<td>UX'0041', UX'005406500730074'</td>
</tr>
</tbody>
</table>

**Important:** In a prepareCall method invocation, you cannot specify the scrollability, updatability, or holdability of result sets that are returned from a stored procedure. Those characteristics are determined by the stored procedure code, when it declares the cursors for the result sets that are returned. If you specify any of the forms of prepareCall that include scrollability, updatability, or holdability parameters, the IBM Data Server Driver for JDBC and SQLJ does not use those parameter values. A prepareCall method with scrollability, updatability, or holdability parameters applies only to preparation of SQL statements other than the CALL statement.

2. Invoke the CallableStatement.setXXX methods to pass values to the input parameters (parameters that are defined as IN or INOUT in the CREATE PROCEDURE statement).

This step assumes that you use standard parameter markers or named parameters. Alternatively, if you use named parameter markers, you use IBM Data Server Driver for JDBC and SQLJ-only methods to pass values to the input parameters.

**Restriction:** If the data source does not support dynamic execution of the CALL statement, you must specify the data types for CALL statement input parameters **exactly** as they are specified in the stored procedure definition.

**Restriction:** Invoking CallableStatement.setXXX methods to pass values to the OUT parameters is not supported. There is no need to set values for the OUT parameters of a stored procedure because the stored procedure does not use those values.

3. Invoke the CallableStatement.registerOutParameter method to register parameters that are defined as OUT in the CREATE PROCEDURE statement with specific data types.

This step assumes that you use standard parameter markers or named parameters. Alternatively, if you use named parameter markers, you use IBM Data Server Driver for JDBC and SQLJ-only methods to register OUT parameters with specific data types.

**Restriction:** If the data source does not support dynamic execution of the CALL statement, you must specify the data types for CALL statement OUT, IN, or INOUT parameters **exactly** as they are specified in the stored procedure definition.

4. Invoke one of the following methods to call the stored procedure:
CallableStatement.executeUpdate
Invoke this method if the stored procedure does not return result sets.

CallableStatement.executeQuery
Invoke this method if the stored procedure returns one result set.

You can invoke CallableStatement.executeQuery for a stored procedure that returns no result sets if you set property allowNullResultSetForExecuteQuery to DB2BaseDataSource.YES (1). In that case, CallableStatement.executeQuery returns null. This behavior does not conform to the JDBC standard.

CallableStatement.execute
Invoke this method if the stored procedure returns multiple result sets, or an unknown number of result sets.

Restriction: IBM Informix data sources do not support multiple result sets.

5. If the stored procedure returns multiple result sets, retrieve the result sets.

Restriction: IBM Informix data sources do not support multiple result sets.

6. Invoke the CallableStatement.getXXX methods to retrieve values from the OUT parameters or INOUT parameters.

7. Invoke the CallableStatement.close method to close the CallableStatement object when you have finished using that object.

The following code illustrates calling a stored procedure that has one input parameter, four output parameters, and no returned ResultSets. The numbers to the right of selected statements correspond to the previously-described steps.

```java
int ifcaret;
int ifcareas;
int xsbytes;
String errbuff;
Connection con;
CallableStatement cstmt;
ResultSet rs;
...
cstmt = con.prepareCall("CALL DSN8.DSNBED2(?,?,?,?,?)");       // Create a CallableStatement object
if (cstmt != null) {
    cstmt.setString (1, "DISPLAY THREAD(*)");            // Set input parameter (DB2 command)
    cstmt.registerOutParameter (2, Types.INTEGER);     // Register output parameters
    cstmt.registerOutParameter (3, Types.INTEGER);
    cstmt.registerOutParameter (4, Types.INTEGER);
    cstmt.registerOutParameter (5, Types.VARCHAR);
    cstmt.executeUpdate();                         // Call the stored procedure
    ifcaret = cstmt.getInt(2);                        // Get the output parameter values
    ifcareas = cstmt.getInt(3);
    xsbytes = cstmt.getInt(4);
    errbuff = cstmt.getString(5);
    cstmt.close();
}
```
Using named parameters in CALL statements in JDBC applications

The IBM Data Server Driver for JDBC and SQLJ provides several ways to use named parameters when you call stored procedures. Named parameters use a different syntax from named parameter markers.

You can use named parameters in either or both of the following places in a JDBC application:

- **In the CALL statement**
  
  With named parameters, you do not need to specify parameters in the CALL statement in the same order that they appear in the stored procedure definition. In addition, you do not need to specify all parameters in the CALL statement. Unspecified parameters take the default values that are specified in the stored procedure definition.

- **In CallableStatement.setXXX, CallableStatement.getXXX, and CallableStatement.registerOutParameter methods**
  
  You can make your programs easier to read by specifying parameter names as they appear in the stored procedure definition, rather than the positions of the parameters in the definition.

To use named parameters with CALL statements, follow these steps:

1. Invoke the Connection.prepareCall method with the CALL statement as its argument to create a CallableStatement object.
   
   To indicate each parameter, you can use a parameter markers (?), or this syntax:
   
   ```
   parameter-name=>?
   ```

   `parameter-name` identifies a parameter in the CREATE PROCEDURE statement. You can explicitly assign the default value or the null value to a named parameter by specifying the DEFAULT keyword or the NULL keyword. For parameters for which a default value is specified in the CREATE PROCEDURE statement, you can implicitly assign the default values to named parameters by omitting those parameters from the CALL statement. You can omit parameters only if all of the omitted parameters have default values in the stored procedure definition.

   You cannot mix named parameters and named parameter markers in the same CALL statement.

2. Invoke the CallableStatement.setXXX methods to pass values to the input parameters (parameters that are defined as IN or INOUT in the CREATE PROCEDURE statement).
   
   You can assign values in either of the following ways:
   
   - By position, using CallableStatement.setXXX(parameterIndex,...)
   - By name, using CallableStatement.setXXX(parameterName,...)

   `parameterName` is a string that is enclosed in double quotation marks, whose value matches a parameter name in the CREATE PROCEDURE statement.
3. Invoke the CallableStatement.registerOutParameter method to register parameters that are defined as OUT in the CREATE PROCEDURE statement with specific data types.

4. Invoke CallableStatement.executeUpdate, CallableStatement.executeQuery, or CallableStatement.execute to execute the stored procedure.

5. If the stored procedure returns multiple result sets, retrieve those result sets. You can register the output parameters in either of the following ways:
   • By position, using CallableStatement.registerOutParameter(parameterIndex,...)
   • By name, using CallableStatement.registerOutParameter(parameterName,...)
     parameterName is a string that is enclosed in double quotation marks, whose value matches a parameter name in the CREATE PROCEDURE statement.

6. Invoke the CallableStatement.getXXX methods to retrieve values from the OUT parameters or INOUT parameters. You can retrieve values in either of the following ways:
   • By position, using CallableStatement.getXXX(parameterIndex,...)
   • By name, using CallableStatement.getXXX(parameterName,...)
     parameterName is a string that is enclosed in double quotation marks, whose value matches a parameter name in the CREATE PROCEDURE statement.

7. Invoke the CallableStatement.close method to close the CallableStatement object when you have finished using that object.

The following code illustrates calling a stored procedure that has the following definition:

```sql
CREATE PROCEDURE SALS (
  OUT retcode INTEGER,
  IN lowsal DOUBLE,
  IN medsal DOUBLE,
  IN highsal DOUBLE DEFAULT 100000,
  IN department CHAR(3) DEFAULT '---')
SPECIFIC JDBC_SALS
DYNAMIC RESULT SETS 0
DETERMINISTIC
LANGUAGE JAVA
PARAMETER STYLE JAVA
NO DBINFO
FENCED
THREADSAFE
MODIFIES SQL DATA
PROGRAM TYPE SUB
EXTERNAL NAME 'MYJAR:MyClass.sals'
```

The input parameters in the CALL statement are represented by named parameters. The third and fourth parameters are called with the default values for the stored procedure. The numbers to the right of selected statements correspond to the previously-described steps.

```java
int hvRetCode; // Host variable for output parameter
Connection con;
CallableStatement cstmt;
ResultSet rs;
...

cstmt = con.prepareCall("CALL SALS(retcode=>?,lowsal=>?,medsal=>?,highsal=>DEFAULT)"); // Prepare the Call statement.
// Implicitly use the default value for the last parameter
// by omitting it.
```
cstmt.setDouble("lowsal", 10000);
cstmt.setDouble("medsal", 50000);
cstmt.registerOutParameter("retcode", Types.INTEGER);
    // Register output parameter
    // Call the stored procedure
    cstmt.executeUpdate();
    hvRetCode = cstmt.getInt("retcode");
    System.out.println("Return code from SALS call: " + hvRetCode);
cstmt.close();

Retrieving data from cursor output parameters in JDBC applications
DB2 for Linux, UNIX, and Windows stored procedures can have OUT parameters of the cursor type. To retrieve data from those parameters in JDBC applications, you use ResultSet objects.

To retrieve data from cursor variables, follow these steps:
1. Define a ResultSet object for each OUT parameter that has the cursor data type.
2. Invoke the Connection.prepareCall method with the CALL statement as its argument to create a CallableStatement object.
3. Invoke the CallableStatement.registerOutParameter method to register the data types of parameters that are defined as OUT in the CREATE PROCEDURE statement.
   The data type for cursor type output parameters is com.ibm.db2.jcc.DB2Types.CURSOR.
4. Call the stored procedure.
5. Invoke the CallableStatement.getObject method to retrieve the ResultSet for each OUT cursor parameter.
   You can call only CallableStatement.getObject or CallableStatement.getString on a cursor parameter. Calling CallableStatement.getString returns a name that is associated with the result set that is returned for the parameter.
   If more than one OUT cursor parameter references the same cursor at the data source, the same ResultSet instance is returned for all parameters.
6. Retrieve rows from the ResultSet object for each OUT cursor parameter.
7. Close the ResultSet.
   If the autocommit value is true, a commit operation occurs only when all of the result sets that are returned by cursor type output parameters or by the stored procedure are closed.

A cursor data type and a stored procedure have the following definitions:

CREATE TYPE myRowType AS ROW (name VARCHAR(128))
CREATE TYPE myCursorType AS myRowType CURSOR
CREATE PROCEDURE MYPROC(IN pempNo VARCHAR(6), OUT pcv1 myCursorType)
    RESULT SETS 0
    LANGUAGE SQL
    BEGIN
        DECLARE c1 CURSOR WITH RETURN FOR
            SELECT empno FROM EMPLOYEE;
        OPEN c1;
        SET pcv1 = CURSOR FOR SELECT name FROM employee WHERE empNo = pempNo;
        OPEN pcv1;
    END

The following code calls stored procedure MYPROC and uses a ResultSet object to retrieve data from cursor pcv1. The numbers to the right of selected statements correspond to the previously-described steps.
Connection con;
ResultSet rs = null; // Output parameter
...
CallableStatement cstmt = conn.prepareCall("CALL MYPROC(?, ?)");
String hvEmpNo = "000500";
cstmt.setString (1, hvEmpNo);
cstmt.registerOutParameter (2, DB2Types.CURSOR);
cstmt.executeUpdate(); // Call the stored procedure
String hvEmpName = null;
rs = (java.sql.ResultSet)cstmt.getObject(2);
while (rs.next()) { // Retrieve result set rows
    hvEmpName = rs.getString(1);
    System.out.println("Employee name for " + hvEmpNo + ": " + hvEmpName);
}
rs.close(); // Close the ResultSet

Invoking stored procedures with ROW parameters in JDBC applications

DB2 for Linux, UNIX, and Windows stored procedures can have parameters of the ROW type. To retrieve or update data in those parameters in JDBC applications, you use Struct objects.

To retrieve or update data in ROW parameters, follow these steps:
1. Define a Struct object for each parameter that has the ROW data type.
   If you are using the SDK for Java Version 6 or later, use the createStruct method of the java.sql.Connection interface. If you are using an earlier version of the SDK for Java, use the createStruct object of the com.ibm.db2.jcc.DB2Connection interface.
2. Invoke the Connection.prepareCall method with the CALL statement as its argument to create a CallableStatement object.
3. Invoke CallableStatement.setXXX methods to assign values to the IN or INOUT parameters in the CREATE PROCEDURE statement.
   Use the CallableStatement.setObject method for ROW parameters.
4. Invoke the CallableStatement.registerOutParameter method to register the data types of parameters that are defined as OUT in the CREATE PROCEDURE statement.
   The data type for ROW type output parameters is java.sql.Types.STRUCT.
5. Call the stored procedure.
6. Invoke the CallableStatement.getObject method to retrieve the value of each OUT ROW parameter. Cast the returned objects as java.sql.Struct values.
7. Retrieve data from the Struct object for each OUT ROW parameter.

A ROW type and a stored procedure have the following definitions:

```sql
CREATE TYPE MYTYPE.PERSON_T AS ROW
ID INTEGER
FIRSTNAME VARCHAR(20)
LASTNAME VARCHAR(20)
SALARY INTEGER

CREATE PROCEDURE MYSR.PERSON_SP
(IN PIN MYTYPE.PERSON_T, OUT POUT MYTYPE.PERSON_T)
LANGUAGE SQL
BEGIN
...
END
```
The following code calls stored procedure MYSP.PERSON_SP and uses Struct objects to assign data to ROW parameter PIN and to retrieve data from ROW parameter POUT. The numbers to the right of selected statements correspond to the previously-described steps.

```java
Connection con;
CallableStatement cstmt;
...
personAttributes = new Object[] {    
    new Integer(1), "John", "Doe", new Integer(60000)
};
person = con.createStruct("MYTYPE.PERSON_T", personAttributes); 1
stmt = con.prepareCall("CALL MYSP.PERSON_SP(?,?,?)"); 2
stmt.setObject(1, person); 3
cstmt.registerOutParameter(2, java.sql.Types.STRUCT); 4
cstmt.execute();
person = (java.sql.Struct)cstmt.getObject(2); 6
Object[] personAttributes = person.getAttributes(); 7
Integer id = (Integer)personAttributes[0];
String firstName = (String)personAttributes[1];
String lastName = (String)personAttributes[2];
Integer salary = (Integer)personAttributes[3];
cstmt.close();
```

- Row types

**Invoking stored procedures with ARRAY of ROW parameters in JDBC applications**

DB2 for Linux, UNIX, and Windows stored procedures can have parameters of the ARRAY of ROW type. To retrieve or update data in those parameters in JDBC applications, you use arrays of Struct objects.

To retrieve or update data in ARRAY of ROW parameters, follow these steps:

1. Define a Struct object for each row of each input parameter that has the ARRAY of ROW data type.
   - If you are using the SDK for Java Version 6 or later, use the createStruct method of the java.sql.Connection interface. If you are using an earlier version of the SDK for Java, use the createStruct object of the com.ibm.db2.jcc.DB2Connection interface.

2. Define an Array object for each array of rows.
   - If you are using the SDK for Java Version 6 or later, use the createArrayOf method of the java.sql.Connection interface. If you are using an earlier version of the SDK for Java, use the createArrayOf object of the com.ibm.db2.jcc.DB2Connection interface.

3. Invoke the Connection.prepareCall method with the CALL statement as its argument to create a CallableStatement object.

4. Invoke CallableStatement.setXXX methods to assign values to the IN or INOUT parameters in the CREATE PROCEDURE statement.
   - Use the CallableStatement.setArray method for ARRAY of ROW parameters.

5. Invoke the CallableStatement.registerOutParameter method to register the data types of parameters that are defined as OUT in the CREATE PROCEDURE statement.
   - The data type for ARRAY of ROW type output parameters is java.sql.Types.ARRAY.

6. Call the stored procedure.
7. Invoke the CallableStatement.getArray method to retrieve the array from each OUT ARRAY of ROW parameter into a java.sql.Array object.
8. Invoke the java.sql.Array.getArray method to retrieve the contents of the java.sql.Array object. Cast the retrieved objects as java.sql.Struct[] arrays.
9. Retrieve data from each element of the array of Struct objects for each OUT ARRAY of ROW parameter.

A ROW type and a stored procedure have the following definitions:

```
CREATE TYPE MYTYPE.PERSON_T AS ROW
  ID INTEGER
  FIRSTNAME VARCHAR(20)
  LASTNAME VARCHAR(20)
  SALARY INTEGER

CREATE TYPE MYTYPE.PEOPLE_T AS MYTYPE.PERSON_T ARRAY[10]
```

```
CREATE PROCEDURE MYSP.PEOPLE_SP
  (IN PIN MYTYPE.PEOPLE_T, OUT POUT MYTYPE.PEOPLE_T)
  LANGUAGE SQL
BEGIN
...
END
```

The following code calls stored procedure MYSP.PEOPLE_SP, and uses arrays of Struct objects to assign data to ARRAY of ROW parameter PIN and to retrieve data from ARRAY of ROW parameter POUT. The numbers to the right of selected statements correspond to the previously described steps.

```java
Connection con;
CallableStatement cstmt;
...

peopleElements = new java.sql.Struct[2];
personAttributes = new Object[] {
  new Integer(1), "John", "Doe", new Integer(60000)
};
peopleElements[0] =
  con.createStruct("MYTYPE.PERSON_T", personAttributes);  // 1
personAttributes = new Object[] {
  new Integer(2), "Jane", "Doe", new Integer(65000)
};
peopleElements[1] =
  con.createStruct("MYTYPE.PERSON_T", personAttributes);
Array people = con.createArrayOf("MYTYPE.PERSON_T", peopleElements);
  // 2
  cstmt = con.prepareCall("CALL MYSP.PEOPLE_SP(?,?)");
  3
  cstmt.setArray(1, people);
  4
  cstmt.registerOutParameter(2, java.sql.Types.ARRAY);
  5
  cstmt.execute();
  6
  java.sql.Array people = cstmt.getArray(2);
  7
  java.sql.Struct[] persons =
    (java.sql.Struct[])people.getArray();
  8
for (int i = 0; i < persons.length; i++) {
  java.sql.Struct person = persons[i];
  Object[] personAttributes = person.getAttributes();
  Integer id = (Integer)personAttributes[0];
  String firstName = (String)personAttributes[1];
  String lastName = (String)personAttributes[2];
  Integer salary = (Integer)personAttributes[3];
}

Invoking stored procedures with nested ROW or ARRAY of ROW types in JDBC applications

In DB2 for Linux, UNIX, and Windows stored procedure parameters, ROW types can be nested. You can retrieve or update data in those parameters in JDBC applications.

To retrieve or update data in parameters with nested ROW or ARRAY of ROW types, follow these steps:

1. Define a Struct object for each of the most deeply nested ROW types, or a Struct[] object for the most deeply nested ARRAY or ROW type.
   - If you are using the SDK for Java Version 6 or later, use the createStruct method of the java.sql.Connection interface. If you are using an earlier version of the SDK for Java, use the createStruct object of the com.ibm.db2.jcc.DB2Connection interface.

2. Repeat step 1 for the next most deeply nested ROW type. Continue this process until you have defined and populated a Struct object for the outermost ROW type.

3. Invoke the Connection.prepareCall method with the CALL statement as its argument to create a CallableStatement object.

4. Invoke CallableStatement.setXXX methods to assign values to the IN or INOUT parameters in the CREATE PROCEDURE statement.
   - Use the CallableStatement.setObject method for ROW parameters.

5. Invoke the CallableStatement.registerOutParameter method to register the data types of parameters that are defined as OUT in the CREATE PROCEDURE statement.
   - The data type for ROW type output parameters is java.sql.Types.STRUCT.

6. Call the stored procedure.

7. Invoke the CallableStatement.getObject method to retrieve the value of each OUT ROW parameter. Cast the returned objects as java.sql.Struct values.

8. Retrieve data from the Struct object for each OUT ROW parameter, and each ROW type that is nested within a ROW parameter.

Suppose that ARRAY and Struct objects are defined as follows:

MYTYPE.SKILLS is an ARRAY type.
CREATE TYPE MYTYPE.SKILLS AS VARCHAR(20) ARRAY[10]

ROW type MYTYPE.PERSON_T contains a field with ARRAY type MYTYPE.SKILLS.
CREATE TYPE MYTYPE.PERSON_T AS ROW
   ID INTEGER
   FIRSTNAME VARCHAR(20)
   LASTNAME VARCHAR(20)
   JOBSKILLS MYTYPE.SKILLS

ROW type MYTYPE.ROPEOPLE_T is an array of objects that have ROW type MYTYPE.PERSON_T.
CREATE TYPE MYTYPE.ROPEOPLE_T AS MYTYPE.PERSON_T ARRAY[10]
ROW type MYTYPE.DEPARTMENT contains a field that has the ARRAY of ROW type MYTYPE.PEOPLE_T.

CREATE TYPE MYTYPE.DEPARTMENT AS ROW
(ID INTEGER,
 DEPTNAME VARCHAR(20),
 DEPTPEOPLE MYTYPE.PEOPLE_T)

Stored procedure MYSP.DEPARTMENT_SP has two parameters, each of which has the MYTYPE.DEPARTMENT type.

CREATE PROCEDURE MYSP.DEPARTMENT_SP
(IN PIN MYTYPE.DEPARTMENT, OUT POUT MYTYPE.DEPARTMENT)
LANGUAGE SQL
BEGIN
...
END

The following code demonstrates how to use Struct objects to assign values to nested ROW objects in a stored procedure input parameter, and how to use Struct objects to retrieve data from nested ROW objects in a stored procedure output parameter. The numbers to the right of selected statements correspond to the previously-described steps.

Connection con;
...
java.sql.Struct[] people = new java.sql.Struct[3];
// Construct an array of Struct objects for the
// MYTYPE.PEOPLE_T array or ROW objects
String[] skills1 = {"java", "C++", "JavaScript"};
// Create and populate the first array for the
// MYTYPE.SKILLS ARRAY object
Object[] attributes1 =
    new Object [] {new Integer (1), "Alpha", "Doe", skills1};
// Create an object with the content of the first
// input row that corresponds to MYTYPE.PERSON_T
people[0] = ((com.ibm.db2.jcc.DB2Connection)con).
    createStruct ("PERSON_T", attributes1);
// Populate the first element of the array of Struct
// for input to the MYTYPE.PEOPLE_T type
String[] skills2 = {"java", "C++", "C"};
// Create and populate the second array for the
// MYTYPE.SKILLS ARRAY object
Object[] attributes2 =
    new Object [] {new Integer (2), "Beta", "Doe", skills2};
// Create an object with the content of the second
// input row that corresponds to MYTYPE.PERSON_T
    createStruct ("PERSON_T", attributes2);
// Populate the second element of the array of Struct
// for input to the MYTYPE.PEOPLE_T type
java.sql.Array peopleArray = {{com.ibm.db2.jcc.DB2Connection)con}.
    createArrayOf("MYTYPE.PEOPLE_T", attributes1);
// Create and populate a Struct object for
// input to the DEPTPEOPLE object
Object[] deptAttributes =
    new Object [] {new Integer (1), "Jcc", peopleArray };
// Create an object with the content of an
// input row for parameter PIN
java.sql.Struct deptStruct = {{com.ibm.db2.jcc.DB2Connection)con}.
    createStruct ("DEPARTMENT", deptAttributes);
// Create and populate a Struct object for
// input to the PIN parameter
java.sql.CallableStatement cs = con.prepareCall("CALL MYSP.DEPARTMENT_SP (?, ?)");
    cs.setObject(1, deptStruct);
// Assign the row object to input parameter PIN
cs.registerOutParameter(2, java.sql.Types.STRUCT);
// Register the output parameter as a STRUCT type

// Call the stored procedure
java.sql.Struct outputStruct = (java.sql.Struct)cs.getObject(2);
// Retrieve the content of the POUT row parameter

Object[] structAttributes = outputStruct.getAttributes();
// Retrieve an array of objects that contains the attributes of the outermost output structure

int departmentID = (Integer)structAttributes[0];
String departmentName = (String)structAttributes[1];
System.out.println("The department ID is: " + departmentID);
System.out.println("The department Name is: " + departmentName);
java.sql.Struct[] departmentPeople =
{(java.sql.Struct[])structAttributes[2];
// Retrieve the contents of the nested structure
java.sql.Struct personStruct;
System.out.println("The people in the department are: ");
for (int i = 0; i < departmentPeople.length; i++) {
    // Retrieve the elements of the inner array of rows
    personStruct = departmentPeople[i];
    structAttributes = personStruct.getAttributes();
    System.out.println("id> " + (Integer)structAttributes[0] + ": " +
        "firstName> " + (String)structAttributes[1] + ": " +
        "lastName> " + (String)structAttributes[2] + ": " +
        "skills> ");
    for (int j = 0; j < ((String[])structAttributes[3]).length; j++)
        System.out.print("--" + ((String[])structAttributes[3])[j]);
}

Retrieving multiple result sets from a stored procedure in a JDBC application

If you call a stored procedure that returns result sets, you need to include code to retrieve the result sets.

The steps that you take depend on whether you know how many result sets are returned, and whether you know the contents of those result sets.

Related tasks:
- "Retrieving data from tables using the Statement.executeQuery method" on page 58
- "Retrieving data from tables using the PreparedStatement.executeQuery method" on page 59
- "Calling stored procedures in JDBC applications" on page 73

Retrieving a known number of result sets from a stored procedure in a JDBC application:

Retrieving a known number of result sets from a stored procedure is a simpler procedure than retrieving an unknown number of result sets.

To retrieve result sets when you know the number of result sets and their contents, follow these steps:
1. Invoke the Statement.executeQuery method, the PreparedStatement.executeQuery method, or the CallableStatement.executeQuery method to call the stored procedure.
Use PreparedStatement.execute if the stored procedure has input parameters.

2. Invoke the getResultSet method to obtain the first result set, which is in a ResultSet object.

3. In a loop, position the cursor using the next method, and retrieve data from each column of the current row of the ResultSet object using getXXX methods.

4. If there are \( n \) result sets, repeat the following steps \( n-1 \) times:
   a. Invoke the getMoreResults method to close the current result set and point to the next result set.
   b. Invoke the getResultSet method to obtain the next result set, which is in a ResultSet object.
   c. In a loop, position the cursor using the next method, and retrieve data from each column of the current row of the ResultSet object using getXXX methods.

The following code illustrates retrieving two result sets. The first result set contains an INTEGER column, and the second result set contains a CHAR column. The numbers to the right of selected statements correspond to the previously described steps.

```java
CallableStatement cstmt;
ResultSet rs;
int i;
String s;
...
cstmt.execute();  // Call the stored procedure
rs = cstmt.getResultSet();  // Get the first result set
while (rs.next()) {  // Position the cursor
    i = rs.getInt(1);  // Retrieve current result set value
    System.out.println("Value from first result set = " + i);  // Print the value
}
cstmt.getMoreResults();  // Point to the second result set
rs = cstmt.getResultSet();  // and close the first result set
while (rs.next()) {  // Position the cursor
    s = rs.getString(1);  // Retrieve current result set value
    System.out.println("Value from second result set = " + s);  // Print the value
}
rs.close();  // Close the result set
cstmt.close();  // Close the statement
```

Retrieving an unknown number of result sets from a stored procedure in a JDBC application:

Retrieving an unknown number of result sets from a stored procedure is a more complicated procedure than retrieving a known number of result sets.

To retrieve result sets when you do not know the number of result sets or their contents, you need to retrieve ResultSets, until no more ResultSets are returned. For each ResultSet, use ResultSetMetaData methods to determine its contents.

After you call a stored procedure, follow these basic steps to retrieve the contents of an unknown number of result sets.

1. Check the value that was returned from the execute statement that called the stored procedure.
   If the returned value is true, there is at least one result set, so you need to go to the next step.
2. Repeat the following steps in a loop:
   a. Invoke the getResultSet method to obtain a result set, which is in a ResultSet object. Invoking this method closes the previous result set.
   b. Use ResultSetMetaData methods to determine the contents of the ResultSet, and retrieve data from the ResultSet.
   c. Invoke the getMoreResults method to determine whether there is another result set. If getMoreResults returns true, go to step [1 on page 85] to get the next result set.

The following code illustrates retrieving result sets when you do not know the number of result sets or their contents. The numbers to the right of selected statements correspond to the previously described steps.

```java
CallableStatement cstmt;
ResultSet rs;
...
boolean resultsAvailable = cstmt.execute(); // Call the stored procedure
while (resultsAvailable) {
    // Test for result sets
    ResultSet rs = cstmt.getResultSet(); // Get a result set
    // Process the ResultSet
    // as you would process
    // a ResultSet from a table

    resultsAvailable = cstmt.getMoreResults(); // Check for next result set
    // (Also closes the
    // previous result set)
}
```

Related tasks:
“Learning about a ResultSet using ResultSetMetaData methods” on page 61

Keeping result sets open when retrieving multiple result sets from a stored procedure in a JDBC application:

The getMoreResults method has a form that lets you leave the current ResultSet open when you open the next ResultSet.

To specify whether result sets stay open, follow this process:

When you call getMoreResults to check for the next ResultSet, use this form:

```java
CallableStatement.getMoreResults(int current);
```

- To keep the current ResultSet open when you check for the next ResultSet, specify a value of `Statement.KEEP_CURRENT_RESULT` for `current`.
- To close the current ResultSet when you check for the next ResultSet, specify a value of `Statement.CLOSE_CURRENT_RESULT` for `current`.
- To close all ResultSet objects, specify a value of `Statement.CLOSE_ALL_RESULTS` for `current`.

The following code keeps all ResultSets open until the final ResultSet has been retrieved, and then closes all ResultSets.

```java
CallableStatement cstmt;
...
boolean resultsAvailable = cstmt.execute(); // Call the stored procedure
if (resultsAvailable==true) {
    // Test for result set
    ResultSet rs1 = cstmt.getResultSet(); // Get a result set
    ...
    resultsAvailable = cstmt.getMoreResults(Statement.KEEP_CURRENT_RESULT);
    // Check for next result set
    // but do not close
    // previous result set
```
if (resultsAvailable==true) { // Test for another result set
    ResultSet rs2 = cstmt.getResultSet(); // Get next result set
    ...
    // Process either ResultSet
}
}

resultsAvailable = cstmt.getMoreResults(Statement.CLOSE_ALL_RESULTS);

Learning about stored procedure parameter names using DB2ParameterMetaData methods:

The DB2ParameterMetaData.getProcedureParameterName method lets you retrieve the defined name of a parameter in an SQL CALL statement.

To invoke ParameterMetaData.getProcedureParameterName, you need to perform these basic steps:
1. Invoke the Connection.prepareCall method with the CALL statement as its argument to create a CallableStatement object.
2. Pass values to the input parameters (parameters that are defined as IN or INOUT in the CREATE PROCEDURE statement).
3. Register parameters that are defined as OUT in the CREATE PROCEDURE statement with specific data types.
4. Call the stored procedure.
5. Invoke CallableStatement.getParameterMetaData to retrieve information about the stored procedure parameters.
6. Cast the retrieved ParameterMetaData object as a DB2ParameterMetaData object.
7. Call the DB2ParameterMetaData.getProcedureParameterName method for each CALL statement parameter for which you need to retrieve the parameter name in the CREATE PROCEDURE statement.

The following code demonstrates how to use DB2ParameterMetaData.getProcedureParameterName to determine the names that correspond to standard parameter markers in a stored procedure that is defined like this:

CREATE PROCEDURE SP
    (OUT PARM CHAR(10), IN CHAR(10))

The numbers to the right of selected statements correspond to the previously-described steps.

Connection con;
...
CallableStatement cstmt = con.prepareCall("CALL SP(?,?)");
    // Create a CallableStatement object
    
    cstmt.setString (2, "INPUT_VALUE");
    // Set input parameter
    
    cstmt.registerOutParameter (1, java.sql.Types.CHAR);
    // Register output parameter
    
    cstmt.executeUpdate();
    // Call the stored procedure

DB2ParameterMetaData md =
    (DB2ParameterMetaData)cstmt.getParameterMetaData ();

    md.getProcedureParameterName(1); // Returns "PARM"
    md.getProcedureParameterName(2); // Returns "2"
The following code demonstrates how to use
DB2ParameterMetaData.getProcedureParameterName to determine the names that
correspond to named parameter markers in a stored procedure that is defined like this:

```
CREATE PROCEDURE SP
(OUT PARM CHAR(10), IN CHAR(10))
```

The numbers to the right of selected statements correspond to the
previously-described steps.

Connection con;

```java
CallableStatement cstmt = con.prepareCall("CALL SP(:output, :input)");  \[1\]
// Create a CallableStatement object
(DB2PreparedStatement)cstmt.setStringAtName("input", "INPUT_VALUE");  \[2\]
// Set input parameter
(DB2CallableStatement)cstmt.registerJccOutParameter
("output", java.sql.Types.CHAR);  \[3\]
// Register output parameter
cstmt.execute();  \[4,5,6\]
```

```java
DB2ParameterMetaData md = (DB2ParameterMetaData)cstmt.getParameterMetaData();  \[5,6\]
md.getProcedureParameterName(1); // Returns "PARM"  \[7\]
md.getProcedureParameterName(2); // Returns "2"
```

### LOBs in JDBC applications with the IBM Data Server Driver for JDBC and SQLJ

The IBM Data Server Driver for JDBC and SQLJ supports methods for updating
and retrieving data from BLOB, CLOB, and DBCLOB columns in a table, and for
calling stored procedures or user-defined functions with BLOB or CLOB
parameters.

**Related reference:**
- "Driver support for JDBC APIs" on page 399
- "Properties for the IBM Data Server Driver for JDBC and SQLJ" on page 326

### Progressive streaming with the IBM Data Server Driver for JDBC and SQLJ

If the data source supports progressive streaming, also known as dynamic data
format, the IBM Data Server Driver for JDBC and SQLJ can use progressive
streaming to retrieve data in LOB or XML columns.

DB2 for z/OS Version 9.1 and later supports progressive streaming for LOBs and
XML objects. DB2 for Linux, UNIX, and Windows Version 9.5 and later, IBM
Informix Version 11.50 and later, and DB2 for i V6R1 and later support progressive
streaming for LOBs.

With progressive streaming, the data source dynamically determines the most
efficient mode in which to return LOB or XML data, based on the size of the LOBs
or XML objects.

Progressive streaming is the default behavior in the following environments:

<table>
<thead>
<tr>
<th>Minimum IBM Data Server Driver for JDBC and SQLJ version</th>
<th>Minimum Data server version</th>
<th>Types of objects</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.53</td>
<td>DB2 for i V6R1</td>
<td>LOB, XML</td>
</tr>
<tr>
<td>Minimum IBM Data Server Driver for JDBC and SQLJ version</td>
<td>Minimum data server version</td>
<td>Types of objects</td>
</tr>
<tr>
<td>--------------------------------------------------------</td>
<td>----------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>3.50</td>
<td>DB2 for Linux, UNIX, and Windows Version 9.5</td>
<td>LOB</td>
</tr>
<tr>
<td>3.50</td>
<td>IBM Informix Version 11.50</td>
<td>LOB</td>
</tr>
<tr>
<td>3.2</td>
<td>DB2 for z/OS Version 9</td>
<td>LOB, XML</td>
</tr>
</tbody>
</table>

You set the progressive streaming behavior on new connections using the IBM Data Server Driver for JDBC and SQLJ `progressiveStreaming` property.

For DB2 for z/OS Version 9.1 and later data sources, or DB2 for Linux, UNIX, and Windows Version 9.5 and later data sources, you can set the progressive streaming behavior for existing connections with the `DB2Connection.setDBProgressiveStreaming(DB2BaseDataSource.YES)` method. If you call `DB2Connection.setDBProgressiveStreaming(DB2BaseDataSource.YES)`, all `ResultSet` objects that are created on the connection use progressive streaming behavior.

When progressive streaming is enabled, you can control when the JDBC driver materializes LOBs with the `streamBufferSize` property. If a LOB or XML object is less than or equal to the `streamBufferSize` value, the object is materialized.

**Important:** With progressive streaming, when you retrieve a LOB or XML value from a ResultSet into an application variable, you can manipulate the contents of that application variable until you move the cursor or close the cursor on the ResultSet. After that, the contents of the application variable are no longer available to you. If you perform any actions on the LOB in the application variable, you receive an `SQLException`. For example, suppose that progressive streaming is enabled, and you execute statements like this:

```java
...  
ResultSet rs = stmt.executeQuery("SELECT CLOBCOL FROM MY_TABLE");  
rs.next(); // Retrieve the first row of the ResultSet  
Clob clobFromRow1 = rs.getClob(1);  
// Put the CLOB from the first column of  
// the first row in an application variable  
String substr1Clob = clobFromRow1.getString(1,50);  
// Retrieve the first 50 bytes of the CLOB  
rs.next(); // Move the cursor to the next row.  
// clobFromRow1 is no longer available.  
// String substr2Clob = clobFromRow1.getString(51,100);  
// This statement would yield an SQLException  
Clob clobFromRow2 = rs.getClob(1);  
// Put the CLOB from the first column of  
// the second row in an application variable  
rs.close(); // Close the ResultSet.  
// clobFromRow2 is also no longer available.  
```

After you execute `rs.next()` to position the cursor at the second row of the ResultSet, the CLOB value in `clobFromRow1` is no longer available to you. Similarly, after you execute `rs.close()` to close the ResultSet, the values in `clobFromRow1` and `clobFromRow2` are no longer available.

If you disable progressive streaming, the way in which the IBM Data Server Driver for JDBC and SQLJ handles LOBs depends on the value of the `fullyMaterializeLobData` property.
Use of progressive streaming is the preferred method of LOB or XML data retrieval.

**LOB locators with the IBM Data Server Driver for JDBC and SQLJ**

The IBM Data Server Driver for JDBC and SQLJ can use LOB locators to retrieve data in LOB columns.

To cause JDBC to use LOB locators to retrieve data from LOB columns, you need to set the `fullyMaterializeLobData` property to `false` and set the `progressiveStreaming` property to `NO` (`DB2BaseDataSource.NO` in an application program).

The effect of `fullyMaterializeLobData` depends on whether the data source supports progressive streaming and the value of the `progressiveStreaming` property:

- If the data source does not support progressive locators:
  - If the value of `fullyMaterializeLobData` is `true`, LOB data is fully materialized within the JDBC driver when a row is fetched. If the value is `false`, LOB data is streamed. The driver uses locators internally to retrieve LOB data in chunks on an as-needed basis. It is highly recommended that you set this value to `false` when you retrieve LOBs that contain large amounts of data. The default is `true`.

- If the data source supports progressive streaming, also known as dynamic data format:
  - The JDBC driver ignores the value of `fullyMaterializeLobData` if the `progressiveStreaming` property is set to `YES` (`DB2BaseDataSource.YES` in an application program) or is not set.

`fullyMaterializeLobData` has no effect on stored procedure parameters.

As in any other language, a LOB locator in a Java application is associated with only one data source. You cannot use a single LOB locator to move data between two different data sources. To move LOB data between two data sources, you need to materialize the LOB data when you retrieve it from a table in the first data source and then insert that data into the table in the second data source.

**LOB operations with the IBM Data Server Driver for JDBC and SQLJ**

The IBM Data Server Driver for JDBC and SQLJ supports methods for updating and retrieving data from BLOB, CLOB, and DBCLOB columns in a table, and for calling stored procedures or user-defined functions with BLOB or CLOB parameters.

Among the operations that you can perform on LOB data under the IBM Data Server Driver for JDBC and SQLJ are:

- Specify a BLOB or column as an argument of the following ResultSet methods to retrieve data from a BLOB or CLOB column:
  - For BLOB columns:
    - `getBinaryStream`
    - `getBlob`
    - `getBytes`
  - For CLOB columns:
    - `getAsciiStream`
    - `getCharacterStream`
Call the following ResultSet methods to update a BLOB or CLOB column in an updatable ResultSet:

For BLOB columns:
- updateBinaryStream
- updateBlob

For CLOB columns:
- updateAsciiStream
- updateCharacterStream
- updateClob

If you specify -1 for the `length` parameter in any of the previously listed methods, the IBM Data Server Driver for JDBC and SQLJ reads the input data until it is exhausted.

Use the following PreparedStatement methods to set the values for parameters that correspond to BLOB or CLOB columns:

For BLOB columns:
- setBytes
- setBlob
- setBinaryStream
- setObject, where the `Object` parameter value is an InputStream.

For CLOB columns:
- setString
- setAsciiStream
- setClob
- setCharacterStream
- setObject, where the `Object` parameter value is a Reader.

If you specify -1 for `length`, the IBM Data Server Driver for JDBC and SQLJ reads the input data until it is exhausted.

Retrieve the value of a JDBC CLOB parameter using the `CallableStatement.getString` method.

Restriction: With IBM Data Server Driver for JDBC and SQLJ type 2 connectivity, you cannot call a stored procedure that has DBCLOB OUT or INOUT parameters.

If you are using the IBM Data Server Driver for JDBC and SQLJ version 4.0 or later, you can perform the following additional operations:

Use ResultSet.updateXXX or PreparedStatement.setXXX methods to update a BLOB or CLOB with a `length` value of up to 2GB for a BLOB or CLOB. For example, these methods are defined for BLOBs:

- `ResultSet.updateBlob(int columnIndex, InputStream x, long length)`
- `ResultSet.updateBlob(String columnLabel, InputStream x, long length)`
- `ResultSet.updateBinaryStream(int columnIndex, InputStream x, long length)`
- `ResultSet.updateBinaryStream(String columnLabel, InputStream x, long length)`
- `PreparedStatement.setBlob(int columnIndex, InputStream x, long length)`
- `PreparedStatement.setBlob(String columnLabel, InputStream x, long length)`
- `PreparedStatement.setBinaryStream(int columnIndex, InputStream x, long length)`
- `PreparedStatement.setBinaryStream(String columnLabel, InputStream x, long length)`

Use ResultSet.updateXXX or PreparedStatement.setXXX methods without the `length` parameter when you update a BLOB or CLOB, to cause the IBM Data Server Driver for JDBC and SQLJ to read the input data until it is exhausted. For example:
ResultSet.updateBlob(int columnIndex, InputStream x)
ResultSet.updateBlob(String columnLabel, InputStream x)
ResultSet.updateBinaryStream(int columnIndex, InputStream x)
ResultSet.updateBinaryStream(String columnLabel, InputStream x)
PreparedStatement.setBlob(int columnIndex, InputStream x)
PreparedStatement.setBlob(String columnLabel, InputStream x)
PreparedStatement.setBinaryStream(int columnIndex, InputStream x)
PreparedStatement.setBinaryStream(String columnLabel, InputStream x)

- Create a Blob or Clob object that contains no data, using the Connection.createBlob or Connection.createClob method.
- Materialize a Blob or Clob object on the client, when progressive streaming or locators are in use, using the Blob.getBinaryStream or Clob.getCharacterStream method.
- Free the resources that a Blob or Clob object holds, using the Blob.free or Clob.free method.

Java data types for retrieving or updating LOB column data in JDBC applications

When the JDBC driver cannot immediately determine the data type of a parameter that is used with a LOB column, you need to choose a parameter data type that is compatible with the LOB data type.

When the deferPrepares property is set to true, and the IBM Data Server Driver for JDBC and SQLJ processes a PreparedStatement.setXXX call, the driver might need to do extra processing to determine data types. This extra processing can impact performance.

Input parameters for BLOB columns

For IN parameters for BLOB columns, or INOUT parameters that are used for input to BLOB columns, you can use one of the following techniques:
- Use a java.sql.Blob input variable, which is an exact match for a BLOB column:
  cstmt.setBlob(parmIndex, blobData);
- Use a CallableStatement.setObject call that specifies that the target data type is BLOB:
  byte[] byteData = {(byte)0x1a, (byte)0x2b, (byte)0x3c};
  cstmt.setObject(parmInd, byteData, java.sql.Types.BLOB);
- Use an input parameter of type of java.io.ByteArrayInputStream with a CallableStatement.setBinaryStream call. A java.io.ByteArrayInputStream object is compatible with a BLOB data type. For this call, you need to specify the exact length of the input data:
  java.io.ByteArrayInputStream byteStream =
    new java.io.ByteArrayInputStream(byteData);
  int numBytes = byteData.length;
  cstmt.setBinaryStream(parmIndex, byteStream, numBytes);

Output parameters for BLOB columns

For OUT parameters for BLOB columns, or INOUT parameters that are used for output from BLOB columns, you can use the following technique:
- Use the CallableStatement.registerOutParameter call to specify that an output parameter is of type BLOB. Then you can retrieve the parameter value into any variable that has a data type that is compatible with a BLOB data type. For example, the following code lets you retrieve a BLOB value into a byte[] variable:
cstmt.registerOutParameter(parmIndex, java.sql.Types.BLOB);
cstmt.execute();
byte[] byteData = cstmt.getBytes(parmIndex);

**Input parameters for CLOB columns**

For IN parameters for CLOB columns, or INOUT parameters that are used for input to CLOB columns, you can use one of the following techniques:

- Use a java.sql.Clob input variable, which is an exact match for a CLOB column:
  ```java
cstmt.setClob(parmIndex, clobData);
  ```
- Use a CallableStatement.setObject call that specifies that the target data type is CLOB:
  ```java
  String charData = "CharacterString";
cstmt.setObject(parmInd, charData, java.sql.Types.CLOB);
  ```
- Use one of the following types of stream input parameters:
  - A java.io.StringReader input parameter with a cstmt.setCharacterStream call:
    ```java
    java.io.StringReader reader = new java.io.StringReader(charData);
cstmt.setCharacterStream(parmIndex, reader, charData.length);
    ```
  - A java.io.ByteArrayInputStream parameter with a cstmt.setAsciiStream call, for ASCII data:
    ```java
    byte[] charDataBytes = charData.getBytes("US-ASCII");
    java.io.ByteArrayInputStream byteStream =
    new java.io.ByteArrayInputStream(charDataBytes);
cstmt.setAsciiStream(parmIndex, byteStream, charDataBytes.length);
    ```

For these calls, you need to specify the exact length of the input data.

- Use a String input parameter with a cstmt.setString call:
  ```java
cstmt.setString(parmIndex, charData);
  ```

If the length of the data is greater than 32KB, and the JDBC driver has no DESCRIBE information about the parameter data type, the JDBC driver assigns the CLOB data type to the input data.

- Use a String input parameter with a cstmt.setObject call, and specify the target data type as VARCHAR or LONGVARCHAR:
  ```java
cstmt.setObject(parmIndex, charData, java.sql.Types.VARCHAR);
  ```

If the length of the data is greater than 32KB, and the JDBC driver has no DESCRIBE information about the parameter data type, the JDBC driver assigns the CLOB data type to the input data.

**Output parameters for CLOB columns**

For OUT parameters for CLOB columns, or INOUT parameters that are used for output from CLOB columns, you can use one of the following techniques:

- Use the CallableStatement.registerOutParameter call to specify that an output parameter is of type CLOB. Then you can retrieve the parameter value into a Clob variable. For example:
  ```java
cstmt.registerOutParameter(parmIndex, java.sql.Types.CLOB);
cstmt.execute();
Clob clobData = cstmt.getClob(parmIndex);
  ```
- Use the CallableStatement.registerOutParameter call to specify that an output parameter is of type VARCHAR or LONGVARCHAR:
  ```java
cstmt.registerOutParameter(parmIndex, java.sql.Types.VARCHAR);
cstmt.execute();
String charData = cstmt.getString(parmIndex);
  ```
This technique should be used only if you know that the length of the retrieved data is less than or equal to 32KB. Otherwise, the data is truncated.

### ROWIDs in JDBC with the IBM Data Server Driver for JDBC and SQLJ

DB2 for z/OS and DB2 for i support the ROWID data type for a column in a database table. A ROWID is a value that uniquely identifies a row in a table.

Although IBM Informix also supports rowids, those rowids have the INTEGER data type. You can select an IBM Informix rowid column into a variable with a four-byte integer data type.

You can use the following ResultSet methods to retrieve data from a ROWID column:

- `getRowId` (JDBC 4.0 and later)
- `getBytes`
- `getObject`

You can use the following ResultSet method to update a ROWID column of an updatable ResultSet:

- `updateRowId` (JDBC 4.0 and later)

  `updateRowId` is valid only if the target database system supports updating of ROWID columns.

If you are using JDBC 3.0, for `getObject`, the IBM Data Server Driver for JDBC and SQLJ returns an instance of the IBM Data Server Driver for JDBC and SQLJ-only class `com.ibm.db2.jcc.DB2RowID`.

If you are using JDBC 4.0, for `getObject`, the IBM Data Server Driver for JDBC and SQLJ returns an instance of the class `java.sql.RowId`.

You can use the following PreparedStatement methods to set a value for a parameter that is associated with a ROWID column:

- `setRowId` (JDBC 4.0 and later)
- `setBytes`
- `setObject`

If you are using JDBC 3.0, for `setObject`, use the IBM Data Server Driver for JDBC and SQLJ-only type `com.ibm.db2.jcc.Types.ROWID` or an instance of the `com.ibm.db2.jcc.DB2RowID` class as the target type for the parameter.

If you are using JDBC 4.0, for `setObject`, use the type `java.sql.Types.ROWID` or an instance of the `java.sql.RowId` class as the target type for the parameter.

You can use the following CallableStatement methods to retrieve a ROWID column as an output parameter from a stored procedure call:

- `getRowId` (JDBC 4.0 and later)
- `getObject`
To call a stored procedure that is defined with a ROWID output parameter, register that parameter to be of the java.sql.Types.ROWID type.

ROWID values are valid for different periods of time, depending on the data source on which those ROWID values are defined. Use the DatabaseMetaData.getRowIdLifetime method to determine the time period for which a ROWID value is valid. The values that are returned for the data sources are listed in the following table.

<table>
<thead>
<tr>
<th>Database server</th>
<th>DatabaseMetaData.getRowIdLifetime</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2 for z/OS</td>
<td>ROWID_VALID_TRANSACTION</td>
</tr>
<tr>
<td>DB2 for Linux, UNIX, and Windows</td>
<td>ROWID_UNSUPPORTED</td>
</tr>
<tr>
<td>DB2 for i</td>
<td>ROWID_VALID_FOREVER</td>
</tr>
<tr>
<td>IBM Informix</td>
<td>ROWID_VALID_FOREVER</td>
</tr>
</tbody>
</table>

Example: Using PreparedStatement.setRowId with a java.sql.RowId target type: Suppose that rid is a RowId object. To set parameter 1, use this form of the setRowId method:

```java
ps.setRowId(1, rid);
```

Example: Using ResultSet.getRowId to retrieve a ROWID value from a data source: To retrieve a ROWID value from the first column of a result set into RowId object rid, use this form of the ResultSet.getRowId method:

```java
java.sql.RowId rid = rs.getRowId(1);
```

Example: Using CallableStatement.registerOutParameter with a java.sql.Types.ROWID parameter type: To register parameter 1 of a CALL statement as a java.sql.Types.ROWID data type, use this form of the registerOutParameter method:

```java
cs.registerOutParameter(1, java.sql.Types.ROWID)
```

“Data types that map to database data types in Java applications” on page 313

**Distinct types in JDBC applications**

A distinct type is a user-defined data type that is internally represented as a built-in SQL data type. You create a distinct type by executing the SQL statement CREATE DISTINCT TYPE.

In a JDBC program, you can create a distinct type using the executeUpdate method to execute the CREATE DISTINCT TYPE statement. You can also use executeUpdate to create a table that includes a column of that type. When you retrieve data from a column of that type, or update a column of that type, you use Java identifiers with data types that correspond to the built-in types on which the distinct types are based.

The following example creates a distinct type that is based on an INTEGER type, creates a table with a column of that type, inserts a row into the table, and retrieves the row from the table:
Invocation of stored procedures with ARRAY parameters in JDBC applications

JDBC applications that run under the IBM Data Server Driver for JDBC and SQLJ can call stored procedures that have ARRAY parameters.

ARRAY parameters are supported in stored procedures on DB2 for Linux, UNIX, and Windows Version 9.5 and later.

You can use java.sql.Array objects as arguments for calling stored procedures with array parameters.

For IN or INOUT parameters, use the DB2Connection.createArrayOf method (JDBC 3.0) or the Connection.createArrayOf method (JDBC 4.0 or later) to create a java.sql.Array object. Use the CallableStatement.setArray method or the CallableStatement.setObject method to assign a java.sql.Array object to an ARRAY stored procedure parameter.

You can register an OUT ARRAY parameter for a stored procedure call by specifying java.sql.Types.ARRAY as the parameter type in a CallableStatement.registerOutParameter call.

There are two ways to retrieve data from an ARRAY output parameter:
- Use the CallableStatement.getArray method to retrieve the data into a java.sql.Array object, and use the java.sql.Array.getArray method to retrieve the contents of the java.sql.Array object into a Java array.

```java
Connection con;
Statement stmt;
ResultSet rs;
String empNumVar;
int shoeSizeVar;
...
stmt = con.createStatement(); // Create a Statement object
stmt.executeUpdate("CREATE DISTINCT TYPE SHOESIZE AS INTEGER");
// Create distinct type
stmt.executeUpdate("CREATE TABLE EMP_SHOE (EMPNO CHAR(6), EMP_SHOE_SIZE SHOESIZE)");
// Create table with distinct type
stmt.executeUpdate("INSERT INTO EMP_SHOE " +
"VALUES ('000010', 6)"); // Insert a row
rs=stmt.executeQuery("SELECT EMPNO, EMP_SHOE_SIZE FROM EMP_SHOE"); // Create ResultSet for query
while (rs.next()) {
    empNumVar = rs.getString(1); // Get employee number
    shoeSizeVar = rs.getInt(2); // Get shoe size (use int
    // because underlying type
    // of SHOESIZE is INTEGER)
    System.out.println("Employee number= " + empNumVar +
    " Shoe size= " + shoeSizeVar);
}
rs.close(); // Close ResultSet
stmt.close(); // Close Statement
```

Figure 17. Creating and using a distinct type

Related reference:
“Data types that map to database data types in Java applications” on page 313
Use the CallableStatement.getArray method to retrieve the data into a java.sql.Array object. Use the java.sql.Array.getResultSet() method to retrieve the data into a ResultSet object. Use ResultSet methods to retrieve elements of the array. Each row of the ResultSet contains two columns:

- An index into the array, which starts at 1
- The array element

**Example:** Suppose that input and output parameters IN_PHONE and OUT_PHONE in stored procedure GET_EMP_DATA are arrays that are defined like this:

```
CREATE TYPE PHONENUMBERS AS VARCHAR(10) ARRAY[5]
```

Call GET_EMP_DATA with the two parameters.

```java
Connection con;
CallableStatement cstmt;
ResultSet rs;
java.sql.Array inPhoneData;
...

// Create a CallableStatement object

// Set input parameter

// Register out parameters

// Call the stored procedure

// Get the output parameter array

System.out.println("Parameter values from GET_EMP_DATA call: ");
```

```
for(int i=0; i<outPhoneNums.length; i++) {
    System.out.print(outPhoneNums[i]);
    System.out.println();
}
```

---

**Savepoints in JDBC applications**

An SQL savepoint represents the state of data and schemas at a particular point in time within a unit of work. You can use SQL statements to set a savepoint, release a savepoint, and restore data and schemas to the state that the savepoint represents.

The IBM Data Server Driver for JDBC and SQLJ supports the following methods for using savepoints:

- `Connection.setSavepoint()` or `Connection.setSavepoint(String name)`
  Sets a savepoint. These methods return a Savepoint object that is used in later releaseSavepoint or rollback operations.

  When you execute either of these methods, DB2 executes the form of the SAVEPOINT statement that includes ON ROLLBACK RETAIN CURSORS.

- `Connection.releaseSavepoint(Savepoint savepoint)`
  Releases the specified savepoint, and all subsequently established savepoints.

- `Connection.rollback(Savepoint savepoint)`
  Rolls back work to the specified savepoint.

- `DatabaseMetaData.supportsSavepoints()`
  Indicates whether a data source supports savepoints.
You can indicate whether savepoints are unique by calling the method `DB2Connection.setSavePointUniqueOption`. If you call this method with a value of `true`, the application cannot set more than one savepoint with the same name within the same unit of recovery. If you call this method with a value of `false` (the default), multiple savepoints with the same name can be created within the same unit of recovery, but creation of a savepoint destroys a previously created savepoint with the same name.

The following example demonstrates how to set a savepoint, roll back to the savepoint, and release the savepoint.

```java
Connection con;
Statement stmt;
ResultSet rs;
String empNumVar;
int shoeSizeVar;
...
con.setAutoCommit(false); // set autocommit OFF
stmt = con.createStatement(); // Create a Statement object
... // Perform some SQL
con.commit(); // Commit the transaction
stmt.executeUpdate("INSERT INTO EMP_SHOE " +
"VALUES ('000010', 6)"); // Insert a row
((com.ibm.db2.jcc.DB2Connection)con).setSavePointUniqueOption(true); // Indicate that savepoints
// are unique within a unit
// of recovery
Savepoint savept = con.setSavepoint("savepoint1"); // Create a savepoint
...
stmt.executeUpdate("INSERT INTO EMP_SHOE " +
"VALUES ('000020', 10)"); // Insert another row
conn.rollback(savept); // Roll back work to the point
// after the first insert
...
con.releaseSavepoint(savept); // Release the savepoint
stmt.close(); // Close the Statement
conn.commit(); // Commit the transaction
```

**Retrieval of automatically generated keys in JDBC applications**

With the IBM Data Server Driver for JDBC and SQLJ, you can retrieve automatically generated keys (also called auto-generated keys) from a table using JDBC 3.0 methods.

An automatically generated key is any value that is generated by the data server, instead of being specified by the user. One type of automatically generated key is the contents of an identity column. An identity column is a table column that provides a way for the data source to automatically generate a numeric value for each row. You define an identity column in a CREATE TABLE or ALTER TABLE
statement by specifying the AS IDENTITY clause when you define a column that
has an exact numeric type with a scale of 0 (SMALLINT, INTEGER, BIGINT,
DECIMAL with a scale of zero, or a distinct type based on one of these types).

For connections to DB2 for z/OS or DB2 for Linux, UNIX, and Windows, the IBM
Data Server Driver for JDBC and SQLJ supports the return of automatically
generated keys for INSERT statements, for searched UPDATE or searched DELETE
statements, or for MERGE statements. For UPDATE, DELETE, or MERGE
statements, you can identify any columns as automatically generated keys, even if
they are not generated by the data server. In this case, the column values that are
returned are the column values for the rows that are modified by the UPDATE,
DELETE, or MERGE statement.

Restriction: If the Connection or DataSource property atomicMultiRowInsert is set
to DB2BaseDataSource.YES (1), you cannot prepare an SQL statement for retrieval of
automatically generated keys and use the PreparedStatement object for batch
updates. The IBM Data Server Driver for JDBC and SQLJ version 3.50 or later
throws an SQLException when you call the addBatch or executeBatch method on a
PreparedStatement object that is prepared to return automatically generated keys.

Related tasks:
"Creating and modifying database objects using the Statement.executeUpdate
method" on page 47
"Updating data in tables using the PreparedStatement.executeUpdate method" on
page 48

Retrieving auto-generated keys for an INSERT statement

With the IBM Data Server Driver for JDBC and SQLJ, you can use JDBC 3.0
methods to retrieve the keys that are automatically generated when you execute an
INSERT statement.

To retrieve automatically generated keys that are generated by an INSERT
statement, you need to perform these steps:

1. Use one of the following methods to indicate that you want to return
   automatically generated keys:
   - If you plan to use the PreparedStatement.executeUpdate method to insert
     rows, invoke one of these forms of the Connection.prepareStatement method
to create a PreparedStatement object:

     The following form is valid for a table on any data source that supports
     identity columns. sql-statement must be a single-row INSERT statement.

     Restriction: For IBM Data Server Driver for JDBC and SQLJ version 3.57 or
     later, the following form is not valid for inserting rows into a view on a DB2
     for z/OS data server.

     Connection.prepareStatement(sql-statement,
     Statement.RETURN_GENERATED_KEYS);

     The following forms are valid only if the data source supports SELECT
     FROM INSERT statements. sql-statement can be a single-row INSERT
     statement or a multiple-row INSERT statement. With the first form, you
     specify the names of the columns for which you want automatically
generated keys. With the second form, you specify the positions in the table
of the columns for which you want automatically generated keys.

     Connection.prepareStatement(sql-statement, String [] columnNames);
     Connection.prepareStatement(sql-statement, int [] columnIndexes);
• If you use the Statement.executeUpdate method to insert rows, invoke one of these forms of the Statement.executeUpdate method:

The following form is valid for a table on any data source that supports identity columns. sql-statement must be a single-row INSERT statement.

Restriction: For IBM Data Server Driver for JDBC and SQLJ version 3.57 or later, the following form is not valid for inserting rows into a view on a DB2 for z/OS data server.

Statement.executeUpdate(sql-statement, Statement.RETURN_GENERATED_KEYS);

The following forms are valid only if the data source supports SELECT FROM INSERT statements. sql-statement can be a single-row INSERT statement or a multiple-row INSERT statement. With the first form, you specify the names of the columns for which you want automatically generated keys. With the second form, you specify the positions in the table of the columns for which you want automatically generated keys.

Statement.executeUpdate(sql-statement, String [] columnNames);
Statement.executeUpdate(sql-statement, int [] columnIndexes);

2. Invoke the PreparedStatement.getGeneratedKeys method or the Statement.getGeneratedKeys method to retrieve a ResultSet object that contains the automatically generated key values.

If you include the Statement.RETURN_GENERATED_KEYS parameter, the data type of the automatically generated keys in the ResultSet is DECIMAL, regardless of the data type of the corresponding column.

The following code creates a table with an identity column, inserts a row into the table, and retrieves the automatically generated key value for the identity column. The numbers to the right of selected statements correspond to the previously described steps.

import java.sql.*;
import java.math.*;
import com.ibm.db2.jcc.*;

Connection con;
Statement stmt;
ResultSet rs;
java.math.BigDecimal iDColVar;
...
stmt = con.createStatement();  // Create a Statement object

stmt.executeUpdate("CREATE TABLE EMP_PHONE (EMPNO CHAR(6), PHONENO CHAR(4), " +
"IDENTCOL INTEGER GENERATED ALWAYS AS IDENTITY)");
    // Create table with identity column
stmt.executeUpdate("INSERT INTO EMP_PHONE (EMPNO, PHONENO) " +
"VALUES ('000010', '5555')", Statement.RETURN_GENERATED_KEYS);  // Insert a row
    // Indicate you want automatically generated keys
rs = stmt.getGeneratedKeys();  // Retrieve the automatically generated key value
    // value
while (rs.next()) {
    java.math.BigDecimal idColVar = rs.getBigDecimal(1);
        // Get automatically generated key
    System.out.println("automatically generated key value = " + idColVar);
}
r.close();  // Close ResultSet
stmt.close();  // Close Statement
import java.sql.*;
import java.math.*;
import com.ibm.db2.jcc.*;

Connection con;
Statement stmt;
ResultSet rs;
...
stmt = con.createStatement();

stmt.executeUpdate("CREATE TABLE EMP_PHONE (EMPNO CHAR(6), PHONENO CHAR(4), " +
"IDENTCOL INTEGER GENERATED ALWAYS AS IDENTITY);
                     // Create table with identity column
String[] id_col = {"IDENTCOL"};
int updateCount = 1
stmt.executeUpdate("INSERT INTO EMP_PHONE (EMPNO, PHONENO) +
"VALUES ('000010', '5555'), ('000020', '5556'), id_col);  // Insert two rows
                     // Indicate you want automatically
                     // generated keys
rs = stmt.getGeneratedKeys();  // Retrieve the automatically
                     // generated key values in a ResultSet.
                     // Two rows are returned.
                     // Create ResultSet for query
while (rs.next()) {
    idColVar = rs.getInt(1);  // Get automatically generated key
                     // values
    System.out.println("automatically generated key value = " + idColVar);
}
stmt.close();
con.close();

Retrieving auto-generated keys for an UPDATE, DELETE, or
MERGE statement

With the IBM Data Server Driver for JDBC and SQLJ, you can use JDBC 3.0
methods to retrieve the keys that are automatically generated when you execute a
searched UPDATE, searched DELETE, or MERGE statement.

To retrieve automatically generated keys that are generated by an UPDATE,
DELETE, or MERGE statement, you need to perform these steps:
1. Construct a String array that contains the names of the columns from which
   you want to return automatically generated keys.
   The array must be an array of column names, and not column indexes.
2. Set the autocommit mode for the connection to false.
3. Use one of the following methods to indicate that you want to return
   automatically generated keys:
   • If you plan to use the PreparedStatement.executeUpdate method to update,
     delete, or merge rows, invoke this form of the Connection.prepareStatement
     method to create a PreparedStatement object:
     Connection.prepareStatement(sql-statement, String [] columnNames);
   • If you use the Statement.executeUpdate method to update, delete, or merge
     rows, invoke this form of the Statement.executeUpdate method:
     Statement.executeUpdate(sql-statement, String [] columnNames);
4. Invoke the PreparedStatement.getGeneratedKeys method or the Statement.getGeneratedKeys method to retrieve a ResultSet object that contains the automatically generated key values.

Suppose that a table is defined like this and has thirty rows:

```sql
CREATE TABLE EMP_BONUS
(EMPNO CHAR(6),
 BONUS DECIMAL(9,2))
```

The following code names the EMPNO column as an automatically generated key, updates the thirty rows in the EMP_BONUS table, and retrieves the values of EMPNO for the updated rows. The numbers to the right of selected statements correspond to the previously described steps.

```java
import java.sql.*;
...
Connection conn;
...
String[] agkNames = {"EMPNO"};
int updateCount = 0;
conn.setAutoCommit(false);
PreparedStatement ps =
 conn.prepareStatement("UPDATE EMP_BONUS SET BONUS = " + " BONUS + 300.00",agkNames);
updateCount = ps.executeUpdate();
ResultSet rs = ps.getGeneratedKeys();
while (rs.next()) {
 String agkEmpNo = rs.getString(1);
 // Get automatically generated key value
 System.out.println("Automatically generated key value = " + agkEmpNo);
} ps.close();
conn.close();
```

**Named parameter markers in JDBC applications**

You can use named parameter markers instead of standard parameter markers in PreparedStatement and CallableStatement objects to assign values to the input parameter markers. You can also use named parameter markers instead of standard parameter markers in CallableStatement objects to register OUT parameters that have named parameter markers.

SQL strings that contain the following SQL elements can include named parameter markers:
- CALL
- DELETE
- INSERT
- MERGE
- PL/SQL block
- SELECT
- SET
- UPDATE

Named parameter markers make your JDBC applications more readable. If you have named parameter markers in an application, set the IBM Data Server Driver for JDBC and SQLJ Connection or DataSource property enableNamedParameterMarkers to DB2BaseDataSource.YES (1) to direct the driver to accept named parameter markers and send them to the data source as standard parameter markers.
If you are connected to a DB2 for Linux, UNIX, and Windows Version 9.7 or later data server, your SQL strings can include PL/SQL blocks with named parameters. Before you can use named parameters in PL/SQL blocks, the DB2_COMPATIBILITY_VECTOR registry variable needs to be set at the data server to allow PL/SQL compilation.

**Related reference:**

["Common IBM Data Server Driver for JDBC and SQLJ properties for all supported database products" on page 327]

[DB2_COMPATIBILITY_VECTOR registry variable]

### Using named parameter markers with PreparedStatement objects

You can use named parameter markers instead of standard parameter markers in PreparedStatement objects to assign values to the parameter markers.

To ensure that applications with named parameters work correctly, regardless of the data server type and version, before you use named parameter markers in your applications, set the Connection or DataSource property enableNamedParameterMarkers to `DB2BaseDataSource.YES`.

To use named parameter markers with PreparedStatement objects, follow these steps:

1. Execute the Connection.prepareStatement method on an SQL statement string that contains named parameter markers. The named parameter markers must follow the rules for SQL host variable names.
   
   You cannot mix named parameter markers and standard parameter markers in the same SQL statement string.
   
   Named parameter markers are case-insensitive.

2. For each named parameter marker, use a `DB2PreparedStatement.setJccXXXAtName` method to assign a value to each named input parameter.
   
   If you use the same named parameter marker more than once in the same SQL statement string, you need to call a `setJccXXXAtName` method for that parameter marker only once.

   **Recommendation:** Do not use the same named parameter marker more than once in the same SQL statement string if the input to that parameter marker is a stream. Doing so can cause unexpected results.

   **Restriction:** You cannot use standard JDBC PreparedStatement.setXXX methods with named parameter markers. Doing so causes an exception to be thrown.

3. Execute the PreparedStatement.

The following code uses named parameter markers to update the phone number to '4657' for the employee with employee number '000010'. The numbers to the right of selected statements correspond to the previously described steps.

```java
Connection con;
PreparedStatement pstmt;
int numUpd;
...
pstmt = con.prepareStatement(  
 "UPDATE EMPLOYEE SET PHONENO=:phonenum WHERE EMPNO=:empnum" );
// Create a PreparedStatement object 1
((com.ibm.db2.jcc.DB2PreparedStatement)pstmt).setJccStringAtName  
("phonenum", "4567");
// Assign a value to phonenum parameter 2
```

Chapter 3. JDBC application programming 103
The following code uses named parameter markers to update values in a PL/SQL block. The numbers to the right of selected statements correspond to the previously described steps.

Connection con;
PreparedStatement pstmt;
int numUpd;
...
String sql =
"BEGIN "+
" UPDATE EMPLOYEE SET PHONENO = :phonenum WHERE EMPNO = :empnum; " +
"END;";
pstmt = con.prepareStatement(sql); // Create a PreparedStatement object
((com.ibm.db2.jcc.DB2PreparedStatement)pstmt).setJccStringAtName
("phonenum", "4567"); // Assign a value to phonenum parameter
((com.ibm.db2.jcc.DB2PreparedStatement)pstmt).setJccStringAtName
("empnum", "000010"); // Assign a value to empnum parameter
numUpd = pstmt.executeUpdate(); // Perform the update
pstmt.close(); // Close the PreparedStatement object

“DB2PreparedStatement interface” on page 520

Using named parameter markers with CallableStatement objects
You can use named parameter markers instead of standard parameter markers in CallableStatement objects to assign values to IN or INOUT parameters and to register OUT parameters.

To ensure that applications with named parameters work correctly, regardless of the data server type and version, before you use named parameter markers in your applications, set the Connection or DataSource property enableNamedParameterMarkers to DB2BaseDataSource.YES.

To use named parameter markers with CallableStatement objects, follow these steps:

1. Execute the Connection.prepareCall method on an SQL statement string that contains named parameter markers.
   The named parameter markers must follow the rules for SQL host variable names.
   You cannot mix named parameter markers and standard parameter markers in the same SQL statement string.
   Named parameter markers are case-insensitive.

2. If you do not know the names of the named parameter markers in the CALL statement, or the mode of the parameters (IN, OUT, or INOUT):
   a. Call the CallableStatement.getParameterMetaData method to obtain a ParameterMetaData object with information about the parameters.
   b. Call the ParameterMetaData.getParameterMode method to retrieve the parameter mode.
   c. Cast the ParameterMetaData object to a DB2ParameterMetaData object.
   d. Call the DB2ParameterMetaData.getParameterMarkerNames method to retrieve the parameter names.
3. For each named parameter marker that represents an OUT parameter, use a `DB2CallableStatement.registerJccOutParameterAtName` method to register the OUT parameter with a data type.

If you use the same named parameter marker more than once in the same SQL statement string, you need to call a `registerJccOutParameterAtName` method for that parameter marker only once. All parameters with the same name are registered as the same data type.

**Restriction:** You cannot use standard JDBC CallableStatement.registerOutParameter methods with named parameter markers. Doing so causes an exception to be thrown.

4. For each named parameter marker for an input parameter, use a `DB2CallableStatement.setJccXXXAtName` method to assign a value to each named input parameter.

`setJccXXXAtName` methods are inherited from DB2PreparedStatement.

If you use the same named parameter marker more than once in the same SQL statement string, you need to call a `setJccXXXAtName` method for that parameter marker only once.

**Recommendation:** Do not use the same named parameter marker more than once in the same SQL statement string if the input to that parameter marker is a stream. Doing so can cause unexpected results.

5. Execute the CallableStatement.

6. Call CallableStatement.getXXX methods or `DB2CallableStatement.getJccXXXAtName` methods to retrieve output parameter values.

The following code illustrates calling a stored procedure that has one input VARCHAR parameter and one output INTEGER parameter, which are represented by named parameter markers. The numbers to the right of selected statements correspond to the previously described steps.

```java
CallableStatement cstmt =
    com.prepareStatement("CALL MYSP(:inparm,:outparm)"); // Create a CallableStatement object
((com.ibm.db2.jcc.DB2CallableStatement)cstmt).
    registerJccOutParameterAtName("outparm", java.sql.Types.INTEGER); // Register OUT parameter data type
((com.ibm.db2.jcc.DB2CallableStatement)cstmt).setJccStringAtName("inparm", "4567"); // Assign a value to inparm parameter
int outssid = cstmt.getInt(2); // Get the output parameter value
```

The following code illustrates the use of named parameter markers in a PL/SQL block. The numbers to the right of selected statements correspond to the previously described steps.

```java
// Read in a PL/SQL block, and assign it to String variable plsql
CallableStatement cstmt = con.prepareCall(plsql); // Create a CallableStatement object
DB2ParameterMetaData pm = (DB2ParameterMetaData)cs.getParameterMetaData(); // Get ParameterMetaData, cast it to DB2ParameterMetaData
String[] markers = pm.getParameterMarkerNames(); // Get parameter marker names
```
Providing extended client information to the data source with IBM Data Server Driver for JDBC and SQLJ-only methods

A set of IBM Data Server Driver for JDBC and SQLJ-only methods provide extra information about the client to the server. This information can be used for accounting, workload management, or debugging.

Extended client information is sent to the database server when the application performs an action that accesses the server, such as executing SQL.

In the IBM Data Server Driver for JDBC and SQLJ version 4.0 or later, the IBM Data Server Driver for JDBC and SQLJ-only methods are deprecated. You should use java.sql.Connection.setClientInfo instead.

The IBM Data Server Driver for JDBC and SQLJ-only methods are listed in the following table.

Table 15. Methods that provide client information to theDB2 server

<table>
<thead>
<tr>
<th>Method</th>
<th>Information provided</th>
</tr>
</thead>
<tbody>
<tr>
<td>setDB2ClientAccountingInformation</td>
<td>Accounting information</td>
</tr>
<tr>
<td>setDB2ClientApplicationInformation</td>
<td>Name of the application that is working with a connection</td>
</tr>
<tr>
<td>setDB2ClientDebugInfo</td>
<td>The CLIENT DEBUGINFO connection attribute for the Unified debugger</td>
</tr>
<tr>
<td>setDB2ClientProgramId</td>
<td>A caller-specified string that helps the caller identify which program is associated with a particular SQL statement. setDB2ClientProgramId does not apply to DB2 for Linux, UNIX, and Windows data servers.</td>
</tr>
<tr>
<td>setDB2ClientUser</td>
<td>User name for a connection</td>
</tr>
<tr>
<td>setDB2ClientWorkstation</td>
<td>Client workstation name for a connection</td>
</tr>
</tbody>
</table>

To set the extended client information, follow these steps:

1. Create a Connection.
2. Cast the java.sql.Connection object to a com.ibm.db2.jcc.DB2Connection.
3. Call any of the methods shown in Table 15.
4. Execute an SQL statement to cause the information to be sent to theDB2 server.
The following code performs the previous steps to pass a user name and a workstation name to the DB2 server. The numbers to the right of selected statements correspond to the previously-described steps.

```java
public class ClientInfoTest {
  public static void main(String[] args) {
    String url = "jdbc:db2://sysmvs1.stl.ibm.com:5021/san_jose";
    try {
      Class.forName("com.ibm.db2.jcc.DB2Driver");
      String user = "db2adm";
      String password = "db2adm";
      Connection conn = DriverManager.getConnection(url, user, password);
      if (conn instanceof DB2Connection) {
        DB2Connection db2conn = (DB2Connection) conn;
        db2conn.setDB2ClientUser("Michael L Thompson");
        db2conn.setDB2ClientWorkstation("sjwkstn1");
        // Execute SQL to force extended client information to be sent
        // to the server
        conn.prepareStatement("SELECT * FROM SYSIBM.SYSDUMMY1" + "WHERE 0 = 1").executeQuery();
      }
    } catch (Throwable e) {
      e.printStackTrace();
    }
  }
}
```

Figure 19. Example of passing extended client information to a DB2 server

“IBM Data Server Driver for JDBC and SQLJ extensions to JDBC” on page 462

Providing extended client information to the data source with client info properties

The IBM Data Server Driver for JDBC and SQLJ version 4.0 supports JDBC 4.0 client info properties, which you can use to provide extra information about the client to the server. This information can be used for accounting, workload management, or debugging.

Extended client information is sent to the database server when the application performs an action that accesses the server, such as executing SQL.

The application can also use the Connection.getClientInfo method to retrieve client information from the database server, or execute the DatabaseMetaData.getClientInfoProperties method to determine which client information the driver supports.

The JDBC 4.0 client info properties should be used instead IBM Data Server Driver for JDBC and SQLJ-only methods, which are deprecated.

To set client info properties, follow these steps:
1. Create a Connection.
2. Call the java.sql.Connection.setClientInfo method to set any of the client info properties that the database server supports.
3. Execute an SQL statement to cause the information to be sent to the database server.
The following code performs the previous steps to pass a client's user name and host name to the DB2 server. The numbers to the right of selected statements correspond to the previously-described steps.

```java
public class ClientInfoTest {
    public static void main(String[] args) {
        String url = "jdbc:db2://sysmvs1.stl.ibm.com:5021/san_jose";
        try {
            Class.forName("com.ibm.db2.jcc.DB2Driver");
            String user = "db2adm";
            String password = "db2adm";
            Connection conn = DriverManager.getConnection(url, 1
            user, password);
            conn.setClientInfo("ClientUser", "Michael L Thompson"); 2
            conn.setClientInfo("ClientHostname", "sjwkstn1");
            // Execute SQL to force extended client information to be sent
            // to the server
            conn.prepareStatement("SELECT * FROM SYSIBM.SYSDUMMY1" + "WHERE 0 = 1").executeQuery(); 3
        } catch (Throwable e) {
            e.printStackTrace();
        }
    }
}
```

*Figure 20. Example of passing extended client information to a DB2 server*

**Client info properties support by the IBM Data Server Driver for JDBC and SQLJ**

JDBC 4.0 includes client info properties, which contain information about a connection to a data source. The DatabaseMetaData.getClientInfoProperties method returns a list of client info properties that the IBM Data Server Driver for JDBC and SQLJ supports.

When you call DatabaseMetaData.getClientInfoProperties, a result set is returned that contains the following columns:

- **NAME**
- **MAX_LEN**
- **DEFAULT_VALUE**
- **DESCRIPTION**

The following table lists the client info property values that the IBM Data Server Driver for JDBC and SQLJ returns for DB2 for Linux, UNIX, and Windows and for DB2 for i.

*Table 16. Client info property values for DB2 for Linux, UNIX, and Windows and for DB2 for i*

<table>
<thead>
<tr>
<th>NAME</th>
<th>MAX_LEN (bytes)</th>
<th>DEFAULT_VALUE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ApplicationName</td>
<td>255</td>
<td>Empty string</td>
<td>The name of the application that is currently using the connection. This value is stored in DB2 special register CURRENT CLIENT_APPLNAME.</td>
</tr>
<tr>
<td>ClientAccountingInformation</td>
<td>255</td>
<td>Empty string</td>
<td>The value of the accounting string from the client information that is specified for the connection. This value is stored in DB2 special register CURRENT CLIENT_ACCTNG.</td>
</tr>
</tbody>
</table>
### Table 16. Client info property values for DB2 for Linux, UNIX, and Windows and for DB2 for i (continued)

<table>
<thead>
<tr>
<th>NAME</th>
<th>MAX_LEN (bytes)</th>
<th>DEFAULT_VALUE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ClientHostname</td>
<td>255</td>
<td>Empty string</td>
<td>The host name of the local host. The host name of the computer on which the application that is using the connection is running. This value is stored in DB2 special register CURRENT CLIENT_WRKSTNNAME.</td>
</tr>
<tr>
<td>ClientUser</td>
<td>255</td>
<td>Empty string</td>
<td>The name of the user on whose behalf the application that is using the connection is running. This value is stored in DB2 special register CURRENT CLIENT_USERID.</td>
</tr>
</tbody>
</table>

The following table lists the client info property values that the IBM Data Server Driver for JDBC and SQLJ returns for DB2 for z/OS when the connection uses type 4 connectivity.

### Table 17. Client info property values for type 4 connectivity to DB2 for z/OS

<table>
<thead>
<tr>
<th>NAME</th>
<th>MAX_LEN (bytes)</th>
<th>DEFAULT_VALUE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ApplicationName</td>
<td>32</td>
<td>The string &quot;db2jcc_application&quot;.</td>
<td>The name of the application that is currently using the connection. This value is stored in DB2 special register CURRENT CLIENT_APPLNAME.</td>
</tr>
<tr>
<td>ClientAccountingInformation</td>
<td>200</td>
<td>A string of the form JCCversionclient-ip, where version is the driver version, and client-ip is the IP address of the client.</td>
<td>The value of the accounting string from the client information that is specified for the connection. This value is stored in DB2 special register CURRENT CLIENT_ACCTNG.</td>
</tr>
<tr>
<td>ClientHostname</td>
<td>18</td>
<td>The string &quot;db2jcc_local&quot;</td>
<td>The host name of the computer on which the application that is using the connection is running. This value is stored in DB2 special register CURRENT CLIENT_WRKSTNNAME.</td>
</tr>
<tr>
<td>ClientUser</td>
<td>16</td>
<td>The user ID that was specified when the connection was established.</td>
<td>The name of the user on whose behalf the application that is using the connection is running. This value is stored in DB2 special register CURRENT CLIENT_USERID.</td>
</tr>
</tbody>
</table>

The following table lists the client info property values that the IBM Data Server Driver for JDBC and SQLJ returns for DB2 for z/OS when the connection uses type 2 connectivity.

### Table 18. Client info property values for type 2 connectivity on DB2 for z/OS

Extended parameter information with the IBM Data Server Driver for JDBC and SQLJ

IBM Data Server Driver for JDBC and SQLJ-only methods and constants let you assign the default value or no value to table columns or ResultSet columns.

The data server must support extended indicators before you can use the methods that provide extended indicator information in your Java applications. If you call one of those methods against a data server that does not support extended indicators, an exception is thrown. Extended parameter information is supported by DB2 for z/OS Version 10 or later, or DB2 for Linux, UNIX, and Windows Version 9.7 or later.

The methods that provide extended parameter information are listed in the following table.
### Extended parameter information methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2PreparedStatement.setDBDefault,</td>
<td>Sets an input parameter to its default value.</td>
</tr>
<tr>
<td>DB2PreparedStatement.setJccDBDefaultAtName</td>
<td></td>
</tr>
<tr>
<td>DB2PreparedStatement.setDBUnassigned,</td>
<td>Indicates that an input parameter is unassigned. This</td>
</tr>
<tr>
<td>DB2PreparedStatement.setJccDBUnassignedAtName</td>
<td>action yields the same behavior that would occur if the input</td>
</tr>
<tr>
<td>DB2ResultSet.updateDBDefault</td>
<td>parameter did not appear in the SQL statement text.</td>
</tr>
</tbody>
</table>

These methods are applicable only for parameter markers that appear in one of the following places:

- The SET list of an UPDATE statement
- The SET list of a MERGE statement
- The VALUES list of an INSERT statement
- The VALUES list of a MERGE statement
- The source table in a MERGE statement
- The SELECT list of an INSERT from SELECT statement

An SQLException is raised if you use these methods in any other context.

Alternatively, you can use the standard PreparedStatement.setObject or ResultSet.updateObject methods with IBM Data Server Driver for JDBC and SQLJ-only constants DB2PreparedStatement.DB_PARAMETER_DEFAULT or DB2PreparedStatement.DB_PARAMETER_UNASSIGNED to assign the default value or no value to parameters.

Extended parameter information can simplify application programs that have several input variables, each of which can send a value or the default value to the data server, or does not need to appear in the SQL statement. Instead of preparing separate statement strings for all combinations of variable values, you can prepare a single statement string. The resulting PreparedStatement object can be used in a homogeneous batch, whereas multiple different PreparedStatement objects cannot be used in a homogeneous batch.

**Related reference:**
- [“DB2PreparedStatement interface” on page 520](#)

### Using DB2PreparedStatement methods or constants to provide extended parameter information

Use DB2PreparedStatement methods or PreparedStatement methods with DB2PreparedStatement constants to assign default values to target columns or to assign no values to target columns.

Follow these steps to send extended client information for a PreparedStatement to the data server.

1. Create a PreparedStatement object.
   
   The SQL statement is a INSERT, UPDATE, or MERGE statement.

2. If you are not using setObject to assign the values, cast the PreparedStatement object to a com.ibm.db2.jcc.DB2PreparedStatement object.

3. Call one of the following methods:
• If you are not using setObject to assign the value:
  – To assign the default value of the target column to the input parameter, call DB2PreparedStatement.setDBDefault or DB2PreparedStatement.setJccDBDefaultAtName.
  – To mark the input parameter as unassigned, call DB2PreparedStatement.setDBUnassigned or DB2PreparedStatement.setJccDBUnassignedAtName.

• If you are using setObject to assign the value:
  – To assign the default value of the target column to the input parameter, call PreparedStatement.setObject with DB2PreparedStatement.DB_PARAMETER_DEFAULT as the assigned value.
  – To mark the input parameter as unassigned, call PreparedStatement.setObject with DB2PreparedStatement.DB_PARAMETER_UNASSIGNED as the assigned value.

4. Execute the SQL statement.

The following code assigns the default values of the target columns to the third and fifth parameters in an INSERT statement. The numbers to the right of selected statements correspond to the previously described steps.

```java
import java.sql.*;
import com.ibm.db2.jcc.*;

Connection conn;
...
PreparedStatement p = conn.prepareStatement("INSERT INTO DEPARTMENT " + 
  "(DEPTNO, DEPTNAME, MGRNO, ADMRDEPT, LOCATION) " + 
  "VALUES (? , ? , ? , ? , ? );
  p.setString(1, "X00");
p.setString(2, "FACILITIES");
p.setString(4, "A00");
((com.ibm.db2.jcc.DB2PreparedStatement)p).setDBDefault(3);  
((com.ibm.db2.jcc.DB2PreparedStatement)p).setDBDefault(5);
int uCount = p.executeUpdate();
...
p.close(); // Close PreparedStatement
```

The following code uses the PreparedStatement.setObject method and DB2PreparedStatement constants to perform the same function as in the previous example. The numbers to the right of selected statements correspond to the previously described steps.

```java
import java.sql.*;
import com.ibm.db2.jcc.*;

Connection conn;
...
PreparedStatement p = conn.prepareStatement("INSERT INTO DEPARTMENT " + 
  "(DEPTNO, DEPTNAME, MGRNO, ADMRDEPT, LOCATION) " + 
  p.setString(1, "X00");
p.setString(2, "FACILITIES");
p.setString(4, "A00");
p.setObject(3, DB2PreparedStatement.DB_PARAMETER_DEFAULT);
p.setObject(5, DB2PreparedStatement.DB_PARAMETER_DEFAULT);
```
In these examples, use of the method DB2PreparedStatement.setDBDefault or the constant DB2PreparedStatement.DB_PARAMETER_DEFAULT simplifies programming of the INSERT operation. If DB2PreparedStatement.setDBDefault or DB2PreparedStatement.DB_PARAMETER_DEFAULT is not used, up to 32 different PreparedStatement objects are necessary to cover all combinations of default and non-default input values.

**Using DB2ResultSet methods or DB2PreparedStatement constants to provide extended parameter information**

Use DB2ResultSet methods or ResultSet methods with DB2PreparedStatement constants to assign default values to target columns in a DB2ResultSet.

Follow these steps to update a ResultSet with extended client information.

1. Create a PreparedStatement object.
   The SQL statement is a SELECT statement.
2. Invoke PreparedStatement.setXXX methods to pass values to any input parameters.
3. Invoke the PreparedStatement.executeQuery method to obtain the result table from the SELECT statement in a ResultSet object.
4. Position the cursor to the row that you want to update or insert.
5. Update columns in the ResultSet row.
   - If you are not using updateObject to update a value:
     - To assign the default value to the target column of the ResultSet, cast the ResultSet to a DB2ResultSet, and call DB2ResultSet.updateDBDefault.
   - If you are using updateObject to assign the value:
     - To assign the default value to the target column of the ResultSet, call ResultSet.updateObject with DB2PreparedStatement.DB_PARAMETER_DEFAULT as the assigned value.
6. Execute ResultSet.updateRow if you are updating an existing row, or ResultSet.insertRow if you are inserting a new row.

The following code inserts a row into a ResultSet with the default value in the second column, and does not modify the value in the first column. The numbers to the right of selected statements correspond to the previously described steps.

```java
import java.sql.*;
import com.ibm.db2.jcc.*;

Connection conn;
...
PreparedStatement p = conn.prepareStatement("SELECT MGRNO, LOCATION " +
   "FROM DEPARTMENT");
ResultSet rs = p.executeQuery();
rs.next();
rs.moveToInsertRow();
((DB2ResultSet)rs).updateDBDefault(2);
rs.insertRow();
...
rs.close(); // Close ResultSet
p.close(); // Close PreparedStatement
```
The following code uses the ResultSet interface with DB2PreparedStatement
constants to perform the same function as in the previous example. The numbers
to the right of selected statements correspond to the previously described steps.

```java
import java.sql.*;
import com.ibm.db2.jcc.*;

Connection conn;
...
PreparedStatement p = conn.prepareStatement (1
    "SELECT MGRNO, LOCATION " +
    "FROM DEPARTMENT");
ResultSet rs = p.executeQuery (); 3
rs.next ();
rs.moveToInsertRow (); 4
rs.updateObject (2, 5
    DB2PreparedStatement.DB_PARAMETER_DEFAULT);
rs.insertRow (); 6
...
rs.close (); // Close ResultSet
p.close (); // Close PreparedStatement
```

---

**Optimistic locking in JDBC applications**

You can write JDBC applications to take advantage of optimistic locking on a data source.

*Optimistic locking* is a technique that applications can use to release locks between
SELECT and UPDATE or DELETE operations. If the selected rows change before
that application updates or deletes them, the UPDATE or DELETE operation fails.
Optimistic locking minimizes the time during which a given resource is
unavailable for use by other transactions.

For connections to a DB2 for i data source, use of optimistic locking requires DB2
for i V6R1 or later.

In general, an application performs these steps to use optimistic locking:

1. Select rows from a table.
2. Release locks on the table.
3. Update the selected rows, if they have not changed.

To check whether the row has changed, the application queries the row change
token. The row change token is not always a completely accurate indicator of
whether the row has changed. If you create a table with a row change timestamp
column, the row change token is completely accurate. If you create the table
without a row change timestamp column, or alter a table to add a row change
timestamp column, the row change token might not accurately reflect updates to a
row. This means that the row change token might indicate that a row has changed,
even though it has not. This condition is called a *false negative* condition.

When you write a JDBC application to perform optimistic locking you follow
similar steps:

1. Prepare and execute a query.
   Indicate whether you want optimistic locking information, and whether that
   information can include false negatives.
2. Determine whether the ResultSet has optimistic locking information, and
   whether that information can produce false negatives.
Based on the type of optimistic locking information, you can decide whether to continue with optimistic locking.

4. Update the selected rows, if the row change token indicates that they have not changed.

The following code demonstrates how a JDBC application can perform optimistic locking. The numbers in the example correspond to the previously listed steps.

```java
com.ibm.db2.jcc.DB2Statement s1 =
    (com.ibm.db2.jcc.DB2Statement)conn.createStatement();
ResultSet rs =
    ((com.ibm.db2.jcc.DB2Statement)s1).executeDB2OptimisticLockingQuery
    ("SELECT EMPNO, SALARY FROM EMP WHERE EMP.LASTNAME = 'HAAS'",
     com.ibm.db2.jcc.DB2Statement.RETURN_OPTLOCK_COLUMN_NO_FALSE_NEGATIVES);
    // Indicate that you plan to do
    // optimistic locking, and that you
    // want optimistic locking information
    // that does not generate
    // false negatives
ResultSetMetaData rsmd = rs.getMetaData();
int optColumns =
    ((com.ibm.db2.jcc.DB2ResultSetMetaData)rsmd).getDB2OptimisticLockingColumns();
    // Retrieve the optimistic locking
    // information.
boolean optColumnsReturned = false;
if (optColumns == 0); // If optimistic locking information is not
    // returned, do not attempt to do
    // optimistic locking.
else if (optColumns == 1); // A value of 1 is never returned if
    // RETURN OPTLOCK_COLUMN_NO_FALSE_NEGATIVES
    // is specified, because 1 indicates
    // that there could be false negatives.
else if (optColumns == 2) // If optimistic locking information is
    optColumnsReturned = true; // returned, and false negatives will not
    // occur, try optimistic locking.
rs.next(); // Retrieve the contents of the ResultSet
int emp_id = rs.getInt(1);
double salary = rs.getDouble(2);
long rowChangeToken = 0;
Object rid = null;
int type = -1;
if (optColumnsReturned) {
    rowChangeToken =
        ((com.ibm.db2.jcc.DB2ResultSet)rs).getDB2RowChangeToken();
    rid = ((com.ibm.db2.jcc.DB2ResultSet)rs).getDB2RID();
    // Get the RID, which uniquely identifies
    // the row.
    int type = ((com.ibm.db2.jcc.DB2ResultSet)rs).getDB2RIDType ();
    // Get the data type of the RID.
}
// ***************************************************
// Release the locks or disconnect from the database.
// Perform some work on the retrieved data.
// Reconnect to the data source.
// ***************************************************

PreparedStatement s2 =
    conn.prepareStatement("UPDATE EMP SET SALARY = ? " +
    "WHERE EMPNO = ? AND ROW CHANGE TOKEN FOR EMP = ? and " +
    "RID_BIT(EMP) = ?");
    // Statement for updating the
    // previously selected rows that
    // have not changed.
s2.setDouble(1, salary+10000);
s2.setInt(2, emp_id);
s2.setLong(3, rowChangeToken);
    // Set the row change token of the
    // previously retrieved row.
if (type == java.sql.Types.BIGINT)
s2.setLong (4, ((Long)rid).longValue());
```

Chapter 3. JDBC application programming  115
else if (type == java.sql.Types.VARBINARY)
    s2.setBytes(4, (byte[]) rid);
    // Set the RID of the previously
    // retrieved row.
    // Use the correct setXXX method
    // for the data type of the RID.

int updateCount = s2.executeUpdate();  // Perform the update.
if (updateCount == 1) {  // Update is successful.
    else {  // Update failed.

**Compound SQL in Java applications**

SQLJ statement clauses in SQLJ applications or SQL statements in JDBC applications can include compound statements.

A compound statement is a BEGIN-END block that includes SQL and procedural statements. All compound statements in JDBC and SQLJ applications are executed dynamically.

The data server must be DB2 for Linux, UNIX, and Windows Version 9.7 or later.

The IBM Data Server Driver for JDBC and SQLJ passes the compound SQL to the data server without modification.

If your compound SQL contains parameter markers, you need to set the Connection or DataSource property enableNamedParameterMarkers to DB2BaseDataSource.YES (1).

In addition, at the data server, you need to set the DB2_COMPATIBILITY_VECTOR registry variable to enable PL/SQL compilation and execution.

The following example shows JDBC code that executes an inlined compound SQL statement. The compound SQL statement contains parameter markers, so you need to set enableNamedParameterMarkers to DB2BaseDataSource.YES (1).

... 

Properties properties = new Properties(); // Create a Properties object
properties.put("user", "db2adm"); // Set user ID for the connection
properties.put("password", "db2adm"); // Set password for the connection
properties.put("enableNamedParameterMarkers",
    new String("",
        String.valueOf(com.ibm.db2.jcc.DB2BaseDataSource.YES + "))); // Set enableNamedParameterMarkers
String url = "jdbc:db2://luw1.myloc.ibm.com:9896/sample"; // Set URL for the data source
Connection conn1 = DriverManager.getConnection(url, properties); // Create the connection
...

// Prepare and execute the compound
// statement in the same way that
// you prepare a single SQL statement

PreparedStatement ps = conn1.prepareStatement("BEGIN atomic " +
    " for row as " +
    " select pk, c1, discretize (c1) as d from source " +
    " do " +
    " if row.d is null then " +
    " insert into except values (row.pk, ?); " +
XML data in JDBC applications

In JDBC applications, you can store data in XML columns and retrieve data from XML columns.

In database tables, the XML built-in data type is used to store XML data in a column as a structured set of nodes in a tree format.

JDBC applications can send XML data to the data server or retrieve XML data from the data server in one of the following forms:

- As textual XML data
- As binary XML data, if the data server supports it

In JDBC applications, you can:

- Store an entire XML document in an XML column using setXXX methods.
- Retrieve an entire XML document from an XML column using getXXX methods.
- Retrieve a sequence from a document in an XML column by using the SQL XMLQUERY function to retrieve the sequence into a serialized sequence in the database, and then using getXXX methods to retrieve the data into an application variable.
- Retrieve a sequence from a document in an XML column by using an XQuery expression, prepended with the string 'XQUERY', to retrieve the elements of the sequence into a result table in the database, in which each row of the result table represents an item in the sequence. Then use getXXX methods to retrieve the data into application variables.
- Retrieve a sequence from a document in an XML column as a user-defined table by using the SQL XMLTABLE function to define the result table and retrieve it. Then use getXXX methods to retrieve the data from the result table into application variables.

JDBC 4.0 java.sql.SQLXML objects can be used to retrieve and update data in XML columns. Invocations of metadata methods, such as ResultSetMetaData.getColumnTypeName return the integer value java.sql.Types.SQLXML for an XML column type.

XML column updates in JDBC applications

In a JDBC application, you can update or insert data into XML columns of a table at a DB2 data server using XML textual data. You can update or insert data into
XML columns of a table using binary XML data (data that is in the Extensible Dynamic Binary XML DB2 Client/Server Binary XML Format), if the data server supports binary XML data.

The following table lists the methods and corresponding input data types that you can use to put data in XML columns.

<table>
<thead>
<tr>
<th>Method</th>
<th>Input data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>PreparedStatement.setAsciiStream</td>
<td>InputStream</td>
</tr>
<tr>
<td>PreparedStatement.setBinaryStream</td>
<td>InputStream</td>
</tr>
<tr>
<td>PreparedStatement.setBlob</td>
<td>Blob</td>
</tr>
<tr>
<td>PreparedStatement.setBytes</td>
<td>byte[]</td>
</tr>
<tr>
<td>PreparedStatement.setCharacterStream</td>
<td>Reader</td>
</tr>
<tr>
<td>PreparedStatement.setClob</td>
<td>Clob</td>
</tr>
<tr>
<td>PreparedStatement.setObject</td>
<td>byte[], Blob, Clob, SQLXML, DB2Xml (deprecated), InputStream, Reader, String</td>
</tr>
<tr>
<td>PreparedStatement.setSQLXML1</td>
<td>SQLXML</td>
</tr>
<tr>
<td>PreparedStatement.setString</td>
<td>String</td>
</tr>
</tbody>
</table>

**Note:**

1. This method requires JDBC 4.0 or later.

The encoding of XML data can be derived from the data itself, which is known as *internally encoded* data, or from external sources, which is known as *externally encoded* data. XML data that is sent to the database server as binary data is treated as internally encoded data. XML data that is sent to the data source as character data is treated as externally encoded data.

**External encoding for Java applications is always Unicode encoding.**

Externally encoded data can have internal encoding. That is, the data might be sent to the data source as character data, but the data contains encoding information. The data source handles incompatibilities between internal and external encoding as follows:

- If the data source is DB2 for Linux, UNIX, and Windows, the database source generates an error if the external and internal encoding are incompatible, unless the external and internal encoding are Unicode. If the external and internal encoding are Unicode, the database source ignores the internal encoding.
- If the database source is DB2 for z/OS, the database source ignores the internal encoding.

Data in XML columns is stored in UTF-8 encoding. The database source handles conversion of the data from its internal or external encoding to UTF-8.

**Example:** The following example demonstrates inserting data from an SQLXML object into an XML column. The data is String data, so the database source treats the data as externally encoded.

```java
public void insertSQLXML()
{
    Connection con = DriverManager.getConnection(url);
    SQLXML info = con.createSQLXML();
    // Create an SQLXML object
```
PreparedStatement insertStmt = null;
String infoData =
"<customerinfo xmlns="http://posample.org" >
  Cid="1000"
</customerinfo>";
info.setString(infoData);
// Populate the SQLXML object
int cid = 1000;
try {
  sqls = "INSERT INTO CUSTOMER (CID, INFO) VALUES (?, ?)";
  insertStmt = con.prepareStatement(sqls);
  insertStmt.setInt(1, cid);
  insertStmt.setSQLXML(2, info);
  // Assign the SQLXML object value
  // to an input parameter
  if (insertStmt.executeUpdate() != 1) {
    System.out.println("insertSQLXML: No record inserted.");
  }
} catch (IOException ioe) {
  ioe.printStackTrace();
} catch (SQLException sqle) {
  System.out.println("insertSQLXML: SQL Exception: " +
                      sqle.getMessage());
  System.out.println("insertSQLXML: SQL State: " +
                      sqle.getSQLState());
  System.out.println("insertSQLXML: SQL Error Code: " +
                      sqle.getErrorCode());
}

Example: The following example demonstrates inserting data from a file into an
XML column. The data is inserted as binary data, so the database server honors the
internal encoding.

public void insertBinStream(Connection conn) {
  PreparedStatement insertStmt = null;
  String sqls = null;
  int cid = 0;
  Statement stmt=null;
  try {
    sqls = "INSERT INTO CUSTOMER (CID, INFO) VALUES (?, ?)";
    insertStmt = conn.prepareStatement(sqls);
    insertStmt.setInt(1, cid);
    File file = new File(fn);
    insertStmt.setBinaryStream(2,
                                new FileInputStream(file), (int)file.length());
    if (insertStmt.executeUpdate() != 1) {
      System.out.println("insertBinStream: No record inserted.");
    }
  } catch (IOException ioe) {
    ioe.printStackTrace();
  } catch (SQLException sqle) {
    System.out.println("insertBinStream: SQL Exception: " +
                        sqle.getMessage());
    System.out.println("insertBinStream: SQL State: " +
                        sqle.getSQLState());
    System.out.println("insertBinStream: SQL Error Code: " +
                        sqle.getErrorCode());
  }
}
**Example:** The following example demonstrates inserting binary XML data from a file into an XML column.

```
...
SQLXML info = conn.createSQLXML();
OutputStream os = info.setBinaryStream();
FileInputStream fis = new FileInputStream("c7.xml");
int read;
while ((read = fis.read()) != -1) {
  os.write(read);
}

PreparedStatement insertStmt = null;
String sqls = null;
int cid = 1015;
sqls = "INSERT INTO MyCustomer (Cid, Info) VALUES (?, ?)");
insertStmt = conn.prepareStatement(sqls);
insertStmt.setInt(1, cid);
insertStmt.setSQLXML(2, info);
insertStmt.executeUpdate();
```

**XML data retrieval in JDBC applications**

In JDBC applications, you use ResultSet.getXXX or ResultSet.getObject methods to retrieve data from XML columns.

In a JDBC application, you can retrieve data from XML columns in a DB2 table as XML textual data. You can retrieve data from XML columns in a table as binary XML data (data that is in the Extensible Dynamic Binary XML DB2 Client/Server Binary XML Format), if the data server supports binary XML data.

You can use one of the following techniques to retrieve XML data:

- Use the ResultSet.getSQLXML method to retrieve the data. Then use a SQLXML.getXXX method to retrieve the data into a compatible output data type. This technique requires JDBC 4.0 or later.
  
  For example, you can retrieve data by using the SQLXML.getBinaryStream method or the SQLXML.getSource method.

- Use a ResultSet.getXXX method other than ResultSet.getObject to retrieve the data into a compatible data type.

- Use the ResultSet.getObject method to retrieve the data, and then cast it to the DB2Xml type and assign it to a DB2Xml object. Then use a DB2Xml.getDB2XXX or DB2Xml.getDB2XmlXXX method to retrieve the data into a compatible output data type.

  You need to use this technique if you are not using a version of the IBM Data Server Driver for JDBC and SQLJ that supports JDBC 4.0.

The following table lists the ResultSet methods and corresponding output data types for retrieving XML data.

<table>
<thead>
<tr>
<th>Method</th>
<th>Output data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResultSet.getAsciiStream</td>
<td>InputStream</td>
</tr>
<tr>
<td>ResultSet.getBinaryStream</td>
<td>InputStream</td>
</tr>
<tr>
<td>ResultSet.getBytes</td>
<td>byte[]</td>
</tr>
<tr>
<td>ResultSet.getCharacterStream</td>
<td>Reader</td>
</tr>
</tbody>
</table>
Table 21. ResultSet methods and data types for retrieving XML data (continued)

<table>
<thead>
<tr>
<th>Method</th>
<th>Output data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResultSet.getObject</td>
<td>Object</td>
</tr>
<tr>
<td>ResultSet.getSQLXML</td>
<td>SQLXML</td>
</tr>
<tr>
<td>ResultSet.getString</td>
<td>String</td>
</tr>
</tbody>
</table>

The following table lists the methods that you can call to retrieve data from a java.sql.SQLXML or a com.ibm.db2.jcc.DB2Xml object, and the corresponding output data types and type of encoding in the XML declarations.

Table 22. SQLXML and DB2Xml methods, data types, and added encoding specifications

<table>
<thead>
<tr>
<th>Method</th>
<th>Output data type</th>
<th>Type of XML internal encoding declaration added</th>
</tr>
</thead>
<tbody>
<tr>

<td>Specified by getDB2XmlBinaryStream targetEncoding parameter</td>
</tr>
<tr>
<td>DB2Xml.getDB2XmlBytes</td>
<td>byte[]</td>
<td>Specified by DB2Xml.getDB2XmlBytes targetEncoding parameter</td>
</tr>
<tr>
<td>DB2Xml.getDB2XmlCharacterStream</td>
<td>Reader</td>
<td>ISO-10646-UCS-2</td>
</tr>
<tr>
<td>DB2Xml.getDB2XmlString</td>
<td>String</td>
<td>ISO-10646-UCS-2</td>
</tr>
</tbody>
</table>

**Note:**
1. The class that is returned is specified by the invoker of getSource, but the class must extend javax.xml.transform.Source.

If the application executes the XMLSERIALIZE function on the data that is to be returned, after execution of the function, the data has the data type that is specified in the XMLSERIALIZE function, not the XML data type. Therefore, the driver handles the data as the specified type and ignores any internal encoding declarations.

**Example:** The following example demonstrates retrieving data from an XML column into an SQLXML object, and then using the SQLXML.getString method to retrieve the data into a string.

```java
public void fetchToSQLXML(long cid, java.sql.Connection conn)
{
    System.out.println(">> fetchToSQLXML: Get XML data as an SQLXML object " +
                      "using getSQLXML");
    PreparedStatement selectStmt = null;
    String sqls = null, stringDoc = null;
    ResultSet rs = null;
```
try{
    sqls = "SELECT info FROM customer WHERE cid = " + cid;
    selectStmt = conn.prepareStatement(sqls);
    rs = selectStmt.executeQuery();
    // Get metadata
    // Column type for XML column is the integer java.sql.Types.OTHER
    ResultSetMetaData meta = rs.getMetaData();
    int colType = meta.getColumnType(1);
    System.out.println("fetchToSQXML: Column type = " + colType);
    while (rs.next()) {
        // Retrieve the XML data with getSQLXML.
        // Then write it to a string with
        // explicit internal ISO-10646-UCS-2 encoding.
        java.sql.SQLXML xml = rs.getSQLXML(1);
        System.out.println (xml.getString());
    } }
    rs.close();
} catch (SQLException sqle) {
    System.out.println("fetchToSQXML: SQL Exception: " +
        sqle.getMessage());
    System.out.println("fetchToSQXML: SQL State: " +
        sqle.getSQLState());
    System.out.println("fetchToSQXML: SQL Error Code: " +
        sqle.getErrorCode());
}

Example: The following example demonstrates retrieving data from an XML column into an SQLXML object, and then using the SQLXML.getBinaryStream method to retrieve the data as binary data into an InputStream.

String sql = "SELECT INFO FROM Customer WHERE Cid='1000'";
PreparedStatement pstmt = con.prepareStatement(sql);
ResultSet resultSet = pstmt.executeQuery();
// Get the result XML as a binary stream
SQLXML sqlxml = resultSet.getSQLXML(1);
InputStream binaryStream = sqlxml.getBinaryStream();

Example: The following example demonstrates retrieving data from an XML column into a String variable.

public void fetchTostring(long cid, java.sql.Connection conn)
{
    System.out.println(">> fetchToString: Get XML data " +
        "using getString");
    PreparedStatement selectStmt = null;
    String sqls = null, stringDoc = null;
    ResultSet rs = null;
    try{
        sqls = "SELECT info FROM customer WHERE cid = " + cid;
        selectStmt = conn.prepareStatement(sqls);
        rs = selectStmt.executeQuery();
        // Get metadata
        // Column type for XML column is the integer java.sql.Types.OTHER
        ResultSetMetaData meta = rs.getMetaData();
        int colType = meta.getColumnType(1);
        System.out.println("fetchToString: Column type = " + colType);   
        while (rs.next()) {
            stringDoc = rs.getString(1);
            System.out.println("Document contents:");
            System.out.println(stringDoc);
        }
    }
Example: The following example demonstrates retrieving data from an XML column into a DB2Xml object, and then using the DB2Xml.getDB2XmlString method to retrieve the data into a string with an added XML declaration with an ISO-10646-UCS-2 encoding specification.

```java
public void fetchToDB2Xml(long cid, java.sql.Connection conn) {
    System.out.println(">> fetchToDB2Xml: Get XML data as a DB2XML object "+
        "using getObject");
    PreparedStatement selectStmt = null;
    String sqls = null, stringDoc = null;
    ResultSet rs = null;
    try{
        sqls = "SELECT info FROM customer WHERE cid = " + cid;
        selectStmt = conn.prepareStatement(sqls);
        rs = selectStmt.executeQuery();
        // Get metadata
        // Column type for XML column is the integer java.sql.Types.OTHER
        ResultSetMetaData meta = rs.getMetaData();
        int colType = meta.getColumnType(1);
        System.out.println("fetchToDB2Xml: Column type= " + colType);
        while (rs.next()) {
            // Retrieve the XML data with getObject, and cast the object
            // as a DB2Xml object. Then write it to a string with
            // explicit internal ISO-10646-UCS-2 encoding.
            com.ibm.db2.jcc.DB2Xml xml =
                (com.ibm.db2.jcc.DB2Xml) rs.getObject(1);
            System.out.println (xml.getDB2XmlString());
        }
        rs.close();
    }
    catch (SQLException sqle) {
        System.out.println("fetchToDB2Xml: SQL Exception: " +
            sqle.getMessage());
        System.out.println("fetchToDB2Xml: SQL State: " +
            sqle.getSQLState());
        System.out.println("fetchToDB2Xml: SQL Error Code: " +
            sqle.getErrorCode());
    }
}
```

“Data types that map to database data types in Java applications” on page 313

Invocation of routines with XML parameters in Java applications

Java applications can call stored procedures at DB2 for Linux, UNIX, and Windows or DB2 for z/OS data sources that have XML parameters.

For native SQL procedures, XML parameters in the stored procedure definition have the XML type. For external stored procedures and user-defined functions on DB2 for Linux, UNIX, and Windows data sources, XML parameters in the routine
definition have the XML AS CLOB type. When you call a stored procedure or user-defined function that has XML parameters, you need to use a compatible data type in the invoking statement.

To call a routine with XML input parameters from a JDBC program, use parameters of the java.sql.SQLXML or com.ibm.db2.jcc.DB2Xml type. To register XML output parameters, register the parameters as the java.sql.Types.SQLXML or com.ibm.db2.jcc.DB2Types.XML type. (The com.ibm.db2.jcc.DB2Xml and com.ibm.db2.jcc.DB2Types.XML types are deprecated.)

**Example:** JDBC program that calls a stored procedure that takes three XML parameters: an IN parameter, an OUT parameter, and an INOUT parameter. This example requires JDBC 4.0 or later.

```java
java.sql.SQLXML in_xml = xmlvar;
java.sql.SQLXML out_xml = null;
java.sql.SQLXML inout_xml = xmlvar;

// Declare an input, output, and
// INOUT XML parameter
...
```

```java
Connection con;
CallableStatement cstmt;
ResultSet rs;
...
```

```java
  cstmt = con.prepareCall("CALL SP_xml(?,?,?)");
  // Create a CallableStatement object
  cstmt.setObject (1, in_xml);  // Set input parameter
  cstmt.setObject (3, inout_xml); // Set inout parameter
  cstmt.registerOutParameter (2, java.sql.Types.SQLXML);
  // Register out and input parameters
  cstmt.registerOutParameter (3, java.sql.Types.SQLXML);
  cstmt.executeUpdate(); // Call the stored procedure
  out_xml = cstmt.getSQLXML(2); // Get the OUT parameter value
  inout_xml = cstmt.getSQLXML(3); // Get the INOUT parameter value
System.out.println("Parameter values from SP_xml call: ");
System.out.println("Output parameter value ");
MyUtilities.printString(out_xml.getString());
  // Use the SQLXML.getString
  // method to convert the out_xml
  // value to a string for printing.
  // Call a user-defined method called
  // printString (not shown) to print
  // the value.
System.out.println("INOUT parameter value ");
MyUtilities.printString(inout_xml.getString());
  // Use the SQLXML.getString
  // method to convert the inout_xml
  // value to a string for printing.
  // Call a user-defined method called
  // printString (not shown) to print
  // the value.
```

To call a routine with XML parameters from an SQLJ program, use parameters of the java.sql.SQLXML or com.ibm.db2.jcc.DB2Xml type.

**Example:** SQLJ program that calls a stored procedure that takes three XML parameters: an IN parameter, an OUT parameter, and an INOUT parameter. This example requires JDBC 4.0 or later.

```java
java.sql.SQLXML in_xml = xmlvar;
java.sql.SQLXML out_xml = null;
java.sql.SQLXML inout_xml = xmlvar;

// Declare an input, output, and
// INOUT XML parameter
```
Java support for XML schema registration and removal

The IBM Data Server Driver for JDBC and SQLJ provides methods that let you write Java application programs to register and remove XML schemas and their components.

The methods are:

**DB2Connection.registerDB2XMLSchema**

Registers an XML schema in DB2, using one or more XML schema documents. There are two forms of this method: one form for XML schema documents that are input from InputStream objects, and one form for XML schema documents that are in a String.

**DB2Connection.deregisterDB2XMLObject**

Removes an XML schema definition from DB2.

**DB2Connection.updateDB2XmlSchema**

Replaces the XML schema documents in a registered XML schema with the XML schema documents from another registered XML schema. Optionally drops the XML schema whose contents are copied. This method is available only for connections to DB2 for Linux, UNIX, and Windows.

Before you can invoke these methods, the stored procedures that support these methods must be installed on the DB2 database server.

*Example: Registration of an XML schema:* The following example demonstrates the use of registerDB2XmlSchema to register an XML schema in DB2 using a single XML schema document (customer.xsd) that is read from an input stream. The SQL schema name for the registered schema is SYSXSR. No additional properties are registered.

```java
public static void registerSchema(
    Connection con,
    String schemaName)
throws SQLException {
    // Define the registerDB2XmlSchema parameters
    String[] xmlSchemaNameQualifiers = new String[1];
    String[] xmlSchemaNames = new String[1];
    String[] xmlSchemaLocations = new String[1];
    InputStream[] xmlSchemaDocuments = new InputStream[1];
    int[] xmlSchemaDocumentsLengths = new int[1];
```
java.io.InputStream[] xmlSchemaDocumentsProperties = new InputStream[1];
int[] xmlSchemaDocumentsPropertiesLengths = new int[1];
InputStream xmlSchemaProperties;
int xmlSchemaPropertiesLength;
// Set the parameter values
xmlSchemaLocations[0] = "";
FileInputStream fi = null;
xmlSchemaNameQualifiers[0] = "SYSXSR";
xmlSchemaNames[0] = schemaName;
try {
  fi = new FileInputStream("customer.xsd");
  xmlSchemaDocuments[0] = new BufferedInputStream(fi);
  } catch (FileNotFoundException e) { 
    e.printStackTrace();
  }
try {
  xmlSchemaDocumentsLengths[0] = (int) fi.getChannel().size();
  System.out.println(xmlSchemaDocumentsLengths[0]);
} catch (IOException e1) { 
  e1.printStackTrace();
}
xmlSchemaDocumentsProperties[0] = null;
xmlSchemaDocumentsPropertiesLengths[0] = 0;
xmlSchemaProperties = null;
xmlSchemaPropertiesLength = 0;
DB2Connection ds = (DB2Connection) con;
// Invoke registerDB2XmlSchema
ds.registerDB2XmlSchema(
  xmlSchemaNameQualifiers,
  xmlSchemaNames,
  xmlSchemaLocations,
  xmlSchemaDocuments,
  xmlSchemaDocumentsLengths,
  xmlSchemaDocumentsProperties,
  xmlSchemaDocumentsPropertiesLengths,
  xmlSchemaProperties,
  xmlSchemaPropertiesLength,
  false);
}

Example: Removal of an XML schema: The following example demonstrates the use of deregisterDB2XmlObject to remove an XML schema from DB2. The SQL schema name for the registered schema is SYSXSR.

class CSXML {
  public static void deregisterSchema(
    Connection con,
    String schemaName)
    throws SQLException {
    // Define and assign values to the deregisterDB2XmlObject parameters
    String xmlSchemaNameQualifier = "SYSXSR";
    String xmlSchemaName = schemaName;
    DB2Connection ds = (DB2Connection) con;
    // Invoke deregisterDB2XmlObject
    ds.deregisterDB2XmlObject(
      xmlSchemaNameQualifier,
      xmlSchemaName);
  }
}

Example: Update of an XML schema: The following example applies only to connections to DB2 for Linux, UNIX, and Windows. It demonstrates the use of updateDB2XmlSchema to update the contents of an XML schema with the contents of another XML schema. The schema that is copied is kept in the repository. The SQL schema name for both registered schemas is SYSXSR.
public static void updateSchema(
    Connection con,
    String schemaNameTarget,
    String schemaNameSource)
throws SQLException {
    // Define and assign values to the updateDB2XmlSchema parameters
    String xmlSchemaNameQualifierTarget = "SYSXSR";
    String xmlSchemaNameQualifierSource = "SYSXSR";
    String xmlSchemaNameTarget = schemaNameTarget;
    String xmlSchemaNameSource = schemaNameSource;
    boolean dropSourceSchema = false;
    DB2Connection ds = (DB2Connection) con;
    // Invoke updateDB2XmlSchema
    ds.updateDB2XmlSchema(
        xmlSchemaNameQualifierTarget,
        xmlSchemaNameTarget,
        xmlSchemaNameQualifierSource,
        xmlSchemaNameSource,
        dropSourceSchema);
}

Transaction control in JDBC applications

In JDBC applications, as in other types of SQL applications, transaction control involves explicitly or implicitly committing and rolling back transactions, and setting the isolation level for transactions.

IBM Data Server Driver for JDBC and SQLJ isolation levels

The IBM Data Server Driver for JDBC and SQLJ supports a number of isolation levels, which correspond to database server isolation levels.

JDBC isolation levels can be set for a unit of work within a JDBC program, using the Connection.setTransactionIsolation method. The default isolation level can be set with the defaultIsolationLevel property.

The following table shows the values of level that you can specify in the Connection.setTransactionIsolation method and their DB2 database server equivalents.

<table>
<thead>
<tr>
<th>JDBC value</th>
<th>DB2 isolation level</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.sql.Connection.TRANSACTION_SERIALIZABLE</td>
<td>Repeatable read</td>
</tr>
<tr>
<td>java.sql.Connection.TRANSACTION_REPEATABLE_READ</td>
<td>Read stability</td>
</tr>
<tr>
<td>java.sql.Connection.TRANSACTION_READ_COMMITTED</td>
<td>Cursor stability</td>
</tr>
<tr>
<td>java.sql.Connection.TRANSACTION_READ_UNCOMMITTED</td>
<td>Uncommitted read</td>
</tr>
</tbody>
</table>

The following table shows the values of level that you can specify in the Connection.setTransactionIsolation method and their IBM Informix equivalents.

<table>
<thead>
<tr>
<th>JDBC value</th>
<th>IBM Informix isolation level</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.sql.Connection.TRANSACTION_SERIALIZABLE</td>
<td>Repeatable read</td>
</tr>
<tr>
<td>java.sql.Connection.TRANSACTION_REPEATABLE_READ</td>
<td>Repeatable read</td>

Committing or rolling back JDBC transactions
In JDBC, to commit or roll back transactions explicitly, use the commit or rollback methods.

For example:
```java
Connection con;
...
con.commit();
```

If autocommit mode is on, the database manager performs a commit operation after every SQL statement completes. To set autocommit mode on, invoke the `Connection.setAutoCommit(true)` method. To set autocommit mode off, invoke the `Connection.setAutoCommit(false)` method. To determine whether autocommit mode is on, invoke the `Connection.getAutoCommit` method.

Connections that participate in distributed transactions cannot invoke the `setAutoCommit(true)` method.

When you change the autocommit state, the database manager executes a commit operation, if the application is not already on a transaction boundary.

While a connection is participating in a distributed transaction, the associated application cannot issue the commit or rollback methods.

Default JDBC autocommit modes
The default autocommit mode depends on the data source to which the JDBC application connects.

Autocommit default for DB2 data sources
For connections to DB2 data sources, the default autocommit mode is true.

Autocommit default for IBM Informix data sources
For connections to IBM Informix data sources, the default autocommit mode depends on the type of data source. The following table shows the defaults.
Table 25. Default autocommit modes for IBM Informix data sources

<table>
<thead>
<tr>
<th>Type of data source</th>
<th>Default autocommit mode for local transactions</th>
<th>Default autocommit mode for global transactions</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANSI-compliant database</td>
<td>true</td>
<td>false</td>
</tr>
<tr>
<td>Non-ANSI-compliant database</td>
<td>false</td>
<td>not applicable</td>
</tr>
<tr>
<td>Non-ANSI-compliant database without logging</td>
<td>true</td>
<td>false</td>
</tr>
</tbody>
</table>

Exceptions and warnings under the IBM Data Server Driver for JDBC and SQLJ

In JDBC applications, SQL errors throw exceptions, which you handle using try/catch blocks. SQL warnings do not throw exceptions, so you need to invoke methods to check whether warnings occurred after you execute SQL statements.

The IBM Data Server Driver for JDBC and SQLJ provides the following classes and interfaces, which provide information about errors and warnings.

SQLException

The SQLException class for handling errors. All JDBC methods throw an instance of SQLException when an error occurs during their execution. According to the JDBC specification, an SQLException object contains the following information:

- An int value that contains an error code. SQLException.getErrorCode retrieves this value.
- A String object that contains the SQLSTATE, or null. SQLException.getSQLState retrieves this value.
- A String object that contains a description of the error, or null. SQLException.getMessage retrieves this value.
- A pointer to the next SQLException, or null. SQLException.getNextException retrieves this value.

When a JDBC method throws a single SQLException, that SQLException might be caused by an underlying Java exception that occurred when the IBM Data Server Driver for JDBC and SQLJ processed the method. In this case, the SQLException wraps the underlying exception, and you can use the SQLException.getCause method to retrieve information about the error.

DB2Diagnosable

The IBM Data Server Driver for JDBC and SQLJ-only interface com.ibm.db2.jcc.DB2Diagnosable extends the SQLException class. The DB2Diagnosable interface gives you more information about errors that occur when the data source is accessed. If the JDBC driver detects an error, DB2Diagnosable gives you the same information as the standard SQLException class. However, if the database server detects the error, DB2Diagnosable adds the following methods, which give you additional information about the error:

getSqlca

Returns an DB2Sqlca object with the following information:

- An SQL error code
- The SQLERRMC values
- The SQLERRP value
- The SQLERRD values
- The SQLWARN values
- The SQLSTATE

getThrowable
Returns a java.lang.Throwable object that caused the SQLException, or null, if no such object exists.

printTrace
Prints diagnostic information.

SQLException subclasses
If you are using JDBC 4.0 or later, you can obtain more specific information than an SQLException provides by catching the following exception classes:
- SQLNonTransientException
  An SQLNonTransientException is thrown when an SQL operation that failed previously cannot succeed when the operation is retried, unless some corrective action is taken. The SQLNonTransientException class has these subclasses:
  - SQLFeatureNotSupportedException
  - SQLNonTransientConnectionException
  - SQLDataException
  - SQLIntegrityConstraintViolationException
  - SQLInvalidAuthorizationSpecException
  - SQLSyntaxException
- SQLTransientException
  An SQLTransientException is thrown when an SQL operation that failed previously might succeed when the operation is retried, without intervention from the application. A connection is still valid after an SQLTransientException is thrown. The SQLTransientException class has these subclasses:
  - SQLTransientConnectionException
  - SQLTransientRollbackException
  - SQLTimeoutException
- SQLRecoverableException
  An SQLRecoverableException is thrown when an operation that failed previously might succeed if the application performs some recovery steps, and retries the transaction. A connection is no longer valid after an SQLRecoverableException is thrown.
- SQLClientInfoException
  A SQLClientInfoException is thrown by the Connection.setClientInfo method when one or more client properties cannot be set. The SQLClientInfoException indicates which properties cannot be set.

BatchUpdateException
A BatchUpdateException object contains the following items about an error that occurs during execution of a batch of SQL statements:
- A String object that contains a description of the error, or null.
- A String object that contains the SQLSTATE for the failing SQL statement, or null
- An integer value that contains the error code, or zero
- An integer array of update counts for SQL statements in the batch, or null
- A pointer to an SQLException object, or null
One BatchUpdateException is thrown for the entire batch. At least one SQLException object is chained to the BatchUpdateException object. The SQLException objects are chained in the same order as the corresponding statements were added to the batch. To help you match SQLException objects to statements in the batch, the error description field for each SQLException object begins with this string:

Error for batch element #n:

n is the number of the statement in the batch.

SQL warnings during batch execution do not throw BatchUpdateExceptions. To obtain information about warnings, use the Statement.getWarnings method on the object on which you ran the executeBatch method. You can then retrieve an error description, SQLSTATE, and error code for each SQLWarning object.

**SQLWarning**

The IBM Data Server Driver for JDBC and SQLJ accumulates warnings when SQL statements return positive SQLCODEs, and when SQL statements return 0 SQLCODEs with non-zero SQLSTATEs.

Calling getWarnings retrieves an SQLWarning object.

**Important:** When a call to Statement.executeUpdate or PreparedStatement.executeUpdate affects no rows, the IBM Data Server Driver for JDBC and SQLJ generates an SQLWarning with error code +100.

When a call to ResultSet.next returns no rows, the IBM Data Server Driver for JDBC and SQLJ does not generate an SQLWarning.

A generic SQLWarning object contains the following information:

- A String object that contains a description of the warning, or null
- A String object that contains the SQLSTATE, or null
- An int value that contains an error code
- A pointer to the next SQLWarning, or null

Under the IBM Data Server Driver for JDBC and SQLJ, like an SQLException object, an SQLWarning object can also contain DB2-specific information. The DB2-specific information for an SQLWarning object is the same as the DB2-specific information for an SQLException object.

**Handling an SQLException under the IBM Data Server Driver for JDBC and SQLJ**

As in all Java programs, error handling for JDBC applications is done using try/catch blocks. Methods throw exceptions when an error occurs, and the code in the catch block handles those exceptions.

The basic steps for handling an SQLException in a JDBC program that runs under the IBM Data Server Driver for JDBC and SQLJ are:

1. Give the program access to the com.ibm.db2.jdbc.DB2Diagnosable interface and the com.ibm.db2.jdbc.DB2Sqlca class. You can fully qualify all references to them, or you can import them:

   ```java
   import com.ibm.db2.jdbc.DB2Diagnosable;
   import com.ibm.db2.jdbc.DB2Sqlca;
   ```
2. Optional: During a connection to a data server, set the retrieveMessagesFromServerOnGetMessage property to true if you want full message text from a SQLException.getMessage call.

3. Optional: During a IBM Data Server Driver for JDBC and SQLJ type 2 connectivity connection to a DB2 for z/OS data source, set the extendedDiagnosticLevel property to EXTENDED_DIAG_MESSAGE_TEXT (241) if you want extended diagnostic information similar to the information that is provided by the SQL GET DIAGNOSTICS statement from an SQLException.getMessage call.

4. Put code that can generate an SQLException in a try block.

5. In the catch block, perform the following steps in a loop:
   a. Test whether you have retrieved the last SQLException. If not, continue to the next step.
   b. Optional: For an SQL statement that executes on an IBM Informix data source, execute the com.ibm.db2.jcc.DB2Statement.getIDSSQLStatementOffSet method to determine which columns have syntax errors.
      DB2Statement.getIDSSQLStatementOffSet returns the offset into the SQL statement of the first syntax error.
   c. Optional: For an SQL statement that executes on an IBM Informix data source, execute the SQLException.getCause method to retrieve any ISAM error messages.
      1) If the Throwable that is returned by SQLException.getCause is not null, perform one of the following sets of steps:
         • Issue SQLException.printStackTrace to print an error message that includes the ISAM error message text. The ISAM error message text is preceded by the string ”Caused by:”.
         • Retrieve the error code and message text for the ISAM message:
             a) Test whether the Throwable is an instance of an SQLException. If so, retrieve the SQL error code from that SQLException.
             b) Execute the Throwable.getMessage method to retrieve the text of the ISAM message.
      d. Check whether any IBM Data Server Driver for JDBC and SQLJ-only information exists by testing whether the SQLException is an instance of DB2Diagnosable. If so:
         1) Cast the object to a DB2Diagnosable object.
         2) Optional: Invoke the DB2Diagnosable.printTrace method to write all SQLException information to a java.io.PrintWriter object.
         3) Invoke the DB2Diagnosable.getThrowable method to determine whether an underlying java.lang.Throwable caused the SQLException.
         4) Invoke the DB2Diagnosable.getSqlca method to retrieve the DB2Sqlca object.
         5) Invoke the DB2Sqlca.getSqlCode method to retrieve an SQL error code value.
         6) Invoke the DB2Sqlca.getSqlErrmc method to retrieve a string that contains all SQLERRMC values, or invoke the DB2Sqlca.getSqlErrmcTokens method to retrieve the SQLERRMC values in an array.
         7) Invoke the DB2Sqlca.getSqlErrp method to retrieve the SQLERRP value.
8) Invoke the DB2Sqlca.getSqlErrd method to retrieve the SQLERRD values in an array.
9) Invoke the DB2Sqlca.getSqlWarn method to retrieve the SQLWARN values in an array.
10) Invoke the DB2Sqlca.getSqlState method to retrieve the SQLSTATE value.
11) Invoke the DB2Sqlca.getMessage method to retrieve error message text from the data source.

e. Invoke the SQLException.getNextException method to retrieve the next SQLException.

The following code demonstrates how to obtain IBM Data Server Driver for JDBC and SQLJ-specific information from an SQLException that is provided with the IBM Data Server Driver for JDBC and SQLJ. The numbers to the right of selected statements correspond to the previously-described steps.

```java
import java.sql.*; // Import JDBC API package
import com.ibm.db2.jcc.DB2Diagnosable; // Import packages for DB2
import com.ibm.db2.jcc.DB2Sqlca; // SQLException support
java.io.PrintWriter printWriter; // For dumping all SQLException information

String url = "jdbc:db2://myhost:9999/myDB:" +
    "retrieveMessagesFromServerOnGetMessage=true;"; // Set properties to retrieve full message text
String user = "db2adm";
String password = "db2adm";
java.sql.Connection con =
    java.sql.DriverManager.getConnection (url, user, password) // Connect to a DB2 for z/OS data source

... try {
    // Code that could generate SQLExceptions
    ...
} catch(SQLException sqle) {
    while(sqle != null) { // Check whether there are more
        // SQLExceptions to process
        //=====> Optional IBM Data Server Driver for JDBC and SQLJ-only error processing
        if (sqle instanceof DB2Diagnosable) {
            // Check if IBM Data Server Driver for JDBC and SQLJ-only information exists
            com.ibm.db2.jcc.DB2Diagnosable diagnosable =
                (com.ibm.db2.jcc.DB2Diagnosable)sqle;
            diagnosable.printStackTrace (printWriter, "");
            java.lang.Throwable throwable =
                diagnosable.getThrowable();
            if (throwable != null) {
                // Extract java.lang.Throwable information
                // such as message or stack trace.
                ...
            }
            DB2Sqlca sqlca = diagnosable.getSqlca();
            // Get DB2Sqlca object
            if (sqlca != null) {
                // Check that DB2Sqlca is not null
                int sqlCode = sqlca.getSqlCode(); // Get the SQL error code
                String sqlErrmc = sqlca.getSqlErrmc();
            }
            ...
        }
    }
}
```

Figure 21. Processing an SQLException under the IBM Data Server Driver for JDBC and SQLJ
// Get the entire SQLERRMC
String[] sqlErrmcTokens = sqlca.getSqlErrmcTokens();
  // You can also retrieve the
  // individual SQLERRMC tokens
String sqlErrp = sqlca.getSqlErrp();
  // Get the SQLERRP
int[] sqlErrd = sqlca.getSqlErrd();
  // Get SQLERRD fields
char[] sqlWarn = sqlca.getSqlWarn();
  // Get SQLWARN fields
String sqlState = sqlca.getSqlState();
  // Get SQLSTATE
String errMsg = sqlca.getMessage();
  // Get error message
System.err.println("Server error message: " + errMsg);
System.err.println("--------------- SQLCA ---------------");
System.err.println("Error code: " + sqlCode);
System.err.println("SQLERRMC: " + sqlErrmc);
if (sqlErrmcTokens != null) {
    for (int i=0; i< sqlErrmcTokens.length; i++) {
        System.err.println(" token "+ i + ": " + sqlErrmcTokens[i]);
    }
}
System.err.println("SQLERRP: " + sqlErrp);
System.err.println(

Handling an SQLWarning under the IBM Data Server Driver for JDBC and SQLJ

Unlike SQL errors, SQL warnings do not cause JDBC methods to throw exceptions. Instead, the Connection, Statement, PreparedStatement, CallableStatement, and
ResultSet classes contain getWarnings methods, which you need to invoke after you execute SQL statements to determine whether any SQL warnings were generated.

The basic steps for retrieving SQL warning information are:

1. Optional: During connection to the database server, set properties that affect SQLWarning objects.
   - If you want full message text from a data server when you execute SQLWarning.getMessage calls, set the retrieveMessagesFromServerOnGetMessage property to true.
   - If you are using IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to a DB2 for z/OS data source, and you want extended diagnostic information that is similar to the information that is provided by the SQL GET DIAGNOSTICS statement when you execute SQLWarning.getMessage calls, set the extendedDiagnosticLevel property to EXTENDED_DIAG_MESSAGE_TEXT (241).

2. Immediately after invoking a method that connects to a database server or executes an SQL statement, invoke the getWarnings method to retrieve an SQLWarning object.

3. Perform the following steps in a loop:
   a. Test whether the SQLWarning object is null. If not, continue to the next step.
   b. Invoke the SQLWarning.getMessage method to retrieve the warning description.
   c. Invoke the SQLWarning.getSQLState method to retrieve the SQLSTATE value.
   d. Invoke the SQLWarning.getErrorCode method to retrieve the error code value.
   e. If you want DB2-specific warning information, perform the same steps that you perform to get DB2-specific information for an SQLException.
   f. Invoke the SQLWarning.getNextWarning method to retrieve the next SQLWarning.

The following code illustrates how to obtain generic SQLWarning information. The numbers to the right of selected statements correspond to the previously-described steps.
Retrieving information from a BatchUpdateException

When an error occurs during execution of a statement in a batch, processing continues. However, `executeBatch` throws a `BatchUpdateException`.

To retrieve information from the `BatchUpdateException`, follow these steps:

1. Use the `BatchUpdateException.getUpdateCounts` method to determine the number of rows that each SQL statement in the batch updated before the exception was thrown.

   getUpdateCount returns an array with an element for each statement in the batch. An element has one of the following values:
   - `n`: The number of rows that the statement updated.
   - `Statement.SUCCESS_NO_INFO`: This value is returned if the number of updated rows cannot be determined. The number of updated rows cannot be determined if the following conditions are true:
     - The application is connected to a subsystem that is in DB2 for z/OS Version 8 new-function mode, or later.
     - The application is using Version 3.1 or later of the IBM Data Server Driver for JDBC and SQLJ.
     - The IBM Data Server Driver for JDBC and SQLJ uses multi-row `INSERT` operations to execute batch updates.
   - `Statement.EXECUTE_FAILED`: This value is returned if the statement did not execute successfully.

2. If the batched statement can return automatically generated keys:
   a. Cast the `BatchUpdateException` to a `com.ibm.db2.jcc.DBBatchUpdateException`.

---

```java
String url = "jdbc:db2://myhost:9999/myDB:" +
    "retrieveMessagesFromServerOnGetMessage=true;";
    // Set properties to retrieve full message
    // text

String user = "db2adm";
String password = "db2adm";
java.sql.Connection con =
    java.sql.DriverManager.getConnection (url, user, password)
    // Connect to a DB2 for z/OS data source

Statement stmt;
ResultSet rs;
SQLWarning sqlwarn;
...

stmt = con.createStatement();     // Create a Statement object
rs = stmt.executeQuery("SELECT * FROM EMPLOYEE");
    // Get the result table from the query

sqlwarn = stmt.getWarnings();    // Get any warnings generated
while (sqlwarn != null) {       // While there are warnings, get and
    // print warning information
        System.out.println ("Warning description: " + sqlwarn.getMessage());
    System.out.println ("SQLSTATE: " + sqlwarn.getSQLState());
    System.out.println ("Error code: " + sqlwarn.getErrorCode());
    sqlwarn=sqlwarn.getNextWarning();   // Get next SQLWarning
}

Figure 22. Example of processing an SQLWarning
```

---

Retrieving information from a BatchUpdateException

When an error occurs during execution of a statement in a batch, processing continues. However, `executeBatch` throws a `BatchUpdateException`.

To retrieve information from the `BatchUpdateException`, follow these steps:

1. Use the `BatchUpdateException.getUpdateCounts` method to determine the number of rows that each SQL statement in the batch updated before the exception was thrown.

   getUpdateCount returns an array with an element for each statement in the batch. An element has one of the following values:
   - `n`: The number of rows that the statement updated.
   - `Statement.SUCCESS_NO_INFO`: This value is returned if the number of updated rows cannot be determined. The number of updated rows cannot be determined if the following conditions are true:
     - The application is connected to a subsystem that is in DB2 for z/OS Version 8 new-function mode, or later.
     - The application is using Version 3.1 or later of the IBM Data Server Driver for JDBC and SQLJ.
     - The IBM Data Server Driver for JDBC and SQLJ uses multi-row `INSERT` operations to execute batch updates.
   - `Statement.EXECUTE_FAILED`: This value is returned if the statement did not execute successfully.

2. If the batched statement can return automatically generated keys:
   a. Cast the `BatchUpdateException` to a `com.ibm.db2.jcc.DBBatchUpdateException`. 
b. Call the DBBatchUpdateException.getDBGeneratedKeys method to retrieve an array of ResultSet objects that contains the automatically generated keys for each execution of the batched SQL statement.

c. Test whether each ResultSet in the array is null.
   Each ResultSet contains:
   • If the ResultSet is not null, it contains the automatically generated keys for an execution of the batched SQL statement.
   • If the ResultSet is null, execution of the batched statement failed.

3. Use SQLException methods getMessage, getSQLState, and getErrorCode to retrieve the description of the error, the SQLSTATE, and the error code for the first error.

4. Use the BatchUpdateException.getNextException method to get a chained SQLException.

5. In a loop, execute the getMessage, getSQLState, getErrorCode, and getNextException method calls to obtain information about an SQLException and get the next SQLException.

The following code fragment demonstrates how to obtain the fields of a BatchUpdateException and the chained SQLException objects for a batched statement that returns automatically generated keys. The example assumes that there is only one column in the automatically generated key, and that there is always exactly one key value, whose data type is numeric. The numbers to the right of selected statements correspond to the previously-described steps.

```java
try {
    // Batch updates
} catch(BatchUpdateException buex) {
    System.err.println("Contents of BatchUpdateException:");
    System.err.println(" Update counts: ");
    int [] updateCounts = buex.getUpdateCounts();
    for (int i = 0; i < updateCounts.length; i++) {
        System.err.println(" Statement " + i + ":" + updateCounts[i]);
    }
    ResultSet[] resultList =
        ((DBBatchUpdateException)buex).getDBGeneratedKeys();
    for (i = 0; i < resultList.length; i++)
    {
        if (resultList[i] == null)
            continue; // Skip the ResultSet for which there was a failure
        else {
            rs.next();
            java.math.BigDecimal idColVar = rs.getBigDecimal(1);
            // Get automatically generated key value
            System.out.println("Automatically generated key value = " + idColVar);
        }
    }
    System.err.println(" Message: " + buex.getMessage());
    System.err.println(" SQLSTATE: " + buex.getSQLState());
    System.err.println(" Error code: " + buex.getErrorCode());
    SQLException ex = buex.getNextException();
    while (ex != null) {
        System.err.println("SQL exception:");
        System.err.println(" Message: " + ex.getMessage());
        System.err.println(" SQLSTATE: " + ex.getSQLState());
        System.err.println(" Error code: " + ex.getErrorCode());
        ex = ex.getNextException();
    }
}
```

Chapter 3. JDBC application programming 137
Disconnecting from data sources in JDBC applications

When you have finished with a connection to a data source, it is essential that you close the connection to the data source. Doing this releases the Connection object's database and JDBC resources immediately.

To close the connection to the data source, use the close method.
For example:
```java
Connection con;
...
con.close();
```

For a connection to a DB2 data source, if autocommit mode is not on, the connection needs to be on a unit-of-work boundary before you close the connection.
For a connection to an IBM Informix database, if the database supports logging, and autocommit mode is not on, the connection needs to be on a unit-of-work boundary before you close the connection.

Related concepts:
“How JDBC applications connect to a data source” on page 27
Chapter 4. SQLJ application programming

Writing an SQLJ application has much in common with writing an SQL application in any other language.

In general, you need to do the following things:
• Import the Java packages that contain SQLJ and JDBC methods.
• Declare variables for sending data to or retrieving data from DB2 tables.
• Connect to a data source.
• Execute SQL statements.
• Handle SQL errors and warnings.
• Disconnect from the data source.

Although the tasks that you need to perform are similar to those in other languages, the way that you execute those tasks, and the order in which you execute those tasks, is somewhat different.

Example of a simple SQLJ application

A simple SQLJ application demonstrates the basic elements that JDBC applications need to include.

Figure 23. Simple SQLJ application

```java
import sqlj.runtime.*;
import java.sql.*;

#sql context EzSqljCtx;
#sql iterator EzSqljNameIter (String LASTNAME);

public class EzSqlj {
    public static void main(String args[])
        throws SQLException
    {
        EzSqljCtx ctx = null;
        String URLprefix = "jdbc:db2:";
        String url;
        url = new String(URLprefix + args[0]);
        // Location name is an input parameter
        String hvmgr="000010";
        String hddeptno="A00";
        try {
            Class.forName("com.ibm.db2.jcc.DB2Driver");
        } catch (Exception e) {
            throw new SQLException("Error in EzSqlj: Could not load the driver");
        } 
        try {
            System.out.println("About to connect using url: " + url);
            Connection con0 = DriverManager.getConnection(url);
            // Create a JDBC Connection
            con0.setAutoCommit(false); // set autocommit OFF
            ctx = new EzSqljCtx(con0);
        }
    }
```
EzSqljNameIter iter;
int count=0;

#sql [ctx] iter =
{SELECT LASTNAME FROM EMPLOYEE};  // Create result table of the SELECT
while (iter.next()) {
    System.out.println(iter.LASTNAME());
    count++;
}
System.out.println("Retrieved " + count + " rows of data");
iter.close();  // Close the iterator
}
catch( SQLException e )
{
    System.out.println ("**** SELECT SQLException...");
    System.out.println ("Error msg: "+ e.getMessage());
    System.out.println ("SQLSTATE: "+ e.getSQLState());
    System.out.println ("Error code: "+ e.getErrorCode());
    e = e.getNextException();  // Check for chained exceptions
}
catch( Exception e )
{
    System.out.println("**** NON-SQL exception = " + e);
    e.printStackTrace();
}
try
{
    #sql [ctx]
    {UPDATE DEPARTMENT SET MGRNO=:hvmgr
        WHERE DEPTNO=:hvdeptno};  // Update data for one department
}
#sql [ctx] {COMMIT};  // Commit the update
}
catch( SQLException e )
{
    System.out.println ("**** UPDATE SQLException...");
    System.out.println ("Error msg: "+ e.getMessage() + ". SQLSTATE=" + e.getSQLState() + ". ErrorCode=" + e.getErrorCode());
    e.printStackTrace();
}
catch( Exception e )
{
    System.out.println("**** NON-SQL exception = " + e);
    e.printStackTrace();
}
ctx.close();
}
Note Description
1 These statements import the java.sql package, which contains the JDBC core API, and the sqlj.runtime package, which contains the SQLJ API. For information on other packages or classes that you might need to access, see "Java packages for SQLJ support".
2 String variables hvmgr and hvdeptno are host identifiers, which are equivalent to DB2 host variables. See "Variables in SQLJ applications" for more information.
3a, 3b, 3c, and 3d These statements demonstrate how to connect to a data source using one of the three available techniques. See "Connecting to a data source using SQLJ" for more details.
4a, 4b, 4c, and 4d These statements demonstrate how to execute SQL statements in SQLJ. Statement 4a demonstrates the SQLJ equivalent of declaring an SQL cursor. Statements 4b and 4c show one way of doing the SQLJ equivalent of executing an SQL OPEN CURSOR and SQL FETCHes. Statement 4d shows how to do the SQLJ equivalent of performing an SQL UPDATE. For more information, see "SQL statements in an SQLJ application".
5 This try/catch block demonstrates the use of the SQLException class for SQL error handling. For more information on handling SQL errors, see "Handling SQL errors in an SQLJ application". For more information on handling SQL warnings, see "Handling SQL warnings in an SQLJ application".
6 This is an example of a comment. For rules on including comments in SQLJ programs, see "Comments in an SQLJ application".
7 This statement closes the connection to the data source. See "Closing the connection to the data source in an SQLJ application".

Connecting to a data source using SQLJ

In an SQLJ application, as in any other DB2 application, you must be connected to a data source before you can execute SQL statements.

You can use one of six techniques to connect to a data source in an SQLJ program. Two use the JDBC DriverManager interface, two use the JDBC DataSource interface, one uses a previously created connection context, and one uses the default connection.

Related concepts:
"How JDBC applications connect to a data source" on page 27

SQLJ connection technique 1: JDBC DriverManager interface

SQLJ connection technique 1 uses the JDBC DriverManager interface as the underlying means for creating the connection.

To use SQLJ connection technique 1, follow these steps:
1. Execute an SQLJ connection declaration clause.
   Doing this generates a connection context class. The simplest form of the connection declaration clause is:
   
   #sql context context-class-name;

   The name of the generated connection context class is context-class-name.

2. Load a JDBC driver by invoking the Class.forName method.
   • For the IBM Data Server Driver for JDBC and SQLJ, invoke Class.forName this way:
Class.forName("com.ibm.db2.jcc.DB2Driver");

This step is unnecessary if you use the JDBC 4.0 driver or later.

3. **Invoke the constructor for the connection context class that you created in step [1 on page 141](#)**

Doing this creates a connection context object that you specify in each SQL statement that you execute at the associated data source. The constructor invocation statement needs to be in one of the following forms:

```
class-name connection-context-object =
  new class-name(String url, boolean autocommit);
```

```
class-name connection-context-object =
  new class-name(String url, String user,
                  String password, boolean autocommit);
```

```
class-name connection-context-object =
  new class-name(String url, Properties info,
                  boolean autocommit);
```

The meanings of the parameters are:

**url**
A string that specifies the location name that is associated with the data source. That argument has one of the forms that are specified in "Connect to a data source using the DriverManager interface with the IBM Data Server Driver for JDBC and SQLJ". The form depends on which JDBC driver you are using.

**user and password**
Specify a user ID and password for connection to the data source, if the data source to which you are connecting requires them.

**info**
Specifies an object of type java.util.Properties that contains a set of driver properties for the connection. For the IBM Data Server Driver for JDBC and SQLJ, you can specify any of the properties listed in "Properties for the IBM Data Server Driver for JDBC and SQLJ".

**autocommit**
Specifies whether you want the database manager to issue a COMMIT after every statement. Possible values are true or false. If you specify false, you need to do explicit commit operations.

The following code uses connection technique 1 to create a connection to location NEWYORK. The connection requires a user ID and password, and does not require autocommit. The numbers to the right of selected statements correspond to the previously-described steps.
SQLJ connection technique 2: JDBC DriverManager interface

SQLJ connection technique 2 uses the JDBC DriverManager interface as the underlying means for creating the connection.

To use SQLJ connection technique 2, follow these steps:

1. Execute an SQLJ connection declaration clause.
   Doing this generates a connection context class. The simplest form of the connection declaration clause is:
   
$$\text{#sql context context-class-name;}$$

   The name of the generated connection context class is `context-class-name`.

2. Load a JDBC driver by invoking the Class.forName method.
   - For the IBM Data Server Driver for JDBC and SQLJ, invoke Class.forName this way:
     
```java
     Class.forName("com.ibm.db2.jcc.DB2Driver");
     ```
   
   This step is unnecessary if you use the JDBC 4.0 driver or later.

3. Invoke the JDBC DriverManager.getConnection method.
   Doing this creates a JDBC connection object for the connection to the data source. You can use any of the forms of getConnection that are specified in "Connect to a data source using the DriverManager interface with the IBM Data Server Driver for JDBC and SQLJ".

   The meanings of the `url`, `user`, and `password` parameters are:

   - `url`
     A string that specifies the location name that is associated with the data source. That argument has one of the forms that are specified in "Connect to a data source using the DriverManager interface with the IBM Data Server Driver for JDBC and SQLJ". The form depends on which JDBC driver you are using.

   - `user` and `password`
     Specify a user ID and password for connection to the data source, if the data source to which you are connecting requires them.
4. **Invoke the constructor for the connection context class that you created in step 1 on page 143**

Doing this creates a connection context object that you specify in each SQL statement that you execute at the associated data source. The constructor invocation statement needs to be in the following form:

```
connection-context-class connection-context-object = new connection-context-class(Connection JDBC-connection-object);
```

The **JDBC-connection-object** parameter is the Connection object that you created in step 3 on page 143.

The following code uses connection technique 2 to create a connection to location NEWYORK. The connection requires a user ID and password, and does not require autocommit. The numbers to the right of selected statements correspond to the previously-described steps.

```java
#sql context Ctx; // Create connection context class Ctx 1
String userid="dbadm"; // Declare variables for user ID and password
String password="dbadm";
String empname; // Declare a host variable
...
try {
   // Load the JDBC driver
   Class.forName("com.ibm.db2.jcc.DB2Driver"); 2
}
catch (ClassNotFoundException e) {
   e.printStackTrace();
}
Connection jdbccon= 3
   DriverManager.getConnection("jdbc:db2://sysmvs1.stl.ibm.com:5021/NEWYORK",
      userid,password);
   // Create JDBC connection object jdbccon
jdbccon.setAutoCommit(false); 4 // Do not autocommit
Ctx myConnCtx=new Ctx(jdbccon);
// Create connection context object myConnCtx
// for the connection to NEWYORK
#sql [myConnCtx] {SELECT LASTNAME INTO :empname FROM EMPLOYEE
   WHERE EMPNO='000010'};
// Use myConnCtx for executing an SQL statement
```

*Figure 25. Using connection technique 2 to connect to a data source*

**SQLJ connection technique 3: JDBC DataSource interface**

SQLJ connection technique 3 uses the JDBC DataSource as the underlying means for creating the connection.

To use SQLJ connection technique 3, follow these steps:

1. Execute an SQLJ **connection declaration clause**.
   - Doing this generates a **connection context class**. The simplest form of the connection declaration clause is:
     ```
     #sql context context-class-name;
     ```
   - The name of the generated connection context class is **context-class-name**.

2. If your system administrator created a DataSource object in a different program, follow these steps. Otherwise, create a DataSource object and assign properties to it.
   a. Obtain the logical name of the data source to which you need to connect.
   b. Create a context to use in the next step.
c. In your application program, use the Java Naming and Directory Interface (JNDI) to get the DataSource object that is associated with the logical data source name.

3. Invoke the JDBC DataSource.getConnection method.
   Doing this creates a JDBC connection object for the connection to the data source. You can use one of the following forms of getConnection:
   - `getConnection();`
   - `getConnection(user, password);`
   The meanings of the `user` and `password` parameters are:
   - `user` and `password`
     Specify a user ID and password for connection to the data source, if the data source to which you are connecting requires them.

4. If the default autocommit mode is not appropriate, invoke the JDBC Connection.setAutoCommit method.
   Doing this indicates whether you want the database manager to issue a COMMIT after every statement. The form of this method is:
   - `setAutoCommit(boolean autocommit);`

5. Invoke the constructor for the connection context class that you created in step 1 on page 144.
   Doing this creates a connection context object that you specify in each SQL statement that you execute at the associated data source. The constructor invocation statement needs to be in the following form:
   - `connection-context-class connection-context-object=
     new connection-context-class(Connection JDBC-connection-object);`
   The `JDBC-connection-object` parameter is the Connection object that you created in step 3.

The following code uses connection technique 3 to create a connection to a location with logical name `jdbc/sampledb`. This example assumes that the system administrator created and deployed a DataSource object that is available through JNDI lookup. The numbers to the right of selected statements correspond to the previously-described steps.

```java
import java.sql.*;
import javax.naming.*;
import javax.sql.*;
...
#sql context CtxSqlj; // Create connection context class CtxSqlj
Context ctx=new InitialContext();
DataSource ds=(DataSource)ctx.lookup("jdbc/sampledb");
Connection con=ds.getConnection();
String empname; // Declare a host variable
...
con.setAutoCommit(false); // Do not autocommit
CtxSqlj myConnCtx=new CtxSqlj(con);
// Create connection context object myConnCtx
#sql [myConnCtx] {SELECT LASTNAME INTO :empname FROM EMPLOYEE
   WHERE EMPNO='000010'};
// Use myConnCtx for executing an SQL statement
```

Figure 26. Using connection technique 3 to connect to a data source

**SQLJ connection technique 4: JDBC DataSource interface**

SQLJ connection technique 4 uses the JDBC DataSource as the underlying means for creating the connection. This technique requires that the DataSource is registered with JNDI.
To use SQLJ connection technique 4, follow these steps:

1. From your system administrator, obtain the logical name of the data source to which you need to connect.

2. Execute an SQLJ connection declaration clause.
   For this type of connection, the connection declaration clause needs to be of this form:
   ```java
   #sql public static context context-class-name
   with (dataSource="logical-name");
   ```
   The connection context must be declared as public and static. `logical-name` is the data source name that you obtained in step 1.

3. Invoke the constructor for the connection context class that you created in step 2.
   Doing this creates a connection context object that you specify in each SQL statement that you execute at the associated data source. The constructor invocation statement needs to be in one of the following forms:
   ```java
   connection-context-class connection-context-object=
   new connection-context-class();
   ```
   ```java
   connection-context-class connection-context-object=
   new connection-context-class (String user,
   String password);
   ```
   The meanings of the `user` and `password` parameters are:
   ```java
   user and password
   ```
   Specify a user ID and password for connection to the data source, if the data source to which you are connecting requires them.

The following code uses connection technique 4 to create a connection to a location with logical name `jdbc/sampledb`. The connection requires a user ID and password.

```java
#sql public static context Ctx
with (dataSource="jdbc/sampledb");
String userid="dbadm"; // Declare variables for user ID and password
String password="dbadm";
String empname; // Declare a host variable

Ctx myConnCtx=new Ctx(userid, password);
#sql [myConnCtx] {SELECT LASTNAME INTO :empname FROM EMPLOYEE
WHERE EMPNO='000010'};
```

Figure 27. Using connection technique 4 to connect to a data source

**SQLJ connection technique 5: Use a previously created connection context**

SQLJ connection technique 5 uses a previously created connection context to connect to the data source.

In general, one program declares a connection context class, creates connection contexts, and passes them as parameters to other programs. A program that uses the connection context invokes a constructor with the passed connection context object as its argument.
Program CtxGen.sqlj declares connection context Ctx and creates instance oldCtx:

```sql
#sql context Ctx;
...
// Create connection context object oldCtx
```

Program test.sqlj receives oldCtx as a parameter and uses oldCtx as the argument of its connection context constructor:

```java
void useContext(sqlj.runtime.ConnectionContext oldCtx)
    // oldCtx was created in CtxGen.sqlj
{
    Ctx myConnCtx=
        new Ctx(oldCtx); // Create connection context object myConnCtx
    // from oldCtx
    #sql [myConnCtx] {SELECT LASTNAME INTO :empname FROM EMPLOYEE
        WHERE EMPNO='000010'}; // Use myConnCtx for executing an SQL statement
...
}
```

**SQLJ connection technique 6: Use the default connection**

SQLJ connection technique 6 uses the default connection to connect to the data source. It should be used only in situations where the database thread is controlled by another resource manager, such as the Java stored procedure environment.

You use the default connection by specifying your SQL statements without a connection context object. When you use this technique, you do not need to load a JDBC driver unless you explicitly use JDBC interfaces in your program.

The default connection context can be:

- The connection context that is associated with the data source that is bound to the logical name jdbc/defaultDataSource
- An explicitly created connection context that has been set as the default connection context with the ConnectionContext.setDefaultContext method. This method of creating a default connection context is not recommended.

The following SQLJ execution clause does not have a connection context, so it uses the default connection context.

```sql
#sql {SELECT LASTNAME INTO :empname FROM EMPLOYEE
    WHERE EMPNO='000010'}; // Use default connection for
    // executing an SQL statement
```

**Java packages for SQLJ support**

Before you can execute SQLJ statements or invoke JDBC methods in your SQLJ program, you need to be able to access all or parts of various Java packages that contain support for those statements.

You can do that either by importing the packages or specific classes, or by using fully-qualified class names. You might need the following packages or classes for your SQLJ program:

- `sqlj.runtime`
  - Contains the SQLJ run-time API.

- `java.sql`
  - Contains the core JDBC API.
**Variables in SQLJ applications**

In DB2 programs in other languages, you use host variables to pass data between
the application program and DB2. In SQLJ programs, you can use host variables or *host expressions*.

A host expression begins with a colon (:). The colon is followed by an optional
parameter mode identifier (IN, OUT, or INOUT), which is followed by a
parenthesized expression clause.

Host variables and host expressions are case sensitive.

A complex expression is an array element or Java expression that evaluates to a
single value. A complex expression in an SQLJ clause must be surrounded by
parentheses.

The following examples demonstrate how to use host expressions.

*Example: Declaring a Java identifier and using it in a SELECT statement:*

In this example, the statement that begins with `#sql` has the same function as a
SELECT statement in other languages. This statement assigns the last name of the
employee with employee number 000010 to Java identifier `empname`.

```java
String empname;
...
#sql [ctxt]
{SELECT LASTNAME INTO :empname FROM EMPLOYEE WHERE EMPNO='000010'};
```

*Example: Declaring a Java identifier and using it in a stored procedure call:*

In this example, the statement that begins with `#sql` has the same function as an
SQL CALL statement in other languages. This statement uses Java identifier `empno`
as an input parameter to stored procedure `A`. The keyword IN, which precedes
`empno`, specifies that `empno` is an input parameter. For a parameter in a CALL
statement, IN is the default. The explicit or default qualifier that indicates how the
parameter is used (IN, OUT, or INOUT) must match the corresponding value in
the parameter definition that you specified in the CREATE PROCEDURE statement
for the stored procedure.

```java
String empno = "0000010";
...
#sql [ctxt] {CALL A (:IN empno)};
```

*Example: Using a complex expression as a host identifier:*

This example uses complex expression `(((int)yearsEmployed++/5)*500)` as a host
expression.

---

*com.ibm.db2.jcc*
Contains the driver-specific implementation of JDBC and SQLJ.

*javax.naming*
Contains methods for performing Java Naming and Directory Interface
(JNDI) lookup.

*javax.sql*
Contains methods for creating DataSource objects.
#sql [ctxt] {UPDATE EMPLOYEE
    SET BONUS:={(int)yearsEmployed++/5)*500} WHERE EMPNO=:empID};

SQLJ performs the following actions when it processes a complex host expression:

- Evaluates each of the host expressions in the statement, from left to right, before assigning their respective values to the database.
- Evaluates side effects, such as operations with postfix operators, according to normal Java rules. All host expressions are fully evaluated before any of their values are passed to DB2.
- Uses Java rules for rounding and truncation.

Therefore, if the value of yearsEmployed is 6 before the UPDATE statement is executed, the value that is assigned to column BONUS by the UPDATE statement is ((int)6/5)*500, or 500. After 500 is assigned to BONUS, the value of yearsEmployed is incremented.

**Restrictions on variable names:** Two strings have special meanings in SQLJ programs. Observe the following restrictions when you use these strings in your SQLJ programs:

- The string __sJT__ is a reserved prefix for variable names that are generated by SQLJ. Do not begin the following types of names with __sJT__:
  - Host expression names
  - Java variable names that are declared in blocks that include executable SQL statements
  - Names of parameters for methods that contain executable SQL statements
  - Names of fields in classes that contain executable SQL statements, or in classes with subclasses or enclosed classes that contain executable SQL statements
- The string _SJ is a reserved suffix for resource files and classes that are generated by SQLJ. Avoid using the string _SJ in class names and input source file names.

**Indicator variables in SQLJ applications**

In SQLJ programs, you can use indicator variables to pass the NULL value to or from a data server, to pass the default value for a column to the data server, or to indicate that a host variable value is unassigned.

A host variable or host expression can be followed by an indicator variable. An indicator variable begins with a colon (:) and has the data type short. For input, an indicator variable indicates whether the corresponding host variable or host expression has the default value, a non-null value, the null value, or is unassigned. An unassigned variable in an SQL statement yields the same results as if the variable and its target column were not in the SQL statement. For output, the indicator variable indicates where the corresponding host variable or host expression has a non-null value or a null value.

In SQLJ programs, indicator variables that indicate a null value perform the same function as assigning the Java null value to a table column. However, you need to use an indicator variable to retrieve the SQL NULL value from a table into a host variable.

You can use indicator variables that assign the default value or the unassigned value to columns to simplify the coding in your applications. For example, if a
table has four columns, and you might need to update any combination of those columns, without the use of default indicator variables or unassigned indicator variables, you need 15 UPDATE statements to perform all possible combinations of updates. With default indicator variables and unassigned indicator variables, you can use one UPDATE statement with all four columns in the SET statement to perform all possible updates. You use the indicator variables to indicate which columns you want to set to their default values, and which columns you do not want to update.

For input, SQLJ supports the use of indicator variables for INSERT, UPDATE, or MERGE statements.

If you customize your SQLJ application, you can assign one of the following values to an indicator variable in an SQLJ application to specify the type of the corresponding input host variable.

<table>
<thead>
<tr>
<th>Indicator value</th>
<th>Equivalent constant</th>
<th>Meaning of value</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>sqlj.runtime.ExecutionContext.DBNull</td>
<td>Null</td>
</tr>
<tr>
<td>-2, -3, -4, -6</td>
<td></td>
<td>Null</td>
</tr>
<tr>
<td>-5</td>
<td>sqlj.runtime.ExecutionContext.DBDefault</td>
<td>Default</td>
</tr>
<tr>
<td>-7</td>
<td>sqlj.runtime.ExecutionContext.DBUnassigned</td>
<td>Unassigned</td>
</tr>
<tr>
<td>short-value &gt;=0</td>
<td>sqlj.runtime.ExecutionContext.DBNonNull</td>
<td>Non-null</td>
</tr>
</tbody>
</table>

If you do not customize the application, you can assign one of the following values to an indicator variable to specify the type of the corresponding input host variable.

<table>
<thead>
<tr>
<th>Indicator value</th>
<th>Equivalent constant</th>
<th>Meaning of value</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>sqlj.runtime.ExecutionContext.DBNull</td>
<td>Null</td>
</tr>
<tr>
<td>-7 &lt;= short-value &lt; -1</td>
<td></td>
<td>Null</td>
</tr>
<tr>
<td>0</td>
<td>sqlj.runtime.ExecutionContext.DBNonNull</td>
<td>Non-null</td>
</tr>
<tr>
<td>short-value &gt;0</td>
<td></td>
<td>Non-null</td>
</tr>
</tbody>
</table>

For output, SQLJ supports the use of indicator variables for the following statements:
- CALL with OUT or INOUT parameters
- FETCH iterator INTO host-variable
- SELECT ... INTO host-variable-1,...,host-variable-n

SQLJ assigns one of the following values to an indicator variable to indicate whether an SQL NULL value was retrieved into the corresponding host variable.

<table>
<thead>
<tr>
<th>Indicator value</th>
<th>Equivalent constant</th>
<th>Meaning of value</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>sqlj.runtime.ExecutionContext.DBNull</td>
<td>Retrieved value is SQL NULL</td>
</tr>
<tr>
<td>0</td>
<td></td>
<td>Retrieved value is not SQL NULL</td>
</tr>
</tbody>
</table>

You cannot use indicator variables to update result sets. To assign null values or default values to result sets, or to indicate that columns are unassigned, call ResultSet.updateObject on the underlying JDBC ResultSet objects of the SQLJ iterators.
The following examples demonstrate how to use indicator variables.

All examples require that the data server supports extended indicators.

*Example of using indicators to assign the default value to columns during an INSERT:*

In this example, the MGRNO and LOCATION columns need to be set to their default values. To do this, the code performs these steps:

1. Assigns the value ExecutionContext.DBNonNull to the indicator variables (deptInd, dNameInd, rptDeptInd) for the input host variables (dept, dName, rptDept) that send non-default values to the target columns.
2. Assigns the value ExecutionContext.DBDefault to the indicator variables (mgrInd, locnInd) for the input host variables (mgr, locn) that send default values to the target columns.
3. Executes an INSERT statement with the host variable and indicator variable pairs as input.

The numbers to the right of selected statements correspond to the previously described steps.

```java
import sqlj.runtime.*;
...
String dept = "F01";
String dName = "SHIPPING";
String rptDept = "A00";
String mgr, locn = null;
short deptInd, dNameInd, mgrInd, rptDeptInd, locnInd;
// Set indicator variables for dept, dName, rptDept to non-null
deptInd = dNameInd = rptDeptInd = ExecutionContext.DBNonNull;  // 1
mgrInd = ExecutionContext.DBDefault;  // 2
locnInd = ExecutionContext.DBDefault;  // 3
#sql [
[INSERT INTO DEPARTMENT
  (DEPTNO, DEPTNAME, MGRNO, ADMRDEPT, LOCATION)
  VALUES (:dept :deptInd, :dName :dNameInd,:mgr :mgrInd,
  :rptDept :rptDeptInd, :locn :locnInd)];
```

*Example of using indicators to assign the default value to leave column values unassigned during an UPDATE:*

In this example, in rows for department F01, the MGRNO column needs to be set to its default value, the DEPTNAME column value needs to be changed to RECEIVING, and the DEPTNO, DEPTNAME, ADMRDEPT, and LOCATION columns need to remain unchanged. To do this, the code performs these steps:

1. Assigns the new value for the DEPTNAME column to the dName input host variable.
2. Assigns the value ExecutionContext.DBDefault to the indicator variable (mgrInd) for the input host variable (mgr) that sends the default value to the target column.
3. Assigns the value ExecutionContext.DBUassigned to the indicator variables (deptInd, dNameInd, rptDeptInd, and locnInd) for the input host variables (dept, dName, rptDept, and locn) that need to remain unchanged by the UPDATE operation.
4. Executes an UPDATE statement with the host variable and indicator variable pairs as input.

The numbers to the right of selected statements correspond to the previously described steps.
Example of using indicators to retrieve NULL values from columns:

In this example, the HIREDATE column can return the NULL value. To handle this case, the code performs these steps:

1. Defines an indicator variable to indicate when the NULL value is returned from HIREDATE.
2. Executes FETCH statements with the host variable and indicator variable pairs as output.
3. Checks the indicator variable to determine whether a NULL value was returned.

The numbers to the right of selected statements correspond to the previously described steps.

Example of assigning default values to result set columns:
In this example, the HIREDATE column in a result set needs to be set to its default value. To do this, the code performs these steps:

1. Retrieves the underlying ResultSet from the iterator that holds the retrieved data.
2. Executes the ResultSet.updateObject method with the DB2PreparedStatement.DB_PARAMETER_DEFAULT constant to assign the default value to the result set column.

The numbers to the right of selected statements correspond to the previously described steps.

```java
#sql public iterator sensitiveUpdateIter
  implements sqlj.runtime.Scrollable, sqlj.runtime.ForUpdate
with (sensitivity=sqlj.runtime.ResultSetIterator.SENSITIVE,
  updateColumns="LASTNAME, HIREDATE") (String, Date);
String name; // Declare host variables
Date hrdate;
sensitiveUpdateIter iter = null;
#sql [ctx] iter = { SELECT LASTNAME, HIREDATE FROM EMPLOYEE};
iter.next();
java.sql.ResultSet rs = iter.getResultSet();
rs.updateString("LASTNAME", "FORREST");
rs.updateObject(2, com.ibm.db2.jcc.DB2PreparedStatement.DB_PARAMETER_DEFAULT);
rs.updateRow();
iter.close();
```

### Comments in an SQLJ application

To document your SQLJ program, you need to include comments. You can use Java comments outside of SQLJ statements and SQL or Java comments in SQLJ statements.

You can include Java comments outside SQLJ clauses, wherever the Java language permits them. Within an SQLJ clause, you can use comments in the following places:

- Within a host expression (enclosed in /* and */ or preceded by //).
- Within an SQL statement in an executable clause, if the data server supports a comment within the SQL statement.
  - For connections to DB2 data servers or Informix data servers, comments can be:
    - Anywhere in the SQL statement text, and enclosed in /* and */ pairs. /* and */ pairs can be nested.
    - At the end of the SQL statement text, and preceded by two hyphens (--).
  - For connections to Informix data servers only, comments can be enclosed in left curly bracket ({" and right curly bracket (}) pairs.

### SQL statement execution in SQLJ applications

You execute SQL statements in a traditional SQL program to create tables, update data in tables, retrieve data from the tables, call stored procedures, or commit or roll back transactions. In an SQLJ program, you also execute these statements, within SQLJ executable clauses.
An executable clause can have one of the following general forms:

```sql
#sql [connection-context] {sql-statement};
#sql [connection-context,execution-context] {sql-statement};
#sql [execution-context] {sql-statement};
```

**execution-context specification**
In an executable clause, you should **always** specify an explicit connection context, with one exception: you do not specify an explicit connection context for a FETCH statement. You include an execution context only for specific cases. See "Control the execution of SQL statements in SQLJ" for information about when you need an execution context.

**connection-context specification**
In an executable clause, if you do not explicitly specify a connection context, the executable clause uses the default connection context.

### Creating and modifying database objects in an SQLJ application

Use SQLJ executable clauses to execute data definition statements (CREATE, ALTER, DROP, GRANT, REVOKE) or to execute INSERT, searched or positioned UPDATE, and searched or positioned DELETE statements.

The following executable statements demonstrate an INSERT, a searched UPDATE, and a searched DELETE:

```sql
#sql [myConnCtx] {INSERT INTO DEPARTMENT VALUES
  ("X00","Operations 2","000030","E01",NULL)};
#sql [myConnCtx] {UPDATE DEPARTMENT
  SET MGRNO="000090" WHERE MGRNO="000030"};
#sql [myConnCtx] {DELETE FROM DEPARTMENT
  WHERE DEPTNO="X00"};
```

### Performing positioned UPDATE and DELETE operations in an SQLJ application

As in DB2 applications in other languages, performing positioned UPDATEs and DELETEs with SQLJ is an extension of retrieving rows from a result table.

The basic steps are:
1. Declare the iterator.
   The iterator can be positioned or named. For positioned UPDATE or DELETE operations, declare the iterator as updatable, using one or both of the following clauses:

   **implements sqlj.runtime.ForUpdate**
   - This clause causes the generated iterator class to include methods for using updatable iterators. This clause is required for programs with positioned UPDATE or DELETE operations.

   **with (updateColumns="column-list")**
   - This clause specifies a comma-separated list of the columns of the result table that the iterator will update. This clause is optional.

You need to declare the iterator as `public`, so you need to follow the rules for declaring and using `public` iterators in the same file or different files.

If you declare the iterator in a file by itself, any SQLJ source file that has addressability to the iterator and imports the generated class can retrieve data and execute positioned UPDATE or DELETE statements using the iterator.
The authorization ID under which a positioned UPDATE or DELETE statement executes depends on whether the statement executes statically or dynamically. If the statement executes statically, the authorization ID is the owner of the plan or package that includes the statement. If the statement executes dynamically the authorization ID is determined by the DYNAMICRULES behavior that is in effect. For the IBM Data Server Driver for JDBC and SQLJ, the behavior is always DYNAMICRULES BIND.

2. Disable autocommit mode for the connection.
   If autocommit mode is enabled, a COMMIT operation occurs every time the positioned UPDATE statement executes, which causes the iterator to be destroyed unless the iterator has the with (holdability=true) attribute. Therefore, you need to turn autocommit off to prevent COMMIT operations until you have finished using the iterator. If you want a COMMIT to occur after every update operation, an alternative way to keep the iterator from being destroyed after each COMMIT operation is to declare the iterator with (holdability=true).

3. Create an instance of the iterator class.
   This is the same step as for a non-updatable iterator.

4. Assign the result table of a SELECT to an instance of the iterator.
   This is the same step as for a non-updatable iterator. The SELECT statement must not include a FOR UPDATE clause.

5. Retrieve and update rows.
   For a positioned iterator, do this by performing the following actions in a loop:
   a. Execute a FETCH statement in an executable clause to obtain the current row.
   b. Test whether the iterator is pointing to a row of the result table by invoking the PositionedIterator.endFetch method.
   c. If the iterator is pointing to a row of the result table, execute an SQL UPDATE... WHERE CURRENT OF :iterator-object statement in an executable clause to update the columns in the current row. Execute an SQL DELETE... WHERE CURRENT OF :iterator-object statement in an executable clause to delete the current row.
   For a named iterator, do this by performing the following actions in a loop:
   a. Invoke the next method to move the iterator forward.
   b. Test whether the iterator is pointing to a row of the result table by checking whether next returns true.
   c. Execute an SQL UPDATE... WHERE CURRENT OF iterator-object statement in an executable clause to update the columns in the current row. Execute an SQL DELETE... WHERE CURRENT OF iterator-object statement in an executable clause to delete the current row.

6. Close the iterator.
   Use the close method to do this.

The following code shows how to declare a positioned iterator and use it for positioned UPDATEs. The numbers to the right of selected statements correspond to the previously described steps.

First, in one file, declare positioned iterator UpdByPos, specifying that you want to use the iterator to update column SALARY:
Then, in another file, use `UpdByPos` for a positioned UPDATE, as shown in the following code fragment:

```java
import java.math.*; // Import this class for BigDecimal data type
#sql public iterator UpdByPos implements sqlj.runtime.ForUpdate
   with(updateColumns="SALARY") (String, BigDecimal);

Figure 28. Example of declaring a positioned iterator for a positioned UPDATE

Then, in another file, use `UpdByPos` for a positioned UPDATE, as shown in the following code fragment:

```java
import java.sql.*; // Import files for SQLJ and JDBC APIs
import java.math.*; // Import this class for BigDecimal data type
import UpdByPos; // Import the generated iterator class that
    // was created by the iterator declaration clause
    // for UpdByName in another file
#sql context HSCtx; // Create a connection context class HSCtx
public static void main (String args[])
{
    try {
        Class.forName("com.ibm.db2.jcc.DB2Driver");
    } catch (ClassNotFoundException e) {
        e.printStackTrace();
    }
    Connection HSjdbccon=
        DriverManager.getConnection("jdbc:db2:SANJOSE");
        // Create a JDBC connection object
    HSjdbccon.setAutoCommit(false);  // Set autocommit off so automatic commits
    // do not destroy the cursor between updates
    HSCtx myConnCtx=new HSCtx(HSjdbccon);
    // Create a connection context object
    UpdByPos upditer; // Declare iterator object of UpdByPos class
    String empnum; // Declares host variable to receive EMPNO
    BigDecimal sal; // and SALARY column values
    #sql [myConnCtx]
    upditer = {SELECT EMPNO, SALARY FROM EMPLOYEE
       WHERE WORKDEPT='D11'};
      // Assign result table to iterator object
    #sql {FETCH :upditer INTO :empnum,:sal};  // Move cursor to next row
    while (!upditer.endFetch())
    // Check if on a row
    {
        #sql [myConnCtx] {UPDATE EMPLOYEE SET SALARY=SALARY*1.05
           WHERE CURRENT OF :upditer};
           // Perform positioned update
        System.out.println("Updating row for " + empnum);
        #sql {FETCH :upditer INTO :empnum,:sal};
        // Move cursor to next row
    }
    upditer.close(); // Close the iterator
    #sql [myConnCtx] {COMMIT}; // Commit the changes
    myConnCtx.close();  // Close the connection context
}

Figure 29. Example of performing a positioned UPDATE with a positioned iterator

The following code shows how to declare a named iterator and use it for positioned UPDATEs. The numbers to the right of selected statements correspond to the previously described steps.
First, in one file, declare named iterator `UpdByName`, specifying that you want to use the iterator to update column `SALARY`:

```java
import java.math.*; // Import this class for BigDecimal data type
#sql public iterator UpdByName implements sqlj.runtime.ForUpdate
   with(updateColumns="SALARY") (String EmpNo, BigDecimal Salary);
```

*Figure 30. Example of declaring a named iterator for a positioned UPDATE*

Then, in another file, use `UpdByName` for a positioned UPDATE, as shown in the following code fragment:

```java
import java.math.*; // Import this class for BigDecimal data type
import sqlj.runtime.*; // Import files for SQLJ and JDBC APIs
import java.sql.*;
import UpdByName; // Import the generated iterator class that was created by the iterator declaration clause for UpdByName in another file

#sql context HSCtx; // Create a connection context class HSCtx
public static void main (String args[])
{
    try {
        Class.forName("com.ibm.db2.jcc.DB2Driver");
    } catch (ClassNotFoundException e) {
        e.printStackTrace();
    }
    Connection HSjdbccon=
        DriverManager.getConnection("jdbc:db2:SANJOSE"); // Create a JDBC connection object
    HSjdbccon.setAutoCommit(false); // Set autocommit off so automatic commits do not destroy the cursor between updates
    HSCtx myConnCtx=new HSCtx(HSjdbccon); // Create a connection context object
    UpdByName upditer; // Declare iterator object of UpdByName class
    String empnum; // Declare host variable to receive EmpNo column values
    #sql [myConnCtx]
        upditer = {SELECT EMPNO, SALARY FROM EMPLOYEE
                  WHERE WORKDEPT='D11'}; // Assign result table to iterator object
    while (upditer.next()) // Move cursor to next row and check if on a row
    {
        empnum = upditer.EmpNo(); // Get employee number from current row
        #sql [myConnCtx]
            {UPDATE EMPLOYEE SET SALARY=SALARY*1.05
             WHERE CURRENT OF :upditer}; // Perform positioned update
        System.out.println("Updating row for " + empnum);
    }
    upditer.close(); // Close the iterator
    #sql [myConnCtx] {COMMIT}; // Commit the changes
    myConnCtx.close(); // Close the connection context
}
```

*Figure 31. Example of performing a positioned UPDATE with a named iterator*
Iterators as passed variables for positioned UPDATE or DELETE operations in an SQLJ application

SQLJ allows iterators to be passed between methods as variables.

An iterator that is used for a positioned UPDATE or DELETE statement can be identified only at runtime. The same SQLJ positioned UPDATE or DELETE statement can be used with different iterators at runtime. If you specify a value of YES for -staticpositioned when you customize your SQLJ application as part of the program preparation process, the SQLJ customizer prepares positioned UPDATE or DELETE statements to execute statically. In this case, the customizer must determine which iterators belong with which positioned UPDATE or DELETE statements. The SQLJ customizer does this by matching iterator data types to data types in the UPDATE or DELETE statements. However, if there is not a unique mapping of tables in UPDATE or DELETE statements to iterator classes, the SQLJ customizer cannot determine exactly which iterators and UPDATE or DELETE statements go together. The SQLJ customizer must arbitrarily pair iterators with UPDATE or DELETE statements, which can sometimes result in SQL errors. The following code fragments illustrate this point.

```java
#sql iterator GeneralIter implements sqlj.runtime.ForUpdate
    ( String );

public static void main ( String args[] )
{
    ...
    GeneralIter iter1 = null;
    #sql [ctxt] iter1 = { SELECT CHAR_COL1 FROM TABLE1 };

    GeneralIter iter2 = null;
    #sql [ctxt] iter2 = { SELECT CHAR_COL2 FROM TABLE2 };
    ...

    doUpdate ( iter1 );
}

public static void doUpdate ( GeneralIter iter )
{
    #sql [ctxt] { UPDATE TABLE1 ... WHERE CURRENT OF :iter };
}
```

Figure 32. Static positioned UPDATE that fails

In this example, only one iterator is declared. Two instances of that iterator are declared, and each is associated with a different SELECT statement that retrieves data from a different table. During customization and binding with -staticpositioned YES, SQLJ creates two DECLARE CURSOR statements, one for each SELECT statement, and attempts to bind an UPDATE statement for each cursor. However, the bind process fails with SQLCODE -509 when UPDATE TABLE1 ...
 ... WHERE CURRENT OF :iter is bound for the cursor for SELECT CHAR_COL2 FROM TABLE2 because the table for the UPDATE does not match the table for the cursor.
You can avoid a bind time error for a program like the one in Figure 32 on page 158 by specifying the bind option SQLERROR(CONTINUE). However, this technique has the drawback that it causes the DB2 database manager to build a package, regardless of the SQL errors that are in the program. A better technique is to write the program so that there is a one-to-one mapping between tables in positioned UPDATE or DELETE statements and iterator classes. Figure 33 shows an example of how to do this.

```
#sql iterator Table2Iter(String);
#sql iterator Table1Iter(String);
  public static void main ( String args[] )
  {
    ...
    Table2Iter iter2 = null;
    #sql [ctxt] iter2 = { SELECT CHAR_COL2 FROM TABLE2 };
    Table1Iter iter1 = null;
    #sql [ctxt] iter1 = { SELECT CHAR_COL1 FROM TABLE1 };
    ...
    doUpdate(iter1);
  }

  public static void doUpdate ( Table1Iter iter )
  {
    ...
    #sql [ctxt] { UPDATE TABLE1 ... WHERE CURRENT OF :iter };
    ...
  }

  public static void doUpdate ( Table2Iter iter )
  {
    ...
    #sql [ctxt] { UPDATE TABLE2 ... WHERE CURRENT OF :iter };
    ...
  }
```

Figure 33. Static positioned UPDATE that succeeds

With this method of coding, each iterator class is associated with only one table. Therefore, the DB2 bind process can always associate the positioned UPDATE statement with a valid iterator.

Making batch updates in SQLJ applications
The IBM Data Server Driver for JDBC and SQLJ supports batch updates in SQLJ. With batch updates, instead of updating rows of a table one at a time, you can direct SQLJ to execute a group of updates at the same time.

You can include the following types of statements in a batch update:
- Searched INSERT, UPDATE, or DELETE, or MERGE statements
- CREATE, ALTER, DROP, GRANT, or REVOKE statements
- CALL statements with input parameters only

Unlike JDBC, SQLJ allows heterogeneous batches that contain statements with input parameters or host expressions. You can therefore combine any of the following items in an SQLJ batch:
- Instances of the same statement
- Different statements
- Statements with different numbers of input parameters or host expressions
- Statements with different data types for input parameters or host expressions
• Statements with no input parameters or host expressions

For all cases except homogeneous batches of INSERT statements, when an error occurs during execution of a statement in a batch, the remaining statements are executed, and a BatchUpdateException is thrown after all the statements in the batch have executed.

For homogeneous batches of INSERT statements, the behavior is as follows:
• If you set atomicMultiRowInsert to DB2BaseDataSource.YES (1) when you run db2sqljcustomize, and the target data server is DB2 for z/OS, when an error occurs during execution of an INSERT statement in a batch, the remaining statements are not executed, and a BatchUpdateException is thrown.
• If you do not set atomicMultiRowInsert to DB2BaseDataSource.YES (1) when you run db2sqljcustomize, or the target data server is not DB2 for z/OS, when an error occurs during execution of an INSERT statement in a batch, the remaining statements are executed, and a BatchUpdateException is thrown after all the statements in the batch have executed.

To obtain information about warnings, use the ExecutionContext.getWarnings method on the ExecutionContext that you used to submit statements to be batched. You can then retrieve an error description, SQLSTATE, and error code for each SQLWarning object.

When a batch is executed implicitly because the program contains a statement that cannot be added to the batch, the batch is executed before the new statement is processed. If an error occurs during execution of the batch, the statement that caused the batch to execute does not execute.

The basic steps for creating, executing, and deleting a batch of statements are:
1. Disable AutoCommit for the connection.
   Do this so that you can control whether to commit changes to already-executed statements when an error occurs during batch execution.
2. Acquire an execution context.
   All statements that execute in a batch must use this execution context.
3. Invoke the ExecutionContext.setBatching(true) method to create a batch.
   Subsequent batchable statements that are associated with the execution context that you created in step 2 are added to the batch for later execution.
   If you want to batch sets of statements that are not batch compatible in parallel, you need to create an execution context for each set of batch compatible statements.
4. Include SQLJ executable clauses for SQL statements that you want to batch.
   These clauses must include the execution context that you created in step 2.
   If an SQLJ executable clause has input parameters or host expressions, you can include the statement in the batch multiple times with different values for the input parameters or host expressions.
   To determine whether a statement was added to an existing batch, was the first statement in a new batch, or was executed inside or outside a batch, invoke the ExecutionContext.getUpdateCount method. This method returns one of the following values:

   **ExecutionContext.ADD_BATCH_COUNT**
   This is a constant that is returned if the statement was added to an existing batch.
**ExecutionContext.NEW_BATCH_COUNT**

This is a constant that is returned if the statement was the first statement in a new batch.

**ExecutionContext.EXEC_BATCH_COUNT**

This is a constant that is returned if the statement was part of a batch, and the batch was executed.

**Other integer**

This value is the number of rows that were updated by the statement. This value is returned if the statement was executed rather than added to a batch.

5. Execute the batch explicitly or implicitly.

   - Invoke the `ExecutionContext.executeUpdateBatch` method to execute the batch explicitly.

     `executeBatch` returns an integer array that contains the number of rows that were updated by each statement in the batch. The order of the elements in the array corresponds to the order in which you added statements to the batch.

   - Alternatively, a batch executes implicitly under the following circumstances:
     - You include a batchable statement in your program that is not compatible with statements that are already in the batch. In this case, SQLJ executes the statements that are already in the batch and creates a new batch that includes the incompatible statement.
     - You include a statement in your program that is not batchable. In this case, SQLJ executes the statements that are already in the batch. SQLJ also executes the statement that is not batchable.
     - After you invoke the `ExecutionContext.setBatchLimit(n)` method, you add a statement to the batch that brings the number of statements in the batch to `n` or greater. `n` can have one of the following values:

       **ExecutionContext.UNLIMITED_BATCH**

       This constant indicates that implicit execution occurs only when SQLJ encounters a statement that is batchable but incompatible, or not batchable. Setting this value is the same as not invoking `setBatchLimit`.

       **ExecutionContext.AUTO BATCH**

       This constant indicates that implicit execution occurs when the number of statements in the batch reaches a number that is set by SQLJ.

       **Positive integer**

       When this number of statements have been added to the batch, SQLJ executes the batch implicitly. However, the batch might be executed before this many statements have been added if SQLJ encounters a statement that is batchable but incompatible, or not batchable.

   To determine the number of rows that were updated by a batch that was executed implicitly, invoke the `ExecutionContext.getBatchUpdateCounts` method. `getBatchUpdateCounts` returns an integer array that contains the number of rows that were updated by each statement in the batch. The order of the elements in the array corresponds to the order in which you added statements to the batch. Each array element can be one of the following values:

   -2  This value indicates that the SQL statement executed successfully, but the number of rows that were updated could not be determined.
-3 This value indicates that the SQL statement failed.

*Other integer*

This value is the number of rows that were updated by the statement.

6. Optionally, when all statements have been added to the batch, disable batching. Do this by invoking the ExecutionContext.setBatching(false) method. When you disable batching, you can still execute the batch implicitly or explicitly, but no more statements are added to the batch. Disabling batching is useful when a batch already exists, and you want to execute a batch compatible statement, rather than adding it to the batch.

If you want to clear a batch without executing it, invoke the ExecutionContext.cancel method.

7. If batch execution was implicit, perform a final, explicit executeBatch to ensure that all statements have been executed.

**Example**

The following example demonstrates batching of UPDATE statements. The numbers to the right of selected statements correspond to the previously described steps.

```java
#sql iterator GetMgr(String); // Declare positioned iterator
...
GetMgr deptiter; // Declare object of GetMgr class
String mgrnum = null; // Declare host variable for manager number
int raise = 400; // Declare raise amount
int currentSalary; // Declare current salary
String url, username, password; // Declare url, user ID, password
...
TestContext c1 = new TestContext(url, username, password, false);
ExecutionContext ec = new ExecutionContext();
ec.setBatching(true);

#sql [c1] deptiter =
{SELECT MGRNO FROM DEPARTMENT}; // Assign the result table of the SELECT // to iterator object deptiter
#sql {FETCH :deptiter INTO :mgrnum}; // Retrieve the first manager number
while (!deptiter.endFetch()) { // Check whether the FETCH returned a row
  #sql [c1]
  {SELECT SALARY INTO :currentSalary FROM EMPLOYEE
   WHERE EMPNO=:mgrnum};
  #sql [c1, ec]
  {UPDATE EMPLOYEE SET SALARY=:(currentSalary+raise)
   WHERE EMPNO=:mgrnum};
  #sql {FETCH :deptiter INTO :mgrnum }; // Fetch the next row
}
ec.executeBatch();
ec.setBatching(false);
#sql [c1] {COMMIT};
depIter.close(); // Close the iterator
c1.close(); // Close the connection
}
```

The following example demonstrates batching of INSERT statements. Suppose that ATOMICITBL is defined like this:

```sql
CREATE TABLE ATOMICITBL(
  INTCOL INTEGER NOT NULL UNIQUE,
  CHARCOL VARCHAR(10))
```
Also suppose that the table already has a row with the values 2 and "val2". Because of the uniqueness constraint on INTCOL, when the following code is executed, the second INSERT statement in the batch fails.

If the target data server is DB2 for z/OS, and this application is customized without atomicMultiRowInsert set to DB2BaseDataSource.YES, the batch INSERT is non-atomic, so the first set of values is inserted in the table. However, if the application is customized with atomicMultiRowInsert set to DB2BaseDataSource.YES, the batch INSERT is atomic, so the first set of values is not inserted.

The numbers to the right of selected statements correspond to the previously described steps.

```java
TestContext ctx = new TestContext (url, username, password, false); 1
ctx.getExecutionContext().setBatching(true); 2,3
try {
    for (int i = 1; i <= 2; ++i) {
        if (i == 1) {
            intVar = 3;
            strVar = "val1";
        }
        if (i == 2) {
            intVar = 1;
            strVar = "val2";
        }
        #sql [ctx] {INSERT INTO ATOMICTBL values(:intVar, :strVar)}; 4
    }
    int[] counts = ctx.getExecutionContext().executeBatch(); 5
    for (int i = 0; i < counts.length; ++i) {
        System.out.println(" count[" + i + "]:" + counts[i]);
    }
} catch (SQLException e) {
    System.out.println(" Exception Caught: " + e.getMessage());
    SQLException excp = null;
    if (e instanceof SQLException) {
        System.out.println(" SQLCode: " + ((SQLException)e).getErrorCode() + " Message: " + e.getMessage());
        excp = ((SQLException)e).getNextException();
        while (excp != null) {
            System.out.println(" SQLCode: " + ((SQLException)excp).getErrorCode() + " Message: " + excp.getMessage());
            excp = excp.getNextException();
        }
    }
}

Data retrieval in SQLJ applications

SQLJ applications use a result set iterator to retrieve result sets. Like a cursor, a result set iterator can be non-scrollable or scrollable.
Just as in DB2 applications in other languages, if you want to retrieve a single row from a table in an SQLJ application, you can write a SELECT INTO statement with a WHERE clause that defines a result table that contains only that row:

```sql
#sql [myConnCtx] {SELECT DEPTNO INTO :hvdeptno 
FROM DEPARTMENT WHERE DEPTNAME="OPERATIONS"};
```

However, most SELECT statements that you use create result tables that contain many rows. In DB2 applications in other languages, you use a cursor to select the individual rows from the result table. That cursor can be non-scrollable, which means that when you use it to fetch rows, you move the cursor serially, from the beginning of the result table to the end. Alternatively, the cursor can be scrollable, which means that when you use it to fetch rows, you can move the cursor forward, backward, or to any row in the result table.

This topic discusses how to use non-scrollable iterators. For information on using scrollable iterators, see "Use scrollable iterators in an SQLJ application".

A result set iterator is a Java object that you use to retrieve rows from a result table. Unlike a cursor, a result set iterator can be passed as a parameter to a method.

The basic steps in using a result set iterator are:
1. Declare the iterator, which results in an iterator class
2. Define an instance of the iterator class.
3. Assign the result table of a SELECT to an instance of the iterator.
4. Retrieve rows.
5. Close the iterator.

There are two types of iterators: positioned iterators and named iterators. Positioned iterators extend the interface `sqlj.runtime.PositionedIterator`. Positioned iterators identify the columns of a result table by their position in the result table. Named iterators extend the interface `sqlj.runtime.NamedIterator`. Named iterators identify the columns of the result table by result table column names.

**Using a named iterator in an SQLJ application**

Use a named iterator to refer to each of the columns in a result table by name.

The steps in using a named iterator are:
1. Declare the iterator.

   You declare any result set iterator using an iterator declaration clause. This causes an iterator class to be created that has the same name as the iterator. For a named iterator, the iterator declaration clause specifies the following information:
   - The name of the iterator
   - A list of column names and Java data types
   - Information for a Java class declaration, such as whether the iterator is `public` or `static`
   - A set of attributes, such as whether the iterator is holdable, or whether its columns can be updated

   When you declare a named iterator for a query, you specify names for each of the iterator columns. Those names must match the names of columns in the result table for the query. An iterator column name and a result table column name that differ only in case are considered to be matching names. The named iterator class that results from the iterator declaration clause contains accessor
There is one accessor method for each column of the iterator. Each accessor method name is the same as the corresponding iterator column name. You use the accessor methods to retrieve data from columns of the result table.

You need to specify Java data types in the iterators that closely match the corresponding DB2 column data types. See "Java, JDBC, and SQL data types" for a list of the best mappings between Java data types and DB2 data types.

You can declare an iterator in a number of ways. However, because a Java class underlies each iterator, you need to ensure that when you declare an iterator, the underlying class obeys Java rules. For example, iterators that contain a `with-clause` must be declared as `public`. Therefore, if an iterator needs to be `public`, it can be declared only where a `public` class is allowed. The following list describes some alternative methods of declaring an iterator:

- **As public, in a source file by itself**
  This method lets you use the iterator declaration in other code modules, and provides an iterator that works for all SQLJ applications. In addition, there are no concerns about having other top-level classes or `public` classes in the same source file.

- **As a top-level class in a source file that contains other top-level class definitions**
  Java allows only one public, top-level class in a code module. Therefore, if you need to declare the iterator as public, such as when the iterator includes a `with-clause`, no other classes in the code module can be declared as public.

- **As a nested static class within another class**
  Using this alternative lets you combine the iterator declaration with other class declarations in the same source file, declare the iterator and other classes as public, and make the iterator class visible to other code modules or packages. However, when you reference the iterator from outside the nesting class, you must fully-qualify the iterator name with the name of the nesting class.

- **As an inner class within another class**
  When you declare an iterator in this way, you can instantiate it only within an instance of the nesting class. However, you can declare the iterator and other classes in the file as public.

  You cannot cast a JDBC ResultSet to an iterator if the iterator is declared as an inner class. This restriction does not apply to an iterator that is declared as a static nested class. See "Use SQLJ and JDBC in the same application" for more information on casting a ResultSet to a iterator.

2. Create an instance of the iterator class.
   You declare an object of the named iterator class to retrieve rows from a result table.

3. Assign the result table of a SELECT to an instance of the iterator.
   To assign the result table of a SELECT to an iterator, you use an SQLJ `assignment clause`. The format of the assignment clause for a named iterator is:
   ```sql
   #sql context-clause iterator-object={select-statement};
   ```
   See "SQLJ assignment-clause" and "SQLJ context-clause" for more information.

4. Retrieve rows.
   Do this by invoking accessor methods in a loop. Accessor methods have the same names as the corresponding columns in the iterator, and have no parameters. An accessor method returns the value from the corresponding column of the current row in the result table. Use the `NamedIterator.next()` method to move the cursor forward through the result table.
To test whether you have retrieved all rows, check the value that is returned when you invoke the next method. `next` returns a `boolean` with a value of `false` if there is no next row.

5. Close the iterator.

   Use the `NamedIterator.close` method to do this.

The following code demonstrates how to declare and use a named iterator. The numbers to the right of selected statements correspond to the previously-described steps.

```
#sql iterator ByName(String LastName, Date HireDate);
   // Declare named iterator ByName

   // Declare object of ByName class
   ByName nameiter; // Declare object of ByName class
   #sql [ctxt]
   nameiter={SELECT LASTNAME, HIREDATE FROM EMPLOYEE}; // Assign the result table of the SELECT
   // to iterator object nameiter
   while (nameiter.next()) // Move the iterator through the result
   // table and test whether all rows retrieved
   {
       System.out.println( nameiter.LastName() + " was hired on " + nameiter.HireDate()); // Use accessor methods LastName and HireDate to retrieve column values
   }
   nameiter.close(); // Close the iterator
}
```

*Figure 34. Example of using a named iterator*

### Related tasks:

- ["Performing positioned UPDATE and DELETE operations in an SQLJ application"](on page 154)
- ["Using a positioned iterator in an SQLJ application"]

### Using a positioned iterator in an SQLJ application

Use a positioned iterator to refer to columns in a result table by their position in the result set.

The steps in using a positioned iterator are:

1. Declare the iterator.

   You declare any result set iterator using an *iterator declaration clause*. This causes an iterator class to be created that has the same name and attributes as the iterator. For a positioned iterator, the iterator declaration clause specifies the following information:
   - The name of the iterator
   - A list of Java data types
   - Information for a Java class declaration, such as whether the iterator is *public* or *static*
   - A set of attributes, such as whether the iterator is holdable, or whether its columns can be updated

   The data type declarations represent columns in the result table and are referred to as columns of the result set iterator. The columns of the result set iterator correspond to the columns of the result table, in left-to-right order. For example, if an iterator declaration clause has two data type declarations, the
first data type declaration corresponds to the first column in the result table, and the second data type declaration corresponds to the second column in the result table.

You need to specify Java data types in the iterators that closely match the corresponding DB2 column data types. See "Java, JDBC, and SQL data types" for a list of the best mappings between Java data types and DB2 data types.

You can declare an iterator in a number of ways. However, because a Java class underlies each iterator, you need to ensure that when you declare an iterator, the underlying class obeys Java rules. For example, iterators that contain a with-clause must be declared as public. Therefore, if an iterator needs to be public, it can be declared only where a public class is allowed. The following list describes some alternative methods of declaring an iterator:

- **As public, in a source file by itself**
  This is the most versatile method of declaring an iterator. This method lets you use the iterator declaration in other code modules, and provides an iterator that works for all SQLJ applications. In addition, there are no concerns about having other top-level classes or public classes in the same source file.

- **As a top-level class in a source file that contains other top-level class definitions**
  Java allows only one public, top-level class in a code module. Therefore, if you need to declare the iterator as public, such as when the iterator includes a with-clause, no other classes in the code module can be declared as public.

- **As a nested static class within another class**
  Using this alternative lets you combine the iterator declaration with other class declarations in the same source file, declare the iterator and other classes as public, and make the iterator class visible from other code modules or packages. However, when you reference the iterator from outside the nesting class, you must fully-qualify the iterator name with the name of the nesting class.

- **As an inner class within another class**
  When you declare an iterator in this way, you can instantiate it only within an instance of the nesting class. However, you can declare the iterator and other classes in the file as public.

  You cannot cast a JDBC ResultSet to an iterator if the iterator is declared as an inner class. This restriction does not apply to an iterator that is declared as a static nested class. See "Use SQLJ and JDBC in the same application" for more information on casting a ResultSet to a iterator.

2. Create an instance of the iterator class.
   You declare an object of the positioned iterator class to retrieve rows from a result table.

3. **Assign the result table of a SELECT to an instance of the iterator.**
   To assign the result table of a SELECT to an iterator, you use an SQLJ assignment clause. The format of the assignment clause for a positioned iterator is:
   ```sql
   #sql context-clause iterator-object={select-statement};
   ```

4. Retrieve rows.
   Do this by executing FETCH statements in executable clauses in a loop. The FETCH statements looks the same as a FETCH statements in other languages.
To test whether you have retrieved all rows, invoke the PositionedIterator.endFetch method after each FETCH. endFetch returns a boolean with the value true if the FETCH failed because there are no rows to retrieve.

5. Close the iterator.
   Use the PositionedIterator.close method to do this.

The following code demonstrates how to declare and use a positioned iterator. The numbers to the right of selected statements correspond to the previously-described steps.

```java
#sql iterator ByPos(String,Date); // Declare positioned iterator ByPos 1
{
  ...
  ByPos positer; // Declare object of ByPos class 2
  String name = null; // Declare host variables
  Date hrdate;
  #sql [ctxt] positer =
    {SELECT LASTNAME, HIREDATE FROM EMPLOYEE}; // Assign the result table of the SELECT
    // to iterator object positer
  #sql {FETCH :positer INTO :name, :hrdate }; // Fetch the first row
  while (!positer.endFetch()) // Check whether the FETCH returned a row
  { System.out.println(name + " was hired in " + hrdate);
    #sql {FETCH :positer INTO :name, :hrdate }; // Fetch the next row
  }
  positer.close(); // Close the iterator 5
}
```

**Multiple open iterators for the same SQL statement in an SQLJ application**

With the IBM Data Server Driver for JDBC and SQLJ, your application can have multiple concurrently open iterators for a single SQL statement in an SQLJ application. With this capability, you can perform one operation on a table using one iterator while you perform a different operation on the same table using another iterator.

When you use concurrently open iterators in an application, you should close iterators when you no longer need them to prevent excessive storage consumption in the Java heap.

The following examples demonstrate how to perform the same operations on a table without concurrently open iterators on a single SQL statement and with concurrently open iterators on a single SQL statement. These examples use the following iterator declaration:
import java.math.*;
#sql public iterator MultiIter(String EmpNo, BigDecimal Salary);

Without the capability for multiple, concurrently open iterators for a single SQL
statement, if you want to select employee and salary values for a specific employee
number, you need to define a different SQL statement for each employee number,
as shown in Figure 36.

Figure 37 demonstrates how you can perform the same operations when you have
the capability for multiple, concurrently open iterators for a single SQL statement.

Figure 36. Example of concurrent table operations using iterators with different SQL
statements

Figure 37 demonstrates how you can perform the same operations when you have
the capability for multiple, concurrently open iterators for a single SQL statement.

Figure 37. Example of concurrent table operations using iterators with the same SQL
statement

**Multiple open instances of an iterator in an SQLJ application**

Multiple instances of an iterator can be open concurrently in a single SQLJ
application. One application for this ability is to open several instances of an
iterator that uses host expressions. Each instance can use a different set of host
expression values.
The following example shows an application with two concurrently open instances of an iterator.

... 
ResultSet myFunc(String empid) // Method to open an iterator and get a resultSet 
{ 
    MyIter iter; 
    #sql iter = {SELECT * FROM EMPLOYEE WHERE EMPNO = :empid}; 
    return iter.getResultSet(); 
} 

// An application can call this method to get a resultSet for each 
// employee ID. The application can process each resultSet separately. 
... 
ResultSet rs1 = myFunc("000100"); // Get employee record for employee ID 000100  
... 
ResultSet rs2 = myFunc("000200"); // Get employee record for employee ID 000200  

Figure 38. Example of opening more than one instance of an iterator in a single application

As with any other iterator, you need to remember to close this iterator after the last time you use it to prevent excessive storage consumption.

**Using scrollable iterators in an SQLJ application**

In addition to moving forward, one row at a time, through a result table, you might want to move backward or go directly to a specific row. The IBM Data Server Driver for JDBC and SQLJ provides this capability.

An iterator in which you can move forward, backward, or to a specific row is called a *scrollable iterator*. A scrollable iterator in SQLJ is equivalent to the result table of a database cursor that is declared as SCROLL.

Like a scrollable cursor, a scrollable iterator can be *insensitive* or *sensitive*. A sensitive scrollable iterator can be *static* or *dynamic*. Insensitive means that changes to the underlying table after the iterator is opened are not visible to the iterator. Insensitive iterators are read-only. Sensitive means that changes that the iterator or other processes make to the underlying table are visible to the iterator. Asensitive means that if the cursor is a read-only cursor, it behaves as an insensitive cursor. If it is not a read-only cursor, it behaves as a sensitive cursor.

If a scrollable iterator is static, the size of the result table and the order of the rows in the result table do not change after the iterator is opened. This means that you cannot insert into result tables, and if you delete a row of a result table, a delete hole occurs. If you update a row of the result table so that the row no longer qualifies for the result table, an update hole occurs. Fetching from a hole results in an SQLException.

If a scrollable iterator is dynamic, the size of the result table and the order of the rows in the result table can change after the iterator is opened. Rows that are inserted or deleted with INSERT and DELETE statements that are executed by the same application process are immediately visible. Rows that are inserted or deleted with INSERT and DELETE statements that are executed by other application processes are visible after the changes are committed.

**Important:** DB2 for Linux, UNIX, and Windows servers do not support dynamic scrollable cursors. You can use dynamic scrollable iterators in your SQLJ applications only if those applications access data on DB2 for z/OS servers, at Version 9 or later.
To create and use a scrollable iterator, you need to follow these steps:

1. Specify an iterator declaration clause that includes the following clauses:
   a. `implements sqlj.runtime.Scrollable`
      This indicates that the iterator is scrollable.
   b. `with (sensitivity=INSENSITIVE|SENSITIVE|ASENSITIVE) or with` (sensitivity=SENSITIVE, dynamic=true|false)
      sensitivity=INSENSITIVE|SENSITIVE|ASENSITIVE indicates whether update or delete operations on the underlying table can be visible to the iterator. The default sensitivity is INSENSITIVE.
      dynamic=true|false indicates whether the size of the result table or the order of the rows in the result table can change after the iterator is opened. The default value of dynamic is false.

   The iterator can be a named or positioned iterator.

   **Example:** The following iterator declaration clause declares a positioned, sensitive, dynamic, scrollable iterator:
   ```sql
   #sql public iterator ByPos
   implements sqlj.runtime.Scrollable
   with (sensitivity=SENSITIVE, dynamic=true) (String);
   ```

   **Example:** The following iterator declaration clause declares a named, insensitive, scrollable iterator:
   ```sql
   #sql public iterator ByName
   implements sqlj.runtime.Scrollable
   with (sensitivity=INSENSITIVE) (String EmpNo);
   ```

   **Restriction:** You cannot use a scrollable iterator to select columns with the following data types from a table on a DB2 for Linux, UNIX, and Windows server:
   - LONG VARCHAR
   - LONG VARGRAPHIC
   - BLOB
   - CLOB
   - XML
   - A distinct type that is based on any of the previous data types in this list
   - A structured type

2. Create an iterator object, which is an instance of your iterator class.

3. If you want to give the SQLJ runtime environment a hint about the initial fetch direction, use the `setFetchDirection(int direction)` method. `direction` can be FETCH_FORWARD or FETCH_REVERSE. If you do not invoke `setFetchDirection`, the fetch direction is FETCH_FORWARD.

4. For each row that you want to access:
   a. Position the cursor using one of the methods listed in the following table.

   **Table 26. sqlj.runtime.Scrollable methods for positioning a scrollable cursor**
<table>
<thead>
<tr>
<th>Method</th>
<th>Positions the cursor</th>
</tr>
</thead>
<tbody>
<tr>
<td>first[4]</td>
<td>On the first row of the result table</td>
</tr>
<tr>
<td>last[5]</td>
<td>On the last row of the result table</td>
</tr>
<tr>
<td>previous[6]</td>
<td>On the previous row of the result table</td>
</tr>
<tr>
<td>next</td>
<td>On the next row of the result table</td>
</tr>
</tbody>
</table>
Table 26. sql.runtime.Scrollable methods for positioning a scrollable cursor (continued)

<table>
<thead>
<tr>
<th>Method</th>
<th>Positions the cursor</th>
</tr>
</thead>
<tbody>
<tr>
<td>absolute(int n)</td>
<td>If n&gt;0, on row n of the result table. If n&lt;0, and m is the number of rows in the result table, on row m+n+1 of the result table.</td>
</tr>
<tr>
<td>relative(int n)</td>
<td>If n&gt;0, on the row that is n rows after the current row.</td>
</tr>
<tr>
<td></td>
<td>If n&lt;0, on the row that is n rows before the current row.</td>
</tr>
<tr>
<td></td>
<td>If n=0, on the current row.</td>
</tr>
<tr>
<td>afterLast</td>
<td>After the last row in the result table</td>
</tr>
<tr>
<td>beforeFirst</td>
<td>Before the first row in the result table</td>
</tr>
</tbody>
</table>

Notes:
1. This method does not apply to connections to IBM Informix.
2. If the cursor is after the last row of the result table, this method positions the cursor on the last row.
3. If the absolute value of n is greater than the number of rows in the result table, this method positions the cursor after the last row if n is positive, or before the first row if n is negative.
4. Suppose that m is the number of rows in the result table and x is the current row number in the result table. If n>0 and x+n>m, the iterator is positioned after the last row. If n<0 and x+n<1, the iterator is positioned before the first row.

For a positioned iterator, perform the following steps:

a. Use a FETCH statement with a fetch orientation clause to position the iterator and retrieve the current row of the result table. Table 27 lists the clauses that you can use to position the cursor.

Table 27. FETCH clauses for positioning a scrollable cursor

<table>
<thead>
<tr>
<th>Method</th>
<th>Positions the cursor</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIRST</td>
<td>On the first row of the result table</td>
</tr>
<tr>
<td>LAST</td>
<td>On the last row of the result table</td>
</tr>
<tr>
<td>PRIOR</td>
<td>On the previous row of the result table</td>
</tr>
<tr>
<td>NEXT</td>
<td>On the next row of the result table</td>
</tr>
<tr>
<td>ABSOLUTE(n)</td>
<td>If n&gt;0, on row n of the result table. If n&lt;0, and m is the number of rows in the result table, on row m+n+1 of the result table.</td>
</tr>
<tr>
<td>RELATIVE(n)</td>
<td>If n&gt;0, on the row that is n rows after the current row.</td>
</tr>
<tr>
<td></td>
<td>If n&lt;0, on the row that is n rows before the current row.</td>
</tr>
<tr>
<td></td>
<td>If n=0, on the current row.</td>
</tr>
<tr>
<td>AFTER</td>
<td>After the last row in the result table</td>
</tr>
<tr>
<td>BEFORE</td>
<td>Before the first row in the result table</td>
</tr>
</tbody>
</table>
### Table 27. FETCH clauses for positioning a scrollable cursor (continued)

<table>
<thead>
<tr>
<th>Method</th>
<th>Positions the cursor</th>
</tr>
</thead>
</table>

**Notes:**

1. This value is not supported for connections to IBM Informix
2. If the cursor is after the last row of the result table, this method positions the cursor on the last row.
3. If the absolute value of \( n \) is greater than the number of rows in the result table, this method positions the cursor after the last row if \( n \) is positive, or before the first row if \( n \) is negative.
4. Suppose that \( m \) is the number of rows in the result table and \( x \) is the current row number in the result table. If \( n>0 \) and \( x+n>m \), the iterator is positioned after the last row. If \( n<0 \) and \( x+n<1 \), the iterator is positioned before the first row.
5. Values are not assigned to host expressions.

b. If update or delete operations by the iterator or by other means are visible in the result table, invoke the getWarnings method to check whether the current row is a hole.

5. Invoke the close method to close the iterator.

The following code demonstrates how to use a named iterator to retrieve the employee number and last name from all rows from the employee table in reverse order. The numbers to the right of selected statements correspond to the previously-described steps.

```java
#sql context Ctx; // Create connection context class Ctx
sql iterator ScrollIter implements sqlj.runtime.Scrollable
   (String EmpNo, String LastName);
{
...
Ctx ctxt =
   new Ctx("jdbc:db2://sysmvs1.stl.ibm.com:5021/NEWYORK",
      userid,password,false); // Create connection context object ctxt
// for the connection to NEWYORK
ScrollIter scrliter;
#sql [ctxt]
   scrliter=SELECT EMPNO, LASTNAME FROM EMPLOYEE;
   scrliter.afterLast();
   while (scrliter.previous())
   {
      System.out.println(scrliter.EmpNo()+ " "+
         + scrliter.LastName());
   }
   scrliter.close();
}
```

**Calling stored procedures in SQLJ applications**

To call a stored procedure, you use an executable clause that contains an SQL CALL statement.
You can execute the CALL statement with host identifier parameters. You can execute the CALL statement with literal parameters only if the DB2 server on which the CALL statement runs supports execution of the CALL statement dynamically.

The basic steps in calling a stored procedure are:
1. Assign values to input (IN or INOUT) parameters.
2. Call the stored procedure.
3. Process output (OUT or INOUT) parameters.
4. If the stored procedure returns multiple result sets, retrieve those result sets.

The following code illustrates calling a stored procedure that has three input parameters and three output parameters. The numbers to the right of selected statements correspond to the previously-described steps.

```java
String FirstName="TOM"; // Input parameters 1
String LastName="NARISINST";
String Address="IBM";
int CustNo; // Output parameters
String Mark;
String MarkErrorText;
...
#sql [myConnCtx] {CALL ADD_CUSTOMER(:IN FirstName, 2
:IN LastName,
:IN Address,
:OUT CustNo,
:OUT Mark,
:OUT MarkErrorText);} 3
// Call the stored procedure
System.out.println("Output parameters from ADD_CUSTOMER call: ");
System.out.println("Customer number for " + LastName + ": " + CustNo);
System.out.println(Mark);
If (MarkErrorText != null)
    System.out.println(" Error messages:" + MarkErrorText);
```

Figure 39. Example of calling a stored procedure in an SQLJ application

Related concepts:
“Retrieving multiple result sets from a stored procedure in an SQLJ application” on page 177

Using named parameters in CALL statements in SQLJ applications

You can use named parameters to map host variable names in a CALL statement to the parameter names in the stored procedure definition.

With named parameters, you do not need to specify parameters in the CALL statement in the same order that they appear in the stored procedure definition. In addition, you do not need to specify all parameters in the CALL statement. Unspecified parameters take the default values that are specified in the stored procedure definition.

To use named parameters with CALL statements, follow these steps:
1. In the CALL statement, assign values to IN or INOUT host variables.

The named parameters point to the host variables. The rules for naming of named parameters and assignment to named parameters must follow the rules for named parameters in SQL CALL statements. You can explicitly assign the default value or the null value to a named parameter by specifying the
DEFAULT keyword or the NULL keyword. For parameters for which a default value is specified in the CREATE PROCEDURE statement, you can implicitly assign the default values to named parameters by omitting those parameters from the CALL statement. You can omit parameters only if all of the omitted parameters have default values in the stored procedure definition.

You cannot mix named parameters and unnamed parameters in the same CALL statement.

2. Process output (OUT or INOUT) parameters.

3. If the stored procedure returns multiple result sets, retrieve those result sets.

The following code illustrates calling a stored procedure that has the following definition:

```sql
CREATE PROCEDURE SALS (  
  OUT retcode INTEGER,  
  IN lowsal DOUBLE,  
  IN medsal DOUBLE,  
  IN highsal DOUBLE DEFAULT 100000,  
  IN department CHAR(3) DEFAULT '---')  
SPECIFIC JDBC_SALS  
DYNAMIC RESULT SETS 0  
DETERMINISTIC  
LANGUAGE JAVA  
PARAMETER STYLE JAVA  
NO DBINFO  
FENCED  
THREADSAFE  
MODIFIES SQL DATA  
PROGRAM TYPE SUB  
EXTERNAL NAME 'MYJAR:MyClass.sals'
```

The input parameters in the CALL statement are represented by named parameters. The third and fourth parameters are called with the default values for the stored procedure. The numbers to the right of selected statements correspond to the previously-described steps.

```java
double hvLowSal=10000; // Host variables for input parameters  
double hvMedSal=50000;  
int hvRetCode; // Host variable for output parameter
```

```sql
#sql [myConnCtx] {CALL SALS(retcode=>:OUT hvRetCode,  
  lowsal=>:IN hvLowSal,  
  medsal=>:IN hvMedSal,  
  highsal=>DEFAULT);}  
// Call the stored procedure.  
// Implicitly use the default  
// value for the last parameter  
// by omitting it.
```

```
System.out.println("Return code from SALS call: " + hvRetCode);  
```

Retrieving data from cursor output parameters in SQLJ applications

DB2 for Linux, UNIX, and Windows stored procedures can have OUT parameters of the cursor type. To retrieve data from those parameters in SQLJ applications, you use iterators or ResultSet objects.

To retrieve data from cursor variables, follow these steps:

1. Define an iterator or ResultSet object for each OUT parameter that has the CURSOR data type in the stored procedure definition.

   Iterators for retrieving cursor OUT parameters can be named or positioned.

2. Assign values to input parameters.
3. Call the stored procedure.
4. Retrieve rows from the cursor parameters.

   - If you declare a positioned iterator for the cursor parameter, use FETCH statements to retrieve the data.
   - If you declare a named iterator for the cursor parameter, use NamedIterator methods to retrieve the data.
   - If you define a ResultSet object for the cursor parameter, use ResultSet methods to position the cursor and retrieve values from result set rows.

5. If the stored procedure returns multiple result sets by opening cursors that are defined as WITH RETURN, retrieve those result sets.

A single stored procedure can return data through multiple result sets as well as CURSOR parameters.

A cursor data type and a stored procedure have the following definitions:

```
CREATE TYPE myRowType AS ROW (name VARCHAR(128))
CREATE TYPE myCursorType AS myRowType CURSOR
CREATE PROCEDURE MYPROC(IN pempNo VARCHAR(6), OUT pcv1 myCursorType)
  RESULT SETS 0
  LANGUAGE SQL
  BEGIN
    SET pcv1 = CURSOR FOR SELECT name FROM employee WHERE empNo = pempNo;
    OPEN pcv1;
  END
```

The following code calls stored procedure MYPROC and uses a positioned iterator to retrieve data from cursor pcv1. The numbers to the right of selected statements correspond to the previously-described steps.

```
#sql iterator Iter (String); // Declare a positioned iterator
...
Iter iter = null; // Output parameter
String hvPempNo="000500"; // Input parameter
#sql [ctx] {CALL MYPROC (:IN hvPempNo, :OUT iter)}; // Call the stored procedure
String hvEmpName = null; // Retrieve rows from the result set
while (true) {
  #sql { FETCH :iter into :hvName };
  if (iter.endFetch()) break;
  System.out.println("Employee name for " + hvPempNo + ": " + hvEmpName);
}
```

The following code calls stored procedure MYPROC and uses a ResultSet object to retrieve data from cursor pcv1. The numbers to the right of selected statements correspond to the previously-described steps.

```
ResultSet rs = null; // Output parameter
String hvPempNo="000500"; // Input parameter
#sql [ctx] {CALL MYPROC (:IN hvPempNo, :OUT rs)}; // Call the stored procedure
String hvEmpName = null;
while (rs.next()) {
  hvEmpName=rs.getString(1);
  System.out.println("Employee name for " + hvPempNo + ": " + hvEmpName);
}
```
Related concepts:
“Retrieving multiple result sets from a stored procedure in an SQLJ application”

Retrieving multiple result sets from a stored procedure in an SQLJ application

Some stored procedures return one or more result sets to the calling program by including the DYNAMIC RESULT SETS n clause in the definition, with n>0, and opening cursors that are defined with the WITH RETURN clause. The calling program needs to retrieve the contents of those result sets.

To retrieve the rows from those result sets, you execute these steps:
1. Acquire an execution context for retrieving the result set from the stored procedure.
2. Associate the execution context with the CALL statement for the stored procedure.
   Do not use this execution context for any other purpose until you have retrieved and processed the last result set.
3. For each result set:
   a. Use the ExecutionContext method getNextResultSet to retrieve the result set.
   b. If you do not know the contents of the result set, use ResultSetMetaData methods to retrieve this information.
   c. Use an SQLJ result set iterator or JDBC ResultSet to retrieve the rows from the result set.

Result sets are returned to the calling program in the same order that their cursors are opened in the stored procedure. When there are no more result sets to retrieve, getNextResultSet returns a null value.

getNextResultSet has two forms:
getNextResultSet();
getNextResultSet(int current);

When you invoke the first form of getNextResultSet, SQLJ closes the currently-open result set and advances to the next result set. When you invoke the second form of getNextResultSet, the value of current indicates what SQLJ does with the currently-open result set before it advances to the next result set:

```java
java.sql.Statement.CLOSE_CURRENT_RESULT
   Specifies that the current ResultSet object is closed when the next ResultSet object is returned.
java.sql.Statement.KEEP_CURRENT_RESULT
   Specifies that the current ResultSet object stays open when the next ResultSet object is returned.
java.sql.Statement.CLOSE_ALL_RESULTS
   Specifies that all open ResultSet objects are closed when the next ResultSet object is returned.
```

The following code calls a stored procedure that returns multiple result sets. For this example, it is assumed that the caller does not know the number of result sets to be returned or the contents of those result sets. It is also assumed that autoCommit is false. The numbers to the right of selected statements correspond to the previously-described steps.
LOBs in SQLJ applications with the IBM Data Server Driver for JDBC and SQLJ

With the IBM Data Server Driver for JDBC and SQLJ, you can retrieve LOB data into Clob or Blob host expressions or update CLOB, BLOB, or DBCLOB columns from Clob or Blob host expressions. You can also declare iterators with Clob or Blob data types to retrieve data from CLOB, BLOB, or DBCLOB columns.

Retrieving or updating LOB data: To retrieve data from a BLOB column, declare an iterator that includes a data type of Blob or byte[]. To retrieve data from a CLOB or DBCLOB column, declare an iterator in which the corresponding column has a Clob data type.

To update data in a BLOB column, use a host expression with data type Blob. To update data in a CLOB or DBCLOB column, use a host expression with data type Clob.

Progressive streaming or LOB locators: In SQLJ applications, you can use progressive streaming, also known as dynamic data format, or LOB locators in the same way that you use them in JDBC applications.

Java data types for retrieving or updating LOB column data in SQLJ applications

When the deferPrepares property is set to true, and the IBM Data Server Driver for JDBC and SQLJ processes an uncustomized SQLJ statement that includes host expressions, the driver might need to do extra processing to determine data types. This extra processing can impact performance.

When the JDBC driver cannot immediately determine the data type of a parameter that is used with a LOB column, you need to choose a parameter data type that is compatible with the LOB data type.

Input parameters for BLOB columns

For input parameters for BLOB columns, you can use either of the following techniques:

- Use a java.sql.Blob input variable, which is an exact match for a BLOB column:
Before you can use a `java.sql.Blob` input variable, you need to create a `java.sql.Blob` object, and then populate that object. 

- Use an input parameter of type of `sqlj.runtime.BinaryStream`. A `sqlj.runtime.BinaryStream` object is compatible with a BLOB data type. For example:
  ```java
  java.io.ByteArrayInputStream byteStream =
  new java.io.ByteArrayInputStream(byteData);
  int numBytes = byteData.length;
  sqlj.runtime.BinaryStream binStream =
  new sqlj.runtime.BinaryStream(byteStream, numBytes);
  #sql {CALL STORPROC(:IN binStream)};
  ```

  You cannot use this technique for INOUT parameters.

### Output parameters for BLOB columns

For output or INOUT parameters for BLOB columns, you can use the following technique:

- Declare the output parameter or INOUT variable with a `java.sql.Blob` data type:
  ```java
  java.sql.Blob blobData = null;
  #sql CALL STORPROC (:OUT blobData)};
  ```

### Input parameters for CLOB columns

For input parameters for CLOB columns, you can use one of the following techniques:

- Use a `java.sql.Clob` input variable, which is an exact match for a CLOB column:
  ```java
  java.sql.Blob blobData = null;
  #sql CALL STORPROC (:IN clobData)};
  ```

Before you can use a `java.sql.Clob` input variable, you need to create a `java.sql.Clob` object, and then populate that object.

- Use one of the following types of stream IN parameters:
  - A `sqlj.runtime.CharacterStream` input parameter:
    ```java
    java.lang.String charData;
    java.io.StringReader reader = new java.io.StringReader(charData);
    sqlj.runtime.CharacterStream charStream =
    new sqlj.runtime.CharacterStream (reader, charData.length);
    #sql {CALL STORPROC(:IN charStream)};
    ```
  - A `sqlj.runtime.UnicodeStream` parameter, for Unicode UTF-16 data:
    ```java
    byte[] charDataBytes = charData.getBytes("UnicodeBigUnmarked");
    java.io.ByteArrayInputStream byteStream =
    new java.io.ByteArrayInputStream(charDataBytes);
    sqlj.runtime.UnicodeStream uniStream =
    new sqlj.runtime.UnicodeStream(byteStream, charDataBytes.length ) ;
    #sql {CALL STORPROC(:IN uniStream)};
    ```
  - A `sqlj.runtime.AsciiStream` parameter, for ASCII data:
    ```java
    byte[] charDataBytes = charData.getBytes("US-ASCII");
    java.io.ByteArrayInputStream byteStream =
    new java.io.ByteArrayInputStream (charDataBytes);
    sqlj.runtime.AsciiStream asciiStream =
    new sqlj.runtime.AsciiStream (byteStream, charDataBytes.length);
    #sql {CALL STORPROC(:IN asciiStream)};
    ```
For these calls, you need to specify the exact length of the input data. You cannot use this technique for INOUT parameters.

- Use a java.lang.String input parameter:
  ```java
  java.lang.String charData;
  #sql {CALL STORPROC(:IN charData)};
  ```

**Output parameters for CLOB columns**

For output or INOUT parameters for CLOB columns, you can use one of the following techniques:

- Use a java.sql.Clob output variable, which is an exact match for a CLOB column:
  ```java
  java.sql.Clob clobData = null;
  #sql {CALL STORPROC(:OUT clobData)};
  ```

- Use a java.lang.String output variable:
  ```java
  java.lang.String charData = null;
  #sql {CALL STORPROC(:OUT charData)};
  ```

  This technique should be used only if you know that the length of the retrieved data is less than or equal to 32KB. Otherwise, the data is truncated.

**Output parameters for DBCLOB columns**

DBCLOB output or INOUT parameters for stored procedures are not supported.

**SQLJ and JDBC in the same application**

You can combine SQLJ clauses and JDBC calls in a single program.

To do this effectively, you need to be able to do the following things:

- Use a JDBC Connection to build an SQLJ ConnectionContext, or obtain a JDBC Connection from an SQLJ ConnectionContext.
- Use an SQLJ iterator to retrieve data from a JDBC ResultSet or generate a JDBC ResultSet from an SQLJ iterator.

**Building an SQLJ ConnectionContext from a JDBC Connection:** To do that:

1. Execute an SQLJ connection declaration clause to create a ConnectionContext class.
2. Load the driver or obtain a DataSource instance.
3. Invoke the SQLJ DriverManager.getConnection or DataSource.getConnection method to obtain a JDBC Connection.
4. Invoke the ConnectionContext constructor with the Connection as its argument to create the ConnectionContext object.

**Obtaining a JDBC Connection from an SQLJ ConnectionContext:** To do this,

1. Execute an SQLJ connection declaration clause to create a ConnectionContext class.
2. Load the driver or obtain a DataSource instance.
3. Invoke the ConnectionContext constructor with the URL of the driver and any other necessary parameters as its arguments to create the ConnectionContext object.
4. Invoke the JDBC ConnectionContext.getConnection method to create the JDBC Connection object.
See "Connect to a data source using SQLJ" for more information on SQLJ connections.

**Retrieving JDBC result sets using SQLJ iterators:** Use the *iterator conversion statement* to manipulate a JDBC result set as an SQLJ iterator. The general form of an iterator conversion statement is:

```
#sql iterator={CAST :result-set};
```

Before you can successfully cast a result set to an iterator, the iterator must conform to the following rules:

- The iterator must be declared as public.
- If the iterator is a positioned iterator, the number of columns in the result set must match the number of columns in the iterator. In addition, the data type of each column in the result set must match the data type of the corresponding column in the iterator.
- If the iterator is a named iterator, the name of each accessor method must match the name of a column in the result set. In addition, the data type of the object that an accessor method returns must match the data type of the corresponding column in the result set.

The code in Figure 41 builds and executes a query using a JDBC call, executes an iterator conversion statement to convert the JDBC result set to an SQLJ iterator, and retrieves rows from the result table using the iterator.

```sql
#sql public iterator ByName(String LastName, Date HireDate);
```

```java
public void HireDates(ConnectionContext connCtx, String whereClause) {
   ByName nameiter; // Declare object of ByName class
   Connection conn=connCtx.getConnection(); // Create JDBC connection
   Statement stmt = conn.createStatement(); // Create JDBC connection
   String query = "SELECT LASTNAME, HIREDATE FROM EMPLOYEE";
   query+=whereClause; // Build the query
   ResultSet rs = stmt.executeQuery(query);
   #sql [connCtx] nameiter = {CAST :rs};
   while (nameiter.next()) {
      System.out.println( nameiter.LastName() + " was hired on " + nameiter.HireDate());
   }
   nameiter.close();
   stmt.close();
}
```

Figure 41. Converting a JDBC result set to an SQLJ iterator

Notes to Figure 41

<table>
<thead>
<tr>
<th>Note</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>This SQLJ clause creates the named iterator class ByName, which has accessor methods LastName() and HireDate() that return the data from result table columns LASTNAME and HIREDATE.</td>
</tr>
<tr>
<td>2</td>
<td>This statement and the following two statements build and prepare a query for dynamic execution using JDBC.</td>
</tr>
<tr>
<td>3</td>
<td>This JDBC statement executes the SELECT statement and assigns the result table to result set rs.</td>
</tr>
</tbody>
</table>
This iterator conversion clause converts the JDBC ResultSet `rs` to SQLJ iterator `nameiter`, and the following statements use `nameiter` to retrieve values from the result table.

The `nameiter.close()` method closes the SQLJ iterator and JDBC ResultSet `rs`.

### Generating JDBC ResultSets from SQLJ iterators:
Use the `getResultSet` method to generate a JDBC ResultSet from an SQLJ iterator. Every SQLJ iterator has a `getResultSet` method. After you access the ResultSet that underlies an iterator, you need to fetch rows using only the ResultSet.

The code in Figure 42 generates a positioned iterator for a query, converts the iterator to a result set, and uses JDBC methods to fetch rows from the table.

```sql
#sql iterator EmpIter(String, java.sql.Date);
{
    EmpIter iter=null;
    #sql [connCtx] iter=
        {SELECT LASTNAME, HIREDATE FROM EMPLOYEE};
    ResultSet rs=iter.getResultSet();
    while (rs.next())
    { System.out.println(rs.getString(1) + " was hired in " +
                        rs.getDate(2));
    }  
    rs.close();
}
```

**Figure 42. Converting an SQLJ iterator to a JDBC ResultSet**

### Notes to Figure 42

<table>
<thead>
<tr>
<th>Note</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>This SQLJ clause executes the SELECT statement, constructs an iterator object that contains the result table for the SELECT statement, and assigns the iterator object to variable <code>iter</code>.</td>
</tr>
<tr>
<td>2</td>
<td>The <code>getResultSet()</code> method accesses the ResultSet that underlies iterator <code>iter</code>.</td>
</tr>
<tr>
<td>3</td>
<td>The JDBC <code>getString()</code> and <code>getDate()</code> methods retrieve values from the ResultSet. The <code>next()</code> method moves the cursor to the next row in the ResultSet.</td>
</tr>
<tr>
<td>4</td>
<td>The <code>rs.close()</code> method closes the SQLJ iterator as well as the ResultSet.</td>
</tr>
</tbody>
</table>

### Rules and restrictions for using JDBC ResultSets in SQLJ applications:
When you write SQLJ applications that include JDBC result sets, observe the following rules and restrictions:

- You cannot cast a ResultSet to an SQLJ iterator if the ResultSet and the iterator have different holdability attributes.
  A JDBC ResultSet or an SQLJ iterator can remain open after a COMMIT operation. For a JDBC ResultSet, this characteristic is controlled by the IBM Data Server Driver for JDBC and SQLJ property `resultSetHoldability`. For an SQLJ iterator, this characteristic is controlled by the `with holdability` parameter of the iterator declaration. Casting a ResultSet that has holdability to an SQLJ iterator that does not, or casting a ResultSet that does not have holdability to an SQLJ iterator that does, is not supported.
- Close the iterator or the underlying ResultSet object as soon as the program no longer uses the iterator or ResultSet, and before the end of the program.
Closing the iterator also closes the ResultSet object. Closing the ResultSet object also closes the iterator object. In general, it is best to close the object that is used last.

- For the IBM Data Server Driver for JDBC and SQLJ, which supports scrollable iterators and scrollable and updatable ResultSet objects, the following restrictions apply:
  - Scrollable iterators have the same restrictions as their underlying JDBC ResultSet objects.
  - You cannot cast a JDBC ResultSet that is not updatable to an SQLJ iterator that is updatable.

**Controlling the execution of SQL statements in SQLJ**

You can use selected methods of the SQLJ ExecutionContext class to control or monitor the execution of SQL statements.

To use ExecutionContext methods, follow these steps:

1. Acquire the default execution context from the connection context.
   
   There are two ways to acquire an execution context:
   - Acquire the default execution context from the connection context. For example:
     ```java
     ExecutionContext execCtx = connCtx.getExecutionContext();
     ```
   - Create a new execution context by invoking the constructor for ExecutionContext. For example:
     ```java
     ExecutionContext execCtx = new ExecutionContext();
     ```

2. Associate the execution context with an SQL statement.
   
   To do that, specify an execution context after the connection context in the execution clause that contains the SQL statement.

3. Invoke ExecutionContext methods.
   
   Some ExecutionContext methods are applicable before the associated SQL statement is executed, and some are applicable only after their associated SQL statement is executed.
   
   For example, you can use method getUpdateCount to count the number of rows that are deleted by a DELETE statement after you execute the DELETE statement.
   
   The following code demonstrates how to acquire an execution context, and then use the getUpdateCount method on that execution context to determine the number of rows that were deleted by a DELETE statement. The numbers to the right of selected statements correspond to the previously-described steps.
   ```java
   ExecutionContext execCtx = new ExecutionContext();
   #sql [connCtx, execCtx] {DELETE FROM EMPLOYEE WHERE SALARY > 10000};
   System.out.println("Deleted " + execCtx.getUpdateCount() + " rows");
   ```
ROWIDs in SQLJ with the IBM Data Server Driver for JDBC and SQLJ

DB2 for z/OS and DB2 for i support the ROWID data type for a column in a table. A ROWID is a value that uniquely identifies a row in a table.

Although IBM Informix also supports rowids, those rowids have the INTEGER data type. You can select an IBM Informix rowid column into a variable with a four-byte integer data type.

If you use columns with the ROWID data type in SQLJ programs, you need to customize those programs.

JDBC 4.0 includes interface java.sql.RowId that you can use in iterators and in CALL statement parameters. If you do not have JDBC 4.0, you can use the IBM Data Server Driver for JDBC and SQLJ-only class com.ibm.db2.jcc.DB2RowID. For an iterator, you can also use the byte[] object type to retrieve ROWID values.

The following code shows an example of an iterator that is used to select values from a ROWID column:
The following code shows an example of calling a stored procedure that takes three ROWID parameters: an IN parameter, an OUT parameter, and an INOUT parameter.

```java
java.sql.RowId in_rowid = rowid;
java.sqlRowId out_rowid = null;
java.sql.RowId inout_rowid = rowid;

// Declare an IN, OUT, and INOUT ROWID parameter

#sql [myConnCtx] {CALL SP_ROWID(:IN in_rowid,
  :OUT out_rowid,
  :INOUT inout_rowid)};
// Call the stored procedure
System.out.println("Parameter values from SP_ROWID call:");
System.out.println("OUT parameter value ");
MyUtilities.printBytes(out_rowid.getBytes());
// Use the getBytes method to
// convert the value to bytes for printing
// Call a user-defined method called
// printBytes (not shown) to print
// the value.
System.out.println("INOUT parameter value ");
MyUtilities.printBytes(inout_rowid.getBytes());
```

Figure 44. Example of calling a stored procedure with a ROWID parameter
**TIMESTAMP WITH TIME ZONE values in SQLJ applications**

DB2 for z/OS supports table columns with the TIMESTAMP WITH TIME ZONE data type. IBM Data Server Driver for JDBC and SQLJ supports update into and retrieval from a column with the TIMESTAMP WITH TIME ZONE data type in SQLJ programs.

When you update or retrieve a TIMESTAMP WITH TIME ZONE value, or call a stored procedure with a TIMESTAMP WITH TIME ZONE parameter, you need to use host variables that are com.ibm.db2.jcc.DBTimestamp objects to retain the time zone information. If you use java.sql.Timestamp objects to pass TIMESTAMP WITH TIME ZONE values to and from the data server, you lose the time zone information.

Because the com.ibm.db2.jcc.DBTimestamp class is a IBM Data Server Driver for JDBC and SQLJ-only class, if you run an uncustomized SQLJ application that uses com.ibm.db2.jcc.DBTimestamp objects, the application receives an SQLException.

**Examples**

Suppose that table TSTABLE has a single column, TSCOL, which has data type TIMESTAMP WITH TIME ZONE. The following code assigns a timestamp value with a time zone to the column, and retrieves the value from the column.

```sql
#sql iterator TSIter(com.ibm.db2.jcc.DBTimestamp TSVar);
{
    ...
    java.util.TimeZone esttz = java.util.TimeZone.getTimeZone("EST");
    // Set the time zone to UTC-5
    java.util.Calendar estcal = java.util.Calendar.getInstance(esttz);
    // Create a calendar instance
    // with the EST time zone
    java.sql.Timestamp ts =
    // Initialize a timestamp object
    // with the datetime value that you
    // want to put in the table
    com.ibm.db2.jcc.DBTimestamp dbts =
        new com.ibm.db2.jcc.DBTimestamp(ts, estcal);
    // Create a datetime object that
    // includes the time zone
    #sql[ctx] {INSERT INTO TSTABLE (TSCOL) VALUES (:dbts)};
    // Insert the datetime object in
    // the table
    #sql[ctx] {COMMIT};
    TSIter iter = null;
    #sql [ctx] iter = {SELECT TSCOL FROM TSTABLE};
    // Assign the result table of the SELECT
    while (iter.next()) {
        System.out.println ("Timestamp=" +
            ((com.ibm.db2.jcc.DBTimestamp)iter.TSVar()).toDBString(true));
        // Use accessor method TSVar to retrieve
        // the TIMESTAMP WITH TIME ZONE value,
        // cast it to a DBTimestamp value,
        // and retrieve its string representation.
        // Value retrieved:
    }
}
```

Suppose that stored procedure TSSP has a single INOUT parameter, TSPARM, which has data type TIMESTAMP WITH TIME ZONE. The following code calls
the stored procedure with a timestamp value that includes a time zone, and retrieves a parameter value with a timestamp value that includes a time zone.

```java
... java.util.TimeZone esttz = java.util.TimeZone.getTimeZone("EST");
    // Set the time zone to UTC-5
java.util.Calendar estcal = java.util.Calendar.getInstance(esttz);
    // Create a calendar instance
    // with the EST time zone
java.sql.Timestamp ts =
    // Initialize a timestamp object
    // with the timestamp value that you
    // want to pass to the stored procedure
com.ibm.db2.jcc.DBTimestamp dbts =
    new com.ibm.db2.jcc.DBTimestamp(ts,estcal);
    // Create a timestamp object that
    // includes the time zone to
    // pass to the stored procedure
#sql[ctx] { CALL TSSP (:INOUT dbts) };
System.out.println ("Output parameter: " + dbts.toDBString (true));
    // Call the stored procedure with
    // the timestamp value as input,
    // and retrieve a timestamp value
    // with a time zone in the same
    // parameter
}
```

### Distinct types in SQLJ applications

In an SQLJ program, you can create a distinct type using the `CREATE DISTINCT TYPE` statement in an executable clause.

You can also use `CREATE TABLE` in an executable clause to create a table that includes a column of that type. When you retrieve data from a column of that type, or update a column of that type, you use Java host variables or expressions with data types that correspond to the built-in types on which the distinct types are based.

The following example creates a distinct type that is based on an `INTEGER` type, creates a table with a column of that type, inserts a row into the table, and retrieves the row from the table:

```java
String empNumVar;
int shoeSizeVar;
...
#sql [myConnCtx] {CREATE DISTINCT TYPE SHOESIZE AS INTEGER WITH COMPARISONS};
    // Create distinct type
#sql [myConnCtx] {COMMIT}; // Commit the create
#sql [myConnCtx] {CREATE TABLE EMP_SHOE
    (EMPNO CHAR(6), EMP_SHOE_SIZE SHOESIZE)};
    // Create table using distinct type
#sql [myConnCtx] {COMMIT}; // Commit the create
#sql [myConnCtx] {INSERT INTO EMP_SHOE
    VALUES('000010',6)}; // Insert a row in the table
#sql [myConnCtx] {COMMIT}; // Commit the INSERT
#sql [myConnCtx] {SELECT EMPNO, EMP_SHOE_SIZE
    INTO :empNumVar, :shoeSizeVar
    FROM EMP_SHOE}; // Retrieve the row
System.out.println("Employee number: " + empNumVar +
    " Shoe size: " + shoeSizeVar);
```

Figure 45. Defining and using a distinct type

**CREATE TYPE (distinct) statement**

**Invocation of stored procedures with ARRAY parameters in SQLJ applications**

SQLJ applications that run under the IBM Data Server Driver for JDBC and SQLJ and connect to DB2 for Linux, UNIX, and Windows data sources can call stored procedures that have ARRAY parameters.

You can use `java.sql.Array` objects as IN, OUT, or INOUT parameters in a stored procedure.

For IN or INOUT parameters, use the `DB2Connection.createArrayOf` method (JDBC 3.0 or earlier) or the `Connection.createArrayOf` method (JDBC 4.0 or later) to create a `java.sql.Array` object.

There are two ways to retrieve data from an ARRAY output stored procedure parameter:

- Use the `java.sql.Array.getArray` method to retrieve the contents of output parameter into a Java array.
- Use a `java.sql.Array.getResultSet` method to retrieve the output parameter data into a `ResultSet` object. Then use `ResultSet` methods to retrieve elements of the array. Each row of the `ResultSet` contains two columns:
  - An index into the array, which starts at 1
  - The array element

You need to retrieve the array elements from the `ResultSet` using the `getObject` method.

**Example:** Suppose that input and output parameters `IN_PHONE` and `OUT_PHONE` in stored procedure `GET_EMP_DATA` are arrays that are defined like this:

```
CREATE TYPE PHONENUMBERS AS VARCHAR(10) ARRAY[5]
```

Call `GET_EMP_DATA` with the two parameters.

```java
Connection con;
String type = "CHAR";
String [] contents = {"1234", "5678", "9101"};
...
com.ibm.db2.jcc.DB2Connection db2con = (com.ibm.db2.jcc.DB2Connection) con;
    // Cast the Connection as a DB2Connection
    // so you can use the
    // DB2Connection.createArrayOf method
java.sql.Array inPhoneData = db2con.createArrayOf(type, contents);
java.sql.Array outPhoneData;
try {
    #sql [db2con] {CALL GET_EMP_DATA(:IN inPhoneData, :OUT outPhoneData ) };
} catch( SQLException e )
{
    throw e;
}
ResultSet rs = outPhoneData.getResultSet();
while (rs.next()) {
    String phoneNum = (String)rs.getObject(2); // Get phone number
    System.out.println("Phone number = "+ phoneNum);
}
```
Savepoints in SQLJ applications

Under the IBM Data Server Driver for JDBC and SQLJ, you can include any form of the SQL SAVEPOINT statement in your SQLJ program.

An SQL savepoint represents the state of data and schemas at a particular point in time within a unit of work. SQL statements exist to set a savepoint, release a savepoint, and restore data and schemas to the state that the savepoint represents.

The following example demonstrates how to set a savepoint, roll back to the savepoint, and release the savepoint.

```
#sql context Ctx; // Create connection context class Ctx
String empNumVar;
int shoeSizeVar;
...
try { // Load the JDBC driver
    Class.forName("com.ibm.db2.jcc.DB2Driver");
} catch (ClassNotFoundException e) {
    e.printStackTrace();
}
Connection jdbccon= // Create JDBC connection object jdbccon
    DriverManager.getConnection("jdbc:db2://sysmvs1.stl.ibm.com:5021/NEWYORK",
        userid,password);
    // Create JDBC connection object jdbccon
jdbccon.setAutoCommit(false); // Do not autocommit
Ctx ctxt=new Ctx(jdbccon);
// Create connection context object myConnCtx
// for the connection to NEWYORK
...
#sql [ctxt] {COMMIT}; // Commit the transaction
// Commit the create
#sql [ctxt]
    {INSERT INTO EMP_SHOE VALUES ('000010', 6)};
// Insert a row
#sql [ctxt]
    {SAVEPOINT SVPT1 ON ROLLBACK RETAIN CURSORS};
// Create a savepoint
...
#sql [ctxt]
    {INSERT INTO EMP_SHOE VALUES ('000020', 10)};
// Insert another row
#sql [ctxt] {ROLLBACK TO SAVEPOINT SVPT1};
// Roll back work to the point
// after the first insert
...
#sql [ctxt] {RELEASE SAVEPOINT SVPT1};
// Release the savepoint
cxt.close();    // Close the connection context
```
XML data in SQLJ applications

In SQLJ applications, you can store data in XML columns and retrieve data from XML columns.

In DB2 tables, the XML built-in data type is used to store XML data in a column as a structured set of nodes in a tree format.

SQLJ applications can send XML data to the data server or retrieve XML data from the data server in one of the following forms:

- As textual XML data
- As binary XML data (data that is in the Extensible Dynamic Binary XML DB2 Client/Server Binary XML Format), if the data server supports it

In SQLJ applications, you can:

- Store an entire XML document in an XML column using INSERT, UPDATE, or MERGE statements.
- Retrieve an entire XML document from an XML column using single-row SELECT statements or iterators.
- Retrieve a sequence from a document in an XML column by using the SQL XMLQUERY function to retrieve the sequence in the database, and then using single-row SELECT statements or iterators to retrieve the serialized XML string data into an application variable.
- Retrieve a sequence from a document in an XML column by using an XQuery expression, prepended with the string ‘XQUERY’, to retrieve the elements of the sequence into a result table in the database, in which each row of the result table represents an item in the sequence. Then use using single-row SELECT statements or iterators to retrieve the data into application variables.
- Retrieve a sequence from a document in an XML column as a user-defined table by using the SQL XMLTABLE function to define the result table and retrieve it. Then use using single-row SELECT statements or iterators to retrieve the data from the result table into application variables.

- You can update or retrieve XML data as textual XML data. Alternatively, for connections to a data server that supports binary XML data, you can update or retrieve XML data as binary XML data.

For data retrieval, you use the Datasource or Connection property xmlFormat to control whether the format of the retrieved data is textual XML or binary XML.

For update of data in XML columns, xmlFormat has no effect. If the input data is binary XML data, and the data server does not support binary XML data, the input data is converted to textual XML data. Otherwise, no conversion occurs.

The format of XML data is transparent to the application. Storage and retrieval of binary XML data on a DB2 for z/OS data server requires version 4.9 or later of the IBM Data Server Driver for JDBC and SQLJ. Storage and retrieval of binary XML data on a DB2 for Linux, UNIX, and Windows data server requires version 4.11 or later of the IBM Data Server Driver for JDBC and SQLJ.
XML column updates in SQLJ applications

In an SQLJ application, you can update or insert data into XML columns of a table at a DB2 data server using XML textual data. You can update or insert data into XML columns of a table using binary XML data (data that is in the Extensible Dynamic Binary XML DB2 Client/Server Binary XML Format), if the data server supports binary XML data.

The host expression data types that you can use to update XML columns are:

- java.sql.SQLXML (requires an SDK for Java Version 6 or later, and the IBM Data Server Driver for JDBC and SQLJ version 4.0 or later)
- com.ibm.db2.jdbc.DB2Xml (deprecated)
- String
- byte
- Blob
- Clob
- sqlj.runtime.AsciiStream
- sqlj.runtime.BinaryStream
- sqlj.runtime.CharacterStream

The encoding of XML data can be derived from the data itself, which is known as internally encoded data, or from external sources, which is known as externally encoded data. XML data that is sent to the database server as binary data is treated as internally encoded data. XML data that is sent to the data source as character data is treated as externally encoded data. The external encoding is the default encoding for the JVM.

External encoding for Java applications is always Unicode encoding.

Externally encoded data can have internal encoding. That is, the data might be sent to the data source as character data, but the data contains encoding information. The data source handles incompatibilities between internal and external encoding as follows:

- If the data source is DB2 for Linux, UNIX, and Windows, the data source generates an error if the external and internal encoding are incompatible, unless the external and internal encoding are Unicode. If the external and internal encoding are Unicode, the data source ignores the internal encoding.
- If the data source is DB2 for z/OS, the data source ignores internal encoding.

Data in XML columns is stored in UTF-8 encoding.

**Example:** Suppose that you use the following statement to insert data from String host expression xmlString into an XML column in a table. xmlString is a character type, so its external encoding is used, whether or not it has an internal encoding specification.

```
#sql [ctx] {INSERT INTO CUSTACC (1, :xmlString)};
```
**Example:** Suppose that you copy the data from xmlString into a byte array with CP500 encoding. The data contains an XML declaration with an encoding declaration for CP500. Then you insert the data from the byte[] host expression into an XML column in a table.

```java
byte[] xmlBytes = xmlString.getBytes("CP500");
#sql[ctx] {INSERT INTO CUSTACC VALUES (4, :xmlBytes)};
```

A byte string is considered to be internally encoded data. The data is converted from its internal encoding scheme to UTF-8, if necessary, and stored in its hierarchical format on the data source.

**Example:** Suppose that you copy the data from xmlString into a byte array with US-ASCII encoding. Then you construct an sqlj.runtime.AsciiStream host expression, and insert data from the sqlj.runtime.AsciiStream host expression into an XML column in a table on a data source.

```java
byte[] b = xmlString.getBytes("US-ASCII");
java.io.ByteArrayInputStream xmlAsciiInputStream =
    new java.io.ByteArrayInputStream(b);
sqlj.runtime.AsciiStream sqljXmlAsciiStream =
    new sqlj.runtime.AsciiStream(xmlAsciiInputStream, b.length);
#sql[ctx] {INSERT INTO CUSTACC VALUES (4, :sqljXmlAsciiStream)};
```

sqljXmlAsciiStream is a stream type, so its internal encoding is used. The data is converted from its internal encoding to UTF-8 encoding and stored in its hierarchical format on the data source.

**Example:** sqlj.runtime.CharacterStream host expression: Suppose that you construct an sqlj.runtime.CharacterStream host expression, and insert data from the sqlj.runtime.CharacterStream host expression into an XML column in a table.

```java
java.io.StringReader xmlReader =
    new java.io.StringReader(xmlString);
sqlj.runtime.CharacterStream sqljXmlCharacterStream =
    new sqlj.runtime.CharacterStream(xmlReader, xmlString.length());
#sql [ctx] {INSERT INTO CUSTACC VALUES (4, :sqljXmlCharacterStream)};
```

sqljXmlCharacterStream is a character type, so its external encoding is used, whether or not it has an internal encoding specification.

**Example:** Suppose that you retrieve a document from an XML column into a java.sql.SQLXML host expression, and insert the data into an XML column in a table.

```java
java.sql.ResultSet rs = s.executeQuery("SELECT * FROM CUSTACC");
rs.next();
java.sql.SQLXML xmlObject = (java.sql.SQLXML)rs.getObject(2);
#sql [ctx] {INSERT INTO CUSTACC VALUES (6, :xmlObject)};
```

After you retrieve the data it is still in UTF-8 encoding, so when you insert the data into another XML column, no conversion occurs.

**Example:** Suppose that you retrieve a document from an XML column into a com.ibm.db2.jcc.DB2XML host expression, and insert the data into an XML column in a table.

```java
java.sql.ResultSet rs = s.executeQuery("SELECT * FROM CUSTACC");
rs.next();
com.ibm.db2.jcc.DB2XML xmlObject = (com.ibm.db2.jcc.DB2XML)rs.getObject(2);
#sql [ctx] {INSERT INTO CUSTACC VALUES (6, :xmlObject)};
```
After you retrieve the data it is still in UTF-8 encoding, so when you insert the data into another XML column, no conversion occurs.

**XML data retrieval in SQLJ applications**

When you retrieve data from XML columns of a database table in an SQLJ application, the output data must be explicitly or implicitly serialized.

The host expression or iterator data types that you can use to retrieve data from XML columns are:

- `java.sql.SQLXML` (requires an SDK for Java Version 6 or later, and the IBM Data Server Driver for JDBC and SQLJ version 4.0 or later)
- `com.ibm.db2.jcc.DB2Xml` (deprecated)
- `String`
- `byte[]`
- `sqlj.runtimeAsciiStream`
- `sqlj.runtime.BinaryStream`
- `sqlj.runtime.CharacterStream`

If the application does not call the `XMLSERIALIZE` function before data retrieval, the data is converted from UTF-8 to the external application encoding for the character data types, or the internal encoding for the binary data types. No XML declaration is added. If the host expression is an object of the `java.sql.SQLXML` or `com.ibm.db2.jcc.DB2Xml` type, you need to call an additional method to retrieve the data from this object. The method that you call determines the encoding of the output data and whether an XML declaration with an encoding specification is added.

The following table lists the methods that you can call to retrieve data from a `java.sql.SQLXML` or a `com.ibm.db2.jcc.DB2Xml` object, and the corresponding output data types and type of encoding in the XML declarations.

<table>
<thead>
<tr>
<th>Method</th>
<th>Output data type</th>
<th>Type of XML internal encoding declaration added</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SQLXML.getBinaryStream</code></td>
<td>InputStream</td>
<td>None</td>
</tr>
<tr>
<td><code>SQLXML.getCharacterStream</code></td>
<td>Reader</td>
<td>None</td>
</tr>
<tr>
<td><code>SQLXML.getSource</code></td>
<td>Source</td>
<td>None</td>
</tr>
<tr>
<td><code>SQLXML.getString</code></td>
<td>String</td>
<td>None</td>
</tr>
<tr>
<td><code>DB2Xml.getDB2AsciiStream</code></td>
<td>InputStream</td>
<td>None</td>
</tr>
<tr>
<td><code>DB2Xml.getDB2BinaryStream</code></td>
<td>InputStream</td>
<td>None</td>
</tr>
<tr>
<td><code>DB2Xml.getDB2Bytes</code></td>
<td>byte[]</td>
<td>None</td>
</tr>
<tr>
<td><code>DB2Xml.getDB2CharacterStream</code></td>
<td>Reader</td>
<td>None</td>
</tr>
<tr>
<td><code>DB2Xml.getDB2String</code></td>
<td>String</td>
<td>None</td>
</tr>
<tr>
<td><code>DB2Xml.getDB2XmlAsciiStream</code></td>
<td>InputStream</td>
<td>US-ASCII</td>
</tr>
<tr>
<td><code>DB2Xml.getDB2XmlBinaryStream</code></td>
<td>InputStream</td>
<td>Specified by getDB2XmlBinaryStream targetEncoding parameter</td>
</tr>
<tr>
<td><code>DB2Xml.getDB2XmlBytes</code></td>
<td>byte[]</td>
<td>Specified by DB2Xml.getDB2XmlBytes targetEncoding parameter</td>
</tr>
<tr>
<td><code>DB2Xml.getDB2XmlCharacterStream</code></td>
<td>Reader</td>
<td>ISO-10646-UCS-2</td>
</tr>
<tr>
<td><code>DB2Xml.getDB2XmlString</code></td>
<td>String</td>
<td>ISO-10646-UCS-2</td>
</tr>
</tbody>
</table>

Chapter 4. SQLJ application programming
If the application executes the XMLSERIALIZE function on the data that is to be returned, after execution of the function, the data has the data type that is specified in the XMLSERIALIZE function, not the XML data type. Therefore, the driver handles the data as the specified type and ignores any internal encoding declarations.

**Example:** Suppose that you retrieve data from an XML column into a String host expression.

```
#sql iterator XmlStringIter (int, String);
#sql [ctx] siter = {SELECT C1, CADOC from CUSTACC};
#sql {FETCH :siter INTO :row, :outString};
```

The String type is a character type, so the data is converted from UTF-8 to the external encoding, which is the default JVM encoding, and returned without any XML declaration.

**Example:** Suppose that you retrieve data from an XML column into a byte[] host expression.

```
#sql iterator XmlByteArrayIter (int, byte[]);
XmlByteArrayIter biter = null;
#sql [ctx] biter = {SELECT c1, CADOC from CUSTACC};
#sql {FETCH :biter INTO :row, :outBytes};
```

The byte[] type is a binary type, so no data conversion from UTF-8 encoding occurs, and the data is returned without any XML declaration.

**Example:** Suppose that you retrieve a document from an XML column into a java.sql.SQLXML host expression, but you need the data in a binary stream.

```
#sql iterator SqlXmlIter (int, java.sql.SQLXML);
SqlXmlIter SQLXMLiter = null;
java.sql.SQLXML outSqlXml = null;
#sql [ctx] SqlXmlIter = {SELECT c1, CADOC from CUSTACC};
#sql {FETCH :SqlXmlIter INTO :row, :outSqlXml};
java.io.InputStream XmlStream = outSqlXml.getBinaryStream();
```

The FETCH statement retrieves the data into the SQLXML object in UTF-8 encoding. The SQLXML.getBinaryStream stores the data in a binary stream.

**Example:** Suppose that you retrieve a document from an XML column into a com.ibm.db2.jcc.DB2Xml host expression, but you need the data in a byte string with an XML declaration that includes an internal encoding specification for UTF-8.

```
#sql iterator DB2XmlIter (int, com.ibm.db2.jcc.DB2Xml);
DB2XmlIter db2xmlIter = null;
com.ibm.db2.jcc.DB2Xml outDB2Xml = null;
#sql [ctx] db2xmlIter = {SELECT c1, CADOC from CUSTACC};
#sql {FETCH :db2xmlIter INTO :row, :outDB2Xml};
byte[] byteArray = outDB2Xml.getBytes("UTF-8");
```

The FETCH statement retrieves the data into the DB2Xml object in UTF-8 encoding. The getDB2XmlBytes method with the UTF-8 argument adds an XML declaration with a UTF-8 encoding specification and stores the data in a byte array.

**XMLCAST in SQLJ applications**

Before you can use XMLCAST to cast a host variable to the XML data type in an SQLJ application, you need to cast the host variable to the corresponding SQL data type.
Example: The following code demonstrates a situation in which it is necessary to cast a String host variable to an SQL character type, such as VARCHAR, before you use XMLCAST to cast the value to the XML data type.

```java
String xmlresult = null;
String varchar_hv = "San Jose";
...
#sql [con] {SELECT XMLCAST(CAST(:varchar_hv AS VARCHAR(32)) AS XML) INTO :xmlresult FROM SYSIBM.SYSDUMMY1};
```

### SQLJ utilization of SDK for Java Version 5 function

Your SQLJ applications can use a number of functions that were introduced with the SDK for Java Version 5.

#### Static import

The static import construct lets you access static members without qualifying those members with the name of the class to which they belong. For SQLJ applications, this means that you can use static members in host expressions without qualifying them.

Example: Suppose that you want to declare a host expression of this form:

```java
double r = cos(PI * E);
```

cos, PI, and E are members of the java.lang.Math class. To declare r without explicitly qualifying cos, PI, and E, include the following static import statement in your program:

```java
import static java.lang.Math.*;
```

#### Annotations

Java annotations are a means for adding metadata to Java programs that can also affect the way that those programs are treated by tools and libraries. Annotations are declared with annotation type declarations, which are similar to interface declarations. Java annotations can appear in the following types of classes or interfaces:

- Class declaration
- Interface declaration
- Nested class declaration
- Nested interface declaration

You cannot include Java annotations directly in SQLJ programs, but you can include annotations in Java source code, and then include that source code in your SQLJ programs.

Example: Suppose that you declare the following marker annotation in a program called MyAnnot.java:

```java
public @interface MyAnnot { }
```

You also declare the following marker annotation in a program called MyAnnot2.java:

```java
public @interface MyAnnot2 { }
```

You can then use those annotations in an SQLJ program:
// Class annotations
@MyAnot2 public @MyAnot class TestAnnotation
{
    // Field annotation
    @MyAnot
    private static final int field1 = 0;
    // Constructor annotation
    @MyAnot2 public @MyAnot TestAnnotation () {} 
    // Method annotation
    @MyAnot
    public static void main (String a[]) 
    {
        TestAnnotation TestAnnotation_o = new TestAnnotation();
        TestAnnotation_o.runThis();
    }
    // Inner class annotation
    public static @MyAnot class TestAnotherInnerClass { }
    // Inner interface annotation
    public static @MyAnot interface TestAnotInnerInterface { }
}

Enumerated types

An enumerated type is a data type that consists of a set of ordered values. The SDK for Java version 5 introduces the <b>enum</b> type for enumerated types.

You can include enums in the following places:
- In Java source files (.java files) that you include in an SQLJ program
- In SQLJ class declarations

Example: The TestEnum.sqlj class declaration includes an enum type:

```java
public class TestEnum2
{
    public enum Color {
        RED, ORANGE, YELLOW, GREEN, BLUE, INDIGO, VIOLET
    }
    Color color;
    ... // Get the value of color
    switch (color) {
        case RED:
            System.out.println("Red is at one end of the spectrum.");
            #sql[ctx] { INSERT INTO MYTABLE VALUES (:color) };
            break;
        case VIOLET:
            System.out.println("Violet is on the other end of the spectrum.");
            break;
        case ORANGE:
        case YELLOW:
        case GREEN:
        case BLUE:
        case INDIGO:
            System.out.println("Everything else is in the middle.");
            break;
    }
}
```

Generics

You can use generics in your Java programs to assign a type to a Java collection. The SQLJ translator tolerates Java generic syntax. Examples of generics that you can use in SQLJ programs are:
- A List of List objects:
  ```java
  List <List<String>> strList2 = new ArrayList<List<String>>();
  ```
• A HashMap in which the key/value pair has the String type:
  
  ```java
  Map<String, String> map = new HashMap<String, String>();
  ```

• A method that takes a List with elements of any type:
  
  ```java
  public void mthd(List<?> obj) {
      ...
  }
  ```

Although you can use generics in SQLJ host variables, the value of doing so is limited because the SQLJ translator cannot determine the types of those host variables.

**Enhanced for loop**

The enhanced for lets you specify that a set of operations is performed on each member of a collection or array. You can use the iterator in the enhanced for loop in host expressions.

**Example:** INSERT each of the items in array names into table TAB.

```java
String[] names = {"ABC", "DEF", "GHI"};
for (String n : names) {
    #sql {INSERT INTO TAB (VARCHARCOL) VALUES(:n) };
}
```

**Varargs**

Varargs make it easier to pass an arbitrary number of values to a method. A Vararg in the last argument position of a method declaration indicates that the last arguments are an array or a sequence of arguments. An SQLJ program can use the passed arguments in host expressions.

**Example:** Pass an arbitrary number of parameters of type Object, to a method that inserts each parameter value into table TAB.

```java
public void runThis(Object... objects) throws SQLException {
    for (Object obj : objects) {
        #sql { INSERT INTO TAB (VARCHARCOL) VALUES(:obj) };
    }
}
```

**Transaction control in SQLJ applications**

In SQLJ applications, as in other types of SQL applications, transaction control involves explicitly or implicitly committing and rolling back transactions, and setting the isolation level for transactions.

**Setting the isolation level for an SQLJ transaction**

To set the isolation level for a unit of work within an SQLJ program, use the SET TRANSACTION ISOLATION LEVEL clause.

The following table shows the values that you can specify in the SET TRANSACTION ISOLATION LEVEL clause and their DB2 equivalents.
### Table 29. Equivalent SQLJ and DB2 isolation levels

<table>
<thead>
<tr>
<th>SET TRANSACTION value</th>
<th>DB2 isolation level</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERIALIZABLE</td>
<td>Repeatable read</td>
</tr>
<tr>
<td>REPEATABLE READ</td>
<td>Read stability</td>
</tr>
<tr>
<td>READ COMMITTED</td>
<td>Cursor stability</td>
</tr>
<tr>
<td>READ UNCOMMITTED</td>
<td>Uncommitted read</td>
</tr>
</tbody>
</table>

The isolation level affects the underlying JDBC connection as well as the SQLJ connection.

**Related concepts:**
- “JDBC connection objects” on page 38
- “Isolation levels”

### Committing or rolling back SQLJ transactions

If you disable autocommit for an SQLJ connection, you need to perform explicit commit or rollback operations. You do this using execution clauses that contain the SQL COMMIT or ROLLBACK statements.

To commit a transaction in an SQLJ program, use a statement like this:

```
#sql [myConnCtx] {COMMIT};
```

To roll back a transaction in an SQLJ program, use a statement like this:

```
#sql [myConnCtx] {ROLLBACK};
```

**Related tasks:**
- “Connecting to a data source using SQLJ” on page 141
- “Committing or rolling back SQLJ transactions”

### Handling SQL errors and warnings in SQLJ applications

SQLJ clauses throw SQLExceptions when SQL errors occur, but not when most SQL warnings occur.

SQLJ generates an SQLException under the following circumstances:
- When any SQL statement returns a negative SQL error code
- When a SELECT INTO SQL statement returns a +100 SQL error code

You need to explicitly check for other SQL warnings.
- For SQL error handling, include try/catch blocks around SQLJ statements.
- For SQL warning handling, invoke the getWarnings method after every SQLJ statement.

### Handling SQL errors in an SQLJ application

SQLJ clauses use the JDBC class java.sql.SQLException for error handling.

To handle SQL errors in SQLJ applications, following these steps:
1. Import the java.sql.SQLException class.
2. Use the Java error handling try/catch blocks to modify program flow when an SQL error occurs.
3. Obtain error information from the SQLException.

You can use the getErrorCode method to retrieve SQL error codes and the getSQLState method to retrieve SQLSTATEs.

If you are using the IBM Data Server Driver for JDBC and SQLJ, obtain additional information from the SQLException by casting it to a DB2Diagnosable object, in the same way that you obtain this information in a JDBC application.

The following code prints out the SQL error that occurred if a SELECT statement fails.

```
try {
  #sql [ctxt] {SELECT LASTNAME INTO :empname
              FROM EMPLOYEE WHERE EMPNO='000010'};
}
catch(SQLException e) {
  System.out.println("Error code returned: "+ e.getErrorCode());
}
```

Related tasks:

“Handling an SQLException under the IBM Data Server Driver for JDBC and SQLJ” on page 131

Handling SQL warnings in an SQLJ application

Other than a +100 SQL error code on a SELECT INTO statement, warnings from the data server do not throw SQLExceptions. To handle warnings from the data server, you need to give the program access to the java.sql.SQLWarning class.

If you want to retrieve data-server-specific information about a warning, you also need to give the program access to the com.ibm.db2.jcc.DB2Diagnosable interface and the com.ibm.db2.jcc.DB2Sqlca class.

To retrieve data-server-specific information about a warning:

1. Set up an execution context for that SQL clause. See "Control the execution of SQL statements in SQLJ" for information on how to set up an execution context.
2. To check for a warning from the data server, invoke the getWarnings method after you execute an SQLJ clause.
   
   getWarnings returns the first SQLWarning object that an SQL statement generates. Subsequent SQLWarning objects are chained to the first one.
3. To retrieve data-server-specific information from the SQLWarning object with the IBM Data Server Driver for JDBC and SQLJ, follow the instructions in "Handle an SQLException under the IBM Data Server Driver for JDBC and SQLJ”.

The following example demonstrates how to retrieve an SQLWarning object for an SQL clause with execution context execCtx. The numbers to the right of selected statements correspond to the previously-described steps.

```
ExecutionContext execCtx=myConnCtx.getExecutionContext();  1
// Get default execution context from
// connection context

SQLWarning sqlWarn;
...
#sql [myConnCtx,execCtx] {SELECT LASTNAME INTO :empname
  FROM EMPLOYEE WHERE EMPNO='000010'};
if ((sqlWarn = execCtx.getWarnings()) != null)  2
  System.out.println("SQLWarning "+ sqlWarn);
```
Closing the connection to a data source in an SQLJ application

When you have finished with a connection to a data source, you need to close the connection to the data source. Doing so releases the DB2 and SQLJ resources for the associated ConnectionContext object immediately.

If you do not close a ConnectionContext object after you use it, unexpected behavior might occur if a Java finalizer closes the ConnectionContext object. Examples of the unexpected behavior are:

- An ObjectClosedException on the underlying ResultSet or Statement objects
- Agent hangs in DB2 stored procedures

To close the connection to the data source, use one of the ConnectionContext.close methods.

- If you execute ConnectionContext.close() or ConnectionContext.close(ConnectionContext.CLOSE_CONNECTION), the connection context, as well as the connection to the data source, are closed.
- If you execute ConnectionContext.close(ConnectionContext.KEEP_CONNECTION) the connection context is closed, but the connection to the data source is not.

The following code closes the connection context, but does not close the connection to the data source.

```java
... ctx = new EzSqljctx(con0); // Create a connection context object
    // from JDBC connection con0
... // Perform various SQL operations
    EzSqljctx.close(ConnectionContext.KEEP_CONNECTION); // Close the connection context but keep
    // the connection to the data source open
```

Chapter 5. Security under the IBM Data Server Driver for JDBC and SQLJ

When you use the IBM Data Server Driver for JDBC and SQLJ, you choose a security mechanism by specifying a value for the securityMechanism Connection or DataSource property, or the db2jcc.securityMechanism global configuration property.

You can set the securityMechanism property in one of the following ways:

- If you use the DriverManager interface, set securityMechanism in a java.util.Properties object before you invoke the form of the getConnection method that includes the java.util.Properties parameter.
- If you use the DataSource interface, and you are creating and deploying your own DataSource objects, invoke the DataSource.setSecurityMechanism method after you create a DataSource object.

You can determine the security mechanism that is in effect for a connection by calling the DB2Connection.getDB2SecurityMechanism method.

The following table lists the security mechanisms that the IBM Data Server Driver for JDBC and SQLJ supports, and the data sources that support those security mechanisms.

Table 30. Data server support for IBM Data Server Driver for JDBC and SQLJ security mechanisms

<table>
<thead>

<th>Supported by DB2 for i</th>
</tr>
</thead>
</table>

Note:

1. These security mechanisms use DRDA encryption. DRDA encryption is not intended to provide confidentiality and integrity of passwords or data over a network that is not secure, such as the Internet. DRDA encryption uses an anonymous key exchange, Diffie-Hellman, which does not provide authentication of the server or the client. DRDA encryption is vulnerable to man-in-the-middle attacks.

2. Available for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity only.

3. The version of the data source must be DB2 for iV6R1 or later.

The following table lists the security mechanisms that the IBM Data Server Driver for JDBC and SQLJ supports, and the value that you need to specify for the `securityMechanism` property to specify each security mechanism.

The default security mechanism is CLEAR_TEXT_PASSWORD_SECURITY. If the server does not support CLEAR_TEXT_PASSWORD_SECURITY but supports ENCRYPTED_USER_AND_PASSWORD_SECURITY, the IBM Data Server Driver for JDBC and SQLJ driver updates the security mechanism to ENCRYPTED_USER_AND_PASSWORD_SECURITY and attempts to connect to the server. Any other mismatch in security mechanism support between the requester and the server results in an error.

Table 31. Security mechanisms supported by the IBM Data Server Driver for JDBC and SQLJ

<table>
<thead>
<tr>
<th>Security mechanism</th>
<th><code>securityMechanism</code> property value</th>

<td>ENCRYPTED_USER_PASSWORD_AND_DATA_SECURITY</td>
</tr>
<tr>
<td>KERBEROS</td>
<td>KERBEROS_SECURITY or PLUGIN_SECURITY</td>
</tr>
<tr>
<td>KRB_SERVER_ENCRYPT</td>
<td>KERBEROS_SECURITY, PLUGIN_SECURITY, ENCRYPTED_PASSWORD_SECURITY, or ENCRYPTED_USER_AND_PASSWORD_SECURITY</td>
</tr>
<tr>
<td>GSSPLUGIN</td>
<td>PLUGIN_SECURITY, or KERBEROS_SECURITY</td>
</tr>
<tr>
<td>GSS_SERVER_ENCRYPT</td>
<td>CLEAR_TEXT_PASSWORD_SECURITY, ENCRYPTED_PASSWORD_SECURITY, ENCRYPTED_USER_AND_PASSWORD_SECURITY, PLUGIN_SECURITY, or KERBEROS_SECURITY</td>
</tr>
</tbody>
</table>

Notes:
1. For PLUGIN_SECURITY, the plugin must be a Kerberos plugin.
2. For PLUGIN_SECURITY, one of the plugins at the server identifies itself as supporting Kerberos.
3. GSS_SERVER_ENCRYPT is a combination of GSSPLUGIN and SERVER_ENCRYPT.

User ID and password security under the IBM Data Server Driver for JDBC and SQLJ

With the IBM Data Server Driver for JDBC and SQLJ, one of the available security methods is user ID and password security.

To specify user ID and password security for a JDBC connection, use one of the following techniques.

For the DriverManager interface: You can specify the user ID and password directly in the DriverManager.getConnection invocation. For example:

```java
import java.sql.*; // JDBC base
...
String id = "dbadm"; // Set user ID
String pw = "dbadm"; // Set password
```
String url = "jdbc:db2://mvs1.sj.ibm.com:5021/san_jose";
    // Set URL for the data source

Connection con = DriverManager.getConnection(url, id, pw);
    // Create connection

Another method is to set the user ID and password directly in the URL string. For example:
import java.sql.*; // JDBC base
...
String url =
    "jdbc:db2://mvs1.sj.ibm.com:5021/san_jose:user=dbadm;password=dbadm;";
    // Set URL for the data source
Connection con = DriverManager.getConnection(url);
    // Create connection

Alternatively, you can set the user ID and password by setting the user ID and password properties in a Properties object, and then invoking the form of the getConnection method that includes the Properties object as a parameter. Optionally, you can set the securityMechanism property to indicate that you are using user ID and password security. For example:
import java.sql.*; // JDBC base
import com.ibm.db2.jcc.*; // IBM Data Server Driver for JDBC
...
Properties properties = new java.util.Properties();
    // Create Properties object
properties.put("user", "dbadm"); // Set user ID for the connection
properties.put("password", "dbadm"); // Set password for the connection
properties.put("securityMechanism",
    new String("" + com.ibm.db2.jcc.DB2BaseDataSource.CLEAR_TEXT_PASSWORD_SECURITY + 
"")); // Set security mechanism to user ID and password
String url = "jdbc:db2://mvs1.sj.ibm.com:5021/san_jose";
    // Set URL for the data source
Connection con = DriverManager.getConnection(url, properties);
    // Create connection

For the DataSource interface: you can specify the user ID and password directly in the DataSource.getConnection invocation. For example:
import java.sql.*; // JDBC base
import com.ibm.db2.jcc.*; // IBM Data Server Driver for JDBC
...
Context ctx=new InitialContext(); // Create context for JNDI
DataSource ds=(DataSource)ctx.lookup("jdbc/sampledb"); // Get DataSource object
String id = "dbadm";
    // Set user ID
String pw = "dbadm";
    // Set password
Connection con = ds.getConnection(id, pw); // Create connection

Alternatively, if you create and deploy the DataSource object, you can set the user ID and password by invoking the DataSource.setUser and DataSource.setPassword methods after you create the DataSource object. Optionally, you can invoke the DataSource.setSecurityMechanism method property to indicate that you are using user ID and password security. For example:
...
ds.setDriverType(4); // Set driver type
ds.setDatabaseName("san_jose"); // Set location
ds.setServerName("mvs1.sj.ibm.com"); // Set server name
ds.setPortNumber(5021); // Set port number
ds.setUser("dbadm"); // Set user ID
ds.setPassword("dbadm"); // Set password
ds.setSecurityMechanism(
    com.ibm.db2.jcc.DB2BaseDataSource.CLEAR_TEXT_PASSWORD_SECURITY);
    // Set security mechanism to
    // user ID and password

Valid characters in passwords: All characters in the ASCII range X'20' (decimal 32) through X'7E' (decimal 126) are valid in passwords, except for the following characters:

- X'20' (space) at the end of a password. The IBM Data Server Driver for JDBC and SQLJ strips space characters at the end of a password.
- X'3B' (semicolon)
- Any characters that cannot be converted to EBCDIC characters, if passwords in plain text are sent to a data server.

RACF password phrase security: If you are connecting to a DB2 for z/OS that is configured for RACF protection, and the RACF version supports RACF password phrases, you can supply a RACF password phrase for the password property value, instead of a simple password. A password phrase must conform to the following rules:

- A password phrase is a character string that can consist of mixed-case letters, numbers, and special characters, including blanks.
- The length of the password phrase can be 9 to 100 characters, or 14 to 100 characters.

Password phrases of between 9 and 13 characters are allowed when the new-password-phrase exit (ICHPWX11) is installed on the z/OS system, and the exit allows password phrases of fewer than 14 characters.
- A password phrase must not contain the user ID, as sequential uppercase or sequential lowercase characters.
- A password phrase must contain at least two alphabetic characters (A through Z or a through z).
- A password phrase must contain at least two non-alphabetic characters (numerics, punctuation, or special characters).
- A password phrase must not contain more than two consecutive characters that are identical.
- If a single quotation mark (') is part of the password phrase, the single quotation mark must be represented as two consecutive single quotation marks (\'').

The following example uses a password phrase for a connection:

```java
import java.sql.*; // JDBC base
import com.ibm.db2.jcc.*; // IBM Data Server Driver for JDBC
// and SQLJ implementation of JDBC
...
Properties properties = new java.util.Properties(); // Create Properties object
properties.put("user", "dbadm"); // Set user ID for the connection
properties.put("password", "a*b!c@ D12345 678"); // Set password phrase for the connection
properties.put("securityMechanism",
    new String("" + com.ibm.db2.jcc.DB2BaseDataSource.CLEAR_TEXT_PASSWORD_SECURITY + "")); // Set security mechanism to
```

Chapter 5. Security under the IBM Data Server Driver for JDBC and SQLJ 205
String url = "jdbc:db2://mvs1.sj.ibm.com:5021/san_jose";
// Set URL for the data source
Connection con = DriverManager.getConnection(url, properties);
// Create connection

User ID-only security under the IBM Data Server Driver for JDBC and SQLJ

With the IBM Data Server Driver for JDBC and SQLJ, one of the available security methods is user-ID only security.

To specify user ID security for a JDBC connection, use one of the following techniques.

**For the DriverManager interface:** Set the user ID and security mechanism by setting the `user` and `securityMechanism` properties in a Properties object, and then invoking the form of the `getConnection` method that includes the Properties object as a parameter. For example:

```java
import java.sql.*; // JDBC base
import com.ibm.db2.jcc.*; // IBM Data Server Driver
// for JDBC and SQLJ
// implementation of JDBC
...
Properties properties = new Properties();
// Create a Properties object
properties.put("user", "db2adm"); // Set user ID for the connection
properties.put("securityMechanism",
        new String("" + com.ibm.db2.jcc.DB2BaseDataSource.USER_ONLY_SECURITY + "));
// Set security mechanism to user ID only
String url = "jdbc:db2://mvs1.sj.ibm.com:5021/san_jose";
// Set URL for the data source
Connection con = DriverManager.getConnection(url, properties);
// Create the connection
```

**For the DataSource interface:** If you create and deploy the DataSource object, you can set the user ID and security mechanism by invoking the `DataSource.setUser` and `DataSource.setSecurityMechanism` methods after you create the DataSource object. For example:

```java
import java.sql.*; // JDBC base
import com.ibm.db2.jcc.*; // IBM Data Server Driver
// for JDBC and SQLJ
// implementation of JDBC
...
com.ibm.db2.jcc.DB2SimpleDataSource db2ds = new com.ibm.db2.jcc.DB2SimpleDataSource();
// Create DB2SimpleDataSource object
db2ds.setDriverType(4); // Set the driver type
db2ds.setDatabaseName("san_jose"); // Set the location
db2ds.setServerName("mvs1.sj.ibm.com"); // Set the server name
```
Encrypted password, user ID, or data security under the IBM Data Server Driver for JDBC and SQLJ

IBM Data Server Driver for JDBC and SQLJ supports encryption of user IDs, passwords, or data when Java applications access data servers.

Those security mechanisms use DRDA encryption. DRDA encryption is not intended to provide confidentiality and integrity of passwords or data over a network that is not secure, such as the Internet. DRDA encryption uses an anonymous key exchange, Diffie-Hellman, which does not provide authentication of the server or the client. DRDA encryption is vulnerable to man-in-the-middle attacks.

The IBM Data Server Driver for JDBC and SQLJ supports 56-bit DES (weak) encryption or 256-bit AES (strong) encryption. AES encryption is available with IBM Data Server Driver for JDBC and SQLJ type 4 connectivity only. You set the encryptionAlgorithm driver property to choose between 56-bit DES encryption (encryptionAlgorithm value of 1) and 256-bit AES encryption (encryptionAlgorithm value of 2). 256-bit AES encryption is used for a connection only if the database server supports it and is configured to use it.

If you use encrypted password security, encrypted user ID security, or encrypted user ID and encrypted password security, the IBM Java Cryptography Extension (JCE) needs to be enabled on your client. The IBM JCE is part of the IBM SDK for Java, Version 1.4.2 or later.

The IBM JCE needs to use 56-bit DES or 256-bit AES encrypted client/server communication from the IBM Data Server Driver for JDBC and SQLJ driver to DB2 for Linux, UNIX, and Windows servers.

For AES encryption, you need an unrestricted policy file for JCE. For the IBM SDK for Java, the file is available at the following location:

When you use AES encryption with the SDK for Java from Oracle, the JCE Unlimited Strength Jurisdiction Policy File needs to be installed. That file is available from Oracle. If the JCE Unlimited Strength Jurisdiction Policy File is not found, a java.security.InvalidKeyException is thrown.

Connections to DB2 for i V6R1 or later servers can use encrypted password security or encrypted user ID and encrypted password security. For encrypted
password security or encrypted user ID and encrypted password security, the IBM Java Cryptography Extension (ibmjceprovider.jar) must be installed on your client. The IBM JCE is part of the IBM SDK for Java, Version 1.4.2 or later.

You can also use encrypted security-sensitive data in addition to encrypted user ID security or encrypted user ID and encrypted password security. You specify encryption of security-sensitive data through the ENCRYPTED_USER_AND_DATA_SECURITY or ENCRYPTED_USER_PASSWORD_AND_DATA_SECURITY securityMechanism value. ENCRYPTED_USER_AND_DATA_SECURITY is valid for connections to DB2 for z/OS servers only, and only for DES encryption (encryptionAlgorithm value of 1).

DB2 for z/OS or DB2 for Linux, UNIX, and Windows database servers encrypt the following data when you specify encryption of security-sensitive data:
- SQL statements that are being prepared, executed, or bound into a package
- Input and output parameter information
- Result sets
- LOB data
- XML data
- Results of describe operations

Before you can use encrypted security-sensitive data, the z/OS Integrated Cryptographic Services Facility needs to be installed and enabled on the z/OS operating system.

To specify encrypted user ID or encrypted password security for a JDBC connection, use one of the following techniques.

**For the DriverManager interface:** Set the user ID, password, and security mechanism by setting the user, password, and securityMechanism properties in a Properties object, and then invoking the form of the getConnection method that includes the Properties object as a parameter. For example, use code like this to set the encrypted user ID, encrypted password, and encrypted security-sensitive data mechanism, with AES encryption:

```java
import java.sql.*; // JDBC base
import com.ibm.db2.jcc.*; // IBM Data Server Driver for JDBC
import com.ibm.db2.jcc.DB2BaseDataSource.*;
... Properties properties = new Properties(); // Create a Properties object
properties.put("user", "dbadm"); // Set user ID for the connection
properties.put("password", "dbadm"); // Set password for the connection
properties.put("securityMechanism", new String("" +
   com.ibm.db2.jcc.DB2BaseDataSource.ENCRYPTED_USER_PASSWORD_AND_DATA_SECURITY + "")); // Set security mechanism to
   // user ID and encrypted password
properties.put("encryptionAlgorithm", "2"); // Request AES security
String url = "jdbc:db2://mvs1.sj.ibm.com:5021/san_jose";
// Set URL for the data source
Connection con = DriverManager.getConnection(url, properties); // Create the connection
```

**For the DataSource interface:** If you create and deploy the DataSource object, you can set the user ID, password, and security mechanism by invoking the DataSource.setSecurityMechanism methods after you create the DataSource object.
For example, use code like this to set the encrypted user ID, encrypted password, and encrypted security-sensitive data security mechanism, with AES encryption:

```java
import java.sql.*; // JDBC base
import com.ibm.db2.jcc.*; // IBM Data Server Driver for JDBC
// and SQLJ implementation of JDBC
...
com.ibm.db2.jcc.DB2SimpleDataSource ds =
    new com.ibm.db2.jcc.DB2SimpleDataSource();
    // Create the DataSource object
ds.setDriverType(4); // Set the driver type
ds.setDatabaseName("san_jose"); // Set the location
ds.setServerName("mvs1.sj.ibm.com"); // Set the server name
ds.setPortNumber(5021); // Set the port number
ds.setUser("db2adm"); // Set the user ID
ds.setPassword("db2adm"); // Set the password
ds.setSecurityMechanism(
    com.ibm.db2.jcc.DB2BaseDataSource.ENCRYPTED_USER_PASSWORD_AND_DATA_SECURITY); // Set security mechanism to
    // User ID and encrypted password
ds.setEncryptionAlgorithm(2); // Request AES encryption
```

**Valid characters in passwords:** All characters in the ASCII range `X'20'` (decimal 32) through `X'7E'` (decimal 126) are valid in passwords, except for the following characters:

- `X'20'` (space) at the end of a password. The IBM Data Server Driver for JDBC and SQLJ strips space characters at the end of a password.
- `X'3B'` (semicolon)
- Any characters that cannot be converted to EBCDIC characters, if passwords in plain text are sent to a data server.

**RACF password phrase security:** If you are connecting to a DB2 for z/OS that is configured for RACF protection, and the RACF version supports RACF password phrases, you can supply a RACF password phrase for the password property value, instead of a simple password. A password phrase must conform to the following rules:

- A password phrase is a character string that can consist of mixed-case letters, numbers, and special characters, including blanks.
- The length of the password phrase can be 9 to 100 characters, or 14 to 100 characters.

Password phrases of between 9 and 13 characters are allowed when the new-password-phrase exit (ICHPWX11) is installed on the z/OS system, and the exit allows password phrases of fewer than 14 characters.

- A password phrase must not contain the user ID, as sequential uppercase or sequential lowercase characters.
- A password phrase must contain at least two alphabetic characters (A through Z or a through z).
- A password phrase must contain at least two non-alphabetic characters (numerics, punctuation, or special characters).
- A password phrase must not contain more than two consecutive characters that are identical.
- If a single quotation mark (') is part of the password phrase, the single quotation mark must be represented as two consecutive single quotation marks ("').
Kerberos security under the IBM Data Server Driver for JDBC and SQLJ

JDBC support for Kerberos security is available for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity only.

To enable JDBC support for Kerberos security, you also need to enable the following components of your software development kit (SDK) for Java:

- Java Cryptography Extension
- Java Generic Security Service (JGSS)
- Java Authentication and Authorization Service (JAAS)

See the documentation for your SDK for Java for information on how to enable these components.

There are three ways to specify Kerberos security for a connection:

- With a user ID and password
- Without a user ID or password
- With a delegated credential

**Kerberos security with a user ID and password**

For this case, Kerberos uses the specified user ID and password to obtain a ticket-granting ticket (TGT) that lets you authenticate to the database server.

You need to set the `user`, `password`, `kerberosServerPrincipal`, and `securityMechanism` properties. Set the `securityMechanism` property to `com.ibm.db2.jcc.DB2BaseDataSource.KERBEROS_SECURITY (11)`. The `kerberosServerPrincipal` property specifies the principal name that the database server registers with a Kerberos Key Distribution Center (KDC).

**For the DriverManager interface**: Set the user ID, password, Kerberos server, and security mechanism by setting the `user`, `password`, `kerberosServerPrincipal`, and `securityMechanism` properties in a Properties object, and then invoking the form of the `getConnection` method that includes the Properties object as a parameter. For example, use code like this to set the Kerberos security mechanism with a user ID and password:

```java
import java.sql.*; // JDBC base
import com.ibm.db2.jcc.*; // IBM Data Server Driver for JDBC
...
Properties properties = new Properties(); // Create a Properties object
properties.put("user", "db2adm"); // Set user ID for the connection
properties.put("password", "db2adm"); // Set password for the connection
properties.put("kerberosServerPrincipal", "sample/srvlsj.ibm.com@SRVLSJ.SJ.IBM.COM");
properties.put("securityMechanism", // Set the Kerberos server
```
new String("" +
    com.ibm.db2.jcc.DB2BaseDataSource.KERBEROS_SECURITY + ");
  // Set security mechanism to
  // Kerberos
String url = "jdbc:db2://mvs1.sj.ibm.com:5021/san_jose";
  // Set URL for the data source
Connection con = DriverManager.getConnection(url, properties);
  // Create the connection

For the DataSource interface: If you create and deploy the DataSource object, set
the Kerberos server and security mechanism by invoking the
DataSource.setKerberosServerPrincipal and DataSource.setSecurityMechanism
methods after you create the DataSource object. For example:

import java.sql.*; // JDBC base
import com.ibm.db2.jcc.*; // IBM Data Server Driver for JDBC
  // and SQLJ implementation of JDBC
...
com.ibm.db2.jcc.DB2SimpleDataSource db2ds =
    new com.ibm.db2.jcc.DB2SimpleDataSource();
  // Create the DataSource object
db2ds.setDriverType(4); // Set the driver type
db2ds.setDatabaseName("san_jose"); // Set the location
db2ds.setUser("db2adm"); // Set the user
db2ds.setPassword("db2adm"); // Set the password
db2ds.setServerName("mvs1.sj.ibm.com");
  // Set the server name
db2ds.setPortNumber(5021); // Set the port number
db2ds.setKerberosServerPrincipal("sample/srvlsj.ibm.com@SRVLSJ.SJ.IBM.COM");
  // Set the Kerberos server
db2ds.setSecurityMechanism(
    com.ibm.db2.jcc.DB2BaseDataSource.KERBEROS_SECURITY);
  // Set security mechanism to
  // Kerberos

Kerberos security with no user ID or password

For this case, the Kerberos default credentials cache must contain a ticket-granting
ticket (TGT) that lets you authenticate to the database server.

You need to set the kerberosServerPrincipal and securityMechanism properties.
Set the securityMechanism property to
com.ibm.db2.jcc.DB2BaseDataSource.KERBEROS_SECURITY (11).

For the DriverManager interface: Set the Kerberos server and security mechanism
by setting the kerberosServerPrincipal and securityMechanism properties in a
Properties object, and then invoking the form of the getConnection method that
includes the Properties object as a parameter. For example, use code like this to set
the Kerberos security mechanism without a user ID and password:

import java.sql.*; // JDBC base
import com.ibm.db2.jcc.*; // IBM Data Server Driver for JDBC
  // and SQLJ implementation of JDBC
...
Properties properties = new Properties(); // Create a Properties object
properties.put("kerberosServerPrincipal", "sample/srvlsj.ibm.com@SRVLSJ.SJ.IBM.COM");
  // Set the Kerberos server
properties.put("securityMechanism",
    new String("" +
        com.ibm.db2.jcc.DB2BaseDataSource.KERBEROS_SECURITY + ");
  // Set security mechanism to
  // Kerberos
String url = "jdbc:db2://mvs1.sj.ibm.com:5021/san_jose";
   // Set URL for the data source
Connection con = DriverManager.getConnection(url, properties);
   // Create the connection

For the DataSource interface: If you create and deploy the DataSource object, set
the Kerberos server and security mechanism by invoking the
DataSource.setKerberosServerPrincipal and DataSource.setSecurityMechanism
methods after you create the DataSource object. For example:

import java.sql.*; // JDBC base
import com.ibm.db2.jcc.*; // IBM Data Server Driver for JDBC
   // and SQLJ implementation of JDBC
...
DB2SimpleDataSource db2ds =
   new com.ibm.db2.jcc.DB2SimpleDataSource();
   // Create the DataSource object
db2ds.setDriverType(4); // Set the driver type
db2ds.setDatabaseName("san_jose"); // Set the location
db2ds.setServerName("mvs1.sj.ibm.com");
   // Set the server name
db2ds.setPortNumber(5021); // Set the port number
db2ds.setKerberosServerPrincipal("sample/srvlsj.ibm.com@SRVLSJ.SJ.IBM.COM");
   // Set the Kerberos server
db2ds.setSecurityMechanism(
   com.ibm.db2.jcc.DB2BaseDataSource.KERBEROS_SECURITY);
   // Set security mechanism to
   // Kerberos

Kerberos security with a delegated credential from another
principal

For this case, you authenticate to the database server using a delegated credential
that another principal passes to you.

You need to set the kerberosServerPrincipal, gssCredential, and
securityMechanism properties. Set the securityMechanism property to
com.ibm.db2.jcc.DB2BaseDataSource.KERBEROS_SECURITY (11).

For the DriverManager interface: Set the Kerberos server, delegated credential, and
security mechanism by setting the kerberosServerPrincipal, and
securityMechanism properties in a Properties object. Then invoke the form of the
getConnection method that includes the Properties object as a parameter. For
example, use code like this to set the Kerberos security mechanism without a user
ID and password:

import java.sql.*; // JDBC base
import com.ibm.db2.jcc.*; // IBM Data Server Driver for JDBC
   // and SQLJ implementation of JDBC
...
Properties properties = new Properties(); // Create a Properties object
properties.put("kerberosServerPrincipal", "sample/srvlsj.ibm.com@SRVLSJ.SJ.IBM.COM");
   // Set the Kerberos server
properties.put("gssCredential", delegatedCredential);
   // Set the delegated credential
properties.put("securityMechanism",
   new String("" +
   com.ibm.db2.jcc.DB2BaseDataSource.KERBEROS_SECURITY + "));
   // Set security mechanism to
   // Kerberos
String url = "jdbc:db2://mvs1.sj.ibm.com:5021/san_jose";
For the **DataSource interface**: If you create and deploy the DataSource object, set the Kerberos server, delegated credential, and security mechanism by invoking the DataSource.setKerberosServerPrincipal, DataSource.setGssCredential, and DataSource.setSecurityMechanism methods after you create the DataSource object. For example:

```java
DB2SimpleDataSource db2ds = new com.ibm.db2.jcc.DB2SimpleDataSource();
// Create the DataSource object
db2ds.setDriverType(4); // Set the driver type
db2ds.setDatabaseName("san_jose"); // Set the location
db2ds.setServerName("mvs1.sj.ibm.com"); // Set the server name
db2ds.setPortNumber(5021); // Set the port number
db2ds.setKerberosServerPrincipal(
  "sample/srvlsj.ibm.com@SRVLSJ.SJ.IBM.COM"); // Set the Kerberos server
db2ds.setGssCredential(delegatedCredential); // Set the delegated credential
db2ds.setSecurityMechanism(
  com.ibm.db2.jcc.DB2BaseDataSource.KERBEROS_SECURITY); // Set security mechanism to Kerberos
```

**IBM Data Server Driver for JDBC and SQLJ security plugin support**

You can create your own authentication mechanisms in the form of loadable libraries, or plugins, that DB2 for Linux, UNIX, and Windows loads to perform user authentication. To support development of security plugins in Java, the IBM Data Server Driver for JDBC and SQLJ provides security plugin support.

IBM Data Server Driver for JDBC and SQLJ security plugin support is available for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to DB2 for Linux, UNIX, and Windows servers only.

To use plugin security, you need a security plugin on the client and another plugin on the server.

The security plugins need to include the following things:

- A class that extends the com.ibm.db2.jcc.DB2JCCPlugin abstract class
  - The com.ibm.db2.jcc.DB2JCCPlugin abstract class is provided with the IBM Data Server Driver for JDBC and SQLJ.
- Within the com.ibm.db2.jcc.DB2JCCPlugin class, a com.ibm.db2.jcc.DB2JCCPlugin.getTicket method
  - This method retrieves a Kerberos ticket for a user and returns security context information in a byte array. The information in the byte array is used by the IBM Data Server Driver for JDBC and SQLJ to access the DB2 database server.
Implementations of several methods that are defined in the
org.ietf.jgss.GSSContext and org.ietf.jgss.GSSCredential interfaces
These method implementations need to follow the Generic Security Service
Application Program Interface, Version 2 (IETF RFC2743) and Generic Security
Service API Version 2: Java-Bindings (IETF RFC2853) specifications. The plugin
must implement and call the following methods:

**GSSContext.dispose**
Releases any system resources and cryptographic information that are
stored in a context object, and invalidates the context.

**GSSContext.getDelegState**
Determines whether credential delegation is enabled on a context.

**GSSContext.getMutualAuthState**
Determines whether mutual authentication is enabled on the context.

**GSSContext.initSecContext**
Starts the context creation phase, and processes any tokens that are
generated by the peer’s acceptSecContext method.

**GSSContext.requestCredDeleg**
Requests that the credentials of the initiator are delegated to the acceptor
when a context is established.

**GSSContext.requestMutualAuth**
Requests mutual authentication when a context is established.

**GSSCredential.dispose**
Releases any sensitive information that the GSSCredential object contains.

Two Java plugin samples are provided in sqllib/samples/java/jdbc to help you
write Java security plugins:

**JCCSimpleGSSPlugin.java**
An implementation of a GSS-API plugin for the server, which performs user ID
and password checking. This sample is a Java version of the C language
sample program gssapi_simple.c.

**JCCKerberosPlugin.java**
A Kerberos security plugin for the client. This sample is a Java version of the C
language sample program IBMk5.c.

When an application program obtains a connection using JDBC plugin security, it
needs to set the following Connection or DataSource properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.user</td>
<td>The user ID under which the Connection is to be obtained</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.password</td>
<td>The password for the user ID</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.securityMechanism</td>
<td>com.ibm.db2.jcc.DB2BaseDataSource.PLUGIN_SECURITY</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.pluginName</td>
<td>The name of the plugin module for a server-side security plugin</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.plugin</td>
<td>The plugin object for a client-side security plugin</td>
</tr>
</tbody>
</table>
Example: The following code sets the properties for a connection that uses GSS-API plugin security. The connection uses the JCCSimpleGSSPlugin sample plugin on the client side, and the gssapi_simple sample plugin on the server side.

```java
java.util.Properties properties = new java.util.Properties();
properties.put("user", "db2admin");
properties.put("password", "admin$db2");
properties.put("pluginName", "gssapi_simple");
properties.put("securityMechanism",
    new String("+com.ibm.db2.jcc.DB2BaseDataSource.PLUGIN_SECURITY="));
com.ibm.db2.jcc.DB2JCCPlugin plugin =
    new com.ibm.db2.jcc.samples.plugins.JCCSimpleGSSplugin();
properties.put("plugin", plugin);
Connection con = java.sql.DriverManager.getConnection(url,
    properties);
```

**Use of alternative security mechanisms with the IBM Data Server Driver for JDBC and SQLJ**

If you are using IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, and you set the retryWithAlternativeSecurityMechanism to com.ibm.db2.jcc.DB2BaseDataSource.YES (1), and the original security mechanism for a connection fails, the driver retries the connection with the most secure alternative security mechanism.

The following table lists the IBM Data Server Driver for JDBC and SQLJ security mechanisms, and the alternative security mechanisms that are used when the original connection has an authorization failure.

**Table 34. Original and alternative IBM Data Server Driver for JDBC and SQLJ security mechanisms**

<table>
<thead>
<tr>
<th>Server authentication type</th>
<th>IBM Data Server Driver for JDBC and SQLJ authentication type for the original connection</th>
<th>IBM Data Server Driver for JDBC and SQLJ authentication type for retrying the connection</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT</td>
<td>• CLEAR_TEXT_PASSWORD_SECURITY</td>
<td>USER_ONLY_SECURITY</td>

</table>

IBM Data Server Driver for JDBC and SQLJ trusted context support

The IBM Data Server Driver for JDBC and SQLJ provides methods that allow you to establish and use trusted connections in Java programs.

Trusted connections are supported for:

- IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to:
  - DB2 for Linux, UNIX, and Windows Version 9.5 or later
  - DB2 for z/OS Version 9.1 or later
  - IBM Informix Version 11.70 or later
- IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS Version 9.1 or later

A three-tiered application model consists of a database server, a middleware server such as WebSphere Application Server, and end users. With this model, the middleware server is responsible for accessing the database server on behalf of end users. Trusted context support ensures that an end user’s database identity and database privileges are used when the middleware server performs any database requests on behalf of that end user.

A trusted context is an object that the database administrator defines that contains a system authorization ID and a set of trust attributes. Currently, for DB2 database servers, a database connection is the only type of context that is supported. The trust attributes identify a set of characteristics of a connection that are required for...
the connection to be considered a trusted connection. The relationship between a
database connection and a trusted context is established when the connection to
the database server is first created, and that relationship remains for the life of the
database connection.

After a trusted context is defined, and an initial trusted connection to the data
server is made, the middleware server can use that database connection under a
different user without reauthenticating the new user at the database server.

To avoid vulnerability to security breaches, an application server that uses these
trusted methods should not use untrusted connection methods.

The DB2ConnectionPoolDataSource class provides several versions of the
getDB2TrustedPooledConnection method, and the DB2XADataSource class
provides several versions of the getDB2TrustedXAConnection method, which allow
an application server to establish the initial trusted connection. You choose a
method based on the types of connection properties that you pass and whether
you use Kerberos security. When an application server calls one of these methods,
the IBM Data Server Driver for JDBC and SQLJ returns an Object[] array with two
elements:
• The first element contains a connection instance for the initial connection.
• The second element contains a unique cookie for the connection instance. The
  cookie is generated by the JDBC driver and is used for authentication during
  subsequent connection reuse.

The DB2PooledConnection class provides several versions of the getDB2Connection
method, and the DB2Connection class provides several versions of the
reuseDB2Connection method, which allow an application server to reuse an
existing trusted connection on behalf of a new user. The application server uses the
method to pass the following items to the new user:
• The cookie from the initial connection
• New connection properties for the reused connection

The JDBC driver checks that the supplied cookie matches the cookie of the
underlying trusted physical connection, to ensure that the connection request
originates from the application server that established the trusted physical
connection. If the cookies match, the connection becomes available for immediate
use by this new user, with the new properties.

**Example:** Obtain the initial trusted connection:
```java
// Create a DB2ConnectionPoolDataSource instance
com.ibm.db2.jcc.DB2ConnectionPoolDataSource dataSource =
new com.ibm.db2.jcc.DB2ConnectionPoolDataSource();
// Set properties for this instance
dataSource.setDatabaseName("STLEC1");
dataSource.setServerName("v7ec167.svl.ibm.com");
dataSource.setDriverType(4);
dataSource.setPortNumber(446);
java.util.Properties properties = new java.util.Properties();
// Set other properties using
// properties.put("property", "value");
// Supply the user ID and password for the connection
String user = "user";
String password = "password";
// Call getDB2TrustedPooledConnection to get the trusted connection
// instance and the cookie for the connection
Object[] objects = dataSource.getDB2TrustedPooledConnection( user, password, properties);
```
Example: Reuse an existing trusted connection:

```java
// The first item that was obtained from the previous getDB2TrustedPooledConnection
// call is a connection object. Cast it to a PooledConnection object.
javax.sql.PooledConnection pooledCon =
    (javax.sql.PooledConnection)objects[0];
properties = new java.util.Properties();
// Set new properties for the reused object using
// properties.put("property", "value");
// The second item that was obtained from the previous getDB2TrustedPooledConnection
// call is the cookie for the connection. Cast it as a byte array.
byte[] cookie = ((byte[]))(objects[1]);
// Supply the user ID for the new connection.
String newUser = "newuser";
// Supply the name of a mapping service that maps a workstation user
// ID to a z/OS RACF ID
String userRegistry = "registry";
// Do not supply any security token data to be traced.
byte[] userSecTk = null;
// Do not supply a previous user ID.
String originalUser = null;
// Call getDB2Connection to get the connection object for the new
// user.
java.sql.Connection con =
    ((com.ibm.db2.jcc.DB2PooledConnection)pooledCon).getDB2Connection(
        cookie,newUser,password,userRegistry,userSecTk,originalUser,properties);
```

IBM Data Server Driver for JDBC and SQLJ support for SSL

The IBM Data Server Driver for JDBC and SQLJ provides support for the Secure Sockets Layer (SSL) through the Java Secure Socket Extension (JSSE).

You can use SSL support in your Java applications if you use IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to DB2 for z/OS Version 9 or later, to DB2 for Linux, UNIX, and Windows Version 9.1, Fix Pack 2 or later, or to IBM Informix Version 11.50 or later.

If you use SSL support for a connection to a DB2 for z/OS data server, and the z/OS version is V1.8, V1.9, or V1.10, the appropriate PTF for APAR PK72201 must be applied to Communication Server for z/OS IP Services.

Connections to all supported data servers can use server authentication. For server authentication, the server sends a certificate to the client, and the client confirms the identity of the server. Connections to DB2 for z/OS data servers can also use client authentication. For client authentication, the client sends a certificate to the server, and the server confirms the identity of the client. Client authentication can be used with SSL encryption or without SSL encryption.

To use SSL connections, you need to:
- Configure connections to the data server to use SSL.
- Configure your Java Runtime Environment to use SSL.
Configuring connections under the IBM Data Server Driver for JDBC and SQLJ to use SSL

To configure database connections under the IBM Data Server Driver for JDBC and SQLJ to use SSL, you need to set the DB2BaseDataSource.sslConnection property to true.

Before a connection to a data source can use SSL, the port to which the application connects must be configured in the database server as the SSL listener port.

1. Set DB2BaseDataSource.sslConnection on a Connection or DataSource instance. Alternatively, you can set the db2.jcc.override.sslConnection or db2.jcc.sslConnection configuration parameter on the driver instance.

2. Optional: Set DB2BaseDataSource.sslTrustStoreLocation on a Connection or DataSource instance to identify the location of the truststore. Alternatively, you can set the db2.jcc.override.sslTrustStoreLocation or db2.jcc.sslTrustStoreLocation configuration parameter on the driver instance. Setting the sslTrustStoreLocation property is an alternative to setting the Java javax.net.ssl.trustStore property. If you set DB2BaseDataSource.sslTrustStoreLocation, javax.net.ssl.trustStore is not used.

3. Optional: Set DB2BaseDataSource.sslTrustStorePassword on a Connection or DataSource instance to identify the truststore password. Alternatively, you can set the db2.jcc.override.sslTrustStorePassword or db2.jcc.sslTrustStorePassword configuration parameter on the driver instance. Setting the sslTrustStorePassword property is an alternative to setting the Java javax.net.ssl.trustStorePassword property. If you set DB2BaseDataSource.sslTrustStorePassword, javax.net.ssl.trustStorePassword is not used.

The following example demonstrates how to set the sslConnection property on a Connection instance:

```java
java.util.Properties properties = new java.util.Properties();
properties.put("user", "xxx");
properties.put("password", "yyy");
properties.put("sslConnection", "true");
java.sql.Connection con =
    java.sql.DriverManager.getConnection(url, properties);
```
Configuring the Java Runtime Environment to use SSL

Before you can use Secure Sockets Layer (SSL) connections in your JDBC and SQLJ applications, you need to configure the Java Runtime Environment to use SSL. An example procedure is provided. However, the procedure might be different depending on the Java Runtime Environment that you use.

Before you can configure your Java Runtime Environment for SSL, you need to satisfy the following prerequisites:

- The Java Runtime Environment must include a Java security provider. The IBM JSSE provider or the SunJSSE provider must be installed. The IBM JSSE provider is automatically installed with the IBM SDK for Java.

  **Restriction:** You can only use the SunJSSE provider only with an Oracle Java Runtime Environment. The SunJSSE provider does not work with an IBM Java Runtime Environment.

- SSL support must be configured on the database server.

To configure your Java Runtime Environment to use SSL, follow these steps:

1. Import a certificate from the database server to a Java truststore on the client.
   - Use the Java keytool utility to import the certificate into the truststore.
   - For example, suppose that the server certificate is stored in a file named jcc.cacert. Issue the following keytool utility statement to read the certificate from file jcc.cacert, and store it in a truststore named cacerts.
     
     ```
     keytool -import -file jcc.cacert -keystore cacerts
     ```
   - 2. Configure the Java Runtime Environment for the Java security providers by adding entries to the java.security file.
      - The format of a security provider entry is:
        
        ```
        security.provider.n=provider-package-name
        ```
      - A provider with a lower value of \( n \) takes precedence over a provider with a higher value of \( n \).
      - The Java security provider entries that you add depend on whether you use the IBM JSSE provider or the SunJSSE provider.
        - If you use the SunJSSE provider, add entries for the Oracle security providers to your java.security file.
        - If you use the IBM JSSE provider, use one of the following methods:
          - **Use the IBMJSSE2 provider (supported for the IBM SDK for Java 1.4.2 and later):**

            **Recommendation:** Use the IBMJSSE2 provider, and use it in FIPS mode.

            - If you do not need to operate in FIPS-compliant mode:
              - For the IBM SDK for Java 1.4.2, add an entry for the IBMJSSE2Provider to the java.security file. Ensure that an entry for the IBMJCE provider is in the java.security file. The java.security file that is shipped with the IBM SDK for Java contains an entry for entries for IBMJCE.
              - For later versions of the IBM SDK for Java, ensure that entries for the IBMJSSE2Provider and the IBMJCE provider are in the java.security file. The java.security file that is shipped with the IBM SDK for Java contains entries for those providers.
            - If you need to operate in FIPS-compliant mode:
- Add an entry for the IBMJCEFIPS provider to your java.security file before the entry for the IBMJCE provider. Do not remove the entry for the IBMJCE provider.
- Enable FIPS mode in the IBMJSSE2 provider. See step 3.

Use the IBMJSSE provider (supported for the IBM SDK for Java 1.4.2 only):
- If you do not need to operate in FIPS-compliant mode, ensure that entries for the IBMJSSEProvider and the IBMJCE provider are in the java.security file. The java.security file that is shipped with the IBM SDK for Java contains entries for those providers.
- If you need to operate in FIPS-compliant mode, add entries for the FIPS-approved provider IBMJSEFIPSProvider and the IBMJCEFIPS provider to your java.security file, before the entry for the IBMJCE provider.

Restriction: If you use the IBMJSSE provider on the Solaris operating system, you need to include an entry for the SunJSSE provider before entries for the IBMJCE, IBMJCEFIPS, IBMJSSE, or IBMJSSE2 providers.

Example: Use a java.security file similar to this one if you need to run in FIPS-compliant mode, and you enable FIPS mode in the IBMJSSE2 provider:

```
# Set the Java security providers
security.provider.1=com.ibm.jsse2.IBMJSSEProvider2
security.provider.2=com.ibm.crypto.fips.provider.IBMJCEFIPS
security.provider.3=com.ibm.crypto.provider.IBMJCE
security.provider.4=com.ibm.security.jgss.IBMJGSSProvider
security.provider.5=com.ibm.security.cert.IBCertPath
security.provider.6=com.ibm.security.sasl.IMBSASL
```

Example: Use a java.security file similar to this one if you need to run in FIPS-compliant mode, and you use the IBMJSSE provider:

```
# Set the Java security providers
security.provider.1=com.ibm.fips.jsse.IBMJSSEFIPSProvider
security.provider.2=com.ibm.crypto.fips.provider.IBMJCEFIPS
security.provider.3=com.ibm.crypto.provider.IBMJCE
security.provider.4=com.ibm.security.jgss.IBMJGSSProvider
security.provider.5=com.ibm.security.cert.IBCertPath
security.provider.6=com.ibm.security.sasl.IMBSASL
```

Example: Use a java.security file similar to this one if you use the SunJSSE provider:

```
# Set the Java security providers
security.provider.1=sun.security.provider.Sun
security.provider.2=com.sun.rsajca.Provider
security.provider.3=com.sun.crypto.provider.SunJCE
security.provider.4=com.sun.net.ssl.internal.ssl.Provider
```

3. If you plan to use the IBM Data Server Driver for JDBC and SQLJ in FIPS-compliant mode, you need to set the com.ibm.jsse2.JSSEFIPS Java system property:

```
com.ibm.jsse2.JSSEFIPS=true
```

Restriction: Non-FIPS-mode JSSE applications cannot run in a JVM that is in FIPS mode.

Restriction: When the IBMJSSE2 provider runs in FIPS mode, it cannot use hardware cryptography.

4. Configure the Java Runtime Environment for the SSL socket factory providers by adding entries to the java.security file. This step is not necessary if you are using the SunJSSE provider and the Java Runtime Environment, 7 or later.
The format of SSL socket factory provider entries are:

ssl.SocketFactory.provider=provider-package-name
ssl.ServerSocketFactory.provider=provider-package-name

Specify the SSL socket factory provider for the Java security provider that you are using.

**Example:** Include SSL socket factory provider entries like these in the java.security file when you enable FIPS mode in the IBMJSSE2 provider:

```
# Set the SSL socket factory provider
ssl.SocketFactory.provider=com.ibm.jsse2.SSLSocketFactoryImpl
ssl.ServerSocketFactory.provider=com.ibm.jsse2.SSLServerSocketFactoryImpl
```

**Example:** Include SSL socket factory provider entries like these in the java.security file when you enable FIPS mode in the IBMJSSE provider:

```
# Set the SSL socket factory provider
ssl.SocketFactory.provider=com.ibm.fips.jsse.JSSESocketFactory
ssl.ServerSocketFactory.provider=com.ibm.fips.jsse.JSServerSocketFactory
```

**Example:** Include SSL socket factory provider entries like these when you use the SunJSSE provider, and the Java Runtime Environment, 6 or earlier:

```
# Set the SSL socket factory provider
ssl.SocketFactory.provider=com.sun.net.ssl.internal.ssl.SSLSocketFactoryImpl
ssl.ServerSocketFactory.provider=com.sun.net.ssl.internal.ssl.SSLServerSocketFactoryImpl
```

5. Configure Java system properties to use the truststore.

To do that, set the following Java system properties:

- **javax.net.ssl.trustStore**
  - Specifies the name of the truststore that you specified with the -keystore parameter in the keytool utility in step 1 on page 221
  - If the IBM Data Server Driver for JDBC and SQLJ property DB2BaseDataSource.sslTrustStoreLocation, db2.jcc.override.sslTrustStoreLocation, or db2.jcc.sslTrustStoreLocation is set, its value overrides the javax.net.ssl.trustStore property value.

- **javax.net.ssl.trustStorePassword (optional)**
  - Specifies the password for the truststore. You do not need to set a truststore password. However, if you do not set the password, you cannot protect the integrity of the truststore.
  - If the IBM Data Server Driver for JDBC and SQLJ property DB2BaseDataSource.sslTrustStorePassword, db2.jcc.override.sslTrustStorePassword, or db2.jcc.sslTrustStorePassword is set, its value overrides the javax.net.ssl.trustStore property value.

**Example:** One way that you can set Java system properties is to specify them as the arguments of the -D option when you run a Java application. Suppose that you want to run a Java application named MySSL.java, which accesses a data source using an SSL connection. You have defined a truststore named cacerts. The following command sets the truststore name when you run the application.

```
java -Djavax.net.ssl.trustStore=cacerts MySSL
```

---

**IBM Data Server Driver for JDBC and SQLJ support for certificate authentication**

The IBM Data Server Driver for JDBC and SQLJ provides support for client support for certificate authentication for connections to DB2 for z/OS Version 10 or later data servers.
Client certificate authentication security on a DB2 for z/OS data server supports the use of digital certificates for mutual authentication by requesters and servers. By using z/OS digital certificates, the Secure Socket Layer (SSL) protocol supports server and client authentication during the handshake phase. A data server can validate the certificates of a client at the server, which prevents the client from obtaining a secure connection without an installation-approved certificate. The authentication of the remote client’s digital certificate is performed by Application Transparent Transport Layer Security (AT-TLS) that is provided with the z/OS Communications Server TCP/IP stack.

The IBM Data Server Driver for JDBC and SQLJ supports certificate authentication for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity only.

You enable IBM Data Server Driver for JDBC and SQLJ certificate authentication by specifying DB2BaseDataSource.TLS_CLIENT_CERTIFICATE_SECURITY as the value of the securityMechanism Connection or DataSource property. If the target data server supports client certificate authentication, and the mutual authentication succeeds, the driver passes a valid Connection object to the application. If the data server does not support client certificate authentication, or the connection was not authenticated using AT-TLS and SSL, the driver throws DisconnectException.

You can use certificate authentication with or without a user ID or a password. If the application does not provide a user ID or password, authentication is performed at the network layer only. If a user ID or password is provided, authentication is performed at the network layer and the data server layer.

To use SSL encryption with certificate authentication, you can set the sslConnection Connection or DataSource property or the db2.jcc.override.sslConnection or db2.jcc.sslConnection configuration property to true.

The following example demonstrates how to enable certificate authentication and user ID and password security in a JDBC application.

```java
com.ibm.db2.jcc.DB2SimpleDataSource dataSource = new
    com.ibm.db2.jcc.DB2SimpleDataSource();
// Specify certificate authentication
dataSource.setSecurityMechanism
    (com.ibm.db2.jcc.DB2BaseDataSource.TLS_CLIENT_CERTIFICATE_SECURITY);
// Set a user ID and password to be passed to the data server
((com.ibm.db2.jcc.DB2BaseDataSource)dataSource).setUser("sysadm");
dataSource.setPassword("password");
// Identify the SSL truststore, keystore and their passwords
System.setProperty("javax.net.ssl.trustStore","c:/temp/SSL/cacerts");
System.setProperty("javax.net.ssl.trustStorePassword","password");
System.setProperty("javax.net.ssl.keyStore","c:/temp/SSL/myKS");
System.setProperty("javax.net.ssl.keyStorePassword","123456");
...
// Create a connection
con = dataSource.getConnection();
```

Security for preparing SQLJ applications with the IBM Data Server Driver for JDBC and SQLJ

You can provide security during SQLJ application preparation by allowing users to customize applications only and limiting access to a specific set of tables during customization. If the target data server is DB2 for z/OS, you can also provide security by allowing customers to prepare but not execute applications.
Allowing users to customize only

You can use one of the following techniques to allow a set of users to customize SQLJ applications, but not to bind or run those applications:

- **Create a database system for customization only (recommended solution):**
  Follow these steps:
  1. Create a new database manager instance. This is the customization-only system.
  2. On the customization-only system, define all the tables and views that are accessed by the SQLJ applications. The table or view definitions must be the same as the definitions on the database manager instance where the application will be bound and will run (the bind-and-run system). Executing the DESCRIBE statement on the tables or views must give the same results on the customization-only system and the bind-and-run system.
  3. On the customization-only system, grant the necessary table or view privileges to users who will customize SQLJ applications.
  4. On the customization-only system, users run the sqlj command with the -compile=true option to create Java byte codes and serialized profiles for their programs. Then they run the db2sqljcustomize command with the -automaticbind NO option to create customized serialized profiles.
  5. Copy the java byte code files and customized serialized profiles to the bind-and-run system.
  6. A user with authority to bind packages on the bind-and-run system runs the db2sqljbind command on the customized serialized profiles that were copied from the customization-only system.

- **Use a stored procedure to do customization:** Write a Java stored procedure that customizes serialized profiles and binds packages for SQLJ applications on behalf of the end user. This Java stored procedure needs to use a JDBC driver package that was bound with one of the DYNAMICRULES options that causes dynamic SQL to be performed under a different user ID from the end user's authorization ID. For example, you might use the DYNAMICRULES option DEFINEBIND or DEFINERUN to execute dynamic SQL under the authorization ID of the creator of the Java stored procedure. You need to grant EXECUTE authority on the stored procedure to users who need to do SQLJ customization. The stored does the following things:
  1. Receives the compiled SQLJ program and serialized profiles in BLOB input parameters
  2. Copies the input parameters to its file system
  3. Runs db2sqljcustomize to customize the serialized profiles and bind the packages for the SQLJ program
  4. Returns the customized serialized profiles in output parameters

- **Use a stand-alone program to do customization:** This technique involves writing a program that performs the same steps as a Java stored procedure that customizes serialized profiles and binds packages for SQLJ applications on behalf of the end user. However, instead of running the program as a stored procedure, you run the program as a stand-alone program under a library server.

Allowing users to customize and bind only

If the target data server is DB2 for z/OS Version 10 or later, you can allow users to customize and bind SQLJ applications, but not to execute the SQL statements in
them, by granting those users the EXPLAIN privilege.

**Restricting table access during customization**

When you customize serialized profiles, you should do online checking, to give the application program information about the data types and lengths of table columns that the program accesses. By default, customization includes online checking.

Online checking requires that the user who customizes a serialized profile has authorization to execute PREPARE and DESCRIBE statements against SQL statements in the SQLJ program. That authorization includes the SELECT privilege on tables and views that are accessed by the SQL statements. If SQL statements contain unqualified table names, the qualifier that is used during online checking is the value of the `db2sqljcustomize -qualifier` parameter. Therefore, for online checking of tables and views with unqualified names in an SQLJ application, you can grant the SELECT privilege only on tables and views with a qualifier that matches the value of the `-qualifier` parameter.
Chapter 6. Building Java database applications

You can build JDBC and SQLJ database applications manually. Alternatively, you can use a Java makefile to build JDBC applications, and use the bldsqlj build file that is shipped with DB2 for Linux, UNIX, and Windows to build SQLJ applications.

Building JDBC applets

You can use a Java makefile or manually execute the javac command to build JDBC applications.

The following steps demonstrate how to build and run the Applt.java sample JDBC applet.

1. Compile Applt.java to produce the file Applt.class with this command:
   
   javac Applt.java

2. Ensure that your working directory is accessible by your web browser, or by your Java applet viewer, if you are using it. If your directory is not accessible, copy the following files into a directory that is accessible:
   - Applt.html
   - Applt.class

3. Copy sqlib\java\db2jcc.jar on Windows or sqlib/java/db2jcc.jar on UNIX, into the same directory as Applt.class and Applt.html.
   If you are using any JDBC 4.0 or later functions, copy db2jcc4.jar instead of db2jcc.jar.

4. If you are using the IBM Data Server Driver for JDBC and SQLJ, connect with that driver by modifying the Applt.html file according to the instructions in the file. For the TCP/IP port number, you should use the database port number 50000.

5. To run this applet, either ensure that a web server is installed and running on your DB2 machine (server or client), or you can use the applet viewer that comes with the SDK for Java by entering the following command in the working directory of your client machine:
   
   appletviewer Applt.html

Building JDBC applications

You can use a Java makefile or manually execute the javac command to build JDBC applications.
The following steps demonstrate how to build and run the DbInfo sample JDBC application.

1. Compile DbInfo.java to produce the file DbInfo.class with this command:
  javac DbInfo.java

2. If you are running a Java application on UNIX in a 64-bit DB2 instance but the software development kit for Java is 32-bit, you need to change the DB2 library path before running the application. For example, on AIX:
   • If using bash or Korn shell:
     export LIBPATH=$HOME/sqllib/lib32
   • If using C shell:
     setenv LIBPATH $HOME/sqllib/lib32

3. Run the Java interpreter on the application with this command:
   java DbInfo

Related tasks:
“Building SQLJ applications” on page 230
“Building JDBC applets” on page 227

[JDBC samples]

---

**Building JDBC routines**

You can use a Java makefile or the javac command to build JDBC routines. After you build those routines, you need to catalog them.

The following steps demonstrate how to build and run these routines:
• The SpServer sample JDBC stored procedure
• The UDFsrv sample user-defined function, which has no SQL statements
• The UDFsqlsv sample user-defined function, which has SQL statements
• To build and run the SpServer.java stored procedure on the server, from the command line:
  1. Compile SpServer.java to produce the file SpServer.class with this command:
     javac SpServer.java
  2. Copy SpServer.class to the sqllib\function directory on Windows operating systems, or to the sqllib/function directory on UNIX.
  3. Catalog the routines by running the spcat script on the server. The spcat script connects to the sample database, uncatalogs the routines if they were previously cataloged by calling SpDrop.db2, then catalogs them by calling SpCreate.db2, and finally disconnects from the database. You can also run the SpDrop.db2 and SpCreate.db2 scripts individually.
  4. Stop and restart the database to allow the new class file to be recognized. If necessary, set the file mode for the class file to "read" so it is readable by the fenced user.
  5. Compile and run the SpClient client application to access the stored procedure class.
• To build and run the UDFsrv.java user-defined function program (user-defined function with no SQL statements) on the server, from the command line:
  1. Compile UDFsrv.java to produce the file UDFsrv.class with this command:
     javac UDFsrv.java
2. Copy UDFsrv.class to the sqllib\function directory on Windows operating systems, or to the sqllib/function directory on UNIX.

3. Compile and run a client program that calls UDFsrv.

   To access the UDFsrv library, you can use the UDFcli.java JDBC application, or the UDFcli.sqlj SQLJ client application. Both versions of the client program contain the CREATE FUNCTION SQL statement that you use to register the user-defined functions with the database, and also contain SQL statements that use the user-defined functions.

   - To build and run the UDFsqlsv.java user-defined function program (user-defined function with SQL statements) on the server, from the command line:

     1. Compile UDFsqlsv.java to produce the file UDFsqlsv.class with this command:

        javac UDFsqlsv.java

     2. Copy UDFsqlsv.class to the sqllib\function directory on Windows operating systems, or to the sqllib/function directory on UNIX.

     3. Compile and run a client program that calls UDFsqlsv.

        To access the UDFsqlsv library, you can use the UDFsqlcl.java JDBC application. The client program contains the CREATE FUNCTION SQL statement that you use to register the user-defined functions with the database, and also contains SQL statements that use the user-defined functions.

---

### Building SQLJ applets

You can use a Java makefile or the bldsqlj build file to build SQLJ applets.

The following steps demonstrate how to build and run the Applt sample SQLJ applet. These steps use the build file, bldsqlj (UNIX), or bldsqlj.bat (Windows), which contains commands to build either an SQLJ applet or application.

The build file takes up to six parameters: $1, $2, $3, $4, $5, and $6 on UNIX, and %1, %2, %3, %4, %5, and %6 on Windows. The first parameter specifies the name of your program. The second parameter specifies the user ID for the database instance, the third parameter specifies the password. The fourth parameter specifies the server name. The fifth parameter specifies the port number. And the sixth parameter specifies the database name. For all but the first parameter, program name, default values can be used. See the build file for details about using default parameter values.

1. Build the applet with this command:

   bldsqlj Applt <userid> <password> <server_name> <port_number> <db_name>

2. Ensure that your working directory is accessible by your web browser, or by your Java applet viewer, if you are using it. If your directory is not accessible, copy the following files into a directory that is accessible:

   - Applt.html
   - Applt.class
   - Applt_Cursor1.class
   - Applt_Cursor2.class
   - Applt_SJProfileKeys.class
   - Applt_SJProfile0.ser

3. Copy sqllib\java\db2jcc.jar on Windows or sqllib\java\db2jcc.jar on UNIX, into the same directory as Applt.class and Applt.html.
   
   If you are using any JDBC 4.0 or later functions, copy db2jcc4.jar instead of db2jcc.jar.
4. If you are using the IBM Data Server Driver for JDBC and SQLJ, connect with that driver by modifying the Applt.html file according to the instructions in the file. For the TCP/IP port number, you should use the database port number 50000.

5. To run this applet, either ensure that a web server is installed and running on your DB2 machine (server or client), or you can use the applet viewer that comes with the SDK for Java by entering the following command in the working directory of your client machine:
   ```
   appletviewer Applt.html
   ```

**Building SQLJ applications**

You can use a Java `makefile` or the `bldsqlj` build file to build SQLJ applications.

The following steps demonstrate how to build and run the TbMod sample SQLJ application. These steps use the build file, `bldsqlj` (UNIX), or `bldsqlj.bat` (Windows), which contains commands to build either an SQLJ applet or application.

The build file takes up to six parameters: $1, $2, $3, $4, $5, and $6 on UNIX, and %1, %2, %3, %4, %5, and %6 on Windows. The first parameter specifies the name of your program. The second parameter specifies the user ID for the database instance, the third parameter specifies the password. The fourth parameter specifies the server name. The fifth parameter specifies the port number. And the sixth parameter specifies the database name. For all but the first parameter, program name, default values can be used. See the build file for details about using default parameter values.

1. Build the application with this command:
   ```
   bldsqlj TbMod <userid> <password> <server_name> <port_number> <db_name>
   ```

2. If you are running a Java application on UNIX in a 64-bit DB2 instance but the software development kit for Java is 32-bit, you need to change the DB2 library path before running the application. For example, on AIX:
   - If using bash or Korn shell:
     ```
     export LIBPATH=$HOME/sqllib/lib32
     ```
   - If using C shell:
     ```
     setenv LIBPATH $HOME/sqllib/lib32
     ```

3. Run the Java interpreter on the application with this command:
   ```
   java TbMod
   ```
Java applet considerations

DB2 databases can be accessed by using Java applets.

Keep the following points in mind when using them:

- For a larger JDBC or SQLJ applet that consists of several Java classes, you might choose to package all its classes in a single JAR file. For an SQLJ applet, you would also have to package its serialized profiles along with its classes. If you choose to do this, add your JAR file into the archive parameter in the "applet" tag. For details, see the documentation for your software development kit for Java.

For SQLJ applets, some browsers do not yet have support for loading a serialized object from a resource file associated with the applet. For example, you will get the following error message when trying to load the supplied sample applet Applt in those browsers:

```
java.lang.ClassNotFoundException: Applt_SJProfile0
```

As a workaround, there is a utility which converts a serialized profile into a profile stored in Java class format. The utility is a Java class called sqlj.runtime.profile.util.SerProfileToClass. It takes a serialized profile resource file as input and produces a Java class containing the profile as output. Your profile can be converted using one of the following commands:

```
profconv Applt_SJProfile0.ser
```

or

```
java sqlj.runtime.profile.util.SerProfileToClass Applt_SJProfile0.ser
```

The class Applt_SJProfile0.class is created as a result. Replace all profiles in .ser format used by the applet with profiles in .class format, and the problem should go away.

- You can place the file db2jcc.jar into a directory that is shared by several applets that might be loaded from your Web site. db2jcc.jar is for applets using the IBM Data Server Driver for JDBC and SQLJ or for any SQLJ applet. This file is in the sql11ib\java directory on Windows operating systems, and in the sql11ib/java directory on UNIX. You might need to add a codebase parameter into the "applet" tag in the HTML file to identify the directory. For details, see the documentation for your software development kit for Java.

If you are using any JDBC 4.0 or later functions, copy db2jcc4.jar instead of db2jcc.jar.

- The JDBC applet server (listener), db2jd, contains signal handling to make it more robust. As a result, you cannot use the CTRL-C key sequence to terminate db2jd. Therefore, the only way to terminate the listener is to kill the process by using kill -9 (for UNIX) or the Task Manager (for Windows).

SQLJ application and applet options for UNIX

The b1dsq1j build script builds SQLJ applications and applets on UNIX operating systems. b1dsq1j specifies a set of SQLJ translator and customizer options.

Recommendation: Use the same SQLJ translator and customizer options that b1dsq1j uses when you build your SQLJ applications and applets on UNIX platforms.

The options that b1dsq1j includes are:

sqlj The SQLJ translator (also compiles the program).

"${profilename}.sqlj"
   The SQLJ source file. The profilename=${1%.sqlj} command removes the extension if it was included in the input file name, so when the extension is added back again, it is not duplicated.

db2sqljcustomize
   The SQLJ profile customizer.

-url Specifies a JDBC URL for establishing a database connection, such as jdbc:db2://servername:50000/sample.

-user Specifies a user ID.

-password Specifies a password.

"${profilename}_SJProfile0"
   Specifies a serialized profile for the program.

Related tasks:
“Building SQLJ applications” on page 230
“Building SQLJ applets” on page 229

Related reference:
SQLJ routine options for UNIX

SQLJ application and applet options for Windows

The b1dsq1j.bat batch file builds SQLJ applications and applets on Windows operating systems. b1dsq1j.bat specifies a set of SQLJ translator and customizer options.

Recommendation: Use the same SQLJ translator and customizer options that b1dsq1j.bat uses when you build your SQLJ applications and applets on Windows operating systems.

The options that b1dsq1j.bat includes are:

sqlj The SQLJ translator (also compiles the program).

%1.sqlj
   The SQLJ source file.
**db2sqljcustomize**

The SQLJ profile customizer.

- **-url**
  Specifies a JDBC URL for establishing a database connection, such as
  `jdbc:db2://servername:50000/sample`.

- **-user**
  Specifies a user ID.

- **-password**
  Specifies a password.

%1_SJProfile0

  Specifies a serialized profile for the program.

- [SQLJ routine options for Windows](#)

---

**Building SQL routines**

You can use a Java makefile or the `bldsqljs` build file to build SQLJ routines. After you build those routines, you need to catalog them.

The following steps demonstrate how to build and run the `SpServer` sample SQLJ stored procedure. These steps use the build file, `bldsqljs` (UNIX), or `bldsqljs.bat` (Windows), which contains commands to build either an SQLJ applet or application.

The build file takes up to six parameters: $1, $2, $3, $4, $5, and $6 on UNIX, and %1, %2, %3, %4, %5, and %6 on Windows. The first parameter specifies the name of your program. The second parameter specifies the user ID for the database instance, the third parameter specifies the password. The fourth parameter specifies the server name. The fifth parameter specifies the port number. And the sixth parameter specifies the database name. For all but the first parameter, program name, default values can be used. See the build file for details about using default parameter values.

1. Build the stored procedure application with this command:
   ```
   bldsqljs SpServer <userid> <password> <server_name> <port_number> <db_name>
   ```

2. Catalog the stored procedure with this command:
   ```
   spcat
   ```

   This script connects to the sample database, uncatalogs the routines if they were previously cataloged by calling `SpDrop.db2`, then catalogs them by calling `SpCreate.db2`, and finally disconnects from the database. You can also run the `SpDrop.db2` and `SpCreate.db2` scripts individually.

3. Stop and restart the database to allow the new class file to be recognized. If necessary, set the file mode for the class file to read, so it is readable by the fenced user.

4. Compile and run the `SpClient` client application to access the stored procedure class. You can build `SpClient` with the application build file, `bldsqlj` (UNIX) or `bldsqlj.bat` (Windows).
SQLJ routine options for UNIX

The bldsqljs build script builds SQLJ routines on UNIX operating systems.

**bldsqljs** specifies a set of SQLJ translator and customizer options.

**Recommendation:** Use the same SQLJ translator and customizer options that bldsqljs uses when you build your SQLJ routines on UNIX platforms.

The options that bldsqljs includes are:

- **sqlj** The SQLJ translator (also compiles the program).
- **"${proiname}.sqlj"** The SQLJ source file. The proiname=${1%.sqlj} command removes the extension if it was included in the input file name, so when the extension is added back again, it is not duplicated.
- **db2sqljcustomize** The SQLJ profile customizer.
- **-url** Specifies a JDBC URL for establishing a database connection, such as jdbc:db2://servername:50000/sample.
- **-user** Specifies a user ID.
- **-password** Specifies a password.
- **"${proiname}_SJProfile0"** Specifies a serialized profile for the program.

SQLJ routine options for Windows

The bldsqljs.bat batch file builds SQLJ routines on Windows operating systems.

**bldsqljs.bat** specifies a set of SQLJ translator and customizer options.

**Recommendation:** Use the same SQLJ translator and customizer options that bldsqljs.bat uses when you build your SQLJ routines on Windows operating systems.

The following SQLJ translator and customizer options are used in the bldsqljs.bat batch file on Windows operating systems. These are the options DB2 recommends that you use to build SQLJ routines (stored procedures and user-defined functions).

- **sqlj** The SQLJ translator (also compiles the program).
- **%1.sqlj** The SQLJ source file.
- **db2sqljcustomize** The DB2 for Java profile customizer.
- **-url** Specifies a JDBC URL for establishing a database connection, such as jdbc:db2://servername:50000/sample.
- **-user** Specifies a user ID.
- **-password** Specifies a password.
- **%1_SJProfile0** Specifies a serialized profile for the program.
Chapter 7. Problem diagnosis with the IBM Data Server Driver for JDBC and SQLJ

The IBM Data Server Driver for JDBC and SQLJ includes diagnostic tools and traces for diagnosing problems during connection and SQL statement execution.

Testing a data server connection

Run the DB2Jcc utility to test a connection to a data server. You provide DB2Jcc with the URL for the data server, for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity or IBM Data Server Driver for JDBC and SQLJ type 2 connectivity. DB2Jcc attempts to connect to the data server, and to execute an SQL statement and a DatabaseMetaData method. If the connection or statement execution fails, DB2Jcc provides diagnostic information about the failure.

Collecting JDBC trace data

Use one of the following procedures to start the trace:

Procedure 1: For IBM Data Server Driver for JDBC and SQLJ type 4 connectivity or IBM Data Server Driver for JDBC and SQLJ type 2 connectivity for DB2 for Linux, UNIX and Windows, the recommended method is to start the trace by setting the db2.jcc.override.traceFile property or the db2.jcc.override.traceDirectory property in the IBM Data Server Driver for JDBC and SQLJ configuration properties file. You can set the db2.jcc.tracePolling and db2.jcc.tracePollingInterval properties before you start the driver to allow you to change global configuration trace properties while the driver is running.

Procedure 2: If you use the DataSource interface to connect to a data source, follow this method to start the trace:

1. Invoke the DB2BaseDataSource.setTraceLevel method to set the type of tracing that you need. The default trace level is TRACE_ALL. See “Properties for the IBM Data Server Driver for JDBC and SQLJ” for information on how to specify more than one type of tracing.
2. Invoke the DB2BaseDataSource.setJccLogWriter method to specify the trace destination and turn the trace on.

Procedure 3:

If you use the DataSource interface to connect to a data source, invoke the javax.sql.DataSource.setLogWriter method to turn the trace on. With this method, TRACE_ALL is the only available trace level.

If you use the DriverManager interface to connect to a data source, follow this procedure to start the trace.

1. Invoke the DriverManager.getConnection method with the(traceLevel) property set in the info parameter or url parameter for the type of tracing that you need. The default trace level is TRACE_ALL. See “Properties for the IBM Data Server Driver for JDBC and SQLJ” for information on how to specify more than one type of tracing.
2. Invoke the DriverManager.setLogWriter method to specify the trace destination and turn the trace on.

After a connection is established, you can turn the trace off or back on, change the trace destination, or change the trace level with the DB2Connection.setJccLogWriter method. To turn the trace off, set the logWriter value to null.

The logWriter property is an object of type java.io.PrintWriter. If your application cannot handle java.io.PrintWriter objects, you can use the traceFile property to specify the destination of the trace output. To use the traceFile property, set the logWriter property to null, and set the traceFile property to the name of the file to which the driver writes the trace data. This file and the directory in which it resides must be writable. If the file already exists, the driver overwrites it.

Procedure 4: If you are using the DriverManager interface, specify the traceFile and traceLevel properties as part of the URL when you load the driver. For example:

```
String url = "jdbc:db2://sysmvs1.stl.ibm.com:5021/san_jose" + 
":traceFile=/u/db2p/jcctrace;" + 
"traceLevel=" + com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DRDA_FLOWS + ";";
```

Procedure 5: Use DB2TraceManager methods. The DB2TraceManager class provides the ability to suspend and resume tracing of any type of log writer.

Example of starting a trace using configuration properties: For a complete example of using configuration parameters to collect trace data, see "Example of using configuration properties to start a JDBC trace".

Trace example program: For a complete example of a program for tracing under the IBM Data Server Driver for JDBC and SQLJ, see "Example of a trace program under the IBM Data Server Driver for JDBC and SQLJ".

**Collecting SQLJ trace data during customization or bind**

To collect trace data to diagnose problems during the SQLJ customization or bind process, specify the -traceLevel and -traceFile options when you run the db2sqljcustomize or db2sqljbind bind utility.

**Formatting information about an SQLJ serialized profile**

The profp utility formats information about each SQLJ clause in a serialized profile. The format of the profp utility is:

```
>>profp-serialized-profile-name
```

Run the profp utility on the serialized profile for the connection in which the error occurs. If an exception is thrown, a Java stack trace is generated. You can determine which serialized profile was in use when the exception was thrown from the stack trace.
Formatting information about an SQLJ customized serialized profile

The db2sqljprint utility formats information about each SQLJ clause in a serialized profile that is customized for the IBM Data Server Driver for JDBC and SQLJ.

Run the db2sqljprint utility on the customized serialized profile for the connection in which the error occurs.

Related reference:
"db2sqljprint - SQLJ profile printer" on page 601

DB2Jcc - IBM Data Server Driver for JDBC and SQLJ diagnostic utility

DB2Jcc verifies that a data server is configured for database access.

To verify the connection, DB2Jcc connects to the specified data server, executes an SQL statement, and executes a java.sql.DatabaseMetadata method.

Authorization

The user ID under which DB2Jcc runs must have the authority to connect to the specified data server and to execute the specified SQL statement.

DB2Jcc Syntax

```
java -classpath /path/to/c classes/your/app/com.ibm.db2.jcc.DB2Jcc 
  [ -version ] 
  [ -configuration confNameOrSpace ]
  [ -help ]
  [ -url spec ]
  [ -user user-ID ]
  [ -password password ]
  [ -sql spec ]
  [ -tracing ]

url-spec:
  jdbc:db2://server[:port]/database

sql-spec:
  SELECT * FROM SYSDUMMY1
```

DB2Jcc parameters

- **-help**
  Specifies that DB2Jcc describes each of the options that it supports. If any other options are specified with -help, they are ignored.

- **-version**
  Specifies that DB2Jcc displays the driver name and version.
-configuration
Specifies that DB2Jcc displays driver configuration information.

-url
Specifies the URL for the data server for which the connection is being tested.
The URL can be a URL for IBM Data Server Driver for JDBC and SQLJ type 2
connectivity or IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.
The variable parts of the -url value are:

server
The domain name or IP address of the operating system on which the
database server resides. server is used only for type 4 connectivity.

port
The TCP/IP server port number that is assigned to the data server. The
default is 446. port is used only for type 4 connectivity.

database
A name for the database server for which the profile is to be customized.
If the connection is to a DB2 for z/OS server, database is the DB2 location
name that is defined during installation. All characters in this value must
be uppercase characters. You can determine the location name by executing
the following SQL statement on the server:
SELECT CURRENT SERVER FROM SYSIBM.SYSDUMMY1;

If the connection is to a DB2 for Linux, UNIX, and Windows server,
database is the database name that is defined during installation.

If the connection is to an IBM Informix data server, database is the database
name. The name is case-insensitive. The server converts the name to
lowercase.

If the connection is to an IBM Cloudscape server, the database is the
fully-qualified name of the file that contains the database. This name must
be enclosed in double quotation marks ("). For example:
"c:/databases/testdb"

-user user-ID
Specifies the user ID that is to be used to test the connection to the data
server.

-password password
Specifies the password for the user ID that is to be used to test the
connection to the data server.

-sql 'sql-statement'
Specifies the SQL statement that is sent to the data server to verify the
connection. If the -sql parameter is not specified, this SQL statement is sent
to the data server:
SELECT * FROM SYSIBM.SYSDUMMY1

-tracing
Specifies that tracing is enabled. The trace destination is System.out.
If you omit the -tracing parameter, tracing is disabled.

Examples

Example: Test the connection to a data server using IBM Data Server Driver for
JDBC and SQLJ type 4 connectivity. Use the default SQL statement to test the
connection. Enable tracing for the test.
Example: Test the connection to a data server using IBM Data Server Driver for JDBC and SQLJ type 2 connectivity. Use the following SQL statement to test the connection:

```java
SELECT COUNT(*) FROM EMPLOYEE
```

Disable tracing for the test.

```java
SELECT COUNT(*) FROM EMPLOYEE
```

Examples of using configuration properties to start a JDBC trace

You can control tracing of JDBC applications without modifying those applications.

Example of writing trace data to one trace file for each connection

Suppose that you want to collect trace data for a program named Test.java, which uses IBM Data Server Driver for JDBC and SQLJ type 4 connectivity. Test.java does no tracing, and you do not want to modify the program, so you enable tracing using configuration properties. You want your trace output to have the following characteristics:

- Trace information for each connection on the same DataSource is written to a separate trace file. Output goes into a directory named /Trace.
- Each trace file name begins with jccTrace1.
- If trace files with the same names already exist, the trace data is appended to them.

Although Test.java does not contain any code to do tracing, you want to set the configuration properties so that if the application is modified in the future to do tracing, the settings within the program will take precedence over the settings in the configuration properties. To do that, use the set of configuration properties that begin with db2.jcc, not db2.jcc.override.

The configuration property settings look like this:

- `db2.jcc.traceDirectory=/Trace`
- `db2.jcc.traceFile=jccTrace1`
- `db2.jcc.traceFileAppend=true`

You want the trace settings to apply only to your stand-alone program Test.java, so you create a file with these settings, and then refer to the file when you invoke the Java program by specifying the `-Ddb2.jcc.propertiesFile` option. Suppose that the file that contains the settings is `/Test/jcc.properties`. To enable tracing when you run Test.java, you issue a command like this:

```java
java -Ddb2.jcc.propertiesFile=/Test/jcc.properties Test
```

Suppose that Test.java creates two connections for one DataSource. The program does not define a logWriter object, so the driver creates a global logWriter object for the trace output. When the program completes, the following files contain the trace data:

- `/Trace/jccTrace1_global_0`
Example of doing a circular trace with a fixed number of files and fixed file size

Suppose that you want to collect trace data for a program named Test.java, which uses IBM Data Server Driver for JDBC and SQLJ type 4 connectivity. Test.java does no tracing, and you do not want to modify the program, so you enable tracing using configuration properties. You want your trace output to have the following characteristics:

- Trace information for each connection on the same DataSource is written to a separate set of trace files.
- The maximum number of trace files that are written for each connection is 4.
- When all trace files are full, the trace overwrites existing trace data, beginning with the first trace file that was written.
- The maximum size of each trace file is 4 MB.
- Each trace file name begins with jcc.log, and is written into a directory named /Trace.
- If trace files with the same names already exist, the trace data is overwritten.

Although Test.java does not contain any code to do tracing, you want to set the configuration properties so that if the application is modified in the future to do tracing, the settings within the program will take precedence over the settings in the configuration properties. To do that, use the set of configuration properties that begin with db2.jcc.

The configuration property settings look like this:

- `db2.jcc.traceFile=jcc.log`
- `db2.jcc.traceOption=1`
- `db2.jcc.traceFileSize=4194304`
- `db2.jcc.traceFileCount=4`
- `db2.jcc.traceFileAppend=false`

You want the trace settings to apply only to your stand-alone program Test.java, so you create a file with these settings, and then refer to the file when you invoke the Java program by specifying the `-Ddb2.jcc.propertiesFile` option. Suppose that the file that contains the settings is `/Test/jcc.properties`. To enable tracing when you run Test.java, you issue a command like this:

```
java -Ddb2.jcc.propertiesFile=/Test/jcc.properties Test
```

Suppose that Test.java creates two connections for one DataSource. The program does not define a logWriter object, so the driver creates a global logWriter object for the trace output. During execution of the program, the IBM Data Server Driver for JDBC and SQLJ writes 17 MB of data for the first connection, and 10 MB of data for the second connection.

When the program completes, the following files contain the trace data:

- `/Trace/jcc.log_global_0.1`
- `/Trace/jcc.log_global_0.2`
- `/Trace/jcc.log_global_0.3`
- `/Trace/jcc.log_global_0.4`
- `/Trace/jcc.log_global_1.1`
- `/Trace/jcc.log_global_1.2`
- `/Trace/jcc.log_global_1.3`
/Trace/jcc.log_global_0.1 contains the last 1 MB of trace data that is written for the first connection, which overwrites the first 1 MB of trace data that was written for that connection.

Example of a trace program under the IBM Data Server Driver for JDBC and SQLJ

You might want to write a single class that includes methods for tracing under the DriverManager interface, as well as the DataSource interface.

The following example shows such a class. The example uses IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

```java
public class TraceExample
{
    public static void main(String[] args)
    {
        sampleConnectUsingSimpleDataSource();
        sampleConnectWithURLUsingDriverManager();
    }

    private static void sampleConnectUsingSimpleDataSource()
    {
        java.sql.Connection c = null;
        java.io.PrintWriter printWriter =
            new java.io.PrintWriter(System.out, true);
            // Prints to console, true means
            // auto-flush so you don't lose trace
        try {
            javax.sql.DataSource ds =
                new com.ibm.db2.jcc.DB2SimpleDataSource();
            ((com.ibm.db2.jcc.DB2BaseDataSource) ds).setServerName("sysmvs1.stl.ibm.com");
            ((com.ibm.db2.jcc.DB2BaseDataSource) ds).setPortNumber(5021);
            ((com.ibm.db2.jcc.DB2BaseDataSource) ds).setDatabaseName("san_jose");
            ((com.ibm.db2.jcc.DB2BaseDataSource) ds).setDriverType(4);
            ds.setLogWriter(printWriter); // This turns on tracing
            // Refine the level of tracing detail
            ((com.ibm.db2.jcc.DB2BaseDataSource) ds).
            setTraceLevel((com.ibm.db2.jcc.DB2SimpleDataSource.TRACE_CONNECTS |
            com.ibm.db2.jcc.DB2SimpleDataSource.TRACE_DRDA_FLOWS));

            // This connection request is traced using trace level
            // TRACE_CONNECTS | TRACE_DRDA_FLOWS
            c = ds.getConnection("myname", "mypass");

            // Change the trace level to TRACE_ALL
            // for all subsequent requests on the connection
            ((com.ibm.db2.jcc.DB2Connection) c).setJccLogWriter(printWriter,
            com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL);
            // The following INSERT is traced using trace level TRACE_ALL
            java.sql.Statement s1 = c.createStatement();
            s1.executeUpdate("INSERT INTO sampleTable(sampleColumn) VALUES(1)");
            s1.close();
            // This code disables all tracing on the connection
        }
    }
}
```

---

Figure 47. Example of tracing under the IBM Data Server Driver for JDBC and SQLJ

Chapter 7. Problem diagnosis with the IBM Data Server Driver for JDBC and SQLJ 241
printWriter.println("[TraceExample] Deadlocks could " +
"occur if the connection is not closed.");
com.ibm.db2.jcc.DB2ExceptionFormatter.printTrace(e, printWriter,
"[TraceExample]");
}

} catch(java.lang.Throwable e) {
// This time, send the PrintWriter to a file.
java.io.PrintWriter printWriter = null;
try {
    printWriter =
    new java.io.PrintWriter(
        new java.io.BufferedOutputStream(
            new java.io.FileOutputStream("/temp/driverLog.txt"), 4096), true);
} catch(java.io.FileNotFoundException e) {
    java.lang.System.err.println("Unable to establish a print writer for trace");
    java.lang.System.err.flush();
    return;
}
try {
    Class.forName("com.ibm.db2.jcc.DB2Driver");
} catch(ClassNotFoundException e) {
    printWriter.println("[TraceExample] " +
"IBM Data Server Driver for JDBC and SQLJ type 4 connectivity " +
"is not in the application classpath. Unable to load driver.");
    printWriter.flush();
    return;
}
try {
    java.sql.Connection c = null;
    // This time, send the PrintWriter to a file.
    java.io.PrintWriter printWriter = null;
}
// This URL describes the target data source for Type 4 connectivity.
// The traceLevel property is established through the URL syntax,
// and driver tracing is directed to file "/temp/driverLog.txt"
// The traceLevel property has type int. The constants
// com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DRDA_FLOWS and
// com.ibm.db2.jcc.DB2BaseDataSource.TRACE_CONNECTS represent
// int values. Those constants cannot be used directly in the
// first getConnection parameter. Resolve the constants to their
// int values by assigning them to a variable. Then use the
// variable as the first parameter of the getConnection method.
String databaseURL =
"jdbc:db2://sysmvs1.stl.ibm.com:5021" +
"/sample:traceFile=/temp/driverLog.txt;traceLevel=" +
(com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DRDA_FLOWS |
com.ibm.db2.jcc.DB2BaseDataSource.TRACE_CONNECTS) + ";";}
Techniques for monitoring IBM Data Server Driver for JDBC and SQLJ Sysplex support

To monitor IBM Data Server Driver for JDBC and SQLJ Sysplex support, you need to monitor the global transport objects pool.

You can monitor the global transport objects pool in either of the following ways:

- Using traces that you start by setting IBM Data Server Driver for JDBC and SQLJ configuration properties
- Using an application programming interface

Configuration properties for monitoring the global transport objects pool

Example: The following set of configuration property settings cause error messages, dump pool error messages, and transport pool statistics to be written every 60 seconds to a file named /home/WAS/logs/srv1/poolstats:

db2.jcc.dumpPool=DUMP_SYSPLEX_MSG|DUMP_POOL_ERROR
db2.jcc.dumpPoolStatisticsOnSchedule=60
db2.jcc.dumpPoolStatisticsOnScheduleFile=/home/WAS/logs/srv1/poolstats

An entry in the pool statistics file looks like this:

    group: DSNDB port: 446 hwmpo: 20 twte: 5 ngipr: 50 ttcpo: 2
        member: port: 446 DB1A hwmiut: 6 hwmt: 2 tmc: 1 trto: 0
        member: port: 446 DB1B hwmiut: 7 hwmt: 2 tmc: 1 trto: 0
        member: port: 446 DB1C hwmiut: 6 hwmt: 1 tmc: 0 trto: 1

The meanings of the fields are:

npr
  The total number of requests that the IBM Data Server Driver for JDBC and SQLJ has made to the pool since the pool was created.

nsr
  The number of successful requests that the IBM Data Server Driver for JDBC and SQLJ has made to the pool since the pool was created. A successful request means that the pool returned an object.

lwroc
  The number of objects that were reused but were not in the pool. This can happen if a Connection object releases a transport object at a transaction boundary. If the Connection object needs a transport object later, and the original transport object has not been used by any other Connection object, the Connection object can use that transport object.

hwroc
  The number of objects that were reused from the pool.

coc
  The number of objects that the IBM Data Server Driver for JDBC and SQLJ created since the pool was created.

aooc
  The number of objects that exceeded the idle time that was specified by db2.jcc.maxTransportObjectIdleTime and were deleted from the pool.

rmoc
  The number of objects that have been deleted from the pool since the pool was created.

nbr
  The number of requests that the IBM Data Server Driver for JDBC and SQLJ made to the pool that the pool blocked because the pool reached its maximum capacity. A blocked request might be successful if an object is returned to the pool before the db2.jcc.maxTransportObjectWaitTime is exceeded and an exception is thrown.

tbt
  The total time in milliseconds for requests that were blocked by the pool. This time can be much larger than the elapsed execution time of the application if the application uses multiple threads.
sbt
The shortest time in milliseconds that a thread waited to get a transport object from the pool. If the time is under one millisecond, the value in this field is zero.

lbt
The longest time in milliseconds that a thread waited to get a transport object from the pool.

abt
The average amount of time in milliseconds that threads waited to get a transport object from the pool. This value is tbt/nbr.

tpo
The number of objects that are currently in the pool.

<table>

**Application programming interfaces for monitoring the global transport objects pool**

You can write applications to gather statistics on the global transport objects pool. Those applications create objects in the DB2PoolMonitor class and invoke methods to retrieve information about the pool.

For example, the following code creates an object for monitoring the global transport objects pool:

```java
import com.ibm.db2.jcc.DB2PoolMonitor;
DB2PoolMonitor transportObjectPoolMonitor =
    DB2PoolMonitor.getPoolMonitor(DB2PoolMonitor.TRANSPORT_OBJECT);
```

After you create the DB2PoolMonitor object, you can use methods in the DB2PoolMonitor class to monitor the pool.
Chapter 8. System monitoring for the IBM Data Server Driver for JDBC and SQLJ

To assist you in monitoring the performance of your applications with the IBM Data Server Driver for JDBC and SQLJ, the driver provides two methods to collect information for a connection.

That information is:

- **Core driver time**
  The sum of elapsed monitored API times that were collected while system monitoring was enabled, in microseconds. In general, only APIs that might result in network I/O or database server interaction are monitored.

- **Network I/O time**
  The sum of elapsed network I/O times that were collected while system monitoring was enabled, in microseconds.

- **Server time**
  The sum of all reported database server elapsed times that were collected while system monitoring was enabled, in microseconds.

- **Application time**
  The sum of the application, JDBC driver, network I/O, and database server elapsed times, in milliseconds.

The two methods are:
- The DB2SystemMonitor interface
- The TRACE_SYSTEM_MONITOR trace level

*To collect system monitoring data using the DB2SystemMonitor interface:* Perform these basic steps:
1. Invoke the DB2Connection.getDB2SystemMonitor method to create a DB2SystemMonitor object.
2. Invoke the DB2SystemMonitor.enable method to enable the DB2SystemMonitor object for the connection.
3. Invoke the DB2SystemMonitor.start method to start system monitoring.
4. When the activity that is to be monitored is complete, invoke DB2SystemMonitor.stop to stop system monitoring.
5. Invoke the DB2SystemMonitor.getCoredriverTimeMicros, DB2SystemMonitor.getNetworkIOtimeMicros, DB2SystemMonitor.getServerTimeMicros, or DB2SystemMonitor.getApplicationTimeMillis methods to retrieve the elapsed time data.
   The server time that is returned by DB2SystemMonitor.getServerTimeMicros includes commit and rollback time.

For example, the following code demonstrates how to collect each type of elapsed time data. The numbers to the right of selected statements correspond to the previously described steps.
import java.sql.*;
import com.ibm.db2.jcc.*;
public class TestSystemMonitor
{
    public static void main(String[] args)
    {
        String url = "jdbc:db2://sysmvs1.svl.ibm.com:5021/san_jose";
        String user="db2adm";
        String password="db2adm";
        try
        {
            // Load the IBM Data Server Driver for JDBC and SQLJ
            Class.forName("com.ibm.db2.jcc.DB2Driver");
            System.out.println("**** Loaded the JDBC driver");

            // Create the connection using the IBM Data Server Driver for JDBC and SQLJ
            Connection conn = DriverManager.getConnection (url,user,password);
            conn.setAutoCommit(false);
            System.out.println("**** Created a JDBC connection to the data source");
            DB2SystemMonitor systemMonitor = ((DB2Connection)conn).getDB2SystemMonitor();
            systemMonitor.enable(true);
            systemMonitor.start(DB2SystemMonitor.RESET_TIMES);
            Statement stmt = conn.createStatement();
            int numUpd = stmt.executeUpdate("UPDATE EMPLOYEE SET PHONENO='4657' WHERE EMPNO='000010'");
            systemMonitor.stop();
            System.out.println("Server elapsed time (microseconds)=" + systemMonitor.getServerTimeMicros());
            System.out.println("Network I/O elapsed time (microseconds)=" + systemMonitor.getNetworkIOTimeMicros());
            System.out.println("Core driver elapsed time (microseconds)=" + systemMonitor.getCoreDriverTimeMicros());
            System.out.println("Application elapsed time (milliseconds)=" + systemMonitor.getApplicationTimeMillis());
            conn.rollback();
            stmt.close();
            conn.close();
        }
        // Handle errors
        catch(ClassNotFoundException e)
        {
            System.err.println("Unable to load the driver, " + e);
        }
        catch(SQLException e)
        {
            System.out.println("SQLException: " + e);
            e.printStackTrace();
        }
    }
}

Figure 48. Example of using DB2SystemMonitor methods to collect system monitoring data

To collect system monitoring information using the trace method: Start a JDBC trace, using configuration properties or Connection or DataSource properties. Include TRACE_SYSTEM_MONITOR when you set the traceLevel property. For example:

String url = "jdbc:db2://sysmvs1.svl.ibm.com:5021/san_jose" +
    ":traceFile=/u/db2p/jcctrace;" +
    "traceLevel=" + com.ibm.db2.jcc.DB2BaseDataSource.TRACE_SYSTEM_MONITOR + ";";

The trace records with system monitor information look similar to this:
IBM Data Server Driver for JDBC and SQLJ remote trace controller

The IBM Data Server Driver for JDBC and SQLJ provides a facility for controlling IBM Data Server Driver for JDBC and SQLJ traces dynamically.

This remote trace controller lets you perform operations like these for multiple driver instances:
- Start, stop, or resume a trace
- Change the output trace file or directory location
- Change the trace level

The remote trace controller uses the Java Management Extensions (JMX) architecture, which is part of the Java Standard Edition, Version 6, or later. The JMX consists of:
- A set of built-in management utilities, which let you do monitoring from a management console such as the Java Monitoring and Management Console (JConsole).
- A set of APIs that let you write applications to perform the same functions.

Enabling the remote trace controller

Enabling the remote trace controller involves enabling Java Management Extensions (JMX) in the IBM Data Server Driver for JDBC and SQLJ, and making the JMX agent available to clients.

The remote trace controller requires Java Standard Edition, Version 6 or later.

The steps for enabling the remote trace controller are:

1. Enable JMX to the IBM Data Server Driver for JDBC and SQLJ by setting the db2.jcc.jmxEnabled global configuration property to true or yes.
   For example, include this string in DB2JccConfiguration.properties:
   
   db2.jcc.jmxEnabled=true

2. Make the JMX agent (the platform MBean server) available to local or remote clients.
   - For local clients:
     Monitoring and management capabilities are automatically made available when the JVM is started. After your application is started, you can use a JMX client such as JConsole to connect locally to your Java process.
   - For remote clients, use one of the following methods:
     - Use the out-of-the-box JMX agent.
       Out-of-the-box management uses JMX built-in management utilities. To enable out-of-the-box management, you need to set a number of Java system properties. You must at least set the following property:
       com.sun.management.jmxremote.port=portNum
       In addition, you should ensure that authentication and SSL are properly configured.
       Full information on enabling out-of-the-box management is at the following URL:
       
Write a JMX agent. This technique is also discussed at:

In the following example, an RMI connector server is created for the
PlatformMBeanServer using the MyCustomJMXAuthenticator object. The
MyCustomJMXAuthenticator class defines how remote credentials are
converted into a JAAS Subject by implementing the JMXAuthenticator
interface:

```
HashMap<String> env = new HashMap<String>();
env.put(JMXConnectorServer.AUTHENTICATOR, new MyCustomJMXAuthenticator());
env.put("jmx.remote.x.access.file", "my.access.file");

MBeanServer mbs =
java.lang.management.ManagementFactory.getPlatformMBeanServer();
JMXServiceURL url =
new JMXServiceURL("service:jmx:rmi:///jndi/rmi:///9999/jmxrmi");

JMXConnectorServer cs =
JMXConnectorServerFactory.newJMXConnectorServer(url, env, mbs);
cs.start();
```

```
public class MyCustomJMXAuthenticator implements JMXAuthenticator {
    public Subject authenticate(Object credentials) {
        // the hash contains username, password, etc...
        Hashtable<String> credentialsHash
            = (Hashtable<String>) credentials;

        // Authenticate using the provided credentials
        ...
        if (authentication-successful) {
            return new Subject(true,
                Collections.singleton
                    (new JMXPrincipal(credentialsHash.get("username"))));
                Collections.EMPTY_SET,
                Collections.EMPTY_SET);
        }

        throw new SecurityException("Invalid credentials");
    }
}
```

### Accessing the remote trace controller

You can access the remote trace controller through out-of-the-box management
tools, or through an application.

You use out-of-the-box management through a JMX-compliant management client,
such as JConsole, which is part of Java Standard Edition, Version 6. Information on
using JConsole for out-of-the-box management is at the following URL:

http://download.oracle.com/javase/6/docs/technotes/guides/management/jconsole.html

In an application that accesses the remote trace controller, the remote trace
controller is a managed bean (MBean). JMX manages resources through JMX
agents. A JMX agent is an MBean server. Each MBean represents a resource. Every
MBean has a name, which you define through an object of class
javax.management.ObjectName. You use the ObjectName object to register and
retrieve MBeans in the MBeanServer.
The MBean name has two parts: the domain and the key properties. For the ObjectName for the IBM Data Server Driver for JDBC and SQLJ remote trace controller, the domain is com.ibm.db2.jcc, and the key properties are name=DB2TraceManager.

An application that accesses the remote trace controller must include these steps:
1. Establish a Remote Method Invocation (RMI) connection to an MBean server.
2. Perform a lookup on the remote trace controller in the MBean server.
3. Invoke trace operations on the MBean.

You can operate on the MBean in the following ways:
• Using an MBean proxy
• Without a proxy, through an MBeanServerConnection.

Examples

Example: accessing the remote trace controller without proxies: This example demonstrates accessing MBeans directly from an MBeanServerConnection. This method is the most generic because it does not require matching interface definitions on the JMX client application.

```java
try {
    System.out.println("\n");
    System.out.println("\n");
    System.out.println("Establish an RMI connection to an MBeanServer");
    System.out.println("\n");
    JMXServiceURL url =
        new JMXServiceURL("service:jmx:rmi:///jndi/rmi://localhost:9999/jmxrmi");
    JMXConnector jmxc = JMXConnectorFactory.connect(url, env);
    MBeanServerConnection mbsc = jmxc.getMBeanServerConnection();

    System.out.println("\n");
    System.out.println("\n");
    System.out.println("Processing MBean");
    System.out.println("\n");
    String objectNameString = "com.ibm.db2.jcc:name=DB2TraceManager";
    ObjectName name = new ObjectName(objectNameString);
    System.out.println("ObjectName="+objectNameString);

    System.out.println("\n");
    System.out.println("\n");
    System.out.println("Print all attributes of the MBean");
    System.out.println("\n");
    System.out.println("TraceDirectory = "+mbsc.getAttribute(name, "TraceDirectory"));
    System.out.println("TraceFile = "+mbsc.getAttribute(name, "TraceFile"));
    System.out.println("TraceFileAppend = "+mbsc.getAttribute(name, "TraceFileAppend"));
    System.out.println("TraceLevel = "+mbsc.getAttribute(name, "TraceLevel"));

    System.out.println("\n");
    System.out.println("\n");
    System.out.println("Invoke some operations on the MBean");
    System.out.println("\n");
    System.out.println("Invoking suspendTrace()..." );
    mbsc.invoke(name, "suspendTrace", null, null);
```
Example: accessing the remote trace controller with proxies: This example demonstrates the creation of a proxy to an MBean. The proxy implements the com.ibm.db2.jcc.mx.DB2TraceManagerMXBean interface. The application makes calls directly on the proxy, and the underlying proxy implementation invokes the MBean operation on the remote MBean server.

```
try {
    System.out.println (""n); System.out.println ("---------------------------------------"); System.out.println ("Establish an RMI connection to an MBeanServer"); System.out.println ("---------------------------------------"); JMXServiceURL url =
        new JMXServiceURL ("service:jmx:rmi:///jndi/rmi://localhost:9999/jmxrmi"); JMConnector jmxc = JMConnectorFactory.connect (url, env);
    MBeanServerConnection mbsc = jmxc.getMBeanServerConnection();

    System.out.println (""n); System.out.println ("---------------------------------------"); System.out.println ("Processing MBean"); System.out.println ("---------------------------------------"); String objectNameString = "com.ibm.db2.jcc:name=DB2TraceManager";
    ObjectName name = new ObjectName (objectNameString);
    System.out.println ("ObjectName="+objectNameString);

    System.out.println (""n); System.out.println ("---------------------------------------"); System.out.println ("Print all attributes of the MBean"); System.out.println ("---------------------------------------");
    com.ibm.db2.jcc.mx.DB2TraceManagerMXBean mbeanProxy =
        JM.newMBeanProxy (mbsc, name,
            com.ibm.db2.jcc.mx.DB2TraceManagerMXBean.class, true);
    System.out.println ("TraceDirectory = "+mbeanProxy.getTraceDirectory()); System.out.println ("TraceFile = "+mbeanProxy.getTraceFile()); System.out.println ("TraceFileAppend = "+mbeanProxy.getTraceFileAppend()); System.out.println ("TraceLevel = "+mbeanProxy.getTraceLevel());
    System.out.println (""n);
    System.out.println ("---------------------------------------"); System.out.println ("Invoke some operations on the MBean"); System.out.println ("---------------------------------------");
    System.out.println ("Invoking suspendTrace()..."n);
    mbeanProxy.suspendTrace();
    System.out.println ("success");
    System.out.println ("Invoking resumeTrace()...");
    mbeanProxy.resumeTrace();
    System.out.println ("success");
} catch (Exception e) {
    System.out.println ("failure");
    e.printStackTrace ();
}
```
Chapter 9. Java client support for high availability on IBM data servers

Client applications that connect to DB2 for Linux, UNIX, and Windows, DB2 for z/OS, or IBM Informix can easily take advantage of the high availability features of those data servers.

Client applications can use the following high availability features:

- **Automatic client reroute**
  Automatic client reroute capability is available on all IBM data servers. Automatic client reroute uses information that is provided by the data servers to redirect client applications from a server that experiences an outage to an alternate server. Automatic client reroute enables applications to continue their work with minimal interruption. Redirection of work to an alternate server is called *failover*.
  For connections to DB2 for z/OS data servers, automatic client reroute is part of the workload balancing feature. In general, for DB2 for z/OS, automatic client reroute should not be enabled without workload balancing.

- **Client affinities**
  Client affinities is a failover solution that is controlled completely by the client. It is intended for situations in which you need to connect to a particular primary server. If an outage occurs during the connection to the primary server, you use client affinities to enforce a specific order for failover to alternate servers.
  Client affinities is not applicable to a DB2 for z/OS data sharing environment, because all members of a data sharing group can access data concurrently. Data sharing is the recommended solution for high availability for DB2 for z/OS.

- **Workload balancing**
  Workload balancing is available on all IBM data servers. Workload balancing ensures that work is distributed efficiently among servers in an IBM Informix high-availability cluster, DB2 for z/OS data sharing group, or DB2 for Linux, UNIX, and Windows DB2 pureScale® instance.

The following table provides links to server-side information about these features.

<table>

Java client support for high availability for connections to DB2 for Linux, UNIX, and Windows servers

DB2 for Linux, UNIX, and Windows servers provide high availability for client applications, through workload balancing and automatic client reroute. This support is available for applications that use Java clients (JDBC, SQLJ, or pureQuery), as well as non-Java clients (ODBC, CLI, .NET, OLE DB, PHP, Ruby, or embedded SQL).

For Java clients, you need to use IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to take advantage of DB2 for Linux, UNIX, and Windows high-availability support. You need IBM Data Server Driver for JDBC and SQLJ version 3.58 or 4.8, or later.

High availability support for connections to DB2 for Linux, UNIX, and Windows servers includes:

**Automatic client reroute**
This support enables a client to recover from a failure by attempting to reconnect to the database through an alternate server. Reconnection to another server is called *failover*. For Java clients, automatic client reroute support is always enabled.

Servers can provide automatic client reroute capability in any of the following ways:

- Several servers are configured in a DB2 pureScale instance. A connection to a database is a connection to a member of that DB2 pureScale instance. Failover involves reconnection to another member of the DB2 pureScale instance. This environment requires that clients use TCP/IP to connect to the DB2 pureScale instance.

- A DB2 pureScale instance and an alternate server are defined for a database. Failover first involves reconnection to another member of the DB2 pureScale instance. Failover to the alternate server is attempted only if no member of the DB2 pureScale instance is available.

- A DB2 pureScale instance is defined for the primary server, and another DB2 pureScale instance is defined for the alternate server. Failover first involves reconnection to another member of the primary DB2 pureScale instance. Failover to the alternate DB2 pureScale instance is attempted only if no member of the primary DB2 pureScale instance is available.

- A database is defined on a single server. The configuration for that database includes specification of an alternate server. Failover involves reconnection to the alternate server.

For Java, client applications, failover for automatic client reroute can be *seamless* or *non-seamless*. With non-seamless failover, when the client application reconnects to another server, an error is always returned to the application, to indicate that failover (connection to the alternate server) occurred. With seamless failover, the driver does not return an error if a connection failure and successful reconnection to an alternate server occur during execution of the first SQL statement in a transaction.
In a DB2 pureScale instance, automatic client reroute support can be used without workload balancing or with workload balancing.

**Workload balancing**

Workload balancing can improve availability of a DB2 pureScale instance. With workload balancing, a DB2 pureScale instance ensures that work is distributed efficiently among members.

Java clients on any operating system support workload balancing. The connection from the client to the DB2 pureScale instance must use TCP/IP.

When workload balancing is enabled, the client gets frequent status information about the members of the DB2 pureScale instance through a server list. The client caches the server list and uses the information in it to determine the member to which the next transaction should be routed.

For Java applications, when JNDI is used, the cached server list can be shared by multiple JVMs for the first connection. However, workload balancing is always performed within the context of a single JVM.

DB2 for Linux, UNIX, and Windows supports two types of workload balancing:

- **Connection-level workload balancing**
  Connection-level workload balancing is performed at connection boundaries. It is not supported for Java clients.

- **Transaction-level workload balancing**
  Transaction-level workload balancing is performed at transaction boundaries. Client support for transaction-level workload balancing is disabled by default for clients that connect to DB2 for Linux, UNIX, and Windows.

**Client affinities**

Client affinities is an automatic client reroute solution that is controlled completely by the client. It is intended for situations in which you need to connect to a particular primary server. If an outage occurs during the connection to the primary server, you use client affinities to enforce a specific order for failover to alternate servers.

**Configuration of DB2 for Linux, UNIX, and Windows automatic client reroute support for Java clients**

For connections to DB2 for Linux, UNIX, and Windows databases, the process for configuration of automatic client reroute support on Java clients is the same for connections to a non-DB2 pureScale environment and a DB2 pureScale environment.

Automatic client reroute support for Java client applications that connect to DB2 for Linux, UNIX, and Windows works for connections that are obtained using the `javax.sql.DataSource`, `javax.sql.ConnectionPoolDataSource`, `javax.sql.XADataSource`, or `java.sql.DriverManager` interface.

To configure automatic client reroute on an IBM Data Server Driver for JDBC and SQLJ client:
1. Set the appropriate properties to specify the primary and alternate server addresses to use if the first connection fails.
   - If your application is using the DriverManager interface for connections:
     a. Specify the server name and port number of the primary server that you want to use in the connection URL.
     b. Set the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber properties to the server name and port number of the alternate server that you want to use.

**Restriction:** Automatic client reroute support for connections that are made with the DriverManager interface has the following restrictions:
- Alternate server information is shared between DriverManager connections only if you create the connections with the same URL and properties.
- You cannot set the clientRerouteServerListJNDIName property or the clientRerouteServerListJNDIContext properties for a DriverManager connection.
- Automatic client reroute is not enabled for default connections (jdbc:default:connection).

- If your application is using the DataSource interface for connections, use one or both of the following techniques:
  - Set the server names and port numbers in DataSource properties:
    a. Set the serverName and portNumber properties to the server name and port number of the primary server that you want to use.
    b. Set the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber properties to the server name and port number of the alternate server that you want to use.
  - Configure JNDI for automatic client reroute by using a DB2ClientRerouteServerList instance to identify the primary server and alternate server.
    a. Create an instance of DB2ClientRerouteServerList.
    DB2ClientRerouteServerList is a serializable Java bean with the following properties:

    | Property name                                      | Data type     |
    |---------------------------------------------------|--------------|
    | com.ibm.db2.jcc.DB2ClientRerouteServerList.alternateServerName | String[]     |
    | com.ibm.db2.jcc.DB2ClientRerouteServerList.alternatePortNumber | int[]        |
    | com.ibm.db2.jcc.DB2ClientRerouteServerList.primaryServerName | String[]     |
    | com.ibm.db2.jcc.DB2ClientRerouteServerList.primaryPortNumber | int[]        |

    getXXX and setXXX methods are defined for each property.

    b. Set the com.ibm.db2.jcc.DB2ClientRerouteServerList.primaryServerName and com.ibm.db2.jcc.DB2ClientRerouteServerList.primaryPortNumber properties to the server name and port number of the primary server that you want to use.

    c. Set the com.ibm.db2.jcc.DB2ClientRerouteServerList.alternateServerName and com.ibm.db2.jcc.DB2ClientRerouteServerList.alternatePortNumber properties to the server names and port numbers of the alternate server that you want to use.
d. To make the DB2ClientRerouteServerList persistent:

1) Bind the DB2ClientRerouteServerList instance to the JNDI registry.

2) Assign the JNDI name of the DB2ClientRerouteServerList object to the IBM Data Server Driver for JDBC and SQLJ clientRerouteServerListJNDIName property.

3) Assign the name of the JNDI context that is used for binding and lookup of the DB2ClientRerouteServerList instance to the clientRerouteServerListJNDIContext property.

When a DataSource is configured to use JNDI for storing automatic client reroute alternate information, the standard server and port properties of the DataSource are not used for a getConnection request. Instead, the primary server address is obtained from the transient clientRerouteServerList information. If the JNDI store is not available due to a JNDI bind or lookup failure, the IBM Data Server Driver for JDBC and SQLJ attempts to make a connection using the standard server and port properties of the DataSource. Warnings are accumulated to indicate that a JNDI bind or lookup failure occurred.

After a failover:
- The IBM Data Server Driver for JDBC and SQLJ attempts to propagate the updated server information to the JNDI store.
- primaryServerName and primaryPortNumber values that are specified in DB2ClientRerouteServerList are used for the connection. If primaryServerName is not specified, the serverName and portNumber values for the DataSource instance are used.

If you configure DataSource properties as well as configuring JNDI for automatic client reroute, the DataSource properties have precedence over the JNDI configuration.

2. Set properties to control the number of retries, time between retries, and the frequency with which the server list is refreshed.

The following properties control retry behavior for automatic client reroute.

**maxRetriesForClientReroute**

The maximum number of connection retries for automatic client reroute.

When client affinities support is not configured, if maxRetriesForClientReroute or retryIntervalForClientReroute is not set, the default behavior is that the connection is retried for 10 minutes, with a wait time between retries that increases as the length of time from the first retry increases.

When client affinities is configured, the default for maxRetriesForClientReroute is 3.

**retryIntervalForClientReroute**

The number of seconds between consecutive connection retries.

When client affinities support is not configured, if retryIntervalForClientReroute or maxRetriesForClientReroute is not set, the default behavior is that the connection is retried for 10 minutes, with a wait time between retries that increases as the length of time from the first retry increases.

When client affinities is configured, the default for retryIntervalForClientReroute is 0 (no wait).
Example of enabling DB2 for Linux, UNIX, and Windows automatic client reroute support in Java applications

Java client setup for DB2 for Linux, UNIX, and Windows automatic client reroute support includes setting several IBM Data Server Driver for JDBC and SQLJ properties.

The following example demonstrates setting up Java client applications for DB2 for Linux, UNIX, and Windows automatic client reroute support.

Suppose that your installation has a primary server and an alternate server with the following server names and port numbers:

<table>
<thead>
<tr>
<th>Server name</th>
<th>Port number</th>
</tr>
</thead>
<tbody>
<tr>
<td>srv1.sj.ibm.com</td>
<td>50000</td>
</tr>
<tr>
<td>srv3.sj.ibm.com</td>
<td>50002</td>
</tr>
</tbody>
</table>

The following code sets up DataSource properties in an application so that the application connects to srv1.sj.ibm.com as the primary server, and srv3.sj.ibm.com as the alternative server. That is, if srv1.sj.ibm.com is down during the initial connection, the driver should connect to srv3.sj.ibm.com.

```java
ds.setDriverType(4);
ds.setServerName("srv1.sj.ibm.com");
ds.setPortNumber("50000");
ds.setClientRerouteAlternateServerName("srv3.sj.ibm.com");
ds.setClientRerouteAlternatePortNumber("50002");
```

The following code configures JNDI for automatic client reroute. It creates an instance of DB2ClientRerouteServerList, binds that instance to the JNDI registry, and assigns the JNDI name of the DB2ClientRerouteServerList object to the clientRerouteServerListJNDIName property.

```java
// Create a starting context for naming operations
InitialContext registry = new InitialContext();
// Create a DB2ClientRerouteServerList object
DB2ClientRerouteServerList address = new DB2ClientRerouteServerList();

// Set the port number and server name for the primary server
address.setPrimaryPortNumber(50000);
address.setPrimaryServerName("srv1.sj.ibm.com");

// Set the port number and server name for the alternate server
int[] port = {50002};
String[] server = {"srv3.sj.ibm.com"};
address.setAlternatePortNumber(port);
address.setAlternateServerName(server);
registry.rebind("serverList", address);
```
// Assign the JNDI name of the DB2ClientRerouteServerList object to the
// clientRerouteServerListJNDIName property
datasource.setClientRerouteServerListJNDIName("serverList");

Configuration of DB2 for Linux, UNIX, and Windows workload balancing support for Java clients

To configure a IBM Data Server Driver for JDBC and SQLJ client application that connects to a DB2 for Linux, UNIX, and Windows DB2 pureScale instance for workload balancing, you need to connect to a member of the DB2 pureScale instance, and set the properties that enable workload balancing and the maximum number of connections.

Java client applications support transaction-level workload balancing. They do not support connection-level workload balancing. Workload balancing is supported only for connections to a DB2 pureScale instance.

Workload balancing support for Java client applications that connect to DB2 for Linux, UNIX, and Windows works for connections that are obtained using the javax.sql.DataSource, javax.sql.ConnectionPoolDataSource, javax.sql.XADataSource, or java.sql.DriverManager interface.

Restriction: Workload balancing support for connections that are made with the DriverManager interface has the following restrictions:
- Alternate server information is shared between DriverManager connections only if you create the connections with the same URL and properties.
- You cannot set the clientRerouteServerListJNDIName property or the clientRerouteServerListJNDIClass property for a DriverManager connection.
- Workload balancing is not enabled for default connections (jdbc:default:connection).

The following table describes the basic property settings for enabling DB2 for Linux, UNIX, and Windows workload balancing for Java applications.

Table 36. Basic settings to enable workload support in Java applications

<table>
<thead>
<tr>
<th>IBM Data Server Driver for JDBC and SQLJ setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableSysplexWLB property</td>
<td>true</td>
</tr>
<tr>
<td>maxTransportObjects property</td>
<td>The maximum number of connections that the requester can make to the DB2 pureScale instance</td>
</tr>
<tr>
<td>Connection address: server</td>
<td>The IP address of a member of a DB2 pureScale instance</td>
</tr>
<tr>
<td>Connection address: port</td>
<td>The SQL port number for the DB2 pureScale instance</td>
</tr>
<tr>
<td>Connection address: database</td>
<td>The database name</td>
</tr>
</tbody>
</table>
Table 36. Basic settings to enable workload support in Java applications (continued)

<table>
<thead>
<tr>
<th>IBM Data Server Driver for JDBC and SQLJ</th>
<th>Value</th>
</tr>
</thead>
</table>

Note:
1. Alternatively, you can use a distributor, such as Websphere Application Server Network Deployment, or multihomed DNS to establish the initial connection to the database.
   - For a distributor, you specify the IP address and port number of the distributor. The distributor analyzes the current workload distribution, and uses that information to forward the connection request to one of the members of the DB2 pureScale instance.
   - For multihomed DNS, you specify an IP address and port number that can resolve to the IP address and port number of any member of the DB2 pureScale instance. Multihomed DNS processing selects a member based on some criterion, such as simple round-robin selection or member workload distribution.

If you want to fine-tune DB2 for Linux, UNIX, and Windows workload balancing support, global configuration properties are available. The properties for the IBM Data Server Driver for JDBC and SQLJ are listed in the following table.

Table 37. Configuration properties for fine-tuning DB2 for Linux, UNIX, and Windows workload balancing support for connections from the IBM Data Server Driver for JDBC and SQLJ

<table>
<thead>
<tr>
<th>IBM Data Server Driver for JDBC and SQLJ</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db2.jcc.maxRefreshInterval</td>
<td>Specifies the maximum amount of time in seconds between refreshes of the client copy of the server list that is used for workload balancing. The default is 10. The minimum valid value is 1.</td>
</tr>
<tr>
<td>db2.jcc.maxTransportObjectIdleTime</td>
<td>Specifies the maximum elapsed time in number of seconds before an idle transport is dropped. The default is 10. The minimum supported value is 0.</td>
</tr>
<tr>
<td>db2.jcc.maxTransportObjectWaitTime</td>
<td>Specifies the number of seconds that the client will wait for a transport to become available. The default is 1. The minimum supported value is 0.</td>
</tr>
<tr>
<td>db2.jcc.minTransportObjects</td>
<td>Specifies the lower limit for the number of transport objects in a global transport object pool. The default value is 0. Any value that is less than or equal to 0 means that the global transport object pool can become empty.</td>
</tr>
</tbody>
</table>

Example of enabling DB2 for Linux, UNIX, and Windows workload balancing support in Java applications

Java client setup for DB2 for Linux, UNIX, and Windows workload balancing support includes setting several IBM Data Server Driver for JDBC and SQLJ properties.

The following example demonstrates setting up Java client applications for DB2 for Linux, UNIX, and Windows workload balancing support.

Before you can set up the client, the servers to which the client connects must be configured in a DB2 pureScale instance.

Follow these steps to set up the client:
1. Verify that the IBM Data Server Driver for JDBC and SQLJ is at the correct level to support workload balancing by following these steps:
a. Issue the following command in a command line window:
   
   ```
   java com.ibm.db2.jcc.DB2Jcc -version
   ```
   
b. Find a line in the output like this, and check that \textit{nnn} is 3.58 or later.
   
c. 
   
   **[jcc] Driver: IBM Data Server Driver for JDBC and SQLJ Architecture nnn xxx**

2. Set IBM Data Server Driver for JDBC and SQLJ properties to enable the connection concentrator or workload balancing:
   
a. Set these Connection or DataSource properties:
      
      - `enableSysplexWLB`
      - `maxTransportObjects`
   
b. Set the `db2.jcc.maxRefreshInterval` global configuration property in a `DB2JccConfiguration.properties` file to set the maximum refresh interval for all DataSource or Connection instances that are created under the driver.

   Start with settings similar to these:

   **Table 38. Example of property settings for workload balancing for DB2 for Linux, UNIX, and Windows**

<table>
<thead>
<tr>
<th>Property</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>enableSysplexWLB</code></td>
<td><code>true</code></td>
</tr>
<tr>
<td><code>maxTransportObjects</code></td>
<td><code>80</code></td>
</tr>
<tr>
<td><code>db2.jcc.maxRefreshInterval</code></td>
<td><code>10</code></td>
</tr>
</tbody>
</table>

   The values that are specified are not intended to be recommended values. You need to determine values based on factors such as the number of physical connections that are available. The number of transport objects must be equal to or greater than the number of connection objects.

3. To fine-tune workload balancing for all DataSource or Connection instances that are created under the driver, set the `db2.jcc.maxTransportObjects` configuration property in a `DB2JccConfiguration.properties` file.

   Start with a setting similar to this one:

   ```
   db2.jcc.maxTransportObjects=1000
   ```

4. **Optional:** Specify alternate server names in the `clientRerouteAlternateServerName` and `clientRerouteAlternatePortNumber` properties. This step is not necessary for enabling workload balancing. However, specifying an alternate server list is useful to ensure that the first connection is successful if the primary server is unavailable.

**Operation of automatic client reroute for connections to DB2 for Linux, UNIX, and Windows from Java clients**

When IBM Data Server Driver for JDBC and SQLJ client reroute support is enabled, a Java application that is connected to a DB2 for Linux, UNIX, and Windows database can continue to run when the primary server has a failure.

Automatic client reroute for a Java application that is connected to a DB2 for Linux, UNIX, and Windows database operates in the following way when support for client affinities is disabled:

1. During each connection to the data source, the IBM Data Server Driver for JDBC and SQLJ obtains primary and alternate server information.
   - For the first connection to a DB2 for Linux, UNIX, and Windows database:
     
     a. If the `clientRerouteAlternateServerName` and `clientRerouteAlternatePortNumber` properties are set, the IBM Data
Server Driver for JDBC and SQLJ loads those values into memory as the alternate server values, along with the primary server values serverName and portNumber.

b. If the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber properties are not set, and a JNDI store is configured by setting the property clientRerouteServerListJNDIName on the DB2BaseDataSource, the IBM Data Server Driver for JDBC and SQLJ loads the primary and alternate server information from the JNDI store into memory.

c. If no DataSource properties are set for the alternate servers, and JNDI is not configured, the IBM Data Server Driver for JDBC and SQLJ checks DNS tables for primary and alternate server information. If DNS information exists, the IBM Data Server Driver for JDBC and SQLJ loads those values into memory.

In a DB2 pureScale environment, regardless of the outcome of the DNS lookup:

1) If configuration property db2.jcc.outputDirectory is set, the IBM Data Server Driver for JDBC and SQLJ searches the directory that is specified by db2.jcc.outputDirectory for a file named jccServerListCache.bin.

2) If db2.jcc.outputDirectory is not set, and the java.io.tmpdir system property is set, the IBM Data Server Driver for JDBC and SQLJ searches the directory that is specified by java.io.tmpdir for a file named jccServerListCache.bin.

3) If jccServerListCache.bin can be accessed, the IBM Data Server Driver for JDBC and SQLJ loads the cache into memory, and obtains the alternate server information from jccServerListCache.bin for the serverName value that is defined for the DataSource object.

d. If no primary or alternate server information is available, a connection cannot be established, and the IBM Data Server Driver for JDBC and SQLJ throws an exception.

- For subsequent connections, the IBM Data Server Driver for JDBC and SQLJ obtains primary and alternate server values from driver memory.

2. The IBM Data Server Driver for JDBC and SQLJ attempts to connect to the data source using the primary server name and port number.

In a non-DB2 pureScale environment, the primary server is a stand-alone server. In a DB2 pureScale environment, the primary server is a member of a DB2 pureScale instance.

If the connection is through the DriverManager interface, the IBM Data Server Driver for JDBC and SQLJ creates an internal DataSource object for automatic client reroute processing.

3. If the connection to the primary server fails:

a. If this is the first connection, the IBM Data Server Driver for JDBC and SQLJ attempts to reconnect to a server using information that is provided by driver properties such as clientRerouteAlternateServerName and clientRerouteAlternatePortNumber.

b. If this is not the first connection, the IBM Data Server Driver for JDBC and SQLJ attempts to make a connection using the information from the latest server list that is returned from the server.

Connection to an alternate server is called *failover*.

The IBM Data Server Driver for JDBC and SQLJ uses the maxRetriesForClientReroute and retryIntervalForClientReroute properties to
determine how many times to retry the connection and how long to wait between retries. An attempt to connect to the primary server and alternate servers counts as one retry.

4. If the connection is not established, maxRetriesForClientReroute and retryIntervalForClientReroute are not set, and the original serverName and portNumber values that are defined on the DataSource are different from the serverName and portNumber values that were used for the current connection, the connection is retried with the serverName and portNumber values that are defined on the DataSource.

5. If failover is successful during the initial connection, the driver generates an SQLWarning. If a successful failover occurs after the initial connection:
   - If seamless failover is enabled, and the following conditions are satisfied, the driver retries the transaction on the new server, without notifying the application.
     - The enableSeamlessFailover property is set to DB2BaseDataSource.YES (1).
     - The connection is not in a transaction. That is, the failure occurs when the first SQL statement in the transaction is executed.
     - There are no global temporary tables in use on the server.
     - There are no open, held cursors.
   - If seamless failover is not in effect, the driver throws an SQLException to the application with error code -4498, to indicate to the application that the connection was automatically reestablished and the transaction was implicitly rolled back. The application can then retry its transaction without doing an explicit rollback first.

A reason code that is returned with error code -4498 indicates whether any database server special registers that were modified during the original connection are reestablished in the failover connection.

You can determine whether alternate server information was used in establishing the initial connection by calling the DB2Connection.alternateWasUsedOnConnect method.

6. After failover, driver memory is updated with new primary and alternate server information that is returned from the new primary server.

**Examples**

*Example: Automatic client reroute to a DB2 for Linux, UNIX, and Windows server when maxRetriesForClientReroute and retryIntervalForClientReroute are not set:* Suppose that the following properties are set for a connection to a database:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableClientAffinitiesList</td>
<td>DB2BaseDataSource.NO (2)</td>
</tr>
<tr>
<td>serverName</td>
<td>host1</td>
</tr>
<tr>
<td>portNumber</td>
<td>port1</td>
</tr>
<tr>
<td>clientRerouteAlternateServerName</td>
<td>host2</td>
</tr>
<tr>
<td>clientRerouteAlternatePortNumber</td>
<td>port2</td>
</tr>
</tbody>
</table>

The following steps demonstrate an automatic client reroute scenario for a connection to a DB2 for Linux, UNIX, and Windows server:

1. The IBM Data Server Driver for JDBC and SQLJ loads host1:port1 into its memory as the primary server address, and host2:port2 into its memory as the alternate server address.
2. On the initial connection, the driver tries to connect to host1:port1.
3. The connection to host1:port1 fails, so the driver tries another connection to host1:port1.
4. The reconnection to host1:port1 fails, so the driver tries to connect to host2:port2.
5. The connection to host2:port2 succeeds.
6. The driver retrieves alternate server information that was received from server host2:port2, and updates its memory with that information. Assume that the driver receives a server list that contains host2:port2, host2a:port2a. host2:port2 is stored as the new primary server, and host2a:port2a is stored as the new alternate server. If another communication failure is detected on this same connection, or on another connection that is created from the same DataSource, the driver tries to connect to host2:port2 as the new primary server. If that connection fails, the driver tries to connect to the new alternate server host2a:port2a.
7. A communication failure occurs during the connection to host2:port2.
8. The driver tries to connect to host2a:port2a.
9. The connection to host2a:port2a is successful.
10. The driver retrieves alternate server information that was received from server host2a:port2a, and updates its memory with that information.

Example: Automatic client reroute to a DB2 for Linux, UNIX, and Windows server in a DB2 pureScale environment, when maxRetriesForClientReroute and retryIntervalForClientReroute are not set, and configuration property db2.jcc.outputDirectory is set: Suppose that the following properties are set for a connection that is established from DataSource A:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableClientAffinitiesList</td>
<td>DB2BaseDataSource.NO (2)</td>
</tr>
<tr>
<td>serverName</td>
<td>host1</td>
</tr>
<tr>
<td>portNumber</td>
<td>port1</td>
</tr>
<tr>
<td>db2.jcc.outputDirectory</td>
<td>/home/tmp</td>
</tr>
</tbody>
</table>

The following steps demonstrate an automatic client reroute scenario for a connection to a DB2 for Linux, UNIX, and Windows server:

1. Using the information in DataSource A, the IBM Data Server Driver for JDBC and SQLJ loads host1:port1 into its memory as the primary server address. The driver searches for cache file jccServerListCache.bin in /home/tmp, but the cache file does not exist.
2. The connection to host1:port1 succeeds. Suppose that the server returns a server list that contains host1:port1 and host2:port2.
3. The driver creates a cache in memory, with an entry that specifies host2:port2 as the alternate server list for host1:port1. The driver then creates the cache file /home/tmp/jccServerListCache.bin, and writes the cache from memory to this file.
4. The connection of Application A to host1:port1 fails, so the driver tries to connect to host2:port2.
5. The connection of Application A to host2:port2 succeeds. Suppose that the server returns a server list that contains host2:port2 and host2a:port2a. host2:port2 is the new primary server, and host2a:port2a is the new alternate server.

6. The driver looks for alternate server information for host2:port2 in the in-memory cache, but does not find any. It creates a new entry in the in-memory cache for host2:port2, with host2a:port2a as the alternate server list. The driver updates cache file /home/tmp/jccServerListCache.bin with the new entry that was added to the in-memory cache.

7. Application A completes, and the JVM exits.

8. Application B, which also uses DataSource A, starts.

9. The driver loads the server list from cache file /home/tmp/jccServerListCache.bin into memory, and finds the entry for host1:port1, which specifies host2:port2 as the alternate server list. The driver sets host2:port2 as the alternate server list for host1:port1.

10. A communication failure occurs when Application B tries to connect to host1:port1.

11. Application B attempts to connect to alternate server host2:port2.

12. The connection to host2:port2 succeeds. Application B continues.

Example: Automatic client reroute to a DB2 for Linux, UNIX, and Windows server when maxRetriesForClientReroute and retryIntervalForClientReroute are set for multiple retries: Suppose that the following properties are set for a connection to a database:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableClientAffinitiesList</td>
<td>DB2BaseDataSource.NO (2)</td>
</tr>
<tr>
<td>serverName</td>
<td>host1</td>
</tr>
<tr>
<td>portNumber</td>
<td>port1</td>
</tr>
<tr>
<td>clientRerouteAlternateServerName</td>
<td>host2</td>
</tr>
<tr>
<td>clientRerouteAlternatePortNumber</td>
<td>port2</td>
</tr>
<tr>
<td>maxRetriesForClientReroute</td>
<td>3</td>
</tr>
<tr>
<td>retryIntervalForClientReroute</td>
<td>2</td>
</tr>
</tbody>
</table>

The following steps demonstrate an automatic client reroute scenario for a connection to a DB2 for Linux, UNIX, and Windows server:

1. The IBM Data Server Driver for JDBC and SQLJ loads host1:port1 into its memory as the primary server address, and host2:port2 into its memory as the alternate server address.

2. On the initial connection, the driver tries to connect to host1:port1.

3. The connection to host1:port1 fails, so the driver tries another connection to host1:port1.

4. The connection to host1:port1 fails again, so the driver tries to connect to host2:port2.

5. The connection to host2:port2 fails.

6. The driver waits two seconds.

7. The driver tries to connect to host1:port1 and fails.

8. The driver tries to connect to host2:port2 and fails.

9. The driver waits two seconds.

10. The driver tries to connect to host1:port1 and fails.
11. The driver tries to connect to host2:port2 and fails.
12. The driver waits two seconds.
13. The driver throws an SQLException with error code -4499.

Operation of workload balancing for connections to DB2 for Linux, UNIX, and Windows

Workload balancing (also called transaction-level workload balancing) for connections to DB2 for Linux, UNIX, and Windows contributes to high availability by balancing work among servers in a DB2 pureScale instance at the start of a transaction.

The following overview describes the steps that occur when a client connects to a DB2 for Linux, UNIX, and Windows DB2 pureScale instance, and transaction-level workload balancing is enabled:

1. When the client first establishes a connection to the DB2 pureScale instance, the member to which the client connects returns a server list with the connection details (IP address, port, and weight) for the members of the DB2 pureScale instance.
   The server list is cached by the client. The default lifespan of the cached server list is 30 seconds.

2. At the start of a new transaction, the client reads the cached server list to identify a server that has unused capacity, and looks in the transport pool for an idle transport that is tied to the under-utilized server. (An idle transport is a transport that has no associated connection object.)
   - If an idle transport is available, the client associates the connection object with the transport.
   - If, after a user-configurable timeout period (db2.jcc.maxTransportObjectWaitTime for a Java client or maxTransportWaitTime for a non-Java client), no idle transport is available in the transport pool and no new transport can be allocated because the transport pool has reached its limit, an error is returned to the application.

3. When the transaction runs, it accesses the server that is tied to the transport.
   When the first SQL statement in a transaction runs, if the IBM Data Server Driver for JDBC and SQLJ receives a communication failure because the data server drops the connection or the blockingReadConnectionTimeout value was exceeded, the driver retries the SQL statement 10 times before it reports an error. On every retry, the driver closes the existing transport, obtains a new transport and then executes the transaction. During these retries, if the maxRetriesForClientReroute and retryIntervalForClientReroute properties are set, their values apply only to the process of obtaining a new transport during each retry.

4. When the transaction ends, the client verifies with the server that transport reuse is still allowed for the connection object.
5. If transport reuse is allowed, the server returns a list of SET statements for special registers that apply to the execution environment for the connection object.

The client caches these statements, which it replays in order to reconstruct the execution environment when the connection object is associated with a new transport.

6. The connection object is then dissociated from the transport, if the client determines that it needs to do so.

7. The client copy of the server list is refreshed when a new connection is made, or every 30 seconds, or the user-configured interval.

8. When transaction-level workload balancing is required for a new transaction, the client uses the previously described process to associate the connection object with a transport.

Application programming requirements for high availability for connections to DB2 for Linux, UNIX, and Windows servers

Failover for automatic client reroute can be seamless or non-seamless. If failover for connections to DB2 for Linux, UNIX, and Windows is not seamless, you need to add code to account for the errors that are returned when failover occurs.

If failover is non-seamless, and a connection is reestablished with the server, SQLCODE -4498 (for Java clients) or SQL30108N (for non-Java clients) is returned to the application. All work that occurred within the current transaction is rolled back. In the application, you need to:

- Check the reason code that is returned with the error. Determine whether special register settings on the failing data sharing member are carried over to the new (failover) data sharing member. Reset any special register values that are not current.
- Execute all SQL operations that occurred during the previous transaction.

The following conditions must be satisfied for failover for connections to DB2 for Linux, UNIX, and Windows to be seamless:

- The application programming language is Java, CLI, or .NET.
- The connection is not in a transaction. That is, the failure occurs when the first SQL statement in the transaction is executed.
- If transaction-level load balancing is enabled, the data server allows transport reuse at the end of the previous transaction.
- All global session data is closed or dropped.
- There are no open, held cursors.
- If the application uses CLI, the application cannot perform actions that require the driver to maintain a history of previously called APIs in order to replay the SQL statement. Examples of such actions are specifying data at execution time, performing compound SQL, or using array input.
- The application is not a stored procedure.
- Autocommit is not enabled. Seamless failover can occur when autocommit is enabled. However, the following situation can cause problems: Suppose that SQL work is successfully executed and committed at the data server, but the connection or server goes down before acknowledgment of the commit operation is sent back to the client. When the client re-establishes the connection, it replays the previously committed SQL statement. The result is that the SQL statement is executed twice. To avoid this situation, turn autocommit off when you enable seamless failover.
Client affinities for DB2 for Linux, UNIX, and Windows

Client affinities is a client-only method for providing automatic client reroute capability.

Client affinities is available for applications that use CLI, .NET, or Java (IBM Data Server Driver for JDBC and SQLJ type 4 connectivity). All rerouting is controlled by the driver.

Client affinities is intended for situations in which you need to connect to a particular primary server. If an outage occurs during the connection to the primary server, you need to enforce a specific order for failover to alternate servers. You should use client affinities for automatic client reroute only if automatic client reroute that uses server failover capabilities does not work in your environment.

As part of configuration of client affinities, you specify a list of alternate servers, and the order in which connections to the alternate servers are tried. When client affinities is in use, connections are established based on the list of alternate servers instead of the host name and port number that are specified by the application. For example, if an application specifies that a connection is made to server1, but the configuration process specifies that servers should be tried in the order (server2, server3, server1), the initial connection is made to server2 instead of server1.

Failure with client affinities is seamless, if the following conditions are true:

- The connection is not in a transaction. That is, the failure occurs when the first SQL statement in the transaction is executed.
- There are no global temporary tables in use on the server.
- There are no open, held cursors.

When you use client affinities, you can specify that if the primary server returns to operation after an outage, connections return from an alternate server to the primary server on a transaction boundary. This activity is known as failback.

Configuration of client affinities for Java clients for DB2 for Linux, UNIX, and Windows connections

To enable support for client affinities in Java applications, you set properties to indicate that you want to use client affinities, and to specify the primary and alternate servers.

The following table describes the property settings for enabling client affinities for Java applications.

<table>
<thead>
<tr>
<th>IBM Data Server Driver for JDBC and SQLJ setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableClientAffinitiesList</td>
<td>DB2BaseDataSource.YES (1)</td>
</tr>
<tr>
<td>clientRerouteAlternateServerName</td>
<td>A comma-separated list of the primary server and alternate servers</td>
</tr>
<tr>
<td>clientRerouteAlternatePortNumber</td>
<td>A comma-separated list of the port numbers for the primary server and alternate servers</td>
</tr>
</tbody>
</table>
Table 39. Property settings to enable client affinities for Java applications (continued)

<table>
<thead>
<tr>
<th>IBM Data Server Driver for JDBC and SQLJ setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableSeamlessFailover</td>
<td>DB2BaseDataSource.YES (1) for seamless failover; DB2BaseDataSource.NO (2) or enableSeamlessFailover not specified for no seamless failover</td>
</tr>
<tr>
<td>maxRetriesForClientReroute</td>
<td>The number of times to retry the connection to each server, including the primary server, after a connection to the primary server fails. The default is 3.</td>
</tr>
<tr>
<td>retryIntervalForClientReroute</td>
<td>The number of seconds to wait between retries. The default is no wait.</td>
</tr>
<tr>
<td>affinityFailbackInterval</td>
<td>The number of seconds to wait after the first transaction boundary to fail back to the primary server. Set this value if you want to fail back to the primary server.</td>
</tr>
</tbody>
</table>

Related reference:
“Common IBM Data Server Driver for JDBC and SQLJ properties for all supported database products” on page 327

Example of enabling client affinities in Java clients for DB2 for Linux, UNIX, and Windows connections

Before you can use client affinities for automatic client reroute in Java applications, you need to set properties to indicate that you want to use client affinities, and to identify the primary alternate servers.

The following example shows how to enable client affinities for failover without failback.

Suppose that you set the following properties for a connection to a database:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableClientAffinitiesList</td>
<td>DB2BaseDataSource.YES (1)</td>
</tr>
<tr>
<td>clientRerouteAlternateServername</td>
<td>host1,host2,host3</td>
</tr>
<tr>
<td>clientRerouteAlternatePortNumber</td>
<td>port1,port2,port3</td>
</tr>
<tr>
<td>maxRetriesForClientReroute</td>
<td>3</td>
</tr>
<tr>
<td>retryIntervalForClientReroute</td>
<td>2</td>
</tr>
</tbody>
</table>

Suppose that a communication failure occurs during a connection to the server that is identified by host1:port1. The following steps demonstrate automatic client reroute with client affinities.

1. The driver tries to connect to host1:port1.
2. The connection to host1:port1 fails.
3. The driver waits two seconds.
4. The driver tries to connect to host1:port1.
5. The connection to host1:port1 fails.
6. The driver waits two seconds.
7. The driver tries to connect to host1:port1.
8. The connection to host1:port1 fails.
9. The driver waits two seconds.
10. The driver tries to connect to host2:port2.
11. The connection to host2:port2 fails.
12. The driver waits two seconds.
13. The driver tries to connect to host2:port2.
14. The connection to host2:port2 fails.
15. The driver waits two seconds.
16. The driver tries to connect to host2:port2.
17. The connection to host2:port2 fails.
18. The driver waits two seconds.
19. The driver tries to connect to host3:port3.
20. The connection to host3:port3 fails.
21. The driver waits two seconds.
22. The driver tries to connect to host3:port3.
23. The connection to host3:port3 fails.
24. The driver waits two seconds.
25. The driver tries to connect to host3:port3.
26. The connection to host3:port3 fails.
27. The driver waits two seconds.
28. The driver throws an SQLException with error code -4499.

The following example shows how to enable client affinities for failover with failback.

Suppose that you set the following properties for a connection to a database:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableClientAffinitiesList</td>
<td>DB2BaseDataSource.YES (1)</td>
</tr>
<tr>
<td>clientRerouteAlternateServerName</td>
<td>host1,host2,host3</td>
</tr>
<tr>
<td>clientRerouteAlternatePortNumber</td>
<td>port1,port2,port3</td>
</tr>
<tr>
<td>maxRetriesForClientReroute</td>
<td>3</td>
</tr>
<tr>
<td>retryIntervalForClientReroute</td>
<td>2</td>
</tr>
<tr>
<td>affinityFailbackInterval</td>
<td>300</td>
</tr>
</tbody>
</table>

Suppose that the database administrator takes the server that is identified by host1:port1 down for maintenance after a connection is made to host1:port1. The following steps demonstrate failover to an alternate server and failback to the primary server after maintenance is complete.

1. The driver successfully connects to host1:port1 on behalf of an application.
2. The database administrator brings down host1:port1.
3. The application tries to do work on the connection.
4. The driver successfully fails over to host2:port2.
5. After a total of 200 seconds have elapsed, the work is committed.
6. After a total of 300 seconds have elapsed, the failback interval has elapsed. The driver checks whether the primary server is up. It is not up, so no failback occurs.
7. After a total of 350 seconds have elapsed, host1:port1 is brought back online. 
8. The application continues to do work on host2:port2, because the latest failback interval has not elapsed. 
9. After a total of 600 seconds have elapsed, the failback interval has elapsed again. The driver checks whether the primary server is up. It is now up. 
10. After a total of 650 seconds have elapsed, the work is committed. 
11. After a total of 651 seconds have elapsed, the application tries to start a new transaction on host2:port2. Failback to host1:port1 occurs, so the new transaction starts on host1:port1.

**Java client support for high availability for connections to IBM Informix servers**

High-availability cluster support on IBM Informix servers provides high availability for client applications, through workload balancing and automatic client reroute. This support is available for applications that use Java clients (JDBC, SQLJ, or pureQuery), or non-Java clients (ODBC, CLI, .NET, OLE DB, PHP, Ruby, or embedded SQL).

For Java clients, you need to use IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to take advantage of IBM Informix high-availability cluster support.

For non-Java clients, you need to use one of the following clients or client packages to take advantage of high-availability cluster support:
- IBM Data Server Client
- IBM Data Server Runtime Client
- IBM Data Server Driver Package
- IBM Data Server Driver for ODBC and CLI

Cluster support for high availability for connections to IBM Informix servers includes:

**Automatic client reroute**

This support enables a client to recover from a failure by attempting to reconnect to the database through any available server in a high-availability cluster. Reconnection to another server is called *failover*. You enable automatic client reroute on the client by enabling workload balancing on the client.

In an IBM Informix environment, primary and standby servers correspond to members of a high-availability cluster that is controlled by a Connection Manager. If multiple Connection Managers exist, the client can use them to determine primary and alternate server information. The client uses alternate Connection Managers only for the initial connection.

Failover for automatic client reroute can be *seamless* or *non-seamless*. With non-seamless failover, when the client application reconnects to an alternate server, the server always returns an error to the application, to indicate that failover (connection to the alternate server) occurred.
For Java, CLI, or .NET client applications, failover for automatic client reroute can be seamless or non-seamless. Seamless failover means that when the application successfully reconnects to an alternate server, the server does not return an error to the application.

**Workload balancing**

Workload balancing can improve availability of an IBM Informix high-availability cluster. When workload balancing is enabled, the client gets frequent status information about the members of a high-availability cluster. The client uses this information to determine the server to which the next transaction should be routed. With workload balancing, IBM Informix Connection Managers ensure that work is distributed efficiently among servers and that work is transferred to another server if a server has a failure.

**Connection concentrator**

This support is available for Java applications that connect to IBM Informix. The connection concentrator reduces the resources that are required on IBM Informix database servers to support large numbers of workstation and web users. With the connection concentrator, only a few concurrent, active physical connections are needed to support many applications that concurrently access the database server. When you enable workload balancing on a Java client, you automatically enable the connection concentrator.

**Client affinities**

Client affinities is an automatic client reroute solution that is controlled completely by the client. It is intended for situations in which you need to connect to a particular primary server. If an outage occurs during the connection to the primary server, you use client affinities to enforce a specific order for failover to alternate servers.

**Configuration of IBM Informix high-availability support for Java clients**

To configure an IBM Data Server Driver for JDBC and SQLJ client application that connects to an IBM Informix high-availability cluster, you need to connect to an address that represents a Connection Manager, and set the properties that enable workload balancing and the maximum number of connections.

High availability support for Java clients that connect to IBM Informix works for connections that are obtained using the `javax.sql.DataSource`, `javax.sql.ConnectionPoolDataSource`, `javax.sql.XADataSource` or `java.sql.DriverManager` interface.

**Restriction:** High availability support for connections that are made with the `DriverManager` interface has the following restrictions:

- Alternate server information is shared between `DriverManager` connections only if you create the connections with the same URL and properties.
- You cannot set the `clientRerouteServerListJNDIName` property or the `clientRerouteServerListJNDIContext` properties for a `DriverManager` connection.
- High availability support is not enabled for default connections (`jdbc:default:connection`).

Before you can enable IBM Data Server Driver for JDBC and SQLJ for high availability for connections to IBM Informix, your installation must have one or more Connection Managers, a primary server, and one or more alternate servers.
The following table describes the basic property settings for enabling workload balancing for Java applications.

**Table 40. Basic settings to enable IBM Informix high availability support in Java applications**

<table>
<thead>
<tr>
<th>IBM Data Server Driver for JDBC and SQLJ setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableSysplexWLB property</td>
<td>true</td>
</tr>
<tr>
<td>maxTransportObjects property</td>
<td>The maximum number of connections that the requester can make to the high-availability cluster</td>
</tr>
<tr>
<td>Connection address: server</td>
<td>The IP address of a Connection Manager. See &quot;Setting server and port properties for connecting to a Connection Manager&quot; on page 276.</td>
</tr>
<tr>
<td>Connection address: port</td>
<td>The SQL port number for the Connection Manager. See &quot;Setting server and port properties for connecting to a Connection Manager&quot; on page 276.</td>
</tr>
<tr>
<td>Connection address: database</td>
<td>The database name</td>
</tr>
</tbody>
</table>

If you want to enable the connection concentrator, but you do not want to enable workload balancing, you can use these properties.

**Table 41. Settings to enable the IBM Informix connection concentrator without workload balancing in Java applications**

<table>
<thead>
<tr>
<th>IBM Data Server Driver for JDBC and SQLJ setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableSysplexWLB property</td>
<td>false</td>
</tr>
<tr>
<td>enableConnectionConcentrator property</td>
<td>true</td>
</tr>
</tbody>
</table>

If you want to fine-tune IBM Informix high-availability support, additional properties are available. The properties for the IBM Data Server Driver for JDBC and SQLJ are listed in the following table. Those properties are configuration properties, and not Connection or DataSource properties.

**Table 42. Properties for fine-tuning IBM Informix high-availability support for connections from the IBM Data Server Driver for JDBC and SQLJ**

<table>
<thead>
<tr>
<th>IBM Data Server Driver for JDBC and SQLJ configuration property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db2.jcc.maxTransportObjectIdleTime</td>
<td>Specifies the maximum elapsed time in number of seconds before an idle transport is dropped. The default is 10. The minimum supported value is 0.</td>
</tr>
<tr>
<td>db2.jcc.maxTransportObjectWaitTime</td>
<td>Specifies the number of seconds that the client will wait for a transport to become available. The default is 1. The minimum supported value is 0.</td>
</tr>
<tr>
<td>db2.jcc.minTransportObjects</td>
<td>Specifies the lower limit for the number of transport objects in a global transport object pool. The default value is 0. Any value that is less than or equal to 0 means that the global transport object pool can become empty.</td>
</tr>
</tbody>
</table>

Setting server and port properties for connecting to a Connection Manager

To set the server and port number for connecting to a Connection Manager, follow this process:

- If your high-availability cluster is using a single Connection Manager, and your application is using the DataSource interface for connections, set the serverName and portNumber properties to the server name and port number of the Connection Manager.

- If your high-availability cluster is using a single Connection Manager, and your application is using the DriverManager interface for connections, specify the server name and port number of the Connection Manager in the connection URL.

- If your high-availability cluster is using more than one Connection manager, and your application is using the DriverManager interface for connections:
  1. Specify the server name and port number of the main Connection Manager that you want to use in the connection URL.
  2. Set the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber properties to the server names and port numbers of the alternative Connection Managers that you want to use.

- If your high-availability cluster is using more than one Connection Manager, and your application is using the DataSource interface for connections, use one of the following techniques:
  - Set the server names and port numbers in DataSource properties:
    1. Set the serverName and portNumber properties to the server name and port number of the main Connection Manager that you want to use.
    2. Set the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber properties to the server names and port numbers of the alternative Connection Managers that you want to use.
  - Configure JNDI for high availability by using a DB2ClientRerouteServerList instance to identify the main Connection Manager and alternative Connection Managers.
    1. Create an instance of DB2ClientRerouteServerList.
    DB2ClientRerouteServerList is a serializable Java bean with the following properties:

<table>
<thead>
<tr>
<th>Property name</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.ibm.db2.jcc.DB2ClientRerouteServerList.alternateServerName</td>
<td>String[]</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2ClientRerouteServerList.alternatePortNumber</td>
<td>int[]</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2ClientRerouteServerList.primaryServerName</td>
<td>String[]</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2ClientRerouteServerList.primaryPortNumber</td>
<td>int[]</td>
</tr>
</tbody>
</table>

getXXX and setXXX methods are defined for each property.

2. Set the com.ibm.db2.jcc.DB2ClientRerouteServerList.primaryServerName and com.ibm.db2.jcc.DB2ClientRerouteServerList.primaryPortNumber properties to the server name and port number of the main Connection Manager that you want to use.

3. Set the com.ibm.db2.jcc.DB2ClientRerouteServerList.alternateServerName and com.ibm.db2.jcc.DB2ClientRerouteServerList.alternatePortNumber
properties to the server names and port numbers of the alternative Connection Managers that you want to use.

4. To make the DB2ClientRerouteServerList persistent:
   a. Bind the DB2ClientRerouteServerList instance to the JNDI registry.
   b. Assign the JNDI name of the DB2ClientRerouteServerList object to the IBM Data Server Driver for JDBC and SQLJ clientRerouteServerListJNDIName property.
   c. Assign the name of the JNDI context that is used for binding and lookup of the DB2ClientRerouteServerList instance to the clientRerouteServerListJNDIContext property.

When a DataSource is configured to use JNDI for storing automatic client reroute alternate information, the standard server and port properties of the DataSource are not used for a getConnection request. Instead, the primary server address is obtained from the transient clientRerouteServerList information. If the JNDI store is not available due to a JNDI bind or lookup failure, the IBM Data Server Driver for JDBC and SQLJ attempts to make a connection using the standard server and port properties of the DataSource. Warnings are accumulated to indicate that a JNDI bind or lookup failure occurred.

After a failover:

- The IBM Data Server Driver for JDBC and SQLJ attempts to propagate the updated server information to the JNDI store.
- primaryServerName and primaryPortNumber values that are specified in DB2ClientRerouteServerList are used for the connection. If primaryServerName is not specified, the serverName value for the DataSource instance is used.

Example of enabling IBM Informix high availability support in Java applications

Java client setup for IBM Informix high availability support includes setting several IBM Data Server Driver for JDBC and SQLJ properties.

The following example demonstrates setting up Java client applications for IBM Informix high availability support.

Before you can set up the client, you need to configure one or more high availability clusters that are controlled by Connection Managers.

Follow these steps to set up the client:

1. Verify that the IBM Data Server Driver for JDBC and SQLJ is at the correct level to support workload balancing by following these steps:
   a. Issue the following command in a command line window:
Find a line in the output like this, and check that `n.nn` is 3.52 or later.

```
[jcc] Driver: IBM Data Server Driver for JDBC and SQLJ Architecture n.nn xxx
```

2. Set IBM Data Server Driver for JDBC and SQLJ properties to enable the connection concentrator or workload balancing:
   a. Set these Connection or DataSource properties:
      - `enableSysplexWLB`
      - `maxTransportObjects`
   b. Set the `db2.jcc.maxRefreshInterval` global configuration property in a `DB2JccConfiguration.properties` file to set the maximum refresh interval for all DataSource or Connection instances that are created under the driver.

   Start with settings similar to these:

<table>
<thead>
<tr>
<th>Property</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableSysplexWLB</td>
<td>true</td>
</tr>
<tr>
<td>maxTransportObjects</td>
<td>80</td>
</tr>
<tr>
<td><code>db2.jcc.maxRefreshInterval</code></td>
<td>10</td>
</tr>
</tbody>
</table>

   The values that are specified are not intended to be recommended values. You need to determine values based on factors such as the number of physical connections that are available. The number of transport objects must be equal to or greater than the number of connection objects.

3. Set IBM Data Server Driver for JDBC and SQLJ configuration properties to fine-tune the workload balancing for all DataSource or Connection instances that are created under the driver. Set the configuration properties in a `DB2JccConfiguration.properties` file by following these steps:
   a. Create a `DB2JccConfiguration.properties` file or edit the existing `DB2JccConfiguration.properties` file.
   b. Set the following configuration property:
      - `db2.jcc.maxTransportObjects`
      Start with a setting similar to this one:
      ```
      db2.jcc.maxTransportObjects=1000
      ```
   c. Include the directory that contains `DB2JccConfiguration.properties` in the CLASSPATH concatenation.
Operation of automatic client reroute for connections to IBM Informix from Java clients

When IBM Data Server Driver for JDBC and SQLJ client reroute support is enabled, a Java application that is connected to an IBM Informix high-availability cluster can continue to run when the primary server has a failure.

Automatic client reroute for a Java application that is connected to an IBM Informix server operates in the following way when automatic client reroute is enabled:

1. During each connection to the data source, the IBM Data Server Driver for JDBC and SQLJ obtains primary and alternate server information.
   - For the first connection to IBM Informix:
     a. The application specifies a server and port for the initial connection. Those values identify a Connection Manager.
     b. The IBM Data Server Driver for JDBC and SQLJ uses the information from the Connection Manager to obtain information about the primary and alternate servers. IBM Data Server Driver for JDBC and SQLJ loads those values into memory.
     c. If the initial connection to the Connection Manager fails:
        - If the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber properties are set, the IBM Data Server Driver for JDBC and SQLJ connects to the Connection Manager that is identified by clientRerouteAlternateServerName and clientRerouteAlternatePortNumber, and obtains information about primary and alternate servers from that Connection Manager. The IBM Data Server Driver for JDBC and SQLJ loads those values into memory as the primary and alternate server values.
        - If the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber properties are not set, and a JNDI store is configured by setting the property clientRerouteServerListJNDIName on the DB2BaseDataSource, the IBM Data Server Driver for JDBC and SQLJ connects to the Connection Manager that is identified by DB2ClientRerouteServerList.alternateServerName and DB2ClientRerouteServerList.alternatePortNumber, and obtains information about primary and alternate servers from that Connection Manager. IBM Data Server Driver for JDBC and SQLJ loads the primary and alternate server information from the Connection Manager into memory.
     d. If clientRerouteAlternateServerName and clientRerouteAlternatePortNumber are not set, and JNDI is not configured, the IBM Data Server Driver for JDBC and SQLJ checks DNS.
tables for Connection Manager server and port information. If DNS information exists, the IBM Data Server Driver for JDBC and SQLJ connects to the Connection Manager, obtains information about primary and alternate servers, and loads those values into memory.

e. If no primary or alternate server information is available, a connection cannot be established, and the IBM Data Server Driver for JDBC and SQLJ throws an exception.

   • For subsequent connections, the IBM Data Server Driver for JDBC and SQLJ obtains primary and alternate server values from driver memory.

2. The IBM Data Server Driver for JDBC and SQLJ attempts to connect to the data source using the primary server name and port number.

If the connection is through the DriverManager interface, the IBM Data Server Driver for JDBC and SQLJ creates an internal DataSource object for automatic client reroute processing.

3. If the connection to the primary server fails:
   a. If this is the first connection, the IBM Data Server Driver for JDBC and SQLJ attempts to reconnect to the original primary server.
   b. If this is not the first connection, the IBM Data Server Driver for JDBC and SQLJ attempts to reconnect to the new primary server, whose server name and port number were provided by the server.
   c. If reconnection to the primary server fails, the IBM Data Server Driver for JDBC and SQLJ attempts to connect to the alternate servers.

   If this is not the first connection, the latest alternate server list is used to find the next alternate server.

Connection to an alternate server is called failover.

The IBM Data Server Driver for JDBC and SQLJ uses the maxRetriesForClientReroute and retryIntervalForClientReroute properties to determine how many times to retry the connection and how long to wait between retries. An attempt to connect to the primary server and alternate servers counts as one retry.

4. If the connection is not established, maxRetriesForClientReroute and retryIntervalForClientReroute are not set, and the original serverName and portNumber values that are defined on the DataSource are different from the serverName and portNumber values that were used for the original connection, retry the connection with the serverName and portNumber values that are defined on the DataSource.

5. If failover is successful during the initial connection, the driver generates an SQLWarning. If a successful failover occurs after the initial connection:

   • If seamless failover is enabled, the driver retries the transaction on the new server, without notifying the application.

The following conditions must be satisfied for seamless failover to occur:

   – The enableSeamlessFailover property is set to DB2BaseDataSource.YES (1).
     If Sysplex workload balancing is in effect (the value of the enableSysplexWLB is true), seamless failover is attempted, regardless of the enableSeamlessFailover setting.
   – The connection is not in a transaction. That is, the failure occurs when the first SQL statement in the transaction is executed.
   – There are no global temporary tables in use on the server.
   – There are no open, held cursors.

   • If seamless failover is not in effect, the driver throws an SQLException to the application with error code -4498, to indicate to the application that the
connection was automatically reestablished and the transaction was implicitly rolled back. The application can then retry its transaction without doing an explicit rollback first.

A reason code that is returned with error code -4498 indicates whether any database server special registers that were modified during the original connection are reestablished in the failover connection.

You can determine whether alternate server information was used in establishing the initial connection by calling the DB2Connection.alternateWasUsedOnConnect method.

6. After failover, driver memory is updated with new primary and alternate server information from the new primary server.

Examples

Example: Automatic client reroute to an IBM Informix server when maxRetriesForClientReroute and retryIntervalForClientReroute are not set: Suppose that the following properties are set for a connection to a database:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableClientAffinitiesList</td>
<td>DB2BaseDataSource.NO (2)</td>
</tr>
<tr>
<td>serverName</td>
<td>host1</td>
</tr>
<tr>
<td>portNumber</td>
<td>port1</td>
</tr>
<tr>
<td>clientRerouteAlternateServerName</td>
<td>host2</td>
</tr>
<tr>
<td>clientRerouteAlternatePortNumber</td>
<td>port2</td>
</tr>
</tbody>
</table>

The following steps demonstrate an automatic client reroute scenario for a connection to IBM Informix:

1. The IBM Data Server Driver for JDBC and SQLJ tries to connect to the Connection Manager that is identified by host1:port1.
2. The connection to host1:port1 fails, so the driver tries to connect to the Connection Manager that is identified by host2:port2.
3. The connection to host2:port2 succeeds.
4. The driver retrieves alternate server information that was received from server host2:port2, and updates its memory with that information.
   Assume that the driver receives a server list that contains host2:port2, host2a:port2a. host2:port2 is stored as the new primary server, and host2a:port2a is stored as the new alternate server. If another communication failure is detected on this same connection, or on another connection that is created from the same DataSource, the driver tries to connect to host2:port2 as the new primary server. If that connection fails, the driver tries to connect to the new alternate server host2a:port2a.
5. The driver connects to host1a:port1a.
6. A failure occurs during the connection to host1a:port1a.
7. The driver tries to connect to host2a:port2a.
8. The connection to host2a:port2a is successful.
9. The driver retrieves alternate server information that was received from server host2a:port2a, and updates its memory with that information.
**Example: Automatic client reroute to an IBM Informix server when**

**maxRetriesForClientReroute and retryIntervalForClientReroute are set for multiple retries:**

Suppose that the following properties are set for a connection to a database:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableClientAffinitiesList</td>
<td>DB2BaseDataSource.NO (2)</td>
</tr>
<tr>
<td>serverName</td>
<td>host1</td>
</tr>
<tr>
<td>portNumber</td>
<td>port1</td>
</tr>
<tr>
<td>clientRerouteAlternateServerName</td>
<td>host2</td>
</tr>
<tr>
<td>clientRerouteAlternatePortNumber</td>
<td>port2</td>
</tr>
<tr>
<td>maxRetriesForClientReroute</td>
<td>3</td>
</tr>
<tr>
<td>retryIntervalForClientReroute</td>
<td>2</td>
</tr>
</tbody>
</table>

The following steps demonstrate an automatic client reroute scenario for a connection to IBM Informix:

1. The IBM Data Server Driver for JDBC and SQLJ tries to connect to the Connection Manager that is identified by host1:port1.
2. The connection to host1:port1 fails, so the driver tries to connect to the Connection Manager that is identified by host2:port2.
3. The connection to host2:port2 succeeds.
4. The driver retrieves alternate server information from the connection manager that is identified by host2:port2, and updates its memory with that information. Assume that the Connection Manager identifies host1a:port1a as the new primary server, and host2a:port2a as the new alternate server.
5. The driver tries to connect to host1a:port1a.
6. The connection to host1a:port1a fails.
7. The driver tries to connect to host2a:port2a.
8. The connection to host2a:port2a fails.
9. The driver waits two seconds.
10. The driver tries to connect to host1a:port1a.
11. The connection to host1a:port1a fails.
12. The driver tries to connect to host2a:port2a.
13. The connection to host2a:port2a fails.
14. The driver waits two seconds.
15. The driver tries to connect to host1a:port1a.
16. The connection to host1a:port1a fails.
17. The driver tries to connect to host2a:port2a.
18. The connection to host2a:port2a fails.
19. The driver waits two seconds.
20. The driver throws an SQLException with error code -4499.
Operation of workload balancing for connections to IBM Informix from Java clients

Workload balancing (also called transaction-level workload balancing) for connections to IBM Informix contributes to high availability by balancing work among servers in a high-availability cluster at the start of a transaction.

The following overview describes the steps that occur when a client connects to an IBM Informix Connection Manager, and workload balancing is enabled:

1. When the client first establishes a connection using the IP address of the
   Connection Manager, the Connection Manager returns the server list and the
   connection details (IP address, port, and weight) for the servers in the cluster.
   The server list is cached by the client. The default lifespan of the cached server
   list is 30 seconds.

2. At the start of a new transaction, the client reads the cached server list to
   identify a server that has untapped capacity, and looks in the transport pool for
   an idle transport that is tied to the under-utilized server. (An idle transport is a
   transport that has no associated connection object.)
   • If an idle transport is available, the client associates the connection object
     with the transport.
   • If, after a user-configurable timeout, no idle transport is available in the
     transport pool and no new transport can be allocated because the transport
     pool has reached its limit, an error is returned to the application.

3. When the transaction runs, it accesses the server that is tied to the transport.
   When the first SQL statement in a transaction runs, if the IBM Data Server
   Driver for JDBC and SQLJ receives a communication failure because the data
   server drops the connection or the blockingReadConnectionTimeout value was
   exceeded, the driver retries the SQL statement 10 times before it reports an
   error. On every retry, the driver closes the existing transport, obtains a new
   transport and then executes the transaction. During these retries, if the
   maxRetriesForClientReroute and retryIntervalForClientReroute properties are
   set, their values apply only to the process of obtaining a new transport during
   each retry.

4. When the transaction ends, the client verifies with the server that transport
   reuse is still allowed for the connection object.

5. If transport reuse is allowed, the server returns a list of SET statements for
   special registers that apply to the execution environment for the connection
   object.
   The client caches these statements, which it replays in order to reconstruct the
   execution environment when the connection object is associated with a new
   transport.

6. The connection object is then dissociated from the transport, if the client
   determines that it needs to do so.

7. The client copy of the server list is refreshed when a new connection is made,
   or every 30 seconds, or at the user-configured interval.
8. When workload balancing is required for a new transaction, the client uses the previously described process to associate the connection object with a transport.

**Application programming requirements for high availability for connections from Java clients to IBM Informix servers**

Failover for automatic client reroute can be seamless or non-seamless. If failover for connections to IBM Informix is not seamless, you need to add code to account for the errors that are returned when failover occurs.

If failover is non-seamless, and a connection is reestablished with the server, SQLCODE -4498 (for Java clients) or SQL30108N (for non-Java clients) is returned to the application. All work that occurred within the current transaction is rolled back. In the application, you need to:

- Check the reason code that is returned with the error. Determine whether special register settings on the failing data sharing member are carried over to the new (failover) data sharing member. Reset any special register values that are not current.
- Execute all SQL operations that occurred during the previous transaction.

The following conditions must be satisfied for seamless failover to occur during connections to IBM Informix databases:

- The application programming language is Java, CLI, or .NET.
- The connection is not in a transaction. That is, the failure occurs when the first SQL statement in the transaction is executed.
- The data server must allow transport reuse at the end of the previous transaction.
- All global session data is closed or dropped.
- There are no open held cursors.
- If the application uses CLI, the application cannot perform actions that require the driver to maintain a history of previously called APIs in order to replay the SQL statement. Examples of such actions are specifying data at execution time, performing compound SQL, or using array input.
- The application is not a stored procedure.
- Autocommit is not enabled. Seamless failover can occur when autocommit is enabled. However, the following situation can cause problems: Suppose that SQL work is successfully executed and committed at the data server, but the connection or server goes down before acknowledgment of the commit operation is sent back to the client. When the client re-establishes the connection, it replays the previously committed SQL statement. The result is that the SQL statement is executed twice. To avoid this situation, turn autocommit off when you enable seamless failover.

In addition, seamless automatic client reroute might not be successful if the application has autocommit enabled. With autocommit enabled, a statement might be executed and committed multiple times.
Client affinities for connections to IBM Informix from Java clients

Client affinities is a client-only method for providing automatic client reroute capability.

Client affinities is available for applications that use CLI, .NET, or Java (IBM Data Server Driver for JDBC and SQLJ type 4 connectivity). All rerouting is controlled by the driver.

Client affinities is intended for situations in which you need to connect to a particular primary server. If an outage occurs during the connection to the primary server, you need to enforce a specific order for failover to alternate servers. You should use client affinities for automatic client reroute only if automatic client reroute that uses server failover capabilities does not work in your environment.

As part of configuration of client affinities, you specify a list of alternate servers, and the order in which connections to the alternate servers are tried. When client affinities is in use, connections are established based on the list of alternate servers instead of the host name and port number that are specified by the application. For example, if an application specifies that a connection is made to server1, but the configuration process specifies that servers should be tried in the order (server2, server3, server1), the initial connection is made to server2 instead of server1.

Failover with client affinities is seamless, if the following conditions are true:

- The connection is not in a transaction. That is, the failure occurs when the first SQL statement in the transaction is executed.
- There are no global temporary tables in use on the server.
- There are no open, held cursors.

When you use client affinities, you can specify that if the primary server returns to operation after an outage, connections return from an alternate server to the primary server on a transaction boundary. This activity is known as failback.

Configuration of client affinities for Java clients for IBM Informix connections

To enable support for client affinities in Java applications, you set properties to indicate that you want to use client affinities, and to specify the primary and alternate servers.

The following table describes the property settings for enabling client affinities for Java applications.

<table>
<thead>
<tr>
<th>IBM Data Server Driver for JDBC and SQLJ setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableClientAffinitiesList</td>
<td>DB2BaseDataSource.YES (1)</td>
</tr>
<tr>
<td>clientRerouteAlternateServerName</td>
<td>A comma-separated list of the primary server and alternate servers</td>
</tr>
<tr>
<td>IBM Data Server Driver for JDBC and SQLJ setting</td>
<td>Value</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-------</td>
</tr>
<tr>
<td>clientRerouteAlternatePortNumber</td>
<td>A comma-separated list of the port numbers for the primary server and alternate servers</td>
</tr>
<tr>
<td>enableSeamlessFailover</td>
<td>DB2BaseDataSource.YES (1) for seamless failover; DB2BaseDataSource.NO (2) or enableSeamlessFailover not specified for no seamless failover</td>
</tr>
<tr>
<td>maxRetriesForClientReroute</td>
<td>The number of times to retry the connection to each server, including the primary server, after a connection to the primary server fails. The default is 3.</td>
</tr>
<tr>
<td>retryIntervalForClientReroute</td>
<td>The number of seconds to wait between retries. The default is no wait.</td>
</tr>
<tr>
<td>affinityFailbackInterval</td>
<td>The number of seconds to wait after the first transaction boundary to fail back to the primary server. Set this value if you want to fail back to the primary server.</td>
</tr>
</tbody>
</table>

**Related reference:**

["Common IBM Data Server Driver for JDBC and SQLJ properties for all supported database products" on page 327](#)

**Example of enabling client affinities in Java clients for IBM Informix connections**

Before you can use client affinities for automatic client reroute in Java applications, you need to set properties to indicate that you want to use client affinities, and to identify the primary alternate servers.

The following example shows how to enable client affinities for failover without failback.

Suppose that you set the following properties for a connection to a database:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableClientAffinitiesList</td>
<td>DB2BaseDataSource.YES (1)</td>
</tr>
<tr>
<td>clientRerouteAlternateServername</td>
<td>host1,host2,host3</td>
</tr>
<tr>
<td>clientRerouteAlternatePortNumber</td>
<td>port1,port2,port3</td>
</tr>
<tr>
<td>maxRetriesForClientReroute</td>
<td>3</td>
</tr>
<tr>
<td>retryIntervalForClientReroute</td>
<td>2</td>
</tr>
</tbody>
</table>

Suppose that a communication failure occurs during a connection to the server that is identified by host1:port1. The following steps demonstrate automatic client reroute with client affinities.

1. The driver tries to connect to host1:port1.
2. The connection to host1:port1 fails.
3. The driver waits two seconds.
4. The driver tries to connect to host1:port1.
5. The connection to host1:port1 fails.
6. The driver waits two seconds.
7. The driver tries to connect to host1:port1.
8. The connection to host1:port1 fails.
9. The driver waits two seconds.
10. The driver tries to connect to host2:port2.
11. The connection to host2:port2 fails.
12. The driver waits two seconds.
13. The driver tries to connect to host2:port2.
14. The connection to host2:port2 fails.
15. The driver waits two seconds.
16. The driver tries to connect to host2:port2.
17. The connection to host2:port2 fails.
18. The driver waits two seconds.
19. The driver tries to connect to host3:port3.
20. The connection to host3:port3 fails.
21. The driver waits two seconds.
22. The driver tries to connect to host3:port3.
23. The connection to host3:port3 fails.
24. The driver waits two seconds.
25. The driver tries to connect to host3:port3.
26. The connection to host3:port3 fails.
27. The driver waits two seconds.
28. The driver throws an SQLException with error code -4499.

The following example shows how to enable client affinities for failover with failback.

Suppose that you set the following properties for a connection to a database:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableClientAffinitiesList</td>
<td>DB2BaseDataSource.YES</td>
</tr>
<tr>
<td>clientRerouteAlternateServername</td>
<td>host1,host2,host3</td>
</tr>
<tr>
<td>clientRerouteAlternatePortNumber</td>
<td>port1,port2,port3</td>
</tr>
<tr>
<td>maxRetriesForClientReroute</td>
<td>3</td>
</tr>
<tr>
<td>retryIntervalForClientReroute</td>
<td>2</td>
</tr>
<tr>
<td>affinityFailbackInterval</td>
<td>300</td>
</tr>
</tbody>
</table>

Suppose that the database administrator takes the server that is identified by host1:port1 down for maintenance after a connection is made to host1:port1. The following steps demonstrate failover to an alternate server and failback to the primary server after maintenance is complete.

1. The driver successfully connects to host1:port1 on behalf of an application.
2. The database administrator brings down host1:port1.
3. The application tries to do work on the connection.
4. The driver successfully fails over to host2:port2.
5. After a total of 200 seconds have elapsed, the work is committed.
6. After a total of 300 seconds have elapsed, the failback interval has elapsed. The driver checks whether the primary server is up. It is not up, so no failback occurs.

7. After a total of 350 seconds have elapsed, host1:port1 is brought back online.

8. The application continues to do work on host2:port2, because the latest failback interval has not elapsed.

9. After a total of 600 seconds have elapsed, the failback interval has elapsed again. The driver checks whether the primary server is up. It is now up.

10. After a total of 650 seconds have elapsed, the work is committed.

11. After a total of 651 seconds have elapsed, the application tries to start a new transaction on host2:port2. Failback to host1:port1 occurs, so the new transaction starts on host1:port1.

Java client direct connect support for high availability for connections to DB2 for z/OS servers

Sysplex workload balancing functionality on DB2 for z/OS servers provides high availability for client applications that connect directly to a data sharing group. Sysplex workload balancing functionality provides workload balancing and automatic client reroute capability. This support is available for applications that use Java clients (JDBC, SQLJ, or pureQuery) that use IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, or non-Java clients (ODBC, CLI, .NET, OLE DB, PHP, Ruby, or embedded SQL). Workload balancing is transparent to applications.

A Sysplex is a set of z/OS systems that communicate and cooperate with each other through certain multisystem hardware components and software services to process customer workloads. DB2 for z/OS subsystems on the z/OS systems in a Sysplex can be configured to form a data sharing group. With data sharing, applications that run on more than one DB2 for z/OS subsystem can read from and write to the same set of data concurrently. One or more coupling facilities provide high-speed caching and lock processing for the data sharing group. The Sysplex, together with the Workload Manager (WLM), dynamic virtual IP address (DVIPA), and the Sysplex Distributor, allow a client to access a DB2 for z/OS database over TCP/IP with network resilience, and distribute transactions for an application in a balanced manner across members within the data sharing group.

Central to these capabilities is a server list that the data sharing group returns on connection boundaries and optionally on transaction boundaries. This list contains the IP address and WLM weight for each data sharing group member. With this information, a client can distribute transactions in a balanced manner, or identify the member to use when there is a communication failure.

The server list is returned on the first successful connection to the DB2 for z/OS data server. After the client has received the server list, the client directly accesses a data sharing group member based on information in the server list.
DB2 for z/OS provides several methods for clients to access a data sharing group. The access method that is set up for communication with the data sharing group determines whether Sysplex workload balancing is possible. The following table lists the access methods and indicates whether Sysplex workload balancing is possible.

**Table 45. Data sharing access methods and Sysplex workload balancing**

<table>
<thead>
<tr>
<th>Data sharing access method</th>
<th>Description</th>
<th>Sysplex workload balancing possible?</th>
</tr>
</thead>
</table>
| Group access              | A requester uses the DB2 group IP address to make an initial connection to the DB2 for z/OS location. A connection to the data sharing group that uses the group IP address and SQL port is always successful if at least one member is started. The server list that is returned by the data sharing group contains:  
  • A list of members that are currently active and can perform work  
  • The WLM weight for each member  
  The group IP address is configured using the z/OS Sysplex distributor. To clients that are outside the Sysplex, the Sysplex distributor provides a single IP address that represents a DB2 location. In addition to providing fault tolerance, the Sysplex distributor can be configured to provide connection load balancing. | Yes |
| Member-specific access    | A requester uses a location alias to make an initial connection to one of the members that is represented by the alias. A connection to the data sharing group that uses the group IP address and alias SQL port is always successful if at least one member is started. The server list that is returned by the data sharing group contains:  
  • A list of members that are currently active, can perform work, and have been configured as an alias  
  • The WLM weight for each member  
  The requester uses this information to connect to the member or members with the most capacity that are also associated with the location alias. Member-specific access is used when requesters need to take advantage of Sysplex workload balancing among a subset of members of a data sharing group. | Yes |
| Single-member access      | Single-member access is used when requesters need to access only one member of a data sharing group. For single-member access, the connection uses the member-specific IP address. | No |

**Note:**
1. For more information on data sharing access methods, see [TCP/IP access methods (DB2 Data Sharing Planning and Administration)](https://www.ibm.com/support/knowledgecenter/SG2479_12.1.0/com.ibm.db2.luw.ap_ref.db2.ref.doc_12.1.0/1210702_1210702.html)
Sysplex workload balancing includes automatic client reroute: Automatic client reroute support enables a client to recover from a failure by attempting to reconnect to the data server through any available member of a Sysplex. Reconnection to another member is called failover. Automatic client reroute can be seamless when the application is rerouted, and the application does not receive an error after a network failure to a data sharing member. An example of a situation in which automatic reroute can be seamless is when a member is shut down for maintenance.

For Java, CLI, or .NET client applications, failover for automatic client reroute can be seamless or non-seamless. Seamless failover means that when the application successfully reconnects to an alternate server, the server does not return an error to the application.

With seamless failover, the IBM Data Server Driver for JDBC and SQLJ sets the application environment from the old server on the new server. This environment includes special register values.

Client direct connect support for high availability with a DB2 Connect server: Client direct connect support for high availability requires a DB2 Connect license, but does not need a DB2 Connect server. The client connects directly to DB2 for z/OS. If you use a DB2 Connect server, but set up your environment for client high availability, you cannot take advantage of some of the features that a direct connection to DB2 for z/OS provides, such as transaction-level workload balancing or automatic client reroute capability that is provided by the Sysplex.

Do not use client affinities: Client affinities should not be used as a high availability solution for direct connections to DB2 for z/OS. Client affinities is not applicable to a DB2 for z/OS data sharing environment, because all members of a data sharing group can access data concurrently. A major disadvantage of client affinities in a data sharing environment is that if failover occurs because a data sharing group member fails, the member that fails might have retained locks that can severely affect transactions on the member to which failover occurs.

**Configuration of Sysplex workload balancing and automatic client reroute for Java clients**

To configure a IBM Data Server Driver for JDBC and SQLJ client application that connects directly to DB2 for z/OS to use Sysplex workload balancing and automatic client reroute, you need to use IBM Data Server Driver for JDBC and SQLJ type 4 connectivity. You also need to connect to an address that represents the data sharing group (for group access) or a subset of the data sharing group (for member-specific access), and set the properties that enable workload balancing and the maximum number of connections.

You should always configure Sysplex workload balancing and automatic client reroute together. When you configure a client to use Sysplex workload balancing, automatic client reroute is also enabled. Therefore, you need to change property settings that are related to automatic client reroute only to fine tune automatic client reroute operation.

The following table describes the basic property settings for Java applications.
<table>
<thead>
<tr>
<th>Data sharing access method</th>
<th>IBM Data Server Driver for JDBC and SQLJ setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group access</td>
<td>enableSysplexWLB property</td>
<td>true</td>

<td>The port number for the DB2 location alias</td>
</tr>
<tr>
<td></td>
<td>database</td>
<td>The name of the DB2 location alias that represents a subset of the members of the data sharing group</td>
</tr>
<tr>
<td>Group access or member-specific access</td>
<td>commandTimeout</td>
<td>Specifies the maximum time in seconds that an application that runs under the IBM Data Server Driver for JDBC and SQLJ waits for any kind of request to the data server to complete before the driver throws an SQLException. The wait time includes time to obtain a transport, perform failover if needed, send the request, and wait for a response. The default is 0.</td>
</tr>
<tr>
<td></td>
<td>connectionTimeout</td>
<td>Specifies the maximum time in seconds that the IBM Data Server Driver for JDBC and SQLJ waits for a reply from a data sharing group when the driver attempts to establish a connection. If the driver does not receive a reply after the amount of time that is specified by connectionTimeout, it throws an SQLException with SQL error code -4499. The default is 0. If connectionTimeout is set to a positive value, that value overrides any other timeout values that are set on a connection, such as loginTimeout.</td>
</tr>
<tr>
<td></td>
<td>maxTransportObjects</td>
<td>Specifies the maximum number of connections that the requester can make to the data sharing group. The default is 1000. To determine the maxTransportObjects value, multiply the expected number of concurrent active connections to the DB2 for z/OS data sharing group by the number of members in the data sharing group.</td>
</tr>
</tbody>
</table>

Additional properties are available for fine tuning Sysplex workload balancing and automatic client reroute. You should initially set up Sysplex workload balancing using only the basic properties. In most cases, you should not need to set any of the additional properties.
The following IBM Data Server Driver for JDBC and SQLJ Connection or DataSource properties can be used to fine-tune Sysplex workload balancing and automatic client reroute:

- `blockingReadConnectionTimeout`
- `enableSeamlessFailover`
- `loginTimeout`
- `maxRetriesForClientReroute`
- `memberConnectTimeout`
- `retryIntervalForClientReroute`

The following IBM Data Server Driver for JDBC and SQLJ configuration properties can be used to fine-tune Sysplex workload balancing and automatic client reroute:

- `db2.jcc.maxRefreshInterval`
- `db2.jcc.maxTransportObjectIdleTime`
- `db2.jcc.maxTransportObjectWaitTime`
- `db2.jcc.minTransportObjects`

Related reference:
- “IBM Data Server Driver for JDBC and SQLJ configuration properties” on page 380
- “Common IBM Data Server Driver for JDBC and SQLJ properties for DB2 for z/OS and IBM Informix” on page 366
- “Common IBM Data Server Driver for JDBC and SQLJ properties for all supported database products” on page 327

Example of enabling DB2 for z/OS Sysplex workload balancing and automatic client reroute in Java applications

Java client setup for Sysplex workload balancing and automatic client reroute includes setting several IBM Data Server Driver for JDBC and SQLJ properties.

The following examples demonstrate setting up Java client applications for Sysplex workload balancing and automatic client reroute for high availability.

Before you can set up the client, you need to configure the following server software:

- WLM for z/OS
  For workload balancing to work efficiently, DB2 work needs to be classified. Classification applies to the first non-SET SQL statement in each transaction. Among the areas by which you need to classify the work are:
  - Authorization ID
  - Client info properties
  - Stored procedure name
    The stored procedure name is used for classification only if the first statement that is issued by the client in the transaction is an SQL CALL statement.

For a complete list of classification attributes, see the information on classification attributes at Classification attributes (DB2 Performance).

- DB2 for z/OS, set up for data sharing

Example of setup with WebSphere Application Server

This example assumes that you are using WebSphere Application Server. The minimum level of WebSphere Application Server is Version 5.1.

Follow these steps to set up the client:
1. Verify that the IBM Data Server Driver for JDBC and SQLJ is at the correct level to support the Sysplex workload balancing by following these steps:
   a. Issue the following command in a command line window
      ```
      java com.ibm.db2.jcc.DB2Jcc -version
      ```
   b. Find a line in the output like this, and check that nnn is 3.50 or later.
      
      ```
      [jcc] Driver: IBM Data Server Driver for JDBC and SQLJ Architecture nnn xxx
      ```

2. In the WebSphere Application Server administrative console, set the IBM Data Server Driver for JDBC and SQLJ data source property enableSysplexWLB to true, to enable Sysplex workload balancing. Enabling Sysplex workload balancing enables automatic client reroute by default.

3. In the WebSphere Application Server administrative console, set other properties for which the defaults are unacceptable. Modify these WebSphere Application Server connection properties. The following settings are recommended when enableSysplexWLB is set to true:

<table>
<thead>
<tr>
<th>Connection property</th>
<th>Recommended setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reap Time</td>
<td>0</td>
<td>Specifies the interval, in seconds, between runs of the pool maintenance thread. The Reap Time interval affects performance. Because connections are not physical connections, disabling pool maintenance by setting this value to 0 is recommended.</td>
</tr>
<tr>
<td>Aged Timeout</td>
<td>0</td>
<td>Specifies the interval in seconds before a physical connection is discarded. Setting Aged Timeout to 0 allows connections to remain in the pool indefinitely.</td>
</tr>
<tr>
<td>Purge Policy</td>
<td>FailingConnectionOnly</td>
<td>Specifies how to purge connections when a stale connection or fatal connection error is detected. Because Sysplex workload balancing isolates WebSphere Application Server from stale connections or fatal connections errors, FailingConnectionOnly is the recommended setting.</td>
</tr>
</tbody>
</table>

   The Maximum Connections value does not need to be changed. Member Connections specifies the maximum number of physical connections that you create in your pool. It does not control the number of physical connections to a data sharing group. With Sysplex workload balancing, connections are logical, and use transports to associate a connection to a data sharing member. Physical connections are managed by transport pools in the driver. The maxTransportObjects property controls the maximum number of connections to the group.

4. Optional: Set IBM Data Server Driver for JDBC and SQLJ configuration properties to fine-tune workload balancing for all DataSource or Connection instances that are created under the driver. Beginning with versions 3.63 and 4.13 of the IBM Data Server Driver for JDBC and SQLJ, the default values should work for most environments.

   Set the configuration properties in a DB2JccConfiguration.properties file by following these steps:
   a. Create a DB2JccConfiguration.properties file or edit the existing DB2JccConfiguration.properties file.
   b. Set the configuration properties in the DB2JccConfiguration.properties file:
      ```
      property=value
      ```
   c. Add the directory path for DB2JccConfiguration.properties to the WebSphere Application Server IBM Data Server Driver for JDBC and SQLJ classpath.
   d. Restart WebSphere Application Server.
Example of setup for DriverManager connections

This example assumes that you are using the DriverManager interface to establish a connection.

Follow these steps to set up the client:

1. Verify that the IBM Data Server Driver for JDBC and SQLJ is at the correct level to support the Sysplex workload balancing and automatic client reroute by following these steps:
   a. Issue the following command in a command line window
      
      java com.ibm.db2.jcc.DB2Jcc -version
      
      b. Find a line in the output like this, and check that nnn is 3.50 or later. A minimum driver level of 3.50 is required for using Sysplex workload balancing and automatic client reroute for DriverManager connections.
      c. 

   [jcc] Driver: IBM Data Server Driver for JDBC and SQLJ Architecture nnn xxx

2. Set the IBM Data Server Driver for JDBC and SQLJ Connection property enableSysplexWLB to enable workload balancing. Enabling Sysplex workload balancing enables automatic client reroute by default. Set any other properties for which the defaults are unacceptable. For most users, the default values do not need to be changed.

   java.util.Properties properties = new java.util.Properties();
   properties.put("user", "xxxx");
   properties.put("password", "yyyy");
   properties.put("enableSysplexWLB", "true");
   java.sql.Connection con =
   java.sql.DriverManager.getConnection(url, properties);

3. Optional: Set IBM Data Server Driver for JDBC and SQLJ configuration properties to fine-tune workload balancing for all DataSource or Connection instances that are created under the driver. Beginning with versions 3.63 and 4.13 of the IBM Data Server Driver for JDBC and SQLJ, the default values should work for most environments. Set the configuration properties in a DB2JccConfiguration.properties file by following these steps:
   a. Create a DB2JccConfiguration.properties file or edit the existing DB2JccConfiguration.properties file.
   b. Set the configuration properties in the DB2JccConfiguration.properties file:
      
      property=value
      
   c. Include the directory that contains DB2JccConfiguration.properties in the CLASSPATH concatenation.
Operation of Sysplex workload balancing for connections from Java clients to DB2 for z/OS servers

Sysplex workload balancing (also called transaction-level workload balancing) for connections to DB2 for z/OS contributes to high availability by balancing work among members of a data sharing group at the start of a transaction.

The following overview describes the steps that occur when a client connects to a DB2 for z/OS Sysplex, and Sysplex workload balancing is enabled:

1. When the client first establishes a connection using the sysplex-wide IP address called the group IP address, or when a connection is reused by another connection object, the server returns member workload distribution information.
   The default lifespan of the cached server list is 30 seconds.

2. At the start of a new transaction, the client reads the cached server list to identify a member that has untapped capacity, and looks in the transport pool for an idle transport that is tied to the under-utilized member. (An idle transport is a transport that has no associated connection object.)
   - If an idle transport is available, the client associates the connection object with the transport.
   - If, after a user-configurable timeout, no idle transport is available in the transport pool and no new transport can be allocated because the transport pool has reached its limit, an error is returned to the application.

3. When the transaction runs, it accesses the member that is tied to the transport. When the first SQL statement in a transaction runs, if the IBM Data Server Driver for JDBC and SQLJ receives a communication failure because the data server drops the connection or the blockingReadConnectionTimeout value was exceeded, the driver retries the SQL statement 10 times before it reports an error. On every retry, the driver closes the existing transport, obtains a new transport and then executes the transaction. During these retries, if the maxRetriesForClientReroute and retryIntervalForClientReroute properties are set, their values apply only to the process of obtaining a new transport during each retry.

4. When the transaction ends, the client verifies with the server that transport reuse is still allowed for the connection object.

5. If transport reuse is allowed, the server returns a list of SET statements for special registers that apply to the execution environment for the connection object.
   The client caches these statements, which it replays in order to reconstruct the execution environment when the connection object is associated with a new transport.

6. The connection object is then disassociated from the transport.
7. The client copy of the server list is refreshed when a new connection is made, or every 30 seconds.
8. When workload balancing is required for a new transaction, the client uses the same process to associate the connection object with a transport.

Operation of automatic client reroute for connections from Java clients to DB2 for z/OS

Automatic client reroute support provides failover support when an IBM data server client loses connectivity to a member of a DB2 for z/OS Sysplex. Automatic client reroute enables the client to recover from a failure by attempting to reconnect to the database through any available member of the Sysplex.

Automatic client reroute is enabled by default when Sysplex workload balancing is enabled.

Client support for automatic client reroute is available in IBM data server clients that have a DB2 Connect license. The DB2 Connect server is not required to perform automatic client reroute.

Automatic client reroute for connections to DB2 for z/OS operates in the following way:

1. After a transaction has been established, if an SQL statement in the transaction fails, the application receives SQL error -30108 with reason code 2. The IBM Data Server Driver for JDBC and SQLJ does not acquire an active transport.
2. The application retries the transaction.
3. The driver attempts to acquire a transport to each member of the data sharing group in the order of their calculated priorities until a transport is acquired. The driver does not attempt to acquire a transport to the member to which the connection failed in step 1.
4. If the driver cannot acquire a transport, the driver attempts to contact the group IP address to check for any members that have become available.
5. If the driver still cannot acquire a transport, the driver continues to execute steps 3 and 4 until a transport is acquired, or the maxRetriesForClientReroute value is reached.
6. The driver returns SQL error -4499 to the application.

Related reference:
“Error codes issued by the IBM Data Server Driver for JDBC and SQLJ” on page 570

Application programming requirements for high availability for connections from Java clients to DB2 for z/OS servers

Failover for automatic client reroute can be seamless or non-seamless. If failover for connections to DB2 for z/OS is not seamless, you need to add code to account for the errors that are returned when failover occurs.

If failover is not seamless, and a connection is reestablished with the server, SQLCODE -30108 (SQL30108N) is returned to the application. All work that occurred within the current transaction is rolled back. In the application, you need to:

- Check the reason code that is returned with the -30108 error to determine whether special register settings that were carried over from the failing data sharing member to the new (failover) data sharing member were the settings at...
the most recent commit point, or the settings at the point of failure. Reset any
special register values that are not current.

- Execute all SQL operations that occurred since the previous commit operation.

The following conditions must be satisfied for seamless failover to occur for direct
connections to DB2 for z/OS:

- The application language is Java, CLI, or .NET.
- The connection is not in a transaction. That is, the failure occurs when the first
  SQL statement in the transaction is executed.
- The data server allows transport reuse at the end of the previous transaction. An excep-
  tion to this condition is if transport reuse is not granted because the application was bound with KEEP_DYNAMIC(YES).
- All global session data is closed or dropped.
- There are no open, held cursors.
- If the application uses CLI, the application cannot perform actions that require
  the driver to maintain a history of previously called APIs in order to replay the
  SQL statement. Examples of such actions are specifying data at execution time,
  performing compound SQL, or using array input.
- The application is not a stored procedure.
- The application is not running in a Federated environment.
- Two-phase commit is used, if transactions are dependent on the success of
  previous transactions. When a failure occurs during a commit operation, the
  client has no information about whether work was committed or rolled back at
  the server. If each transaction is dependent on the success of the previous
  transaction, use two-phase commit. Two-phase commit requires the use of XA
  support.
Chapter 10. Java 2 Platform, Enterprise Edition

The Java 2 Platform, Enterprise Edition (J2EE), reduces the cost and complexity of developing multi-tier services.

In today’s global business environment, organizations need to extend their reach, lower their costs, and lower their response times by providing services that are easily accessible to their customers, employees, suppliers, and other business partners. These services need to have the following characteristics:

- Highly available, to meet the requirements of global business environment
- Secure, to protect the privacy of the users and the integrity of the enterprise
- Reliable and scalable, so that business transactions are accurately and promptly processed

In most cases, these services are provided with the help of multi-tier applications with each tier serving a specific purpose.

J2EE achieves these benefits by defining a standard architecture that is delivered as the following elements:

- J2EE Application Model, a standard application model for developing multi-tier, thin-client services
- J2EE Platform, a standard platform for hosting J2EE applications
- J2EE Compatibility Test Suite for verifying that a J2EE platform product complies with the J2EE platform standard
- J2EE Reference Implementation for demonstrating the capabilities of J2EE, and for providing an operational definition of the J2EE platform

Application components of Java 2 Platform, Enterprise Edition support

The Java 2 Platform, Enterprise Edition (J2EE) provides the runtime environment for hosting J2EE applications.

The runtime environment defines four application component types that a J2EE product must support:

- Application clients are Java programming language programs that are typically GUI programs that execute on a desktop computer. Application clients have access to all of the facilities of the J2EE middle tier.
- Applets are GUI components that typically execute in a web browser, but can execute in a variety of other applications or devices that support the applet programming model.
- Servlets, JavaServer Pages (JSPs), filters, and web event listeners typically execute in a web server and might respond to HTTP requests from web clients. Servlets, JSPs, and filters can be used to generate HTML pages that are an application's user interface. They can also be used to generate XML or other format data that is consumed by other application components. Servlets, pages created with the JSP technology, web filters, and web event listeners are referred to collectively in this specification as web components. Web applications are composed of web components and other data such as HTML pages.
• Enterprise JavaBeans (EJB) components execute in a managed environment that supports transactions. Enterprise beans typically contain the business logic for a J2EE application.

The application components listed above can divided into three categories, based on how they can be deployed and managed:
• Components that are deployed, managed, and executed on a J2EE server.
• Components that are deployed, managed on a J2EE server, but are loaded to and executed on a client machine.
• Components whose deployment and management are not completely defined by this specification. Application clients can be under this category.

The runtime support for these components is provided by containers.

Java 2 Platform, Enterprise Edition containers

A container provides a federated view of the underlying Java 2 Platform, Enterprise Edition (J2EE) APIs to the application components.

A typical J2EE product will provide a container for each application component type; application client container, applet container, web container, and enterprise bean container. The container tools also understand the file formats for packaging the application components for deployment.

The specification requires that these containers provide a Java-compatible runtime environment. This specification defines a set of standard services that each J2EE product must support. These standard services are:
• HTTP service
• HTTPS service
• Java transaction API
• Remote invocation method
• Java IDL
• JDBC API
• Java message service
• Java naming and directory interface
• JavaMail
• JavaBeans activation framework
• Java API for XML parsing
• Connector architecture
• Java authentication and authorization service

Java 2 Platform, Enterprise Edition Server

One part of a Java 2 Platform, Enterprise Edition (J2EE) container is a server.

A J2EE Product Provider typically implements the J2EE server-side functionality. The J2EE client functionality is typically built on J2SE technology.

The IBM WebSphere Application Server is a J2EE-compliant server.

Java 2 Platform, Enterprise Edition database requirements

Java 2 Platform, Enterprise Edition requires a data server to store business data. The data server must be accessible through the JDBC API.
The database is accessible from web components, enterprise beans, and application client components. The database need not be accessible from applets.

**Java Naming and Directory Interface (JNDI)**

JNDI enables Java platform-based applications to access multiple naming and directory services.

It is a part of the Java Enterprise application programming interface (API) set. JNDI makes it possible for developers to create portable applications that are enabled for a number of different naming and directory services, including: file systems; directory services such as Lightweight Directory Access Protocol (LDAP) and Novell Directory Services, and distributed object systems such as the Common Object Request Broker Architecture (CORBA), Java Remote Method Invocation (RMI), and Enterprise JavaBeans (EJB).

The JNDI API has two parts: an application-level interface used by the application components to access naming and directory services and a service provider interface to attach a provider of a naming and directory service.

**Java transaction management**

Java 2 Platform, Enterprise Edition (J2EE) simplifies application programming for distributed transaction management.

J2EE includes support for distributed transactions through two specifications, Java Transaction API (JTA) and Java Transaction Service (JTS). JTA is a high-level, implementation-independent, protocol-independent API that allows applications and application servers to access transactions. In addition, the JTA is always enabled.

The IBM Data Server Driver for JDBC and SQLJ implements the JTA and JTS specifications.

For IBM Data Server Driver for JDBC and SQLJ type 4 connectivity distributed transactions are supported to DB2 for Linux, UNIX, and Windows, DB2 for z/OS, and DB2 for i servers.

JTA specifies standard Java interfaces between a transaction manager and the parties involved in a distributed transaction system: the resource manager, the application server, and the transactional applications.

JTS specifies the implementation of a Transaction Manager which supports JTA and implements the Java mapping of the OMG Object Transaction Service (OTS) 1.1 specification at the level below the API. JTS propagates transactions using IIOP.

JTA and JTS allow application J2EE servers to take the burden of transaction management off of the component developer. Developers can define the transactional properties of EJB technology based components during design or deployment using declarative statements in the deployment descriptor. The application server takes over the transaction management responsibilities.

In the DB2 and WebSphere Application Server environment, WebSphere Application Server assumes the role of transaction manager, and DB2 acts as a resource manager. WebSphere Application Server implements JTS and part of JTA.
and the JDBC drivers also implement part of JTA so that WebSphere Application Server and DB2 can provide coordinated distributed transactions.

It is not necessary to configure DB2 to be JTA-enabled in the WebSphere Application Server environment because the JDBC drivers automatically detect this environment.

The IBM Data Server Driver for JDBC and SQLJ provides these two DataSource classes:

- com.ibm.db2.jcc.DB2ConnectionPoolDataSource
- com.ibm.db2.jcc.DB2XADataSource

WebSphere Application Server provides pooled connections to databases. If the application will be involved in a distributed transaction, the com.ibm.db2.jdbc.DB2XADataSource class should be used when defining DB2 data sources within the WebSphere Application Server.

For the detail information about how to configure the WebSphere Application Server with DB2, refer to WebSphere Application Server InfoCenter at:

**Example of a distributed transaction that uses JTA methods**

Distributed transactions typically involve multiple connections to the same data source or different data sources, which can include data sources from different manufacturers.

The best way to demonstrate distributed transactions is to contrast them with local transactions. With local transactions, a JDBC application makes changes to a database permanent and indicates the end of a unit of work in one of the following ways:

- By calling the Connection.commit or Connection.rollback methods after executing one or more SQL statements
- By calling the Connection.setAutoCommit(true) method at the beginning of the application to commit changes after every SQL statement

Figure 49 outlines code that executes local transactions.

```java
con1.setAutoCommit(false); // Set autocommit off
// execute some SQL
...
con1.commit(); // Commit the transaction
// execute some more SQL
...
con1.rollback(); // Roll back the transaction
con1.setAutoCommit(true); // Enable commit after every SQL statement
...
// Execute some more SQL, which is automatically committed after
// every SQL statement.
```

Figure 49. Example of a local transaction

In contrast, applications that participate in distributed transactions cannot call the Connection.commit, Connection.rollback, or Connection.setAutoCommit(true) methods within the distributed transaction. With distributed transactions, the Connection.commit or Connection.rollback methods do not indicate transaction boundaries. Instead, your applications let the application server manage transaction boundaries.
Figure 50 demonstrates an application that uses distributed transactions. While the code in the example is running, the application server is also executing other EJBs that are part of this same distributed transaction. When all EJBs have called utx.commit(), the entire distributed transaction is committed by the application server. If any of the EJBs are unsuccessful, the application server rolls back all the work done by all EJBs that are associated with the distributed transaction.

```java
javax.transaction.UserTransaction utx;
// Use the begin method on a UserTransaction object to indicate
// the beginning of a distributed transaction.
utx.begin();
...
// Execute some SQL with one Connection object.
// Do not call Connection methods commit or rollback.
...
// Use the commit method on the UserTransaction object to
// drive all transaction branches to commit and indicate
// the end of the distributed transaction.
utx.commit();
...
```

*Figure 50. Example of a distributed transaction under an application server*

Figure 51 illustrates a program that uses JTA methods to execute a distributed transaction. This program acts as the transaction manager and a transactional application. Two connections to two different data sources do SQL work under a single distributed transaction.

```java
class XASample
{
    javax.sql.XADataSource xaDS1;
    javax.sql.XADataSource xaDS2;
    javax.sql.XAConnection xacconn1;
    javax.sql.XAConnection xacconn2;
    javax.transaction.xa.XAResource xares1;
    javax.transaction.xa.XAResource xares2;
    java.sql.Connection conn1;
    java.sql.Connection conn2;

    public static void main(String[] args) throws java.sql.SQLException
    {
        XASample xat = new XASample();
        xat.runThis(args);
    }

    public void runThis(String[] args)
    {
        byte[] gtrid = new byte[] { 0x44, 0x11, 0x55, 0x66 };
        byte[] bqual = new byte[] { 0x00, 0x22, 0x00 };
        int rc1 = 0;
        int rc2 = 0;

        try
        {
            javax.naming.InitialContext context = new javax.naming.InitialContext();
        }
    }
}
```

*Figure 51. Example of a distributed transaction that uses the JTA*
/*
 * Note that javax.sql.XADataSource is used instead of a specific
 * driver implementation such as com.ibm.db2.jcc.DB2XADataSource.
 */
xaDS1 = (javax.sql.XADataSource)context.lookup("checkingAccounts");
xaDS2 = (javax.sql.XADataSource)context.lookup("savingsAccounts");

// The XADatasource contains the user ID and password.
// Get the XAConnection object from each XADataSource
xaconn1 = xaDS1.getXAConnection();
xaconn2 = xaDS2.getXAConnection();

// Get the java.sql.Connection object from each XAConnection
conn1 = xaconn1.getConnection();
conn2 = xaconn2.getConnection();

// Get the XAResource object from each XAConnection
xares1 = xaconn1.getXAResource();
xares2 = xaconn2.getXAResource();

// Create the Xid object for this distributed transaction.
// This example uses the com.ibm.db2.jcc.DB2Xid implementation
// of the Xid interface. This Xid can be used with any JDBC driver
// that supports JTA.
javax.transaction.xa.Xid xid1 =
    new com.ibm.db2.jcc.DB2Xid(100, gtrid, bqual);

// Start the distributed transaction on the two connections.
// The two connections do NOT need to be started and ended together.
// They might be done in different threads, along with their SQL operations.
xares1.start(xid1, javax.transaction.xa.XAResource.TMNOFLAGS);
xares2.start(xid1, javax.transaction.xa.XAResource.TMNOFLAGS);

... // Do the SQL operations on connection 1.
... // Do the SQL operations on connection 2.

... // Now end the distributed transaction on the two connections.
xares1.end(xid1, javax.transaction.xa.XAResource.TMSUCCESS);
xares2.end(xid1, javax.transaction.xa.XAResource.TMSUCCESS);

// If connection 2 work had been done in another thread,
// a thread.join() call would be needed here to wait until the
// connection 2 work is done.
try
{
    // Now prepare both branches of the distributed transaction.
    // Both branches must prepare successfully before changes
    // can be committed.
    // If the distributed transaction fails, an XAException is thrown.
    rc1 = xares1.prepare(xid1);
    if(rc1 == javax.transaction.xa.XAResource.XA_OK)
    {
        // Prepare was successful. Prepare the second connection.
        rc2 = xares2.prepare(xid1);
        if(rc2 == javax.transaction.xa.XAResource.XA_OK)
        {
            // Both connections prepared successfully and neither was read-only.
            xares1.commit(xid1, false);
xares2.commit(xid1, false);
        }
        else if(rc2 == javax.transaction.xa.XAException.XA_RDONLY)
        {
            // The second connection is read-only, so just commit the
            // first connection.
xares1.commit(xid1, false);
        }
    }
    else if(rc1 == javax.transaction.xa.XAException.XA_RDONLY)
    {
        // SQL for the first connection is read-only (such as a SELECT).
        // The prepare committed it. Prepare the second connection.
        rc2 = xares2.prepare(xid1);
    }
}

304 Developing Java Applications
if(rc2 == javax.transaction.xa.XAResource.XA_OK)
{ // The first connection is read-only but the second is not.
    // Commit the second connection.
    xares2.commit(xid1, false);
}
else if(rc2 == javax.transaction.xa.XAException.XA_RDONLY)
{ // Both connections are read-only, and both already committed,
    // so there is nothing more to do.
}
}
} catch (javax.transaction.xa.XAException xae)
{ // Distributed transaction failed, so roll it back.
    // Report XAException on prepare/commit.
    System.out.println("Distributed transaction prepare/commit failed. " +
        "Rolling it back.");
    System.out.println("XAException error code = " + xae.errorCode);
    System.out.println("XAException message = " + xae.getMessage());
    xae.printStackTrace();
    try
    {
        xares1.rollback(xid1);
    }
    catch (javax.transaction.xa.XAException xae1)
    { // Report failure of rollback.
        System.out.println("distributed Transaction rollback xares1 failed");
        System.out.println("XAException error code = " + xae1.errorCode);

}

**Recommendation:** For better performance, complete a distributed transaction before you start another distributed or local transaction.

**Setting the transaction timeout value for an XAResource instance**

Use the XAResource.setTransactionTimeout method to reduce occurrences of deadlocks in a DB2 database that is the target of distributed transactions.

A distributed transaction to DB2 for Linux, UNIX, and Windows that ends, but cannot be prepared, is not an indoubt transaction. Therefore, the transaction manager cannot recover the transaction, and the DB2 resource manager does not put the transaction in its list of indoubt transactions. The DB2 resource manager does not roll back the transaction immediately, but waits until all connections to the database are released. During this period of inactivity, the transaction continues to hold locks on the database. If the transaction manager does not disconnect all connections to the database to allow rollback, the ended transaction continues to lock database records. If another application attempts to access those locked records, a deadlock can occur.

In a Java application that uses distributed transactions and IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, you can prevent a transaction from holding locks on a database indefinitely by calling the XAResource.setTransactionTimeout method to set a timeout value on transactions.

To set the transaction timeout value for an XAResource instance:

1. On the DB2 for Linux, UNIX, and Windows instance, issue this command to cause the instance to check for timeout values.
   
   ```  
   DB2 UPDATE DBM CFG USING RESYNC_INTERVAL seconds  
   ``
   
   *seconds* needs to be less than the minimum timeout value that you set for a transaction.

2. In your application, after you create an XAResource object, call the XAResource.setTransactionTimeout method to set the timeout value.
   
   You can check the current timeout value by calling XAResource.getTransactionTimeout.

---

**Enterprise Java Beans**

The Enterprise Java beans architecture is a component architecture for the development and deployment of component-based distributed business applications.

Applications that are written using the Enterprise Java beans architecture can be written once, and then deployed on any server platform that supports the Enterprise Java beans specification. Java 2 Platform, Enterprise Edition (J2EE)
applications implement server-side business components using Enterprise Java beans (EJBs) that include session beans and entity beans.

Session beans represent business services and are not shared between users. Entity beans are multi-user, distributed transactional objects that represent persistent data. The transactional boundaries of a EJB application can be set by specifying either container-managed or bean-managed transactions.

The sample program AccessEmployee.ear uses Enterprise Java beans to implement a J2EE application to access a data source. You can find this sample in the SQLLIB/samples/websphere directory.

The EJB sample application provides two business services. One service allows the user to access information about an employee (which is stored in the EMPLOYEE table of the sample database) through that employee's employee number. The other service allows the user to retrieve a list of the employee numbers, so that the user can obtain an employee number to use for querying employee data.

The following sample uses EJBs to implement a J2EE application to access a data source. The sample utilizes the Model-View-Controller (MVC) architecture, which is a commonly-used GUI architecture. The JSP is used to implement the view (the presentation component). A servlet acts as the controller in the sample. It controls the workflow and delegates the user's request to the model, which is implemented using EJBs. The model component of the sample consists of two EJBs, one session bean and one entity bean. The container-managed persistence (CMP) bean, Employee, represents the distributed transactional objects that represent the persistent data in the EMPLOYEE table of the sample database. The term container-managed persistence means that the EJB container handles all database access required by the entity bean. The bean's code contains no database access (SQL) calls. As a result, the bean's code is not tied to a specific persistent storage mechanism (database). The session bean, AccessEmployee, acts as the Façade of the entity bean and provides a uniform client access strategy. This Façade design reduces the network traffic between the EJB client and the entity bean and is more efficient in distributed transactions than if the EJB client accesses the entity bean directly. Access to the database server can be provided from the session bean or entity bean. The two services of the sample application demonstrate both approaches to accessing the database server. In the first service, the entity bean is used:

```
// This method returns an employee's information by
// interacting with the entity bean located by the
// provided employee number
public EmployeeInfo getEmployeeInfo(String empNo) throws java.rmi.RemoteException
{
  Employee employee = null;
  try
  }
  employee = employeeHome.findByPrimaryKey(new EmployeeKey(empNo));
  EmployeeInfo empInfo = new EmployeeInfo(empNo);
  //set the employee's information to the dependent value object
  empInfo.setEmpno(employee.getEmpno());
  empInfo.setFirstName (employee.getFirstName());
  empInfo.setMidInit(employee.getMidInit());
  empInfo.setLastName(employee.getLastName());
  empInfo.setWorkDept(employee.getWorkDept());
  empInfo.setPhoneNo(employee.getPhoneNo());
  empInfo.setHireDate(employee.getHireDate());
  empInfo.setJob(employee.getJob());
```
empInfo.setEdLevel(employee.getEdLevel());
empInfo.setSex(employee.getSex());
empInfo.setBirthDate(employee.getBirthDate());
empInfo.setSalary(employee.getSalary());
empInfo.setBonus(employee.getBonus());
empInfo.setComm(employee.getComm());
return empInfo;
}
catch (java.rmi.RemoteException rex)
{
    ......

In the second service, which displays employee numbers, the session bean, AccessEmployee, directly accesses the database table.

/**
 * Get the employee number list.
 * @return Collection
 */
public Collection getEmpNoList()
{
    ResultSet rs = null;
    PreparedStatement ps = null;
    Vector list = new Vector();
    DataSource ds = null;
    Connection con = null;
    try
    {
        ds = getDataSource();
        con = ds.getConnection();
        String schema = getEnvProps(DBschema);
        String query = "Select EMPNO from " + schema + ".EMPLOYEE";
        ps = con.prepareStatement(query);
        ps.executeQuery();
        rs = ps.getResultSet();
        EmployeeKey pk;
        while (rs.next())
        {
            pk = new EmployeeKey();
            pk.employeeId = rs.getString(1);
            list.addElement(pk.employeeId);
        }
    rs.close();
    return list;
Chapter 11. JDBC and SQLJ connection pooling support

Connection pooling is part of JDBC DataSource support, and is supported by the IBM Data Server Driver for JDBC and SQLJ.

The IBM Data Server Driver for JDBC and SQLJ provides a factory of pooled connections that are used by WebSphere Application Server or other application servers. The application server actually does the pooling. Connection pooling is completely transparent to a JDBC or SQLJ application.

Connection pooling is a framework for caching physical data source connections, which are equivalent to DB2 threads. When JDBC reuses physical data source connections, the expensive operations that are required for the creation and subsequent closing of java.sql.Connection objects are minimized.

Without connection pooling, each java.sql.Connection object represents a physical connection to the data source. When the application establishes a connection to a data source, DB2 creates a new physical connection to the data source. When the application calls the java.sql.Connection.close method, DB2 terminates the physical connection to the data source.

In contrast, with connection pooling, a java.sql.Connection object is a temporary, logical representation of a physical data source connection. The physical data source connection can be serially reused by logical java.sql.Connection instances. The application can use the logical java.sql.Connection object in exactly the same manner as it uses a java.sql.Connection object when there is no connection pooling support.

With connection pooling, when a JDBC application invokes the DataSource.getConnection method, the data source determines whether an appropriate physical connection exists. If an appropriate physical connection exists, the data source returns a java.sql.Connection instance to the application. When the JDBC application invokes the java.sql.Connection.close method, JDBC does not close the physical data source connection. Instead, JDBC closes only JDBC resources, such as Statement or ResultSet objects. The data source returns the physical connection to the connection pool for reuse.

Connection pooling can be homogeneous or heterogeneous.

With homogeneous pooling, all Connection objects that come from a connection pool should have the same properties. The first logical Connection that is created with the DataSource has the properties that were defined for the DataSource. However, an application can change those properties. When a Connection is returned to the connection pool, an application server or a pooling module should reset the properties to their original values. However, an application server or pooling module might not reset the changed properties. The JDBC driver does not modify the properties. Therefore, depending on the application server or pool module design, a reused logical Connection might have the same properties as those that are defined for the DataSource or different properties.

With heterogeneous pooling, Connection objects with different properties can share the same connection pool.
Chapter 12. IBM Data Server Driver for JDBC and SQLJ
statement caching

The IBM Data Server Driver for JDBC and SQLJ can use an internal statement cache to improve the performance of Java applications by caching and pooling prepared statements.

Internal statement caching is available for connections that use IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, or for connections that use IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.

You enable internal statement caching in any of the following ways:

- By setting one of the following properties to a positive value:
  - com.ibm.db2.jcc.DB2ConnectionPoolDataSource.maxStatements, for objects that are created using the javax.sql.ConnectionPoolDataSource interface.
  - com.ibm.db2.jcc.DB2XADatasource.maxStatements, for objects that are created using the javax.sql.XADataSource interface.
  - com.ibm.db2.jcc.DB2SimpleDataSource.maxStatements, for objects that are created using the com.ibm.db2.jcc.DB2SimpleDataSource interfaces.
- By setting the maxStatements property in a URL, and passing the URL to the DriverManager.getConnection method.

When internal statement caching is enabled, the IBM Data Server Driver for JDBC and SQLJ can cache PreparedStatement objects, CallableStatement objects, and JDBC resources that are used by SQLJ statements when those objects or resources are logically closed. When you explicitly or implicitly invoke the close method on a statement, you logically close the statement.

Reuse of a previously cached statement is transparent to applications. The statement cache exists for the life of an open connection. When the connection is closed, the driver deletes the statement cache and closes all pooled statements.

A logically open statement becomes ineligible for caching under either of the following circumstances:

- An exception occurs on the statement.
- JDBC 4.0 method Statement.setPoolable(false) is called.

When the IBM Data Server Driver for JDBC and SQLJ attempts to cache a statement, and the internal statement cache is full, the driver purges the least recently used cached statement, and inserts the new statement.

The internal statement cache is purged under the following conditions:

- A SET statement is issued that affects target objects of the SQL statement.
- A SET statement is executed that the IBM Data Server Driver for JDBC and SQLJ does not recognize.
- The IBM Data Server Driver for JDBC and SQLJ detects that a property that modifies target objects of the SQL statement was modified during connection reuse. currentSchema is an example of a property that modifies target objects of an SQL statement.
In a Java program, you can test whether the internal statement cache is enabled by issuing the DatabaseMetaData.supportsStatementPooling method. The method returns true if the internal statement cache is enabled.

The IBM Data Server Driver for JDBC and SQLJ does not check whether the definitions of target objects of statements in the internal statement cache have changed. If you execute SQL data definition language statements in an application, you need to disable internal statement caching for that application.

The internal statement cache requires extra memory. If memory becomes constrained, you can increase the JVM size, or decrease the value of maxStatements.

“Common IBM Data Server Driver for JDBC and SQLJ properties for all supported database products” on page 327
Chapter 13. JDBC and SQLJ reference information

The IBM implementations of JDBC and SQLJ provide a number of application programming interfaces, properties, and commands for developing JDBC and SQLJ applications.

Data types that map to database data types in Java applications

To write efficient JDBC and SQLJ programs, you need to use the best mappings between Java data types and table column data types.

The following tables summarize the mappings of Java data types to JDBC and database data types for a DB2 for Linux, UNIX, and Windows, DB2 for z/OS, or IBM Informix system.

Data types for updating table columns

The following table summarizes the mappings of Java data types to database data types for PreparedStatement.setXXX or ResultSet.updateXXX methods in JDBC programs, and for input host expressions in SQLJ programs. When more than one Java data type is listed, the first data type is the recommended data type.

### Table 49. Mappings of Java, JDBC, and SQL data types for calling stored procedures and user-defined functions (continued)

<table>
<thead>
<tr>
<th>Java data type</th>
<th>JDBC data type</th>
<th>SQL data type</th>
</tr>
</thead>
</table>

**Notes:**

1. This parameter data type is supported for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to DB2 for Linux, UNIX, and Windows only.
2. This parameter data type is supported for stored procedure calls only.
3. A stored procedure or user-defined function that is defined with a SMALLINT parameter can be invoked with a boolean or byte parameter. However, this is not recommended.
4. DECIMAL parameters in Java routines are valid only for connections to DB2 Version 9.1 for z/OS or later database servers. DECIMAL parameters in Java routines are not supported for connections to DB2 for Linux, UNIX, and Windows or DB2 for i. Use of DECIMAL requires the SDK for Java Version 5 (1.5) or later.
5. This mapping is valid only if the database server can determine the data type of the column.
6. BINARY and VARBINARY are valid for connections to DB2 Version 9.1 for z/OS or later database servers or DB2 for i5/OS Version 3 and later database servers.
7. BIGINT is valid for connections to DB2 Version 9.1 for z/OS or later database servers, DB2 V9.1 for Linux, UNIX, and Windows or later database servers, and all supported DB2 for i database servers.
8. \( p \) indicates the timestamp precision, which is the number of digits in the fractional part of the timestamp. \( 0 < p < 12 \). The default is 6. \( \text{TIMESTAMP}(p) \) is supported for connections to DB2 for Linux, UNIX, and Windows V9.1 and later and DB2 for z/OS V10 and later only.
9. The WITH TIME ZONE clause is supported for connections to DB2 for z/OS V10 and later only.

### Data types in Java stored procedures and user-defined functions

The following table summarizes mappings of the SQL parameter data types in a CREATE PROCEDURE or CREATE FUNCTION statement to the data types in the corresponding Java stored procedure or user-defined function method.

For DB2 for Linux, UNIX, and Windows, if more than one Java data type is listed for an SQL data type, only the first Java data type is valid.

For DB2 for z/OS, if more than one Java data type is listed, and you use a data type other than the first data type as a method parameter, you need to include a method signature in the EXTERNAL clause of your CREATE PROCEDURE or CREATE FUNCTION statement that specifies the Java data types of the method parameters.

### Table 50. Mappings of SQL data types in a CREATE PROCEDURE or CREATE FUNCTION statement to data types in the corresponding Java stored procedure or user-defined function program

</table>

Notes:
1. This parameter data type is supported for stored procedures only.
2. For a stored procedure or user-defined function on a DB2 for Linux, UNIX, and Windows server, only the first data type is valid.
3. BIGINT is valid for connections to DB2 Version 9.1 for z/OS or later database servers or DB2 V9.1 for Linux, UNIX, and Windows or later database servers.
4. DECIMAL parameters in Java routines are valid only for connections to DB2 Version 9.1 for z/OS or later database servers. DECIMAL parameters in Java routines are not supported for connections to for Linux, UNIX, and Windows or DB2 for i. Use of DECIMAL requires the SDK for Java Version 5 (1.5) or later.
5. BINARY and VARBINARY are valid for connections to DB2 Version 9.1 for z/OS or later database servers.
6. $p$ indicates the timestamp precision, which is the number of digits in the fractional part of the timestamp. $0 < p < 12$. The default is 6. TIMESTAMP($p$) is supported for connections to DB2 for Linux, UNIX, and Windows V9.7 and later and DB2 for z/OS V10 and later only.
7. The WITH TIME ZONE clause is supported for connections to DB2 for z/OS V10 and later only.

Date, time, and timestamp values that can cause problems in JDBC and SQLJ applications

You might receive unexpected results in JDBC and SQLJ applications if you use date, time, and timestamp values that do not correspond to real dates and times.

The following items might cause problems:
- Use of the hour ‘24’ to represent midnight
- Use of a date between October 5, 1582, and October 14, 1582, inclusive
Problems with using the hour '24' as midnight

The IBM Data Server Driver for JDBC and SQLJ uses Java data types for its internal processing of input and output parameters and ResultSet content in JDBC and SQLJ applications. The Java data type that is used by the driver is based on the best match for the corresponding SQL type when the target SQL type is known to the driver.

For values that are assigned to or retrieved from DATE, TIME, or TIMESTAMP SQL types, the IBM Data Server Driver for JDBC and SQLJ uses java.sql.Date for DATE SQL types, java.sql.Time for TIME SQL types, and java.sql.Timestamp for TIMESTAMP SQL types.

When you assign a string value to a DATE, TIME, or TIMESTAMP target, the IBM Data Server Driver for JDBC and SQLJ uses Java facilities to convert the string value to a java.sql.Date, java.sql.Time, or java.sql.Timestamp value. If a string representation of a date, time, or timestamp value does not correspond to a real date or time, Java adjusts the value to a real date or time value. In particular, Java adjusts an hour value of '24' to '00' of the next day. This adjustment can result in an exception for a timestamp value of '9999-12-31 24:00:00.0', because the adjusted year value becomes '10000'.

Important: To avoid unexpected results when you assign or retrieve date, time, or timestamp values in JDBC or SQLJ applications, ensure that the values are real date, time, or timestamp values. In addition, do not use '24' as the hour component of a time or timestamp value.

If a value that does not correspond to a real date or time, such as a value with an hour component of '24', is stored in a TIME or TIMESTAMP column, you can avoid adjustment during retrieval by executing the SQL CHAR function against that column in the SELECT statement that defines a ResultSet. Executing the CHAR function converts the date or time value to a character string value on the database side. However, if you use the getTime or getTimestamp method to retrieve that value from the ResultSet, the IBM Data Server Driver for JDBC and SQLJ converts the value to a java.sql.Time or java.sql.Timestamp type, and Java adjusts the value. To avoid date adjustment, execute the CHAR function against the column value, and retrieve the value from the ResultSet with the getString method.

The following examples show the results of updating DATE, TIME, or TIMESTAMP columns in JDBC or SQLJ applications, when the application data does not represent real dates or times.

<table>
<thead>
<tr>
<th>String input value</th>
<th>Target type in database</th>
<th>Value sent to table column, or exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>2008-13-35</td>
<td>DATE</td>
<td>2009-02-04</td>

</tbody>
</table>

Problems with using dates in the range October 5, 1582, through October 14, 1582

The Java java.util.Date and java.util.Timestamp classes use the Julian calendar for dates before October 4, 1582, and the Gregorian calendar for dates starting with October 4, 1582. In the Gregorian calendar, October 4, 1582, is followed by October 15, 1582. If a Java program encounters a java.util.Date or java.util.Timestamp value that is between October 5, 1582, and October 14, 1582, inclusive, Java adds 10 days to that date. Therefore, a DATE or TIMESTAMP value in a DB2 table that has a value between October 5, 1582, and October 14, 1582, inclusive, is retrieved in a Java program as a java.util.Date or java.util.Timestamp value between October 15, 1582, and October 24, 1582, inclusive. A java.util.Date or java.util.Timestamp value in a Java program that is between October 5, 1582, and October 14, 1582, inclusive, is stored in a DB2 table as a DATE or TIMESTAMP value between October 15, 1582, and October 24, 1582, inclusive.

Example: Retrieve October 10, 1582, from a DATE column.

```java
// DATETABLE has one date column with one row.
// Its value is 1582-10-10.
java.sql.ResultSet rs = statement.executeQuery(select * from DATETABLE);
rs.next();
System.out.println(rs.getDate(1)); // Value is retrieved as 1582-10-20
```

Example: Store October 10, 1582, in a DATE column.

```java
java.sql.Date d = java.sql.Date.valueOf("1582-10-10");
java.sql.PreparedStatement ps = c.prepareStatement("Insert into DATETABLE values(?)");
ps.setDate(1, d);
ps.executeUpdate(); // Value is inserted as 1582-10-20
```

To retrieve a value in the range October 5, 1582, to October 14, 1582, from a DB2 table without date adjustment, execute the SQL CHAR function against the DATE or TIMESTAMP column in the SELECT statement that defines a ResultSet. Executing the CHAR function converts the date or time value to a character string value on the database side.
To store a value in the range October 5, 1582, to October 14, 1582 in a DB2 table without date adjustment, you can use one of the following techniques:

- For a JDBC or an SQLJ application, use the setString method to assign the value to a String input parameter. Cast the input parameter as VARCHAR, and execute the DATE or TIMESTAMP function against the result of the cast. Then store the result of the DATE or TIMESTAMP function in the DATE or TIMESTAMP column.

- For a JDBC application, set the Connection or DataSource property sendDataAsIs to true, and use the setString method to assign the date or timestamp value to the input parameter. Then execute an SQL statement to assign the String value to the DATE or TIMESTAMP column.

**Example:** Retrieve October 10, 1582, from a DATE column without date adjustment.

```java
// DATETABLE has one date column called DATECOL with one row.
// Its value is 1582-10-10.
java.sql.ResultSet rs =
    statement.executeQuery(SELECT CHAR(DATECOL) FROM DATETABLE);
rs.next();
System.out.println(rs.getString(1)); // Value is retrieved as 1582-10-10
```

**Example:** Store October 10, 1582, in a DATE column without date adjustment.

```java
String s = "1582-10-10";
java.sql.Statement stmt = c.createStatement;
java.sql.PreparedStatement ps =
    c.prepareStatement("Insert INTO DATETABLE VALUES " +
    "(DATE(CAST (?) AS VARCHAR))");
ps.setString(1, s);
ps.executeUpdate(); // Value is inserted as 1582-10-10
```

### Data loss for timestamp data in JDBC and SQLJ applications

For DB2 for z/OS Version 10 or later, or DB2 for Linux, UNIX, and Windows Version 9.7 or later, you can specify the precision of the fractional part of a TIMESTAMP column, with a maximum precision of 12 digits. The fractional part of a Java timestamp value can have up to 9 digits of precision. Depending on the column definition, data loss can occur when you update a TIMESTAMP(p) column or retrieve data from a TIMESTAMP(p) column.

#### Data loss for input data

If you use a setTimestamp call to pass a timestamp value to a TIMESTAMP(p) column, the maximum precision of the Java value that is sent to the data source is 9. If you use a setTimestamp call to pass a timestamp value to a TIMESTAMP column at a data source that does not support TIMESTAMP(p), the maximum precision of the Java value that is sent to the data source is 6. For input to a TIMESTAMP(p) column, if the precision of the target column is less than the precision of the input value, the data source truncates the excess digits in the fractional part of the timestamp.

If you use a setString call to pass the input value, it is possible to send a value with a precision of greater than 9 to the data source.

For IBM Data Server Driver for JDBC and SQLJ version 3.59 or later, no data loss occurs if the TIMESTAMP(p) column is big enough to accommodate the input.
value. For IBM Data Server Driver for JDBC and SQLJ version 3.58 or earlier, data loss depends on the setting of the deferPrepares property and the sendDataAsIs property:

- If sendDataAsIs is set to `true`, the IBM Data Server Driver for JDBC and SQLJ sends the string to the data source as-is, so the fractional part of the timestamp value can be more than 9 digits. If the value of $p$ in the `TIMESTAMP(p)` column is greater than or equal to the number of digits in the fractional part of the input data, no data loss occurs.

- If sendDataAsIs is set to `false`, data loss depends on the deferPrepares setting.

- If deferPrepares is set to `true`, the first time that an UPDATE statement is executed, the IBM Data Server Driver for JDBC and SQLJ sends the string to the data source as-is, so the fractional part of the timestamp value can be more than 9 digits. If the value of $p$ in the `TIMESTAMP(p)` column is greater than or equal to the number of digits in the fractional part of the input data, no data loss occurs.

  For subsequent executions of the UPDATE statement, the IBM Data Server Driver for JDBC and SQLJ can determine that the target data type is a `TIMESTAMP` data type. If the data source supports `TIMESTAMP(p)` columns, the driver converts the input value to a `java.sql.Timestamp` value with a maximum precision of 9. If the data source does not support `TIMESTAMP(p)` columns, the driver converts the input value to a `java.sql.Timestamp` value with a maximum precision of 6. Data loss occurs if the original value has more precision than the converted `java.sql.Timestamp` value, or if the `java.sql.Timestamp` value has more precision than the `TIMESTAMP(p)` column.

- If deferPrepares is set to `false`, the IBM Data Server Driver for JDBC and SQLJ can determine that the target data type is a `TIMESTAMP` data type. If the data source supports `TIMESTAMP(p)` columns, the driver converts the input value to a `java.sql.Timestamp` value with a maximum precision of 9. If the data source does not support `TIMESTAMP(p)` columns, the driver converts the input value to a `java.sql.Timestamp` value with a maximum precision of 6. Data loss occurs if the original value has more precision than the converted `java.sql.Timestamp` value, or if the `java.sql.Timestamp` value has more precision than the `TIMESTAMP(p)` column.

You can lessen data loss for input timestamp values by using a `setString` call and setting `sendDataAsIs` to `true`. However, if you set `sendDataAsIs` to `true`, you need to ensure that application data types are compatible with data source data types.

### Data loss for output data

When you use a `getTimestamp` or `getString` call to retrieve data from a `TIMESTAMP(p)` column, the IBM Data Server Driver for JDBC and SQLJ converts the value to a `java.sql.Timestamp` value with a maximum precision of 9. If the source value has a precision of greater than 9, the driver truncates the fractional part of the retrieved value to nine digits. If you do not want truncation to occur, in the `SELECT` statement that retrieves the `TIMESTAMP(p)` value, you can cast the `TIMESTAMP(p)` value to a character data type, such as `VARCHAR`, and use `getString` to retrieve the value from the `ResultSet`.

### Retrieval of special values from DECFLOAT columns in Java applications

Special handling is necessary if you retrieve values from DECFLOAT columns, and the DECFLOAT columns contain the values NaN, Infinity, or -Infinity.
The recommended Java data type for retrieval of DECFLOAT column values is java.math.BigDecimal. However, you receive SQL error code -4231 if you perform either of these operations:

- Retrieve the value NaN, Infinity, or -Infinity from a DECFLOAT column using the JDBC java.sql.ResultSet.getBigDecimal or java.sql.ResultSet.getObject method
- Retrieve the value NaN, Infinity, or -Infinity from a DECFLOAT column into a java.math.BigDecimal variable in an SQLJ clause of an SQLJ program

You can circumvent this restriction by testing for the -4231 error, and retrieving the special value using the java.sql.ResultSet.getDouble or java.sql.ResultSet.getString method.

Suppose that the following SQL statements were used to create and populate a table.

```
CREATE TABLE TEST.DECFLOAT_TEST
(
  INT_VAL INT,
  DECFLOAT_VAL DECFLOAT
);
INSERT INTO TEST.DECFLOAT_TEST (INT_VAL, DECFLOAT_VAL) VALUES (1, 123.456),
INSERT INTO TEST.DECFLOAT_TEST (INT_VAL, DECFLOAT_VAL) VALUES (2, INFINITY),
INSERT INTO TEST.DECFLOAT_TEST (INT_VAL, DECFLOAT_VAL) VALUES (3, -123.456),
INSERT INTO TEST.DECFLOAT_TEST (INT_VAL, DECFLOAT_VAL) VALUES (4, -INFINITY),
INSERT INTO TEST.DECFLOAT_TEST (INT_VAL, DECFLOAT_VAL) VALUES (5, NaN);
```

The following code retrieves the contents of the DECFLOAT column using the java.sql.ResultSet.getBigDecimal method. If retrieval fails because the column value is NaN, INFINITY, or -INFINITY, the program retrieves the value using the java.sql.ResultSet.getBigDouble method.

```
final static int DECFLOAT_SPECIALVALUE_ENCOUNTERED = -4231;
java.sql.Connection con =
  java.sql.DriverManager.getConnection("jdbc:db2://localhost:50000/sample" ,
  "userid", "password");
java.sql.Statement stmt = con.createStatement();
java.sql.ResultSet rs = stmt.executeQuery(
  "SELECT INT_VAL, DECFLOAT_VAL FROM TEST.DECFLOAT_TEST ORDER BY INT_VAL");
int i = 0;
while (rs.next()) {
  try {
    System.out.println("\nRow " + ++i);
    System.out.println("INT_VAL = " + rs.getInt(1));
    System.out.println("DECFLOAT_VAL= " + rs.getBigDecimal(2));
  }
  catch (java.sql.SQLException e) {
    System.out.println("Caught SQLException" + e.getMessage());
    if (e.getErrorCode() == DECFLOAT_SPECIALVALUE_ENCOUNTERED) {
      // getBigDecimal failed because the retrieved value is NaN, INFINITY, or -INFINITY, so retry with getDouble.
      double d = rs.getDouble(2);
      if (d == Double.POSITIVE_INFINITY) {
        System.out.println("DECFLOAT_VAL = +INFINITY");
      } else if (d == Double.NEGATIVE_INFINITY) {
        System.out.println("DECFLOAT_VAL = -INFINITY");
      } else if (d == Double.NaN) {
        System.out.println("DECFLOAT_VAL = NaN");
      } else {
        System.out.println("DECFLOAT_VAL = " + d);
      }
    } else {
      e.printStackTrace();
    }
  }
}
```
The following code retrieves the contents of the DECFLOAT column using the java.sql.ResultSet.getBigDecimal method. If retrieval fails because the column value is NaN, INFINITY, or -INFINITY, the program retrieves the value using the java.sql.ResultSet.getString method.

```java
final static int DECFLOAT_SPECIALVALUE_ENCOUNTERED = -4231;
java.sql.Connection con =
    java.sql.DriverManager.getConnection("jdbc:db2://localhost:50000/sample"
    , "userid", "password");
java.sql.Statement stmt = con.createStatement();
java.sql.ResultSet rs = stmt.executeQuery(
    "SELECT INT_VAL, DECFLOAT_VAL FROM TEST.DECFLOAT_TEST ORDER BY INT_VAL");
i = 0;
while (rs.next()) {
    try {
        System.out.println("\nRow " + ++i);
        System.out.println("INT_VAL = " + rs.getInt(1));
        System.out.println("DECFLOAT_VAL = " + rs.getBigDecimal(2));
    } catch (java.sql.SQLException e) {
        System.out.println("Caught SQLException" + e.getMessage());
        if (e.getErrorCode() == DECFLOAT_SPECIALVALUE_ENCOUNTERED) {
            // getBigDecimal failed because the retrieved value is NaN,
            // INFINITY, or -INFINITY, so retry with getString.
            System.out.println("DECFLOAT_VAL = " + rs.getString(2));
        } else {
            e.printStackTrace();
        }
    }
}
```

Properties for the IBM Data Server Driver for JDBC and SQLJ

IBM Data Server Driver for JDBC and SQLJ properties define how the connection to a particular data source should be made. Most properties can be set for a DataSource object or for a Connection object.

Methods for setting the properties

Properties can be set in one of the following ways:

- Using setXXX methods, where XXX is the unqualified property name, with the first character capitalized.

  Properties are applicable to the following IBM Data Server Driver for JDBC and SQLJ-specific implementations that inherit from com.ibm.db2.jcc.DB2BaseDataSource:
  - com.ibm.db2.jcc.DB2SimpleDataSource
  - com.ibm.db2.jcc.DB2ConnectionPoolDataSource
  - com.ibm.db2.jcc.DB2XADDataSource

- In a java.util.Properties value in the info parameter of a DriverManager.getConnection call.

- In a java.lang.String value in the url parameter of a DriverManager.getConnection call.

Some properties with an int data type have predefined constant field values. You must resolve constant field values to their integer values before you can use those values in the url parameter. For example, you cannot use com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL in a url parameter. However, you can build a URL string that includes com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL, and assign the URL string to a String variable. Then you can use the String variable in the url parameter:
String url =
"jdbc:db2://sysmvs1.stl.ibm.com:5021/STLEC1" +
":user=dbadm;password=dbadm;" +
"traceLevel=" +
(com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL) + ";

Connection con =
java.sql.DriverManager.getConnection(url);

Common IBM Data Server Driver for JDBC and SQLJ
properties for all supported database products

Most of the IBM Data Server Driver for JDBC and SQLJ properties apply to all
database products that the driver supports.

Unless otherwise noted, all properties are in com.ibm.db2.jcc.DB2BaseDataSource.

Those properties are:

affinityFailbackInterval
Specifies the length of the interval, in seconds, that the IBM Data Server Driver
for JDBC and SQLJ waits between attempts to fail back an existing connection
to the primary server. A value that is less than or equal to 0 means that the
connection does not fail back. The default is DB2BaseDataSource.NOT_SET (0).

Attempts to fail back connections to the primary server are made at transaction
boundaries, after the specified interval elapses.

affinityFailbackInterval is used only if the values of properties
enableSeamlessFailover and enableClientAffinitiesList are
DB2BaseDataSource.YES (1).

affinityFailbackInterval applies only to IBM Data Server Driver for JDBC and
SQLJ type 4 connectivity.

allowNextOnExhaustedResultSet
Specifies how the IBM Data Server Driver for JDBC and SQLJ handles a
ResultSet.next() call for a forward-only cursor that is positioned after the last
row of the ResultSet. The data type of this property is int.

Possible values are:

DB2BaseDataSource.YES (1)
For a ResultSet that is defined as TYPE_FORWARD_ONLY,
ResultSet.next() returns false if the cursor was previously positioned
after the last row of the ResultSet. false is returned, regardless of
whether the cursor is open or closed.
DB2BaseDataSource.NO (2)
For a ResultSet that is defined as TYPE_FORWARD_ONLY, when
ResultSet.next() is called, and the cursor was previously positioned
after the last row of the ResultSet, the driver throws a
java.sql.SQLException with error text "Invalid operation: result set is
closed." This is the default.

allowNullResultSetForExecuteQuery
Specifies whether the IBM Data Server Driver for JDBC and SQLJ returns null
when Statement.executeQuery, PreparedStatement.executeQuery, or
CallableStatement.executeQuery is used to execute a CALL statement for a
stored procedure that does not return any result sets.

Possible values are:
DB2BaseDataSource.NOT_SET (0)
The behavior is the same as for DB2BaseDataSource.NO.

DB2BaseDataSource.YES (1)
The IBM Data Server Driver for JDBC and SQLJ returns null when
Statement.executeQuery, PreparedStatement.executeQuery, or
CallableStatement.executeQuery is used to execute a CALL statement for a
stored procedure that does not return any result sets. This
behavior does not conform to the JDBC standard.

DB2BaseDataSource.NO (2)
The IBM Data Server Driver for JDBC and SQLJ throws an
SQLException when Statement.executeQuery,
PreparedStatement.executeQuery, or CallableStatement.executeQuery is
used to execute a CALL statement for a stored procedure that does not
return any result sets. This behavior conforms to the JDBC standard.

atomicMultiRowInsert
Specifies whether batch operations that use PreparedStatement methods to
modify a table are atomic or non-atomic. The data type of this property is int.

For connections to DB2 for z/OS, this property applies only to batch INSERT
operations.

For connections to DB2 for Linux, UNIX, and Windows or IBM Informix, this
property applies to batch INSERT, MERGE, UPDATE or DELETE operations.

Possible values are:
DB2BaseDataSource.YES (1)
Batch operations are atomic. Insertion of all rows in the batch is
considered to be a single operation. If insertion of a single row fails,
the entire operation fails with a BatchUpdateException. Use of a batch
statement that returns auto-generated keys fails with a
BatchUpdateException.

If atomicMultiRowInsert is set to DB2BaseDataSource.YES (1):
• Execution of statements in a heterogeneous batch is not allowed.
• If the target data source is DB2 for z/OS the following operations
  are not allowed:
  – Insertion of more than 32767 rows in a batch results in a
    BatchUpdateException.
  – Calling more than one of the following methods against the same
    parameter in different rows results in a BatchUpdateException:
    – PreparedStatement.setAsciiStream
- PreparedStatement.setCharacterStream
- PreparedStatement.setUnicodeStream

**DB2BaseDataSource.NO** (2)
Batch inserts are non-atomic. Insertion of each row is considered to be a separate execution. Information on the success of each insert operation is provided by the int[] array that is returned by Statement.executeBatch.

**DB2BaseDataSource.NOT_SET** (0)
Batch inserts are non-atomic. Insertion of each row is considered to be a separate execution. Information on the success of each insert operation is provided by the int[] array that is returned by Statement.executeBatch. This is the default.

**blockingReadConnectionTimeout**
The amount of time in seconds before a connection socket read times out. This property applies only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, and affects all requests that are sent to the data source after a connection is successfully established. The default is 0. A value of 0 means that there is no timeout.

**clientDebugInfo**
Specifies a value for the CLIENT DEBUGINFO connection attribute, to notify the data server that stored procedures and user-defined functions that are using the connection are running in debug mode. CLIENT DEBUGINFO is used by the DB2 Unified Debugger. The data type of this property is String. The maximum length is 254 bytes.

This property applies only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

**clientRerouteAlternateServerName**
Specifies one or more server names for client reroute. The data type of this property is String.

When enableClientAffinitiesList=DB2BaseDataSource.YES (1), clientRerouteAlternateServerName must contain the name of the primary server as well as alternate server names. The server that is identified by serverName and portNumber is the primary server. That server name must appear at the beginning of the clientRerouteAlternateServerName list.

If more than one server name is specified, delimit the server names with commas (,) or spaces. The number of values that is specified for clientRerouteAlternateServerName must match the number of values that is specified for clientRerouteAlternatePortNumber.

clientRerouteAlternateServerName applies to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for Linux, UNIX, and Windows and IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

**clientRerouteAlternatePortNumber**
Specifies one or more port numbers for client reroute. The data type of this property is String.

When enableClientAffinitiesList=DB2BaseDataSource.YES (1), clientRerouteAlternatePortNumber must contain the port number for the primary server as well as port numbers for alternate servers. The server that is identified by serverName and portNumber is the primary server. That port number must appear at the beginning of the clientRerouteAlternatePortNumber list.
If more than one port number is specified, delimit the port numbers with commas (,) or spaces. The number of values that is specified for clientRerouteAlternatePortNumber must match the number of values that is specified for clientRerouteAlternateServerName.

clientRerouteAlternatePortNumber applies to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for Linux, UNIX, and Windows and IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

**clientRerouteServerListJNDIName**
Identifies a JNDI reference to a DB2ClientRerouteServerList instance in a JNDI repository of reroute server information. clientRerouteServerListJNDIName applies only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, and to connections that are established through the DataSource interface.

If the value of clientRerouteServerListJNDIName is not null, clientRerouteServerListJNDIName provides the following functions:
- Allows information about reroute servers to persist across JVMs
- Provides an alternate server location if the first connection to the data source fails

**clientRerouteServerListJNDIContext**
Specifies the JNDI context that is used for binding and lookup of the DB2ClientRerouteServerList instance. clientRerouteServerListJNDIContext applies only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, and to connections that are established through the DataSource interface.

If clientRerouteServerListJNDIContext is not set, the IBM Data Server Driver for JDBC and SQLJ creates an initial context using system properties or the jndi.properties file.

clientRerouteServerListJNDIContext can be set only by using the following method:
```java
public void setClientRerouteServerListJNDIContext(javax.naming.Context registry)
```

**commandTimeout**
Specifies the maximum time in seconds that an application that runs under the IBM Data Server Driver for JDBC and SQLJ waits for SQL operations to complete before the driver throws an SQLException. The wait time includes time to obtain a transport, perform failover if needed, send the request, and wait for a response. The data type of this parameter is int. The default is 0, which means that there is no timeout.

If the java.sql.Statement.setQueryTimeout method is invoked, the query timeout value that is set through Statement.setQueryTimeout overrides the commandTimeout value.

commandTimeout applies to the execution of Statement, PreparedStatement, and CallableStatement methods execute, executeQuery, and executeUpdate. commandTimeout also applies to the executeBatch method if property queryTimeoutInterruptProcessingMode has the value INTERRUPT_PROCESSING_MODE_CLOSE_SOCKET (2).

The SQL error code that is returned with the SQLException depends on the data server and the value of property queryTimeoutInterruptProcessingMode:
- For connections to DB2 for z/OS data servers, -30108 is returned.
- Automatic client reroute processing is not initiated if the commandTimeout value is exceeded.
- For connections to other data servers:
– If the `queryTimeoutInterruptProcessingMode` value is
   `INTERRUPT_PROCESSING_MODE_STATEMENT_CANCEL` (1), -952 is
   returned.
– If the `queryTimeoutInterruptProcessingMode` value is
   `INTERRUPT_PROCESSING_MODE_CLOSE_SOCKET` (2), -30108 is
   returned.

If configuration property `db2.jcc.enableInetAddressGetHostName` is set to true, the following situations might occur:

- Actual wait times might exceed the `commandTimeout` value. This situation
  can occur when the driver needs to do several DNS lookup operations to
  resolve IP addresses to host names. The amount by which the wait time
  exceeds the `commandTimeout` value depends on the number of DNS lookup
  operations, and the amount of time that each DNS lookup operation takes.
- The extra time that is required for DNS lookup operations might cause more
  timeout conditions than if `db2.jcc.enableInetAddressGetHostName` is set to
  `false`.

`connectionCloseWithInFlightTransaction`

Specifies whether the IBM Data Server Driver for JDBC and SQLJ throws an
SQLException or rolls back a transaction without throwing an SQLException
when a connection is closed in the middle of the transaction. Possible values
are:

`DB2BaseDataSource.NOT_SET` (0)

  The behavior is the same as for
  `DB2BaseDataSource.CONNECTION_CLOSE_WITH_EXCEPTION`.

`DB2BaseDataSource.CONNECTION_CLOSE_WITH_EXCEPTION` (1)

  When a connection is closed in the middle of a transaction, an
  SQLException with error -4471 is thrown.

`DB2BaseDataSource.CONNECTION_CLOSE_WITH_ROLLBACK` (2)

  When a connection is closed in the middle of a transaction, the
  transaction is rolled back, and no SQLException is thrown.

`connectionTimeout`

Specifies the maximum time in seconds that the IBM Data Server Driver for
JDBC and SQLJ waits for a reply from a group of data servers when the driver
attempts to establish a connection. If the driver does not receive a reply after
the amount of time that is specified by `connectionTimeout`, the driver throws
an SQLException with SQL error code -4499. The data type of this parameter is
int. The default value is 0.

`connectionTimeout` applies only to connections to a DB2 for z/OS data sharing
group, DB2 pureScale instance, or IBM Informix high availability cluster.

If `connectionTimeout` is set to a positive value, that value overrides any other
timeout values that are set on a connection, such as `loginTimeout`. A
connection is attempted to the member of the group of data servers with the
greatest load capacity. If none of the members are up, a connection is
attempted to the group IP address that is specified on the `DataSource`. If the
connection cannot be established with any of the data servers within the
amount of time that is specified by `connectionTimeout`, an SQLException is
thrown.

If `connectionTimeout` is set to 0, and automatic client reroute is not enabled,
there is no time limit.
If connectionTimeout is set to 0, and automatic client reroute is enabled against a DB2 for z/OS data sharing group, DB2 pureScale instance, or IBM Informix high availability cluster, automatic client reroute properties such as maxRetriesForClientReroute and retryIntervalForClientReroute control the amount of time that is needed to establish the connection.

If configuration property db2.jcc.enableInetAddressGetHostName is set to true, the following situations might occur:

- Actual wait times might exceed the connectionTimeout value. This situation can occur when the driver needs to do several DNS lookup operations to resolve IP addresses to host names. The amount by which the wait time exceeds the connectionTimeout value depends on the number of DNS lookup operations, and the amount of time that each DNS lookup operation takes.
- The extra time that is required for DNS lookup operations might cause more timeout conditions than if db2.jcc.enableInetAddressGetHostName is set to false.

**databaseName**

Specifies the name for the data source. This name is used as the database portion of the connection URL. The name depends on whether IBM Data Server Driver for JDBC and SQLJ type 4 connectivity or IBM Data Server Driver for JDBC and SQLJ type 2 connectivity is used.

For IBM Data Server Driver for JDBC and SQLJ type 4 connectivity:

- If the connection is to a DB2 for z/OS server, the databaseName value is the DB2 location name that is defined during installation. All characters in this value must be uppercase characters. You can determine the location name by executing the following SQL statement on the server:
  ```sql
  SELECT CURRENT SERVER FROM SYSIBM.SYSDUMMY1;
  ```
- If the connection is to a DB2 for Linux, UNIX, and Windows server, the databaseName value is the database name that is defined during installation.
- If the connection is to an IBM Informix server, database is the database name. The name is case-insensitive. The server converts the name to lowercase.
- If the connection is to an IBM Cloudscape server, the databaseName value is the fully-qualified name of the file that contains the database. This name must be enclosed in double quotation marks ("."). For example:
  ```sql
  "c:/databases/testdb"
  ```

If this property is not set, connections are made to the local site.

For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity:

- The databaseName value is the database name that is defined during installation, if the value of the serverName connection property is null. If the value of serverName property is not null, the databaseName value is a database alias.

**decimalSeparator**

Specifies the decimal separator for input and output, for decimal, floating point, or decimal floating-point data values. The data type of this property is int.

If the value of the sendDataAsIs property is true, decimalSeparator affects only output values.

Possible values are:
DB2BaseDataSource.DECIMAL_SEPARATOR_NOT_SET (0)
A period is used as the decimal separator. This is the default.

DB2BaseDataSource.DECIMAL_SEPARATOR_PERIOD (1)
A period is used as the decimal separator.

DB2BaseDataSource.DECIMAL_SEPARATOR_COMMA (2)
A comma is used as the decimal separator.

When DECIMAL_SEPARATOR_COMMA is set, the result of
ResultSet.getString on a decimal, floating point, or decimal
floating-point value has a comma as a separator. However, if the
toString method is executed on a value that is retrieved with a
ResultSet.getXXX method that returns a decimal, floating point, or
decimal floating-point value, the result has a decimal point as the
decimal separator.

decimalStringFormat
Specifies the string format for data that is retrieved from a DECIMAL or
DECIMAL column when the SDK for Java is Version 1.5 or later. The data
type of this property is int. Possible values are:

DB2BaseDataSource.DECIMAL_STRING_FORMAT_NOT_SET (0)
The IBM Data Server Driver for JDBC and SQLJ returns decimal values
in the format that the java.math.BigDecimal.toString method returns
them. This is the default.

For example, the value 0.0000000004 is returned as 4E-10.

DB2BaseDataSource.DECIMAL_STRING_FORMAT_TO_STRING (1)
The IBM Data Server Driver for JDBC and SQLJ returns decimal values
in the format that the java.math.BigDecimal.toString method returns
them.

For example, the value 0.0000000004 is returned as 4E-10.

DB2BaseDataSource.DECIMAL_STRING_FORMAT_TO_PLAIN_STRING (2)
The IBM Data Server Driver for JDBC and SQLJ returns decimal values
in the format that the java.math.BigDecimal.toPlainString method
returns them.

For example, the value 0.0000000004 is returned as 0.0000000004.

This property has no effect for earlier versions of the SDK for Java. For those
versions, the IBM Data Server Driver for JDBC and SQLJ returns decimal
values in the format that the java.math.BigDecimal.toString method returns
them.

defaultIsolationLevel
Specifies the default transaction isolation level for new connections. The data
type of this property is int. When defaultIsolationLevel is set on a DataSource,
all connections that are created from that DataSource have the default isolation
level that is specified by defaultIsolationLevel.

For DB2 data sources, the default is
java.sql.Connection.TRANSACTION_READ_COMMITTED.

For IBM Informix databases, the default depends on the type of data source.
The following table shows the defaults.
Table 53. Default isolation levels for IBM Informix databases

<table>
<thead>
<tr>
<th>Type of data source</th>
<th>Default isolation level</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANSI-compliant database with logging</td>
<td>java.sql.Connection.TRANSACTION_SERIALIZABLE</td>
</tr>
<tr>
<td>Database without logging</td>
<td>java.sql.Connection.TRANSACTION_READ_UNCOMMITTED</td>
</tr>
<tr>
<td>Non-ANSI-compliant database with logging</td>
<td>java.sql.Connection.TRANSACTION_READ_COMMITTED</td>
</tr>
</tbody>
</table>

**deferPrepare**

Specifies whether invocation of the Connection.prepareStatement method results in immediate preparation of an SQL statement on the data source, or whether statement preparation is deferred until the PreparedStatement.executeUpdate method is executed. The data type of this property is boolean.

deferPrepare is supported for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for Linux, UNIX, and Windows, and for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

Possible values are:

- **true** Statement preparation on the data source does not occur until the PreparedStatement.executeUpdate method is executed. This is the default.
- **false** Statement preparation on the data source occurs when the Connection.prepareStatement method is executed.

Deferring prepare operations can reduce network delays. However, if you defer prepare operations, you need to ensure that input data types match column types.

**description**

A description of the data source. The data type of this property is String.

downgradeHoldCursorsUnderXa

Specifies whether cursors that are defined WITH HOLD can be opened under XA connections.

downgradeHoldCursorsUnderXa applies to:

- IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to DB2 for z/OS servers.
- IBM Data Server Driver for JDBC and SQLJ type 4 connectivity or IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for Linux, UNIX, and Windows servers.

The default is false, which means that a cursor that is defined WITH HOLD cannot be opened under an XA connection. An exception is thrown when an attempt is made to open that cursor.

If downgradeHoldCursorsUnderXa is set to true, a cursor that is defined WITH HOLD can be opened under an XA connection. However, the cursor has the following restrictions:

- When the cursor is opened under an XA connection, the cursor does not have WITH HOLD behavior. The cursor is closed at XA End.
- A cursor that is open before XA Start on a local transaction is closed at XA Start.

**driverType**

For the DataSource interface, determines which driver to use for connections. The data type of this property is int. Valid values are 2 or 4. 2 is the default.
**enableClientAffinitiesList**

Specifies whether the IBM Data Server Driver for JDBC and SQLJ enables client affinities for cascaded failover support. The data type of this property is int. Possible values are:

**DB2BaseDataSource.YES** (1)

The IBM Data Server Driver for JDBC and SQLJ enables client affinities for cascaded failover support. This means that only servers that are specified in the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber properties are retried. The driver does not attempt to reconnect to any other servers.

For example, suppose that clientRerouteAlternateServerName contains the following string:

host1,host2,host3

Also suppose that clientRerouteAlternatePortNumber contains the following string:

port1,port2,port3

When client affinities are enabled, the retry order is:

1. host1:port1
2. host2:port2
3. host3:port3

**DB2BaseDataSource.NO** (2)

The IBM Data Server Driver for JDBC and SQLJ does not enable client affinities for cascaded failover support.

**DB2BaseDataSource.NOT_SET** (0)

The IBM Data Server Driver for JDBC and SQLJ does not enable client affinities for cascaded failover support. This is the default.

The effect of the maxRetriesForClientReroute and retryIntervalForClientReroute properties differs depending on whether enableClientAffinitiesList is enabled.

This property applies only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

**enableNamedParameterMarkers**

Specifies whether support for named parameter markers is enabled in the IBM Data Server Driver for JDBC and SQLJ. The data type of this property is int. Possible values are:

**DB2BaseDataSource.YES** (1)

Named parameter marker support is enabled in the IBM Data Server Driver for JDBC and SQLJ.

**DB2BaseDataSource.NO** (2)

Named parameter marker support is not enabled in the IBM Data Server Driver for JDBC and SQLJ.

The driver sends an SQL statement with named parameter markers to the target data source without modification. The success or failure of the statement depends on a number of factors, including the following ones:

- Whether the target data source supports named parameter markers
- Whether the deferPrepares property value is true or false
- Whether the sendDataAsIs property value is true or false
**Recommendation:** To avoid unexpected behavior in an application that uses named parameter markers, set enableNamedParameterMarkers to YES.

**DB2BaseDataSource.NOT_SET (0)**

The behavior is the same as the behavior for **DB2BaseDataSource.NO (2).** This is the default.

**enableSeamlessFailover**

Specifies whether the IBM Data Server Driver for JDBC and SQLJ uses seamless failover for client reroute. The data type of this property is int.

For connections to DB2 for z/OS, if enableSysplexWLB is set to true, enableSeamlessFailover has no effect. The IBM Data Server Driver for JDBC and SQLJ uses seamless failover regardless of the enableSeamlessFailover setting.

Possible values of enableSeamlessFailover are:

**DB2BaseDataSource.YES (1)**

The IBM Data Server Driver for JDBC and SQLJ uses seamless failover.

This means that the driver does not throw an SQLException with SQL error code -4498 after a failed connection has been successfully re-established if the following conditions are true:

- The connection was not being used for a transaction at the time the failure occurred.
- There are no outstanding global resources, such as global temporary tables or open, held cursors, or connection states that prevent a seamless failover to another server.

When seamless failover occurs, after the connection to a new data source has been established, the driver re-issues the SQL statement that was being processed when the original connection failed.

**Recommendation:** Set the queryCloseImplicit property to **DB2BaseDataSource.QUERY_CLOSE_IMPLICIT_NO (2)** when you set enableSeamlessFailover to **DB2BaseDataSource.YES**, if the application uses held cursors.

**DB2BaseDataSource.NO (2)**

The IBM Data Server Driver for JDBC and SQLJ does not use seamless failover.

When this setting is in effect, if a server goes down, the driver tries to fail back or fail over to an alternate server. If failover or failback is successful, the driver throws an SQLException with SQL error code -4498, which indicates that a connection failed but was successfully reestablished. An SQLException with SQL error code -4498 informs the application that it should retry the transaction during which the connection failure occurred. If the driver cannot reestablish a connection, it throws an SQLException with SQL error code -4499.

**DB2BaseDataSource.NOT_SET (0)**

The IBM Data Server Driver for JDBC and SQLJ does not use seamless failover. This is the default.

**enableSysplexWLB**

Indicates whether the Sysplex workload balancing function of the IBM Data Server Driver for JDBC and SQLJ is enabled. The data type of enableSysplexWLB is boolean. The default is false.
enablSysplexWLBApplies only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

**fetchSize**
Specifies the default fetch size for ResultSet objects that are generated from Statement objects. The data type of this property is int.

The fetchSize default can be overridden by the Statement.setFetchSize method. The fetchSize property does not affect Statement objects that already exist when fetchSize is set.

Possible values of fetchSize are:

0 or positive-integer
The default fetchSize value for newly created Statement objects. If the fetchSize property value is invalid, the IBM Data Server Driver for JDBC and SQLJ sets the default fetchSize value to 0.

**DB2BaseDataSource.FETCHSIZE_NOT_SET (-1)**
Indicates that the default fetchSize value for Statement objects is 0. This is the property default.

The fetchSize property differs from the queryDataSize property. fetchSize affects the number of rows that are returned, and queryDataSize affects the number of bytes that are returned.

**fullyMaterializeLobData**
Indicates whether the driver retrieves LOB locators for FETCH operations. The data type of this property is boolean.

The effect of fullyMaterializeLobData depends on whether the data source supports progressive streaming, which is also known as dynamic data format:

- If the data source does not support progressive streaming:
  If the value of fullyMaterializeLobData is true, LOB data is fully materialized within the JDBC driver when a row is fetched. If the value is false, LOB data is streamed. The driver uses locators internally to retrieve LOB data in chunks on an as-needed basis. It is highly recommended that you set this value to false when you retrieve LOBs that contain large amounts of data. The default is true.

- If the data source supports progressive streaming:
  The JDBC driver ignores the value of fullyMaterializeLobData if the progressiveStreaming property is set to DB2BaseDataSource.YES or DB2BaseDataSource.NOT_SET.

This property has no effect on stored procedure parameters or on LOBs that are fetched using scrollable cursors. LOB stored procedure parameters are always fully materialized. LOBs that are fetched using scrollable cursors use LOB locators if progressive streaming is not in effect.

**implicitRollbackOption**
Specifies the actions that the IBM Data Server Driver for JDBC and SQLJ takes when a transaction encounters a deadlock or a timeout. Possible values are:

**DB2BaseDataSource.IMPLICIT_ROLLBACK_OPTION_NOT_CLOSE_CONNECTION (1)**
The IBM Data Server Driver for JDBC and SQLJ throws an SQLException with an SQL error code that indicates that a deadlock or timeout occurred. The SQL error code is the SQL error code that is generated by the data server after a deadlock or timeout. The driver does not close the connection.
DB2BaseDataSource.IMPLICIT_ROLLBACK_OPTION_CLOSE_CONNECTION (2)
The IBM Data Server Driver for JDBC and SQLJ throws a DisconnectException with SQL error code -4499 when a deadlock or timeout occurs. The driver closes the connection. If automatic client reroute or Sysplex workload balancing is enabled, the driver disables automatic failover behavior.

DB2BaseDataSource.IMPLICIT_ROLLBACK_OPTION_NOT_SET (0)
This is the default. The IBM Data Server Driver for JDBC and SQLJ throws an SQLException with an SQL error code that indicates that a deadlock or timeout occurred. The SQL error code is the SQL error code that is generated by the data server after a deadlock or timeout. The driver does not close the connection.

interruptProcessingMode
Specifies the behavior of the IBM Data Server Driver for JDBC and SQLJ when an application executes the Statement.cancel method. Possible values are:

DB2BaseDataSource.INTERRUPT_PROCESSING_MODE_DISABLED (0)
Interrupt processing is disabled. When an application executes Statement.cancel, the IBM Data Server Driver for JDBC and SQLJ does nothing.

DB2BaseDataSource.INTERRUPT_PROCESSING_MODE_STATEMENT_CANCEL (1)
When an application executes Statement.cancel, the IBM Data Server Driver for JDBC and SQLJ cancels the currently executing statement, if the data server supports interrupt processing. If the data server does not support interrupt processing, the IBM Data Server Driver for JDBC and SQLJ throws an SQLException that indicates that the feature is not supported.

INTERRUPT_PROCESSING_MODE_STATEMENT_CANCEL is the default.
For DB2 for Linux, UNIX, and Windows clients, when interruptProcessingMode is set to INTERRUPT_PROCESSING_MODE_STATEMENT_CANCEL, the DB2 Connect setting for INTERRUPT_ENABLED and the DB2 registry variable setting for DB2CONNECT_DISCONNECT_ON_INTERRUPT override this value.

DB2BaseDataSource.INTERRUPT_PROCESSING_MODE_CLOSE_SOCKET (2)
When an application executes Statement.cancel, the IBM Data Server Driver for JDBC and SQLJ drops the underlying socket. The connection is not closed and can be reused to resubmit the statement. When the connection is reused, the driver obtains a new socket.

For connections to DB2 for z/OS data servers, the IBM Data Server Driver for JDBC and SQLJ always uses this value, regardless of the value that is specified.

keepAliveTimeout
The maximum time in seconds before each TCP KeepAlive signal is sent to the data server. The data type of this property is int. The default is 15 seconds.

IBM Data Server Driver for JDBC and SQLJ type 4 connectivity uses the TCP/IP protocol to communicate with data servers. To prevent potential failover issues caused by timeouts within the TCP/IP layer, it is necessary to adjust the TCP/IP KeepAlive parameters on the client. Decreasing the KeepAlive values on the client improves timely detection of server failures.
keepAliveTimeout is supported only for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

**loginTimeout**

The maximum time in seconds to wait for a connection to a data source. After the number of seconds that are specified by loginTimeout have elapsed, the driver closes the connection to the data source. The data type of this property is int. The default is 0. A value of 0 means that the timeout value is the default system timeout value. This property is not supported for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.

If the data server environment is a DB2 for z/OS Sysplex workload balancing environment or a DB2 pureScale environment, the wait time for a connection is determined by a combination of loginTimeout, maxRetriesForClientReroute, and retryIntervalForClientReroute. loginTimeout determines only the time for a single attempt to establish a connection to a data server. There might be multiple attempts to establish a connection, based on the maxRetriesForClientReroute value. There might also be gaps between attempts to establish a connection, based on the retryIntervalForClientReroute value.

During automatic client reroute processing, the memberConnectTimeout property takes precedence over the loginTimeout property.

**logWriter**

The character output stream to which all logging and trace messages for the DataSource object are printed. The data type of this property is java.io.PrintWriter. The default value is null, which means that no logging or tracing for the DataSource is output.

**maxRetriesForClientReroute**

During automatic client reroute, limit the number of retries if the primary connection to the data source fails.

The data type of this property is int.

The IBM Data Server Driver for JDBC and SQLJ uses the maxRetriesForClientReroute property only if the retryIntervalForClientReroute property is also set.

If the enableClientAffinitiesList is set to DB2BaseDataSource.NO (2), an attempt to connect to the primary server and alternate servers counts as one retry. If enableClientAffinitiesList is set to DB2BaseDataSource.YES (1), each server that is specified by the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber values is retried the number of times that is specified by maxRetriesForClientReroute.

The default for maxRetriesForClientReroute is determined as follows:

- If enableClientAffinitiesList is DB2BaseDataSource.YES (1), the default is 0.
- For connections to the DB2 for Linux, UNIX, and Windows or IBM Informix data servers, if maxRetriesForClientReroute and retryIntervalForClientReroute are not set, the connection is retried for 10 minutes, with a wait time between retries that increases as the length of time from the first retry increases.
- For connections to DB2 for z/OS data servers:
  - For version 3.66 or 4.16, or later, of the IBM Data Server Driver for JDBC and SQLJ:
    - If the enableSysplexWLB property is set to true, the default for maxRetriesForClientReroute is 1.
- If the `enableSysplexWLB` property is set to `false`, and
  `maxRetriesForClientReroute` and `retryIntervalForClientReroute` are not
  set, the connection is retried for 10 minutes, with a wait time between
  retries that increases as the length of time from the first retry increases.

- For version 3.64, 4.14, 3.65, or 4.15 of the IBM Data Server Driver for
  JDBC and SQLJ:
  - If the `enableSysplexWLB` property is set to `true`, and
    `maxRetriesForClientReroute` and `retryIntervalForClientReroute` are not
    set:
      • For the first connection to a data sharing group, if
        `maxRetriesForClientReroute` and `retryIntervalForClientReroute` are
        not set, and the `enableSysplexWLB` property is set to `true`, the
        default is to retry five times with a retry interval of 0.
      • For a failover during a subsequent connection to a data sharing
        group, if `maxRetriesForClientReroute` and `retryIntervalForClientReroute` are not set, the `enableSysplexWLB`
        property is set to `true`, and a cached server list or an alternate server
        is specified, the default is to retry the connection for 10 minutes,
        with a wait time between retries that increases as the length of time
        from the first retry increases.

- If the `enableSysplexWLB` property is set to `false`, and
  `maxRetriesForClientReroute` and `retryIntervalForClientReroute` are not
  set, the connection is retried for 10 minutes, with a wait time between
  retries that increases as the length of time from the first retry increases.

- For versions of the IBM Data Server Driver for JDBC and SQLJ before
  3.64 or 4.14, if `maxRetriesForClientReroute` and
  `retryIntervalForClientReroute` are not set, the connection is retried for 10
  minutes, with a wait time between retries that increases as the length of
time from the first retry increases.

If the value of `maxRetriesForClientReroute` is 0, client reroute processing does
not occur.

**maxStatements**

Controls an internal statement cache that is associated with a Connection. The
data type of this property is `int`. Possible values are:

**positive integer**

Enables the internal statement cache for a Connection, and specifies the
number of statements that the IBM Data Server Driver for JDBC and
SQLJ keeps open in the cache.

**0 or negative integer**

Disables internal statement caching for the Connection. 0 is the default.

`com.ibm.db2.jcc.DB2SimpleDataSource.maxStatements` controls the internal
statement cache that is associated with a Connection only when the Connection
object is created. `com.ibm.db2.jcc.DB2SimpleDataSource.maxStatements` has no
effect on caching in an already existing Connection object.

`com.ibm.db2.jcc.DB2SimpleDataSource.maxStatements` applies only to IBM
Data Server Driver for JDBC and SQLJ type 4 connectivity.

**memberConnectTimeout**

Specifies the amount of time in seconds before an attempt to open a socket to a
member of a DB2 for z/OS data sharing group, DB2 pureScale instance, or
IBM Informix high availability cluster fails. The data type of this property is
`int`. 
memberConnectTimeout applies only to socket connection attempts to different
members during automatic client reroute processing. The
memberConnectTimeout property takes precedence over the loginTimeout
property.

For connections to DB2 for z/OS data servers, the default is one second. For
connections to other data servers, the default is 0.

If the memberConnectTimeout value is less than or equal to 0, the driver uses
the loginTimeout value to determine how long to wait before failing a
connection request.

The memberConnectTimeout value is used for every socket open operation to
each member in a member list.

For a connection to a DB2 for z/OS data sharing group, after all attempts to
open a socket to all members fail, the driver retries the socket open using a
group IP address. For that retry, the driver uses the loginTimeout value to
determine how long to wait before failing the connection request.

password
The password to use for establishing connections. The data type of this
property is String. When you use the DataSource interface to establish a
connection, you can override this property value by invoking this form of the
DataSource.getConnection method:

getConnection(user, password);

portNumber
The port number where the DRDA server is listening for requests. The data
type of this property is int.

progressiveStreaming
Specifies whether the JDBC driver uses progressive streaming when
progressive streaming is supported on the data source.

DB2 for z/OS Version 9.1 and later supports progressive streaming for LOBs
and XML objects. DB2 for Linux, UNIX, and Windows Version 9.5 and later,
and IBM Informix Version 11.50 and later support progressive streaming for
LOBs.

With progressive streaming, also known as dynamic data format, the data
source dynamically determines the most efficient mode in which to return LOB
or XML data, based on the size of the LOBs or XML objects. The value of the
streamBufferSize parameter determines whether the data is materialized when
it is returned.

The data type of progressiveStreaming is int. Valid values are
DB2BaseDataSource.YES (1) and DB2BaseDataSource.NO (2). If the
progressiveStreaming property is not specified, the progressiveStreaming value
is DB2BaseDataSource.NOT_SET (0).

If the connection is to a data source that supports progressive streaming, and
the value of progressiveStreaming is DB2BaseDataSource.YES or
DB2BaseDataSource.NOT_SET, the JDBC driver uses progressive streaming to
return LOBs and XML data.

If the value of progressiveStreaming is DB2BaseDataSource.NO, or the data
source does not support progressive streaming, the way in which the JDBC
driver returns LOB or XML data depends on the value of the
fullyMaterializeLobData property.
queryCloseImplicit
  Specifies whether cursors are closed immediately after all rows are fetched.
  queryCloseImplicit applies only to connections to IBM Data Server Driver for
  JDBC and SQLJ type 4 connectivity to DB2 for z/OS Version 8 or later, and
  IBM Data Server Driver for JDBC and SQLJ type 4 connectivity or IBM Data
  Server Driver for JDBC and SQLJ type 2 connectivityDB2 for Linux, UNIX, and
  Windows Version 9.7 or later. Possible values are:

  DB2BaseDataSource.QUERY_CLOSE_IMPLICIT_YES (1)
  Close cursors immediately after all rows are fetched.
  A value of DB2BaseDataSource.QUERY_CLOSE_IMPLICIT_YES can provide
  better performance because this setting results in less network traffic.

  DB2BaseDataSource.QUERY_CLOSE_IMPLICIT_NO (2)
  Do not close cursors immediately after all rows are fetched.

  DB2BaseDataSource.QUERY_CLOSE_IMPLICIT_COMMIT (3)
  Perform these actions:
  • Implicitly close the cursor after all rows are fetched.
  • If the application is in autocommit mode, implicitly send a commit
    request to the data source for the current unit of work.

  Important: When this value is set, there might be impacts on other
  resources, just as an explicit commit operation might impact other
  resources. For example, other non-held cursors are closed, LOB locators
  go out of scope, progressive references are reset, and scrollable cursors
  lose their position.

  Restriction: The following restrictions apply to
  QUERY_CLOSE_IMPLICIT_COMMIT behavior:
  • This behavior applies only to SELECT statements that are issued by
    the application. It does not apply to SELECT statements that are
    generated by the IBM Data Server Driver for JDBC and SQLJ.
  • If QUERY_CLOSE_IMPLICIT_COMMIT is set, and the application is
    not in autocommit mode, the driver uses the default behavior
    (QUERY_CLOSE_IMPLICIT_NOT_SET behavior). If
    QUERY_CLOSE_IMPLICIT_COMMIT is the default behavior, the
    driver uses QUERY_CLOSE_IMPLICIT_YES behavior.
  • If QUERY_CLOSE_IMPLICIT_COMMIT is set, and the data source
    does not support QUERY_CLOSE_IMPLICIT_COMMIT behavior, the
    driver uses QUERY_CLOSE_IMPLICIT_YES behavior.
  • This behavior is not supported for batched statements.
  • This behavior is supported on an XA Connection only when the
    connection is in a local transaction.

  DB2BaseDataSource.QUERY_CLOSE_IMPLICIT_NOT_SET (0)
  This is the default. The following table describes the behavior for a
  connection to each type of data source.

<table>
<thead>
<tr>
<th>Data source</th>
<th>Version</th>
<th>Data sharing environment</th>
<th>Behavior</th>
</tr>
</thead>

</tbody>
</table>
queryDataSize

Specifies a hint that is used to control the amount of query data, in bytes, that is returned from the data source on each fetch operation. This value can be used to optimize the application by controlling the number of trips to the data source that are required to retrieve data.

Use of a larger value for queryDataSize can result in less network traffic, which can result in better performance. For example, if the result set size is 50 KB, and the value of queryDataSize is 32767 (32KB), two trips to the database server are required to retrieve the result set. However, if queryDataSize is set to 65535 (64 KB), only one trip to the data source is required to retrieve the result set.

The following table lists minimum, maximum, and default values of queryDataSize for each data source.

Table 54. Default, minimum, and maximum values of queryDataSize

</tr>
</tbody>
</table>

Note:
1. If you specify a value between the minimum and maximum value that is not a valid value, the IBM Data Server Driver for JDBC and SQLJ sets queryDataSize to the nearest valid value.

queryTimeoutInterruptProcessingMode

Specifies what happens when the query timeout interval for a Statement object expires. Valid values are:

DB2BaseDataSource.-
INTERRUPT_PROCESSING_MODE_STATEMENT_CANCEL (1)

Specifies that when the query timeout interval for a Statement object expires, the IBM Data Server Driver for JDBC and SQLJ cancels the currently executing SQL statement and throws an exception with SQL error -952, if the data server supports interruption of SQL statements. If the data server does not support interruption of SQL statements, the driver throws an exception that indicates that the feature is not supported.

For connections to data servers other than DB2 for z/OS, INTERRUPT_PROCESSING_MODE_STATEMENT_CANCEL is the default.

For connections to DB2 for z/OS data servers, INTERRUPT_PROCESSING_MODE_STATEMENT_CANCEL is not a possible value. If it is specified, the driver uses INTERRUPT_PROCESSING_MODE_CLOSE_SOCKET instead.

DB2BaseDataSource.INTERRUPT_PROCESSING_MODE_CLOSE_SOCKET (2)

Specifies that the underlying socket is dropped and the connection is closed when the query timeout interval for a Statement object expires.

For connections to data servers other than DB2 for z/OS, when the Statement object times out:

- If automatic client reroute is not enabled and enableSysplexWLB is set to false, an exception with SQL error code -4499 is thrown. Any
subsequent operations on the Statement object, or on any other
Statement objects that were created from the same connection receive
an Exception that indicates that the connection is closed. After a
Statement object times out, the application must establish a new
connection before it can execute a new transaction.

- If automatic client reroute is enabled, and enableSysplexWLB is set
to false, the IBM Data Server Driver for JDBC and SQLJ tries to
re-establish a connection. If a new connection is successfully
re-established, the driver returns an SQL error code of -4498.
However, the driver does not execute the timed-out SQL statements
again, even if enableSeamlessFailover is set to
DB2BaseDataSource.YES (1).

- If enableSysplexWLB is set to true, the IBM Data Server Driver for
JDBC and SQLJ tries to re-establish a connection. If a new
connection is successfully re-established, the driver returns an SQL
error code of -30108. However, the driver does not execute the
timed-out SQL statements again, even if enableSeamlessFailover is
set to DB2BaseDataSource.YES (1).

For connections to DB2 for z/OS, when the Statement object times out:

- If enableSysplexWLB is set to false, an exception with SQL error
code -4499 is thrown. Any subsequent operations on the Statement
object, or on any other Statement objects that were created from the
same connection receive an Exception that indicates that the
connection is closed. After a Statement object times out, the
application must establish a new connection before it can execute a
new transaction.

- If enableSysplexWLB is set to true, the IBM Data Server Driver for
JDBC and SQLJ tries to re-establish a connection. If a new
connection is successfully re-established, the driver returns an SQL
error code of -30108. However, the driver does not execute the
timed-out SQL statements again, even if enableSeamlessFailover is
set to DB2BaseDataSource.YES (1).

**resultSetHoldability**

Specifies whether cursors remain open after a commit operation. The data type
of this property is int. Valid values are:

- **DB2BaseDataSource.HOLD_CURSORS_OVER_COMMIT (1)**
  Leave cursors open after a commit operation.
  
  This setting is not valid for a connection that is part of a distributed
  (XA) transaction.

- **DB2BaseDataSource.CLOSE_CURSORS_AT_COMMIT (2)**
  Close cursors after a commit operation.

- **DB2BaseDataSource.NOT_SET (0)**
  This is the default value. The behavior is:
  
  - For connections that are part of distributed (XA) transactions,
    cursors are closed after a commit operation.
  
  - For connections that are not part of a distributed transaction:
    
    - For connections to all versions of DB2 for z/OS, DB2 for Linux,
      UNIX, and Windows, or DB2 for i servers, or to Cloudscape
      Version 8.1 or later servers, cursors remain open after a commit
      operation.
– For connections to all versions of IBM Informix, or to Cloudscape versions earlier than Version 8.1, cursors are closed after a commit operation.

**retrieveMessagesFromServerOnGetMessage**

Specifies whether JDBC SQLException.getMessage or SQLWarning.getMessage calls cause the IBM Data Server Driver for JDBC and SQLJ to invoke a DB2 for z/OS stored procedure that retrieves the message text for the error. The data type of this property is boolean. The default is false, which means that the full message text is not returned to the client.

For example, if retrieveMessagesFromServerOnGetMessage is set to true, a message similar to this one is returned by SQLException.getMessage after an attempt to perform an SQL operation on nonexistent table ADMF001.NO_TABLE:

```
ADMF001.NO_TABLE IS AN UNDEFINED NAME. SQLCODE=-204, SQLSTATE=42704, DRIVER=3.50.54
```

If retrieveMessagesFromServerOnGetMessage is set to false, a message similar to this one is returned:

```
DB2 SQL Error: SQLCODE=-204, SQLSTATE=42704, DRIVER=3.50.54
```

An alternative to setting this property to true is to use the IBM Data Server Driver for JDBC and SQLJ-only DB2Sqlca.getMessage method in applications. Both techniques result in a stored procedure call, which starts a unit of work.

**retryIntervalForClientReroute**

For automatic client reroute, specifies the amount of time in seconds between connection retries.

The data type of this property is int.

The IBM Data Server Driver for JDBC and SQLJ uses the retryIntervalForClientReroute property only if the maxRetriesForClientReroute property is also set.

If maxRetriesForClientReroute or retryIntervalForClientReroute is not set, the IBM Data Server Driver for JDBC and SQLJ performs retries for 10 minutes.

If the enableClientAffinitiesList is set to DB2BaseDataSource.NO (2), an attempt to connect to the primary server and alternate servers counts as one retry. The driver waits the number of seconds that is specified by retryIntervalForClientReroute before retrying the connection. If enableClientAffinitiesList is set to DB2BaseDataSource.YES (1), each server that is specified by the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber values is retried after the number of seconds that is specified by retryIntervalForClientReroute.

The default for retryIntervalForClientReroute is determined as follows:

- If enableClientAffinitiesList is DB2BaseDataSource.YES (1), the default is 0.
- For connections to the DB2 for Linux, UNIX, and Windows or IBM Informix data servers, if maxRetriesForClientReroute and retryIntervalForClientReroute are not set, the connection is retried for 10 minutes, with a wait time between retries that increases as the length of time from the first retry increases.
- For connections to DB2 for z/OS data servers:
  - For version 3.64 or 4.14 or later of the IBM Data Server Driver for JDBC and SQLJ:
- If the enableSysplexWLB property is set to true, and
  maxRetriesForClientReroute and retryIntervalForClientReroute are not set:
  - For the first connection to a data sharing group, if
    maxRetriesForClientReroute and retryIntervalForClientReroute are not set, and the enableSysplexWLB property is set to true, the
default is to retry five times with a retry interval of 0.
  - For a failover during a subsequent connection to a data sharing
    group, if maxRetriesForClientReroute and
    retryIntervalForClientReroute are not set, the enableSysplexWLB
    property is set to true, and a cached server list or an alternate server
    is specified, the default is to retry the connection for 10 minutes,
    with a wait time between retries that increases as the length of time
    from the first retry increases.
- If the enableSysplexWLB property is set to false, and
  maxRetriesForClientReroute and retryIntervalForClientReroute are not set, the connection is retried for 10 minutes, with a wait time between
  retries that increases as the length of time from the first retry increases.

For versions of the IBM Data Server Driver for JDBC and SQLJ before
3.64 or 4.14, if maxRetriesForClientReroute and
retryIntervalForClientReroute are not set, the connection is retried for 10
minutes, with a wait time between retries that increases as the length of
time from the first retry increases.

securityMechanism
  Specifies the DRDA security mechanism. The data type of this property is int.
  Possible values are:

  CLEAR_TEXT_PASSWORD_SECURITY (3)
    User ID and password

  USER_ONLY_SECURITY (4)
    User ID only

  ENCRYPTED_PASSWORD_SECURITY (7)
    User ID, encrypted password

  ENCRYPTED_USER_AND_PASSWORD_SECURITY (9)
    Encrypted user ID and password

  KERBEROS_SECURITY (11)
    Kerberos. This value does not apply to connections to IBM Informix.

  ENCRYPTED_USER_AND_DATA_SECURITY (12)
    Encrypted user ID and encrypted security-sensitive data. This value
    applies to connections to DB2 for z/OS only.

  ENCRYPTED_USER_PASSWORD_AND_DATA_SECURITY (13)
    Encrypted user ID and password, and encrypted security-sensitive
    data. This value does not apply to connections to IBM Informix.

  PLUGIN_SECURITY (15)
    Plug-in security. This value applies to connections to DB2 for Linux,
    UNIX, and Windows only.

  ENCRYPTED_USER_ONLY_SECURITY (16)
    Encrypted user ID. This value does not apply to connections to IBM
    Informix.
**TLS_CLIENT_CERTIFICATE_SECURITY** (18)

Client certificate security, using SSL. This value applies to connections to DB2 for z/OS Version 10 and later only.

If this property is specified, the specified security mechanism is the only mechanism that is used. If the security mechanism is not supported by the connection, an exception is thrown.

The default value for securityMechanism is provided by the db2.jcc.securityMechanism configuration property. If the db2.jcc.securityMechanism configuration property is also not specified, the default value for securityMechanism is CLEAR_TEXT_PASSWORD_SECURITY.

If the data server does not support CLEAR_TEXT_PASSWORD_SECURITY but supports ENCRYPTED_USER_AND_PASSWORD_SECURITY, the IBM Data Server Driver for JDBC and SQLJ driver upgrades the security mechanism to ENCRYPTED_USER_AND_PASSWORD_SECURITY and attempts to connect to the server. Any other mismatch in security mechanism support between the requester and the server results in an error.

This property does not apply to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.

Security mechanisms ENCRYPTED_PASSWORD_SECURITY, ENCRYPTED_USER_AND_PASSWORD_SECURITY, ENCRYPTED_USER_AND_DATA_SECURITY, ENCRYPTED_USER_PASSWORD_AND_DATA_SECURITY, and ENCRYPTED_USER_ONLY_SECURITY use DRDA encryption. DRDA encryption is not intended to provide confidentiality and integrity of passwords or data over a network that is not secure, such as the Internet. DRDA encryption uses an anonymous key exchange, Diffie-Hellman, which does not provide authentication of the server or the client. DRDA encryption is vulnerable to man-in-the-middle attacks.

**sendDataAsIs**

Specifies that the IBM Data Server Driver for JDBC and SQLJ does not convert input parameter values to the target column data types. The data type of this property is boolean. The default is false.

You should use this property only for applications that always ensure that the data types in the application match the data types in the corresponding database tables.

**serverName**

The host name or the TCP/IP address of the data source. The data type of this property is String.

**sslConnection**

Specifies whether the IBM Data Server Driver for JDBC and SQLJ uses an SSL socket to connect to the data source. If sslConnection is set to true, the connection uses an SSL socket. If sslConnection is set to false, the connection uses a plain socket.

The default value for sslConnection is provided by the db2.jcc.sslConnection configuration property. If the db2.jcc.sslConnection configuration property is also not specified, the default value for sslConnection is false.

This property is applicable only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.
**sslTrustStoreLocation**

Specifies the name of the Java truststore on the client that contains the server certificate for an SSL connection.

The IBM Data Server Driver for JDBC and SQLJ uses this option only if the sslConnection property is set to true.

If sslTrustStoreLocation is set, and sslConnection is set to true, the IBM Data Server Driver for JDBC and SQLJ uses the sslTrustStoreLocation value instead of the value in the javax.net.ssl.trustStore Java property.

The default value for sslTrustStoreLocation is provided by the db2.jcc.sslTrustStoreLocation configuration property. If the db2.jcc.sslTrustStoreLocation configuration property is also not specified, the default value for sslTrustStoreLocation is null.

This property is applicable only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

**sslTrustStorePassword**

Specifies the password for the Java truststore on the client that contains the server certificate for an SSL connection.

The IBM Data Server Driver for JDBC and SQLJ uses this option only if the sslConnection property is set to true.

If sslTrustStorePassword is set, and sslConnection is set to true, the IBM Data Server Driver for JDBC and SQLJ uses the sslTrustStorePassword value instead of the value in the javax.net.ssl.trustStorePassword Java property.

The default value for sslTrustStorePassword is provided by the db2.jcc.sslTrustStorePassword configuration property. If the db2.jcc.sslTrustStorePassword configuration property is also not specified, the default value for sslTrustStorePassword is null.

This property is applicable only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

**stripTrailingZerosForDecimalNumbers**

Specifies whether the IBM Data Server Driver for JDBC and SQLJ removes trailing zeroes when it retrieves data from a DECFLOAT, DECIMAL, or NUMERIC column. This property is meaningful only if the SDK for Java is Version 1.5 or later. The data type of this property is int.

Possible values are:

**DB2BaseDataSource.NOT_SET (0)**

The IBM Data Server Driver for JDBC and SQLJ does not remove trailing zeroes from the retrieved value. This is the default.

**DB2BaseDataSource.YES (1)**

The IBM Data Server Driver for JDBC and SQLJ removes trailing zeroes when it retrieves a value from a DECFLOAT, DECIMAL, or NUMERIC column as a java.math.BigDecimal object.

For example, when the driver retrieves the value 234.04000, it returns the value 234.04 to the application.

**DB2BaseDataSource.NO (2)**

The IBM Data Server Driver for JDBC and SQLJ does not remove trailing zeroes from the retrieved value.
**timerLevelForQueryTimeOut**
Specifies the level at which the IBM Data Server Driver for JDBC and SQLJ creates a java.util.Timer object for waiting for query execution to time out. Possible values are:

**DB2BaseDataSource.QUERYTIMEOUT_STATEMENT_LEVEL (1)**
The IBM Data Server Driver for JDBC and SQLJ creates a Timer object for each Statement object. When the Statement object is closed, the driver deletes the Timer object. This is the default.

**DB2BaseDataSource.QUERYTIMEOUT_CONNECTION_LEVEL (2)**
The IBM Data Server Driver for JDBC and SQLJ creates a Timer object for each Connection object. When the Connection object is closed, the driver deletes the Timer object.

**DB2BaseDataSource.QUERYTIMEOUT_DISABLED (-1)**
The IBM Data Server Driver for JDBC and SQLJ does not create a Timer object to control query execution timeout.

**timestampFormat**
Specifies the format in which the result of the ResultSet.getString or CallableStatement.getString method against a TIMESTAMP column is returned. The data type of timestampFormat is int.

Possible values of timestampFormat are:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Integer value</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.ISO</td>
<td>1</td>
<td>yyyy-mm-dd-hh:mm:ss.nnnnnnnnn</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.JDBC</td>
<td>5</td>
<td>yyyy-mm-dd hh:mm:ss.nnnnnnnnn</td>
</tr>
</tbody>
</table>

Note:
1. The number of digits in the fractional part of the timestamp depends on the precision of the TIMESTAMP(p) column in the source table. If p<9, p digits are returned. If p>=9, 9 digits are returned, and the remaining digits are truncated.

The default is com.ibm.db2.jcc.DB2BaseDataSource.JDBC.

timestampFormat affects the format of output only.

**timestampPrecisionReporting**
Specifies whether trailing zeroes are truncated in the result of a ResultSet.getString call for a TIMESTAMP value. The data type of this property is int. Possible values are:

**TIMESTAMP_JDBC_STANDARD (1)**
Trailing zeroes are truncated in the result of a ResultSet.getString call for a TIMESTAMP value. This is the default.

For example:
- A TIMESTAMP value of 2009-12-01-11.30.00.100000 is truncated to 2009-12-01-11.30.00.1 after retrieval.

**TIMESTAMP_ZERO_PADDING (2)**
Trailing zeroes are not truncated in the result of a ResultSet.getString call for a TIMESTAMP value.
**traceDirectory**

Specifies a directory into which trace information is written. The data type of this property is `String`. When `traceDirectory` is specified, trace information for multiple connections on the same `DataSource` is written to multiple files.

When `traceDirectory` is specified, a connection is traced to a file named `traceFile_origin_n`. 

*n* is the *n*th connection for a `DataSource`.

`origin` indicates the origin of the log writer that is in use. Possible values of `origin` are:

- **cpds** The log writer for a `DB2ConnectionPoolDataSource` object.
- **driver** The log writer for a `DB2Driver` object.
- **global** The log writer for a `DB2TraceManager` object.
- **sds** The log writer for a `DB2SimpleDataSource` object.
- **xads** The log writer for a `DB2XADataSource` object.

If the `traceFile` property is also specified, the `traceDirectory` value is not used.

**traceFile**

Specifies the name of a file into which the IBM Data Server Driver for JDBC and SQLJ writes trace information. The data type of this property is `String`. The `traceFile` property is an alternative to the `logWriter` property for directing the output trace stream to a file.

**traceFileAppend**

Specifies whether to append to or overwrite the file that is specified by the `traceFile` property. The data type of this property is `boolean`. The default is `false`, which means that the file that is specified by the `traceFile` property is overwritten.

**traceLevel**

Specifies what to trace. The data type of this property is `int`.

You can specify one or more of the following traces with the `traceLevel` property:

- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_NONE (X'00')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_CONNECTION_CALLS (X'01')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_STATEMENT_CALLS (X'02')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_RESULT_SET_CALLS (X'04')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DRIVER_CONFIGURATION (X'10')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_CONNECTS (X'20')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DRDA_FLOWS (X'40')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_RESULT_SET_META_DATA (X'80')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_PARAMETER_META_DATA (X'100')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DIAGNOSTICS (X'200')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_SQLJ (X'400')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_XA_CALLS (IBM Data Server Driver for JDBC and SQLJ type 2 connectivity for DB2 for Linux, UNIX, and Windows only) (X'800')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_META_CALLS (X'2000')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DATASOURCE_CALLS (X'4000')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_LARGE_OBJECT_CALLS (X'8000')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_SYSTEM_MONITOR (X'20000')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_TRACEPOINTS (X'40000')`
- `com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL (X'FFFFFFFF')`
To specify more than one trace, use one of these techniques:

- Use bitwise OR (|) operators with two or more trace values. For example, to trace DRDA flows and connection calls, specify this value for traceLevel:
  
  ```
  TRACE_DRDA_FLOWS|TRACE_CONNECTION_CALLS
  ```

- Use a bitwise complement (~) operator with a trace value to specify all except a certain trace. For example, to trace everything except DRDA flows, specify this value for traceLevel:
  
  ```
  ~TRACE_DRDA_FLOWS
  ```

**traceFileCount**

Specifies the maximum number of trace files for circular tracing. The IBM Data Server Driver for JDBC and SQLJ uses this property only when traceOption is set to `DB2BaseDataSource.TRACE_OPTION_CIRCULAR (1)`. The data type of this property is int. The default value is 2.

**traceFileSize**

Specifies the maximum size of each trace file, for circular tracing. The IBM Data Server Driver for JDBC and SQLJ uses this property only when traceOption is set to `DB2BaseDataSource.TRACE_OPTION_CIRCULAR (1)`. The data type of this property is int. The default value is 10485760 (10 MB).

**useJDBC41DefinitionForGetColumns**

Specifies whether the DatabaseMetaData.getColumns method returns a result set with a column with the name `SCOPE_CATALOG` or `SCOPE_CATLOG`. Possible values are:

- **DB2BaseDataSource.NOT_SET (0)**
  
  Specifies that for version 4.13 or later of the IBM Data Server Driver for JDBC and SQLJ, the result set from DatabaseMetaData.getColumns contains a column named `SCOPE_CATALOG`. For version 4.12 or earlier of the IBM Data Server Driver for JDBC and SQLJ, that column is named `SCOPE_CATLOG`.

- **DB2BaseDataSource.YES (1)**
  
  Specifies that for version 4.13 or later of the IBM Data Server Driver for JDBC and SQLJ, the result set from DatabaseMetaData.getColumns contains a column named `SCOPE_CATALOG`. For version 4.12 or earlier of the IBM Data Server Driver for JDBC and SQLJ, that column is named `SCOPE_CATLOG`.

- **DB2BaseDataSource.NO (2)**
  
  Specifies that for all versions of the IBM Data Server Driver for JDBC and SQLJ, the result set from DatabaseMetaData.getColumns contains a column named `SCOPE_CATLOG`.

**traceOption**

Specifies the way in which trace data is collected. The data type of this property is int. Possible values are:

- **DB2BaseDataSource.NOT_SET (0)**
  
  Specifies that a single trace file is generated, and that there is no limit to the size of the file. This is the default.

  If the value of traceOption is NOT_SET, the traceFileSize and traceFileCount properties are ignored.

- **DB2BaseDataSource.TRACE_OPTION_CIRCULAR (1)**
  
  Specifies that the IBM Data Server Driver for JDBC and SQLJ does circular tracing. Circular tracing is done as follows:
1. When an application writes its first trace record, the driver creates a file.
2. The driver writes trace data to the file.
3. When the size of the file is equal to the value of property traceFileSize, the driver creates another file.
4. The driver repeats steps 2 and 3 until the number of files to which data has been written is equal to the value of property traceFileCount.
5. The driver writes data to the first trace file, overwriting the existing data.
6. The driver repeats steps 3 through 5 until the application completes.

The file names for the trace files are the file names that are determined by the traceFile or traceDirectory property, appended with .1 for the first file, .2 for the second file, and so on.

**user**
The user ID to use for establishing connections. The data type of this property is String. When you use the DataSource interface to establish a connection, you can override this property value by invoking this form of the DataSource.getConnection method:
```
getConnection(user, password);
```

**xaNetworkOptimization**
Specifies whether XA network optimization is enabled for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity. You might need to disable XA network optimization in an environment in which an XA Start and XA End are issued from one Java process, and an XA Prepare and an XA Commit are issued from another Java process. With XA network optimization, the XA Prepare can reach the data source before the XA End, which results in an XAER_PROTO error. To prevent the XAER_PROTO error, disable XA network optimization.

The default is true, which means that XA network optimization is enabled. If xaNetworkOptimization is false, which means that XA network optimization is disabled, the driver closes any open cursors at XA End time.

xaNetworkOptimization can be set on a DataSource object, or in the url parameter in a getConnection call. The value of xaNetworkOptimization cannot be changed after a connection is obtained.

**Common IBM Data Server Driver for JDBC and SQLJ properties for DB2 servers**

Some of the IBM Data Server Driver for JDBC and SQLJ properties apply to DB2 for z/OS and DB2 for Linux, UNIX, and Windows only.

Unless otherwise noted, all properties are in com.ibm.db2.jcc.DB2BaseDataSource.

Those properties are:

**clientAccountingInformation**
Specifies accounting information for the current client for the connection. This information is for client accounting purposes. This value can change during a connection. The data type of this property is String. The maximum length is 255 bytes. A Java empty string ("") is valid for this value, but a Java null value is not valid.
clientApplicationInformation
Specifies the application or transaction name of the end user's application. You can use this property to provide the identity of the client end user for accounting and monitoring purposes. This value can change during a connection. The data type of this property is String. For a DB2 for z/OS server, the maximum length is 32 bytes. For a DB2 for Linux, UNIX, and Windows server, the maximum length is 255 bytes. A Java empty string ("") is valid for this value, but a Java null value is not valid.

clientProgramId
Specifies a value for the client program ID that can be used to identify the end user. The data type of this property is String, and the length is 80 bytes. If the program ID value is less than 80 bytes, the value must be padded with blanks.

clientProgramName
Specifies an application ID that is fixed for the duration of a physical connection for a client. The value of this property becomes the correlation ID on a DB2 for z/OS server. Database administrators can use this property to correlate work on a DB2 for z/OS server to client applications. The data type of this property is String. The maximum length is 12 bytes. If this value is null, the IBM Data Server Driver for JDBC and SQLJ supplies a value of db2jcc_thread-name.

This property applies only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

concurrentAccessResolution
Specifies whether the IBM Data Server Driver for JDBC and SQLJ requests that a read transaction can access a committed and consistent image of rows that are incompatibly locked by write transactions, if the data source supports accessing currently committed data, and the application isolation level is cursor stability (CS) or read stability (RS). This option has the same effect as the DB2 CONCURRENTACCESSRESOLUTION bind option. Possible values are:

DB2BaseDataSource.-
CONCURRENTACCESS_USE_CURRENTLY_COMMITTED (1)
The IBM Data Server Driver for JDBC and SQLJ requests that:
• Read transactions access the currently committed data when the data is being updated or deleted.
• Read transactions skip rows that are being inserted.

DB2BaseDataSource.CONCURRENTACCESS_WAIT_FOR_OUTCOME (2)
The IBM Data Server Driver for JDBC and SQLJ requests that:
• Read transactions wait for a commit or rollback operation when they encounter data that is being updated or deleted.
• Read transactions do not skip rows that are being inserted.

DB2BaseDataSource.CONCURRENTACCESS_NOT_SET (0)
Enables the data server's default behavior for read transactions when lock contention occurs. This is the default value.

currentDegree
Specifies the degree of parallelism for the execution of queries that are dynamically prepared. The type of this property is String. The currentDegree value is used to set the CURRENT DEGREE special register on the data source. If currentDegree is not set, no value is passed to the data source.

currentExplainMode
Specifies the value for the CURRENT EXPLAIN MODE special register. The
CURRENT EXPLAIN MODE special register enables and disables the Explain facility. The data type of this property is String. The maximum length is 254 bytes. This property applies only to connections to data sources that support the CURRENT EXPLAIN MODE special register.

**currentFunctionPath**

Specifies the SQL path that is used to resolve unqualified data type names and function names in SQL statements that are in JDBC programs. The data type of this property is String. For a DB2 for Linux, UNIX, and Windows server, the maximum length is 254 bytes. For a DB2 for z/OS server, the maximum length is 2048 bytes. The value is a comma-separated list of schema names. Those names can be ordinary or delimited identifiers.

**currentMaintainedTableTypesForOptimization**

Specifies a value that identifies the types of objects that can be considered when the data source optimizes the processing of dynamic SQL queries. This register contains a keyword representing table types. The data type of this property is String.

Possible values of currentMaintainedTableTypesForOptimization are:

- **ALL**
  - Indicates that all materialized query tables will be considered.

- **NONE**
  - Indicates that no materialized query tables will be considered.

- **SYSTEM**
  - Indicates that only system-maintained materialized query tables that are refresh deferred will be considered.

- **USER**
  - Indicates that only user-maintained materialized query tables that are refresh deferred will be considered.

**currentPackagePath**

Specifies a comma-separated list of collections on the server. The database server searches these collections for JDBC and SQLJ packages.

The precedence rules for the currentPackagePath and currentPackageSet properties follow the precedence rules for the CURRENT PACKAGESET and CURRENT PACKAGE PATH special registers.

**currentPackageSet**

Specifies the collection ID to search for JDBC and SQLJ packages. The data type of this property is String. The default is NULLID. If currentPackageSet is set, its value overrides the value of jdbcCollection.

Multiple instances of the IBM Data Server Driver for JDBC and SQLJ can be installed at a database server by running the DB2Binder utility multiple times. The DB2binder utility includes a -collection option that lets the installer specify the collection ID for each IBM Data Server Driver for JDBC and SQLJ instance. To choose an instance of the IBM Data Server Driver for JDBC and SQLJ for a connection, you specify a currentPackageSet value that matches the collection ID for one of the IBM Data Server Driver for JDBC and SQLJ instances.

The precedence rules for the currentPackagePath and currentPackageSet properties follow the precedence rules for the CURRENT PACKAGESET and CURRENT PACKAGE PATH special registers.

**currentRefreshAge**

Specifies a timestamp duration value that is the maximum duration since a
The REFRESH TABLE statement was processed on a system-maintained REFRESH DEFERRED materialized query table such that the materialized query table can be used to optimize the processing of a query. This property affects dynamic statement cache matching. The data type of this property is long.

**currentSchema**

Specifies the default schema name that is used to qualify unqualified database objects in dynamically prepared SQL statements. The value of this property sets the value in the CURRENT SCHEMA special register on the database server. The schema name is case-sensitive, and must be specified in uppercase characters.

**cursorSensitivity**

Specifies whether the `java.sql.ResultSet.TYPE_SCROLL_SENSITIVE` value for a JDBC ResultSet maps to the SENSITIVE DYNAMIC attribute, the SENSITIVE STATIC attribute, or the ASENSITIVE attribute for the underlying database cursor. The data type of this property is int. Possible values are `TYPE_SCROLL_SENSITIVE_STATIC (0)`, `TYPE_SCROLL_SENSITIVE_DYNAMIC (1)`, or `TYPE_SCROLL_ASENSITIVE (2)`. The default is `TYPE_SCROLL_SENSITIVE_STATIC`.

If the data source does not support sensitive dynamic scrollable cursors, and `TYPE_SCROLL_SENSITIVE_DYNAMIC` is requested, the JDBC driver accumulates a warning and maps the sensitivity to SENSITIVE STATIC. For DB2 for i database servers, which do not support sensitive static cursors, `java.sql.ResultSet.TYPE_SCROLL_SENSITIVE` always maps to SENSITIVE DYNAMIC.

**dateFormat**

Specifies:

- The format in which the String argument of the PreparedStatement.setString method against a DATE column must be specified.
- The format in which the result of the ResultSet.getString or CallableStatement.getString method against a DATE column is returned.

The data type of dateFormat is int.

Possible values of dateFormat are:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Integer value</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.ISO</td>
<td>1</td>
<td>yyyy-mm-dd</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.USA</td>
<td>2</td>
<td>mm/dd/yyyy</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.EUR</td>
<td>3</td>
<td>dd.mm.yyyy</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.JIS</td>
<td>4</td>
<td>yyyy-mm-dd</td>
</tr>
</tbody>
</table>

The default is `com.ibm.db2.jcc.DB2BaseDataSource.ISO`.

**decimalRoundingMode**

Specifies the rounding mode for assignment to decimal floating-point variables or DECIMAL columns on DB2 for z/OS or DB2 for Linux, UNIX, and Windows data servers.

Possible values are:

- **DB2BaseDataSource.ROUND_DOWN (1)**
  
  Rounds the value towards 0 (truncation). The discarded digits are ignored.

- **DB2BaseDataSource.ROUND_CEILING (2)**
  
  Rounds the value towards positive infinity. If all of the discarded digits
are zero or if the sign is negative the result is unchanged other than
the removal of the discarded digits. Otherwise, the result coefficient is
incremented by 1.

**DB2BaseDataSource.ROUND_HALF_EVEN (3)**
Rounds the value to the nearest value; if the values are equidistant,
rounds the value so that the final digit is even. If the discarded digits
represent greater than half (0.5) of the value of one in the next left
position then the result coefficient is incremented by 1. If they
represent less than half, then the result coefficient is not adjusted (that
is, the discarded digits are ignored). Otherwise the result coefficient is
unaltered if its rightmost digit is even, or is incremented by 1 if its
rightmost digit is odd (to make an even digit).

**DB2BaseDataSource.ROUND_HALF_UP (4)**
Rounds the value to the nearest value; if the values are equidistant,
rounds the value away from zero. If the discarded digits represent
greater than or equal to half (0.5) of the value of one in the next left
position then the result coefficient is incremented by 1. Otherwise the
discarded digits are ignored.

**DB2BaseDataSource.ROUND_FLOOR (6)**
Rounds the value towards negative infinity. If all of the discarded
digits are zero or if the sign is positive the result is unchanged other
than the removal of discarded digits. Otherwise, the sign is negative
and the result coefficient is incremented by 1.

**DB2BaseDataSource.ROUND_UNSET (-2147483647)**
No rounding mode was explicitly set. The IBM Data Server Driver for
JDBC and SQLJ does not use the decimalRoundingMode to set the
rounding mode on the data server. The rounding mode is
ROUND_HALF_EVEN.

If you explicitly set the decimalRoundingMode value, that value updates the
CURRENT DECFLOAT Rounding MODE special register value on a DB2
for z/OS data server.

If you explicitly set the decimalRoundingMode value, that value does not
update the CURRENT DECFLOAT Rounding MODE special register value
on a DB2 for Linux, UNIX, and Windows data server. If the value to which
you set decimalRoundingMode is not the same as the value of the CURRENT
DECFLOAT Rounding MODE special register, an Exception is thrown. To
change the data server value, you need to set that value with the
decflt_rounding database configuration parameter.

decimalRoundingMode does not affect decimal value assignments. The IBM
Data Server Driver for JDBC and SQLJ always rounds decimal values down.

**enableExtendedDescribe**
Specifies whether the IBM Data Server Driver for JDBC and SQLJ requests
extended describe information from the data server when it prepares a
statement.

Extended describe information provides:
- Additional descriptive information for a cursor or a result set
- Information about whether a column:
  - Can be updated
  - Is a primary key or a preferred candidate key member
  - Is an expression or a table column
- is a generated column or a table column
- The fully qualified view or table name
- The fully qualified column name

Possible values are:

**DB2BaseDataSource.NOT_SET (0)**

The IBM Data Server Driver for JDBC and SQLJ requests extended describe information. This is the default.

**DB2BaseDataSource.YES (1)**

The IBM Data Server Driver for JDBC and SQLJ requests extended describe information.

**DB2BaseDataSource.NO (2)**

The IBM Data Server Driver for JDBC and SQLJ does not request extended describe information.

Setting `enableExtendedDescribe` to `DB2BaseDataSource.NO` can result in a performance benefit because it avoids the extra processing that the driver must do to provide the additional information. However, if you specify this as option, some methods throw an exception or return unexpected results. The following table lists the behavior of methods when `enableExtendedDescribe` is set to `DB2BaseDataSource.NO`.

<table>
<thead>
<tr>
<th>Method</th>
<th>Result when extended describe is off</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection.findAutoGeneratedKeysColumn</td>
<td>Returns an array of empty strings (&quot;&quot;)</td>
</tr>
<tr>
<td>DB2ResultSetMetaData.getDBTemporalColumnType</td>
<td>Returns -1</td>
</tr>
<tr>
<td>ResultSet.getMetaData on the ResultSet object that is returned by PreparedStatement.getGeneratedKeys</td>
<td>Returns null</td>
</tr>
<tr>
<td>ResultSet.insertRow, ResultSet.deleteRow, ResultSet.updateRow</td>
<td>SQLException with error code -4474, SQLSTATE 42808 (column not updatable)</td>
</tr>
<tr>
<td>ResultSet.updateXXX methods</td>
<td>SQLException with error code -4474, SQLSTATE 42808 (column not updatable)</td>
</tr>
<tr>
<td>ResultSetMetaData.getTableName,</td>
<td>Returns an empty string (&quot;&quot;)</td>
</tr>
<tr>
<td>ResultSetMetaData.getSchemaName,</td>
<td></td>
</tr>
<tr>
<td>ResultSetMetaData.getColumnName</td>
<td></td>
</tr>
<tr>
<td>ResultSetMetaData.isAutoIncrement</td>
<td>Returns <code>false</code></td>
</tr>
</tbody>
</table>

**enableExtendedIndicators**

Specifies whether support for extended indicators is enabled in the IBM Data Server Driver for JDBC and SQLJ. Possible values are:

**DB2BaseDataSource.YES (1)**

Support for extended indicators is enabled in the IBM Data Server Driver for JDBC and SQLJ.

**DB2BaseDataSource.NO (2)**

Support for extended indicators is disabled in the IBM Data Server Driver for JDBC and SQLJ.

**DB2BaseDataSource.NOT_SET (0)**

Support for extended indicators is enabled in the IBM Data Server Driver for JDBC and SQLJ. This is the default value.

**enableRowsetSupport**

Specifies whether the IBM Data Server Driver for JDBC and SQLJ uses
multiple-row FETCH for forward-only cursors or scrollable cursors, if the data server supports multiple-row FETCH. The data type of this property is int.

For connections to DB2 for z/OS, when enableRowsetSupport is set, its value overrides the useRowsetCursor property value.

Possible values are:

**DB2BaseDataSource.YES (1)**

Specifies that:

- For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for z/OS, multiple-row FETCH is used for scrollable cursors and forward-only cursors, if the data server supports multiple-row FETCH.
- For IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, or IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for Linux, UNIX, and Windows, multiple-row fetch is used for scrollable cursors, if the data server supports multiple-row FETCH.

**DB2BaseDataSource.NO (2)**

Specifies that multiple-row fetch is not used.

**DB2BaseDataSource.NOT_SET (0)**

Specifies that if the enableRowsetSupport property is not set:

- For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for z/OS, multiple-row fetch is not used.
- For IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to DB2 for z/OS, multiple-row fetch is used if useRowsetCursor is set to true.
- For connections to DB2 for Linux, UNIX, and Windows, multiple row fetch is used for scrollable cursors, if the data server supports multiple-row FETCH.

For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for z/OS, multiple-row fetch is not compatible with progressive streaming. Therefore, if progressive streaming is used for a FETCH operation, multiple-row FETCH is not used.

**encryptionAlgorithm**

Specifies whether the IBM Data Server Driver for JDBC and SQLJ uses 56-bit DES (weak) encryption or 256-bit AES (strong) encryption. The data type of this property is int. Possible values are:

1. The driver uses 56-bit DES encryption.
   
   This value is the default, unless configuration property `db2.jcc.encryptionAlgorithm` provides a different default.

2. The driver uses 256-bit AES encryption, if the database server supports it. 256-bit AES encryption is available for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity only.

For AES encryption, you need an unrestricted policy file for JCE. For the IBM SDK for Java, the file is available at the following location:

The SDK for Java from Oracle might support AES encryption, but not DES encryption. When you use AES encryption with the SDK for Java from Oracle, the JCE Unlimited Strength Jurisdiction Policy File needs to be installed. That file is available from Oracle.
Strength Jurisdiction Policy File is not found, a java.security.InvalidKeyException is thrown. 

encryptionAlgorithm can be specified only if the securityMechanism or db2.jcc.securityMechanism value is ENCRYPTED_PASSWORD_SECURITY (7) or ENCRYPTED_USER_AND_PASSWORD_SECURITY (9).

fullyMaterializeInputStreams
Indicates whether streams are fully materialized before they are sent from the client to a data source. The data type of this property is boolean. The default is false.

If the value of fullyMaterializeInputStreams is true, the JDBC driver fully materialized the streams before sending them to the server.

gssCredential
For a data source that uses Kerberos security, specifies a delegated credential that is passed from another principal. The data type of this property is org.ietf.jgss.GSSCredential. Delegated credentials are used in multi-tier environments, such as when a client connects to WebSphere Application Server, which, in turn, connects to the data source. You obtain a value for this property from the client, by invoking the GSSContext.getDelegCred method. GSSContext is part of the IBM Java Generic Security Service (GSS) API. If you set this property, you also need to set the Mechanism and KerberosServerPrincipal properties.

This property is applicable only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

For more information on using Kerberos security with the IBM Data Server Driver for JDBC and SQLJ, see "Using Kerberos security under the IBM Data Server Driver for JDBC and SQLJ".

kerberosServerPrincipal
For a data source that uses Kerberos security, specifies the name that is used for the data source when it is registered with the Kerberos Key Distribution Center (KDC). The data type of this property is String.

This property is applicable only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

pdqProperties
Specifies properties that control the interaction between the IBM Data Server Driver for JDBC and SQLJ and the client optimization feature of pureQuery.

The data type of this property is String.

Set the pdqProperties property only if you are using the client optimization feature of pureQuery. See the Integrated Data Management Information Center for information about valid values for pdqProperties.

readOnly
Specifies whether the connection is read-only. The data type of this property is boolean. The default is false.

resultSetHoldabilityForCatalogQueries
Specifies whether cursors for queries that are executed on behalf of DatabaseMetaData methods remain open after a commit operation. The data type of this property is int.

When an application executes DatabaseMetaData methods, the IBM Data Server Driver for JDBC and SQLJ executes queries against the catalog of the target data source. By default, the holdability of those cursors is the same as
the holdability of application cursors. To use different holdability for catalog queries, use the resultSetHoldabilityForCatalogQueries property. Possible values are:

**DB2BaseDataSource.HOLD_CURSORS_OVER_COMMIT (1)**
Leave cursors for catalog queries open after a commit operation, regardless of the resultSetHoldability setting.

**DB2BaseDataSource.CLOSE_CURSORS_AT_COMMIT (2)**
Close cursors for catalog queries after a commit operation, regardless of the resultSetHoldability setting.

**DB2BaseDataSource.NOT_SET (0)**
Use the resultSetHoldability setting for catalog queries. This is the default value.

**returnAlias**
Specifies whether the JDBC driver returns rows for table aliases and synonyms for DatabaseMetaData methods that return table information, such as getTables. The data type of returnAlias is int. Possible values are:

0 Do not return rows for aliases or synonyms of tables in output from DatabaseMetaData methods that return table information.

1 For tables that have aliases or synonyms, return rows for aliases and synonyms of those tables, as well as rows for the tables, in output from DatabaseMetaData methods that return table information. This is the default.

**statementConcentrator**
Specifies whether the IBM Data Server Driver for JDBC and SQLJ uses the data source's statement concentrator functionality. The statement concentrator is the ability to bypass preparation of a statement when it is the same as a statement in the dynamic statement cache, except for literal values. Statement concentrator functionality applies only to SQL statements that have literals but no parameter markers. Possible values are:

**DB2BaseDataSource.STATEMENT_CONCENTRATOR_OFF (1)**
The IBM Data Server Driver for JDBC and SQLJ does not use the data source's statement concentrator functionality.

**DB2BaseDataSource.STATEMENT_CONCENTRATOR_WITH_LITERALS (2)**
The IBM Data Server Driver for JDBC and SQLJ uses the data source's statement concentrator functionality.

**DB2BaseDataSource.STATEMENT_CONCENTRATOR_NOT_SET (0)**
Enables the data server's default behavior for statement concentrator functionality. This is the default value.

For DB2 for Linux, UNIX, and Windows data sources that support statement concentrator functionality, the functionality is used if the STMT_CONC configuration parameter is set to ON at the data source. Otherwise, statement concentrator functionality is not used.

For DB2 for z/OS data sources that support statement concentrator functionality, the functionality is not used if statementConcentrator is not set.

**streamBufferSize**
Specifies the size, in bytes, of the JDBC driver buffers for chunking LOB or
XML data. The JDBC driver uses the streamBufferSize value whether or not it uses progressive streaming. The data type of streamBufferSize is int. The default is 1048576.

If the JDBC driver uses progressive streaming, LOB or XML data is materialized if it fits in the buffers, and the driver does not use the fullyMaterializeLobData property.

DB2 for z/OS Version 9.1 and later supports progressive streaming for LOBs and XML objects. DB2 for Linux, UNIX, and Windows Version 9.5 and later, and IBM Informix Version 11.50 and later support progressive streaming for LOBs.

**supportsAsynchronousXARollback**
Specifies whether the IBM Data Server Driver for JDBC and SQLJ supports asynchronous XA rollback operations. The data type of this property is int. The default is DB2BaseDataSource.NO (2). If the application runs against a BEA WebLogic Server application server, set supportsAsynchronousXARollback to DB2BaseDataSource.YES (1).

**sysSchema**
Specifies the schema of the shadow catalog tables or views that are searched when an application invokes a DatabaseMetaData method. The sysSchema property was formerly called cliSchema.

**timeFormat**
Specifies:
- The format in which the String argument of the PreparedStatement.setString method against a TIME column must be specified.
- The format in which the result of the ResultSet.getString or CallableStatement.getString method against a TIME column is returned.

The data type of timeFormat is int.

Possible values of timeFormat are:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Integer value</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.ISO</td>
<td>1</td>
<td>hh:mm:ss</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.USA</td>
<td>2</td>
<td>hh:mm am or hh:mm pm</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.EUR</td>
<td>3</td>
<td>hh:mm:ss</td>
</tr>
<tr>
<td>com.ibm.db2.jcc.DB2BaseDataSource.JIS</td>
<td>4</td>
<td>hh:mm:ss</td>
</tr>
</tbody>
</table>

The default is com.ibm.db2.jcc.DB2BaseDataSource.ISO.

**timestampOutputType**
Specifies whether the IBM Data Server Driver for JDBC and SQLJ returns a java.sql.Timestamp object or a com.ibm.db2.jcc.DBTime object when the standard JDBC interfaces ResultSet.getTimestamp, CallableStatement.getTimestamp, ResultSet.getObject, or CallableStatement.getObject are called to return timestamp information.

Possible values are:

**DB2BaseDataSource.JDBC_TIMESTAMP** (1)
The IBM Data Server Driver for JDBC and SQLJ returns java.sql.Timestamp objects from ResultSet.getTimestamp, CallableStatement.getTimestamp, ResultSet.getObject, or CallableStatement.getObject calls.
**DB2BaseDataSource.JCC_DBTIMESTAMP** (2)
The IBM Data Server Driver for JDBC and SQLJ returns com.ibm.db2.jcc.DBTimestamp objects from ResultSet.getTimestamp, CallableStatement.getTimestamp, ResultSet.getObject, or CallableStatement.getObject calls.

**DB2BaseDataSource.NOT_SET** (0)
This is the default behavior.
The behavior is the same as the behavior for DB2BaseDataSource.JDBC_TIMESTAMP.

**useCachedCursor**
Specifies whether the underlying cursor for PreparedStatement objects is cached and reused on subsequent executions of the PreparedStatement. The data type of useCachedCursor is boolean.

If useCachedCursor is set to true, the cursor for PreparedStatement objects is cached, which can improve performance. true is the default.

Set useCachedCursor to false if PreparedStatement objects access tables whose column types or lengths change between executions of those PreparedStatement objects.

**useIdentityValLocalForAutoGeneratedKeys**
Specifies whether the IBM Data Server Driver for JDBC and SQLJ uses only the SQL built-in function IDENTITY_VAL_LOCAL to determine automatically generated key values. The data type of this property is boolean. Possible values are:

- **true**
  Specifies that the IBM Data Server Driver for JDBC and SQLJ always uses the SQL built-in function IDENTITY_VAL_LOCAL to determine automatically generated key values. The driver uses IDENTITY_VAL_LOCAL even if it is possible to use SELECT FROM INSERT.
  Specify true if the target data server supports SELECT FROM INSERT, but the target objects do not. For example, SELECT FROM INSERT is not valid for a table on which a trigger is defined.

- **false**
  Specifies that the IBM Data Server Driver for JDBC and SQLJ determines whether to use SELECT FROM INSERT or IDENTITY_VAL_LOCAL to determine automatically generated keys. false is the default.

**useJDBC4ColumnNameAndLabelSemantics**
Specifies how the IBM Data Server Driver for JDBC and SQLJ handles column labels in ResultSetMetaData.getColumnName, ResultSetMetaData.getColumnLabel, and ResultSet.findColumn method calls.

Possible values are:

**DB2BaseDataSource.YES** (1)
The IBM Data Server Driver for JDBC and SQLJ uses the following rules, which conform to the JDBC 4.0 specification, to determine the value that ResultSetMetaData.getColumnName, ResultSetMetaData.getColumnLabel, and ResultSet.findColumn return:

- The column name that is returned by ResultSetMetaData.getColumnName is its name from the database.
• The column label that is returned by ResultSetMetaData.getColumnLabel is the label that is specified with the SQL AS clause. If the SQL AS clause is not specified, the label is the name of the column.
• ResultSet.findColumn takes the label for the column, as specified with the SQL AS clause, as input. If the SQL AS clause was not specified, the label is the column name.
• The IBM Data Server Driver for JDBC and SQLJ does not use a column label that is assigned by the SQL LABEL ON statement.

These rules apply to IBM Data Server Driver for JDBC and SQLJ version 3.50 and later, for connections to the following database systems:
• DB2 for z/OS Version 8 or later
• DB2 for Linux, UNIX, and Windows Version 8.1 or later
• DB2 UDB for iSeries® V5R3 or later

For earlier versions of the driver or the database systems, the rules for a useJDBC4ColumnNameAndLabelSemantics value of DB2BaseDataSource.NO apply, even if useJDBC4ColumnNameAndLabelSemantics is set to DB2BaseDataSource.YES.

DB2BaseDataSource.NO (2)
The IBM Data Server Driver for JDBC and SQLJ uses the following rules to determine the values that ResultSetMetaData.getColumnName, ResultSetMetaData.getColumnLabel, and ResultSet.findColumn return:

If the data source does not support the LABEL ON statement, or the source column is not defined with the LABEL ON statement:
• The value that is returned by ResultSetMetaData.getColumnName is its name from the database, if no SQL AS clause is specified. If the SQL AS clause is specified, the value that is returned is the column label.
• The value that is returned by ResultSetMetaData.getColumnLabel is the label that is specified with the SQL AS clause. If the SQL AS clause is not specified, the value that is returned is the name of the column.
• ResultSet.findColumn takes the column name as input.

If the source column is defined with the LABEL ON statement:
• The value that is returned by ResultSetMetaData.getColumnName is the column name from the database, if no SQL AS clause is specified. If the SQL AS clause is specified, the value that is returned is the column label that is specified in the AS clause.
• The value that is returned by ResultSetMetaData.getColumnLabel is the label that is specified in the LABEL ON statement.
• ResultSet.findColumn takes the column name as input.

These rules conform to the behavior of the IBM Data Server Driver for JDBC and SQLJ before Version 3.50.

DB2BaseDataSource.NOT_SET (0)
This is the default behavior.
For the IBM Data Server Driver for JDBC and SQLJ version 3.50 and earlier, the default behavior for useJDBC4ColumnNameAndLabelSemantics is the same as the behavior for DB2BaseDataSource.NO.

For the IBM Data Server Driver for JDBC and SQLJ version 4.0 and later:

- The default behavior for useJDBC4ColumnNameAndLabelSemantics is the same as the behavior for DB2BaseDataSource.YES, for connections to the following database systems:
  - DB2 for z/OS Version 8 or later
  - DB2 for Linux, UNIX, and Windows Version 8.1 or later
  - DB2 UDB for iSeries V5R3 or later
- For connections to earlier versions of these database systems, the default behavior for useJDBC4ColumnNameAndLabelSemantics is DB2BaseDataSource.NO.

**xmlFormat**

Specifies the format that is used to retrieve XML data from the data server. The XML format cannot be modified after a connection is established. Possible values are:

- **com.ibm.db2.jcc.DB2BaseDataSource.XML_FORMAT_NOT_SET (-Integer.MAX_VALUE)**
  - Specifies that the default XML format is used. The default is textual XML format.

- **com.ibm.db2.jcc.DB2BaseDataSource.XML_FORMAT_TEXTUAL (0)**
  - Specifies that the XML textual format is used.

- **com.ibm.db2.jcc.DB2BaseDataSource.XML_FORMAT_BINARY (1)**
  - Specifies that the binary XML format is used.

  When binary XML is used, the XML data that is passed to the IBM Data Server Driver for JDBC and SQLJ cannot refer to external entities, internal entities, or internal DTDs. External DTDs are supported only if those DTDs were previously registered in the data source.

**com.ibm.db2.jcc.DB2ConnectionPoolDataSource.maxStatements**

Controls an internal statement cache that is associated with a PooledConnection. The data type of this property is int. Possible values are:

- **positive integer**
  - Enables the internal statement cache for a PooledConnection, and specifies the number of statements that the IBM Data Server Driver for JDBC and SQLJ keeps open in the cache.

- **0 or negative integer**
  - Disables internal statement caching for the PooledConnection. 0 is the default.

maxStatements controls the internal statement cache that is associated with a PooledConnection only when the PooledConnection object is created. maxStatements has no effect on caching in an already existing PooledConnection object.

maxStatements applies only to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS, and to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.
Common IBM Data Server Driver for JDBC and SQLJ properties for DB2 for z/OS and IBM Informix

Some of the IBM Data Server Driver for JDBC and SQLJ properties apply to IBM Informix and DB2 for z/OS database servers.

Properties that apply to IBM Informix and DB2 for z/OS are:

**enableConnectionConcentrator**
Indicates whether the connection concentrator function of the IBM Data Server Driver for JDBC and SQLJ is enabled.

The data type of enableConnectionConcentrator is boolean. The default is false.

enableConnectionConcentrator applies only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

**keepDynamic**
Specifies whether the data source keeps already prepared dynamic SQL statements in the dynamic statement cache after commit points so that those prepared statements can be reused. The data type of this property is int. Valid values are DB2BaseDataSource.YES (1) and DB2BaseDataSource.NO (2).

If the keepDynamic property is not specified, the keepDynamic value is DB2BaseDataSource.NOT_SET (0). If the connection is to a DB2 for z/OS server, caching of dynamic statements for a connection is not done if the property is not set. If the connection is to an IBM Informix data source, caching of dynamic statements for a connection is done if the property is not set.

keepDynamic is used with the DB2Binder -keepdynamic option. The keepDynamic property value that is specified must match the -keepdynamic value that was specified when DB2Binder was run.

For a DB2 for z/OS database server, dynamic statement caching can be done only if the EDM dynamic statement cache is enabled on the data source. The CACHEDYN subsystem parameter must be set to DB2BaseDataSource.YES to enable the dynamic statement cache.

**maxTransportObjects**
Specifies the maximum number of transport objects that can be used for all connections with the associated DataSource object. The IBM Data Server Driver for JDBC and SQLJ uses transport objects and a global transport objects pool to support the connection concentrator and Sysplex workload balancing. There is one transport object for each physical connection to the data source.

The data type of this property is int.

The maxTransportObjects value is ignored if the enableConnectionConcentrator or enableSysplexWLB properties are not set to enable the use of the connection concentrator or Sysplex workload balancing.

If the maxTransportObjects value has not been reached, and a transport object is not available in the global transport objects pool, the pool creates a new transport object.
transport object. If the maxTransportObjects value has been reached, the application waits for the amount of time that is specified by the db2.jcc.maxTransportObjectWaitTime configuration property. After that amount of time has elapsed, if there is still no available transport object in the pool, the pool throws an SQLException.

maxTransportObjects does not override the db2.jcc.maxTransportObjects configuration property. maxTransportObjects has no effect on connections from other DataSource objects. If the maxTransportObjects value is larger than the db2.jcc.maxTransportObjects value, maxTransportObjects does not increase the db2.jcc.maxTransportObjects value.

For version 3.63 or 4.13 or later of the IBM Data Server Driver for JDBC and SQLJ, the default value for maxTransportObjects is 1000. For earlier versions of the IBM Data Server Driver for JDBC and SQLJ, the default value for maxTransportObjects is -1, which means that the number of transport objects for the DataSource is limited only by the db2.jcc.maxTransportObjects value for the driver.

Related concepts:
“Example of enabling DB2 for z/OS Sysplex workload balancing and automatic client reroute in Java applications” on page 292

Common IBM Data Server Driver for JDBC and SQLJ properties for IBM Informix and DB2 Database for Linux, UNIX, and Windows

Some of the IBM Data Server Driver for JDBC and SQLJ properties apply to IBM Informix and DB2 for Linux, UNIX, and Windows database servers.

Properties that apply to IBM Informix and DB2 for Linux, UNIX, and Windows are:

**currentLockTimeout**
Specifies whether DB2 for Linux, UNIX, and Windows servers wait for a lock when the lock cannot be obtained immediately. The data type of this property is int. Possible values are:

- integer Wait for integer seconds. integer is between -1 and 32767, inclusive.
- LOCK_TIMEOUT_NO_WAIT Do not wait for a lock. This is the default.
- LOCK_TIMEOUT_WAIT_INDEFINITELY Wait indefinitely for a lock.
- LOCK_TIMEOUT_NOT_SET Use the default for the data source.

IBM Data Server Driver for JDBC and SQLJ properties for DB2 Database for Linux, UNIX, and Windows

Some of the IBM Data Server Driver for JDBC and SQLJ properties apply only to DB2 for Linux, UNIX, and Windows servers.

Those properties are:

**connectNode**
Specifies the target database partition server that an application connects to. The data type of this property is int. The value can be between 0 and 999. The
default is database partition server that is defined with port 0. connectNode applies to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to DB2 for Linux, UNIX, and Windows servers only.

currentExplainSnapshot

Specifies the value for the CURRENT EXPLAIN SNAPSHOT special register. The CURRENT EXPLAIN SNAPSHOT special register enables and disables the Explain snapshot facility. The data type of this property is String. The maximum length is eight bytes. This property applies only to connections to data sources that support the CURRENT EXPLAIN SNAPSHOT special register, such as DB2 for Linux, UNIX, and Windows.

currentQueryOptimization

Specifies a value that controls the class of query optimization that is performed by the database manager when it binds dynamic SQL statements. The data type of this property is int. The possible values of currentQueryOptimization are:

0   Specifies that a minimal amount of optimization is performed to generate an access plan. This class is most suitable for simple dynamic SQL access to well-indexed tables.
1   Specifies that optimization roughly comparable to DB2 for Linux, UNIX, and Windows Version 1 is performed to generate an access plan.
2   Specifies a level of optimization higher than that of DB2 for Linux, UNIX, and Windows Version 1, but at significantly less optimization cost than levels 3 and above, especially for very complex queries.
3   Specifies that a moderate amount of optimization is performed to generate an access plan.
5   Specifies a significant amount of optimization is performed to generate an access plan. For complex dynamic SQL queries, heuristic rules are used to limit the amount of time spent selecting an access plan. Where possible, queries will use materialized query tables instead of the underlying base tables.
7   Specifies a significant amount of optimization is performed to generate an access plan. This value is similar to 5 but without the heuristic rules.
9   Specifies the maximum amount of optimization is performed to generate an access plan. This can greatly expand the number of possible access plans that are evaluated. This class should be used to determine if a better access plan can be generated for very complex and very long-running queries using large tables. Explain and performance measurements can be used to verify that a better plan has been generated.

optimizationProfile

Specifies an optimization profile that is used during SQL optimization. The data type of this property is String. The optimizationProfile value is used to set the OPTIMIZATION PROFILE special register. The default is null.

optimizationProfile applies to DB2 for Linux, UNIX, and Windows servers only.
**optimizationProfileToFlush**
Specifications of an optimization profile that is to be removed from the optimization profile cache. The data type of this property is String. The default is null.

**plugin**
The name of a client-side JDBC security plug-in. This property has the object type and contains a new instance of the JDBC security plug-in method.

**pluginName**
The name of a server-side security plug-in module.

**retryWithAlternativeSecurityMechanism**
Specifies whether the IBM Data Server Driver for JDBC and SQLJ retries a connection with an alternative security mechanism if the security mechanism that is specified by property securityMechanism is not supported by the data source. The data type of this property is int. Possible values are:

- com.ibm.db2.jcc.DB2BaseDataSource.YES (1)
  Retry the connection using an alternative security mechanism. The IBM Data Server Driver for JDBC and SQLJ issues warning code +4222 and retries the connection with the most secure available security mechanism.

- com.ibm.db2.jcc.DB2BaseDataSource.NO (2) or com.ibm.db2.jcc.DB2BaseDataSource.NOT_SET (0)
  Do not retry the connection using an alternative security mechanism.

**useTransactionRedirect**
Specifies whether the DB2 system directs SQL statements to different database partitions for better performance. The data type of this property is boolean. The default is false.

This property is applicable only under the following conditions:
- The connection is to a DB2 for Linux, UNIX, and Windows server that uses a partitioned database environment.
- The partitioning key remains constant throughout a transaction.

If useTransactionRedirect is true, the IBM Data Server Driver for JDBC and SQLJ sends connection requests to the DPF node that contains the target data of the first directable statement in the transaction. DB2 for Linux, UNIX, and Windows then directs the SQL statement to different partitions as needed.

---

**IBM Data Server Driver for JDBC and SQLJ properties for DB2 for z/OS**

Some of the IBM Data Server Driver for JDBC and SQLJ properties apply only to DB2 for z/OS servers.

Those properties are:

**accountingInterval**
Specifies whether DB2 accounting records are produced at commit points or on termination of the physical connection to the data source. The data type of this property is String.
If the value of accountingInterval is "COMMIT", and there are no open, held cursors, DB2 writes an accounting record each time that the application commits work. If the value of accountingInterval is "COMMIT", and the application performs a commit operation while a held cursor is open, the accounting interval spans that commit point and ends at the next valid accounting interval end point. If the value of accountingInterval is not "COMMIT", accounting records are produced on termination of the physical connection to the data source.

The accountingInterval property sets the accounting-interval parameter for an underlying RRSAF signon call. If the value of subsystem parameter ACCUMACC is not NO, the ACCUMACC value overrides the accountingInterval setting.

accountingInterval applies only to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS. accountingInterval is not applicable to connections under CICS or IMS, or for Java stored procedures.

The accountingInterval property overrides the db2.jcc.accountingInterval configuration property.

charOutputSize
Specifies the maximum number of bytes to use for INOUT or OUT stored procedure parameters that are registered as Types.CHAR charOutputSize applies only to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for z/OS database servers.

Because DESCRIBE information for stored procedure INOUT and OUT parameters is not available at run time, by default, the IBM Data Server Driver for JDBC and SQLJ sets the maximum length of each character INOUT or OUT parameter to 32767. For stored procedures with many Types.CHAR parameters, this maximum setting can result in allocation of much more storage than is necessary.

To use storage more efficiently, set charOutputSize to the largest expected length for any Types.CHAR INOUT or OUT parameter.

charOutputSize has no effect on INOUT or OUT parameters that are registered as Types.VARCHAR or Types.LONGVARCHAR. The driver uses the default length of 32767 for Types.VARCHAR and Types.LONGVARCHAR parameters.

The value that you choose for charOutputSize needs to take into account the possibility of expansion during character conversion. Because the IBM Data Server Driver for JDBC and SQLJ has no information about the server-side CCSID that is used for output parameter values, the driver requests the stored procedure output data in UTF-8 Unicode. The charOutputSize value needs to be the maximum number of bytes that are needed after the parameter value is converted to UTF-8 Unicode. UTF-8 Unicode characters can require up to three bytes. (The euro symbol is an example of a three-byte UTF-8 character.) To ensure that the value of charOutputSize is large enough, if you have no information about the output data, set charOutputSize to three times the defined length of the largest CHAR parameter.

clientUser
Specifies the current client user name for the connection. This information is for client accounting purposes. Unlike the JDBC connection user name, this value can change during a connection. For a DB2 for z/OS server, the maximum length is 16 bytes.

This property applies only to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.
**clientWorkstation**
Specifies the workstation name for the current client for the connection. This information is for client accounting purposes. This value can change during a connection. The data type of this property is String. For a DB2 for z/OS server, the maximum length is 18 bytes. A Java empty string (""") is valid for this value, but a Java null value is not valid.

This property applies only to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.

**currentLocaleLCtype**
Specifies the LC_CTYPE locale that is used to execute SQL statements that use a built-in function that references a locale. The data type of this property is String. If currentLocaleLCtype is set, the IBM Data Server Driver for JDBC and SQLJ sets the CURRENT LOCALE LC_CTYPE special register on the data server to the property value. currentLocaleLCtype has no default.

currentLocaleLCtype can be set only at the start of a connection, and cannot be changed while the connection is active.

**currentSQLID**
Specifies:
- The authorization ID that is used for authorization checking on dynamically prepared CREATE, GRANT, and REVOKE SQL statements.
- The owner of a table space, database, storage group, or synonym that is created by a dynamically issued CREATE statement.
- The implicit qualifier of all table, view, alias, and index names specified in dynamic SQL statements.

currentSQLID sets the value in the CURRENT SQLID special register on a DB2 for z/OS server. If the currentSQLID property is not set, the default schema name is the value in the CURRENT SQLID special register.

**enableMultiRowInsertSupport**
Specifies whether the IBM Data Server Driver for JDBC and SQLJ uses multi-row INSERT for batched INSERT or MERGE operations, when the target data server is a DB2 for z/OS server that supports multi-row INSERT. The batch operations must be PreparedStatement calls with parameter markers. The data type of this property is boolean. The default is true.

The enableMultiRowInsertSupport value cannot be changed for the duration of a connection. enableMultiRowInsertSupport must be set to false if INSERT FROM SELECT statements are executed in a batch. Otherwise, the driver throws a BatchUpdateException.

**jdbcCollection**
Specifies the collection ID for the packages that are used by an instance of the IBM Data Server Driver for JDBC and SQLJ at run time. The data type of jdbcCollection is String. The default is NULLID.

This property is used with the DB2Binder -collection option. The DB2Binder utility must have previously bound IBM Data Server Driver for JDBC and SQLJ packages at the server using a -collection value that matches the jdbcCollection value.

The jdbcCollection setting does not determine the collection that is used for SQLJ applications. For SQLJ, the collection is determined by the -collection option of the SQLJ customizer.

jdbcCollection does not apply to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.
maxConnCachedParamBufferSize

Specifies the maximum size of an internal buffer that is used for caching input parameter values for PreparedStatement objects. The buffer caches values on the native code side that are passed from the driver's Java code side for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS. The buffer is used by all PreparedStatement objects for a Connection. The default is 1048576 (1MB). The default should be adequate for most users. Set maxConnCachedParamBufferSize to a larger value if many applications that run under the driver instance have PreparedStatement objects with large numbers of input parameters or large input parameters. The maxConnCachedParamBufferSize value should be larger than the maximum size of all input parameter data for a Connection. However, you also need to take into account the total number of connections and the maximum amount of memory that is available when you set the maxConnCachedParamBufferSize value.

The buffer exists for the life of a Connection, unless it reaches the maximum size. If that happens, the buffer is freed on each call to the native code. The corresponding buffer on the Java code side is freed on PreparedStatement.clearParameters and PreparedStatement.close calls. The buffers are not cleared if an application calls PreparedStatement.clearParameters, and the buffers have not reached the maximum size.

maxRowsetSize

Specifies the maximum number of bytes that are used for rowset buffering for each statement, when the IBM Data Server Driver for JDBC and SQLJ uses multiple-row FETCH for cursors. The data type of this property is int. The default is 32767.

maxRowsetSize applies only to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.

reportLongTypes

Specifies whether DatabaseMetaData methods report LONG VARCHAR and LONG VARGRAPHIC column data types as long data types. The data type of this property is short. Possible values are:

- com.ibm.db2.jcc.DB2BaseDataSource.NO (2)
- com.ibm.db2.jcc.DB2BaseDataSource.NOT_SET (0)

Specifies that DatabaseMetaData methods that return information about a LONG VARCHAR or LONG VARGRAPHIC column return java.sql.Types.VARCHAR in the DATA_TYPE column and VARCHAR or VARGRAPHIC in the TYPE_NAME column of the result set. This is the default for DB2 for z/OS Version 9 or later.

- com.ibm.db2.jcc.DB2BaseDataSource.YES (1)

Specifies that DatabaseMetaData methods that return information about a LONG VARCHAR or LONG VARGRAPHIC column return java.sql.Types.LONGVARCHAR in the DATA_TYPE column and LONG VARCHAR or LONG VARGRAPHIC in the TYPE_NAME column of the result set.

sendCharInputsUTF8

Specifies whether the IBM Data Server Driver for JDBC and SQLJ converts character input data to the CCSID of the DB2 for z/OS database server, or sends the data in UTF-8 encoding for conversion by the database server. sendCharInputsUTF8 applies to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for z/OS database servers only. The data type of
this property is int. If this property is also set at the driver level
db2.jcc.sendCharInputsUTF8, this value overrides the driver-level value.

Possible values are:

**com.ibm.db2.jcc.DB2BaseDataSource.NO (2)**
Specifies that the IBM Data Server Driver for JDBC and SQLJ converts
character input data to the target encoding before the data is sent to
the DB2 for z/OS database server.
com.ibm.db2.jcc.DB2BaseDataSource.NO is the default.

**com.ibm.db2.jcc.DB2BaseDataSource.YES (1)**
Specifies that the IBM Data Server Driver for JDBC and SQLJ sends
character input data to the DB2 for z/OS database server in UTF-8
encoding. The database server converts the data from UTF-8 encoding
to the target CCSID.

Specify com.ibm.db2.jcc.DB2BaseDataSource.YES only if conversion to
the target CCSID by the SDK for Java causes character conversion
problems. The most common problem occurs when you use IBM Data
Server Driver for JDBC and SQLJ type 2 connectivity to insert a
Unicode line feed character (U+000A) into a table column that has
CCSID 37, and then retrieve that data from a non-z/OS client. If the
SDK for Java does the conversion during insertion of the character into
the column, the line feed character is converted to the EBCDIC new
line character X’15’. However, during retrieval, some SDKs for Java on
operating systems other than z/OS convert the X’15’ character to the
Unicode next line character (U+0085) instead of the line feed character
(U+000A). The next line character causes unexpected behavior for some
XML parsers. If you set sendCharInputsUTF8 to
com.ibm.db2.jcc.DB2BaseDataSource.YES, the DB2 for z/OS database
server converts the U+000A character to the EBCDIC line feed
character X’25’ during insertion into the column, so the character is
always retrieved as a line feed character.

Conversion of data to the target CCSID on the database server might
cause the IBM Data Server Driver for JDBC and SQLJ to use more
memory than conversion by the driver. The driver allocates memory
for conversion of character data from the source encoding to the
encoding of the data that it sends to the database server. The amount
of space that the driver allocates for character data that is sent to a
table column is based on the maximum possible length of the data.
UTF-8 data can require up to three bytes for each character. Therefore,
if the driver sends UTF-8 data to the database server, the driver needs
to allocate three times the maximum number of characters in the input
data. If the driver does the conversion, and the target CCSID is a
single-byte CCSID, the driver needs to allocate only the maximum
number of characters in the input data.

**sessionTimeZone**
Specifies the setting for the CURRENT SESSION TIME ZONE special register.
The data type of this property is String.

The sessionTimeZone value is a time zone value that is in the format of sth:tm.
s is the sign, th is the time zone hour, and tm is time zone minutes. The range
of valid values is -12:59 to +14:00.

**sqljEnableClassLoaderSpecificProfiles**
Specifies whether the IBM Data Server Driver for JDBC and SQLJ allows using
and loading of SQLJ profiles with the same Java name in multiple J2EE
application (.ear) files. The data type of this property is boolean. The default is false. sqljEnableClassLoaderSpecificProfiles is a DataSource property. This property is primarily intended for use with WebSphere Application Server.

**ssid**
Specifies the name of the local DB2 for z/OS subsystem to which a connection is established using IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS. The data type of this property is String.

The ssid property overrides the db2.jcc.ssid configuration property.

ssid can be the subsystem name for a local subsystem or a group attachment name or subgroup attachment name.

Specification of a single local subsystem name allows more than one subsystem on a single LPAR to be accessed as a local subsystem for connections that use IBM Data Server Driver for JDBC and SQLJ type 2 connectivity.

Specification of a group attachment name or subgroup attachment name allows failover processing to occur if a data sharing group member fails. If the DB2 subsystem to which an application is connected fails, the connection terminates. However, when new connections use that group attachment name or subgroup attachment name, DB2 for z/OS uses group or subgroup attachment processing to find an active DB2 subsystem to which to connect.

ssid applies only to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for z/OS.

**useRowsetCursor**
Specifies whether the IBM Data Server Driver for JDBC and SQLJ always uses multiple-row FETCH for scrollable cursors if the data source supports multiple-row FETCH. The data type of this property is boolean.

This property applies only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, or to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for z/OS. If the enableRowsetSupport property is not set, the default for useRowsetCursor is true. If the enableRowsetSupport property is set, the useRowsetCursor property is not used.

Applications that use the JDBC 1 technique for performing positioned update or delete operations should set useRowSetCursor to false. Those applications do not operate properly if the IBM Data Server Driver for JDBC and SQLJ uses multiple-row FETCH.

### IBM Data Server Driver for JDBC and SQLJ properties for IBM Informix

Some of the IBM Data Server Driver for JDBC and SQLJ properties apply only to IBM Informix databases. Those properties correspond to IBM Informix environment variables.

Properties that are shown in uppercase characters in the following information must be specified in uppercase. For those properties, getXXX and setXXX methods are formed by prepending the uppercase property name with get or set. For example:

```java
boolean dbDate = DB2BaseDateSource.getDBDATE();
```

The IBM Informix-specific properties are:

**DBANSIWARN**
Specifies whether the IBM Data Server Driver for JDBC and SQLJ instructs the
IBM Informix database to return an SQLWarning to the application if an SQL statement does not use ANSI-standard syntax. The data type of this property is boolean. Possible values are:

**false or 0**
Do not send a value to the IBM Informix database that instructs the database to return an SQLWarning to the application if an SQL statement does not use ANSI-standard syntax. This is the default.

**true or 1**
Send a value to the IBM Informix database that instructs the database to return an SQLWarning to the application if an SQL statement does not use ANSI-standard syntax.

You can use the DBANSIWARN IBM Data Server Driver for JDBC and SQLJ property to set the DBANSIWARN IBM Informix property, but you cannot use the DBANSIWARN IBM Data Server Driver for JDBC and SQLJ property to reset the DBANSIWARN IBM Informix property.

**DBDATE**
Specifies the end-user format of DATE values. The data type of this property is String. Possible values are in the description of the DBDATE environment variable in *IBM Informix Guide to SQL: Reference*.

The default value is "Y4MD-".

**DBPATH**
Specifies a colon-separated list of values that identify the database servers that contain databases. The data type of this property is String. Each value can be:

- A full path name
- A relative path name
- The server name of an IBM Informix database server
- A server name and full path name

The default ".".

**DBSPACETEMP**
Specifies a comma-separated or colon-separated list of existing dbspaces in which temporary tables are placed. The data type of this property is String.

If this property is not set, no value is sent to the server. The value for the DBSPACETEMP environment variable is used.

**DBTEMP**
Specifies the full path name of an existing directory in which temporary files and temporary tables are placed. The data type of this property is String. The default is "/tmp".

**DBUPSPACE**
Specifies the maximum amount of system disk space and maximum amount of memory, in kilobytes, that the UPDATE STATISTICS statement can use when it constructs multiple column distributions simultaneously. The data type of this property is String.

The format of DBUPSPACE is "maximum-disk-space:maximum-memory".

If this property is not set, no value is sent to the server. The value for the DBUPSPACE environment variable is used.

**DB_LOCALE**
Specifies the database locale, which the database server uses to process
locale-sensitive data. The data type of this property is String. Valid values are the same as valid values for the DB_LOCALE environment variable. The default value is null.

**DELIMIDENT**
Specifies whether delimited SQL identifiers can be used in an application. The data type of this property is boolean. Possible values are:

- **false**
  The application cannot contain delimited SQL identifiers. Double quotation marks ("') or single quotation marks (') delimit literal strings. This is the default.

- **true**
  The application can contain delimited SQL identifiers. Delimited SQL identifiers must be enclosed in double quotation marks ("'). Single quotation marks (') delimit literal strings.

**IFX_DIRECTIVES**
Specifies whether the optimizer allows query optimization directives from within a query. The data type of this property is String. Possible values are:

- **"1" or "ON"**
  Optimization directives are accepted.

- **"0" or "OFF"**
  Optimization directives are not accepted.

If this property is not set, no value is sent to the server. The value for the IFX_DIRECTIVES environment variable is used.

**IFX_EXTDIRECTIVES**
Specifies whether the optimizer allows external query optimization directives from the sysdirectives system catalog table to be applied to queries in existing applications. Possible values are:

- **"1" or "ON"**
  External query optimization directives are accepted.

- **"0" or "OFF"**
  External query optimization are not accepted.

If this property is not set, no value is sent to the server. The value for the IFX_EXTDIRECTIVES environment variable is used.

**IFX_UPDDESC**
Specifies whether a DESCRIBE of an UPDATE statement is permitted. The data type of this property is String.

Any non-null value indicates that a DESCRIBE of an UPDATE statement is permitted. The default is "1".

**IFX_XASTDCOMPLIANCE_XAEND**
Specifies whether global transactions are freed only after an explicit rollback, or after any rollback. The data type of this property is String. Possible values are:

- **"0"**
  Global transactions are freed only after an explicit rollback. This behavior conforms to the X/Open XA standard.

- **"1"**
  Global transactions are freed after any rollback.

If this property is not set, no value is sent to the server. The value for the IFX_XASTDCOMPLIANCE_XAEND environment variable is used.

**INFORMIXOPCACHE**
Specifies the size of the memory cache, in kilobytes, for the staging-area
blobspace of the client application. The data type of this property is String. A value of "0" indicates that the cache is not used.

If this property is not set, no value is sent to the server. The value for the INFORMIXOPCACHE environment variable is used.

**INFORMIXSTACKSIZE**
Specifies the stack size, in kilobytes, that the database server uses for the primary thread of a client session. The data type of this property is String.

If this property is not set, no value is sent to the server. The value for the INFORMIXSTACKSIZE environment variable is used.

**NODEFDAC**
Specifies whether the database server prevents default table privileges (SELECT, INSERT, UPDATE, and DELETE) from being granted to PUBLIC when a new table is created during the current session, in a database that is not ANSI compliant. The data type of this property is String. Possible values are:

"yes" The database server prevents default table privileges from being granted to PUBLIC when a new table is created during the current session, in a database that is not ANSI compliant.

"no" The database server does not prevent default table privileges from being granted to PUBLIC when a new table is created during the current session, in a database that is not ANSI compliant. This is the default.

**OPTCOMPIND**
Specifies the preferred method for performing a join operation on an ordered pair of tables. The data type of this property is String. Possible values are:

"0" The optimizer chooses a nested-loop join, where possible, over a sort-merge join or a hash join.

"1" When the isolation level is repeatable read, the optimizer chooses a nested-loop join, where possible, over a sort-merge join or a hash join. When the isolation level is not repeatable read, the optimizer chooses a join method based on costs.

"2" The optimizer chooses a join method based on costs, regardless of the transaction isolation mode.

If this property is not set, no value is sent to the server. The value for the OPTCOMPIND environment variable is used.

**OPTOFC**
Specifies whether to enable optimize-OPEN-FETCH-CLOSE functionality. The data type of this property is String. Possible values are:

"0" Disable optimize-OPEN-FETCH-CLOSE functionality for all threads of applications.

"1" Enable optimize-OPEN-FETCH-CLOSE functionality for all cursors in all threads of applications.

If this property is not set, no value is sent to the server. The value for the OPTOFC environment variable is used.

**PDQPRIO**
Specifies the degree of parallelism that the database server uses. The
PDQPRIORITY value affects how the database server allocates resources, including memory, processors, and disk reads. The data type of this property is String. Possible values are:

"HIGH"
   When the database server allocates resources among all users, it gives as many resources as possible to queries.

"LOW" or "1"
   The database server fetches values from fragmented tables in parallel.

"OFF" or "0"
   Parallel processing is disabled.

If this property is not set, no value is sent to the server. The value for the PDQPRIORITY environment variable is used.

PSORT_DBTEMP
   Specifies the full path name of a directory in which the database server writes temporary files that are used for a sort operation. The data type of this property is String.

If this property is not set, no value is sent to the server. The value for the PSORT_DBTEMP environment variable is used.

PSORT_NPROCS
   Specifies the maximum number of threads that the database server can use to sort a query. The data type of this property is String. The maximum value of PSORT_NPROCS is "10".

If this property is not set, no value is sent to the server. The value for the PSORT_NPROCS environment variable is used.

STMT_CACHE
   Specifies whether the shared-statement cache is enabled. The data type of this property is String. Possible values are:

"0"   The shared-statement cache is disabled.

"1"   A 512 KB shared-statement cache is enabled.

If this property is not set, no value is sent to the server. The value for the STMT_CACHE environment variable is used.

dumpPool
   Specifies the types of statistics on global transport pool events that are written, in addition to summary statistics. The global transport pool is used for the connection concentrator and Sysplex workload balancing.

   The data type of dumpPool is int. dumpPoolStatisticsOnSchedule and dumpPoolStatisticsOnScheduleFile must also be set for writing statistics before any statistics are written.

   You can specify one or more of the following types of statistics with the db2.jcc.dumpPool property:
      • DUMP_REMOVE_OBJECT (hexadecimal: X'01', decimal: 1)
      • DUMP_GET_OBJECT (hexadecimal: X'02', decimal: 2)
      • DUMP_WAIT_OBJECT (hexadecimal: X'04', decimal: 4)
      • DUMP_SET_AVAILABLE_OBJECT (hexadecimal: X'08', decimal: 8)
      • DUMP_CREATE_OBJECT (hexadecimal: X'10', decimal: 16)
      • DUMP_SYSPLEX_MSG (hexadecimal: X'20', decimal: 32)
      • DUMP_POOL_ERROR (hexadecimal: X'80', decimal: 128)
To trace more than one type of event, add the values for the types of events that you want to trace. For example, suppose that you want to trace DUMP_GET_OBJECT and DUMP_CREATE_OBJECT events. The numeric equivalents of these values are 2 and 16, so you specify 18 for the dumpPool value.

The default is 0, which means that only summary statistics for the global transport pool are written.

This property does not have a setXXX or a getXXX method.

dumpPoolStatisticsOnSchedule
Specifies how often, in seconds, global transport pool statistics are written to the file that is specified by dumpPoolStatisticsOnScheduleFile. The global transport object pool is used for the connection concentrator and Sysplex workload balancing.

The default is -1. -1 means that global transport pool statistics are not written.

This property does not have a setXXX or a getXXX method.

dumpPoolStatisticsOnScheduleFile
Specifies the name of the file to which global transport pool statistics are written. The global transport pool is used for the connection concentrator and Sysplex workload balancing.

If dumpPoolStatisticsOnScheduleFile is not specified, global transport pool statistics are not written.

This property does not have a setXXX or a getXXX method.

maxTransportObjectIdleTime
Specifies the amount of time in seconds that an unused transport object stays in a global transport object pool before it can be deleted from the pool. Transport objects are used for the connection concentrator and Sysplex workload balancing.

The default value for maxTransportObjectIdleTime is 10. Setting maxTransportObjectIdleTime to a value less than 0 causes unused transport objects to be deleted from the pool immediately. Doing this is not recommended because it can cause severe performance degradation.

This property does not have a setXXX or a getXXX method.

maxTransportObjectWaitTime
Specifies the maximum amount of time in seconds that an application waits for a transport object if the maxTransportObjects value has been reached. Transport objects are used for the connection concentrator and Sysplex workload balancing. When an application waits for longer than the maxTransportObjectWaitTime value, the global transport object pool throws an SQLException.

The default value for maxTransportObjectWaitTime is 1. Any negative value means that applications wait forever.

This property does not have a setXXX or a getXXX method.

minTransportObjects
Specifies the lower limit for the number of transport objects in a global transport object pool for the connection concentrator and Sysplex workload balancing. When a JVM is created, there are no transport objects in the pool. Transport objects are added to the pool as they are needed. After the
minTransportObjects value is reached, the number of transport objects in the global transport object pool never goes below the minTransportObjects value for the lifetime of that JVM.

The default value for minTransportObjects is 0. Any value that is less than or equal to 0 means that the global transport object pool can become empty.

This property does not have a setXXX or a getXXX method.

### IBM Data Server Driver for JDBC and SQLJ configuration properties

The IBM Data Server Driver for JDBC and SQLJ configuration properties have driver-wide scope.

The following table summarizes the configuration properties and corresponding Connection or DataSource properties, if they exist.

**Table 55. Summary of Configuration properties and corresponding Connection and DataSource properties**

<table>
<thead>
<tr>
<th>Configuration property name</th>

</tbody>
</table>

**Note:**

1. The Connection or DataSource property setting overrides the configuration property setting. The configuration property provides a default value for the Connection or DataSource property.
2. The configuration property setting overrides the Connection or DataSource property.
3. The corresponding Connection or DataSource property is defined only for IBM Informix.
4. The configuration property applies to DB2 for z/OS.
5. The configuration property applies to IBM Informix.
6. The configuration property applies to DB2 for Linux, UNIX, and Windows.

The meanings of the configuration properties are:

**db2.jdbc.accountingInterval**

Specifies whether DB2 accounting records are produced at commit points or on termination of the physical connection to the data source. If the value of `db2.jdbc.accountingInterval` is COMMIT, DB2 accounting records are produced at commit points. For example:
db2.jcc.accountingInterval=COMMIT

Otherwise, accounting records are produced on termination of the physical
connection to the data source.

db2.jcc.accountingInterval applies only to IBM Data Server Driver for JDBC
and SQLJ type 2 connectivity on DB2 for z/OS. db2.jcc.accountingInterval is
not applicable to connections under CICS or IMS, or for Java stored
procedures.

You can override db2.jcc.accountingInterval by setting the accountingInterval
property for a Connection or DataSource object.

This configuration property applies only to DB2 for z/OS.

db2.jcc.allowSqljDuplicateStaticQueries
Specifies whether multiple open iterators on a single SELECT statement in an
SQLJ application are allowed under IBM Data Server Driver for JDBC and
SQLJ type 2 connectivity.

To enable this support, set db2.jcc.allowSqljDuplicateStaticQueries to YES or
true.

db2.jcc.charOutputSize
Specifies the maximum number of bytes to use for INOUT or OUT stored
procedure parameters that are registered as Types.CHAR.

Because DESCRIBE information for stored procedure INOUT and OUT
parameters is not available at run time, by default, the IBM Data Server Driver
for JDBC and SQLJ sets the maximum length of each character INOUT or OUT
parameter to 32767. For stored procedures with many Types.CHAR parameters,
this maximum setting can result in allocation of much more storage than is
necessary.

To use storage more efficiently, set db2.jcc.charOutputSize to the largest
expected length for any Types.CHAR INOUT or OUT parameter.

db2.jcc.charOutputSize has no effect on INOUT or OUT parameters that are
registered as Types.VARCHAR or Types.LONGVARCHAR. The driver uses the default
length of 32767 for Types.VARCHAR and Types.LONGVARCHAR parameters.

The value that you choose for db2.jcc.charOutputSize needs to take into
account the possibility of expansion during character conversion. Because the
IBM Data Server Driver for JDBC and SQLJ has no information about the
server-side CCSID that is used for output parameter values, the driver requests
the stored procedure output data in UTF-8 Unicode. The
db2.jcc.charOutputSize value needs to be the maximum number of bytes that
are needed after the parameter value is converted to UTF-8 Unicode. UTF-8
Unicode characters can require up to three bytes. (The euro symbol is an
example of a three-byte UTF-8 character.) To ensure that the value of
db2.jcc.charOutputSize is large enough, if you have no information about the
output data, set db2.jcc.charOutputSize to three times the defined length of the
largest CHAR parameter.

This configuration property applies only to DB2 for z/OS.

db2.jcc.currentSchema or db2.jcc.override.currentSchema
Specifies the default schema name that is used to qualify unqualified database
objects in dynamically prepared SQL statements. This value of this property
sets the value in the CURRENT SCHEMA special register on the database
server. The schema name is case-sensitive, and must be specified in uppercase
characters.
This configuration property applies only to DB2 for z/OS or DB2 for Linux, UNIX, and Windows.

**db2.jcc.currentSQLID or db2.jcc.override.currentSQLID**

Specifies:

- The authorization ID that is used for authorization checking on dynamically prepared CREATE, GRANT, and REVOKE SQL statements.
- The owner of a table space, database, storage group, or synonym that is created by a dynamically issued CREATE statement.
- The implicit qualifier of all table, view, alias, and index names specified in dynamic SQL statements.

currentSQLID sets the value in the CURRENT SQLID special register on a DB2 for z/OS server. If the currentSQLID property is not set, the default schema name is the value in the CURRENT SQLID special register.

This configuration property applies only to DB2 for z/OS.

**db2.jcc.decimalRoundingMode or db2.jcc.override.decimalRoundingMode**

Specifies the rounding mode for assignment to decimal floating-point variables or DECIMAL columns on DB2 for z/OS or DB2 for Linux, UNIX, and Windows data servers.

Possible values are:

- **com.ibm.db2.jcc.DB2BaseDataSource.ROUND_DOWN (1)**
  Rounds the value towards 0 (truncation). The discarded digits are ignored.

- **com.ibm.db2.jcc.DB2BaseDataSource.ROUND_CEILING (2)**
  Rounds the value towards positive infinity. If all of the discarded digits are zero or if the sign is negative the result is unchanged other than the removal of the discarded digits. Otherwise, the result coefficient is incremented by 1.

- **com.ibm.db2.jcc.DB2BaseDataSource.ROUND_HALF_EVEN (3)**
  Rounds the value to the nearest value; if the values are equidistant, rounds the value so that the final digit is even. If the discarded digits represents greater than half (0.5) of the value of one in the next left position then the result coefficient is incremented by 1. If they represent less than half, then the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise the result coefficient is unaltered if its rightmost digit is even, or is incremented by 1 if its rightmost digit is odd (to make an even digit).

- **com.ibm.db2.jcc.DB2BaseDataSource.ROUND_HALF_UP (4)**
  Rounds the value to the nearest value; if the values are equidistant, rounds the value away from zero. If the discarded digits represent greater than or equal to half (0.5) of the value of one in the next left position then the result coefficient is incremented by 1. Otherwise the discarded digits are ignored.

- **com.ibm.db2.jcc.DB2BaseDataSource.ROUND_FLOOR (6)**
  Rounds the value towards negative infinity. If all of the discarded digits are zero or if the sign is positive the result is unchanged other than the removal of discarded digits. Otherwise, the sign is negative and the result coefficient is incremented by 1.

- **com.ibm.db2.jcc.DB2BaseDataSource.ROUND_UNSET (-2147483647)**
  No rounding mode was explicitly set. The IBM Data Server Driver for
JDBC and SQLJ does not use the decimalRoundingMode to set the rounding mode on the database server. The rounding mode is ROUND_HALF_EVEN.

If you explicitly set the db2.jcc.decimalRoundingMode or db2.jcc.override.decimalRoundingMode value, that value updates the CURRENT DECFLT ROUNDING MODE special register value on a DB2 for z/OS data server.

If you explicitly set the db2.jcc.decimalRoundingMode or db2.jcc.override.decimalRoundingMode value, that value does not update the CURRENT DECFLT ROUNDING MODE special register value on a DB2 for Linux, UNIX, and Windows data server. If the value to which you set db2.jcc.decimalRoundingMode or db2.jcc.override.decimalRoundingMode is not the same as the value of the CURRENT DECFLT ROUNDING MODE special register, an Exception is thrown. To change the data server value, you need to set that value with the decflt_rounding database configuration parameter.

decimalRoundingMode does not affect decimal value assignments. The IBM Data Server Driver for JDBC and SQLJ always rounds decimal values down.

db2.jcc.defaultSQLState
Specifies the SQLSTATE value that the IBM Data Server Driver for JDBC and SQLJ returns to the client for SQLException or SQLWarning objects that have null SQLSTATE values. This configuration property can be specified in the following ways:

db2.jcc.defaultSQLState
  If db2.jcc.defaultSQLState is specified with no value, the IBM Data Server Driver for JDBC and SQLJ returns 'FFFFF'.

db2.jcc.defaultSQLState=xxxxx
  xxxxx is the value that the IBM Data Server Driver for JDBC and SQLJ returns when the SQLSTATE value is null. If xxxxx is longer than five bytes, the driver truncates the value to five bytes. If xxxxx is shorter than five bytes, the driver pads xxxxx on the right with blanks.

If db2.jcc.defaultSQLState is not specified, the IBM Data Server Driver for JDBC and SQLJ returns a null SQLSTATE value.

This configuration property applies only to DB2 for z/OS.

db2.jcc.disableSQLJProfileCaching
Specifies whether serialized profiles are cached when the JVM under which their application is running is reset. db2.jcc.disableSQLJProfileCaching applies only to applications that run in a resettable JVM (applications that run in the CICS, IMS, or Java stored procedure environment), and use IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS. Possible values are:

YES  SQLJ serialized profiles are not cached every time the JVM is reset, so that new versions of the serialized profiles are loaded when the JVM is reset. Use this option when an application is under development, and new versions of the application and its serialized profiles are produced frequently.

NO   SQLJ serialized profiles are cached when the JVM is reset. NO is the default.

This configuration property applies only to DB2 for z/OS.
**db2.jcc.dumpPool**

Specifies the types of statistics on global transport pool events that are written, in addition to summary statistics. The global transport pool is used for the connection concentrator and Sysplex workload balancing.

You can specify one or more of the following types of statistics with the db2.jcc.dumpPool property:
- **DUMP_REMOVE_OBJECT** (hexadecimal: X'01', decimal: 1)
- **DUMP_GET_OBJECT** (hexadecimal: X'02', decimal: 2)
- **DUMP_WAIT_OBJECT** (hexadecimal: X'04', decimal: 4)
- **DUMP_SET_AVAILABLE_OBJECT** (hexadecimal: X'08', decimal: 8)
- **DUMP_CREATE_OBJECT** (hexadecimal: X'10', decimal: 16)
- **DUMP_SYSPLEX_MSG** (hexadecimal: X'20', decimal: 32)
- **DUMP_POOL_ERROR** (hexadecimal: X'80', decimal: 128)

To trace more than one type of event, add the values for the types of events that you want to trace. For example, suppose that you want to trace DUMP_GET_OBJECT and DUMP_CREATE_OBJECT events. The numeric equivalents of these values are 2 and 16, so you specify 18 for the db2.jcc.dumpPool value.

The default is 0, which means that only summary statistics for the global transport pool are written.

This configuration property applies only to DB2 for z/OS or IBM Informix.

**db2.jcc.dumpPoolStatisticsOnSchedule**

Specifies how often, in seconds, global transport pool statistics are written to the file that is specified by db2.jcc.dumpPoolStatisticsOnScheduleFile. The global transport object pool is used for the connection concentrator and Sysplex workload balancing.

The default is -1. -1 means that global transport pool statistics are not written.

This configuration property applies only to DB2 for z/OS or IBM Informix.

**db2.jcc.dumpPoolStatisticsOnScheduleFile**

Specifies the name of the file to which global transport pool statistics are written. The global transport pool is used for the connection concentrator and Sysplex workload balancing.

If db2.jcc.dumpPoolStatisticsOnScheduleFile is not specified, global transport pool statistics are not written.

This configuration property applies only to DB2 for z/OS or IBM Informix.

**db2.jcc.enableInetAddressGetHostName**

Specifies whether the IBM Data Server Driver for JDBC and SQLJ uses the InetAddress.getHostName and InetAddress.getCanonicalHostName methods to determine the host name for an IP address.

db2.jcc.enableInetAddressGetHostName applies only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity. Possible values are:

- **true**
  - The IBM Data Server Driver for JDBC and SQLJ uses the InetAddress.getHostName and InetAddress.getCanonicalHostName methods to determine the host name for an IP address.
  - When you specify true, applications might take longer to run because of the additional time that is required for DNS lookup operations.
The IBM Data Server Driver for JDBC and SQLJ uses the InetAddress.getHostAddress method to determine the host name for an IP address. false is the default.

db2.jcc.override.enableMultiRowInsertSupport
Specifies whether the IBM Data Server Driver for JDBC and SQLJ uses multi-row INSERT for batched INSERT or MERGE operations, when the target data server is a DB2 for z/OS server that supports multi-row INSERT. The batch operations must be PreparedStatement calls with parameter markers. The default is true.

db2.jcc.override.enableMultiRowInsertSupport must be set to false if INSERT FROM SELECT statements are executed in a batch. Otherwise, the driver throws a BatchUpdateException.

Possible values are:

true Specifies that the IBM Data Server Driver for JDBC and SQLJ uses multi-row INSERT for batched INSERT or MERGE operations, when the target data server is a DB2 for z/OS server that supports multi-row INSERT. This is the default.

false Specifies that the IBM Data Server Driver for JDBC and SQLJ does not use multi-row INSERT for batched INSERT or MERGE operations, when the target data server is a DB2 for z/OS server that supports multi-row INSERT.

db2.jcc.encryptionAlgorithm or db2.jcc.override.encryptionAlgorithm
Specifies whether the IBM Data Server Driver for JDBC and SQLJ uses 56-bit DES (weak) encryption or 256-bit AES (strong) encryption.

db2.jcc.encryptionAlgorithm or db2.jcc.override.encryptionAlgorithm can be specified only if db2.jcc.securityMechanism or db2.jcc.override.securityMechanism is set to 7 or 9.

Possible values are:

1 The driver uses 56-bit DES encryption.

2 The driver uses 256-bit AES encryption, if the database server supports it. 256-bit AES encryption is available for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity only.

For AES encryption, you need an unrestricted policy file for JCE. For the IBM SDK for Java, the file is available at the following location:

The SDK for Java from Oracle might support AES encryption, but not DES encryption. When you use AES encryption with the SDK for Java from Oracle, the JCE Unlimited Strength Jurisdiction Policy File needs to be installed. That file is available from Oracle. If the JCE Unlimited Strength Jurisdiction Policy File is not found, a java.security.InvalidKeyException is thrown.

db2.jcc.encryptionAlgorithm can be specified only if the db2.jcc.securityMechanism, db2.jcc.override.securityMechanism, or securityMechanisim value is set for encrypted password security or encrypted user ID and password security.

db2.jcc.jmXEnabled
Specifies whether the Java Management Extensions (JMX) is enabled for the
IBM Data Server Driver for JDBC and SQLJ instance. JMX must be enabled before applications can use the remote trace controller.

Possible values are:

**true or yes**

Indicates that JMX is enabled.

**Any other value**

Indicates that JMX is disabled. This is the default.

**db2.jcc.lobOutputSize**

Specifies the number of bytes of storage that the IBM Data Server Driver for JDBC and SQLJ needs to allocate for output LOB values when the driver cannot determine the size of those LOBs. This situation occurs for LOB stored procedure output parameters. `db2.jcc.lobOutputSize` applies only to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.

The default value for `db2.jcc.lobOutputSize` is 1048576. For systems with storage limitations and smaller LOBs, set the `db2.jcc.lobOutputSize` value to a lower number.

For example, if you know that the output LOB size is at most 64000, set `db2.jcc.lobOutputSize` to 64000.

This configuration property applies only to DB2 for z/OS.

**db2.jcc.maxConnCachedParamBufferSize**

Specifies the maximum size of an internal buffer that is used for caching input parameter values for PreparedStatement objects. The buffer caches values on the native code side that are passed from the driver's Java code side for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS. The buffer is used by all PreparedStatement objects for a Connection. The default is 1048576 (1MB). The default should be adequate for most users. Set `db2.jcc.maxConnCachedParamBufferSize` to a larger value if many applications that run under the driver instance have PreparedStatement objects with large numbers of input parameters or large input parameters. The `db2.jcc.maxConnCachedParamBufferSize` should be larger than the maximum size of all input parameter data for a Connection. However, you also need to take into account the total number of connections and the maximum amount of memory that is available when you set the `db2.jcc.maxConnCachedParamBufferSize` value.

The buffer exists for the life of a Connection, unless it reaches the maximum specified size. If that happens, the buffer is freed on each call to the native code. The corresponding buffer on the Java code side is freed on PreparedStatement.clearParameters and PreparedStatement.close calls. The buffers are not cleared if an application calls PreparedStatement.clearParameters, and the buffers have not reached the maximum size.

**db2.jcc.maxRefreshInterval**

For workload balancing, specifies the maximum amount of time in seconds between refreshes of the client copy of the server list. The minimum valid value is 1.

For version 3.63 or 4.13 or later of the IBM Data Server Driver for JDBC and SQLJ, the default is 10 seconds. For earlier versions of the driver, the default is 30 seconds.

**db2.jcc.maxTransportObjectIdleTime**

Specifies the amount of time in seconds that an unused transport object stays...
in a global transport object pool before it can be deleted from the pool. Transport objects are used for the connection concentrator and Sysplex workload balancing.

The default value for `db2.jcc.maxTransportObjectIdleTime` is 10. Setting `db2.jcc.maxTransportObjectIdleTime` to a value less than 0 causes unused transport objects to be deleted from the pool immediately. Doing this is not recommended because it can cause severe performance degradation.

`db2.jcc.maxTransportObjects`
Specifies the upper limit for the number of transport objects in a global transport object pool for the connection concentrator and Sysplex workload balancing. When the number of transport objects in the pool reaches the `db2.jcc.maxTransportObjects` value, transport objects that have not been used for longer than the `db2.jcc.maxTransportObjectIdleTime` value are deleted from the pool.

For version 3.63 or 4.13 or later of the IBM Data Server Driver for JDBC and SQLJ, the default is 1000. For earlier versions of the driver, the default is -1. Any value that is less than or equal to 0 means that there is no limit to the number of transport objects in the global transport object pool.

`db2.jcc.maxTransportObjectWaitTime`
Specifies the maximum amount of time in seconds that an application waits for a transport object if the `db2.jcc.maxTransportObjects` value has been reached. Transport objects are used for the connection concentrator and Sysplex workload balancing. When an application waits for longer than the `db2.jcc.maxTransportObjectWaitTime` value, the global transport object pool throws an SQLException.

Any negative value means that applications wait forever.

For version 3.63 or 4.13 or later of the IBM Data Server Driver for JDBC and SQLJ, the default is 1 second. For earlier versions of the driver, the default is -1.

`db2.jcc.minTransportObjects`
Specifies the lower limit for the number of transport objects in a global transport object pool for the connection concentrator and Sysplex workload balancing. When a JVM is created, there are no transport objects in the pool. Transport objects are added to the pool as they are needed. After the `db2.jcc.minTransportObjects` value is reached, the number of transport objects in the global transport object pool never goes below the `db2.jcc.minTransportObjects` value for the lifetime of that JVM.

The default value for `db2.jcc.minTransportObjects` is 0. Any value that is less than or equal to 0 means that the global transport object pool can become empty.

`db2.jcc.outputDirectory`
Specifies where the IBM Data Server Driver for JDBC and SQLJ stores temporary log or cache files.

If this property is set, the IBM Data Server Driver for JDBC and SQLJ stores the following files in the specified directory:

`jccServerListCache.bin`
Contains a copy of the primary and alternate server information for automatic client reroute in a DB2 pureScale environment.
This file applies only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to DB2 for Linux, UNIX, and Windows.

If db2.jcc.outputDirectory is not specified, the IBM Data Server Driver for JDBC and SQLJ searches for a directory that is specified by the java.io.tmpdir system property. If the java.io.tmpdir system property is also not specified, the driver uses only the in-memory cache for the primary and alternate server information. If a directory is specified, but jccServerListCache.bin cannot be accessed, the driver uses only the in-memory cache for the server list.

**jccdiag.log**
Contains diagnostic information that is written by the IBM Data Server Driver for JDBC and SQLJ.

If db2.jcc.outputDirectory is not specified, the IBM Data Server Driver for JDBC and SQLJ searches for a directory that is specified by the java.io.tmpdir system property. If the java.io.tmpdir system property is also not specified, the driver does not write diagnostic information to jccdiag.log. If a directory is specified, but jccdiag.log cannot be accessed, the driver does not write diagnostic information to jccdiag.log.

**connlicj.bin**
Contains information about IBM Data Server Driver for JDBC and SQLJ license verification, for direct connections to DB2 for z/OS. The IBM Data Server Driver for JDBC and SQLJ writes this file when server license verification is performed successfully for a data server. When a copy of the license verification information is stored at the client, performance of license verification on subsequent connections can be improved.

If db2.jcc.outputDirectory is not specified, the IBM Data Server Driver for JDBC and SQLJ searches for a directory that is specified by the java.io.tmpdir system property. If the java.io.tmpdir system property is also not specified, the driver does not store a copy of server license verification information at the client. If a directory is specified, but connlicj.bin cannot be accessed, the driver does not store a copy of server license verification information at the client.

The IBM Data Server Driver for JDBC and SQLJ does not create the directory. You must create the directory and assign the required file permissions.

db2.jcc.outputDirectory can specify an absolute path or a relative path. However, an absolute path is recommended.

**db2.jcc.pkList**
Specifies a package list that is used for the underlying RRSAF CREATE THREAD call when a JDBC or SQLJ connection to a data source is established. Specify this property if you do not bind plans for your SQLJ programs or for the JDBC driver. If you specify this property, do not specify db2.jcc.planName.

db2.jcc.pkList applies only to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS. db2.jcc.pkList does not apply to applications that run under CICS or IMS, or to Java stored procedures. The JDBC driver ignores the db2.jcc.pkList setting in those cases.

**Recommendation:** Use db2.jcc.pkList instead of db2.jcc.planName.

The format of the package list is:
The default value of db2.jcc.pkList is NULLID.*.

If you specify the -collection parameter when you run
com.ibm.db2.jdbc.DB2Binder, the collection ID that you specify for IBM Data
Server Driver for JDBC and SQLJ packages when you run
com.ibm.db2.jcc.DB2Binder must also be in the package list for the
db2.jcc.pkList property.

You can override db2.jcc.pkList by setting the pkList property for a Connection
or DataSource object.

The following example specifies a package list for an IBM Data Server Driver
for JDBC and SQLJ instance whose packages are in collection JDBCCID. SQLJ
applications that are prepared under this driver instance are bound into
collections SQLJCID1, SQLJCID2, or SQLJCID3.

db2.jcc.pkList=JDBCCID.*,SQLJCID1.*,SQLJCID2.*,SQLJCID3.*

This configuration property applies only to DB2 for z/OS.

db2.jcc.planName

Specifies a DB2 for z/OS plan name that is used for the underlying RRSAF
CREATE THREAD call when a JDBC or SQLJ connection to a data source is
established. Specify this property if you bind plans for your SQLJ programs
and for the JDBC driver packages. If you specify this property, do not specify
db2.jcc.pkList.

db2.jcc.planName applies only to IBM Data Server Driver for JDBC and SQLJ
type 2 connectivity on DB2 for z/OS. db2.jcc.planName does not apply to
applications that run under CICS or IMS, or to Java stored procedures. The
JDBC driver ignores the db2.jcc.planName setting in those cases.

If you do not specify this property or the db2.jcc.pkList property, the IBM Data
Server Driver for JDBC and SQLJ uses the db2.jcc.pkList default value of
NULLID.*.

If you specify db2.jcc.planName, you need to bind the packages that you
produce when you run com.ibm.db2.jcc.DB2Binder into a plan whose name is
the value of this property. You also need to bind all SQLJ packages into a plan
whose name is the value of this property.

You can override db2.jcc.planName by setting the planName property for a
Connection or DataSource object.

The following example specifies a plan name of MYPLAN for the IBM Data
Server Driver for JDBC and SQLJ JDBC packages and SQLJ packages.

db2.jcc.planName=MYPLAN

This configuration property applies only to DB2 for z/OS.

db2.jcc.progressiveStreaming or db2.jcc.override.progressiveStreaming

Specifies whether the JDBC driver uses progressive streaming when
progressive streaming is supported on the data source.

With progressive streaming, also known as dynamic data format, the data
source dynamically determines the most efficient mode in which to return LOB
or XML data, based on the size of the LOBs or XML objects.
Valid values are:

1  Use progressive streaming, if the data source supports it.
2  Do not use progressive streaming.

**db2.jcc.rollbackOnShutdown**

Specifies whether DB2 for z/OS forces a rollback operation and disables further operations on JDBC connections that are in a unit of work during processing of JVM shutdown hooks.

db2.jcc.rollbackOnShutdown applies to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity only.

db2.jcc.rollbackOnShutdown does not apply to the CICS, IMS, stored procedure, or WebSphere Application Server environments.

Possible values are:

**yes or true**

The IBM Data Server Driver for JDBC and SQLJ directs DB2 for z/OS to force a rollback operation and disables further operations on JDBC connections that are in a unit of work during processing of JVM shutdown hooks.

**Any other value**

The IBM Data Server Driver for JDBC and SQLJ takes no action with respect to rollback processing during processing of JVM shutdown hooks. This is the default.

This configuration property applies only to DB2 for z/OS.

**db2.jcc.securityMechanism or db2.jcc.override.securityMechanism**

Specifies the DRDA security mechanism. Possible values are:

3  User ID and password
4  User ID only
7  User ID, encrypted password
9  Encrypted user ID and password
11 Kerberos. This value does not apply to connections to IBM Informix.
12 Encrypted user ID and encrypted security-sensitive data. This value applies to connections to DB2 for z/OS only.
13 Encrypted user ID and password, and encrypted security-sensitive data. This value does not apply to connections to IBM Informix.
15 Plug-in security. This value applies to connections to DB2 for Linux, UNIX, and Windows only.
16 Encrypted user ID. This value does not apply to connections to IBM Informix.
18 Client certificate security, using SSL. This value applies to connections to DB2 for z/OS Version 10 and later only.

The security mechanism that is specified by this property is the only mechanism that is used. If the security mechanism is not supported by the connection, an exception is thrown.

The default value for db2.jcc.securityMechanism is 3. If the server does not support user ID and password security, but supports encrypted user ID and
password security (9), the IBM Data Server Driver for JDBC and SQLJ driver
upgrades the security mechanism to encrypted user ID and password security
and attempts to connect to the server. Any other mismatch in security
mechanism support between the requester and the server results in an error.

This property does not apply to IBM Data Server Driver for JDBC and SQLJ
type 2 connectivity on DB2 for z/OS.

db2.jcc.sendCharInputsUTF8
Specifies whether the IBM Data Server Driver for JDBC and SQLJ converts
color input data to the CCSID of the DB2 for z/OS database server, or
sends the data in UTF-8 encoding for conversion by the database server.
db2.jcc.sendCharInputsUTF8 applies to IBM Data Server Driver for JDBC and
SQLJ type 2 connectivity to DB2 for z/OS database servers only. If this
property is also set at the connection level, the connection-level setting
overrides this value.

Possible values are:

- **no, false, or 2**
  Specifies that the IBM Data Server Driver for JDBC and SQLJ converts
color input data to the target encoding before the data is sent to
the DB2 for z/OS database server. This is the default.

- **yes, true, or 1**
  Specifies that the IBM Data Server Driver for JDBC and SQLJ sends
color input data to the DB2 for z/OS database server in UTF-8
encoding. The data source converts the data from UTF-8 encoding to
the target CCSID.

Specify yes, true, or 1 only if conversion to the target CCSID by the
SDK for Java causes character conversion problems. The most common
problem occurs when you use IBM Data Server Driver for JDBC and
SQLJ type 2 connectivity to insert a Unicode line feed character
(U+000A) into a table column that has CCSID 37, and then retrieve that
data from a non-z/OS client. If the SDK for Java does the conversion
during insertion of the character into the column, the line feed
character is converted to the EBCDIC new line character X'15'.
However, during retrieval, some SDKs for Java on operating systems
other than z/OS convert the X'15' character to the Unicode next line
character (U+0085) instead of the line feed character (U+000A). The
next line character causes unexpected behavior for some XML parsers.
If you set db2.jcc.sendCharInputsUTF8 to yes, the DB2 for z/OS
database server converts the U+000A character to the EBCDIC line feed
color character X'25' during insertion into the column, so the character is
always retrieved as a line feed character.

Conversion of data to the target CCSID on the data source might cause
the IBM Data Server Driver for JDBC and SQLJ to use more memory
than conversion by the driver. The driver allocates memory for
conversion of character data from the source encoding to the encoding
of the data that it sends to the data source. The amount of space that
the driver allocates for character data that is sent to a table column is
based on the maximum possible length of the data. UTF-8 data can
require up to three bytes for each character. Therefore, if the driver
sends UTF-8 data to the data source, the driver needs to allocate three
times the maximum number of characters in the input data. If the
driver does the conversion, and the target CCSID is a single-byte CCSID, the driver needs to allocate only the maximum number of characters in the input data.

For example, any of the following settings for `db2.jcc.sendCharInputsUTF8` causes the IBM Data Server Driver for JDBC and SQLJ to convert input character strings to UTF-8, rather than the target encoding, before sending the data to the data source:

```
db2.jcc.sendCharInputsUTF8=yes
db2.jcc.sendCharInputsUTF8=true
db2.jcc.sendCharInputsUTF8=1
```

This configuration property applies only to DB2 for z/OS.

### `db2.jcc.sqljToolsExitJVMOnCompletion`

Specifies whether the Java programs that underlie SQLJ tools such as `db2sqljcustomize` and `db2sqljbind` issue the `System.exit` call on return to the calling programs.

Possible values are:

- **true**  
  Specifies that the Java programs that underlie SQLJ tools issue the `System.exit` call upon completion. `true` is the default.

- **false**  
  Specifies that the Java programs that underlie SQLJ tools do not issue the `System.exit` call.

### `db2.jcc.sqljUncustomizedWarningOrException`

Specifies the action that the IBM Data Server Driver for JDBC and SQLJ takes when an uncustomized SQLJ application runs.

`db2.jcc.sqljUncustomizedWarningOrException` can have the following values:

- **0**  
  The IBM Data Server Driver for JDBC and SQLJ does not throw a Warning or Exception when an uncustomized SQLJ application is run. This is the default.

- **1**  
  The IBM Data Server Driver for JDBC and SQLJ throws a Warning when an uncustomized SQLJ application is run.

- **2**  
  The IBM Data Server Driver for JDBC and SQLJ throws an Exception when an uncustomized SQLJ application is run.

This configuration property applies only to DB2 for z/OS or DB2 for Linux, UNIX, and Windows.

### `db2.jcc.ssid`

Specifies the DB2 for z/OS subsystem to which applications make connections with IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.

The `db2.jcc.ssid` value can be the name of the local DB2 subsystem or a group attachment name or subgroup attachment name.

For example:

```
db2.jcc.ssid=DB2A
```

The `ssid` Connection and `DataSource` property overrides `db2.jcc.ssid`.

If you specify a group attachment name or subgroup attachment name, and the DB2 subsystem to which an application is connected fails, the connection terminates. However, when new connections use that group attachment name or subgroup attachment name, DB2 for z/OS uses group attachment or subgroup attachment processing to find an active DB2 subsystem to which to connect.
If you do not specify the db2.jcc.ssid property, the IBM Data Server Driver for JDBC and SQLJ uses the SSID value from the application defaults load module. When you install DB2 for z/OS, an application defaults load module is created in the prefix.SDSNEXIT data set and the prefix.SDSNLOAD data set. Other application defaults load modules might be created in other data sets for selected applications.

The IBM Data Server Driver for JDBC and SQLJ must load an application defaults load module before it can read the SSID value. z/OS searches data sets in the following places, and in the following order, for the application defaults load module:

1. Job pack area (JPA)
2. TASKLIB
3. STEPLIB or JOBLIB
4. LPA
5. Libraries in the link list

You need to ensure that if your system has more than one copy of the application defaults load module, z/OS finds the data set that contains the correct copy for the IBM Data Server Driver for JDBC and SQLJ first.

This configuration property applies only to DB2 for z/OS.

**db2.jcc.sslConnection or db2.jcc.override.sslConnection**

This property specifies whether the IBM Data Server Driver for JDBC and SQLJ uses an SSL socket to connect to the data source. If the value is `true`, the connection uses an SSL socket. If the value is `false`, the connection uses a plain socket.

The `db2.jcc.override.sslConnection` property overrides the `sslConnection` property for a Connection or DataSource object.

If no property is specified, the default value is `false`.

This property is applicable only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

**db2.jcc.sslTrustStoreLocation or db2.jcc.override.sslTrustStoreLocation**

This property specifies the name of the Java truststore on the client that contains the server certificate for an SSL connection.

The IBM Data Server Driver for JDBC and SQLJ uses this option only if the `db2.jcc.sslConnection`, `db2.jcc.override.sslConnection`, or `sslConnection` property is set to `true`.

If `db2.jcc.sslTrustStoreLocation` or `db2.jcc.override.sslTrustStoreLocation` or `sslTrustStoreLocation` is set, and `db2.jcc.sslConnection`, `db2.jcc.override.sslConnection`, or `sslConnection` is set to `true`, the IBM Data Server Driver for JDBC and SQLJ uses the `db2.jcc.sslTrustStoreLocation`, `db2.jcc.override.sslTrustStoreLocation`, or `sslTrustStoreLocation` value instead of the value in the `javax.net.ssl.trustStore` Java property.

The `db2.jcc.override.sslTrustStoreLocation` property overrides the `sslTrustStoreLocation` property for a Connection or DataSource object.

If no property is specified, the default value is null.

This property is applicable only to IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

**db2.jcc.sslTrustStorePassword or db2.jcc.override.sslTrustStorePassword**

This property specifies the password for the Java truststore on the client that contains the server certificate for an SSL connection.
The IBM Data Server Driver for JDBC and SQLJ uses this option only if the
db2.jcc.sslConnection, db2.jcc.override.sslConnection, or sslConnection property
is set to true.

If db2.jcc.sslTrustStorePassword, db2.jcc.override.sslTrustStorePassword, or
sslTrustStorePassword is set, and db2.jcc.sslConnection,
db2.jcc.override.sslConnection, or sslConnection is set to true, the IBM Data
Server Driver for JDBC and SQLJ uses the db2.jcc.sslTrustStorePassword,
db2.jcc.override.sslTrustStorePassword, or sslTrustStorePassword value instead
of the value in the javax.net.ssl.trustStorePassword Java property.

The db2.jcc.override.sslTrustStorePassword property overrides the
sslTrustStorePassword property for a Connection or DataSource object.

If no property is specified, the default value is null.

This property is applicable only to IBM Data Server Driver for JDBC and SQLJ
type 4 connectivity.

db2.jcc.traceDirectory or db2.jcc.override.traceDirectory

Enables the IBM Data Server Driver for JDBC and SQLJ trace for Java driver
code, and specifies a directory into which trace information is written. When
db2.jcc.override.traceDirectory is specified, trace information for multiple
connections on the same DataSource is written to multiple files.

When db2.jcc.override.traceDirectory is specified, a connection is traced to a
file named file-name_origin_n.
  - n is the nth connection for a DataSource.
  - If neither db2.jcc.traceFileFileName nor db2.jcc.override.traceFileFileName is
    specified, file-name is traceFile. If db2.jcc.traceFileFileName or
db2.jcc.override.traceFileFileName is also specified, file-name is the value of
db2.jcc.traceFileFileName or db2.jcc.override.traceFileFileName.
  - origin indicates the origin of the log writer that is in use. Possible values of
    origin are:
      - cpds  The log writer for a DB2ConnectionPoolDataSource object.
      - driver The log writer for a DB2Driver object.
      - global The log writer for a DB2TraceManager object.
      - sds    The log writer for a DB2SimpleDataSource object.
      - xads   The log writer for a DB2XADatasource object.

The db2.jcc.override.traceDirectory property overrides the traceDirectory
property for a Connection or DataSource object.

For example, specifying the following setting for db2.jcc.override.traceDirectory
enables tracing of the IBM Data Server Driver for JDBC and SQLJ Java code to
files in a directory named /SYSTEM/tmp:
db2.jcc.override.traceDirectory=/SYSTEM/tmp

You should set the trace properties under the direction of IBM Software
Support.

db2.jcc.traceLevel or db2.jcc.override.traceLevel

Specifies what to trace.

The db2.jcc.override.traceLevel property overrides the traceLevel property for
a Connection or DataSource object.
You specify one or more trace levels by specifying a decimal value. The trace
tevels are the same as the trace levels that are defined for the traceLevel
property on a Connection or DataSource object.

To specify more than one trace level, do an OR (|) operation on the values,
and specify the result in decimal in the db2.jcc.traceLevel or
db2.jcc.override.traceLevel specification.

For example, suppose that you want to specify TRACE_DRDA_FLOWS and
TRACE_CONNECTIONS for db2.jcc.override.traceLevel.
TRACE_DRDA_FLOWS has a hexadecimal value of X'40'.
TRACE_CONNECTION_CALLS has a hexadecimal value of X'01'. To specify
both traces, do a bitwise OR operation on the two values, which results in
X'41'. The decimal equivalent is 65, so you specify:
    db2.jcc.override.traceLevel=65

**db2.jcc.traceFile or db2.jcc.override.traceFile**
Enables the IBM Data Server Driver for JDBC and SQLJ trace for Java driver
code, and specifies the name on which the trace file names are based.

Specify a fully qualified z/OS UNIX System Services file name for the
db2.jcc.override.traceFile property value.

The db2.jcc.override.traceFile property overrides the traceFile property for a
Connection or DataSource object.

For example, specifying the following setting for db2.jcc.override.traceFile
enables tracing of the IBM Data Server Driver for JDBC and SQLJ Java code to
a file named /SYSTEM/tmp/jdbctrace:
    db2.jcc.override.traceFile=/SYSTEM/tmp/jdbctrace

You should set the trace properties under the direction of IBM Software
Support.

**db2.jcc.traceFileAppend or db2.jcc.override.traceFileAppend**
Specifies whether to append to or overwrite the file that is specified by the
db2.jcc.override.traceFile property. Valid values are true or false. The default
is false, which means that the file that is specified by the traceFile property is
overwritten.

The db2.jcc.override.traceFileAppend property overrides the traceFileAppend
property for a Connection or DataSource object.

For example, specifying the following setting for
db2.jcc.override.traceFileAppend causes trace data to be added to the existing
trace file:
    db2.jcc.override.traceFileAppend=true

You should set the trace properties under the direction of IBM Software
Support.

**db2.jcc.traceFileCount**
Specifies the maximum number of trace files for circular tracing. The IBM Data
Server Driver for JDBC and SQLJ uses this property only when
db2.jcc.traceOption is set to 1. The default value is 2.

This property does not apply to IBM Data Server Driver for JDBC and SQLJ
type 2 connectivity on DB2 for z/OS.

You should set the trace properties under the direction of IBM Software
Support.
**db2.jcc.traceFileSize**

Specifies the maximum size of each trace file, for circular tracing. The IBM Data Server Driver for JDBC and SQLJ uses this property only when db2.jcc.traceOption is set to 1. The default value is 10485760 (10 MB).

This property does not apply to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.

You should set the trace properties under the direction of IBM Software Support.

**db2.jcc.traceOption**

Specifies the way in which trace data is collected. The data type of this property is int. Possible values are:

0  Specifies that a single trace file is generated, and that there is no limit to the size of the file. This is the default.

1  Specifies that the IBM Data Server Driver for JDBC and SQLJ does circular tracing. Circular tracing is done as follows:

1. When an application writes its first trace record, the driver creates a file.
2. The driver writes trace data to the file.
3. When the size of the file is equal to the value of property db2.jcc.traceFileSize, the driver creates another file.
4. The driver repeats steps 2 and 3 until the number of files to which data has been written is equal to the value of property db2.jcc.traceFileCount.
5. The driver writes data to the first trace file, overwriting the existing data.
6. The driver repeats steps 2 through 5 until the application completes.

The file names for the trace files are the file names that are determined by the db2.jcc.traceFile, db2.jcc.override.traceFile, db2.jcc.traceDirectory, db2.jcc.override.traceDirectory property, appended with .1 for the first file, .2 for the second file, and so on.

This property does not apply to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.

You should set the trace properties under the direction of IBM Software Support.

**db2.jcc.tracePolling**

Indicates whether the IBM Data Server Driver for JDBC and SQLJ polls the global configuration file for changes in trace directives and modifies the trace behavior to match the new trace directives. Possible values are true or false. False is the default.

The IBM Data Server Driver for JDBC and SQLJ modifies the trace behavior at the beginning of the next polling interval after the configuration properties file is changed. If db2.jcc.tracePolling is set to true while an application is running, the trace is enabled, and information about all the PreparedStatement objects that were created by the application before the trace was enabled are dumped to the trace destination.

db2.jcc.tracePolling polls the following global configuration properties:
- db2.jcc.override.traceLevel
- db2.jcc.override.traceFile
- db2.jcc.override.traceDirectory
- db2.jcc.override.traceFileAppend

**db2.jcc.tracePollingInterval**

Specifies the interval, in seconds, for polling the IBM Data Server Driver for JDBC and SQLJ global configuration file for changes in trace directives. The property value is a positive integer. The default is 60. For the specified trace polling interval to be used, the db2.jcc.tracePollingInterval property must be set before the driver is loaded and initialized. Changes to db2.jcc.tracePollingInterval after the driver is loaded and initialized have no effect.

**db2.jcc.t2zosTraceFile**

Enables the IBM Data Server Driver for JDBC and SQLJ trace for C/C++ native driver code for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity, and specifies the name on which the trace file names are based. This property is required for collecting trace data for C/C++ native driver code.

Specify a fully qualified z/OS UNIX System Services file name for the db2.jcc.t2zosTraceFile property value.

For example, specifying the following setting for db2.jcc.t2zosTraceFile enables tracing of the IBM Data Server Driver for JDBC and SQLJ C/C++ native code to a file named /SYSTEM/tmp/jdbctraceNative:

```
db2.jcc.t2zosTraceFile=/SYSTEM/tmp/jdbctraceNative
```

You should set the trace properties under the direction of IBM Software Support.

This configuration property applies only to DB2 for z/OS.

**db2.jcc.t2zosTraceBufferSize**

Specifies the size, in kilobytes, of a trace buffer in virtual storage that is used for tracing the processing that is done by the C/C++ native driver code. This value is also the maximum amount of C/C++ native driver trace information that can be collected.

Specify an integer between 64 (64 KB) and 4096 (4096 KB). The default is 256 (256 KB).

The JDBC driver determines the trace buffer size as shown in the following table:

<table>
<thead>
<tr>
<th>Specified value (n)</th>
<th>Trace buffer size (KB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;64</td>
<td>64</td>
</tr>
<tr>
<td>64&lt;=n&lt;128</td>
<td>64</td>
</tr>
<tr>
<td>128&lt;=n&lt;256</td>
<td>128</td>
</tr>
<tr>
<td>256&lt;=n&lt;512</td>
<td>256</td>
</tr>
<tr>
<td>512&lt;=n&lt;1024</td>
<td>512</td>
</tr>
<tr>
<td>1024&lt;=n&lt;2048</td>
<td>1024</td>
</tr>
<tr>
<td>2048&lt;=n&lt;4096</td>
<td>2048</td>
</tr>
<tr>
<td>n&gt;=4096</td>
<td>4096</td>
</tr>
</tbody>
</table>

db2.jcc.t2zosTraceBufferSize is used only if the db2.jcc.t2zosTraceFile property is set.

**Recommendation:** To avoid a performance impact, specify a value of 1024 or less.
For example, to set a trace buffer size of 1024 KB, use this setting:
```
db2.jcc.t2zosTraceBufferSize=1024
```
You should set the trace properties under the direction of IBM Software Support.

This configuration property applies only to DB2 for z/OS.

**db2.jcc.t2zosTraceWrap**

Enables or disables wrapping of the SQLJ trace. `db2.jcc.t2zosTraceWrap` can have one of the following values:

- 1 Wrap the trace
- 0 Do not wrap the trace

The default is 1. This parameter is optional. For example:
```
DB2SQLJ_TRACE_WRAP=0
```

You should set `db2.jcc.t2zosTraceWrap` only under the direction of IBM Software Support.

This configuration property applies only to DB2 for z/OS.

**db2.jcc.useCcsid420ShapedConverter**

Specifies whether Arabic character data that is in EBCDIC CCSID 420 maps to Cp420S encoding.

`db2.jcc.useCcsid420ShapedConverter` applies only to connections to DB2 for z/OS database servers.

If the value of `db2.jcc.useCcsid420ShapedConverter` is `true`, CCSID 420 maps to Cp420S encoding. If the value of `db2.jcc.useCcsid420ShapedConverter` is `false`, CCSID 420 maps to Cp420 encoding. `false` is the default.

This configuration property applies only to DB2 for z/OS.

**Related concepts:**

“Customization of IBM Data Server Driver for JDBC and SQLJ configuration properties” on page 19

---

**Driver support for JDBC APIs**

The JDBC drivers that are supported by DB2 and IBM Informix database systems have different levels of support for JDBC methods.

The following tables list the JDBC interfaces and indicate which drivers supports them. The drivers and their supported platforms are:

**Table 56. JDBC drivers for DB2 and IBM Informix database systems**

<table>
<thead>
<tr>
<th>JDBC driver name</th>
<th>Associated data source</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM Data Server Driver for JDBC and SQLJ</td>
<td>DB2 for Linux, UNIX, and Windows, DB2 for z/OS, or IBM Informix</td>
</tr>
<tr>
<td>IBM Informix JDBC Driver (IBM Informix JDBC Driver)</td>
<td>IBM Informix</td>
</tr>
</tbody>
</table>

If a method has JDBC 2.0 and JDBC 3.0 forms, the IBM Data Server Driver for JDBC and SQLJ supports all forms. The DB2 JDBC Type 2 Driver for Linux, UNIX and Windows supports only the JDBC 2.0 forms.
### Table 57. Support for java.sql.Array methods

<table>
<thead>
<tr>
<th>JDBC method</th>
<th>IBM Data Server Driver for JDBC and SQLJ support</th>
<th>IBM Informix JDBC Driver support</th>
</tr>
</thead>
<tbody>
<tr>
<td>free</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>getArray</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>getBaseType</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>getBaseTypeName</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>getResultSet</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Notes:**
1. Under the IBM Data Server Driver for JDBC and SQLJ, Array methods are supported for connections to DB2 for Linux, UNIX, and Windows data sources only.
2. This is a JDBC 4.0 method.

### Table 58. Support for java.sql.BatchUpdateException methods

<table>
<thead>
<tr>
<th>JDBC method</th>
<th>IBM Data Server Driver for JDBC and SQLJ support</th>
<th>IBM Informix JDBC Driver support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Methods inherited from java.lang.Exception</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>getUpdateCounts</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### Table 59. Support for java.sql.Blob methods

<table>
<thead>
<tr>
<th>JDBC method</th>
<th>IBM Data Server Driver for JDBC and SQLJ support</th>
<th>IBM Informix JDBC Driver support</th>
</tr>
</thead>
<tbody>
<tr>
<td>free</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>getBinaryStream</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>getBytes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>length</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>position</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>setBinaryStream</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>setByte</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>truncate</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Notes:**
1. This is a JDBC 4.0 method.
2. Supported forms of this method include the following JDBC 4.0 form:
   ```java
getBinaryStream(long pos, long length)
```
3. For versions of the IBM Data Server Driver for JDBC and SQLJ before version 3.50, these methods cannot be used if a Blob is passed to a stored procedure as an IN or INOUT parameter, and the methods are used on the Blob in the stored procedure.

### Table 60. Support for java.sql.CallableStatement methods

<table>

<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>setTransactionIsolation</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>setTypeMap</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Notes:
1. This is a JDBC 4.1 method.
2. This is a JDBC 4.0 method.
3. Under IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, an SQLException is thrown if the timeout parameter value is less than 0. Under IBM Data Server Driver for JDBC and SQLJ type 2 connectivity, an SQLException is thrown if the timeout parameter value is not 0.
4. If the stored procedure in the CALL statement is on DB2 for z/OS, the parameters of the CALL statement cannot be expressions.
5. The driver does not use the setting. For the IBM Data Server Driver for JDBC and SQLJ, a connection can be set as read-only through the readOnly property for a Connection or DataSource object.

Table 64. Support for javax.sql.ConnectionEvent methods

Notes:

1. DB2 data sources return false for this method. IBM Informix data sources return true.
2. This is a JDBC 4.1 method.
3. This method is supported for connections to DB2 for Linux, UNIX, and Windows and IBM Informix only.
4. Under the IBM Data Server Driver for JDBC and SQLJ, DB2 data sources and IBM Informix data sources return true for this method. Under the IBM Informix JDBC Driver, IBM Informix data sources return false.
5. Under the IBM Data Server Driver for JDBC and SQLJ, DB2 data sources and IBM Informix data sources return false for this method. Under the IBM Informix JDBC Driver, IBM Informix data sources return true.
6. DB2 data sources return true for this method. IBM Informix data sources return false.
7. This is a JDBC 4.0 method.
8. This method returns the additional column that is described by the JDBC 4.0 specification.
9. JDBC 3.0 and earlier implementations of the IBM Data Server Driver for JDBC and SQLJ return "IBM DB2 JDBC Universal Driver Architecture."
   The JDBC 4.0 implementation of the IBM Data Server Driver for JDBC and SQLJ returns "IBM Data Server Driver for JDBC and SQLJ."
10. The JDBC 4.0 form and previous forms of this method are supported.
11. The DB2 JDBC Type 2 Driver for Linux, UNIX and Windows does not support the JDBC 3.0 form of this method.
12. The method can be executed, but it returns an empty ResultSet.
### Table 68. Support for java.sql.DataSource methods

<table>

<thead>
<tr>
<th>JDBC method</th>
<th>IBM Data Server Driver for JDBC and SQLJ support</th>
<th>IBM Informix JDBC Driver support</th>
</tr>
</thead>
</table>

Notes:
1. If the value of the length parameter is -1, all of the data from the InputStream or Reader is read and sent to the data source.
2. Supported forms of this method include the following JDBC 4.0 forms:
   - `setAsciiStream(int parameterIndex, InputStream x, long length)`
   - `setAsciiStream(int parameterIndex, InputStream x)`
3. Supported forms of this method include the following JDBC 4.0 forms:
   - `setBinaryStream(int parameterIndex, InputStream x, long length)`
   - `setBinaryStream(int parameterIndex, InputStream x)`
4. Supported forms of this method include the following JDBC 4.0 form:
   - `setBlob(int parameterIndex, InputStream inputStream, long length)`
5. Supported forms of this method include the following JDBC 4.0 forms:
   - `setCharacterStream(int parameterIndex, Reader reader, long length)`
   - `setCharacterStream(int parameterIndex, Reader reader)`
6. Supported forms of this method include the following JDBC 4.0 form:
   - `setClob(int parameterIndex, Reader reader, long length)`
7. This is a JDBC 4.0 method.
8. The database server does no timezone adjustment for datetime values. The JDBC driver adjusts a value for the local timezone before sending the value to the server if you specify a form of the setDate, setTime, or setTimestamp method that includes a java.util.Calendar parameter.
9. The following form of setNull is not supported:
   - `setNull(int parameterIndex, int jdbcType, String typeName)`
10. `setString` is not supported if the column has the FOR BIT DATA attribute or the data type is BLOB.

<th>IBM Informix JDBC Driver support</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notes:
1. `getBinaryStream` is not supported for CLOB columns.
2. `getMetaData` pads the schema name, if the returned schema name is less than 8 characters, to fill 8 characters.
3. The database server does no timezone adjustment for datetime values. The JDBC driver adjusts a value for the local timezone after retrieving the value from the server if you specify a form of the `getDateTime`, `getTimestamp`, or `getTimestamp` method that includes a `java.util.Calendar` parameter.
4. The following form of the `getObject` method is not supported:
   `getObject(int parameterIndex, java.util.Map map)`
5. Supported forms of this method include the following JDBC 4.0 forms:
   `updateAsciiStream(int columnIndex, InputStream x)`
   `updateAsciiStream(String columnLabel, InputStream x)`
   `updateAsciiStream(int columnIndex, InputStream x, long length)`
   `updateAsciiStream(String columnLabel, InputStream x, long length)`
6. Supported forms of this method include the following JDBC 4.0 forms:
   `updateBinaryStream(int columnIndex, InputStream x)`
   `updateBinaryStream(String columnLabel, InputStream x)`
   `updateBinaryStream(int columnIndex, InputStream x, long length)`
   `updateBinaryStream(String columnLabel, InputStream x, long length)`
7. Supported forms of this method include the following JDBC 4.0 forms:
   `updateBlob(int columnIndex, InputStream x)`
   `updateBlob(String columnLabel, InputStream x)`
   `updateBlob(int columnIndex, InputStream x, long length)`
   `updateBlob(String columnLabel, InputStream x, long length)`
8. Supported forms of this method include the following JDBC 4.0 forms:
   `updateCharacterStream(int columnIndex, Reader reader)`
   `updateCharacterStream(String columnLabel, Reader reader)`
   `updateCharacterStream(int columnIndex, Reader reader, long length)`
   `updateCharacterStream(String columnLabel, Reader reader, long length)`
9. Supported forms of this method include the following JDBC 4.0 forms:
   `updateClob(int columnIndex, Reader reader)`
   `updateClob(String columnLabel, Reader reader)`
   `updateClob(int columnIndex, Reader reader, long length)`
   `updateClob(String columnLabel, Reader reader, long length)`
10. This is a JDBC 4.0 method.

Table 77. Support for java.sql.ResultSetMetaData methods

Table 98. Support for java.sql.Statement methods (continued)

<table>
<thead>
<tr>
<th>JDBC method</th>
<th>IBM Data Server Driver for JDBC and SQLJ support</th>
<th>IBM Informix JDBC Driver support</th>
</tr>
</thead>
</table>

**Notes:**

1. This is a JDBC 4.1 method.
2. For the IBM Data Server Driver for JDBC and SQLJ, Statement.cancel is supported only in the following environments:
   - Type 2 and type 4 connectivity from a Linux, UNIX, or Windows client to a DB2 for Linux, UNIX, and Windows server, Version 8 or later
   - Type 2 and type 4 connectivity from a Linux, UNIX, or Windows client to a DB2 for z/OS server, Version 9 or later
   - Type 4 connectivity from a z/OS client to a DB2 for Linux, UNIX, and Windows server, Version 8 or later
   - Type 4 connectivity from a z/OS client to a DB2 for z/OS server, Version 8 or later
   The action that the IBM Data Server Driver for JDBC and SQLJ takes when the application executes Statement.cancel is also dependent on the setting of the DB2BaseDataSource.interruptProcessingMode property.
3. Not supported for stored procedure ResultSets.
4. For DB2 for i, this method is supported only for a seconds value of 0.
5. For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS, Statement.setQueryTimeout is supported only if Connection or DataSource property queryTimeoutInterruptProcessingMode is set to INTERRUPT_PROCESSING_MODE_CLOSE_SOCKET.
6. For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for Linux, UNIX, and Windows, Statement.setQueryTimeout is supported only if Connection or DataSource property queryTimeoutInterruptProcessingMode is set to INTERRUPT_PROCESSING_MODE_STATEMENT_CANCEL.
7. For the IBM Data Server Driver for JDBC and SQLJ Version 4.0 and later, Statement.setQueryTimeout is supported for the following methods:
   - Statement.execute
   - Statement.executeUpdate
   - Statement.executeQuery
   Statement.setQueryTimeout is supported for the Statement.executeBatch method only when property queryTimeoutInterruptProcessingMode is set to INTERRUPT_PROCESSING_MODE_CLOSE_SOCKET (2).
8. This is a JDBC 4.0 method.

<td>Yes</td>
</tr>
</tbody>
</table>

Notes:
1. This method is supported for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to a DB2 for Linux, UNIX, and Windows server or IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.
2. When the end method is called, the IBM Data Server Driver for JDBC and SQLJ closes the underlying cursor, even if the TMSUSPEND flag is specified.
3. This method is supported for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to DB2 for Linux, UNIX, and Windows Version 9.1 or later.

**IBM Data Server Driver for JDBC and SQLJ support for SQL escape syntax**

The IBM Data Server Driver for JDBC and SQLJ supports SQL escape syntax, as described in the JDBC 1.0 specification.
This is the same syntax that is used in vendor escape clauses in ODBC and CLI applications.

SQL escape syntax is supported in JDBC and SQLJ applications.

**SQLJ statement reference information**

SQLJ statements are used for transaction control and SQL statement execution.

**SQLJ clause**

The SQL statements in an SQLJ program are in SQLJ clauses.

**Syntax**

```
#sql
connection-declaration-clause
iterator-declaration-clause
executable-clause
```

**Usage notes**

Keywords in an SQLJ clause are case sensitive, unless those keywords are part of an SQL statement in an executable clause.

**Related reference:**

- “SQLJ iterator-declaration-clause” on page 431
- “SQLJ executable-clause” on page 432
- “SQLJ connection-declaration-clause” on page 430

**SQLJ host-expression**

A host expression is a Java variable or expression that is referenced by SQLJ clauses in an SQLJ application program.

**Syntax**

```
: simple-variable
      IN
      OUT
      INOUT (complex-expression)
INDICATOR : simple-variable
      (complex-expression)
```

**Description**

: Indicates that the variable or expression that follows is a host expression. The colon must immediately precede the variable or expression.

**IN|OUT|INOUT**

For a host expression that is used as a parameter in a stored procedure call, identifies whether the parameter provides data to the stored procedure (IN), retrieves data from the stored procedure (OUT), or does both (INOUT). The default is IN.

**simple-variable**

Specifies a Java unqualified identifier.

**complex-expression**

Specifies a Java expression that results in a single value.
**INDICATOR :simple-variable or INDICATOR : (complex-expression)**

Specifies the optional indicator variable for the corresponding Java host variable. The data type of the indicator variable must be the Java short type. The only valid values for :simple-variable or : (complex-expression) are:

For customized applications, and for input, only these values are valid:

<table>
<thead>
<tr>
<th>Indicator value</th>
<th>Equivalent constant</th>
<th>Meaning of value</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>sqlj.runtime.ExecutionContext.DBNull</td>
<td>Null</td>
</tr>
<tr>
<td>-2, -3, -4, -6</td>
<td></td>
<td>Null</td>
</tr>
<tr>
<td>-5</td>
<td>sqlj.runtime.ExecutionContext.DBDefault</td>
<td>Default</td>
</tr>
<tr>
<td>-7</td>
<td>sqlj.runtime.ExecutionContext.DBUnassigned</td>
<td>Unassigned</td>
</tr>
<tr>
<td>short-value &gt;=0</td>
<td>sqlj.runtime.ExecutionContext.DBNonNull</td>
<td>Non-null</td>
</tr>
</tbody>
</table>

For uncustomized applications, and for input, only these values are valid:

<table>
<thead>
<tr>
<th>Indicator value</th>
<th>Equivalent constant</th>
<th>Meaning of value</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>sqlj.runtime.ExecutionContext.DBNull</td>
<td>Null</td>
</tr>
<tr>
<td>-7 &lt;= short-value &lt; -1</td>
<td></td>
<td>Null</td>
</tr>
<tr>
<td>0</td>
<td>sqlj.runtime.ExecutionContext.DBNonNull</td>
<td>Non-null</td>
</tr>
<tr>
<td>short-value &gt;0</td>
<td></td>
<td>Non-null</td>
</tr>
</tbody>
</table>

For customized or uncustomized applications, and for output, SQLJ sets one of these values:

<table>
<thead>
<tr>
<th>Indicator value</th>
<th>Equivalent constant</th>
<th>Meaning of value</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>sqlj.runtime.ExecutionContext.DBNull</td>
<td>Retrieved value is SQL NULL</td>
</tr>
<tr>
<td>0</td>
<td></td>
<td>Retrieved value is not SQL NULL</td>
</tr>
</tbody>
</table>

**Usage notes**

- A complex expression must be enclosed in parentheses.
- ANSI/ISO rules govern where a host expression can appear in a static SQL statement.
- Indicator variables are required in the following cases:
  - For input, when a Java primitive type is used to assign the NULL value to a table column.
  - For output, when a Java primitive type is used for a host variable, and the source column can return NULL values.
  - If an SQL NULL value is returned, and no indicator variable is defined, an SQLNullException is thrown.

Indicator variables are not required for input or output of a Java null value as an SQL NULL, if the data type of the host variable is:

  - The data type of a Java class
  - A custom database type that the driver supports

**variable-n**

- For output, indicator variables are valid in the following types of statements:
  - CALL statement with OUT or INOUT parameters
  - FETCH positioned-iterator INTO variable-1, ..., variable-n
  - SELECT column-1, ..., column-n INTO variable-1, ..., variable-n
Related concepts:
“Variables in SQLJ applications” on page 148

**SQLJ implements-clause**
The implements clause derives one or more classes from a Java interface.

**Syntax**
```
  implements interface-element
```

**interface-element:**
```
sqlj.runtime.ForUpdate
sqlj.runtime.Scrollable
user-specified-interface-class
```

**Description**
**interface-element**
```
  Specifies a user-defined Java interface, the SQLJ interface
  sqlj.runtime.ForUpdate or the SQLJ interface sqlj.runtime.Scrollable.
```

You need to implement sqlj.runtime.ForUpdate when you declare an iterator
for a positioned UPDATE or positioned DELETE operation. See "Perform
positioned UPDATE and DELETE operations in an SQLJ application" for
information on performing a positioned UPDATE or positioned DELETE
operation in SQLJ.

You need to implement sqlj.runtime.Scrollable when you declare a scrollable
iterator. See "Use scrollable iterators in an SQLJ application" for information on
scrollable iterators.

**Related tasks:**
“Using scrollable iterators in an SQLJ application” on page 170
“Performing positioned UPDATE and DELETE operations in an SQLJ application”
on page 154

**SQLJ with-clause**
The with clause specifies a set of one or more attributes for an iterator or a
connection context.

**Syntax**
```
  with (with-element)
```

**with-element:**
Description

**holdability**
For an iterator, specifies whether an iterator keeps its position in a table after a COMMIT is executed. The value for holdability must be true or false.

**sensitivity**
For an iterator, specifies whether changes that are made to the underlying table can be visible to the iterator after it is opened. The value must be INSENSITIVE, SENSITIVE, or ASENSITIVE. The default is ASENSITIVE.
For connections to IBM Informix, only INSENSITIVE is supported.

**dynamic**
For an iterator that is defined with sensitivity=SENSITIVE, specifies whether the following cases are true:
- When the application executes positioned UPDATE and DELETE statements with the iterator, those changes are visible to the iterator.
- When the application executes INSERT, UPDATE, and DELETE statements within the application but outside the iterator, those changes are visible to the iterator.

The value for dynamic must be true or false. The default is false.

DB2 for Linux, UNIX, and Windows servers do not support dynamic scrollable cursors. Specify true only if your application accesses data on DB2 for z/OS servers, at Version 9 or later.
For connections to IBM Informix, only false is supported. IBM Informix does not support dynamic cursors.

**updateColumns**
For an iterator, specifies the columns that are to be modified when the iterator is used for a positioned UPDATE statement. The value for updateColumns must be a literal string that contains the column names, separated by commas.

**column-name**
For an iterator, specifies a column of the result table that is to be updated using the iterator.

**Java-ID**
For an iterator or connection context, specifies a Java variable that identifies a user-defined attribute of the iterator or connection context. The value of java-constant-expression is also user-defined.

**dataSource**
For a connection context, specifies the logical name of a separately-created
DataSource object that represents the data source to which the application will connect. This option is available only for the IBM Data Server Driver for JDBC and SQLJ.

**Usage notes**

- The value on the left side of a with element must be unique within its with clause.
- If you specify updateColumns in a with element of an iterator declaration clause, the iterator declaration clause must also contain an implements clause that specifies the sqlj.runtime.ForUpdate interface.
- If you do not customize your SQLJ program, the JDBC driver ignores the value of holdability that is in the with clause. Instead, the driver uses the JDBC driver setting for holdability.

**Related concepts:**
- “SQLJ and JDBC in the same application” on page 180

**Related tasks:**
- “Using scrollable iterators in an SQLJ application” on page 170
- “Performing positioned UPDATE and DELETE operations in an SQLJ application” on page 154
- “Connecting to a data source using SQLJ” on page 141

**SQLJ connection-declaration-clause**

The connection declaration clause declares a connection to a data source in an SQLJ application program.

**Syntax**

```
context—Java-class-name implements-clause with-clause
```

**Description**

**Java-modifiers**

Specifies modifiers that are valid for Java class declarations, such as static, public, private, or protected.

**Java-class-name**

Specifies a valid Java identifier. During the program preparation process, SQLJ generates a connection context class whose name is this identifier.

**implements-clause**

See "SQLJ implements-clause" for a description of this clause. In a connection declaration clause, the interface class to which the implements clause refers must be a user-defined interface class.

**with-clause**

See "SQLJ with-clause" for a description of this clause.

**Usage notes**

- SQLJ generates a connection class declaration for each connection declaration clause you specify. SQLJ data source connections are objects of those generated connection classes.
- You can specify a connection declaration clause anywhere that a Java class definition can appear in a Java program.
Related tasks:
“Connecting to a data source using SQLJ” on page 141

Related reference:
“SQLJ with-clause” on page 428
“SQLJ implements-clause” on page 428

**SQLJ iterator-declaration-clause**

An iterator declaration clause declares a positioned iterator class or a named iterator class in an SQLJ application program.

An iterator contains the result table from a query. SQLJ generates an iterator class for each iterator declaration clause you specify. An iterator is an object of an iterator class.

An iterator declaration clause has a form for a positioned iterator and a form for a named iterator. The two kinds of iterators are distinct and incompatible Java types that are implemented with different interfaces.

**Syntax**

```
<table>
<thead>
<tr>
<th>Java-modifiers</th>
<th>iterator-Java-class-name</th>
<th>implements-clause</th>
<th>with-clause</th>
</tr>
</thead>
</table>
```

```
( positioned-iterator-column-declarations )
```

```
| Java-data-type |
```

```
| Java-data-type | Java-ID |
```

**Description**

**Java-modifiers**
Any modifiers that are valid for Java class declarations, such as static, public, private, or protected.

**Java-class-name**
Any valid Java identifier. During the program preparation process, SQLJ generates an iterator class whose name is this identifier.

**implements-clause**
See “SQLJ implements-clause” for a description of this clause. For an iterator declaration clause that declares an iterator for a positioned UPDATE or positioned DELETE operation, the implements clause must specify interface
sqlj.runtime.ForUpdate. For an iterator declaration clause that declares a scrollable iterator, the implements clause must specify interface sqlj.runtime.Scannable.

**with-clause**

See "SQLJ with-clause" for a description of this clause.

**positioned-iterator-column-declarations**

Specifies a list of Java data types, which are the data types of the columns in the positioned iterator. The data types in the list must be separated by commas. The order of the data types in the positioned iterator declaration is the same as the order of the columns in the result table. For online checking during serialized profile customization to succeed, the data types of the columns in the iterator must be compatible with the data types of the columns in the result table. See ‘Java, JDBC, and SQL data types’ for a list of compatible data types.

**named-iterator-column-declarations**

Specifies a list of Java data types and Java identifiers, which are the data types and names of the columns in the named iterator. Pairs of data types and names must be separated by commas. The name of a column in the iterator must match, except for case, the name of a column in the result table. For online checking during serialized profile customization to succeed, the data types of the columns in the iterator must be compatible with the data types of the columns in the result table. See ‘Java, JDBC, and SQL data types’ for a list of compatible data types.

**Usage notes**

- An iterator declaration clause can appear anywhere in a Java program that a Java class declaration can appear.
- When a named iterator declaration contains more than one pair of Java data types and Java IDs, all Java IDs within the list must be unique. Two Java IDs are not unique if they differ only in case.

**Related concepts:**

- “Data retrieval in SQLJ applications” on page 163

**Related tasks:**

- “Using scrollable iterators in an SQLJ application” on page 170
- “Using a positioned iterator in an SQLJ application” on page 166
- “Using a named iterator in an SQLJ application” on page 164

**Related reference:**

- “SQLJ with-clause” on page 428
- “SQLJ implements-clause” on page 428

**SQLJ executable-clause**

An executable clause contains an SQL statement or an assignment statement. An assignment statement assigns the result of an SQL operation to a Java variable.

This topic describes the general form of an executable clause.

**Syntax**

```
context-clause | statement-clause | assignment-clause
```

432  Developing Java Applications
**Usage notes**

- An executable clause can appear anywhere in a Java program that a Java statement can appear.
- SQLJ reports negative SQL codes from executable clauses through class java.sql.SQLException.
  If SQLJ raises a run-time exception during the execution of an executable clause, the value of any host expression of type OUT or INOUT is undefined.

**Related reference:**

- “SQLJ statement-clause”
- “SQLJ context-clause”
- “SQLJ assignment-clause” on page 437

**SQLJ context-clause**

A context clause specifies a connection context, an execution context, or both. You use a connection context to connect to a data source. You use an execution context to monitor and modify SQL statement execution.

**Syntax**

```java
<connection-context\>[\]<execution-context\>[\]<connection-context, execution-context\>
```

**Description**

**connection-context**

Specifies a valid Java identifier that is declared earlier in the SQLJ program. That identifier must be declared as an instance of the connection context class that SQLJ generates for a connection declaration clause.

**execution-context**

Specifies a valid Java identifier that is declared earlier in the SQLJ program. That identifier must be declared as an instance of class sqlj.runtime.ExecutionContext.

**Usage notes**

- If you do not specify a connection context in an executable clause, SQLJ uses the default connection context.
- If you do not specify an execution context, SQLJ obtains the execution context from the connection context of the statement.

**Related tasks:**

- “Controlling the execution of SQL statements in SQLJ” on page 183
- “Connecting to a data source using SQLJ” on page 141

**SQLJ statement-clause**

A statement clause contains an SQL statement or a SET TRANSACTION clause.

**Syntax**

```java
<SQL-statement\>[\]<SET-TRANSACTION-clause\>
```
Description

SQL-statement
You can include SQL statements in Table 104 in a statement clause.

SET-TRANSACTION-clause
Sets the isolation level for SQL statements in the program and the access mode for the connection. The SET TRANSACTION clause is equivalent to the SET TRANSACTION statement, which is described in the ANSI/ISO SQL standard of 1992 and is supported in some implementations of SQL.

Table 104. Valid SQL statements in an SQLJ statement clause (continued)

<table>
<thead>
<tr>
<th>Statement</th>
<th>Applicable data sources</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRUNCATE</td>
<td>1</td>
</tr>
<tr>
<td>UPDATE</td>
<td>1 2 3</td>
</tr>
</tbody>
</table>

Note: The SQL statement applies to connections to the following data sources:
1. DB2 for z/OS
2. DB2 for Linux, UNIX, and Windows
3. IBM Informix
   a. IBM Informix, for the SYSMASTER database only.

Usage notes

- SQLJ supports both positioned and searched DELETE and UPDATE operations.
- For a FETCH statement, a positioned DELETE statement, or a positioned UPDATE statement, you must use an iterator to refer to rows in a result table.

Related tasks:
“Setting the isolation level for an SQLJ transaction” on page 197

Related reference:
“SQLJ SET-TRANSACTION-clause”

SQLJ SET-TRANSACTION-clause

The SET TRANSACTION clause sets the isolation level for the current unit of work.

Syntax

```
SET TRANSACTION ISOLATION LEVEL READ COMMITTED
```

Description

**ISOLATION LEVEL**

 Specifies one of the following isolation levels:

- **READ COMMITTED**
  Specifies that the current DB2 isolation level is cursor stability.

- **READ UNCOMMITTED**
  Specifies that the current DB2 isolation level is uncommitted read.

- **REPEATABLE READ**
  Specifies that the current DB2 isolation level is read stability.

- **SERIALIZABLE**
  Specifies that the current DB2 isolation level is repeatable read.

Usage notes

You can execute SET TRANSACTION only at the beginning of a transaction.
Related tasks:
“Setting the isolation level for an SQLJ transaction” on page 197

SQLJ assignment-clause
The assignment clause assigns the result of an SQL operation to a Java variable.

Syntax
```
Java-ID = { fullselect | order-by-clause | optimize-for-clause | isolation-clause | queryno-clause | fetch-first-clause | iterator-conversion-clause }
```

Description
- **Java-ID**: Identifies an iterator that was declared previously as an instance of an iterator class.
- **fullselect**: Generates a result table.
- **iterator-conversion-clause**: See "SQLJ iterator-conversion-clause" for a description of this clause.

Usage notes
- If the object that is identified by *Java-ID* is a positioned iterator, the number of columns in the result set must match the number of columns in the iterator. In addition, the data type of each column in the result set must be compatible with the data type of the corresponding column in the iterator. See "Java, JDBC, and SQL data types" for a list of compatible Java and SQL data types.
- If the object that is identified by *Java-ID* is a named iterator, the name of each accessor method must match, except for case, the name of a column in the result set. In addition, the data type of the object that an accessor method returns must be compatible with the data type of the corresponding column in the result set.
- You can put an assignment clause anywhere in a Java program that a Java assignment statement can appear. However, you cannot put an assignment clause where a Java assignment expression can appear. For example, you cannot specify an assignment clause in the control list of a for statement.

“SQLJ iterator-conversion-clause”

SQLJ iterator-conversion-clause
The iterator conversion clause converts a JDBC ResultSet to an iterator.

Syntax
```
CAST host-expression
```
**Description**

`host-expression`  
Identifies the JDBC ResultSet that is to be converted to an SQLJ iterator.

**Usage notes**

- If the iterator to which the JDBC ResultSet is to be converted is a positioned iterator, the number of columns in the ResultSet must match the number of columns in the iterator. In addition, the data type of each column in the ResultSet must be compatible with the data type of the corresponding column in the iterator.
- If the iterator is a named iterator, the name of each accessor method must match, except for case, the name of a column in the ResultSet. In addition, the data type of the object that an accessor method returns must be compatible with the data type of the corresponding column in the ResultSet.
- When an iterator that is generated through the iterator conversion clause is closed, the ResultSet from which the iterator is generated is also closed.

**Interfaces and classes in the sqlj.runtime package**

The `sqlj.runtime` package defines the run-time classes and interfaces that are used directly or indirectly by the SQLJ programmer.

Classes such as `AsciiStream` are used directly by the SQLJ programmer. Interfaces such as `ResultSetIterator` are implemented as part of generated class declarations.

**sqlj.runtime interfaces**

The following table summarizes the interfaces in `sqlj.runtime`.

<table>
<thead>
<tr>
<th>Interface name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectionContext</td>
<td>Manages the SQL operations that are performed during a connection to a data source.</td>
</tr>
<tr>
<td>ForUpdate</td>
<td>Implemented by iterators that are used in a positioned UPDATE or DELETE statement.</td>
</tr>
<tr>
<td>NamedIterator</td>
<td>Implemented by iterators that are declared as named iterators.</td>
</tr>
<tr>
<td>PositionedIterator</td>
<td>Implemented by iterators that are declared as positioned iterators.</td>
</tr>
<tr>
<td>ResultSetIterator</td>
<td>Implemented by all iterators to allow query results to be processed using a JDBC ResultSet.</td>
</tr>
<tr>
<td>Scrollable</td>
<td>Provides a set of methods for manipulating scrollable iterators.</td>
</tr>
</tbody>
</table>

**sqlj.runtime classes**

The following table summarizes the classes in `sqlj.runtime`.

<table>
<thead>
<tr>
<th>Class name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>AsciiStream</td>
<td>A class for handling an input stream whose bytes should be interpreted as ASCII.</td>
</tr>
<tr>
<td>BinaryStream</td>
<td>A class for handling an input stream whose bytes should be interpreted as binary.</td>
</tr>
</tbody>
</table>
Table 106. Summary of sqlj.runtime classes (continued)

<table>
<thead>
<tr>
<th>Class name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>CharacterStream</td>
<td>A class for handling an input stream whose bytes should be interpreted as Character.</td>
</tr>
<tr>
<td>DefaultRuntime</td>
<td>Implemented by SQLJ to satisfy the expected runtime behavior of SQLJ for most JVM environments. This class is for internal use only and is not described in this documentation.</td>
</tr>
<tr>
<td>ExecutionContext</td>
<td>Implemented when an SQLJ execution context is declared, to control the execution of SQL operations.</td>
</tr>
<tr>
<td>Indicator</td>
<td>Defines constants for indicator variable values.</td>
</tr>
<tr>
<td>RuntimeContext</td>
<td>Defines system-specific services that are provided by the runtime environment. This class is for internal use only and is not described in this documentation.</td>
</tr>
<tr>
<td>SQLNullException</td>
<td>Derived from the java.sql.SQLException class. An sqlj.runtime.SQLNullException is thrown when an SQL NULL value is fetched into a host identifier with a Java primitive type.</td>
</tr>
<tr>
<td>StreamWrapper</td>
<td>Wraps a java.io.InputStream instance.</td>
</tr>
<tr>
<td>UnicodeStream</td>
<td>A class for handling an input stream whose bytes should be interpreted as Unicode.</td>
</tr>
</tbody>
</table>

**sqlj.runtime.ConnectionContext interface**

The sqlj.runtime.ConnectionContext interface provides a set of methods that manage SQL operations that are performed during a session with a specific data source.

Translation of an SQLJ connection declaration clause causes SQLJ to create a connection context class. A connection context object maintains a JDBC Connection object on which dynamic SQL operations can be performed. A connection context object also maintains a default ExecutionContext object.

**Variables**

**CLOSE_CONNECTION**

Format:
```
public static final boolean CLOSE_CONNECTION=true;
```

A constant that can be passed to the close method. It indicates that the underlying JDBC Connection object should be closed.

**KEEP_CONNECTION**

Format:
```
public static final boolean KEEP_CONNECTION=false;
```

A constant that can be passed to the close method. It indicates that the underlying JDBC Connection object should not be closed.

**Methods**

**close()**

Format:
```
public abstract void close() throws SQLException
```

Performs the following functions:
- Releases all resources that are used by the given connection context object
- Closes any open ConnectedProfile objects
close() is equivalent to close(CLOSE_CONNECTION).

close(boolean)
Format:
public abstract void close (boolean close-connection) throws SQLException

Performs the following functions:
• Releases all resources that are used by the given connection context object
• Closes any open ConnectedProfile objects
• Closes the underlying JDBC Connection object, depending on the value of the close-connection parameter

Parameters:

close-connection
Specifies whether the underlying JDBC Connection object is closed when a connection context object is closed:

CLOSE_CONNECTION
Closes the underlying JDBC Connection object.

KEEP_CONNECTION
Does not close the underlying JDBC Connection object.

getConnectedProfile
Format:
public abstract ConnectedProfile getConnectedProfile(Object profileKey) throws SQLException

This method is used by code that is generated by the SQLJ translator. It is not intended for direct use by application programs.

getConnection
Format:
public abstract Connection getConnection()

Returns the underlying JDBC Connection object for the given connection context object.

getExecutionContext
Format:
public abstract ExecutionContext getExecutionContect()

Returns the default ExecutionContext object that is associated with the given connection context object.

isClosed
Format:
public abstract boolean isClosed()

Returns true if the given connection context object has been closed. Returns false if the connection context object has not been closed.
Constructors

The following constructors are defined in a concrete implementation of the ConnectionContext interface that results from translation of the statement #sql
context Ctx:

_ctx(String, boolean)_
Format:
    public Ctx(String url, boolean autocommit)
    throws SQLException

Parameters:

url
    The representation of a data source, as specified in the JDBC getConnection method.

autocommit
    Whether autocommit is enabled for the connection. A value of true means that autocommit is enabled. A value of false means that autocommit is disabled.

_ctx(String, String, String, boolean)_
Format:
    public Ctx(String url, String user, String password, boolean autocommit)
    throws SQLException

Parameters:

url
    The representation of a data source, as specified in the JDBC getConnection method.

user
    The user ID under which the connection to the data source is made.

password
    The password for the user ID under which the connection to the data source is made.

autocommit
    Whether autocommit is enabled for the connection. A value of true means that autocommit is enabled. A value of false means that autocommit is disabled.

_ctx(String, Properties, boolean)_
Format:
    public Ctx(String url, Properties info, boolean autocommit)
    throws SQLException

Parameters:

url
    The representation of a data source, as specified in the JDBC getConnection method.

info
    An object that contains a set of driver properties for the connection. Any of the IBM Data Server Driver for JDBC and SQLJ properties can be specified.
Whether autocommit is enabled for the connection. A value of true means that autocommit is enabled. A value of false means that autocommit is disabled.

**Ctx(Connection)**
Format:
public Ctx(java.sql.Connection JDBC-connection-object)
throws SQLException

Parameters:
JDBC-connection-object
A previously created JDBC Connection object.

If the constructor call throws an SQLException, the JDBC Connection object remains open.

**Ctx(ConnectionContext)**
Format:
public Ctx(sqlj.runtime.ConnectionContext SQLJ-connection-context-object)
throws SQLException

Parameters:
SQLJ-connection-context-object
A previously created SQLJ ConnectionContext object.

The following constructors are defined in a concrete implementation of the ConnectionContext interface that results from translation of the statement
context Ctx with (dataSource = "jdbc/TestDS");

**Ctx()**
Format:
public Ctx() throws SQLException

**Ctx(String, String)**
Format:
public Ctx(String user, String password)
throws SQLException

Parameters:
user
The user ID under which the connection to the data source is made.

password
The password for the user ID under which the connection to the data source is made.

**Ctx(Connection)**
Format:
public Ctx(java.sql.Connection JDBC-connection-object)
throws SQLException

Parameters:
JDBC-connection-object
A previously created JDBC Connection object.
If the constructor call throws an SQLException, the JDBC Connection object remains open.

**Ctx(ConnectionContext)**
Format:
public Ctx(sqlj.runtime.ConnectionContext SQLJ-connection-context-object) throws SQLException

Parameters:
**SQLJ-connection-context-object**  
A previously created SQLJ ConnectionContext object.

**Methods**

The following additional methods are generated in a concrete implementation of the ConnectionContext interface that results from translation of the statement #sql context Ctx;:

**getDefaultContext**
Format:
public static Ctx getDefaultContext()

Returns the default connection context object for the Ctx class.

**getProfileKey**
Format:
public static Object getProfileKey(sqlj.runtime.profile.Loader loader, String profileName) throws SQLException

This method is used by code that is generated by the SQLJ translator. It is not intended for direct use by application programs.

**getProfile**
Format:
public static sqlj.runtime.profile.Profile getProfile(Object key)

This method is used by code that is generated by the SQLJ translator. It is not intended for direct use by application programs.

**getTypeMap**
Format:
public static java.util.Map getTypeMap()

Returns an instance of a class that implements java.util.Map, which is the user-defined type map that is associated with the ConnectionContext. If there is no associated type map, Java null is returned.

This method is used by code that is generated by the SQLJ translator for executable clauses and iterator declaration clauses, but it can also be invoked in an SQLJ application for direct use in JDBC statements.

**setDefaultContext**
Format:
public static void Ctx setDefaultContext(Ctx default-context)

Sets the default connection context object for the Ctx class.

**Recommendation:** Do not use this method for multithreaded applications. Instead, use explicit contexts.
sqlj.runtime.ForUpdate interface

SQLJ implements the sqlj.runtime.ForUpdate interface in SQLJ programs that contain an iterator declaration clause with implements sqlj.runtime.ForUpdate.

An SQLJ program that does positioned UPDATE or DELETE operations (UPDATE...WHERE CURRENT OF or DELETE...WHERE CURRENT OF) must include an iterator declaration clause with implements sqlj.runtime.ForUpdate.

Methods

getCursorName
Format:
public abstract String getCursorName() throws SQLException

This method is used by code that is generated by the SQLJ translator. It is not intended for direct use by application programs.

sqlj.runtime.NamedIterator interface

The sqlj.runtime.NamedIterator interface is implemented when an SQLJ application executes an iterator declaration clause for a named iterator.

A named iterator includes result table column names, and the order of the columns in the iterator is not important.

An implementation of the sqlj.runtime.NamedIterator interface includes an accessor method for each column in the result table. An accessor method returns the data from its column of the result table. The name of an accessor method matches the name of the corresponding column in the named iterator.

Methods (inherited from the ResultSetIterator interface)

close
Format:
public abstract void close() throws SQLException

Releases database resources that the iterator uses.

isClosed
Format:
public abstract boolean isClosed() throws SQLException

Returns a value of true if the close method has been invoked. Returns false if the close method has not been invoked.

next
Format:
public abstract boolean next() throws SQLException

Advances the iterator to the next row. Before an instance of the next method is invoked for the first time, the iterator is positioned before the first row of the result table. next returns a value of true when a next row is available and false when all rows have been retrieved.

sqlj.runtime.PositionedIterator interface

The sqlj.runtime.PositionedIterator interface is implemented when an SQLJ application executes an iterator declaration clause for a positioned iterator.
The order of columns in a positioned iterator must be the same as the order of columns in the result table, and a positioned iterator does not include result table column names.

Methods

sqlj.runtime.PositionedIterator inherits all ResultSetIterator methods, and includes the following additional method:

**endFetch**

Format:

```java
public abstract boolean endFetch() throws SQLException
```

Returns a value of true if the iterator is not positioned on a row. Returns a value of false if the iterator is positioned on a row.

sqlj.runtime.ResultSetIterator interface

The sqlj.runtime.ResultSetIterator interface is implemented by SQLJ for all iterator declaration clauses.

An untyped iterator can be generated by declaring an instance of the sqlj.runtime.ResultSetIterator interface directly. In general, use of untyped iterators is not recommended.

Variables

**ASENSITIVE**

Format:

```java
public static final int ASENSITIVE
```

A constant that can be returned by the getSensitivity method. It indicates that the iterator is defined as ASENSITIVE.

This value is not returned by IBM Informix.

**FETCH_FORWARD**

Format:

```java
public static final int FETCH_FORWARD
```

A constant that can be used by the following methods:

- Set by sqlj.runtime.Scrollable.setFetchDirection and sqlj.runtime.ExecutionContext.setFetchDirection
- Returned by sqlj.runtime.ExecutionContext.getFetchDirection

It indicates that the iterator fetches rows in a result table in the forward direction, from first to last.

**FETCH_REVERSE**

Format:

```java
public static final int FETCH_REVERSE
```

A constant that can be used by the following methods:

- Set by sqlj.runtime.Scrollable.setFetchDirection and sqlj.runtime.ExecutionContext.setFetchDirection
- Returned by sqlj.runtime.ExecutionContext.getFetchDirection

It indicates that the iterator fetches rows in a result table in the backward direction, from last to first.
This value is not returned by IBM Informix.

**FETCH_UNKNOWN**

Format:

```java
public static final int FETCH_UNKNOWN
```

A constant that can be used by the following methods:

- Set by `sqlj.runtime.Scrollable.setFetchDirection` and `sqlj.runtime.ExecutionContext.setFetchDirection`
- Returned by `sqlj.runtime.ExecutionContext.getFetchDirection`

It indicates that the iterator fetches rows in a result table in an unknown order.

This value is not returned by IBM Informix.

**INSENSITIVE**

Format:

```java
public static final int INSENSITIVE
```

A constant that can be returned by the `getSensitivity` method. It indicates that the iterator is defined as INSENSITIVE.

**SENSITIVE**

Format:

```java
public static final int SENSITIVE
```

A constant that can be returned by the `getSensitivity` method. It indicates that the iterator is defined as SENSITIVE.

This value is not returned by IBM Informix.

**Methods**

**clearWarnings**

Format:

```java
public abstract void clearWarnings() throws SQLException
```

After `clearWarnings` is called, `getWarnings` returns null until a new warning is reported for the iterator.

**close**

Format:

```java
public abstract void close() throws SQLException
```

Closes the iterator and releases underlying database resources.

**getFetchSize**

Format:

```java
synchronized public int getFetchSize() throws SQLException
```

Returns the number of rows that should be fetched by SQLJ when more rows are needed. The returned value is the value that was set by the `setFetchSize` method, or 0 if no value was set by `setFetchSize`.

**getResultSet**

Format:

```java
public abstract ResultSet ResultSet() throws SQLException
```

Returns the JDBC ResultSet object that is associated with the iterator.
getRow
Format:
synchronized public int getRow() throws SQLException

Returns the current row number. The first row is number 1, the second is number 2, and so on. If the iterator is not positioned on a row, 0 is returned.

getSensitivity
Format:
synchronized public int getSensitivity() throws SQLException

Returns the sensitivity of the iterator. The sensitivity is determined by the sensitivity value that was specified or defaulted in the with clause of the iterator declaration clause.

getWarnings
Format:
public abstract SQLWarning getWarnings() throws SQLException

Returns the first warning that is reported by calls on the iterator. Subsequent iterator warnings are be chained to this SQLWarning. The warning chain is automatically cleared each time the iterator moves to a new row.

isClosed
Format:
public abstract boolean isClosed() throws SQLException

Returns a value of true if the iterator is closed. Returns false otherwise.

next
Format:
public abstract boolean next() throws SQLException

Advances the iterator to the next row. Before next is invoked for the first time, the iterator is positioned before the first row of the result table. next returns a value of true when a next row is available and false when all rows have been retrieved.

setFetchSize
Format:
synchronized public void setFetchSize(int number-of-rows) throws SQLException

Gives SQLJ a hint as to the number of rows that should be fetched when more rows are needed.

Parameters:

number-of-rows
The expected number of rows that SQLJ should fetch for the iterator that is associated with the given execution context.

If number-of-rows is less than 0 or greater than the maximum number of rows that can be fetched, an SQLException is thrown.

sqlj.runtime.Scrollable interface

sqlj.runtime.Scrollable provides methods to move around in the result table and to check the position in the result table.

Chapter 13. JDBC and SQLJ reference information 447
sqlj.runtime.Scrollable is implemented when a scrollable iterator is declared.

**Methods**

**absolute(int)**

Format:

```java
public abstract boolean absolute (int n) throws SQLException
```

Moves the iterator to a specified row.

If \( n > 0 \), positions the iterator on row \( n \) of the result table. If \( n < 0 \), and \( m \) is the number of rows in the result table, positions the iterator on row \( m + n + 1 \) of the result table.

If the absolute value of \( n \) is greater than the number of rows in the result table, positions the cursor after the last row if \( n \) is positive, or before the first row if \( n \) is negative.

absolute(0) is the same as beforeFirst(). absolute(1) is the same as first(). absolute(-1) is the same as last().

Returns true if the iterator is on a row. Otherwise, returns false.

**afterLast()**

Format:

```java
public abstract void afterLast() throws SQLException
```

Moves the iterator after the last row of the result table.

**beforeFirst()**

Format:

```java
public abstract void beforeFirst() throws SQLException
```

Moves the iterator before the first row of the result table.

**first()**

Format:

```java
public abstract boolean first() throws SQLException
```

Moves the iterator to the first row of the result table.

Returns true if the iterator is on a row. Otherwise, returns false.

**getFetchDirection()**

Format:

```java
public abstract int getFetchDirection() throws SQLException
```

Returns the fetch direction of the iterator. Possible values are:

- `sqlj.runtime.ResultSetIterator.FETCH_FORWARD`
  
  Rows are processed in a forward direction, from first to last.

- `sqlj.runtime.ResultSetIterator.FETCH_REVERSE`
  
  Rows are processed in a backward direction, from last to first.

- `sqlj.runtime.ResultSetIterator.FETCH_UNKNOWN`
  
  The order of processing is not known.

**isAfterLast()**

Format:

```java
public abstract boolean isAfterLast() throws SQLException
```
Returns true if the iterator is positioned after the last row of the result table. Otherwise, returns false.

**isBeforeFirst()**
Format:
```java
public abstract boolean isBeforeFirst() throws SQLException
```
Returns true if the iterator is positioned before the first row of the result table. Otherwise, returns false.

**isFirst()**
Format:
```java
public abstract boolean isFirst() throws SQLException
```
Returns true if the iterator is positioned on the first row of the result table. Otherwise, returns false.

**isLast()**
Format:
```java
public abstract boolean isLast() throws SQLException
```
Returns true if the iterator is positioned on the last row of the result table. Otherwise, returns false.

**last()**
Format:
```java
public abstract boolean last() throws SQLException
```
Moves the iterator to the last row of the result table. Returns true if the iterator is on a row. Otherwise, returns false.

**previous()**
Format:
```java
public abstract boolean previous() throws SQLException
```
Moves the iterator to the previous row of the result table. Returns true if the iterator is on a row. Otherwise, returns false.

**relative(int)**
Format:
```java
public abstract boolean relative(int n) throws SQLException
```
If \(n>0\), positions the iterator on the row that is \(n\) rows after the current row. If \(n<0\), positions the iterator on the row that is \(n\) rows before the current row. If \(n=0\), positions the iterator on the current row.

The cursor must be on a valid row of the result table before you can use this method. If the cursor is before the first row or after the last row, the method throws an SQLException.

Suppose that \(m\) is the number of rows in the result table and \(x\) is the current row number in the result table. If \(n>0\) and \(x+n\geq m\), the iterator is positioned after the last row. If \(n<0\) and \(x+n<1\), the iterator is positioned before the first row.

Returns true if the iterator is on a row. Otherwise, returns false.

**setFetchDirection(int)**
Format:
public abstract void setFetchDirection (int) throws SQLException

Gives the SQLJ runtime environment a hint as to the direction in which rows of this iterator object are processed. Possible values are:

- `sqlj.runtime.ResultSetIterator.FETCH_FORWARD`
  Rows are processed in a forward direction, from first to last.
- `sqlj.runtime.ResultSetIterator.FETCH_REVERSE`
  Rows are processed in a backward direction, from last to first.
- `sqlj.runtime.ResultSetIterator.FETCH_UNKNOWN`
  The order of processing is not known.

### `sqlj.runtime.AsciiStream` class

The `sqlj.runtime.AsciiStream` class is for an input stream of ASCII data with a specified length.

The `sqlj.runtime.AsciiStream` class is derived from the `java.io.InputStream` class, and extends the `sqlj.runtime.StreamWrapper` class. SQLJ interprets the bytes in an `sqlj.runtime.AsciiStream` object as ASCII characters. An `InputStream` object with ASCII characters needs to be passed as a `sqlj.runtime.AsciiStream` object.

#### Constructors

- **AsciiStream(InputStream)**
  Format:
  ```java
  public AsciiStream(java.io.InputStream input-stream)
  ```
  Creates an ASCII `java.io.InputStream` object with an unspecified length.
  Parameters:
  - `input-stream`
    The `InputStream` object that SQLJ interprets as an `AsciiStream` object.

- **AsciiStream(InputStream, int)**
  Format:
  ```java
  public AsciiStream(java.io.InputStream input-stream, int length)
  ```
  Creates an ASCII `java.io.InputStream` object with a specified length.
  Parameters:
  - `input-stream`
    The `InputStream` object that SQLJ interprets as an `AsciiStream` object.
  - `length`
    The length of the `InputStream` object that SQLJ interprets as an `AsciiStream` object.

### `sqlj.runtime.BinaryStream` class

The `sqlj.runtime.BinaryStream` class is for an input stream of binary data with a specified length.

The `sqlj.runtime.BinaryStream` class is derived from the `java.io.InputStream` class, and extends the `sqlj.runtime.StreamWrapper` class. SQLJ interprets the bytes in an `sqlj.runtime.BinaryStream` object as Binary characters. An `InputStream` object with Binary characters needs to be passed as a `sqlj.runtime.BinaryStream` object.
Constructors

**BinaryStream(InputStream)**

Format:

```java
public BinaryStream(java.io.InputStream input-stream)
```

Creates a Binary java.io.InputStream object with an unspecified length.

Parameters:

*input-stream*

The InputStream object that SQLJ interprets as a BinaryStream object.

**BinaryStream(InputStream, int)**

Format:

```java
public BinaryStream(java.io.InputStream input-stream, int length)
```

Creates a Binary java.io.InputStream object with a specified length.

Parameters:

*input-stream*

The InputStream object that SQLJ interprets as a BinaryStream object.

*length*

The length of the InputStream object that SQLJ interprets as an BinaryStream object.

**sqlj.runtime.CharacterStream class**

The sqlj.runtime.CharacterStream class is for an input stream of character data with a specified length.

The sqlj.runtime.CharacterStream class is derived from the java.io.Reader class, and extends the java.io.FilterReader class. SQLJ interprets the bytes in an sqlj.runtime.CharacterStream object as interpreted as Unicode data. A Reader object with Unicode data needs to be passed as a sqlj.runtime.CharacterStream object.

Constructors

**CharacterStream(InputStream)**

Format:

```java
public CharacterStream(java.io.Reader input-stream)
```

Creates a character java.io.Reader object with an unspecified length.

Parameters:

*input-stream*

The Reader object that SQLJ interprets as a CharacterStream object.

**CharacterStream(InputStream, int)**

Format:

```java
public CharacterStream(java.io.Reader input-stream, int length)
```

Creates a character java.io.Reader object with a specified length.

Parameters:

*input-stream*

The Reader object that SQLJ interprets as a CharacterStream object.
The length of the Reader object that SQLJ interprets as a CharacterStream object.

**Methods**

**getReader**
Format:
```
public Reader getReader()
```

Returns the underlying Reader object that is wrapped by the CharacterStream object.

**getLength**
Format:
```
public void getLength()
```

Returns the length in characters of the wrapped Reader object, as specified by the constructor or in the last call to setLength.

**setLength**
Format:
```
public void setLength (int length)
```

Sets the number of characters that are read from the Reader object when the object is passed as an input argument to an SQL operation.

Parameters:

**length**

The number of characters that are read from the Reader object.

**sqlj.runtime.ExecutionContext class**
The sqlj.runtime.ExecutionContext class is defined for execution contexts. An execution context is used to control the execution of SQL statements.

**Variables**

**ADD_BATCH_COUNT**
Format:
```
public static final int ADD_BATCH_COUNT
```

A constant that can be returned by the getUpdateCount method. It indicates that the previous statement was not executed but was added to the existing statement batch.

**AUTO_BATCH**
Format:
```
public static final int AUTO_BATCH
```

A constant that can be passed to the setBatchLimit method. It indicates that implicit batch execution should be performed, and that SQLJ should determine the batch size.

**DBDefault**
Format:
```
public static final short DBDefault=-5;
```
A constant that can be assigned to an indicator variable. It specifies that the corresponding host variable value that is passed to the data server is the default value.

**DBNonNull**
Format:
```
public static final short DBNonNull=0;
```

A constant that can be assigned to an indicator variable. It specifies that the corresponding host variable value that is passed to the data server is a non-null value.

**DBNull**
Format:
```
public static final short DBNull=-1;
```

A constant that can be assigned to an indicator variable. It specifies that the corresponding host variable value that is passed to the data server is the SQL NULL value.

**DBUnassigned**
Format:
```
public static final short DBUnassigned=-7;
```

A constant that can be assigned to an indicator variable. It specifies that no value for the corresponding host variable is passed to the data server.

**EXEC_BATCH_COUNT**
Format:
```
public static final int EXEC_BATCH_COUNT
```

A constant that can be returned from the getUpdateCount method. It indicates that a statement batch was just executed.

**EXCEPTION_COUNT**
Format:
```
public static final int EXCEPTION_COUNT
```

A constant that can be returned from the getUpdateCount method. It indicates that an exception was thrown before the previous execution completed, or that no operation has been performed on the execution context object.

**NEW_BATCH_COUNT**
Format:
```
public static final int NEW_BATCH_COUNT
```

A constant that can be returned from the getUpdateCount method. It indicates that the previous statement was not executed, but was added to a new statement batch.

**QUERY_COUNT**
Format:
```
public static final int QUERY_COUNT
```

A constant that can be passed to the setBatchLimit method. It indicates that the previous execution produced a result set.

**UNLIMITED_BATCH**
Format:
public static final int UNLIMITED_BATCH

A constant that can be returned from the getUpdateCount method. It indicates that statements should continue to be added to a statement batch, regardless of the batch size.

Constructors:

ExecutionContext

Format:
public ExecutionContext()

Creates an ExecutionContext instance.

Methods

cancel

Format:
public void cancel() throws SQLException

Cancels an SQL operation that is currently being executed by a thread that uses the execution context object. If there is a pending statement batch on the execution context object, the statement batch is canceled and cleared.

The cancel method throws an SQLException if the statement cannot be canceled.

execute

Format:
public boolean execute() throws SQLException

This method is used by code that is generated by the SQLJ translator. It is not intended for direct use by application programs.

executeBatch

Format:
public synchronized int[] executeBatch() throws SQLException

Executes the pending statement batch and returns an array of update counts. If no pending statement batch exists, null is returned. When this method is called, the statement batch is cleared, even if the call results in an exception.

Each element in the returned array can be one of the following values:

-2 This value indicates that the SQL statement executed successfully, but the number of rows that were updated could not be determined.

-3 This value indicates that the SQL statement failed.

Other integer

This value is the number of rows that were updated by the statement.

The executeBatch method throws an SQLException if a database error occurs while the statement batch executes.

executeQuery

Format:
public RTResultSet executeQuery() throws SQLException

This method is used by code that is generated by the SQLJ translator. It is not intended for direct use by application programs.
**executeUpdate**
Format:
```java
public int executeUpdate() throws SQLException
```
This method is used by code that is generated by the SQLJ translator. It is not intended for direct use by application programs.

**getBatchLimit**
Format:
```java
synchronized public int getBatchLimit()
```
Returns the number of statements that are added to a batch before the batch is implicitly executed.

The returned value is one of the following values:

- **UNLIMITED_BATCH**
  - This value indicates that the batch size is unlimited.

- **AUTO_BATCH**
  - This value indicates that the batch size is finite but unknown.

- **Other integer**
  - The current batch limit.

**getBatchUpdateCounts**
Format:
```java
public synchronized int[] getBatchUpdateCounts()
```
Returns an array that contains the number of rows that were updated by each statement that successfully executed in a batch. The order of elements in the array corresponds to the order in which statements were inserted into the batch. Returns null if no statements in the batch completed successfully.

Each element in the returned array can be one of the following values:

- **-2**
  - This value indicates that the SQL statement executed successfully, but the number of rows that were updated could not be determined.

- **-3**
  - This value indicates that the SQL statement failed.

- **Other integer**
  - This value is the number of rows that were updated by the statement.

**getFetchDirection**
Format:
```java
synchronized public int getFetchDirection() throws SQLException
```
Returns the current fetch direction for scrollable iterator objects that were generated from the given execution context. If a fetch direction was not set for the execution context, sqlj.runtime.ResultSetIterator.FETCH_FORWARD is returned.

**getFetchSize**
Format:
```java
synchronized public int getFetchSize() throws SQLException
```
Returns the number of rows that should be fetched by SQLJ when more rows are needed. This value applies only to iterator objects that were generated from the given execution context. The returned value is the value that was set by the setFetchSize method, or 0 if no value was set by setFetchSize.
getMaxFieldSize
Format:
public synchronized int getMaxFieldSize()

Returns the maximum number of bytes that are returned for any string (character, graphic, or varying-length binary) column in queries that use the given execution context. If this limit is exceeded, SQLJ discards the remaining bytes. A value of 0 means that the maximum number of bytes is unlimited.

getMaxRows
Format:
public synchronized int getMaxRows()

Returns the maximum number of rows that are returned for any query that uses the given execution context. If this limit is exceeded, SQLJ discards the remaining rows. A value of 0 means that the maximum number of rows is unlimited.

getNextResultSet()
Format:
public ResultSet getNextResultSet() throws SQLException

After a stored procedure call, returns a result set from the stored procedure.
A null value is returned if any of the following conditions are true:
• There are no more result sets to be returned.
• The stored procedure call did not produce any result sets.
• A stored procedure call has not been executed under the execution context.
When you invoke getNextResultSet(), SQLJ closes the currently-open result set and advances to the next result set.
If an error occurs during a call to getNextResultSet, resources for the current JDBC ResultSet object are released, and an SQLException is thrown. Subsequent calls to getNextResultSet return null.

getNextResultSet(int)
Formats:
public ResultSet getNextResultSet(int current)

After a stored procedure call, returns a result set from the stored procedure.
A null value is returned if any of the following conditions are true:
• There are no more result sets to be returned.
• The stored procedure call did not produce any result sets.
• A stored procedure call has not been executed under the execution context.
If an error occurs during a call to getNextResultSet, resources for the current JDBC ResultSet object are released, and an SQLException is thrown. Subsequent calls to getNextResultSet return null.
Parameters:
current
Indicates what SQLJ does with the currently open result set before it advances to the next result set:
java.sql.Statement.CLOSE_CURRENT_RESULT
   Specifies that the current ResultSet object is closed when the next
   ResultSet object is returned.

java.sql.Statement.KEEP_CURRENT_RESULT
   Specifies that the current ResultSet object stays open when the next
   ResultSet object is returned.

java.sql.Statement.CLOSE_ALL_RESULTS
   Specifies that all open ResultSet objects are closed when the next
   ResultSet object is returned.

getQueryTimeout
   Format:
   public synchronized int getQueryTimeout()

   Returns the maximum number of seconds that SQL operations that use the
given execution context object can execute. If an SQL operation exceeds the
limit, an SQLException is thrown. The returned value is the value that was set
by the setQueryTimeout method, or 0 if no value was set by setQueryTimeout.
0 means that execution time is unlimited.

getUpdateCount
   Format:
   public abstract int getUpdateCount() throws SQLException

   Returns:

   ExecutionContext.ADD_BATCH_COUNT
      If the statement was added to an existing batch.

   ExecutionContext.NEW_BATCH_COUNT
      If the statement was the first statement in a new batch.

   ExecutionContext.EXCEPTION_COUNT
      If the previous statement generated an SQLException, or no previous
      statement was executed.

   ExecutionContext.EXEC_BATCH_COUNT
      If the statement was part of a batch, and the batch was executed.

   ExecutionContext.QUERY_COUNT
      If the previous statement created an iterator object or JDBC ResultSet.

   Other integer
      If the statement was executed rather than added to a batch. This value is
      the number of rows that were updated by the statement.

getWarnings
   Format:
   public synchronized SQLWarning getWarnings()

   Returns the first warning that was reported by the last SQL operation that was
executed using the given execution context. Subsequent warnings are chained
to the first warning. If no warnings occurred, null is returned.
getWarnings is used to retrieve positive SQLCODEs.

isBatching
   Format:
   public synchronized boolean isBatching()
Returns true if batching is enabled for the execution context. Returns false if batching is disabled.

registerStatement
Format:
public RTStatement registerStatement(ConnectionContext connCtx,
Object profileKey, int stmtNdx)
throws SQLException

This method is used by code that is generated by the SQLJ translator. It is not intended for direct use by application programs.

releaseStatement
Format:
public void releaseStatement() throws SQLException

This method is used by code that is generated by the SQLJ translator. It is not intended for direct use by application programs.

setBatching
Format:
public synchronized void setBatching(boolean batching)

Parameters:

batching
Indicates whether batchable statements that are registered with the given execution context can be added to a statement batch:

true
Statements can be added to a statement batch.

false
Statements are executed individually.

setBatching affects only statements that occur in the program after setBatching is called. It does not affect previous statements or an existing statement batch.

setBatchLimit
Format:
public synchronized void setBatchLimit(int batchSize)

Sets the maximum number of statements that are added to a batch before the batch is implicitly executed.

Parameters:

batch-size
One of the following values:

ExecutionContext.UNLIMITED_BATCH
Indicates that implicit execution occurs only when SQLJ encounters a statement that is batchable but incompatible, or not batchable. Setting this value is the same as not invoking setBatchLimit.

ExecutionContext.AUTO_BATCH
Indicates that implicit execution occurs when the number of statements in the batch reaches a number that is set by SQLJ.

Positive integer
The number of statements that are added to the batch before SQLJ executes the batch implicitly. The batch might be executed before this
many statements have been added if SQLJ encounters a statement that is batchable but incompatible, or not batchable.

setBatchLimit affects only statements that occur in the program after setBatchLimit is called. It does not affect an existing statement batch.

**setFetchDirection**
Format:  
public synchronized void setFetchDirection(int direction) throws SQLException

Gives SQLJ a hint as to the current fetch direction for scrollable iterator objects that were generated from the given execution context.

Parameters:

direction
One of the following values:

- sqlj.runtime.ResultSetIterator.FETCH_FORWARD
  Rows are fetched in a forward direction. This is the default.

- sqlj.runtime.ResultSetIterator.FETCH_REVERSE
  Rows are fetched in a backward direction.

- sqlj.runtime.ResultSetIterator.FETCH_UNKNOWN
  The order of fetching is unknown.

Any other input value results in an SQLException.

**setFetchSize**
Format:  
synchronized public void setFetchSize(int number-of-rows) throws SQLException

Gives SQLJ a hint as to the number of rows that should be fetched when more rows are needed.

Parameters:

number-of-rows
The expected number of rows that SQLJ should fetch for the iterator that is associated with the given execution context.

If number-of-rows is less than 0 or greater than the maximum number of rows that can be fetched, an SQLException is thrown.

**setMaxFieldSize**
Format:  
public void setMaxFieldSize(int max-bytes)

Specifies the maximum number of bytes that are returned for any string (character, graphic, or varying-length binary) column in queries that use the given execution context. If this limit is exceeded, SQLJ discards the remaining bytes.

Parameters:

max-bytes
The maximum number of bytes that SQLJ should return from a BINARY, VARBINARY, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC column. A value of 0 means that the number of bytes is unlimited. 0 is the default.
**setMaxRows**

Format:
```
public synchronized void setMaxRows(int max-rows)
```

Specifies the maximum number of rows that are returned for any query that uses the given execution context. If this limit is exceeded, SQLJ discards the remaining rows.

When `setMaxRows` is invoked at run time on a statically executed SELECT statement, `setMaxRows` limits the maximum number of rows in the result table through IBM Data Server Driver for JDBC and SQLJ processing only. Data server optimization that limits the number of rows in the result table does not occur unless the FETCH FIRST n ROWS ONLY clause is also added to the SELECT statement. If FETCH FIRST n rows ONLY is added to the SELECT statement, and `setMaxRows(m)` is called, the maximum number of rows is the smaller of n and m. The driver discards the rest of the rows.

**Parameters:**

*max-rows*

The maximum number of rows that SQLJ should return for a query that uses the given execution context. A value of 0 means that the number of rows is unlimited. 0 is the default.

**setQueryTimeout**

Format:
```
public synchronized void setQueryTimeout(int timeout-value)
```

Specifies the maximum number of seconds that SQL operations that use the given execution context object can execute. If an SQL operation exceeds the limit, an SQLException is thrown.

For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS data servers, `setQueryTimeout` is supported only if `Connection` or `DataSource` property `queryTimeoutInterruptProcessingMode` is set to `INTERRUPT_PROCESSING_MODE_CLOSE_SOCKET`.

**Parameters:**

*timeout-value*

The maximum number of seconds that SQL operations that use the given execution context object can execute. 0 means that execution time is unlimited. 0 is the default.

**Related tasks:**

"Controlling the execution of SQL statements in SQLJ" on page 183

**sqlj.runtime.SQLNullException class**

The `sqlj.runtime.SQLNullException` class is derived from the `java.sql.SQLException` class.

An `sqlj.runtime.SQLNullException` is thrown when an SQL NULL value is fetched into a host identifier with a Java primitive type. The SQLSTATE value for an instance of `SQLNullException` is '22002'.

**sqlj.runtime.StreamWrapper class**

The `sqlj.runtime.StreamWrapper` class wraps a `java.io.InputStream` instance and extends the `java.io.InputStream` class.

Constructors

StreamWrapper(InputStream)
Format:
protected StreamWrapper(InputStream input-stream)
Creates an sqlj.runtime.StreamWrapper object with an unspecified length.
Parameters:
input-stream
The InputStream object that the sqlj.runtime.StreamWrapper object wraps.

StreamWrapper(InputStream, int)
Format:
protected StreamWrapper(java.io.InputStream input-stream, int length)
Creates an sqlj.runtime.StreamWrapper object with a specified length.
Parameters:
input-stream
The InputStream object that the sqlj.runtime.StreamWrapper object wraps.
length
The length of the InputStream object in bytes.

Methods

getInputStream
Format:
public InputStream getInputStream()
Returns the underlying InputStream object that is wrapped by the StreamWrapper object.

getLength
Format:
public void getLength()
Returns the length in bytes of the wrapped InputStream object, as specified by the constructor or in the last call to setLength.

setLength
Format:
public void setLength (int length)
Sets the number of bytes that are read from the wrapped InputStream object when the object is passed as an input argument to an SQL operation.
Parameters:
length
The number of bytes that are read from the wrapped InputStream object.
Related reference:

- “sqlj.runtime.CharacterStream class” on page 451
- “sqlj.runtime.BinaryStream class” on page 450
- “sqlj.runtime.AsciiStream class” on page 450

**sqlj.runtime.UnicodeStream class**

The sqlj.runtime.UnicodeStream class is for an input stream of Unicode data with a specified length.

The sqlj.runtime.UnicodeStream class is derived from the java.io.InputStream class, and extends the sqlj.runtime.StreamWrapper class. SQLJ interprets the bytes in an sqlj.runtime.UnicodeStream object as Unicode characters. An InputStream object with Unicode characters needs to be passed as a sqlj.runtime.UnicodeStream object.

**Constructors**

*UnicodeStream(InputStream)*

Format:

```java
public UnicodeStream(java.io.InputStream input-stream)
```

Creates a Unicode java.io.InputStream object with an unspecified length.

Parameters:

*input-stream*

The InputStream object that SQLJ interprets as an UnicodeStream object.

*UnicodeStream(InputStream, int)*

Format:

```java
public UnicodeStream(java.io.InputStream input-stream, int length)
```

Creates a Unicode java.io.InputStream object with a specified length.

Parameters:

*input-stream*  
The InputStream object that SQLJ interprets as an UnicodeStream object.

*length*  
The length of the InputStream object that SQLJ interprets as an UnicodeStream object.

---

**IBM Data Server Driver for JDBC and SQLJ extensions to JDBC**

The IBM Data Server Driver for JDBC and SQLJ provides a set of extensions to the support that is provided by the JDBC specification.
To use IBM Data Server Driver for JDBC and SQLJ-only methods in classes that have corresponding, standard classes, cast an instance of the related, standard JDBC class to an instance of the IBM Data Server Driver for JDBC and SQLJ-only class. For example:

```java
javax.sql.DataSource ds =
    new com.ibm.db2.jcc.DB2SimpleDataSource();
((com.ibm.db2.jcc.DB2BaseDataSource) ds).setServerName("sysmvs1.stl.ibm.com");
```

Table 107 summarizes the IBM Data Server Driver for JDBC and SQLJ-only interfaces.

**Table 107. Summary of IBM Data Server Driver for JDBC and SQLJ-only interfaces provided by the IBM Data Server Driver for JDBC and SQLJ**

<table>
<thead>
<tr>
<th>Interface name</th>
<th>Applicable data sources</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2CallableStatement</td>
<td>1 2</td>
<td>Extends the java.sql.CallableStatement and the com.ibm.db2.jcc.DB2PreparedStatement interfaces.</td>
</tr>
<tr>
<td>DB2Connection</td>
<td>1 2 3</td>
<td>Extends the java.sql.Connection interface.</td>
</tr>
<tr>
<td>DB2DatabaseMetaData</td>
<td>1 2 3</td>
<td>Extends the java.sql.DatabaseMetaData interface.</td>
</tr>
<tr>
<td>DB2Diagnosable</td>
<td>1 2 3</td>
<td>Provides a mechanism for getting DB2 diagnostics from a DB2 SQLException.</td>
</tr>
<tr>
<td>DB2ParameterMetaData</td>
<td>2</td>
<td>Extends the java.sql.ParameterMetaData interface.</td>
</tr>
<tr>
<td>DB2ResultSet</td>
<td>1 2 3</td>
<td>Extends the java.sql.ResultSet interface.</td>
</tr>
<tr>
<td>DB2RowID</td>
<td>1 2</td>
<td>Used for declaring Java objects for use with the ROWID data type.</td>

SQLCA (SQL communications area)

DBBatchUpdateException interface

The com.ibm.db2.jcc.DBBatchUpdateException interface is used for retrieving error information about batch execution of statements that return automatically generated keys.

DBBatchUpdateException methods

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

getDBGeneratedKeys

Format:
public java.sql.ResultSet[] getDBGeneratedKeys()
throws java.sql.SQLException

Retrieves automatically generated keys that were created when INSERT statements were executed in a batch. Each ResultSet object that is returned contains the automatically generated keys for a single statement in the batch. ResultSet objects that are null correspond to failed statements.

DB2Administrator class

Instances of the com.ibm.db2.jcc.DB2Administrator class are used to retrieve DB2CataloguedDatabase objects. DB2Administrator applies to DB2 for Linux, UNIX, and Windows databases only.

DB2Administrator methods

gGetInstance

Format:
public static DB2Administrator getInstance()

Returns an instance of the DB2Administrator class.

gGetCataloguedDatabases

Format:
public DB2CataloguedDatabase[] getCataloguedDatabases()
throws java.sql.SQLException

Retrieves an array that contains a DB2CataloguedDatabase object for each local database in the local database directory.

If a local DB2 system is available, and the catalog contains no databases, an array with length zero is returned. If no local DB2 system is available, null is returned. If the local system is not a DB2 for Linux, UNIX, and Windows system, an SQLException is thrown.

DB2BaseDataSource class

The com.ibm.db2.jcc.DB2BaseDataSource class is the abstract data source parent class for all IBM Data Server Driver for JDBC and SQLJ-specific implementations of javax.sql.DataSource, javax.sql.ConnectionPoolDataSource, and javax.sql.XADataSource.

DB2BaseDataSource implements the java.sql.Wrapper interface.
**DB2BaseDataSource properties**

The following properties are defined only for the IBM Data Server Driver for JDBC and SQLJ.

You can set all properties on a DataSource or in the `url` parameter in a `DriverManager.getConnection` call.

All properties except the following properties have a `setXXX` method to set the value of the property and a `getXXX` method to retrieve the value:
- `dumpPool`
- `dumpPoolStatisticsOnSchedule`
- `dumpPoolStatisticsOnScheduleFile`
- `maxTransportObjectIdleTime`
- `maxTransportObjectWaitTime`
- `minTransportObjects`

A `setXXX` method has this form:

```java
void setProperty-name(data-type property-value)
```

A `getXXX` method has this form:

```java
data-type getProperty-name()
```

*Property-name* is the unqualified property name. For properties that are not specific to IBM Informix, the first character of the property name is capitalized. For properties that are used only by IBM Informix, all characters of the property name are capitalized.

The following table lists the IBM Data Server Driver for JDBC and SQLJ properties and their data types.

<table>

</table>

**Note:** The property applies to connections to the following data sources:
1. DB2 for z/OS
2. DB2 for Linux, UNIX, and Windows
3. IBM Informix

### DB2BaseDataSource fields

The following constants are defined only for the IBM Data Server Driver for JDBC and SQLJ.

**public final static int IMPLICIT_ROLLBACK_OPTION_NOT_SET = 0**

A constant for the implicitRollbackOption property. This value indicates that a connection is not closed when a deadlock or timeout occurs. This value causes the same behavior as `IMPLICIT_ROLLBACK_OPTION_NOT_CLOSE_CONNECTION`.

**public final static int IMPLICIT_ROLLBACK_OPTION_NOT_CLOSE_CONNECTION = 1**

A constant for the implicitRollbackOption property. This value indicates that a connection is not closed when a deadlock or timeout occurs. The IBM Data Server Driver for JDBC and SQLJ returns the error code that the data server generates for a deadlock or timeout.

**public final static int IMPLICIT_ROLLBACK_OPTION_CLOSE_CONNECTION = 2**

A constant for the implicitRollbackOption property. This value indicates that a connection is closed when a deadlock or timeout occurs.

**public final static int INTERRUPT_PROCESSING_MODE_DISABLED = 0**

A constant for the interruptProcessingMode property. This value indicates that interrupt processing is disabled.

**public final static int INTERRUPT_PROCESSING_MODE_STATEMENT_CANCEL = 1**

A constant for the interruptProcessingMode property. This value indicates that the IBM Data Server Driver for JDBC and SQLJ cancels the currently executing statement when an application executes Statement.cancel, if the data server supports interrupt processing.

**public final static int INTERRUPT_PROCESSING_MODE_CLOSE_SOCKET = 2**

A constant for the interruptProcessingMode property. This value indicates that the IBM Data Server Driver for JDBC and SQLJ drops the underlying socket and closes the connection when an application executes Statement.cancel.

**public final static int NOT_SET = 0**

The default value for properties.

**public final static int YES = 1**

The YES value for properties.

**public final static int NO = 2**

The NO value for properties.
public final static int QUERYTIMEOUT_DISABLED = -1
A constant for the timerLevelForQueryTimeOut property. This value indicates
that Timer objects for waiting for queries to time out are not created.

public final static int QUERYTIMEOUT_STATEMENT_LEVEL = 1
A constant for the timerLevelForQueryTimeOut property. This value indicates
that Timer objects for waiting for queries to time out are created at the
Statement level.

public final static int QUERYTIMEOUT_CONNECTION_LEVEL = 2
A constant for the timerLevelForQueryTimeOut property. This value indicates
that Timer objects for waiting for queries to time out are created at the
Connection level.

public final static int TRACE_OPTION_CIRCULAR = 1
A constant for the traceOption property. This value indicates that the IBM Data
Server Driver for JDBC and SQLJ uses circular tracing.

**DB2BaseDataSource methods**

In addition to the getXXX and setXXX methods for the DB2BaseDataSource
properties, the following methods are defined only for the IBM Data Server Driver
for JDBC and SQLJ.

**getReference**
Format:
```java
public javax.naming.Reference getReference()
throws javax.naming.NamingException
```

Retrieves the Reference of a DataSource object. For an explanation of a
Reference, see the description of javax.naming.Referenceable in the Java

**Related reference:**
"[Properties for the IBM Data Server Driver for JDBC and SQLJ]" on page 326

**DB2CallableStatement interface**

The com.ibm.db2.jcc.DB2CallableStatement interface extends the
java.sql.CallableStatement and the com.ibm.db2.jcc.DB2PreparedStatement
interfaces.

**DB2CallableStatement methods**

The following methods are defined only for the IBM Data Server Driver for JDBC
and SQLJ.

**getDBTimestamp**
Formats:
```java
public DBTimestamp getDBTimestamp(int parameterIndex)
throws SQLException
```

```java
public DBTimestamp getDBTimestamp(String parameterName)
throws SQLException
```

Returns the value of a TIMESTAMP OUT or INOUT parameter as a
DBTimestamp object. If the value of the parameter is NULL, the returned value
is null.

Parameters:
**parameterIndex**
The number of the parameter whose value is being retrieved.

**parameterName**
The name of the parameter whose value is being retrieved.

This method is not supported for connections to IBM Informix.

**getJccArrayAtName**
Format:
```
public java.sql.Array getJccArrayAtName(String parameterMarkerName)
  throws java.sql.SQLException
```
Retrieves an ARRAY value that is designated by a named parameter marker as a java.sql.Array value.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

**parameterMarkerName**
The name of the parameter marker for which a value is retrieved.

**getJccBigDecimalAtName**
Format:
```
public java.math.BigDecimal getJccBigDecimalAtName(String parameterMarkerName)
  throws java.sql.SQLException

public java.math.BigDecimal getJccBigDecimalAtName(String parameterMarkerName, int scale)
  throws java.sql.SQLException
```
Retrieves a DECIMAL value that is designated by a named parameter marker as a java.math.BigDecimal value.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

**parameterMarkerName**
The name of the parameter marker for which a value is retrieved.

**scale**
The scale of the value that is retrieved.

**getJccBlobAtName**
Formats:
```
public java.sql.Blob getJccBlobAtName(String parameterMarkerName)
  throws java.sql.SQLException
```
Retrieves a BLOB value that is designated by a named parameter marker as a java.sql.Blob value.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

**parameterMarkerName**
The name of the parameter marker for which a value is retrieved.

**getJccBooleanAtName**
Format:
public boolean getJccBooleanAtName(String parameterMarkerName)
    throws java.sql.SQLException

Retrieves a BIT or BOOLEAN value that is designated by a named parameter marker as a boolean value.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

    parameterMarkerName
    The name of the parameter marker for which a value is retrieved.

getJccByteAtName
Format:
public byte getJccByteAtName(String parameterMarkerName)
    throws java.sql.SQLException

Retrieves a TINYINT value that is designated by a named parameter marker as a byte value.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

    parameterMarkerName
    The name of the parameter marker for which a value is retrieved.

getJccBytesAtName
Format:
public byte[] getJccBytesAtName(String parameterMarkerName)
    throws java.sql.SQLException

Retrieves a BINARY or VARBINARY value that is designated by a named parameter marker as an array of byte values.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

    parameterMarkerName
    The name of the parameter marker for which a value is retrieved.

getJccClobAtName
Format:
public java.sql.Blob getJccClobAtName(String parameterMarkerName)
    throws java.sql.SQLException

Retrieves a CLOB value that is designated by a named parameter marker as a java.sql.Clob value.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

    parameterMarkerName
    The name of the parameter marker for which a value is retrieved.

getJccDateAtName
Format:

public java.sql.Date getJccDateAtName(String parameterMarkerName)
    throws java.sql.SQLException
public java.sql.Date getJccDateAtName(String parameterMarkerName, java.util.Calendar cal)
    throws java.sql.SQLException

Retrieves a DATE value that is designated by a named parameter marker as a java.sql.Date value.
This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

parameterMarkerName
The name of the parameter marker for which a value is retrieved.

cal
The java.util.Calendar object that the IBM Data Server Driver for JDBC and SQLJ uses to construct the date.

getJccDoubleAtName
Format:
public double getJccDoubleAtName(String parameterMarkerName)
    throws java.sql.SQLException

Retrieves a DOUBLE value that is designated by a named parameter marker as a double value.
This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

parameterMarkerName
The name of the parameter marker for which a value is retrieved.

getJccFloatAtName
Format:
public double getJccFloatAtName(String parameterMarkerName)
    throws java.sql.SQLException

Retrieves a FLOAT value that is designated by a named parameter marker as a double value.
This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

parameterMarkerName
The name of the parameter marker for which a value is retrieved.

getJccIntAtName
Format:
public int getJccIntAtName(String parameterMarkerName)
    throws java.sql.SQLException

Retrieves a INTEGER value that is designated by a named parameter marker as a int value.
This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).
Parameters:

`parameterMarkerName`

The name of the parameter marker for which a value is retrieved.

**getJccLongAtName**

Format:

```java
public long getJccLongAtName(String parameterMarkerName)
throws java.sql.SQLException
```

Retrieves a BIGINT value that is designated by a named parameter marker as a long value.

This method can be called only if the enableNamedParameterMarkers property is set to `DB2BaseDataSource.YES` (1).

Parameters:

`parameterMarkerName`

The name of the parameter marker for which a value is retrieved.

**getJccObjectAtName**

Formats:

```java
public java.sql.Object getJccObjectAtName(String parameterMarkerName)
throws java.sql.SQLException
```

```java
public java.sql.Object getJccObjectAtName(String parameterMarkerName, Map map)
throws java.sql.SQLException
```

Retrieves a value that is designated by a named parameter marker as a `java.sql.Object` value.

This method can be called only if the enableNamedParameterMarkers property is set to `DB2BaseDataSource.YES` (1).

Parameters:

`parameterMarkerName`

The name of the parameter marker for which a value is retrieved.

`map`

The mapping from SQL type names to Java classes.

**getJccRowIdAtName**

Format:

```java
public java.sql.RowId getJccRowIdAtName(String parameterMarkerName)
throws java.sql.SQLException
```

Retrieves a ROWID value that is designated by a named parameter marker as a `java.sql.RowId` value.

This method can be called only if the enableNamedParameterMarkers property is set to `DB2BaseDataSource.YES` (1).

This method requires the IBM Data Server Driver for JDBC and SQLJ Version 4.8 or later.

Parameters:

`parameterMarkerName`

The name of the parameter marker for which a value is retrieved.

**getJccShortAtName**

Format:
public short getJccShortAtName(String parameterMarkerName)
   throws java.sql.SQLException

Retrieves a SMALLINT value that is designated by a named parameter marker as a short value.
This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).
Parameters:
   parameterMarkerName
       The name of the parameter marker for which a value is retrieved.

getJccSQLXMLAtName
Format:
public java.sql.SQLXML getJccSQLXMLAtName(String parameterMarkerName)
   throws java.sql.SQLException

Retrieves a SQLXML value that is designated by a named parameter marker as a java.sql.SQLXML value.
This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).
This method requires the IBM Data Server Driver for JDBC and SQLJ Version 4.8 or later.
Parameters:
   parameterMarkerName
       The name of the parameter marker for which a value is retrieved.

getJccStringAtName
Format:
public java.lang.String getJccStringAtName(String parameterMarkerName)
   throws java.sql.SQLException

Retrieves a CHAR, VARCHAR, or LONGVARCHAR value that is designated by a named parameter marker as a java.lang.String value.
This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).
Parameters:
   parameterMarkerName
       The name of the parameter marker for which a value is retrieved.

getJccTimeAtName
Formats:
public java.sql.Time getJccTimeAtName(String parameterMarkerName)
   throws java.sql.SQLException
public java.sql.Time getJccTimeAtName(String parameterMarkerName,
   java.util.Calendar cal)
   throws java.sql.SQLException

Retrieves a TIME value that is designated by a named parameter marker as a java.sql.Time value.
This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).
Parameters:
**getJccTimestampAtName**

Formats:

```java
public java.sql.Timestamp getJccTimestampAtName(String parameterMarkerName)
    throws java.sql.SQLException
public java.sql.Timestamp getJccTimestampAtName(String parameterMarkerName,
    java.util.Calendar cal)
    throws java.sql.SQLException
```

Retrieves a TIMESTAMP value that is designated by a named parameter marker as a java.sql.Timestamp value.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

- **parameterMarkerName**: The name of the parameter marker for which a value is retrieved.
- **cal**: The java.util.Calendar object that the IBM Data Server Driver for JDBC and SQLJ uses to construct the time.

---

**registerJccOutParameterAtName**

Formats:

```java
public void registerJccOutParameterAtName(String parameterMarkerName, int sqlType)
    throws java.sql.SQLException
public void registerJccOutParameterAtName(String parameterMarkerName, int sqlType, int scale)
    throws java.sql.SQLException
public void registerJccOutParameterAtName(String parameterMarkerName, int sqlType, String typeName)
    throws java.sql.SQLException
```

Registers an OUT parameter that is identified by `parameterMarkerName` as the JDBC type `sqlType`.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

- **parameterMarkerName**: The name of the parameter marker for the parameter that is to be registered.
- **sqlType**: The JDBC type code, as defined in java.sql.Types, of the parameter that is to be registered.
- **scale**: The scale of the parameter that is to be registered. This parameter applies only to this case.
If sqlType is java.sql.Types.DECIMAL or java.sql.Types.NUMERIC, scale is the number of digits to the right of the decimal point.

typeName
If jdbcType is java.sql.Types.DISTINCT or java.sql.Types.REF, the fully-qualified name of the SQL user-defined type of the parameter that is to be registered.

setDBTimestamp
Format:
public void setDBTimestamp(String parameterName, DBTimestamp timestamp) throws java.sql.SQLException

Assigns a DBTimestamp value to an IN or INOUT parameter.
Parameters:

parameterName
The name of the parameter to which a DBTimestamp variable value is assigned.

timestamp
The DBTimestamp value that is assigned to the parameter.

This method is not supported for connections to IBM Informix.

setJccXXXAtName methods
These methods are inherited from DB2PreparedStatement.

DB2CataloguedDatabase class
The com.ibm.db2.jcc.DB2CataloguedDatabase class contains methods that retrieve information about a local DB2 for Linux, UNIX, and Windows database.

No database connection is needed for calling DB2CataloguedDatabase methods.

DB2CataloguedDatabase methods

getServerName
Format:
public String getServerName()

Retrieves the name of the server on which the database resides.

getPortNumber
Format:
public int getPortNumber()

Retrieves the port number that is associated with the DB2 instance.

getDatabaseName
Format:
public String getDatabaseName()

Retrieves the database name.

getDatabaseAlias
Format:
public String getDatabaseAlias()
Retrieves the database alias.

**DB2ClientRerouteServerList class**

The com.ibm.db2.jcc.DB2ClientRerouteServerList class implements the java.io.Serializable and javax.naming.Referenceable interfaces.

**DB2ClientRerouteServerList methods**

- **getAlternatePortNumber**
  Format:
  ```java
  public int[] getAlternatePortNumber()
  ```
  Retrieves the port numbers that are associated with the alternate servers.

- **getAlternateServerName**
  Format:
  ```java
  public String[] getAlternateServerName()
  ```
  Retrieves an array that contains the names of the alternate servers. These values are IP addresses or DNS server names.

- **getPrimaryPortNumber**
  Format:
  ```java
  public int getPrimaryPortNumber()
  ```
  Retrieves the port number that is associated with the primary server.

- **getPrimaryServerName**
  Format:
  ```java
  public String[] getPrimaryServerName()
  ```
  Retrieves the name of the primary server. This value is an IP address or a DNS server name.

- **setAlternatePortNumber**
  Format:
  ```java
  public void setAlternatePortNumber(int[] alternatePortNumberList)
  ```
  Sets the port numbers that are associated with the alternate servers.

- **setAlternateServerName**
  Format:
  ```java
  public void setAlternateServerName(String[] alternateServer)
  ```
  Sets the alternate server names for servers. These values are IP addresses or DNS server names.

- **setPrimaryPortNumber**
  Format:
  ```java
  public void setPrimaryPortNumber(int primaryPortNumber)
  ```
  Sets the port number that is associated with the primary server.

- **setPrimaryServerName**
  Format:
  ```java
  public void setPrimaryServerName(String primaryServer)
  ```
Sets the primary server name for a server. This value is an IP address or a DNS server name.

Related concepts:
Chapter 9, “Java client support for high availability on IBM data servers,” on page 285

DB2Connection interface
The com.ibm.db2.jcc.DB2Connection interface extends the java.sql.Connection interface.

DB2Connection implements the java.sql.Wrapper interface.

DB2Connection methods
The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

alternateWasUsedOnConnect
Format:
public boolean alternateWasUsedOnConnect()
  throws java.sql.SQLException

Returns true if the driver used alternate server information to obtain the connection. The alternate server information is available in the transient clientRerouteServerList information on the DB2BaseDataSource, which the database server updates as primary and alternate servers change.

changeDB2Password
Format:
public abstract void changeDB2Password(String oldPassword,
  String newPassword)
  throws java.sql.SQLException

Changes the password for accessing the data source, for the user of the Connection object.

Parameter descriptions:
oldPassword
  The original password for the Connection.

newPassword
  The new password for the Connection.

createArrayOf
Format:
Array createArrayOf(String typeName,
  Object[] elements)
  throws SQLException;

Creates a java.sql.Array object.

Parameter descriptions:
typeName
  The SQL data type of the elements of the array map to. typeName can be a built-in data type or a distinct type.

elements
  The elements that populate the Array object.
**createStruct**

Format:

```java
Struct createStruct(String type, 
Object[] attributes)
throws SQLException;
```

Returns a java.sql.Struct object that maps to `typeName` and has the attributes that are specified by `attributes`.

Parameter descriptions:

- **typeName**
  - The SQL data type of the SQL structured type that the Struct object maps to. `typeName` is the name of a user-defined type that has been defined on the data server.

- **attributes**
  - The attributes that populate the returned Struct object.

**deregisterDB2XmlObject**

Formats:

```java
public void deregisterDB2XmlObject(String sqlIdSchema, 
String sqlIdName)
throws SQLException
```

Removes a previously registered XML schema from the data source.

Parameter descriptions:

- **sqlIdSchema**
  - The SQL schema name for the XML schema. `sqlIdSchema` is a String value with a maximum length of 128 bytes. The value of `sqlIdSchema` must conform to the naming rules for any SQL schema name. The name cannot begin with the string ‘SYS’. If the value of `sqlIdSchema` is null, the database system uses the value in the CURRENT SCHEMA special register.

- **sqlIdName**
  - The SQL name for the XML schema. `sqlIdName` is a String value with a maximum length of 128 bytes. The value of `sqlIdName` must conform to the rules for an SQL identifier. If the value of `sqlIdSchema` is null, the value of `sqlIdName` can be null. In that case, the database system generates the value for `sqlIdName`.

**getDB2ClientAccountingInformation**

Format:

```java
public String getDB2ClientAccountingInformation()
throws SQLException
```

Returns accounting information for the current client.

**getDB2ClientApplicationInformation**

Format:

```java
public String getDB2ClientApplicationInformation()
throws java.sql.SQLException
```

Returns application information for the current client.
**Important:** getDB2ClientApplicationInformation is deprecated in the JDBC 4.0 implementation of the IBM Data Server Driver for JDBC and SQLJ. Use java.sql.Connection.getClientInfo instead.

getDB2ClientProgramId
Format:
```java
public String getDB2ClientProgramId()
throws java.sql.SQLException
```

Returns the user-defined program identifier for the client. The program identifier can be used to identify the application at the data source.

getDB2ClientProgramId does not apply to DB2 for Linux, UNIX, and Windows data servers.

getDB2ClientUser
Format:
```java
public String getDB2ClientUser()
throws java.sql.SQLException
```

Returns the current client user name for the connection. This name is not the user value for the JDBC connection.

**Important:** getDB2ClientUser is deprecated in the JDBC 4.0 implementation of the IBM Data Server Driver for JDBC and SQLJ. Use java.sql.Connection.getClientInfo instead.

getDB2ClientWorkstation
Format:
```java
public String getDB2ClientWorkstation()
throws java.sql.SQLException
```

Returns current client workstation name for the current client.

**Important:** getDB2ClientWorkstation is deprecated in the JDBC 4.0 implementation of the IBM Data Server Driver for JDBC and SQLJ. Use java.sql.Connection.getClientInfo instead.

getDB2Correlator
Format:
```java
String getDB2Correlator()
throws java.sql.SQLException
```

Returns the value of the crrtkn (correlation token) instance variable that DRDA sends with the ACCRDB command. The correlation token uniquely identifies a logical connection to a server.

getDB2CurrentPackagePath
Format:
```java
public String getDB2CurrentPackagePath()
throws java.sql.SQLException
```

Returns the list of DB2 package collections that are searched for JDBC and SQLJ packages.

The getDB2CurrentPackagePath method applies only to connections to DB2 database systems.

getDB2CurrentPackageSet
Format:
public String getDB2CurrentPackageSet()
    throws java.sql.SQLException

    Returns the collection ID for the connection.

    The getDB2CurrentPackageSet method applies only to connections to DB2
database systems.

getDB2ProgressiveStreaming
Format:
public int getDB2ProgressiveStreaming()
    throws java.sql.SQLException

    Returns the current progressive streaming setting for the connection.

    The returned value depends on whether the data source supports progressive
streaming, how the progressiveStreaming property is set, and whether
DB2Connection.setProgressiveStreaming was called:
• If the data source does not support progressive streaming, 2 (NO) is always
  returned, regardless of the progressiveStreaming property setting.
• If the data source supports progressive streaming, and
  DB2Connection.setProgressiveStreaming was called, the returned value is the
  value that DB2Connection.setProgressiveStreaming set.
• If the data source supports progressive streaming, and
  DB2Connection.setProgressiveStreaming was not called, the returned value is
  2 (NO) if progressiveStreaming was set to DB2BaseDataSource.NO. If
  progressiveStreaming was set to DB2BaseDataSource.YES or was not set, the
  returned value is 1 (YES).

getDB2SecurityMechanism
Format:
public int getDB2SecurityMechanism()
    throws java.sql.SQLException

    Returns the security mechanism that is in effect for the connection:
3   Clear text password security
4   User ID-only security
7   Encrypted password security
9   Encrypted user ID and password security
11  Kerberos security
12  Encrypted user ID and data security
13  Encrypted user ID, password, and data security
15  Plugin security
16  Encrypted user ID-only security

getDB2SystemMonitor
Format:
public abstract DB2SystemMonitor getDB2SystemMonitor()
    throws java.sql.SQLException

    Returns the system monitor object for the connection. Each IBM Data Server
Driver for JDBC and SQLJ connection can have a single system monitor.
**getDBConcurrentAccessResolution**
Format:
```java
public int getDBConcurrentAccessResolution()
throws java.sql.SQLException
```
Returns the concurrent access setting for the connection. The concurrent access setting is set by the setDBConcurrentAccessResolution method or by the concurrentAccessResolution property.
getDBConcurrentAccessResolution applies only to connections to DB2 for z/OS and DB2 for Linux, UNIX, and Windows.

**getDBProgressiveStreaming**
Format:
```java
public int getDB2ProgressiveStreaming()
throws java.sql.SQLException
```
Returns the current progressive streaming setting for the connection.
The returned value depends on whether the data source supports progressive streaming, how the progressiveStreaming property is set, and whether DB2Connection.setProgressiveStreaming was called:
- If the data source does not support progressive streaming, 2 (NO) is always returned, regardless of the progressiveStreaming property setting.
- If the data source supports progressive streaming, and DB2Connection.setProgressiveStreaming was called, the returned value is the value that DB2Connection.setProgressiveStreaming set.
- If the data source supports progressive streaming, and DB2Connection.setProgressiveStreaming was not called, the returned value is 2 (NO) if progressiveStreaming was set to DB2BaseDataSource.NO. If progressiveStreaming was set to DB2BaseDataSource.YES or was not set, the returned value is 1 (YES).

**getDBStatementConcentrator**
Format:
```java
public int getDBStatementConcentrator()
throws java.sql.SQLException
```
Returns the statement concentrator use setting for the connection. The statement concentrator use setting is set by the setDBStatementConcentrator method or by the statementConcentrator property.

**getJccLogWriter**
Format:
```java
public PrintWriter getJccLogWriter()
throws java.sql.SQLException
```
Returns the current trace destination for the IBM Data Server Driver for JDBC and SQLJ trace.

**getJccSpecialRegisterProperties**
Format:
```java
public java.util.Properties getJccSpecialRegisterProperties()
throws java.sql.SQLException
```
Returns a java.util.Properties object, in which the keys are the special registers that are supported at the target data source, and the key values are the current values of those special registers.
This method does not apply to connections to IBM Informix data sources.

**getSavePointUniqueOption**

Format:
```
public boolean getSavePointUniqueOption()
        throws java.sql.SQLException
```

Returns `true` if `setSavePointUniqueOption` was most recently called with a value of `true`. Returns `false` otherwise.

**installDB2JavaStoredProcedure**

Format:
```
public void DB2Connection.installDB2JavaStoredProcedure(
        java.io.InputStream jarFile,
        int jarFileLength,
        String jarId)
        throws java.sql.SQLException
```

Invokes the sqlj.install_jar stored procedure on a DB2 for Linux, UNIX, and Windows server to create a new definition of a JAR file in the catalog for that server.

Parameter descriptions:

*jarFile*

   The contents of the JAR file that is to be defined to the server.

*jarFileLength*

   The length of the JAR file that is to be defined to the server.

*jarId*

   The name of the JAR in the database, in the form `schema.JAR-id` or `JAR-id`. This is the name that you use when you refer to the JAR in SQL statements. If you omit `schema`, the database system uses the SQL authorization ID that is in the CURRENT SCHEMA special register. The owner of the JAR is the authorization ID in the CURRENT SQLID special register.

This method does not apply to connections to IBM Informix data sources.

**isDB2Alive**

Format:
```
public boolean DB2Connection.isDB2Alive()
        throws java.sql.SQLException
```

Returns `true` if the socket for a connection to the data source is still active.

**Important:** `isDB2Alive` is deprecated in the JDBC 4.0 implementation of the IBM Data Server Driver for JDBC and SQLJ. Use `Connection.isDBValid` instead.

**isDBValid**

Format:
```
public boolean DB2Connection.isDBValid(boolean throwException, int timeout)
        throws java.sql.SQLException
```

Returns `true` if the connection has not been closed and is still valid. Returns `false` otherwise.

Parameter descriptions:
throwException
Specifies whether isDBValid throws an SQLException if the connection is not valid. Possible values are:

- **true**: isDBValid throws an SQLException if the connection is not valid.
- **false**: isDBValid throws an SQLException only if the value of `timeout` is not valid.

`timeout`
The time in seconds to wait for completion of a database operation that the driver submits. The driver submits that database operation to the data source to validate the connection. If the timeout period expires before the database operation completes, isDBValid returns `false`. A value of 0 indicates that there is no timeout period for the database operation.

For IBM Data Server Driver for JDBC and SQLJ type 4 connectivity, isDBValid throws an SQLException if the value of `timeout` is less than 0.

For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity, isDBValid throws an SQLException if the value of `timeout` is not equal to 0.

This method does not apply to connections to IBM Informix data sources.

`prepareDB2OptimisticLockingQuery`
Format:
```java
public java.sql.PreparedStatement DB2Connection.prepareDB2OptimisticLockingQuery(String sql, int returnOptimisticLockingColumns) throws SQLException
```

Creates a PreparedStatement object that can request optimistic locking information.

Parameter descriptions:
- **sql**: The SQL statement that is to be prepared.
- **returnOptimisticLockingColumns**: Specifies whether optimistic locking columns are returned. Possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DB2Statement.RETURN_OPTLOCK_COLUMN_NONE (0)</code></td>
<td>Do not return optimistic locking columns.</td>
</tr>
<tr>
<td><code>DB2Statement.RETURN_OPTLOCK_COLUMN_ALWAYS (1)</code></td>
<td>Add row change columns to the result set even if they do not uniquely represent a single row. This setting is equivalent to the database prepare attribute WITH ROW CHANGE COLUMNS POSSIBLY DISTINCT.</td>
</tr>
<tr>
<td><code>DB2Statement.RETURN_OPTLOCK_COLUMN_NO_FALSE_NEGATIVES (2)</code></td>
<td>Add row change columns to the result set only if they uniquely represent a single row. This setting is equivalent to the database prepare attribute WITH ROW CHANGE COLUMNS ALWAYS DISTINCT.</td>
</tr>
</tbody>
</table>

`reconfigureDB2Connection`
Format:
```java
public void reconfigureDB2Connection(java.util.Properties properties) throws SQLException
```

Table 110. Values for the returnOptimisticLockingColumns parameter
Reconfigures a connection with new settings. The connection does not need to be returned to a connection pool before it is reconfigured. This method can be called while a transaction is in progress, and can be used for trusted or untrusted connections.

Trusted connections are supported for:

- IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to:
  - DB2 for Linux, UNIX, and Windows Version 9.5 or later
  - DB2 for z/OS Version 9.1 or later
  - IBM Informix Version 11.70 or later
- IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS Version 9.1 or later

Parameter descriptions:

properties
New properties for the connection. These properties override any properties that are already defined on the DB2Connection instance.

registerDB2XmlSchema
Formats:

public void registerDB2XmlSchema(String[] sqlIdSchema,
String[] sqlIdName,
String[] xmlSchemaLocations,
InputStream[] xmlSchemaDocuments,
int[] xmlSchemaDocumentsLengths,
InputStream[] xmlSchemaDocumentsProperties,
int[] xmlSchemaDocumentsPropertiesLengths,
InputStream xmlSchemaProperties,
int xmlSchemaPropertiesLength,
boolean isUsedForShredding)
throws SQLException

public void registerDB2XmlSchema(String[] sqlIdSchema,
String[] sqlIdName,
String[] xmlSchemaLocations,
String[] xmlSchemaDocuments,
String[] xmlSchemaDocumentsProperties,
String xmlSchemaProperties,
boolean isUsedForShredding)
throws SQLException

Registers an XML schema with one or more XML schema documents. If multiple XML schema documents are processed with one call to registerDB2XmlSchema, those documents are processed as part of a single transaction.

The first form of registerDB2XmlSchema is for XML schema documents that are read from an input stream. The second form of registerDB2XmlSchema is for XML schema documents that are read from strings.

Parameter descriptions:

sqlIdSchema
The SQL schema name for the XML schema. Only the first element of the sqlIdSchema array is used. sqlIdSchema is a String value with a maximum length of 128 bytes. The value of sqlIdSchema must conform to the naming rules for any SQL schema name. The name cannot begin with the string ‘SYS’. If the value of sqlIdSchema is null, the database system uses the value in the CURRENT SCHEMA special register.

sqlIdName
The SQL name for the XML schema. Only the first element of the
sqlIdName array is used. sqlIdName is a String value with a maximum length of 128 bytes. The value of sqlIdName must conform to the rules for an SQL identifier. If the value of sqlIdSchema is null, the value of sqlIdName can be null. In that case, the database system generates the value for sqlIdName.

xmlSchemaLocations
XML schema locations for the primary XML schema documents of the schemas that are being registered. XML schema location values are normally in URI format. Each xmlSchemaLocations value is a String value with a maximum length of 1000 bytes. The value is used only to match the information that is specified in the XML schema document that references this document. The database system does no validation of the format, and no attempt is made to resolve the URI.

xmlSchemaDocuments
The content of the primary XML schema documents. Each xmlSchemaDocuments value is a String or InputStream value with a maximum length of 30 MB. The values must not be null.

xmlSchemaDocumentsLengths
The lengths of the XML schema documents in the xmlSchemaDocuments parameter, if the first form of registerDB2XmlSchema is used. Each xmlSchemaDocumentsLengths value is an int value.

xmlSchemaDocumentsProperties
Contains properties of the primary XML schema documents, such as properties that are used by an external XML schema versioning system. The database system does no validation of the contents of these values. They are stored in the XSR table for retrieval and used in other tools and XML schema repository implementations. Each xmlSchemaDocumentsProperties value is a String or InputStream value with a maximum length of 5 MB. A value is null if there are no properties to be passed.

xmlSchemaDocumentsPropertiesLengths
The lengths of the XML schema properties in the xmlSchemaDocumentsProperties parameter, if the first form of registerDB2XmlSchema is used. Each xmlSchemaDocumentsPropertiesLengths value is an int value.

xmlSchemaProperties
Contains properties of the entire XML schema, such as properties that are used by an external XML schema versioning system. The database system does no validation of the contents of this value. They are stored in the XSR table for retrieval and used in other tools and XML schema repository implementations. The xmlSchemaProperties value is a String or InputStream value with a maximum length of 5 MB. The value is null if there are no properties to be passed.

xmlSchemaPropertiesLengths
The length of the XML schema property in the xmlSchemaProperties parameter, if the first form of registerDB2XmlSchema is used. The xmlSchemaPropertiesLengths value is an int value.

isUsedForShredding
Indicates whether there are annotations in the schema that are to be used for XML decomposition. isUsedForShredding is a boolean value.

This method does not apply to connections to IBM Informix data sources.
setDBConcurrentAccessResolution
Format:
public void setDBConcurrentAccessResolution(int concurrentAccessResolution)
throws java.sql.SQLException

Specifies whether the IBM Data Server Driver for JDBC and SQLJ requests that a read transaction can access a committed and consistent image of rows that are incompatibly locked by write transactions, if the data source supports accessing currently committed data, and the application isolation level is cursor stability (CS) or read stability (RS). This option has the same effect as the DB2 CONCURRENTACCESSRESOLUTION bind option.

setDBConcurrentAccessResolution affects only statements that are created after setDBConcurrentAccessResolution is executed.

setDBConcurrentAccessResolution applies only to connections to DB2 for z/OS and DB2 for Linux, UNIX, and Windows.

Parameter descriptions:
concurrentAccessResolution
One of the following integer values:

DB2BaseDataSource-.CONCURRENTACCESS_USE_CURRENTLY_COMMITTED (1)
The IBM Data Server Driver for JDBC and SQLJ requests that:
- Read transactions access the currently committed data when the data is being updated or deleted.
- Read transactions skip rows that are being inserted.

DB2BaseDataSource.CONCURRENTACCESS_WAIT_FOR_OUTCOME (2)
The IBM Data Server Driver for JDBC and SQLJ requests that:
- Read transactions wait for a commit or rollback operation when they encounter data that is being updated or deleted.
- Read transactions do not skip rows that are being inserted.

DB2BaseDataSource.CONCURRENTACCESS_NOT_SET (0)
Enables the data server's default behavior for read transactions when lock contention occurs. This is the default value.

setDBProgressiveStreaming
Format:
public void setDBProgressiveStreaming(int newSetting)
throws java.sql.SQLException

Sets the progressive streaming setting for all ResultSet objects that are created on the connection.

Parameter descriptions:
newSetting
The new progressive streaming setting. Possible values are:

DB2BaseDataSource.YES (1)
Enable progressive streaming. If the data source does not support progressive streaming, this setting has no effect.

DB2BaseDataSource.NO (2)
Disable progressive streaming.
**setDBStatementConcentrator**

Format:
```
public void setDBStatementConcentrator(int statementConcentratorUse)
    throws java.sql.SQLException
```

Specifies whether the IBM Data Server Driver for JDBC and SQLJ uses the data source's statement concentrator functionality. The statement concentrator is the ability to bypass preparation of a statement when it is the same as a statement in the dynamic statement cache, except for literal values. Statement concentrator functionality applies only to SQL statements that have literals but no parameter markers. setDBStatementConcentrator overrides the setting of the statementConcentrator Connection or DataSource property.

setDBStatementConcentrator affects only statements that are created after setDBStatementConcentrator is executed.

Parameter descriptions:

**statementConcentratorUse**

One of the following integer values:

- `DB2BaseDataSource.STatementConcentratorOff (1)`
  The IBM Data Server Driver for JDBC and SQLJ does not use the data source's statement concentrator functionality.

- `DB2BaseDataSource.STatementConcentratorWithLiterals (2)`
  The IBM Data Server Driver for JDBC and SQLJ uses the data source's statement concentrator functionality.

- `DB2BaseDataSource.STatementConcentratorNotSet (0)`
  Enables the data server's default behavior for statement concentrator functionality. This is the default value.

  For DB2 for Linux, UNIX, and Windows data sources that support statement concentrator functionality, the functionality is used if the STMT_CONC configuration parameter is set to ON at the data source. Otherwise, statement concentrator functionality is not used.

  For DB2 for z/OS data sources that support statement concentrator functionality, the functionality is not used if statementConcentrator is not set.

**removeDB2JavaStoredProcedure**

Format:
```
public void removeDB2JavaStoredProcedure(String jarId)
    throws java.sql.SQLException
```

Invokes the sqlj.remove_jar stored procedure on a DB2 for Linux, UNIX, and Windows server to delete the definition of a JAR file from the catalog for that server.

Parameter descriptions:

**jarId**

The name of the JAR in the database, in the form `schema.JAR-id` or `JAR-id`. This is the name that you use when you refer to the JAR in SQL statements. If you omit `schema`, the database system uses the SQL authorization ID that is in the CURRENT SCHEMA special register.

This method does not apply to connections to IBM Informix data sources.
replaceDB2JavaStoredProcedure
Format:
```java
public void DB2Connection.replaceDB2JavaStoredProcedure(
    java.io.InputStream jarFile,
    int jarFileLength,
    String jarId
) throws java.sql.SQLException
```

Invokes the sqlj.replace_jar stored procedure on a DB2 for Linux, UNIX, and Windows server to replace the definition of a JAR file in the catalog for that server.

Parameter descriptions:

**jarFile**
The contents of the JAR file that is to be replaced on the server.

**jarFileLength**
The length of the JAR file that is to be replace on the server.

**jarId**
The name of the JAR in the database, in the form `schema.JAR-id` or `JAR-id`.
This is the name that you use when you refer to the JAR in SQL statements. If you omit `schema`, the database system uses the SQL authorization ID that is in the CURRENT SCHEMA special register. The owner of the JAR is the authorization ID in the CURRENT SQLID special register.

This method does not apply to connections to IBM Informix data sources.

reuseDB2Connection (trusted connection reuse)
Formats:
```java
public void reuseDB2Connection(byte[] cookie,
    String user,
    String password,
    String usernameRegistry,
    byte[] userSecToken,
    String originalUser,
    java.util.Properties properties)
throws java.sql.SQLException
```

Trusted connections are supported for:
- IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to:
  - DB2 for Linux, UNIX, and Windows Version 9.5 or later
  - DB2 for z/OS Version 9.1 or later
  - IBM Informix Version 11.70 or later
- IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS Version 9.1 or later

The second of these forms of reuseDB2Connection does not apply to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.

These forms of reuseDB2Connection are used by a trusted application server to reuse a preexisting trusted connection on behalf of a new user. Properties that
can be reset are passed, including the new user ID. The database server resets the associated physical connection. If reuseDB2Connection executes successfully, the connection becomes available for immediate use, with different properties, by the new user.

Parameter descriptions:

**cookie**
A unique cookie that the JDBC driver generates for the Connection instance. The cookie is known only to the application server and the underlying JDBC driver that established the initial trusted connection. The application server passes the cookie that was created by the driver when the pooled connection instance was created. The JDBC driver checks that the supplied cookie matches the cookie of the underlying trusted physical connection to ensure that the request originated from the application server that established the trusted physical connection. If the cookies match, the connection becomes available for immediate use, with different properties, by the new user.

**user**
The client ID that the database system uses to establish the database authorization ID. If the user was not authenticated by the application server, the application server needs to pass a client ID that represents an unauthenticated user.

**password**
The password for **user**.

**gssCredential**
If the data source uses Kerberos security, specifies a delegated credential that is passed from another principal.

**userNameRegistry**
A name that identifies a mapping service that maps a workstation user ID to a z/OS RACF ID. An example of a mapping service is the Integrated Security Services Enterprise Identity Mapping (EIM). The mapping service is defined by a plugin. Valid values for **userNameRegistry** are defined by the plugin providers. If **userNameRegistry** is null, no mapping of **user** is done.

**userSecToken**
The client's security tokens. This value is traced as part of DB2 for z/OS accounting data. The content of **userSecToken** is described by the application server and is referred to by the database system as an application server security token.

**originalUser**
The original user ID that was used by the application server.

**properties**
Properties for the reused connection.

**reuseDB2Connection (untrusted reuse with reauthentication)**

Formats:

```java
public void reuseDB2Connection(String user,
    String password,
    java.util.Properties properties)
throws java.sql.SQLException

public void reuseDB2Connection(
    org.ietf.jgss.GSSCredential gssCredential,
    java.util.Properties properties)
throws java.sql.SQLException
```
The first of these forms of reuseDB2Connection is not supported for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.

The second of these forms of reuseDB2Connection does not apply to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS.

In a heterogeneous pooling environment, these forms of reuseDB2Connection reuse an existing Connection instance after reauthentication.

Parameter description:

**user**
The authorization ID that is used to establish the connection.

**password**
The password for the authorization ID that is used to establish the connection.

**gssCredential**
If the data source uses Kerberos security, specifies a delegated credential that is passed from another principal.

**properties**
Properties for the reused connection. These properties override any properties that are already defined on the DB2Connection instance.

**reuseDB2Connection (untrusted or trusted reuse without reauthentication)**

Formats:

```java
public void reuseDB2Connection(java.util.Properties properties)
  throws java.sql.SQLException
```

Reuses an existing Connection instance without reauthentication. This method is intended for reuse of a Connection instance when the properties do not change.

Trusted connections are supported for:

- IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to:
  - DB2 for Linux, UNIX, and Windows Version 9.5 or later
  - DB2 for z/OS Version 9.1 or later
  - IBM Informix Version 11.70 or later
- IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS Version 9.1 or later

This method is for dirty reuse of a connection. This means that the connection state is not reset when the object is reused from the pool. Special register settings and property settings remain in effect unless they are overridden by passed properties. Global temporary tables are not deleted. Properties that are not specified are not re-initialized. All JDBC standard transient properties, such as the isolation level, autocommit mode, and read-only mode are reset to their JDBC defaults. Certain properties, such as user, password, databaseName, serverName, portNumber, planName, and pkList remain unchanged.

Parameter description:

**properties**
Properties for the reused connection. These properties override any properties that are already defined on the DB2Connection instance.

**setDB2ClientAccountingInformation**

Format:
public void setDB2ClientAccountingInformation(String info)
    throws java.sql.SQLException

Specifies accounting information for the connection. This information is for
client accounting purposes. This value can change during a connection.

setDB2ClientAccountingToken applies only to connections to DB2 for z/OS.

Parameter description:

 info 
     User-specified accounting information.

     The maximum length depends on the data server version. See "Client info
     properties support by the IBM Data Server Driver for JDBC and SQLJ" on
     page 108 for the maximum lengths.

     A Java empty string ("") or a Java null value is valid for this parameter.

Important: setDB2ClientAccountingInformation is deprecated in the JDBC 4.0
implementation of the IBM Data Server Driver for JDBC and SQLJ. Use
java.sql.Connection.setClientInfo instead.

setDB2ClientApplicationInformation

Format:

public String setDB2ClientApplicationInformation(String info)
    throws java.sql.SQLException

Specifies application information for the current client.

Important: setDB2ClientApplicationInformation is deprecated in the JDBC 4.0
implementation of the IBM Data Server Driver for JDBC and SQLJ. Use
java.sql.Connection.setClientInfo instead.

Parameter description:

 info 
     User-specified application information.

     The maximum length depends on the data server version. See "Client info
     properties support by the IBM Data Server Driver for JDBC and SQLJ" on
     page 108 for the maximum lengths.

     A Java empty string ("") or a Java null value is valid for this parameter.

setDB2ClientDebugInfo

Formats:

public void setDB2ClientDebugInfo(String debugInfo)
    throws java.sql.SQLException

public void setDB2ClientDebugInfo(String mgrInfo,
    String traceInfo)
    throws java.sql.SQLException

Sets a value for the CLIENT DEBUGINFO connection attribute, to notify the
database system that stored procedures and user-defined functions that are
using the connection are running in debug mode. CLIENT DEBUGINFO is
used by the DB2 Unified Debugger. Use the first form to set the entire CLIENT
DEBUGINFO string. Use the second form to modify only the session manager
and trace information in the CLIENT DEBUGINFO string.

Setting the CLIENT DEBUGINFO attribute to a string of length greater than
zero requires one of the following privileges:
• The DEBUGSESSION privilege
• SYSADM authority
Parameter description:

**debugInfo**

A string of up to 254 bytes, in the following form:

Mip:port,Ip,Ppid,Ttid,Cid,Llvl

The parts of the string are:

**Mip:** Session manager IP address and port number

**Ip**  Client IP address

**Ppid**  Client process ID

**Ttid**  Client thread ID (optional)

**Cid**  Data connection generated ID

**Llvl**  Debug library diagnostic trace level

For example:

M9.72.133.89:8355,I9.72.133.89,P4552,T123,C1,L0

See the description of SET CLIENT DEBUGINFO for a detailed description of this string.

**mgrInfo**

A string of the following form, which specifies the IP address and port number for the Unified Debugger session manager.

Mip:port

For example:

M9.72.133.89:8355

See the description of SET CLIENT DEBUGINFO for a detailed description of this string.

**trcInfo**

A string of the following form, which specifies the debug library diagnostics trace level.

Llvl

For example:

L0

See the description of SET CLIENT DEBUGINFO for a detailed description of this string.

**setDB2ClientProgramId**

Format:

```java
public abstract void setDB2ClientProgramId(String program-ID)
throws java.sql.SQLException
```

Sets a user-defined program identifier for the connection, on DB2 for z/OS servers. That program identifier is an 80-byte string that is used to identify the caller.

**setDB2ClientProgramId** does not apply to DB2 for Linux, UNIX, and Windows or IBM Informix data servers.
The DB2 for z/OS server places the string in IFCID 316 trace records along with other statistics, so that you can identify which program is associated with a particular SQL statement.

**setDB2ClientUser**

Format:
```java
public void setDB2ClientUser(String user)
    throws java.sql.SQLException
```

Specifies the current client user name for the connection. This name is for client accounting purposes, and is not the user value for the JDBC connection. Unlike the user for the JDBC connection, the current client user name can change during a connection.

Parameter description:

`user`

The user ID for the current client. The maximum length depends on the server.

The maximum length depends on the data server version. See "Client info properties support by the IBM Data Server Driver for JDBC and SQLJ" on page 108 for the maximum lengths.

A Java empty string (""") or a Java null value is valid for this parameter.

**Important:** setDB2ClientUser is deprecated in the JDBC 4.0 implementation of the IBM Data Server Driver for JDBC and SQLJ. Use java.sql.Connection.setClientInfo instead.

**setDB2ClientWorkstation**

Format:
```java
public void setDB2ClientWorkstation(String name)
    throws java.sql.SQLException
```

Specifies the current client workstation name for the connection. This name is for client accounting purposes. The current client workstation name can change during a connection.

Parameter description:

`name`

The workstation name for the current client.

The maximum length depends on the data server version. See "Client info properties support by the IBM Data Server Driver for JDBC and SQLJ" on page 108 for the maximum lengths.

A Java empty string (""") or a Java null value is valid for this parameter.

**Important:** getDB2ClientWorkstation is deprecated in the JDBC 4.0 implementation of the IBM Data Server Driver for JDBC and SQLJ. Use java.sql.Connection.getClientInfo instead.

**setDB2CurrentPackagePath**

Format:
```java
public void setDB2CurrentPackagePath(String packagePath)
    throws java.sql.SQLException
```

Specifies a list of collection IDs that the database system searches for JDBC and SQLJ packages.
The `setDB2CurrentPackagePath` method applies only to connections to DB2 database systems.

Parameter description:

`packagePath`
A comma-separated list of collection IDs.

**setDB2CurrentPackageSet**
Format:

```java
public void setDB2CurrentPackageSet(String packageSet)
throws java.sql.SQLException
```

Specifies the collection ID for the connection. When you set this value, you also set the collection ID of the IBM Data Server Driver for JDBC and SQLJ instance that is used for the connection.

The `setDB2CurrentPackageSet` method applies only to connections to DB2 database systems.

Parameter description:

`packageSet`
The collection ID for the connection. The maximum length for the `packageSet` value is 18 bytes. You can invoke this method as an alternative to executing the SQL SET CURRENT PACKAGESET statement in your program.

**setDB2ProgressiveStreaming**
Format:

```java
public void setDB2ProgressiveStreaming(int newSetting)
throws java.sql.SQLException
```

Sets the progressive streaming setting for all ResultSet objects that are created on the connection.

Parameter descriptions:

`newSetting`
The new progressive streaming setting. Possible values are:

- **DB2BaseDataSource.YES (1)**
  Enable progressive streaming. If the data source does not support progressive streaming, this setting has no effect.

- **DB2BaseDataSource.NO (2)**
  Disable progressive streaming.

**setJccLogWriter**
Formats:

```java
public void setJccLogWriter(PrintWriter logWriter)
throws java.sql.SQLException
```

```java
public void setJccLogWriter(PrintWriter logWriter, int traceLevel)
throws java.sql.SQLException
```

Enables or disables the IBM Data Server Driver for JDBC and SQLJ trace, or changes the trace destination during an active connection.

Parameter descriptions:
logWriter
An object of type java.io.PrintWriter to which the IBM Data Server Driver for JDBC and SQLJ writes trace output. To turn off the trace, set the value of logWriter to null.

traceLevel
Specifies the types of traces to collect. See the description of the traceLevel property in “Properties for the IBM Data Server Driver for JDBC and SQLJ” for valid values.

setSavePointUniqueOption
Format:

public void setSavePointUniqueOption(boolean flag)
throws java.sql.SQLException

Specifies whether an application can reuse a savepoint name within a unit of recovery. Possible values are:

true  A Connection.setSavepoint(savepoint-name) method cannot specify the same value for savepoint-name more than once within the same unit of recovery.

false  A Connection.setSavepoint(savepoint-name) method can specify the same value for savepoint-name more than once within the same unit of recovery.

When false is specified, if the Connection.setSavepoint(savepoint-name) method is executed, and a savepoint with the name savepoint-name already exists within the unit of recovery, the database manager destroys the existing savepoint, and creates a new savepoint with the name savepoint-name.

Reuse of a savepoint is not the same as executing Connection.releaseSavepoint(savepoint-name).
Connection.releaseSavepoint(savepoint-name) releases savepoint-name, and any savepoints that were subsequently set.

updateDB2XmlSchema
Format:

public void updateDB2XmlSchema(String[] targetSqlIdSchema,
String[] targetSqlIdName,
String[] sourceSqlIdSchema,
String[] sourceSqlIdName,
String[] xmlSchemaLocations,
boolean dropSourceSchema)
throws SQLException

Updates the contents of an XML schema with the contents of another XML schema in the XML schema repository, and optionally drops the source schema. The schema documents in the target XML schema are replaced with the schema documents from the source XML schema. Before updateDB2XmlSchema can be called, registration of the source and target XML schemas must be completed.

The SQL ALTERIN privilege is required for updating the target XML schema. The SQL DROPIN privilege is required for dropping the source XML schema.

Parameter descriptions:

targetSqlIdSchema
The SQL schema name for a registered XML schema that is to be updated.
targetSqlIdSchema is a String value with a maximum length of 128 bytes.
**targetSqlIdName**

- The name of the registered XML schema that is to be updated.
- *targetSqlIdName* is a String value with a maximum length of 128 bytes.

**sourceSqlIdName**

- The SQL schema name for a registered XML schema that is used to update the target XML schema. *sourceSqlIdName* is a String value with a maximum length of 128 bytes.

**sourceSqlIdName**

- The name of the registered XML schema that is used to update the target XML schema. *sourceSqlIdName* is a String value with a maximum length of 128 bytes.

**dropSourceSchema**

- Indicates whether the source XML schema is to be dropped after the target XML schema is updated. *dropSourceSchema* is a boolean value. `false` is the default.

This method does not apply to connections to IBM Informix data sources.

### DB2ConnectionPoolDataSource class

`DB2ConnectionPoolDataSource` is a factory for `PooledConnection` objects. An object that implements this interface is registered with a naming service that is based on the Java Naming and Directory Interface (JNDI).

The `com.ibm.db2.jcc.DB2ConnectionPoolDataSource` class extends the `com.ibm.db2.jcc.DB2BaseDataSource` class, and implements the `javax.sql.ConnectionPoolDataSource`, `java.io.Serializable`, and `javax.naming.Referenceable` interfaces.

### DB2ConnectionPoolDataSource properties

These properties are defined only for the IBM Data Server Driver for JDBC and SQLJ. "Properties for the IBM Data Server Driver for JDBC and SQLJ" for explanations of these properties.

These properties have a `setXXX` method to set the value of the property and a `getXXX` method to retrieve the value. A `setXXX` method has this form:

`void setProperty-name(data-type property-value)`

A `getXXX` method has this form:

`data-type getProperty-name()`
Property-name is the unqualified property name, with the first character capitalized.

The following table lists the IBM Data Server Driver for JDBC and SQLJ properties and their data types.

### Table 111. DB2ConnectionPoolDataSource properties and their data types

<table>
<thead>
<tr>
<th>Property name</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.ibm.db2.jcc.DB2ConnectionPoolDataSource.maxStatements</td>
<td>int</td>
</tr>
</tbody>
</table>

**DB2ConnectionPoolDataSource methods**

**getDB2PooledConnection**

Formats:

```java
public DB2PooledConnection getDB2PooledConnection(String user,
                                                 String password,
                                                 java.util.Properties properties)
throws java.sql.SQLException

public DB2PooledConnection getDB2PooledConnection(
                                                 org.ietf.jgss.GSSCredential gssCredential,
                                                 java.util.Properties properties)
throws java.sql.SQLException
```

Establishes the initial untrusted connection in a heterogeneous pooling environment.

The first form `getDB2PooledConnection` provides a user ID and password. The second form of `getDB2PooledConnection` is for connections that use Kerberos security.

Parameter descriptions:

**user**
The authorization ID that is used to establish the connection.

**password**
The password for the authorization ID that is used to establish the connection.

**gssCredential**
If the data source uses Kerberos security, specifies a delegated credential that is passed from another principal.

**properties**
Properties for the connection.

**getDB2TrustedPooledConnection**

Formats:

```java
public Object[] getDB2TrustedPooledConnection(String user,
                                              String password,
                                              java.util.Properties properties)
throws java.sql.SQLException

public Object[] getDB2TrustedPooledConnection(
                                              java.util.Properties properties)
throws java.sql.SQLException

public Object[] getDB2TrustedPooledConnection(
                                              org.ietf.jgss.GSSCredential gssCredential,
                                              java.util.Properties properties)
throws java.sql.SQLException
```

An application server using a system authorization ID uses this method to establish a trusted connection.
Trusted connections are supported for:

- IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to:
  - DB2 for Linux, UNIX, and Windows Version 9.5 or later
  - DB2 for z/OS Version 9.1 or later
  - IBM Informix Version 11.70 or later
- IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS Version 9.1 or later

The following elements are returned in Object[]:

- The first element is a trusted DB2PooledConnection instance.
- The second element is a unique cookie for the generated pooled connection instance.

The first form getDB2TrustedPooledConnection provides a user ID and password, while the second form of getDB2TrustedPooledConnection uses the user ID and password of the DB2ConnectionPoolDataSource object. The third form of getDB2TrustedPooledConnection is for connections that use Kerberos security.

Parameter descriptions:

**user**

The DB2 authorization ID that is used to establish the trusted connection to the database server.

**password**

The password for the authorization ID that is used to establish the trusted connection.

**gssCredential**

If the data source uses Kerberos security, specifies a delegated credential that is passed from another principal.

**properties**

Properties for the connection.

**DB2DatabaseMetaData interface**

The com.ibm.db2.jcc.DB2DatabaseMetaData interface extends the java.sql.DatabaseMetaData interface.

**DB2DatabaseMetaData methods**

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

**getDBFunctionColumns**

Format:

```java
public java.sql.ResultSet getDBFunctionColumns(
    String catalog,
    String schemaPattern,
    String modulePattern,
    String functionNamePattern,
    String columnNamePattern)
```

throws java.sql.SQLException

Chapter 13. JDBC and SQLJ reference information  501
Returns a ResultSet object that describes parameters and return values for user-defined functions or built-in functions that are defined at a data source. The function parameters and return values for which information is returned match the catalog name, schema pattern, module pattern, function name pattern, and column name pattern that are specified by the input parameters. The ResultSet has the following columns:

<table>
<thead>
<tr>
<th>Column number</th>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FUNCTION_CAT</td>
<td>String</td>
<td>Name of the catalog. The value is null if this function does not have catalogs.</td>
</tr>
<tr>
<td>2</td>
<td>FUNCTION_SCHEM</td>
<td>String</td>
<td>Name of the schema containing FUNCTION_NAME. This value can be null.</td>
</tr>
<tr>
<td>3</td>
<td>FUNCTION_NAME</td>
<td>String</td>
<td>Name of the function.</td>
</tr>
<tr>
<td>4</td>
<td>COLUMN_NAME</td>
<td>String</td>
<td>Name of the function parameter.</td>
</tr>
<tr>
<td>5</td>
<td>COLUMN_TYPE</td>
<td>Short</td>
<td>Parameter type:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- functionColumnUnknown (0): unknown</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- functionColumnIn (1): input</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- functionColumnInOut (2): input or output</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- functionColumnResult (3): result set column</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- functionColumnOut (4): output</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- functionColumnReturn (5): returned value</td>
</tr>
<tr>
<td>6</td>
<td>DATA_TYPE</td>
<td>int</td>
<td>SQL data type of the parameter that is identified by COLUMN_NAME.</td>
</tr>
<tr>
<td>7</td>
<td>TYPE_NAME</td>
<td>String</td>
<td>Character string representing the name of the data type corresponding to DATA_TYPE.</td>
</tr>
<tr>
<td>8</td>
<td>PRECISION</td>
<td>int</td>
<td>The precision of an exact numeric parameter.</td>
</tr>
<tr>
<td>9</td>
<td>LENGTH</td>
<td>int</td>
<td>The length of the parameter,</td>
</tr>
<tr>
<td>10</td>
<td>SCALE</td>
<td>short</td>
<td>The scale of an exact numeric parameter.</td>
</tr>
<tr>
<td>11</td>
<td>RADIX</td>
<td>short</td>
<td>10, 2, or null:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- If DATA_TYPE is an approximate numeric data type, this parameter contains the value 2.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- If DATA_TYPE is an exact numeric data type, this parameter contains the value 10.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- For data types where the radix is not applicable, this value is null.</td>
</tr>
<tr>
<td>12</td>
<td>NULLABLE</td>
<td>short</td>
<td>Specifies whether the parameter can contain NULL values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>functionNoNulls (0)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The parameter cannot contains NULL values.</td>
</tr>
<tr>
<td></td>

<td>The name of the module that contains the function. This value can be null.</td>
</tr>
</tbody>
</table>

Parameter descriptions:

catalog

An empty string or '%'.

schemaName

Specifies the schema name (qualifier) of the objects for which information is to be returned.

The value can identify a single schema name, or it can identify more than one schema name by including the pattern-matching character percent (%).

modulePattern

Specifies the name of the module for which parameter information is to be returned.

The value can identify a single module name, or it can identify more than one module name by including the pattern-matching character percent (%).

functionNamePattern

Specifies the name of the function for which parameter information is to be returned.

The value can identify a single schema name, or it can identify more than one procedure name by including the pattern-matching character percent (%).

columnNamePattern

Specifies the parameters for which parameter information is to be returned.

The value can identify a single schema name, or it can identify more than one parameter name by including the pattern-matching character percent (%).

This method applies to connections to DB2 for Linux, UNIX, and Windows 9.7 or later data sources only. A SqlFeatureNotSupportedException is thrown if the data source is any other data source.

getDBFunctions

Format:

```java
public java.sql.ResultSet getDBFunctions(
    String catalog,
    String schemaPattern,
    String modulePattern,
    String functionNamePattern)
throws java.sql.SQLException
```

Returns a ResultSet object that describes user-defined functions or built-in functions that are defined at a data source. The functions for which information is returned match the catalog name, schema pattern, module...
pattern, and function name pattern that are specified by the input parameters. The ResultSet has the following columns:

<table>
<thead>
<tr>
<th>Column number</th>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FUNCTION_CAT</td>
<td>String</td>
<td>Name of the catalog. The value is null if this function does not have catalogs.</td>
</tr>
<tr>
<td>2</td>
<td>FUNCTION_SCHEM</td>
<td>String</td>
<td>Name of the schema containing FUNCTION_NAME. This value can be null.</td>
</tr>
<tr>
<td>3</td>
<td>FUNCTION_NAME</td>
<td>String</td>
<td>Name of the function.</td>
</tr>
<tr>
<td>4</td>
<td>REMARKS</td>
<td>String</td>
<td>Descriptive information about the parameter, or null.</td>
</tr>
</tbody>
</table>
| 5             | FUNCTION_TYPE       | short       | Function type. Possible values are:
|               |                     |             | • functionResultUnknown (0): Whether a value or a table is returned is unknown. |
|               |                     |             | • functionNoTable (1): A table is not returned.                              |
|               |                     |             | • functionReturnsTable (2): A table is returned.                             |
| 6             | SPECIFIC_NAME       | String      | The name that uniquely identifies the function within its schema.            |
| 7             | FUNCTION_MODULE     | String      | The name of the module that contains the function. This value can be null.   |

Parameter descriptions:

**catalog**
An empty string or '%'.

**schemaName**
Specifies the schema name (qualifier) of the objects for which information is to be returned.

The value can identify a single schema name, or it can identify more than one schema name by including the pattern-matching character percent (%).

**modulePattern**
Specifies the name of the module for which parameter information is to be returned.

The value can identify a single module name, or it can identify more than one module name by including the pattern-matching character percent (%).

**functionNamePattern**
Specifies the name of the function for which parameter information is to be returned.

The value can identify a single schema name, or it can identify more than one function name by including the pattern-matching character percent (%).

This method applies to connections to DB2 for Linux, UNIX, and Windows 9.7 or later data sources only. A SqlFeatureNotSupportedException is thrown if the data source is any other data source.

**getDBProcedureColumns**
Format:
```java
public java.sql.ResultSet getDBProcedureColumns(
    String catalog,
    String schemaPattern,
```
```java
String modulePattern,
String procedureNamePattern,
String columnNamePattern)
throws java.sql.SQLException
```

Returns a ResultSet object that describes parameters and return values for stored procedures that are defined at a data source. The stored procedure parameters and return values for which information is returned match the catalog name, schema pattern, module pattern, procedure name pattern, and column name pattern that are specified by the input parameters. The ResultSet has the following columns:

<table>
<thead>
<tr>
<th>Column number</th>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>PROCEDURE_CAT</td>
<td>String</td>
<td>Name of the catalog. The value is null if this procedure does not have catalogs.</td>

<td></td>
<td></td>
<td>• procedureColumnReturn (5): returned value</td>
</tr>
<tr>
<td>6</td>
<td>DATA_TYPE</td>
<td>int</td>
<td>SQL data type of the parameter that is identified by COLUMN_NAME.</td>
</tr>
<tr>
<td>7</td>
<td>TYPE_NAME</td>
<td>String</td>
<td>Character string representing the name of the data type corresponding to DATA_TYPE.</td>
</tr>
<tr>
<td>8</td>
<td>PRECISION</td>
<td>int</td>
<td>The precision of an exact numeric parameter.</td>
</tr>
<tr>
<td>9</td>
<td>LENGTH</td>
<td>int</td>
<td>The length of the parameter.</td>
</tr>
<tr>
<td>10</td>
<td>SCALE</td>
<td>short</td>
<td>The scale of an exact numeric parameter.</td>
</tr>
<tr>
<td>11</td>
<td>RADIX</td>
<td>short</td>
<td>10, 2, or null:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• If DATA_TYPE is an approximate numeric data type, this parameter contains the value 2.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• If DATA_TYPE is an exact numeric data type, this parameter contains the value 10.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• For data types where the radix is not applicable, this value is null.</td>
</tr>
<tr>
<td>12</td>
<td>NULLABLE</td>
<td>short</td>
<td>Specifies whether the parameter can contain NULL values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>procedureNoNulls (0)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The parameter cannot contain NULL values.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>procedureNullable (1)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The parameter can contain NULL values.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>procedureNullableUnknown (2)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The nullability of the parameter is unknown.</td>
</tr>
<tr>
<td>13</td>
<td>REMARKS</td>
<td>String</td>
<td>Descriptive information about the parameter, or null.</td>
</tr>
<tr>
<td>14</td>
<td>COLUMN_DEF</td>
<td>String</td>
<td>Default value for the parameter.</td>
</tr>
</tbody>

</tbody>
</table>

Parameter descriptions:

**catalog**
An empty string or '%'.

**schemaName**
Specifies the schema name (qualifier) of the objects for which information is to be returned.

The value can identify a single schema name, or it can identify more than one schema name by including the pattern-matching character percent (%).

**modulePattern**
Specifies the name of the module for which parameter information is to be returned.

The value can identify a single module name, or it can identify more than one module name by including the pattern-matching character percent (%).

**procedureNamePattern**
Specifies the name of the procedure for which parameter information is to be returned.

The value can identify a single schema name, or it can identify more than one procedure name by including the pattern-matching character percent (%).

**columnNamePattern**
Specifies the parameters for which parameter information is to be returned.

The value can identify a single schema name, or it can identify more than one parameter name by including the pattern-matching character percent (%).

This method applies to connections to DB2 for Linux, UNIX, and Windows 9.7 or later data sources only. A SqlFeatureNotSupportedException is thrown if the data source is any other data source.

**getDBProcedures**
Format:
public java.sql.ResultSet getDBProcedures(
        String catalog,
        String schemaPattern,
        String modulePattern,
        String procedureNamePattern)
        throws java.sql.SQLException

Returns a ResultSet object that describes stored procedures that are defined at a data source. The stored procedures for which information is returned match the catalog name, schema pattern, module pattern, and procedure name pattern that are specified by the input parameters. The ResultSet has the following columns:

<table>
<thead>
<tr>
<th>Column number</th>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>PROCEDURE_CAT</td>
<td>String</td>
<td>Name of the catalog. The value is null if this procedure does not have catalogs.</td>
</tr>
<tr>
<td>2</td>
<td>PROCEDURE_SCHEM</td>
<td>String</td>
<td>Name of the schema containing PROCEDURE_NAME. This value can be null.</td>
</tr>
<tr>
<td>3</td>
<td>PROCEDURE_NAME</td>
<td>String</td>
<td>Name of the procedure.</td>

<td>Reserved</td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>Reserved</td>
<td></td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Reserved</td>
<td></td>
<td></td>
</tr>
<tr>
<td>7</td>
<td>REMARKS</td>
<td>String</td>
<td>Descriptive information about the parameter, or null.</td>
</tr>
<tr>
<td>8</td>
<td>PROCEDURE_TYPE</td>
<td>short</td>
<td>Procedure type. Possible values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• procedureResultUnknown (0): Whether a value is returned is unknown.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• procedureNoResult (1): No value is returned.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>• procedureReturnsResult (2): A value is returned.</td>
</tr>
<tr>
<td>9</td>
<td>SPECIFIC_NAME</td>
<td>String</td>
<td>The name that uniquely identifies the procedure within its schema.</td>
</tr>
<tr>
<td>10</td>
<td>PROCEDURE_MODULE</td>
<td>String</td>
<td>The name of the module that contains the procedure. This value can be null.</td>
</tr>
</tbody>
</table>

Parameter descriptions:

**catalog**
An empty string or '%'.

**schemaName**
Specifies the schema name (qualifier) of the objects for which information is to be returned.

The value can identify a single schema name, or it can identify more than one schema name by including the pattern-matching character percent (%).

**modulePattern**
Specifies the name of the module for which parameter information is to be returned.

The value can identify a single module name, or it can identify more than one module name by including the pattern-matching character percent (%).

**procedureNamePattern**
Specifies the name of the procedure for which parameter information is to be returned.
The value can identify a single schema name, or it can identify more than one procedure name by including the pattern-matching characters percent (%).

This method applies to connections to DB2 for Linux, UNIX, and Windows 9.7 or later data sources only. A SqlFeatureNotSupportedException is thrown if the data source is any other data source.

getDBUDTs
Format:
public java.sql.ResultSet getDBUDTs(
   String catalog,
   String schemaPattern,
   String modulePattern,
   String typeNamePattern,
   int[] types)
throws java.sql.SQLException

Returns a ResultSet object that describes user-defined types that are defined at a data source. The user-defined types for which information is returned match the catalog name, schema pattern, module pattern, type name pattern and types that are specified by the input parameters. The ResultSet has the following columns:

<table>
<thead>
<tr>
<th>Column number</th>
<th>Column name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>TYPE_CAT</td>
<td>String</td>
<td>Name of the catalog. The value is null if this user-defined type does not have catalogs.</td>
</tr>
<tr>
<td>2</td>
<td>TYPE_SCHEM</td>
<td>String</td>
<td>Name of the schema containing TYPE_NAME. This value can be null.</td>
</tr>
<tr>
<td>3</td>
<td>TYPE_NAME</td>
<td>String</td>
<td>Name of the user-defined type.</td>
</tr>
<tr>
<td>4</td>
<td>CLASS_NAME</td>
<td>String</td>
<td>The Java class name of the user-defined type.</td>
</tr>
</tbody>
</table>
| 5             | DATA_TYPE     | int       | One of the following type values that is defined in java.sql.Types:
   • JAVA_OBJECT (2000)
   • DISTINCT (2001)
   • STRUCT (2002) |
| 6             | REMARKS       | String    | Descriptive information about the user-defined type, or null. |
| 7             | BASE_TYPE     | short     | If DATA_TYPE is DISTINCT, or DATA_TYPE is STRUCT and REFERENCE_GENERATION is USER_DEFINED, the type code from java.sql.Types of the data type on which the user-defined type is based. Otherwise, this value is null. |
| 8             | TYPE_MODULE   | String    | The name of the module that contains the user-defined type. This value can be null. |

Parameter descriptions:

catalog
   An empty string or '%'.

schemaName
   Specifies the schema name (qualifier) of the objects for which information is to be returned.

   The value can identify a single schema name, or it can identify more than one schema name by including the pattern-matching character percent (%).
modulePattern
Specifies the name of the module for which parameter information is to be returned.

The value can identify a single module name, or it can identify more than one module name by including the pattern-matching character percent (%).

typeNamePattern
Specifies the name of the user-defined type for which parameter information is to be returned.

The value can identify a single type name, or it can identify more than one procedure name by including the pattern-matching character percent (%).

types
Specifies the types of user-defined types for which parameter information is to be returned. Each array entry can contain one of the following values:

- JAVA_OBJECT (2000)
- DISTINCT (2001)
- STRUCT (2002)

If the array is null, information about all types is returned.

This method applies to connections to DB2 for Linux, UNIX, and Windows 9.7 or later data sources only. A SqlFeatureNotSupportedException is thrown if the data source is any other data source.

isIDSDatabaseAnsiCompliant
Format:
public boolean isIDSDatabaseAnsiCompliant();

Returns true if the current active IBM Informix database is ANSI-compliant. Returns false otherwise.

An ANSI-compliant database is a database that was created with the WITH LOG MODE ANSI option.

This method applies to connections to IBM Informix data sources only. An SQLException is thrown if the data source is not an IBM Informix data source.

isIDSDatabaseLogging
Format:
public boolean isIDSDatabaseLogging();

Returns true if the current active IBM Informix database supports logging. Returns false otherwise.

An IBM Informix database that supports logging is a database that was created with the WITH LOG MODE ANSI option, the WITH BUFFERED LOG, or the WITH LOG option.

This method applies to connections to IBM Informix data sources only. An SQLException is thrown if the data source is not an IBM Informix data source.

isResetRequiredForDB2eWLM
Format:
public boolean isResetRequiredForDB2eWLM();

Returns true if the target database server requires clean reuse to support eWLM. Returns false otherwise.
supportsDB2ProgressiveStreaming
Format:
public boolean supportsDB2ProgressiveStreaming();

Returns true if the target data source supports progressive streaming. Returns false otherwise.

DB2Diagnosable interface
The com.ibm.db2.jcc.DB2Diagnosable interface provides a mechanism for getting DB2 diagnostics from an SQLException.

DB2Diagnosable methods
The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

getSqlca
Format:
public DB2Sqlca getSqlca();

Returns a DB2Sqlca object from a java.sql.Exception that is produced under a IBM Data Server Driver for JDBC and SQLJ.

getThrowable
Format:
public Throwable getThrowable();

Returns a java.lang.Throwable object from a java.sql.Exception that is produced under a IBM Data Server Driver for JDBC and SQLJ.

printTrace
Format:
static public void printTrace(java.io.PrintWriter printWriter, String header);

Prints diagnostic information after a java.sql.Exception is thrown under a IBM Data Server Driver for JDBC and SQLJ.

Parameter descriptions:
printWriter
The destination for the diagnostic information.

header
User-defined information that is printed at the beginning of the output.

Related tasks:
“Handling SQL warnings in an SQLJ application” on page 199
“Handling an SQLException under the IBM Data Server Driver for JDBC and SQLJ” on page 131

DB2DataSource class
The com.ibm.db2.jcc.DB2DataSource class extends the DB2BaseDataSource class, and implements the javax.sql.DataSource, java.io.Serializable, and javax.naming.Referenceable interfaces.
DB2DataSource methods

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

setSpecialRegisters

Format:
```
public void setSpecialRegisters(java.util.Properties properties)
    throws java.sql.SQLException
```

For each key and value pair in the java.util.Properties object, sets the data server special register that is specified by the key to the corresponding value.

This method does not apply to connections to IBM Informix data servers.

Parameter description:

properties

A java.util.Properties object that contains key and value pairs, in which each key is the name of a special register, and each value is the value to which you want to set that special register. For example, suppose that ds is a previously defined DataSource object. Set the property values in the following way.

```
Properties prop = new Properties();
prop.add("CURRENT SCHEMA", "SYSPROC");
prop.add("CURRENT PACKAGESET", "PRODUCTION");
((com.ibm.db2.jdbc.DB2BaseDataSource) ds).setSpecialRegisters(prop);
```

Certain special registers can be set through IBM Data Server Driver for JDBC and SQLJ properties. If you set a special register value by setting one of those properties in a java.util.Properties object, and then use setSpecialRegisters to set a value for the same special register, the value that is set through setSpecialRegisters overrides the value that is set through the property. In the following example, CURRENT SCHEMA is set to USER002:

```
Properties prop = new Properties();
((com.ibm.db2.jdbc.DB2BaseDataSource) ds).setCurrentSchema("USER001");
props. put ("CURRENT SCHEMA", "USER002");
((com.ibm.db2.jdbc.DB2BaseDataSource) ds).setSpecialRegisters(prop);
```

DB2Driver class

The com.ibm.db2.jcc.DB2Driver class extends the java.sql.Driver interface.

DB2Driver methods

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

changeDB2Password

Format:
```
public static void changeDB2Password (String url,
    String userid,
    String oldPassword,
    String newPassword)
    throws java.sql.SQLException
```

Changes the password for accessing a data server that is specified by the url parameter, for the user that is specified by the userid parameter. This method can change an unexpired or expired password.
changeDB2Password is supported for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity only.

changeDB2Password is not supported for connections to IBM Informix.

Parameter descriptions:

url
- The URL for the data server for which a user's password is being changed.
- The url value uses the syntax for a URL for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

userid
- The user whose password is being changed.

oldPassword
- The original password for the user.

newPassword
- The new password for the user.

Related reference:
- “URL format for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity” on page 30

**DB2ExceptionFormatter class**

The com.ibm.db2.jcc.DB2ExceptionFormatter class contains methods for printing diagnostic information to a stream.

**DB2ExceptionFormatter methods**

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

**printTrace**

Formats:

- static public void printTrace(java.sql.SQLException sqlException, java.io.PrintWriter printWriter, String header)
- static public void printTrace(DB2Sqlca sqlca, java.io.PrintWriter printWriter, String header)
- static public void printTrace(java.lang.Throwable throwable, java.io.PrintWriter printWriter, String header)

Prints diagnostic information after an exception is thrown.

Parameter descriptions:

sqlException|sqlca|throwable
- The exception that was thrown during a previous JDBC or Java operation.

printWriter
- The destination for the diagnostic information.

header
- User-defined information that is printed at the beginning of the output.

“Example of a trace program under the IBM Data Server Driver for JDBC and SQLJ” on page 241

DB2FileReference class
The com.ibm.db2.jcc.DB2FileReference class is an abstract class that defines methods that support insertion of data into tables from file reference variables. This class applies only to IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for z/OS Version 9 or later.

DB2FileReference fields
The following constants define types codes only for the IBM Data Server Driver for JDBC and SQLJ.

public static final short MAX_FILE_NAME_LENGTH = 255
The maximum length of the file name for a file reference variable.

DB2FileReference methods
The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

gDriverType
Format:
public int getDriverType()
Returns the server data type of the file reference variable. This type is one of the values in com.ibm.db2.jcc.DB2Types.

gFileEncoding
Format:
public String getFileEncoding()
Returns the encoding of the data in the file for a DB2FileReference object.

gFileName
Format:
public String getFileName()
Returns the file name for a DB2FileReference object.

gFileCcsid
Format:
public int getFileCcsid()
Returns the CCSID of the data in the file for a DB2FileReference object.

sFileName
Format:
public String setFileName(String fileName)
throws java.sql.SQLException
Sets the file name in a DB2FileReference object.

Parameter descriptions:
**fileName**

The name of the input file for the file reference variable. The name must specify an existing HFS file.

---

**DB2JCCPlugin class**

The com.ibm.db2.jcc.DB2JCCPlugin class is an abstract class that defines methods that can be implemented to provide DB2 for Linux, UNIX, and Windows plug-in support. This class applies only to DB2 for Linux, UNIX, and Windows.

---

**DB2JCCPlugin methods**

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

**getTicket**

Format:

```java
public abstract byte[] getTicket(String user,
                                 String  password,
                                 byte[] returnedToken)
```

throws org.ietf.jgss.GSSException

Retrieves a Kerberos ticket for a user.

Parameter descriptions:

- **user**
  - The user ID for which the Kerberos ticket is to be retrieved.

- **password**
  - The password for user.

- **returnedToken**

---

**DB2ParameterMetaData interface**

The com.ibm.db2.jcc.DB2ParameterMetaData interface extends the java.sql.ParameterMetaData interface.

---

**DB2ParameterMetaData methods**

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

**getMaxStringUnitBits**

Format:

```java
public int getMaxStringUnitBits (int param)
```

throws java.sql.SQLException

Returns the maximum number of bits in a string unit for single-byte and double-byte character data types. The value that is returned is:

- **8**  For a character column that is defined with OCTETS.
- **16** For a character column that is defined with CODEUNITS16.
- **32** For a character column that is defined with CODEUNITS32.

Parameter descriptions:

- **param**
  - The ordinal position of a parameter in the CALL statement.
This method applies only to connections to DB2 for Linux, UNIX, and Windows Version 10.5 or later data servers.

**getParameterMarkerNames**

Format:

```java
public String[] getParameterMarkerNames()
throws java.sql.SQLException
```

Returns a list of the parameter marker names that are used in an SQL statement.

This method returns null if the enableNamedParameterMarkers property is set DB2BaseDataSource.NOT_SET or DB2BaseDataSource.NO, or if there are no named parameter markers in the SQL statement.

**getProcedureParameterName**

Format:

```java
public String getProcedureParameterName(int param)
throws java.sql.SQLException
```

Returns the name in the CREATE PROCEDURE statement of a parameter in an SQL CALL statement. If the parameter has no name in the CREATE PROCEDURE statement, the ordinal position of the parameter in the CREATE PROCEDURE statement is returned.

Parameter descriptions:

- **param**
  - The ordinal position of the parameter in the CALL statement.

This method applies to connections to DB2 for Linux, UNIX, and Windows 9.7 or later data servers only.

### DB2PooledConnection class

The com.ibm.db2.jcc.DB2PooledConnection class provides methods that an application server can use to switch users on a preexisting trusted connection.

Trusted connections are supported for:

- IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to:
  - DB2 for Linux, UNIX, and Windows Version 9.5 or later
  - DB2 for z/OS Version 9.1 or later
  - IBM Informix Version 11.70 or later
- IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS Version 9.1 or later

### DB2PooledConnection methods

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

**getConnection (untrusted or trusted reuse without reauthentication)**

Format:

```java
public DB2Connection getConnection()
throws java.sql.SQLException
```

This method is for dirty reuse of a connection. This means that the connection state is not reset when the object is reused from the pool. Special register settings and property settings remain in effect unless they are overridden by
passed properties. Global temporary tables are not deleted. Properties that are not specified are not re-initialized. All JDBC standard transient properties, such as the isolation level, autocommit mode, and read-only mode are reset to their JDBC defaults. Certain properties, such as user, password, databaseName, serverName, portNumber, planName, and pkList remain unchanged.

**getDB2Connection (trusted reuse)**

Formats:

```java
public DB2Connection getDB2Connection(byte[] cookie,
    String user,
    String password,
    String userRegistry,
    byte[] userSecToken,
    String originalUser,
    java.util.Properties properties)
throws java.sql.SQLException
```

```java
public Connection getDB2Connection(byte[] cookie,
    org.ietf.GSSCredential gssCredential,
    String usernameRegistry,
    byte[] userSecToken,
    String originalUser,
    java.util.Properties properties)
throws java.sql.SQLException
```

Switches the user that is associated with a trusted connection without authentication.

The second form of getDB2Connection is supported only for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

Parameter descriptions:

**cookie**

A unique cookie that the JDBC driver generates for the Connection instance. The cookie is known only to the application server and the underlying JDBC driver that established the initial trusted connection. The application server passes the cookie that was created by the driver when the pooled connection instance was created. The JDBC driver checks that the supplied cookie matches the cookie of the underlying trusted physical connection to ensure that the request originated from the application server that established the trusted physical connection. If the cookies match, the connection can become available, with different properties, for immediate use by a new user.

**user**

The client identity that is used by the data source to establish the authorization ID for the database server. If the user was not authenticated by the application server, the application server must pass a user identity that represents an unauthenticated user.

**password**

The password for user.

**gssCredential**

If the data source uses Kerberos security, specifies a delegated credential that is passed from another principal.

**userNameRegistry**

A name that identifies a mapping service that maps a workstation user ID to a z/OS RACF ID. An example of a mapping service is the Integrated Security Services Enterprise Identity Mapping (EIM). The mapping service
is defined by a plugin. Valid values for userNameRegistry are defined by the
plugin providers. If userNameRegistry is null, the connection does not use a
mapping service.

userSecToken
The client's security tokens. This value is traced as part of DB2 for z/OS
accounting data. The content of userSecToken is described by the application
server and is referred to by the data source as an application server
security token.

originalUser
The client identity that sends the original request to the application server.
originalUser is included in DB2 for z/OS accounting data as the original
user ID that was used by the application server.

properties
Properties for the reused connection. These properties override any
properties that are already defined on the DB2PooledConnection instance.

getDB2Connection (untrusted reuse with reauthentication)
Formats:
public DB2Connection getDB2Connection(
 String user,
 String password,
 java.util.Properties properties)
 throws java.sql.SQLException
public DB2Connection getDB2Connection(org.ietf.jgss.GSSCredential gssCredential,
 java.util.Properties properties)
 throws java.sql.SQLException

Switches the user that is associated with a untrusted connection, with
authentication.

The first form getDB2Connection provides a user ID and password. The
second form of getDB2Connection is for connections that use Kerberos security.

Parameter descriptions:

user
The user ID that is used by the data source to establish the authorization
ID for the database server.

password
The password for user.

properties
Properties for the reused connection. These properties override any
properties that are already defined on the DB2PooledConnection instance.

getDB2Connection (untrusted or trusted reuse without reauthentication)
Formats:
public java.sql.Connection getDB2Connection{
 java.util.Properties properties}
 throws java.sql.SQLException

Reuses an untrusted connection, without reauthentication.

This method is for dirty reuse of a connection. This means that the connection
state is not reset when the object is reused from the pool. Special register
settings and property settings remain in effect unless they are overridden by
passed properties. Global temporary tables are not deleted. Properties that are
not specified are not re-initialized. All JDBC standard transient properties, such
as the isolation level, autocommit mode, and read-only mode are reset to their
JDBC defaults. Certain properties, such as user, password, databaseName, serverName, portNumber, planName, and pkList remain unchanged.

Parameter descriptions:

properties
   Properties for the reused connection. These properties override any properties that are already defined on the DB2PooledConnection instance.

   “DB2ConnectionPoolDataSource class” on page 499

DB2PoolMonitor class

The com.ibm.db2.jcc.DB2PoolMonitor class provides methods for monitoring the global transport objects pool that is used for the connection concentrator and Sysplex workload balancing.

DB2PoolMonitor fields

The following fields are defined only for the IBM Data Server Driver for JDBC and SQLJ.

public static final int TRANSPORT_OBJECT = 1
   This value is a parameter for the DB2PoolMonitor.getPoolMonitor method.

DB2PoolMonitor methods

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

agedOutObjectCount
   Format:
   public abstract int agedOutObjectCount()

   Retrieves the number of objects that exceeded the idle time that was specified by db2.jcc.maxTransportObjectIdleTime and were deleted from the pool.

createdObjectCount
   Format:
   public abstract int createdObjectCount()

   Retrieves the number of objects that the IBM Data Server Driver for JDBC and SQLJ created since the pool was created.

getMonitorVersion
   Format:
   public int getMonitorVersion()

   Retrieves the version of the DB2PoolMonitor class that is shipped with the IBM Data Server Driver for JDBC and SQLJ.

getPoolMonitor
   Format:
   public static DB2PoolMonitor getPoolMonitor(int monitorType)

   Retrieves an instance of the DB2PoolMonitor class.
Parameter descriptions:

monitorType
- The monitor type. This value must be
  DB2PoolMonitor.TRANSPORT_OBJECT.

heavyWeightReusedObjectCount
- Format:
  public abstract int heavyWeightReusedObjectCount()

  Retrieves the number of objects that were reused from the pool.

lightWeightReusedObjectCount
- Format:
  public abstract int lightWeightReusedObjectCount()

  Retrieves the number of objects that were reused but were not in the pool. This
  can happen if a Connection object releases a transport object at a transaction
  boundary. If the Connection object needs a transport object later, and the
  original transport object has not been used by any other Connection object, the
  Connection object can use that transport object.

longestBlockedRequestTime
- Format:
  public abstract long longestBlockedRequestTime()

  Retrieves the longest amount of time that a request was blocked, in
  milliseconds.

numberOfConnectionReleaseRefused
- Format:
  public abstract int numberOfConnectionReleaseRefused()

  Retrieves the number of times that the release of a connection was refused.

numberOfRequestsBlocked
- Format:
  public abstract int numberOfRequestsBlocked()

  Retrieves the number of requests that the IBM Data Server Driver for JDBC
  and SQLJ made to the pool that the pool blocked because the pool reached its
  maximum capacity. A blocked request might be successful if an object is
  returned to the pool before the db2.jcc.maxTransportObjectWaitTime is
  exceeded and an exception is thrown.

numberOfRequestsBlockedDataSourceMax
- Format:
  public abstract int numberOfRequestsBlockedDataSourceMax()

  Retrieves the number of requests that the IBM Data Server Driver for JDBC
  and SQLJ made to the pool that the pool blocked because the pool reached the
  maximum for the DataSource object.

numberOfRequestsBlockedPoolMax
- Format:
  public abstract int numberOfRequestsBlockedPoolMax()
Retrieves the number of requests that the IBM Data Server Driver for JDBC and SQLJ made to the pool that the pool blocked because the maximum number for the pool was reached.

**removedObjectCount**
Format:
```
public abstract int removedObjectCount()
```
Retrieves the number of objects that have been deleted from the pool since the pool was created.

**shortestBlockedRequestTime**
Format:
```
public abstract long shortestBlockedRequestTime()
```
Retrieves the shortest amount of time that a request was blocked, in milliseconds.

**successfullRequestsFromPool**
Format:
```
public abstract int successfullRequestsFromPool()
```
Retrieves the number of successful requests that the IBM Data Server Driver for JDBC and SQLJ has made to the pool since the pool was created. A successful request means that the pool returned an object.

**totalPoolObjects**
Format:
```
public abstract int totalPoolObjects()
```
Retrieves the number of objects that are currently in the pool.

**totalRequestsToPool**
Format:
```
public abstract int totalRequestsToPool()
```
Retrieves the total number of requests that the IBM Data Server Driver for JDBC and SQLJ has made to the pool since the pool was created.

**totalTimeBlocked**
Format:
```
public abstract long totalTimeBlocked()
```
Retrieves the total time in milliseconds for requests that were blocked by the pool. This time can be much larger than the elapsed execution time of the application if the application uses multiple threads.

**DB2PreparedStatement interface**

**DB2PreparedStatement fields**
The following constants are defined only for the IBM Data Server Driver for JDBC and SQLJ.

```
public static DBIndicatorDefault DB_PARAMETER_DEFAULT
```
This constant can be used with standard interfaces, such as
PrepareStatement.setObject or ResultSet.updateObject to indicate that the
default value is assigned to the associated parameter.

public static DBIndicatorUnassigned DB_PARAMETER_UNASSIGNED

This constant can be used with standard interfaces, such as
PrepareStatement.setObject or ResultSet.updateObject to indicate that the
associated parameter is unaassigned.

**DB2PreparedStatement methods**

The following methods are defined only for the IBM Data Server Driver for JDBC
and SQLJ.

**executeDB2QueryBatch**

Format:

```java
public void executeDB2QueryBatch()
    throws java.sql.SQLException
```

Executes a statement batch that contains queries with parameters.
This method is not supported for connections to IBM Informix data sources.

**getDBGeneratedKeys**

Format:

```java
public java.sql.ResultSet[] getDBGeneratedKeys()
    throws java.sql.SQLException
```

Retrieves automatically generated keys that were created when INSERT
statements were executed in a batch. Each ResultSet object that is returned
contains the automatically generated keys for a single statement in the batch.
getDBGeneratedKeys returns an array of length 0 under the following
conditions:
- getDBGeneratedKeys is called out of sequence. For example, if
getDBGeneratedKeys is called before executeBatch, an array of length 0 is
returned.
- The PreparedStatement that is executed in a batch was not created using one
of the following methods:
  - Connection.prepareStatement(String sql, int[] autoGeneratedKeys)
  - Connection.prepareStatement(String sql, String[] autoGeneratedColumnNames)
  - Connection.prepareStatement(String sql, Statement.RETURN_GENERATED_KEYS)

If getDBGeneratedKeys is called against a PreparedStatement that was created
using one of the previously listed methods, and the PreparedStatement is not
in a batch, a single ResultSet is returned.

**getEstimateCost**

Format:

```java
public int getEstimateCost()
    throws java.sql.SQLException
```

Returns the estimated cost of an SQL statement from the data server after the
data server dynamically prepares the statement successfully. This value is the
same as the fourth element in the sqlerrd array of the SQLCA.

If the deferPrepares property is set to true, calling getEstimateCost causes the
data server to execute a dynamic prepare operation.

If the SQL statement cannot be prepared, or the data server does not return
estimated cost information at prepare time, getEstimateCost returns -1.
getEstimateRowCount
Format:
public int getEstimateRowCount()
    throws java.sql.SQLException

Returns the estimated row count for an SQL statement from the data server after the data server dynamically prepares the statement successfully. This value is the same as the third element in the sqlerrd array of the SQLCA.

If the deferPrepares property is set to true, calling getEstimateRowCount causes the data server to execute a dynamic prepare operation.

If the SQL statement cannot be prepared, or the data server does not return estimated row count information at prepare time, getEstimateRowCount returns -1.

setDBTimestamp
Format:
public void setDBTimestamp(int parameterIndex,
    DBTimestamp timestamp)
    throws java.sql.SQLException

Assigns a DBTimestamp value to a parameter.

Parameters:

parameterIndex
    The index of the parameter marker to which a DBTimestamp variable value is assigned.

timestamp
    The DBTimestamp value that is assigned to the parameter marker.

This method is not supported for connections to IBM Informix data sources.

setJccArrayAtName
Format:
public void setJccArrayAtName(String parameterMarkerName,
    java.sql.Array x)
    throws java.sql.SQLException

Assigns a java.sql.Array value to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

parameterMarkerName
    The name of the parameter marker to which a value is assigned.

x
    The java.sql.Array value that is assigned to the named parameter marker.

setJccAsciiStreamAtName
Formats:
Supported by the IBM Data Server Driver for JDBC and SQLJ version 3.57 and later:

public void setJccAsciiStreamAtName(String parameterMarkerName,
    java.io.InputStream x, int length)
    throws java.sql.SQLException
Supported by the IBM Data Server Driver for JDBC and SQLJ version 4.7 and later:

```java
public void setJccAsciiStreamAtName(String parameterMarkerName,
        java.io.InputStream x)
        throws java.sql.SQLException
```

Assigns an ASCII value in a java.io.InputStream to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

- `parameterMarkerName`
  - The name of the parameter marker to which a value is assigned.
- `x`
  - The ASCII java.io.InputStream value that is assigned to the parameter marker.
- `length`
  - The length in bytes of the java.io.InputStream value that is assigned to the named parameter marker.

```java
public void setJccAsciiStreamAtName(String parameterMarkerName,
        java.io.InputStream x, long length)
        throws java.sql.SQLException
```

**setJccBigDecimalAtName**

Format:

```java
public void setJccBigDecimalAtName(String parameterMarkerName,
        java.math.BigDecimal x)
        throws java.sql.SQLException
```

Assigns a java.math.BigDecimal value to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

- `parameterMarkerName`
  - The name of the parameter marker to which a value is assigned.
- `x`
  - The java.math.BigDecimal value that is assigned to the named parameter marker.

**setJccBinaryStreamAtName**

Formats:

Supported by the IBM Data Server Driver for JDBC and SQLJ version 3.57 and later:

```java
public void setJccBinaryStreamAtName(String parameterMarkerName,
        java.io.InputStream x, int length)
        throws java.sql.SQLException
```

Supported by the IBM Data Server Driver for JDBC and SQLJ version 4.7 and later:

```java
public void setJccBinaryStreamAtName(String parameterMarkerName,
        java.io.InputStream x, long length)
        throws java.sql.SQLException
```

Assigns a binary value in a java.io.InputStream to a named parameter marker.
This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

`parameterMarkerName`
- The name of the parameter marker to which a value is assigned.

`x`
- The binary java.io.InputStream value that is assigned to the parameter marker.

`length`
- The number of bytes of the java.io.InputStream value that are assigned to the named parameter marker.

`setJccBlobAtName`

Format:

Supported by the IBM Data Server Driver for JDBC and SQLJ version 3.57 and later:

```java
public void setJccBlobAtName(String parameterMarkerName,
   java.sql.Blob x)
   throws java.sql.SQLException
```

Supported by the IBM Data Server Driver for JDBC and SQLJ version 4.7 and later:

```java
public void setJccBlobAtName(String parameterMarkerName,
   java.io.InputStream x)
   throws java.sql.SQLException
```

```java
public void setJccBlobAtName(String parameterMarkerName,
   java.io.InputStream x, long length)
   throws java.sql.SQLException
```

Assigns a BLOB value to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

`parameterMarkerName`
- The name of the parameter marker to which a value is assigned.

`x`
- The java.sql.Blob value or java.io.InputStream value that is assigned to the parameter marker.

`length`
- The number of bytes of the java.io.InputStream value that are assigned to the named parameter marker.

`setJccBooleanAtName`

Format:

```java
public void setJccBooleanAtName(String parameterMarkerName,
   boolean x)
   throws java.sql.SQLException
```

Assigns a boolean value to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:
**parameterMarkerName**

The name of the parameter marker to which a value is assigned.

x  The boolean value that is assigned to the named parameter marker.

**setJccByteAtName**

Format:

```java
public void setJccByteAtName(String parameterMarkerName,
   byte x)
   throws java.sql.SQLException
```

Assigns a byte value to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

- **parameterMarkerName**
  The name of the parameter marker to which a value is assigned.
- **x**  The byte value that is assigned to the named parameter marker.

**setJccBytesAtName**

Format:

```java
public void setJccBytesAtName(String parameterMarkerName,
   byte[] x)
   throws java.sql.SQLException
```

Assigns an array of byte values to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

- **parameterMarkerName**
  The name of the parameter marker to which a value is assigned.
- **x**  The byte array that is assigned to the named parameter marker.

**setJccCharacterStreamAtName**

Formulas:

Supported by the IBM Data Server Driver for JDBC and SQLJ version 3.57 and later:

```java
public void setJccCharacterStreamAtName(String parameterMarkerName,
   java.io.Reader x, int length)
   throws java.sql.SQLException
```

Supported by the IBM Data Server Driver for JDBC and SQLJ version 4.7 and later:

```java
public void setJccCharacterStreamAtName(String parameterMarkerName,
   java.io.Reader x)
   throws java.sql.SQLException

public void setJccCharacterStreamAtName(String parameterMarkerName,
   java.io.Reader x, long length)
   throws java.sql.SQLException
```

Assigns a Unicode value in a java.io.Reader to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:
**parameterMarkerName**

The name of the parameter marker to which a value is assigned.

**x**

The Unicode java.io.Reader value that is assigned to the named parameter marker.

**length**

The number of characters of the java.io.InputStream value that are assigned to the named parameter marker.

**setJccClobAtName**

Formats:

Supported by the IBM Data Server Driver for JDBC and SQLJ version 3.57 and later:

```java
public void setJccClobAtName(String parameterMarkerName,
   java.sql.Clob x)
   throws java.sql.SQLException
```

Supported by the IBM Data Server Driver for JDBC and SQLJ version 4.7 and later:

```java
public void setJccClobAtName(String parameterMarkerName,
   java.io.Reader x)
   throws java.sql.SQLException

public void setJccClobAtName(String parameterMarkerName,
   java.io.Reader x, long length)
   throws java.sql.SQLException
```

Assigns a CLOB value to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

**parameterMarkerName**

The name of the parameter marker to which a value is assigned.

**x**

The java.sql.Clob value or java.io.Reader value that is assigned to the named parameter marker.

**length**

The number of bytes of the java.io.InputStream value that are assigned to the named parameter marker.

**setJccDateAtName**

Formats:

```java
public void setJccDateAtName(String parameterMarkerName,
   java.sql.Date x)
   throws java.sql.SQLException

public void setJccDateAtName(String parameterMarkerName,
   java.sql.Date x,
   java.util.Calendar cal)
   throws java.sql.SQLException
```

Assigns a java.sql.Date value to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

**parameterMarkerName**

The name of the parameter marker to which a value is assigned.
The java.sql.Date value that is assigned to the named parameter marker.

cal
The java.util.Calendar object that the IBM Data Server Driver for JDBC and SQLJ uses to construct the date.

**setJccDBTimestampAtName**
Format:
```
public void setJccDBTimestampAtName(String parameterMarkerName,
DBTimestamp timestamp)
throws java.sql.SQLException
```
Assigns a DBTimestamp value to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

*parameterMarkerName*

The name of the parameter marker to which a DBTimestamp variable value is assigned.

*timeStamp*

The DBTimestamp value that is assigned to the named parameter marker.

This method is not supported for connections to IBM Informix data sources.

**setJccDBDefaultAtName**
Formats:
```
public void setJccDBDefaultAtName(String parameterMarkerName)
throws SQLException
```
Assigns the default value to a named parameter marker. Execution of setJccDBDefaultAtName produces the same results as using the literal DEFAULT in the SQL string, instead of the parameter marker name.

Parameters:

*parameterMarkerName*

The name of the parameter marker to which a value is assigned.

This method is not supported for connections to IBM Informix data sources.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

**setJccDBUnassignedAtName**
Formats:
```
public void setJccDBUnassignedAtName(String parameterMarkerName)
throws SQLException
```
Does not assign a value to the specified named parameter. Execution of setJccDBUnassignedAtName produces the same result as if the specified parameter marker name had not appeared in the SQL string.

Parameters:

*parameterMarkerName*

The name of the parameter marker whose value is to be unassigned.

This method is not supported for connections to IBM Informix data sources.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).
**setJccDoubleAtName**

Format:
```
public void setJccDoubleAtName(String parameterMarkerName,
        double x)
        throws java.sql.SQLException
```

Assigns a value of type double to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property
is set to DB2BaseDataSource.YES (1).

Parameters:

- `parameterMarkerName`  
The name of the parameter marker to which a value is assigned.
- `x`  
The value of type double that is assigned to the parameter marker.

**setJccFloatAtName**

Format:
```
public void setJccFloatAtName(String parameterMarkerName,
        float x)
        throws java.sql.SQLException
```

Assigns a value of type float to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property
is set to DB2BaseDataSource.YES (1).

Parameters:

- `parameterMarkerName`  
The name of the parameter marker to which a value is assigned.
- `x`  
The value of type float that is assigned to the parameter marker.

**setJccIntAtName**

Format:
```
public void setJccIntAtName(String parameterMarkerName,
        int x)
        throws java.sql.SQLException
```

Assigns a value of type int to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property
is set to DB2BaseDataSource.YES (1).

Parameters:

- `parameterMarkerName`  
The name of the parameter marker to which a value is assigned.
- `x`  
The value of type int that is assigned to the parameter marker.

**setJccLongAtName**

Format:
```
public void setJccLongAtName(String parameterMarkerName,
        long x)
        throws java.sql.SQLException
```

Assigns a value of type long to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property
is set to DB2BaseDataSource.YES (1).
Parameters:

parameterMarkerName
The name of the parameter marker to which a value is assigned.

x The value of type long that is assigned to the parameter marker.

setJccNullAtName
Format:

public void setJccNullAtName(String parameterMarkerName,
   int jdbcType)
   throws java.sql.SQLException
public void setJccNullAtName(String parameterMarkerName,
   int jdbcType,
   String typeName)
   throws java.sql.SQLException

Assigns the SQL NULL value to a named parameter marker.
This method can be called only if the enableNamedParameterMarkers property
is set to DB2BaseDataSource.YES(1).

Parameters:

parameterMarkerName
The name of the parameter marker to which a value is assigned.

jdbcType
The JDBC type code of the NULL value that is assigned to the parameter
marker, as defined in java.sql.Types.

typeName
If jdbcType is java.sql.Types.DISTINCT or java.sql.Types.REF, the
fully-qualified name of the SQL user-defined type of the NULL value that
is assigned to the parameter marker.

setJccObjectAtName
Formats:

public void setJccObjectAtName(String parameterMarkerName,
   java.sql.Object x)
   throws java.sql.SQLException
public void setJccObjectAtName(String parameterMarkerName,
   java.sql.Object x,
   int targetJdbcType)
   throws java.sql.SQLException
public void setJccObjectAtName(String parameterMarkerName,
   java.sql.Object x,
   int targetJdbcType,
   int scale)
   throws java.sql.SQLException

Assigns a value with type java.lang.Object to a named parameter marker.
This method can be called only if the enableNamedParameterMarkers property
is set to DB2BaseDataSource.YES(1).

Parameters:

parameterMarkerName
The name of the parameter marker to which a value is assigned.

x The value with type Object that is assigned to the parameter marker.
**targetJdbcType**

The data type, as defined in java.sql.Types, that is assigned to the input value when it is sent to the data source.

**scale**

The scale of the value that is assigned to the parameter marker. This parameter applies only to these cases:

- If `targetJdbcType` is java.sql.Types.DECIMAL or java.sql.Types.Numeric, `scale` is the number of digits to the right of the decimal point.
- If `x` has type java.io.InputStream or java.io.Reader, `scale` is the length of the data in the Stream or Reader object.

**setJccShortAtName**

Format:

```java
public void setJccShortAtName(String parameterMarkerName, short x)
throws java.sql.SQLException
```

Assigns a value of type short to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

- `parameterMarkerName` The name of the parameter marker to which a value is assigned.
- `x` The value of type short that is assigned to the parameter marker.

**setJccSQLXMLAtName**

Format:

```java
public void setJccSQLXMLAtName(String parameterMarkerName, java.sql.SQLXML x)
throws java.sql.SQLException
```

Assigns a value of type java.sql.SQLXML to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

This method is supported only for connections to DB2 for Linux, UNIX, and Windows Version 9.1 or later or DB2 for z/OS Version 9 or later.

Parameters:

- `parameterMarkerName` The name of the parameter marker to which a value is assigned.
- `x` The value of type java.sql.SQLXML that is assigned to the parameter marker.

**setJccStringAtName**

Format:

```java
public void setJccStringAtName(String parameterMarkerName, String x)
throws java.sql.SQLException
```

Assigns a value of type String to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).
Assigns a java.sql.Time value to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

parameterMarkerName
   The name of the parameter marker to which a value is assigned.

x  The java.sql.Time value that is assigned to the parameter marker.

cal  The java.util.Calendar object that the IBM Data Server Driver for JDBC and SQLJ uses to construct the time.

Assigns a java.sql.Timestamp value to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

parameterMarkerName
   The name of the parameter marker to which a value is assigned.

x  The java.sql.Timestamp value that is assigned to the parameter marker.

cal  The java.util.Calendar object that the IBM Data Server Driver for JDBC and SQLJ uses to construct the timestamp.

Assigns a java.io.InputStream value to a named parameter marker.

This method requires that the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

parameterMarkerName
   The name of the parameter marker to which a value is assigned.

x  The java.io.InputStream value that is assigned to the parameter marker.
Assigns a Unicode value in a java.io.InputStream to a named parameter marker.

This method can be called only if the enableNamedParameterMarkers property is set to DB2BaseDataSource.YES (1).

Parameters:

`parameterMarkerName`  
The name of the parameter marker to which a value is assigned.

`x`  
The Unicode java.io.InputStream value that is assigned to the parameter marker.

`length`  
The number of bytes of the java.io.InputStream value that are assigned to the parameter marker.

**setDBDefault**

Formats:

```java
public void setDBDefault(int parameterIndex)
  throws SQLException
```

Assigns the default value to the specified parameter. Execution of setDBDefault produces the same results as using the literal DEFAULT in the SQL string, instead of the parameter.

Parameters:

`parameterIndex`  
The number of the parameter whose value is being updated.

This method is not supported for connections to IBM Informix data sources.

**setDBUnassigned**

Formats:

```java
public void setDBUnassigned(int parameterIndex)
  throws SQLException
```

Does not assign a value to the specified parameter. Execution of setDBUnassigned produces the same result as if the specified parameter had not appeared in the SQL string.

Parameters:

`parameterIndex`  
The number of the parameter whose value is to be unassigned.

This method is not supported for connections to IBM Informix data sources.

**Related tasks:**

“Making batch queries in JDBC applications” on page 60

**DB2ResultSet interface**

The com.ibm.db2.jcc.DB2ResultSet interface is used to create objects from which IBM Data Server Driver for JDBC and SQLJ-only query information can be obtained.

DB2ResultSet implements the java.sql.Wrapper interface.
DB2ResultSet fields

The following fields are defined only for the IBM Data Server Driver for JDBC and SQLJ.

The integer constants in the following table are used in the column descriptor information that getDB2RowDescriptor returns. These constants contain information about the column values that are returned by getDB2RowAsBytes. All fields are defined as public static int.

<table>
<thead>
<tr>
<th>Field value</th>
<th>Description of returned data</th>
</tr>
</thead>
<tbody>
<tr>
<td>REPRESENTATION_FIXED_STRING (0)</td>
<td>Fixed-length string data</td>
</tr>
<tr>
<td>REPRESENTATION_BIG_ENDIAN (1)</td>
<td>Signed binary format in which the most significant byte is stored in the highest address</td>
</tr>
<tr>
<td>REPRESENTATION_LITTLE_ENDIAN (2)</td>
<td>Signed binary format in which the least significant byte is stored in the highest address</td>
</tr>
<tr>
<td>REPRESENTATION_VARIABLE_STRING (2)</td>
<td>String data that begins with a two-byte length field</td>
</tr>
<tr>
<td>REPRESENTATION_NUL_TERMINATED_STRING (3)</td>
<td>Nul-terminated string data</td>
</tr>
<tr>
<td>REPRESENTATION_FIXED_BYTES (4)</td>
<td>Fixed-length byte string</td>
</tr>
<tr>
<td>REPRESENTATION_VARIABLE_BYTES (5)</td>
<td>Byte string that begins with a two-byte length field</td>
</tr>
<tr>
<td>REPRESENTATION_NUL_TERMINATED_BYTES (7)</td>
<td>Nul-terminated byte data</td>
</tr>
<tr>
<td>REPRESENTATION_FIXED_BINARY (15)</td>
<td>Fixed-length binary string</td>
</tr>
<tr>
<td>REPRESENTATION_VARIABLE_BINARY (16)</td>
<td>Binary string that begins with a two-byte length field</td>
</tr>
<tr>
<td>REPRESENTATION_Packed_DECIMAL (48)</td>
<td>Nul-terminated binary string</td>
</tr>
<tr>
<td>REPRESENTATION_NUMERIC_CHARACTER (50)</td>
<td>Character-based, fixed-point format</td>
</tr>
<tr>
<td>REPRESENTATION_ZONED_DECIMAL (51)</td>
<td>Zoned-decimal format that is returned by IBM System i and IBM System z</td>
</tr>
<tr>
<td>REPRESENTATION_COBOL2_ZONED_DECIMAL (53)</td>
<td>Zoned-decimal format that is returned by Windows or UNIX systems</td>
</tr>
<tr>
<td>REPRESENTATION_HEXADECIMAL_FLOATING_POINT (64)</td>
<td>S/390 hexadecimal floating point format</td>
</tr>
<tr>
<td>REPRESENTATION_DECIMAL_FLOATING_POINT (66)</td>
<td>Decimal floating point format</td>
</tr>
<tr>
<td>REPRESENTATION_IEEE_754_FLOATING_POINT_BYTE_REVERSED (71)</td>
<td>IEEE floating-point format in which the least significant byte is stored in the highest address</td>
</tr>
<tr>
<td>REPRESENTATION_IEEE_754_FLOATING_POINT (72)</td>
<td>IEEE floating-point format in which the most significant byte is stored in the highest address</td>
</tr>
</tbody>
</table>

DB2ResultSet methods

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

getDB2RowChangeToken
Format:
```java
public long DB2ResultSet.getDB2RowChangeToken()
throws java.sql.SQLException
```

Returns the row change token for the current row, if it is available. Returns 0 if optimistic locking columns were not requested or are not available.

This method applies only to connections to DB2 for Linux, UNIX, and Windows.

getDB2RID
Format:
public Object DB2ResultSet.getDB2RID()
         throws java.sql.SQLException

Returns the RID for the current row, if it is available. The RID is available if optimistic locking columns were requested and are available. Returns null if optimistic locking columns were not requested or are not available.

This method applies only to connections to DB2 for Linux, UNIX, and Windows.

getDB2RIDType
Format:
public int DB2ResultSet.getDB2RIDType()
         throws java.sql.SQLException

Returns the data type of the RID column in a DB2ResultSet. The returned value maps to a java.sql.Types constant. If the DB2ResultSet does not contain a RID column, java.sql.Types.NULL is returned.

This method applies only to connections to DB2 for Linux, UNIX, and Windows.

getDBRowDataAsBytes
Format:
public Object [] getDBRowDataAsBytes()
         throws SQLException

Returns an Object array that represents the data in the current row of an open ResultSet object.

This method does not apply to connections to IBM Informix.

getDBRowDataAsBytes cannot be called if the ResultSet object on which it operates meets any of the following conditions:

• A ResultSet row that is being retrieved has been updated, deleted, or inserted.
• The ResultSet object was created for optimistic locking.

The returned information includes:
• The data in raw byte array format
• The offset to the data for each column

Suppose that obj is an instance of the returned Object array. The format of the Object array is:

obj[0]  A byte array that describes the row data.

obj[1]  An integer array that contains the offset into obj[0] of each column description. The offsets can be used to determine the length of the data that is returned for each column. That length represents the length of the raw data, and not the defined length of the column.

If a ResultSet object contains a column of any of the following types, the offset value for that column value in obj[1] is -1. -1 indicates that a value for that column is not returned.

• BLOB
• CLOB
• DBCLOB
• XML

The byte array in obj[0] has the following format:
There is one rnnn...dd set for each column in the row.

The following table describes the contents of the row data:

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>r</td>
<td>A single byte that has one of the following values:</td>
</tr>
<tr>
<td></td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>1</td>
</tr>
<tr>
<td>nn</td>
<td>A two-byte NULL indicator for a column value. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>-1</td>
</tr>
<tr>
<td></td>
<td>0</td>
</tr>
<tr>
<td>dd...dd</td>
<td>Raw byte data for a column value.</td>
</tr>
</tbody>
</table>

getDBRowDescriptor
Format:
public int [] getDBRowDescriptor()
    throws SQLException

Returns an int array that contains descriptive information about each column of the row data that is returned by getDBRowDataAsBytes.

This method does not apply to connections to IBM Informix.

Suppose that returnedInfo is an instance of the array that is returned by getDBRowDescriptor. The format of the returned array is:

returnedInfo[0]
    The number of columns in the row data. Suppose that this value is n.

returnedInfo[1] through returnedInfo[4*n]
    n repeating groups of four integer values. Each group contains descriptive information for a single column. That information is:

<table>
<thead>
<tr>
<th>Column descriptor number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The data type of the column, expressed as an SQLTYPE value. This value is the same as the SQLTYPE value that is returned in an SQLDA.</td>
</tr>
<tr>
<td>2</td>
<td>The CCSID of the column, for a character data type. For a DECIMAL data type, this value is the scale of the column.</td>
</tr>
<tr>
<td>3</td>
<td>The defined length of the column, for all data types except DECIMAL. For a DECIMAL data type, this value is the precision of the column. For varying-length character data types, this value might be greater than the number of returned bytes.</td>
</tr>
<tr>
<td>4</td>
<td>Additional information about the column. Possible values are described in &quot;DB2ResultSet fields&quot; on page 533.</td>
</tr>
</tbody>
</table>

getDBTimestamp
Format:
public DBTimestamp getDBTimestamp(int parameterIndex)
    throws SQLException
public DBTimestamp getDBTimestamp(String parameterName)
    throws SQLException

Returns the value in the current row of a TIMESTAMP or TIMESTAMP WITH
TIME ZONE column that is in a DB2ResultSet object as a DBTimestamp object.
For a TIMESTAMP column, the returned value has the local time zone. If the
value of the DB2ResultSet column is NULL, the returned value is null.

Parameters:
  
  parameterIndex
    The number of the column in the DB2ResultSet whose value is being
    retrieved.
  
  parameterName
    The name of the column in the DB2ResultSet whose value is being
    retrieved.

updateDBDefault
  Formats:
public void updateDBDefault(int parameterIndex)
    throws SQLException
public void updateDBDefault(String columnName)
    throws SQLException

Assigns the default value to the specified column in a DB2ResultSet object.
This method does not update the underlying table.

Parameters:
  
  parameterIndex
    The number of the column in the DB2ResultSet whose value is being
    updated.
  
  columnName
    The name of the column in the DB2ResultSet whose value is being
    updated.

  This method is not supported for connections to IBM Informix data sources.

DB2ResultSetMetaData interface
  The com.ibm.db2.jcc.DB2ResultSetMetaData interface provides methods that
  provide information about a ResultSet object.

Before a com.ibm.db2.jcc.DB2ResultSetMetaData method can be used, a
java.sql.ResultSetMetaData object that is returned from a
java.sql.ResultSet.getMetaData call needs to be cast to
com.ibm.db2.jcc.DB2ResultSetMetaData.

DB2ResultSetMetaData methods:

The following methods are defined only for the IBM Data Server Driver for JDBC
and SQLJ.

getDB2OptimisticLockingColumns
  Format:
  public int getDB2OptimisticLockingColumns()
    throws java.sql.SQLException
Returns a value that indicates whether optimistic locking columns are available. Possible values are:

0  Optimistic locking columns are not available.
1  Optimistic locking columns are available, but the change token might not have the granularity to prevent false negatives.
2  Optimistic locking columns are available, and the change token has the granularity to prevent false negatives.

**getDBTemporalColumnType**

Format:

```java
public int getDBTemporalColumnType (int column)
throws java.sql.SQLException
```

Returns:

-1  If `column` is not a ROW BEGIN, ROW END or TRANSACTION START ID column.
1   If `column` is a ROW BEGIN column.
2   If `column` is a ROW END column.
3   If `column` is a TRANSACTION START ID column.

Parameter descriptions:

`column`

The ordinal position of a column in the ResultSet.

**getMaxStringUnitBits**

Format:

```java
public int getMaxStringUnitBits (int column)
throws java.sql.SQLException
```

Returns the maximum number of bits in a string unit for single-byte and double-byte character data types. The value that is returned is:

8   For a character column that is defined with OCTETS.
16  For a character column that is defined with CODEUNITS16.
32  For a character column that is defined with CODEUNITS32.

Parameter descriptions:

`column`

The ordinal position of a column in the ResultSet.

This method applies only to connections to DB2 for Linux, UNIX, and Windows Version 10.5 or later data servers.

**isDB2ColumnNameDerived**

Format:

```java
public boolean isDB2ColumnNameDerived (int column)
throws java.sql.SQLException
```

Returns true if the name of a ResultSet column is in the SQL SELECT list that generated the ResultSet.

For example, suppose that a ResultSet is generated from the SQL statement

```
SELECT EMPNAME, SUM(SALARY) FROM EMP.
```

Column name EMPNAME
is derived from the SQL SELECT list, but the name of the column in the
ResultSet that corresponds to SUM(SALARY) is not derived from the SELECT
list.

Parameter descriptions:

**column**
The ordinal position of a column in the ResultSet.

**DB2RowID interface**
The com.ibm.db2.jcc.DB2RowID interface is used for declaring Java objects for use
with the SQL ROWID data type.

The com.ibm.db2.jcc.DB2RowID interface does not apply to connection to IBM
Informix.

**DB2RowID methods**
The following method is defined only for the IBM Data Server Driver for JDBC
and SQLJ.

**getBytes**
Format:
```
public byte[] getBytes()
```

Converts a com.ibm.jcc.DB2RowID object to bytes.

**Related concepts:**
“ROWIDs in SQLJ with the IBM Data Server Driver for JDBC and SQLJ” on page
184
“ROWIDs in JDBC with the IBM Data Server Driver for JDBC and SQLJ” on page
94

**DB2SimpleDataSource class**
The com.ibm.db2.jcc.DB2SimpleDataSource class extends the DB2BaseDataSource
class.

A DB2BaseDataSource object does not support connection pooling or distributed
transactions. It contains all of the properties and methods that the
DB2BaseDataSource class contains. In addition, DB2SimpleDataSource contains the
following IBM Data Server Driver for JDBC and SQLJ-only properties.

DB2SimpleDataSource implements the java.sql.Wrapper interface.

**DB2SimpleDataSource methods**
The following method is defined only for the IBM Data Server Driver for JDBC
and SQLJ.

**setPassword**
Format:
```
public synchronized void setPassword(String password)
```

Sets the password for the DB2SimpleDataSource object. There is no
corresponding getPassword method. Therefore, the password cannot be
encrypted because there is no way to retrieve the password so that you can
decrypt it.
DB2Sqlca class

The com.ibm.db2.jcc.DB2Sqlca class is an encapsulation of the SQLCA.

DB2Sqlca methods

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

getMessage
Format:
public abstract String getMessage()

Returns error message text.

getSqlCode
Format:
public abstract int getSqlCode()

Returns an SQL error code value.

getSqlErrd
Format:
public abstract int[] getSqlErrd()

Returns an array, each element of which contains an SQLCA SQLERRD.

getSqlErrmc
Format:
public abstract String getSqlErrmc()

Returns a string that contains the SQLCA SQLERRMC values, delimited with spaces.

getSqlErrmcTokens
Format:
public abstract String[] getSqlErrmcTokens()

Returns an array, each element of which contains an SQLCA SQLERRMC token.

getSqlErrp
Format:
public abstract String getSqlErrp()

Returns the SQLCA SQLERRP value.

getSqlState
Format:
public abstract String getSqlState()
getSqlWarn

Format:
```
public abstract char[] getSqlWarn()
```

Returns the SQLCA SQLSTATE value.

getSqlWarn

Format:
```
public abstract char[] getSqlWarn()
```

Returns an array, each element of which contains an SQLCA SQLWARN value.

Related tasks:
- "Handling SQL warnings in an SQLJ application" on page 199
- "Handling an SQLException under the IBM Data Server Driver for JDBC and SQLJ" on page 131

### DB2Statement interface

The `com.ibm.db2.jcc.DB2Statement` interface extends the `java.sql.Statement` interface.

DB2Statement implements the `java.sql.Wrapper` interface.

#### DB2Statement fields

The following fields are defined only for the IBM Data Server Driver for JDBC and SQLJ:

- `public static final int RETURN_OPTLOCK_COLUMN_NONE = 0`
- `public static final int RETURN_OPTLOCK_COLUMN_ALWAYS = 1`
- `public static final int RETURN_OPTLOCK_COLUMN_NO_FALSE_NEGATIVES = 2`

These values are arguments for the `DB2Statement.executeDB2OptimisticLockingQuery` method.

#### DB2Statement methods

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

**executeDB2OptimisticLockingQuery**

Format:
```
public java.sql.ResultSet DB2Statement.executeDB2OptimisticLockingQuery(
    String sql,
    int returnOptLockingColumns)
throws java.sql.SQLException
```

Executes an SQL query statement, and returns a ResultSet that contains optimistic locking information, if it is requested.

Parameter descriptions:

- `sql` An SQL SELECT statement that returns a single ResultSet.
- `returnOptLockingColumns` Specifies whether optimistic locking columns are returned. Possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2Statement.RETURN_OPTLOCK_COLUMN_NONE (0)</td>
<td>Do not return optimistic locking columns.</td>
</tr>
</tbody>
</table>

---

540  Developing Java Applications
getAffectedRowCount
Format:
public int getAffectedRowCount()
throws java.sql.SQLException

Returns the number of rows that are affected by successful execution of an SQL statement. If the SQL statement is INSERT, UPDATE, or DELETE, getAffectedRowCount returns the same value that is returned by java.sql.Statement.getUpdateCount.

The value that is returned by getAffectedRowCount is the same information that is returned by the data server in the SQLCA after successful execution of an SQL statement.

getDB2ClientProgramId
Format:
public String getDB2ClientProgramId()
throws java.sql.SQLException

Returns the user-defined client program identifier for the connection, which is stored on the data source.

getDB2ClientProgramId does not apply to DB2 for Linux, UNIX, and Windows data servers.

setDB2ClientProgramId
Format:
public abstract void setDB2ClientProgramId(String program-ID)
throws java.sql.SQLException

Sets a user-defined program identifier for the connection on a data server. That program identifier is an 80-byte string that is used to identify the caller.

setDB2ClientProgramId does not apply to DB2 for Linux, UNIX, and Windows data servers.

The DB2 for z/OS server places the string in IFCID 316 trace records along with other statistics, so that you can identify which program is associated with a particular SQL statement.

getIDSBigSerial
Format:
public int getIDSBigSerial()
throws java.sql.SQLException

Retrieves an automatically generated key from a BIGSERIAL column after the automatically generated key was inserted by a previously executed INSERT statement.

Chapter 13. JDBC and SQLJ reference information
541
The following conditions must be true for getIDSBigSerial to execute successfully:

- The INSERT statement is the last SQL statement that is executed before this method is called.
- The table into which the row is inserted contains a BIGSERIAL column.
- The form of the JDBC Connection.prepareStatement method or Statement.executeUpdate method that prepares or executes the INSERT statement does not have parameters that request automatically generated keys.

This method applies only to connections to IBM Informix databases.

**getIDSBigSerial**

Format:

```java
public int getIDSBigSerial()
    throws java.sql.SQLException
```

Retrieves an automatically generated key from a BIGSERIAL column after the automatically generated key was inserted by a previously executed INSERT statement.

The following conditions must be true for getIDSBigSerial to execute successfully:

- The INSERT statement is the last SQL statement that is executed before this method is called.
- The table into which the row is inserted contains a BIGSERIAL column.
- The form of the JDBC Connection.prepareStatement method or Statement.executeUpdate method that prepares or executes the INSERT statement does not have parameters that request automatically generated keys.

This method applies only to connections to IBM Informix databases.

**getIDSSerial**

Format:

```java
public long getIDSSerial()
    throws java.sql.SQLException
```

Retrieves an automatically generated key from a SERIAL column after the automatically generated key was inserted by a previously executed INSERT statement.

The following conditions must be true for getIDSSerial to execute successfully:

- The INSERT statement is the last SQL statement that is executed before this method is called.
- The table into which the row is inserted contains a SERIAL column.
- The form of the JDBC Connection.prepareStatement method or Statement.executeUpdate method that prepares or executes the INSERT statement does not have parameters that request automatically generated keys.

This method applies only to connections to IBM Informix databases.

**getIDSSerial8**

Format:

```java
public long getIDSSerial8()
    throws java.sql.SQLException
```

Retrieves an automatically generated key from a SERIAL8 column after the automatically generated key was inserted by a previously executed INSERT statement.

The following conditions must be true for getIDSSerial8 to execute successfully:

- The INSERT statement is the last SQL statement that is executed before this method is called.
- The table into which the row is inserted contains a SERIAL8 column.
- The form of the JDBC Connection.prepareStatement method or Statement.executeUpdate method that prepares or executes the INSERT statement does not have parameters that request automatically generated keys.

This method applies only to connections to IBM Informix data sources.

**getIDSSQLStatementOffSet**

Format:

```java
public int getIDSSQLStatementOffSet()
    throws java.sql.SQLException
```

Retrieves an automatically generated key from a SERIAL column after the automatically generated key was inserted by a previously executed INSERT statement.

The following conditions must be true for getIDSSQLStatementOffSet to execute successfully:

- The INSERT statement is the last SQL statement that is executed before this method is called.
- The table into which the row is inserted contains a SERIAL column.
- The form of the JDBC Connection.prepareStatement method or Statement.executeUpdate method that prepares or executes the INSERT statement does not have parameters that request automatically generated keys.

This method applies only to connections to IBM Informix data sources.
After an SQL statement executes on an IBM Informix data source, if the statement has a syntax error, getIDDSQLStatementOffSet returns the offset into the statement text of the syntax error.

getIDDSQLStatementOffSet returns:

- 0, if the statement does not have a syntax error.
- -1, if the data source is not IBM Informix.

This method applies only to connections to IBM Informix data sources.

Related reference:
["DB2PreparedStatement interface" on page 520](#)

**DB2SystemMonitor interface**

The com.ibm.db2.jcc.DB2SystemMonitor interface is used for collecting system monitoring data for a connection. Each connection can have one DB2SystemMonitor instance.

**DB2SystemMonitor fields**

The following fields are defined only for the IBM Data Server Driver for JDBC and SQLJ.

```java
public final static int RESET_TIMES
public final static int ACCUMULATE_TIMES
```

These values are arguments for the DB2SystemMonitor.start method.
- RESET_TIMES sets time counters to zero before monitoring starts.
- ACCUMULATE_TIMES does not set time counters to zero.

**DB2SystemMonitor methods**

The following methods are defined only for the IBM Data Server Driver for JDBC and SQLJ.

**enable**

Format:
```java
public void enable(boolean on) throws java.sql.SQLException
```

Enables the system monitor that is associated with a connection. This method cannot be called during monitoring. All times are reset when enable is invoked.

**getApplicationTimeMillis**

Format:
```java
public long getApplicationTimeMillis() throws java.sql.SQLException
```

Returns the sum of the application, JDBC driver, network I/O, and database server elapsed times. The time is in milliseconds.

A monitored elapsed time interval is the difference, in milliseconds, between these points in the JDBC driver processing:

**Interval beginning**
- When start is called.

**Interval end**
- When stop is called.
getApplicationTimeMillis returns 0 if system monitoring is disabled. Calling this method without first calling the stop method results in an SQLException.

**getCoreDriverTimeMicros**

Format:

```java
public long getCoreDriverTimeMicros()
    throws java.sql.SQLException
```

Returns the sum of elapsed monitored API times that were collected while system monitoring was enabled. The time is in microseconds.

A monitored API is a JDBC driver method for which processing time is collected. In general, elapsed times are monitored only for APIs that might result in network I/O or database server interaction. For example, PreparedStatement.setXXX methods and ResultSet.getXXX methods are not monitored.

Monitored API elapsed time includes the total time that is spent in the driver for a method call. This time includes any network I/O time and database server elapsed time.

A monitored API elapsed time interval is the difference, in microseconds, between these points in the JDBC driver processing:

**Interval beginning**

When a monitored API is called by the application.

**Interval end**

Immediately before the monitored API returns control to the application.

getCoreDriverTimeMicros returns 0 if system monitoring is disabled. Calling this method without first calling the stop method, or calling this method when the underlying JVM does not support reporting times in microseconds results in an SQLException.

**getNetworkIOTimeMicros**

Format:

```java
public long getNetworkIOTimeMicros()
    throws java.sql.SQLException
```

Returns the sum of elapsed network I/O times that were collected while system monitoring was enabled. The time is in microseconds.

Elapsed network I/O time includes the time to write and read DRDA data from network I/O streams. A network I/O elapsed time interval is the time interval to perform the following operations in the JDBC driver:

- Issue a TCP/IP command to send a DRDA message to the database server. This time interval is the difference, in microseconds, between points immediately before and after a write and flush to the network I/O stream is performed.

- Issue a TCP/IP command to receive DRDA reply messages from the database server. This time interval is the difference, in microseconds, between points immediately before and after a read on the network I/O stream is performed.

Network I/O time intervals are captured for all send and receive operations, including the sending of messages for commits and rollbacks.

The time spent waiting for network I/O might be impacted by delays in CPU dispatching at the database server for low-priority SQL requests.
getNetworkIOTimeMicros returns 0 if system monitoring is disabled. Calling this method without first calling the stop method, or calling this method when the underlying JVM does not support reporting times in microseconds results in an SQLException.

**getServerTimeMicros**

Format:
```
public long getServerTimeMicros()
```

throws java.sql.SQLException

Returns the sum of all reported database server elapsed times that were collected while system monitoring was enabled. The time is in microseconds.

The database server reports elapsed times under these conditions:
- The database server supports returning elapsed time data to the client.
  - DB2 for Linux, UNIX, and Windows Version 9.5 and later and DB2 for z/OS support this function.
- The database server performs operations that can be monitored. For example, database server elapsed time is not returned for commits or rollbacks.

**For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for Linux, UNIX, and Windows, and IBM Data Server Driver for JDBC and SQLJ type 4 connectivity:** The database server elapsed time is defined as the elapsed time to parse the request data stream, process the command, and generate the reply data stream at the database server. Network time to receive or send the data stream is not included. The database server elapsed time interval is the difference, in microseconds, between these points in the database server processing:

**Interval beginning**
- When the operating system dispatches the database server to process a TCP/IP message that is received from the JDBC driver.

**Interval end**
- When the database server is ready to issue the TCP/IP command to return the reply message to the client.

**For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity to DB2 for z/OS:** The database server elapsed time interval is the difference, in microseconds, between these points in the JDBC driver native processing:

**Interval beginning**
- The z/OS Store Clock (STCK) value when a JDBC driver native method calls the RRS attachment facility to process an SQL request.

**Interval end**
- The z/OS Store Clock (STCK) value when control returns to the JDBC driver native method following an RRS attachment facility call to process an SQL request.

getServerTimeMicros returns 0 if system monitoring is disabled. Calling this method without first calling the stop method results in an SQLException.

**start**

Format:
```
public void start (int lapMode)
```

throws java.sql.SQLException
If the system monitor is enabled, start begins the collection of system monitoring data for a connection. Valid values for lapMode are RESET_TIMES or ACCUMULATE_TIMES.

Calling this method with system monitoring disabled does nothing. Calling this method more than once without an intervening stop call results in an SQLException.

**stop**

Format:

```java
public void stop()

throws java.sql.SQLException
```

If the system monitor is enabled, stop ends the collection of system monitoring data for a connection. After monitoring is stopped, monitored times can be obtained with the getXXX methods of DB2SystemMonitor.

Calling this method with system monitoring disabled does nothing. Calling this method without first calling start, or calling this method more than once without an intervening start call results in an SQLException.

**Related concepts:**

Chapter 8, “System monitoring for the IBM Data Server Driver for JDBC and SQLJ,” on page 249

**DB2TraceManager class**

The com.ibm.db2.jcc.DB2TraceManager class controls the global log writer.

The global log writer is driver-wide, and applies to all connections. The global log writer overrides any other JDBC log writers. In addition to starting the global log writer, the DB2TraceManager class provides the ability to suspend and resume tracing of any type of log writer. That is, the suspend and resume methods of the DB2TraceManager class apply to all current and future DriverManager log writers, DataSource log writers, or IBM Data Server Driver for JDBC and SQLJ-only connection-level log writers.

**DB2TraceManager methods**

**getTraceManager**

Format:

```java
static public DB2TraceManager getTraceManager()

throws java.sql.SQLException
```

Gets an instance of the global log writer.

**setLogWriter**

Formats:

```java
public abstract void setLogWriter(String traceDirectory,
    String baseTraceFileName, int traceLevel)

throws java.sql.SQLException
```

```java
public abstract void setLogWriter(String traceFile,
    boolean fileAppend, int traceLevel)

throws java.sql.SQLException
```

```java
public abstract void setLogWriter(java.io.PrintWriter logWriter,
    int traceLevel)

throws java.sql.SQLException
```

Enables a global trace. After setLogWriter is called, all calls for DataSource or Connection traces are discarded until DB2TraceManager.unsetLogWriter is called.
When setLogWriter is called, all future Connection or DataSource traces are redirected to a trace file or PrintWriter, depending on the form of setLogWriter that you use. If the global trace is suspended when setLogWriter is called, the specified settings take effect when the trace is resumed.

Parameter descriptions:

**traceDirectory**

Specifies a directory into which global trace information is written. This setting overrides the settings of the traceDirectory and logWriter properties for aDataSource or DriverManager connection.

When the form of setLogWriter with the traceDirectory parameter is used, the JDBC driver sets the traceFileAppend property to false when setLogWriter is called, which means that the existing log files are overwritten. Each JDBC driver connection is traced to a different file in the specified directory. The naming convention for the files in that directory depends on whether a non-null value is specified for baseTraceFileName:

- If a null value is specified for baseTraceFileName, a connection is traced to a file named traceFile_global_n. 
  n is the nth JDBC driver connection.
- If a non-null value is specified for baseTraceFileName, a connection is traced to a file named baseTraceFileName_global_n.

baseTraceFileName is the value of the baseTraceFileName parameter.

**baseTraceFileName**

Specifies the stem for the names of the files into which global trace information is written. The combination of baseTraceFileName and traceDirectory determines the full path name for the global trace log files.

**traceFileName**

Specifies the file into which global trace information is written. This setting overrides the settings of the traceFile and logWriter properties for a DataSource or DriverManager connection.

When the form of setLogWriter with the traceFileName parameter is used, only one log file is written.

traceFileName can include a directory path.

**logWriter**

Specifies a character output stream to which all global log records are written.

This value overrides the logWriter property on a DataSource or DriverManager connection.

**traceLevel**

Specifies what to trace.

You can specify one or more of the following traces with the traceLevel parameter:

- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_NONE (X'00')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_CONNECTION_CALLS (X'01')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_STATEMENT_CALLS (X'02')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_RESULT_SET_CALLS (X'04')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DRIVER_CONFIGURATION (X'10')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_CONNECTS (X'20')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DRDA_FLOWS (X'40')
To specify more than one trace, use one of these techniques:

- Use bitwise OR (|) operators with two or more trace values. For example, to trace DRDA flows and connection calls, specify this value for traceLevel:
  
  \[
  \text{TRACE_DRDA_FLOWS|TRACE_CONNECTION_CALLS}
  \]

- Use a bitwise complement (tilde (~)) operator with a trace value to specify all except a certain trace. For example, to trace everything except DRDA flows, specify this value for traceLevel:
  
  \[
  \sim\text{TRACE_DRDA_FLOWS}
  \]

**fileAppend**

Specifies whether to append to or overwrite the file that is specified by the traceFile parameter. true means that the existing file is not overwritten.

**unsetLogWriter**

Format:

```java
public abstract void unsetLogWriter()
throws java.sql.SQLException
```

Disables the global log writer override for future connections.

**suspendTrace**

Format:

```java
public void suspendTrace()
throws java.sql.SQLException
```

Suspends all global, Connection-level, or DataSource-level traces for current and future connections. suspendTrace can be called when the global log writer is enabled or disabled.

**resumeTrace**

Format:

```java
public void resumeTrace()
throws java.sql.SQLException
```

Resumes all global, Connection-level, or DataSource-level traces for current and future connections. resumeTrace can be called when the global log writer is enabled or disabled. If the global log writer is disabled, resumeTrace resumes Connection-level or DataSource-level traces. If the global log writer is enabled, resumeTrace resumes the global trace.

**getLogWriter**

Format:
public abstract java.io.PrintWriter getLogWriter()
    throws java.sql.SQLException

Returns the PrintWriter for the global log writer, if it is set. Otherwise, getLogWriter returns null.

getTraceFile
Format:
public abstract String getTraceFile()
    throws java.sql.SQLException

Returns the name of the destination file for the global log writer, if it is set. Otherwise, getTraceFile returns null.

getTraceDirectory
Format:
public abstract String getTraceDirectory()
    throws java.sql.SQLException

Returns the name of the destination directory for global log writer files, if it is set. Otherwise, getTraceDirectory returns null.

getTraceLevel
Format:
public abstract int getTraceLevel()
    throws java.sql.SQLException

Returns the trace level for the global trace, if it is set. Otherwise, getTraceLevel returns -1 (TRACE_ALL).

getTraceFileAppend
Format:
public abstract boolean getTraceFileAppend()
    throws java.sql.SQLException

Returns true if the global trace records are appended to the trace file. Otherwise, getTraceFileAppend returns false.

“Properties for the IBM Data Server Driver for JDBC and SQLJ” on page 326

DB2TraceManagerMXBean interface
The com.ibm.db2.jcc.mx.DB2TraceManagerMXBean interface is the means by which an application makes DB2TraceManager available as an MXBean for the remote trace controller.

DB2TraceManagerMXBean methods
setTraceFile
Format:
public void setTraceFile(String traceFile,
    boolean fileAppend, int traceLevel)
    throws java.sql.SQLException

Specifies the name of the file into which the remote trace manager writes trace information, and the type of information that is to be traced.

Parameter descriptions:
traceFileName
Specifies the file into which global trace information is written. This setting overrides the settings of the traceFile and logWriter properties for a
DataSource or DriverManager connection.

When the form of setLogWriter with the traceFileName parameter is used, only one log file is written.

traceFileName can include a directory path.

fileAppend
Specifies whether to append to or overwrite the file that is specified by the
traceFile parameter. true means that the existing file is not overwritten.

traceLevel
Specifies what to trace.

You can specify one or more of the following traces with the traceLevel
parameter:
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_NONE (X'00')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_CONNECTION_CALLS (X'01')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_STATEMENT_CALLS (X'02')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_RESULT_SET_CALLS (X'04')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DRIVER_CONFIGURATION (X'10')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_CONNECTS (X'20')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DRDA_FLOWS (X'40')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_RESULT_RESULT_SET_META_DATA (X'80')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_PARAMETER_META_DATA (X'100')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DIAGNOSTICS (X'200')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_SQLJ (X'400')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_XA_CALLS (IBM Data Server
Driver for JDBC and SQLJ type 2 connectivity for DB2 for Linux,
UNIX, and Windows only) (X'800')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_META_CALLS (X'2000')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DATASOURCE_CALLS (X'4000')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_LARGE_OBJECT_CALLS (X'8000')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_SYSTEM_MONITOR (X'20000')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_TRACEPOINTS () (X'40000')
• com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL (X'FFFFFFFF')

To specify more than one trace, use one of these techniques:
• Use bitwise OR (|) operators with two or more trace values. For
example, to trace DRDA flows and connection calls, specify this value
for traceLevel:
  TRACE_DRDA_FLOWS|TRACE_CONNECTION_CALLS
• Use a bitwise complement (tilde (~)) operator with a trace value to
specify all except a certain trace. For example, to trace everything except
DRDA flows, specify this value for traceLevel:
  ~TRACE_DRDA_FLOWS

getTraceFile
Format:
public void getTraceFile()
  throws java.sql.SQLException

Returns the name of the destination file for the remote trace controller, if it is
set. Otherwise, getTraceFile returns null.
**setTraceDirectory**

Format:
```java
public void setTraceDirectory(String traceDirectory,
                               String baseTraceFileName,
                               int traceLevel) throws java.sql.SQLException
```

Specifies the name of the directory into which the remote trace controller writes trace information, and the type of information that is to be traced.

Parameter descriptions:

**traceDirectory**
Specifies a directory into which trace information is written. This setting overrides the settings of the traceDirectory and logWriter properties for a DataSource or DriverManager connection.

Each JDBC driver connection is traced to a different file in the specified directory. The naming convention for the files in that directory depends on whether a non-null value is specified for baseTraceFileName:

- If a null value is specified for baseTraceFileName, a connection is traced to a file named traceFile_global_n.
  - n is the nth JDBC driver connection.
- If a non-null value is specified for baseTraceFileName, a connection is traced to a file named baseTraceFileName_global_n.
  - baseTraceFileName is the value of the baseTraceFileName parameter.
  - n is the nth JDBC driver connection.

**baseTraceFileName**
Specifies the stem for the names of the files into which global trace information is written. The combination of baseTraceFileName and traceDirectory determines the full path name for the global trace log files.

**traceLevel**
Specifies what to trace.

You can specify one or more of the following traces with the traceLevel parameter:

- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_NONE (X'00')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_CONNECTION_CALLS (X'01')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_STATEMENT_CALLS (X'02')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_RESULT_SET_CALLS (X'04')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DRIVER_CONFIGURATION (X'10')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_CONNECTS (X'20')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DRAA_FLOWS (X'40')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_RESULT_SET_META_DATA (X'80')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_PARAMETER_META_DATA (X'100')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DIAGNOSTICS (X'200')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_SQLJ (X'400')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_XA_CALLS (IBM Data Server Driver for JDBC and SQLJ type 2 connectivity for DB2 for Linux, UNIX, and Windows only) (X'800')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_META_CALLS (X'2000')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_DATASOURCE_CALLS (X'4000')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_LARGE_OBJECT_CALLS (X'8000')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_SYSTEM_MONITOR (X'20000')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_TRACEPOINTS () (X'40000')
- com.ibm.db2.jcc.DB2BaseDataSource.TRACE_ALL (X'FFFFFFFF')
To specify more than one trace, use one of these techniques:

- Use bitwise OR (|) operators with two or more trace values. For example, to trace DRDA flows and connection calls, specify this value for traceLevel:
  
  ```
  TRACE_DRDA_FLOWS|TRACE_CONNECTION_CALLS
  ```

- Use a bitwise complement (tilde (~)) operator with a trace value to specify all except a certain trace. For example, to trace everything except DRDA flows, specify this value for traceLevel:

  ```
  ~TRACE_DRDA_FLOWS
  ```

**getTraceFileAppend**

Format:

```java
public abstract boolean getTraceFileAppend()
throws java.sql.SQLException
```

Returns true if trace records that are generated by the trace controller are appended to the trace file. Otherwise, getTraceFileAppend returns false.

**getTraceDirectory**

Format:

```java
public void getTraceDirectory()
throws java.sql.SQLException
```

Returns the name of the destination directory for trace records that are generated by the trace controller, if it is set. Otherwise, getTraceDirectory returns null.

**getTraceLevel**

Format:

```java
public void getTraceLevel()
throws java.sql.SQLException
```

Returns the trace level for the trace records that are generated by the trace controller, if it is set. Otherwise, getTraceLevel returns -1 (TRACE_ALL).

**unsetLogWriter**

Format:

```java
public abstract void unsetLogWriter()
throws java.sql.SQLException
```

Disables the global log writer override for future connections.

**suspendTrace**

Format:

```java
public void suspendTrace()
throws java.sql.SQLException
```

Suspends all global, Connection-level, or DataSource-level traces for current and future connections. suspendTrace can be called when the global log writer is enabled or disabled.

**resumeTrace**

Format:

```java
public void resumeTrace()
throws java.sql.SQLException
```

Resumes all global, Connection-level, or DataSource-level traces for current and future connections. resumeTrace can be called when the global log writer is
enabled or disabled. If the global log writer is disabled, resumeTrace resumes
Connection-level or DataSource-level traces. If the global log writer is enabled,
resumeTrace resumes the global trace.

DB2Struct interface
The com.ibm.db2.jcc.DB2Struct interface provides IBM Data Server Driver for JDBC
and SQLJ-only methods for working with Struct objects.

DB2Struct methods
getMetaData
Format:
java.sql.ResultSetMetaData getMetaData()
  throws SQLException

Returns metadata for a DB2Struct object.

DB2Types class
The com.ibm.db2.jcc.DB2Types class provides fields that define IBM Data Server
Driver for JDBC and SQLJ-only data types.

DB2Types fields
The following constants define types codes only for the IBM Data Server Driver for
JDBC and SQLJ.
• public final static int BLOB_FILE = -100002
• public final static int CLOB_FILE = -100003
• public final static int CURSOR = -100008
• public final static int DECFLOAT = -100001
• public final static int XML_AS_BLOB_FILE = -100004
• public final static int XML_AS_CLOB_FILE = -100005
• public final static int TIMESTAMPTZ =-100010

DB2XADatasource class
DB2XADatasource is a factory for XADatasource objects. An object that
implements this interface is registered with a naming service that is based on the
Java Naming and Directory Interface (JNDI).

The com.ibm.db2.jcc.DB2XADatasource class extends the
com.ibm.db2.jcc.DB2BaseDataSource class, and implements the
javax.sql.XADatasource, java.io.Serializable, and javax.naming.Referenceable
interfaces.

DB2XADatasource methods
getDB2trustedXAConnection
Formats:
public Object[] getDB2trustedXAConnection(String user,
   String password,
   java.util.Properties properties)
  throws java.sql.SQLException
public Object[] getDB2trustedXAConnection(
   java.util.Properties properties)
  throws java.sql.SQLException
public Object[] getDB2TrustedXAConnection(
    org.ietf.jgss.GSSCredential gssCredential,
    java.util.Properties properties)
throws java.sql.SQLException

An application server using a system authorization ID uses this method to establish a trusted connection.

Trusted connections are supported for:
• IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to:
  – DB2 for Linux, UNIX, and Windows Version 9.5 or later
  – DB2 for z/OS Version 9.1 or later
  – IBM Informix Version 11.70 or later
• IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS Version 9.1 or later

The following elements are returned in Object[]:
• The first element is a DB2TrustedXAConnection instance.
• The second element is a unique cookie for the generated XA connection instance.

The first form getDB2TrustedXAConnection provides a user ID and password. The second form of getDB2TrustedXAConnection uses the user ID and password of the DB2XADataSource object. The third form of getDB2TrustedXAConnection is for connections that use Kerberos security.

Parameter descriptions:

user
   The authorization ID that is used to establish the trusted connection.

password
   The password for the authorization ID that is used to establish the trusted connection.

gssCredential
   If the data source uses Kerberos security, specifies a delegated credential that is passed from another principal.

properties
   Properties for the connection.

getDB2TrustedPooledConnection
Format:
public Object[] getDB2TrustedPooledConnection(java.util.Properties properties)
throws java.sql.SQLException

An application server using a system authorization ID uses this method to establish a trusted connection, using the user ID and password for the DB2XADataSource object.

Trusted connections are supported for:
• IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to:
  – DB2 for Linux, UNIX, and Windows Version 9.5 or later
  – DB2 for z/OS Version 9.1 or later
  – IBM Informix Version 11.70 or later
• IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS Version 9.1 or later
The following elements are returned in Object[]:

- The first element is a trusted DB2TrustedPooledConnection instance.
- The second element is a unique cookie for the generated pooled connection instance.

Parameter descriptions:

- **properties**
  Properties for the connection.

### getDB2XAConnection

Format:

```java
public DB2XAConnection getDB2XAConnection(String user,
  String password,
  java.util.Properties properties)
throws java.sql.SQLException
```

Establishes the initial untrusted connection in a heterogeneous pooling environment.

The first form getDB2PooledConnection provides a user ID and password. The second form of getDB2XAConnection is for connections that use Kerberos security.

Parameter descriptions:

- **user**
  The authorization ID that is used to establish the connection.

- **password**
  The password for the authorization ID that is used to establish the connection.

- **gssCredential**
  If the data source uses Kerberos security, specifies a delegated credential that is passed from another principal.

- **properties**
  Properties for the connection.

### DB2Xml interface

The com.ibm.db2.jcc.DB2Xml interface is used for declaring Java objects for use with the DB2 XML data type.

### DB2Xml methods

The following method is defined only for the IBM Data Server Driver for JDBC and SQLJ.

- **closeDB2Xml**
  Format:
public void closeDB2Xml()
    throws SQLException

    Releases the resources that are associated with a com.ibm.jcc.DB2Xml object.

getDB2AsciiStream
    Format:
    public java.io.InputStream getDB2AsciiStream()
    throws SQLException

    Retrieves data from a DB2Xml object, and converts the data to US-ASCII encoding.

getDB2BinaryStream
    Format:
    public java.io.InputStream getDB2BinaryStream()
    throws SQLException

    Retrieves data from a DB2Xml object as a binary stream. The character encoding of the bytes in the binary stream is defined in the XML 1.0 specification.

getDB2Bytes
    Format:
    public byte[] getDB2Bytes()
    throws SQLException

    Retrieves data from a DB2Xml object as a byte array. The character encoding of the bytes is defined in the XML 1.0 specification.

getDB2CharacterStream
    Format:
    public java.io.Reader getDB2CharacterStream()
    throws SQLException

    Retrieves data from a DB2Xml object as a java.io.Reader object.

getDB2String
    Format:
    public String getDB2String()
    throws SQLException

    Retrieves data from a DB2Xml object as a String value.

getDB2XmlAsciiStream
    Format:
    public InputStream getDB2XmlAsciiStream()
    throws SQLException

    Retrieves data from a DB2Xml object, converts the data to US-ASCII encoding, and imbeds an XML declaration with an encoding specification for US-ASCII in the returned data.

getDB2XmlBinaryStream
    Format:
    public java.io.InputStream getDB2XmlBinaryStream(String targetEncoding)
    throws SQLException
Retrieves data from a DB2Xml object as a binary stream, converts the data to targetEncoding, and imbeds an XML declaration with an encoding specification for targetEncoding in the returned data.

Parameter:

targetEncoding

A valid encoding name that is listed in the IANA CharSet Registry. The encoding names that are supported by the DB2 server are listed in "Mappings of CCSIDs to encoding names for serialized XML output data".

getDB2XmlBytes

Format:

public byte[] getDB2XmlBytes(String targetEncoding)
throws SQLException

Retrieves data from a DB2Xml object as a byte array, converts the data to targetEncoding, and imbeds an XML declaration with an encoding specification for targetEncoding in the returned data.

Parameter:

targetEncoding

A valid encoding name that is listed in the IANA CharSet Registry. The encoding names that are supported by the DB2 server are listed in "Mappings of CCSIDs to encoding names for serialized XML output data".

getDB2XmlCharacterStream

Format:

public java.io.Reader getDB2XmlCharacterStream()
throws SQLException

Retrieves data from a DB2Xml object as a java.io.Reader object, converts the data to ISO-10646-UCS-2 encoding, and imbeds an XML declaration with an encoding specification for ISO-10646-UCS-2 in the returned data.

getDB2XmlString

Format:

public String getDB2XmlString()
throws SQLException

Retrieves data from a DB2Xml object as a String object, converts the data to ISO-10646-UCS-2 encoding, and imbeds an XML declaration with an encoding specification for ISO-10646-UCS-2 in the returned data.

isDB2XmlClosed

Format:

public boolean isDB2XmlClosed()
throws SQLException

Indicates whether a com.ibm.jcc.DB2Xml object has been closed.
DBTimestamp class

The com.ibm.db2.jcc.DBTimestamp class can be used to create timestamp objects with a precision of up to picoseconds and time zone information. This class is primarily for support of the SQL TIMESTAMP WITH TIME ZONE data type, which is supported only by DB2 for z/OS.

The com.ibm.db2.jcc.DBTimestamp class is a subclass of the java.sql.Timestamp class. Therefore, a com.ibm.db2.jcc.DBTimestamp object can be used with any methods that normally operate on a java.sql.Timestamp object, or take a java.sql.Timestamp object as an argument.

The IBM Data Server Driver for JDBC and SQLJ returns a DBTimestamp object for all JDBC methods that return timestamp information, such as ResultSet.getTimestamp or CallableStatement.getTimestamp.

DBTimestamp constructor

The following constructor is defined only for the IBM Data Server Driver for JDBC and SQLJ.

DBTimestamp

Formats:

public DBTimestamp(long time,
   java.util.Calendar calendar)
   throws java.sql.SQLException

public DBTimestamp(long time)
   throws java.sql.SQLException

public DBTimestamp(java.sql.Timestamp timestamp)
   throws java.sql.SQLException

public DBTimestamp(java.sql.Timestamp timestamp,
   java.util.Calendar calendar)
   throws java.sql.SQLException

Constructs a DBTimestamp object.

Parameter descriptions:

time
   The number of milliseconds since January 1, 1970.

timestamp
   A Timestamp value with a precision of up to picoseconds.

calendar
   The Calendar value that provides the time zone.

DBTimestamp methods

getPicos

Formats:
public long getPicos()

Returns the fractional seconds component of a DBTimestamp value.

**getTimeZone**

Formats:

```java
public java.util.TimeZone getTimeZone()
```

Returns the time zone component of a DBTimestamp value.

**setPicos**

Format:

```java
public void setPicos(long p)
    throws SQLException
```

Assigns the given value to the fractional seconds component of a DBTimestamp value.

Parameter descriptions:

- **p** A value between 0 and 999999999999, inclusive, which is the fractional seconds component of a DBTimestamp value.

**setTimeZone**

Format:

```java
public void setTimeZone(java.util.TimeZone timeZone)
    throws SQLException
```

Assigns the given value to the time zone component of a DBTimestamp value.

Parameter descriptions:

- **timeZone** The time zone component of a DBTimestamp value.

**valueOfDBString**

Format:

```java
public static DBTimestamp valueOfDBString(String s)
    throws java.lang.IllegalArgumentException
```

Constructs a DBTimestamp value from the string representation of a timestamp value.

Parameter descriptions:

- **s** The string representation of a timestamp value. The value must be in one of the following formats:
  - `yyyyMMdd-th:tm`
  - `yyyyMMdd hh:mm:ss[.fffffffffffffff]-th:tm`
  - `yyyyMMdd hh:mm:ss[.fffffffffffffff]`
  - `yyyyMMdd hh:mm:ss[.fffffffffffffff]`
  - `yyyyMMdd hh:mm:ss[.fffffffffffffff]`
  - `yyyyMMdd hh:mm:ss[.fffffffffffffff]`

  - `yyyyMMdd` is a year.
  - `mm` is a month.
  - `dd` is a day.
  - `hh` is hours.
  - `mm` is minutes.
  - `ss` is seconds.
  - `[.fffffffffffffff]` is one to 12 optional fractions of seconds.
  - `th` is the hours component of a time zone.
  - `tm` is the minutes component of a time zone.
toDBString
Format:
public String toDBString(boolean includeTimeZone)

Returns the string representation of a DBTimestamp object.
The returned value has one of the following formats:

```
yyyy-mm-dd.hh:mm:ss[.ffffffffffff]-th:tm
yyyy-mm-dd.hh:mm:ss[.ffffffffffff]
```

Parameter description:

`includeTimeZone`
Specifies whether to include the time zone (`-th:tm`) in the returned string.

### JDBC differences between versions of the IBM Data Server Driver for JDBC and SQLJ

Before you can upgrade your JDBC applications from older to newer versions of the IBM Data Server Driver for JDBC and SQLJ, you need to understand the differences between those drivers.

#### Supported methods

For a list of methods that the IBM Data Server Driver for JDBC and SQLJ supports, see the information on driver support for JDBC APIs.

#### Use of progressive streaming by the JDBC drivers

For IBM Data Server Driver for JDBC and SQLJ, Version 3.50 and later, progressive streaming, which is also known as dynamic data format, behavior is the default for LOB retrieval, for connections to DB2 for Linux, UNIX, and Windows Version 9.5 and later.

Progressive streaming is supported in the IBM Data Server Driver for JDBC and SQLJ Version 3.1 and later, but for IBM Data Server Driver for JDBC and SQLJ version 3.2 and later, progressive streaming behavior is the default for LOB and XML retrieval, for connections to DB2 for z/OS Version 9.1 and later.

Previous versions of the IBM Data Server Driver for JDBC and SQLJ did not support progressive streaming.

**Important:** With progressive streaming, when you retrieve a LOB or XML value from a ResultSet into an application variable, you can manipulate the contents of that application variable until you move the cursor or close the cursor on the ResultSet. After that, the contents of the application variable are no longer available to you. If you perform any actions on the LOB in the application variable, you receive an SQLException. For example, suppose that progressive streaming is enabled, and you execute statements like this:

```java
... ResultSet rs = stmt.executeQuery("SELECT CLOBCOL FROM MY_TABLE");
rs.next(); // Retrieve the first row of the ResultSet
Clob clobFromRow1 = rs.getClob(1);
    // Put the CLOB from the first column of
    // the first row in an application variable
String substr1Clob = clobFromRow1.getSubString(1,50);
    // Retrieve the first 50 bytes of the CLOB
```
rs.next(); // Move the cursor to the next row.
// clobFromRow1 is no longer available.
// String substr2Clob = clobFromRow1.getSubString(51,100);
// This statement would yield an SQLException
Clob clobFromRow2 = rs.getClob(1);
// Put the CLOB from the first column of
// the second row in an application variable
rs.close(); // Close the ResultSet.
// clobFromRow2 is also no longer available.

After you execute rs.next() to position the cursor at the second row of the
ResultSet, the CLOB value in clobFromRow1 is no longer available to you.
Similarly, after you execute rs.close() to close the ResultSet, the values in
clobFromRow1 and clobFromRow2 are no longer available.

To avoid errors that are due to this changed behavior, you need to take one of the
following actions:
• Modify your applications.
  Applications that retrieve LOB data into application variables can manipulate
  the data in those application variables only until the cursors that were used to
  retrieve the data are moved or closed.
• Disable progressive streaming by setting the progressiveStreaming property to
  DB2BaseDataSource.NO (2).

ResultSetMetaData values for IBM Data Server Driver for JDBC and SQLJ

For the IBM Data Server Driver for JDBC and SQLJ version 4.0 and later, the
default behavior of ResultSetMetaData.getColumnName and
ResultSetMetaData.getColumnLabel differs from the default behavior for earlier
JDBC drivers.

If you need to use IBM Data Server Driver for JDBC and SQLJ version 4.0 or later,
but your applications need to return the ResultSetMetaData.getColumnName and
ResultSetMetaData.getColumnLabel values that were returned with older JDBC
drivers, you can set the useJDBC4ColumnNameAndLabelSemantics Connection and
DataSource property to DB2BaseDataSource.NO (2).

Batch updates with automatically generated keys have different
results in different driver versions

With the IBM Data Server Driver for JDBC and SQLJ version 3.52 or later,
preparing an SQL statement for retrieval of automatically generated keys is
supported.

With the IBM Data Server Driver for JDBC and SQLJ version 3.50 or version 3.51,
preparing an SQL statement for retrieval of automatically generated keys and
using the PreparedStatement object for batch updates causes an SQLException.

Versions of the IBM Data Server Driver for JDBC and SQLJ before Version 3.50 do
not throw an SQLException when an application calls the addBatch or
executeBatch method on a PreparedStatement object that is prepared to return
automatically generated keys. However, the PreparedStatement object does not
return automatically generated keys.
Batch updates of data on DB2 for z/OS servers have different results in different driver versions

After you successfully invoke an executeBatch statement, the IBM Data Server Driver for JDBC and SQLJ returns an array. The purpose of the array is to indicate the number of rows that are affected by each SQL statement that is executed in the batch.

If the following conditions are true, the IBM Data Server Driver for JDBC and SQLJ returns `Statement.SUCCESS_NO_INFO` (-2) in the array elements:

- The application is connected to a subsystem that is in DB2 for z/OS Version 8 new-function mode, or later.
- The application is using Version 3.1 or later of the IBM Data Server Driver for JDBC and SQLJ.
- The IBM Data Server Driver for JDBC and SQLJ uses multi-row INSERT operations to execute batch updates.

This occurs because with multi-row INSERT, the database server executes the entire batch as a single operation, so it does not return results for individual SQL statements.

If you are using an earlier version of the IBM Data Server Driver for JDBC and SQLJ, or you are connected to a data source other than DB2 for z/OS Version 8 or later, the array elements contain the number of rows that are affected by each SQL statement.

Batch updates and deletes of data on DB2 for z/OS servers have different size limitations in different driver versions

Before IBM Data Server Driver for JDBC and SQLJ version 3.59 or 4.9, a DisconnectException with error code -4499 was thrown for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to DB2 for z/OS if the size of an update or delete batch was greater than 32KB. Starting with version 3.59 or 4.9, this restriction no longer exists, and the exception is no longer thrown.

Initial value of the CURRENT CLIENT_ACCTNG special register

For a JDBC or SQLJ application that runs under the IBM Data Server Driver for JDBC and SQLJ version 2.6 or later, using type 4 connectivity, the initial value for the DB2 for z/OS CURRENT CLIENT_ACCTNG special register is the concatenation of the DB2 for z/OS version and the value of the clientWorkStation property. For any other JDBC driver, version, and connectivity, the initial value is not set.

Properties that control the use of multi-row FETCH

Before version 3.7 and version 3.51 of the IBM Data Server Driver for JDBC and SQLJ, multi-row FETCH support was enabled and disabled through the useRowsetCursor property, and was available only for scrollable cursors, and for IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to DB2 for z/OS. Starting with version 3.7 and 3.51:

- For IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS, the IBM Data Server Driver for JDBC and SQLJ uses only the enableRowsetSupport property to determine whether to use multi-row FETCH for scrollable or forward-only cursors.
• For IBM Data Server Driver for JDBC and SQLJ type 4 connectivity to DB2 for z/OS or DB2 for Linux, UNIX, and Windows, or IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for Linux, UNIX, and Windows, the IBM Data Server Driver for JDBC and SQLJ uses the enableRowsetSupport property to determine whether to use multi-row FETCH for scrollable cursors, if enableRowsetSupport is set. If enableRowsetSupport is not set, the driver uses the useRowsetCursor property to determine whether to use multi-row FETCH.

**JDBC 1 positioned updates and deletes and multi-row FETCH**

Before version 3.7 and version 3.51 of the IBM Data Server Driver for JDBC and SQLJ, multi-row FETCH from DB2 for z/OS tables was controlled by the useRowsetCursor property. If an application contained JDBC 1 positioned update or delete operations, and multi-row FETCH support was enabled, the IBM Data Server Driver for JDBC and SQLJ permitted the update or delete operations, but unexpected updates or deletes might occur.

Starting with version 3.7 and 3.51 of the IBM Data Server Driver for JDBC and SQLJ, the enableRowsetSupport property enables or disables multi-row FETCH from DB2 for z/OS tables or DB2 for Linux, UNIX, and Windows tables. The enableRowsetSupport property overrides the useRowsetCursor property. If multi-row FETCH is enabled through the enableRowsetSupport property, and an application contains a JDBC 1 positioned update or delete operation, the IBM Data Server Driver for JDBC and SQLJ throws an SQLException.

**Valid forms of prepareStatement for retrieval of automatically generated keys from a DB2 for z/OS view**

Starting with version 3.57 or version 4.7 of the IBM Data Server Driver for JDBC and SQLJ, if you are inserting data into a view on a DB2 for z/OS data server, and you want to retrieve automatically generated keys, you need to use one of the following methods to prepare the SQL statement that inserts rows into the view:

```java
Connection.prepareStatement(sql-statement, String [] columnNames);
Connection.prepareStatement(sql-statement, int [] columnIndexes);
Statement.executeUpdate(sql-statement, String [] columnNames);
Statement.executeUpdate(sql-statement, int [] columnIndexes);
```

**Data loss for TIMESTAMP(p) column updates using setString**

If you use a setString call to pass an input value to a TIMESTAMP(p) column, it is possible to send a value with a precision of greater than nine to the column.

Before version 3.59 or version 4.9 of the IBM Data Server Driver for JDBC and SQLJ, data loss could occur if the sendDataAsIs property was set to false, and the precision of the input value was greater than nine.

Starting with version 3.59 and version 4.9 of the IBM Data Server Driver for JDBC and SQLJ, data loss does not occur if the TIMESTAMP(p) column is large enough to accommodate the input value.

**Change to result set column name for getColumns**

In version 4.12 or earlier of the IBM Data Server Driver for JDBC and SQLJ, the DatabaseMetaData.getColumns method returned a result set that contained a column named SCOPE_CATLOG. In version 4.13 or later of the IBM Data Server Driver for JDBC and SQLJ, the name of that column is SCOPE_CATALOG. If you
want the IBM Data Server Driver for JDBC and SQLJ to continue to use the column name SCOPE_CATLOG, set DataSource or Connection property useJDBC41DefinitionForGetColumns to DB2BaseDataSource.NO (2).

**Changes to defaults for global configuration properties db2.jcc.maxRefreshInterval, db2.jcc.maxTransportObjects, and db2.jcc.maxTransportObjectWaitTime**

The default values for global configuration properties db2.jcc.maxRefreshInterval, db2.jcc.maxTransportObjects, and db2.jcc.maxTransportObjectWaitTime change in version 3.63 and 4.13 of the IBM Data Server Driver for JDBC and SQLJ. The following table lists the old and new defaults.

<table>
<thead>
<tr>
<th>Configuration property</th>
<th>Default before versions 3.63 and 4.13</th>
<th>Default for versions 3.63 and 4.13 or later</th>
</tr>
</thead>
<tbody>
<tr>
<td>db2.jcc.maxRefreshInterval</td>
<td>30 seconds</td>
<td>10 seconds</td>
</tr>
<tr>
<td>db2.jcc.maxTransportObjects</td>
<td>-1 (unlimited)</td>
<td>1000</td>
</tr>
<tr>
<td>db2.jcc.maxTransportObjectWaitTime</td>
<td>-1 (unlimited)</td>
<td>1 second</td>
</tr>
</tbody>
</table>

**Changes to default values for Connection and DataSource property maxTransportObjects**

The default value for Connection and DataSource properties maxTransportObjects changes in version 3.63 and 4.13 of the IBM Data Server Driver for JDBC and SQLJ. The following table lists the old and new defaults.

<table>
<thead>
<tr>
<th>Connection and DataSource property</th>
<th>Default value before versions 3.63 and 4.13</th>
<th>Default value for versions 3.63 and 4.13 or later</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxTransportObjects</td>
<td>-1 (unlimited)</td>
<td>1000</td>
</tr>
</tbody>
</table>

**Changes to default value for Connection and DataSource properties maxRetriesForClientReroute and retryIntervalForClientReroute for connections to a DB2 for z/OS data sharing group (driver versions 3.64 and 4.14)**

The default value for Connection and DataSource properties maxRetriesForClientReroute and retryIntervalForClientReroute change in version 3.64 and 4.14 of the IBM Data Server Driver for JDBC and SQLJ for connections to a DB2 for z/OS data sharing group. The following table lists the old and new defaults.
<table>
<thead>
<tr>
<th>Connection and DataSource property</th>
<th>Default value before versions 3.64 and 4.14</th>
<th>Default value for versions 3.64 and 4.14 or later</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxRetriesForClientReroute and retryIntervalForClientReroute</td>
<td>If maxRetriesForClientReroute and retryIntervalForClientReroute are not set, and the application has not made its first successful connection, the connection is retried for 10 minutes, with a wait time between retries that increases as the length of time from the first retry increases.</td>
<td>For connections to a DB2 for z/OS data server:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• For the first connection to a data sharing group, if maxRetriesForClientReroute and retryIntervalForClientReroute are not set, and the enableSysplexWLB property is set to true, the default is to retry five times with a retry interval of 0.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• For a failover during a subsequent connection to a data sharing group, if maxRetriesForClientReroute and retryIntervalForClientReroute are not set, the enableSysplexWLB property is set to true, and a cached server list or an alternate server is specified, the default is to retry the connection for 10 minutes, with a wait time between retries that increases as the length of time from the first retry increases.</td>
</tr>
</tbody>
</table>

**Changes to the meaning and default value for Connection and DataSource property maxRetriesForClientReroute for connections to a DB2 for z/OS data sharing group (driver versions 3.66 and 4.16)**

The meaning and default value for Connection and DataSource property maxRetriesForClientReroute change in version 3.66 and 4.16 of the IBM Data Server Driver for JDBC and SQLJ for connections to a DB2 for z/OS data sharing group.

The following table shows the old and new defaults.
The meaning of an attempt to access the data sharing group has changed, so the meaning of a retry has changed. Formerly, an attempt to connect was an attempt to connect to one data sharing member, or to the group IP address. With versions 3.66 and 4.16 or later of the driver, a single attempt to access the data sharing group is an attempt to connect to all members except the failed member, and to the group IP address. As a result, it might be appropriate to lower the value of maxRetriesForClientReroute.

### Changes to default values for client info properties for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS

The default values for client info properties for IBM Data Server Driver for JDBC and SQLJ type 2 connectivity on DB2 for z/OS change in version 3.64 and 4.14 of the IBM Data Server Driver for JDBC and SQLJ. The following table lists the old and new defaults.

<table>
<thead>
<tr>
<th>Client info property</th>
<th>Default value before versions 3.64 and 4.14</th>
<th>Default value for versions 3.64 and 4.14 or later</th>
</tr>
</thead>
<tbody>
<tr>
<td>ApplicationName</td>
<td>Empty string</td>
<td>The string &quot;db2jcc_application&quot;</td>
</tr>
<tr>
<td>ClientAccountingInformation</td>
<td>Empty string</td>
<td>Empty string</td>
</tr>
<tr>
<td>ClientHostname</td>
<td>Empty string</td>
<td>The string &quot;RRSAF&quot;</td>
</tr>
<tr>
<td>ClientUser</td>
<td>Empty string</td>
<td>The user ID that was specified for the connection. If no user ID was specified, the RACF user ID is used.</td>
</tr>
</tbody>
</table>
Changes to the behavior of the xmlFormat property

Starting with version 4.15 of the IBM Data Server Driver for JDBC and SQLJ, the xmlFormat Connection and DataSource property applies only to XML data retrieval, instead of to XML data update and retrieval. In addition, the default behavior has changed to retrieval of XML data in textual XML format, regardless of whether the data server supports binary XML format.

For update of data in XML columns, xmlFormat has no effect. If the input data is binary XML data, and the data server does not support binary XML data, the input data is converted to textual XML data. Otherwise, no conversion occurs.

Related concepts:
‘Examples of ResultSetMetaData.getColumnName and ResultSetMetaData.getColumnLabel values’

Examples of ResultSetMetaData.getColumnName and ResultSetMetaData.getColumnLabel values

For the IBM Data Server Driver for JDBC and SQLJ version 4.0 and later, the default behavior of ResultSetMetaData.getColumnName and ResultSetMetaData.getColumnLabel differs from the default behavior for earlier JDBC drivers. You can use the useJDBC4ColumnNameAndLabelSemantics property to change this behavior.

The following examples show the values that are returned for IBM Data Server Driver for JDBC and SQLJ Version 4.0, and for previous JDBC drivers, when the useJDBC4ColumnNameAndLabelSemantics property is not set.

All queries use a table that is defined like this:
CREATE TABLE MYTABLE(INTCOL INT)

Example: The following query contains an AS CLAUSE, which defines a label for a column in the result set:
SELECT MYCOL AS MYLABEL FROM MYTABLE

The following table lists the ResultSetMetaData.getColumnName and ResultSetMetaData.getColumnName values that are returned for the query:

<table>
<thead>
<tr>
<th>Target data source</th>
<th>Behavior before IBM Data Server Driver for JDBC and SQLJ Version 4.0</th>
<th>Behavior for IBM Data Server Driver for JDBC and SQLJ Version 4.0 and later</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2 for Linux, UNIX, and Windows</td>
<td>MYLABEL</td>
<td>MYLABEL</td>
</tr>
<tr>
<td>IBM Informix</td>
<td>MYLABEL</td>
<td>MYLABEL</td>
</tr>
<tr>
<td>DB2 for z/OS Version 8 or later, and DB2 UDB for iSeries V5R3 and later</td>
<td>MYLABEL</td>
<td>MYLABEL</td>
</tr>
</tbody>
</table>
### Table 113. ResultSetMetaData.getColumnName and ResultSetMetaData.getColumnLabel before and after IBM Data Server Driver for JDBC and SQLJ Version 4.0 for a query with an AS CLAUSE (continued)

<table>
<thead>
<tr>
<th>Target data source</th>
<th>Behavior before IBM Data Server Driver for JDBC and SQLJ Version 4.0</th>
<th>Behavior for IBM Data Server Driver for JDBC and SQLJ Version 4.0 and later</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>getColumnName value</td>
<td>getColumnLabel value</td>
</tr>
<tr>
<td>DB2 for z/OS Version 7, and DB2 UDB for iSeries V5R2</td>
<td>MYLABEL</td>
<td>MYLABEL</td>
</tr>
</tbody>
</table>

**Example:** The following query contains no AS clause:

```sql
SELECT MYCOL FROM MYTABLE
```

The ResultSetMetaData.getColumnName and ResultSetMetaData.getColumnLabel methods on the query return MYCOL, regardless of the target data source.

**Example:** On a DB2 for z/OS or DB2 for i data source, a LABEL ON statement is used to define a label for a column:

```sql
LABEL ON COLUMN MYTABLE.MYCOL IS 'LABELONCOL'
```

The following query contains an AS CLAUSE, which defines a label for a column in the ResultSet:

```sql
SELECT MYCOL AS MYLABEL FROM MYTABLE
```

The following table lists the ResultSetMetaData.getColumnName and ResultSetMetaData.getColumnLabel values that are returned for the query.

### Table 114. ResultSetMetaData.getColumnName and ResultSetMetaData.getColumnLabel before and after IBM Data Server Driver for JDBC and SQLJ Version 4.0 for a table column with a LABEL ON statement in a query with an AS CLAUSE

<table>
<thead>
<tr>
<th>Target data source</th>
<th>Behavior before IBM Data Server Driver for JDBC and SQLJ Version 4.0</th>
<th>Behavior for IBM Data Server Driver for JDBC and SQLJ Version 4.0 and later</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>getColumnName value</td>
<td>getColumnLabel value</td>
</tr>
<tr>
<td>DB2 for z/OS Version 8 or later, and DB2 UDB for iSeries V5R3 and later</td>
<td>MYLABEL</td>
<td>LABELONCOL</td>
</tr>
<tr>
<td>DB2 for z/OS Version 7, and DB2 UDB for iSeries V5R2</td>
<td>MYLABEL</td>
<td>LABELONCOL</td>
</tr>
</tbody>
</table>

**Example:** On a DB2 for z/OS or DB2 for i data source, a LABEL ON statement is used to define a label for a column:

```sql
LABEL ON COLUMN MYTABLE.MYCOL IS 'LABELONCOL'
```

The following query contains no AS CLAUSE:

```sql
SELECT MYCOL FROM MYTABLE
```

The following table lists the ResultSetMetaData.getColumnName and ResultSetMetaData.getColumnLabel values that are returned for the query.
Table 115. ResultSetMetaData.getColumnName and ResultSetMetaData.getColumnName before and after IBM Data Server Driver for JDBC and SQLJ Version 4.0 for a table column with a LABEL ON statement in a query with no AS CLAUSE

<table>
<thead>
<tr>
<th>Target data source</th>
<th>Behavior before IBM Data Server Driver for JDBC and SQLJ Version 4.0</th>
<th>Behavior for IBM Data Server Driver for JDBC and SQLJ Version 4.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB2 for z/OS Version 8 or later, and DB2 UDB for i5/OS V5R3 and later</td>
<td>getColumnLabel value = MYCOL</td>
<td>getColumnLabel value = MYCOL</td>
</tr>
<tr>
<td>DB2 for z/OS Version 7, and DB2 UDB for i5/OS V5R2</td>
<td>getColumnLabel value = MYCOL</td>
<td>getColumnLabel value = MYLABEL</td>
</tr>
</tbody>
</table>

SDK for Java differences that affect the IBM Data Server Driver for JDBC and SQLJ

Differences in the behavior among versions of the SDK for Java can cause variations in the results that you receive when you run programs under the IBM Data Server Driver for JDBC and SQLJ.

Retrieved values for DBCS substitution characters

When you retrieve a DBCS substitution character, such as ‘XFCCFC’ in code page Cp943, from a database table, the retrieved value differs, depending on whether you are using an IBM SDK for Java or an SDK for Java from Oracle.

For an SDK for Java from Oracle, the substitution character is retrieved as U+0000. For an IBM SDK for Java, the substitution character is retrieved as ‘XFFFD’.

Supported code pages

IBM SDKs for Java support more DBCS code pages than SDKs for Java from Oracle. Therefore, if you get errors because of unsupported code pages with an SDK for Java from Oracle, try using an IBM SDK for Java.

IBM SDK for Java requirement for encryption

The IBM SDKs for Java support 256-bit encryption, but the SDKs for Java from Oracle do not have this support. Therefore, if you use any of the IBM Data Server Driver for JDBC and SQLJ security mechanisms that include encryption, you need to use an IBM SDK for Java.

Support for system monitoring

Support for system monitoring in the IBM Data Server Driver for JDBC and SQLJ includes collection of core driver time and network I/O time. Retrieval of this information requires capabilities that are in any SDK for Java Version 5 or later. However, the IBM SDK for Java Version 1.4.2 also has support that enables collection of core driver time and network I/O time. If you use the IBM SDK for Java Version 1.4.2, the core driver time and network I/O time are rounded to the nearest microsecond. If you use an SDK for Java Version 5 or later, the core driver time and network I/O time are rounded to the nearest nanosecond.
Error codes issued by the IBM Data Server Driver for JDBC and SQLJ

Warning codes in the ranges +4200 to +4299, and +4450 to +4499, and error codes in the ranges -4200 to -4299, and -4450 to -4499 are reserved for the IBM Data Server Driver for JDBC and SQLJ.

When you call the SQLException.getMessage method after a IBM Data Server Driver for JDBC and SQLJ error occurs, a string is returned that includes:

- Whether the connection is a type 2 or type 4 connection
- Diagnostic information for IBM Software Support
- The level of the driver
- An explanatory message
- The error code
- The SQLSTATE

For example:

```
[jcc][t4][20128][12071][3.50.54] Invalid queryBlockSize specified: 1,048,576,012.
Using default query block size of 32,767. ERRORCODE=0, SQLSTATE=
```

The IBM Data Server Driver for JDBC and SQLJ issues the following warning codes:

**+4204** Message text: Errors were encountered and tolerated as specified by the RETURN DATA UNTIL clause.

Explanation: Tolerated errors include federated connection, authentication, and authorization errors. This warning applies only to connections to DB2 for Linux, UNIX, and Windows servers. It is issued only when a cursor operation, such as a ResultSet.next or ResultSet.previous call, returns false.

SQLSTATE: 02506

**+4222** Message text: text-from-getMessage

Explanation: A warning condition occurred during connection to the data source.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

**+4223** Message text: text-from-getMessage

Explanation: A warning condition occurred during initialization.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

**+4225** Message text and explanation: text-from-getMessage

Explanation: A warning condition occurred when data was sent to a server or received from a server.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

**+4226** Message text and explanation: text-from-getMessage

Explanation: A warning condition occurred during customization or bind.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

**+4228** Message text: text-from-getMessage
Explanation: An warning condition occurred that does not fit in another category.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

+4450 Message text: Feature not supported: feature-name

Explanation: The specified value is not a valid option.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

+4460 Message text: text-from-getMessage

Explanation: The specified value is invalid or out of range.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

+4461 Message text: text-from-getMessage

Explanation: A required value is missing.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

+4462 Message text: text-from-getMessage

Explanation: The requested operation cannot be performed because the target resource is closed.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

+4470 Message text: text-from-getMessage

Explanation: The requested operation cannot be performed because the target resource is in use.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

+4471 Message text: text-from-getMessage

Explanation: The requested operation cannot be performed because the target resource cannot be changed.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

+4472 Message text: text-from-getMessage

Explanation: The requested operation cannot be performed because the target resource is unavailable.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

+4474 Message text: text-from-getMessage

Explanation: The requested operation cannot be performed because the target resource cannot be changed.

User response: Call SQLException.getMessage to retrieve specific information about the problem.

The IBM Data Server Driver for JDBC and SQLJ issues the following error codes:

-1224 Message text: The database manager is not able to accept new requests, has terminated all requests in progress, or has terminated the specified request because of an error or a forced interrupt.
**Explanation:** For connections to DB2 for Linux, UNIX, and Windows data servers, see [SQL1224N](#) for details.

For connections to DB2 for z/OS data servers, this error indicates the DB2 for z/OS server thread that is associated with the application abnormally terminated. Server diagnostics that are related to the application need to be collected. The application can be identified by its unique application ID. DB2 for z/OS externalizes the application ID in messages and traces as the connection correlation token (CRRTKN) and logical unit of work ID (LUWID). Message DSNL027I is generated on the z/OS console when a DB2 for z/OS thread abnormally terminates. DSNL027I provides a reason code for the failure. In most cases, DB2 for z/OS generates a z/OS SVC dump, which is needed to solve the problem.

**SQLSTATE:** 2D521

-4200 **Message text:** Invalid operation: An invalid COMMIT or ROLLBACK has been called in an XA environment during a Global Transaction.

**Explanation:** An application that was in a global transaction in an XA environment issued a commit or rollback. A commit or rollback operation in a global transaction is invalid.

**SQLSTATE:** 2D521

-4201 **Message text:** Invalid operation: setAutoCommit(true) is not allowed during Global Transaction.

**Explanation:** An application that was in a global transaction in an XA environment executed the setAutoCommit(true) statement. Issuing setAutoCommit(true) in a global transaction is invalid.

**SQLSTATE:** 2D521

-4203 **Message text:** Error executing function. Server returned rc.

**Explanation:** An error occurred on an XA connection during execution of an SQL statement.

For network optimization, the IBM Data Server Driver for JDBC and SQLJ delays some XA flows until the next SQL statement is executed. If an error occurs in a delayed XA flow, that error is reported as part of the SQLException that is thrown by the current SQL statement.

-4210 **Message text:** Timeout getting a transport object from pool.

**SQLSTATE:** 57033

-4211 **Message text:** Timeout getting an object from pool.

**SQLSTATE:** 57033

-4212 **Message text:** Sysplex member unavailable.

-4213 **Message text:** Timeout.

**SQLSTATE:** 57033

-4214 **Message text:** text-from-getMessage

**Explanation:** Authorization failed.

**User response:** Call SQLException.getMessage to retrieve specific information about the problem.

**SQLSTATE:** 28000
-4220  Message text: text-from-getMessage
Explanation: An error occurred during character conversion.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4221  Message text: text-from-getMessage
Explanation: An error occurred during encryption or decryption.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4222  Message text: text-from-getMessage
Explanation: An error occurred during connection to the data source.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4223  Message text: text-from-getMessage
Explanation: An error occurred during initialization.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4224  Message text: text-from-getMessage
Explanation: An error occurred during resource cleanup.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4225  Message text: text-from-getMessage
Explanation: An error occurred when data was sent to a server or received from a server.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4226  Message text: text-from-getMessage
Explanation: An error occurred during customization or bind.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4227  Message text: text-from-getMessage
Explanation: An error occurred during reset.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4228  Message text: text-from-getMessage
Explanation: An error occurred that does not fit in another category.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4229  Message text: text-from-getMessage
Explanation: An error occurred during a batch execution.
User response: Call SQLException.getMessage to retrieve specific information about the problem.
Message text: An error occurred during the conversion of column column-number of type sql-data-type with value value to a value of type java.math.BigDecimal.

Message text: Feature not supported: feature-name
SQLSTATE: 0A504

Message text: text-from-getMessage
Explanation: The specified value is not a valid option.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

Message text: text-from-getMessage
Explanation: The specified value is invalid or out of range.
User response: Call SQLException.getMessage to retrieve specific information about the problem.
SQLSTATE: 42815

Message text: text-from-getMessage
Explanation: A required value is missing.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

Message text: text-from-getMessage
Explanation: The specified value has a syntax error.
User response: Call SQLException.getMessage to retrieve specific information about the problem.
SQLSTATE: 42601

Message text: text-from-getMessage
Explanation: The requested operation cannot be performed because the target resource is closed.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

Message text: text-from-getMessage
Explanation: The requested operation cannot be performed because the target resource is in use.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

Message text: text-from-getMessage
Explanation: The requested operation cannot be performed because the target resource is unavailable.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

Message text: text-from-getMessage
Explanation: The requested operation cannot be performed because the target resource is no longer available.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4474 Message text: text-from-getMessage
Explanation: The requested operation cannot be performed because the target resource cannot be changed.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4475 Message text: text-from-getMessage
Explanation: The requested operation cannot be performed because access to the target resource is restricted.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4476 Message text: text-from-getMessage
Explanation: The requested operation cannot be performed because the operation is not allowed on the target resource.
User response: Call SQLException.getMessage to retrieve specific information about the problem.

-4496 Message text: An SQL OPEN for a held cursor was issued on an XA connection. The JDBC driver does not allow a held cursor to be opened on the database server for an XA connection.

-4497 Message text: The application must issue a rollback. The unit of work has already been rolled back in the DB2 server, but other resource managers involved in the unit of work might not have rolled back their changes. To ensure integrity of the application, all SQL requests are rejected until the application issues a rollback.

-4498 Message text: A connection failed but has been re-established. Special register settings have been replayed if necessary. Host name or IP address of the connection: host-name. Service name or port number of the connection: service-name. Reason code: reason-code. Failure code: failure-code. Error code: error-code.
Explanation: The connection has been reestablished. In some cases, the network connection or transport to the server is not established until the next use. After the connection is reestablished, all session resources are set to their initial default values. The application is rolled back to the previous commit point. The reason code indicates which special register values are applied to the new connection. Possible values for the reason code are:

1 All special register settings were returned to their values at the point of failure. The connection was reestablished within the current group.

2 All special register settings were returned to their values at the previous commit point. The connection was reestablished within the current group.

3 All special registers were returned to their settings at the point of failure. The connection was reestablished in a new group.

4 All special register settings were returned to their values at the previous commit point. The connection was reestablished in a new group.
failure-code indicates the error that caused the connection to fail:

1  A communication failure occurred.
2  The data server closed the connection.
3  An SQL error occurred.
4  The client closed the connection.

error-code depends on the value of failure-code:

Failure code: 1 or 2
   Error code: The Java SocketException message that was returned.

Failure code: 3
   Error code: The SQL error code that was returned by the SQL
statement that caused the connection to fail.

Failure code: 4
   Error code: The following value:
      2 The driver received an interrupt or cancel request.

For client reroute against DB2 for z/OS servers, special register values that
were set after the last commit point are not re-established.
The application is rolled back to the previous commit point. The
connection state and global resources such as global temporary tables and
open held cursors might not be maintained.

-4499  Message text: text-from-getMessage
   Explanation: A fatal error occurred that resulted in a disconnect from the
data source. The existing connection has become unusable.
   User response: Call SQLException.getMessage to retrieve specific
information about the problem.
   SQLSTATE: 08001 or 58009

-30108  Message text: A connection failed in an automatic client reroute
   environment. The transaction was rolled back. Host name or IP address:
host-name. Service name or port number: service-name. Reason code:
reason-code. Connection failure code: connection-failure-code. Underlying
error: underlying-error.
   Explanation: See SQL30108N
   User response: Call SQLException.getMessage to retrieve specific
information about the problem.
   SQLSTATE: 08506

-99999  Message text: The IBM Data Server Driver for JDBC and SQLJ issued an
error that does not yet have an error code.

How to find IBM Data Server Driver for JDBC and SQLJ version and environment information

To determine the version of the IBM Data Server Driver for JDBC and SQLJ, as well as information about the environment in which the driver is running, run the DB2Jcc utility on the command line.

**DB2Jcc syntax**

```
java -version -configuration -help
```

**DB2Jcc option descriptions**

- **-version**
  Specifies that the IBM Data Server Driver for JDBC and SQLJ displays its name and version.
Specifies that the IBM Data Server Driver for JDBC and SQLJ displays its name and version, and information about its environment, such as information about the Java runtime environment, operating system, path information, and license restrictions.

Specifies that the DB2Jcc utility describes each of the options that it supports. If any other options are specified with -help, they are ignored.

**Commands for SQLJ program preparation**

To prepare SQLJ programs for execution, you use commands to translate SQLJ source code into Java source code, compile the Java source code, create and customize SQLJ serialized profiles, and bind DB2 packages.

**sqlj - SQLJ translator**

The sqlj command translates an SQLJ source file into a Java source file and zero or more SQLJ serialized profiles. By default, the sqlj command also compiles the Java source file.

**Authorization**

None

**Command syntax**

```

-compile=true | -compile=false
-linemap=NO | -linemap=YES
-smap=NO | -smap=YES
-encoding=encoding
-db2optimize

-ser2class
-status
-version
-C-help

-JJVM-option
-SQLJ-source-file-name
```

**Command parameters**

- **-help**
  Specifies that the SQLJ translator describes each of the options that the translator supports. If any other options are specified with -help, they are ignored.

- **-dir=directory**
  Specifies the name of the directory into which SQLJ puts .java files that are
generated by the translator and .class files that are generated by the compiler.  
The default is the directory that contains the SQLJ source files.

The translator uses the directory structure of the SQLJ source files when it puts
the generated files in directories. For example, suppose that you want the
translator to process two files:

- file1.sqlj, which is not in a Java package
- file2.sqlj, which is in Java package sqlj.test

Also suppose that you specify the parameter -dir=/src when you invoke the
translator. The translator puts the Java source file for file1.sqlj in directory /src
and puts the Java source file for file2.sqlj in directory /src/sqlj/test.

-d=directory
Specifies the name of the directory into which SQLJ puts the binary files that
are generated by the translator and compiler. These files include the .ser files,
the name_SJProfileKeys.class files, and the .class files that are generated by the
compiler.

The default is the directory that contains the SQLJ source files.

The translator uses the directory structure of the SQLJ source files when it puts
the generated files in directories. For example, suppose that you want the
translator to process two files:

- file1.sqlj, which is not in a Java package
- file2.sqlj, which is in Java package sqlj.test

Also suppose that you specify the parameter -d=/src when you invoke the
translator. The translator puts the serialized profiles for file1.sqlj in directory
/src and puts the serialized profiles for file2.sqlj in directory /src/sqlj/test.

-compile=true|false
Specifies whether the SQLJ translator compiles the generated Java source into
bytecodes.

true
The translator compiles the generated Java source code. This is the default.

false
The translator does not compile the generated Java source code.

-linemap=no|yes
Specifies whether line numbers in Java exceptions match line numbers in the
SQLJ source file (the .sqlj file), or line numbers in the Java source file that is
generated by the SQLJ translator (the .java file).

no Line numbers in Java exceptions match line numbers in the Java source
file. This is the default.

yes
Line numbers in Java exceptions match line numbers in the SQLJ source
file.

-smap=no|yes
Specifies whether the SQLJ translator generates a source map (SMAP) file for
each SQLJ source file. An SMAP file is used by some Java language debug
tools. This file maps lines in the SQLJ source file to lines in the Java source file
that is generated by the SQLJ translator. The file is in the Unicode UTF-8
encoding scheme. Its format is described by Original Java Specification Request
(JSR) 45, which is available from this web site:
http://www.jcp.org

no Do not generated SMAP files. This is the default.
yes
Generate SMAP files. An SMAP file name is SQLJ-source-file-name.java.smap. The SQLJ translator places the SMAP file in the same directory as the generated Java source file.

-encoding=encoding-name
Specifies the encoding of the source file. Examples are JIS or EUC. If this option is not specified, the default converter for the operating system is used.

-db2optimize
Specifies that the SQLJ translator generates code that enables SQLJ context caching in a WebSphere Application Server environment for applications that run against DB2 data servers.

-db2optimize causes a user-defined context to extend a custom driver class, which enables context caching and connection caching in WebSphere Application Server.

Because context caching is enabled by using an instance of IBM Data Server Driver for JDBC and SQLJ class sqlj.runtime.ref.DefaultContext, db2jcc.jar must be in the CLASSPATH when you translate and compile the Java application.

You cannot use connection sharing in WebSphere Application Server if you use context caching.

Important: Context caching that is enabled by the -db2optimize option can provide performance benefits over connection pooling and statement pooling that is provided by WebSphere Application Server. However, context caching can result in significant resource consumption in the application server, and might have unintended side effects if it is not used correctly. For example, if two applications use an SQLJ profile with the same name, they might overwrite each other, because both use sqlj.runtime.ref.DefaultContext. Use context caching only if:

- The system is not storage-constrained.
- Cached statements are often reused on the same Connection.
- All applications have distinct names for their SQLJ profiles.

-ser2class
Specifies that the SQLJ translator converts .ser files to .class files.

-status
Specifies that the SQLJ translator displays status messages as it runs.

-version
Specifies that the SQLJ translator displays the version of the IBM Data Server Driver for JDBC and SQLJ. The information is in this form:
IBM SQLJ xxxx.xxxx.xx

-C-help
Specifies that the SQLJ translator displays help information for the Java compiler.

-C-compiler-option
Specifies a valid Java compiler option that begins with a dash (-). Do not include spaces between -C and the compiler option. If you need to specify multiple compiler options, precede each compiler option with -C. For example:
-C-g -C-verbose

All options are passed to the Java compiler and are not used by the SQLJ translator, except for the following options:
-classpath
   Specifies the user class path that is to be used by the SQLJ translator and the Java compiler. This value overrides the CLASSPATH environment variable.

-sourcepath
   Specifies the source code path that the SQLJ translator and the Java compiler search for class or interface definitions. The SQLJ translator searches for .sqlj and .java files only in directories, not in JAR or zip files.

-JJVM-option
   Specifies an option that is to be passed to the Java virtual machine (JVM) in which the sqlj command runs. The option must be a valid JVM option that begins with a dash (-). Do not include spaces between -J and the JVM option. If you need to specify multiple JVM options, precede each compiler option with -J. For example:
   -J-Xmx128m -J-Xmx1m

SQLJ-source-file-name
   Specifies a list of SQLJ source files to be translated. This is a required parameter. All SQLJ source file names must have the extension .sqlj.

Output

For each source file, program-name.sqlj, the SQLJ translator produces the following files:
   • The generated source program
      The generated source file is named program-name.java.
   • A serialized profile file for each connection context class that is used in an SQLJ executable clause
      A serialized profile name is of the following form:
      program-name_SJProfileIDNumber.ser
   • If the SQLJ translator invokes the Java compiler, the class files that the compiler generates.

Examples

   sqlj -encoding=UTF8 -C-O MyApp.sqlj

db2sqljcustomize - SQLJ profile customizer

db2sqljcustomize processes an SQLJ profile, which contains embedded SQL statements.

By default, db2sqljcustomize produces four DB2 packages: one for each isolation level. db2sqljcustomize augments the profile with DB2-specific information for use at run time.

Authorization

The privilege set of the process must include one of the following authorities:
• DBADM authority
• If the package does not exist, the BINDADD privilege, and one of the following privileges:
   – CREATEIN privilege
   – IMPLICIT_SCHEMA authority on the database if the schema name of the package does not exist
• If the package exists:
  – ALTERIN privilege on the schema
  – BIND privilege on the package

The user also needs all privileges that are required to compile any static SQL statements in the application. Privileges that are granted to groups are not used for authorization checking of static statements.

**Command syntax**

```
db2sqljcustomize
  -help

-url jdbc:db2://server[:port]/database
  -user user-ID
  -datasource JNDI-name
    -property=value

-password password
  -automaticbind YES
  -automaticbind NO
  -pkgversion AUTO
  -pkgversion version-id

-bindoptions "options-string"
  -storebindoptions
  -collection collection-name

-onlinecheck YES
  -onlinecheck NO
  -qualifier qualifier-name
  -rootpkgname package-name-stem
  -singlepkgname package-name

-longpkgname
c
  -staticpositioned NO
  -staticpositioned YES
```
Notes:
1 These options can be specified in any order.
2 COLLECTION is not a valid BIND option for DB2 for z/OS. However, COLLECTION can be specified as a -bindoptions argument in db2sqljcustomize or db2sqljbind, to change the collection at bind time, or to bind the same serialized profile file into multiple collections.
3 FUNCPATH can be specified as an alias for PATH.

**DB2 for Linux, UNIX, and Windows options:**

1. BLOCKING UNAMBIG
2. BLOCKING ALL
3. BLOCKING NO
4. EXPLAIN NO
5. EXPLAIN YES
6. EXPLSNAP NO
7. EXPLSNAP ALL
8. EXPLSNAP YES
9. INSERT DEF
10. INSERT BUF
11. ISOLATION CS
12. ISOLATION RR
13. ISOLATION RS
14. ISOLATION UR
15. QUALIFIER
16. SQLERROR NOPACKAGE
17. SQLERROR CONTINUE
18. SQLERROR CHECK
19. VALIDATE RUN
20. VALIDATE BIND

**DB2 for Linux, UNIX, and Windows options:**

1. DEGREE 1
2. DEGREE ANY
3. CONCURRENTACCESSRESOLUTION WAIT FOR OUTCOME
4. CONCURRENTACCESSRESOLUTION WAITFOROUTCOME
5. CONCURRENTACCESSRESOLUTION USE CURRENTLY COMMITTED
6. CONCURRENTACCESSRESOLUTION USECURRENTLYCOMMITTED
7. FEDERATED NO
8. FEDERATED YES
9. EXTENDEDINDICATOR NO
10. EXTENDEDINDICATOR YES
11. INSERT DEF
12. INSERT BUF
13. ISOLATION CS
14. ISOLATION RR
15. ISOLATION RS
16. ISOLATION UR
17. QUALIFIER
18. QUERYOPT optimization-level
19. SQLERROR NOPACKAGE
20. SQLERROR CONTINUE
21. SQLERROR CHECK
Notes:
1. These options can be specified in any order.

### Command parameters

- `-help`
  Specifies that the SQLJ customizer describes each of the options that the customizer supports. If any other options are specified with `-help`, they are ignored.

- `-url`
  Specifies the URL for the data source for which the profile is to be customized. A connection is established to the data source that this URL represents if the `-automaticbind` or `-onlinecheck` option is specified as YES or defaults to YES. The variable parts of the `-url` value are:

  **server**
  The domain name or IP address of the z/OS system on which the DB2 subsystem resides.

  **port**
  The TCP/IP server port number that is assigned to the DB2 subsystem. The default is 446.

- `-url`
  Specifies the URL for the data source for which the profile is to be customized. A connection is established to the data source that this URL represents if the `-automaticbind` or `-onlinecheck` option is specified as YES or defaults to YES. The variable parts of the `-url` value are:

  **server**
  The domain name or IP address of the operating system on which the database server resides.

  **port**
  The TCP/IP server port number that is assigned to the database server. The default is 446.

- `database`
  A name for the database server for which the profile is to be customized.

  If the connection is to a DB2 for z/OS server, `database` is the DB2 location name that is defined during installation. All characters in this value must be uppercase characters. You can determine the location name by executing the following SQL statement on the server:
  ```sql
  SELECT CURRENT SERVER FROM SYSIBM.SYSDUMMY1;
  ```

  If the connection is to a DB2 for Linux, UNIX, and Windows server, `database` is the database name that is defined during installation.

  If the connection is to an IBM Cloudscape server, the `database` is the fully-qualified name of the file that contains the database. This name must be enclosed in double quotation marks ("."). For example:

  "c:/databases/testdb"
property=value;
   A property for the JDBC connection.

property=value;
   A property for the JDBC connection.

-dataSource JNDI-name
   Specifies the logical name of a DataSource object that was registered with JNDI. The DataSource object represents the data source for which the profile is to be customized. A connection is established to the data source if the -automaticbind or -onlinecheck option is specified as YES or defaults to YES. Specifying -datasource is an alternative to specifying -url. The DataSource object must represent a connection that uses IBM Data Server Driver for JDBC and SQLJ type 4 connectivity.

-user user-ID
   Specifies the user ID to be used to connect to the data source for online checking or binding a package. You must specify -user if you specify -url. You must specify -user if you specify -datasource, and the DataSource object that JNDI-name represents does not contain a user ID.

-password password
   Specifies the password to be used to connect to the data source for online checking or binding a package. You must specify -password if you specify -url. You must specify -password if you specify -datasource, and the DataSource object that JNDI-name represents does not contain a password.

-automaticbind YES|NO
   Specifies whether the customizer binds DB2 packages at the data source that is specified by the -url parameter.
   The default is YES.
   The number of packages and the isolation levels of those packages are controlled by the -rootpkgname and -singlepkgname options.
   Before the bind operation can work, the following conditions need to be met:
   • TCP/IP and DRDA must be installed at the target data source.
   • Valid -url, -username, and -password values must be specified.
   • The -username value must have authorization to bind a package at the target data source.

-pkgversion AUTO|version-id
   Specifies the package version that is to be used when packages are bound at the server for the serialized profile that is being customized. db2sqljcustomize stores the version ID in the serialized profile and in the DB2 package. Run-time version verification is based on the consistency token, not the version name. To automatically generate a version name that is based on the consistency token, specify -pkgversion AUTO.
   The default is that there is no version.

-bindoptions options-string
   Specifies a list of options, separated by spaces. These options have the same function as DB2 precompile and bind options with the same names. If you are preparing your program to run on a DB2 for z/OS system, specify DB2 for z/OS options. If you are preparing your program to run on a DB2 for Linux, UNIX, and Windows system, specify DB2 for Linux, UNIX, and Windows options.

Notes on bind options:
Specify ISOLATION only if you also specify the -singlepkgname option.

The value for STATICREADONLY is YES for servers that support STATICREADONLY, and NO for other servers. When you specify STATICREADONLY YES, DB2 processes ambiguous cursors as if they were read-only cursors. For troubleshooting iterator declaration errors, you need to explicitly specify STATICREADONLY NO, or declare iterators so that they are unambiguous. For example, if you want an iterator to be unambiguously updatable, declare the iterator to implement sqlj.runtime.ForUpdate. If you want an iterator to be read-only, include the FOR READ ONLY clause in SELECT statements that use the iterator.

**Important:** Specify only those program preparation options that are appropriate for the data source at which you are binding a package. Some values and defaults for the IBM Data Server Driver for JDBC and SQLJ are different from the values and defaults for DB2.

- **-storebindoptions**
  Specifies that values for the -bindoptions and -staticpositioned parameters are stored in the serialized profile. If db2sqljbind is invoked without the -bindoptions or -staticpositioned parameter, the values that are stored in the serialized profile are used during the bind operation. When multiple serialized profiles are specified for one invocation of db2sqljcustomize, the parameter values are stored in each serialized profile. The stored values are displayed in the output from the db2sqljprint utility.

- **-collection collection-name**
  The qualifier for the packages that db2sqljcustomize binds. db2sqljcustomize stores this value in the customized serialized profile, and it is used when the associated packages are bound. If you do not specify this parameter, db2sqljcustomize uses a collection ID of NULLID.

- **-onlinecheck YES|NO**
  Specifies whether online checking of data types in the SQLJ program is to be performed. The -url or -datasource option determines the data source that is to be used for online checking. The default is YES if the -url or -datasource parameter is specified. Otherwise, the default is NO.

- **-qualifier qualifier-name**
  Specifies the qualifier that is to be used for unqualified objects in the SQLJ program during online checking. This value is not used as the qualifier when the packages are bound.

- **-rootpkgname|-singlepkgname**
  Specifies the names for the packages that are associated with the program. If -automaticbind is NO, these package names are used when db2sqljbind runs. The meanings of the parameters are:

  - **-rootpkgname package-name-stem**
    Specifies that the customizer creates four packages, one for each of the four DB2 isolation levels. The names for the four packages are:

    - `package-name-stem1`
      For isolation level UR

    - `package-name-stem2`
      For isolation level CS

    - `package-name-stem3`
      For isolation level RS
For isolation level RR

If -longpkgname is not specified, *package-name-stem* must be an alphanumeric string of seven or fewer bytes.

If -longpkgname is specified, *package-name-stem* must be an alphanumeric string of 127 or fewer bytes.

### -singlepkgname *package-name*

Specifies that the customizer creates one package, with the name *package-name*. If you specify this option, your program can run at only one isolation level. You specify the isolation level for the package by specifying the ISOLATION option in the -bindoptions options string.

If -longpkgname is not specified, *package-name* must be an alphanumeric string of eight or fewer bytes.

If -longpkgname is specified, *package-name* must be an alphanumeric string of 128 or fewer bytes.

Using the -singlepkgname option is not recommended.

**Recommendation:** If the target data source is DB2 for z/OS, use uppercase characters for the *package-name-stem* or *package-name* value. DB2 for z/OS systems that are defined with certain CCSID values cannot tolerate lowercase characters in package names or collection names.

If you do not specify -rootpkgname or -singlepkgname, *db2sqljcustomize* generates four package names that are based on the serialized profile name. A serialized profile name is of the following form:

```
program-name_SJProfileIDNumber.ser
```

The four generated package names are of the following form:

```
Bytes-from-program-nameIDNumberPkgIsolation
```

*Table 117* shows the parts of a generated package name and the number of bytes for each part.

The maximum length of a package name is maxlen. maxlen is 8 if -longpkgname is not specified. maxlen is 128 if -longpkgname is specified.

**Table 117. Parts of a package name that is generated by db2sqljcustomize**

<table>
<thead>
<tr>
<th>Package name part</th>
<th>Number of bytes</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bytes-from-program-name</td>
<td>( m = \min(\text{Length}(\text{program-name}), \maxlen - 1 - \text{Length}(\text{IDNumber})) )</td>
<td>First ( m ) bytes of ( \text{program-name} ), in uppercase</td>
</tr>
<tr>
<td>IDNumber</td>
<td>Length(IDNumber)</td>
<td>IDNumber</td>
</tr>
<tr>
<td>PkgIsolation</td>
<td>1</td>
<td>1, 2, 3, or 4. This value represents the transaction isolation level for the package. See <em>Table 118</em></td>
</tr>
</tbody>
</table>

*Table 118* shows the values of the PkgIsolation portion of a package name that is generated by *db2sqljcustomize*.

**Table 118. PkgIsolation values and associated isolation levels**

<table>
<thead>
<tr>
<th>PkgNumber value</th>
<th>Isolation level for package</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Uncommitted read (UR)</td>
</tr>
<tr>
<td>2</td>
<td>Cursor stability (CS)</td>
</tr>
</tbody>
</table>
Table 118. PkgIsolation values and associated isolation levels (continued)

<table>
<thead>
<tr>
<th>PkgNumber value</th>
<th>Isolation level for package</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Read stability (RS)</td>
</tr>
<tr>
<td>4</td>
<td>Repeatable read (RR)</td>
</tr>
</tbody>
</table>

Example: Suppose that a profile name is ThisIsMyProg_SJProfile111.ser. The db2sqljcustomize option -longpkgname is not specified. Therefore, Bytes-from-program-name is the first four bytes of ThisIsMyProg, translated to uppercase, or THIS. IDNumber is 111. The four package names are:

THIS1111
THIS1112
THIS1113
THIS1114

Example: Suppose that a profile name is ThisIsMyProg_SJProfile111.ser. The db2sqljcustomize option -longpkgname is specified. Therefore, Bytes-from-program-name is ThisIsMyProg, translated to uppercase, or THISISMYPROG. IDNumber is 111. The four package names are:

THISISMYPROG1111
THISISMYPROG1112
THISISMYPROG1113
THISISMYPROG1114

Example: Suppose that a profile name is A_SJProfile0.ser. Bytes-from-program-name is A. IDNumber is 0. Therefore, the four package names are:

A01
A02
A03
A04

Letting db2sqljcustomize generate package names is not recommended. If any generated package names are the same as the names of existing packages, db2sqljcustomize overwrites the existing packages. To ensure uniqueness of package names, specify -rootpkgname.

-longpkgname
Specifies that the names of the DB2 packages that db2sqljcustomize generates can be up to 128 bytes. Use this option only if you are binding packages at a server that supports long package names. If you specify -singlepkgname or -rootpkgname, you must also specify -longpkgname under the following conditions:
• The argument of -singlepkgname is longer than eight bytes.
• The argument of -rootpkgname is longer than seven bytes.

-staticpositioned NO|YES
For iterators that are declared in the same source file as positioned UPDATE statements that use the iterators, specifies whether the positioned UPDATEs are executed as statically bound statements. The default is NO. NO means that the positioned UPDATEs are executed as dynamically prepared statements.

-zosDescProcParms
Specifies that db2sqljcustomize queries the DB2 catalog at the target data source to determine the SQL parameter data types that correspond to the host variables in CALL statements.
-zosDescProcParms applies only to programs that run on DB2 for z/OS data servers.

If -zosDescProcParms is specified, and the authorization ID under which db2sqljcustomize runs does not have read access to the SYSIBM.SYSROUTINES
catalog table, db2sqljcustomize returns an error and uses the host variable data types in the CALL statements to determine the SQL data types.

Specification of -zosDescProcParms can lead to more efficient storage usage at run time. If SQL data type information is available, SQLJ has information about the length and precision of INOUT and OUT parameters, so it allocates only the amount of memory that is needed for those parameters. Availability of SQL data type information can have the biggest impact on storage usage for character INOUT parameters, LOB OUT parameters, and decimal OUT parameters.

When -zosDescProcParms is specified, the DB2 data server uses the specified or default value of -zosProcedurePath to resolve unqualified names of stored procedures for which SQL data type information is requested.

If -zosDescProcParms is not specified, db2sqljcustomize uses the host variable data types in the CALL statements to determine the SQL data types. If db2sqljcustomize determines the wrong SQL data type, an SQL error might occur at run time. For example, if the Java host variable type is String, and the corresponding stored procedure parameter type is VARCHAR FOR BIT DATA, an SQL run-time error such as -4220 might occur.

-zosProcedurePath procedure-path
Specifies a list of schema names that DB2 for z/OS uses to resolve unqualified stored procedure names during online checking of an SQLJ program.

-zosProcedurePath applies to programs that are to be run on DB2 for z/OS database servers only.

The list is a String value that is a comma-separated list of schema names that is enclosed in double quotation marks. The DB2 database server inserts that list into the SQL path for resolution of unqualified stored procedure names. The SQL path is:
SYSIBM, SYSFUN, SYSPROC, procedure-path, qualifier-name, user-ID

qualifier-name is the value of the -qualifier parameter, and user-ID is the value of the -user parameter.

The DB2 database server tries the schema names in the SQL path from left to right until it finds a match with the name of a stored procedure that exists on that database server. If the DB2 database server finds a match, it obtains the information about the parameters for that stored procedure from the DB2 catalog. If the DB2 database server does not find a match, SQLJ sets the parameter data without any DB2 catalog information.

If -zosProcedurePath is not specified, the DB2 database server uses this SQL path:
SYSIBM, SYSFUN, SYSPROC, qualifier-name, user-ID

If the -qualifier parameter is not specified, the SQL path does not include qualifier-name.

-genDBRM
Specifies that db2sqljcustomize generates database request modules (DBRMs). Those DBRMs can be used to create DB2 for z/OS packages.

-genDBRM applies to programs that are to be run on DB2 for z/OS database servers only.
If -genDBRM and -automaticbind NO are specified, db2sqljcustomize creates the DBRMs but does not bind them into DB2 packages. If -genDBRM and -automaticbind YES are specified, db2sqljcustomize creates the DBRMs and binds them into DB2 packages.

One DBRM is created for each DB2 isolation level. The naming convention for the generated DBRM files is the same as the naming convention for packages. For example, if -rootpkgname SQLJSA0 is specified, and -genDBRM is also specified, the names of the four DBRM files are:

- SQLJSA01
- SQLJSA02
- SQLJSA03
- SQLJSA04

-DBRMDir directory-name

When -genDBRM is specified, -DBRMDir specifies the local directory into which db2sqljcustomize puts the generated DBRM files. The default is the current directory.

-DBRMDir applies to programs that are to be run on DB2 for z/OS database servers only.

-tracefile file-name

Enables tracing and identifies the output file for trace information. This option should be specified only under the direction of IBM Software Support.

-tracelevel

If -tracefile is specified, indicates what to trace while db2sqljcustomize runs. The default is TRACE_SQLJ. This option should be specified only under the direction of IBM Software Support.

serialized-profile-name|file-name.grp

Specifies the names of one or more serialized profiles that are to be customized. The specified serialized profile must be in a directory that is named in the CLASSPATH environment variable.

A serialized profile name is of the following form:

program-name_SJProfileIDNumber.ser

You can specify the serialized profile name with or without the .ser extension. 

program-name is the name of the SQLJ source program, without the extension .sqlj. n is an integer between 0 and m-1, where m is the number of serialized profiles that the SQLJ translator generated from the SQLJ source program.

You can specify serialized profile names in one of the following ways:

- List the names in the db2sqljcustomize command. Multiple serialized profile names must be separated by spaces.

- Specify the serialized profile names, one on each line, in a file with the name file-name.grp, and specify file-name.grp in the db2sqljcustomize command.

If you specify more than one serialized profile name, and if you specify or use the default value of -automaticbind YES, db2sqljcustomize binds a single DB2 package from the profiles. When you use db2sqljcustomize to create a single DB2 package from multiple serialized profiles, you must also specify the -rootpkgname or -singlepkgname option.

If you specify more than one serialized profile name, and you specify -automaticbind NO, if you want to bind the serialized profiles into a single
DB2 package when you run db2sqljbind, you need to specify the same list of serialized profile names, in the same order, in db2sqljcustomize and db2sqljbind.

If you specify one or more file-name.grp files, and you specify -automaticbind NO, when you run db2sqljbind, you must specify that same list of files, and in the same order in which the files were customized.

You cannot run db2sqljcustomize on individual files, and then group those files when you run db2sqljbind.

**Output**

When db2sqljcustomize runs, it creates a customized serialized profile. It also creates DB2 packages, if the automaticbind value is YES.

**Examples**

```
   db2sqljcustomize -user richler -password mordecai
                   -url jdbc:db2://server:50000/sample -collection duddy
                   -bindoptions "EXPLAIN YES" pgmname_SJProfile0.ser
```

**Usage notes**

*Online checking is always recommended:* It is highly recommended that you use online checking when you customize your serialized profiles. Online checking determines information about the data types and lengths of DB2 host variables, and is especially important for the following items:

- **Predicates with java.lang.String host variables and CHAR columns**
  Unlike character variables in other host languages, Java String host variables are not declared with a length attribute. To optimize a query properly that contains character host variables, DB2 needs the length of the host variables. For example, suppose that a query has a predicate in which a String host variable is compared to a CHAR column, and an index is defined on the CHAR column. If DB2 cannot determine the length of the host variable, it might do a table space scan instead of an index scan. Online checking avoids this problem by providing the lengths of the corresponding character columns.

- **Predicates with java.lang.String host variables and GRAPHIC columns**
  Without online checking, DB2 might issue a bind error (SQLCODE -134) when it encounters a predicate in which a String host variable is compared to a GRAPHIC column.

- **Column names in the result table of an SQLJ SELECT statement at a remote server:**
  Without online checking, the driver cannot determine the column names for the result table of a remote SELECT.

*Customizing multiple serialized profiles together:* Multiple serialized profiles can be customized together to create a single DB2 package. If you do this, and if you specify -staticpositioned YES, any positioned UPDATE or DELETE statement that references a cursor that is declared earlier in the package executes statically, even if the UPDATE or DELETE statement is in a different source file from the cursor declaration. If you want -staticpositioned YES behavior when your program consists of multiple source files, you need to order the profiles in the db2sqljcustomize command to cause cursor declarations to be ahead of positioned UPDATE or DELETE statements in the package. To do that, list profiles that
contain SELECT statements that assign result tables to iterators before profiles that contain the positioned UPDATE or DELETE statements that reference those iterators.

**Using a customized serialized profile at one data source that was customized at another data source:** You can run `db2sqljcustomize` to produce a customized serialized profile for an SQLJ program at one data source, and then use that profile at another data source. You do this by running `db2sqljbind` multiple times on customized serialized profiles that you created by running `db2sqljcustomize` once. When you run the programs at these data sources, the DB2 objects that the programs access must be identical at every data source. For example, tables at all data sources must have the same encoding schemes and the same columns with the same data types.

**Using the -collection parameter:** `db2sqljcustomize` stores the DB2 collection name in each customized serialized profile that it produces. When an SQLJ program is executed, the driver uses the collection name that is stored in the customized serialized profile to search for packages to execute. The name that is stored in the customized serialized profile is determined by the value of the -collection parameter. Only one collection ID can be stored in the serialized profile. However, you can bind the same serialized profile into multiple package collections by specifying the COLLECTION option in the -bindoptions parameter. To execute a package that is in a collection other than the collection that is specified in the serialized profile, include a SET CURRENT PACKAGESET statement in the program.

**Using the VERSION parameter:** Use the VERSION parameter to bind two or more versions of a package for the same SQLJ program into the same collection. You might do this if you have changed an SQLJ source program, and you want to run the old and new versions of the program.

To maintain two versions of a package, follow these steps:

1. Change the code in your source program.
2. Translate the source program to create a new serialized profile. Ensure that you do not overwrite your original serialized profile.
3. Run `db2sqljcustomize` to customize the serialized profile and create DB2 packages with the same package names and in the same collection as the original packages. Do this by using the same values for -rootpkgname and -collection when you bind the new packages that you used when you created the original packages. Specify the VERSION option in the -bindoptions parameter to put a version ID in the new customized serialized profile and in the new packages.

   It is essential that you specify the VERSION option when you perform this step. If you do not, you overwrite your original packages.

When you run the old version of the program, DB2 loads the old versions of the packages. When you run the new version of the program, DB2 loads the new versions of the packages.

**Binding packages and plans on DB2 for z/OS:** You can use the `db2sqljcustomize -genDBRM` parameter to create DBRMs on your local system. You can then transfer those DBRMs to a DB2 for z/OS system, and bind them into packages there. If you plan to use this technique, you need to transfer the DBRM files to the z/OS system.
as binary files, to a partitioned data set with record format FB and record length 80. When you bind the packages, you need to specify the following bind option values:

**ENCODING(EBCDIC)**

The IBM Data Server Driver for JDBC and SQLJ on DB2 for z/OS requires EBCDIC encoding for your packages.

**DYNAMICRULES(BIND)**

This option ensures consistent authorization rules when SQLJ uses dynamic SQL. SQLJ uses dynamic SQL for positioned UPDATE or DELETE operations that involve multiple SQLJ programs.

**EXTENDEDINDICATOR bind option behavior:** If the EXTENDEDINDICATOR bind option is not specified in the -bindoptions options string, and the target data server supports extended indicators, bind operations use EXTENDEDINDICATOR(YES). If EXTENDEDINDICATOR(NO) is explicitly specified, and the application contains extended indicator syntax, unexpected behavior can occur because the IBM Data Server Driver for JDBC and SQLJ treats extended indicators as NULL values.

Related reference:

- [BIND command](#)

**db2sqljbind - SQLJ profile binder**

`db2sqljbind` binds DB2 packages for a serialized profile that was previously customized with the `db2sqljcumtize` command.

Applications that run with the IBM Data Server Driver for JDBC and SQLJ require packages but no plans. If the `db2sqljcumtize` -automaticbind option is specified as YES or defaults to YES, `db2sqljcumtize` binds packages for you at the data source that you specify in the -url parameter. However, if -automaticbind is NO, if a bind fails when `db2sqljcumtize` runs, or if you want to create identical packages at multiple locations for the same serialized profile, you can use the `db2sqljbind` command to bind packages.

**Authorization**

The privilege set of the process must include one of the following authorities:

- DBADM authority
- If the package does not exist, the BINDADD privilege, and one of the following privileges:
  - CREATEIN privilege
  - IMPLICIT_SCHEMA authority on the database if the schema name of the package does not exist
- If the package exists:
  - ALTERIN privilege on the schema
  - BIND privilege on the package

The user also needs all privileges that are required to compile any static SQL statements in the application. Privileges that are granted to groups are not used for authorization checking of static statements.

**Command syntax**
db2sqljbind -help

-url jdbc:db2://server:/database -user user-ID

-datasource JNDI-name

-password password -bindoptions "options-string" -staticpositioned NO -staticpositioned YES

gendbrm -DBRMDir directory-name

-tracefile file-name -tracelevel TRACE_SQLJ

-tracelevel TRACE_NONE

TRACE_ALL

serialized-profile-name file-name.grp

options-string:

DB2 for z/OS options:

DB2 for z/OS options:

DB2 Database for Linux, UNIX, and Windows options:
Notes:
1 These options can be specified in any order.
2 COLLECTION is not a valid BIND option for DB2 for z/OS. However, COLLECTION can be specified as a -bindoptions argument in db2sqljcustomize or db2sqljbind, to change the collection at bind time, or to bind the same serialized profile file into multiple collections.
3 FANCPATH can be specified as an alias for PATH.

DB2 for Linux, UNIX, and Windows options
**Notes:**

1. These options can be specified in any order.

**Command parameters**

- **-help**
  Specifies that db2sqljbind describes each of the options that it supports. If any other options are specified with -help, they are ignored.

- **-url**
  Specifies the URL for the data source for which the profile is to be customized.
  A connection is established to the data source that this URL represents if the -automaticbind or -onlinecheck option is specified as YES or defaults to YES.
  The variable parts of the -url value are:

  - **server**
    The domain name or IP address of the operating system on which the database server resides.

  - **port**
    The TCP/IP server port number that is assigned to the database server.
    The default is 446.

  - **database**
    A name for the database server for which the profile is to be customized.
    If the connection is to a DB2 for z/OS server, database is the DB2 location name that is defined during installation. All characters in this value must be uppercase characters. You can determine the location name by executing the following SQL statement on the server:
    `SELECT CURRENT SERVER FROM SYSIBM.SYSDUMMY1;`
    If the connection is to a DB2 for Linux, UNIX, and Windows server, database is the database name that is defined during installation.
    If the connection is to an IBM Cloudscape server, the database is the fully-qualified name of the file that contains the database. This name must be enclosed in double quotation marks ("). For example:
    "c:/databases/testdb"
property=value;
   A property for the JDBC connection.

-datasource JNDI-name
   Specifies the logical name of a DataSource object that was registered with
   JNDI. The DataSource object represents the data source for which the profile is
   to be customized. A connection is established to the data source if the
   -automaticbind or -onlinecheck option is specified as YES or defaults to YES.
   Specifying -datasource is an alternative to specifying -url. The DataSource
   object must represent a connection that uses IBM Data Server Driver for JDBC
   and SQLJ type 4 connectivity.

-user user-ID
   Specifies the user ID to be used to connect to the data source for binding the
   package.

-password password
   Specifies the password to be used to connect to the data source for binding the
   package.

-bindoptions options-string
   Specifies a list of options, separated by spaces. These options have the same
   function as DB2 precompile and bind options with the same names. If you are
   preparing your program to run on a DB2 for z/OS system, specify DB2 for
   z/OS options. If you are preparing your program to run on a DB2 for Linux,
   UNIX, and Windows system, specify DB2 for Linux, UNIX, and Windows
   options.

Notes on bind options:
   • Specify VERSION only if the following conditions are true:
     – If you are binding a package at a DB2 for Linux, UNIX, and Windows
       system, the system is at Version 8 or later.
     – You rerun the translator on a program before you bind the associated
       package with a new VERSION value.
   • The value for STATICREADONLY is YES for servers that support
     STATICREADONLY, and NO for other servers. When you specify
     STATICREADONLY YES, DB2 processes ambiguous cursors as if they were
     read-only cursors. For troubleshooting iterator declaration errors, you need
     to explicitly specify STATICREADONLY NO, or declare iterators so that they
     are unambiguous. For example, if you want an iterator to be unambiguously
     updatable, declare the iterator to implement sqlj.runtime.ForUpdate. If you
     want an iterator to be read-only, include the FOR READ ONLY clause in
     SELECT statements that use the iterator.

Important: Specify only those program preparation options that are
   appropriate for the data source at which you are binding a package. Some
   values and defaults for the IBM Data Server Driver for JDBC and SQLJ are
   different from the values and defaults for DB2.

-staticpositioned NO|YES
   For iterators that are declared in the same source file as positioned UPDATE
   statements that use the iterators, specifies whether the positioned UPDATEs
   are executed as statically bound statements. The default is NO. NO means that
   the positioned UPDATEs are executed as dynamically prepared statements.
   This value must be the same as the -staticpositioned value for the previous
db2sqljcustomize invocation for the serialized profile.
-genDBRM
Specifies that db2sqljbind generates database request modules (DBRMs) from
the serialized profile, and that db2sqljbind does not perform remote bind
operations.

-genDBRM applies to programs that are to be run on DB2 for z/OS database
servers only.

-DBRMDir directory-name
When -genDBRM is specified, -DBRMDir specifies the local directory into
which db2sqljbind puts the generated DBRM files. The default is the current
directory.

-DBRMDir applies to programs that are to be run on DB2 for z/OS database
servers only.

-tracefile file-name
Enables tracing and identifies the output file for trace information. This option
should be specified only under the direction of IBM Software Support.

-tracelevel
If -tracefile is specified, indicates what to trace while db2sqljcustomize runs.
The default is TRACE_SQLJ. This option should be specified only under the
direction of IBM Software Support.

serialized-profile-name|file-name.grp
Specifies the names of one or more serialized profiles from which the package
is bound. A serialized profile name is of the following form:

program-name_SJProfile0Number.ser

program-name is the name of the SQLJ source program, without the extension
.sqlj. n is an integer between 0 and m-1, where m is the number of serialized
profiles that the SQLJ translator generated from the SQLJ source program.

You can specify serialized profile names in one of the following ways:
• List the names in the db2sqljcustomize command. Multiple serialized profile
  names must be separated by spaces.
• Specify the serialized profile names, one on each line, in a file with the name
  file-name.grp, and specify file-name.grp in the db2sqljbind command.

If you specify more than one serialized profile name to bind a single DB2
package from several serialized profiles, you must have specified the same
serialized profile names, in the same order, when you ran db2sqljcustomize.

If you specify one or more file-name.grp files, you must have run
db2sqljcustomize once with that same list of files. The order in which you
specify the files in db2sqljbind must be the same as the order in
db2sqljcustomize.

You cannot run db2sqljcustomize on individual files, and then group those files
when you run db2sqljbind.

Examples
db2sqljbind -user richler -password mordecai
-url jdbc:db2://server:50000/sample -bindoptions "EXPLAIN YES"
pgmname_SJProfile0.ser
Usage notes

**Package names produced by db2sqljbind**: The names of the packages that are created by db2sqljbind are the names that you specified using the-rootpkgname or -singlepkgname parameter when you ran db2sqljcustomize. If you did not specify -rootpkgname or -singlepkgname, the package names are the first seven bytes of the profile name, appended with the isolation level character.

**DYNAMICRULES value for db2sqljbind**: The DYNAMICRULES bind option determines a number of run-time attributes for the DB2 package. Two of those attributes are the authorization ID that is used to check authorization, and the qualifier that is used for unqualified objects. To ensure the correct authorization for dynamically executed positioned UPDATE and DELETE statements in SQLJ programs, db2sqljbind always binds the DB2 packages with the DYNAMICRULES(BIND) option. You cannot modify this option. The DYNAMICRULES(BIND) option causes the SET CURRENT SQLID statement and the SET CURRENT SCHEMA statement to have no impact on an SQLJ program, because those statements affect only dynamic statements that are bound with DYNAMICRULES values other than BIND.

With DYNAMICRULES(BIND), unqualified table, view, index, and alias names in dynamic SQL statements are implicitly qualified with value of the bind option QUALIFIER. If you do not specify QUALIFIER, DB2 uses the authorization ID of the package owner as the implicit qualifier. If this behavior is not suitable for your program, you can use one of the following techniques to set the correct qualifier:

- Force positioned UPDATE and DELETE statements to execute statically. You can use the -staticpositioned YES option of db2sqljcustomize or db2sqljbind to do this if the cursor (iterator) for a positioned UPDATE or DELETE statement is in the same package as the positioned UPDATE or DELETE statement.
- Fully qualify DB2 table names in positioned UPDATE and positioned DELETE statements.

**EXTENDEDINDICATOR bind option behavior**: If the EXTENDEDINDICATOR bind option is not specified in the -bindoptions options string, and the target data server supports extended indicators, bind operations use EXTENDEDINDICATOR(NO). If EXTENDEDINDICATOR(NO) is explicitly specified, and the application contains extended indicator syntax, unexpected behavior can occur because the IBM Data Server Driver for JDBC and SQLJ treats extended indicators as NULL values.

- [BIND command](#)

**db2sqljprint - SQLJ profile printer**

db2sqljprint prints the contents of the customized version of a profile as plain text.

**Authorization**

None

**Command syntax**

```
db2sqljprint --profilename
```
Command parameters

filename

Specifies the relative or absolute name of an SQLJ profile file. When an SQLJ file is translated into a Java source file, information about the SQL operations it contains is stored in SQLJ-generated resource files called profiles. Profiles are identified by the suffix _SJProfileN (where N is an integer) following the name of the original input file. They have a .ser extension. Profile names can be specified with or without the .ser extension.

Examples

db2sqljprint pgmname_SJProfile0.ser
Appendix A. Overview of the DB2 technical information

DB2 technical information is available in multiple formats that can be accessed in multiple ways.

DB2 technical information is available through the following tools and methods:

- DB2 Information Center
  - Topics (Task, concept and reference topics)
  - Sample programs
  - Tutorials
- DB2 books
  - PDF files (downloadable)
  - PDF files (from the DB2 PDF DVD)
  - Printed books
- Command-line help
  - Command help
  - Message help

Note: The DB2 Information Center topics are updated more frequently than either the PDF or the hardcopy books. To get the most current information, install the documentation updates as they become available, or refer to the DB2 Information Center at ibm.com.

You can access additional DB2 technical information such as technotes, white papers, and IBM Redbooks® publications online at ibm.com. Access the DB2 Information Management Software Library site at [http://www.ibm.com/software/data/sw-library/](http://www.ibm.com/software/data/sw-library/).

Documentation feedback

We value your feedback on the DB2 documentation. If you have suggestions for how to improve the DB2 documentation, send an e-mail to db2docs@ca.ibm.com. The DB2 documentation team reads all of your feedback, but cannot respond to you directly. Provide specific examples wherever possible so that we can better understand your concerns. If you are providing feedback on a specific topic or help file, include the topic title and URL.

Do not use this email address to contact DB2 Customer Support. If you have a DB2 technical issue that the documentation does not resolve, contact your local IBM service center for assistance.

Displaying SQL state help from the command line processor

DB2 products return an SQLSTATE value for conditions that can be the result of an SQL statement. SQLSTATE help explains the meanings of SQL states and SQL state class codes.

To start SQL state help, open the command line processor and enter:

```
? sqlstate or ? class code
```
where sqlstate represents a valid five-digit SQL state and class code represents the first two digits of the SQL state.
For example, ? 08003 displays help for the 08003 SQL state, and ? 08 displays help for the 08 class code.

Accessing different versions of the DB2 Information Center

Documentation for other versions of DB2 products is found in separate information centers on ibm.com®.

For DB2 Version 10.1 topics, the DB2 Information Center URL is http://publib.boulder.ibm.com/infocenter/db2luw/v10r1.

For DB2 Version 9.8 topics, the DB2 Information Center URL is http://publib.boulder.ibm.com/infocenter/db2luw/v9r8/.

For DB2 Version 9.7 topics, the DB2 Information Center URL is http://publib.boulder.ibm.com/infocenter/db2luw/v9r7/.

For DB2 Version 9.5 topics, the DB2 Information Center URL is http://publib.boulder.ibm.com/infocenter/db2luw/v9r5.

For DB2 Version 9.1 topics, the DB2 Information Center URL is http://publib.boulder.ibm.com/infocenter/db2luw/v9/.

For DB2 Version 8 topics, go to the DB2 Information Center URL at: http://publib.boulder.ibm.com/infocenter/db2luw/v8/.

DB2 tutorials

The DB2 tutorials help you learn about various aspects of DB2 products. Lessons provide step-by-step instructions.

Before you begin

You can view the XHTML version of the tutorial from the Information Center at http://publib.boulder.ibm.com/infocenter/db2luw/v10r1/.

Some lessons use sample data or code. See the tutorial for a description of any prerequisites for its specific tasks.

DB2 tutorials

To view the tutorial, click the title.

pureXML®
Set up a DB2 database to store XML data and to perform basic operations with the native XML data store.

DB2 troubleshooting information

A wide variety of troubleshooting and problem determination information is available to assist you in using DB2 database products.
DB2 documentation

Troubleshooting information can be found in the *Troubleshooting and Tuning Database Performance* or the Database fundamentals section of the *DB2 Information Center*, which contains:

- Information about how to isolate and identify problems with DB2 diagnostic tools and utilities.
- Solutions to some of the most common problems.
- Advice to help solve other problems you might encounter with your DB2 database products.

IBM Support Portal

See the IBM Support Portal if you are experiencing problems and want help finding possible causes and solutions. The Technical Support site has links to the latest DB2 publications, TechNotes, Authorized Program Analysis Reports (APARs or bug fixes), fix packs, and other resources. You can search through this knowledge base to find possible solutions to your problems.

**Terms and Conditions**

Permissions for the use of these publications is granted subject to the following terms and conditions.

**Personal use**: You may reproduce these Publications for your personal, non-commercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these Publications, or any portion thereof, without the express consent of IBM.

**Commercial use**: You may reproduce, distribute and display these Publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these Publications, or reproduce, distribute or display these Publications or any portion thereof outside your enterprise, without the express consent of IBM.

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the Publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the Publications is detrimental to its interest or, as determined by IBM, the instructions stated previously are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

Appendix B. Notices

This information was developed for products and services offered in the U.S.A. Information about non-IBM products is based on information available at the time of first publication of this document and is subject to change.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information about the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, NY 10504-1785
U.S.A.

For license inquiries regarding double-byte character set (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing
Legal and Intellectual Property Law
IBM Japan, Ltd.
1623-14, Shimotsuruma, Yamato-shi
Kanagawa 242-8502 Japan

The following paragraph does not apply to the United Kingdom or any other country/region where such provisions are inconsistent with local law:

INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION “AS IS” WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY, OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions; therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements, changes, or both in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to websites not owned by IBM are provided for convenience only and do not in any manner serve as an endorsement of those
websites. The materials at those websites are not part of the materials for this IBM product and use of those websites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information that has been exchanged, should contact:

IBM Canada Limited
U59/3600
3600 Steeles Avenue East
Markham, Ontario L3R 9Z7
CANADA

Such information may be available, subject to appropriate terms and conditions, including, in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement, or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems, and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements, or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility, or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information may contain examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious, and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating
platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Each copy or any portion of these sample programs or any derivative work must include a copyright notice as follows:

© (your company name) (year). Portions of this code are derived from IBM Corp. Sample Programs. © Copyright IBM Corp. _enter the year or years_. All rights reserved.

**Trademarks**

IBM, the IBM logo, and ibm.com are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the web at [Copyright and trademark information](http://www.ibm.com/legal/copytrade.shtml).

The following terms are trademarks or registered trademarks of other companies

- Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.
- Java and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle, its affiliates, or both.
- UNIX is a registered trademark of The Open Group in the United States and other countries.
- Intel, Intel logo, Intel Inside, Intel Inside logo, Celeron, Intel SpeedStep, Itanium, and Pentium are trademarks or registered trademarks of Intel Corporation or its subsidiaries in the United States and other countries.
- Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

Other company, product, or service names may be trademarks or service marks of others.

security
IBM Data Server Driver for JDBC and SQLJ
encrypted security-sensitive data 207
encrypted user ID or encrypted password 207
Kerberos 210
security mechanisms 201
user ID and password 203
security (continued)
IBM Data Server Driver for JDBC and SQLJ (continued)
user ID only 206
plug-ins
JDBC support 213
SQLJ program preparation 225
SET TRANSACTION clause 436
setTransactionTimeout method 306
SQL statements
error handling
SQLJ applications 198
executing
JDBC interfaces 47
SQLJ applications 154, 183
help
displaying 603
SQLException
IBM Data Server Driver for JDBC and SQLJ 131
SQLJ
accessing packages for 147
applets
building 229
using 231
applications
24 as hour value 320
building 230
compiler options (UNIX) 232
compiler options (Windows) 232
driver 139
invalid Gregorian date 320
programming 139
transaction control 197
assignment clause 437
batch updates 159
building routines 233
calling stored procedures 174
classes 426
collecting trace data 235
comments 153
compound SQL 116
creating to data source 141
creating using default context 147
collection declaration clause 430
context clause 433
cursor OUT parameter 175
datasource interface 144, 146
dB2 tables
creating 154
modifying 154
DriverManager interface 141, 143
drivers 2
evironment variables 19
error handling 198
executable clauses 432
executing SQL 154
execution context 183
execution control 183
existing connections 146
host expressions 148, 149, 426
implements clause 428
installing runtime environment 19
isolation levels 197
iterator conversion clause 437
iterator declaration clause 431
multiple instances of iterator 170
multiple iterators on table 168
named parameters 174
SQLJ (continued)

- problem diagnosis 235
- Profile Binder command 595
- Profile Printer command 601
- program preparation 579
- result set iterator 164
- retrieving SQLCA 198
- routines
  - compiler options (UNIX) 234
  - compiler options (Windows) 234
  - scrollable iterators 170
  - SDK for Java Version 5 functions 195
  - SET TRANSACTION clause 436
  - SQLWarning 199
  - statement reference 426
  - transactions 198
  - translator command 579
  - variable names 148, 149
  - with-clause 428
- sqlj command 579
- SQLJ variable names
  - restrictions 148, 149
- sqlj.runtime package 438
  - sqlj.runtime.AsciStream 450, 461
  - sqlj.runtime.BinaryStream 450
  - sqlj.runtime.CharacterStream 451
  - sqlj.runtime.ConnectionContext 439
  - sqlj.runtime.ExecutionContext 452
  - sqlj.runtime.ForUpdate 444
  - sqlj.runtime.NamedIterator 444
  - sqlj.runtime.PositionedIterator 445
  - sqlj.runtime.ResultSetIterator 445
  - sqlj.runtime.Scrollable 448
  - sqlj.runtime.SQLNullException 460
  - sqlj.runtime.UnicodeStream 462
- SQLSTATE
- IBM Data Server Driver for JDBC and SQLJ errors 577
- SQLWarning
- IBM Data Server Driver for JDBC and SQLJ 135
- SQLJ applications 199

SSID
- IBM Data Server Driver for JDBC and SQLJ 380

SSL
- configuring
  - Java Runtime Environment 221
  - IBM Data Server Driver for JDBC and SQLJ 219
- sslConnection property 220
- statement caching
- IBM Data Server Driver for JDBC and SQLJ 311
- Statement.executeQuery 58

stored procedures
- calling
  - CallableStatement class 73
  - JDBC applications 96
  - SQLJ applications 174, 188
  - DB2 for z/OS 73
- keeping result sets open in JDBC applications 86
- retrieving result sets
  - known number (JDBC) 84
  - multiple (JDBC) 84
  - multiple (SQLJ) 177
  - unknown number (JDBC) 85

Sysplex
- direct connections to DB2 for z/OS 295
- support 288

Sysplex support, example of enabling
- IBM Data Server Driver for JDBC and SQLJ 292

T

- terms and conditions
- publications 605
- time stamps
  - data loss avoidance
    - JDBC applications 323
    - SQLJ applications 323
  - time value adjustment
    - JDBC applications 320
    - SQLJ applications 320
  - TIMESTAMP data type
    - data loss
      - JDBC applications 323
      - SQLJ applications 323
  - TIMESTAMP WITH TIME ZONE
    - IBM Data Server Driver for JDBC and SQLJ 186

trace controller 251

traces
- IBM Data Server Driver for JDBC and SQLJ 225, 239, 241

transaction control
- JDBC 127
- SQLJ 197

transaction-level load balancing
- client application 255

troubleshooting
- online information 605
- tutorials 605

trusted contexts
- JDBC support 217
- tutorials
  - list 604
  - problem determination 605
  - troubleshooting 605
  - Visual Explain 604

U

UNIX
- SQLJ applications 232
- SQLJ routines 234
- updatable ResultSet
  - inserting row 70
  - JDBC 63, 64
  - testing for delete hole 69
  - testing for inserted row 71

updates
- data
  - PreparedStatement.executeUpdate method 48

URL format
- DB2BaseDataSource class 30, 33

user ID and password security
- IBM Data Server Driver for JDBC and SQLJ 203

user ID-only security
- IBM Data Server Driver for JDBC and SQLJ 206

W

warnings
- IBM Data Server Driver for JDBC and SQLJ 129

Windows
- SQLJ applications 232
- SQLJ routines 234
