IBM Systems - iSeries
Pthread APIs

Version 5 Release 4
Note

Before using this information and the product it supports, be sure to read the information in “Notices,” on page 279.
pthread_condattr_getpshared()—Get Process Shared
Attribute from Condition Attributes Object
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_condattr_init()—Initialize Condition Variable
Attribute in Condition Attributes Object
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_cond_broadcast()—Broadcast Condition to All Waiting Threads
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_cond_destroy()—Destroy Condition Variable
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_cond_init()—Initialize Condition Variable
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_cond_signal()—Signal Condition to One Waiting Thread
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_cond_timedwait()—Timed Wait for Condition
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.

 Related Information
 Example

 pthread_cond_wait()—Wait for Condition
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_create()—Create Thread
  Usage Notes
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_delay_np()—Delay for Requested Interval.
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_detach()—Detach Thread
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_equal()—Compare Two Threads
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_exit()—Terminate Calling Thread
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_extendedjoin_np()—Wait for Thread with Extended Options
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

 pthread_getcancelstate_np()—Get Cancel State.
  Authorities and Locks
  Parameters
  Return Value
  Error Conditions.
  Related Information
  Example

Pthread APIs

Before you get started with Pthreads

Many details in Multithreaded applications will affect your interpretation of how the Pthread APIs work. Multithreaded applications also contains important general information about threads. The information includes how process architecture and process behavior change when running a threaded program, what parts of the system are not available for use when running a threaded program, and tips on performance and debugging of threaded jobs.

Programming with Pthreads

- Pthread concepts and references
  - “What are Pthreads?” on page 232
  - “Primitive data types for Pthreads” on page 232 — Naming conventions for primitive data types in threaded programs.
  - “Feature test macros for Pthreads” on page 233 — Descriptions of supported and unsupported feature test macros.
  - “i5/OS Pthreads versus the POSIX standard, the Single UNIX Specification, and other threads implementations” on page 234
  - “Header files for Pthread functions” on page 254
  - “Pthread glossary” on page 255 — Definitions of some common Pthread terms.
  - “Other Sources of Pthread Information” on page 260
- Pthread programming basic tasks — Information to get you started with Pthreads programming.
  - “Writing and compiling threaded programs” on page 260
  - “Running threaded programs” on page 261
- “Troubleshooting Pthread errors” on page 262 — Descriptions of common errors users encounter when programming with Pthreads.

Pthread APIs

For information about the examples included with the APIs, see the “Information on the Pthread API examples” on page 269. See Code disclaimer information for information pertaining to code examples.

For information about specific groups of Pthread APIs, see:

- “Thread management APIs” on page 270
- “Thread specific storage APIs” on page 272
- “Thread cancellation APIs” on page 272
- “Mutex synchronization APIs” on page 273
- “Condition variable synchronization APIs” on page 275
- “Read/write lock synchronization APIs” on page 276
- “Signals APIs” on page 277
- “Unsupported Pthread APIs” on page 228

The Pthread APIs are:

- “pthread_atfork()—Register Fork Handlers” on page 228 (Register Fork Handlers)
- “pthread_atfork_np()—Register Fork Handlers with Extended Options” on page 229 (Register Fork Handlers with Extended Options)
- “pthread_attr_destroy()—Destroy Thread Attributes Object” on page 7 (Destroy Thread Attributes Object) destroys a thread attributes object and allows the system to reclaim any resources associated with that thread attributes object.
- “pthread_attr_getdetachstate()—Get Thread Attributes Object Detachstate” on page 8 (Get Thread Attributes Object Detachstate) returns the detach state attribute from the thread attributes object specified.
- “pthread_attr_getguardsize()—Get Guard Size” on page 229 (Get Guard Size)
- “pthread_attr_getinheritsched()—Get Thread Attribute Object Inherit Scheduling Attributes” on page 10 (Get Thread Attribute Object Inherit Scheduling Attributes) returns the inheritsched attribute from the thread attributes object specified.
- “pthread_attr_getschedparam()—Get Thread Attributes Object Scheduling Parameters” on page 12 (Get Thread Attributes Object Scheduling Parameters) returns the scheduling parameters attribute from the thread attributes object.
- “pthread_attr_getschedpolicy()—Get Scheduling Policy” on page 229 (Get Scheduling Policy)
- “pthread_attr_getscope()—Get Scheduling Scope” on page 229 (Get Scheduling Scope)
- “pthread_attr_getstackaddr()—Get Stack Address” on page 229 (Get Stack Address)
- “pthread_attr_getstacksize()—Get Stack Size” on page 230 (Get Stack Size)
- “pthread_attr_init()—Initialize Thread Attributes Object” on page 14 (Initialize Thread Attributes Object) initializes a thread attributes object to the default thread attributes.
- “pthread_attr_setdetachstate()—Set Thread Attributes Object Detachstate” on page 16 (Set Thread Attributes Object Detachstate) sets the detach state of the thread attributes object.
- “pthread_attr_setguardsize()—Set Guard Size” on page 230 (Set Guard Size)
- “pthread_attr_setinheritsched()—Set Thread Attribute Inherit Scheduling Attributes” on page 18 (Set Thread Attribute Inherit Scheduling Attributes) sets the inheritsched attribute in the thread attributes object specified.
- “pthread_attr_setschedparam()—Set Thread Attributes Object Scheduling Parameters” on page 20 (Set Thread Attributes Object Scheduling Parameters) sets the scheduling parameters in the thread attributes object.
- “pthread_attr_setschedpolicy()—Set Scheduling Policy” on page 230 (Set Scheduling Policy)
- “pthread_attr_setscope()—Set Scheduling Scope” on page 230 (Set Scheduling Scope)
- “pthread_attr_setstackaddr()—Set Stack Address” on page 230 (Set Stack Address)
- “pthread_attr_setstacksize()—Set Stack Size” on page 231 (Set Stack Size)
- “pthread_cancel()—Cancel Thread” on page 22 (Cancel Thread) requests cancellation of the target thread.
- “pthread_cleanup_peek_np()—Copy Cleanup Handler from Cancellation Cleanup Stack” on page 24 (Copy Cleanup Handler from Cancellation Cleanup Stack) returns a copy of the cleanup handler entry that the next call to pthread_cleanup_pop() would pop.
- “pthread_cleanup_pop()—Pop Cleanup Handler off of Cancellation Cleanup Stack” on page 27 (Pop Cleanup Handler off of Cancellation Cleanup Stack) pops the last cleanup handler from the cancellation cleanup stack.
- “pthread_cleanup_push()—Push Cleanup Handler onto Cancellation Cleanup Stack” on page 29 (Push Cleanup Handler onto Cancellation Cleanup Stack) pushes a cancellation cleanup routine onto the calling threads cancellation cleanup stack.
- “pthread_clear_exit_np()—Clear Exit Status of Thread” on page 31 (Clear Exit Status of Thread) clears the exit status of the thread.
- “pthread_condattr_destroy()—Destroy Condition Variable Attributes Object” on page 33 (Destroy Condition Variable Attributes Object) destroys the condition variable attributes object specified by attr, and indicates that any storage that the system has associated with the object be de-allocated.
• “pthread_condattr_getpshared()—Get Process Shared Attribute from Condition Attributes Object” on page 35 (Get Process Shared Attribute from Condition Attributes Object) retrieves the current setting of the process shared attribute from the condition attributes object.

• “pthread_condattr_init()—Initialize Condition Variable Attributes Object” on page 36 (Initialize Condition Variable Attributes Object) initializes the condition variable attributes object specified by attr to the default attributes.

• “pthread_condattr_setpshared()—Set Process Shared Attribute in Condition Attributes Object” on page 38 (Set Process Shared Attribute in Condition Attributes Object) sets the current pshared attribute for the condition attributes object.

• “pthread_cond_broadcast()—Broadcast Condition to All Waiting Threads” on page 46 (Broadcast Condition to All Waiting Threads) wakes up all threads that are currently waiting on the condition variable specified by cond.

• “pthread_cond_destroy()—Destroy Condition Variable” on page 49 (Destroy Condition Variable) destroys the condition variable specified by cond.

• “pthread_cond_init()—Initialize Condition Variable” on page 50 (Initialize Condition Variable) initializes a condition variable object with the specified attributes for use.

• “pthread_cond_signal()—Signal Condition to One Waiting Thread” on page 53 (Signal Condition to One Waiting Thread) wakes up at least one thread that is currently waiting on the condition variable specified by cond.

• “pthread_cond_timedwait()—Timed Wait for Condition” on page 55 (Timed Wait for Condition) blocks the calling thread, waiting for the condition specified by cond to be signaled or broadcast to.

• “pthread_cond_wait()—Wait for Condition” on page 59 (Wait for Condition) blocks the calling thread, waiting for the condition specified by cond to be signaled or broadcast to.

• “pthread_create()—Create Thread” on page 62 (Create Thread) creates a thread with the specified attributes and runs the C function start_routine in the thread with the single pointer argument specified.

• “pthread_delay_np()—Delay Thread for Requested Interval” on page 65 (Delay Thread for Requested Interval) causes the calling thread to delay for the deltotime specified.

• “pthread_detach()—Detach Thread” on page 67 (Detach Thread) indicates that system resources for the specified thread should be reclaimed when the thread ends.

• “pthread_equal()—Compare Two Threads” on page 69 (Compare Two Threads) compares two Pthread handles for equality.

• “pthread_exit()—Terminate Calling Thread” on page 71 (Terminate Calling Thread) terminates the calling thread, making its exit status available to any waiting threads.

• “pthread_exitdjoin_np()—Wait for Thread with Extended Options” on page 73 (Wait for Thread with Extended Options) waits for a thread to terminate, optionally detaches the thread, then returns the threads exit status.

• “pthread_getcancelstate_np()—Get Cancel State” on page 76 (Get Cancel State) gets the current cancel state of the thread.

• “pthread_getconcurrency()—Get Process Concurrency Level” on page 78 (Get Process Concurrency Level) retrieves the current concurrency level for the process.

• “pthread_getpthreadoption_np()—Get Pthread Run-Time Option Data” on page 79 (Get Pthread Run-Time Option Data) gets option data from the pthread run-time for the process.

• “pthread_getschedparam()—Get Thread Scheduling Parameters” on page 82 (Get Thread Scheduling Parameters) retrieves the scheduling parameters of the thread.

• “pthread_getspecific()—Get Thread Local Storage Value by Key” on page 84 (Get Thread Local Storage Value by Key) retrieves the thread local storage value associated with the key. pthread_getspecific() may be called from a data destructor.

• “pthread_getthreadid_np()—Retrieve Unique ID for Calling Thread” on page 86 (Retrieve Unique ID for Calling Thread) retrieves the unique integral identifier that can be used to identify the calling thread in some context for application debugging or tracing support.
• “pthread_getunique_np()—Retrieve Unique ID for Target Thread” on page 88 (Retrieve a Unique ID for Target Thread) retrieves the unique integral identifier that can be used to identify the thread in some context for application debugging or tracing support.

• “pthread_get_expiration_np()—Get Condition Expiration Time from Relative Time” on page 91 (Get Condition Expiration Time from Relative Time) computes an absolute time by adding the specified relative time (delta) to the current system time.

• “pthread_is_initialthread_np()—Check if Running in the Initial Thread” on page 93 (Check if Running in the Initial Thread) returns true or false, indicating if the current thread is the initial thread of the process.

• “pthread_is_multithreaded_np()—Check Current Number of Threads” on page 95 (Check the Current Number of Threads) returns true or false, indicating whether the current process has more than one thread.

• “pthread_join()—Wait for and Detach Thread” on page 97 (Wait for and Detach Thread) waits for a thread to terminate, detaches the thread, then returns the threads exit status.

• “pthread_join_np()—Wait for Thread to End” on page 99 (Wait for Thread to End) waits for a thread to terminate, then returns the threads exit status, while leaving the data structures of the thread available for a later call to pthread_join(), pthread_join_np(), pthread_detach(), or pthread_extendedjoin_np()
• “pthread_mutexattr_setprioceling()—Set Mutex Priority Ceiling Attribute” on page 231 (Set Mutex Priority Ceiling Attribute)
• “pthread_mutexattr_setprotocol()—Set Mutex Protocol Attribute” on page 231 (Set Mutex Protocol Attribute)
• “pthread_mutexattr_setpshared()—Set Process Shared Attribute in Mutex Attributes Object” on page 127 (Set Process Shared Attribute in Mutex Attributes Object) sets the current pshared attribute for the mutex attributes object.
• “pthread_mutexattr_settype()—Set Mutex Type Attribute” on page 129 (Set Mutex Type Attribute) sets the type attribute in the mutex attributes object specified by attr.
• “pthread_mutex_destroy()—Destroy Mutex” on page 130 (Destroy Mutex) destroys the named mutex.
• “pthread_mutex_getrioceling()—Get Mutex Priority Ceiling” on page 232 (Get Mutex Priority Ceiling)
• “pthread_mutex_init()—Initialize Mutex” on page 132 (Initialize Mutex) initializes a mutex with the specified attributes for use.
• “pthread_mutex_lock()—Lock Mutex” on page 135 (Lock Mutex) acquires ownership of the mutex specified.
• “pthread_mutex_setprioceling()—Set Mutex Priority Ceiling” on page 232 (Set Mutex Priority Ceiling)
• “pthread_mutex_timedlock_np()—Lock Mutex with Time-Out” on page 139 (Lock Mutex with Time-Out) acquires ownership of the mutex specified.
• “pthread_mutex_trylock()—Lock Mutex with No Wait” on page 142 (Lock Mutex with No Wait) attempts to acquire ownership of the mutex specified without blocking the calling thread.
• “pthread_mutex_unlock()—Unlock Mutex” on page 146 (Unlock Mutex) unlocks the mutex specified.
• “pthread_once()—Perform One-Time Initialization” on page 148 (Perform One-Time Initialization) performs one time initialization based on a specific once_control variable.
• “pthread_rwlockattr_destroy()—Destroy Read/Write Lock Attribute” on page 150 (Destroy Read/Write Lock Attribute) destroys a read/write lock attributes object and allows the systems to reclaim any resources associated with that read/write lock attributes object.
• “pthread_rwlockattr_getpshared()—Get Pshared Read/Write Lock Attribute” on page 152 (Get Pshared Read/Write Lock Attribute) retrieves the current setting of the process shared attribute from the read/write lock attributes object.
• “pthread_rwlockattr_init()—Initialize Read/Write Lock Attribute” on page 160 (Initialize Read/Write Lock Attribute) initializes the read/write lock attributes object referred to by attr to the default attributes.
• “pthread_rwlockattr_setpshared()—Set Pshared Read/Write Lock Attribute” on page 161 (Set Pshared Read/Write Lock Attribute) sets the current pshared attribute for the read/write attributes object.
• “pthread_rwlock_destroy()—Destroy Read/Write Lock” on page 162 (Destroy Read/Write Lock) destroys the named read/write lock.
• “pthread_rwlock_init()—Initialize Read/Write Lock” on page 163 (Initialize Read/Write Lock) initializes a new read/write lock with the specified attributes for use.
• “pthread_rwlock_rdlock()—Get Shared Read Lock” on page 166 (Get Shared Read Lock) attempts to acquire a shared read lock on the read/write lock specified by rwlock.
• “pthread_rwlock_timedrdlock_np()—Get Shared Read Lock with Time-Out” on page 168 (Get Shared Read Lock with Time-Out) attempts to acquire a shared read lock on the read/write lock specified by rwlock.
• “pthread_rwlock_timedwrlock_np()—Get Exclusive Write Lock with Time-Out” on page 172 (Get Exclusive Write Lock with Time-Out) attempts to acquire an exclusive write lock on the read/write lock specified by rwlock.
• “pthread_rwlock_trypdlock()—Get Shared Read Lock with No Wait” on page 176 (Get Shared Read Lock with No Wait) attempts to acquire a shared read lock on the read/write lock specified by rwlock.

Pthread APIs 5
• “pthread_rwlock_trywrlock()”—Get Exclusive Write Lock with No Wait” on page 179 (Get Exclusive Write Lock with No Wait) attempts to acquire an exclusive write lock on the read/write lock specified by rwlock.

• “pthread_rwlock_unlock()”—Unlock Exclusive Write or Shared Read Lock” on page 182 (Unlock Exclusive Write or Shared Read Lock) unlocks a shared read or exclusive write lock held by the calling thread.

• “pthread_rwlock_wrlock()”—Get Exclusive Write Lock” on page 184 (Get Exclusive Write Lock) attempts to acquire an exclusive write lock on the read/write lock specified by rwlock.

• “pthread_self()”—Get Pthread Handle” on page 186 (Get Pthread Handle) returns the Pthread handle of the calling thread.

• “pthread_setcancelstate()”—Set Cancel State” on page 188 (Set Cancel State) sets the cancel state to one of PTHREAD_CANCEL_ENABLE or PTHREAD_CANCEL_DISABLE and returns the old cancel state into the location specified by oldstate (if oldstate is non-NULL).

• “pthread_setcanceltype()”—Set Cancel Type” on page 190 (Set Cancel Type) sets the cancel type to one of PTHREAD_CANCEL_DEFERRED or PTHREAD_CANCELASYNCHRONOUS and returns the old cancel type into the location specified by oldtype (if oldtype is non-NULL)

• “pthread_setconcurrency()”—Set Process Concurrency Level” on page 192 (Set Process Concurrency Level) sets the current concurrency level for the process.

• “pthread_setschedparam()”—Set Target Thread Scheduling Parameters” on page 196 (Set Target Thread Scheduling Parameters) sets the scheduling parameters of the target thread.

• “pthread_setspecific()”—Set Thread Local Storage by Key” on page 199 (Set Thread Local Storage by Key) sets the thread local storage value associated with a key.

• “pthread_set_mutexattr_default_np()”—Set Default Mutex Attributes Object Kind Attribute” on page 201 (Set Default Mutex Attributes Object Kind Attribute) sets the kind attribute in the default mutex attribute object.

• “pthread_sigmask()”—Set or Get Signal Mask” on page 202 (Set or Get Signal Mask) examines or modifies the signal blocking mask for the current thread.

• “pthread_signal_to_cancel_np()”—Convert Signals to Cancel Requests” on page 206 (Convert Signals to Cancel Requests) causes a pthread_cancel() to be delivered to the target thread when the first signal specified in set arrives.

• “pthread_testcancel()”—Create Cancellation Point” on page 209 (Create Cancellation Point) creates a cancellation point in the calling thread.

• “pthread_test_exit_np()”—Test Thread Exit Status” on page 211 (Test Thread Exit Status) returns the current state of the thread along with its exit status.

• “pthread_trace_init_np()”—Initialize or Re-initialize pthread tracing” on page 214 (Initialize or Reinitialize Pthread Tracing) initializes or refreshes both the Pthreads library trace level and the application trace level.

• “PTHREAD_TRACE_NP”—Macro to optionally execute code based on trace level” on page 220 (Execute Code Based on Trace Level (Macro)) is used to execute optional code based on the current application trace level.

• “pthread_unlock_global_np()”—Unlock Global Mutex” on page 225 (Unlock Global Mutex) unlocks a global mutex provided by the pthreads run-time.

• “sched_yield()”—Yield Processor to Another Thread” on page 226 (Yield Processor to Another Thread) yields the processor from the currently executing thread to another ready-to-run, active thread of equal or higher priority.
APIs

These are the APIs for this category.

pthread_attr_destroy()—Destroy Thread Attributes Object

Syntax:
#include <pthread.h>
int pthread_attr_destroy(pthread_attr_t *attr);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_attr_destroy() function destroys a thread attributes object and allows the system to reclaim any resources associated with that thread attributes object. This does not have an effect on any threads created using this thread attributes object.

Authorities and Locks
None.

Parameters
attr (Input) The address of the thread attributes object to be destroyed

Return Value
0     pthread_attr_destroy() was successful.
value pthread_attr_destroy() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_attr_destroy() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

Related Information
• The <pthread.h> header file. See “Header files for Pthread functions” on page 254
• “pthread_attr_init()—Initialize Thread Attributes Object” on page 14—Initialize Thread Attributes Object

Example
See Code disclaimer information for information pertaining to code examples.
#define MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

void *threadfunc(void *parm)
{
    printf("Thread created using an default attributes\n");
    return NULL;
int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=0;
    pthread_attr_t pta;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Create a thread attributes object\n");
    rc = pthread_attr_init(&pta);
    checkResults("pthread_attr_init()\n", rc);

    printf("Create a thread using the attributes object\n");
    rc = pthread_create(&thread, &pta, threadfunc, NULL);
    checkResults("pthread_create()\n", rc);

    printf("Create a thread using the default attributes\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);

pthread_attr_getdetachstate()—Get Thread Attributes Object
Detachstate

Syntax:
#include <pthread.h>
int pthread_attr_getdetachstate(const pthread_attr_t *attr,
                                 int *detachstate);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes
The **pthread_attr_getdetachstate()** function returns the detach state attribute from the thread attributes object specified. The detach state of a thread indicates whether the system is allowed to free thread resources when a thread terminates.

The detach state specifies one of **PTHREAD_CREATE_DETACHED** or **PTHREAD_CREATE_JOINABLE**. The default detach state (**DEFAULT_DETACHSTATE**) is **PTHREAD_CREATE_JOINABLE**.

**Authorities and Locks**
None.

**Parameters**

*attr*

(Input) The address of the thread attributes object

*detachstate*

(Output) The address of the variable to contain the returned detach state

**Return Value**

0  **pthread_attr_getdetachstate()** was successful.

value  **pthread_attr_getdetachstate()** was not successful. *value* is set to indicate the error condition.

**Error Conditions**

If **pthread_attr_getdetachstate()** was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

**Related Information**

- The `<pthread.h>` header file. See "Header files for Pthread functions" on page 254

- "**pthread_detach()**—Detach Thread" on page 67—Detach Thread
- "**pthread_join()**—Wait for and Detach Thread" on page 97—Wait for and Detach Thread

**Example**

See [Code disclaimer information](#) for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=0;
    pthread_attr_t pta;
    int state;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Create a thread attributes object\n");
    rc = pthread_attr_init(&pta);
```
checkResults("pthread_attr_init()\n", rc);

printf("Get detach state\n");
rc = pthread_attr_getdetachstate(&pta, &state);
checkResults("pthread_attr_getdetachstate()\n", rc);

printf("The thread attributes object indicates: ");
switch (state) {
  case PTHREAD_CREATE_DETACHED:
    printf("DETACHED\n");
    break;
  case PTHREAD_CREATE_JOINABLE:
    printf("JOINABLE\n");
    break;
}

printf("Destroy thread attributes object\n");
rc = pthread_attr_destroy(&pta);
checkResults("pthread_attr_destroy()\n", rc);

printf("Main completed\n");
return 0;
}

Output:
Enter Testcase - QP0WTEST/TAGDS0
Create a thread attributes object
Get detach state
The thread attributes object indicates: JOINABLE
Destroy thread attributes object
Main completed

API introduced: V4R3
Authorities and Locks

None.

Parameters

attr    (Input) Address of thread creation attributes

inheritsched
    (Output) Address of the variable to receive the inheritsched attribute

Return Value

0    pthread_attr_getinheritsched() was successful.

value    pthread_attr_getinheritsched() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_attr_getinheritsched() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
    The value specified for the argument is not correct.

checkResults("pthread_attr_setinheritsched()\n", rc);
showInheritSched(&attr);

rc = pthread_attr_destroy(&attr);
checkResults("pthread_attr_destroy()\n", rc);
printf("Main completed\n");
return 0;
```

**Output:**
Enter Testcase - QP0WTEST/TPGIS0
Inherit Sched - PTHREAD_EXPLICIT_SCHED
Inherit Sched - PTHREAD_INHERIT_SCHED
Main completed

API introduced: V4R3

---

**pthread_attr_getschedparam()—Get Thread Attributes Object Scheduling Parameters**

**Syntax:**
```c
#include <pthread.h>
#include <sched.h>
int pthread_attr_getschedparam(const pthread_attr_t *attr,
                                struct sched_param *param);
```

**Service Program Name:** QP0WPTH
Default Public Authority: USE
Threadsafe: Yes
Signal Safe: Yes

The `pthread_attr_getschedparam()` function returns the scheduling parameters attribute from the thread attributes object. The default i5/OS scheduling policy is SCHED_OTHER and cannot be changed to another scheduling policy.

The `sched_policy` field of the `param` parameter is always returned as SCHED_OTHER. The `sched_priority` field of the `param` structure is set to the priority of the target thread at the time of the call.

**Note:** Do not use `pthread_setschedparam()` to set the priority of a thread if you also use another mechanism (outside of the pthread APIs) to set the priority of a thread. If you do, `pthread_setschedparam()` returns only the information that was set by the pthread interfaces. `pthread_setschedparam()` or modification of the thread attribute using `pthread_attr_setschedparam()`.
Authorities and Locks
None.

Parameters
attr  (Input)  The address of the thread attributes object
param (Output) The address of the variable to contain the returned scheduling parameters

Return Value
0  pthread_attr_getschedparam() was successful.
value  pthread_attr_getschedparam() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_attr_getschedparam() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

API introduced: V4R3

pthread_attr_init()—Initialize Thread Attributes Object

Syntax:
#include <pthread.h>
int pthread_attr_init(pthread_attr_t *attr);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_attr_init() function initializes a thread attributes object to the default thread attributes. The thread attributes object can be used in a call to pthread_create() to specify attributes of the new thread.

Authorities and Locks
None.

Parameters
attr (Input/Output) The address of the thread attributes object to be initialized

Return Value
0 pthread_attr_init() was successful.
value pthread_attr_init() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_attr_init() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.
[EINVAL]

The value specified for the argument is not correct.

Related Information
• The <pthread.h> header file. See “Header files for Pthread functions” on page 254

API introduced: V4R3
pthread_attr_setdetachstate()—Set Thread Attributes Object Detachstate

Syntax:
#include <pthread.h>
int pthread_attr_setdetachstate(pthread_attr_t *attr, int detachstate);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_attr_setdetachstate() function sets the detach state of the thread attributes object. The detach state of a thread indicates whether the system is allowed to free thread resources (including but not limited to thread exit status) when the thread terminates. Some resources (like automatic storage) are always freed when a thread ends.

The detach state specifies one of PTHREAD_CREATE_DETACHED or PTHREAD_CREATE_JOINABLE. The default detach state (DEFAULT_DETACHSTATE) is PTHREAD_CREATE_JOINABLE.

Authorities and Locks
None.

Parameters
attr  (Input) The address of the thread attributes object.
detachstate  (Output) The detach state, one of PTHREAD_CREATE_JOINABLE or PTHREAD_CREATE_DETACHED.

Return Value
0  pthread_attr_setdetachstate() was successful.
value  pthread_attr_setdetachstate() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_attr_setdetachstate() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

pthread_attr_setinheritsched()—Set Thread Attribute Inherit Scheduling Attributes

Syntax:
#include <pthread.h>
#include <sched.h>
int pthread_attr_setinheritsched(pthread_attr_t *attr, 
   int *inheritsched);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threading: Yes
Signal Safe: Yes

The pthread_attr_setinheritsched() function sets the inheritsched attribute in the thread attributes object specified. The inheritsched attribute should be one of PTHREAD_EXPLICIT_SCHED or PTHREAD_INHERIT_SCHED. The default inheritsched attribute is PTHREAD_EXPLICIT_SCHED, with a default priority of zero.

Use the inheritsched attribute to inherit or explicitly specify the scheduling attributes when creating new threads.

Authorities and Locks
None.

Parameters
attr (Input) Address of thread creation attributes

inheritsched (Output) Address of the variable to receive the inheritsched attribute

Return Value
0  pthread_attr_setinheritsched() was successful
value  pthread_attr_setinheritsched() was not successful. value is set to indicate the error condition

Error Conditions
If pthread_attr_setinheritsched() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

Inherit Sched - PTHREAD_INHERIT_SCHED
Main completed
**pthread_attr_setschedparam()—Set Thread Attributes Object Scheduling Parameters**

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_attr_setschedparam(pthread_attr_t *attr,
    const struct sched_param *param);
```

Service Program Name: QP0WPTH

Default Public Authority: *USE

Threadsafe: Yes

Signal Safe: Yes

The `pthread_attr_setschedparam()` function sets the scheduling parameters in the thread attributes object. The supported i5/OS scheduling policy is SCHED_OTHER. Attempting to set the `sched_policy` field of the `param` parameter other than SCHED_OTHER causes the EINVAL error. The `sched_priority` field of the `param` parameter must range from PRIORITY_MIN to PRIORITY_MAX or the ENOTSUP error occurs.

All reserved fields in the scheduling parameters structure must be binary zero or the EINVAL error occurs.

**Note:** Do not use `pthread_setschedparam()` to set the priority of a thread if you also use another mechanism (outside of the pthread APIs) to set the priority of a thread. If you do, `pthread_setschedparam()` returns only that information that was set by the pthread interfaces (`pthread_setschedparam()` or modification of the thread attribute using `pthread_attr_setschedparam()`).

**Authorities and Locks**

None.

**Parameters**

- `attr` (Input/Output) The address of the thread attributes object
- `param` (Input) Address of the variable containing the scheduling parameters

**Return Value**

- `0` `pthread_attr_setschedparam()` was successful.
- `*value` `pthread_attr_setschedparam()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**

If `pthread_attr_setschedparam()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

- `[EINVAL]`
  
  The value specified for the argument is not correct.

- `[ENOTSUP]`
  
  The value specified for the priority argument is not supported.

API introduced: V4R3

pthread_cancel()—Cancel Thread

Syntax:
#include <pthread.h>
int pthread_cancel(pthread_t thread);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_cancel() function requests cancellation of the target thread. The target thread is cancelled, based on its ability to be cancelled.

When cancelability is disabled, all cancels are held pending in the target thread until the thread changes the cancelability. When cancelability is deferred, all cancels are held pending in the target thread until the thread changes the cancelability, calls a function that is a cancellation point, or calls pthread_testcancel(), thus creating a cancellation point. When cancelability is asynchronous, all cancels are acted upon immediately, interrupting the thread with its processing.

Note: You should not use asynchronous thread cancellation through the PTHREAD_CANCELASYCHRONOUS option of pthread_setcanceltype() in your application. See the common user errors section of this document for more information.

The following functions are cancellation points:
• pthread_cond_timedwait()
• pthread_cond_wait()
• pthread_delay_np()
• pthread_join()
• pthread_join_np()
• pthread_extendedjoin_np()
• pthread_testcancel()

After action is taken for the target thread to be cancelled, the following events occur in that thread.
1. The thread calls cancellation cleanup handlers with cancellation disabled until the last cancellation cleanup handler returns. The handlers are called in Last In, First Out (LIFO) order.
2. Data destructors are called for any thread-specific data entries that have a non NULL value for both the value and the destructor.
3. When the last cancellation cleanup handler returns, the thread is terminated and a status of `PTHREAD_CANCELED` is made available to any threads joining the target.
4. Any mutexes that are held by a thread that terminates, are abandoned and are no longer valid. Subsequent calls by other threads that attempt to acquire the abandoned mutex (`pthread_mutex_lock()` or `pthread_mutex_trylock()`) fail with an `EOWNERTERM` error.
5. Application visible process resources are not released. This includes but is not limited to mutexes, file descriptors, or any process level cleanup actions.

A cancellation cleanup handler should not exit by `longjmp()` or `siglongjmp()`.

In the i5/OS implementation of threads, the initial thread is special. Termination of the initial thread by `pthread_exit()`, `pthread_cancel()` or any other thread termination mechanism terminates the entire process.

**Authorities and Locks**

None.

**Parameters**

`thread` (Input) Pthread handle to the target thread

**Return Value**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>pthread_cancel()</code> was successful.</td>
</tr>
<tr>
<td>value</td>
<td><code>pthread_cancel()</code> was not successful. <code>value</code> is set to indicate the error condition.</td>
</tr>
</tbody>
</table>

**Error Conditions**

If `pthread_cancel()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

<table>
<thead>
<tr>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[EINVAL]</td>
<td>The value specified for the argument is not correct.</td>
</tr>
<tr>
<td>[ESRCH]</td>
<td>No thread could be found that matched the thread ID specified.</td>
</tr>
</tbody>
</table>

```c
#include <pthread.h>
#include <stdio.h>
#include "check.h"

void *threadfunc(void *parm)
{
    printf("Entered secondary thread\n");
    while (1) {
        printf("Secondary thread is looping\n");
        pthread_testcancel();
        sleep(1);
    }
    return NULL;
}

int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=0;
    printf("Entering testcase\n");
    /* Create a thread using default attributes */
    printf("Create thread using the NULL attributes\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);
    checkResults("pthread_create(NULL)\n", rc);
    /* sleep() is not a very robust way to wait for the thread */
    sleep(2);
    printf("Cancel the thread\n");
    rc = pthread_cancel(thread);
    checkResults("pthread_cancel()\n", rc);
    /* sleep() is not a very robust way to wait for the thread */
    sleep(3);
    printf("Main completed\n");
    return 0;
}
```

Output:
Entering testcase
Create thread using the NULL attributes
Entered secondary thread
Secondary thread is looping
Secondary thread is looping
Cancel the thread
Main completed

API introduced: V4R3

pthread_cleanup_peek_np()—Copy Cleanup Handler from Cancellation Cleanup Stack

Syntax:
#include <pthread.h>
int pthread_cleanup_peek_np(pthread_cleanup_entry_np_t *entry);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The `pthread_cleanup_peek_np()` function returns a copy of the cleanup handler entry that the next call to `pthread_cleanup_pop()` would pop. The handler remains on the cancellation cleanup stack after the call to `pthread_cleanup_peek_np()`.

During this thread cancellation cleanup, the thread calls cancellation cleanup handlers with cancellation disabled until the last cancellation cleanup handler returns. The handlers are called in Last In, First Out (LIFO) order. Automatic storage for the invocation stack frame of the function that registered the handler is still present when the cancellation cleanup handler is executed.

The `pthread_cleanup_push()` and the matching `pthread_cleanup_pop()` call should be in the same lexical scope (that is, same level of brackets {}).

The `pthread_cleanup_peek_np()` function has no scoping rules.

**Note:** This function is not portable.

**Authorities and Locks**
None.

**Parameters**
None.

**Return Value**

0  `pthread_cleanup_peek_np()` was successful.

value  `pthread_cleanup_peek_np()` was not successful. value is set to indicate the error condition.

**Error Conditions**

If `pthread_cleanup_peek_np()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

[ENOENT]

The cancellation cleanup stack is empty.

# Example

See [Code disclaimer information](#) for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

void cleanupHandler1(void *arg) { printf("In Handler 1
"); return; }
void cleanupHandler2(void *arg) { printf("In Handler 2
"); return; }
void cleanupHandler3(void *arg) { printf("In Handler 3
"); return; }

int args[3] = {0,0,0};

int main(int argc, char **argv)
{
    int rc=0;
    pthread_cleanup_entry_np_t entry;

    printf("Enter Testcase - \%s
", argv[0]);

    printf("Check for absence of cleanup handlers\n");
    rc = pthread_cleanup_peek_np(&entry);
    if (rc != ENOENT)
        printf("pthread_cleanup_peek_np(), expected ENOENT\n");
        exit(1);

    printf("Push some cancellation cleanup handlers\n");
    pthread_cleanup_push(cleanupHandler1, &args[0]);
    pthread_cleanup_push(cleanupHandler2, &args[1]);

    printf("Check for cleanupHandler2\n");
    rc = pthread_cleanup_peek_np(&entry);
    checkResults("pthread_cleanup_peek_np(2)\n", rc);
    if (entry.handler != cleanupHandler2 ||
        entry.arg != &args[1])
        printf("Did not get expected handler(2) information!\n");
        exit(1);

    pthread_cleanup_push(cleanupHandler3, &args[2]);

    printf("Check for cleanupHandler3\n");
    rc = pthread_cleanup_peek_np(&entry);
    checkResults("pthread_cleanup_peek_np(3)\n", rc);
    if (entry.handler != cleanupHandler3 ||
        entry.arg != &args[2])
        printf("Did not get expected handler(3) information!\n");
        exit(1);

    pthread_cleanup_pop(0);
    pthread_cleanup_pop(0);
    pthread_cleanup_pop(0);

    printf("Main completed\n");
    return 0;
}
```

**Output:**

Enter Testcase - QP0WTEST/TPCLPP0
Check for absence of cleanup handlers
Push some cancellation cleanup handlers
Check for cleanupHandler2
Check for cleanupHandler3
Main completed
**pthread_cleanup_pop()—Pop Cleanup Handler off of Cancellation Cleanup Stack**

Syntax:
```c
#include <pthread.h>
void pthread_cleanup_pop(int execute);
```

Service Program Name: QP0WPTH
Default Public Authority: USE
Threading: Yes
Signal Safe: No

The `pthread_cleanup_pop()` function pops the last cleanup handler from the cancellation cleanup stack. If the `execute` parameter is nonzero, the handler is called with the argument specified by the `pthread_cleanup_push()` call with which the handler was registered.

The `pthread_cleanup_push()` and the matching `pthread_cleanup_pop()` call should be in the same lexical scope (that is, same level of brackets `{}`).

When the thread calls `pthread_exit()` or is cancelled by `pthread_cancel()`, the cancellation cleanup handlers are called with the argument specified by the `pthread_cleanup_push()` call that the handler was registered with.

During this thread cancellation cleanup, the thread calls cancellation cleanup handlers with cancellation disabled until the last cancellation cleanup handler returns. The handlers are called in Last In, First Out (LIFO) order. Automatic storage for the invocation stack frame of the function that registered the handler is still present when the cancellation cleanup handler is executed.

When a cancellation cleanup handler is called because of a call to `pthread_cleanup_pop()`, the cancellation cleanup handler does not necessarily run with cancellation disabled. The cancellation state and cancellation type are not changed by a call to `pthread_cleanup_pop()`.

A cancellation cleanup handler should not exit using `longjmp()` or `siglongjmp()`. If a cleanup handler takes an exception, the exception condition is handled and ignored and processing continues. You can look in the job log of the job to see exception messages generated by cancellation cleanup handlers.

**Authorities and Locks**

None.

**Parameters**

`execute`

(Input) Boolean value indicating whether the cancellation cleanup handler should be executed

**Return Value**

None.

Example

See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

void cleanupHandler(void *arg)
{
    printf("In the cleanup handler\n");
}

void *threadfunc(void *parm)
{
    printf("Entered secondary thread, you should see the cleanup handler\n");
    pthread_cleanup_push(cleanupHandler, NULL);
    sleep(1); /* Simulate more code here */
    pthread_cleanup_pop(1);
    return NULL;
}

int main(int argc, char **argv)
{
    pthread_t     thread;
    int           rc=0;

    printf("Enter Testcase - %s\n", argv[0]);
    /* Create a thread using default attributes */
    printf("Create thread using the NULL attributes\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);
    checkResults("pthread_create(NULL)\n", rc);
    /* sleep() is not a very robust way to wait for the thread */
    sleep(5);
    printf("Main completed\n");
    return 0;
}
```

Output:

Enter Testcase - QP0WTEST/TPCLP00
Create thread using the NULL attributes
Entered secondary thread, you should see the cleanup handler
In the cleanup handler
Main completed

API introduced: V4R3
The `pthread_cleanup_push()` function pushes a cancellation cleanup routine onto the calling threads cancellation cleanup stack. When the thread calls `pthread_exit()` or is cancelled by `pthread_cancel()`, the cancellation cleanup handlers are called with the argument `arg`.

The cancellation cleanup handlers are also called when they are removed from the cancellation cleanup stack by a call to `pthread_cleanup_pop()` and a non-zero `execute` argument is specified.

The `pthread_cleanup_push()` and the matching `pthread_cleanup_pop()` call should be in the same lexical scope (that is, same level of brackets `{}`).

When the thread calls `pthread_exit()` or is cancelled by `pthread_cancel()`, the cancellation cleanup handlers are called with the argument specified by the `pthread_cleanup_push()` call that the handler was registered with.

During this thread cancellation cleanup processing, the thread calls cancellation cleanup handlers with cancellation disabled until the last cancellation cleanup handler returns. The handlers are called in Last In, First Out (LIFO) order. Automatic storage for the invocation stack frame of the function that registered the handler are still present when the cancellation cleanup handler is executed.

When a cancellation cleanup handler is called because of a call to `pthread_cleanup_pop()`, the cancellation cleanup handler does not necessarily run with cancellation disabled. The cancellation state and cancellation type are not changed by a call to `pthread_cleanup_pop()`.

A cancellation cleanup handler should not exit using `longjmp()` or `siglongjmp()`. If a cleanup handler takes an exception, the exception condition is handled and ignored and processing continues. You can look in the job log of the job to see exception messages generated by cancellation cleanup handlers.

### Authorities and Locks

None.

### Parameters

- **routine**
  - (Input) The cancellation cleanup routine

- **arg**
  - (Input) Argument that is passed to the start routine if it is called

### Return Value

None.

Example

See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

void cleanupHandler(void *arg)
{
    printf("In the cleanup handler\n");
}

void *threadfunc(void *parm)
{
    printf("Entered secondary thread\n");
    pthread_cleanup_push(cleanupHandler, NULL);
    while (1) {
        pthread_testcancel();
        sleep(1);
    }
    pthread_cleanup_pop(0);
    return NULL;
}

int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=0;

    printf("Enter Testcase = %s\n", argv[0]);

    /* Create a thread using default attributes */
    printf("Create thread using the NULL attributes\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);
    checkResults("pthread_create(NULL)\n", rc);

    /* sleep() is not a very robust way to wait for the thread */
    sleep(2);

    printf("Cancel the thread\n");
    rc = pthread_cancel(thread);
    checkResults("pthread_cancel()\n", rc);

    /* sleep() is not a very robust way to wait for the thread */
    sleep(3);
    printf("Main completed\n");
    return 0;
}
```

Output:
Enter Testcase - QP0WTEST/TPCLPU0
Create thread using the NULL attributes
Entered secondary thread
Cancel the thread
In the cleanup handler
Main completed

API introduced: V4R3

### pthread_clear_exit_np()—Clear Exit Status of Thread

**Syntax:**

```c
#include <pthread.h>
int pthread_clear_exit_np(void);
```

**Service Program Name:** QP0WPTH
**Default Public Authority:** *USE
**Threadsafe:** Yes
**Signal Safe:** Yes

The `pthread_clear_exit_np()` function clears the exit status of the thread. If the thread is currently exiting due to a call to `pthread_exit()` or is the target of a `pthread_cancel()`, then `pthread_clear_exit_np()` can be used in conjunction with `setjmp()`, `longjmp()`, and `pthread_setcancelstate()` to prevent a thread from terminating, and 'handle' the exit condition.

The only supported way to prevent thread exit during the condition in which `pthread_exit()` was called, or action is being taken for the target of a `pthread_cancel()` is shown in the example. It consists of using `longjmp()` from a cancellation cleanup handler back into some thread routine that is still on the invocation stack. From that routine, the functions `pthread_clear_exit_np()`, and `pthread_setcancelstate()` are used to restore the state of the thread before the condition that was causing the thread exit.

**Note:** This function is not portable.

### Authorities and Locks

None.

### Parameters

None.

### Return Value

- **0** `pthread_clear_exit_np()` was successful.
- **value** `pthread_clear_exit_np()` was not successful. `value` is set to indicate the error condition.

### Error Conditions

If `pthread_clear_exit_np()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

- **EINVAL**
  
  The thread is not currently exiting
Related Information

- "pthread_exit()—Terminate Calling Thread" on page 71—Terminate Calling Thread
- "pthread_cancel()—Cancel Thread" on page 22—Cancel Thread

Example

See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include <except.h>
#include <setjmp.h>
#include "check.h"

int threadStatus=1;

void cleanupHandler(void *p)
{
    jmp_buf *j = (jmp_buf *)p;

    /* Warning, it is quite possible that using combinations of */
    /* setjmp(), longjmp(), pthread_clear_exit_np(), and */
    /* pthread_setcancelstate() to handle thread exits or */
    /* cancellation could result in looping or non-cancelable */
    /* threads if done incorrectly. */
    printf("In cancellation cleanup handler. Handling the thread exit
");
    longjmp(*j, 1);
    printf("The exit/cancellation was not stopped!
");
    return;
}

do *threadfunc(void *parm)
{
    jmp_buf j;
    int rc, old;

    printf("Inside secondary thread\n");
    if (setjmp(j)) {
        /* Returned from longjmp after stopping the thread exit */
        /* Since longjmp was called from within the cancellation */
        /* cleanup handler, we must clear the exit state of the */
        /* thread and reset the cancelability state to what it was */
        /* before the cancellation cleanup handlers were called */
        /* (Cancellation cleanup handlers are called with */
        /* thread cancellation disabled) */
        printf("Stopped the thread exit, now clean up the states\n");

        printf("Clear exit state\n");
        rc = pthread_clear_exit_np();
        checkResults("pthread_clear_exit_np()\n", rc);

        printf("Restore cancel state\n");
        rc = pthread_setcancelstate(PTHREAD_CANCEL_ENABLE, &old);
        checkResults("pthread_setcancelstate()\n", rc);
        /* This example was successful */
        threadStatus = 0;
    }
    else {
        printf("Pushing cleanup handler that will stop the exit\n");
        pthread_cleanup_push(cleanupHandler, &j);
        /* This exit will be stopped by cleanupHandler2 and the */
        /* pthread_clear_exit_np() that is done above */
        pthread_exit(__VOID(threadStatus));
        printf("Did not expect to get here! Left status as 1.\n");
```

32 IBM Systems - iSeries: Pthread APIs
int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=0;
    char c;
    void *status;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Create thread that will demonstrate handling an exit\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);
    checkResults("pthread_create()\n", rc);

    rc = pthread_join(thread, &status);
    checkResults("pthread_join()\n", rc);
    if ((__INT(status) != 0)) {

        exit(1);
    }
    printf("Main completed\n");
    return 0;
}

Output:
Enter Testcase - QP0WTEST/TPCEXITO
Create thread that will demonstrate handling an exit
Inside secondary thread
Pushing cleanup handler that will stop the exit
In cancellation cleanup handler. Handling the thread exit
Stopped the thread exit, now clean up the states
Clear exit state
Restore cancel state
Main completed

API introduced: V4R3

pthread_condattr_destroy()—Destroy Condition Variable Attributes Object

Syntax:
#include <pthread.h>
int pthread_condattr_destroy(pthread_condattr_t *attr);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threading Safe: Yes
Signal Safe: Yes

The pthread_condattr_destroy() function destroys the condition variable attributes object specified by attr, and indicates that any storage that the system has associated with the object be de-allocated. Destroying a condition variable object in no way affects any of the condition variables that were created with that object.
Authorities and Locks
None.

Parameters
attr (Input) The address of the condition variable attributes object to be destroyed

Return Value
0 pthread_condattr_destroy() was successful.
value pthread_condattr_destroy() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_condattr_destroy() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

Related Information
• The <pthread.h> header file. See “Header files for Pthread functions” on page 254.
• pthread_condattr_init()—Initialize Condition Variable Attributes Object on page 36—Initialize Condition Variable Attributes Object
• pthread_cond_init()—Initialize Condition Variable on page 50—Initialize Condition Variable

Example
See Code disclaimer information for information pertaining to code examples.

```c
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_cond_t cond;

int main(int argc, char **argv)
{
    int rc=0;
    pthread_condattr_t attr;

    printf("Entering testcase\n");

    printf("Create a default condition attribute\n");
    rc = pthread_condattr_init(&attr);
    checkResults("pthread_condattr_init\n", rc);

    printf("Create the condition using the condition attributes object\n");
    rc = pthread_cond_init(&cond, &attr);
    checkResults("pthread_cond_init\n", rc);

    printf("- At this point, the condition with its default attributes\n");
    printf("- Can be used from any threads that want to use it\n");

    printf("Destroy cond attribute\n");
    rc = pthread_condattr_destroy(&attr);
    checkResults("pthread_condattr_destroy\n", rc);

    printf("Destroy condition\n");
    rc = pthread_cond_destroy(&cond);
```
checkResults("pthread_cond_destroy()\n", rc);

printf("Main completed\n");
return 0;
}

Output:

Entering testcase
Create a default condition attribute
Create the condition using the condition attributes object
- At this point, the condition with its default attributes
- Can be used from any threads that want to use it
Destroy cond attribute
Destroy condition
Main completed

API introduced: V4R3

pthread_condattr_getpshared()—Get Process Shared Attribute from Condition Attributes Object

Syntax:
#include <pthread.h>
int pthread_condattr_getpshared(const pthread_condattr_t *attr, int *pshared);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_condattr_getpshared() function retrieves the current setting of the process shared attribute from the condition attributes object. The process shared attribute indicates whether the condition that is created using the condition attributes object can be shared between threads in separate processes (PTHREAD_PROCESS_SHARED) or shared only between threads within the same process (PTHREAD_PROCESS_PRIVATE).

Even if the condition in storage is accessible from two separate processes, it cannot be used from both processes unless the process shared attribute is PTHREAD_PROCESS_SHARED.

The default pshared attribute for condition attributes objects is PTHREAD_PROCESS_PRIVATE.

Authorities and Locks
None.

Parameters
attr  (Input) Address of the variable that contains the condition attributes object
pshared  (Output) Address of the variable to contain the pshared attribute result

Return Value
0  pthread_condattr_getpshared() was successful.
value  pthread_condattr_getpshared() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_condattr_getpshared() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

See the example for “Example” on page 39.

API introduced: V4R3

pthread_condattr_init()—Initialize Condition Variable Attributes Object

Syntax:
#include <pthread.h>
int pthread_condattr_init(pthread_condattr_t *attr);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threading Safe: Yes
Signal Safe: Yes

The pthread_condattr_init() function initializes the condition variable attributes object specified by attr to the default attributes. The condition variable attributes object is used to create condition variables with the pthread_cond_init() function.

Authorities and Locks
None.

Parameters
attr  (Output) The address of the variable to contain the condition variable attributes object

Return Value
0  pthread_condattr_init() was successful.
value  pthread_condattr_init() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_condattr_init() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

Related Information

API introduced: V4R3

pthread_condattr_setpshared()—Set Process Shared Attribute in Condition Attributes Object

Syntax:
#include <pthread.h>
int pthread_condattr_setpshared(pthread_condattr_t *attr,
  int pshared);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The `pthread_condattr_setpshared()` function sets the current pshared attribute for the condition attributes object. The process shared attribute indicates whether the condition that is created using the condition attributes object can be shared between threads in separate processes (PTHREAD_PROCESS_SHARED) or shared between threads within the same process (PTHREAD_PROCESS_PRIVATE).

Even if the condition is in storage that is accessible from two separate processes, it cannot be used from both processes unless the process shared attribute is PTHREAD_PROCESS_SHARED.

The default pshared attribute for condition attributes objects is PTHREAD_PROCESS_PRIVATE.

Authorities and Locks
None.

Parameters
attr  (Input) Address of the variable containing the condition attributes object
pshared  (Input) One of PTHREAD_PROCESS_SHARED or PTHREAD_PROCESS_PRIVATE

Return Value
0  `pthread_condattr_setpshared()` was successful.
value  `pthread_condattr_setpshared()` was not successful. value is set to indicate the error condition.

Error Conditions
If `pthread_condattr_setpshared()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
  The value specified for the argument is not correct.

Pthread APIs 45
This example was run under the i5/OS QShell Interpreter. In the QShell Interpreter, a program gets descriptors 0, 1, and 2 as the standard files; the parent and child I/O is directed to the console. When run in the QShell Interpreter, the output shows the intermixed output from both parent and child processes and gives a feeling for the time sequence of operations occurring in each job.

The QShell interpreter allows you to run multithreaded programs as if they were interactive. See the QShell documentation for a description of the QIBM_MULTI_THREADED shell variable, which allows you to start multithreaded programs.

The QShell Interpreter is option 30 of Base i5/OS.

API introduced: V4R3

pthread_cond_broadcast()—Broadcast Condition to All Waiting Threads

Syntax:
#include <pthread.h>
int pthread_cond_broadcast(pthread_cond_t *cond);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The `pthread_cond_broadcast()` function wakes up all threads that are currently waiting on the condition variable specified by `cond`. If no threads are currently blocked on the condition variable, this call has no effect.
When the threads that were the target of the broadcast wake up, they contend for the mutex that they have associated with the condition variable on the call to `pthread_cond_timedwait()` or `pthread_cond_wait()`.

The signal and broadcast functions can be called by a thread whether or not it currently owns the mutex associated with the condition variable. If predictable scheduling behavior is required from the applications viewpoint however, the mutex should be locked by the thread calling `pthread_cond_signal()` or `pthread_cond_broadcast()`.

**Note:** For dependable use of condition variables, and to ensure that you do not lose wake up operations on condition variables, your application should always use a boolean predicate and a mutex with the condition variable.

**Authorities and Locks**

None.

**Parameters**

`cond`  (Input) Pointer to the condition variable that is to be broadcast to

**Return Value**

0  `pthread_cond_broadcast()` was successful.

value  `pthread_cond_broadcast()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**

If `pthread_cond_broadcast()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

**Example**

See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

/* For safe condition variable usage, must use a boolean predicate and */
/* a mutex with the condition. */
int conditionMet = 0;
pthread_cond_t cond = PTHREAD_COND_INITIALIZER;
pthread_mutex_t mutex = PTHREAD_MUTEX_INITIALIZER;
```
#define NTHREADS 5

void *threadfunc(void *parm)
{
    int rc;

    rc = pthread_mutex_lock(&mutex);
    checkResults("pthread_mutex_lock()\n", rc);

    while (!conditionMet) {
        printf("Thread blocked\n");
        rc = pthread_cond_wait(&cond, &mutex);
        checkResults("pthread_cond_wait()\n", rc);
    }

    rc = pthread_mutex_unlock(&mutex);
    checkResults("pthread_mutex_unlock()\n", rc);
    return NULL;
}

int main(int argc, char **argv)
{
    int rc=0;
    int i;
    pthread_t threadid[NTHREADS];

    printf("Enter Testcase - \%s\n", argv[0]);

    printf("Create \%d threads\n", NTHREADS);
    for(i=0; i<NTHREADS; ++i) {
        rc = pthread_create(&threadid[i], NULL, threadfunc, NULL);
        checkResults("pthread_create()\n", rc);
    }

    sleep(5); /* Sleep is not a very robust way to serialize threads */
    rc = pthread_mutex_lock(&mutex);
    checkResults("pthread_mutex_lock()\n", rc);

    /* The condition has occured. Set the flag and wake up any waiting threads */
    conditionMet = 1;
    printf("Wake up all waiting threads...\n");
    rc = pthread_cond_broadcast(&cond);
    checkResults("pthread_cond_broadcast()\n", rc);

    rc = pthread_mutex_unlock(&mutex);
    checkResults("pthread_mutex_unlock()\n", rc);

    printf("Wait for threads and cleanup\n");
    for (i=0; i<NTHREADS; ++i) {
        rc = pthread_join(threadid[i], NULL);
        checkResults("pthread_join()\n", rc);
    }
    pthread_cond_destroy(&cond);
    pthread_mutex_destroy(&mutex);

    printf("Main completed\n");
    return 0;
}

Output:
Entering testcase
Create 5 threads
Thread blocked
Thread blocked
Thread blocked
Thread blocked
Thread blocked
Wake up all waiting threads...
Wait for threads and cleanup
Main completed

API introduced: V4R3

pthread_cond_destroy()—Destroy Condition Variable

Syntax:

```
#include <pthread.h>
int pthread_cond_destroy(pthread_cond_t *cond);
```

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The `pthread_cond_destroy()` function destroys the condition variable specified by `cond`. If threads are currently blocked on the condition variable, the `pthread_cond_destroy()` fails with the EBUSY error.

Authorities and Locks
None.

Parameters

`cond` (Input) Address of the condition variable to destroy

Return Value

0 `pthread_cond_destroy()` was successful.

value `pthread_cond_destroy()` was not successful. value is set to indicate the error condition.

Error Conditions

If `pthread_cond_destroy()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

[EBUSY]

The condition variable was in use.

Related Information

- "pthread_cond_init()—Initialize Condition Variable" on page 50—Initialize Condition Variable
- "pthread_cond_signal()—Signal Condition to One Waiting Thread" on page 53—Signal Condition to One Waiting Thread
Example
See Code disclaimer information for information pertaining to code examples.

```
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_cond_t cond;

int main(int argc, char **argv)
{
    int rc=0;
    pthread_mutexattr_t attr;
    printf("Entering testcase\n");

    printf("Create the condition using the condition attributes object\n");
    rc = pthread_cond_init(&cond, NULL);
    checkResults("pthread_cond_init()\n", rc);

    printf("- At this point, the condition with its default attributes\n");
    printf("- Can be used from any threads that want to use it\n");

    printf("Destroy condition\n");
    rc = pthread_cond_destroy(&cond);
    checkResults("pthread_cond_destroy()\n", rc);

    printf("Main completed\n");
    return 0;
}
```

Output:
Entering testcase
Create the condition using the condition attributes object
- At this point, the condition with its default attributes
- Can be used from any threads that want to use it
Destroy condition
Main completed

API introduced: V4R3

 pthread_cond_init()—Initialize Condition Variable

Syntax:
```
#include <pthread.h>
int pthread_cond_init(pthread_cond_t *cond,
                        const pthread_condattr_t *attr);
pthread_cond_t cond = PTHREAD_COND_INITIALIZER;
```

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes
The `pthread_cond_init()` function initializes a condition variable object with the specified attributes for use. The new condition may be used immediately for serializing threads. If `attr` is specified as `NULL`, all attributes are set to the default condition attributes for the newly created condition.

With these declarations and initialization:

```c
pthread_cond_t cond2;
pthread_cond_t cond3;
pthread_condattr_t attr;
pthread_condattr_init(&attr);
```

The following four condition variable initialization mechanisms have equivalent function:

```c
pthread_cond_t cond1 = PTHREAD_MUTEX_INITIALIZER;
pthread_cond_init(&cond2, NULL);
pthread_cond_init(&cond3, &attr);
```

All four condition variables are created with the default condition attributes.

Every condition variable must eventually be destroyed with `pthread_cond_destroy()`.

Once a condition variable is created, it cannot be validly copied or moved to a new location. If the condition variable is copied or moved to a new location, the new object is not valid and cannot be used. Attempts to use the new object cause the `EINVAL` error.

Static initialization using the `PTHREAD_COND_INITIALIZER` does not immediately initialize the mutex. Instead, on first use, the functions `pthread_cond_wait()`, `pthread_cond_timedwait()`, `pthread_cond_signal()`, and `pthread_cond_broadcast()` branch into a slow path and cause the initialization of the condition. Due to this delayed initialization, the results of calling `pthread_cond_destroy()` on a condition variable that was initialized using static initialization and not used yet cause `pthread_cond_destroy()` to fail with the `EINVAL` error.

### Authorities and Locks

None.

### Parameters

- `cond` (Output) The address of the condition variable to initialize
- `attr` (Input) The address of the condition attributes object to use for initialization

### Return Value

- `0` `pthread_cond_init()` was successful.
- `value` `pthread_cond_init()` was not successful. `value` is set to indicate the error condition.

### Error Conditions

If `pthread_cond_init()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

- `[EINVAL]`

  The value specified for the argument is not correct.

Example

See [Code disclaimer information](#) for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_cond_t cond1 = PTHREAD_COND_INITIALIZER;
pthread_cond_t cond2;
pthread_cond_t cond3;

int main(int argc, char **argv)
{
    int rc=0;
    pthread_condattr_t attr;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Create the default cond attributes object\n");
    rc = pthread_condattr_init(&attr);
    checkResults("pthread_condattr_init()\n", rc);

    printf("Create the all of the default conditions in different ways\n");
    rc = pthread_cond_init(&cond2, NULL);
    checkResults("pthread_cond_init()\n", rc);

    rc = pthread_cond_init(&cond3, &attr);
    checkResults("pthread_cond_init()\n", rc);

    printf("- At this point, the conditions with default attributes\n");
    printf("- Can be used from any threads that want to use them\n");

    printf("Cleanup\n");
    pthread_condattr_destroy(&attr);
    pthread_cond_destroy(&cond1);
    pthread_cond_destroy(&cond2);
    pthread_cond_destroy(&cond3);

    printf("Main completed\n");
    return 0;
}
```

Output:

Enter Testcase - QP0WTEST/TPCOI0
Create the default cond attributes object
Create the all of the default conditions in different ways
- At this point, the conditions with default attributes
- Can be used from any threads that want to use them
Cleanup

pthread_cond_signal()—Signal Condition to One Waiting Thread

Syntax:
#include <pthread.h>
int pthread_cond_signal(pthread_cond_t *cond);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The `pthread_cond_signal()` function wakes up at least one thread that is currently waiting on the condition variable specified by `cond`. If no threads are currently blocked on the condition variable, this call has no effect.

When the thread that was the target of the signal wakes up, it contends for the mutex that it has associated with the condition variable on the call to `pthread_cond_timedwait()` or `pthread_cond_wait()`.

The signal and broadcast functions can be called by a thread whether or not it currently owns the mutex associated with the condition variable. If predictable scheduling behavior is required from the applications viewpoint, however, the mutex should be locked by the thread that calls `pthread_cond_signal()` or `pthread_cond_broadcast()`.

**Note:** For dependable use of condition variables, and to ensure that you do not lose wake-up operations on condition variables, your application should always use a Boolean predicate and a mutex with the condition variable.

**Authorities and Locks**
None.

**Parameters**

- **cond** (Input) Address of the condition variable to be signaled

**Return Value**

- **0** `pthread_cond_signal()` was successful.
- **value** `pthread_cond_signal()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**

If `pthread_cond_signal()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

**[EINVAL]**

The condition specified is not valid.

**Related Information**

API introduced: V4R3

pthread_cond_timedwait()—Timed Wait for Condition

Syntax:
#include <pthread.h>
#include <time.h>
int pthread_cond_timedwait(pthread_cond_t *cond,
    pthread_mutex_t *mutex,
    const struct timespec *abstime);
The `pthread_cond_timedwait()` function blocks the calling thread, waiting for the condition specified by `cond` to be signaled or broadcast to.

When `pthread_cond_timedwait()` is called, the calling thread must have `mutex` locked. The `pthread_cond_timedwait()` function atomically unlocks the mutex and performs the wait for the condition. In this case, atomically means with respect to the mutex and the condition variable and other access by threads to those objects through the pthread condition variable interfaces.

If the wait is satisfied or times out, or if the thread is canceled, before the thread is allowed to continue, the mutex is automatically acquired by the calling thread. If `mutex` is not currently locked, an `EPERM` error results. You should always associate only one mutex with a condition at a time. Using two different mutexes with the same condition at the same time could lead to unpredictable serialization in your application.

The time to wait is specified by the `abstime` parameter as an absolute system time at which the wait expires. If the current system clock time passes the absolute time specified before the condition is signaled, an `ETIMEDOUT` error results. After the wait begins, the wait time is not affected by changes to the system clock.

Although time is specified in seconds and nanoseconds, the system has approximately millisecond granularity. Due to scheduling and priorities, the amount of time you actually wait might be slightly more or less than the amount of time specified.

The current absolute system time can be retrieved as a timeval structure using the system clock interface `gettimeofday()`. The timeval structure can easily have a delta value added to it and be converted to a timespec structure. The MI time interfaces can be used to retrieve the current system time. The MI time also needs to be converted to a timespec structure before use by `pthread_cond_timedwait()` using the `qp0zConvertTime()` interface.

This function is a cancellation point.

**Note:** For dependable use of condition variables, and to ensure that you do not lose wake-up operations on condition variables, your application should always use a Boolean predicate and a mutex with the condition variable.

### Authorities and Locks

For successful completion, the mutex lock associated with the condition variable must be locked before you call `pthread_cond_timedwait()`.

### Parameters

- **cond** (Input) Address of the condition variable to wait for
- **mutx** (Input) Address of the locked mutex associated with the condition variable
- **abstime** (Input) Address of the absolute system time at which the wait expires

### Return Value

- **0** `pthread_cond_timedwait()` was successful.
value  pthread_cond_timedwait() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_cond_timedwait() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINV AL]
The value specified for the argument is not correct.

[EPERM]
The mutex specified is not locked by the caller.

[ETIMEDOUT]
The wait timed out without being satisfied.

pthread_cond_wait()—Wait for Condition

Syntax:
#include <pthread.h>
int pthread_cond_wait(pthread_cond_t *cond,
                  pthread_mutex_t *mutex);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_cond_wait() function blocks the calling thread, waiting for the condition specified by cond to be signaled or broadcast to.

When pthread_cond_wait() is called, the calling thread must have mutex locked. The pthread_cond_wait() function atomically unlocks mutex and performs the wait for the condition. In this case, atomically means with respect to the mutex and the condition variable and another threads access to those objects through the pthread condition variable interfaces.

If the wait is satisfied, or if the thread is canceled, before the thread is allowed to continue, the mutex is automatically acquired by the calling thread. If mutex is not currently locked, an EPERM error results. You should always associate only one mutex with a condition at a time. Using two different mutexes with the same condition at the same time could lead to unpredictable serialization issues in your application.

This function is a cancellation point.

Note: For dependable use of condition variables, and to ensure that you do not lose wake up operations on condition variables, your application should always use a boolean predicate and a mutex with the condition variable.

Authorities and Locks
For successful completion, the mutex lock associated with the condition variable is must be locked prior to calling pthread_cond_wait().
Parameters

**cond**  (Input) Address of the condition variable to wait on

**mutex** (Input) Address of the mutex associated with the condition variable

Return Value

0  *pthread_cond_wait()* was successful.

*value*  *pthread_cond_wait()* was not successful. *value* is set to indicate the error condition.

Error Conditions

If *pthread_cond_wait()* was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

[EPERM]

The mutex specified is not locked by the caller.

API introduced: V4R3
**pthread_create()—Create Thread**

Syntax:
```c
#include <pthread.h>
int pthread_create(pthread_t *thread, const pthread_attr_t *attr,
        void *(*start_routine)(void *), void *arg);
```

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The `pthread_create()` function creates a thread with the specified attributes and runs the C function `start_routine` in the thread with the single pointer argument specified. The new thread may, but does not always, begin running before `pthread_create()` returns. If `pthread_create()` completes successfully, the Pthread handle is stored in the contents of the location referred to by `thread`.

If the `start_routine` returns normally, it is as if there was an implicit call to `pthread_exit()` using the return value of `start_routine` as the status. The function passed as `start_routine` should correspond to the following C function prototype:
```c
void *threadStartRoutineName(void *);
```

If the thread attributes object represented by `attr` is modified later, the newly created thread is not affected. If `attr` is NULL, the default thread attributes are used.

With the following declarations and initialization,
```c
pthread_t t;
void *foo(void *);
pthread_attr_t attr;
pthread_attr_init(&pta);
```

the following two thread creation mechanisms are functionally equivalent:
```c
rc = pthread_create(&t, NULL, foo, NULL);
rc = pthread_create(&t, &attr, foo, NULL);
```

The cancellation state of the new thread is `PTHREAD_CANCEL_ENABLE`. The cancellation type of the new thread is `PTHREAD_CANCEL_DEFERRED`.

The signal information maintained in the new thread is as follows:
- The signal mask is inherited from the creating thread.
- The set of signals pending for the new thread is empty.

If you attempt to create a thread in a job that is not capable of starting threads, `pthread_create()` fails with the `EBUSY` error. If you attempt to create a thread from a location in which thread creation is not allowed, `pthread_create()` fails with the `EBUSY` error. See the `pthread_get pthreadoption_np()` function, option `PTHREAD_OPTION_THREAD_CAPABLE_NP`, for details about how to determine whether thread creation is currently allowed in your process.

In the i5/OS implementation, the initial thread is special. Termination of the initial thread by `pthread_exit()` or any other thread termination mechanism terminates the entire process.

The i5/OS implementation does not set a hard limit on the number of threads that can be created. The `PTHREAD_THREADS_MAX` macro is implemented as a function call, and returns different values depending on the administrative setting of the maximum number of threads for the process. The default
is NO MAX and has the numeric value of 2147483647 (0x7FFFFFFF). Realistically, the number of threads is limited by the amount of storage available to the job.

Currently, thread creation is not allowed after process termination has been started. For example, after a call to exit(), destructors for C++ static objects, functions registered with atexit() or CEE4RAGE() are allowed to run. If these functions attempt to create a thread, pthread_create() fails with the EBUSY error. Similar failures occur if other mechanisms are used to call pthread_create() after process termination has started.

Usage Notes

1. If you attempt to create a thread in a job that is not capable of starting threads or for some other reason, thread creation is not allowed, and pthread_create() fails with the EBUSY error.
2. For the best performance during thread creation, you should always use pthread_join() or pthread_detach(). This allows resources to be reclaimed or reused when the thread terminates.
3. The i5/OS implementation of threads allows the user ID to be changed on a per-thread basis. If, at the time the application creates the first thread, the application has not associated a process user identity with the job, the system uses the identity of the current user to set the process user identity for the job. The process user identity is used by some operating system support when operations that require authorization checks are done against a multithreaded job from outside that job. The application can set the process user identity using the Set Job User Identity(QWTSJUID) or QtSetJuid() Set Job User Identity APIs. See the Security APIs for more details.

Authorities and Locks

None.

Parameters

thread (Output) Pthread handle to the created thread
attr (Input) The thread attributes object containing the attributes to be associated with the newly created thread. If NULL, the default thread attributes are used.

start Routine

arg (Input) An address for the argument for the threads start routine

Return Value

0 pthread_create() was successful.

value pthread_create() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_create() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

[EAGAIN]

The system did not have enough resources to create another thread or the maximum number of threads for this job has been reached.

[EBUSY]

The system cannot allow thread creation in this process at this time.

/* Set up multiple parameters to pass to the thread */
parm = malloc(sizeof(thread_parm_t));
parm->value = 77;
strcpy(parm->string, "Inside secondary thread");
rc = pthread_create(&thread, &pta, threadfunc, (void *)parm);
checkResults("pthread_create(&pta)\n", rc);

printf("Destroy thread attributes object\n");
rc = pthread_attr_destroy(&pta);
checkResults("pthread_attr_destroy()\n", rc);

/* sleep() is not a very robust way to wait for the thread */
sleep(5);
```
printf("Main completed\n");
return 0;
}

Output:
Enter Testcase - QP0WTEST/TPCRT0
Create a thread attributes object
Create thread using the NULL attributes
Create thread using the default attributes
Destroy thread attributes object
Inside secondary thread, parm = 77
Inside secondary thread, parm = 5
Main completed

API introduced: V4R3

pthread_delay_np()—Delay Thread for Requested Interval

Syntax:
#include <pthread.h>
#include <time.h>
int pthread_delay_np(const struct timespec *deltatime);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The `pthread_delay_np()` function causes the calling thread to delay for the deltatime specified.

Although time is specified in seconds and nanoseconds, the system has approximately millisecond granularity. Due to scheduling and priorities, the amount of time you actually wait might be slightly more or less than the amount of time specified.

During the time that the thread is blocked in `pthread_delay_np()`, any asynchronous signals that are delivered to the thread have their actions taken. After the signal action (such as running a signal handler), the wait resumes if the specified interval has not yet elapsed.

The `pthread_delay_np()` function is a cancellation point.

Note: This function is not portable.

Authorities and Locks
None.

Parameters

interval
   (Input) Address of the timespec structure containing the interval to wait

Return Value

0   `pthread_delay_np()` was successful.
value  pthread_delay_np() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_delay_np() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

Related Information
• The <pthread.h> header file. See “Header files for Pthread functions” on page 254.

Example
See Code disclaimer information for information pertaining to code examples.

```
#define _MULTI_THREADED
#include <stdio.h>
#include <qp0z1170.h>
#include <time.h>
#include <pthread.h>
#include "check.h"

#define NTHREADS 5

void *threadfunc(void *parm)
{
    int rc;
    struct timespec ts = {0, 0};
    
    /* 5 and 1/2 seconds */
    ts.tv_sec = 5;
    ts.tv_nsec = 500000000;

    printf("Thread blocked\n");
    rc = pthread_delay_np(&ts);
    if (rc != 0) {
        printf("pthread_delay_np() - return code %d\n", rc);
        return (void*)&rc;
    }

    printf("Wait timed out!\n");

    return NULL;
}

int main(int argc, char **argv)
{
    int rc=0;
    int i;
    pthread_t threadid[NTHREADS];
    void *status;
    int fail=0;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Create %d threads\n", NTHREADS);
    for(i=0; i<NTHREADS; ++i) {
        rc = pthread_create(&threadid[i], NULL, threadfunc, NULL);
        checkResults("pthread_create()\n", rc);
    }

    printf("Wait for threads and cleanup\n");
    for (i=0; i<NTHREADS; ++i) {
```
rc = pthread_join(threadid[i], &status);
checkResults("pthread_join()\n", rc);
if (status != NULL) {
    fail = 1;
}
if (fail) {
    printf("At least one thread failed!\n");
    exit(1);
    printf("Main completed\n");
    return 0;
}

Output:
Enter Testcase - QP0WTEST/TPDLY0
Create 5 threads
Thread blocked
Thread blocked
Thread blocked
Thread blocked
Wait for threads and cleanup

API introduced: V4R3

pthread_detach()—Detach Thread

Syntax:
#include <pthread.h>
int pthread_detach(pthread_t thread);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_detach() function indicates that system resources for the specified thread should be reclaimed when the thread ends. If the thread is already ended, resources are reclaimed immediately. This routine does not cause the thread to end. After pthread_detach() has been issued, it is not valid to try to pthread_join() with the target thread.

Eventually, you should call pthread_join() or pthread_detach() for every thread that is created joinable (with a detach state of PTHREAD_CREATE_JOINABLE) so that the system can reclaim all resources associated with the thread. Failure to join to or detach threads that can be joined causes memory and other resource leaks until the process ends.

If thread does not represent a valid undetached thread, pthread_detach() will return ESRCH.
Authorities and Locks
None.

Parameters
thread (Input) Pthread handle to the target thread

Return Value
0 pthread_detach() was successful.
value pthread_detach() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_detach() was not successful, the error condition returned usually indicates one of the following
errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

[ESRCH]
No item could be found that matches the specified value.

Example
See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include <unistd.h>
#include <errno.h>
#include "check.h"

void *threadfunc(void *parm)
{
    printf("Inside secondary thread\n");
    return NULL;
}

int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=0;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Create thread using attributes that allow join or detach\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);
    checkResults("pthread_create()\n", rc);
    sleep(5);

    printf("Detach the thread after it terminates\n");
```
rc = pthread_detach(thread);
checkResults("pthread_detach()\n", rc);

printf("Detach the thread again (expect ESRCH)\n");
rc = pthread_detach(thread);
if (rc != ESRCH)
{
    printf("Got an unexpected result! rc=%d\n", rc);
    exit(1);
}
printf("Second detach fails correctly\n");

/* sleep() is not a very robust way to wait for the thread */
sleep(5);
printf("Main completed\n");
return 0;

Output:
Enter Testcase - QP0WTEST/TPDET0
Create thread using attributes that allow join or detach
Inside secondary thread
Detach the thread after it terminates
Detach the thread again (expect ESRCH)
Second detach fails correctly
Main completed

API introduced: V4R3

pthread_equal()—Compare Two Threads

Syntax:
#include <pthread.h>
int pthread_equal(pthread_t t1, pthread_t t2);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_equal() function compares two Pthread handles for equality.

Authorities and Locks
None.

Parameters

t1 (Input) Pthread handle for thread 1
t2 (Input) Pthread handle for thread 2

Return Value
0 The Pthread handles do not refer to the same thread.
1 The Pthread handles refer to the same thread.
Error Conditions
None.

Example
See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_t theThread;

void *threadfunc(void *parm)
{
    printf("Inside secondary thread\n");
    theThread = pthread_self();
    return NULL;
}

int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=0;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Create thread using default attributes\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);
    checkResults("pthread_create()\n", rc);

    /* sleep() is not a very robust way to wait for the thread */
    sleep(5);

    printf("Check if global vs local pthread_t are equal\n");
    if (!pthread_equal(thread, theThread)) {
        printf("Unexpected results on pthread_equal()!\n");
        exit(1);
    }
    printf("pthread_equal returns true\n");

    printf("Main completed\n");
    return 0;
}
```

Output:
Enter Testcase - QP0WTEST/TPEQU0
Create thread using default attributes
Inside secondary thread
Check if global vs local pthread_t are equal
pthread_equal returns true
Main completed

API introduced: V4R3
pthread_exit()—Terminate Calling Thread

Syntax:
#include <pthread.h>
void pthread_exit(void *status);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsae: Yes
Signal Safe: No

The pthread_exit() function terminates the calling thread, making its exit status available to any waiting threads. Normally, a thread terminates by returning from the start routine that was specified in the pthread_create() call which started it. An implicit call to pthread_exit() occurs when any thread returns from its start routine. (With the exception of the initial thread, at which time an implicit call to exit() occurs). The pthread_exit() function provides an interface similar to exit() but on a per-thread basis.

Note that in the i5/OS implementation of threads, the initial thread is special. Termination of the initial thread by pthread_exit() or any thread termination mechanism terminates the entire process.

The following activities occur in this order when a thread terminates by a return from its start routine or pthread_exit() or thread cancellation:
1. Any cancellation cleanup handlers that have been pushed and not popped will be executed in reverse order with cancellation disabled.
2. Data destructors are called for any thread specific data entries that have a non NULL value for both the value and the destructor.
3. The thread terminates.
4. Thread termination may possibly cause the system to run i5/OS cancel handlers (registered with the #pragma cancel_handler directive), or C++ destructors for automatic objects.
5. If thread termination is occurring in the initial thread, it will cause the system to terminate all other threads, then run C++ static object destructors, activation group cleanup routines and atexit() functions.
6. Any mutexes that are held by a thread that terminates, become `abandoned’ and are no longer valid. Subsequent calls by other threads that attempt to acquire the abandoned mutex through pthread_mutex_lock() will deadlock. Subsequent calls by other threads that attempt to acquire the abandoned mutex through pthread_mutex_trylock() will return EBUSY.
7. No release of any application visible process resources occur. This includes but is not limited to mutexes, file descriptors, or any process level cleanup actions.

Do not call pthread_exit() from a cancellation cleanup handler or destructor function that was called as a result of either an implicit or explicit call to pthread_exit(). If pthread_exit() is called from a cancellation cleanup handler, the new invocation of pthread_exit() will continue cancellation cleanup processing using the next cancellation cleanup handler that was pushed. If pthread_exit() is called from a data destructor, the new invocation of pthread_exit() will skip all subsequent calls to any data destructors (regardless of the number of destructor iterations that have completed), and terminate the thread.

Cleanup handlers and data destructors are not called when the application calls exit() or abort() or otherwise terminates the process. Cleanup handlers and data destructors are not called when a thread terminates by any proprietary i5/OS mechanism other than the Pthread interfaces.

The meaning of the status parameter is determined by the application except for the following conditions:
1. When the thread has been canceled using pthread_cancel(), the exit status of PTHREAD_CANCELED will be made available.
2. When the thread has been terminated as a result of an unhandled i5/OS exception, operator
intervention or other proprietary i5/OS mechanism, the exit status of **PTHREAD_EXCEPTION_NP**
will be made available.

No address error checking is done on the *status* parameter. Do not call `pthread_exit()` with, or return the
address of, a variable in a threads automatic storage. This storage will be unavailable after the thread
terminates.

**Note:** If `pthread_exit()` is called by application code after step 3 in the above list, `pthread_exit()` will fail
with the CPF1F81 exception. This indicates that the thread is already considered terminated by the
system, and `pthread_exit()` cannot continue. If your code does not handle this exception, it will appear as
if the call to `pthread_exit()` was successful.

**Authorities and Locks**
None.

**Parameters**

*status*  (Input) exit status of the thread

**Return Value**

`pthread_exit()` does not return.

**Error Conditions**
None.

Output:
Enter Testcase - QP0WTEST/TPEXIT0
Create thread using attributes that allow join
Wait for the thread to exit
Inside secondary thread
Got secondary thread status as expected
Main completed

API introduced: V4R3

 pthread_extendedjoin_np()—Wait for Thread with Extended Options

Syntax:
#include <pthread.h>
int pthread_extendedjoin_np(pthread_t thread, void **status,
    pthread_joinoption_np_t *options);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_extendedjoin_np() function waits for a thread to terminate, optionally detaches the thread, then returns the threads exit status.

If the options parameter is specified as NULL or the contents of the pthread_joinoption_np_t structure represented by options parameter is binary 0, then the behavior of pthread_extendedjoin_np() is equivalent to pthread_join().

The deltotime field of the options parameter can be used to specify the amount of elapsed time to wait before the wait times out. If the wait times out, the ETIMEDOUT error is returned and the thread is not detached. For an infinite wait, specify a seconds value of 0, and a nanoseconds value of 0.

The leaveThreadAllocated field of the options parameter can be used to specify that the pthread_extendedjoin_np() function should NOT implicitly detach the thread when the join completes successfully. If the leaveThreadAllocated option is used, the thread should later be detached using pthread_join(), pthread_detach(), or pthread_extendedjoin_np() without specifying the leaveThreadAllocated option.
The reserved fields of the options parameter are for use by possible future extensions to pthread_extendedjoin_np(). If any reserved fields of the options parameter are not zero, the EINVAL error is returned.

If the status parameter is NULL, the threads exit status is not returned.

The meaning of the threads exit status (value returned to the status memory location) is determined by the application except for the following conditions:
1. When the thread has been canceled using pthread_cancel(), the exit status of PTHREAD_CANCELED is made available.
2. When the thread has been terminated as a result of an unhandled i5/OS exception, operator intervention, or other proprietary i5/OS mechanism, the exit status of PTHREAD_EXCEPTION_NP is made available.

Eventually, you should call pthread_join(), pthread_detach() or pthread_extendedjoin_np() without specifying the leaveThreadAllocated option for every thread that is created joinable (with a detach state of PTHREAD_CREATE_JOINABLE) so that the system can reclaim all resources associated with the thread. Failure to join to or detach joinable threads causes memory and other resource leaks until the process ends.

Authorities and Locks
None.

Parameters
thread  (Input) Pthread handle to the target thread
status  (Input/Output) Address of the variable to receive the thread’s exit status
options  (Input) Address of the join options structure specifying optional behavior of this API.

Return Value
0    pthread_extendedjoin_np() was successful.
value    pthread_extendedjoin_np() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_extendedjoin_np() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.
[EINVAL]
    The value specified for the argument is not correct.
[ESRCH]
    The thread specified could not be found.
[ETIMEDOUT]
    The time specified in the deltatime field of the options parameter elapsed without the target thread terminating.

    printf("Create thread using attributes that allow join\n");
    rc = pthread_create(&t, NULL, thread, NULL);
    checkResults("pthread_create()\n", rc);

    memset(&joinoption, 0, sizeof(pthread_joinoption_np_t));
    joinoption.deltatime.tv_sec = 3;
    joinoption.leaveThreadAllocated = 1;

    printf("Join to the thread, timeout in 3 seconds, no implicit detach\n");
    rc = pthread_extendedjoin_np(t, &status, &joinoption);
    if (rc != ETIMEDOUT) {
        printf("Join did not timeout as expected! rc=%d\n", rc);
        exit(1);
    }

    /* Call pthread_extendedjoin_np the same as a normal */
    /* pthread_join() call. */
    /* i.e. Implicit Detach is done, and Infinite wait */
    printf("Normal join to the thread\n");
    rc = pthread_extendedjoin_np(t, &status, NULL);
    checkResults("pthread_extendedjoin_np(no-options)\n", rc);
    if (__INT(status) != 42) {
        printf("Got the incorrect thread status!\n");
        exit(1);
    }
}
```

Pthread APIs 75
printf("Main completed\n");
return(0);
}

Output
Entering testcase QP0WTEST/TPJOIN0
Create thread using attributes that allow join
Join to the thread, timeout in 3 seconds, no implicit detach
Entered thread
Normal join to the thread
Ending thread
Main completed

API introduced: V4R3

pthread_getcancelstate_np()—Get Cancel State

Syntax:
#include <pthread.h>
int pthread_getcancelstate_np(int *cancelState);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threatsafe: Yes
Signal Safe: Yes

The pthread_getcancelstate_np() function gets the current cancel state of the thread. Cancel state is either PTHREAD_CANCEL_ENABLE or PTHREAD_CANCEL_DISABLE. For more information on cancelability, see "Thread cancellation APIs" on page 272.

When cancelability is disabled, all cancels are held pending in the target thread until the thread changes the cancelability. When cancelability is deferred, all cancels are held pending in the target thread until the thread changes the cancelability, calls a function that is a cancellation point, or calls pthread_testcancel(), thus creating a cancellation point. When cancelability is asynchronous, all cancels are acted upon immediately, interrupting the thread with its processing.

Notes:
1. Your application should not use asynchronous thread cancellation through the PTHREAD_CANCELASYNCHRONOUS option of pthread_setcanceltype(). See the common user errors section of this document for more information.
2. This function is not portable.

Authorities and Locks
None.

Parameters
cancelstate
(Output) Address of the variable to receive the cancel state.

Return Value
0 pthread_getcancelstate_np() was successful.
value  pthread_getcancelstate_np() was not successful. value is set to indicate the error condition.

**Error Conditions**

If pthread_getcancelstate_np() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

    current cancel state is 0
Calling pthread_exit() will allow cancellation cleanup handlers to run
In cancellation cleanup handler
    current cancel state is 1
Main completed

API introduced: V4R3

pthread_getconcurrency()—Get Process Concurrency Level

Syntax:
#include <pthread.h>
int pthread_getconcurrency();

Service Program Name: QP0WTCH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_getconcurrency() function retrieves the current concurrency level for the process. A value of 0 indicates that the threads implementation chooses the concurrency level that best suits the application. A concurrency level greater than zero indicates that the application wishes to inform the system of its desired concurrency level.

The concurrency level is not used by the i5/OS threads implementation. Each user thread is always bound to a kernel thread.
Authorities and Locks
None.

Parameters
None.

Return Value
value  pthread_getconcurrency() returns the current concurrency level.

Error Conditions
None.

Related Information
- The <pthread.h> header file. See “Header files for Pthread functions” on page 254.
- “pthread_setconcurrency()—Set Process Concurrency Level” on page 192—Set Process Concurrency Level

API introduced: V4R3

pthread_getpthreadoption_np()—Get Pthread Run-Time Option Data

Syntax:
#include <pthread.h>
int pthread_getpthreadoption_np(pthread_option_np_t *optionData);

Service Program Name: QP0WTCBH
Default Public Authority: *USE
Threading: Yes
Signal Safe: Yes

The pthread_getpthreadoption_np() function gets option data from the pthread run-time for the process.

Input and output data is specified and returned uniquely based on the specified optionData. See the table below for details about input and output. The option field in the optionData parameter is always required. Other fields may be input, output, or ignored, based on the specific option used.

For all options, every reserved field in the structure represented by optionData must be binary zero or the EINVAL error is returned. Unless otherwise noted for an option, the target field in the option parameter is always ignored.

The currently supported options, the data they represent, and the valid operations are as follows:
option field of the option parameter | Description
---|---
PTHREAD_OPTION_POOL_NP | When a thread terminates and it is detached or joined to, certain data structures from the pthreads run-time are maintained in a pool for possible reuse by future threads. This improves performance for creating threads. Typically, an application should not be concerned with this storage pool. Use this option to determine what the current maximum size of the allowed storage pool is. The optionValue field of the optionData parameter is set to the current maximum number of thread structures, which is maintained in the storage pool. By default, the maximum size of the storage reuse pool contains enough room for 512 thread structures.

PTHREAD_OPTION_POOL_CURRENT_NP | When a thread terminates and it is detached or joined to, certain data structures from the pthreads run-time are maintained in a pool for possible reuse by future threads. This improves performance for creating threads. Typically, an application should not be concerned with this storage pool. Use this option to determine how many thread structures are currently in the storage pool. The optionValue field of the optionData parameter is set to the current number of thread structures, which are contained in the storage pool. By default, the storage pool contains no thread structures. When a thread terminates and is detached or joined to and the current size of the pool is less than the maximum size, the thread structure is added to the pool.

PTHREAD_OPTION_THREAD_CAPABLE_NP | Not all i5/OS jobs can start threads at all times. Use this option to determine whether thread creation is currently allowed for your process. The optionValue field of the optionData parameter is set to indicate whether thread creation is currently allowed. The field is set to 0 to indicate that thread creation is not allowed, the field will be set to 1 to indicate thread creation is allowed. If thread creation is not allowed, pthread_create() fails with the EBUSY error. See pthread_create() for more details.

Authorities and Locks
None.

Parameters
option (Input/Output) Address of the variable containing option information and to contain output option information.

Return Value
0 pthread_getpthreadoption_np() was successful.

value pthread_getpthreadoption_np() was not successful. value is set to indicate the error condition.
Error Conditions

If `pthread_getpthreadoption_np()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

Example

See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

void *threadfunc(void *parm)
{
    printf("Inside the thread\n");
    return NULL;
}

void showCurrentSizeOfPool(void)
{
    int rc,
    pthread_option_np_t opt;

    memset(&opt, 0, sizeof(opt));
    opt.option = PTHREAD_OPTION_POOL_CURRENT_NP;
    rc = pthread_getpthreadoption_np(&opt);
    checkResults("pthread_getpthreadoption_np()\n", rc);

    printf("Current number of thread structures in pool is %d\n", opt.optionValue);
    return;
}

int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=0;
    pthread_option_np_t opt;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Create thread using the NULL attributes\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);
    checkResults("pthread_create(NULL)\n", rc);

    memset(&opt, 0, sizeof(opt));
    opt.option = PTHREAD_OPTION_POOL_NP;
    rc = pthread_getpthreadoption_np(&opt);
    checkResults("pthread_getpthreadoption_np()\n", rc);

    printf("Current maximum pool size is %d thread structures\n", opt.optionValue);

    return;
}
```
showCurrentSizeOfPool();

printf("Joining to the thread may it to the storage pool\n");
rc = pthread_join(thread, NULL);
checkResults("pthread_join()", rc);

showCurrentSizeOfPool();
printf("Main completed\n");
return 0;
}

Output:

Enter Testcase - QP0WTEST/TPGEmoP
Create thread using the NULL attributes
Current maximum pool size is 512 thread structures
Current number of thread structures in pool is 0
Joining to the thread may it to the storage pool
Inside the thread
Current number of thread structures in pool is 1
Main completed

API introduced: V4R3

pthread_getschedparam()—Get Thread Scheduling Parameters

Syntax:
#include <pthread.h>
#include <sched.h>
int pthread_getschedparam(pthread_t thread, int *policy,
    struct sched_param *param);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_getschedparam() function retrieves the scheduling parameters of the thread. The default i5/OS scheduling policy is SCHED_OTHER and cannot be changed to another scheduling policy.

The sched_policy field of the param parameter is always returned as SCHED_OTHER. The sched_priority field of the param structure is set to the priority of the target thread at the time of the call.

Note: Do not use pthread_setschedparam() to set the priority of a thread if you also use another mechanism (other than the pthread APIs) to set the priority of a thread. If you do, pthread_getschedparam() returns only that information that was set by the pthread interfaces such as pthread_setschedparam() or a modification of the thread attribute using pthread_attr_setschedparam().

Authorities and Locks
None.

Parameters

thread (Input) Pthread handle representing the target thread
policy (Output) Address of the variable to contain the scheduling policy
param (Output) Address of the variable to contain the scheduling parameters
Return Value

0  pthread_getschedparam() was successful.
value  pthread_getschedparam was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_getschedparam() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

Related Information

- The <pthread.h> header file. See “Header files for Pthread functions” on page 254.
- “pthread_setschedparam()—Set Target Thread Scheduling Parameters” on page 196—Set Target Thread Scheduling Parameters

Example

See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <sched.h>
#include <stdio.h>
#include "check.h"

void *threadfunc(void *parm)
{
    printf("Inside secondary thread\n");
    sleep(5); /* Sleep is not a very robust way to serialize threads */
    return NULL;
}

int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=0;
    struct sched_param param;
    int policy;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Create thread using default attributes\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);
    checkResults("pthread_create()\n", rc);

    printf("Get scheduling parameters\n");
    rc = pthread_getschedparam(thread, &policy, &param);
    checkResults("pthread_getschedparam()\n", rc);

    printf("The thread scheduling parameters indicate:\n"
    "policy = %d\n", policy);
    printf("priority = %d\n",
        param.sched_priority);

    printf("Main completed\n");
    return 0;
}
```

Output:
Enter Testcase - QP0WTEST/TPGSP0
Create thread using default attributes
Get scheduling parameters
The thread scheduling parameters indicate:
policy = 0
priority = 0
Main completed

API introduced: V4R3

pthread_getspecific()—Get Thread Local Storage Value by Key

Syntax:
#include <pthread.h>
void *pthread_getspecific(pthread_key_t key);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_getspecific() function retrieves the thread local storage value associated with the key. pthread_getspecific() may be called from a data destructor.

The thread local storage value is a variable of type void * that is local to a thread, but global to all of the functions called within that thread. It is accessed by the key.

Authorities and Locks
None.

Parameters
key  (Input) The thread local storage key returned from pthread_key_create()

Return Value
value  pthread_getspecific() was successful. value is set to indicate the current thread specific data pointer stored at the key location.

NULL  pthread_getspecific() returned the null thread specific data value stored at the key location or the key was out of range.

Error Conditions
None.

Example

See [Code disclaimer information](#) for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

#define NUMTHREADS 3
pthread_key_t tlsKey = 0;

void globalDestructor(void *value)
{
    printf("In the globalDestructor
");
    free(value);
    pthread_setspecific(tlsKey, NULL);
}

void showGlobal(void)
{
    void    *global;
    pthread_id_np_t tid;

    global = pthread_getspecific(tlsKey);
    pthread_getunique_np((pthread_t *)global, &tid);
    printf("showGlobal: global data stored for thread 0x%.8x%.8x\n", tid);
}

void *threadfunc(void *parm)
{
    int     rc;
    int     *myThreadDataStructure;
    pthread_t me = pthread_self();

    printf("Inside secondary thread\n");

    myThreadDataStructure = malloc(sizeof(pthread_t) + sizeof(int) * 10);
    memcpy(myThreadDataStructure, &me, sizeof(pthread_t));
    pthread_setspecific(tlsKey, myThreadDataStructure);
    showGlobal();
    pthread_exit(NULL);
}

int main(int argc, char **argv)
{
    pthread_t thread[NUMTHREADS];
    int     rc=0;
    int     i=0;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Create a thread local storage key\n");
    rc = pthread_key_create(&tlsKey, globalDestructor);
    checkResults("pthread_key_create()\n", rc);
    /* The key can now be used from all threads */

    printf("Create %d threads using joinable attributes\n", NUMTHREADS);
    for (i=0; i<NUMTHREADS; ++i) {
        rc = pthread_create(&thread[i], NULL, threadfunc, NULL);
        checkResults("pthread_create()\n", rc);
    }

    return 0;
}
```

Example

See [Code disclaimer information](#) for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

#define NUMTHREADS 3
pthread_key_t tlsKey = 0;

API introduced: V4R3

pthread_getthreadid_np()—Retrieve Unique ID for Calling Thread

Syntax:
#include <pthread.h>
pthread_id_np_t pthread_getthreadid_np(void);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_getthreadid_np() function retrieves the unique integral identifier that can be used to identify the calling thread in some context for application debugging or tracing support.

In some implementations, the thread ID is equivalent to the pthread_t type. In the i5/OS implementation, the pthread_t is an opaque Pthread handle. For the ability to identify a thread using a thread ID (unique number), the pthread_getunique_np() and pthread_getthreadid_np() interfaces are provided.

The i5/OS machine implementation of threads provides a 64-bit thread ID. The thread ID is returned as a structure containing the high and low order 4 bytes of the 64-bit ID. This allows applications created by compilers that do not yet support 64-bit integral values to effectively use the 64-bit thread ID.
If your code requires the unique integer identifier for the calling thread often, or in a loop, the `pthread_getthreadid_np()` function can significantly improve performance over the combination of `pthread_self()` and `pthread_getunique_np()` calls that provide equivalent behavior.

For example:
```c
pthread_id_np_t tid;
tid = pthread_getthreadid_np();
```

is significantly faster than these calls, but provides the same behavior.
```c
pthread_id_np_t tid;
pthread_t self;
sel = pthread_self();

pthread_getunique_np(&self, &tid);
```

As always, if you are calling any function too often, you can improve performance by storing the results in a variable or passing to other functions that require the results.

**Note:** This function is not portable.

**Authorities and Locks**

None.

**Parameters**

None.

**Return Value**

The `pthread_id_np_t` structure identifying the thread.

**Error Conditions**

None.

**Related Information**

- The `<pthread.h>` header file. See "Header files for Pthread functions" on page 254.
- "`pthread_self()`—Get Pthread Handle" on page 186—Get Pthread Handle
- "`pthread_getunique_np()`—Retrieve Unique ID for Target Thread" on page 88—Retrieve Unique ID for Target Thread

**Example**

See [Code disclaimer information](#) for information pertaining to code examples.
```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

#define NUMTHREADS 3

void *threadfunc(void *parm)
{
    printf("Thread 0x%.8x %.8x started\n", pthread_getthreadid_np());
    return NULL;
}

int main(int argc, char **argv)
{
```
#include <pthread.h>

int pthread_getunique_np(pthread_t thread, pthread_id_np_t *id);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_getunique_np() function retrieves the unique integral identifier that can be used to identify the thread in some context for application debugging or tracing support.
In some implementations, the thread ID is equivalent to the pthread_t type. In the i5/OS implementation, the pthread_t is an opaque Pthread handle. For the ability to identify a thread using a thread ID (unique number), the `pthread_getunique_np()` and `pthread_getthreadid_np()` interfaces are provided.

The i5/OS machine implementation of threads provides a 64-bit thread ID. The thread ID is returned as a structure containing the high and low order 4 bytes of the 64-bit ID. This allows applications created by compilers that do not yet support 64-bit integral values to effectively use the 64-bit thread ID.

If your code requires the unique integer identifier for the calling thread often, or in a loop, the `pthread_getthreadid_np()` function can significantly improve performance over the combination of `pthread_self()` and `pthread_getunique_np()` calls that provide equivalent behavior.

For example:
```c
pthread_id_np_t tid;
tid = pthread_getthreadid_np();
```

is significantly faster than these calls, but provides the same behavior.
```c
pthread_id_np_t tid;
pthread_t self;
self = pthread_self();
pthread_getunique_np(&self, &tid);
```

As always, if you are calling any function too often, you can improve performance by storing the results in a variable or passing to other functions that require the results.

**Note:** This function is not portable.

### Authorities and Locks

None.

### Parameters

- **thread** (Input) Address of the thread to retrieve the unique integer ID for
- **id** (Output) Address of the thread ID structure to contain the 64-bit thread ID.

### Return Value

- **0** `pthread_getunique_np()` was successful.
- **value** `pthread_getunique_np()` was not successful. `value` is set to indicate the error condition.

### Error Conditions

If `pthread_getunique_np()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

- **[EINVAL]**

  The value specified for the argument is not correct.

### Related Information

Example

See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

#define NUMTHREADS 3

void *threadfunc(void *parm)
{
    pthread_id_np_t tid;
    pthread_t me = pthread_self();

    pthread_getunique_np(&me, &tid);
    printf("Thread 0x%.8x %.8x started\n", tid);
    return NULL;
}

int main(int argc, char **argv)
{
    pthread_t thread[NUMTHREADS];
    int rc=0;
    pthread_id_np_t tid;
    int i=0;
    pthread_t me = pthread_self();

    printf("Enter Testcase - %s\n", argv[0]);
    pthread_getunique_np(&me, &tid);
    printf("Main Thread 0x%.8x %.8x\n", tid);

    printf("Create %d threads using joinable attributes\n", NUMTHREADS);
    for (i=0; i<NUMTHREADS; ++i) {
        rc = pthread_create(&thread[i], NULL, threadfunc, NULL);
        checkResults("pthread_create()\n", rc);
        pthread_getunique_np(&thread[i], &tid);
        printf("Created thread 0x%.8x %.8x\n", tid);
    }

    printf("Join to threads\n");
    for (i=0; i<NUMTHREADS; ++i) {
        rc = pthread_join(thread[i], NULL);
        checkResults("pthread_join()\n", rc);
    }

    printf("Main completed\n");
    return 0;
}
```

Output:

Enter Testcase - QP0WTEST/TPGETU0
Main Thread 0x00000000 0000006c
Create 3 threads using joinable attributes
Created thread 0x00000000 0000006d
Thread 0x00000000 0000006d started

Join to threads
Thread 0x00000000 0000006f started
Thread 0x00000000 0000006e started
Main completed
The `pthread_get_expiration_np()` function computes an absolute time by adding the specified relative time (`delta`) to the current system time. The resulting absolute time output in the `abstime` parameter can be used as the expiration time in a call to `pthread_cond_timedwait()`.

The current system time is retrieved from the system clock.

**Note:** This function is not portable.

**Authorities and Locks**
None.

**Parameters**
- `delta` (Input) Elapsed time to add to the current system time
- `abstime` (Output) Address of the returned value representing the expiration time

**Return Value**
- `0` `pthread_get_expiration_np()` was successful.
- `value` `pthread_get_expiration_np()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**
If `pthread_get_expiration_np()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

- `[EINVAL]`
  
  The value specified for the argument is not correct.

API introduced: V4R3

pthread_is_initialthread_np()—Check if Running in the Initial Thread

Syntax:
#include <pthread.h>
#include <sched.h>
int pthread_is_initialthread_np(void);

Threading: Yes
Signal Safe: Yes

The pthread_is_initialthread_np() function returns true or false, indicating if the current thread is the initial thread of the process. A return value true (non 0) indicates that the calling thread is the initial thread. A return value of false (0) indicates that the calling thread is running in a secondary thread.

Note: This function is not portable.
Authorities and Locks
None.

Parameters
None.

Return Value
0 The calling thread is a secondary thread.
value The calling thread is the initial thread.

Error Conditions
None.

Related Information

Example
See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

#define NUMTHREADS 1

void *function(void *parm) {
    printf("Inside the function\n");
    if (pthread_is_initialthread_np()) {
        printf("In the initial thread\n");
    } else {
        printf("In a secondary thread\n");
    }
    return NULL;
}

int main(int argc, char **argv) {
    pthread_t thread[NUMTHREADS];
    int rc=0;
    int i=0;

    printf("Enter Testcase - \%s\n", argv[0]);

    printf("Create \%d threads\n", NUMTHREADS);
    for (i=0; i<NUMTHREADS; ++i) {
        rc = pthread_create(&thread[i], NULL, function, NULL);
        checkResults("pthread_create()\n", rc);
        printf("Main: Currently \%d threads\n",
            pthread_is_initialthread_np() + 1);
    }

    printf("Join to threads\n");
    for (i=0; i<NUMTHREADS; ++i) {
        rc = pthread_join(thread[i], NULL);
```
checkResults("pthread_join()\n", rc);
}

function(NULL);
printf("Main completed\n");
return 0;
}

Output:
Enter Testcase - QP0WTEST/TPISINO
Create 1 threads
Join to threads
Inside the function

Inside the function
In the initial thread
Main completed

API introduced: V4R3

pthread_is_multithreaded_np()—Check Current Number of Threads

Syntax:
#include <pthread.h>
unsigned int pthread_is_multithreaded_np(void);

Service Program Name: QP0WPTH
Default Public Authority: USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_is_multithreaded_np() function returns true or false, indicating whether the current process has more than one thread. A return value of zero indicates that the calling thread is the only thread in the process. A value not equal to zero, indicates that there were multiple other threads in the process at the time of the call to pthread_is_multithreaded_np().

The total number of threads currently in the process can be determined by adding 1 to the return value of pthread_is_multithreaded_np().

Note: This function is not portable.

Authorities and Locks
None.

Parameters
None.

Return Value
0 No other threads exist in the process.
value There are currently value+1 total threads in the process.

Error Conditions
None.

pthread_join()—Wait for and Detach Thread

Syntax:
#include <pthread.h>
int pthread_join(pthread_t thread, void **status);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_join() function waits for a thread to terminate, detaches the thread, then returns the threads exit status.

If the status parameter is NULL, the threads exit status is not returned.

The meaning of the threads exit status (value returned to the status memory location) is determined by the application, except for the following conditions:
1. When the thread has been canceled using pthread_cancel(), the exit status of PTHREAD_CANCELED is made available.
2. When the thread has been terminated as a result of an unhandled i5/OS exception, operator intervention or other proprietary i5/OS mechanism, the exit status of PTHREAD_EXCEPTION_NP is made available.

Eventually, you should call pthread_join(), pthread_detach() or pthread_extendedjoin_np() without specifying the leaveThreadAllocated option for every thread that is created joinable (with a detach state of PTHREAD_CREATE_JOINABLE) so that the system can reclaim all resources associated with the thread. Failure to join to or detach joinable threads causes memory and other resource leaks until the process ends.

Authorities and Locks
None.

Parameters
thread  (Input) Pthread handle to the target thread
status   (Output) Address of the variable to receive the thread’s exit status

Return Value
0   pthread_join() was successful.
value   pthread_join() was not successful. value is set to indicate the error condition.
Error Conditions
If pthread_join() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

[ESRCH]
The thread specified could not be found.

Related Information
- The <pthread.h> header file. See "Header files for Pthread functions" on page 254

Example
See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

int okStatus = 34;

void *threadfunc(void *parm)
{
    printf("Inside secondary thread\n");
    return __VOID(okStatus);
}

int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=0;
    void *status;

    printf("Enter Testcase - %s\n", argv[0]);
    printf("Create thread using attributes that allow join\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);
    checkResults("pthread_create()", rc);
    printf("Wait for the thread to exit\n");
    rc = pthread_join(thread, &status);
    checkResults("pthread_join()", rc);
    if (__INT(status) != okStatus) {
        printf("Secondary thread failed\n");
        exit(1);
    }
    printf("Got secondary thread status as expected\n");
    printf("Main completed\n");
    return 0;
}
```

Output:
Enter Testcase - QP0WTEST/TPJOIN0
Create thread using attributes that allow join
Wait for the thread to exit
Inside secondary thread
Got secondary thread status as expected
Main completed

API introduced: V4R3

pthread_join_np()—Wait for Thread to End

Syntax:
#include <pthread.h>
int pthread_join_np(pthread_t thread, void **status);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_join_np() function waits for a thread to terminate, then returns the threads exit status, while leaving the data structures of the thread available for a later call to pthread_join(), pthread_join_np(), pthread_detach(), or pthread_extendedjoin_np().

If the status parameter is NULL, the thread’s exit status is not returned.

The meaning of the threads exit status (value returned to the status memory location) is determined by the application except for the following conditions:
1. When the thread has been canceled using pthread_cancel(), the exit status of PTHREAD_CANCELED is made available.
2. When the thread has been terminated as a result of an unhandled i5/OS exception, operator intervention, or other proprietary i5/OS mechanism, the exit status of PTHREAD_EXCEPTION_NP is made available.

Eventually, you should call pthread_join(), pthread_detach(), or pthread_extendedjoin_np() without specifying the leaveThreadAllocated option for every thread that is created joinable (with a detach state of PTHREAD_CREATE_JOINABLE) so that the system can reclaim all resources associated with the thread. Failure to join to or detach joinable threads causes memory and other resource leaks until the process ends.

Note: This function is not portable.

Authorities and Locks
None.

Parameters
thread (Input) Pthread handle to the target thread
status (Output) Address of the variable to receive the thread’s exit status

Return Value
0 pthread_join_np() was successful.
value  pthread_join_np() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_join_np() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

[ESRCH]
The thread specified could not be found.

With pthread_join_np(), we can join repeatedly
Got secondary thread status as expected
Main completed

API introduced: V4R3

pthread_key_create()—Create Thread Local Storage Key

Syntax:
#include <pthread.h>
int pthread_key_create(pthread_key_t *key, void (*destructor)(void *));

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_key_create() function creates a thread local storage key for the process and associates the destructor function with that key. After a key is created, that key can be used to set and get per-thread data pointer. When pthread_key_create() completes, the value associated with the newly created key is NULL.

When a thread terminates, if both the value and the destructor associated with a thread local storage key are not NULL, the destructor function is called. The stored pointer associated with the key is set to NULL before the call to the destructor function. The parameter passed to the destructor function when it is called is the value of the pointer before it was set to NULL that is associated with that key in the thread that is terminating.

After calling the destructors, if there are still non NULL values in the thread associated with the keys, the process is repeated. After PTHREAD_DESTRUCTOR_ITERATIONS attempts to destroy the thread local storage, no further attempts are made for that thread local storage value/key combination.

Do not call pthread_exit() from a destructor function.

A destructor function is not called as a result of the application calling pthread_key_delete().
Authorities and Locks
None.

Parameters

key  (Output) The address of the variable to contain the thread local storage key

destructor  (Input) The address of the function to act as a destructor for this thread local storage key

Return Value

0  pthread_key_create() was successful.

value  pthread_key_create() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_key_create() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

[EAGAIN]

The system did not have enough resources, or the maximum of PTHREAD_KEYS_MAX would have been exceeded.

[ENOMEM]

Not enough memory to create the key.

- (but global to all functions in that thread)
- storage
Delete a thread local storage key
Main completed

API introduced: V4R3

**pthread_key_delete()**—Delete Thread Local Storage Key

Syntax:
#include <pthread.h>
int pthread_key_delete(pthread_key_t key);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The **pthread_key_delete()** function deletes a process-wide thread local storage key. The **pthread_key_delete()** function does not run any destructors for the values associated with key in any threads. After a key is deleted, it may be returned by a subsequent call to **pthread_key_create()**.

An attempt to delete a key that is out of range or not valid fails with EINVAL. An attempt to delete a valid key that has already been deleted or has not been returned from **pthread_key_create()** fails with ENOENT.

Top | "Pthread APIs," on page 102 | APIs by category
Authorities and Locks

None.

Parameters

key  (Input) The thread local storage key returned from pthread_key_create()

Return Value

0     pthread_key_delete() was successful.
value pthread_key_delete() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_key_delete() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

A destructor function is not called as a result of the application calling pthread_key_delete().

[EINVAL]

The value specified for the argument is not correct.

[ENOENT]

An entry for the key is not currently allocated.

API introduced: V4R3

pthread_kill()—Send Signal to Thread

Syntax:
#include <pthread.h>
#include <signal.h>
int pthread_kill(pthread_t thread, int sig);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_kill() function requests that the signal sig be delivered to the specified thread. The signal to be sent is specified by sig and is either zero or one of the signals from the list of defined signals in the <signal.h> header file. If sig is zero, error checking is performed, but no signal is sent to the target thread.

A thread can use pthread_kill() to send a signal to itself. If the signal is not blocked or ignored, at least one pending unblocked signal is delivered to the sender before pthread_kill() returns. If there are no other pending unblocked signals, the delivered signal is sig.

The pthread_kill() API in no way changes the effect or scope of a signal. Even though a signal can be sent to a specific thread using the pthread_kill() API, the behavior that occurs when the signal is delivered is unchanged.

For example, sending a SIGKILL signal to a thread using pthread_kill() ends the entire process, not simply the target thread. SIGKILL is defined to end the entire process, regardless of the thread it is delivered to, or how it is sent.
Authorities and Locks

None.

Parameters

thread (Input) Pthread handle of the target thread

sig (Input) The signal number to be delivered or zero to validate the pthread_t

Return Value

0 pthread_kill() was successful.

value pthread_kill() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_kill() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[ESRCH]

No thread could be found that matched the thread ID specified.

[EINVAL]

The value specified for the argument is not correct.

[ENOTSIGINIT]

The process is not enabled for signals.

API introduced: V4R3

pthread_lock_global_np()—Lock Global Mutex

Syntax:
#include <pthread.h>
int pthread_lock_global_np(void);

Service Program Name: QP0WTCBH
Default Public Authority: *USE
Threatsafe: Yes
Signal Safe: Yes

The pthread_lock_global_np() function locks a global mutex provided by the pthreads run-time. The global mutex is a recursive mutex with a name of “QP0W_GLOBAL_MTX”. The global mutex is not currently used by the pthreads run-time to serialize access to any system resources, and is provided for application use only.

The maximum number of recursive locks by the owning thread is 32,767. After which, attempts to lock the mutex will return the ERECURSE error.

Note: This function is not portable

Authorities and Locks
None.

Parameters
None.

Return Value

0  pthread_lock_global_np() was successful.
value  pthread_lock_global_np() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_lock_global_np() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

[ERECURSE]
The recursive mutex cannot be recursively locked again.
Related Information

- The `<pthread.h>` header file. See "Header files for Pthread functions" on page 254.
- "pthread_unlock-global_np()—Unlock Global Mutex" on page 225

Example

See Code disclaimer information for information pertaining to code examples.

```c
#include <pthread.h>
#include <stdio.h>
#include "check.h"

/*
 * This example shows the corruption that can result if no
 * serialization is done and also shows the use of
 * pthread_lock-global_np(). Call this test with no parameters
 * to use pthread_lock-global_np() to protect the critical data,
 * between more than one (possibly unrelated) functions.

API introduced: V4R3
The `pthread_mutexattr_destroy()` function destroys a mutex attributes object and allows the system to reclaim any resources associated with that mutex attributes object. This does not have an effect on any mutexes created using this mutex attributes object.

**Authorities and Locks**
None.

**Parameters**

attr (Input) Address of the mutex attributes object to be destroyed

**Return Value**

0 `pthread_mutexattr_destroy()` was successful.

value `pthread_mutexattr_destroy()` was not successful. value is set to indicate the error condition.

**Error Conditions**

If `pthread_mutexattr_destroy()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

**Related Information**

- The `<pthread.h>` header file. See “Header files for Pthread functions” on page 254.
- “`pthread_mutexattr_init()`—Initialize Mutex Attributes Object” on page 121—Initialize Mutex Attributes Object
- “`pthread_mutex_init()`—Initialize Mutex” on page 132—Initialize Mutex

**Example**

See Code disclaimer information for information pertaining to code examples.

```c
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_mutex_t mutex;

int main(int argc, char **argv)
{
    int rc=0;
    pthread_mutexattr_t mta;

    printf("Entering testcase\n");

    printf("Create a default mutex attribute\n");
    rc = pthread_mutexattr_init(&mta);
    checkResults("pthread_mutexattr_init\n", rc);

    printf("Create the mutex using a mutex attributes object\n");
    rc = pthread_mutex_init(&mutex, &mta);
```

Pthread APIs  111
checkResults("pthread_mutex_init(mta)\n", rc);

printf("- At this point, the mutex with its default attributes\n");
printf("- Can be used from any threads that want to use it\n");

printf("Destroy mutex attribute\n");
rc = pthread_mutexattr_destroy(&mta);
checkResults("pthread_mutexattr_destroy()\n", rc);

printf("Destroy mutex\n");
rc = pthread_mutex_destroy(&mutex);
checkResults("pthread_mutex_destroy()\n", rc);

printf("Main completed\n");
return 0;
}

Output:
Entering testcase
Create a default mutex attribute
Create the mutex using a mutex attributes object
- At this point, the mutex with its default attributes
- Can be used from any threads that want to use it
Destroy mutex attribute
Destroy mutex
Main completed

API introduced: V4R3

pthread_mutexattr_getkind_np()—Get Mutex Kind Attribute

Syntax:
#include <pthread.h>
int pthread_mutexattr_getkind_np(const pthread_mutexattr_t *attr,
    int *kind);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_mutexattr_getkind_np() function retrieves the kind attribute from the mutex attributes object specified by attr. The mutex kind attribute is used to create mutexes with different behaviors.

The kind returned is one of PTHREAD_MUTEX_NONRECURSIVE_NP or PTHREAD_MUTEX_RECURSIVE_NP.

A recursive mutex can be locked repeatedly by the owner. The mutex does not become unlocked until the owner has called pthread_mutex_unlock() for each successful lock request that it has outstanding on the mutes.

Note: This function is not portable.

Authorities and Locks
None.
Parameters

attr  (Input) Address of the mutex attributes object
kind (Output) Address of the variable to receive the kind attribute

Return Value

0   pthread_mutexattr_getkind_np() was successful.
value   pthread_mutexattr_getkind_np() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_mutexattr_getkind_np() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

Example

See Code disclaimer information for information pertaining to code examples.

```c
#include <pthread.h>
#include <stdio.h>
#include "check.h"

void showKind(pthread_mutexattr_t *mta) {
  int rc;
  int kind;

  printf("Check kind attribute\n");
  rc = pthread_mutexattr_getkind_np(mta, &kind);
  checkResults("pthread_mutexattr_getpshared()\n", rc);

  printf("The pshared attributed is: ");
  switch (kind) {
    case PTHREAD_MUTEX_NONRECURSIVE_NP:
      printf("PTHREAD_MUTEX_NONRECURSIVE_NP\n");
      break;
    case PTHREAD_MUTEX_RECURSIVE_NP:
      printf("PTHREAD_MUTEX_RECURSIVE_NP\n");
      break;
    default:
      printf("! kind Error kind=%d !\n", kind);
      exit(1);
  }
  return;
}

int main(int argc, char **argv)
{
  int rc=0;
  pthread_mutexattr_t mta;
```
int pshared=0;

printf("Enter Testcase - *s\n", argv[0]);

printf("Create a default mutex attribute\n");
rc = pthread_mutexattr_init(&mta);
checkResults("pthread_mutexattr_init()\n", rc);
showKind(&mta);

printf("Change mutex kind attribute\n");
rc = pthread_mutexattr_setkind_np(&mta, PTHREAD_MUTEX_RECURSIVE_NP);
checkResults("pthread_mutexattr_setkind()\n", rc);
showKind(&mta);

printf("Destroy mutex attribute\n");
rc = pthread_mutexattr_destroy(&mta);
checkResults("pthread_mutexattr_destroy()\n", rc);

printf("Main completed\n");
return 0;
}

Output:
Enter Testcase - QP0WTEST/TPMTXAKNO
Create a default mutex attribute
Check kind attribute
The pshared attributed is:
PTHREAD_MUTEX_NONRECURSIVE_NP

Main completed

API introduced: V4R3

pthread_mutexattr_getname_np()—Get Name from Mutex Attributes Object

Syntax:
#include <pthread.h>
int pthread_mutexattr_getname_np(const pthread_mutexattr_t *attr, char *name);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_mutexattr_getname_np() function retrieves the name attribute associated with the mutex attribute specified by attr. The buffer specified by name must be at least 16 characters in length. If the length of the mutex name is less than or equal to 15 characters, it is null terminated in the output buffer.

By default, each pthread_mutex_t has the name “QP0WMTX UNNAMED” associated with it. The name attribute is used by various i5/OS system utilities to aid in debugging and service. One example is the WRKJOB command, which has a ‘work with mutexes’ menu choice to show which mutexes are currently locked and which mutexes are being waited for.
If you should give unique names to all mutexes created to aid in debugging deadlock or performance problems. Use the CL command **WRKJOB**, option 20, to help debug mutex deadlocks.

**Authorities and Locks**
None.

**Parameters**
- **attr** (Input) Address of the mutex attributes object
- **name** (Output) Address of a 16-byte character buffer to receive the name

**Return Value**
- **0** `pthread_mutexattr_getname_np()` was successful.
- **value** `pthread_mutexattr_getname_np()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**
If `pthread_mutexattr_getname_np()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

*EINV VAL*

The value specified for the argument is not correct.

API introduced: V4R3

pthread_mutexattr_getpshared()—Get Process Shared Attribute from Mutex Attributes Object

Syntax:
#include <pthread.h>
int pthread_mutexattr_getpshared(const pthread_mutexattr_t *attr, int *pshared);

Service Program Name: QP0WPTHR
Default Public Authority: USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_mutexattr_getpshared() function retrieves the current setting of the process shared attribute from the mutex attributes object. The process shared attribute indicates whether the mutex that is created using the mutex attributes object can be shared between threads in separate processes (PTHREAD_PROCESS_SHARED) or shared between threads within the same process (PTHREAD_PROCESS_PRIVATE).

Even if the mutex in storage is accessible from two separate processes, it cannot be used from both processes unless the process shared attribute is PTHREAD_PROCESS_SHARED.

The default pshared attribute for mutex attributes objects is PTHREAD_PROCESS_PRIVATE.

Authorities and Locks
None.
Parameters
attr  (Input) Address of the variable that contains the mutex attributes object
pshared  (Output) Address of the variable to contain the pshared attribute result

Return Value
0  pthread_mutexattr_getpshared() was successful.
value  pthread_mutexattr_getpshared() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_mutexattr_getpshared() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.
[EINVAL]

* The value specified for the argument is not correct.

Main completed

API introduced: V4R3

pthread_mutexattr_gettype()—Get Mutex Type Attribute

Syntax:
#include <pthread.h>
int pthread_mutexattr_gettype(const pthread_mutexattr_t *attr,
   int *type);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_mutexattr_gettype() function retrieves the type attribute from the mutex attributes object specified by attr. The mutex type attribute is used to create mutexes with different behaviors.

The type returned is one of PTHREAD_MUTEX_DEFAULT, PTHREAD_MUTEX_NORMAL,
PTHREAD_MUTEX_RECURSIVE, PTHREAD_MUTEX_ERRORCHECK, or
PTHREAD_MUTEX.OwnerTerm_NP.

The default mutex type (or PTHREAD_MUTEX_DEFAULT) is PTHREAD_MUTEX_NORMAL.

Mutex Types

A normal mutex cannot be locked repeatedly by the owner. Attempts by a thread to relock an already held mutex, or to lock a mutex that was held by another thread when that thread terminated, cause a deadlock condition.
A recursive mutex can be locked repeatedly by the owner. The mutex does not become unlocked until the owner has called `pthread_mutex_unlock()` for each successful lock request that it has outstanding on the mutex.

An errorcheck mutex checks for deadlock conditions that occur when a thread relocks an already held mutex. If a thread attempts to relock a mutex that it already holds, the lock request fails with the `EDEADLK` error.

An ownerterm mutex is an i5/OS extension to the errorcheck mutex type. An ownerterm mutex checks for deadlock conditions that occur when a thread relocks an already held mutex. If a thread attempts to relock a mutex that it already holds, the lock request fails with the `EDEADLK` error. An ownerterm mutex also checks for deadlock conditions that occur when a thread attempts to lock a mutex that was held by another thread when that thread terminated (an orphaned mutex). If a thread attempts to lock an orphaned mutex, the lock request fails with the `EOWNERTERM` error.

**Authorities and Locks**

None.

**Parameters**

- `attr` (Input) Address of the mutex attributes object
- `type` (Output) Address of the variable to receive the type attribute

**Return Value**

- `0` `pthread_mutexattr_gettype()` was successful.
- `value` `pthread_mutexattr_gettype()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**

If `pthread_mutexattr_gettype()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

- `EINVAL`
  
  The value specified for the argument is not correct.

API introduced: V4R3

pthread_mutexattr_init()—Initialize Mutex Attributes Object

Syntax:
#include <pthread.h>
int pthread_mutexattr_init(pthread_mutexattr_t *attr);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes
The `pthread_mutexattr_init()` function initializes the mutex attributes object referenced by `attr` to the default attributes. The mutex attributes object can be used in a call to `pthread_mutex_init()` to create a mutex.

**Authorities and Locks**

None.

**Parameters**

attr  (Input/Output) Address of the variable to contain the mutex attributes object

**Return Value**

0  `pthread_mutexattr_init()` was successful.

value  `pthread_mutexattr_init()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**

If `pthread_mutexattr_init()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

**[EINVAL]**

The value specified for the argument is not correct.

pthread_mutexattr_setkind_np()—Set Mutex Kind Attribute

Syntax:
#include <pthread.h>
int pthread_mutexattr_setkind_np(pthread_mutexattr_t *attr,
int kind);

Service Program Name: QP0WPTHR
Default Public Authority: USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_mutexattr_setkind_np() function sets the kind attribute in the mutex attributes object specified by attr. The mutex kind attribute is used to create mutexes with different behaviors.

The kind set may be one of PTHREAD_MUTEX_NONRECURSIVE_NP or PTHREAD_MUTEX_RECURSIVE_NP.

A recursive mutex can be locked repeatedly by the owner. The mutex does not become unlocked until the owner has called pthread_mutex_unlock() for each successful lock request that it has outstanding on the mutex. The maximum number of recursive locks by the owning thread is 32,767.

Note: This function is not portable

Authorities and Locks
None.

Parameters
attr (Input) Address of the mutex attributes object
kind (Input) Variable containing the kind attribute.
Return Value

0  pthread_mutexattr_setkind_np() was successful.
value  pthread_mutexattr_setkind_np() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_mutexattr_setkind_np() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

Example

See Code disclaimer information for information pertaining to code examples.

```c
#include <pthread.h>
#include <stdio.h>
#include "check.h"

void showKind(pthread_mutexattr_t *mta) {
    int rc;
    int kind;

    printf("Check kind attribute\n");
    rc = pthread_mutexattr_getkind_np(mta, &kind);
    checkResults("pthread_mutexattr_getpshared()\n", rc);

    printf("The pshared attributed is: ");
    switch (kind) {
    case PTHREAD_MUTEX_NONRECURSIVE_NP:
        printf("PTHREAD_MUTEX_NONRECURSIVE_NP\n");
        break;
    case PTHREAD_MUTEX_RECURSIVE_NP:
        printf("PTHREAD_MUTEX_RECURSIVE_NP\n");
        break;
    default:
        printf("! kind Error kind=%d !\n", kind);
        exit(1);
    }
    return;
}

int main(int argc, char **argv) {
    int rc=0;
    pthread_mutexattr_t mta;
    int pshared=0;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Create a default mutex attribute\n");
    rc = pthread_mutexattr_init(&mta);
    checkResults("pthread_mutexattr_init()\n", rc);
    showKind(&mta);
    return rc;
}
```

124  IBM Systems - iSeries: Pthread APIs
printf("Change mutex kind attribute\n");
rc = pthread_mutexattr_setkind_np(&mta, PTHREAD_MUTEX_RECURSIVE_NP);
checkResults("pthread_mutexattr_setkind()\n", rc);
showKind(&mta);

printf("Destroy mutex attribute\n");
rc = pthread_mutexattr_destroy(&mta);
checkResults("pthread_mutexattr_destroy()\n", rc);

printf("Main completed\n");
return 0;
}

Output:
Enter Testcase - QP0WTEST/TPMTEXAKN0
Create a default mutex attribute
Check kind attribute
The pshared attributed is:
PTHREAD_MUTEX_NONRECURSIVE_NP
Change mutex kind attribute
Check kind attribute

pthread_mutexattr_setname_np()—Set Name in Mutex Attributes Object

Syntax:
#include <pthread.h>
int pthread_mutexattr_setname_np(pthread_mutexattr_t *attr, const char *name);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threading Safe: Yes
Signal Safe: Yes

The `pthread_mutexattr_setname_np()` function changes the name attribute associated with the mutex attribute specified by `attr`. The buffer specified by `name` must contain a null terminated string of 15 characters or less in length (not including the NULL). If the length of `name` is greater than 15 characters, the excess characters are ignored. If `name` is null, the mutex name attribute is reset to the default.

By default, each pthread_mutex_t has the name “QP0WMTX UNNAMED” associated with it. The name attribute is used by various i5/OS system utilities to aid in debug and service. One example is the WRKJOB command, which has a ‘work with mutexes’ menu choice to show which mutexes are currently locked and which mutexes are being waited for.

If you should give unique names to all mutexes created to aid in debugging deadlock or performance problems. Use the CL command WRKJOB, option 20, to help debug mutex deadlocks.

Note: This function is not portable.
Authorities and Locks
None.

Parameters
attr  (Input) Address of the mutex attributes object
name  (Input) Address of a null terminated character buffer containing the name

Return Value
0     pthread_mutexattr_setname_np() was successful.
value pthread_mutexattr_setname_np() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_mutexattr_setname_np() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

Related Information

• "pthread_mutexattr_getname_np()—Get Name from Mutex Attributes Object” on page 114—Get Name from Mutex Attributes Object
• “pthread_mutex_init()—Initialize Mutex” on page 132—Initialize Mutex

Example
See Code disclaimer information for information pertaining to code examples.

```c
#include <pthread.h>
#include <stdio.h>
#include "check.h"

int main(int argc, char **argv)
{
    int rc=0;
    pthread_mutexattr_t mta;
    char mutexname[16];

    printf("Entering testcase\n");

    printf("Create a default mutex attribute\n");
    rc = pthread_mutexattr_init(&mta);
    checkResults("pthread_mutexattr_init\n", rc);

    memset(mutexname, 0, sizeof(mutexname));
    printf("Find out what the default name of the mutex is\n");
    rc = pthread_mutexattr_getname_np(&mta, mutexname);
    checkResults("pthread_mutexattr_getname_np\n", rc);

    printf("The default mutex name will be: %.15s\n", mutexname);
    printf(" At this point, mutexes created with this attribute\n");
    printf(" will show up by name on many i5/OS debug and service screens\n");
    printf(" The default attribute contains a special automatically\n");
    printf(" incrementing name that changes for each mutex created in \n");
    printf(" the process\n");
```
printf("Destroy mutex attribute\n");
rc = pthread_mutexattr_destroy(&mta);
checkResults("pthread_mutexattr_destroy()\n", rc);
printf("Main completed\n");
return 0;
}

Output:
Entering testcase
Create a default mutex attribute
Find out what the default name of the mutex is
The default mutex name will be: QP0WMTX UNNAMED
The new mutex name will be: <My Mutex>
Destroy mutex attribute
Main completed

API introduced: V4R3

pthread_mutexattr_setpshared()—Set Process Shared Attribute in Mutex Attributes Object

Syntax:
#include <pthread.h>
int pthread_mutexattr_setpshared(pthread_mutexattr_t *attr,
int pshared);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_mutexattr_setpshared() function sets the current pshared attribute for the mutex attributes object. The process shared attribute indicates whether the mutex that is created using the mutex attributes object can be shared between threads in separate processes (PTHREAD_PROCESS_SHARED) or shared between threads within the same process (PTHREAD_PROCESS_PRIVATE).

Even if the mutex in storage is accessible from two separate processes, it cannot be used from both processes unless the process shared attribute is PTHREAD_PROCESS_SHARED.

The default pshared attribute for mutex attributes objects is PTHREAD_PROCESS_PRIVATE.

Authorities and Locks
None.

Parameters
attr (Input) Address of the variable containing the mutex attributes object
pshared (Input) One of PTHREAD_PROCESS_SHARED or PTHREAD_PROCESS_PRIVATE

Return Value
0 pthread_mutexattr_setpshared() was successful.
value  pthread_mutexattr_setpshared() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_mutexattr_setpshared() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVVAL]

The value specified for the argument is not correct.

Related Information
- The <pthread.h> header file. See "Header files for Pthread functions" on page 254.
- "pthread_mutex_init()—Initialize Mutex" on page 132—Initialize Mutex

Example
See Code disclaimer information for information pertaining to code examples.

```c
#include <pthread.h>
#include <stdio.h>
#include "check.h"

void showPshared(pthread_mutexattr_t *mta) {
    int rc;
    int pshared;

    printf("Check pshared attribute\n");
    rc = pthread_mutexattr_getpshared(mta, &pshared);
    checkResults("pthread_mutexattr_getpshared()\n", rc);

    printf("The pshared attributed is: ");
    switch (pshared) {
    case PTHREAD_PROCESS_PRIVATE:
        printf("PTHREAD_PROCESS_PRIVATE\n");
        break;
    case PTHREAD_PROCESS_SHARED:
        printf("PTHREAD_PROCESS_SHARED\n");
        break;
    default :
        printf("! pshared Error \n\n");
        exit(1);
    }
    return;
}

int main(int argc, char **argv) {
    int rc=0;
    pthread_mutexattr_t mta;
    int pshared=0;

    printf("Entering testcase\n");

    printf("Create a default mutex attribute\n");
    rc = pthread_mutexattr_init(&mta);
    checkResults("pthread_mutexattr_init()\n", rc);
    showPshared(&mta);

    printf("Change pshared attribute\n");
    rc = pthread_mutexattr_setpshared(&mta, PTHREAD_PROCESS_SHARED);
    checkResults("pthread_mutexattr_setpshared()\n", rc);
```

128  IBM Systems - iSeries: Pthread APIs
showPshared(&mta);

printf("Destroy mutex attribute\n");
rc = pthread_mutexattr_destroy(&mta);
checkResults("pthread_mutexattr_destroy()\n", rc);

printf("Main completed\n");
return 0;

}
An ownerterm mutex is an i5/OS extension to the errorcheck mutex type. An ownerterm mutex checks for deadlock conditions that occur when a thread re-locks an already held mutex. If a thread attempts to relock a mutex that it already holds, the lock request fails with the EDEADLK error. An ownerterm mutex also checks for deadlock conditions that occur when a thread attempts to lock a mutex that was held by another thread when that thread terminated (an orphaned mutex). If a thread attempts to lock an orphaned mutex, the lock request fails with the EOWNERTERM error.

**Authorities and Locks**
None.

**Parameters**

attr  (Input) Address of the mutex attributes object  
type  (Input) Address of the type attribute to be set.

**Return Value**

0     pthread_mutexattr_settype() was successful.  
value  pthread_mutexattr_settype() was not successful. value is set to indicate the error condition.

**Error Conditions**

If pthread_mutexattr_settype() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]  
The value specified for the argument is not correct.

API introduced: V4R3

---

### pthread_mutex_destroy()—Destroy Mutex

**Syntax:**

```c
#include <pthread.h>  
int pthread_mutex_destroy(pthread_mutex_t *mutex);
```

**Service Program Name:** QP0WPTHR  
**Default Public Authority:** *USE  
**Threadsafe:** Yes  
**Signal Safe:** Yes
The `pthread_mutex_destroy()` function destroys the named mutex. The destroyed mutex can no longer be used.

If `pthread_mutex_destroy()` is called on a mutex that is locked by another thread, the request fails with an **EBUSY** error. If the calling thread has the mutex locked, any other threads waiting for the mutex using a call to `pthread_mutex_lock()` at the time of the call to `pthread_mutex_destroy()` fails with the **EDESTROYED** error.

Mutex initialization using the **PTHREAD_MUTEX_INITIALIZER** does not immediately initialize the mutex. Instead, on first use, `pthread_mutex_lock()` or `pthread_mutex_trylock()` branches into a slow path and causes the initialization of the mutex. Because a mutex is not just a simple memory object and requires that some resources be allocated by the system, an attempt to call `pthread_mutex_destroy()` or `pthread_mutex_unlock()` on a mutex that has statically initialized using `PTHREAD_MUTEX_INITIALIZER` and was not yet locked causes an **EINVAL** error.

Every mutex must eventually be destroyed with `pthread_mutex_destroy()`. The machine eventually detects the error if a mutex is not destroyed, but the storage is deallocated or corrupted. The machine then creates LIC log synchronization entries that indicate the failure to help debug the problem. Large numbers of these entries can affect system performance and hinder debug capabilities for other system problems. Always use `pthread_mutex_destroy()` before freeing mutex storage to prevent these debug LIC log entries.

**Note:** Once a mutex is created, it cannot be validly copied or moved to a new location.

**Authorities and Locks**

None.

**Parameters**

`mutex`  (Input)  Address of the mutex to be destroyed

**Return Value**

0  `pthread_mutex_destroy()` was successful.

`value`  `pthread_mutex_destroy()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**

If `pthread_mutex_destroy()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

**[EBUSY]**

The mutex is currently owned by another thread.

**[EINVAL]**

The value specified for the argument is not correct.

**Related Information**

- The `<pthread.h>` header file. See “Header files for Pthread functions” on page 254
- “`pthread_mutex_init()`—Initialize Mutex” on page 132—Initialize Mutex
- “`pthread_mutex_lock()`—Lock Mutex” on page 135—Lock Mutex
- “`pthread_mutex_trylock()`—Lock Mutex with No Wait” on page 142—Lock Mutex with No Wait
- “`pthread_mutex_unlock()`—Unlock Mutex” on page 146—Unlock Mutex
Example
See Code disclaimer information for information pertaining to code examples.

```c
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_mutex_t mutex;

int main(int argc, char **argv)
{
    int rc=0;
pthread_mutexattr_t mta;

    printf("Entering testcase\n");
    printf("Create the mutex using the NULL attributes (default)\n");
    rc = pthread_mutex_init(&mutex, NULL);
    checkResults("pthread_mutex_init(NULL)\n", rc);

    printf("Destroy all mutexes\n");
    pthread_mutex_destroy(&mutex);
    checkResults("pthread_mutex_destroy()\n", rc);

    printf("Main completed\n");
    return 0;
}
```

Output:
Entering testcase
Create the mutex using the NULL attributes (default)
Destroy all mutexes
Main completed

API introduced: V4R3

### pthread_mutex_init()—Initialize Mutex

**Syntax:**

```c
#include <pthread.h>
int pthread_mutex_init(pthread_mutex_t *mutex,
                        const pthread_mutexattr_t *attr);
```

**Service Program Name:** QP0WPTH

**Default Public Authority:** USE

**Threadsafe:** Yes

**Signal Safe:** Yes

The `pthread_mutex_init()` function initializes a mutex with the specified attributes for use. The new mutex may be used immediately for serializing critical resources. If `attr` is specified as NULL, all attributes are set to the default mutex attributes for the newly created mutex.

With these declarations and initialization:
The following three mutex initialization mechanisms have equivalent function.

```c
pthread_mutex_t mutex2;
pthread_mutex_t mutex3;
pthread_mutexattr_t mta;
pthread_mutexattr_init(&mta);
```

All three mutexes are created with the default mutex attributes.

Every mutex must eventually be destroyed with `pthread_mutex_destroy()`. The machine eventually detects the error if a mutex is not destroyed. Large numbers of these entries can affect system performance. Always use `pthread_mutex_destroy()` before freeing or reusing mutex storage.

Once a mutex is created, it cannot be validly copied or moved to a new location. If the mutex is copied or moved to a new location, the new object is not valid and cannot be used. Attempts to use the new object result in the EINVAL error.

**Note:** Mutex initialization using the `PTHREAD_MUTEX_INITIALIZER` does not immediately initialize the mutex. Instead, on first use, the `pthread_mutex_lock()` or `pthread_mutex_trylock()` functions branch into a slow path and cause the initialization of the mutex. Because a mutex is not just a simple memory object and requires that some resources be allocated by the system, an attempt to call `pthread_mutex_destroy()` or `pthread_mutex_unlock()` on a mutex that was statically initialized using `PTHREAD_MUTEX_INITIALIZER` and was not yet locked causes an EINVAL error.

### Authorities and Locks

None.

### Parameters

- **mutex** (Input) The address of the variable to contain a mutex object.
- **attr** (Input) The address of the variable containing the mutex attributes object.

### Return Value

- **0** `pthread_mutex_init()` was successful.
- **value** `pthread_mutex_init()` was not successful. `value` is set to indicate the error condition.

### Error Conditions

If `pthread_mutex_init()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

- **[EINVAL]**

  The value specified for the argument is not correct.

- **[ENOMEM]**

  The system cannot allocate the resources required to create the mutex.

### Related Information

- The `<pthread.h>` header file. See "Header files for Pthread functions" on page 254.
- "`pthread_mutex_destroy()`—Destroy Mutex" on page 130—Destroy Mutex
Example

See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_mutex_t mutex = PTHREAD_MUTEX_INITIALIZER;
pthread_mutex_t mutex2;
pthread_mutex_t mutex3;

int main(int argc, char **argv)
{
    int rc=0;
    pthread_mutexattr_t mta;

    printf("Enter Testcase - %s\n", argv[0]);
    printf("Create a default mutex attribute\n");
    rc = pthread_mutexattr_init(&mta);
    checkResults("pthread_mutexattr_init\n", rc);

    printf("Create the mutexes using the default mutex attributes\n");
    printf("First mutex created via static PTHREAD_MUTEX_INITIALIZER\n");
    printf("Create the mutex using the NULL attributes (default)\n");
    rc = pthread_mutex_init(&mutex3, NULL);
    checkResults("pthread_mutex_init(NULL)\n", rc);

    printf("Create the mutex using a mutex attributes object\n");
    rc = pthread_mutex_init(&mutex2, &mta);
    checkResults("pthread_mutex_init(mta)\n", rc);

    printf("- At this point, all mutexes can be used with their\n");
    printf("- default attributes from any threads that want to\n");
    printf("- use them\n");

    printf("Destroy all mutexes\n");
    pthread_mutex_destroy(&mutex);
    pthread_mutex_destroy(&mutex2);
    pthread_mutex_destroy(&mutex3);

    printf("Main completed\n");
    return 0;
}
```

Output:
Enter Testcase - QP0WTEST/TPMTXIN0
Create a default mutex attribute
Create the mutexes using the default mutex attributes
First mutex created via static PTHREAD_MUTEX_INITIALIZER
Create the mutex using the NULL attributes (default)
Create the mutex using a mutex attributes object
- At this point, all mutexes can be used with their
- default attributes from any threads that want to
- use them
Destroy all mutexes
Main completed
The EDEADLK mutex.

A deadlock held Mutex attempts
the construct.

Mutexes. A initialized attempt
pthread_mutex_trylock mutex.

Mutex the initialization
is introduced:
int introduced:
pthread_mutex_lock(pthread_mutex_t *mutex);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_mutex_lock() function acquires ownership of the mutex specified. If the mutex currently is
locked by another thread, the call to pthread_mutex_lock() blocks until that thread relinquishes
ownership by a call to pthread_mutex_unlock().

If a signal is delivered to a thread while that thread is waiting for a mutex, when the signal handler
returns, the wait resumes. pthread_mutex_lock() does not return EINTR like some other blocking
function calls.

Use the CL command WRKJOB, option 20, to help you debug mutex deadlocks.

Destroying a held mutex is a common way to serialize destruction of objects that are protected by that
mutex. This action is allowed. The call to pthread_mutex_lock() may fail with the EDESTROYED error if the
mutex is destroyed by the thread that was currently holding it.

Mutex initialization using the PTHREAD_MUTEX_INITIALIZER does not immediately initialize the
mutex. Instead, on first use, pthread_mutex_timedlock_np() or pthread_mutex_lock() or
pthread_mutex_trylock() branches into a slow path and causes the initialization of the mutex. Because a
mutex is not just a simple memory object and requires that some resources be allocated by the system, an
attempt to call pthread_mutex_destroy() or pthread_mutex_unlock() on a mutex that was statically
initialized using PTHREAD_MUTEX_INITIALIZER and was not yet locked causes an EINVAL error.

A pthread mutex is a structure of type pthread_mutex_t that implement a behavior based on the Pthread
mutexes. An MI mutex is a structure built into the machine that implement a similar sort of serialization
construct.

The maximum number of recursive locks by the owning thread is 32,767. When this number is exceeded,
attempt to lock the mutex return the ERECURSE error.

**Mutex Types**

A normal mutex cannot be locked repeatedly by the owner. Attempts by a thread to relock an already
held mutex, or to lock a mutex that was held by another thread when that thread terminated, result in a
deadlock condition.

A recursive mutex can be locked repeatedly by the owner. The mutex does not become unlocked until the
owner has called pthread_mutex_unlock() for each successful lock request that it has outstanding on the
mutex.

An error check mutex checks for deadlock conditions that occur when a thread relocks an already held
mutex. If a thread attempts to relock a mutex that it already holds, the lock request fails with the
EDEADLK error.
An ownerterm mutex is an i5/OS extension to the errorcheck mutex type. An ownerterm mutex checks for deadlock conditions that occur when a thread relocks an already held mutex. If a thread attempts to relock a mutex that it already holds, the lock request fails with the EDEADLK error. An ownerterm mutex also checks for deadlock conditions that occur when a thread attempts to lock a mutex that was held by another thread when that thread terminated (an orphaned mutex). If a thread attempts to lock an orphaned mutex, the lock request fails with the EOWNERTERM error.

When a thread terminates while holding a mutex lock on a normal or errorcheck mutex, other threads that wait for that mutex will block forever. The pthreads run-time simulates the deadlock that has occurred in your application. When you are attempting to debug these deadlock scenarios, the CL command WRKJOB, option 20 shows the thread as in a condition wait. Displaying the call stack shows that the function `deadlockOnOrphanedMutex` is in the call stack.

When a thread attempts to acquire a normal mutex that it already holds, the thread will block forever. The pthreads run-time simulates the deadlock that has occurred in your application. When you are attempting to debug these deadlock scenarios, the CL command WRKJOB, option 20, shows the thread as in a condition wait. Displaying the call stack will show that the function `deadlockOnAlreadyHeldMutex` is in the call stack.

To change these behaviors, use an errorcheck or ownerterm mutex type.

**Authorities and Locks**
None.

**Parameters**

`mutex` (Input) The address of the mutex to lock

**Return Value**

0       `pthread_mutex_lock()` was successful.

Value `pthread_mutex_lock()` was not successful. Value is set to indicate the error condition.

**Error Conditions**

If `pthread_mutex_lock()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

[EDESTROYED]

While waiting for the mutex lock to be satisfied, the mutex was destroyed.

[EOWNERTERM]

A thread terminated the holding of the mutex, and the mutex is an ownerterm mutex type.

[EDEADLK]

A thread attempted to relock an already held mutex, and the mutex is an errorcheck mutex type.

[ERECURSE]

The recursive mutex cannot be recursively locked again.

API introduced: V4R3
**pthread_mutex_timedlock_np()—Lock Mutex with Time-Out**

Syntax:
```c
#include <pthread.h>
#include <time.h>
int pthread_mutex_timedlock_np(pthread_mutex_t *mutex,
    const struct timespec *deltatime);
```

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The `pthread_mutex_timedlock_np()` function acquires ownership of the `mutex` specified. If the mutex is currently locked by another thread, the call to `pthread_mutex_timedlock_np()` will block until the specified `deltatime` has elapsed or the holding thread relinquishes ownership by a call to `pthread_mutex_unlock()`.

Performing a `pthread_mutex_timedlock_np()` wait for a mutex has different semantics related to signal handling than the `pthread_mutex_lock()` function. If a signal is delivered to a thread while that thread is performing a timed wait for a mutex, the signal is held pending until either the mutex is acquired or the time-out occurs. At that time the signal handler will run, when the signal handler returns, `pthread_mutex_timedlock_np()` will return the results of the timed mutex wait.

Use the CL command WRKJOB, option 20 for a screen that will aid in debugging mutex deadlocks.

Destroying a held mutex is a common way to serialize destruction of objects that are protected by that mutex, and is allowed. The call to `pthread_mutex_timedlock_np()` may fail with the **EDESTROYED** error if the mutex is destroyed by the thread that was currently holding it.

Note that mutex initialization using the `PTHREAD_MUTEX_INITIALIZER` does not immediately initialize the mutex. Instead, on first use, `pthread_mutex_timedlock_np()`, `pthread_mutex_lock()` or `pthread_mutex_trylock()` branches into a slow path and causes the initialization of the mutex. Because a mutex is not just a simple memory object, and requires that some resources be allocated by the system, an attempt to call `pthread_mutex_destroy()` or `pthread_mutex_unlock()` on a mutex that has was statically initialized using `PTHREAD_MUTEX_INITIALIZER` and was not yet locked will result in an **EINVAL** error.

A pthread mutex is a structure of type `pthread_mutex_t` that implement a behavior based on the PThread mutexes. An MI mutex is a structure built into the machine that implement a similar sort of serialization construct.

The maximum number of recursive locks by the owning thread is 32,767. After which, attempts to lock the mutex will return the **ERECURSE** error.

**Note:** This function is not portable

**Mutex Types**

A normal mutex cannot be locked repeatedly by the owner. Attempts by a thread to relock an already held mutex, or to lock a mutex that was held by another thread when that thread terminated result in a deadlock condition.

A recursive mutex can be locked repeatedly by the owner. The mutex does not become unlocked until the owner has called `pthread_mutex_unlock()` for each successful lock request that it has outstanding on the mutex.
An errorcheck mutex checks for deadlock conditions that occur when a thread re-locks an already held mutex. If a thread attempts to relock a mutex that it already holds, the lock request fails with the EDEADLK error.

An ownerterm mutex is an i5/OS extension to the errorcheck mutex type. An ownerterm mutex checks for deadlock conditions that occur when a thread re-locks an already held mutex. If a thread attempts to relock a mutex that it already holds, the lock request fails with the EDEADLK error. An ownerterm mutex also checks for deadlock conditions that occur when a thread attempts to lock a mutex that was held by another thread when that thread terminated (an orphaned mutex). If a thread attempts to lock an orphaned mutex, the lock request fails with the EOWNERTERM error.

When a thread terminates while holding a mutex lock on a normal or errorcheck mutex, other threads that wait for that mutex will block forever, or until the specified deltatime has elapsed. The pthreads run-time simulates the deadlock that has occurred in your application. When attempting to debug these deadlock scenarios, the CL command WRKJOB, option 20 will show the thread as in a condition wait. Displaying the call stack will show that the function deadlockOnOrphanedMutex or timedDeadlockOnOrphanedMutex is in the call stack.

When a thread attempts to acquire a normal mutex that it already holds, the thread will block forever, or until the specified deltatime has elapsed. The pthreads run-time simulates the deadlock that has occurred in your application. When attempting to debug these deadlock scenarios, the CL command WRKJOB, option 20 will show the thread as in a condition wait. Displaying the call stack will show that the function deadlockOnAlreadyHeldMutex or timedDeadlockOnAlreadyHeldMutex is in the call stack.

In order to change these behaviors, use an errorcheck or ownerterm mutex type.

**Authorities and Locks**

None.

**Parameters**

mutex (Input) The address of the mutex to lock

**Return Value**

0  pthread_mutex_timedlock_np() was successful.

value  pthread_mutex_timedlock_np() was not successful. value is set to indicate the error condition.

**Error Conditions**

If pthread_mutex_timedlock_np() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

[EDESTROYED]

While waiting for the mutex lock to be satisfied, the mutex was destroyed.

[EBUSY]

The attempt to lock the mutex timed out because the mutex was already locked.

[EOWNERTERM]

A thread terminated holding the mutex, and the mutex is an ownerterm mutex type.
A thread attempted to relock an already held mutex, and the mutex is an errorcheck mutex type.

The recursive mutex cannot be recursively locked again.

Example

See Code disclaimer information for information pertaining to code examples.

```c
#define __MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_mutex_t mutex = PTHREAD_MUTEX_INITIALIZER;

void *threadFunc(void *parm)
{
    int rc;
    int i;
    struct timespec deltatime;

    deltatime.tv_sec = 5;
    deltatime.tv_nsec = 0;

    printf("Timed lock the mutex from a secondary thread\n");
    rc = pthread_mutex_timedlock_np(&mutex, &deltatime);
    if (rc != EBUSY) {
        printf("Got an incorrect return code from pthread_mutex_timedlock_np\n");
    }
    printf("Thread mutex timeout\n");
    return 0;
}

int main(int argc, char **argv)
{
    int rc=0;
    pthread_t thread;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Acquire the mutex in the initial thread\n");
    rc = pthread_mutex_lock(&mutex);
    checkResults("pthread_mutex_lock\n", rc),

    printf("Create a thread\n");
    rc = pthread_create(&thread, NULL, threadFunc, NULL);
    checkResults("pthread_create\n", rc);

    printf("Join to the thread\n");
    rc = pthread_join(thread, NULL);
    checkResults("pthread_join\n", rc);

    return rc;
}
```

Pthread APIs 141
printf("Destroy mutex
");
pthread_mutex_destroy(&mutex);
printf("Main completed
");
return 0;
}

#include "pthreads.h"
int pthread_mutex_trylock(pthread_mutex_t *mutex);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_mutex_trylock() function attempts to acquire ownership of the mutex specified without blocking the calling thread. If the mutex is currently locked by another thread, the call to pthread_mutex_trylock() returns an error of EBUSY.

A failure of EDEADLK indicates that the mutex is already held by the calling thread.

Mutex initialization using the PTHREAD_MUTEX_INITIALIZER does not immediately initialize the mutex. Instead, on first use, pthread_mutex_timedlock_np() or pthread_mutex_lock() or pthread_mutex_trylock() branches into a slow path and causes the initialization of the mutex. Because a mutex is not just a simple memory object and requires that some resources be allocated by the system, an attempt to call pthread_mutex_destroy() or pthread_mutex_unlock() on a mutex that was statically initialized using PTHREAD_MUTEX_INITIALIZER and was not yet locked causes an EINVAL error.

The maximum number of recursive locks by the owning thread is 32,767. When this number is exceeded, attempts to lock the mutex return the ERECURSE error.

Mutex Types
A normal mutex cannot be locked repeatedly by the owner. Attempts by a thread to relock an already held mutex, or to lock a mutex that was held by another thread when that thread terminated, cause a deadlock condition.

A recursive mutex can be locked repeatedly by the owner. The mutex does not become unlocked until the owner has called pthread_mutex_unlock() for each successful lock request that it has outstanding on the mutex.
An errorcheck mutex checks for deadlock conditions that occur when a thread relocks an already held mutex. If a thread attempts to relock a mutex that it already holds, the lock request fails with the EDEADLK error.

An ownerterm mutex is an i5/OS extension to the errorcheck mutex type. An ownerterm mutex checks for deadlock conditions that occur when a thread relocks an already held mutex. If a thread attempts to relock a mutex that it already holds, the lock request fails with the EDEADLK error. An ownerterm mutex also checks for deadlock conditions that occur when a thread attempts to lock a mutex that was held by another thread when that thread terminated (an orphaned mutex). If a thread attempts to lock an orphaned mutex, the lock request fails with the EOWNERTERM error.

When a thread terminates while holding a mutex lock on a normal or errorcheck mutex, other threads that wait for that mutex will block forever. The pthreads run-time simulates the deadlock that has occurred in your application. When you are attempting to debug these deadlock scenarios, the CL command WRKJOB, option 20, shows the thread as in a condition wait. Displaying the call stack shows that the function deadlockOnOrphanedMutex is in the call stack.

API introduced: V4R3

pthread_mutex_unlock()—Unlock Mutex

Syntax:
#include <pthread.h>
int pthread_mutex_unlock(pthread_mutex_t *mutex);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_mutex_unlock() function unlocks the mutex specified. If the calling thread does not currently hold the mutex (via a previous call to pthread_mutex_lock(), pthread_mutex_trylock(), or pthread_mutex_timedlock_np()) the unlock request fails with the EPERM error.

Mutex initialization using the PTHREAD_MUTEX_INITIALIZER does not immediately initialize the mutex. Instead, on first use, pthread_mutex_timedlock_np() or pthread_mutex_lock() or pthread_mutex_trylock() branches into a slow path and causes the initialization of the mutex. Because a mutex is not just a simple memory object and requires that some resources be allocated by the system, an attempt to call pthread_mutex_destroy() or pthread_mutex_unlock() on a mutex that was statically initialized using PTHREAD_MUTEX_INITIALIZER and was not yet locked causes an EINVAL error.

Mutex Types
A normal mutex cannot be locked repeatedly by the owner. Attempts by a thread to relock an already held mutex, or to lock a mutex that was held by another thread when that thread terminated, cause a deadlock condition.

A recursive mutex can be locked repeatedly by the owner. The mutex does not become unlocked until the owner has called pthread_mutex_unlock() for each successful lock request that it has outstanding on the mutex.

An errorcheck mutex checks for deadlock conditions that occur when a thread relocks an already held mutex. If a thread attempts to relock a mutex that it already holds, the lock request fails with the EDEADLK error.

An ownerterm mutex is an i5/OS extension to the errorcheck mutex type. An ownerterm mutex checks for deadlock conditions that occur when a thread relocks an already held mutex. If a thread attempts to relock a mutex that it already holds, the lock request fails with the EDEADLK error. An ownerterm mutex also checks for deadlock conditions that occur when a thread attempts to lock a mutex that was held by another thread when that thread terminated (an orphaned mutex). If a thread attempts to lock an orphaned mutex, the lock request fails with the EOWNERTERM error.
When a thread terminates while holding a mutex lock on a normal or errorcheck mutex, other threads that wait for that mutex will block forever. The pthreads run-time simulates the deadlock that has occurred in your application. When you are attempting to debug these deadlock scenarios, the CL command WRKJOB, option 20, shows the thread as in a condition wait. Displaying the call stack shows that the function deadlockOnOrphanedMutex is in the call stack.

Displaying the call stack shows that the function deadlockOnAlreadyHeldMutex is in the call stack.

To change these behaviors, use an errorcheck or ownerterm mutex type.

Authors and Locks
For successful completion, the mutex lock must be held before you call pthread_mutex_unlock().

Parameters
mutex (Input) Address of the mutex to unlock

Return Value
0 pthread_mutex_unlock() was successful.
value pthread_mutex_unlock() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_mutex_unlock() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

[EPERM]
The mutex is not currently held by the caller.

    rc = pthread_mutex_destroy(&mutex);
    checkResults("pthread_mutex_destroy()\n", rc);

    printf("Main completed\n");
    return 0;
}

Output:
Entering testcase
Lock the mutex
Unlock the mutex
Destroy the mutex
Main completed

API introduced: V4R3

pthread_once()—Perform One-Time Initialization

Syntax:
#include <pthread.h>
int pthread_once(pthread_once_t *once_control, void (*init_routine)(void));

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_once() function performs one time initialization based on a specific once_control variable. The
init_routine is called only one time when multiple calls to pthread_once() use the same once_control.

The once_control variable is not set until the init_routine returns. If the init_routine is a cancellation point
and the thread calling the init_routine by pthread_once() is cancelled, the once_control variable will not be
set and a subsequent call to pthread_once() using that once_control variable will result in another call to
the init_routine.

You must initialize the once_control variable to PTHREAD_ONCE_INIT prior to calling pthread_once() with it.

The function passed as init_routine must correspond to the following C function prototype:
void initRoutine(void);
Authorities and Locks

None.

Parameters

once_control
   (Input) The control variable associated with this initialization.

init_routine
   (Input) A function pointer to a routine that takes no parameters and returns no value.

Return Value

0   pthread_once() was successful.

value   pthread_once() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_once() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
   The value specified for the argument is not correct.

Related Information

API introduced: V4R3

**pthread_rwlockattr_destroy()**—Destroy Read/Write Lock Attribute

Syntax:
#include <pthread.h>
int pthread_rwlockattr_destroy(pthread_rwlockattr_t *attr);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threading: Yes
Signal Safe: Yes

The `pthread_rwlockattr_destroy()` function destroys a read/write lock attributes object and allows the systems to reclaim any resources associated with that read/write lock attributes object. This does not have an effect on any read/write lock already created using this read/write lock attributes object.
Authorities and Locks
None.

Parameters

attr (Input) Address of the read/write lock attributes object to be destroyed

Return Value

0 pthread_rwlockattr_destroy() was successful.
value pthread_rwlockattr_destroy() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_rwlockattr_destroy() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

Related Information

- The <pthread.h> header file. See “Header files for Pthread functions” on page 254.

rc = pthread_rwlock_destroy(&rwlock2);
checkResults("pthread_rwlock_destroy(2)\n", rc);
printf("Main completed\n");
return 0;
}

Output:
Enter Testcase - QP0WTST/TPRWLAI0
Create a default rwlock attribute
Use the rwlock attributes to created rwlocks here
The rwlock is now ready for use.
The rwlock that was statically initialized was ready when
the main routine was entered
Destroy rwlock attribute
Use the rwlocks
Destroy the rwlocks
Main completed

API introduced: V4R3

pthread_rwlockattr_getpshared()—Get Pshared Read/Write Lock Attribute

Syntax:
#include <pthread.h>
int pthread_rwlockattr_getpshared(const pthread_rwlockattr_t *attr,
      int *pshared);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_rwlockattr_getpshared() function retrieves the current setting of the process shared attribute
from the read/write lock attributes object. The process shared attribute indicates whether the read/write
lock that is created using the read/write lock attributes object can be shared between threads in separate
processes (PTHREAD_PROCESS_SHARED) or shared only between threads within the same process
(PTHREAD_PROCESS_PRIVATE).
Even if the read/write lock in storage is accessible from two separate processes, it cannot be used from both processes unless the process shared attribute is PTHREAD_PROCESS_SHARED.

The default pshared attribute for read/write lock attributes objects is PTHREAD_PROCESS_PRIVATE.

Authorities and Locks
None.

Parameters
attr (Input) Address of the variable that contains the read/write lock attributes object
pshared (Output) Address of the variable to contain the pshared attribute result

Return Value
0 pthread_rwlockattr_getpshared() was successful.
value pthread_rwlockattr_getpshared() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_rwlockattr_getpshared() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINV AL] The value specified for the argument is not correct.

}

Output:

This example was run under the i5/OS QShell Interpreter. In the QShell Interpreter, a program gets descriptors 0, 1, 2 as the standard files, the parent and child I/O is directed to the console. When run in the QShell Interpreter, the output shows the intermixed output from both parent and child processes, and gives a feeling for the time sequence of operations occurring in each job.

The QShell interpreter allows you to run multithreaded programs as if they were interactive. See the QShell documentation for a description of the QIBM_MULTI_THREADED shell variable which allows you to start multithreaded programs.

The QShell Interpreter is option 30 of Base i5/OS.

API introduced: V4R3

pthread_rwlockattr_init()—Initialize Read/Write Lock Attribute

Syntax:
#include <pthread.h>

int pthread_rwlockattr_init(pthread_rwlockattr_t *attr);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_rwlockattr_init() function initializes the read/write lock attributes object referred to by attr to the default attributes. The read/write lock attributes object can be used in a call to pthread_rwlock_init() to create a read/write lock.

Authorities and Locks
None.

Parameters
attr (Output) Address of the variable to contain the read/write lock attributes object
Return Value

0     pthread_rwlockattr_init() was successful.
value pthread_rwlockattr_init() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_rwlockattr_init() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

Related Information

• The <pthread.h> header file. See “Header files for Pthread functions” on page 254.
• “pthread_rwlockattr_destroy()—Destroy Read/Write Lock Attribute” on page 150—Destroy Read/Write Lock Attribute
• “pthread_rwlock_init()—Initialize Read/Write Lock” on page 163—Initialize Read/Write Lock

Example

See Code disclaimer information for information pertaining to code examples.

See the “Example” on page 151.

API introduced: V4R3

pthread_rwlockattr_setpshared()—Set Pshared Read/Write Lock Attribute

Syntax:

#include <pthread.h>
int pthread_rwlockattr_setpshared(pthread_rwlockattr_t *attr, int pshared);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_rwlockattr_setpshared() function sets the current pshared attribute for the read/write attributes object. The process shared attribute indicates whether the read/write lock that is created using the read/write lock attributes object can be shared between threads in separate processes (PTHREAD_PROCESS_SHARED) or shared only between threads in the same process (PTHREAD_PROCESS_PRIVATE).

Even if the read/write lock in storage is accessible from two separate processes, it cannot be used from both processes unless the process shared attribute is PTHREAD_PROCESS_SHARED.

Authorities and Locks

None.
Parameters

attr  (Input) Address of the variable containing the read/write lock attributes object

pshared  (Input) One of PTHREAD_PROCESS_SHARED or PTHREAD_PROCESS_PRIVATE

Return Value

0  pthread_rwlockattr_setpshared() was successful.

value  pthread_rwlockattr_setpshared() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_rwlockattr_setpshared() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

Related Information

• “pthread_rwlock_init()—Initialize Read/Write Lock” on page 163—Initialize Read/Write Lock

Example

See Code disclaimer information for information pertaining to code examples.

See the “Example” on page 153.

API introduced: V4R3

pthread_rwlock_destroy()—Destroy Read/Write Lock

Syntax:
#include <pthread.h>
int pthread_rwlock_destroy(pthread_rwlock_t *rwlock);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threading: Yes
Signal Safe: Yes

The pthread_rwlock_destroy() function destroys the named read/write lock. The destroyed read/write lock can no longer be used.

If pthread_rwlock_destroy() is called on a read/write lock on a mutex that is locked by another thread for either reading or writing, the request fails with an EBUSY error.
If `pthread_rwlock_destroy()` is used by a thread when it owns the read/write lock, and other threads are waiting for the read/write lock to become available (with calls to `pthread_rwlock_rdlock()`, `pthread_rwlock_wrlock()`, `pthread_rwlock_timedrdlock_np()` or `pthread_rwlock_timedwrlock_np()` APIs), the read/write lock is destroyed safely, and the waiting threads wake up with the EDESTROYED error. Threads calling `pthread_rwlock_tryrdlock()` or `pthread_rwlock_trywrlock()` return with either the EBUSY or EINVAL error, depending on when they called those functions.

Once a read/write lock is created, it cannot be validly copied or moved to a new location.

### Authorities and Locks

None.

### Parameters

**rwlock**

(Input) Address of the read/write lock to be destroyed

### Return Value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><code>pthread_rwlock_destroy()</code> was successful.</td>
</tr>
<tr>
<td>value</td>
<td><code>pthread_rwlock_destroy()</code> was not successful. <code>value</code> is set to indicate the error condition.</td>
</tr>
</tbody>
</table>

### Error Conditions

If `pthread_rwlock_destroy()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

- **[EINVAL]**
  
  The value specified for the argument is not correct.

### Related Information

- The `<pthread.h>` header file. See “Header files for Pthread functions” on page 254.
- “`pthread_rwlock_init()—Initialize Read/Write Lock`”—Initialize Read/Write Lock

### Example

See Code disclaimer information for information pertaining to code examples.

See the “Example” on page 165.

API introduced: V4R3

**pthread_rwlock_init()—Initialize Read/Write Lock**

Syntax:

```c
#include <pthread.h>

int pthread_rwlock_init(pthread_rwlock_t *rwlock, const pthread_rwlockattr_t *attr);
```
The `pthread_rwlock_init()` function initializes a new read/write lock with the specified attributes for use. The new read/write lock may be used immediately for serializing critical resources. If `attr` is specified as `NULL`, all attributes are set to the default read/write lock attributes for the newly created read/write lock.

With these declarations and initializations:

```c
pthread_rwlock_t rwlock2;
pthread_rwlock_t rwlock3;
pthread_rwlockattr_t attr;
pthread_rwlockattr_init(&attr);
```

The following three read/write lock initialization mechanisms have equivalent function.

```c
pthread_rwlock_t rwlock1 = PTHREAD_RWLOCK_INITIALIZER;
pthread_rwlock_init(&rwlock2, NULL);
pthread_rwlock_init(&rwlock, &attr);
```

All three read/write locks are created with the default read/write lock attributes.

Every read/write lock must eventually be destroyed with `pthread_rwlock_destroy()`. Always use `pthread_rwlock_destroy()` before freeing or reusing read/write lock storage.

**Authorities and Locks**

None.

**Parameters**

- **rwlock** (Output) The address of the variable to contain a read/write lock
- **attr** (Input) The address of the variable containing the read/write lock attributes object

**Return Value**

0  `pthread_rwlock_init()` was successful.

value  `pthread_rwlock_init()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**

If `pthread_rwlock_init()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

**[EINVAL]**

The value specified for the argument is not correct.

**Related Information**

- The `<pthread.h>` header file. See “Header files for Pthread functions” on page 254
- “pthread_rwlockattr_init()—Initialize Read/Write Lock Attribute” on page 160—Initialize Read/Write Lock Attribute
- “pthread_rwlock_destroy()—Destroy Read/Write Lock” on page 162—Destroy Read/Write Lock
Example

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_rwlock_t rwlock;

void *rdlockThread(void *arg)
{
    int rc;

    printf("Entered thread, getting read lock\n");
    rc = pthread_rwlock_rdlock(&rwlock);
    checkResults("pthread_rwlock_rdlock()\n", rc);
    printf("got the rwlock read lock\n");

    sleep(5);

    printf("unlock the read lock\n");
    rc = pthread_rwlock_unlock(&rwlock);
    checkResults("pthread_rwlock_unlock()\n", rc);
    printf("Secondary thread unlocked\n");
    return NULL;
}

void *wrlockThread(void *arg)
{
    int rc;

    printf("Entered thread, getting write lock\n");
    rc = pthread_rwlock_wrlock(&rwlock);
    checkResults("pthread_rwlock_wrlock()\n", rc);

    printf("Got the rwlock write lock, now unlock\n");
    rc = pthread_rwlock_unlock(&rwlock);
    checkResults("pthread_rwlock_unlock()\n", rc);
    printf("Secondary thread unlocked\n");
    return NULL;
}

int main(int argc, char **argv)
{
    int rc=0;
    pthread_t thread, thread1;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Main, initialize the read write lock\n");
    rc = pthread_rwlock_init(&rwlock, NULL);
    checkResults("pthread_rwlock_init()\n", rc);

    printf("Main, grab a read lock\n");
    rc = pthread_rwlock_rdlock(&rwlock);
    checkResults("pthread_rwlock_rdlock()\n", rc);

    printf("Main, grab the same read lock again\n");
    rc = pthread_rwlock_rdlock(&rwlock);
    checkResults("pthread_rwlock_rdlock() second\n", rc);

    printf("Main, create the read lock thread\n");
    rc = pthread_create(&thread, NULL, rdlockThread, NULL);
    checkResults("pthread_create\n", rc);

    printf("Main - unlock the first read lock\n");
    rc = pthread_rwlock_unlock(&rwlock);
    return rc;
}
```

checkResults("pthread_rwlock_unlock() \n", rc);

printf("Main, create the write lock thread\n");
rc = pthread_create(&thread1, NULL, wrlockThread, NULL);
checkResults("pthread_create\n", rc);
sleep(5);
printf("Main - unlock the second read lock\n");
rc = pthread_rwlock_unlock(&rwlock);
checkResults("pthread_rwlock_unlock() \n", rc);

printf("Main, wait for the threads\n");
rc = pthread_join(thread, NULL);
checkResults("pthread_join\n", rc);
rc = pthread_join(thread1, NULL);
checkResults("pthread_join\n", rc);
rc = pthread_rwlock_destroy(&rwlock);
checkResults("pthread_rwlock_destroy() \n", rc);

printf("Main completed\n");
return 0;
}

Output:
Enter Testcase - QP0WTEST/TPRWLINI0
Main, initialize the read write lock
Main, grab a read lock
Main, grab the same read lock again
Main, create the read lock thread
Main - unlock the first read lock
Main, create the write lock thread
Entered thread, getting read lock
got the rwlock read lock
Entered thread, getting write lock
Main - unlock the second read lock
Main, wait for the threads
unlock the read lock
Secondary thread unlocked
Got the rwlock write lock, now unlock
Secondary thread unlocked
Main completed

API introduced: V4R3

pthread_rwlock_rdlock()—Get Shared Read Lock

Syntax:
#include <pthread.h>
int pthread_rwlock_rdlock(pthread_rwlock_t *rwlock);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_rwlock_rdlock() function attempts to acquire a shared read lock on the read/write lock specified by rwlock.
Any number of threads can hold shared read locks on the same read/write lock object. If any thread holds an exclusive write lock on a read/write lock object, no other threads are allowed to hold a shared read or exclusive write lock.

If no threads are holding an exclusive write lock on the read/write lock, the calling thread successfully acquires the shared read lock.

If the calling thread already holds a shared read lock on the read/write lock, another read lock can be successfully acquired by the calling thread. If more than one shared read lock is successfully acquired by a thread on a read/write lock object, that thread is required to successfully call `pthread_rwlock_unlock()` a matching number of times.

With a large number of readers and relatively few writers, there is the possibility of writer starvation. If threads are waiting for an exclusive write lock on the read/write lock and there are threads that currently hold a shared read lock, the shared read lock request is granted.

If the read/write lock is destroyed while `pthread_rwlock_rdlock()` is waiting for the shared read lock, the EDESTROYED error is returned.

If a signal is delivered to the thread while it is waiting for the lock, the signal handler (if any) runs, and the thread resumes waiting.

**Read/Write Lock Deadlocks**

If a thread ends while holding a write lock, the attempt by another thread to acquire a shared read or exclusive write lock will not be successful. In this case, the attempt to acquire the lock will deadlock. If a thread ends while holding a read lock, the system automatically releases the read lock.

For the `pthread_rwlock_rdlock()` function, the pthreads run-time simulates the deadlock that has occurred in your application. When you are attempting to debug these deadlock scenarios, the CL command WRKJOB, option 20, shows the thread as in a condition wait. Displaying the call stack shows that the function `deadlockOnOrphanedRWLock` is in the call stack.

**Upgrade / Downgrade a Lock**

If the calling thread currently holds an exclusive write lock on the read/write lock object, the shared read lock request is granted. After the shared read lock request is granted, the calling thread holds both the shared read and the exclusive write lock for the specified read/write lock object. If the thread calls `pthread_rwlock_unlock()` while holding one or more shared read locks and one or more exclusive write locks, the exclusive write locks are unlocked first. If more than one outstanding exclusive write lock was held by the thread, a matching number of successful calls to `pthread_rwlock_unlock()` must be done before all write locks are unlocked. At that time, subsequent calls to `pthread_rwlock_unlock()` unlock the shared read locks.

This behavior can be used to allow your application to upgrade or downgrade one lock type to another. See “Shared read/write locks are released at thread termination” on page 241.

**Authorities and Locks**

None.

**Parameters**

rwlock

(Input) The address of the read/write lock
Return Value

0     pthread_rwlock_rdlock() was successful.

value    pthread_rwlock_rdlock() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_rwlock_rdlock() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

[EDESTROYED]

The lock was destroyed while waiting.

Example

See Code disclaimer information for information pertaining to code examples.

See the “Example” on page 165.

API introduced: V4R3

Example: pthread_rwlock_timedrdlock_np()—Get Shared Read Lock with Time-Out

Syntax:

```c
#include <pthread.h>
#include <time.h>
int pthread_rwlock_timedrdlock_np(pthread_rwlock_t *rwlock,
const struct timespec *deltatime);
```
Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The `pthread_rwlock_timedrdlock_np()` function attempts to acquire a shared read lock on the read/write lock specified by `rwlock`. If the shared read lock cannot be acquired in the `deltatime` specific, `pthread_rwlock_timedrdlock_np()` returns the `EBUSY` error.

Any number of threads can hold shared read locks on the same read/write lock object. If any thread holds an exclusive write lock on a read/write lock object, no other threads are allowed to hold a shared read or exclusive write lock.

If no threads are holding an exclusive write lock on the read/write lock, the calling thread successfully acquires the shared read lock.

If the calling thread already holds a shared read lock on the read/write lock, another read lock can be successfully acquired by the calling thread. If more than one shared read lock is successfully acquired by a thread on a read/write lock object, that thread is required to successfully call `pthread_rwlock_unlock()` a matching number of times.

With a large number of readers and relatively few writers, there is the possibility of writer starvation. If threads are waiting for an exclusive write lock on the read/write lock and there are threads that currently hold a shared read lock, the shared read lock request is granted.

If the read/write lock is destroyed while `pthread_rwlock_timedrdlock_np()` is waiting for the shared read lock, the `EDESTROYED` error is returned.

If a signal is delivered to the thread while it is waiting for the lock, the signal handler (if any) runs, and the thread resumes waiting. For a timed wait, when the thread resumes waiting after the signal handler runs, the wait time is reset. For example, suppose a thread specifies that it should wait for a lock for 5 seconds, and a signal handler runs in that thread after 2.5 seconds. After returning from the signal handler, the thread will resume its wait for another 5 seconds. The resulting wait is longer than the specified 5 seconds.

**Read/Write Lock Deadlocks**

If a thread ends while holding a write lock, the attempt by another thread to acquire a shared read or exclusive write lock will not succeed. In this case, the attempt to acquire the lock will return the `EBUSY` error after the specified time elapses for the lock operation. If a thread ends while holding a read lock, the system automatically releases the read lock.

For the `pthread_rwlock_timedrdlock_np()` function, the threads run-time simulates the deadlock that has occurred in your application. When you are attempting to debug these deadlock scenarios, the CL command WRKJOB, option 20, shows the thread as in a condition wait. Displaying the call stack shows that the function `timedDeadlockOnOrphanedRWLock` is in the call stack.

**Upgrade / Downgrade a Lock**

If the calling thread currently holds an exclusive write lock on the read/write lock object, the shared read lock request is granted. After the shared read lock request is granted, the calling thread holds both the shared read and the exclusive write lock for the specified read/write lock object. If the thread calls `pthread_rwlock_unlock()` while holding one or more shared read locks and one or more exclusive write locks, the exclusive write locks are unlocked first. If more than one outstanding exclusive write lock was held by the thread, a matching number of successful calls to `pthread_rwlock_unlock()` must be done before all write locks are unlocked. At that time, subsequent calls to `pthread_rwlock_unlock()` will unlock the shared read locks.
You can use this behavior to allow your application to upgrade or downgrade one lock type to another. See “Read/write locks can be upgraded/downgraded” on page 242.

Authorities and Locks
None.

Parameters
rwlock
  (Input)  The address of the read/write lock
deltatime
  (Input)  The number of seconds and nanoseconds to wait for the lock before returning an error

Return Value
0  pthread_rwlock_timedrdlock_np() was successful.
value  pthread_rwlock_timedrdlock_np() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_rwlock_timedrdlock_np() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINV AL]
The value specified for the argument is not correct.

[EBUSY]
The lock could not be acquired in the time specified.

[EDESTROYED]
The lock was destroyed while waiting.

API introduced: V4R3

pthread_rwlock_timedwrlock_np()—Get Exclusive Write Lock with Time-Out

Syntax:
#include <pthread.h>
#include <time.h>
int pthread_rwlock_timedwrlock_np(pthread_rwlock_t *rwlock,
const struct timespec *deltatime);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_rwlock_timedwrlock_np() function attempts to acquire an exclusive write lock on the read/write lock specified by rwlock. If the exclusive write lock cannot be acquired in the deltatime specific, pthread_rwlock_timedwrlock_np() returns the EBUSY error.

Only one thread can hold an exclusive write lock on a read/write lock object. If any thread holds an exclusive write lock on a read/write lock object, no other threads are allowed to hold a shared read or exclusive write lock.

If no threads are holding an exclusive write lock or shared read lock on the read/write lock, the calling thread successfully acquires the exclusive write lock.

If the calling thread already holds an exclusive write lock on the read/write lock, another write lock can be successfully acquired by the calling thread. If more than one exclusive write lock is successfully acquired by a thread on a read/write lock object, that thread is required to successfully call pthread_rwlock_unlock() a matching number of times.

With a large number of readers and relatively few writers, there is the possibility of writer starvation. If threads are waiting for an exclusive write lock on the read/write lock and there are threads that currently hold a shared read lock, the subsequent attempts to acquire a shared read lock request are granted, while attempts to acquire the exclusive write lock wait.
If the read/write lock is destroyed while `pthread_rwlock_timedwrlock_np()` is waiting for the shared read lock, the EDESTROYED error is returned.

If a signal is delivered to the thread while it is waiting for the lock, the signal handler (if any) runs, and the thread resumes waiting. For a timed wait, when the thread resumes waiting after the signal handler runs, the wait time is reset. For example, suppose a thread specifies that it should wait for a lock for 5 seconds, and a signal handler runs in that thread after 2.5 seconds. After returning from the signal handler, the thread resumes its wait for another 5 seconds. The resulting wait is longer than the specified 5 seconds.

**Read/Write Lock Deadlocks**

If a thread ends while holding a write lock, the attempt by another thread to acquire a shared read or exclusive write lock will not succeed. In this case, the attempt to acquire the lock returns the EBUSY error after the specified time elapses for the lock operation. If a thread ends while holding a read lock, the system automatically releases the read lock.

For the `pthread_rwlock_timedwrlock_np()` function, the pthreads run-time simulates the deadlock that has occurred in your application. When you are attempting to debug these deadlock scenarios, the CL command WRKJOB, option 20, shows the thread as in a condition wait. Displaying the call stack shows that the function `timedDeadlockOnOrphanedRWriteLock` is in the call stack.

**Upgrade / Downgrade a Lock**

If the calling thread currently holds a shared read lock on the read/write lock object and no other threads are holding a shared read lock, the exclusive write request is granted. After the exclusive write lock request is granted, the calling thread holds both the shared read and the exclusive write lock for the specified read/write lock object. If the thread calls `pthread_rwlock_unlock()` while holding one or more shared read locks and one or more exclusive write locks, the exclusive write locks are unlocked first. If more than one outstanding exclusive write lock was held by the thread, a matching number of successful calls to `pthread_rwlock_unlock()` must be done before all write locks are unlocked. At that time, subsequent calls to `pthread_rwlock_unlock()` unlock the shared read locks.

You can use this behavior to allow your application to upgrade or downgrade one lock type to another. See “Read/write locks can be upgraded/downgraded” on page 242.

**Authorities and Locks**

None.

**Parameters**

`rwlock`

(Input) The address of the read/write lock

`deltatime`

(Input) The number of seconds and nanoseconds to wait for the lock before returning an error

**Return Value**

0 - `pthread_rwlock_timedwrlock_np()` was successful.

value - `pthread_rwlock_timedwrlock_np()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**

If `pthread_rwlock_timedwrlock_np()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.
The value specified for the argument is not correct.

The lock could not be acquired in the time specified.

The lock was destroyed while waiting.

**pthread_rwlock_tryrdlock()—Get Shared Read Lock with No Wait**

**Syntax:**

```c
#include <pthread.h>
int pthread_rwlock_tryrdlock(pthread_rwlock_t *rwlock);
```

**Service Program Name:** QP0WPTH
**Default Public Authority:** USE
**Threadsafe:** Yes
**Signal Safe:** Yes

The `pthread_rwlock_tryrdlock()` function attempts to acquire a shared read lock on the read/write lock specified by `rwlock`. If the shared read lock cannot be acquired immediately, `pthread_rwlock_tryrdlock()` returns the EBUSY error.

Any number of threads can hold shared read locks on the same read/write lock object. If any thread holds an exclusive write lock on a read/write lock object, no other threads will be allowed to hold a shared read or exclusive write lock.

If there are no threads holding an exclusive write lock on the read/write lock, the calling thread will successfully acquire the shared read lock.

If the calling thread already holds a shared read lock on the read/write lock, another read lock can be successfully acquired by the calling thread. If more than one shared read lock is successfully acquired by a thread on a read/write lock object, that thread is required to successfully call `pthread_rwlock_unlock()` a matching number of times.

With a large number of readers, and relatively few writers, there is the possibility of writer starvation. If there are threads waiting for an exclusive write lock on the read/write lock and there are threads that currently hold a shared read lock, the shared read lock request will be granted.

**Read/Write Lock Deadlocks**

If a thread ends while holding a write lock, the attempt by another thread to acquire a shared read or exclusive write lock will not be successful. In this case, the attempt to acquire the lock will return the EBUSY error. If a thread ends while holding a read lock, the system automatically releases the read lock.

**Upgrade / Downgrade a Lock**

If the calling thread currently holds an exclusive write lock on the read/write lock object, the shared read lock request will be granted. After the shared read lock request is granted, the calling thread holds both the shared read and the exclusive write lock for the specified read/write lock object. If the thread calls `pthread_rwlock_unlock()` while holding one or more shared read locks and one or more exclusive write locks, the exclusive write locks are unlocked first. If more than one outstanding exclusive write lock was held by the thread, a matching number of successful calls to `pthread_rwlock_unlock()` must be done before all write locks are unlocked. At that time, subsequent calls to `pthread_rwlock_unlock()` will unlock the shared read locks.
This behavior can be used to allow your application to upgrade or downgrade one lock type to another. See “Read/write locks can be upgraded/downgraded” on page 242.

**Authorities and Locks**

None.

**Parameters**

rwlock

(Input) The address of the read/write lock

**Return Value**

0  \textit{pthread_rwlock_tryrdlock()} was successful.

\textit{value}  \textit{pthread_rwlock_tryrdlock()} was not successful. \textit{value} is set to indicate the error condition.

**Error Conditions**

If \textit{pthread_rwlock_tryrdlock()} was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

\[\text{EINVAL}\]

The value specified for the argument is not correct.

\[\text{EBUSY}\]

The lock could not be immediately acquired.

**Example**

See \textit{Code disclaimer information} for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_rwlock_t rwlock = PTHREAD_RWLOCK_INITIALIZER;

void *rdlockThread(void *arg)
{
    int rc;
```
```c
int count = 0;

printf("Entered thread, getting read lock with mp wait\n");
Retry:
rc = pthread_rwlock_tryrdlock(&rwlock);
if (rc == EBUSY) {
    if (count >= 10) {
        printf("Retried too many times, failure!\n");
        exit(EXIT_FAILURE);
    }
    ++count;
    printf("Could not get lock, do other work, then RETRY...\n");
    sleep(1);
    goto Retry;
}
checkResults("pthread_rwlock_tryrdlock() failed", rc);

sleep(2);

printf("unlock the read lock\n");
rc = pthread_rwlock_unlock(&rwlock);
checkResults("pthread_rwlock_unlock() failed", rc);

printf("Secondary thread complete\n");
return NULL;
}

int main(int argc, char **argv)
{
    int rc=0;
    pthread_t thread;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Main, get the write lock\n");
    rc = pthread_rwlock_wrlock(&rwlock);
    checkResults("pthread_rwlock_wrlock() failed", rc);

    printf("Main, create the try read lock thread\n");
    rc = pthread_create(&thread, NULL, rdlockThread, NULL);
    checkResults("pthread_create\n", rc);

    printf("Main, wait a bit holding the write lock\n");
    sleep(5);

    printf("Main, Now unlock the write lock\n");
    rc = pthread_rwlock_unlock(&rwlock);
    checkResults("pthread_rwlock_unlock() failed", rc);

    printf("Main, wait for the thread to end\n");
    rc = pthread_join(thread, NULL);
    checkResults("pthread_join\n", rc);

    rc = pthread_rwlock_destroy(&rwlock);

API introduced: V4R3

pthread_rwlock_trywrlock()—Get Exclusive Write Lock with No Wait

Syntax:
#include <pthread.h>
int pthread_rwlock_trywrlock(pthread_rwlock_t *rwlock);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
ThreadSafe: Yes
Signal Safe: Yes

The pthread_rwlock_trywrlock() function attempts to acquire an exclusive write lock on the read/write lock specified by rwlock. If the exclusive write lock cannot be immediately acquired, pthread_rwlock_timedwrlock_np() returns the EBUSY error.

Only one thread can hold an exclusive write lock on a read/write lock object. If any thread holds an exclusive write lock on a read/write lock object, no other threads will be allowed to hold a shared read or exclusive write lock.

If there are no threads holding an exclusive write lock or shared read lock on the read/write lock, the calling thread will successfully acquire the exclusive write lock.

If the calling thread already holds an exclusive write lock on the read/write lock, another write lock can be successfully acquired by the calling thread. If more than one exclusive write lock is successfully acquired by a thread on a read/write lock object, that thread is required to successfully call pthread_rwlock_unlock() a matching number of times.

With a large number of readers, and relatively few writers, there is the possibility of writer starvation. If there are threads waiting for an exclusive write lock on the read/write lock and there are threads that currently hold a shared read lock, the subsequent attempts to acquire a shared read lock request will be granted, while attempts to acquire the exclusive write lock will return the EBUSY error.

Read/Write Lock Deadlocks
If a thread ends while holding a write lock, the attempt by another thread to acquire a shared read or exclusive write lock will not be successful. In this case, the attempt to acquire the lock will return the EBUSY error. If a thread ends while holding a read lock, the system automatically releases the read lock.

Upgrade / Downgrade a Lock
If the calling thread currently holds a shared read lock on the read/write lock object and there are no other threads holding a shared read lock, the exclusive write request will be granted. After the exclusive
write lock request is granted, the calling thread holds both the shared read, and the exclusive write lock for the specified read/write lock object. If the thread calls `pthread_rwlock_unlock()` while holding one or more shared read locks and one or more exclusive write locks, the exclusive write locks are unlocked first. If more than one outstanding exclusive write lock was held by the thread, a matching number of successful calls to `pthread_rwlock_unlock()` must be done before all write locks are unlocked. At that time, subsequent calls to `pthread_rwlock_unlock()` will unlock the shared read locks.

This behavior can be used to allow your application to upgrade or downgrade one lock type to another. See “Read/write locks can be upgraded/downgraded” on page 242.

Authorities and Locks
None.

Parameters
`rwlock`
(Input) The address of the read/write lock

Return Value

0    `pthread_rwlock_trywrlock()` was successful.

value `pthread_rwlock_trywrlock()` was not successful. `value` is set to indicate the error condition.

Error Conditions
If `pthread_rwlock_trywrlock()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the argument is not correct.

[EBUSY]
The lock could not be acquired in the timed specified.

API introduced: V4R3

pthread_rwlock_unlock()—Unlock Exclusive Write or Shared Read Lock

Syntax:
#include <pthread.h>
int pthread_rwlock_unlock(pthread_rwlock_t *rwlock);

Service Program Name: QP0WPHTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_rwlock_unlock() function unlocks a shared read or exclusive write lock held by the calling thread.

A thread should call pthread_rwlock_unlock() once for each time that the thread successfully called pthread_rwlock_rdlock(), pthread_rwlock_tryrdlock(), pthread_rwlock_trywrlock(), pthread_rwlock_timedrdlock(), or pthread_rwlock_timedwrlock() to acquire a shared read or exclusive write lock. For example, if a thread holds 4 shared read locks on a read/write lock object, the thread must call pthread_rwlock_unlock() 4 times before the read/write lock becomes completely unlocked.
If a thread holds both shared read and exclusive write locks for the specified read/write lock object, the exclusive write locks are unlocked first. If more than one outstanding exclusive write lock was held by the thread, a matching number of successful calls to `pthread_rwlock_unlock()` must be done before all write locks are unlocked. When all write locks are unlocked, subsequent calls to `pthread_rwlock_unlock()` unlock the shared read locks.

**Authorities and Locks**

For successful completion, either a shared read or exclusive write lock must be held on the read/write lock before you call `pthread_rwlock_unlock()`.

**Parameters**

`rwlock`

(Input) The address of the read/write lock

**Return Value**

0  
`pthread_rwlock_unlock()` was successful.

value  
`pthread_rwlock_unlock()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**

If `pthread_rwlock_unlock()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

**[EINVAL]**

The value specified for the argument is not correct.

**[EPERM]**

A shared read or exclusive write lock was not held by the calling thread and could not be unlocked.

API introduced: V4R3

**pthread_rwlock_wrlock()—Get Exclusive Write Lock**

Syntax:

```
#include <pthread.h>
int pthread_rwlock_wrlock(pthread_rwlock_t *rwlock);
```

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The *pthread_rwlock_wrlock()* function attempts to acquire an exclusive write lock on the read/write lock specified by *rwlock*.

Only one thread can hold an exclusive write lock on a read/write lock object. If any thread holds an exclusive write lock on a read/write lock object, no other threads are allowed to hold a shared read or exclusive write lock.

If no threads are holding an exclusive write lock or shared read lock on the read/write lock, the calling thread successfully acquires the exclusive write lock.

If the calling thread already holds an exclusive write lock on the read/write lock, another write lock can be successfully acquired by the calling thread. If more than one exclusive write lock is successfully acquired by a thread on a read/write lock object, that thread is required to successfully call *pthread_rwlock_unlock()* a matching number of times.

With a large number of readers and relatively few writers, there is the possibility of writer starvation. If threads are waiting for an exclusive write lock on the read/write lock and there are threads that currently hold a shared read lock, the subsequent attempts to acquire a shared read lock request are granted, while attempts to acquire the exclusive write lock wait.

If the read/write lock is destroyed while *pthread_rwlock_wrlock()* is waiting for the shared read lock, the EDESTROYED error is returned.

If a signal is delivered to the thread while it is waiting for the lock, the signal handler (if any) runs, and the thread resumes waiting.

**Read/Write Lock Deadlocks**

If a thread ends while holding of a write lock, the attempt by another thread to acquire a shared read or exclusive write lock will not succeed. In this case, the attempt to acquire the lock does not return and will deadlock. If a thread ends while holding a read lock, the system automatically releases the read lock.

For the *pthread_rwlock_wrlock()* function, the pthreads run-time simulates the deadlock that has occurred in your application. When you are attempting to debug these deadlock scenarios, the CL command WRKJOB, option 20, shows the thread as in a condition wait. Displaying the call stack shows that the function *timedDeadlockOnOrphanedRWLock* is in the call stack.

184 IBM Systems - iSeries: Pthread APIs
Upgrade / Downgrade a Lock

If the calling thread currently holds a shared read lock on the read/write lock object and no other threads are holding a shared read lock, the exclusive write request is granted. After the exclusive write lock request is granted, the calling thread holds both the shared read, and the exclusive write lock for the specified read/write lock object. If the thread calls `pthread_rwlock_unlock()` while holding one or more shared read locks and one or more exclusive write locks, the exclusive write locks are unlocked first. If more than one outstanding exclusive write lock was held by the thread, a matching number of successful calls to `pthread_rwlock_unlock()` must be done before all write locks are unlocked. At that time, subsequent calls to `pthread_rwlock_unlock()` unlock the shared read locks.

You can use this behavior to allow your application to upgrade or downgrade one lock type to another. See “Read/write locks can be upgraded/downgraded” on page 242.

Authorities and Locks

None.

Parameters

rwlock

(Input) The address of the read/write lock

Return Value

0  `pthread_rwlock_wrlock()` was successful.

value  `pthread_rwlock_wrlock()` was not successful. value is set to indicate the error condition.

Error Conditions

If `pthread_rwlock_wrlock()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

[EDESTROYED]

The lock was destroyed while waiting.

API introduced: V4R3

pthread_self()—Get Pthread Handle

Syntax:
#include <pthread.h>
pthread_t pthread_self(void);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_self() function returns the Pthread handle of the calling thread. The pthread_self() function does NOT return the integral thread of the calling thread. You must use pthread_getthreadid_np() to return an integral identifier for the thread.

If your code requires the unique integer identifier for the calling thread often, or in a loop, the pthread_getthreadid_np() function can provide significant performance improvements over the combination of pthread_self(), and pthread_getunique_np() calls that provide equivalent behavior.

For example:

```
pthread_id_np_t tid;
tid = pthread_getthreadid_np();
```

is significantly faster than these calls, but provides the same behavior.

```
pthread_id_np_t tid;
pthread_t self;
self = pthread_self();
pthread_getunique_np(&self, &tid);
```

As always, if you are calling any function too often, performance improvements can be gained by storing the results in a variable and or passing to other functions which require the results.

Authorities and Locks
None.

Parameters
None.

Return Value

```
pthread_t
pthread_self() returns the Pthread handle of the calling thread.
```

Error Conditions
None.

- “pthread_gettid_np()—Retrieve Unique ID for Calling Thread” on page 86—Retrieve Unique ID for Calling Thread
- “pthread_getunique_np()—Retrieve Unique ID for Target Thread” on page 88—Retrieve Unique ID for Target Thread

Example

See Code disclaimer information for information pertaining to code examples.

```c
#include <pthread.h>
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_t theThread;

void *threadfunc(void *parm)
{
    printf("Inside secondary thread\n");
    theThread = pthread_self();
    return NULL;
}

int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=0;

    printf("Entering testcase\n");

    printf("Create thread using default attributes\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);
    checkResults("pthread_create()\n", rc);

    /* sleep() is not a very robust way to wait for the thread */
    sleep(5);

    printf("Check if the thread got its thread handle\n");
    if (!pthread_equal(thread, theThread)) {
        printf("Unexpected results on pthread_equal()!\n");
        exit(1);
    }
    printf("pthread_self() returned the thread handle\n");
    printf("Main completed\n");
    return 0;
}
```

Output:

Entering testcase
Create thread using default attributes
Inside secondary thread
Check if the thread got its thread handle
pthread_self() returned the thread handle
Main completed

API introduced: V4R3
**pthread_setcancelstate()—Set Cancel State**

Syntax:
```c
#include <pthread.h>
int pthread_setcancelstate(int state, int *oldstate);
```

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The `pthread_setcancelstate()` function sets the cancel state to one of `PTHREAD_CANCEL_ENABLE` or `PTHREAD_CANCEL_DISABLE` and returns the old cancel state into the location specified by `oldstate` (if `oldstate` is non-NULL).

When cancelability is disabled, all cancels are held pending in the target thread until the thread changes the cancelability. When cancelability is deferred, all cancels are held pending in the target thread until the thread changes the cancelability, calls a function which is a cancellation point or calls `pthread_testcancel()`, thus creating a cancellation point. When cancelability is asynchronous, all cancels are acted upon immediately, interrupting the thread with its processing.

**Note:** It is recommended that your application not use asynchronous thread cancellation through the `PTHREAD_CANCELASYNCHRONOUS` option of `pthread_setcanceltype()`. See the common user errors section of this document for more information.

**Authorities and Locks**
None.

**Parameters**
- **state** (Input) New cancel state (one of `PTHREAD_CANCEL_ENABLE` or `PTHREAD_CANCEL_DISABLE`)
- **oldstate** (Output) Address of variable to contain old cancel state. (NULL is allowed)

**Return Value**
- 0 `pthread_setcancelstate()` was successful.
- value `pthread_setcancelstate()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**
If `pthread_setcancelstate()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

- The value specified for the argument is not correct.

**Related Information**
- The `<pthread.h>` header file. See “Header files for Pthread functions” on page 254.
- `pthread_cancel()—Cancel Thread` on page 22—Cancel Thread

- `pthread_setcanceltype()—Set Cancel Type` on page 190—Set Cancel Type
Example

See Code disclaimer information for information pertaining to code examples.

```c
#include <assert.h>
#include <stdio.h>
#include <unistd.h>
#include "check.h"

void *threadfunc(void *parm)
{
  int i = 0;
  printf("Entered secondary thread\n");
  pthread_setcancelstate(PTHREAD_CANCEL_DISABLE, NULL);
  while (1) {
    printf("Secondary thread is looping\n");
    pthread_testcancel();
    sleep(1);
    if (++i == 5) {
      /* Since default cancel type is deferred, changing the state */
      /* will allow the next cancellation point to cancel the thread */
      printf("Cancel state set to ENABLE\n");
      pthread_setcancelstate(PTHREAD_CANCEL_ENABLE, NULL);
    }
  } /* infinite */
  return NULL;
}

int main(int argc, char **argv)
{
  pthread_t thread;
  int rc=0;

  printf("Entering testcase\n");

  /* Create a thread using default attributes */
  printf("Create thread using the NULL attributes\n");
  rc = pthread_create(&thread, NULL, threadfunc, NULL);
  checkResults("pthread_create(NULL)\n", rc);

  /* sleep() is not a very robust way to wait for the thread */
  sleep(3);

  printf("Cancel the thread\n");
  rc = pthread_cancel(thread);
  checkResults("pthread_cancel()\n", rc);

  /* sleep() is not a very robust way to wait for the thread */
  sleep(3);
  printf("Main completed\n");
  return 0;
}
```

Output:

Entering testcase
Create thread using the NULL attributes
Entered secondary thread
Secondary thread is looping
Secondary thread is looping
Cancel the thread
Secondary thread is looping
Cancel state set to ENABLE
Main completed
**pthread_setcanceltype()—Set Cancel Type**

Syntax:
```c
#include <pthread.h>
int pthread_setcanceltype(int type, int *oldtype);
```

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The `pthread_setcanceltype()` function sets the cancel `type` to one of `PTHREAD_CANCEL_DEFERRED` or `PTHREAD_CANCELASYNCHRONOUS` and returns the old cancel type into the location specified by `oldtype` (if `oldtype` is non-NULL)

Cancelable consists of 3 separate states (disabled, deferred, asynchronous) that can be represented by 2 boolean values.

<td>PTHREAD_CANCEL_ENABLE</td>
<td>PTHREAD_CANCEL_DEFERRED</td>
</tr>
<tr>
<td>asynchronous</td>
<td>PTHREADCANCEL_ENABLE</td>
<td>PTHREAD_CANCELASYNCHRONOUS</td>
</tr>
</tbody>
</table>

The default cancelability state is deferred.

When cancelability is disabled, all cancels are held pending in the target thread until the thread changes the cancelability. When cancelability is deferred, all cancels are held pending in the target thread until the thread changes the cancelability, calls a function which is a cancellation point or calls `pthread_testcancel()`, thus creating a cancellation point. When cancelability is asynchronous, all cancels are acted upon immediately, interrupting the thread with its processing.

**Note:** It is recommended that your application not use asynchronous thread cancellation through the `PTHREAD_CANCELASYNCHRONOUS` option of `pthread_setcanceltype()`. See the common user errors section of this document for more information.

**Authorities and Locks**

None.

**Parameters**

- **type** *(Input)* New cancel type (one of `PTHREADCANCEL_DEFERRED` or `PTHREADCANCELASYNCHRONOUS`)
- **oldtype** *(Output)* Address of variable to contain old cancel type. *(NULL is allowed)*
Return Value

0  pthread_setcanceltype() was successful.
value  pthread_setcanceltype() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_setcanceltype() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

Example

See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_mutex_t mutex = PTHREAD_MUTEX_INITIALIZER;

void cleanupHandler(void *parm)
{
  int rc;
  printf("Inside cleanup handler, unlock mutex\n");
  rc = pthread_mutex_unlock((pthread_mutex_t *)parm);
  checkResults("pthread_mutex_unlock\n", rc);
}

void *threadfunc(void *parm)
{
  int rc;
  int oldtype;

  printf("Entered secondary thread, lock mutex\n");
  rc = pthread_mutex_lock(&mutex);
  checkResults("pthread_mutex_lock\n", rc);

  pthread_cleanup_push(cleanupHandler, &mutex);
  /* We must assume there is a good reason for async. cancellability */
  /* and also, we must assume that if we get interrupted, it is */
  /* appropriate to unlock the mutex. More than likely it is not */
  /* because we will have left some data structures in a strange state */
  /* if we are async. interrupted while holding the mutex */
  rc = pthread_setcanceltype(PTHREAD_CANCEL_ASYNCHRONOUS, &oldtype);
  checkResults("pthread_setcanceltype\n", rc);

  printf("Secondary thread is now looping\n");
  while (1) { sleep(1); }
  printf("Unexpectedly got out of loop!\n");
  pthread_cleanup_pop(0);
```

Pthread APIs  191
return NULL;
}

int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=0;
    void *status;

    printf("Enter Testcase - %s\n", argv[0]);

    /* Create a thread using default attributes */
    printf("Create thread using the NULL attributes\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);
    checkResults("pthread_create(NULL)\n", rc);

    /* sleep() is not a very robust way to wait for the thread */
    sleep(1);
    printf("Cancel the thread\n");
    rc = pthread_cancel(thread);
    checkResults("pthread_cancel()\n", rc);

    rc = pthread_join(thread, &status);
    if (status != PTHREAD_CANCELED) {
        printf("Unexpected Thread status\n");
        exit(1);
    }
    printf("Main completed\n");
    return 0;
}

Output:
Enter Testcase - QP0WTEST/TPSETCANT0
Create thread using the NULL attributes
Entered secondary thread, lock mutex
Secondary thread is now looping
Cancel the thread
Inside cleanup handler, unlock mutex
Main completed

API introduced: V4R3

pthread_setconcurrency()—Set Process Concurrency Level

Syntax:
#include <pthread.h>
int pthread_setconcurrency(int concurrency);

Service Program Name: QP0WTCBH
Default Public Authority: *USE
Threading Safe: Yes
Signal Safe: No

The pthread_setconcurrency() function sets the current concurrency level for the process.

A concurrency value of zero indicates that the threads implementation chooses the concurrency level that best suits the application. A concurrency level greater than zero indicates that the application wants to inform the system of its desired concurrency level.
The concurrency level is not used by the i5/OS threads implementation, but is stored for subsequent calls to `pthread_getconcurrency`. Each user thread is always bound to a kernel thread.

**Authorities and Locks**
None.

**Parameters**

concurrency

(Input) The new concurrency level for the process

**Return Value**

0  `pthread_setconcurrency()` was successful.
value `pthread_setcon concurrency()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**

If `pthread_setconcurrency()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

**Related Information**

- The `<pthread.h>` header file. See “Header files for Pthread functions” on page 254.

API introduced: V4R3

---

**pthread_setpthreadoption_np()—Set Pthread Run-Time Option Data**

Syntax:

```c
#include <pthread.h>
int pthread_setpthreadoption_np(pthread_option_np_t *optionData);
```

Service Program Name: QP0WTCBH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The `pthread_setpthreadoption_np()` function sets option data in the pthread run-time for the process.

Input data is specified uniquely based on the specified `optionData`. See the table below for details about input and output. The option field in the `optionData` parameter is always required; other fields may be input, output, or ignored, based on the specific option used.
For all options, every reserved field in the structure represented by \textit{optionData} must be binary zero or the \texttt{EINVAL} error is returned. Unless otherwise noted for an option, the \texttt{target} field in the \textit{option} parameter is always ignored, and the contents of the \textit{optionData} structure is not changed by the \texttt{pthread_setpthreadoption_np()} function.

The currently supported options, the data they represent, and the valid operations are as follows:

<table>
<thead>
<tr>
<th>\textbf{option field of the option parameter}</th>
<th>\textbf{Description}</th>
</tr>
</thead>
<tbody>
<tr>
<td>PTHREAD_OPTION_POOL_NP</td>
<td>When a thread terminates and is detached or joined to, certain data structures from the pthreads run-time are maintained in a pool for possible reuse by future threads. This improves performance for creating threads. Typically, an application should not be concerned with this storage pool. Use this option to set the current maximum size of the allowed storage pool. The \textit{optionValue} field of the \textit{optionData} parameter is used to set the current maximum number of thread structures that will be allowed in the storage pool. By default, the \textit{optionValue} field must be a valid integer greater than or equal to zero, or the \texttt{EINVAL} error is returned. The default maximum size of the storage reuse pool contains enough room for 512 thread structures.</td>
</tr>
<tr>
<td>PTHREAD_OPTION_POOL_CURRENT_NP</td>
<td>If the \textit{option} field of the \textit{optionData} parameter is set to this option, the \texttt{EINVAL} error is returned.</td>
</tr>
<tr>
<td>PTHREAD_OPTION_THREAD_CAPABLE_NP</td>
<td>If the \textit{option} field of the \textit{optionData} parameter is set to this option, the \texttt{EINVAL} error is returned.</td>
</tr>
</tbody>
</table>

\textbf{Authorities and Locks}

None.

\textbf{Parameters}

\texttt{option} (Input/Output) Address of the variable containing option information and to contain output option information.

\textbf{Return Value}

0 \hspace{1em} \texttt{pthread_getpthreadoption_np()} was successful.

\texttt{value} \hspace{1em} \texttt{pthread_getpthreadoption_np()} was not successful. \texttt{value} is set to indicate the error condition.

\textbf{Error Conditions}

If \texttt{pthread_getpthreadoption_np()} was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

\texttt{[EINVAL]}

The value specified for the argument is not correct.

API introduced: V4R3

**pthread_setschedparam()**—Set Target Thread Scheduling Parameters

Syntax:
#include <pthread.h>
#include <sched.h>
int pthread_setschedparam(pthread_t thread, int policy,
const struct sched_param *param);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No
The `pthread_setschedparam()` function sets the scheduling parameters of the target thread. The supported i5/OS scheduling policy is `SCHED_OTHER`. An attempt to set the policy to a value other than this cause the EINVAL error. The `sched_priority` field of the `param` parameter must range from `PRIORITY_MIN` to `PRIORITY_MAX` or the ENOTSUP error occurs.

All reserved fields in the scheduling parameters structure must be binary 0 or the EINVAL error occurs.

**Note:** Do not use `pthread_setschedparam()` to set the priority of a thread if you also use another mechanism (outside of the pthread APIs) to set the priority of a thread. If you do, `pthread_setschedparam()` returns only that information that was set by the pthread interfaces (`pthread_setschedparam()` or modification of the thread attribute using `pthread_attr_setschedparam()`).

### Authorities and Locks
None.

### Parameters
- **thread** (Input) Pthread handle of the target thread
- **policy** (Input) Scheduling policy (must be `SCHED_OTHER`)
- **param** (Input) Scheduling parameters

### Return Value
- 0 `pthread_setschedparam()` was successful.
- value `pthread_setschedparam()` was not successful. value is set to indicate the error condition.

### Error Conditions
If `pthread_setschedparam()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

- **[EINVAL]**
  
  The value specified for the argument is not correct.

- **[ENOTSUP]**
  
  The value specified for the priority argument is not supported.

### Related Information
- The `<pthread.h>` header file. See “Header files for Pthread functions” on page 254.
- “pthread_getschedparam()—Get Thread Scheduling Parameters” on page 82—Get Thread Scheduling Parameters

### Example
See [Code disclaimer information](#) for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <sched.h>
#include <stdio.h>
#include "check.h"

#define BUMP_PRIO 1

API introduced: V4R3

pthread_setspecific()—Set Thread Local Storage by Key

Syntax:
#include <pthread.h>
int pthread_setspecific(pthread_key_t key, const void *value);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The pthread_setspecific() function sets the thread local storage value associated with a key. The pthread_setspecific() function may be called from within a data destructor.

The thread local storage value is a variable of type void * that is local to a thread, but global to all of the functions called within that thread. It is accessed by the key.

Authorities and Locks
None.

Parameters
key (Input) The thread local storage key returned from pthread_key_create().

value (Input) The pointer to store at the key location for the calling thread.

Return Value
0 pthread_setspecific() was successful.

value pthread_setspecific() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_setspecific() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
The value specified for the key is not correct.

API introduced: V4R3

pthread_set_mutexattr_default_np()—Set Default Mutex Attributes
Object Kind Attribute

Syntax:
#include <pthread.h>
#include <sched.h>
int pthread_set_mutexattr_default_np(int kind);

Service Program Name: QP0WPTH
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes
The `pthread_set_mutexattr_default_np()` function sets the kind attribute in the default mutex attribute object. The default mutex attributes object is used when `pthread_mutex_init()` is called to specify a NULL pointer for the mutex attributes object parameter.

The `kind` set may be one of `PTHREAD_MUTEX_NONRECURSIVE_NP` or `PTHREAD_MUTEX_RECURSIVE_NP`.

The `pthread_set_mutexattr_default_np()` function does not affect any currently existing mutex attributes objects, nor does it affect the subsequent behavior of `pthread_mutexattr_init()` or the `PTHREAD_MUTEX_INITIALIZER` macro.

Calls to `pthread_set_mutexattr_default_np()` change how the run-time of the threads creates default mutexes for all code running in the current process. You can negatively affect other code in your process that uses pthread mutexes by using this function.

Use of this function is not recommended because it can affect the creation of mutexes that your application does not directly own.

**Note:** This function is not portable.

**Authorities and Locks**
None.

**Parameters**

- **kind** (Input) Variable containing the kind attribute

**Return Value**

- **0** `pthread_set_mutexattr_default()` was successful.
- **value** `pthread_set_mutexattr_default()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**

If `pthread_set_mutexattr_default()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

`[EINVAL]`

The value specified for the argument is not correct.

**Related Information**

- The `<pthread.h>` header file. See “Header files for Pthread functions” on page 254.
- “`pthread_mutexattr_setkind_np()`—Set Mutex Kind Attribute” on page 123—Set Mutex Kind Attribute

API introduced: V4R3

**pthread_sigmask()—Set or Get Signal Mask**

Syntax:
#include <pthread.h>
#include <signal.h>

int pthread_sigmask(int how, const sigset_t *set, sigset_t *oset);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: Yes

The `pthread_sigmask()` function examines or modifies the signal blocking mask for the current thread.

The signals SIGKILL or SIGStop cannot be blocked. Any attempt to use `pthread_sigmask()` to block these signals is simply ignored, and no error is returned.

SIGFPE, SIGILL, and SIGSEGV signals that are not artificially generated by `kill()`, `pthread_kill()` or `raise()` (that is, were generated by the system as a result of a hardware or software exception) are not blocked.

If there are any pending unblocked signals after `pthread_sigmask()` has changed the signal mask, at least one of those signals is delivered to the process before `pthread_sigmask()` returns.

If `pthread_sigmask()` fails, the signal mask of the thread is not changed.

The possible values for `how`, which are defined in the `<signal.h>` header file, are as follows:

**SIG_BLOCK**
Indicates that the set of signals given by `set` should be blocked, in addition to the set currently being blocked

**SIG_UNBLOCK**
Indicates that the set of signals given by `set` should not be blocked. These signals are removed from the current set of signals being blocked

**SIG_SETMASK**
Indicates that the set of signals given by `set` should replace the old set of signals being blocked

The `set` parameter points to a signal set that contains the new signals that should be blocked or unblocked (depending on the value of `how`), or it points to the new signal mask if the value of `how` is SIG_SETMASK. If `set` is a NULL pointer, the set of blocked signals is not changed. If `set` is NULL, the value of `how` is ignored.

The signal set manipulation functions (`sigemptyset()`, `sigfillset()`, `sigaddset()`, and `sigdelset()`) must be used to establish the new signal set pointed to by `set`.

The `pthread_sigmask()` function determines the current signal set and returns this information in `*oset`. If `set` is NULL, `oset` returns the current set of signals being blocked. When `set` is not NULL, the set of signals pointed to by `oset` is the previous set.

**Authorities and Locks**
None.

**Parameters**

`how`  (Input) The way in which the signal set is changed
set  (Input) A pointer to a set of signals to be used to change the currently blocked set. This value can be NULL.

oset  (Output) A pointer to the space where the previous signal mask is stored. This value can be NULL.

Return Value

0  pthread_sigmask() was successful.

value  pthread_sigmask() was not successful. value is set to indicate the error condition.

Error Conditions

If pthread_sigmask() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

[ENOTSIGNIT]

The process is not enabled for signals.

API introduced: V4R3

pthread_signal_to_cancel_np()—Convert Signals to Cancel Requests

Syntax:
#include <pthread.h>
int pthread_signal_to_cancel_np(sigset_t *set, pthread_t *thread);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_signal_to_cancel_np() function causes a pthread_cancel() to be delivered to the target thread when the first signal specified in set arrives.

All threads in the process should have the signals specified by set blocked from the time of the call to pthread_signal_to_cancel_np() until the time when the pthread_cancel() is delivered to the target thread.
If `pthread_signal_to_cancel_np()` has been called, but a signal has not yet been converted to a `pthread_cancel()`, a subsequent call to `pthread_signal_to_cancel_np()` overrides the first call.

The `pthread_signal_to_cancel_np()` function creates a service thread (called the SignalToCancel thread) to perform the signal to cancel conversion. This conversion occurs asynchronously to the thread that called `pthread_signal_to_cancel_np()`.

The SignalToCancel thread blocks all signals and performs a `sigwait()` on the set of signals specified by set. When `sigwait()` returns, indicating that one of the signals in set was synchronously received, the SignalToCancel thread calls `pthread_cancel()` using the thread specified as the target.

Since the SignalToCancel thread processing occurs asynchronously, the caller of `pthread_signal_to_cancel_np()` is not notified of errors that may occur during the processing of the SignalToCancel thread. If the target thread has terminated or the signals specified by set are not valid, the caller of `pthread_signal_to_cancel_np()` is not notified.

Note: This function is not portable.

**Authorities and Locks**
None.

**Parameters**
- `set` (Input) The set of signals that will be converted to `pthread_cancel()` requests
- `thread` (Input) The thread that will be canceled when a signal in set arrives

**Return Value**
- `0` `pthread_signal_to_cancel_np()` was successful.
- `non-zero value` `pthread_signal_to_cancel_np()` was not successful. `value` is set to indicate the error condition.

**Error Conditions**
If `pthread_signal_to_cancel_np()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]

The value specified for the argument is not correct.

API introduced: V4R3

pthread_testcancel()—Create Cancellation Point

Syntax:
#include <pthread.h>
void pthread_testcancel(void);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafes: Yes
Signal Safe: No

The pthread_testcancel() function creates a cancellation point in the calling thread. If cancelability is
currently disabled, this function has no effect. For more information on cancelability, see [Thread cancellation APIs” on page 272](#)

When cancelability is disabled, all cancels are held pending in the target thread until the thread changes
the cancelability. When cancelability is deferred, all cancels are held pending in the target thread until the
thread changes the cancelability, calls a function that is a cancellation point, or calls `pthread_testcancel()`, thus creating a cancellation point. When cancelability is asynchronous, all cancels are acted upon immediately, interrupting the thread with its processing.

**Note:** You should not use asynchronous thread cancellation through the `PTHREAD_CANCELASYNC` option of `pthread_setcanceltype()`. See the common user errors section of this document for more information.

**Authorities and Locks**

Main completed

API introduced: V4R3

pthread_test_exit_np()—Test Thread Exit Status

Syntax:
#include <pthread.h>
#include <sched.h>
int pthread_test_exit_np(void **status);
The `pthread_test_exit_np()` function returns the current state of the thread along with its exit status.

If the thread is currently processing an exit condition due to a call to `pthread_exit()` or cancellation due to being the target of a `pthread_cancel()`, `pthread_test_exit_np()` returns `PTHREAD_STATUS_EXIT_NP` and sets the exit status pointed to by the status parameter to be the current thread exit status.

If the thread is currently running and is not running cancellation cleanup handlers or data destructors while terminating, `pthread_test_exit_np()` returns `PTHREAD_STATUS_ACTIVE_NP`, and does not return the exit status.

**Note:** This function is not portable.

**Authorities and Locks**

None.

**Parameters**

- **status**  
  Pointer to the parameter to receive the exit status if `PTHREAD_STATUS_EXIT_NP` is returned.

**Return Value**

- **PTHREAD_STATUS_ACTIVE_NP**  
  The thread is currently not exiting.

- **PTHREAD_STATUS_EXIT_NP**  
  The thread is currently exiting.

**Error Conditions**

If `pthread_test_exit_np()` was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

- **[EINVAL]**  
  The values specified for the argument are not correct.

API introduced: V4R3

pthread_trace_init_np()—Initialize or Re-initialize pthread tracing

Syntax:
#include <pthread.h>
int pthread_trace_init_np(void);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

The pthread_trace_init_np() API initializes or refreshes both the Pthreads library trace level and the application trace level. The Pthreads library trace level is maintained internally by the Pthreads library, while the application trace level is stored in the Qp0wTraceLevel external variable and can be used by the PTHREAD_TRACE_NP() macro.

When a program or service program that uses the Pthread APIs causes the Pthread APIs to be loaded (activated), the Pthreads library automatically calls the pthread_trace_init_np() function in order to initialize tracing based on the value of the QIBM_PTHREAD_TRACE_LEVEL environment variable at that time.

The application can call pthread_trace_init_np() at an arbitrary time during execution to initialize or refresh the current Pthreads library tracing level and the application trace level. The trace level is set based on the value of the QIBM_PTHREAD_TRACE_LEVEL environment variable at the time of the call. The new tracing level is also returned.

The Pthreads library tracing level is used to control trace records written by the Pthreads library functions at runtime. The following table describes the preprocessor macros representing the various trace levels, the setting of the QIBM_PTHREAD_TRACE_LEVEL environment variable, and the conditions that are traced.

<table>
<thead>
<tr>
<th>Trace Level</th>
<th>EnvVar</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PTHREAD_TRACE_NONE_NP</td>
<td>&quot;QIBM_PTHREAD_TRACE_LEVEL=0&quot; (or not set)</td>
<td>No tracing is performed by the Pthreads library. Application tracing may still be done.</td>
</tr>
<tr>
<td>PTHREAD_TRACE_ERROR_NP</td>
<td>&quot;QIBM_PTHREAD_TRACE_LEVEL=1&quot;</td>
<td>Error level traces error conditions and the causes of most error return codes.</td>
</tr>
<tr>
<td>Trace Level</td>
<td>EnvVar</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PTHREAD_TRACE_INFO_NP</td>
<td>&quot;QIBM_PTHREAD_TRACE_LEVEL=2&quot;</td>
<td>Informational level traces error level tracepoints, plus entry to and exit from functions, parameters passed to and return codes from functions, major changes in control flow.</td>
</tr>
<tr>
<td>PTHREAD_TRACE_VERBOSE_NP</td>
<td>&quot;QIBM_PTHREAD_TRACE_LEVEL=3&quot;</td>
<td>Verbose level traces informational level tracepoints, plus detailed information about application parameters, threads and data structures including information about Pthreads library processing information.</td>
</tr>
</tbody>
</table>

The application provides tracing support similar to the Pthreads library using the `PTHREAD_TRACE_NP` macro.

The `PTHREAD_TRACE_NP` macro uses the external variable `Qp0wTraceLevel`. `Qp0wTraceLevel` may be used directly by the application to set application trace level without effecting the current Pthread library trace level. Set the value of `Qp0wTraceLevel` to one of `PTHREAD_TRACE_NONE_NP`, `PTHREAD_TRACE_ERROR_NP`, `PTHREAD_TRACE_INFO_NP`, or `PTHREAD_TRACE_VERBOSE_NP`.

The `PTHREAD_TRACE_NP` macro can be used in conjunction with the following APIs to put trace records into the user trace flight recorder. The following system APIs defined in the `qp0ztrc.h` header file:

- `Qp0zUprintf` - print formatted trace data
- `Qp0zDump` - dump formatted hex data
- `Qp0zDumpStack` - dump the call stack of the calling thread
- `Qp0zDumpTargetStack` - dump the call stack of the target thread

The trace records are written to the user trace flight recorder and can be accessed by the following CL commands:

- `DMPUSRTRC` - dump the contents of a specified job’s trace
- `CHGUSRTRC` - change attributes (size, wrapping, clear) of a specified job’s trace
- `DLTUSRTRC` - delete the persistent trace object associated with a job’s trace

**Authorities and Locks**

None.

**Parameters**

None.

**Return Value**

- **value** The new trace level. One of `PTHREAD_TRACE_NONE_NP`, `PTHREAD_TRACE_ERROR_NP`, `PTHREAD_TRACE_INFO_NP`, or `PTHREAD_TRACE_VERBOSE_NP`.

**Error Conditions**

None.

rc = pthread_create(&thread[i], NULL, theThread, gData);
checkResults("pthread_create()\n", rc);

/* Wait for the thread to complete, "
and release their resources\n");
rc = pthread_join(thread[i], NULL);
checkResults("pthread_join()\n", rc);
}

pthread_key_delete(threadSpecificKey);
}
PTHREAD_TRACE_NP(Qp0zUprintf("Main completed\n"),
                 PTHREAD_TRACE_INFO_NP);

return 0;
}

Output

Use CL command **DMPUSRTRC** to output the following tracing information that the example creates. The **DMPUSRTRC** CL command causes the following information to be put into file QTEMP/QAP0ZDMP or to standard output depending on the options used for the CL command.

Note the following:
- The trace records are indented and labeled based on thread id plus a microsecond timestamp at the time the tracepoint was cut. In the following trace record, the value 00000018 indicates the thread ID of the thread that created the tracepoint. The value 972456 indicates that the tracepoint occurred 972456 microseconds after the last timestamp indicator.
  
  00000018:972456 pthread_trace_init_np(): New traceLevel=2

- You can use the Pthread library tracepoints to debug incorrect calls to the Pthreads library from your application.

- The following trace output occurs when the optional parameter 'PTHREAD_TRACING' IS specified when calling this program. The 'PTHREAD_TRACING' parameter causes the **pthread_trace_init_np**() function to be used which initializes the Pthreads library tracing.

- There is **significantly** more information traced than the example shown in the documentation for the **PTHREAD_TRACE_NP**() macro

- The function names for threads and data destructors are traced.

- The values for many Pthread API parameters are traced, allowing application debug.

- Some internal Pthread API information is traced at an information-level tracing when the control flow information is critical.

Pthread APIs 219
API introduced: V4R3

**PTHREAD_TRACE_NP()**—Macro to optionally execute code based on trace level

Syntax:
```
#include <pthread.h>

PTHREAD_TRACE_NP(optionalCode, desiredTraceLevel);
```

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threadsafe: Yes
Signal Safe: No

An application can use the **PTHREAD_TRACE_NP()** macro to execute optional code based on the current application trace level. The *optionalCode* to be executed can include multiple statements and can be surrounded by the C/C++ begin/end block operators (the curly brackets { }). The *optionalCode* can include pre-condition or post-condition logic, tracepoint information, or any other desired C/C++ statements.

If the current application trace level is set to a level equal to or higher than the *desiredTraceLevel*, then the code executes.

The current Pthread library trace level is set automatically when a program or service program that uses the Pthread APIs causes the Pthread APIs to be loaded (activated) or when the application explicitly calls the **pthread_trace_init_np()** function. In either case, the Pthreads library trace level is set based on the value of the **QIBM_PTHREAD_TRACE_LEVEL** environment variable at that time.

If the preprocessor value **PTHREAD_TRACE_NDEBUG** is defined, then the call to **PTHREAD_TRACE_NP()** is compiled out and does not generate any executable runtime code. Use **PTHREAD_TRACE_NDEBUG** for production level code that should not perform any tracing, or leave tracepoints in the code to assist user’s of your application.

The **pthread_trace_init_np()** API initializes or refreshes both the Pthreads library trace level and the application trace level. The Pthreads library trace level is maintained internally by the Pthreads library, while the application trace level is stored in the *Qp0wTraceLevel* external variable, and can be used by the **PTHREAD_TRACE_NP()** macro.

The **PTHREAD_TRACE_NP()** macro uses the external variable *Qp0wTraceLevel*. *Qp0wTraceLevel* may be used directly by the application to set application trace level without effecting the current Pthread library trace level. Set the value of *Qp0wTraceLevel* to one of the following:
- **PTHREAD_TRACE_NONE_NP**
- **PTHREAD_TRACE_ERROR_NP**
• PTHREAD_TRACE_INFO_NP
• PTHREAD_TRACE_VERBOSE_NP

For consistent tracing behavior, the application should use the following table as a guide to choosing value of the desiredTraceLevel parameter.

<table>
<thead>
<tr>
<th>Desired Trace Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PTHREAD_TRACE_NONE_NP</td>
<td>The optionalCode always runs, even when the current trace level is set to none. It is recommended that this level is only used at development time.</td>
</tr>
<tr>
<td>PTHREAD_TRACE_ERROR_NP</td>
<td>The optionalCode runs if the current trace level is set to an error level or higher. Use the error level to trace error conditions and the reasons for error return codes.</td>
</tr>
<tr>
<td>PTHREAD_TRACE_INFO_NP</td>
<td>The optionalCode runs if the current trace level is set to an informational level or higher. Use the informational level to trace functions’ entry and exit, functions’ parameters and return codes and major changes in control flow.</td>
</tr>
<tr>
<td>PTHREAD_TRACE_VERBOSE_NP</td>
<td>The optionalCode runs if the current trace level is set to a verbose level or higher. Use the Verbose level traces informational level tracepoints, plus detailed information about application parameters, threads and data structures including information about Pthreads library processing information.</td>
</tr>
</tbody>
</table>

The PTHREAD_TRACE_NP() macro can be used in conjunction with the following APIs to put trace records into the user trace flight recorder. The following system APIs defined in the qp0ztrc.h header file:

- Qp0zUprintf - print formatted trace data
- Qp0zDump - dump formatted hex data
- Qp0zDumpStack - dump the call stack of the calling thread
- Qp0zDumpTargetStack - dump the call stack of the target thread

The trace records are written to the user trace flight recorder and can be accessed by the following CL commands:

- DMPUSRTRC - dump the contents of a specified job’s trace
- CHGUSRTRC - change attributes (size, wrapping, clear) of a specified job’s trace
- DLTUSRTRC - delete the persistent trace object associated with a job’s trace

Authorities and Locks

None.

Parameters

None.

Return Value

None.

Error Conditions

None.

    pthread_key_delete(threadSpecificKey);
    PTHREAD_TRACE_NP(Qp0zUprintf("Main completed\n"),
                     PTHREAD_TRACE_INFO_NP);
    return 0;
}

Output
Use CL command DMPUSRTRC to output the following tracing information that the example creates. The DMPUSRTRC CL command causes the following information to be put into file QTEMP/QAP0ZDMP or to standard output depending on the options used for the CL command.

Note the following:

- The trace records are indented and labeled based on thread id plus a microsecond timestamp at the time the tracepoint was cut. In the following trace record, the value 0000000D indicates the thread ID of the thread that created the tracepoint. The value 133520 indicates that the tracepoint occurred 133520 microseconds after the last timestamp indicator.

  0000000D:133520 Create/start a thread

- You can use the Pthread library tracepoints to debug incorrect calls to the Pthreads library from your application.

- The following trace output occurs when the optional parameter ‘PTHREAD_TRACING’ is NOT specified when calling this program. Since ‘PTHREAD_TRACING’ is not specified, the application directly sets the Qp0woTraceLevel external variable, causing only application level tracing to occur, and skipping any Pthreads library tracing.

User Trace Dump for job 096932/KULACK/PTHREADT. Size: 300K, Wrapped 0 times.

pthread_unlock_global_np()—Unlock Global Mutex

Syntax:
#include <pthread.h>
int pthread_unlock_global_np(void);

Service Program Name: QP0WTCBH
Default Public Authority: *USE
Threading: Yes
Signal Safe: Yes

The pthread_unlock_global_np() function unlocks a global mutex provided by the pthreads run-time. The global mutex is a recursive mutex with a name of "QP0W_GLOBAL_MTX". The global mutex is not currently used by the pthreads run-time to serialize access to any system resources, and is provided for application use only.

Note: This function is not portable

Authorities and Locks
For successful completion, the global mutex lock must be held prior to calling pthread_unlock_global_np().

Parameters
None.

Return Value
0   pthread_unlock_global_np() was successful.
value  pthread_unlock_global_np() was not successful. value is set to indicate the error condition.

Error Conditions
If pthread_unlock_global_np() was not successful, the error condition returned usually indicates one of the following errors. Under some conditions, the value returned could indicate an error other than those listed here.

[EINVAL]
    The value specified for the argument is not correct.

[EPERM]
    The mutex is not currently held by the caller.

sched_yield()—Yield Processor to Another Thread

Syntax:
#include <sched.h>
int sched_yield(void);

Service Program Name: QP0WPTHR
Default Public Authority: *USE
Threading: Yes
Signal Safe: Yes

The sched_yield() function yields the processor from the currently executing thread to another
ready-to-run, active thread of equal or higher priority.

If no threads of equal or higher priority are active and ready to run, sched_yield() returns immediately,
and the calling thread continues to run until its time has expired.

Authorities and Locks
None.

Parameters
None.

Return Value
0 sched_yield() was successful.
value sched_yield() was not successful. value is set to indicate the error condition.

Error Conditions
The sched_yield() API does not currently return an error.

Related Information

Unsupported Pthread APIs

The following functions are not supported by the iSeries™ implementation of pthreads. These functions are all defined and provided by the system. You can create and compile with these functions in your application. If the unsupported functions are called, when the application runs the functions immediately fail with the ENOSYS error, and your application can take the appropriate action, such as ignoring the error and continuing.

`pthread_atfork()—Register Fork Handlers`

Syntax:
The pthread_atfork() function is not supported by this implementation. The function returns ENOSYS.

**pthread_atfork_np()—Register Fork Handlers with Extended Options**

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_atfork(int *userstate,  
                  void (*prepare)(void),  
                  void (*parent)(void),  
                  void (*child)(void));
```

The pthread_atfork_np() function is not supported by this implementation. The function returns ENOSYS.

**pthread_attr_getguardsize()—Get Guard Size**

Syntax:
```c
#include <pthread.h>
int pthread_attr_getguardsize(const pthread_attr_t *attr,  
                               size_t *guardsize);
```

The pthread_attr_getguardsize() function is not supported by this implementation. The function returns ENOSYS.

**pthread_attr_getschedpolicy()—Get Scheduling Policy**

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_attr_getschedpolicy(pthread_attr_t *attr,  
                                int *policy);
```

The pthread_attr_getschedpolicy() function is not supported by this implementation. The function returns ENOSYS.

**pthread_attr_getscope()—Get Scheduling Scope**

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_attr_getscope(pthread_attr_t *attr,  
                          int *contentionscope);
```

The pthread_attr_getscope() function is not supported by this implementation. The function returns ENOSYS.

**pthread_attr_getstackaddr()—Get Stack Address**

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_attr_getstackaddr(const pthread_attr_t *attr, 
    void **stackaddr);
```

The `pthread_attr_getstackaddr()` function is not supported by this implementation. The function returns `ENOSYS`.

---

### pthread_attr_getstacksize()—Get Stack Size

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_attr_getstacksize(const pthread_attr_t *attr, 
    size_t *stacksize);
```

The `pthread_attr_getstacksize()` function is not supported by this implementation. The function returns `ENOSYS`.

---

### pthread_attr_setguardsize()—Set Guard Size

Syntax:
```c
#include <pthread.h>
int pthread_attr_setguardsize(pthread_attr_t *attr, 
    size_t guardsize);
```

The `pthread_attr_setguardsize()` function is not supported by this implementation. The function returns `ENOSYS`.

---

### pthread_attr_setschedpolicy()—Set Scheduling Policy

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_attr_setschedpolicy(pthread_attr_t *attr, 
    int policy);
```

The `pthread_attr_setschedpolicy()` function is not supported by this implementation. The function returns `ENOSYS`.

---

### pthread_attr_setscope()—Set Scheduling Scope

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_attr_setscope(pthread_attr_t *attr, 
    int contentionscope);
```

The `pthread_attr_setscope()` function is not supported by this implementation. The function returns `ENOSYS`.

---

### pthread_attr_setstackaddr()—Set Stack Address

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_attr_setstackaddr(pthread_attr_t *attr, 
    void *stackaddr);
```
The `pthread_attr_setstackaddr()` function is not supported by this implementation. The function returns ENOSYS.

**pthread_attr_setstacksize()—Set Stack Size**

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_attr_setstacksize(pthread_attr_t *attr,
                           size_t stacksize);
```

The `pthread_attr_setstacksize()` function is not supported by this implementation. The function returns ENOSYS.

**pthread_mutexattr_getprioceiling()—Get Mutex Priority Ceiling Attribute**

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_mutexattr_getprioceiling(const pthread_mutexattr_t *attr,
                                   int *prioceiling);
```

The `pthread_mutexattr_getprioceiling()` function is not supported by this implementation. The function returns ENOSYS.

**pthread_mutexattr_getprotocol()—Get Mutex Protocol Attribute**

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_mutexattr_getprotocol(const pthread_mutexattr_t *attr,
                                  int *protocol);
```

The `pthread_mutexattr_getprotocol()` function is not supported by this implementation. The function returns ENOSYS.

**pthread_mutexattr_setprioceiling()—Set Mutex Priority Ceiling Attribute**

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_mutexattr_setprioceiling(pthread_mutexattr_t *attr,
                                    int prioceiling);
```

The `pthread_mutexattr_setprioceiling()` function is not supported by this implementation. The function returns ENOSYS.

**pthread_mutexattr_setprotocol()—Set Mutex Protocol Attribute**

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_mutexattr_setprotocol(pthread_mutexattr_t *attr,
                                  int protocol);
```
The pthread_mutexattr_setprotocol() function is not supported by this implementation. The function returns ENOSYS.

**pthread_mutex_getprioceiling()—Get Mutex Priority Ceiling**

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_mutex_getprioceiling(const pthread_mutex_t *mutex, int *prioceiling);
```

The pthread_mutex_getprioceiling() function is not supported by this implementation. The function returns ENOSYS.

**pthread_mutex_setprioceiling()—Set Mutex Priority Ceiling**

Syntax:
```c
#include <pthread.h>
#include <sched.h>
int pthread_mutex_setprioceiling(pthread_mutex_t *mutex, int prioceiling, int *oldceiling);
```

The pthread_mutex_setprioceiling() function is not supported by this implementation. The function returns ENOSYS.

---

**Concepts**

These are the concepts for this category.

**What are Pthreads?**

Portable Operating System Interface for Computer Environments (POSIX) is an interface standard governed by the IEEE and based on UNIX. POSIX is an evolving family of standards that describe a wide spectrum of operating system components ranging from C language and shell interfaces to system administration.

The Pthread interfaces described in this section are based on a subset of the application programming interfaces (APIs) defined in the POSIX standard (ANSI/IEEE Standard 1003.1, 1996 Edition OR ISO/IEC 9945-1: 1996) and the Single UNIX Specification, Version 2, 1997. The implementation of these APIs is not compliant with these standards. However, the implementation does attempt to duplicate the portable nature of the interfaces defined by the standards. Differences between Pthreads in i5/OS and other thread types are described in "i5/OS Pthreads versus the POSIX standard, the Single UNIX Specification, and other threads implementations" on page 234.

**Primitive data types for Pthreads**

The Pthread types and functions have the following naming conventions. If the type of object is not a thread, **object** represents the type of object, **action** is an operation to be performed on the object, **np** or **NP** indicates that the name or symbol is a non-portable extension to the API set, and **PURPOSE** indicates the use or purpose of the symbol.

**types**

```c
pthread[_[object]][_np]_t
```
functions

pthread[_object]_action[.np]

After creating the primitive objects of type pthread_cond_t and pthread_mutex_t using the appropriate initialization functions, those objects must not be copied or moved to a new location. If the condition variable or mutex is copied or moved to a new location, the new primitive object is not valid or usable. Attempts to use the new object result in the EINVAL error.
The i5/OS implementation of pthreads defines the _POSIX_THREADS and _POSIX_THREAD_PROCESS_SHARED feature test macros. See "Unsupported preprocessor and feature test macros" on page 235 for a complete list of unsupported feature test macros.

i5/OS Pthreads versus the POSIX standard, the Single UNIX Specification, and other threads implementations

Although the Pthread interfaces described in this document are based on a subset of the APIs defined in the POSIX standard and the Single UNIX Specification, the implementation of these APIs is not compliant with these standards. This means that applications written in other versions of threads are not necessarily portable to i5/OS. Below is a list of the differences between the Pthread APIs and other threads implementations.

- All thread definitions in pthread.h
- Unsupported preprocessor and feature test macros
- Unsupported APIs
- Unsupported constants
- Unsupported cancellation points
- Unsupported sysconf() configuration variables
- Thread priority and scheduling
- Thread ID vs. Pthread Handle (pthread_t)
- Thread ID value and size
- Mutexes return EDEADLK when re-locked by owner
- Return values from thread start routines are not integers
- Threads do not necessarily start before pthread_create() returns
- Initial thread is special, cannot pthread_exit()
- Pthread APIs cause asynchronous signals initialization
- Not all jobs can create threads; pthread_create() fails with EBUSY
- Read/write locks are recursive
- Shared read/write locks are released at thread termination
- "Read/write locks can be upgraded/downgraded" on page 242
- Read/write locks do not favor writers
- Spawn API provides more POSIX-like process model
- C++ destructors and Pthread termination
- Unhandled exceptions terminate the thread (not the process)
- Exceptions vs. Asynchronous signals vs. ANSI C signals
- "Mutexes can be named to aid in application debug" on page 254

All thread definitions in pthread.h

For Pthreads on the iSeries, all feature test macros, preprocessor values, data structures, types, and function prototypes are located in the pthread.h header file instead of the system header files that are specified by POSIX or the Single UNIX Specification.
Unsupported preprocessor and feature test macros

The following Pthread feature test macros are not defined on the server:

- _POSIX_THREAD_ATTR_STACKADDR
- _POSIX_THREAD_ATTR_STACKSIZE
- _POSIX_THREAD_PRIO_INHERIT
- _POSIX_THREAD_PRIO_PROTECT
- _POSIX_THREAD_SAFE_FUNCTIONS
- _POSIX_THREAD_PRIORITY_SCHEDULING

Unsupported constants

The following constants related to threads are not defined on the server.

- PTHREAD_STACK_MIN
- PTHREAD_PRIO_INHERIT
- PTHREAD_PRIO_NONE
- PTHREAD_PRIO_PROTECT

Unsupported cancellation points

i5/OS does not support the full set of cancellation points. Although the APIs may be provided, they are not necessarily cancellation points. The only cancellation points currently supported are those APIs that are part of the Pthread run-time. Those APIs are the following:

- pthread_cond_timedwait()
- pthread_cond_wait()
- pthread_delay_np()
- pthread_join()
- pthread_join_np()
- pthread_testcancel()

An appropriate alternative to create cancellation points for these APIs might be like the following example. You can use this example to create a cancellation point out of any function that is asynchronous signal safe. See [Signal Concepts](#) for a list of functions that are asynchronous signal safe. If a function is not asynchronous signal safe, you should not use this form of asynchronous cancellation because it corrupt data.

Example

See [Code disclaimer information](#) for information pertaining to code examples.

```c
... preceding code ...
int oldtype=0;
/* if cancellation is currently disabled, this will have no effect */
/* if cancellation is currently enabled, we'll set it to asynchronous */
/* for the duration of this call to try to simulate a cancellation point */
pthread_setcanceltype(PTHREAD_CANCELASYNCHRONOUS, &oldtype);
/* call kernel API that you want to be a cancel point. You should */
/* only call functions which are asynchronous signal safe in this block. */
/* Validating the asynchronous signal safety of the function will */
```
/* ensure that the asynchronous cancellation does not negatively */
/* affect the API or corrupt the data that the API uses */
APICallHere();
/* Restore the cancellation type that was previously in effect */
pthread_setcanceltype(oldtype, &oldtype);
... following code ...

Unsupported sysconf() configuration variables

The following sysconf() configuration variables related to threads are not supported on the server.

- _SC_THREAD_DESTRUCTOR_ITERATIONS
- _SC_THREAD_PRIORITY_SCHEDULING
- _SC_THREADS
- _SC_THREAD_ATTR_STACKADDR
- _SC_THREAD_ATTR_STACKSIZE
- _SC_THREAD_KEYS_MAX
- _SC_THREAD_PRIO_INHERIT
- _SC_THREAD_PRIO_PROTECT
- _SC_THREAD_PROCESS_SHARED
- _SC_THREAD_SAFE_FUNCTIONS
- _SC_THREAD_STACK_MIN
- _SC_THREAD_THREADS_MAX

Thread priority and scheduling

The default thread creation attributes of the iSeries implementation of Pthreads uses an explicitly specified priority of DEFAULT_PRIO_NP. Some implementations inherit the scheduling priority and policy of the creating thread by default. For better performance, the iSeries implementation chooses to start each thread with an explicit priority so that, when a thread is created, the priority of the creating thread does not need to be retrieved at run-time.

An iSeries thread competes for scheduling resources against other threads in the system, not solely against other threads in the process. The scheduler is a delay cost scheduler based on several delay cost curves (priority ranges). The POSIX standard and the Single UNIX Specification refers to this as scheduling scope and scheduling policy, which cannot be changed from the default of SCHED_OTHER in this implementation.

The following Pthread APIs support a scheduling policy of only SCHED_OTHER.

- pthread_setschedparam (SCHED_OTHER only supported)
- pthread_getschedparam
- pthread_attr_setschedparam
- pthread_attr_getschedparam

The priority of a thread is specified as a number that represents the value that is added to the priority of the process. Changing the priority of the process affects the priority of all of the threads within that process. The default priority for a thread is DEFAULT_PRIO_NP, which is no change from the process priority.
On the iSeries, numerically lower priority values indicate higher priority with regard to scheduling. The
`pthread.h` and `sched.h` header files define the priority constants in a way that is consistent with the
threads standard, but opposite of priority specifications on the iSeries. When you specify a priority of -99
in a call to `pthread_setschedparam()`, the priority of the target thread is lowered to the lowest possible
value.

For example, process P1 is at iSeries priority 20 and contains a thread T1 that specifies a Pthread priority
adjustment of -18. Process P2 is at iSeries priority 25 and contains thread T2 that specifies a priority of -5.
The result is that the system schedules the threads using the iSeries priority for T1 as 38 and for T2 as 30.
The thread scheduling is specified at a system level, and although process P2 runs at a lower priority
ranking than process P1, thread T2 within process P2 runs at a higher priority ranking than thread T1 in
process P1, and thus gets more processing resources.

**Thread ID vs. Pthread Handle (pthread_t)**

In many threads implementations, the `pthread_t` abstract type is implemented as an integer (4 byte)
thread ID. In the iSeries implementation of Pthreads, the thread ID is a 64-bit integral value and the
`pthread_t` is an abstraction (structure) that contains that value and others. This abstraction helps to allow
the implementation to scale to thousands of threads in a process.

Do not allow your program to rely on the internal structure or size of the `pthread_t` in a non-portable
fashion, such as comparisons of thread IDs. For portable comparison, use the `pthread_equal()` API. This
documentation occasionally refers to the `pthread_t` as a Pthread handle to try to prevent the
misconception that it represents a single integer value.

**Thread ID value and size**

In some threads implementations, the thread ID is a 4-byte integer that starts at 1 and increases by 1
every time a thread is created. This integer can be used in a non-portable fashion by an application.

To assist in the portability problem with the application and to allow retrieval of the thread ID, the
iSeries implementation has provided the `pthread_getunique_np()` function to retrieve the thread ID from
the Pthread handle. This thread ID is a 64-bit integer value. Because some compilers do not yet support a
full 64-bit integer data type, the value is returned in a structure containing two 4-byte integers.

**Mutexes return EDEADLK when re-locked by owner**

Some threads implementations return the EDEADLK error when a mutex attempts to relock a mutex that
it already owns. The POSIX standard specifies that the results are undefined when a mutex is re-locked
by the owner. The Single UNIX Specification addresses these issues by providing a new mutex attribute
called `type`.

The iSeries threads support takes the same implementation route that the Single UNIX Specification
suggests, and it also causes the thread to deadlock when it attempts to re-lock a normal (non-recursive)
mutex. Because many users of Pthreads do not check return codes from functions, the deadlock protects
applications from corrupted data that might result if they attempt to relock an already held mutex, then
unlock the mutex as if the lock was successful.
Return values from thread start routines are not integers

Return values from a thread are defined to be of type `void *`. On some platforms, a `void *` and an integer can be easily interchanged with no loss of information. Until Version 4 Release 2, this was not true on the iSeries. The iSeries enforces stricter pointer rules to both prevent and detect application bugs or a malicious program's behavior. Thus, when converting integers to pointers by a mechanism not directly supported by your compiler, the valid pointer information is lost, and the pointer is always set to `NULL` (regardless of its binary value).

New support put into the system in Version 4 Release 2 allows you to store an integer into a pointer, and still have the pointer be non-NULL. You cannot store to, read from, or defer a pointer created by this mechanism, but the pointer appears non-NULL.

The macros `__INT()` and `__VOID()` are provided to aid in compatibility and allow you to easily store and retrieve integer information in pointer variables even if your compiler does not support the direct typecast. These macros allow explicit conversion from a pointer to an integer and from an integer to a pointer.

**Note:** The macros `__INT()` and `__VOID()` result in function calls.

**Example**

The following example shows the correct way to store and retrieve integer information in pointer variables.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

int main(int argc, char **argv)
{
    void *status1 = __VOID(5);
    void *status2 = __VOID(999);

    if (status1 == NULL) {
        printf("Status1 pointer is NULL\n");
    } else {
        printf("Status1 pointer is non-NULL\n");
    }

    if (status1 == status2) {
        printf("Both status variables as pointers are equal\n");
    } else {
        if (status1 < status2) {
            printf("Status1 is greater than status2\n");
        } else {
            if (status1 < status2) {
                printf("Status1 is less than status2\n");
            } else {

                238 IBM Systems - iSeries: Pthread APIs
Threads do not necessarily start before pthread_create() returns

A thread may or may not start running before the return from pthread_create(). Depending on the amount of time left in the creating threads, time slice, and the other activity on the system, the creating thread may return before the new thread runs.

The thread implementations of some systems guarantee a certain ordered behavior for thread creation versus the execution of the first statement in the new thread. On the iSeries, it is unknown which happens first, the execution of the first instruction in the new thread or the return from pthread_create().

The following example shows an incorrectly written application.

See Code disclaimer information for information pertaining to code examples.

```c
#include <pthread.h>
#include <stdio.h>
#include "check.h"

pthread_t thread;

void *threadfunc(void *parm) {
    pthread_id_np_t tid;
    #error "This is an ERROR."
    #error "The 'thread' variable is shared between threads"
    #error "and must be protected by a mutex."
    pthread_getunique_np(&thread, &tid);
    printf("Thread 0x%.8x %.8x started\n", tid);
    return NULL;
}

int main(int argc, char **argv) {
    int rc=0;
    printf("The pointers are unordered!\n");
    printf("Pointer values stored in status variables are:\n";
    status1 = %.8x %.8x %.8x %.8x
    status2 = %.8x %.8x %.8x %.8x
    printf("Integer values stored in status variables are:\n";
    status1 = %d
    status2 = %d
    return;
}
```

Output:
Status1 pointer is non-NULL
Status1 is less then status2
Pointer values stored in status variables are:
status1 = 80000000 00000000 00008302 00000005
status2 = 80000000 00000000 00008302 000003e7
Integer values stored in status variables are:
status1 = 5
status2 = 999
printf("Enter Testcase - \%s\n", argv[0]);

#error "This is an ERROR."
#error "The order of thread thread startup, and return from"
#error "the pthread_create() API is NOT deterministic."
rc = pthread_create(&thread, NULL, threadfunc, NULL);
checkResults("pthread_create(NULL)\n", rc);

/* sleep() isn't a very robust way to wait for the thread */
sleep(5);

printf("Main completed\n");
return 0;

Initial thread is special, cannot pthread_exit()

The initial thread in an i5/OS process is special because of these characteristics:

- If the initial thread calls pthread_exit(), the process terminates.
- If the initial thread is the target of a pthread_cancel() request that is acted upon, the process terminates.
- If the initial thread terminates through any other action, the process terminates.
- Many i5/OS APIs and commands target jobs. Some of these APIs target resources that are allocated to threads for retrieval or modification. If this is the case, the resources that displayed, modified, or retrieved may be the resources owned by the initial thread.

For example, the CL command WRKACTJOB allows you to display information such as the call stack for a job. Since a job does not have a call stack and the call stack is thread scoped, the call stack of the initial thread is displayed when you choose to display the call stack of a job.

Other APIs or CL commands that operate against jobs have undergone similar changes. See the specific documentation for the API or CL command of concern.

Pthread APIs cause asynchronous signals initialization

When a job is running in i5/OS, by default it is not enabled for POSIX signals. The system never delivers a Posix signal to a job that is not enabled for signals.

The job is initialized for signals with the default POSIX signals environment when any thread in the job calls any API defined to implicitly enable signals. The main categories of APIs that enable signals are the signals APIs and some process-related APIs related to signals. For example, some of the APIs that enable signals are Qp0sEnableSignals(), kill(), sigaction(), sigprocmask(), getpid(), and spawn(). After the initialization for signals occurs within a job, the system can deliver signals to that job if they are generated by another job or by the system.

When a program in a job uses Pthreads, that job is automatically enabled for signals when the Pthreads service program is loaded (either dynamically or statically). Loading the service program that contains the Pthread APIs causes the job to be initialized for signals, regardless of whether the application actually calls the pthread APIs. All pthread programs can implicitly receive signals if another job or the system generates a signal for the threaded job.

If the application calls Qp0sDisableSignals() to disable signals for the job, the Pthreads APIs do not function correctly. Do not use Qp0sDisableSignals() in a threaded job.
Not all jobs can create threads; pthread_create() fails with EBUSY

Because many parts of the operating system are not yet thread safe, not every job is allowed to start threads. The pthread_create() API fails with the EBUSY error when the process is not allowed to create threads. See “Running threaded programs” on page 261 for information about how to start a job that can create threads.

For details about how thread creation is currently allowed for your process, you can see the pthread_getphtreadoption_np() API, option PTHREAD_OPTION_THREAD_CAPABLE_NP.

See Multithreaded applications for an introduction to threads and general API information about iSeries threads.

Read/write locks are recursive

The i5/OS implementation of read/write locks provides a recursive behavior not only for shared read locks (as the thread standard specifies), but for exclusive write locks as well. The following statements apply to read/write locks on i5/OS:

- A thread can acquire any number of shared read locks on a read/write lock. Each successful shared read lock that is acquired must be released by a call to pthread_rwlock_unlock().
- A thread can acquire any number of exclusive write locks on a read/write lock. Each successful exclusive write lock that is acquired must be released by a call to pthread_rwlock_unlock().

Shared read/write locks are released at thread termination

If a thread is the owner of one or more shared read locks acquired by pthread_rwlock_unlock(), pthread_rwlock_tryrdlock(), or pthread_rwlock_timedrdlock_np(), when that thread terminates, the shared read locks are automatically released by the system. If a thread holds a shared read lock, it does not modify the resources associated with that lock. It is then safe for the runtime support to unlock the read lock without indicating an error condition or causing the process to wait. For performance reasons, your application should unlock all held locks before the thread ends.

If a thread is the owner of one or more exclusive write locks acquired by pthread_rwlock_wrlock(), pthread_rwlock_trywrlock(), or pthread_rwlock_timedwrlock_np(), when that thread terminates, the exclusive write locks are not automatically released by the system. This is an error in the application and indicates that the data associated with the lock is in an inconsistent state. If another thread attempts to get a shared read or exclusive write lock on the lock, that thread blocks forever.
Read/write locks can be upgraded/downgraded

The i5/iOS implementation of read/write locks allows a thread to effectively change a read lock to a write lock, or change a write lock to a read lock, without an intervening unlocked and unprotected section of code. The following items describe read/write lock behavior that allows these changes. This behavior is outside of the definition of the Single UNIX Specification. An application written to be portable to the Single UNIX Specification should not attempt to acquire a shared read lock and a shared write lock on the same read/write lock at the same time.

- If a thread currently holds a shared read lock, an attempt by the same thread to acquire an exclusive write lock succeeds if no other threads hold a shared read lock. The thread then holds both an exclusive write lock and a shared read lock.
- If a thread currently holds an exclusive write lock, an attempt by the thread to acquire a shared read lock succeeds. The thread then holds both an exclusive write lock and a shared read lock.
- If a thread holds one or more shared read locks and one or more exclusive write locks on the same read/write lock object at the same time, a call to pthread_rwlock_unlock() always unlocks the exclusive write lock FIRST.
- When multiple exclusive write locks and multiple exclusive read locks are held by the same thread on the same read/write lock object, the behavior of pthread_rwlock_unlock() is as follows:
  - A call to the pthread_rwlock_unlock() function always unlocks the most recent exclusive write lock first.
  - Subsequent calls to pthread_rwlock_unlock() first reduce the count of any outstanding exclusive write locks held by the thread until all exclusive write locks are unlocked.
  - After all outstanding exclusive write locks are unlocked and the thread holds only shared read locks on the read/write lock object, a call to pthread_rwlock_unlock() function then unlocks the most recent shared read lock.
  - Subsequent calls to pthread_rwlock_unlock() reduce the count of any outstanding shared read locks held by the thread until all shared read locks are unlocked.

For a thread to change a shared read lock to an exclusive write lock, the thread should perform the following actions:

```c
{  
    pthread_rwlock_t rwlock = PTHREAD_RWLOCK_INITIALIZER;
    pthread_rwlock_rdlock(&rwlock);
    ...
    /* Thread holding a read lock decides it needs to upgrade to a write lock */
    /* Now Upgrade to write lock */
    pthread_rwlock_wrlock(&rwlock);
    ...
    /* write lock (and read lock) are held here.*/
    /* We have effectively upgraded to a write lock */
    /*"Downgrade" back to a only the read lock */
    pthread_rwlock_unlock(&rwlock);
    ...
    /* unlock the read lock */
    pthread_rwlock_unlock(&rwlock);
}
```

For a thread to change an exclusive write lock to a shared read lock, the thread should perform the following actions:

```c
{  
    pthread_rwlock_t rwlock = PTHREAD_RWLOCK_INITIALIZER;
    pthread_rwlock_wrlock(&rwlock);
    ...
    /* Thread holding the write lock decides it needs to downgrade to a read lock */
    /* Get the read lock, so we are holding BOTH read and write locks */
    pthread_rwlock_rdlock(&rwlock);
}
```
Read/write locks do not favor writers

The i5/OS implementation of read/write locks does not favor writers. If your application has a large number of readers contending for the same lock, the writers may not be allowed to write.

The i5/OS implementation of `pthread_rwlock_tryrdlock()`, for example, does not completely honor the Single UNIX Specification in its treatment of reader/writer contention.

The standard states the following: "The function pthread_rwlock_tryrdlock() applies a read lock as in the pthread_rwlock_rdlock() function with the exception that the function fails if any thread holds a write lock on rwlock or there are writers blocked on rwlock."

In the i5/OS implementation, if `pthread_rwlock_tryrdlock()` is used on a read/write lock that has multiple readers holding the lock and multiple waiting writers blocked on the lock, the `pthread_rwlock_tryrdlock()` are allowed to complete successfully.

Spawn API provides more POSIX-like process model

The iSeries uses a call/return mechanism when your application calls programs. A new process is not started when you call a program, instead the program runs and returns to its caller. You can use activation groups to separate or partition the program resources from the caller.

For the more POSIX-like behavior of running each program in a separate process (and thus taking advantage of thread safety, encapsulation, and protection that the new process may give you), use the `spawn()` API to start the program.

You also can use the capability provided in `spawn()` to allow the child process to start multiple threads. See the `spawn()` API documentation for a description of the `SPAWN_SETTHREAD_NP` flag in the inheritance structure.

A CL command for using SPAWN is also available from the QUSRTOOL library. See SPAWN CL command, QUSRTOOL example for more information about the SPAWN CL command.
C++ destructors and Pthread termination

Unlike some other implementations of threads, C++ destructors for automatic objects are allowed to run in a well defined and consistent manner when a thread is terminated.

The following list includes some of the causes of thread termination:
- A thread calls pthread_exit() or returns from the thread start routine.
- A thread is the target of pthread_cancel().
- A thread is ended due to an unhandled exception.
- A thread is in a process that contains another thread that calls exit() or abort().
- A thread is in a process that is terminated by the system administrator.
- A thread is being terminated by the system administrator.

When a thread terminates, the following occurs:
1. If the thread was ended using pthread_exit(), pthread_cancel() or return from the thread start routine, then cancellation cleanup handlers and data destructors are run.
2. The thread is terminated. At the time that the thread is terminated, both C++ destructors for automatic objects and i5/OS cancel handlers run.

If a Pthread is terminated using a non-Pthread method (an i5/OS exception, a different thread termination primitive provided by the system, exit() or abort(), or other job termination method), Pthread cancellation cleanup handlers and data destructors do not run.

Example

This example shows the relationship between C++ destructors and Pthread cleanup mechanisms.

See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <stdio.h>
#include <qp0z1170.h>
#include <time.h>
#include <pthread.h>
#include "check.h"

#define bufferSize 100
#define threadRc 55

pthread_key_t tlskey;

void dataDestructor(void *parm);
void cancelHandler(void *parm);
void *threadfunc(void *parm);
void level2(void);
void level3(void);

class A {
public:
    A(char *label);
    ~A();
private:
    pthread_id_np_t tid;
    char buffer[bufferSize];
};

void dataDestructor(void *parm) {
    printf("In data destructor\n");
}
```
void cancelHandler(void *parm) {
    printf("In cancellation cleanup handler\n");
}

void *threadfunc(void *parm) {
    A *object("start routine object");
    level2();
    return NULL;
}

void level2(void) {
    A *object("Second level object");
    level3();
}

void level3(void) {
    int rc;
    struct timespec ts = {5, 0};
    A *object("Third level object");

    pthread_setspecific(tlskey, &tlskey);
    pthread_cleanup_push(cancelHandler, NULL);
    printf("Thread blocked\n");
    rc = pthread_delay_np(&ts);
    if (rc != 0) {
        printf("pthread_delay_np() - return code %d\n", rc);
        return;
    }
    printf("Calling pthread_exit()\n");
    pthread_exit(__VOID(threadRc));
    pthread_cleanup_pop(0);
}

int main(int argc, char **argv) {
    int rc=0;
    int i;
    pthread_t threadid;
    void *status;
    int fail=0;

    printf("Enter Testcase - %s\n", argv[0]);
    rc = pthread_key_create(&tlskey, dataDestructor);
    checkResults("pthread_key_create()\n", rc);

    printf("---------- Start pthread_cancel() example ----------\n");
    printf("Create a thread\n");
    rc = pthread_create(&threadid, NULL, threadfunc, NULL);
    checkResults("pthread_create()\n", rc);

    sleep(2);
    rc = pthread_cancel(threadid);
    checkResults("pthread_cancel()\n", rc);

    rc = pthread_join(threadid, &status);
    checkResults("pthread_join()\n", rc);
    if (status != PTHREAD_CANCELED) {
        printf("Canceled thread did not return the expected results\n");
        fail = 1;
    }

    printf("---------- Start pthread_exit() example ----------\n");
    printf("Create a thread\n");
    rc = pthread_create(&threadid, NULL, threadfunc, NULL);
    checkResults("pthread_create()\n", rc);
}

Pthread APIs 245
checkResults("pthread_create()\n", rc);
rc = pthread_join(threadid, &status);
checkResults("pthread_join()\n", rc);
if (__INT(status) != threadRc) {
  printf("pthread_exit() thread did not return the expected results\n");
  fail = 1;
}
}
pthread_key_delete(tlskey);
if (fail) {
  printf("At least one thread failed!\n");
  exit(1);
}
printf("Main completed\n");
return 0;

A::A(char *label) {
  strncpy(buffer, label, bufferSize);
  pthread_t me;
  me = pthread_self();
  pthread_getunique_np(&me, &tid);
  printf("\"%s\" instantiated in thread 0x%.8x %.8x\n", buffer, tid);
}
A::~A() {
  printf("\"%s\" destroyed in thread 0x%.8x %.8x\n", buffer, tid);
}

Output:
Enter Testcase - QP0WTEST/TPCPPO
---------- Start pthread_cancel() example ----------
Create a thread
`start routine object' instantiated in thread 0x00000000 00000161

Main completed
Unhandled exceptions terminate the thread (not the process)

On a UNIX system, when an invalid or illegal software condition is encountered (such as dividing by zero or using an invalid pointer), a signal is generated. If the signal is not handled, the process is terminated.

The operating system does not generate a signal for these events, but instead, generates an exception message. The exception message moves up the call stack, allowing each stack frame (function on the stack or invocation entry) a chance to handle the exception. Each function invocation may choose to handle or not to handle the exception. If the exception is not handled, the message continues to the next stack frame.

When the exception message reaches certain boundaries on the call stack (like a main() entry point, usually called control boundaries) certain events take place. These events include changing the exception to a different type, terminating the process, terminating the activation group, or terminating the thread. If an unhandled exception condition happens in a secondary thread and moves all the way to the first invocation in the thread without being handled, the resulting action will be to terminate the thread. During this percolation, if the exception hits a control boundary and is not handled, it may terminate the process.

A signal is never automatically generated for an exception message. When an unhandled exception terminates the thread, Pthread cancellation cleanup handlers and Pthread data destructors do not run and the thread is terminated immediately with a return status of PTHREAD_EXCEPTION_NP. PTHREAD_EXCEPTION_NP is a macro similar to the PTHREAD_CANCELED macro, and is not NULL or a valid pointer.

On a UNIX system, this same activity may terminate the process due to the signal that is generated.

In order to have your application terminate the process, when the exception occurs, you must handle it and explicitly terminate the process. The following example handles all hardware exceptions using the ANSI C signal model and uses the Pthread signal SIGABRT to terminate the process.

You can also turn the exception message into a Posix signal and it may be handled. See “Exceptions vs. Asynchronous signals vs. ANSI C signals” on page 249 for more information.

Example

See [Code disclaimer information](#) for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <stdio.h>
#include <qpz1170.h>
#include <time.h>
#include <signal.h>
#include <pthread.h>
#include "check.h"

void abortTheProcessWhenAnExceptionOccurs(int sigNumber);
void *threadfunc1(void *parm);

void *threadfunc1(void *parm)
{
    char *p=NULL;
    printf("Thread1: Unhandled exception (pointer fault) about to happen\n");
    *p = `!';
    printf("Thread1: After exception\n");
    return NULL;
}
```

Pthread APIs 247
void abortTheProcessWhenAnExceptionOccurs(int sigNumber) {
    /* In a multithreaded environment this is a little difficult. We have to */
    /* re-enable the ANSI C handler immediately, because that is the way it */
    /* is defined. (A better alternative may be direct monitor exception    */
    /* handlers that are always valid in the function which they are     */
    /* registered, and with direct monitors, we can catch the hardware     */
    /* exception before it is converted to an ANSI C signal               */
    signal(SIGALL, abortTheProcessWhenAnExceptionOccurs);
    /* Since ANSI C signals and hardware exceptions are only handled in */
    /* the same thread that caused them, we send the Posix signal to      */
    /* the calling thread (The signal is delivered before returning from */
    /* pthread_kill()).                                                   */
    printf("Mapping ANSI signal %d to posix signal SIGABRT. "        
            "Aborting the process\n", sigNumber);
    pthread_kill(pthread_self(), SIGABRT);
    return;
}

int main(int argc, char **argv)
{
    int rc=0;
    pthread_t threadid;
    void *status;

    printf("----------- Setup Signal Mapping/Handling -------------\n");
    printf("- Register ANSI C signal handler to map ALL\n"          
            " ANSI C signals & hardware exceptions to Posix signals\n");
    /* If we want to do debug, or determine what when wrong a little more easily, */
    /* we could use the abortTheProcessWhenAnExceptionOccurs function to delay */
    /* the thread, or */
    /* dump failure data of some sort. */
    signal(SIGALL, abortTheProcessWhenAnExceptionOccurs);

    printf("----------- Start memory fault thread ---------------\n");
    printf("Create a thread\n");
    rc = pthread_create(&threadid, NULL, threadfunc1, NULL);
    checkResults("pthread_create()\n", rc);

    rc = pthread_join(threadid, &status);
    checkResults("pthread_join()\n", rc);

    printf("Main completed\n");
    return 0;
}

Output:

----------- Setup Signal Mapping/Handling -------------
- Register ANSI C signal handler to map ALL
  ANSI C signals & hardware exceptions to Posix signals
----------- Start memory fault thread ---------------
Create a thread
Thread1: Unhandled exception (pointer fault) about to happen
Mapping ANSI signal 5 to posix signal SIGABRT. Aborting the process
Exceptions vs. Asynchronous signals vs. ANSI C signals

iSeries distinguishes between hardware exceptions, POSIX signals (sometimes called asynchronous signals), and ANSI C signals. POSIX signals use the APIs kill(), sigaction(), pthread_kill(), alarm(), pause(), and others for signal interaction. ANSI C signals use the APIs raise(), signal(), and abort() for signal interaction.

Many other systems, by default, generate a POSIX signal whenever a software or hardware exception occurs (such as using a pointer that is not valid, or an error caused by dividing by zero), and on those systems, a POSIX signal may be equivalent and indistinguishable from an ANSI C signal. If the signal is not handled, this results in the termination of the process.

The operating system does not generate a signal for these hardware or software problems, but instead, generates an exception message. The exception message moves up the call stack, allowing each stack frame (function on the stack or invocation entry) a chance to handle the exception. Each function invocation may choose whether or not to handle the exception. If the exception is not handled, the message continues to the next stack frame.

When the exception message reaches certain boundaries on the call stack (such as a main() entry point, usually called control boundaries), certain events take place. These events include changing the exception to a different type, terminating the process, terminating the activation group, or terminating the thread. If an exception that is not handled occurs in a secondary thread and moves all the way to the first invocation in the thread without being handled, the resulting action is to terminate the thread. During this movement, if the exception hits a control boundary and is not handled, it may terminate the process.

The integrated language environment (ILE) C was present on the system before the POSIX signals implementation. Therefore, the ILE C uses the robust iSeries exception model to implement ANSI C signals (raise(), signal(), abort()). The ILE C also provides the generation of an ANSI C signal when it detects a hardware exception. Thus, using the signal() API, you can monitor and handle hardware exceptions.

A signal is never automatically generated for an exception message. iSeries hardware and software exceptions cannot be detected using asynchronous signal mechanisms. In other words, if you use sigaction() for the SIGSEGV signal, you will not detect that signal when a pointer that is not valid is used. If you use signal(), you will detect SIGSEGV when your code uses an invalid pointer.

If the preferred signal model is the asynchronous signal model, you can use iSeries exception handlers or ANSI C signal handlers to generate a asynchronous signal when those events occur.

The following example shows how an error caused by dividing by zero and the use of an invalid pointer might be changed into an asynchronous signal. The following example uses ANSI C signal handlers to perform the signal mapping.

Example

See Code disclaimer information for information pertaining to code examples.

```c
#include _MULTI_THREADED
#include <stdio.h>
#include <q00z1170.h>
#include <time.h>
#include <signal.h>
#include <pthread.h>
#include "check.h"

void my AnsiSignalMapperHdlr(int sigNumber);
void *threadfunc1(void *parm);
void *threadfunc2(void *parm);
```

Pthread APIs 249
void *threadfunc1(void *parm)
{
    char *p=NULL;
    printf("Thread1: Unhandled exception (pointer fault) about to happen\n");
    *p = '\n';
    printf("Thread1: After exception\n");
    return NULL;
}

void *threadfunc2(void *parm)
{
    int i1=0, i2=1, i3=0;
    printf("Thread2: Unhandled exception (divide by zero) about to happen\n");
    i1 = i2 / i3;
    printf("Thread2: After exception\n");
    return NULL;
}

void myAnsiSignalMapperHdlr(int sigNumber)
{
    /* In a multithreaded environment, this is slightly difficult. We have to */
    /* re-enable the ANSI C handler immediately, because that is the way it */
    /* is defined. (A better alternative may be direct monitor exception */
    /* handlers which are always valid in the function which they are */
    /* registered, and with direct monitors, we can catch the hardware */
    /* exception before it is converted to an ANSI C signal */
    signal(SIGALL, myAnsiSignalMapperHdlr);
    /* Since ANSI C signals and hardware exceptions will only be handled in */
    /* the same thread that caused them, we will send the POSIX signal to */
    /* the calling thread (The signal will be delivered before returning from */
    /* pthread_kill() */
    printf("Mapping ANSI signal to POSIX signal %d\n", sigNumber);
    pthread_kill(pthread_self(), sigNumber);
    return;
}

void fpViolationHldr(int sigNumber)
{
    printf("Thread 0x%.8x %.8x "
           "Handled floating point failure SIGFPE (signal %d)\n",
           pthread_gettid_np(), sigNumber);
    /* By definition, returning from a POSIX signal handler handles the signal*/
}

void segFaultHdlr(int sigNumber)
{
    printf("Thread 0x%.8x %.8x "
           "Handed segmentation violation SIGSEGV (signal %d)\n",
           pthread_gettid_np(), sigNumber);
    /* By definition, returning from a POSIX signal handler handles the signal*/
}

int main(int argc, char **argv)
{
    int rc=0;
    pthread_t threadid;
    struct sigaction actions;
    void *status;

    printf("---------- Setup Signal Mapping/Handling ----------\n");
    printf("- Register ANSI C signal handler to map ALL\n"
           " ANSI C signals & hardware exceptions to POSIX signals\n");
    signal(SIGALL, myAnsiSignalMapperHdlr);

    printf("- Register normal POSIX signal handling mechanisms\n"
           " for floating point violations, and segmentation faults\n"
           "- Other signals take the default action for asynchronous signals\n");
    memset(&actions, 0, sizeof(actions));
    sigemptyset(&actions.sa_mask);
Example Output

------------- Setup Signal Mapping/Handling -------------
- Register ANSI C signal handler to map ALL
  ANSI C signals & hardware exceptions to POSIX signals
- Register normal POSIX signal handling mechanisms
  for floating point violations, and segmentation faults
- Other signals take the default action for asynchronous signals

------------- Start memory fault thread -------------
Create a thread
Thread: Unhandled exception (pointer fault) about to happen
Mapping ANSI signal to POSIX signal 5
Thread 0x00000000 0000000022 Handled segmentation violation SIGSEGV (signal 5)
Thread: After exception

------------- Start divide by 0 thread -------------
Create a thread
Thread2: Unhandled exception (divide by zero) about to happen
Mapping ANSI signal to POSIX signal 2
Thread 0x00000000 0000000023 Handled floating point failure SIGFPE (signal 2)
Thread2: After exception

Main completed

Example

The following example shows how a divide by zero error, and a dereference of a pointer that is not valid might be mapped to generate a POSIX (asynchronous) signal. This example uses exception handlers to perform the signal mapping.

See [Code disclaimer information](#) for information pertaining to code examples.
#include <qusec.h> /* System API error Code structure */
#include <qmh.h>  /* Message Handler common defs */
#include <qmhchgem.h> /* Change exception message */
#include <pthread.h>
#include "check.h"

void myHardwareExceptionMapper(_INTRPT_Hndlr_Parms_T *exception);
void *threadfunc1(void *parm);
void *threadfunc2(void *parm);

void *threadfunc1(void *parm)
{
  char *p=NULL;
  /* Watch for all ESCAPE type exceptions. Other types may be used for */
  /* job log messages or C++ exceptions or other control flow in the process*/
  /* Adjust the message type as required by your application. */
  #pragma exception_handler (myHardwareExceptionMapper, 0, _C1_ALL, _C2_MH_ESCAPE)
  printf("Thread1: Unhandled exception (pointer fault) about to happen\n");
  *p = '!';
  printf("Thread1: After exception\n");
  #pragma disable_handler
  return NULL;
}

void *threadfunc2(void *parm)
{
  int i1=0, i2=1, i3=0;

rc = pthread_join(threadid, &status);
checkResults("pthread_join()\n", rc);

Pthread APIs 253
printf("Main completed\n");
return 0;
}

Output
-------
Set up Signal Mapping/Handling
- The threads will register iSeries Exception handler to map
  hardware exceptions to POSIX signals
- Register normal POSIX signal handling mechanisms
  for floating point violations, and segmentation faults
- Other signals take the default action for asynchronous signals

Start memory fault thread

Create a thread
Thread: Unhandled exception (pointer fault) about to happen

Handling system exception
Mapping Exception MCH3601 to POSIX signal 5
Thread 0x00000000 00000024 Handled segmentation violation SIGSEV (signal 5)
Thread1: After exception

Start divide by 0 thread

Create a thread
Thread2: Unhandled exception (divide by zero) about to happen

Handling system exception
Mapping Exception MCH1211 to POSIX signal 2
Thread 0x00000000 00000025 Handled floating point failure SIGFPE (signal 2)
Thread2: After exception

Main completed

Mutexes can be named to aid in application debug

The i5/OS threads support of mutexes allows the application to name mutexes. Named mutexes can be
used to aid in problem determination. The performance and behavioral characteristics of named mutexes
are identical to normal mutexes.

When an application is using mutexes and has deadlocked, you may be able to determine which mutexes
are being used by the application more easily if the mutexes being used are named.

You can use the DSPJOB CL command to help debug the application. From DSPJOB, choose option 19 -
Display mutexes, if active or option 20 - Display threads, if active to view the mutexes and threads
being used by the application.

See “pthread_mutexattr_setname_np()—Set Name in Mutex Attributes Object” on page 125 and
“pthread_mutexattr_getname_np()—Get Name from Mutex Attributes Object” on page 114 if you would
like to use named mutexes in your application.

Header files for Pthread functions

Programs that use the Pthread functions must include one or more header files that contain information
that the functions need. Header files include the following:
- Macro definitions
- Data type definitions
- Structure definitions
- Function prototypes
The header files are provided in the QSYSINC library which can be installed as an option. Make sure QSYSINC is on your system before compiling programs that use these header files.

**Where to Find Header Files**

<table>
<thead>
<tr>
<th>Name of Header File</th>
<th>Name of File in QSYSINC</th>
<th>Name of Member</th>
</tr>
</thead>
<tbody>
<tr>
<td>pthread.h</td>
<td>H</td>
<td>PTHREAD</td>
</tr>
<tr>
<td>sched.h</td>
<td>H</td>
<td>SCHED</td>
</tr>
</tbody>
</table>

You can display a header file in QSYSINC by using one of the following methods:

- Use your editor. For example, to display the `pthread.h` header file using the Source Entry Utility editor, enter the following command:
  ```
  STRSEU SRCFILE(QSYSINC/H) SRCMBR(PTHREAD) OPTION(5)
  ```

- Use the Display Physical File Member command. For example, to display the `sched.h` header file, enter the following command:
  ```
  DSPPFM FILE(QSYSINC/H) MBR(SCHED)
  ```

You can print a header file in QSYSINC by using one of the following methods:

- Use your editor. For example, to print the `pthread.h` header file using the Source Entry Utility editor, enter the following command:
  ```
  STRSEU SRCFILE(QSYSINC/H) SRCMBR(PTHREAD) OPTION(6)
  ```

- Use your Copy File command. For example, to print the `sched.h` header file, enter the following command:
  ```
  CPYF FROMFILE(QSYSINC/H) TOFILE(*PRINT) FROMMBR(SCHED)
  ```

**Pthread glossary**

**A**

attribute object

Any of the Pthreads data structures that are used to specify the initial states when creating certain resources (threads, mutexes, and condition variables). A thread attribute object can be used to create a thread. A mutex attributes object can be used to create a mutex. A condition attributes object can be used to create a condition. Functions that create attribute objects are `pthread_attr_init()`, `pthread_mutexattr_init()`, and `pthread_condattr_init()`.

**C**

cancel

A cancel is delivered to a thread when `pthread_cancel()` is issued and stops a thread. A cancel can be held pending if the target thread has cancellation DISABLED or DEFERRED. The cancel may be acted upon when cancellation is set to ENABLED or ASYNCHRONOUS.

cancellation cleanup handler

A function registered to perform some cleanup action. Cancellation cleanup handlers are called if a thread calls `pthread_exit()` or is the target of a `pthread_cancel()`. Cancellation cleanup handlers are stacked onto a cancellation cleanup stack and can be pushed and popped using the `pthread_cleanup_push()` and `pthread_cleanup_pop()` functions.

cancellation point

A function that causes a pending cancel to be delivered if the cancellation state is ENABLED, and
the cancellation type is DEFERRED, pthread_testcancel() can be used to create a cancellation point. For a list of other functions that are cancellation points, see pthread_cancel().

cancellation state
Either of two values (ENABLED or DISABLED) that describe whether cancels in the current thread are acted upon or held pending. If ENABLED, the cancellation is acted upon immediately based on the current cancellation type. If DISABLED, the cancel is held pending until it is ENABLED. You can modify the cancellation state using the pthread_setcancelstate() function.

cancellation type
Either of two values (DEFERRED or ASYNCHRONOUS) that describe how cancels are acted upon in the current thread when the cancellation state is ENABLED. If DEFERRED, the cancel is held pending, if ASYNCHRONOUS, the cancel is acted upon immediately, thus ending the thread with a status of PTHREAD_CANCELED. You can modify the cancellation type using the pthread_setcanceltype() function.

condition variable
An abstraction that allows a thread to wait for an event to occur. The condition variable is used with a Boolean predicate that indicates the presence or absence of the event and a mutex that protects both the predicate and the resources associated with the event. The condition variable has no ownership associated with it. See pthread_cond_init(), and other functions whose names begin with pthread_cond_.

D
detach a thread
To mark a thread so that the system reclaims the thread resources when the thread ends. If the thread has already ended, the resources are freed immediately. After a thread’s resources are freed, the exit status is no longer available, and the thread cannot be detached or joined to. Use the pthread_attr_setdetachstate(), or pthread_detach() functions to detach a thread, or the pthread_join() function to wait for and then detach a thread.

E
exit status
The return value from a thread. A variable of type void *, which typically contains some pointer to a control block pointer or return value, that shows under what conditions the thread ended. The thread can be ended and the exit status can be set by returning from the thread start routine, by calling pthread_exit(), or by canceling a thread using pthread_cancel().

G
global mutex
A single mutex that is stored globally to the process that is provided by the pthreads library to allow easy serialization (a mechanism that allows only one thread to act at one time) to application resources. See the functions pthread_lock_global_np() or pthread_unlock_global_np().

I
initial thread
The thread that is started automatically by the system when a job or process is started. Every job has at least one thread. That thread is often referred to as the initial thread or the primary thread. Threads other than the initial thread are referred to as secondary threads. If the initial thread ends, it causes all secondary threads and the job to end. See also ‘Secondary thread’.
**J**

*join to a thread*

To wait for a thread to complete, detach the thread, and optionally return its exit status. Use `pthread_join()` to wait for a thread to complete.

**M**

*main thread*

See initial thread.

*multithread capable*

This term is specific to iSeries. See thread capable.

*multithreaded*

A process that has multiple active threads. In the iSeries documentation, the term multithreaded is sometimes used as a synonym for multithread capable.

*mutex*

An abstraction that allows two or more threads to cooperate in a MUTual EXclusion protocol that allows safe access to shared resources. See `pthread_mutex_init()` or other functions whose names begin with `pthread_mutex_`. Also see recursive mutex, named mutex, global mutex.

**N**

*named mutex*

A mutex with an associated text name used for identification and debugging. The name is used in some system dumps and debug or thread-management user interfaces. The name does not affect the behavior of the mutex, only the ability to debug the use of that mutex. The Pthread run-time names all mutexes by default. See the functions `pthread_mutexattr_setname_np()` or `pthread_mutexattr_getname_np()`.

**O**

*orphaned mutex*

A mutex that was held by a thread when that thread ended. Any application data or resources associated with the mutex are most likely in an inconsistent state if a mutex is orphaned. An orphaned mutex is not available to be locked by another thread and causes a locking thread to block indefinitely or to get the EBUSY error when attempting to trylock the mutex.

**P**

*POSIX thread handle*

The `pthread_t` data type that is returned to a creator of a POSIX thread. The `pthread_t` represents an opaque handle to the POSIX thread. It should not be modified except through the use of the `pthread` functions. The `pthread_create()` or `pthread_self()` function returns the POSIX thread handle. The `pthread_equal()` function can be used to confirm whether two handles refer to the same thread. The POSIX thread handle is sometimes referred to as the thread ID.

*primary thread*

See initial thread.

*Pthread*

recursive mutex

A mutex that can be acquired again by the owning thread. A recursive mutex does not become unlocked until the number of unlock requests equals the number of successful lock requests. A non-recursive (normal) mutex causes an EDEADLK error if an attempt is made by the owning thread to lock it a second time. See the functions pthread_mutexattr_setkind_np() or pthread_mutexattr_getkind_np().

scheduling parameters

Information describing the scheduling characteristics of a thread. The sched_param structure contains scheduling parameters. On the iSeries, the scheduling parameters allow you to only specify the priority of the thread. Scheduling Policy is restricted to the proprietary iSeries scheduling policy. Use the pthread_attr_setschedparam(), pthread_attr_getschedparam(), pthread_setschedparam(), or pthread_getschedparam() functions to manipulate scheduling parameters.

scheduling policy

Information describing which algorithm is used to schedule threads within the process or system. Some scheduling policies are Round Robin or FIFO. iSeries uses the SCHED_OTHER constant to indicate the delay cost scheduling that the system uses. The scheduling parameter functions support only the SCHED_OTHER policy, and the pthread_attr_getschedpolicy() and pthread_attr_setschedpolicy() functions are not supported.

scope

Information describing whether the scheduling policy indicates that threads compete directly with other threads within the process or the system. iSeries schedules threads within the system, and the pthread_attr_setscope() and pthread_attr_getscope() functions are not supported.

secondary thread

Any thread started by or on behalf of the application that is not the initial thread. Secondary threads are started by calling pthread_create() or another library service that creates threads. Secondary threads have no parent/child relationship.

signal

An asynchronous mechanism for interrupting the processing of a thread. The system delivers a signal to a thread when the application programmer takes explicit or implicit action to cause the signal to be delivered. The signal can be sent to a thread or process, but is always delivered to a specific thread.

signal handler

A function registered by the application programmer that the system executes when a signal is delivered to a thread. The function runs immediately in the thread, interrupting any application processing that is in progress.

signal safe

A function, macro or operating system service that can be called safely from a signal handler. The function always acts in a well-defined manner. It does not rely on any external state or locks that might be in an inconsistent state at the time the signal handler function is called by the system.

signal unsafe

A function, macro or operating system service that cannot be called safely from within a signal handler. A signal unsafe function may acquire locks or otherwise change the state of a resource. When the signal is delivered to the thread, the signal handler runs. The state of the resource or the lock managed by the signal unsafe function is unknown because it was interrupted by the signal before it completed. If the signal unsafe function is called again, the results are non-deterministic.
thread  An independent sequence of execution of program code and processing context inside a process. A unique unit of work or flow of control within a process. A thread runs a procedure asynchronously with other threads running the same or different procedures within the process. All threads within a process equally share activation group and process resources (heap storage, static storage, open files, socket descriptors, other communications ports, environment variables, and so on). A thread has few resources (mutexes, locks, automatic storage, thread specific storage) that are not shared. On a multiprocessor system, multiple threads in a process can run concurrently.

thread capable job  The only job that can create threads. Certain system behavior and the architecture of the process changes slightly to support i5/OS threads. If a job is not thread capable, attempts to create a thread result in the EBUSY error. You can create a thread capable process by using the spawn() interface or by using other iSeries job-creation commands that allow you to specify that the new job should be thread capable.

thread ID  The unique integral number can be used to identify the thread. This integral number is available for retrieval using the pthread_getunique_np() interface. Although no Pthread interfaces use the integral thread ID to identify a thread for manipulation, thread ID is sometimes used to describe the pthread_t data type that represents the abstraction to a thread. See POSIX thread handle.

thread local storage (TLS)  See thread specific storage.

threadsafe  A function, macro or operating system service that can be called from multiple threads in a process at the same time. The function always acts in a well-defined manner. The end results are as if the function was called by each thread in turn, even though all of the threads were running the function at the same time. Some APIs have restrictions about how they can be called in order for them to be thread safe. See the API documentation for all APIs or system services that you use in a multithreaded job.

thread specific storage  Storage that is not shared between threads, but that can be accessed by all functions within that thread. Usually, thread specific storage is indexed by a key. The key is a global value visible to all threads, and it is used to retrieve the thread-specific value of the storage associated with that key. Also called thread private storage, thread local storage or TLS. See the pthread_getspecific(), pthread_setspecific(), pthread_key_create(), and pthread_key_delete() functions.

thread unsafe  A function, macro, or operating system service that cannot be called from multiple threads is called thread unsafe. If this function is used in multiple threads or in a process that has multiple threads active, the results are undefined. A thread unsafe function can corrupt or negatively interact with data in another function (thread safe or otherwise) that appears to be unrelated to the first function. Do NOT use thread unsafe functions in your multithreaded application. Do NOT call programs or service programs that use thread-unsafe functions. See the API documentation for all APIs or system services that you use in a multithreaded job.
Other Sources of Pthread Information

The following standards are the base reference documents from which the APIs in this section originated:

The following sources also provide information about Pthreads:

- “Programming with POSIX Threads” by David R. Butenhof, ISBN#: 0201633922
- The Internet newsgroup comp.programming.threads

Writing and compiling threaded programs

When writing and compiling code that use threads or that run in a threaded job, make sure to do the following:

- Ensure that all of the APIs or system services that you use are threadsafe. See Multithreaded applications for an introduction to threads and general information about i5/OS threads.
- Insert the following lines into any module that uses the thread data types or definitions.
  ```c
  #define _MULTI_THREADED
  #include <pthread.h>
  ```
  The preprocessor definition _MULTI_THREADED must come before the pthread.h.
  See “Header files for Pthread functions” on page 254 for more information on header files.
  See “Using the _MULTI_THREADED preprocessor definition” for more information on the _MULTI_THREADED preprocessor definition.
- Compile the program normally; use the CRTCMOD followed by the CRTPGM or CRTSRVPGM commands. You can also use the CRTBNDC CL command to create your threaded program.
- Since Pthread APIs can operate on functions and data which could exist in different compilation units (modules), the same storage model and data model must be used throughout all compilation units within a program or service program that uses Pthread APIs. Otherwise, unpredictable behavior and failures will occur. Refer to the information on teraspace and single-level store in the ILE Concepts book for more information on storage model and data model.

Using the _MULTI_THREADED preprocessor definition

The _MULTI_THREADED preprocessor value is used to indicate that your application uses the kernel threads model. The preprocessor value can also be used by other parts of the system to create threadsafe macros. For example, the fpUTC() macro of ILE C can use the _MULTI_THREADED preprocessor value. You should always define the _MULTI_THREADED preprocessor value in source files that run in kernel threaded jobs.
Running threaded programs

When you run a threaded program, the job that runs a threaded program must be specially initialized by the system to support threads. Currently, several mechanisms allow you to start a job that is capable of creating multiple kernel threads:

- Use the i5/OS™ QShell Interpreter. In the QShell Interpreter, a program gets descriptors 0, 1, and 2 as the standard files; the parent and child I/O is directed to the console. The QShell interpreter allows you to run multithreaded programs as if they were interactive. See Qshell for a description of the QIBM_MULTI_THREADED shell variable, which, when set to ‘Y’, allows you to run multithreaded programs the same way you run any other program. The QShell Interpreter is option 30 of Base i5/OS.
- Use the spawn() API. The spawn() API has a flag in the spawn inheritance structure that allows you to turn on the multithread capability for the child job. The QUSRTOOL library also provides source code and an example CL command to allow you to create and use a SPAWN CL command in a way that is similar to the SBMJOB CL command. See the "SPAWN CL command, QUSRTOOL example" for more information.
- Use the SBMJOB CL command. Setting the ‘Allow multiple threads’ parameter (keyword ALWMLTTHD) on the CL command allows you to turn on the multithread capability of the submitted job.
- Use the CRTJOBD CL command to create a special job description; then create your job using a mechanism that will use the job description. Setting the ‘Allow multiple threads’ parameter (keyword ALWMLTTHD) on the job description allows you to turn on the multithread capability of the jobs that are created using that job description.

"Pthread APIs," on page 3 | APIs by category

SPAWN CL command, QUSRTOOL example

When you test your threaded application, you may want to quickly spawn new processes and debug the programs started in those processes. An example tool that creates a SPAWN CL command has been placed into the QUSRTOOL library for your use on the system. (See Creating the SPAWN command below.)

You can install the QUSRTOOL library (Option 7) of the base operating system when using the RSTLIICPGM CL command. On the GO LICPGM menu, it appears as the Example Tools Library.

The spawn example shows how you might write a CL command and a command processing program to allow you to spawn jobs from the command line. The call to spawn() starts a new process that allows you to inherit the current environment (file descriptors, socket descriptors, and environment variables) from the current process. By default, it allows you to create threads in the child process and allows you to automatically issue the commands required to debug the spawned child. If you want more functionality from the command, you can easily edit it.

Creating the SPAWN command

To use the example tool to create the SPAWN command, see the QATTINFO file in the QUSRTOOL library. The members AAAAREADME and AAAMAP in that file contain information and instructions for unpacking various QUSRTOOL examples and utilities. Read these members and follow the instructions for using the package and unpack package utilities on the SPAWN source files.

The member that contains the SPAWN example information is TP0ZINFO in the QATTINFO file. The TP0ZINFO member contains a table that lists the source files that must be unpacked to create the SPAWN example. The TP0ZINFO member also contains instructions for creating the example CL command and lists which source members are used for SPAWN in case you want to modify the SPAWN CL command to suit your own specific needs.
Troubleshooting Pthread errors

The following are common errors users encounter when programming with Pthreads. Follow the appropriate link to find instructions for correcting these errors:

- Cannot find header files pthread.h or qp0ztype.h or qp0zptha.h
- Thread creation (pthread_create()) fails with EBUSY or 3029
- Mixing thread models or API sets
- Reserved fields must be binary zero
- Powerful i5/OS cleanup mechanisms allow application deadlock (cancel_handler and C++ automatic destructors)
- Thread creation using C++ methods as target does not work
- MCH3402 from pointer returned by pthread_join()

Cannot find header files pthread.h or qp0ztype.h or qp0zptha.h

You may find that your compilation fails because the system header files required to compile a threaded program or to use the threaded interfaces cannot be found. This problem has one of several causes:

- If you get failure messages similar to the following:
  KULACK/QCSC/MYPGM line 5: Unable to find #include file *LIBL/H(PTHREAD).
  you might have one of two problems:
  - Either your system does not have the C header files for openness (the QSYSINC library) installed, you are on a Version 4 Release 2 system and you do not have the PTF installed (PTF number 5769SS1-J664741) that provides the Pthread header files.
  - Your compile command is not searching the correct locations for system header files.
  In order to correct these problems, do one of the following:
  - Install the Openness includes (System Openness Includes, 5769-SS1 Option 3) and the QSYSINC library, install the PTF support (PTF number 5769SS1-J664741) for kernel threads header files.
  - Correct your search paths or library list.
- If you get failure messages similar to the following:
  QSYSINC/H/PTHREAD line 48: Unable to find #include file QCPA/H(PTHREAD).
  QSYSINC/H/PTHREAD line 60: #error "#ifndef _MULTI_THREADED"
  QSYSINC/H/PTHREAD line 61: #error "#ifndef QP0Z_CPA_THREADS_PRESENT"
  you have forgotten to define the _MULTI_THREADED preprocessor symbol. Use the C preprocessor statement ‘#define _MULTI_THREADED’ in your application, or define _MULTI_THREADED on the CRTMOD or other compile command that you use to compile your modules. Because the CPA toolkit supported threads before kernel threads being introduced on the server, if you do not define _MULTI_THREADED when compiling your C modules, the system attempts to compile your application using the CPA header files. The recommended threads model is kernel threads. You must define _MULTI_THREADED when you compile your application.
- If you get failure messages similar to the following:
  QCPA/H/PTHREAD line 171: Unable to find #include file *LIBL/H(QP0ZTYPE).
  QCPA/H/PTHREAD line 183: Unable to find #include file *LIBL/H(QP0ZPTH).”
  you have forgotten to define the _MULTI_THREADED preprocessor symbol. Use the C preprocessor statement #define _MULTI_THREADED in your application, or define _MULTI_THREADED on the CRTMOD or other compile command that you use to compile your modules. Because the CPA toolkit supported threads prior to kernel threads being introduced on the server0, if you do not define
MULTI_THREADED when compiling your C modules, the system attempts to compile your application using the CPA header files. The recommended threads model is kernel threads. You must define MULTITHREADED when you compile your application.

Thread creation (pthread_create()) fails with EBUSY or 3029

Because many parts of the operating system are not yet thread safe, not every job can start threads. The pthread_create() API fails with the EBUSY error when the process is not allowed to create threads. See "Running threaded programs" on page 261 for information about how to start a job that can create threads.

Mixing thread models or API sets

If you mix Pthread APIs with other threads management APIs that might be provided on the system, your application can enter an unknown state. For example, you should not use Java or the IBM open class libraries threads implementations to manipulate a thread that was created using the Pthread APIs. Similarly, if you use a PThread API like pthread_cancel() on a thread created and managed by the JVM, you can get unexpected results.

The following example demonstrates this problem. A Java application creates several Java threads. One Java thread runs normally and eventually calls a native method. The native method uses the pthread_self() API to store the POSIX thread handle for the thread. The native method then returns to Java and continues to run normal Java code in the Java virtual machine (JVM). Eventually, another Java thread in the application calls a native method. The new native method uses the stored POSIX thread handle in a call to pthread_cancel(). This causes cause the Java thread to be terminated with Pthread semantics. The Java thread cleanup requirements or the tendency of Java to end the thread with a Java exception may not be honored. The application may not get the results that you expect. Do not manipulate threads from one thread model with APIs from another.

The following example also demonstrates this problem. The priorities of a Pthread may sometimes be manipulated using both Pthread and iSeries proprietary interfaces. If they are manipulated, the priorities are always set correctly; however the priority returned from the Pthread interface pthread_getschedparam() is only correct if the priority was always set using either the pthread_setschedparam() interface or another interface, but not both. If multiple interfaces have been used to set the priority of the thread, pthread_getschedparam() always returns the priority set by the last pthread_setschedparam().

Reserved fields must be binary zero

The i5/OS implementation of many APIs requires that reserved fields in certain parameters or data structures be set to binary zero before using a structure as input to an API or system service. You should initialize the structure using memset() or an initialization API provided by the system, such as pthread_condattr_init(). Using structures with reserved fields that are non-zero causes the EINVAL error.
**Powerful i5/OS cleanup mechanisms allow application deadlock (cancel_handler and C++ automatic destructors)**

i5/OS provides a set of powerful cleanup mechanisms. In i5/OS, an application has the ability to register a cancel handler. Your application can enable a cancel handler by using the `#pragma cancel_handler` preprocessor statement if it is written in C or C++ or by using the `CEERTX()` API.

A cancel handler is similar to a Pthread cancellation cleanup handler. However, a cancel handler runs whenever the stack frame or function for which it was registered ends in any way other than a normal return. Pthread cancellation cleanup handlers run only when the thread is terminated with `pthread_exit()` or `pthread_cancel()` or when the thread returns from the threads start routine.

The cancel handler is guaranteed to run for all conditions that cause the stack frame to end (other than return), such as thread termination, job termination, calls to `exit()`, `abort()`, exceptions that percolate up the stack, and cancel stack frames. Similarly, C++ destructors for automatic C++ objects are guaranteed to run when the stack frame (function) or scope in which it was registered ends.

These mechanisms ensure that your application can always clean up its resources. With the added power of these mechanisms, an application can easily cause a deadlock.

The following is an example of such a problem:

An application has a function `foo()` that registers a cancel handler called `cleanup()`. The function `foo()` is called by multiple threads in the application. The application is ended abnormally with a call to `abort()` or by system operator intervention (with the `ENDJOB *IMMED CL` command).

When this job is ended, every thread is immediately terminated. When the system terminates a thread by terminating each call stack entry in the thread, it eventually reaches the function `foo()` in that thread. When function `foo()` is reached, the system recognizes that it must not remove that function from the call stack without running the function `cleanup()`, and so the system runs `cleanup()`. Because your application is multithreaded, all of the job ending and cleanup processing proceeds in parallel in each thread. Also, because `abort()` or `ENDJOB *IMMED` was used, the current state and location of each thread in your application is cannot be determined. When the `cleanup()` function runs, it is very difficult for the application to correctly assume that any specific cleanup can be done. Any resources that the `cleanup()` function attempts to acquire may be held by other threads in the process, other jobs in the system, or possibly by the same thread running the `cleanup()` function. The state of application variables or resources that your application manipulates may be in an inconsistent state because the call to `abort()` or `ENDJOB *IMMED` asynchronously interrupted every thread in the process at the same time. The application can easily reach a deadlock when running the cancel handlers or C++ destructors.

Do not attempt to acquire locks or resources in cancel handlers or C++ automatic object destructors without preparing for the possibility that the resources cannot be acquired.

**Important**

Neither a cancel handler nor a destructor for a C++ object can prevent the call stack entry from being terminated, but the termination of the call stack entry (and therefore the job or thread) is delayed until the cancel handler or destructor completes.

If the cancel handler or destructor does not complete, the system does not continue terminating the call stack entry (and possibly the job or thread). The only alternative at this point is to use the `WRKJOB CL` command (option 20) to end the thread, or the `ENDJOB *IMMED CL` command. If the `ENDJOB *IMMED` command causes a cancel handler to run in the first place, the only option left is the `ENDJOBABN CL` command because any remaining cancel handlers are still guaranteed to run.
The `ENDJOBABN` CL command is not recommended. The `ENDJOBABN` command causes the job to be terminated with no further cleanup allowed (application or operating system). If the application is suspended while trying to access certain operating system resources, those resources may be damaged. If operating system resources are damaged, you may need to take various reclaim, deletion, or recovery steps and, in extreme conditions, restart the system.

**Recommendations**

If you want to cleanup your job or application, you can use one of the following mechanisms:

- If you want to do process level or activation group cleanup for normal termination, use the C `atexit()` function to register your cleanup function. The `atexit()` function provides a mechanism to run cleanup after the activation group and possibly the threads, are terminated. This action significantly reduces the complexity.

- If you always want a chance to do process level or activation group cleanup in all cases (normal and abnormal), you could use the Register Activation Group Exit (CEE4RAGE()) system API. The `CEE4RAGE()` function provides a mechanism to run cleanup after the activation group (and possibly the threads) are terminated. This action significantly reduces the complexity.

- You can safely use cancel handlers. Simplify your cancel handlers so that they only unlock or release resources and do not attempt to acquire any new resources or locks.

- You can remove your cancel handlers and create a CL command, program, or tool that terminates your application in a more controlled fashion:
  
  - One possibility is a tool that uses a signal to terminate the application. When the signal comes in, your application can get control in a single location (preferably by using the `sigwait()` API to safely and synchronously get the signal), and then perform some level of cleanup. Then it can use `exit()` or `abort()` to end the application from within. Often this action is sufficient to remove the complexity.
  
  - A second possibility is to use the `ENDJOB *CNTRLD` CL command and have your application dedicate a thread to watching for the controlled end condition. The application thread can use the `QUSRJOBI` (Get Job Information) or the `QWCRTVCA` (Retrieve Current Attributes) APIs to look at the `End Status` information associated with your job. The `End Status` indicates that the job is ending in a controlled fashion, and your application can take safe and synchronous steps to clean up and exit.
  
  - A third possibility is to use the asynchronous signals support and set up a handler for the `SIGTERM` asynchronous signal. Support has been added to the system so that, if an `ENDJOB *CNTRLD` is done and the target job has a handler registered for the `SIGTERM` signal, that signal gets delivered to the target job. You should dedicate a thread for handling signals by using the `sigwait()` API in the dedicated thread. When the signal handling thread detects a `SIGTERM` signal using the `sigwait()` API, it can safely clean up and terminate the application. The system support for the delivery of the `SIGTERM` signal when `ENDJOB *CNTRLD` is issued was added in the base OS/400 in Version 4 Release 3 Modification 0 and is also available in Version 4 Release 2 Modification 0 through program temporary fixes (PTFs) 5769SS1-SF47161 and 5769SS1-SF47175. For more information about ending your job, see the `Work Management` topic.
  
  - A fourth possibility includes other interprocess communications (IPC) mechanisms that can also be used to indicate that your application should terminate in a safe and controlled fashion.

- If you want to do thread-level cleanup, use the pthread APIs, such as `pthread_cleanup_push()`, `pthread_cleanup_pop()`, and `pthread_key_create()` to create cancellation cleanup functions that run when the thread terminates under normal conditions. Often your cleanup functions do not need to run when the job ends. The most common use for these functions is to free heap storage or unlock resources. Unlocking resources is safe in a cancel handler, and you do not need to use `free()` on heap storage when the entire job is ending anyway.
Thread creation using C++ methods as target does not work

Often, as a C++ programmer, you may want to abstract the concept of a thread into a C++ class. To do this, you must realize that the Pthread APIs are C language APIs. The Pthread APIs use functions that have C linkage and calling conventions. For your application to successfully use the pthread functions, you must provide helper functions of the appropriate type and linkage for the Pthread APIs that take function pointers as parameters.

When sharing objects between threads, always be aware of which thread is manipulating the object, which thread is responsible for freeing the object, and what thread safety issues are created by sharing objects between threads.

The following example shows how to successfully create a program that abstracts a thread into a C++ class. It can be easily extended to provide a mechanism by which the thread creation and manipulation itself is also encapsulated into the class.

Example

See Code disclaimer information for information pertaining to code examples.

/* This C++ example must be compiled with VisualAge C++ for OS/400 */
#define _MULTI_THREADED
#include <stdio.h>
#include <stdlib.h>
#include <stddef.h>
#include <pthread.h>

class ThreadClass {
public:
    ThreadClass(char *s) {
        data1 = 42; data2 = strlen(s);
        strncpy(str, s, sizeof(str)-1);
        str[49]=0;
    }
    void *run(void);
private:
    int     data1;
    int     data2;
    char    str[50];
};

extern "C" void *ThreadStartup(void *);

int main(int argc, char **argv)
{
    ThreadClass *t=NULL;
    pthread_t thread;
    int rc;
    // Use printf instead of cout.
    // At the time this test was written, the C++ standard class library
    // was not thread safe.
    printf("Entered test %s\n", argv[0]);

    printf("Create a ThreadClass object\n");
    t = new ThreadClass("Testing C++ object/thread creation\n");

    printf("Start a real thread to process the ThreadClass object\n");
    // #define COMPILE_ERROR
    #ifdef COMPILE_ERROR
    // This is an ERROR. You cannot create a thread by using a pointer
    // to a member function. Thread creation requires a C linkage function.
    // If you remove the comments from the line '#define COMPILE_ERROR'
    // the compiler will give a message similar to this:
    // "ATESTCPP0.C", line 46.53: 1540-055: (S) "void*(ThreadClass::*)(*)"*
    // cannot be converted to "extern "C" void(*)(void*)".

266   IBM Systems - iSeries: Pthread APIs
rc = pthread_create(&thread, NULL, ThreadClass::run, NULL);
#else
// Instead, this is the correct way to start a thread on a C++ object
rc = pthread_create(&thread, NULL, ThreadStartup, t);
#endif
if (rc)
   {printf("Failed to create a thread\n");
exit(EXIT_FAILURE);
}

printf("Waiting for thread to complete\n");
rc = pthread_join(thread, NULL);
if (rc)
   {printf("Failed to join to the thread, rc=%d\n");
exit(EXIT_FAILURE);
}
printf("Testcase complete\n");
exit(EXIT_SUCCESS);

// This function is a helper function. It has normal C linkage, and is
// as the base for newly created ThreadClass objects. It runs the
// run method on the ThreadClass object passed to it (as a void *).
// After the ThreadClass method completes normally (i.e returns),
// we delete the object.
void *ThreadStartup(void *tgtObject)
   {
   ThreadClass *tgtObject = (ThreadClass *) _tgtObject;
   printf("Running thread object in a new thread\n");
   void *threadResult = tgtObject->run();
   printf("Deleting object\n");
   delete tgtObject;
   return threadResult;
   }

void *ThreadClass::run(void)
   {
   printf("Entered the thread for object %.8x %.8x %.8x %.8x\n", this);

   printf("Object identity: %d, %d: %s\n", data1, data2, str);
   return NULL;
   }

Output
Entered test QPMWTEST/ACPOBJ
Create a ThreadClass object
Start a real thread to process the ThreadClass object
Waiting for thread to complete
Running thread object in a new thread
Entered the thread for object 80000000 00000000 d017dad2 57001f60
Object identity: 42, 35: Testing C++ object/thread creation
Deleting object
Testcase complete

MCH3402 from pointer returned by pthread_join()

Be sure that no threads return pointers to items that can be destroyed when a thread terminates. For example, the threads stack is transitory. It needs to exist only for the life of the thread, and it may be destroyed when the thread terminates. If you return the address of an automatic variable or use the address of an automatic variable as an argument to pthread_exit(), you may experience MCH3402 errors when you use the address.
Example

The following example contains code that brings up the MCH3402 error.

See Code disclaimer information for information pertaining to code examples.

```c
#define _MULTI_THREADED
#include <pthread.h>
#include <stdio.h>
#include "check.h"

void *threadfunc(void *parm)
{
    int rc = 2;
    printf("Inside secondary thread, return address of local variable.\n");
    return &rc; /* THIS IS AN ERROR! */
    /* AT THIS POINT, THE STACK FOR THIS THREAD MAY BE DESTROYED */
}

int main(int argc, char **argv)
{
    pthread_t thread;
    int rc=1;
    void *status;

    printf("Enter Testcase - %s\n", argv[0]);

    printf("Create thread that returns status incorrectly\n");
    rc = pthread_create(&thread, NULL, threadfunc, NULL);
    checkResults("pthread_create()\n", rc);

    printf("Join to thread\n");
    rc = pthread_join(thread, &status);
    checkResults("pthread_join()\n", rc);
    printf("Checking results from thread. Expect MCH3402\n");
    /* Monitor for the MCH3402 exception in this range */
    #pragma exception_handler(TestOk, 0, 0, _C2_ALL, _CTLA_HANDLE_NO_MSG, "MCH3402")
    rc = *(int *)status;
    #pragma disable_handler
    TestFailed:
        printf("Did not get secondary thread results (exception) as expected!\n");
        goto TestComplete;

    TestOk: /* Control goes here for an MCH3402 exception */
        printf("Got an MCH3402 as expected\n");

    TestComplete:
        printf("Main completed\n");
        return rc;
}
```

Output

Enter Testcase - QP0WTEST/TPJOIN7
Create thread that returns status incorrectly
Join to thread
Inside secondary thread, return address of local variable.
Checking results from thread. Expect MCH3402
Got an MCH3402 as expected
Main completed
Information on the Pthread API examples

The API documentation includes example programs for each API. The "File check.h used by API examples programs" shown below is used for all of the examples. It should be named check.h (member CHECK in file H in a library in the library list).

In most cases, error checking that is contained in the examples causes the program to exit() if any failure is detected. In some cases, error checking is left out of the examples for brevity. In general, the error checking that is provided should not be considered complete enough for all applications. All return codes from any system functions should be validated and appropriate action should be taken when failures occur.

The examples are provided "as-is" for demonstration and education purposes only. They do not necessarily provide or implement an appropriate level of error checking to be used for production code and should not be used directly for that purpose.

Be sure to see "Writing and compiling threaded programs" on page 260 and "Running threaded programs" on page 261 for more information about compiling and running the example programs.

To create the examples, make sure the member CHECK is created in a file H in your library list. Use CRTCMOD on the name that you download the member to, then use CRTPGM to compile the module into a program object. Alternatively, you can use CRTBNDC to compile and link the program in one step.

When you run the example programs, you must be aware of a requirement:

The job that runs a threaded program must be specially initialized by the system to support threads. Currently, several mechanisms allow you to start a job that is capable of creating multiple kernel threads.

- Use the i5/OS QShell Interpreter
- Use the spawn() API.
- Use the SMJOB CL command.
- Use the CRTJJOBD CL command to create a special job description, then create your job using a mechanism that will use the job description.

See "Running threaded programs" on page 261 for detailed information on these methods.

See Code disclaimer information for information pertaining to code examples.

File check.h used by API examples programs

This example header file must be in the library list when you compile the example programs.

```c
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <errno.h>

static void checkResults(char *string, int rc)
{
    if (rc)
    {
        printf("Error on : %s, rc=%d",
                        string, rc);
        exit(EXIT_FAILURE);
    }```

Pthread APIs 269
Thread management APIs

Thread management APIs allow a program to manipulate threads. The APIs actually create, destroy and otherwise manage the active or ended threads within the application. The APIs allow the manipulation of some of the thread attributes of an active thread.

A program can also setup or change the characteristics of a thread attributes object. The thread attributes object is used at thread creation time. The new thread is created with the attributes that are specified in the attributes object. After the thread has been created, the attributes object is no longer required.

The table below lists important thread attributes, their default values, and all supported values.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default value</th>
<th>Supported values</th>
</tr>
</thead>
<tbody>
<tr>
<td>detachstate</td>
<td>PTHREAD_CREATE_JOINABLE</td>
<td>PTHREAD_CREATE_JOINABLE, PTHREAD_CREATE_DETACHED</td>
</tr>
<tr>
<td>schedparam</td>
<td>SCHED_OTHER with priority equal to PRIORITY_DEFAULT (0)</td>
<td>SCHED_OTHER with priority &lt;= PTHREAD_PRIO_MAX and priority &gt;= PTHREAD_PRIO_MIN</td>
</tr>
<tr>
<td>contentionscope</td>
<td>PTHREAD_SCOPE_SYSTEM</td>
<td>PTHREAD_SCOPE_SYSTEM</td>
</tr>
<tr>
<td>inheritsched</td>
<td>PTHREAD_EXPLICIT_SCHED, priority equal to PRIORITY_DEFAULT (0)</td>
<td>PTHREAD_EXPLICIT_SCHED or PTHREAD_INHERIT_SCHED</td>
</tr>
<tr>
<td>schedpolicy</td>
<td>SCHED_OTHER</td>
<td>SCHED_OTHER</td>
</tr>
</tbody>
</table>

For information about the examples included with the APIs, see the "Information on the Pthread API examples" on page 269.

The thread management APIs are:

- "pthread_attr_destroy()—Destroy Thread Attributes Object" on page 7 (Destroy Thread Attributes Object) destroys a thread attributes object and allows the system to reclaim any resources associated with that thread attributes object.
- "pthread_attr_getdetachstate()—Get Thread Attributes Object Detachstate" on page 8 (Get Thread Attributes Object Detachstate) returns the detach state attribute from the thread attributes object specified.
- "pthread_attr_getinheritsched()—Get Thread Attribute Object Inherit Scheduling Attributes” on page 10 (Get Thread Attribute Object Inherit Scheduling Attributes) returns the inheritsched attribute from the thread attributes object specified.
- "pthread_attr_getschedparam()—Get Thread Attributes Object Scheduling Parameters” on page 12 (Get Thread Attributes Object Scheduling Parameters) returns the scheduling parameters attribute from the thread attributes object.
- "pthread_attr_init()—Initialize Thread Attributes Object” on page 14 (Initialize Thread Attributes Object) initializes a thread attributes object to the default thread attributes.
- "pthread_attr_setdetachstate()—Set Thread Attributes Object Detachstate” on page 16 (Set Thread Attributes Object Detachstate) sets the detach state of the thread attributes object.
• “pthread_attr_setinheritsched”—Set Thread Attribute Inherit Scheduling Attributes” on page 18 (Set Thread Attribute Inherit Scheduling Attributes) sets the inheritsched attribute in the thread attributes object specified.

• “pthread_attr_setschedparam”—Set Thread Attributes Object Scheduling Parameters” on page 20 (Set Thread Attributes Object Scheduling Parameters) sets the scheduling parameters in the thread attributes object.

• “pthread_clear_exit_np”—Clear Exit Status of Thread” on page 31 (Clear Exit Status of Thread) clears the exit status of the thread.

• “pthread_create”—Create Thread” on page 62 (Create Thread) creates a thread with the specified attributes and runs the C function start_routine in the thread with the single pointer argument specified.

• “pthread_delay_np”—Delay Thread for Requested Interval” on page 65 (Delay Thread for Requested Interval) causes the calling thread to delay for the deltatime specified.

• “pthread_detach”—Detach Thread” on page 67 (Detach Thread) indicates that system resources for the specified thread should be reclaimed when the thread ends.

• “pthread_equal”—Compare Two Threads” on page 69 (Compare Two Threads) compares two Pthread handles for equality.

• “pthread_exit”—Terminate Calling Thread” on page 71 (Terminate Calling Thread) terminates the calling thread, making its exit status available to any waiting threads.

• “pthread_extendedjoin_np”—Wait for Thread with Extended Options” on page 73 (Wait for Thread with Extended Options) waits for a thread to terminate, optionally detaches the thread, then returns the threads exit status.

• “pthread_getconcurrency”—Get Process Concurrency Level” on page 78 (Get Process Concurrency Level) retrieves the current concurrency level for the process.

• “pthread_getpthreadoption_np”—Get Pthread Run-Time Option Data” on page 79 (Get Pthread Run-Time Option Data) gets option data from the pthread run-time for the process.

• “pthread_getschedparam”—Get Thread Scheduling Parameters” on page 82 (Get Thread Scheduling Parameters) retrieves the scheduling parameters of the thread.

• “pthread_getthreadid_np”—Retrieve Unique ID for Calling Thread” on page 86 (Retrieve Unique ID for Calling Thread) retrieves the unique integral identifier that can be used to identify the calling thread in some context for application debugging or tracing support.

• “pthread_getunique_np”—Retrieve Unique ID for Target Thread” on page 88 (Retrieve a Unique ID for Target Thread) retrieves the unique integral identifier that can be used to identify the thread in some context for application debugging or tracing support.

• “pthread_is_initialthread_np”—Check if Running in the Initial Thread” on page 93 (Check if Running in the Initial Thread) returns true or false, indicating if the current thread is the initial thread of the process.

• “pthread_is_multithreaded_np”—Check Current Number of Threads” on page 95 (Check the Current Number of Threads) returns true or false, indicating whether the current process has more than one thread.

• “pthread_join”—Wait for and Detach Thread” on page 97 (Wait for and Detach Thread) waits for a thread to terminate, detaches the thread, then returns the threads exit status.

• “pthread_join_np”—Wait for Thread to End” on page 99 (Wait for Thread to End) waits for a thread to terminate, then returns the threads exit status, while leaving the data structures of the thread available for a later call to pthread_join(), pthread_join_np(), pthread_detach(), or pthread_extendedjoin_np() (Perform One-Time Initialization) performs one time initialization based on a specific once_control variable.

• “pthread_self”—Get Pthread Handle” on page 186 (Get Pthread Handle) returns the Pthread handle of the calling thread.

• “pthread_setconcurrency”—Set Process Concurrency Level” on page 192 (Set Process Concurrency Level) sets the current concurrency level for the process.
Thread specific storage APIs

Thread specific storage is used by your threaded application when you need global storage that is ‘private’ to a thread. The storage is allocated and stored by the thread, and can be associated with a destructor function. When the thread ends using one of the pthread mechanisms, the destructor function runs and cleans up the thread local storage. The thread specific storage can replace global storage, because any function in a thread that requests the thread specific storage will get the same value. Functions in another thread that request the thread specific storage will get the thread specific storage owned by the thread that they are called in.

For information about the examples included with the APIs, see the “Information on the Pthread API examples” on page 269.

The thread specific storage APIs are:

- **“pthread_getspecific()—Get Thread Local Storage Value by Key” on page 84** (Get Thread Local Storage Value by Key) retrieves the thread local storage value associated with the key. pthread_getspecific() may be called from a data destructor.
- **“pthread_key_create()—Create Thread Local Storage Key” on page 101** (Create Thread Local Storage Key) creates a thread local storage key for the process and associates the destructor function with that key.
- **“pthread_key_delete()—Delete Thread Local Storage Key” on page 103** (Delete Thread Local Storage Key) deletes a process-wide thread local storage key.
- **“pthread_setspecific()—Set Thread Local Storage by Key” on page 199** (Set Thread Local Storage by Key) sets the thread local storage value associated with a key.

Thread cancellation APIs

You can use thread cancellation APIs to cause a thread to end prematurely, or to aid in cleanup when a thread is ended (either prematurely or normally). The thread cancellation APIs work together to provide a mechanism for thread cleanup and protecting threaded resources from cancellation. The thread cancellation APIs only provide clean up and protection in relationship to other pthread APIs. You cannot protect from or clean up when a thread ends as a result of your process ending (normally or abnormally), or when the thread ends by some mechanism outside of the pthread API set. Some examples of mechanisms that can terminate a thread that are outside o the pthread API set are the ENDJOB "IMMED
CL command, a thread ending from an unhandled exception, or the operator terminating a thread using the work with threads screen (Option 20 from the WRKJOB display).

The table below lists the thread cancelability states, the cancellation types, and the cancellation action. Cancelability consists of three separate states (disabled, deferred, asynchronous) that can be represented by two boolean values. The default cancelability state is deferred.

<table>
<thead>
<tr>
<th>Cancelability</th>
<th>Cancelability State</th>
<th>Cancelability Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>disabled</td>
<td>PTHREAD_CANCEL_DISABLE</td>
<td>PTHREAD_CANCEL_DEFERRED</td>
</tr>
<tr>
<td>disabled</td>
<td>PTHREAD_CANCEL_DISABLE</td>
<td>PTHREAD_CANCEL_DEFERRED</td>
</tr>
<tr>
<td>deferred</td>
<td>PTHREAD_CANCEL_ENABLE</td>
<td>PTHREAD_CANCEL_DEFERRED</td>
</tr>
<tr>
<td>asynchronous</td>
<td>PTHREAD_CANCEL_ENABLE</td>
<td>PTHREAD_CANCEL ASYNCHRONOUS</td>
</tr>
</tbody>
</table>

For information about the examples included with the APIs, see the “Information on the Pthread API examples” on page 269.

The thread cancellation APIs are:
- "pthread_cancel()—Cancel Thread” on page 22 (Cancel Thread) requests cancellation of the target thread.
- "pthread_cleanup_peek_np()—Copy Cleanup Handler from Cancellation Cleanup Stack” on page 24 (Copy Cleanup Handler from Cancellation Cleanup Stack) returns a copy of the cleanup handler entry that the next call to pthread_cleanup_pop() would pop.
- "pthread_cleanup_pop()—Pop Cleanup Handler off of Cancellation Cleanup Stack” on page 27 (Pop Cleanup Handler off of Cancellation Cleanup Stack) pops the last cleanup handler from the cancellation cleanup stack.
- "pthread_cleanup_push()—Push Cleanup Handler onto Cancellation Cleanup Stack” on page 29 (Push Cleanup Handler onto Cancellation Cleanup Stack) pushes a cancellation cleanup routine onto the calling threads cancellation cleanup stack.
- "pthread_getcancelstate_np()—Get Cancel State” on page 76 (Get Cancel State) gets the current cancel state of the thread.
- "pthread_setcancelstate()—Set Cancel State” on page 188 (Set Cancel State) sets the cancel state to one of PTHREAD_CANCEL_ENABLE or PTHREAD_CANCEL_DISABLE and returns the old cancel state into the location specified by oldstate (if oldstate is non-NULL).
- "pthread_setcanceltype()—Set Cancel Type” on page 190 (Set Cancel Type) sets the cancel type to one of PTHREAD_CANCEL_DEFERRED or PTHREAD_CANCEL ASYNCHRONOUS and returns the old cancel type into the location specified by oldtype (if oldtype is non-NULL)
- "pthread_test_exit_np()—Test Thread Exit Status” on page 211 (Test Thread Exit Status) returns the current state of the thread along with its exit status.
- "pthread_testcancel()—Create Cancellation Point” on page 209 (Create Cancellation Point) creates a cancellation point in the calling thread.

Mutex synchronization APIs

Thread synchronization is required whenever two threads share a resource or need to be aware of what the other threads in a process are doing. Mutexes are the most simple and primitive object used for the co-operative mutual exclusion required to share and protect resources. One thread owns a mutex by locking it successfully, when another thread tries to lock the mutex, that thread will not be allowed to successfully lock the mutex until the owner unlocks it. The mutex support provides different types and behaviors for mutexes that can be tuned to your application requirements.
The table below lists important mutex attributes, their default values, and all supported values.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default value</th>
<th>Supported values</th>
</tr>
</thead>
<tbody>
<tr>
<td>pshared</td>
<td>PTHREAD_PROCESS_PRIVATE</td>
<td>PTHREAD_PROCESS_PRIVATE or PTHREAD_PROCESS_SHARED</td>
</tr>
<tr>
<td>kind (non portable)</td>
<td>PTHREAD_MUTEX_NONRECURSIVE_NP</td>
<td>PTHREAD_MUTEX_NONRECURSIVE_NP or PTHREAD_MUTEX_RECURSIVE_NP</td>
</tr>
<tr>
<td>name (non portable)</td>
<td>&quot;QP0WMTX UNNAMED“</td>
<td>Any name that is 15 characters or less. If not terminated by a null character, name is truncated to 15 characters.</td>
</tr>
<tr>
<td>type</td>
<td>PTHREAD_MUTEX_DEFAULT (PTHREAD_MUTEX_NORMAL)</td>
<td>PTHREAD_MUTEX_DEFAULT or PTHREAD_MUTEX_NORMAL or PTHREAD_MUTEX_RECURSIVE or PTHREAD_MUTEX_ERRORCHECK or PTHREAD_MUTEX_OWNERTERM_NP</td>
</tr>
</tbody>
</table>

The Mutex synchronization APIs are:

- “pthread_lock_global_np”—Lock Global Mutex” on page 108 (Lock Global Mutex) locks a global mutex provided by the pthreads run-time.
- “pthread_mutex_destroy()”—Destroy Mutex” on page 130 (Destroy Mutex) destroys the named mutex.
- “pthread_mutex_init()”—Initialize Mutex” on page 132 (Initialize Mutex) initializes a mutex with the specified attributes for use.
- “pthread_mutex_lock()”—Lock Mutex” on page 135 (Lock Mutex) acquires ownership of the mutex specified.
- “pthread_mutex_timedlock_np()”—Lock Mutex with Time-Out” on page 139 (Lock Mutex with Time-Out) acquires ownership of the mutex specified.
- “pthread_mutex_trylock()”—Lock Mutex with No Wait” on page 142 (Lock Mutex with No Wait) attempts to acquire ownership of the mutex specified without blocking the calling thread.
- “pthread_mutex_unlock()”—Unlock Mutex” on page 146 (Unlock Mutex) unlocks the mutex specified.
- “pthread_mutexattr_destroy()”—Destroy Mutex Attributes Object” on page 110 (Destroy Mutex Attributes Object) destroys a mutex attributes object and allows the system to reclaim any resources associated with that mutex attributes object.
- “pthread_mutexattr_getkind_np()”—Get Mutex Kind Attribute” on page 112 (Get Mutex Kind Attribute) retrieves the kind attribute from the mutex attributes object specified by attr.
- “pthread_mutexattr_getname_np()”—Get Name from Mutex Attributes Object” on page 114 (Get Name from Mutex Attributes Object) retrieves the name attribute associated with the mutex attribute specified by attr.
- “pthread_mutexattr_getpshared()”—Get Process Shared Attribute from Mutex Attributes Object” on page 116 (Get Process Shared Attribute from Mutex Attributes Object) retrieves the current setting of the process shared attribute from the mutex attributes object.
- “pthread_mutexattr_gettype()”—Get Mutex Type Attribute” on page 118 (Get Mutex Type Attribute) retrieves the type attribute from the mutex attributes object specified by attr.
- “pthread_mutexattr_init()”—Initialize Mutex Attributes Object” on page 121 (Initialize Mutex Attributes Object) initializes the mutex attributes object referenced by attr to the default attributes.

For information about the examples included with the APIs, see the “Information on the Pthread API examples” on page 269.
Condition variable synchronization APIs

Condition variables are synchronization objects that allow threads to wait for certain events (conditions) to occur. Condition variables are slightly more complex than mutexes, and the correct use of condition variables requires the thread to co-operatively use a specific protocol in order to ensure safe and consistent serialization. The protocol for using condition variables includes a mutex, a boolean predicate (true/false expression) and the condition variable itself. The threads that are cooperating using condition variables can wait for a condition to occur, or can wake up other threads that are waiting for a condition.

The table below lists important conditional variables attributes, their default values, and all supported values.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default value</th>
<th>Supported values</th>
</tr>
</thead>
<tbody>
<tr>
<td>pshared</td>
<td>PTHREAD_PROCESS_PRIVATE</td>
<td>PTHREAD_PROCESS_PRIVATE or PTHREAD_PROCESS_SHARED</td>
</tr>
</tbody>
</table>

For information about the examples included with the APIs, see the "Information on the Pthread API examples" on page 269.

The Condition variable synchronization APIs are:

- "pthread_cond_broadcast()—Broadcast Condition to All Waiting Threads” on page 46 (Broadcast Condition to All Waiting Threads) wakes up all threads that are currently waiting on the condition variable specified by cond.
- "pthread_cond_destroy()—Destroy Condition Variable” on page 49 (Destroy Condition Variable) destroys the condition variable specified by cond.
- "pthread_cond_init()—Initialize Condition Variable” on page 50 (Initialize Condition Variable) initializes a condition variable object with the specified attributes for use.
- "pthread_cond_signal()—Signal Condition to One Waiting Thread” on page 53 (Signal Condition to One Waiting Thread) wakes up at least one thread that is currently waiting on the condition variable specified by cond.
- "pthread_cond_timedwait()—Timed Wait for Condition” on page 55 (Timed Wait for Condition) blocks the calling thread, waiting for the condition specified by cond to be signaled or broadcast to.
- "pthread_cond_wait()—Wait for Condition” on page 59 (Wait for Condition) blocks the calling thread, waiting for the condition specified by cond to be signaled or broadcast to.
Read/write lock synchronization APIs

Read/write locks help you build more complex applications without using mutexes and condition variables to provide your own read/write locking primitive object. Read/Write locks provide a synchronization mechanism that allow threads in an application to more accurately reflect the type of access to a shared resource that they require.

Many threads can acquire the same read/write lock if they acquire a shared read lock on the read/write lock object. Only one thread can acquire an exclusive write lock on a read/write lock object. When an exclusive write lock is held, no other threads are allowed to hold any lock.

The table below lists important read/write lock attributes, their default values, and all supported values.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default value</th>
<th>Supported values</th>
</tr>
</thead>
<tbody>
<tr>
<td>pshared</td>
<td>PTHREAD_PROCESS_PRIVATE</td>
<td>PTHREAD_PROCESS_PRIVATE or PTHREAD_PROCESS_SHARED</td>
</tr>
</tbody>
</table>

For information about the examples included with the APIs, see the “Information on the Pthread API examples” on page 269.

The Read/write lock synchronization APIs are:

- "pthread_rwlock_destroy()—Destroy Read/Write Lock” on page 162 (Destroy Read/Write Lock) destroys the named read/write lock.
- "pthread_rwlock_init()—Initialize Read/Write Lock” on page 163 (Initialize Read/Write Lock) initializes a new read/write lock with the specified attributes for use.
- "pthread_rwlock_rdlock()—Get Shared Read Lock” on page 166 (Get Shared Read Lock) attempts to acquire a shared read lock on the read/write lock specified by rwlock.
- "pthread_rwlock_timedrdlock_np()—Get Shared Read Lock with Time-Out” on page 168 (Get Shared Read Lock with Time-Out) attempts to acquire a shared read lock on the read/write lock specified by rwlock.
- "pthread_rwlock_timedwrlock_np()—Get Exclusive Write Lock with Time-Out” on page 172 (Get Exclusive Write Lock with Time-Out) attempts to acquire an exclusive write lock on the read/write lock specified by rwlock.
The examples about APIs signals in the page 269.

Signals APIs

Signal APIs can be used to manipulate signals in a threaded process. Signals can be sent to individual threads, the signal mask of a thread can be changed. When a signal is sent to a thread, the actions associated with the signal (such as stopping, continuing or terminating) never affect only the thread, all signal actions are defined to affect the process. When a signal handler is called, it is called in the thread that the signal was delivered to.

Using signals correctly in a multithreaded process can be difficult. The recommended way to handle signals in a multithreaded process is to mask off all signals in all threads, then use the signals sigwait() API in a single thread to wait for any signal to be delivered to the process.

For information about the examples included with the APIs, see the "Information on the Pthread API examples" on page 269.

The Signals APIs are:

- "pthread_kill()—Send Signal to Thread" on page 105 (Send Signal to Thread) requests that the signal sig be delivered to the specified thread.
- "pthread_sigmask()—Set or Get Signal Mask" on page 202 (Set or Get Signal Mask) examines or modifies the signal blocking mask for the current thread.
- "pthread_signal_to_cancel_np()—Convert Signals to Cancel Requests" on page 206 (Convert Signals to Cancel Requests) causes a pthread_cancel() to be delivered to the target thread when the first signal specified in set arrives.
