Virtual Private Networking (VPN)

A virtual private network (VPN) allows your company to securely extend its private intranet over the existing framework of a public network, such as the Internet. With VPN, your company can control network traffic while providing important security features such as authentication and data privacy.

VPN is an optionally-installable component of iSeries™ Navigator, the graphical user interface (GUI) for i5/OS®. It allows you to create a secure end-to-end path between any combination of host and gateway. VPN uses authentication methods, encryption algorithms, and other precautions to ensure that data sent between the two endpoints of its connection remains secure.

VPN runs on the network layer of the TCP/IP layered communications stack model. Specifically, VPN uses the IP Security Architecture (IPSec) open framework. IPSec provides base security functions for the Internet, as well as furnishes flexible building blocks from which you can create robust, secure virtual private networks.

VPN also supports Layer 2 Tunnel Protocol (L2TP) VPN solutions. L2TP connections, which are also called virtual lines, provide cost-effective access for remote users by allowing a corporate network server to manage the IP addresses assigned to its remote users. Further, L2TP connections provide secure access to your system or network when you protect them with IPSec.

It is important that you understand the effect a VPN will have on your entire network. Correct planning and implementation are essential to your success. Review these topics to ensure that you know how VPNs work and how you might use them:

- The ◄ image to mark where new or changed information ends.

To find other information about what's new or changed this release, see the Memo to Users.

Printable PDF

Use this to view and print a PDF of this information.

To view or download the PDF version of this document, select Virtual private networking (VPN) (about 509 KB).

Saving PDF files

To save a PDF on your workstation for viewing or printing:
1. Right-click the PDF in your browser (right-click the link above).
2. Click Save Target As if you are using Internet Explorer. Click Save Link As if you are using Netscape Communicator.
3. Navigate to the directory in which you would like to save the PDF.
4. Click Save.

Downloading Adobe Acrobat Reader

You need Adobe Acrobat Reader to view or print these PDFs. You can download a copy from the Adobe Web site (www.adobe.com/products/acrobat/readstep.html).

VPN concepts

It is important that you have at least a basic knowledge of standard VPN technologies. This topic provides you with conceptual information about the protocols VPN uses in its implementation.

Virtual private networking (VPN) uses several important TCP/IP protocols to protect data traffic. To better understand how any VPN connection works, familiarize yourself with these protocols and concepts and how VPN uses them:

IP Security (IPSec) protocols

IPSec provides a stable, long lasting base for providing network layer security.

IPSec supports all of the cryptographic algorithms in use today, and can also accommodate newer, more powerful algorithms as they become available. IPSec protocols address these major security issues:

Data origin authentication
Verifies that each datagram was originated by the claimed sender.

Data integrity
Verifies that the contents of a datagram were not changed in transit, either deliberately or due to random errors.

Data confidentiality
Conceals the content of a message, typically by using encryption.
Replay protection
Ensures that an attacker cannot intercept a datagram and play it back at some later time.

Automated management of cryptographic keys and security associations
Ensures that your VPN policy can be used throughout the extended network with little or no manual configuration.

VPN uses two IPSec protocols to protect data as it flows through the VPN: Authentication Header (AH) and Encapsulating Security Payload (ESP). The other part of IPSec enablement is the Internet Key Exchange (IKE) protocol, or key management. While IPSec encrypts your data, IKE supports automated negotiation of security associations (SAs), and automated generation and refreshing of cryptographic keys.

Note: Some VPN configurations could have a security vulnerability depending on how IPSec is configured. The vulnerability affects configurations where IPSec is configured to employ Encapsulating Security Payload (ESP) in tunnel mode with confidentiality (encryption), but without integrity protection (authentication) or Authentication Header (AH). The default configuration when ESP is selected always includes an authentication algorithm that provides integrity protection. Therefore, unless the authentication algorithm in the ESP transform is removed, VPN configurations will be protected from this vulnerability. The IBM® Universal Connection VPN configuration is not affected by this vulnerability.

To check if your system is affected by this security vulnerability follow these steps:
2. Right-click on the data policy you want to check and select Properties.
3. Click on the Proposals tab.
4. Select any of the data protection proposals that are using the ESP protocol and click Edit.
5. Click on the Transforms tab.
6. Select any transforms from the list that use the ESP protocol and click Edit.
7. Verify that the Authentication algorithm has any other value then None.

The Internet Engineering Task Force (IETF) formally defines IPSec in Request for Comment (RFC) 2401, Security Architecture for the Internet Protocol. You can view this RFC on the Internet at the following Web site: http://www.rfc-editor.org.

The principal IPSec protocols are listed below:

Related concepts
“Key management” on page 6
A dynamic VPN provides additional security for your communications by using the Internet Key Exchange (IKE) protocol for key management. IKE allows the VPN servers on each end of the connection to negotiate new keys at specified intervals.

Related information
http://www.rfc-editor.org

Authentication Header
The Authentication Header (AH) protocol provides data origin authentication, data integrity, and replay protection. However, AH does not provide data confidentiality, which means that all of your data is sent in the clear.

AH ensures data integrity with the checksum that a message authentication code, like MD5, generates. To ensure data origin authentication, AH includes a secret shared key in the algorithm that it uses for authentication. To ensure replay protection, AH uses a sequence number field within the AH header. It is
worth noting here, that these three distinct functions are often lumped together and referred to as authentication. In the simplest terms, AH ensures that your data has not been tampered with en route to its final destination.

Although AH authenticates as much of the IP datagram as possible, the values of certain fields in the IP header cannot be predicted by the receiver. AH does not protect these fields, known as mutable fields. However, AH always protects the payload of the IP packet.

The Internet Engineering Task Force (IETF) formally defines AH in Request for Comment (RFC) 2402, *IP Authentication Header*. You can view this RFC on the Internet at the following Web site: http://www.rfc-editor.org.

**Ways of using AH**

You can apply AH in two ways: transport mode or tunnel mode. In transport mode, the IP header of the datagram is the outermost IP header, followed by the AH header and then the payload of the datagram. AH authenticates the entire datagram, except the mutable fields. However, the information contained in the datagram is transported in the clear and is, therefore, subject to eavesdropping. Transport mode requires less processing overhead than tunnel mode, but does not provide as much security.

Tunnel mode creates a new IP header and uses it as the outermost IP header of the datagram. The AH header follows the new IP header. The original datagram (both the IP header and the original payload) comes last. AH authenticates the entire datagram, which means that the responding system can detect whether the datagram changed while in transit.

When either end of a security association is a gateway, use tunnel mode. In tunnel mode the source and destination addresses in the outermost IP header do not need to be the same as those in the original IP header. For example, two security gateways may operate an AH tunnel to authenticate all traffic between the networks they connect together. In fact, this is a very typical configuration.

The main advantage to using tunnel mode, is that tunnel mode totally protects the encapsulated IP datagram. In addition, tunnel mode makes it possible to use private addresses.

**Why AH?**

In many cases, your data only requires authentication. While the Encapsulating Security Payload (ESP) protocol can perform authentication, AH does not affect your system performance as does ESP. Another advantage of using AH, is that AH authenticates the entire datagram. ESP, however, does not authenticate the leading IP header or any other information that comes before the ESP header.

In addition, ESP requires strong cryptographic algorithms in order to be put into effect. Strong cryptography is restricted in some regions, while AH is not regulated and can be used freely around the world.

**Using ESN with AH**

If you use the AH protocol then you might want to enable Extended Sequence Number (ESN). ESN allows you to transmit large volumes of data at a high speed with out re-keying. The VPN connection uses a 64-bit sequence numbers instead of 32-bit numbers over IPsec. Using 64-bit sequence numbers allows more time before re-keying, which prevents sequence number exhaustion and minimizes the use of system resources.

**What algorithms does AH use to protect my information?**

AH uses algorithms known as hashed message authentication codes (HMAC). Specifically, VPN uses either HMAC-MD5 or HMAC-SHA. Both MD5 and SHA take variable-length input data and a secret key.
to produce fixed-length output data (called a hash value). If the hashes of two messages match, then it is very likely that the messages are the same. Both MD5 and SHA encode the message length in their output, but SHA is regarded as more secure because it produces larger hashes.

The Internet Engineering Task Force (IETF) formally defines HMAC-MD5 in Request for Comments (RFC) 2085, HMAC-MD5 IP Authentication with Replay Prevention. The Internet Engineering Task Force (IETF) formally defines HMAC-SHA in Request for Comments (RFC) 2404, The Use of HMAC-SHA-1-96 within ESP and AH. You can view these RFCs on the Internet at the following Web site: http://www.rfc-editor.org.

**Related concepts**

“Encapsulating Security Payload”

The Encapsulating Security Payload (ESP) protocol provides data confidentiality, and also optionally provides data origin authentication, data integrity checking, and replay protection.

**Related information**

http://www.rfc-editor.org

**Encapsulating Security Payload**

The Encapsulating Security Payload (ESP) protocol provides data confidentiality, and also optionally provides data origin authentication, data integrity checking, and replay protection.

The difference between ESP and the Authentication Header (AH) protocol is that ESP provides encryption, while both protocols provide authentication, integrity checking, and replay protection. With ESP, both communicating systems use a shared key for encrypting and decrypting the data they exchange.

If you decide to use both encryption and authentication, then the responding system first authenticates the packet and then, if the first step succeeds, the system proceeds with decryption. This type of configuration reduces processing overhead, as well as reduces your vulnerability to denial-of-service attacks.

**Two ways of using ESP**

You can apply ESP in two ways: transport mode or tunnel mode. In transport mode, the ESP header follows the IP header of the original IP datagram. If the datagram already has an IPSec header, then the ESP header goes before it. The ESP trailer and the optional authentication data follow the payload.

Transport mode does not authenticate or encrypt the IP header, which might expose your addressing information to potential attackers while the datagram is in transit. Transport mode requires less processing overhead than tunnel mode, but does not provide as much security. In most cases, hosts use ESP in transport mode.

Tunnel mode creates a new IP header and uses it as the outermost IP header of the datagram, followed by the ESP header and then the original datagram (both the IP header and the original payload). The ESP trailer and the optional authentication data are appended to the payload. When you use both encryption and authentication, ESP completely protects the original datagram because it is now the payload data for the new ESP packet. ESP, however, does not protect the new IP header. Gateways must use ESP in tunnel mode.

**What algorithms does ESP use to protect my information?**

ESP uses a symmetric key that both communicating parties use to encrypt and decrypt the data they exchange. The sender and the receiver must agree on the key before secure communication takes place between them. VPN uses Data Encryption Standard (DES), triple-DES (3DES), RC5, RC4, or Advanced Encryption Standard (AES) for encryption.
If you choose the AES algorithm for encryption then you might want to enable Extended Sequence Number (ESN). ESN allows you to transmit large volumes of data at a high speed. The VPN connection uses a 64-bit sequence numbers instead of 32-bit numbers over IPSec. Using 64-bit sequence numbers allows more time before re-keying, which prevents sequence number exhaustion and minimizes the use of system resources.

The Internet Engineering Task Force (IETF) formally defines DES in Request for Comment (RFC) 1829, *The ESP DES-CBC Transform*. The Internet Engineering Task Force (IETF) formally defines 3DES in RFC 1851, *The ESP Triple DES Transform*. You can view these and other RFCs on the Internet at the following Web address: http://www.rfc-editor.org.

ESP uses HMAC-MD5 and HMAC-SHA algorithms to provide authentication functions. Both MD5 and SHA take variable-length input data and a secret key to produce fixed-length output data (called a hash value). If the hashes of two messages match, then it is very likely that the messages are the same. Both MD5 and SHA encode the message length in their output, but SHA is regarded as more secure because it produces larger hashes.

The Internet Engineering Task Force (IETF) formally defines HMAC-MD5 in Request for Comments (RFC) 2085, *HMAC-MD5 IP Authentication with Replay Prevention*. The Internet Engineering Task Force (IETF) formally defines HMAC-SHA in Request for Comments (RFC) 2404, *The Use of HMAC-SHA-1-96 within ESP and AH*. You can view these and other RFCs on the Internet at the following Web address: http://www.rfc-editor.org.

**Related concepts**

"Authentication Header" on page 3

The Authentication Header (AH) protocol provides data origin authentication, data integrity, and replay protection. However, AH does not provide data confidentiality, which means that all of your data is sent in the clear.

**Related information**

[http://www.rfc-editor.org](http://www.rfc-editor.org)

**AH and ESP combined**

VPN allows you to combine AH and ESP for host-to-host connections in transport mode.

Combining these protocols protects the entire IP datagram. Although combining the two protocols offers more security, the processing overhead involved may outweigh the benefit.

**Key management**

A dynamic VPN provides additional security for your communications by using the Internet Key Exchange (IKE) protocol for key management. IKE allows the VPN servers on each end of the connection to negotiate new keys at specified intervals.

With each successful negotiation, the VPN servers regenerate the keys that protect a connection, thus making it more difficult for an attacker to capture information from the connection. Additionally, if you use perfect forward secrecy, attackers cannot derive future keys based on past keying information.

The VPN key manager is IBM’s implementation of the Internet Key Exchange (IKE) protocol. The key manager supports the automatic negotiation of security associations (SAs), as well as the automatic generation and refresh of cryptographic keys.

A **security association (SA)** contains information that is necessary to use the IPSec protocols. For example, an SA identifies algorithm types, key lengths and lifetimes, participating parties, and encapsulation modes.
Cryptographic keys, as the name implies, lock, or protect, your information until it safely reaches its final destination.

**Note:** Securely generating your keys is the most important factor in establishing a secure and private connection. If your keys are compromised, then your authentication and encryption efforts, no matter how strong, become worthless.

**Phases of key management**

The VPN key manager uses two distinct phases in its implementation.

**Phase 1**

Phase 1 establishes a master secret from which subsequent cryptographic keys are derived in order to protect user data traffic. This is true even if no security protection yet exists between the two endpoints. VPN uses either RSA signature mode or preshared keys to authenticate phase 1 negotiations, as well as to establish the keys that protect the IKE messages that flow during the subsequent phase 2 negotiations.

A *preshared key* is a nontrivial string up to 128 characters long. Both ends of a connection must agree on the preshared key. The advantage of using preshared keys is their simplicity, the disadvantage is that a shared secret must be distributed out-of-band, for example over the telephone or through registered mail, before IKE negotiations. Treat your preshared key like a password.

*RSA Signature* authentication provides more security than preshared keys because this mode uses digital certificates to provide authentication. You must configure your digital certificates by using Digital Certificate Manager (5722-SS1 Option 34). In addition, some VPN solutions require RSA Signature for interoperability. For example, Windows® 2000 VPN uses RSA Signature as its default authentication method. Finally, RSA Signature provides more scalability than preshared keys. The certificates that you use must come from certificate authorities that both key servers trust.

**Phase 2**

Phase 2, however, negotiates the security associations and keys that protect the actual application data exchanges. Remember, up to this point, no application data has actually been sent. Phase 1 protects the phase 2 IKE messages.

Once phase 2 negotiations are complete, your VPN establishes a secure, dynamic connection over the network and between the endpoints that you defined for your connection. All data that flows across the VPN is delivered with the degree of security and efficiency that was agreed on by the key servers during the phase 1 and phase 2 negotiation processes.

In general, phase 1 negotiations are negotiated once a day, while phase 2 negotiations are refreshed every 60 minutes or as often as every five minutes. Higher refresh rates increase your data security, but decrease system performance. Use short key lifetimes to protect your most sensitive data.

When you create a dynamic VPN by using iSeries Navigator, you must define an IKE policy to enable phase 1 negotiations and a data policy to govern phase 2 negotiations. Optionally, you can use the New Connection wizard. The wizard automatically creates each of the configuration objects VPN requires to work properly, including an IKE policy, data policy.

[http://www.rfc-editor.org](http://www.rfc-editor.org)

**Layer 2 Tunnel Protocol (L2TP)**

Layer 2 Tunneling Protocol (L2TP) connections, which are also called virtual lines, provide cost-effective access for remote users by allowing a corporate network systems to manage the IP addresses assigned to its remote users. Further, L2TP connections provide secure access to your system or network when you use them in conjunction with IP Security (IPSec).

L2TP supports two tunnel modes: the voluntary tunnel and the compulsory tunnel. The major difference between these two tunnel modes is the endpoint. On the voluntary tunnel, the tunnel ends at the remote client whereas the compulsory tunnel ends at the ISP.

With an L2TP **compulsory tunnel**, a remote host initiates a connection to its Internet Service Provider (ISP). The ISP then establishes an L2TP connection between the remote user and the corporate network. Although the ISP establishes the connection, you decide how to protect the traffic by using VPN. With a compulsory tunnel, the ISP must support L2TP.

With an L2TP **voluntary tunnel**, the connection is created by the remote user, typically by using an L2TP tunneling client. As a result, the remote user sends L2TP packets to its ISP which forwards them on to the corporate network. With a voluntary tunnel, the ISP does not need to support L2TP. The scenario, Protect an L2TP voluntary tunnel with IPSec provides you with an example of how to configure a branch office system to connect to its corporate network through a gateway system with an L2TP tunnel protected by VPN.

You can view a visual presentation about the concept of **L2TP voluntary tunnels protected by IPSec**. This requires the Flash plug-in. Alternatively, you can use the HTML version of this presentation.

L2TP is actually a variation of an IP encapsulation protocol. The L2TP tunnel is created by encapsulating an L2TP frame inside a User Datagram Protocol (UDP) packet, which in turn is encapsulated inside an IP packet. The source and destination addresses of this IP packet define the endpoints of the connection. Because the outer encapsulating protocol is IP, you can apply IPSec protocols to the composite IP packet. This protects the data that flows within the L2TP tunnel. You can then apply Authentication Header (AH), Encapsulated Security Payload (ESP), and the Internet Key Exchange (IKE) protocol in a straightforward way.

**Related concepts**

"Scenario: Protecting an L2TP voluntary tunnel with IPSec" on page 23
In this scenario, you learn how to setup a connection between a branch office host and a corporate
office that uses L2TP protected by IPSec. The branch office has a dynamically assigned IP address, while the corporate office has a static, globally routable IP address.

**Network address translation for VPN**

VPN provides a means for performing network address translation, called VPN NAT. VPN NAT differs from traditional NAT in that it translates addresses before applying the IKE and IPSec protocols. Refer to this topic to learn more.

Network address translation (NAT) takes your private IP addresses and translates them into public IP addresses. This helps conserve valuable public addresses while at the same time allows hosts in your network to access services and remote hosts across the Internet (or other public network).

In addition, if you use private IP addresses, they can collide with similar, incoming IP addresses. For example, you may want to communicate with another network but both networks use 10.***.*** addresses, causing the addresses to collide and all packets to be dropped. Applying NAT to your outbound addresses might appear to be the answer to this problem. However, if the data traffic is protected by a VPN, conventional NAT will not work because it changes the IP addresses in the security associations (SA) that VPN requires to function. To avoid this problem, VPN provides its own version of network address translation called VPN NAT. VPN NAT performs address translation before the SA validation by assigning an address to the connection when the connection starts. The address remains associated with the connection until you delete the connection.

**Note:** FTP does not support VPN NAT at this time.

**How should I use VPN NAT?**

There are two different types of VPN NAT that you need to consider before you begin. They are:

**VPN NAT for preventing IP address conflicts**

This type of VPN NAT allows you to avoid possible IP address conflicts when you configure a VPN connection between networks or systems with similar addressing schemes. A typical scenario is one where both companies want to create VPN connections by using one of the designated private IP address ranges. For example, 10.***.***. How you configure this type of VPN NAT depends on whether your system is the initiator or the responder for the VPN connection. When your system is the connection initiator, you can translate your local addresses into ones that are compatible with your VPN connection partner’s address. When your system is the connection responder, you can translate your VPN partner’s remote addresses into ones that are compatible with your local addressing scheme. Configure this type of address translation only for your dynamic connections.

**VPN NAT for hiding local addresses**

This type of VPN NAT is used primarily to hide the real IP address of your local system by translating its address to another address that you make publicly available. When you configure VPN NAT, you can specify that each publicly known IP address be translated to one of a pool of hidden addresses. This also allows you to balance the traffic load for an individual address across multiple addresses. VPN NAT for local addresses requires that your system act as the responder for its connections.

Use VPN NAT for hiding local addresses if you answer yes to these questions:

1. Do you have one or more systems that you want people to access by using a VPN?
2. Do you need to be flexible about the actual IP addresses of your systems?
3. Do you have one or more globally routable IP addresses?

The scenario, Use network address translation for VPN provides you with an example of how to configure VPN NAT to hide local addresses on your System i”™ model.

For step-by-step instructions on how to set up VPN NAT on your system, use the online help available from the VPN interface in iSeries Navigator.

“Scenario: Using network address translation for VPN” on page 35
In this scenario, your company wants to exchange sensitive data with one of its business partners by using VPN. To further protect the privacy of your company’s network structure, your company will also use VPN NAT to hide the private IP address of the system it uses to host the applications to which your business partner has access.

“Planning worksheet for manual connections” on page 40
Complete this worksheet before you configure a manual connection.

NAT compatible IPSec with UDP

UDP encapsulation allows IPSec traffic to pass through a conventional NAT device. Review this topic for more information about what it is and why you should use it for your VPN connections.

The problem: Conventional NAT breaks VPN

Network address translation (NAT) allows you to hide your unregistered private IP addresses behind a set of registered IP addresses. This helps to protect your internal network from outside networks. NAT also helps to alleviate the IP address depletion problem, since many private addresses can be represented by a small set of registered addresses.

Unfortunately, conventional NAT does not work on IPSec packets because when the packet goes through a NAT device, the source address in the packet changes, thereby invalidating the packet. When this happens, the receiving end of the VPN connection discards the packet and the VPN connection negotiations fail.

The solution: UDP encapsulation

In a nutshell, UDP encapsulation wraps an IPSec packet inside a new, but duplicate, IP/UDP header. The address in the new IP header gets translated when it goes through the NAT device. Then, when the packet reaches its destination, the receiving end strips off the additional header, leaving the original IPSec packet, which will now pass all other validations.

You can only apply UDP encapsulation to VPNs that will use IPSec ESP in either tunnel mode or transport mode. In addition, at V5R2, the system can only act as a client for UDP encapsulation. That is, it can only initiate UDP encapsulated traffic.

The graphics below illustrate the format of a UDP encapsulated ESP packet in tunnel mode:

Original IPv4 datagram:

After applying IPSec ESP in tunnel mode:

After applying UDP Encapsulation:
The graphics below illustrate the format of a UDP encapsulated ESP packet in transport mode:

**Original IPv4 datagram:**

![Original IPv4 datagram diagram]

**After applying IPSec ESP in transport mode:**

![After applying IPSec ESP in transport mode diagram]

**After applying UDP Encapsulation:**

![After applying UDP Encapsulation diagram]

After the packet is encapsulated, the system sends the packet to its VPN partner over UDP port 4500. Typically, VPN partners perform IKE negotiations over UDP port 500. However, when IKE detects NAT during key negotiation, subsequent IKE packets are sent over source port 4500, destination port 4500. This also means that port 4500 must be unrestricted in any applicable filter rules. The receiving end of the connection can determine whether the packet is an IKE packet or a UDP encapsulated packet because the first 4 bytes of the UDP payload are set to zero on an IKE packet. For it to work properly, both ends of the connection must support UDP encapsulation.

**Related concepts**

"Scenario: Firewall Friendly VPN" on page 29

In this scenario, a large insurance company wants to establish a VPN between a gateway in Chicago and a host in Minneapolis when both networks are behind a firewall.

**IP Compression (IPComp)**

IPComp reduces the size of IP datagrams by compressing the datagrams to increase the communication performance between two VPN partners.

The IP Payload Compression protocol (IPComp) reduces the size of IP datagrams by compressing the datagrams to increase the communication performance between two partners. The intent is to increase overall communication performance when the communication is over slow or congested links. IPComp does not provide any security and must be used along with either an AH or an ESP transform when the communication occurs over a VPN connection.

The Internet Engineering Task Force (IETF) formally defines IPComp in Request for Comments (RFC) 2393, *IP Payload compression Protocol (IPComp)*. You can view this RFC on the Internet at the following Web site: http://www.rfc-editor.org.

**VPN and IP filtering**

IP filtering and VPN are closely related. In fact, most VPN connections require filter rules to work properly. This topic provides you information about what filters VPN requires, as well as other filtering concepts related to VPN.
Most VPN connections require filter rules to work properly. The filter rules required depend on the type of VPN connection that you are configuring as well as what type of traffic you want to control. In general, each connection will have a policy filter. The policy filter defines which addresses, protocols, and ports can use the VPN. In addition, connections that support the Internet Key Exchange (IKE) protocol typically have rules that are written explicitly to allow IKE processing over the connection.

In OS/400® V5R1 or later, VPN can generate these rules automatically. Whenever possible, allow VPN to generate your policy filters for you. Not only will this help to eliminate errors, but it also eliminates the need for you to configure the rules as a separate step by using the Packet Rules editor in iSeries Navigator.

There are, of course, exceptions. Review these topics to learn more about other, less common, VPN and filtering concepts and techniques that may apply to your particular situation:

Related concepts
“Configuring VPN packet rules” on page 47

If you are creating a connection for the first time, allow VPN to automatically generate the VPN packet rules for you. You can do this by either using the New Connection wizard or the VPN properties pages to configure your connection.

VPN connections with no policy filters
If the connection endpoints of your VPN are single, specific, IP addresses and you want to start the VPN without having to write or activate filter rules on the system, you can configure a dynamic policy filter.

A policy filter rule defines which addresses, protocols, and ports can use a VPN and directs the appropriate traffic through the connection. In some cases, you may want to configure a connection that does not require a policy filter rule. For example, you may have non-VPN packet rules loaded on the interface that your VPN connection will use, so rather than deactivating the active rules on that interface, you decide to configure the VPN so that your system manages all filters dynamically for the connection. The policy filter for this type of connection is referred to as a dynamic policy filter. Before you can use a dynamic policy filter for your VPN connection, all of the following must be true:

- The connection can only be initiated by the local system.
- The data endpoints of the connection must be single systems. That is, they cannot be a subnet or a range of addresses.
- No policy filter rule can be loaded for the connection.

If your connection meets this criteria, then you can configure the connection so that it does not require a policy filter. When the connection starts, traffic between the data endpoints will flow across the it regardless of what other packet rules are loaded on your system.

For step-by-step instructions on how to configure a connection so that it does not require a policy filter, use the online help for VPN.

Implicit IKE
In order for IKE negotiations to occur for your VPN, you need to allow UDP datagrams over port 500 for this type of IP traffic. However, if there are no filter rules on the system specifically written to permit IKE traffic, then the system will implicitly allow IKE traffic to flow.

To establish a connection, most VPNs require Internet Key Exchange (IKE) negotiations to occur before IPSec processing can happen. IKE uses the well-known port 500, so for IKE to work properly, you need to allow UDP datagrams over port 500 for this type of IP traffic. If there are no filter rules on the system specifically written to permit IKE traffic, then IKE traffic is implicitly allowed. However, rules written specifically for UDP port 500 traffic are handled based on what is defined in the active filter rules.
VPN scenarios

Review these scenarios to become familiar with the technical and configuration details involved with each of these basic connection types.

AS/400 Internet Security: Implementing AS/400 Virtual Private Networks, SG24-5404-00
AS/400 Internet Security Scenarios: A Practical Approach, SG24-5954-00

Scenario: Basic branch office connection

In this scenario, your company wants to establish a VPN between the subnets of two remote departments through a pair of System i models acting as VPN gateways.

Situation

Suppose your company wants to minimize the costs incurred from communicating to and among its own branches. Today, your company uses frame relay or leased lines, but you want to explore other options for transmitting internal confidential data that are less expensive, more secure, and globally accessible. By exploiting the Internet, you can easily establish a virtual private network (VPN) to meet the needs of your company.

Your company and its branch office both require VPN protection across the Internet, but not within their respective intranets. Because you consider the intranets trusted, the best solution is to create a gateway-to-gateway VPN. In this case, both gateways are connected directly to the intervening network. In other words, they are border or edge systems, which are not protected by firewalls. This example serves as a useful introduction to the steps involved in setting up a basic VPN configuration. When this scenario refers to the term, Internet, it refers to the intervening network between the two VPN gateways, which might be the company’s own private network or the public Internet.

Important: This scenario shows the System i model security gateways attached directly to the Internet. The absence of a firewall is intended to simplify the scenario. It does not imply that the use of a firewall is not necessary. In fact, consider the security risks involved any time you connect to the Internet.

Advantages

This scenario has the following advantages:

• Using the Internet or an existing intranet reduces the cost of private lines between remote subnets.
• Using the Internet or an existing intranet reduces the complexity of installing and maintaining private lines and associated equipment.
• Using the Internet allows remote locations to connect to almost anywhere in the world.
• Using VPN provides users access to all systems and resources on either side of the connection just as though they were connected using a leased line or wide area network (WAN) connection.
• Using industry standard encryption and authentication methods ensures the security of sensitive information passed from one location to another.
• Exchanging your encryption keys dynamically and regularly simplifies setup and minimizes the risk of your keys being decoded and security being breached.
• Using private IP addresses in each remote subnet makes it unnecessary to allocate valuable public IP addresses to each client.

Objectives

In this scenario, MyCo, Inc. wants to establish a VPN between the subnets of its Human Resources and Finance departments through a pair of System i models. Both systems will act as VPN gateways. In terms of VPN configurations, a gateway performs key management and applies IPSec to the data that flows through the tunnel. The gateways are not the data endpoints of the connection.

The objectives of this scenario are as follows:
• The VPN must protect all data traffic between the Human Resources department’s subnet and the Finance department’s subnet.
• Data traffic does not require VPN protection once it reaches either of the department’s subnets.
• All clients and hosts on each network have full access to the other’s network, including all applications.
• The gateway systems can communicate with each other and access each other’s applications.

Details

The following figure illustrates the network characteristics of MyCo.

Human Resources Department
• System-A runs on OS/400 Version 5 Release 2 (V5R2) or later and acts as the Human Resources Department’s VPN gateway.
• Subnet is 10.6.0.0 with mask 255.255.0.0. This subnet represents the data endpoint of the VPN tunnel at the MyCo Rochester site.
• System-A connects to the Internet with IP address 204.146.18.227. This is the connection endpoint. That is, System-A performs key management and applies IPSec to incoming and outgoing IP datagrams.
• System-A connects to its subnet with IP address 10.6.11.1.
• System-B is a production system in the Human Resources subnet that runs standard TCP/IP applications.
Finance Department

- System-C runs on OS/400 Version 5 Release 2 (V5R2) or later and acts as the Finance Department’s VPN gateway.
- Subnet is 10.196.8.0 with mask 255.255.255.0. This subnet represents the data endpoint of the VPN tunnel at the MyCo Endicott site.
- System-C connects to the Internet with IP address 208.222.150.250. This is the connection endpoint. That is, System-C performs key management and applies IPSec to incoming and outgoing IP datagrams.
- System-C connects to its subnet with IP address 10.196.8.5.

Configuration tasks

You must complete each of these tasks to configure the branch office connection described in this scenario:

Note: Before you start these tasks verify the TCP/IP routing to ensure that the two gateway systems can communicate with each other across the Internet. This ensures that hosts on each subnet route properly to their respective gateway for access to the remote subnet.

Configuring VPN on System-A

Complete these task to configure System-A:

1. In iSeries Navigator, expand System-A → Network → IP Policies.
2. Right-click Virtual Private Networking and select New Connection to start the New Connection wizard.
3. Review the Welcome page for information about what objects the wizard creates.
4. Click Next to go to the Connection Name page.
5. In the Name field, enter HRgw2FINgw.
6. Optional: Specify a description for this connection group.
7. Click Next to go to the Connection Scenario page.
8. Select Connect your gateway to another gateway.
9. Click Next to go to the Internet Key Exchange Policy page.
10. Select Create a new policy and then select Balance security and performance.
11. Click Next to go to the Certificate for Local Connection Endpoint page.
12. Select No to indicate that you will not be using certificates to authenticate the connection.
13. Click Next to go to the Local Key Server page.
14. Select Version 4 IP address from the Identifier type field.
15. Select 204.146.18.227 from the IP address field.
16. Click Next to go to the Remote Key Server page.
17. Select Version 4 IP address in the Identifier type field.
18. Enter 208.222.150.250 in the Identifier field.
19. Enter topsecretstuff in the Pre-shared key field.
20. Click Next to go to the Local Data Endpoint page.
21. Select IP version 4 subnet from the Identifier type field.
22. Enter 10.6.0.0 in the Identifier field.
23. Enter 255.255.0.0 in the Subnet mask field.
24. Click Next to go to the Remote Data Endpoint page.
25. Select IP version 4 subnet from the Identifier type field.
26. Enter 10.196.8.0 in the Identifier field.
27. Enter 255.255.255.0 in the Subnet mask field.
28. Click Next to go to the Data Services page.
29. Accept the default values, and then click Next to go to the Data Policy page.
30. Select Create a new policy and then select Balance security and performance.
31. Select Use the RC4 encryption algorithm.
32. Click Next to go to the Applicable Interfaces page.
33. Select TRLINE from the Line table.
34. Click Next to go to the Summary page. Review the objects that the wizard will create to ensure they are correct.
35. Click Finish to complete the configuration.
36. When the Activate Policy Filters dialog box appears, select Yes, activate the generated policy filters then select Permit all other traffic.
37. Click OK to complete the configuration. When prompted, specify that you want to activate the rules on all interfaces.

Configuring VPN on System-C

Follow the same steps you used to configure VPN on System-A, changing IP addresses as necessary. Use your planning worksheets for guidance.

When you finish configuring the Finance Department VPN gateway, your connections will be in an on-demand state, which means the connection starts when IP datagrams that this VPN connection must protect are sent. The next step is to start the VPN servers, if they are not already started.

Starting VPN

After you have configured your VPN connection on System A and C you need to start your VPN connection.

Follow these steps to start VPN:
1. In iSeries Navigator, expand the system → Network → IP Policies.
2. Right-click Virtual Private Networking and select Start.

Testing a connection

After you finish configuring both systems and you have successfully started the VPN servers, test the connectivity to ensure that the remote subnets can communicate with each other.

To test your connection, follow these steps:
1. In iSeries Navigator, expand System-A → Network.
2. Right-click TCP/IP Configuration and select Utilities and then select Ping.
3. From the Ping from dialog box, enter System-C in the Ping field.
4. Click Ping Now to enter System-C in the Ping field.
5. Click OK when you are finished.

Scenario: Basic business to business connection

In this scenario, your company wants to establish a VPN between a client workstation in your manufacturing division and a client workstation in the supply department of your business partner.
Situation

Many companies use frame relay or leased lines to provide secure communications with their business partners, subsidiaries, and vendors. Unfortunately, these solutions are often expensive and geographically limiting. VPN offers an alternative for companies who want private, cost-effective communications.

Suppose you are a major parts supplier to a manufacturer. Since it is critical that you have the specific parts and quantities at the exact time required by the manufacturing firm, you always need to be aware of the manufacturer’s inventory status and production schedules. Perhaps you handle this interaction manually today, and find it time consuming, expensive and even inaccurate at times. You want to find an easier, faster, and more effective way to communicate with your manufacturing company. However, given the confidentiality and time-sensitive nature of the information you exchange, the manufacturer does not want to publish it on its corporate Web site or distribute it monthly in an external report. By exploiting the public Internet, you can easily establish a virtual private network (VPN) to meet the needs of both companies.

Objectives

In this scenario, MyCo wants to establish a VPN between a host in its parts division and a host in the manufacturing department of one their business partners, TheirCo.

Because the information these two companies share is highly confidential, it must be protected while it travels across the Internet. In addition, data must not flow in the clear within either company’s networks because each network considers the other untrusted. In other words, both companies require end-to-end authentication, integrity, and encryption.

Important: The intent of this scenario is to introduce, by example, a simple host-to-host VPN configuration. In a typical network environment, you will also need to consider firewall configuration, IP addressing requirements, and routing, among others.
Details

The following figure illustrates the network characteristics of MyCo and TheirCo:

MyCo Supply Network
- System-A runs on OS/400 Version 5 Release 2 (V5R2) or later.
- System-A has an IP address of 10.6.1.1. This is the connection endpoint, as well as the data endpoint. That is, System-A performs IKE negotiations and applies IPSec to incoming and outgoing IP datagrams and is also the source and destination for data that flows through the VPN.
- System-A is in subnet 10.6.0.0 with mask 255.255.0.0
- Only System-A can initiate the connection with System-C.

TheirCo Manufacturing Network
- System-C runs on OS/400 Version 5 Release 2 (V5R2) or later.
- System-C has an IP address of 10.196.8.6. This is the connection endpoint, as well as the data endpoint. That is, System-A performs IKE negotiations and applies IPSec to incoming and outgoing IP datagrams and is also the source and destination for data that flows through the VPN.
- System-C is in subnet 10.196.8.0 with mask 255.255.255.0

Configuration tasks

You must complete each of these tasks to configure the business to business connection described in this scenario:

Note: Before you start these tasks verify the TCP/IP routing to ensure that the two gateway systems can communicate with each other across the Internet. This ensures that hosts on each subnet route properly to their respective gateway for access to the remote subnet.

Related concepts
- TCP/IP routing and workload balancing
Completing the planning worksheets

The planning checklists illustrate the type of information you need before you begin configuring the VPN. All answers on the prerequisite checklist must be YES before you proceed with VPN setup.

Note: These worksheets apply to System-A, repeat the process for System-C, reversing IP addresses as necessary.

**Configuring VPN on System-A**

Complete the following steps to configure a VPN connection on System-A.

Use the information from your planning worksheets to configure VPN on System-A as follows:

1. In iSeries Navigator, expand your system → Network → IP Policies.
2. Right-click **Virtual Private Networking** and select **New Connection** to start the Connection wizard.
3. Review the **Welcome** page for information about what objects the wizard creates.
4. Click **Next** to go to the **Connection Name** page.
5. In the **Name** field, enter MyCo2TheirCo.
6. Optional: Specify a description for this connection group.
7. Click **Next** to go to the **Connection Scenario** page.
8. Select **Connect your host to another host**.
9. Click **Next** to go to the **Internet Key Exchange Policy** page.
10. Select **Create a new policy** and then select **Highest security, lowest performance**.
11. Click **Next** to go to the **Certificate for Local Connection Endpoint** page.
12. Select **Yes** to indicate that you will be using certificates to authenticate the connection. Then, select the certificate that represents System-A.

  **Note:** If you want to use a certificate to authenticate the local connection endpoint, you must first create the certificate in the Digital Certificate Manager (DCM).

13. Click **Next** to go to the **Local Connection Endpoint Identifier** page.
14. Select **Version 4 IP address** as the identifier type. The associated IP address must be 10.6.1.1. Again, this information is defined in the certificate that you create in DCM.
15. Click **Next** to go to the **Remote Key Server** page.
16. Select **Version 4 IP address** in the **Identifier type** field.
17. Enter 10.196.8.6 in the **Identifier** field.
18. Click **Next** to go to the **Data Services** page.
19. Accept the default values, and then click **Next** to go to the **Data Policy** page.
20. Select **Create a new policy** and then select **Highest security, lowest performance**. Select **Use the RC4 encryption algorithm**.
21. Click **Next** to go to the **Applicable Interfaces** page.
22. Select **TRLINE**.
23. Click **Next** to go to the **Summary** page. Review the objects that the wizard will create to ensure they are correct.
24. Click **Finish** to complete the configuration.
25. When the **Activate Policy Filters** dialog box appears, select **No, packet rules will be activated at a later time** and then click **OK**.

The next step is to specify that only System-A can initiate this connection. Do this by customizing the properties of the dynamic-key group, MyCo2TheirCo, that the wizard created:

1. Click **By Group** in the left pane of the VPN interface, the new dynamic-key group, MyCo2TheirCo, displays in the right pane. Right-click it and select **Properties**.
2. Go to the **Policy** page and select the **Local system initiates connection** option.
3. Click **OK** to save your changes.

**Configuring VPN on System-C**

Follow the same steps you used to configure VPN on System-A, changing IP addresses as necessary. Use your planning worksheets for guidance.
When you finish configuring the Finance Department VPN gateway, your connections will be in an on-demand state, which means the connection starts when IP datagrams that this VPN connection must protect are sent. The next step is to start the VPN servers, if they are not already started.

**Activating packet rules**
The VPN wizard automatically creates the packet rules that this connection requires to work properly. However, you must activate them on both systems before you can start the VPN connection.

To activate packet rules on System-A, follow these steps:
1. In iSeries Navigator, expand **System-A → Network → IP Policies**.
2. Right-click **Packet Rules** and select **Activate**. This opens the Activate Packet Rules dialog box.
3. Select whether you want to activate only the VPN generated rules, only a selected file, or both the VPN generated rules and a selected file. You might choose the latter, for instance, if you have miscellaneous PERMIT and DENY rules that you want to enforce on the interface in addition to the VPN generated rules.
4. Select the interface on which you want the rules activated. In this case, select **All interfaces**.
5. Click **OK** on the dialog box to confirm that you want to verify and activate the rules on the interface or interfaces you specified. After you click OK, the system checks the rules for syntax and semantic errors and reports the results in a message window at the bottom of the editor. For error messages that are associated with a specific file and line number, you can right-click the error and select **Go To Line** to highlight the error in the file.
6. Repeat these steps to activate packet rules on System-C.

**Starting a connection**
After you have configured your VPN connection you need to start your VPN connection.

Follow these steps to start the MyCo2TheirCo connection from System-A:
1. In iSeries Navigator, expand **System-A → Network → IP Policies**.
2. If the VPN server is not started, right-click **Virtual Private Networking** and select **Start**. This starts the VPN server.
3. Expand **Virtual Private Networking → Secure Connections**.
4. Click **All Connections** to display a list of connections in the right pane.
5. Right-click **MyCo2TheirCo** and select **Start**.
6. From the View menu, select **Refresh**. If the connection starts successfully, the status will change from **Idle** to **Enabled**. The connection may take a few minutes to start, so periodically refresh until the status changes to **Enabled**.

**Testing a connection**
After you finish configuring both systems and you have successfully started the VPN servers, test the connectivity to ensure that the remote subnets can communicate with each other.

To test your connection, follow these steps:
1. In iSeries Navigator, expand **System-A → Network**.
2. Right-click **TCP/IP Configuration** and select **Utilities** and then select **Ping**.
3. From the **Ping from** dialog box, enter **System-C** in the **Ping** field.
4. Click **Ping Now** to verify connectivity from System-A to System-C.
5. Click **OK** when you are finished.
Scenario: Protecting an L2TP voluntary tunnel with IPSec

In this scenario, you learn how to setup a connection between a branch office host and a corporate office that uses L2TP protected by IPSec. The branch office has a dynamically assigned IP address, while the corporate office has a static, globally routable IP address.

Situation

Suppose your company has a small branch office in another state. Throughout any given workday the branch office may require access to confidential information about an System i model within your corporate intranet. Your company currently uses an expensive leased line to provide the branch office access to the corporate network. Although your company wants to continue providing secure access to your intranet, you ultimately want to reduce the expense associated with the leased line. This can be done by creating a Layer 2 Tunnel Protocol (L2TP) voluntary tunnel that extends your corporate network, such that the branch office appears to be part of your corporate subnet. VPN protects the data traffic over the L2TP tunnel.

With an L2TP voluntary tunnel, the remote branch office establishes a tunnel directly to the L2TP network server (LNS) of the corporate network. The functionality of the L2TP access concentrator (LAC) resides at the client. The tunnel is transparent to the remote client’s Internet Service Provider (ISP), so the ISP is not required to support L2TP. If you want to read more about L2TP concepts, see Layer 2 Tunnel Protocol (L2TP).

Important: This scenario shows the security gateways attached directly to the Internet. The absence of a firewall is intended to simplify the scenario. It does not imply that the use of a firewall is not necessary. Consider the security risks involved any time you connect to the Internet.

Objectives

In this scenario, a branch office system connects to its corporate network through a gateway system with an L2TP tunnel protected by VPN.

The main objectives of this scenario are:
- The branch office system always initiates the connection to the corporate office.
- The branch office system is the only system at the branch office network that needs access to the corporate network. In other words, its role is that of a host, not a gateway, in the branch office network.
- The corporate system a host computer in the corporate office network.
Details

The following figure illustrates the network characteristics for this scenario:

System-A
- Must have access to TCP/IP applications on all systems in the corporate network.
- Receives dynamically assigned IP addresses from its ISP.
- Must be configured to provide L2TP support.

System-B
- Must have access to TCP/IP applications on System-A.
- Subnet is 10.6.0.0 with mask 255.255.0.0. This subnet represents the data endpoint of the VPN tunnel at the corporate site.
- Connects to the Internet with IP address 205.13.237.6. This is the connection endpoint. That is, System-B performs key management and applies IPSec to incoming and outgoing IP datagrams.
- Connects to its subnet with IP address 10.6.11.1.

In L2TP terms, System-A acts as the L2TP initiator, while System-B acts as the L2TP terminator.

Configuration tasks

Assuming that TCP/IP configuration already exists and works, you must complete the following tasks:

Related concepts
“Layer 2 Tunnel Protocol (L2TP)” on page 8
Layer 2 Tunneling Protocol (L2TP) connections, which are also called virtual lines, provide cost-effective access for remote users by allowing a corporate network systems to manage the IP addresses assigned to its remote users. Further, L2TP connections provide secure access to your system or network when you use them in conjunction with IP Security (IPSec).

Configuring VPN on System-A

Complete the following steps to configure a VPN connection on System-A.

Use the information from your planning worksheets to configure VPN on System-A as follows:

1. **Configure the Internet Key Exchange policy**
   b. Right-click Internet Key Exchange Policies and select New Internet Key Exchange Policy.
   c. On the Remote Server page, select Version 4 IP address as the identifier type and then enter 205.13.237.6 in the IP address field.
   d. On the Associations page, select Preshared key to indicate that this connection uses a preshared key to authenticate this policy.
   e. Enter the preshared key in the Key field. Treat your preshared key like a password.
   f. Select Key Identifier for the local key server identifier type, and then enter the key identifier in the Identifier field. For example, thisisthekeyid. Remember that the local key server has a dynamically assigned IP address which is impossible to know in advance. System-B uses this identifier to identify the System-A when System-A initiates a connection.
   g. On the Transforms page, click Add to add the transforms that System-A proposes to System-B for key protection and to specify whether the IKE policy uses identity protection when initiating phase 1 negotiations.
   h. On the IKE Policy Transform page, select Preshared key for your authentication method, SHA for your hash algorithm, and 3DES-CBC for your encryption algorithm. Accept the default values for Diffie-Hellman group and Expire IKE keys after.
   i. Click OK to return to the Transforms page.
   j. Select IKE aggressive mode negotiation (no identity protection).

*Note:* If you use preshared keys and aggressive mode negotiation together in your configuration, select obscure passwords that are unlikely to be cracked in attacks that scan the dictionary. It is also recommended you periodically change your passwords.
   k. Click OK to save your configurations.

2. **Configure the data policy**
   a. From the VPN interface, right-click Data policies and select New Data Policy.
   b. On the General page, specify the name of the data policy. For example, 12tpremoteuser
   c. Go to the Proposals page. A proposal is a collection of protocols that the initiating and responding key servers use to establish a dynamic connection between two endpoints. You can use a single data policy in several connection objects. However, not all remote VPN key servers necessarily have the same data policy properties. Therefore, you can add several proposals to one data policy. When establishing a VPN connection to a remote key server, there must be at least one matching proposal in the data policy of the initiator and the responder.
   d. Click Add to add a data policy transform
   e. Select Transport for the encapsulation mode.
   f. Click OK to return to the Transforms page.
   g. Specify a key expiration value.
   h. Click OK to save your new data policy.

3. **Configure the dynamic-key group**
   a. From the VPN interface, expand Secure Connections.
   b. Right-click By Group and select New Dynamic-Key Group.
   c. On the General page, specify a name for the group. For example, 12tptocorp.
   d. Select Protects a locally initiated L2TP tunnel.
e. For system role, select **Both systems are hosts**.

f. Go to the **Policy** page. Select the data policy you created in the step **Configure the data policy**, l2tpremoteuser, from the **Data policy** drop-down list.

g. Select **Local system initiates connection** to indicate that only System-A can initiate connections with System-B.

h. Go to the **Connections** page. Select **Generate the following policy filter rule for this group**. Click **Edit** to define the parameters of the policy filter.

i. On the **Policy Filter - Local Addresses** page, select **Key Identifier** for the identifier type.

j. For the identifier, select the key identifier, thisisthekeyid, that you defined in the IKE policy.

k. Go the **Policy Filter - Remote Addresses** page. Select IP **version 4 address** from the **Identifier type** drop-down list.

l. Enter 205.13.237.6 in the **Identifier** field.

m. Go to the **Policy Filter - Services** page. Enter 1701 in the **Local Port** and **Remote Port** fields. Port 1701 is the well-known port for L2TP.

n. Select **UDP** from the **Protocol** drop-down list.

o. Click **OK** to return to the **Connections** page.

p. Go to the **Interfaces** page. Select any line or PPP profile to which this group will apply. You have not created the PPP profile for this group yet. After you do so, you will need to edit the properties of this group so that the group applies to the PPP profile you create in the next step.

q. Click **OK** to create the dynamic-key group, l2ptocorp.

4. **Configure the dynamic-key connection**

a. From the VPN interface, expand **By Group**. This displays a list of all dynamic-key groups you have configured on System-A.

b. Right-click **l2ptocorp** and select **New Dynamic-Key Connection**.

c. On the **General** page, specify an optional description for the connection.

d. For the remote key server, select **Version 4 IP address** for the identifier type.

e. Select 205.13.237.6 from the **IP address** drop-down list.

f. Deselect **Start on-demand**.

g. Go to the **Local Addresses** page. Select **Key identifier** for the identifier type and then select thisisthekeyid from the **Identifier** drop-down list.

h. Go to the **Remote Addresses** page. Select **IP version 4 address** for the identifier type.

i. Enter 205.13.237.6 in the **Identifier** field.

j. Go to the **Services** page. Enter 1701 in the **Local Port** and **Remote Port** fields. Port 1701 is the well-known port for L2TP.

k. Select **UDP** from the **Protocol** drop-down list

l. Click **OK** to create the dynamic-key connection.

**Related tasks**

"Configuring VPN on System-B” on page 28

To configure a VPN connection on System-B follow the same steps you used to configure a VPN connection on System-A, and change IP addresses and identifiers as necessary.

**Configuring a PPP connection profile and virtual line on System-A**

Now that a VPN connection is configured on System-A you need to create the PPP profile for System-A. The PPP profile has no physical line associated with it; instead, it uses a virtual line. This is because the PPP traffic tunnels through the L2TP tunnel, while VPN protects the L2TP tunnel.

Follow these steps to create a PPP connection profile for System-A:

1. In iSeries Navigator, expand System-A → **Network** → **Remote Access Services**.

2. Right-click **Originator Connection Profiles** and select **New Profile**.
3. On the **Setup** page, select **PPP** for the protocol type.
4. For Mode selections, select **L2TP (virtual line)**.
5. Select **Initiator on-demand (voluntary tunnel)** from the **Operating mode** drop-down list.
6. Click **OK** to go to the PPP profiles properties pages.
7. On the **General** page, enter a name that identifies the type and the destination of the connection. In this case, enter **toCORP**. The name you specify must be 10 characters, or less.
8. Optional: Specify a description for the profile.
9. Go to the **Connection** page.
10. In the **Virtual line name** field, select **tocorp** from the drop-down list. Remember that this line has no associated physical interface. The virtual line describes various characteristics of this PPP profile; for example, the maximum frame size, authentication information, the local host name, and so on. The **L2TP Line Properties** dialog box opens.
11. On the **General** page, enter a description for the virtual line.
12. Go to the **Authentication** page.
13. In the **Local host name** field, enter the host name of the local key server, **SystemA**.
14. Click **OK** to save the new virtual line description and return to the **Connection** page.
15. Enter the remote tunnel endpoint address, 205.13.237.6, in the **Remote tunnel endpoint address** field.
16. Select **Requires IPSec Protection** and select the dynamic-key group you created in previous step **L2tp2corp** from the **Connection group name** drop-down list.
17. Go to the **TCP/IP Settings** page.
18. In the **Local IP address** section, select **Assigned by remote system**.
19. In the **Remote IP address** section, select **Use fixed IP address**. Enter 10.6.11.1, which is the remote system’s IP address in its subnet.
20. In the routing section, select **Define additional static routes** and click **Routes**. If there is no routing information provided in the PPP profile, then System-A is only able to reach the remote tunnel endpoint but not any other system on the 10.6.0.0 subnet.
21. Click **Add** to add a static route entry.
22. Enter the subnet, 10.6.0.0, and the subnet mask, 255.255.0.0 to route all 10.6.*.* traffic through the L2TP tunnel.
23. Click **OK** to add the static route.
24. Click **OK** to close the Routing dialog box.
25. Go to the **Authentication** page to set the user name and password for this PPP profile.
26. In the Local system identification section, select **Allow the remote system to verify the identity of this system**.
27. Under **Authentication protocol to use** select **Require encrypted password (CHAP-MD5)**. In the Local system identification section, select **Allow the remote system to verify the identity of this system**.
28. Enter the user name, **SystemA**, and a password.
29. Click **OK** to save the PPP profile.

**Applying the l2tptocorp dynamic-key group to the toCorp PPP profile**

After you have your PPP connection profile configured, you need to go back to the dynamic-key group, l2tptocorp, you created and associate it with the PPP profile.

To associate your dynamic-key group with your PPP profile follow these steps:
1. In iSeries Navigator, expand your **system → Network → IP Policies → Virtual Private Networking → Secure Connections → By Group**.
2. Right-click the dynamic-key group, 12tptocorp, and select Properties.
3. Go to the Interfaces page and select Apply this group for the PPP profile you created in "Configuring a PPP connection profile and virtual line on System-A" on page 26, tocorp.
4. Click OK to apply 12tptocorp to the PPP profile, tocorp.

Configuring VPN on System-B
To configure a VPN connection on System-B follow the same steps you used to configure a VPN connection on System-A, and change IP addresses and identifiers as necessary.

Take these other points into consideration before you begin:
• The identify the remote key server by the key identifier you specified for the local key server on System-A. For example, thisisthekeyid.
• Use the exact same preshared key.
• Make sure your transforms match the ones you configured on System-A, or connections will fail.
• Do not specify Protects a locally initiated L2TP tunnel on the General page of the dynamic-key group.
• Remote system initiates the connection.
• Specify that the connection should start on-demand.

Related tasks
"Configuring VPN on System-A” on page 25
Complete the following steps to configure a VPN connection on System-A.

Configuring a PPP connection profile and virtual line on System-B
Now that a VPN connection is configured on System-B you need to create the PPP profile for System-B. The PPP profile has no physical line associated with it; instead, it uses a virtual line. This is because the PPP traffic tunnels through the L2TP tunnel, while VPN protects the L2TP tunnel.

Follow these steps to create a PPP connection profile for System-B:
2. Right-click Responder Connection Profiles and select New Profile.
3. On the Setup page, select PPP for the protocol type.
4. For Mode selections, select L2TP (virtual line).
5. Select Terminator (network server) from the Operating mode drop-down list.
6. Click OK to PPP profiles properties pages.
7. On the General page, enter a name that identifies the type and the destination of the connection. In this case, enter tobranch. The name you specify must be 10 characters, or less.
8. Optional: Specify a description for the profile
9. Go to the Connection page.
10. Select the IP address of the local tunnel endpoint, 205.13.237.6.
11. In the Virtual line name field, select tobranch from the drop-down list. Remember that this line has no associated physical interface. The virtual line describes various characteristics of this PPP profile; for example, the maximum frame size, authentication information, the local host name, and so on. The L2TP Line Properties dialog box opens.
12. On the General page, enter a description for the virtual line.
13. Go to the Authentication page
14. In the Local host name field, enter the host name of the local key server, SystemB.
15. Click OK to save the new virtual line description and return to the Connection page.
16. Go to the TCP/IP Settings page.
17. In the Local IP address section, select the fixed IP address of the local system, 10.6.11.1.
18. In the Remote IP address section, select Address pool as the address assignment method. Enter a starting address, and then specify the number of addresses that can be assigned to the remote system.

19. Select Allow remote system to access other networks (IP forwarding).

20. Go to the Authentication page to set the user name and password for this PPP profile.

21. In the Local system identification section, select Allow the remote system to verify the identity of this system. This opens the Local System Identification dialog box.

22. Under Authentication protocol to use select Require encrypted password (CHAP-MD5).

23. Enter the user name, System-B, and a password.

24. Click OK to save the PPP profile.

Activating packet rules
The VPN wizard automatically creates the packet rules that this connection requires to work properly. However, you must activate them on both systems before you can start the VPN connection.

To activate packet rules on System-A, follow these steps:
1. In iSeries Navigator, expand System-A → Network → IP Policies.
2. Right-click Packet Rules and select Activate. This opens the Activate Packet Rules dialog box.
3. Select whether you want to activate only the VPN generated rules, only a selected file, or both the VPN generated rules and a selected file. You might choose the latter, for instance, if you have miscellaneous PERMIT and DENY rules that you want to enforce on the interface in addition to the VPN generated rules.
4. Select the interface on which you want the rules activated. In this case, select All interfaces.
5. Click OK on the dialog box to confirm that you want to verify and activate the rules on the interface or interfaces you specified. After you click OK, the system checks the rules for syntax and semantic errors and reports the results in a message window at the bottom of the editor. For error messages that are associated with a specific file and line number, you can right-click the error and select Go To Line to highlight the error in the file.
6. Repeat these steps to activate packet rules on System-B.

Scenario: Firewall Friendly VPN
In this scenario, a large insurance company wants to establish a VPN between a gateway in Chicago and a host in Minneapolis when both networks are behind a firewall.

Situation
Suppose you are a large home owner’s insurance company based in Minneapolis and you just opened a new branch in Chicago. Your Chicago branch needs to access the customer database from the Minneapolis headquarters. You want to make sure the information being transferred is secure because the database contains confidential information about your customers such as, names, addresses, and phone numbers. You decide to connect both branches over the internet using a Virtual Private Network (VPN). Both branches are behind a firewall and are using Network Address Translation (NAT) to hide their unregistered private IP addresses behind a set of registered IP addresses. However, VPN connections have some well known incompatibilities with NAT. A VPN connection discards packets sent through a NAT device because NAT changes the IP address in the packet, thereby invalidating the packet. However, you can still use a VPN connection with NAT if you implement UDP encapsulation.

In this scenario, the private IP address from the Chicago network is put in a new IP header and gets translated when it goes through Firewall-C (see following image). Then, when the packet reaches the Firewall-D, it will translate the destination IP address to the IP address of System-E, therefore the packet will be forwarded to System-E. Finally, when the packet reaches System-E it strips off the UDP header, leaving the original IPSec packet, which will now pass all validations and allow a secure VPN connection.
Objectives

In this scenario, a large insurance company wants to establish a VPN between a gateway in Chicago (Client) and a host in Minneapolis (Server) when both networks are behind a firewall.

The objectives of this scenario are as follows:
- The Chicago branch gateway always initiates the connection to the Minneapolis host.
- The VPN must protect all data traffic between the Chicago gateway and the Minneapolis host.
- Allow all users in the Chicago gateway to access an iSeries database located in the Minneapolis network over a VPN connection.

Details

The following figure illustrates the network characteristics for this scenario:

![Network Diagram]

Chicago Network - Client
- iSeries Gateway-B runs on i5/OS Version 5 Release 4 (V5R4)
- Gateway-B connects to the internet with IP address 214.72.189.35 and is the connection end point of the VPN tunnel. Gateway-B performs IKE negotiations and applies UDP encapsulation to outgoing IP datagrams.
- Gateway-B and PC-A is in subnet 10.8.11.0 with mask 255.255.255.0
- PC-A is the source and destination for data that flows through the VPN connection, therefore it is the data endpoint of the VPN tunnel.
- Only Gateway-B can initiate the connection with System-E.
- Firewall-C has a Masq NAT rule with the public IP address of 129.42.105.17 that hides the IP address of Gateway-B

Minneapolis Network - Server
- System-E runs on i5/OS Version 5 Release 4 (V5R4)
- System-E has an IP address of 56.172.1.1.
- System-E is the responder for this scenario.
- Firewall-D has and IP address of 146.210.18.51.
- Firewall-D has a Static NAT rule that maps the public IP (146.210.18.15) to the private IP of System-E (56.172.1.1). Therefore, from the clients perspective the IP address of System-E is the public IP address (146.210.18.51) of Firewall-D.

Configuration tasks
Related concepts

“Key management” on page 6

A dynamic VPN provides additional security for your communications by using the Internet Key Exchange (IKE) protocol for key management. IKE allows the VPN servers on each end of the connection to negotiate new keys at specified intervals.

“NAT compatible IPSec with UDP” on page 10

UDP encapsulation allows IPSec traffic to pass through a conventional NAT device. Review this topic for more information about what it is and why you should use it for your VPN connections.

Completing the planning worksheets

The following planning checklists illustrate the type of information you need before you begin configuring the VPN. All answers on the prerequisite checklist must be YES before you proceed with VPN setup.

Note: There are separate worksheets for both Gateway-B and System-E.

Table 5. System requirements

<table>

Configuring VPN on Gateway-B

Complete the following steps to configure a VPN connection on Gateway-B.

1. Use the information from your planning worksheets to configure VPN on Gateway-B as follows:
   1. In iSeries Navigator, expand your system ➔ Network ➔ IP Policies.
   2. Right-click Virtual Private Networking and select New Connection to start the Connection wizard.
   3. Review the Welcome page for information about what objects the wizard creates.
   4. Click Next to go to the Connection Name page.
   5. In the Name field, enter CHIgw2MINhost.
   6. Optional: Specify a description for this connection group.
   7. Click Next to go to the Connection Scenario page.
   8. Select Connect your gateway to another host.
   9. Click Next to go to the Internet Exchange Policy page.
   10. Select Create a new policy and then select Balance security and performance.

   Note: If you get an error message stating "The certificate request could not be processed" you can ignore it because you are not using certificates for the key exchange.

11. Optional: If you have certificates installed you will see the Certificate for Local Connection Endpoint page. Select No to indicate that you will be using certificates to authenticate the connection.
12. Click Next to go to the Local Key Server page.
13. Select IP version 4 as the Identifier type field.
14. Select 214.72.189.35 from the IP address field.
15. Click Next to go to the Remote Key Server page.
16. Select IP version 4 address in the Identifier type field.
17. Enter 146.210.18.51 in the Identifier field.

**Note:** Gateway B is initiating a connection to a Static NAT you must specify main mode key exchange in order to enter a single IP for the remote key. Main mode key exchange is selected by default when you create a connection with the VPN Connection Wizard. If aggressive mode is used in this situation, a non IPV4 type of remote identifier must be entered from remote key.

18. Enter topsecretstuff in the Pre-shared key field
19. Click Next to go to the Local Data Endpoint page.
20. Select IP version 4 subnet from the Identifier type field.
21. Enter 10.8.0.0 in the Identifier field.
22. Enter 255.255.255.0 in the Subnet mask field.
23. Click Next to go to the Data Services page.
24. Accept the default values, and then click Next to go to the Data Policy page.
25. Select Create a new policy and then select Balance security and performance.
26. Click Next to go to the Applicable Interfaces page.
27. Select TRLINE from the Line table.
28. Click Next to go to the Summary page.
29. Review the objects that the wizard will create to ensure they are correct.
30. Click Finish to complete the configuration.
31. When the Activate Policy Filters dialog box appears, select Yes, activate the generated policy filters then select Permit all other traffic.
32. Click OK to complete the configuration.

**Configuring VPN on System-E**
Complete the following steps to configure a VPN connection on System-E.

Use the information from your planning worksheets to configure VPN on System-E as follows:
1. In iSeries Navigator, expand your system + Network + IP Policies.
2. Right-click Virtual Private Networking and select New Connection to start the Connection wizard.
3. Review the Welcome page for information about what objects the wizard creates.
4. Click Next to go to the Connection Name page.
5. In the Name field, enter CH1gw2MINhost.
6. Optional: Specify a description for this connection group.
7. Click Next to go to the Connection Scenario page.
8. Select Connect your host to another gateway.
9. Click Next to go to the Internet Key Exchange Policy page.
10. Select Create a new policy and then select Balanced security and performance.

**Note:** If you get an error message stating “The certificate request could not be processed” you can ignore it because you are not using certificates for the key exchange.
11. Optional: If you have certificates installed you will see the **Certificate for Local Connection Endpoint** page. Select No to indicate that you will be using certificates to authenticate the connection.

12. Click **Next** to go to the **Local Key Server** page.

13. Select **IP version 4 address** as the **Identifier type** field.

14. Select 56.172.1.1 from the **IP address** field.

15. Click **Next** to go to the **Remote Key Server** page.

16. Select **IP version 4 address** in the **Identifier type** field.

17. Enter 129.42.105.17 in the **Identifier** field.

**Note:** If the Firewall-C IP address is unknown, you can use *ANYIP* as the identifier for the remote key server.

18. Enter *topsecretstuff* in the **Pre-shared key** field

19. Click **Next** to go to the **Remote Data Endpoint** page.

20. Select **IP version 4 subnet** from the **Identifier type** field.

21. Enter 10.8.11.0 in the **Identifier** field.

22. Enter 255.255.255.0 in the **Subnet mask** field.

23. Click **Next** to go to the **Data Services** page.

24. Accept the default values, and then click **Next** to go to the Data Policy page.

25. Select **Create a new policy** and then select **Balanced security and performance**.

26. Click **Next** to go to the **Applicable Interfaces** page.

27. Select **TRLINE** from the Line table.

28. Click **Next** to go to the **Summary** page.

29. Review the objects that the wizard will create to ensure they are correct.

30. Click **Finish** to complete the configuration.

31. When the **Activate Policy Filters** dialog box appears, select **Yes**, activate the generated policy filters then select **Permit all other traffic**.

32. Click **OK** to complete the configuration.

**Starting Connection**

After you have configured your VPN connection on System-E you need to start your VPN connection.

Follow these steps to confirm that CHIgw2MINhost connection on System-E is active:

1. In iSeries Navigator, expand **System-E → Network → Secure Connections → All Connections**.

2. View **CHIgw2MINhost** and verify that the **Status** field is **Idle** or **On-Demand**.

Follow these steps to start the CHIgw2MINhost connection from Gateway-B:

1. In iSeries Navigator, expand **Gateway-B → Network → IP Policies**.

2. If the VPN server is not started, right-click **Virtual Private Networking** and select **Start**.

3. Expand **Virtual Private Networking → Secure Connections**.

4. Click **All Connections** to display a list of connections in the right pane.

5. Right-click **CHIgw2MINhost** and select **Start**.

6. From the **View** menu, select **Refresh**. If the connection starts successfully, the **Status** field will change from **Starting** or **On-Demand** to **Enabled**. The connection may take a short time to start, so periodically refresh until the status changes to **Enabled**.

**Testing the connection**

After you finish configuring both Gateway-B and System-E and you have successfully started the VPN servers, test the connectivity to ensure that both systems can communicate with each other.
To test your connections, follow these steps:

1. Find a system on the PC-A network and open a Telnet session.
2. Specify the public IP address for System-E, which is 146.210.18.51.
3. Specify any login information if it is needed. If you can view the login screen then the connection is working.

**Scenario: Using network address translation for VPN**

In this scenario, your company wants to exchange sensitive data with one of its business partners by using VPN. To further protect the privacy of your company’s network structure, your company will also use VPN NAT to hide the private IP address of the system it uses to host the applications to which your business partner has access.

**Situation**

Suppose you are the network administrator for a small manufacturing company in Minneapolis. One of your business partners, a parts supplier in Chicago, wants to starting doing more of their business with your company over the Internet. It is critical that your company have the specific parts and quantities at the exact time it needs them, so the supplier needs to be aware of your company’s inventory status and production schedules. Currently you handle this interaction manually, but you find it time consuming, expensive and even inaccurate at times, so you are more than willing to investigate your options.

Given the confidentiality and time-sensitive nature of the information you exchange, you decide to create a VPN between your supplier’s network and your company’s network. To further protect the privacy of your company’s network structure, you decide you will need to hide the private IP address of the system that hosts the applications to which the supplier has access.

You can use VPN’s to not only create the connection definitions on the VPN gateway in your company’s network, but also to provide the address translation you need to hide your local private addresses. Unlike conventional network address translation (NAT), which changes the IP addresses in the security associations (SAs) that VPN requires to function, VPN NAT performs address translation before the SA validation by assigning an address to the connection when the connection starts.

**Objectives**

The objectives of this scenario are to:

- allow all clients in the supplier network to access a single host system in the manufacturer’s network over a gateway-to-gateway VPN connection.
- hide the private IP address of the host system in the manufacturer’s network, by translating it to a public IP address by using network address translation for VPN (VPN NAT).

**Details**

The following diagram illustrates the network characteristics of both the supplier network and the manufacturing network:
• VPN gateway-A is configured to always initiate connections to VPN gateway-B.
• VPN gateway-A defines the destination endpoint for the connection as 204.146.18.252 (the public address assigned to System-C).
• System-C has a private IP address in the manufacturer’s network of 10.6.100.1.
• A public address of 204.146.18.252 has been defined in the local service pool on VPN gateway-B for System-C’s private address, 10.6.100.1.
• VPN gateway-B translates System-C’s public address to its private address, 10.6.100.1, for inbound datagrams. VPN gateway-B translates returning, outbound, datagrams from 10.6.100.1 back to System-C’s public address, 204.146.18.252. As far as clients in the supplier network are concerned, System-C has an IP address of 204.146.18.252. They will never be aware that address translation has occurred.

Configuration tasks

You must complete each of the following tasks to configure the connection described in this scenario:
1. Configure a basic gateway-to-gateway VPN between VPN gateway-A and VPN gateway-B.
2. Define a local service pool on VPN gateway-B to hide System-C’s private address behind the public identifier, 204.146.18.252.
3. Configure VPN gateway-B to translate local addresses using local service pool addresses.

Related concepts

“Network address translation for VPN” on page 9
VPN provides a means for performing network address translation, called VPN NAT. VPN NAT differs from traditional NAT in that it translates addresses before applying the IKE and IPSec protocols. Refer to this topic to learn more.

Planning for VPN

The first step to successfully using VPN is planning. This topic provides information about migrating from prior releases, setup requirements, and links to a planning advisor that will generate a planning worksheet that is customized to your specifications.
Planning is an essential part of your total VPN solution. There are many complex decisions you need to make to ensure that your connection works properly. Use these resources to gather all the information that you need to ensure that your VPN is a success:

- **VPN setup requirements**
- **Determine what type of VPN to create**
- **Use the VPN planning advisor**

  The planning advisor asks you questions about your network and based on your answers, it provides you with suggestions for creating your VPN.

  **Note:** Use the VPN planning advisor only for connections that support the Internet Key Exchange (IKE) protocol. Use the planning worksheet for manual connections for your manual connection types.

- **Complete the VPN planning worksheets**

After you come up with a plan for your VPN, you can begin configuring it.

**Related tasks**

- Use the VPN planning advisor
- “Configuring VPN” on page 42

  After planning for your VPN, you can begin configuring it. This topic provides you with an overview of what you can do with VPN and how to do it.

**VPN setup requirements**

Use this information to ensure that you meet the minimum requirements for creating a VPN connection.

To function properly on iSeries and with network clients, ensure your system and client PC meet the following requirements:

**System requirements**

- OS/400 Version 5 Release 2 (5722-SS1) or later
- Digital Certificate Manager (5722-SS1 Option 34)
- iSeries Access for Windows (5722-XE1)
- iSeries Navigator
  - Network component of iSeries Navigator
- Set the retain server security data (QRETSVRSEC “SEC”) system value to 1
- TCP/IP must be configured, including IP interfaces, routes, local host name, and local domain name

**Client requirements**

- A workstation with a Windows 32-bit operating system properly connected to your system, and configured for TCP/IP
- A 233 Mhz processing unit
- 32 MB RAM for Windows 95 clients
- 64 MB RAM for Windows NT® 4.0 and Windows 2000 clients
- iSeries Access for Windows and iSeries Navigator installed on the client PC
- Software that supports the IP Security (IPSec) protocol
- Software that supports L2TP, if remote users will use L2TP to establish a connection with your system

**Related tasks**

  View this information to begin finding and correcting your VPN connection problems.
Determining what type of VPN to create

This information can help you decide on various connection types you can setup.

Determining how you will use your VPN is one of the first steps in successful planning. To do this, you need to understand the role that both the local key server and the remote key server play in the connection. For example, are the connection endpoints different from the data endpoints. Are they the same or some combination of both? Connection endpoints authenticate and encrypt (or decrypt) data traffic for the connection, and optionally provide key management with the Internet Key Exchange (IKE) protocol. Data endpoints, however, define the connection between two systems for IP traffic that flows across the VPN; for example, all TCP/IP traffic between 123.4.5.6 and 123.7.8.9. Typically, when the connection and data endpoints are different, the VPN server is a gateway. When they are the same, the VPN server is a host.

Various types of VPN implementations that are well suited to most business needs follow:

Gateway-to-gateway
The connection endpoints of both systems are different from the data endpoints. The IP Security (IPSec) protocol protects traffic as it travels between the gateways. However, IPSec does not protect data traffic on either side of the gateways within the internal networks. This is a common setup for connections between branch offices because traffic that is routed beyond the branch office gateways, into the internal networks, is often considered trusted.

Gateway-to-host
IPSec protects data traffic as it travels between your gateway and a host in a remote network. VPN does not protect data traffic in the local network because you consider it trusted.

Host-to-gateway
VPN protects data traffic as it travels between a host in the local network and a remote gateway. VPN does not protect data traffic in the remote network.

Host-to-host
The connection endpoints are the same as the data endpoints on both the local and the remote systems. VPN protects data traffic as it travels between a host in the local network and a host in the remote network. This type of VPN provides end-to-end IPSec protection.

Completing VPN planning worksheets
Use the VPN planning worksheets to gather detailed information about your VPN usage plans. You need this information to adequately plan your VPN strategy. You can also use this information to configure your VPN.

If you prefer, you can print and complete the planning worksheets to gather detailed information about your VPN usage plans.

Choose the worksheet for the type of connection you want to create.
• Planning worksheet for dynamic connections
• Planning worksheet for manual connections
• VPN planning advisor
  Or, if you prefer, use the advisor for interactive planning and configuration guidance. The planning advisor asks you questions about your network and based on your answers, it provides you with suggestions for creating your VPN.

Note: Use the VPN planning advisor only for your dynamic connections. Use the planning worksheet for manual connections for your manual connection types.
If you will create multiple connections with similar properties, you may want to set the VPN defaults. The default values you configure seed the VPN property sheets. This means that you are not required to configure the same properties multiple times. To set the VPN defaults, select Edit from the VPN main menu, and then select **Defaults**.

### Planning worksheet for dynamic connections

Complete this worksheet before you configure a dynamic connection.

Before you create your dynamic VPN connections, complete this worksheet. The worksheet assumes you will use the New Connection Wizard. The wizard allows you to set up a VPN based on your basic security requirements. In some cases, you may need to refine the properties that the wizard configures for a connection. For example, you may decide that you require journaling or that you want the VPN server to start each time TCP/IP starts. If this is the case, right-click the dynamic-key group or connection that the wizard created and select **Properties**.

Answer each question before you proceed with your VPN setup.

Configuring VPN

After planning for your VPN, you can begin configuring it. This topic provides you with an overview of what you can do with VPN and how to do it.

The VPN interface provides you with several different ways to configure your VPN connections. Keep reading to help you decide which type of connection to configure and how to do it.

Related concepts

“Planning for VPN” on page 36

The first step to successfully using VPN is planning. This topic provides information about migrating from prior releases, setup requirements, and links to a planning advisor that will generate a planning worksheet that is customized to your specifications.

What type of connection should I configure?

A **dynamic** connection is one that dynamically generates and negotiates the keys that secure your connection, while it is active, by using the Internet Key Exchange (IKE) protocol. Dynamic connections provide an extra level of security for the data that flows across it because the keys change, automatically, at regular intervals. Consequently, an attacker is less likely to capture a key, have time to break it, and use it to divert or capture the traffic the key protects.

A **manual** connection, however, does not provide support for IKE negotiations, and consequently, automatic key management. Further, both ends of the connection require you to configure several attributes that must match exactly. Manual connections use static keys that do not refresh or change while the connection is active. You must stop a manual connection to change its associated key. If you consider this a security risk, you may want to create a dynamic connection instead.

How do I configure a dynamic VPN connection?

VPN is actually a group of configuration objects that define the characteristics of a connection. A dynamic VPN connection requires each of these objects to work properly. Follow the links below for specific information about how to configure each of the VPN configuration objects:

**Tip:** Configure connections with the New Connection wizard

In general, you can use the Connection wizard to create all of your dynamic connections. The wizard automatically creates each of the configuration objects VPN requires to work properly, including the packet rules. If you specify that you want the wizard to activate the VPN packet rules for you, you can skip to step six below, Start the connection. Otherwise, after the wizard finishes configuring your VPN, you must activate the packet rules and then you can start the connection.

If you choose not to use the wizard to configure your dynamic VPN connections, follow these steps to complete the configuration:

1. Configure VPN security policies
   You must define VPN security policies for all of your dynamic connections. The Internet Key Exchange policy and data policy dictate how IKE protects its phase 1 and phase 2 negotiations.
2. Configure secure connections
   Once you have defined the security policies for a connection, you must then configure the secure connection. For dynamic connections, the secure connection object includes a dynamic-key group and a dynamic-key connection. The **dynamic-key group** defines the common characteristics of one or more VPN connections, while the **dynamic-key connection** defines the characteristics of individual data connections between pairs of endpoints. The dynamic-key connection exists within the dynamic-key group.
Note: You only need to complete the next two steps, Configure packet rules and Define an interface for the rules, if you select The policy filter rule will be defined in Packet Rules option on the Dynamic-Key Group - Connections page in the VPN interface. Otherwise, these rules are created as part of your VPN configurations and are applied to the interface you specify.

It is recommended that you always allow the VPN interface to create your policy filter rules for you. Do this by selecting the Generate the following policy filter for this group option on the Dynamic-Key Group - Connections page.

3. Configure packet rules
After you complete your VPN configurations, you must create and apply filter rules that allow data traffic to flow through the connection. The VPN pre-IPSec rules permit all IKE traffic on the specified interfaces so that IKE can negotiate connections. The policy filter rule defines which addresses, protocols, and ports can use the associated new dynamic-key group.

If you are migrating from either V4R4 or V4R5 and have VPN connections and policy filters you want to continue using with the current release, review the topic, Migrate policy filters to the current release to ensure that your old policy filters and new policy filters will work together as you intend.

4. Define an interface for the rules
After you configure the packet rules and any other rules that you need to enable your VPN connection, you must define an interface to which to apply them.

5. Activate packet rules
After you define an interface for your packet rules, you must activate them before you can start the connection.

6. Start the connection
Complete this task to start your connections.

How do I configure a manual VPN connection?
Just as the name suggests, a manual connection is one where you must configure all of your VPN properties by hand, including inbound and outbound keys. Follow the links below for specific information about how to configure a manual connection:

1. Configure manual connections
   Manual connections define the characteristics of a connection including what security protocols and the connection and data endpoints.

   Note: You only need to complete the next two steps, Configure policy filter rule and Define an interface for the rules, if you select The policy filter rule will be defined in Packet Rules option on the Manual Connection - Connection page in the VPN interface. Otherwise, these rules are created as part of your VPN configurations.

   It is recommended that you always allow the VPN interface to create your policy filter rules for you. Do this by selecting the Generate a policy filter that matches the data endpoints option on the Manual Connection - Connection page.

2. Configure policy filter rule
   After you configure the attributes of the manual connection, you must create and apply a policy filter rule that allows data traffic to flow through the connection. The policy filter rule defines which addresses, protocols, and ports can use the associated connection.

3. Define an interface for the rules
   After you configure the packet rules and any other rules that you need to enable your VPN connection, you must define an interface to which to apply them.

4. Activate packet rules
   After you define an interface for your packet rules, you must activate them before you can start the connection.

5. Start the connection
Complete this task to start connections that are initiated locally.

**Configuring VPN connections with the New Connection wizard**

The New Connection wizard allows you to create a virtual private network (VPN) between any combination of hosts and gateways.

For example, host-to-host, gateway-to-host, host-to-gateway, or gateway-to-gateway.

The wizard automatically creates each of the configuration objects VPN requires to work properly, including the packet rules. However, if you need to add function to your VPN; for example, journaling or network address translation for VPN (VPN NAT), you may want further refine your VPN through the property sheets of the appropriate dynamic-key group or connection. To do this, you must first stop the connection if it is active. Then, right-click the dynamic-key group or connection, and select **Properties**.

Complete the VPN planning advisor before you begin. The advisor provides you with a means for gathering important information that you will need to create your VPN.

To create a VPN with the Connection wizard, follow these steps:

1. In iSeries Navigator, expand your **system → Network → IP Policies**.
2. Right-click **Virtual Private Networking** and select **New Connection** to start the wizard.
3. Complete the wizard to create a basic VPN connection. Click **Help** if you need assistance.

**Related tasks**

**VPN planning advisor**

**Configuring VPN security policies**

After you determine how you will use your VPN you must define your VPN security policies.

**Note:** After you configure your VPN security policies, you must then configure the secure connections.

**Related tasks**

“Configuring a secure VPN connection” on page 46

After you have configured the security policies for your connection, you must then configure the secure connection.

**Configuring an Internet Key Exchange (IKE) policy**

The IKE policy defines what level of authentication and encryption protection IKE uses during phase 1 negotiations.

IKE phase 1 establishes the keys that protect the messages that flow in the subsequent phase 2 negotiations. You do not need to define an IKE policy when you create a manual connection. In addition, if you create your VPN with the New Connection wizard, the wizard can create your IKE policy for you.

VPN uses either RSA signature mode or preshared keys to authenticate phase 1 negotiations. If you plan to use digital certificates for authenticating the key servers, you must first configure them by using the Digital Certificate Manager (5722-SS1 Option 34). The IKE policy also identifies which remote key server will use this policy.

To define an IKE policy or make changes to an existing one, follow these steps:

1. In iSeries Navigator, expand your **system → Network → IP Policies → Virtual Private Networking → IP Security Policies**.
2. To create a new policy, right-click **Internet Key Exchange Policies** and select **New Internet Key Exchange Policy**. To make changes to an existing policy, click **Internet Key Exchange Policies** in the left pane then right-click the policy you want to change in the right pane, and select **Properties**.
3. Complete each of the property sheets. Click Help if you have questions about how complete a page or any of its fields.

4. Click OK to save your changes.

It is recommended that you use main mode negotiation whenever a preshared key is used for authentication. They provide a more secure exchange. If you must use preshared keys and aggressive mode negotiation, select obscure passwords that are unlikely to be cracked in attacks that scan the dictionary. It is also recommended you periodically change your passwords. To force a key exchange to use main mode negotiation, perform the following tasks:

1. In iSeries Navigator, expand your system → Network → IP Policies.

2. Select Virtual Private Networking → IP Security Policies → Internet Key Exchange Policies to view the currently defined key exchange policies within the right-hand pane.

3. Right-click a particular key exchange policy and select Properties.

5. In the Identity protection field, deselect IKE aggressive mode negotiation (no identity protection).

6. Click OK to return to the Properties dialog.

7. Click OK again to save your changes.

Note: When you set the identity protection field, the change is effective for all exchanges with remote key servers, because there is only one responding IKE policy for the entire system. Main mode negotiation ensures that the initiating system can only request a main mode key policy exchange.

Related concepts

“Key management” on page 6

A dynamic VPN provides additional security for your communications by using the Internet Key Exchange (IKE) protocol for key management. IKE allows the VPN servers on each end of the connection to negotiate new keys at specified intervals.

Related tasks

Digital Certificate Manager

Configuring a data policy

A data policy defines what level of authentication or encryption protects data as it flows through the VPN.

The communicating systems agree on these attributes during the Internet Key Exchange (IKE) protocol phase 2 negotiations. You do not need to define a data policy when you create a manual connection. In addition, if you create your VPN with the New Connection wizard, the wizard can create a data policy for you.

To define a data policy or make changes to an existing one, follow these steps:

2. To create a new data policy, right-click Data Policies and select New Data Policy. To make changes to an existing data policy, click Data Policies (in the left pane) then right-click the data policy you want to change (in the right pane) and select Properties.

3. Complete each of the property sheets. Click Help if you have questions about how complete a page or any of its fields.

4. Click OK to save your changes.

Related concepts

“Key management” on page 6

A dynamic VPN provides additional security for your communications by using the Internet Key
Exchange (IKE) protocol for key management. IKE allows the VPN servers on each end of the connection to negotiate new keys at specified intervals.

Configuring a secure VPN connection

After you have configured the security policies for your connection, you must then configure the secure connection.

For dynamic connections, the secure connection object includes a dynamic-key group and a dynamic-key connection.

The **dynamic-key group** defines the common characteristics of one or more VPN connections. Configuring a dynamic-key group allows you to use the same policies, but different data endpoints for each connection within the group. Dynamic-key groups also allow you to successfully negotiate with remote initiators when the data endpoints proposed by the remote system are not specifically known ahead of time. It does this by associating the policy information in the dynamic-key group with a policy filter rule with an IPSEC action type. If the specific data endpoints offered by the remote initiator fall within the range specified in the IPSEC filter rule, they can be subjected to the policy defined in the dynamic-key group.

The **dynamic-key connection** defines the characteristics of individual data connections between pairs of endpoints. The dynamic-key connection exists within the dynamic-key group. After you configure a dynamic-key group to describe what policies connections in the group use, you need to create individual dynamic-key connections for connections that you initiate locally.

To configure the secure connection object, complete both the Part 1 and Part 2 tasks:

**Related concepts**

“Configuring VPN security policies” on page 44

After you determine how you will use your VPN you must define your VPN security policies.

“Configuring VPN packet rules” on page 47

If you are creating a connection for the first time, allow VPN to automatically generate the VPN packet rules for you. You can do this by either using the New Connection wizard or the VPN properties pages to configure your connection.

**Related tasks**

“Activating VPN packet rules” on page 51

You must activate the VPN packet rules before you can start your VPN connections.

**Part 1: Configure a dynamic-key group**

1. In iSeries Navigator, expand your **system → Network → IP Policies → Virtual Private Networking → Secure Connections**.
2. Right-click **By Group** and select **New Dynamic-Key Group**.
3. Click **Help** if you have questions about how complete a page or any of its fields.
4. Click **OK** to save your changes.

**Part 2: Configure a dynamic-key connection**

1. In iSeries Navigator, expand your **system → Network → IP Policies → Virtual Private Networking → Secure Connections → By Group**.
2. In the left-pane of the iSeries Navigator window, right-click the dynamic-key group you created in part one and select **New Dynamic-Key Connection**.
3. Click **Help** if you have questions about how complete a page or any of its fields.
4. Click **OK** to save your changes.

After you complete these steps, you need to activate the packet rules that the connection requires to work properly.
Note: In most cases, allow the VPN interface to generate your VPN packet rules automatically by selecting the **Generate the following policy filter for this group** option on the **Dynamic-Key Group - Connections** page. However, if you select the **The policy filter rule will be defined in Packet Rules** option, you must then configure VPN packet rules by using the Packet Rules editor and then activate them.

**Configuring a manual connection**

A manual connection is one where you must configure all of your VPN properties with out using any wizards.

Further, both ends of the connection require you to configure several elements that must match *exactly*. For example, your inbound keys must match the remote system’s outbound keys or the connection will fail.

Manual connections use static keys that are not refreshed or changed while the connection is active. You must stop a manual connection in order to change its associated key. If you consider this a security risk, and both ends of the connection support the Internet Key Exchange (IKE) protocol, you may want to consider setting up a dynamic connection instead.

To define the properties for your manual connection, follow these steps:

1. In iSeries Navigator, expand your **system → Network → IP Policies → Virtual Private Networking → Secure Connections**.
2. Right-click **All Connections** and select **New Manual Connection**.
3. Complete each of the property sheets. Click **Help** if you have questions about how complete a page or any of its fields.
4. Click **OK** to save your changes.

Note: In most cases, allow the VPN interface to generate your VPN packet rules automatically by selecting the **Generate a policy filter that matches the data endpoints** option on the **Manual Connection - Connection** page. However, if you select the **The policy filter rule will be defined in Packet Rules** option, you must then configure a policy filter rule by hand and then activate them.

**Related tasks**

"Configuring a policy filter rule" on page 49

Use this information to learn how to edit your policy filter rules.

**Configuring VPN packet rules**

If you are creating a connection for the first time, allow VPN to automatically generate the VPN packet rules for you. You can do this by either using the New Connection wizard or the VPN properties pages to configure your connection.

If you decide to create your VPN packet rules by using the Packet Rules editor in iSeries Navigator, create any additional rules this way as well. Conversely, if you have VPN generate your policy filter rules, create all additional policy filter rules this way.

In general, VPns require two types of filter rules: Pre-IPSec filter rules and policy filter rules. Review the topics below to learn how to configure these rules by using the Packet Rules editor in iSeries Navigator. If you want to read about other VPN and filtering options, see the VPN and IP filtering section of the VPN concepts topic.

- Configuring the pre-IPSec filter rule
  - The pre-IPSec rules are any rules on your system that come before rules with an IPSEC action type. This topic only discusses the pre-IPSec rules that VPN requires to work properly. In this case, the pre-IPSec rules are a pair of rules that allow IKE processing over the connection. IKE allows dynamic
key generation and negotiations to occur for your connection. You may need to add other pre-IPSec rules depending on your particular network environment and security policy.

**Note:** You only need to configure this type of pre-IPSec rule if you already have other rules that permit IKE for specific systems. If there are no filter rules on the system specifically written to permit IKE traffic, then IKE traffic is implicitly allowed.

- Configure a policy filter rule
  The policy filter rule defines the traffic that can use the VPN and what data protection policy to apply to that traffic.

### Things to consider before you begin

When you add filter rules to an interface, the system automatically adds a default DENY rule for that interface. This means that any traffic not explicitly permitted is denied. You cannot see or change this rule. As a result, you may find that traffic that previously worked mysteriously fails after you activate your VPN filter rules. If you want to allow traffic other than VPN on the interface, you must add explicit PERMIT rules to do so.

After you configure the appropriate filter rules, you must define the interface to which they apply, and then activate them.

It is essential that you configure your filter rules properly. If you do not, the filter rules can block all IP traffic coming into and going out of your system. This includes your connection to iSeries Navigator, which you use to configure the filter rules.

If the filter rules do not permit iSeries Navigator traffic, iSeries Navigator cannot communicate with your system. If you find yourself in this situation, you must log on to your system using an interface that still has connectivity, such as the operations console. Use the RMVTCPBL command to remove all filters on this system. This command also ends the *VPN servers and then restarts them. Then, configure your filters and reactivate them.

#### Related concepts

“VPN and IP filtering” on page 11
IP filtering and VPN are closely related. In fact, most VPN connections require filter rules to work properly. This topic provides you information about what filters VPN requires, as well as other filtering concepts related to VPN.

#### Related tasks

“Configuring a secure VPN connection” on page 46
After you have configured the security policies for your connection, you must then configure the secure connection.

### Configuring the pre-IPSec filter rule

This information can help you create filter rules for inbound and outbound traffic.

**Attention:** Complete this task only if you have specified that you do not want VPN to generate your policy filter rule automatically.

A pair of Internet Key Exchange (IKE) servers dynamically negotiate and refresh keys. IKE uses the well-known port, 500. For IKE to work properly, you need to allow UDP datagrams over port 500 for this IP traffic. To do this, you will create a pair of filter rules; one for inbound traffic and one for outbound traffic, so that your connection can dynamically negotiate keys to protect the connection:

1. In iSeries Navigator, expand your **system → Network → IP Policies**.
2. Right-click **Packet Rules** and select **Rules Editor**. This opens the Packet Rules editor, which allows you to create or edit filter and NAT rules for your system.
3. On the Welcome window, select **Create a new packet rules file** and click **OK**.
4. From the Packet Rules editor select Insert → Filter.

5. On the General page, specify a set name for your VPN filter rules. It is recommended that you create at least three different sets: one for your pre-IPSec filter rules, one for your policy filter rules, and one for miscellaneous PERMIT and DENY filter rules. Name the set that contains your pre-IPSec filter rules with a prefix of preipsec. For example, preipsec filters.

6. In the Action field, select PERMIT from the drop-down list.

7. In the Direction field, select OUTBOUND from the drop-down list.

8. In the Source address name field, select = from the first drop-down list and then enter the IP address of the local key server in the second field. You specified the IP address of the local key server in the IKE policy.

9. In the Destination address name field, select = from the first drop-down list and then enter the IP address of the remote key server in the second field. You also specified the IP address of the remote key server in the IKE policy.

10. On the Services page, select Service. This enables the Protocol, Source port, and Destination port fields.

11. In the Protocol field, select UDP from the drop-down list.

12. For Source port, select = in the first field, then enter 500 in the second field.

13. Repeat the previous step for Destination port.

14. Click OK.

15. Repeat these steps to configure the INBOUND filter. Use the same set name and reverse addresses as necessary.

Note: A less secure, but easier option for permitting IKE traffic through the connection, is to configure only one pre-IPSec filter, and use wildcard values (*) in the Direction, Source address name, and Destination address name fields.

The next step is to configure a policy filter rule to define what IP traffic the VPN connection protects.

Related tasks

Configuring a policy filter rule

Use this information to learn how to edit your policy filter rules.

Configuring a policy filter rule

Use this information to learn how to edit your policy filter rules.

Attention: Complete this task only if you have specified that you do not want VPN to generate your policy filter rule automatically.

The policy filter rule (a rule where action=IPSEC) defines which addresses, protocols, and ports can use the VPN. It also identifies the policy that will be applied to traffic in the VPN connection. To configure a policy filter rule, follow these steps:

Note: If you just configured the pre-IPSec rule (for dynamic connections, only) the Packet Rules editor will still be open; go to step 4.

1. In iSeries Navigator, expand your system → Network → IP Policies.

2. Right-click Packet Rules and select Rules Editor. This opens the Packet Rules editor, which allows you to create or edit filter and NAT rules for your system.

3. On the Welcome window, select Create a new packet rules file and click OK.

4. From the Packet Rules editor select Insert → Filter.

5. On the General page, specify a set name for your VPN filter rules. It is recommended that you create at least three different sets: one for your pre-IPSec filter rules, one for your policy filter rules, and one for miscellaneous PERMIT and DENY filter rules. For example, policy filters.
6. In the **Action** field, select **IPSEC** from the drop-down list. The **Direction** field defaults to OUTBOUND and you cannot change it. Although this field defaults to OUTBOUND, it is actually bi-directional. OUTBOUND displays to clarify the semantics of the input values. For example, source values are local values, and destination values are remote values.

7. For **Source address name**, select = in the first field, and then enter the IP address of the local data endpoint in the second field. You can also specify a range of IP addresses or an IP address plus a subnet mask after you define them by using the **Define Addresses** function.

8. For **Destination address name**, select = in the first field, and then enter the IP address of the remote data endpoint in the second field. You can also specify a range of IP addresses or an IP address plus a subnet mask after you define them by using the **Define Addresses** function.

9. In the **Journaling** field, specify what level of journaling you require.

10. In the **Connection name** field, select the connection definition to which these filter rules apply.

11. (optional) Enter a description.

12. On the **Services** page, select **Service**. This enables the **Protocol**, **Source port**, and **Destination port** fields.

13. In the **Protocol** field, **Source port**, and **Destination port** fields, select the appropriate value for the traffic. Or, you can select the asterisk (*) from the drop-down list. This allows any protocol using any port to use the VPN.

14. Click **OK**.

The next step is to define the interface to which these filter rules apply.

**Note:** When you add filter rules for an interface, the system automatically adds a default DENY rule for that interface. This means that any traffic not explicitly permitted is denied. You cannot see or change this rule. As a result, you may find that connections that previously worked mysteriously fail after you activate your VPN packet rules. If you want to allow traffic other than VPN on the interface, you must add explicit PERMIT rules to do so.

- “Configuring the pre-IPSec filter rule” on page 48
  This information can help you create filter rules for inbound and outbound traffic.

- “Defining an interface for the VPN filter rules”
  After you configure your VPN packet rules and any other rules that you need to enable your VPN connection, you must define the interface to which to they apply.

**Defining an interface for the VPN filter rules**

After you configure your VPN packet rules and any other rules that you need to enable your VPN connection, you must define the interface to which to they apply.

To define an interface to which to apply your VPN filter rules, follow these steps:

**Note:** If you just configured the VPN packet rules, the Packet Rules interface will still be open; go to step four.

1. In iSeries Navigator, expand your **system** → **Network** → **IP Policies**.

2. Right-click **Packet Rules** and select **Rules Editor**. This opens the Packet Rules editor, which allows you to create or edit filter and NAT rules for your system.

3. On the Welcome window, select **Create a new packet rules file** and click **OK**.

4. From the Packet Rules editor select **Insert** → **Filter Interface**.

5. On the **General** page, select **Line name**, and then select the line description to which your VPN packet rules apply from the drop-down list.
6. (optional) Enter a description.
7. On the Filter Sets page, click Add to add each set name for the filters you just configured.
8. Click OK.
9. Save your rules file. The file is saved into the integrated file system on your system with an extension of .i3p.

Note: Do not save your file into the following directory:
/QIBM/UserData/OS400/TCPIP/RULEGEN
This directory is for system use only. If you ever need to use the RMVTCPTBL "ALL command to deactivate packet rules, the command will delete all files within this directory.

After you define an interface for your filter rules, you must activate them before you can start the VPN.

Related tasks
“Configuring a policy filter rule” on page 49
Use this information to learn how to edit your policy filter rules.
“Activating VPN packet rules”
You must activate the VPN packet rules before you can start your VPN connections.

Activating VPN packet rules
You must activate the VPN packet rules before you can start your VPN connections.

You cannot activate (or deactivate) packet rules when you have VPN connections running on your system. So, before you activate your VPN filter rules, ensure that there are no active connections associated with them.

If you created your VPN connections with the New Connection wizard, you can choose to have the associated rules activated, automatically, for you. Be aware that, if there are other packet rules active on any of the interfaces you specify, the VPN policy filter rules will replace them.

If you choose to activate your VPN generated rules by using the Packet Rules Editor, follow these steps:
1. In iSeries Navigator, expand your system → Network → IP Policies.
2. Right-click Packet Rules and select Activate. This opens the Activate Packet Rules dialog box.
3. Select whether you want to activate only the VPN generated rules, only a selected file, or both the VPN generated rules and a selected file. You might choose the latter, for instance, if you have miscellaneous PERMIT and DENY rules that you want to enforce on the interface in addition to the VPN generated rules.
4. Select the interface on which you want the rules activated. You can choose to activate on a specific interface, on a point-to-point identifier, or on all interfaces and all point-to-point identifiers.
5. Click OK on the dialog box to confirm that you want to verify and activate the rules on the interface or interfaces you specified. After you click OK, the system checks the rules for syntax and semantic errors and reports the results in a message window at the bottom of the editor. For error messages that are associated with a specific file and line number, you can right-click the error and select Go To Line to highlight the error in the file.

After you activate your filter rules, you can start your VPN connection.

Related tasks
“Configuring a secure VPN connection” on page 46
After you have configured the security policies for your connection, you must then configure the secure connection.

After you configure your VPN packet rules and any other rules that you need to enable your VPN connection, you must define the interface to which they apply.
Configure Traffic Flow Confidentiality (TFC)

If your data policy is configured for Tunnel mode you can use Traffic Flow Confidentiality (TFC) to conceal the actual length of the data packets transferred over a VPN connection.

TFC adds extra padding to the packets being sent and sends dummy packets with different lengths at random intervals to conceal the actual length of the packets. Use TFC for extra security against attackers who might guess the type of data being sent from the length of the packet. When you enable TFC you gain more security, but at the cost of system performance. Therefore, you should test your systems performance before and after you enable TFC on a VPN connection. TFC is not negotiated by IKE, and user should only enable TFC when both systems support it.

To enable TFC on a VPN connection follow these steps:

1. In iSeries Navigator, expand your server > Network > IP Policies > Virtual Private Networking > Secure Connections > All Connections.
2. Right-click the connection you want to enable TFC and select Properties.

Configuring Extended Sequence Number (ESN)

You can use Extended Sequence Number (ESN) to increase the data transfer rate for a VPN connection.

If you use the AH protocol or the ESP protocol and AES as the encryption algorithm you might want to enable ESN. ESN allows you to transmit large volumes of data at a high speed without re-keying. The VPN connection uses a 64-bit sequence numbers instead of 32-bit numbers over IPSec. Using 64-bit sequence numbers allows more time before re-keying, which prevents sequence number exhaustion and minimizes the use of system resources.

To enable ESN on a VPN connection follow these steps:

1. In iSeries Navigator, expand your system > Network > IP Policies > Virtual Private Networking
2. Right-click on Virtual Private Networking and select Properties.
3. On the General tab select Use Extended Sequence Number (ESN).

Starting a VPN connection

Complete this task to start connections you will initiate locally.

These instructions assume you have properly configured your VPN connection. Follow these steps to start your VPN connection:

1. In iSeries Navigator, expand your system > Network > IP Policies.
2. If the VPN server is not started, right-click Virtual Private Networking and select Start.
3. Ensure your packet rules are activated.
5. Click All Connections to display a list of connections in the right pane.
6. Right-click the connection you want to start and select Start. To start multiple connections, select each connection you want to start, right-click and select Start.

Related tasks

Managing VPN

Describes various tasks you can perform to manage your active VPN connections, including how to make changes to, monitor, or delete them.

Use the VPN interface in iSeries Navigator to handle all of your management tasks, including:

Setting default attributes for your connections

The default values seed the panels that you use to create new policies and connections. You can set defaults for security levels, key session management, key lifetimes, and connection lifetimes.

The default security values seed various fields when you initially create new VPN objects.

To set default security values for your VPN connections, follow these steps:
1. In iSeries Navigator, expand your system → Network → IP Policies.
2. Right-click Virtual Private Networking and select Defaults.
3. Click Help if you have questions about how complete a page or any of its fields.
4. Click OK after you have completed each of the property sheets.

Resetting connections in error state

Resetting connections in error returns them to the idle state.

To refresh a connection that is in the error state, follow these steps:
1. In iSeries Navigator, expand your system → Network → IP Policies → Virtual Private Networking → Secure Connections
2. Click All Connections to display a list of connections in the right pane.
3. Right-click the connection you want to reset and select Reset. This resets the connection to the idle state. To reset multiple connections that are in the error state, select each connection you want to reset, right-click and select Reset.

Viewing error information

Complete this task to help you determine why your connection is in error.

To view information about connections in error, follow these steps:
1. In iSeries Navigator, expand your system → Network → IP Policies → Virtual Private Networking → Secure Connections
2. Click All Connections to display a list of connections in the right pane.
3. Right-click the connection in error that you want to view and select Error Information.

Related tasks

“Getting started with VPN troubleshooting” on page 55
View this information to begin finding and correcting your VPN connection problems.

Viewing attributes of active connections

Complete this task to check the status and other attributes of your active connections.

To view the current attributes of an active or on-demand connection, follow these steps:
1. In iSeries Navigator, expand your system → Network → IP Policies → Virtual Private Networking → Secure Connections
2. Click All Connections to display a list of connections in the right pane.
3. Right-click the active or on-demand connection that you want to view and select Properties.
4. Go to the **Current Attributes** page to view the attributes of the connection.

You can also view the attributes of all connections from the iSeries Navigator window. By default, the only attributes that display are Status, Description, and Connection Type. You can change what data displays by following these steps:

1. In iSeries Navigator, expand your **system** → **Network** → **IP Policies** → **Virtual Private Networking** → **Secure Connections**
2. Click **All Connections** to display a list of connections in the right pane.
3. From the **Objects** menu, select **Columns**. This opens a dialog box which allows you to select which attributes you want to display in the iSeries Navigator window.

Be aware that when you change the columns to view, the changes are not specific to a particular user or PC, but rather, are system-wide.

**Related concepts**

"Common VPN Connection Manager error messages" on page 67

Describes some of the more common VPN Connection Manager error messages you may encounter.

**Viewing the VPN server trace**

Allows you to configure, start, stop, and view the VPN Connection Manager and VPN Key Manager server traces. This is similar to using the TRCTCPAPP *VPN command from the character-based interface except that you can view the trace while a connection is active.

To view the VPN server trace, follow these steps:

1. In iSeries Navigator, expand your **system** → **Network** → **IP Policies**.
2. Right-click **Virtual Private Networking**, select **Diagnostic Tools**, and then **Server Trace**.

To specify what type of trace you want the VPN Key Manager and the VPN Connection Manager to generate, follow these steps:

1. From the **Virtual Private Networking Trace** window, click **(Options)**.
2. On the **Connection Manager** page, specify what type of trace you want the Connection Manager server to run.
3. On the **Key Manager** page, specify what type of trace you want the Key Manager server to run.
4. Click **Help** if you have questions about how complete a page or any of its fields.
5. Click **OK** to save your changes.
6. Click **(Start)** to start the trace. Click **(Refresh)** periodically to view the latest trace information.

**Viewing VPN server job logs**

Follow these instructions to view the job logs for the VPN Key Manager and the VPN Connection Manager.

To view the current job logs of either the VPN Key Manager or the VPN Connection Manager, follow these steps:

1. In iSeries Navigator, expand your **system** → **Network** → **IP Policies**.
2. Right-click **Virtual Private Networking** and select **Diagnostic Tools** and then select whichever server job log you want to view.
**Viewing attributes of Security Associations (SA)**

Complete this task to display the attributes of the Security Associations (SAs) that are associated with an enabled connection.

To view the attributes of the security associations (SAs) that are associated with an enabled connection. To do so, follow these steps:

1. In iSeries Navigator, expand your system → Network → IP Policies → Virtual Private Networking → Secure Connections
2. Click All Connections to display a list of connections in the right pane.
3. Right-click the appropriate active connection and select Security Associations. The resulting window allows you to view the properties of each of the SAs associated with a specific connection.

**Stopping a VPN connection**

Complete this task to stop active connections.

To stop an active or on-demand connection, follow these steps:

1. In iSeries Navigator, expand your system → Network → IP Policies → Virtual Private Networking → Secure Connections
2. Click All Connections to display a list of connections in the right pane.
3. Right-click the connection you want to stop and select Stop. To stop multiple connections, select each connection you want to stop, right-click and select Stop.

**Deleting VPN configuration objects**

Before you delete a VPN configuration object from the VPN policy database, make sure you understand how it affects other VPN connections and connection groups.

If you are certain you need to delete a VPN connection from the VPN policy database, perform the following steps:

1. In iSeries Navigator, expand your system → Network → IP Policies → Virtual Private Networking → Secure Connections
2. Click All Connections to display a list of connections in the right pane.
3. Right-click the connection you want to delete and select Delete.

**Troubleshooting VPN**

Refer to this topic when you experience problems with your VPN connections.

VPN is a complex and rapidly changing technology that requires at least a basic knowledge of standard IPSec technologies. You must also be familiar with IP packet rules because VPN requires several filter rules in order to work properly. Because of this complexity, you may, from time to time, experience trouble with your VPN connections. Troubleshooting your VPN is not always an easy task. You must understand your system and your network environments, as well as the components you use to manage them. The following topics provide you with hints on how to troubleshoot the various problems you may encounter while using VPN:

**Getting started with VPN troubleshooting**

View this information to begin finding and correcting your VPN connection problems.

There are several ways to begin analyzing VPN problems:

1. Always make sure that you have applied the latest Program Temporary Fixes (PTFs).
2. Ensure that you meet the minimum VPN setup requirements.
3. Review any error messages that are found in the Error Information window or in the VPN server job logs for both the local and the remote systems. In fact, when you are troubleshooting VPN connection problems it is often necessary to look at both ends of the connection. Further, you need to take into account that there are four addresses you must check: The local and remote connection endpoints, which are the addresses where IPSec is applied to the IP packets, and the local and remote data endpoints, which are the source and destination addresses of the IP packets.

4. If the error messages you find do not provide enough information to solve the problem, check the IP filter journal.

5. The communication trace on the system offers you a another place to find general information about whether the local system receives or sends connection requests.

6. The Trace TCP Application (TRCTCPAPP) command provides yet another way to isolate problems. Typically, IBM Service uses TRCTCPAPP to obtain trace output in order to analyze connection problems.

Other things to check
If an error occurs after you set up a connection, and you are not sure where in the network the error occurred, try reducing the complexity of your environment. For example, instead of investigating all parts of a VPN connection at one time, start with the IP connection itself. The following list gives you some basic guidelines on how to start VPN problem analysis, from the simplest IP connection to the more complex VPN connection:

1. Start with an IP configuration between the local and remote host. Remove any IP filters on the interface that both the local and remote system use for communicating. Can you PING from the local to the remote host?

   **Note:** Remember to prompt on the PING command; enter the remote system address and use PF10 for additional parameters, then enter the local IP address. This is particularly important when you have multiple physical or logical interfaces. It ensures that the right addresses are placed in the PING packets.

   If you answer **yes**, then proceed to step 2. If you answer **no**, then check your IP configuration, interface status, and routing entries. If the configuration is correct, use a communication trace to check, for example, that a PING request leaves the system. If you send a PING request but you receive no response, the problem is most likely the network or remote system.

   **Note:** There may be intermediate routers or firewall that do IP packet filtering and may be filtering the PING packets. PING is typically based on the ICMP protocol. If the PING is successful, you
know you have connectivity. If the PING is unsuccessful, you only know the PING failed. You may want to try other IP protocols between the two systems, such as Telnet or FTP to verify connectivity.

2. Check the filter rules for VPN and ensure that they are activated. Does filtering start successfully? If you answer yes, then proceed to step 3. If you answer no, then check for error messages in the Packet Rules window in iSeries Navigator. Ensure that the filter rules do not specify Network Address Translation (NAT) for any VPN traffic.

3. Start your VPN connection. Does the connection start successfully? If you answer yes, then proceed to step 4. If you answer no, then check the QTOVMAN job log, the QTKVPNIKE job logs for errors. When you use VPN, your Internet Service Provider (ISP) and every security gateway in your network must support the Authentication Header (AH) and Encapsulated Security Payload (ESP) protocols. Whether you choose to use AH or ESP depends on the proposals you define for your VPN connection.

4. Are you able to activate a user session over the VPN connection? If you answer yes, then the VPN connection works as required. If you answer no, then check the packet rules and the VPN dynamic-key groups and connections for filter definitions that do not allow the user traffic you want.

**Common VPN configuration errors and how to fix them**

This information identifies the most common user errors and provides possible resolutions.

This section describes of some of the more common problems that occur with VPN, and links you to tips on how to resolve them.

**Note:** When you configure VPN, you are actually creating several different configuration objects, each of which VPN requires to enable a connection. In terms of the VPN GUI, these objects are: The IP Security Policies and the Secure Connections. So, when this information refers to an object, it is referring to one or more of these parts of the VPN.

**VPN error message: TCP5B28**

When you attempt to activate filter rules on an interface, you get this message: TCP5B28 CONNECTION_DEFINITION order violation

**Symptom:**
When you attempt to activate filter rules on a specific interface, you receive this error message:

TCP5B28: CONNECTION_DEFINITION order violation

**Possible resolution:**
The filter rules you were attempting to activate contained connection definitions that were ordered differently than in a previously activated set of rules. The easiest way to resolve this error is to activate the rules file on all interfaces instead of on a specific interface.

**VPN error message: Item not found**

When you right-click a VPN object and select either Properties or Delete, you get a message that says, Item not found.

**Symptom:**
When you right-click an object in the Virtual Private Networking window and either select Properties or Delete, the following message appears:
Possible resolution:

- You may have deleted the object or renamed it, and have not refreshed the window yet. Consequently, the object still appears in the Virtual Private Networking window. To verify that this is the case, from the View menu, select Refresh. If the object still appears in the Virtual Private Networking window, continue to the next item in this list.

- When you configured the properties for the object, a communication error may have occurred between the VPN server and your system. Many of the objects that appear in the VPN window relate to more than one object in the VPN policy database. This means that communication errors may cause some of the objects in the database to continue to be related to an object in the VPN. Whenever you create or update an object, an error will occur when the loss of synchronization actually happens. The only way to fix the problem is to select OK on the error window. This launches the property sheet for the object in error. Only the name field on the property sheet has a value in it. Everything else is blank (or contains default values). Enter the correct attributes of the object, and select OK to save your changes.

- A similar error occurs when you try to delete the object. To fix this problem, complete the blank property sheet that opens when you click OK on the error message. This updates any links to the VPN policy database that were lost. You can now delete the object.

**VPN error message: PARAMETER PINBUF IS NOT VALID**

When you attempt to start a connection, you get a message that says, PARAMETER PINBUF IS NOT VALID...

**Symptom:**

When you attempt to start a connection, a message similar to the following appears:

Possible resolution:

This happens when your system is set to use certain locales to which lowercase letters do not map correctly. To fix this error, either make sure that all objects use only uppercase letters, or change the locale of the system.
VPN error message: Item not found, Remote key server...
When you select Properties for a dynamic-key connection, you get an error that says that the server cannot find the remote key server you specified.

Symptom:
When you select Properties for a dynamic-key connection, a message like the following appears:

![Virtual Private Networking - 9...](image)

Possible resolution:
This happens when you create a connection with a particular remote key server identifier, and then the remote key server is removed from its dynamic-key group. To fix this error, click OK on the error message. This opens the property sheet for the dynamic-key connection that is in error. From here, you can either add the remote key server back into the dynamic-key group, or select another remote key server identifier. Click OK on the property sheet to save your changes.

VPN error message: Unable to update the object
When you select OK on the property sheet for a dynamic-key group or manual connection, you get a message that tells you the system cannot update the object.

Symptom:
When you select OK on the property sheet for a dynamic-key group or manual connection, the following message appears:

![Virtual Private Networking - R...](image)

Possible resolution:
This error happens when an active connection is using the object you are trying to change. You cannot make changes to an object within an active connection. To make changes to an object, identify the appropriate active connection and then, right-click it and select Stop from the resulting context menu.

VPN error message: Unable to encrypt key...
You get a message that says that the system cannot encrypt your keys because the QRETSVRSEC value must be set to 1.

Symptom:
The following error message appears:
Possible resolution:  
QRETSVRSEC is a system value that indicates whether your system can store encrypted keys on it. If this value is set to 0, then preshared keys and the keys for the algorithms in a manual connection cannot be stored in the VPN policy database. To fix this problem, use a 5250 emulation session to your system. Type `wrksysval` at the command line and press Enter. Look for QRETSVRSEC in the list and type 2 (change) next to it. On the next panel, type 1 and press Enter.

Related concepts

"VPN error: All keys are blank"  
When you view the properties of a manual connection, all preshared keys and the algorithm keys for the connection are blank.

VPN error message: CPF9821  
When you try to expand or open the IP Policies container in iSeries Navigator, the CPF9821- Not authorized to program QTFRPRS in QSYS library message appears.

Symptom:  
When you try to expand the IP Policies container in iSeries Navigator, the CPF9821- Not authorized to program QTFRPRS in QSYS library message appears.

Possible resolution:  
You may not have the required authority to retrieve the current status of Packet Rules or the VPN connection manager. Ensure that you have *IOSYSCFG authority to get access to the Packet Rules functions in iSeries Navigator.

VPN error: All keys are blank  
When you view the properties of a manual connection, all preshared keys and the algorithm keys for the connection are blank.

Symptom:  
All preshared keys and the algorithm keys for manual connections are blank.

Possible resolution:  
This happens whenever the system value QRETSVRSEC is set back to 0. Setting this system value to 0 erases all of the keys in the VPN policy database. To fix this problem, you must set the system value to 1 and then reenter all of the keys. Refer to Error message: Unable to encrypt keys for more information about how to do this.

Related concepts

"VPN error message: Unable to encrypt key..." on page 59  
You get a message that says that the system cannot encrypt your keys because the QRETSVRSEC value must be set to 1.

VPN error: Sign-on for a different system appears when using Packet Rules  
The first time you use the Packet Rules interface in iSeries, a sign-on display appears for a system other than the current one.
Symptom:
The first time you use Packet Rules, a sign-on display appears for a system other than the current one.

Possible resolution:
Packet Rules uses unicode to store the packet security rules in the integrated file system. The additional sign-on allows iSeries Access for Windows to obtain the appropriate conversion table for unicode. This will only occur once.

VPN error: Blank connection status in iSeries Navigator window
A connection has no value in the Status column in the iSeries Navigator window.

Symptom:
A connection has no value in the Status column in the iSeries Navigator window.

Possible resolution:
The blank status value indicates that the connection is in the middle of starting. That is, it is not running yet, but it has not had an error yet either. When you refresh the window, the connection will either display a status of Error, Enabled, On-demand, or Idle.

VPN error: Connection has enabled status after you stop it
After you stop a connection, the iSeries Navigator window indicates that the connection is still enabled.

Symptom:
After you stop a connection, the iSeries Navigator window indicates that the connection is still enabled.

Possible resolution:
This typically happens because you have not refreshed the iSeries Navigator window yet. As such, the window contains outdated information. To fix this, from the View menu, select Refresh.

VPN error: 3DES not a choice for encryption
When you are working with an IKE policy transform, data policy transform, or a manual connection, the 3DES encryption algorithm is not a choice.

Symptom:
When working with an IKE policy transform, data policy transform, or a manual connection, the 3DES encryption algorithm is not a choice.

Possible resolution:
Most likely, you only have the Cryptographic Access Provider AC2 (5722-AC2) product installed on your system, and not Cryptographic Access Provider AC3 (5722-AC3). AC2 only allows for the Data Encryption Standard (DES) encryption algorithm due to restrictions on key lengths.

VPN error: Unexpected columns display in the iSeries Navigator window
Set up the columns you want to display in the iSeries Navigator window for your VPN connections; then, when you look at it later, different columns display.

Symptom:
You set up the columns you want to display in the iSeries Navigator window for your VPN connections; then, when you look at it later, different columns display.

Possible resolution:
When you change the columns to view, the changes are not specific to a particular user or PC, but rather, are system-wide. So, when someone else changes the columns in the window, the changes affect everyone viewing connections on that system.

VPN error: Active filter rules fail to deactivate
When you try to deactivate the current set of filter rules, the message, The active rules failed to be deactivated appears in the results window.
Symptom: When you try to deactivate the current set of filter rules, the message, The active rules failed to be deactivated appears in the results window.

Possible resolution: Typically, this error message means that there is at least one active VPN connection. You must stop each of the connections that have a status of enabled. To do this, right-click each of the active connections and select Stop. You can now deactivate the filter rules.

VPN error: The key connection group for a connection changes
When you create a dynamic-key connection, you specify a dynamic-key group and an identifier for the remote key server. Later, when you view the properties of the related connection object, the General page of the property sheet displays the same remote key server identifier, but a different dynamic-key group.

Symptom: When you create a dynamic-key connection, you specify a dynamic-key group and an identifier for the remote key server. Later, when you select Properties on the related connection object, the General page of the property sheet displays the same remote key server identifier, but a different dynamic-key group.

Possible resolution: The identifier is the only information stored in the VPN policy database that refers to the remote key server of the dynamic-key connection. When VPN looks up a policy for a remote key server, it looks for the first dynamic-key group that has that remote key server identifier in it. So, when you view the properties for one these connections, it uses the same dynamic-key group that VPN found. If you do not want to associate the dynamic-key group with that remote key server, you can do one of the following:

1. Remove the remote key server from the dynamic-key group.
2. Expand By Groups in the left pane of the VPN interface, and select and drag the dynamic-key group you want to the top of the table in the right pane. This ensures that VPN checks this dynamic-key group first for the remote key server.

Troubleshooting VPN with the QIPFILTER journal
View this information to learn about VPN filter rules.

The QIPFILTER journal is located in the QUSRSYS library and contains information about filter rule sets, as well as information about whether an IP datagram was permitted or denied. Logging is performed based on the journaling option you specify in your filter rules.

Related tasks
“Getting started with VPN troubleshooting” on page 58
View this information to begin finding and correcting your VPN connection problems.

How to enable the IP Packet Filter journal
Use the Packet Rules editor in iSeries Navigator to activate the QIPFILTER journal. You must enable the logging function for each individual filter rule. There is no function that allows logging for all IP datagrams going into or out of the system.

Note: To enable the QIPFILTER journal, your filters must be deactivated.

The following steps describe how to enable journaling for a particular filter rule:
1. In iSeries Navigator, expand your system → Network → IP Policies.
2. Right-click Packet Rules and select Configuration. This displays the Packet Rules interface.
3. Open an existing filter rule file.
4. Double-click the filter rule you want to journal.
5. On the **General** page, select **FULL** in the **Journaling** field as in the dialog box shown above. This enables logging for this particular filter rule.

6. Click **OK**.

7. Save and activate the changed filter rule file.

If an IP datagram matches the definitions of the filter rule, an entry is made in the QIPFILTER journal.

**How to use the QIPFILTER journal**

i5/OS automatically creates the journal the first time you activate IP packet filtering. To view the entry-specific details in the journal, you can display the journal entries on the screen or you can use an output file.

By copying the journal entries to the output file, you can easily view the entries using query utilities such as Query/400 or SQL. You can also write your own HLL programs to process the entries in the output files.

The following is an example of the Display Journal (DSPJRN) command:

```
DSPJRN JRN(QIPFILTER) JRNCODE((M)) ENTTYP((TF)) OUTPUT(*OUTFILE)
         OUTFILFMT(*TYPE4) OUTFILE(mylib/myfile) ENTDTALEN(*VARLEN +CALC)
```

Use the following steps to copy the QIPFILTER journal entries to the output file:

1. Create a copy of the system-supplied output file QSYS/QATOFIFP into a user library by using the Create Duplicate Object (CRTDUPOBJ) command. The following is an example of the CRTDUPOBJ command:

   ```
   CRTDUPOBJ OBJ(QATOFIPF) FROMLIB(QSYS) OBJTYPE(*FILE) TOLIB(mylib)
   NEWOBJ(myifile)
   ```

2. Use the Display Journal (DSPJRN) command to copy the entries from the QUSRSDS/QIPFILTER journal to the output file you created in the previous step.

If you copy the DSPJRN into an output file that does not exist, the system creates a file for you, but this file does not contain the correct field descriptions.

**Note:** The QIPFILTER journal only contains permit or deny entries for filter rules where the journaling option is set to FULL. For example, if you set up only PERMIT filter rules, IP datagrams that are not explicitly permitted are denied. For those denied datagrams, no entry is added to the journal. For problem analysis you might add a filter rule that explicitly denies all other traffic and performs FULL journaling. Then, you will get DENY entries in the journal for all IP datagrams that are denied. Due to performance reasons, it is not recommended that you enable journaling for all filter rules. Once your filter sets are tested, reduce the journaling to a useful subset of entries.

See QIPFILTER journal fields for a table that describes the QIPFILTER output file.

**QIPFILTER journal fields**

The following table describes the fields in the QIPFILTER output file:

<table>

**Troubleshooting VPN with the QVPN journal**

Provides information about IP traffic and connections.

VPN uses a separate journal to log information about the IP traffic and connections called the QVPN journal. The QVPN is stored in the QUSR SYS library. The journal code is M and the journal type is TS. You will rarely use journal entries on a daily basis. Instead, you might find them useful for
troubleshooting and verifying that your system, keys, and connections are functioning in the manner that you specified. For example, journal entries help you understand what happens to your data packets. They also keep you informed of your current VPN status.

**How to enable the VPN journal**

Use the virtual private networking interface in iSeries Navigator to activate the VPN journal. There is no function that allows logging for all VPN connections. Therefore, you must enable the logging function for each individual dynamic-key group or manual connection.

The following steps describe how to enable the journal function for a particular dynamic-key group or manual connection:

1. In iSeries Navigator, expand your **system → Network → IP Policies → Virtual Private Networking → Secure Connections**.
2. For dynamic-key groups, expand **By Group** and then right-click the dynamic key group for which you want to enable journaling and select **Properties**.
3. For manual connections, expand **All Connections** and then right-click the manual connection for which you want to enable journaling.
4. On the **General** page, select the level of journaling you require. You have the choice between four options. These are:
   - **None**: No journaling occurs for this connection group.
   - **All**: Journaling occurs for all connection activities, such as starting or stopping a connection, or key refreshes, as well as IP traffic information.

**Connection Activity**

Journaling occurs for such connection activity as starting or stopping a connection.

**IP traffic**

Journaling occurs for all of the VPN traffic that is associated with this connection. A log entry is made every time a filter rule is invoked. The system records IP traffic information in the journal QIPFILTER, which is located in the QUSRsys library.

5. Click **OK**.
6. Start the connection to activate journaling.

**Note:** Before you can stop journaling, make sure that the connection is inactive. To change the journaling status of a connection group, make sure that no active connections are associated with that particular group.

**How to use the VPN journal**

To view the entry-specific details in the VPN journal, you can display the entries on the screen or you can use the output file.

By copying the journal entries to the output file, you can easily view the entries by using query utilities such as Query/400 or SQL. You can also write your own HLL programs to process the entries in the output files. The following is an example of the Display Journal (DSPJRN) command:

```
DSPJRN JRN(QVPN) JRNCDE((M)) ENTTYP((TS)) OUTPUT(*OUTFILE) OUTFILFMT(*TYPE4)
OUTFILE(mylib/myfile) ENTDATALEN(*VARLEN *CALC)
```

Use the following steps to copy the VPN journal entries to the output file:

1. Create a copy of the system-supplied output file QSYS/QATOVSOF into a user library. You can do this by using the Create Duplicate Object (CRTDUPOBJ) command. The following is an example of the CRTDUPOBJ command:

```
CRTDUPOBJ OBJ(QATOVSOF) FROMLIB(QSYS) OBJTYPE(*FILE) TOLIB(mylib)
NEWOBJ(myfile)
```
2. Use the Display Journal (DSPJRN) command to copy the entries from the QUSRYSYS/QVPN journal to the output file created in the previous step. If you attempt to copy the DSPJRN into an output file that does not exist, the system creates a file for you, but this file does not contain the correct field descriptions.

See QVPN journal fields for a table that describes the fields in the QVPN output file.

**QVPN journal fields**

The following table describes the fields in the QVPN output file:

<table>
<thead>

Troubleshooting VPN with the VPN job logs

Describes the various job logs that VPN uses.

When you encounter problems with your VPN connections, it is always advisable to analyze the job logs. In fact, there are several job logs that contain error messages and other information related to a VPN environment.

It is important that you analyze job logs on both sides of the connection if both sides are iSeries systems. When a dynamic connection fails to start, it is helpful if you understand what is happening on the remote system.

The VPN jobs, QTOVMAN and QTOKVPNIKE, run in the subsystem QSYSWRK. You can view their respective job logs from iSeries Navigator.

This section introduces the most important jobs for a VPN environment. The following list shows the job names with a brief explanation of what the job is used for:

QTCPIP
This job is the base job that starts all the TCP/IP interfaces. If you have fundamental problems with TCP/IP in general, analyze the QTCPIP job log.

QTOKVPNIKE
The QTOKVPNIKE job is the VPN key manager job. The VPN key manager listens to UDP port 500 to perform the Internet Key Exchange (IKE) protocol processing.

QTOVMAN
This job is the connection manager for VPN connections. The related job log contains messages for every connection attempt that fails.

QTPPANSxxx
This job is used for PPP dial-up connections. It answers to connection attempts where *ANS is defined in a PPP profile.

QTPPPPCTL
This is a PPP job for dial-out connections.

QTPPPL2TP
This is the Layer Two Tunneling Protocol (L2TP) manager job. If you have problems setting up an L2TP tunnel, look for messages in this job log.

Related tasks
“Getting started with VPN troubleshooting” on page 55
View this information to begin finding and correcting your VPN connection problems.

Common VPN Connection Manager error messages
Describes some of the more common VPN Connection Manager error messages you may encounter.
In general, the VPN Connection Manager logs two messages in the QTOVMAN job log when an error occurs with a VPN connection. The first message provides details regarding the error. You can view information about these errors in iSeries Navigator by right-clicking the connection in error and selecting Error Information.

The second message describes the action you were attempting to perform on the connection when the error occurred. For example, starting or stopping it. Messages TCP8601, TCP8602, and TCP860A, described below, are typical examples of these second messages.

<table>
<thead>
<tr>

Troubleshooting VPN with the communications trace

IBM i5/OS provides the capability to trace data on a communications line, such as a local area network (LAN) or wide area network (WAN) interface. The average user may not understand the entire contents of the trace data. However, you can use the trace entries to determine whether a data exchange between the local and the remote systems took place.

Starting the communications trace

Use the Start Communications Trace (STRCMNTRC) command to start the communications trace on your system. The following is an example of the STRCMNTRC command:

```
STRCMNTRC CFGOBJ(TRNLNE) CFGTYPE(*LIN) MAXSTG(2048) TEXT('VPN Problems')
```

The command parameters are explained in the following list:

- **CFGOBJ (Configuration object)**
  The name of the configuration object to trace. The object is either a line description, a network interface description, or a network server description.

- **CFGTYPE (Configuration type)**
  Whether a line (*LIN), a network interface (*NWI), or a network server (*NWS) is being traced.

- **MAXSTG (Buffer size)**
  The buffer size for the trace. The default value is set to 128 KB. The range goes from 128 KB to 64
MB. The actual maximum system-wide buffer size is defined within the System Service Tools (SST). Therefore, you may receive an error message when using a larger buffer size on the STRCMNTRC command than defined in the SST. Keep in mind that the sum of buffer sizes specified on all started communications traces must not exceed the maximum buffer size defined in the SST.

DTADIR (Data direction)
The direction of data traffic to be traced. The direction can be outbound traffic only (*SND), inbound traffic only (*RCV), or both directions (*BOTH).

TRCFULL (Trace full)
What occurs when the trace buffer is full. This parameter has two possible values. The default value is *WRAP, which means, when the trace buffer is full, the trace wraps to the beginning. The oldest trace records are written over by new ones as they are collected.

The second value *STOPTRC let the trace stop when the trace buffer, specified in the MAXSTG parameter is full of trace records. As general rule, always define the buffer size to be large enough to store all the trace records. If the trace wraps, you may lose important trace information. If you experience a highly intermittent problem, define the trace buffer to be large enough that a wrap of the buffer will not discard any important information.

USRDTA (Number of user bytes to trace)
Defines the number of data to be traced in the user data part of the data frames. By default only the first 100 bytes of user data are captured for LAN interfaces. For all other interfaces, all user data is captured. Make sure you specify *MAX if you suspect problems in the user data of a frame.

TEXT (Trace description)
Provides a meaningful description of the trace.

Stopping the communications trace
If you do not otherwise specify, the trace typically stops as soon as the condition for which you are tracing occurs. Use the End Communications Trace (ENDCMNTRC) command to stop the trace. The following command is an example of the ENDCMNTRC command:

ENDCMNTRC CFGOBJ(TRNLNE) CFGTYPE(*LIN)

The command has two parameters:

CFGOBJ (Configuration object)
The name of the configuration object for which the trace is running. The object is either a line description, a network interface description, or a network server description.

CFGTYPE (Configuration type)
Whether a line (*LIN), a network interface (*NWI), or a network server (*NWS) is being traced.

Printing the trace data
After you stop the communications trace, you need to print the trace data. Use the Print Communications Trace (PRTCMNTRC) command to perform this task. Since all line traffic is captured during the trace period, you have multiple filter options for output generation. Try to keep the spooled file as small as possible. This makes the analysis faster and more efficient. In the case of a VPN problem, filter on IP traffic only and, if possible, on a specific IP address. You also have the option of filtering on a specific IP port number. The following is an example of the PRTCMNTRC command:

PRTCMNTRC CFGOBJ(TRNLNE) CFGTYPE(*LIN) FMTTCP(*YES) TCPIPADDR(‘10.50.21.1) SLTPORT(500) FMTBCD(*NO)

In this example, the trace is formatted for IP traffic and contains only data for the IP address, where the source or destination address is 10.50.21.1 and the source or destination IP port number is 500.
Only the most important command parameters for analyzing VPN problems, are explained below:

**CFGOBJ (Configuration object)**

The name of the configuration object for which the trace is running. The object is either a line description, a network interface description, or a network server description.

**CFGTYPE (Configuration type)**

Whether a line (*LIN), a network interface (*NWI), or a network server (*NWS) is being traced.

**FMTTCP (Format TCP/IP data)**

Whether to format the trace for TCP/IP and UDP/IP data. Specify *YES to format the trace for IP data.

**TCPIPADDR (Format TCP/IP data by address)**

This parameter consists of two elements. If you specify IP addresses on both elements, only IP traffic between those addresses will print.

**SLTPORT (IP port number)**

The IP port number to filter.

**FMTBCD (Format broadcast data)**

Whether all broadcast frames are printed. Yes is the default. If you do not want; for example, Address Resolution Protocol (ARP) requests, specify *NO; otherwise you may be overwhelmed with broadcast messages.
