Note

Before using this information and the product it supports, read the information in “Notices” on page 229.
About IBM Content Manager OnDemand for iSeries Common Server Administration Guide (SC27-1161)

The information in this book can help administrators maintain an IBM® Content Manager OnDemand for iSeries Common Server Version 5 Release 4 (OnDemand) system.

This book describes how to:
- Maintain the database
- Manage disk and archive storage
- Use the administrative client to define reports to the system and maintain other types of objects on the system
- Load reports and other types of data into the system
- Use administrative commands to complete other types of tasks

Before you begin, IBM recommends that you familiarize yourself with concepts and terminology used in this book. See the IBM Content Manager OnDemand for iSeries Common Server: Planning and Installation Guide for information about OnDemand.

Who should read this book

This book is of primary interest to administrators who are responsible for implementing and maintaining an OnDemand system. Some administrators can use this book and the tools described in it to define reports to the system. Other administrators can use this book and the tools described in it to maintain users, groups, printers, and so forth. Still other administrators can use the administrative commands described in this book to maintain the database, disk and archive storage, extract documents from the system, and so forth.

How this book is organized

Part 1, “Database administration,” on page 1 describes the key database objects that you will need to understand to perform the tasks in this book, describes how to maintain the database, and provides information about backup and recovery. This part contains the following sections:
- Chapter 1, “Database concepts,” on page 3
- Chapter 2, “Database maintenance,” on page 5
- Chapter 3, “Migrating and importing index data,” on page 9

Part 2, “Storage administration,” on page 13 contains information about managing disk and archive storage devices and objects. This part has the following section:
- Chapter 4, “Document storage,” on page 15
- Chapter 5, “Backup and recovery,” on page 23

Part 3, “Using iSeries Navigator for OnDemand administration,” on page 27 contains information about iSeries™ Navigator, a program that you can use to define and maintain objects on the system. For example, you can use iSeries Navigator to define reports to OnDemand and maintain OnDemand users, groups and printers. This part contains the following sections:
Chapter 6, “Installation,” on page 29 describes the hardware, software, memory, and disk space requirements for the administrative client and how to install the administrative client.

Chapter 7, “Introduction,” on page 33 provides an introduction to the iSeries Navigator, including how to start the program, log on to a server, and maintain passwords, describes the types of tasks that you can do with the iSeries Navigator, and contains information about the system parameters that you can maintain with the iSeries Navigator.

Chapter 8, “Concepts,” on page 45 provides an overview of the OnDemand objects: users, groups, printers, migration policies and storage sets, application groups, applications, and folders.

Chapter 9, “Examples,” on page 61 provides step-by-step instructions for using the iSeries Navigator to define users, groups, printers, migration policies and storage sets, and reports to the system.

Part 4, “Loading data,” on page 107 provides information about and examples of loading reports on the system. This part contains the following sections:

Chapter 10, “Loading spooled file data,” on page 109
Chapter 12, “Loading user-defined data,” on page 125
Chapter 11, “Loading image files,” on page 117
Chapter 13, “Restarting a load process,” on page 133
Chapter 14, “Deleting a report,” on page 135

Part 5, “Server administration,” on page 137 describes errors and alerts, system logging and how to find the server job system logging, how to find the server job, and how to restart journaling.

Appendix B, “System log messages,” on page 147 contains many of the most common messages found in the OnDemand System Log.

Appendix C, “5250 host connection to client viewer,” on page 173 describes the OnDemand 5250 Host Connection, which allows an i5/OS application to send information to the OnDemand client workstation viewer program (the viewer).

Appendix D, “Server printing and faxing,” on page 179 describes how to define some of the server print parameters in your Common Server application definition.

Appendix E, “API and user exit reference,” on page 183 describes the OnDemand APIs.

Appendix F, “Automating ARSLOAD data loading,” on page 221 describes how to automate the ARSLOAD command.

Appendix G, “Alternative to starting the administrative client,” on page 223 describes a different way to start the administrative client.

**Conventions and terminology used in this book**

Prerequisite and related information

Use the iSeries Information Center as your starting point for looking up iSeries technical information. You can access the Information Center two ways:

- From the following Web site:
  http://www.ibm.com/eserver/iseries/infocenter
- From CD-ROMs that ship with your IBM i5/OS order:
  *iSeries Information Center*, SK3T-4091-04. This package also includes the PDF versions of iSeries manuals, *iSeries Information Center: Supplemental Manuals*, SK3T-4092-01, which replaces the Softcopy Library CD-ROM.

The iSeries Information Center contains advisors and important topics such as CL commands, system application programming interfaces (APIs), logical partitions, clustering, Java™, TCP/IP, Web serving, and secured networks. It also includes links to related IBM Redbooks™ and Internet links to other IBM Web sites such as the Technical Studio and the IBM home page.

OnDemand Information Center

In addition to the iSeries Information Center (previously mentioned), be sure to visit the OnDemand Information Center, which focuses only on information pertaining to CM OnDemand. The OnDemand Information Center provides fast, online centralized access to product information. It is a task-based documentation repository that allows you to search across the entire product library for commands, error codes, or any other topic of interest. You can bookmark pages of interest or common reference, allowing them to easily be retrieved for future reference.

To access the OnDemand Information center, go to
http://publib.boulder.ibm.com/infocenter/cmod83/index.jsp

Traditional product documentation has been moved from the library page to the support page on the CM OnDemand for iSeries product Web site. To see a list of all available OnDemand for iSeries product documentation, go to http://www.ibm.com/software/data/ondemand/400/support.html Look in the left hand column, under the “Self help” section, “Learn” subheading.

iSeries Navigator

IBM iSeries Navigator is a powerful graphical interface for managing your iSeries servers. iSeries Navigator functionality includes system navigation, configuration, planning capabilities, and online help to guide you through your tasks. iSeries Navigator makes operation and administration of the server easier and more productive and is the only user interface to the new, advanced features of the i5/OS operating system. It also includes Management Central for managing multiple servers from a central server.

For more information on iSeries Navigator, see the iSeries Information Center.

How to send your comments

Your feedback is important in helping to provide the most accurate and high-quality information. If you have any comments about this book or any other iSeries documentation, fill out the readers' comment form at the back of this book.
If you prefer to send comments by mail, use the readers’ comment form with the address that is printed on the back. If you are mailing a readers’ comment form from a country other than the United States, you can give the form to the local IBM branch office or IBM representative for postage-paid mailing.

If you prefer to send comments by FAX, use either of the following numbers:
  – United States, Canada, and Puerto Rico: 1-800-937-3430
  – Other countries: 1-507-253-5192

If you prefer to send comments electronically, use one of these e-mail addresses:
  – Comments on books:
    RCHCLERK@us.ibm.com
  – Comments on the iSeries Information Center:
    RCHINFOC@us.ibm.com

Be sure to include the following:
  • The name of the book or iSeries Information Center topic.
  • The publication number of a book.
  • The page number or topic of a book to which your comment applies.

Product support

Product support is available on the Web. See www.ibm.com/software/data/ondemand/400/support.html

The IBM support center maintains product updates for OnDemand. You can obtain the latest product updates for the end-user client and the administrative client from IBM service on the Web at ftp://service.software.ibm.com/software/ondemand/fixes/.

The current list of OnDemand server and iSeries Navigator component PTFs is available in informational APAR III4053.

If you encounter problems or errors running any of the OnDemand programs, you can call the IBM support center to obtain software problem and defect support.
Summary of changes

This edition of IBM Content Manager OnDemand for iSeries Common Server Administration Guide contains new technical information. There may be some instances where changes were made, but change bars are missing. Significant changes to note are:

- The two Content Manager OnDemand for iSeries publications that apply to Spool File Archive, Object Archive, Record Archive, and AnyStore have not been updated for Version 5 Release 4. This software has become very stable and has not had significant changes since Version 5 Release 3. If you have a need to review documentation for any of those listed, you can consult the Content Manager OnDemand for iSeries Installation Guide and the Content Manager OnDemand for iSeries Administration Guide for Version 5 Release 3. All publications that relate to Common Server have been updated for Version 5 Release 4.

- Significant additions have been made to the Spool File Archive to Common Server Migration utility documentation in Appendix A of the Content Manager OnDemand for iSeries Common Server Planning and Installation Guide.

- A new capability within the Spool File Archive to Common Server Migration utility now allows you to reduce the number of joblogs produced during a successful run of the migration program. See Appendix A of the Content Manager OnDemand for iSeries Common Server Planning and Installation Guide for more information.

- Additional detail has been added regarding Disk Storage Manager (DSM) and Archive Storage Manager (ASM). The majority of the additions have been made in the Content Manager OnDemand for iSeries Common Server Administration Guide.
Part 1. Database administration

This part is of primary interest to administrators responsible for configuring and maintaining the OnDemand database. This part is organized as follows:

- Database concepts
- Database maintenance
- Migrating and importing index data
Chapter 1. Database concepts

This section provides an overview of the key database objects:

- System
- Instance
- Database
- Table
- Index
- Journals and Journal Receivers

System

A database system represents a physical machine that contains a copy of the database manager. In OnDemand, the server is the physical machine referred to as the system.

Instance

An OnDemand instance is a logical server environment consisting of a server and its own separate database and disk space. Each OnDemand instance (the server, database and disk):

- Has its own definition of folders, application groups, applications and printers
- Must run in a single CCSID
- Has different security (users, groups, folder and application group permissions)
- Must have its name specified on commands if it is not the default instance
- Has its own System Log

Some reasons you might have multiple instances on a machine are:

- To have distinct test and production environments
- To have databases using different CCSIDs

For OnDemand, IBM recommends that you name your primary production, or only, instance QUSROND. This is the default OnDemand instance that is used on all OnDemand commands unless you explicitly specify a different instance name. Using this as your primary OnDemand instance will save you from having to specify an instance name in most cases.

Database

A collection of data that is stored in tables. In OnDemand, generally speaking, there are two types of tables:

- System tables, which contain information about the objects you define to the system, such as users, groups, application groups, applications, folders, storage sets, and printers. There are also system tables that contain information OnDemand uses to control and maintain the system.
- Application group tables, which contain the index data for the reports that you load on the system.
Table

A table consists of data logically arranged in columns and rows. For example, when you create an application group, the system creates a table definition that contains one column for each field that you define. When you load a report into an application group, the system adds one row to an application group table for each document contained in the report.

Index

In OnDemand, an index is a key that points to a document. An index allows more efficient access to documents by creating a direct path to a document through pointers.

You define indexes when you create an application group. The indexes should contain information that uniquely identify a document, such as date, account number, and customer name. Indexes are populated by values extracted from a report when you load a report on the system. Each row in an application group table identifies one document.

However, keep in mind that you do not want lots of indexes on a report just to have indexes. You should have a good business reason to have an index. While indexes can help you find documents faster, having too many of them can slow you down when you load reports on the system. Every time you add a new row (document) to a table, you have to add a row to each and every one of the indexes for that table. So the more indexes that you have, the longer it may take when you load a report.

The SQL optimizer automatically chooses the most efficient way to access data in tables. The optimizer takes indexes into consideration when determining the fastest access path to data.

Journals and journal receivers

Each database includes recovery journals and journal receivers, which are used to recover from application or system errors. In combination with database backups, journals are used to recover the consistency of the database right up to a point in time when an error occurred.

All instances have journals associated with them. These journals keep records of database changes. Journals prevent a failure (system power, application error) from leaving a database in an inconsistent state. They restore the state of a database to the point before the change. Journals can also enable forward recovery to any point in time before the failure.

In planning for disaster recovery, be sure to remember that journals must be stored off site, or at least safely away from the disaster, in order to recover your database beyond the point of the last full, off line backup.
Chapter 2. Database maintenance

You need to maintain the OnDemand database to keep it performing in an optimal manner. IBM recommends that you run the following database maintenance tasks on a regular basis:

- Expire index data that has reached its life of data and indexes period
- Migrate indexes to archive storage, if your organization needs to keep indexes for some period of time after users no longer need to retrieve the documents to which they point. This is not recommended.

Before you begin

IBM recommends that you do the following:

- Keep the index data for any given version of a report in the database on disk at least until such time that 99 percent of the requests for the report have passed. As a rule of thumb, if there is any chance that someone in your organization will need to retrieve a version of a report, keep the index data in the database – don’t allow it to be migrated.
- Expire data periodically, and migrate index data only when absolutely necessary.
- Select Multiple Loads per Database Table when you define the Database Organization within your application group definitions. With this selection, each time that you load a report into an application group, OnDemand inserts the index records into an existing database table. Index records for every report loaded into the application group are stored in the same database table. OnDemand maintains the application group data so that, as far as a user querying the application group knows, they appear to reside in one database table. OnDemand automatically segments the application group data when it grows beyond a certain size. OnDemand maintains a segment table for each application group. The segment table provides faster query performance by limiting searches to a specific table of application group data, using a date value to construct the query. This method is the default, and should be used in most cases.

Expiring index data

Indexes expire (are eligible for removal) because their life of data period has passed. The indexes, and the documents that they point to, can then be removed from the system. When you remove an index, information about the document to which it points is removed from the database (the document can no longer be retrieved). However, because indexes are eligible to be removed does not mean that they will be deleted from the database. OnDemand does not delete expired index data from the database until expiration processing runs.

The application group expiration policy determines when index data is eligible for deletion from the database. You define the expiration policy when you create the application group. The following properties on the Storage Management page comprise the expiration policy:

- Life of Data and Indexes. The length of time in days to maintain index data and documents on the system. After the index data has been on the system for this number of days, it is eligible to be deleted.
**Note:** If you specify Never Expire, then expiration processing is disabled for the application group. (That is, index data will not be removed from the database.)

- Expiration Type. Determines whether individual indexes or an entire table of index data is deleted at a time. When OnDemand deletes index data, it either deletes a row (if the Expiration Type is Document) or deletes a table (if the Expiration Type is Segment or Load). The amount of index data in a table and the number of reports the data represents is determined by the Database Organization. If the Database Organization is Multiple Loads per Database Table, then by default, a table of index data can hold up to 10 million indexes. These types of tables usually hold the indexes for many reports. If the Database Organization is Single Load per Database Table, then each table holds the indexes for one and only one load.

A table of index data is not eligible to be deleted until the latest date in any of its rows reaches the Life of Data and Indexes period. For example, suppose that the Life Of Data and Indexes is set to 365 days, the Expiration Type is set to Segment, and the Database Organization is set to Multiple Loads per Database Table. By default, a table will contain approximately 10 million rows. Further, suppose that a report is loaded into the application group once every month and that each report adds one million rows to the database. Each table can hold the index data from approximately 40 reports. Using these assumptions, the data that is loaded into the application group in January will not be eligible to be deleted by expiration processing until 40 months (more than three years). If you need to remove the index data for a report as soon as it reaches its Life of Data and Indexes period, then set the Database Organization to Single Load per Database Table and set the Expiration Type to Segment or Load. (And run expiration processing at least once a month.)

OnDemand’s disk storage manager and the archive storage manager delete the documents that expired index data points to independently of each other. OnDemand uses the application group’s expiration policy to determine when indexes and documents expire and should be removed from the system. The archive storage manager marks documents for removal based on the criteria specified in the migration policy. However, you should specify the same criteria to the disk storage manager and the archive storage manager. In other words, the sum of the Duration values for all migration policy storage levels plus the value for the Days in Cache should equal the Life of Data and Indexes value in the application group.

### How to expire index data

OnDemand does not delete expired index data from the database until expiration processing runs. The STRDSMOND command is the expiration utility. You can schedule the STRDSMOND command to run automatically or you can run it manually. You should make sure that the STRDSMOND command runs periodically so that OnDemand deletes indexes when it is time to do so (so that expired documents can no longer be retrieved).

When the STRDSMOND command removes indexes, it saves the following message in the System Log:

```
128 ApplGrp Segment Expire (ApplGrp) (Segment)
```

One message is saved in the System Log for each table that was deleted during expiration processing.
Note: While not recommended, if you have migrated indexes to archive media, then the STRASMOND command will perform expiration processing on that index data.

**Migrating indexes**

Note: This section provides an overview of the process of migrating index data from the database to archive storage. See Chapter 3, “Migrating and importing index data,” on page 9 for information about configuring the system for migration processing.

OnDemand provides automatic migration to move indexes from the database to archive storage to maintain seldom used indexes for long periods of time.

Important: If you use migration to move indexes to archive storage, make sure that you migrate them after there is no longer a need to retrieve the documents to which they point.

The STRDSMOND command uses an application group’s migration policy to control when migration of indexes for an application group occurs:

- Migration of Indexes. If you specify No Migration, then migration of indexes is disabled for the application group. (That is, index data will not be migrated.) If you specify Migrate After \( n \) Days, then index data is eligible to be migrated after reaching the specified number of days. Indexes will be migrated the next time that the STRDSMOND command runs.

- Life of Data and Indexes. The length of time in days to maintain index data on the system. For migration, this value must be greater than the Migrate After \( n \) Days value.

OnDemand does not migrate index data from the database to archive media until migration processing runs. The STRDSMOND command is the migration utility. You can control automatic migration processing by scheduling the command to run with the appropriate options. You can also manually start migration processing by running the command from the command line.

After a migrated table is successfully loaded into the System Migration application group, the table is deleted from the database. However, OnDemand keeps track of all migrated tables. That way, if index data in a migrated table is needed, then OnDemand can alert an administrator to take action (such as manually import the table back into the database).

**How to migrate indexes**

You can control automatic migration processing by scheduling the STRDSMOND command to run with the appropriate options. You can also manually start migration processing by running the STRDSMOND command from the command line.

When the STRDSMOND command migrates indexes, it saves the following messages in the System Log. A set of three messages should be saved in the System Log for each table that is migrated from the database to archive storage:

166 ApplGrp Segment Export (ApplGrp) (Segment)
14 DB Info Exported (SQL Code)
87 ApplGrp Load (System Migration)
The first message identifies a table of application group index data that is to be migrated from the database to archive storage. The second message reports the status of exporting the table from the database to temporary storage. The third message reports the loading of information about the migrated table into the System Migration application group. The System Migration application group must be assigned to a storage set that identifies an archive storage media type (such as optical or tape).
Chapter 3. Migrating and importing index data

Index migration is the process by which OnDemand moves index data from the database to archive storage. This process optimizes database storage space while allowing you to maintain index data for a very long time. You typically migrate index data after users no longer need to access the information, but for legal or other business requirements, you still need to maintain the data for some number of years. If a user queries index data that has been migrated, an administrator must import a copy of the migrated table into the database. After maintaining the imported table in the database for a specified number of days, OnDemand deletes it from the database.

This section provides information about importing index data into the database, including what happens when a user queries for migrated data, how to import the index table or tables required by the query, and what happens after you import a table into the database.

IBM assumes that an experienced OnDemand administrator will use the information provided in this section. If you have questions about any of the topics in this section or if you would like help configuring your system to support migrating and importing of index data, please contact the IBM support center.

In general, migrating index data is not recommended.

Configuring the system

There are a number of things you should consider regarding system configuration before you make any decisions about index migration.

System Log messages

OnDemand provides the System Log for administrators to monitor the system. When you install and configure OnDemand, you initialize the System Log tables. The System Log is critical to the operation of the system.

When OnDemand processes a query for application group indexes that have been migrated to archive storage, it saves a message in the System Log and sends a message to the System Log user exit program. A message is also sent to the QSYSOPR message queue.

You can configure the system to examine the messages that OnDemand sends to the System Log user exit and mail them to an administrator or send them to another program. You can also configure the System Log user exit program to determine what action to take when a user queries for data that has been migrated to archive storage. See Appendix B, “System log messages,” on page 147 for more information and a list of the most common System Log messages.

System Log user exit program

When a client queries index data that has been migrated to archive storage, OnDemand saves message number 168 ApplGrp Segment Not Available in the System Log. OnDemand also sends the message to the System Log user exit program. If you have defined your own System Log user exit program, then you can determine the action to take when OnDemand sends the message to the
System Log user exit program. For example, you may want the program to notify an administrator that a request for a table of migrated index data has occurred. Please see the IBM Content Manager OnDemand for iSeries Common Server Planning and Installation Guide for more information about the System Log user exit program.

**Archive Storage Manager**

Before OnDemand can migrate index data to archive storage, you must configure a migration policy with the information that the archive storage manager uses to maintain the data. The migration policy should maintain the data indefinitely. If you need the system to maintain a backup copy of the index data, then you should specify this in the migration policy.

**Storage sets**

OnDemand uses the System Migration application group to manage all index data that is migrated to archive storage. You must assign the System Migration application group to a storage set that identifies an archive storage media type.

**Application groups**

When you define an application group, you specify the storage management information that determines how long OnDemand maintains data stored in the application group and when OnDemand takes certain actions. For example:

- Life of Data and Indexes. Determines the length of time that OnDemand maintains index data and report data stored in the application group.
- Migration of Indexes. Determines the number of days before OnDemand moves index data from the database to archive storage.

You should plan to migrate index data only after users no longer need to access the reports to which it refers. Only in exceptional situations should users need to access index data that has been migrated. If a user needs to access index data that has been migrated to archive media, the process of importing the table back into the database requires manual actions by an administrator, and usually results in a significant delay in completing the query. The import process also requires additional space in the database to hold the imported tables, additional log file storage, and temporary storage on the server to run the import process.

- Keep Imported Migrated Indexes. Determines how long that OnDemand maintains the imported index data in the database before it is scheduled for deletion.

If you need to maintain index data in archive storage, then you must configure the Migration of Indexes in your application groups. You must specify the number of days to keep the index data on disk in Keep Imported Migrated Indexes. OnDemand will schedule imported index data for deletion from the database after it resides in the database for the number of days specified in Keep Imported Migrated Indexes or Life of Data and Indexes, whichever occurs first.

You can use the administrative client to configure your application groups.

---

**What happens when a user queries migrated data**

There are several ways to be notified when a user requests queries migrated index data.
Message to the user
When the server determines that the index data required to complete a query has been migrated to archive storage, it sends a message to the client program. The message states that the data required to complete the query is not available and that the user should contact an administrator.

Message to the System Log
When OnDemand determines that the index data required to complete a query has been migrated to archive storage, it saves a message in the System Log. An administrator can open the System Log folder to search for and display messages in the System Log.

OnDemand also sends a message to the QSYSOPR message queue and the System Log user exit program. You can configure the system to examine the message and send an alert to an administrator or call another program to take some action. See Appendix B, “System log messages,” on page 147 for more information and a list of the most common System Log messages.

Importing index data
If index data is to be imported back from archive media, it is important to consider the following:

Verify database storage space
Importing migrated index data from archive storage back into the database requires additional database storage. Before you import the index data, you should verify that sufficient free space is available.

Verify database log file space
Importing migrated index data from archive storage back into the database requires database journal storage. Before you import the index data, you should verify that sufficient free space is available.

Run the STRIMPOND command
OnDemand provides the STRIMPOND command to import tables of migrated index data from archive storage back into the database. (The name of the application group and the index table to import can be obtained from the message that OnDemand saved in the System Log.)

After the STRIMPOND command completes the import operation, you can open the System Log folder to see the messages that were generated by the import process. The messages will reference the ARSADMIN program name. See Appendix B, “System log messages,” on page 147 for more information and a list of the most common System Log messages.

See online help for more information about the STRIMPOND command and its parameters.

After you import index data
After you import index data from archive storage back into the database, you should notify the user to retry the query.
Expiring imported migrated indexes

OnDemand schedules an imported index table for deletion after it resides in the database for the number of days specified in the Length of Time to Keep Imported Indexes property in application groups. After an imported index data reaches the specified value, the next time that the STRDSMOND command runs, the imported index table is deleted from the database. (However, the table still exists in archive storage.)

You typically configure the STRDSMOND command to run automatically on a regular schedule. You can also run the STRDSMOND command manually.

Configuring index migration

If you find that your users are often querying for index data that has been migrated to archive storage, then IBM recommends that you configure your application groups to increase the length of time that OnDemand maintains the index data in the database. This should reduce the number of queries that need migrated index data.

Keeping imported migrated indexes

OnDemand schedules imported index data for deletion after the index data resides in the database for the number of days specified in Keep Imported Migrated Indexes or Life of Data and Indexes, whichever occurs first.
Part 2. Storage administration

This part is of primary interest to administrators responsible for configuring and maintaining disk and archive storage. This part is organized as follows:

- Document storage
- Backup and recovery
Chapter 4. Document storage

This section is organized as follows:

- Defining document storage management
- Migrating documents
- Removing documents

Defining document storage management

The document storage management definitions determine where and when OnDemand stores documents and how it maintains them.

When you load a document into OnDemand, you assign it to an application group. The application group is the last document storage management component that you define, because it requires storage set and migration policy definitions, which you must create first. The application group identifies the storage set and determines where documents should be loaded. You assign each application group to a storage set. You can load documents onto disk, onto archive media, or onto both disk storage and archive storage. The disk storage manager maintains documents on disk. The archive storage manager maintains documents on archive media. The archive storage manager uses a migration policy to determine where to store documents and how long to maintain them. After a document ages for the specified number of days, the migration process can move it from disk to archive storage.

Application groups

The application group is the last component that you must define because it requires storage set and migration policy definitions. The application group provides a way to group related documents. All documents in the application group are loaded on the media that is part of the storage set to which the application group is assigned. All documents in the application group migrate according to the rules that are defined for the application group’s migration policy.

Use the administrative client to create the application groups that determine the document storage for your documents. You typically define one application group for each set of your documents that have similar storage requirements. For example, documents that must be retained for a specific length of time, in specific storage locations and stored on specific types of media.

Loading

An application group definition contains the rules for loading documents into an application group. It requires one or more storage sets, which you must create first. The application group determines if documents are loaded onto disk, archive storage, or both. If the application group causes documents to be stored only on disk, then the migration policy specifies when (or if) documents are copied to archive storage.

See the following properties on the Storage Management tab of the application group:

- Storage Set Name. Determines where documents will be loaded.
Note: If you specify Cache Only, documents can only be loaded onto disk. This value cannot be changed later, so carefully consider possible future requirements before you select Cache Only. Unless you are certain that you will never want to migrate the data for this application group from disk (cache), a better choice might be to create your own migration policy or select another storage set from the pulldown list. Your new migration policy/storage set (like the alternative one that is shipped with OnDemand) could be defined to use ASP01 (the system Auxiliary Storage Pool on disk on your iSeries system) as the first level of storage, and then later optical or tape could be added.

- Cache Data. Determines if documents will be loaded into disk storage.

Note: If the storage set is a cache-only storage set, documents must be loaded onto disk. For this reason, you cannot select No for Cache Data if the storage set is cache-only.

- Migrate Data from Cache (on the Advanced panel). If you specify When Data is Loaded, then documents will be loaded into archive storage. (Migration is disabled for the application group.)

Migrating

Migration is the process of copying documents from disk to archive storage as controlled by the rules of the application group’s migration policy. However, because a document is eligible to be migrated does not mean that it will be migrated. Other factors affect migration, such as the frequency with which you run migration processing (migration cannot take place until you run migration processing).

A migration policy contains the rules for migrating the documents in an application group. The Storage Management tab defines how long a document stays on disk and, through the storage set and migration policy, where the document will be moved next. The migration policy level identifies the next location.

See the following settings on the Storage Management tab:

- Storage Set Name. Determines the next location for documents.

  Note: If you specify Cache Only, then migration is disabled for the application group.

- Migrate Data From Cache. Determines when documents are eligible to be migrated.

  Note: If you specify No or When Data is Loaded, then migration is disabled for the application group.

Disk storage manager

The Disk Storage Manager (DSM; initiated using the STRDSMOND command) maintains documents on disk. Documents migrate from disk storage to archive storage based on the migration policy that is defined for the application group. The disk storage manager can delete documents after they exceed the Cache Data for n Days or Life of Data, whichever occurs first. See "Removing documents” on page 19 for more information.
Archive storage manager

The Archive Storage Manager (ASM; initiated using the STRASMOND command) is the interface to the archive media (typically optical or tape). The archive storage manager maintains a backup or long-term copy of documents. Before loading documents, you must define storage sets and migration policies, optical volumes, tape devices, and tape volumes. The archive storage manager can delete documents after they exceed the retention period specified in the migration policy levels and reach the expiration level. See “Removing documents” on page 19 for more information.

Migrating documents

OnDemand provides automatic migration to copy documents from disk storage to archive storage (for documents that were not copied to archive storage during the load process) and to make documents eligible for deletion to maintain free space on disk. Automatic migration is provided using the Start Disk Storage Management (STRDSMOND) and Start Archived Storage Management (STRASMOND) commands. Migration helps to ensure that there is sufficient free space on disk, where faster response time can provide the most benefit to your users.

Important:

1. You should run migration processing on a regular schedule to make sure that a backup copy of your documents gets created as soon as practically possible. If you defer the migration of documents to archive storage, and disk storage were to become corrupted, then you could be left without a copy of your documents.

2. The STRASMOND command must only be run in batch (SBMJOB parameter set to *YES). Running this command interactively (with SBMJOB(*NO)) may cause SQL errors.

3. Loading data (ADDRPTOND, STRMONOND, arload, arsdoc add) can be done while running the Archive Storage Management (STRASMOND) command, but loading data is not recommended while the Disk Storage Management (STRDSMOND) command is running. Further, running DSM and ASM at the same time should not cause a problem, although most often you will run STRDSMOND with the Run ASM parameter set to *YES, which will cause ASM to run after DSM completes.

4. By default, the QUSROND default instance is used, and will produce the desired results for most systems. If you need to run the STRASMOND command for multiple instances, you must issue the command separately for each instance. Note that if you initiate the archive storage manager by running the STRDSMOND command with RUNASM(*YES), then the instance name is passed from the disk storage manager and no further specifications are needed.

5. If you run STRDSMOND for a specific application group (rather than the default of *ALL) and you set the Run ASM (RUNASM) parameter to *YES, be aware that ASM will run for all application groups, even though you have named a specific application group for DSM to use. You can, however, name a specific Policy for ASM to process, if desired. Also note that when you specify RUNASM(*YES), OnDemand will initiate a separate batch job for ASM.

6. If you specify Cache Data for 90 Days on the Storage Management tab within the application group, DSM will keep the data in the i5/OS IFS directory for 90 days after the report date (a segment field) before it removes the data from the IFS CACHE directory. Important: If the data has not been sent to ASM and the Cache Data for xx Days has been reached, the data will be lost. The expiration and migration information is set at the time the data is archived and cannot be
changed. To determine when data is sent to ASM, select the Advanced button on the Storage Manager tab within the Application Group. Remember, the Life of Data and Indexes should be the total of Cache Data days from the application group and the sum of the Duration at this level for all levels of the Migration Policy that is used for this application group. For example, the value for Cache Data days is 90 days, the Migration Policy for this application group has two levels, 100 days at the diskpool level and 7 years at the optical level so the Life of Data and Indexes value should be set to 2745 days.

Data is passed to ASM based on the criteria specified within the Migrate Data from Cache section on the Advanced panel of the Storage Management tab:

- **No** Data is never passed to the archive media.
- **When Data is Loaded** Archive objects will be passed to ASM when the store process runs from one of the load processes such as ADDRTOND, STRMONOND, arsload, arsdoc add.
- **Next Cache Migration** Archived objects will be passed to ASM the next time STRDSMOND is run.
- **After xx Days in Cache** Archived objects will be passed to ASM after xx days and when STRDSMOND is run. **Note:** After the data is sent to ASM and has entered a level as specified in the migration policy, the number of days at that level cannot be changed for that particular data. If you change any of these values in the migration policy, only newly archived documents will be affected. All previously archived documents are unaffected.

You control automatic migration processing by scheduling the STRDSMOND and STRASMOND commands to run with the appropriate options. See your operating system information for details about how to schedule tasks. You can also start migration processing by running the command manually.

The STRDSMOND command uses an application group’s storage management information to control when movement of data for an application group occurs:

- If you use **Next Cache Migration** to control when migration for an application group occurs, then the disk storage manager runs migration processing each time that you start the STRDSMOND command with the appropriate options.
- If you use **After n Days in Cache** to control when migration for an application group occurs, then a document must be stored on disk for at least the specified number of days before it is eligible to be migrated.

The disk space that migrated documents occupy can be reused after expiration processing completes. When you run migration processing, you should also run expiration processing so that the disk storage manager can reclaim the disk storage space occupied by migrated documents.

**Migration processing in the system log**

When you run the STRDSMOND command, it saves messages about its activities in the system log. The types of messages saved in the system log depend on the options that you specify when you run the STRDSMOND command and can be found by searching on user ARSMAINT for the time period that STRDSMOND was running. The number of messages saved in the system log during a migration process depend on the options that you specify for the STRDSMOND command,
the number of application groups and segments of data processed. While it may be possible to run multiple STRDSMOND commands for different application groups within the same instance or different instances, it is not recommended. Table 1 lists the messages you could see in the system log following migration processing.

Table 1. Messages from the STRDSMOND command in the OnDemand System Log

<table>
<thead>
<tr>
<th>Message Number</th>
<th>Message Information</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>110 Cache Migration</td>
<td>(Date) (Server)</td>
<td>About to begin disk migration on the specified server.</td>
</tr>
<tr>
<td>197 Cache Migration</td>
<td>(ApplGrp) (ObjName) (Server)</td>
<td>One of these messages for each storage object migrated to archive storage. Migration copies a storage object if its &quot;After n Days in Cache&quot; period has passed or the application group uses the &quot;Next Cache Migration&quot; migration method.</td>
</tr>
<tr>
<td>124 Filesystem Statistics</td>
<td>(% full) (server)</td>
<td>One of these messages each time you run the STRDSMOND command. Message is Informational only, to report the percentage of space used in the system auxiliary storage pool (ASP).</td>
</tr>
</tbody>
</table>

Removing documents

Documents expire (are eligible for removal) because their disk expiration date or archive retention period has passed. Expired documents can then be removed by the storage managers. The disk storage manager identifies documents for removal by using the application group’s expiration information. The archive storage manager marks documents for removal based on the criteria defined in the migration policy.

Documents expire from disk when they reach their disk expiration date. If a document’s disk expiration date is less than its Life of Data period, then the document is simply removed from disk storage. Subsequent requests for the document are satisfied by the archive storage manager. When the document reaches its Life of Data period, information about it is removed from the OnDemand database (the document can no longer be retrieved). When the document’s archive retention period has passed, information about it is removed from the archive storage manager database.

Because a document is eligible to be removed does not mean that it will be deleted from storage. The disk storage manager does not delete expired documents from storage until expiration processing runs. During expiration processing, the archive storage manager deletes information about expired documents from its database. However, the actual documents may remain on archive media until such time that the media on which they reside is reinitialized.

Important: The disk storage manager and the archive storage manager delete documents independently of each other. Each uses its own criteria to determine when documents expire and should be removed from the system. Each uses its own utilities to remove documents. However, for final removal of documents from the system, you should specify the same criteria to the disk storage manager and the archive storage manager. In other words, the sum of the Duration values for all migration policy storage levels plus the value for the Days in Cache should equal the Life of Data and Indexes value in the application group.
Removing documents from disk storage

The options specified on the Storage Management tab when the application group is created determines when documents are eligible for deletion from disk. The options on the Storage Management tab are as follows:

- **Cache Data for n Days.** The length of time in days to keep documents on disk. After a document reaches this value, it is eligible to be deleted from disk.
- **Life of Data.** The length of time in days to maintain documents on the system.

**Note:** If you specify Never Expire, then expiration processing is disabled for the application group.

- **Expiration Type.** Determines whether one or more documents are eligible to be deleted at a time. For example, by default, the Load expiration type means that the set of documents that were loaded together will also expire together.

**Note:** Segment (in contrast to Load) is another possible choice for expiration type. This is the first time that a segment has been mentioned. Up to now, the term documents has been used, which is the data object that most people associate with the OnDemand system. However, administrators who maintain the system may also work with segments, which represent many documents, and storage objects, which are containers of compressed documents that are maintained by the storage managers.

The disk storage manager does not delete expired documents from disk until expiration processing runs. The STRDSMOND command is the expiration utility. You can schedule the STRDSMOND command to run automatically or you can run it manually. You should make sure that the STRDSMOND command runs periodically so that the disk storage manager can reclaim the space that is occupied by expired documents.

Expiration processing in the system log

When you run the STRDSMOND command, it saves messages about its activities in the system log. These messages can be found by searching on user ARSMAINT for the time period that STRDSMOND was running. The types of messages saved in the system log depend on the options that you specify when you run the STRDSMOND command. The number of messages saved in the system log each time that expiration processing runs depends on the options that you specify for the STRDSMOND command and the number of application groups and segments of data processed. [Table 2] lists the messages you could see in the system log following expiration processing.

**Table 2. Messages from the STRDSMOND command in the OnDemand System Log**

<table>
<thead>
<tr>
<th>Message Number</th>
<th>Message Information</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>109 Cache Expiration</td>
<td>(Date) (Min%) (Max%) (Server)</td>
<td>About to begin disk expiration processing on the specified server.</td>
</tr>
<tr>
<td>196 Cache Migration</td>
<td>(ApplGrp) (ObjName) (Server)</td>
<td>One of these messages for each storage object deleted from disk. A storage object is eligible to be deleted when its &quot;Cache Data for n Days&quot; or &quot;Life of Data&quot; period has passed, whichever occurs first.</td>
</tr>
</tbody>
</table>
Table 2. Messages from the STRDSMOND command in the OnDemand System Log (continued)

<table>
<thead>
<tr>
<th>Message Number</th>
<th>Message Information</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>124 Filesystem Statistics (filesystem) (% full) (Server)</td>
<td>One of these messages each time you run the STRDSMOND command. Message is Informational only, to report the percentage of space used in the system auxiliary storage pool (ASP).</td>
<td></td>
</tr>
</tbody>
</table>

**Important:** In addition to the messages listed in Table 2 on page 20, you should monitor the system log every day for messages that indicate that your disk space is becoming full. The STRDSMOND command automatically saves a message in the system log when the amount of space used in a disk storage file system exceeds a threshold. The threshold is 90%.

### Removing documents from archive storage

**Note:** Removing a document from archive storage means that the backup or long-term copy of the document will be deleted from the system. You typically remove documents from archive storage when you no longer have a business or legal requirement to keep them.

A migration policy specifies the criteria that makes a document eligible for deletion. Documents become eligible for deletion under the following conditions:

- Administrators delete documents from archive media (using the Remove Report from OnDemand (RMVRPTOND) command)
- An archived document exceeds the time criteria defined in the migration policy (processed by the Start Archived Storage Management (STRASMOND) command)

The archive storage manager does not delete information about expired documents from its database until expiration processing runs. You can run expiration processing either automatically or manually using the STRASMOND command (or you can use the STRDSMOND command with the Run ASM parameter set to *YES). You should make sure that expiration processing runs periodically to allow the archive storage manager to reuse storage space that is occupied by expired documents. When expiration processing runs, the archive storage manager deletes documents from its database. The storage space that these documents occupy then may become reusable.
Chapter 5. Backup and recovery

It is important to implement a backup plan that will serve to protect your data archives in the event your organization experiences a disaster, large or small. You need to have a plan and prepare so that you can recover.

Backup considerations

Items you need to consider when planning your regular backups include:

- How to recover the optical or tape media itself
  
  You should consider having a copy of the media stored at an offsite location.

- How to recover the data on disk
  
  You should have procedures in place that backup all of the OnDemand data that normally resides on disk, as well as any stored data that has not yet migrated to optical or tape.

Remember: Disk backups will contain database files that reflect the actual archive data location and status at the time of backup. DO NOT restore from a backup that is one week old. Archived data might have migrated to optical or tape, but database control files identify incorrectly the archived data location as disk. In order to minimize this situation, you should save your database library(s) and save your OnDemand Integrated File System directories on the same schedule to keep them synchronized. Perform the backups at least as frequently as you run the disk storage management (STRDSMOND) or archive storage management (STRASMOND) commands. (Possibly even more frequently if you often manually delete reports that are stored in OnDemand.)

The following objects need to be saved by the appropriate i5/OS commands:

- The OnDemand licensed program (5722-RD1)

- User profiles QRDARS400, QRDARS4001, QRDARS4002, QRDARS4003, QRDARS4004, QRDARS4005, QONDADM, and QRDARSADM, and one for each instance that exists (which has the same name as the instance)

- Authorization lists QRDARS400, QONDADM, QRDARSADM, and one for each instance that exists (which has the same name as the instance)

- All objects in QUSRRDARS library

- All objects in any other libraries that contain data for your OnDemand instances. For example, the QUSROND library if you are using the default QUSROND instance, or any other library by the name of any other instance on your system.

- Output queues that are being monitored, as well as any output queues that are being used as processed queues or error queues for your monitors.

  These output queues can contain OnDemand processed spooled files. Saving the output queues does not save the data in them. There is no save command to save spooled files.

- Integrated File System directories

  Each instance that is created in OnDemand has an Integrated File System directory that is named the same as the instance. To backup only the OnDemand data that resides on disk, you could backup all items that are found in the Integrated File System directory /QIBM/UserData/OnDemand/<instance>
where <instance> is the name of your OnDemand instance. Remember that the name of the default instance is QUSROND.

Attention: OnDemand Common Server migration policies allow you to specify a disk pool as one of the possible storage levels (as an alternative to optical or tape media, for example). If you use disk pools in any of your migration policy storage levels, the simplest approach to make sure that the data in the disk pool is saved and restored properly for an instance is to do the following:

To perform the save:
1. Unmount the file system CALL QRDARS/QRLCASMUFs PARM('QUSROND')
2. Save the directory structure /dev/QASP01/ONDEMAND_QUSROND*
3. Save the directory structure /QIBM/UserData/OnDemand/QUSROND

To perform the restore, if necessary:
1. Unmount the file system CALL QRDARS/QRLCASMUFs PARM('QUSROND')
2. Restore the directory structure /dev/QASP01/ONDEMAND_QUSROND*
3. Restore the directory structure /QIBM/UserData/OnDemand/QUSROND

Note that the instance name (such as the default QUSROND instance in the example) and Auxiliary Storage Pool name (such as ASP01 in the example) must be changed to match your actual environment.

* Integrated File System directories for OnDemand Web Enablement Kit (ODWEK)*

If you have implemented ODWEK, you should also backup all items that are found in the Integrated File System directory /QIBM/UserData/OnDemand/WWW.

* Symbolic links* in IFS directory /usr/bin that start with ARS
* Configuration files*

See Chapters 8 and 9 of the *IBM Content Manager OnDemand for iSeries Common Server Planning and Installation Guide* for more information and a list of configuration files.

---

**Recovery considerations**

Contact your OnDemand support provider for instructions on recovering your OnDemand archives in the event of a disaster. Many factors can influence the recovery plan, depending on the frequency and extent of the backups you have available.

---

**Reports**

OnDemand can store copies of reports and resources on disk storage and archive storage:

* The primary purpose of disk storage is short-term, high-speed storage and retrieval of reports.
* The primary purpose of archive storage is long-term storage and retrieval of reports. The reports in archive storage can also be used as backup copies in the event that disk storage becomes corrupted or unavailable. Archive storage consists of optical or tape storage volumes.

Most customers configure the system to copy reports to disk storage and archive media at the same time, when they load a report into the system.

OnDemand can retrieve a copy of a report from archive storage after the report has been deleted from disk storage or if the copy on disk storage is unavailable.
However, you must configure the system to maintain multiple copies of reports. You configure OnDemand to use archive storage by defining migration policies and storage sets that identify archive storage, assigning application groups to the storage sets, and configuring other storage management parameters in application groups.

**Note:** If you do not plan to copy reports to archive storage, then we recommend that you take regular backups of the data on disk. However, if a media failure occurs or disk storage becomes corrupted, users cannot retrieve reports until the backups are restored.
Part 3. Using iSeries Navigator for OnDemand administration

This part contains information about using iSeries Navigator to define and maintain objects on the system. For example, you can use iSeries Navigator to define reports to OnDemand and maintain OnDemand users, groups, printers, storage sets and migration policies.

This part describes a typical system, including requirements about users of the system and data to be loaded on the system, and contains examples and ideas about how to implement the requirements. This part is organized in roughly the order that you define your first report to OnDemand. This part starts with adding users and groups to the system, shows how to define a printer, and then moves into procedures for adding a migration policy and storage set. Later chapters provide detailed instructions about defining a report: adding an application group, an application, and a folder.
Chapter 6. Installation

This section describes the hardware, software, memory, and disk space requirements for installing and using the administrative client.

Hardware

The administrative client requires the following hardware:

- Pentium® or Pentium compatible 800 MHz or faster processor
- A super-VGA display and adapter with a minimum resolution of 800x600
- Physical connection to the network, such as a Token Ring or Ethernet network adapter
- A CD-ROM drive for installation (optional, if you plan to install the administrative client from a network file server)

Software

To install or use the administrative client, you must be running Windows 2000, Windows XP, or Windows Server 2003 on your computer. To install the administrative client from a CD-ROM, the CD-ROM drivers must be installed on your computer. To install the administrative client from a network file server, the appropriate network software must be running on your computer. To connect to an OnDemand server, the standard TCP/IP support for the Windows operating system must be running on your computer.

To use the iSeries Navigator interface to the OnDemand Administrator and for additional OnDemand administrative functions, you must install the iSeries Navigator OnDemand Administrative Functions component within iSeries Access Express. IBM recommends that you apply the most current service pack for iSeries Access Express, if one is available.

Memory

The administrative client requires a PC with at least 256 MB of memory (RAM). Your PC may need more memory if you run more than one application at the same time.

Disk space

To install OnDemand clients, disk space requirements depend on the features that you select.

You need at least 100 MB of free disk space to install all of the OnDemand features. To install only the software required for the administrative client in a single language, you need at least 50 MB of available disk space.

For more information on disk space requirements for each OnDemand feature, follow these steps:

1. Run the Setup program for the OnDemand client software.
2. Read and accept the license agreement.
3. Select the Custom setup type.
4. The summary information lists the disk space requirements for the features that you selected.

**Installing the iSeries Navigator interface to OnDemand**

To use the OnDemand Archive component (also known as plug-in) of iSeries Navigator, you must install iSeries Access Express Version 5 Release 4 on your Windows workstation. Refer to the iSeries Access Express installation documentation for detailed information on installing iSeries Access Express and iSeries Navigator.

The OnDemand Archive component of iSeries Navigator is required to work with:
- Migration Policies
- Monitor Definitions
- Optical Storage Groups
- Optical Volumes
- Tape Devices
- Tape Volumes
- Disk Pool Storage Groups (ASPs)

The Install Plug-in option of iSeries Navigator can be used to install the OnDemand Archive function. Follow the instructions below to perform the installation:
- Open iSeries Navigator using Start, Programs, iSeries Access Express, and iSeries Navigator or use the iSeries Navigator icon that may appear on your Windows desktop.
- Select Install Plug-ins.
- Select the Server from which you want to install the OnDemand for iSeries Archive plug-in.
- Log on to the server.
- A list of the available iSeries plug-ins will be gathered and displayed.
- Select the OnDemand for iSeries Administrative Functions.
- Select Next twice to continue.
- Select Finished to complete installation.

**Installing the administrative client**

The Setup program installs the OnDemand client software on the PC. **Note:** If you receive a CD-ROM that contains Client software at a level below 7.1.0.4, you must update the Administrator Client software from the Internet to the 7.1.0.4 level or higher. To download the OnDemand Clients, go to the internet FTP web site at ftp://service.software.ibm.com/software/ondemand/fixes/.

You can install all of the OnDemand features at once, or individual features as you need them.

**Running Setup**

When you run the Setup program, the Setup screens show the names of the OnDemand directories so you know where the files are being placed.

Information about network installations is available in the *IBM Content Manager OnDemand: Windows Client Customization Guide*. 
To install on a PC
To install from the CD-ROM or to install from a network file server, follow these instructions:
1. Insert the CD-ROM in the appropriate drive or obtain the drive letter of the network drive on which the OnDemand software is located on the network file server.
2. From the Windows taskbar, click Start, and then choose Run.
3. Type x:\client\win32\setup (where x is the letter of your CD-ROM drive or the network drive).
4. Click OK.
5. After the Setup program starts, click Next to continue.
6. Read and accept the license agreement, and then click Next to continue.
7. Click Next to accept the destination drive and directory, or specify a destination and then click Next.
8. Select the Custom setup type and then click Next to continue.
9. Select OnDemand Administrator and select your language. (You can also select other components that you want to install on the PC at this time.)
10. Click Next to continue. Follow the instructions on the screen to complete the installation.

To install on a network file server
Information about network installations is available in the IBM Content Manager OnDemand: Windows Client Customization Guide.

To use automated install
Automated install allows administrators to standardize the OnDemand installation for all users in an organization. It also allows administrators to install OnDemand clients without the presence of users at their PCs. To read more about automated install, see the IBM Content Manager OnDemand: Windows Client Customization Guide.

To uninstall
You can use Add/Remove Programs in Control Panel to remove the OnDemand client from your PC. Add/Remove Programs removes the directories for OnDemand and any references to OnDemand in system files.

To run the uninstall
1. From the Windows taskbar, click Start. Choose Settings, and then choose Control Panel.
2. Double-click Add/Remove Programs.
3. From the list, select OnDemand32.
4. Click Add/Remove.
5. Click OK.
Chapter 7. Introduction

The administrative functions in OnDemand are set up using iSeries Navigator and the OnDemand Administrator, and include:

- Defining reports to the system
- Adding and maintaining OnDemand users and groups
- Adding and maintaining server printers
- Maintaining storage sets and migration policies
- Creating summaries about users, groups, applications, application groups, storage sets, folders, and printers
- Adding and maintaining servers
- Setting system parameters for OnDemand servers and client programs
- Copying items from one OnDemand server to another
- Tracking changes made to the system. When you use the iSeries Navigator to add or update the database, OnDemand places a document in the system log which shows the changes that you made.

The following is a list of the administrative items that are maintained directly through iSeries Navigator:

- Tape devices
- Tape volumes
- Optical storage groups
- Optical volumes
- Disk pool storage groups
- Monitor definitions
- Migration policies

The items that are maintained through the OnDemand Administrator are:

- Users
- Groups
- Applications
- Application groups
- Storage sets
- Folders
- Printers

The OnDemand Administrator is launched by right-clicking on Common Server Administration within the OnDemand Archive section of iSeries Navigator. From the resulting pop-up menu, click Client Administrative Functions to launch the OnDemand Administrator.

Getting started

- You can collapse and expand areas in the navigator pane (on the left) to make it easier to see. A plus sign next to an area means there are items inside.
- When you click on an area in the navigator pane, the items appear in the list pane (on the right).
• To make the panes narrower or wider, point to the vertical bar between the two panes of the window until the pointer turns into a two-headed arrow. Then click and hold the left mouse button and drag it in either direction.
• Use buttons on the toolbar to switch between the different ways to look at items: large or small icons, a list, or details.
• To query the server for a new list of items, press the F5 key or select Refresh List from the View menu.
• After you log on to a server, the status bar shows the OnDemand userid and the name and version number of the OnDemand server.

Using online help
Online help provides information to assist you with completing tasks. The administrative client online help contains information about the options, fields, and commands on the windows, dialog boxes, and property sheets that you see when using the program.

To display the online help, press F1 any time that the administrative client is active in Windows. Help is available for dialog box commands and options. The main help topic for each dialog box usually contains information about the kinds of tasks you can perform. For example, the online help about Logical Views lets you learn how to create public and private logical views. The online help provides brief procedures rather than lengthy descriptions.

Adding a server
You can use the New Server command to add a server.
1. In the OnDemand section of iSeries Navigator, right click Common Server Administration. In the resulting context menu, click Client Administrative Functions, then logon.
2. Click once on OnDemand Servers at the top of the list of servers in the left panel of the OnDemand Administrator.
3. From the File menu, select New Server to open the Add a Server dialog box.
4. Type the name of the server in the Server field. The server name identifies the server in the navigator pane of the administrator window. You can use an alias, the actual computer or network name of the server, or any other identifier you choose. By default, the administrative client copies what you type to the Host Name field.
5. Verify the value of the Host Name field. (By default, the Host Name field contains the same value as the Server field.) The host name can be a host name alias, fully-qualified host name, or IP address of the server.
6. Verify the Protocol. Choose from TCP/IP or Local:
   • TCP/IP. Use TCP/IP (Transmission Control Protocol/Internet Protocol) as the network protocol. To use TCP/IP, the server and the client must include TCP/IP in the protocol stack.
   • Local. Use the local file system manager to communicate with the server. This is most often used when your archived data is on a CD-ROM.
7. For TCP/IP, verify the Port Number that the server monitors for client program requests.
   The default value, 0 (zero), means that the server monitors the port number of the OnDemand TCP/IP service. By default, the server monitors port number 1445. If you plan to use a port number other than 1445, then you must enter a valid port number. If you have more than one instance defined to OnDemand, then you would have separate server definitions for every instance with
unique port numbers for each instance. The value range is from 0 to 65535. To see what ports are currently in use on your system, enter the Work with TCP/IP Network Status (WRKTCPSTS) command with OPTION(*CNN).

8. You should clear the Attempt Unified Logon check box. (Unified Logon is used only for Windows servers.)

9. If you are adding a Local server, specify a Directory and select an Operating System and a Database. See the online help for assistance.

10. Click OK to add the server.

Logging on a server

1. Point to the server and double click the left mouse button to open the Logon dialog box.

2. Enter your OnDemand userid and password in the spaces provided and click OK. **Note:** For a Local server, the built-in userid is admin; no password is assigned to the admin userid.

Changing passwords

**Note:** This section applies only if you are using OnDemand userids and passwords rather than i5/OS userids and passwords. See the IBM Content Manager OnDemand for iSeries Common Server Planning and Installation Guide section titled OnDemand user relationship to i5/OS user profiles for important information about passwords.

Changing a password

To change a user’s password:

1. Select and expand the library server.

2. Select Users.

3. In the User ID list, point to the userid and click the right mouse button.

4. From the pop-up menu, select Update to open the Update a User dialog box.

5. Type the new password in the Password field.

**Note:** When creating a password, the value that you specify can be a maximum of 20 characters. However, the password authentication that is built into OnDemand verifies only the first eight characters that are entered by the user. The additional characters are provided for customers that choose to implement their own password security by using the logon user exit.

6. Verify the new password by retyping it into the Verify Password field.

7. Click OK. OnDemand updates the database and returns to the main window.

Changing an expired password

OnDemand provides password expiration processing to help you manage security on the system. You can set a value that represents the time in days that passwords assigned to users remain valid. After a user’s password reaches the value that you specify, the user must change the password. See “System parameters” on page 36 for information about how OnDemand expires passwords.

After a password reaches the expiration value, the next time the userid is used to log on to a server, OnDemand prompts the user to enter a new password.
The user must enter the current password for the userid, a new password, and verify the new password by retyping the new password

System parameters

OnDemand system parameters allow you to establish the following operational settings for client programs and servers.

Maximum Password Age

Sets a time limit for passwords and determines when OnDemand prompts users to change passwords. The default setting is Password Never Expires, meaning that passwords do not expire and OnDemand never prompts users to change passwords. If you select Password Always Expires, then users must change to new passwords each time that they log on to a server. To set a specific time limit for passwords, select Expires In ___ Days and enter the number of days that passwords are valid in the space provided. The value can be from 1 (one) to 365.

If you are linking your OnDemand userids to i5/OS user profiles, then Maximum Password Age should be set to Password Never Expires. If you specify a value for Maximum Password Age, then OnDemand may force a user to change their password before it is required by i5/OS.

Minimum Password Length

Determines whether passwords are required. If passwords are required, also determines the fewest number of characters that passwords can contain. The default value is At Least 8 Characters.

If you select Permit Blank Password, meaning that passwords are not required, then the valid password length is 0 (zero) to 20 characters.

If you are linking your OnDemand userids to i5/OS user profiles, then Minimum Password Length should be set to Allow Blank Password. This prevents OnDemand from trying to impose its own rules on the length of a password and allows i5/OS to use its own rules.

To set a specific minimum password length, select At Least ___ Characters and enter a number in the space provided. The value can be from 1 (one) to 20 characters.

Note: When creating a password, the value that you specify can be a maximum of 20 characters. However, the password authentication that is built into OnDemand verifies only the first eight characters that are entered by the user. The additional characters are provided for customers that choose to implement their own password security by using the logon user exit. Contact the IBM support center for more information about the logon user exit.

Inactivity Time Out

Determines when OnDemand terminates sessions between inactive clients and the server. The default setting is Time Out in 60 Minutes. The value can be from 1 (one) to 1440 (24 hours).

The period of inactivity is measured between requests to a server. For example, when a user enters a query, OnDemand searches the database and builds the
document list. This completes a request to the server. If the user does not work with the items in the document list, open another folder, or invoke another query before the inactivity time out occurs, OnDemand automatically terminates the session with the client.

Use caution when you set the inactivity time out. For example, assume that you set the inactivity time out to 10 (ten). You log on to OnDemand to add an application group. Creating the application group takes you 15 minutes to complete. After entering all of the information about the application group, you click OK to create the application group. OnDemand issues a message that shows a time out has occurred. You must logoff the server, and you cannot save the information you entered about the application group.

**System Logging**

Determines the messages that OnDemand saves in the system log. OnDemand provides the system log to help you track activity and monitor the system. OnDemand saves messages that are generated by the various commands, such as the ADDRPTOND command. OnDemand can save a message in the system log when the following events occur:

- A user logs on to the system
- A user logs off the system
- A user logon fails
- Application group data is queried, retrieved, loaded, updated, deleted, or maintained

**User Exit Logging**

OnDemand provides a user exit at each of the four system log event points. These exits allow you to filter the messages that OnDemand saves in the system log and take action when a particular event occurs. For example, you can provide a user exit program that sends a message to a security administrator when someone attempts and fails to log on to the system. You can also use a user exit to determine what information appears in the system log.

If you plan to migrate index data to archive storage, then we recommend that you configure the system to save application group messages in the system log and send them to a system log user exit program. You should design a system log user exit program to notify an administrator when a query for migrated data occurs. Before a query for migrated data can be completed, an administrator must import a copy of the table or tables that are required from archive storage to the database.

See the *IBM Content Manager OnDemand for iSeries Common Server: Planning and Installation Guide* for help with configuring the system log user exit.

**Login Processing**

The login processing system parameters allow you to specify whether userid and passwords are case sensitive.

Before continuing with this section, please refer to the OnDemand userid relationship to i5/OS user profiles section in the *IBM Content Manager OnDemand for iSeries Common Server: Planning and Installation Guide* for a detailed explanation of the significance of choosing to relate your OnDemand users to existing i5/OS user profiles. It is important that you understand that concept before you make your choices for Login processing.
Now that you understand the relationship between OnDemand users and your i5/OS users, you should note the following:

- If your OnDemand userids are linked to your i5/OS user profiles (which is the default when OnDemand is installed), and if your i5/OS security level is set to 0 or 1, you SHOULD NOT check the Password Case Sensitive checkbox.
- If your OnDemand userids are linked to your i5/OS user profiles (which is the default), and if your i5/OS security level is set to 2 or 3, you SHOULD check the Password Case Sensitive checkbox.
- Regardless of your system security level, you should NEVER check the UserID Case Sensitive checkbox if your OnDemand users are linked to your i5/OS user profiles.
- If you are using OnDemand userids and passwords that are not linked to i5/OS user profiles (which is not the default), then you can set the two Login processing checkboxes as you choose.

By default, userids and passwords are case insensitive. When you add a user, OnDemand converts lowercase letters in the userid to uppercase. A person can type letters in a userid in uppercase, lowercase, or mixed case letters. For example, if you add the userid LaGuarde, a person can enter LAGUARDE, laguarde, or LaGuarde to log on to the server.

If you select UserID Case Sensitive, then a user must type the userid exactly as it was entered when the user was added. For example, if you add the userid LaGuarde, then the user must enter LaGuarde to log on to the server.

If you select Password Case Sensitive, then a user must type the password exactly as it was entered when the user was added. For example, if you set the password to Spring2Far, then the user must enter Spring2Far to log on to the system.

We strongly encourage you to decide whether you want userids and passwords to be case sensitive when you install the system, change the defaults if necessary, and do not change the settings again. Otherwise:

- If userids are initially case insensitive and you later choose UserID Case Sensitive, then userids that were added before you changed the parameter must be entered in uppercase. The same is true for passwords.
- If userids are initially case sensitive and you later clear UserID Case Sensitive, then the userids that were added before you changed the parameter that contain mixed or lowercase letters will no longer be valid. The same is true for passwords.

**Setting system parameters**

To set the system parameters for an OnDemand server:

1. Log on to the server.
2. Point to the server and click the right mouse button.
3. From the pop-up menu, select System Parameters to open the System Parameters dialog box. Figure 1 on page 39 shows an example of the System Parameters dialog box.
4. To change the Minimum Password Age, select the appropriate option. If you select Expires In, enter the number of days in the space provided.

5. To change the Minimum Password Length, select the appropriate option. If you select At Least, enter the number of characters in the space provided.

6. To change the Inactivity Time Out, select the appropriate option. If you select Time Out In, enter the number of minutes in the space provided.

7. To choose a System Logging, User Exit Logging, or Login Processing option, select the check box next to the item.

8. To generate a summary of the system parameters and display the information in a window where it can be viewed and printed, click Summary.

9. When you have finished making changes to the system parameters, click Update. OnDemand stores the changes in the database and returns to the administrator window. (Click Cancel to close the System Parameters dialog box without saving your changes.)

---

**Adding items to a server**

This section explains how to add items to a server. You can use commands or a drag-and-drop operation to add items to a server.

**Note:** When you use the administrative client to add or update the database, OnDemand adds a record to the system log that shows the changes you made.

**New command**

After logging on to a server, select the area, for example, Users. From the File menu, select the New command to open the Add dialog box.
Copy command

After logging on to a server, select the area. In the list pane, point to the item that you want to copy and click the right mouse button. From the pop-up menu, select Copy to open the Add dialog box. The fields in the Add dialog box contain information copied from the item you selected. Before you can add the item, you must change the item name. Depending on the item you want to add, you may need to change other fields.

Export command

The Export command is like the Copy command, except OnDemand adds the item to a different server. You can use the Export command to export items from the source server, and add (Import) them to the destination server.

After logging on to the server that contains the item you want to export, select the area. In the list pane, point to the item that you want to export and click the right mouse button. From the pop-up menu, select Export to open the Export dialog box. Verify the destination server. Then click Export to add the item to the server.

Notes:

- If the item exists on the destination server, the export fails.
- When exporting/importing an OnDemand application definition from one hardware platform to another (for example, from OnDemand for iSeries to OnDemand for Multiplatforms or the reverse), you must update the OnDemand application definition after the export to ensure that the correct indexer is named. An application definition being exported from an iSeries server may have "OS/400" selected for the Indexer value on the Indexer Information tab, which is not valid on any platform other than iSeries. Similarly, an application definition being imported to an iSeries server from CM OnDemand for Multiplatforms might have "ACIF" selected as the Indexer, which is not valid on the iSeries.

Drag and drop operation

You can copy and export items using a drag-and-drop operation. For example, to export items from one server and add them to another, select one or more items from the list pane and, while holding the left mouse button down, point to the destination server. Then release the mouse button. If you are logged on to the destination server, then OnDemand opens the Export dialog box. If you are not logged on to the destination server, then OnDemand opens the Logon dialog box. After verifying options in the Export dialog box, click Export to copy the items to the server.

Note: If the item exists on the destination server, the export fails.

You can also use a drag-and-drop operation to copy an item. For example, to copy a user, select the userid from the User ID list and, while holding the left mouse button down, point to the same server on which the user is listed. Then release the mouse button to open the Add dialog box.
Report Wizard

OnDemand provides user assistance and easy-to-use tools to help you administer OnDemand. The Report Wizard helps you add a report to OnDemand by asking questions, which allows you to progress in an organized manner toward completing an application group, application, and folder. Here are a few things to remember about the Report Wizard:

- You move through the Report Wizard by answering questions that appear on the screen.
- You can return to the previous screen at any time by clicking Previous.
- You can advance to the next screen at any time by clicking Next.
- You can advance to the final screen by clicking Finish. By choosing Finish, you permit the Report Wizard to make all remaining decisions for you.
- You can obtain online help for a screen at any time by clicking Help or pressing F1.

Important: The Report Wizard processes your own input files. You must select a sample input file to proceed. Then, the graphical indexer is invoked to allow you to mark the data to define your indexing parameters. The graphical indexer that is invoked through the Report Wizard is the same graphical tool that is invoked directly by selecting Sample Data and then clicking on the Modify button from the indexer information tab of an OnDemand application definition.

You can use the Report Wizard to add an application group, application, and folder for a selected report. These actions include defining indexing information, defining database and folder fields, configuring data and storage management, specifying whether the application group can contain more than one application, and naming the application group, application, and folder.

You can also use the Report Wizard to add an application to an existing application group. This action includes defining indexing information, specifying storage information, and identifying the application within the application group. To add an application to an application group, the application group must have a database field to hold the values that uniquely identify an application within the application group. The field must contain at least one unassigned application identifier. See the Field Information page in application groups for detailed information about application identifiers.

Starting the Report Wizard

From the administrative wizard, log on to the server to which you want to add the report.

- To define a new application group, application, and folder, click the Report Wizard icon on the toolbar.
- To add an application to an existing application group:
  - Under the server, select Application Groups
  - Select the name of the application group to which you want to add the application
  - Click the Report Wizard icon on the toolbar

Follow the on-screen instructions to add the report.
Using the Report Wizard

The screens in the Report Wizard are described below. On most screens, standard options will already be selected for you. Unless you have a clear reason not to, accept the defaults.

Note: Depending on how you use the Report Wizard, you may not see all of the screens described below.

Introduction screen
Provides a brief explanation of the Report Wizard (see Figure 2). First choose the data type of the report you are defining. Click Select Sample Data button to select a file that contains a sample of the actual report data. The Wizard lets you select a spooled file on the server (search by user profile or by output queue) and copies that sample data to your workstation for you to use for indexing.

![Report Wizard](image)

Figure 2. Report Wizard

When you click OK, the Report Wizard reads the data into the Report window.

Report window
Displays the sample data file and provides easy-to-use tools to help you define indexing information, database fields, and folder fields. Press F1 to display the online help for options and commands available from the Report window. Use the online help to learn how to define triggers, fields, and indexes, database fields, and folder fields.

Important: When you have finished defining the indexing, database, and folder information, be sure to save your changes when prompted.
Managing data screen
When you load a report into the system, you can specify that you want report data to be stored in Large Objects. You also need to specify how you want OnDemand to manage annotations that users attach to pages of the report.

Application identifier screen
When you use the Report Wizard to add an application to an existing application group, you must specify the name of the application and select a value that uniquely identifies the application within the application group.

Storage management screen
Determines where the storage manager maintains copies of reports, and how and when OnDemand deletes report data from the system.

Applications in the application group screen
If the report that you are defining is one of several that will be stored in the same application group, you can use the Report Wizard to define an application ID field. An application ID field is a database field that contains values that identify an application within the application group. IBM recommends that you always define an application ID field. See Figure 23 on page 88 for an example. You may not think that you need an application ID field at the time that you create your application group, if you are adding an application group that will hold only one application at the current time. However, if you decide later to add other applications to the application group (or if you want to maintain multiple versions of your application definitions) and you then need to define an application ID field for the application group, you will not be able to do so because an application ID field cannot be added after the application group is created. (All fields must be added during the original application group definition.) Also note that the application ID field can be hidden from users that do not require it to search for documents. See the online help for more information about the application ID field.

Name screen
Specify the names of the application group, application, and folder. After you enter the names, OnDemand queries the server to make sure that the names are valid and unique.

Wizard complete screen
Confirms the selections you made for the report. Click Display to view details about the application group, application, and folder. From the detail report window, choose the Print icon from the toolbar to print a copy of the detail report.

Note: When you are satisfied with the selections you made for the report, click Finish to complete defining the report. OnDemand adds the application group, application, and folder to the library server, closes the Report Wizard, and returns to the administrator window.
Chapter 8. Concepts

You can use iSeries Navigator to setup and maintain OnDemand tape devices, tape volumes, optical storage groups, optical volumes, disk pool storage groups, output queue monitors, and migration policies.

You can use the OnDemand Administrator within iSeries Navigator to maintain OnDemand users, groups, printers, storage groups, application groups, applications, and folders. To use this tool, right click on Common Server Administration within the OnDemand Archive section of iSeries Navigator. Select Client Administrative Functions from the resulting menu. This will launch the OnDemand Administrator.

Migration Policies

Migration policies contain migration and storage media characteristics for data archived using OnDemand. The information is used by the archive storage management process (ASM), also referred to as the migration process, to determine if and when archived data should be moved as it ages through a hierarchy of storage media having different performance and capacity characteristics. Examples of these media types include disk, optical, and tape storage. Each step in the movement of data through this storage hierarchy is referred to as a migration policy storage level, or simply, a storage level. Each policy must contain at least one storage level. Additional levels may be defined to meet your storage and retrieval requirements. The STRASMOND command is the command used to force the data to move to the next storage level in the migration policy. A report is produced when ASM is run and has a spooled file name of QPRLCASM1. The report provides a list of actions that the ASM process performed. This report should be checked each time ASM is run to ensure that processing of the data completed successfully. If a failed condition is found, it is important to check the joblog for the STRASMOND job to determine the cause of the failure.

The migration policy also specifies:

- If separate archived files are to be aggregated, or combined, with other archived files having similar retention and migration characteristics. Enabling aggregation is usually recommended because it can improve performance by allowing OnDemand to manage a smaller number of larger objects rather than a large number of small objects. However, it is important to understand that an aggregate must reach its maximum size or exceed its time period before the aggregated object can flow to the first level of the Migration Policy. Because of this, you should be cautious of large aggregate sizes. If you are aggregating many small objects, it is possible for the aggregate not to be migrated to the first level of the Migration Policy for many months. For this reason, you may prefer to aggregate after a specified time period rather than by size.

- If two copies of archived data are to be kept at some or all levels in the migration sequence.

- If a one-time backup is performed.

The migration policy name can be up to 60 characters long and must not be a duplicate of another policy within the same instance. If the Enable aggregation is selected, the archive storage management process combines individual archived objects on disk into larger objects to provide efficient processing. This process
occurs prior to migration of the object from disk to the first storage level. The aggregation process appends to the same file (aggregate) until the aggregate is 'closed.' The aggregate is closed when it either reaches a specified maximum size or a specified number of days. Storage levels can be added before or after a pre-existing storage level. Existing storage levels can also be changed or removed, however these changes will not affect migrated data already residing at this level. If a one-time tape backup is requested, a tape media type must be specified.

## Monitor Definitions

Monitor definitions are used to specify what output queue will be monitored for spooled files to be processed. If defining more than one monitor job, specify a unique job name for each monitor. OnDemand will only process spooled files that are in a ready (RDY) state. When the monitor job selects a spooled file from the selected output queue for archiving (also known as loading), it needs to determine which application group and application to associate with the spooled file so that the file can be archived correctly. Since the only data available to the monitor are the attributes of the selected spooled file, the application group name and application name must be derived from the contents of one of these attributes. Not all attributes are suitable for this purpose. OnDemand will examine the contents of up to three of the following nine attributes, in the order specified in the Check first, Check next, Check last selections:

- Spooled file name
- Form type
- User data
- Job name
- User-defined options 1 through 4
- User-defined data

The attribute selected from the 'Check first' pulldown list is examined first. If the value of this attribute does not match the name of an existing application group, OnDemand examines the attribute selected from the 'Check next' pulldown list, if specified. If the value of this attribute does not match an application group name, the attribute selected from the 'Check last' pulldown list, if specified, is checked. If a valid application group is not determined using the above method, the spooled file is moved to another output queue designated as an 'error' queue which is defined in this monitor definition. If the spooled file is successfully archived, it can be moved to a 'processed' queue or deleted according to the specifications in the monitor definition. The same process is followed to find a valid application name, unless you specify that the application name is the same as the application group name.

The monitor can be started manually, by a job scheduler, or started when the subsystem starts. The monitor can be ended manually, after a specified time period, after all queue entries are processed, or it can be specified when the monitor is started.

The first time you start a monitor for a particular output queue, it is best to do it when there are no spooled files in the output queue. When a monitor is started for the first time, an empty data queue with the same name as the output queue is created, which will receive entries for all spooled files that appear in the output queue in Ready status. Once the output queue monitor has been started (and therefore the data queue has been created), you can then begin moving the spooled
files that you wish to capture into the output queue. The data queue entries that get created will trigger the monitor to process each spooled file.

**Tape devices**

When a tape backup is requested, or if you will use tape as an archive media, you must define a tape device to OnDemand. The tape device name you specify must match the name of an existing i5/OS tape device description. A media type must be specified from the list of supported media types for either read or write operations. If the tape device being defined has an automatic cartridge loader (ACL), the number of cartridges can be specified. A value of zero specifies that this device does not have an ACL. OnDemand can be used with an automated tape library; if a tape library will be used, the name must be specified. If a tape manager other than OnDemand (such as BRMS) is used, a media library does not need to be specified.

**Tape volumes**

Tape volumes that can be used by OnDemand must be defined. The name of the volume specified must match the name that was used when the tape volume was initialized. The instance to which the tape volume belongs must be specified, along with the capacity and media type of the volume. The media type tells OnDemand which tape device to use. A media device library can be specified if an automated tape library is used. Leave this field blank if a tape manager other than OnDemand (such as BRMS) is used. A tape volume can be marked full, preventing OnDemand from writing any additional data to the volume. OnDemand will automatically mark the volume full when it detects that the tape is full.

**Optical storage groups**

Optical storage groups are used by OnDemand to group sets of optical volumes together to store related data. A storage group lets you group together reports that have similar storage requirements such as days on disk or expiration days. By referring to a specific storage group in your migration policy, you can control which reports are stored on a particular set of optical volumes. If optical volumes are defined as rewritable, the space can be reused on the volume by defining a free space threshold percent and volume full reset. If the volume full reset is not defined, once the volume is marked full it remains full unless manually changed. The optical storage group can also be defined as the primary or backup storage group.

**Optical volumes**

Optical volumes that can be used by OnDemand must be defined. The name of the volume specified must match the name that was used when the optical volume was initialized. The OnDemand instance and optical storage group to which the volume belongs must be specified. The capacity and volume type (primary or backup) of the volume is also required. An optical volume can be marked full, preventing OnDemand from writing any additional data to the volume. OnDemand will automatically mark the volume full when it detects that it is full.
Disk pool storage groups

The disk pool storage group is used to identify an i5/OS auxiliary storage pool (ASP) that the archive storage management process may use as storage media when migrating archived data. You must specify a pool number ranging from 1 to 32 which corresponds to an existing ASP. The type of data, primary or backup, that will be stored to the defined ASP must also be specified.

Users

When you define an OnDemand user, you create a userid with which a person in your organization logs on to the OnDemand server. You can optionally add the userid to folders and application groups permissions, which is one way to let the user open folders and access data.

Each person in your organization logs on to the server using an OnDemand userid. OnDemand authenticates the userid and determines the usage and administrative authority available to that person, based on the userid. It is important that you understand the details in the OnDemand userid relationship to i5/OS user profiles topic in the IBM Content Manager OnDemand for iSeries Common Server Planning and Installation Guide (SC27–1158) before you continue with this section.

An OnDemand userid does not necessarily have to identify an individual by name. However, for accounting purposes, most customers assign an OnDemand userid to each person that will use the system. When you initialize the system, OnDemand automatically creates the QONDADM userid. The QONDADM userid has system administrator authority. A system administrator can perform the basic user functions, such as logging on the system and opening folders, and administrative functions, such as defining users and groups to OnDemand, and creating, updating, and deleting application groups, applications, folders, migration policies and storage sets, and printers.

Note: The QONDADM userid has an initial password of QONDADM1. Because the QONDADM userid has system authority, we force you to change the password the first time you sign on.

When naming OnDemand users, the name that you specify:
- Can contain one to 10 or 128 characters (bytes) depending on whether you are linking i5/OS user profiles to your OnDemand users. If you are linking the two, then the user names should match your i5/OS user profile names.
- Cannot include the ‘ (apostrophe), * (asterisk), % (percent), + (plus), _ (underscore), [ (left bracket), ] (right bracket), ” (double quote), or blank character
- Must be unique to the server

You can specify a userid in mixed case. By default, OnDemand ignores the case (for example, LaGuarde is the same as laguarde). OnDemand converts lowercase letters in a user name to uppercase (LaGuarde is stored as LAGUARDE). However, depending on how you configure the Login Processing system parameters, userid processing on your system may be different (the case may be significant). See “System parameters” on page 36 for more information.
User types

When you add a user to OnDemand, you specify the User Type. The User Type and the Authority determines the types of tasks that the user can do when logged on to the system. You can choose from the following User Types:

User  Users can log on to OnDemand, open folders that they are authorized to access, and search for and retrieve data from application groups that they are authorized to access. Users can be given authority to do other things on the system.

User Administrator  A user that can also add, update, and delete users and user administrators. A user administrator can be given authority to do other things on the system.

Application Group/Folder Administrator  A user that can also add, update, and delete application groups, applications, and folders. An application group/folder administrator is automatically given Logical Views permission to all application groups. An application group/folder administrator can be given authority to do other things on the system.

System Administrator  A user that can also add, update, and delete any user, group, application group, application, or folder on the system. A system administrator is automatically given Logical Views permission to all application groups. A system administrator is also the only user that can maintain storage sets and printers.

Note: When adding or updating a user, you are not permitted to set the User Type or Authority to a level that exceeds your own. For example, a user with Create Users and Create Groups authority cannot create a user with Create Folders authority.

By default, only the user, the user that created the user, user administrators, and system administrators can view or maintain the user. See the User Permissions page for more information.

Only a system administrator, an application group/folder administrator, a user with administrator authority for an application group, or a user with add document permission can store data in an application group.

Only a system administrator, an application group/folder administrator, or a user with delete document permission can delete data from an application group.

Users who need to run server commands such as those listed in Appendix A, “Command reference,” on page 143 or server APIs from OSHELL such as those listed in Appendix E, “API and user exit reference,” on page 183 need to have QRDARSADM as the group profile (or a supplemental group) in their i5/OS user profile.

Authority

The Authority options allow the user to do other things in OnDemand. For example, A User Type of User can be permitted to create users. The authority options that you can select depend on the User Type. For example, if the User Type is Application Group/Folder Administrator, then by definition, the user can
create application groups and folders. Therefore, the only additional authorities that the user can be given are Create Users and Create Groups. Choose from the following:

**Create Users**
An optional authority for users and application group/folder administrators:
- If the User Type is User, lets the user create users with a User Type of User.
- If the User Type is Application Group/Folder Administrator, lets the user create users with a User Type of User or a User Type of Application Group/Folder Administrator.

**Note:** Users with Create Users authority can maintain the users that they create, so long as they remain an administrator of the user.

**Create Groups**
An optional authority for users, user administrators, and application group/folder administrators. Lets the user create groups. Users with Create Groups authority can maintain the groups they create, so long as they remain a group owner.

**Note:** These group definitions are not the same as i5/OS group profiles, although the names may match if you find that easier to maintain.

**Create Application Groups**
An optional authority for users and user administrators. Lets the user create application groups. Users with Create Application Groups authority can maintain the application groups that they create, so long as they remain an application group administrator.

**Create Folders**
An optional authority for users and user administrators. Lets the user create folders. Users with Create Folders authority can maintain the folders that they create, so long as they remain a folder administrator.

**Note:** When adding or updating a user, you are not permitted to set the User Type or Authority to a level that exceeds your own. For example, a user with Create Users and Create Groups authority cannot create a user with Create Folders authority.

---

**Groups**

OnDemand groups are a means to organize users of the system by function, authorization, or any other purpose that you might require. You do not have to assign a user to a group, however doing so can simplify administration of users with similar requirements and capabilities.

When you define a group, you can add users to the group and specify folder and application group permissions that are common to all of the users that belong to the group. The permissions determine the types of actions users assigned to the group can perform on the system.

When naming groups, the name that you specify:
- Can contain one to 128 characters (bytes)
• Cannot include the ’ (apostrophe), * (asterisk), % (percent), + (plus), _
  (underscore), [ (left bracket), ] (right bracket), ” (double quote), or blank
  character
• Can be mixed case. However, the case does not create a unique name (LaGuarde
  is the same as laguarde)
• Must be unique to the server

You can assign a group owner. The group owner can add users to and remove
users from the group. To maintain a group’s application group and folder
permissions, the group owner must have administrator authority for the
application groups and folders or be an application group/folder administrator or
a system administrator. If you do not assign a group owner, only a system
administrator user can maintain the group.

Note: These group definitions are not the same as i5/OS group profiles, although
the names may match if you find that easier to maintain.

Printers

OnDemand supports two types of server print devices: a fax machine and a
physical printer. A server print device always has an output queue on the server
and is defined using the OnDemand iSeries Navigator administrative client.

PSF/400 is required for formatting Advanced Function Presentation™ (AFP™)
print output from OnDemand. (PSF/400 may also be required by some fax software as
well.) PSF/400 allows you to use electronic forms, images, graphics, and
typographical fonts in the documents that you print. PSF/400 accepts input data
streams, such as AFP and line data and prepares the data for the destination print
device.

When a user selects an item and chooses server print, OnDemand retrieves a copy
of the item and places it on the output queue associated with the server printer.

Storage sets

Storage sets are defined for application groups with similar storage management
characteristics, such as the length of time that files are maintained in the
application group and the type of media on which the files are stored. A storage
set is created automatically when you create a migration policy, and the names are
identical. You do not have to manually create a storage set.

If you plan to maintain application group data in archive storage, then you must
specify a storage set name in the application group definition that matches the
migration policy to be used. Also, the sum of the Duration values for all migration
policy storage levels plus the value for the Days in Cache should equal the Life of
Data and Indexes value in the application group.

Application groups

An application group represents the data that you store in OnDemand and the
documents that users query, view, print, and fax using OnDemand client programs.
For example, the data can be reports generated by an application program, index
data, and annotations created by users.
When you define an application group, you specify properties of the application group, such as the organization of the database and the storage characteristics for the files that are to be stored in the application group. You also define the database fields that will hold index data extracted from the reports that you store in the application group.

OnDemand extracts index data from the reports that you load into an application group and places the data in the database fields that you define. OnDemand uses the index values to identify the documents that meet the search criteria entered by a user.

When you define an application group, you can also select the types of application group messages that OnDemand saves in the system log.

When you define an application group, you specify permissions that let users access and maintain the application group and application group data. You can identify the groups and users that can access data stored in the application group with OnDemand client programs. You can specify the types of functions that users can perform, such as viewing, printing, and annotating reports. You can assign administrator authority to a user or a group. Administrator authority allows a user to update the application group, for example, to authorize other users to access data stored in the application group.

OnDemand organizes information about an application group into tabs: General, Message Logging, Storage Management, Permissions, Field Definition, and Field Information. Each tab contains options, fields for you to enter information about the application group, and command buttons.

**Applications**

You typically define an application for each different type of report or source of data that you plan to store in OnDemand.

When you define an application, you assign the application to an application group and specify the physical and logical characteristics of the report. The physical characteristics of a report include the code page, the type of data found in the input file, and information about carriage control characters. The logical characteristics of a report include the different ways that you want to present the information contained in the report to your users.

The OnDemand data indexing, loading, and viewing programs use the information that you provide to process the report. For example, you can specify the parameters that the OnDemand indexing program uses to locate and extract index data from the report. You can create logical views for the application. Logical views represent different ways to display pages of the report. You can set up printing options, such as defining a default printer for users and printing options for AFP and line data documents.

OnDemand organizes information about an application into tabs: General, View Information, Indexer Information, Load Information, Logical View Fields, Logical Views, and Print Options. Each tab contains options, fields for you to enter information about the application, and command buttons.
Folders

A folder provides users the means to access the reports that you store in OnDemand. A user opens a folder, constructs a query, and retrieves documents from the application groups that can be searched from the folder. The user can use the folder to view, print, annotate, fax, and e-mail documents.

When you define a folder, you specify the properties of the folder, such as the name and description of the folder, create the search and display fields that appear when the user opens the folder, and map the folder fields to application group database fields.

You can also specify the groups and users that can open the folder with OnDemand client programs and other folder permissions. For example, you can authorize a user to be the folder administrator. The folder administrator can authorize other users to open the folder and make changes to the folder fields.

OnDemand organizes information about a folder into tabs: General, Permissions, Field Definition, Field Information, and Field Mapping. Each tab contains options, fields for you to enter information about the folder, and command buttons.

About application groups, applications, and folders

Before you can store a report into OnDemand, you must create an application group and an application. Before users can search for and retrieve data, you must create a folder.

- Users open a folder to search for reports that you load into OnDemand. You define one or more search fields for the folder. A folder search field is mapped to an application group database field.
- Each database field that you define represents a category of information in the report, such as a customer name, invoice number, or balance. When you add an application group, OnDemand creates a database table. The database fields that you define are columns in the table.
- You define an application for each report that you plan to store in OnDemand. When you add an application to the system, you define information that the OnDemand viewing, indexing, and loading programs use. When you define indexing information, you identify the name, location, and length of each category of index information that you want to extract from the report. When you define loading information, you map index fields in the report to application group database fields.
- When you load a report into the system, OnDemand stores the index values extracted from the report into database fields in records that are added to an application group table.
- OnDemand uses the index values to identify the documents that meet the search criteria that the user entered into the folder search fields.

When you want to define a report to OnDemand, your first task is to identify the application group from which OnDemand obtains information about the index fields and how documents are to be maintained on the system. When you define an application group, you specify how you want OnDemand to structure information in the database and define the database fields. When you define an application group, you also specify how you want OnDemand to maintain data on the system. For example, you might specify that report data should be maintained on disk storage for 60 days and in archive storage for five years. OnDemand
maintains all of the data stored in the application group the same way. OnDemand maintains each report that you store in the application group for the same length of time.

- You can store the report in an existing application group. However, you must be able to index the report using the database fields that are already defined in the application group. You cannot directly add or remove database fields from an application group (see “Adding a new field to an existing application group/application/folder” on page 104 for more information). The storage management information for the application group must support the length of time that you want OnDemand to maintain the report on the system and how and where that you want OnDemand to store and maintain the report data.

  You can verify information about an existing application group with the Properties command. The General tab shows the database organization for the application group. The Storage Management tab shows the data migration information. The Field Definition tab shows the application group database fields.

- If there are no application groups defined to OnDemand or there are no application groups that support the database and storage management requirements of the report, then you must add an application group to the system.

After you add an application group, you must define an application for the report. Most customers create an OnDemand application for each different type of report or source of data that they plan to store in OnDemand. When you create an application, you must assign it to an application group. The application group determines where OnDemand will store the report data. When you create an application, you also specify information that the OnDemand client programs use to view and print pages of the report and you specify instructions for the data indexing and loading programs.

The last step in the process of adding a report to OnDemand is to create a folder. Users open the folder to search for, display, and print reports. When you define a folder, you select the application group that contains the data that you want users to search when they open the folder. By creating folders that can search specific application groups, you can determine the reports that are available to users when they open a folder.

When you define a folder, you define search and display fields. You specify characteristics of the folder fields, such as default search operators and whether OnDemand displays default search values for the fields when a user opens the folder. You also map the folder fields to application group database fields.

**OnDemand permissions**

Permissions are the means by which OnDemand determines who can open folders and search for documents stored in application groups. OnDemand also uses permissions to determine who can maintain folders and application groups with the administrative client.

By default, only an application group/folder administrator, a system administrator, or the person who adds the folder can open and maintain the folder. By default, only an application group/folder administrator, a system administrator or the person who adds the application group can access data stored in the application group or maintain the application group.
OnDemand provides several ways for you to specify permissions. You can specify permissions when you add or update a folder or an application group. You can also add, remove, or update a user’s or group’s folder or application group permissions when you add or update the user or group.

As both a convenience and security measure, you can assign a user to a group. OnDemand groups allow you to organize users by function, authorization, or any other logical grouping that you might require. When you assign a user to a group, the user obtains the permissions that are in effect for the group. For example, suppose that you create a group and authorize the group to open the Student Information folder. Any user that you assign to the group automatically obtains permission to open the Student Information folder. If you assign a user to more than one group, the user normally obtains the permissions of all of the groups. However, there are exceptions. See "Specifying permissions" for details.

Note: These group definitions are not the same as i5/OS group profiles, although the names may match if you find that easier to maintain.

You can specify a default set of permissions for folders and application groups. OnDemand uses the default permissions when users and groups do not have specific permissions for the folder or application group. If you specify permissions for a group, then the group permissions take precedence over the default permissions. If you specify permissions for a user, then the user permissions take precedence, regardless of any group that the user may belong to or the default permissions that you specified.

Folder permissions

You can specify default (*)PUBLIC) folder permissions and folder permissions for specific groups and users. The default permissions provide every user and group defined to the server with the permissions that you specify. Permissions for a group provide the users that you add to the group with the permissions that you specify for the group. Permissions for a user provide the user with the permissions that you specify. By default, only an application group/folder administrator, a system administrator or the person who adds the folder can open and maintain the folder.

Refer to online help for details about setting folder permissions.

Application group permissions

You can specify default (*)PUBLIC) application group permissions and application group permissions for specific groups and users. The default permissions provide every user and group defined to the server with the permissions that you specify. Permissions for a group provide the users that you add to the group with the permissions that you specify for the group. Permissions for a user provide the user with the permissions that you specify. By default, only an application group/folder administrator, a system administrator or the person who adds the application group can access data stored in the application group and maintain the application group.

Refer to online help for details about setting application group permissions.

Specifying permissions

To ease the administration of OnDemand, most customers organize their users into groups, add the groups to folders and application groups, and specify permissions
for the groups. You should plan your groups before you begin creating them. After you start using the system, you may find it difficult to change the organization of your groups.

**Note:** These group definitions are not the same as i5/OS group profiles, although the names may match if you find that easier to maintain.

When you add a user to a group, the user automatically obtains the permissions that were specified for the group. When you add a user to more than one group, the user normally obtains the permissions of all of the groups. For example, using the group properties listed in Table 3, a user that belongs to both groups can open the Student Bills and Student Transcripts folders.

**Table 3. Group permissions**

<table>
<thead>
<tr>
<th>Group</th>
<th>GID</th>
<th>Folders</th>
<th>Permission</th>
</tr>
</thead>
<tbody>
<tr>
<td>Admissions</td>
<td>80100</td>
<td>Student Transcripts</td>
<td>Access</td>
</tr>
<tr>
<td>Accounting</td>
<td>80101</td>
<td>Student Bills</td>
<td>Access</td>
</tr>
</tbody>
</table>

Most situations involve adding a group to a folder, specifying permissions for the group, and then adding users to the group. However, there may be situations when you need to deny a group of users access to a folder. When you use groups to deny access to a folder, you must understand how OnDemand determines folder permissions for a group (and users assigned to the group). For example, consider the group properties listed in Table 4.

**Table 4. Group permissions**

<table>
<thead>
<tr>
<th>Group</th>
<th>GID</th>
<th>Folders</th>
<th>Permission</th>
</tr>
</thead>
<tbody>
<tr>
<td>Admissions</td>
<td>80100</td>
<td>Student Bills</td>
<td>None</td>
</tr>
<tr>
<td>Admissions</td>
<td>80100</td>
<td>Student Transcripts</td>
<td>Access</td>
</tr>
<tr>
<td>Accounting</td>
<td>80101</td>
<td>Student Bills</td>
<td>Access</td>
</tr>
<tr>
<td>Accounting</td>
<td>80101</td>
<td>Student Transcripts</td>
<td>Access</td>
</tr>
</tbody>
</table>

A user that belongs to both groups can not open the Student Bills folder.

When a user belongs to more than one group, OnDemand uses the group identifier (GID) to determine the user’s permissions. When two (or more) groups provide permissions for the same folder, the user obtains the permissions of the group with the lowest GID.

It is important to note that you cannot change a GID after a group has been created. You can, however, modify the value that is presented as the suggested GID when the group is created.

In the example depicted in Table 4, both groups have been added to the Student Bills folder. Since the Admissions group has a lower GID than the Accounting group, OnDemand uses the permissions specified for the Admissions group to determine the permissions of a user that is assigned to both groups. Consequently, users assigned to both groups cannot access the Student Bills folder.

You’re probably asking yourself, “Why would I assign a user to more than one group?” or “Why would I create a group with no access to a folder?” Perhaps some examples will help answer these questions (and clarify the OnDemand permission hierarchy). As you review the examples, please remember the following rules:
• By default, only an application group/folder administrator, a system administrator, or the person who created the folder can access the folder
• You can use the *PUBLIC name to specify default permissions for all other users
• You can specify permissions for specific groups and users:
  – All of the users that belong to a group that you add to a folder will obtain the permissions that you specify for the group
  – A user that belongs to two (or more) groups that have been added to the same folder will obtain the permissions of the group that has the lowest GID
  – The permissions that you specify for a user override all other permissions, including any default permissions (*PUBLIC) and any groups to which the user belongs and that are added to the folder

Examples
The examples that follow show how to add groups to folders and specify folder permissions. The same considerations hold true for adding groups to application groups and specifying application group permissions.

Providing a group of users access to a folder: Let’s say that you want to provide a single group of users access to a folder. Complete the following steps:
1. With *PUBLIC selected, clear all of the permissions check boxes (this is the default).
2. Add the group to the folder.
3. Select the Access check box.

Users assigned to the group automatically obtain permission to open the folder.

Denying a group of users access to a folder: Let’s say that you want to prohibit a single group of users from accessing a folder, while allowing all other users defined to the server to open the folder. Complete the following steps:
1. With *PUBLIC selected, select the Access check box (this lets all users open the folder).
2. Add the group to the folder.
3. Clear all the permissions check boxes.

Users assigned to the group cannot open the folder.

Providing one group of users access and denying another group of users access to the same folder: Let’s say that you want to allow a group of users to access a folder. However, you need to prohibit certain users in the group from accessing the folder. You could exclude the users from the group that can access the folder. However, there may be other folders that you want the users to access as part of the group. To solve this, create two groups, one without access to the folder and the other with access to the folder, and assign the users to the respective groups. For example:
1. Create the “no access” group. This group must have a lower GID than the “access” group. Add users to the group.
2. Create the “access” group. Add users to the group.
3. With *PUBLIC selected, clear all of the permissions check boxes (this is the default).
4. Add the “access” group to the folder.
5. Select the Access check box.
6. Add the “no access” group to the folder.
7. Clear all of the permissions check boxes.

If you later need to deny other users access to the folder, simply add the users to the “no access” group. You can also move users from one group to the other.

Denying one user in a group access to a folder: Let’s say that you want to prohibit one user in a group from accessing a folder. After adding the group to the folder and specifying the access permission, all users assigned to the group can open the folder. To override the group permissions, we can add an individual user to the folder and set permissions at the user level. Complete the following steps.
1. With *PUBLIC selected, clear all of the permissions check boxes (this is the default).
2. Add the group to the folder.
3. Select the Access check box.
4. Add the user to the folder.
5. Clear all the permissions check boxes.

Even though the user belongs to the group, the user cannot open the folder.

Providing one user in a group administrator authority: Let’s say that you want to provide one user in a group the ability to administer the folder. Complete the following steps.
1. With *PUBLIC selected, clear all of the permissions check boxes (this is the default).
2. Add the group to the folder.
3. Select the Access check box.
4. Add the user to the folder.
5. Select the Administrator check box.

Only the user that you added can administer the folder; the other users in the group can open the folder.

Specifying default permissions: The default (*PUBLIC) permissions that you specify for an application group or a folder will apply to every user or group defined to the server who is not provided with specific permissions.

For example, suppose that you specify Access as the default permission for an application group. Every user and group that is not provided with specific permissions can access the data that is stored in the application group. Then, you specify Access as the default permission for a folder. Every user and group that is not provided with specific permissions can open the folder. Later, you add a user, without specifying application group or folder permissions. The user can open the folder and access the data stored in the application group.

While default permissions do provide flexibility to maintain your system, you must make sure that using the default permissions does not circumvent your security strategy. Rather than specifying default permissions for application groups and folders, you may want to use groups as a means to implement your security strategy. For example, you can clear all of the permissions under *PUBLIC and then add groups to a folder and specify the appropriate permissions for each group. When you add a user to the system, you can assign the user to a group. The user automatically obtains the permissions of the group. If the group does not have access to a particular application group or folder, then neither does the user.
With this strategy, until you assign the user to a group, or provide the user with specific permissions, the user cannot access the folder.

**Hints and tips**

1. To simplify the task of providing access to application groups and folders, give access to a group rather than a user. When a new user needs access, add the user to the group.

2. To allow an Application Group/Folder Administrator to see groups in the permissions list, add the Application Group/Folder Administrator to the groups that require access to application groups and folders.

3. To allow multiple users to administer the same groups, create a group of users and make that group the group owner for any groups that need to be administered by multiple users.

4. The Create Groups authority is most effectively used if it is combined with the Create Users authority or added to a User Administrator. Because the purpose of a group is to give a set of users permissions to another object, it is not very useful if the user that creates the group does not have access to any users. Otherwise, the user that creates a group must be given access to each user that needs to be added to the group.

5. If you need to reset the OnDemand information related to your optical volumes, issue the following program call (with no parameters):
   
   ```
   CALL PGM(QRDARS/QRLCASMROV)
   ```

   Running this program updates the Optical Volume Capacity, recalculates the Optical Bytes Used, and sets the Optical Volume Full Flag to Y or N based on the Optical Bytes Used. This program can only be run by a user profile with QONDADM group or supplemental group profile in their user profile.

   You should not run this program while the Archive Storage Manager (ASM) or the Disk Storage Manager (DSM) with ASM(*YES) are running. The program may cause some or all optical volumes that are known to OnDemand to be mounted to check for space.
Chapter 9. Examples

The examples that follow demonstrate how to use the OnDemand iSeries Navigator component to:

- Create tape devices that are available for use by OnDemand if tape archival is selected.
- Add tape volumes which are available for use by OnDemand.
- Create optical storage groups which are used to group sets of optical volumes together to store related data.
- Add optical volumes which are available for use by OnDemand.
- Create a disk pool storage group definition to identify an i5/OS® Auxiliary Storage Pool (ASP) that the archive storage management (ASM) process may use as storage media when migrating archived data.
- Create monitor definitions which contain information about the output queue to be monitored, the handling of the spooled files being archived, and information about starting and ending the monitor job.
- Create migration policies which provide migration and storage media characteristics for data archived using OnDemand.

The examples that follow also demonstrate how to use the OnDemand Administrator to:

- Add users and groups to the system. Users on the system obtain permission to open folders and access application group data from a group.
- Define a server printer that can be used as the default printer for an application.
- Define a migration policy and storage set.
- Add a report to the system. To add a report, create an application group, an application, and a folder.

System configuration

The example assumes that an external customer (Customer XYZ) accesses the system by using the OnDemand Web Enablement Kit (ODWEK) feature. However, for purposes of demonstrating how the system works and how to use the administrative client to implement the requirements, these users could easily represent another department within the company.

Here are the assumptions about the system:

- Two groups of users: the customer service department and users at Customer XYZ.
- A sample telephone bill report. The telephone report is generated by an application program running on an iSeries system with OnDemand installed.
- Disk storage. When a report is loaded into the system, OnDemand stores a copy on disk and maintains the report on disk for 60 days.
- Archive storage. When a report is loaded into the system, OnDemand stores a copy of the report in archive storage. The archive storage manager maintains the report on optical storage for five years.
Adding tape devices

1. To add a tape device to OnDemand, left click on the plus sign in front of Common Server Administration from the OnDemand Archive plug-in of iSeries Navigator, right click on Tape Devices and select New Tape Device.

2. First, the name of the tape device you want to add to OnDemand must be specified. The name must match the name of an existing i5/OS tape device description. In this example, the name of the tape device is TAP01. You may also provide a brief description for your tape device.

3. From the list of supported media types, select the media type for this tape device. In this example, the media type is 8MM.

4. Once you select the media type, the Add button for the Read and Write operations is no longer grayed out. Click on the add button to add the 8MM media type to the Read and Write operations. If the device you are using has an automatic cartridge loader, you can specify the number of cartridges the loader holds. In the example, leave this at 0. Leave the media library blank. If you are using a media library such as the IBM 3494 tape library with OnDemand, specify the library name here.

5. Click on OK to create the tape device. See Figure 3.

![Tape Device](image)

**Figure 3. Tape device**

Adding tape volumes

1. To add tape volumes to OnDemand, left click on the plus sign in front of Common Server Administration from the OnDemand Archive plug-in of iSeries Navigator, right click on Tape Volumes and select New Tape Volume.

2. First, specify the name of the tape volume that you want to make available to OnDemand. The volume name must match the name you used when you initialized the tape volume on your iSeries server. For the example, the name of the volume is OND001.
3. Next, specify the total capacity of the tape volume in megabytes. For the example, specify a capacity of 2300 MB.

4. For media type, use the pull down to select the correct type. For the example, select 8MM.

5. For this example, leave media device library blank. Also, make sure Tape is full is not checked.

6. The migration policy, which will be created later, will request a tape backup. So, for this example, make the volume type Backup. If, instead, the plan was to use this tape volume for the primary archive media for some of the OnDemand data, you would leave the volume type set to Primary as shown in Figure 4. For this example, however, set the volume type to Backup.

7. Then click OK to create the volume. See Figure 4.

**Figure 4. Tape volume**

### Creating optical storage groups

1. To create an optical storage group, left click on the plus sign in front of Common Server Administration from the OnDemand Archive plug-in of iSeries Navigator, right click on Optical Storage Groups and select New Storage Group.

2. The optical storage group is used to group sets of optical volumes together for use by OnDemand. For the example, call the optical storage group OPTSTG. You may also provide a brief description.

3. The optical volumes are rewritable and support the dynamic reuse of space without reinitializing the entire volume. So for this example, check the Volume full reset box and set the Free space threshold percent at 40 by clicking on the up arrow. This indicates when the volume full flag is reset. In the example, when there is 40 percent free space available on the volume, the full flag is reset and the volume can again be used for newly migrated data.

---

Chapter 9. Examples  63
4. This optical storage group will contain primary volumes; mark the type as Primary.

5. Leave the instance as the default QUSROND and click OK to create the optical storage group. See Figure 5.

![Figure 5. Optical storage group](image)

### Adding optical volumes

1. To add optical volumes to OnDemand, left click on the plus sign in front of Common Server Administration from the OnDemand Archive plug-in of iSeries Navigator, right click on Optical Volumes and select New Common Server Optical Volume.

2. The volume name specified must match the name used when the volume was initialized in the optical library. A single disk has two sides which are considered volumes. As you will see in a later step, the opposite side volume name must be specified. The name for this volume is OND00001.

3. Remember that the optical storage group was Primary, which means that all the volumes assigned to that storage group must also be of type Primary. Therefore, mark this volume as Primary.

4. Leave the instance as the default of QUSROND.

5. For this example, use a 2.6 GB optical disk. The capacity is for one side of the disk (one volume), so for the example, specify 1300 MB.

6. The volume being defined is a rewritable volume. To select the Optical media family, use the pull down and select REWT. You can also use the pull down for the Optical storage group and select the storage group that was created earlier, OPTSTG. The volume is defined as REWT, so it is not necessary to specify the Optical library. (See the online help for more information.) You may specify the library for documentation purposes if you like. In the example, this field will be left blank.

7. Leave the volume marked as not full. This flag will automatically be set to full when the optical volume has reached its capacity. Remember when the storage
Creating disk pool storage groups

1. To create a Disk pool storage group, left click on the plus sign in front of Common Server Administration from the OnDemand Archive plug-in of iSeries Navigator, right click on Disk Pool Storage Groups and select New OnDemand Disk Pool.

2. Identify an i5/OS Auxiliary Storage Pool (ASP) that the archive storage management (ASM) process may use as storage media when migrating archived data. For the example, specify the ASP as 3. You may also provide a brief description for the disk pool storage group.

3. The type for the disk pool is Primary and the instance is the default QUSROND. Click OK to create the disk pool storage group. See Figure 7 on page 66.
Creating monitor definitions

1. To create a monitor definition, left click on the plus sign in front of Common Server Administration from the OnDemand Archive plug-in of iSeries Navigator, right click on Monitor Definitions and select New Monitor.

2. When the New Monitor window opens up, the general page will be displayed. Specify the name and library of the output queue to monitor. For this example, specify the output queue as MONITORQ in library QRDARS. (However, your monitored output queues should not be placed in QRDARS library, since that library can be replaced during a software upgrade.) The job name is automatically filled in with the same name as the monitored output queue you specified. This can be changed, but for the example leave it as MONITORQ. You may also provide a brief description for the monitor definition.

3. When the monitor job selects a spooled file from the specified output queue for processing, it needs to determine which application group to associate with the spooled file so that the file can be archived correctly. The only data available to the monitor are the attributes of the selected spooled file. The application group name must be derived from the contents of one of these attributes. Use the pull down to select the attribute that the monitor should use for comparing to find the application group with the matching name. For the example, use Spooled file name. You can also specify what the monitor should check next and last if it does not find a match on check first. In this example, leave check next and last blank.

4. You can check the box to have the monitor job determine the application name used or you can specify what the monitor should check for comparing to find the application name. In this example, check the box and let the monitor job determine the application name.

5. You may also specify the job description, library and instance to be used for this monitor job. Leave these values as the default for this example.

6. Once the general page has been completed you can click on the Start and End Methods tab. There are several options for starting and ending the monitor job. Accept the defaults for this example which are to start and end the monitor manually. However you can specify whether the monitor will be started from a
job scheduler or when a subsystem starts. You can also specify to have the
monitor job end at a specific time of day, after a certain period of time, after all
entries have been processed from the output queue, or you can specify the end
time as a parameter when the monitor is started.

**Note:** The first time you start a monitor for a particular output queue, it is best
to do it when there are no spooled files in the output queue. When a monitor is
started for the first time, an empty data queue with the same name as the
output queue is created, which will receive entries for all spooled files that
appear in the output queue in Ready status. Once the output queue monitor
has been started (and therefore the data queue has been created), you can then
begin moving the spooled files that you wish to capture into the output queue.
The data queue entries that get created will trigger the monitor to process each
spooled file.

7. Next click on the Actions Taken on Spooled Files tab. This specifies what
OnDemand should do with a spooled file once it has been successfully
processed. The options are to have it deleted from the system or moved to an
output queue you specify. In the example, the spooled file will be moved to a
processed output queue called PROCESSED in library QUSRRDARS. You must
also specify where you want the spooled files to be sent should they fail to
process. In the example, specify ERROR in library QUSRRDARS as the error
queue.

8. Click on OK to create the monitor definition. See [Figure 8 on page 68](#), [Figure 9
on page 69](#) and [Figure 10 on page 70](#).

Creating migration policies

1. To create a new migration policy, left click on the plus sign in front of Common Server Administration from the OnDemand Archive plug-in of iSeries Navigator, right click on Migration Policies and select New policy.

2. First you must specify the name of your migration policy. The name can be up to 60 characters long, but must not duplicate the name of another policy within the same instance. For this example, choose POLICY1 as the new policy name. You may also provide a brief description of the migration policy you are creating.

3. You can choose whether or not you want to enable aggregation. If aggregation is enabled, you must select whether you want to close the aggregate only when the maximum size is reached or after a specified time period is reached. Accept the default to enable aggregation and close the aggregate after the maximum size if reached. However, change the maximum size, by clicking on the up arrow, to 10,000 kilobytes. (See “Migration Policies” on page 45 for more information on migration policies and aggregation.)

4. You may also specify if a tape backup is requested. Request a tape backup and select the Media type by clicking on the pull down and selecting 8MM.
5. The Instance is the logical server environment that will contain the archive data to which this migration policy will relate. For this example, leave the Instance as the default of QUSROND.

6. In this example, when a report is archived into OnDemand, a copy is stored on disk for 60 days. A copy is also maintained in optical storage for 5 years. This information will be used to set up the storage levels within the migration policy. For the first level, click on Add After, this opens the New Policy Level window. Assign a level identifier and this identifier must be unique within this policy. For this example use 0010 as the level identifier. You may also provide a brief description of this level. For the media, select Disk pool and the duration at this level should be 60 days. For the primary storage group, click on the pull down to see a list of available disk pool storage groups. Select the one created earlier called ASP01, then click OK. This will add the storage level in the storage levels window within the policy. To add the next level, select the level that was just added and then click on Add After. Specify the level identifier as 0020 with a brief description. The media is Optical and the number of days is 1825 (5 years). Choose the optical storage group that was created earlier, OPTSTG, as the primary storage group. Click OK, and you should now see both storage levels listed for the migration policy. In both storage levels, the Create backup copy option was not selected. However, you can select this option and specify a backup storage group causing the migration process to create a duplicate copy of the archived data when it is moved to this level.

7. Click on OK to create the migration policy. Clicking OK will also create an OnDemand storage set of the exact same name. When you define an application group to OnDemand, you can select the storage set name that matches this migration policy, which will cause OnDemand to archive that application group data as defined here. See Figure 11.

![New Migration Policy - Rdr400h.charlotte.ibm.com](image)

**Figure 11. Migration policy**
Adding users

The basics

In general, here is how you work in the administrative client to add a user:

1. In the OnDemand Archive section of iSeries Navigator, right click Common Server Administration. In the resulting context menu, click Client Administrative Functions, then logon.

2. Choose a server and select Users.

3. Pick one of two ways to add a user.

4. Define the properties of the user by completing fields in the Add a User dialog box.

5. Optionally add the user to groups. See the online help for more details.

6. Optionally add the user to application groups and set application group permissions.

7. Optionally add the group to folders and set folder permissions.

8. When finished, add the user by clicking OK in the Add a User dialog box.

Notes:

1. To add a user, the logon userid must be a user with create users authority, a user administrator, or a system administrator.

2. To make problem determination easier, IBM recommends that each user profile that will be used to load reports (ADDRPTOND, STRMONOND, arsload, arsdoc add) have a home directory in IFS on the iSeries server. If a home directory exists for a user profile running one of the load commands, any output files and temporary files will be placed in that user profile’s home directory rather than “lost” within the entire root directory on the iSeries system. To create a home directory for a user profile, issue the following command:

   MD '/home/usrprf/'

   where usrprf is the name of the user profile that will be used to load reports.

Table 5 shows the minimum authority requirements are needed to perform the specified actions.

Note: For starting the monitors and loading documents, it is assumed that the user performing these functions has proper authority to the output queue being monitored or the document being loaded using the Add Report to OnDemand (ADDRPTOND) command. Providing proper authority to the output queue can be done by granting specific authority to the output queue or giving *SPLCTL to the user profile. Be aware that *SPLCTL means that the user will be able to view any spooled file in any output queue on the system.

Table 5. Authority Requirements

<table>
<thead>
<tr>
<th>Action</th>
<th>Minimum authority requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creating an instance</td>
<td>The user profile used to create an instance must have all the special authorities of a *SECOFR User Class.</td>
</tr>
<tr>
<td>Action</td>
<td>Minimum authority requirements</td>
</tr>
<tr>
<td>-----------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Starting the servers</td>
<td>To start the servers using the Start TCP/IP Server (STRTCPSVR) command and specifying *ONDMD for the SERVER parameter, you must have QONDADM user profile specified as a group or supplemental group profile in your user profile and you must have *USE authority to the STRTCPSVR command (and End TCP/IP Server (ENDTCPSVR) command to end the servers). To start the servers using the QRDARS/QLMCTL program, you must have QONDADM user profile specified as a group or supplemental group profile in your user profile.</td>
</tr>
<tr>
<td>Using the OnDemand Archive plug-in of iSeries Navigator for administrative functions</td>
<td>To use the OnDemand Archive plug-in of the iSeries Navigator (part of iSeries Access) to perform all administrative functions except Migration Policies, you must have QONDADM user profile specified as a group or supplemental group profile in your user profile. To work with Migration Policies, you must also have your OnDemand user ID defined as an Application Group/Folder Administrator in the OnDemand Administrator Client.</td>
</tr>
<tr>
<td>Starting the monitors to archive spooled files</td>
<td>To start the OnDemand monitor(s) for a specific output queue using the Start Monitor for OnDemand (STRMONOND) command, you must have QONDADM user profile specified as a group or supplemental group profile in your user profile. The user issuing the STRMONOND command must also be defined as an Administrator on the Permissions tab for every Application Group to which a spooled file in the monitored output queue might be archived to, or have your OnDemand user ID defined as an Application Group/Folder Administrator in the OnDemand Administrator Client. If you would like to add the STRMONOND command to the i5/OS job scheduler, the profile specified in the USER parameter of the Add Job Schedule Entry (ADDBSCDE) command should have QONDADM user profile specified as a group or supplemental group profile and must also be defined as an Administrator on the Permissions tab for every Application Group to which a spooled file in the monitored output queue might be archived to, or have your OnDemand user ID defined as an Application Group/Folder Administrator in the OnDemand Administrator Client.</td>
</tr>
<tr>
<td>Storing spooled files manually</td>
<td>Using the Add Report to OnDemand (ADDRPTOND) command to store spooled files manually requires the same minimum authority as the user profile used to run the OnDemand monitors (as described above).</td>
</tr>
</tbody>
</table>
Table 5. Authority Requirements (continued)

<table>
<thead>
<tr>
<th>Action</th>
<th>Minimum authority requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manually removing a document from OnDemand</td>
<td>To manually remove a document from OnDemand using the Remove Report from OnDemand (RMVRPTOND) command, you must have QONDADM user profile specified as a group or supplemental group profile in your user profile. The user issuing the RMVRPTOND command must also be defined as an Application Group/Folder Administrator, or have Delete authority on the Permissions tab for the Application Group (in the OnDemand Administrator Client) from which the document is being removed.</td>
</tr>
<tr>
<td>Using the Start Disk Storage Management (STRDSMOND) and the Start Archived Storage Management (STRASMOND) commands</td>
<td>To run the Start Disk Storage Management (STRDSMOND) and the Start Archived Storage Management (STRASMOND) commands, you must have QONDADM user profile specified as a group or supplemental group profile in your user profile. If you would like to add these commands to the i5/OS job scheduler, the profile specified in the USER parameter of the Add Job Schedule Entry (ADDJOBSCDE) command should have QONDADM user profile specified as a group or supplemental group profile. Alternately, you might choose to use the instance user profile (the user profile with a name that matches the instance name) for the USER parameter.</td>
</tr>
<tr>
<td>Printing on the server</td>
<td>To print a document from the OnDemand end user client to a server printer, you must have Access permission for the Folder and Access permission for the Application Group that the document is archived to. To use the Print Report from OnDemand (PRTRPTOND) command to reprint a document using a 5250 session, you must have Access permission for the Folder and Access permission for the Application Group that the document is archived to and you must have QONDADM user profile specified as a group or supplemental group profile in your user profile.</td>
</tr>
</tbody>
</table>

Choose a server

1. On the left side of the administrator window, click the name of the server to which you want to add the user.
2. Expand the areas of the server. Double click the server name or click the + (plus) to the left of the server name.
3. Select Users.

Two ways to add a user

This section explains how to add a user by using the New User command. You can also add a user by copying an existing user definition.

New User command: From the File menu, select New User to open the Add a User dialog box.

Copy command: You can use the copy command to add a user. In the User ID list, point to the user that you want to copy and click the right mouse button. Select Copy from the pop-up menu to open the Add a User dialog box. The fields in the dialog box contain information copied from the user you selected. At a minimum, you need to change the User ID (userid must be unique to the server).
Adding the user
In the Add a User dialog box, click OK. The administrative client adds the user to the database and returns to the main window.

Examples
First, review the requirements of the users that need to access the telephone bill reports.

- One set of userids for the customer service department. Identify one user as a user administrator. The user administrator can add other users.
- One userid for Customer XYZ.

On the example system, users obtain permissions from groups. This means that the users are not added to application groups and folders. When groups are defined, users are added to the groups.

Note: The steps that follow do not show how to add all of the sample users to the system. Two users will be added; you can repeat the steps to add the others.

Adding the customer service users
Use the New User command to add a user.

1. First, point to Users and click the right mouse button. From the pop-up menu, select New User to open the Add a User Dialog box.
2. In the User ID field, enter the name of the user: CSR1 If your OnDemand userids are linked to your i5/OS user profiles, then this userid must also exist as an i5/OS user profile.
3. Accept the UID generated by OnDemand.
4. Set the user’s initial password to the userid. In the Password field, enter: CSR1 If your OnDemand userids are linked to your i5/OS user profiles, then this password will be ignored.
5. In Verify Password, enter: CSR1
6. In the Description field, enter: Customer Service Representative
7. Under User Type, select User Administrator. The user will be able to maintain userids on the system.
8. Click the User Information tab.
9. Complete the fields on the User Information page, such as the Name, Department, and Phone Number.
10. Click the General tab.

The user will obtain application group and folder permissions from a group. Add the user to the group when the group is added to the system. Therefore, do not add the user to application groups, folders, or groups at this time.

Figure 12 on page 76 shows the Add a User dialog box with the basic information completed.
11. At this point, the properties of the user meet the requirements. Click OK to add the user.

Use the Copy command to add another user.

1. Point to CSR1 and click the right mouse button. From the pop-up menu, select Copy to open the Add a User Dialog box.

2. In the User ID field, replace CSR1 with CSR2 If your OnDemand userids are linked to your i5/OS user profiles, then this userid must also exist as an i5/OS user profile.

3. Accept the UID generated by OnDemand.

4. Set the user’s initial password to the userid. In the Password field, enter: CSR2 If your OnDemand userids are linked to your i5/OS user profiles, then this password will be ignored.

5. In the Verify Password, enter: CSR2

6. Under User Type, select User.

7. Click the User Information tab.

8. Replace the information in the fields on the User Information page.

9. Click the General tab.

Figure 12. Add a User dialog box - basic information

![Add a User dialog box](image)

Figure 13 on page 77 shows the Add a User dialog box with the basic information completed.
At this point, the properties of the user meet the requirements. Click OK to add the user.

Adding groups

In general, here is how you work in the administrative client to add a group:
1. Choose a server and select Groups.
2. Pick one of two ways to add a group.
3. Define the properties of the group by completing fields in the Add a Group dialog box.
4. Optionally assign a group owner.
5. Optionally add users to the group.
6. Optionally add the group to application groups and set application group permissions.
7. Optionally add the group to folders and set folder permissions.
8. When finished, add the group by clicking OK in the Add a Group dialog box.

Note: To add a group, the logon userid must be a user with create groups authority or a system administrator.

Choose a server

1. On the left side of the window, click the name of the server to which you want to add the group.
2. Expand the areas of the server. Double click the server name or click the + (plus) to the left of the server name.

Two ways to add a group

This section explains how to add a group by using the New Group command. You can also add a group by copying an existing group definition.
**New Group command**
From the File menu, select New Group to open the Add a Group dialog box.

**Copy command**
You can use the copy command to add a group. In the Name list, point to the
group that you want to copy and click the right mouse button. Select Copy from
the pop-up menu to open the Add a Group dialog box. The fields in the dialog box
contain information copied from the group you selected. At a minimum, you need
to change the group name (group names must be unique to the server).

**Note:** These are not the same as group profiles in i5/OS. However, the names may
match if you find that easier to maintain.

**Adding users**
You can add one or more users to the group. Complete the following steps to add
a user to a group.
1. From the List of Users list, select the user.
2. Click Add. The administrative client moves the user to the Users in the Group
list.
   To remove a user from the group, select the user in the Users in the Group list
   and click Remove.

**Adding the group**
In the Add a Group dialog box, click OK. The administrative client adds the group
to the database and returns to the main window.

**Examples**
Review the requirements of the groups that need to access the sample telephone
bill reports.
- Customer service group. Users that belong to the group can open the telephone
  bill report folder and query documents stored in the telephone bill report
  application group. When the report is added to the system, the group will be
  added to the application group and the folder. Identify a group owner. The
group owner can add new customer service users to the group and remove
users from the group.
- Customer XYZ group. Users that belong to the group can also open the
  telephone bill report folder and query documents stored in the telephone bill
  report application group. However, you can limit access to documents that
  contain a specific customer name and account number. When the report is added
to the system, add the group to the application group and the folder and specify
the necessary restrictions.
- Users. Add the users that were defined in “Adding users” on page 72 to the
groups.

**Adding the customer service group**
Use the New Group command to add the group.
1. First, point to Groups and click the right mouse button. From the pop-up
   menu, select New Group to open the Add a Group Dialog box.
2. In the Name field, enter the name of the group: CustomerService
3. Accept the GID generated by OnDemand.
4. From the Group Owner list, select the user that can add users to and remove
   users from the group: CSR1
Note: The user that you select does not obtain permissions from the group unless you add the user to the group (see step 6). However, a group owner can add their userid to the group at any time.

5. In the Description field, enter: *Access to Telephone Bill Reports; call Leonard Little, x90565, for more information*

6. From the List of Users list, select and add users to the group: CSR1, CSR2, CSR3, CSR4, and CSR5

   Figure 14 shows the Add a Group dialog box with the basic information completed.

![Add a Group dialog box](image)

Figure 14. Add a Group dialog box

7. At this point, the properties of the group meet the requirements. Click OK to add the group.

Adding the Customer XYZ group

Use the Copy command to add the group.

1. Point to Customer Service and click the right mouse button. From the pop-up menu, select Copy to open the Add a Group Dialog box.

2. In the Name field, replace *CustomerService* with *CustomerXYZ*

3. Accept the GID generated by OnDemand.

4. Use a system administrator to maintain the group. Therefore, do not assign a group owner. In the Group Owner list, replace CSR1 with *NONE.*

5. Replace the contents of the Description field with: *Access to Telephone Bill Reports by Customer XYZ*

6. From the Users in the Group list, remove CSR1, CSR2, CSR3, CSR4, and CSR5.

7. From the List of Users list, add XYZ1.

   Figure 15 on page 80 shows the Add a Group dialog box with the basic information completed.
8. Click OK to add the group.

Adding server printers

In general, here is how you work in the administrative client to add a server printer:

1. Choose a server and select Printers.
2. Pick one of two ways to add a server printer.
3. Define the properties of the server printer by completing fields in the Add a Printer dialog box. Search for *printer, adding* in the online help for more details.
4. When finished, add the server printer by clicking OK in the Add a Printer dialog box.

Notes:
1. To add a server printer, the logon userid must be a system administrator.
2. Server print is supported for spooled file data types of SCS, SCS-extended, AFPDS, and LINE.

Choose a server

1. On the left side of the main window, click the name of the server to which you want to add the server printer.
2. Expand the areas of the server. Double click the server name or click the + (plus) to the left of the server name.
3. Select Printers.

Two ways to add a server printer

This section explains how to add a server printer by using the New Printer command. You can also add a server printer by copying an existing server printer definition.

New Printer command
From the File menu, select New Printer to open the Add a Printer dialog box. Figure 16 on page 81 shows an example of the Add a Printer dialog box.
Copy command
You can use the copy command to add a server printer. In the Name list, point to the server printer that you want to copy and click the right mouse button. Select Copy from the pop-up menu to open the Add a Printer dialog box. The fields in the dialog box contain information copied from the server printer you selected. At a minimum, you need to change the name (printer names must be unique to the server).

Adding the server printer
In the Add a Printer dialog box, click OK. The administrative client adds the server printer to the database and returns to the main window.

Examples
Add a server printer that can be selected as the default server printer for the application (added in “Adding a report” on page 82). The physical printer resides in the customer service department. By default, when users of the telephone bill report application select a document and choose the server printer command, OnDemand sends the document to this print device.

Adding the server printer
Use the New Printer command to add the server printer.
1. First, point to Printers and click the right mouse button. From the pop-up menu, select New Printer to open the Add a Printer dialog box.
2. In the Name field, type the name of the server printer: Customer Service printer
3. In the Description field, type: Customer Service printer for the telephone bill report application
4. In the Server Queue Name, type: ip60cs If no library name is entered (as in the example), OnDemand assumes *LIBL; otherwise, enter a value such as QUSRSYS/PRT04 to identify both the library name and the output queue name.
5. Accept the default Printer Type of Printer

Figure 16 shows the completed Add a Printer dialog box.

Figure 16. Add a Printer dialog box

6. At this point, the properties of the server printer meet the requirements. Click OK to add the server printer.
Adding storage sets

A storage set is automatically added each time you create a migration policy. The name of the storage set that is created is an exact match of the name of the migration policy. See “Creating migration policies” on page 70 for details on migration policies.

Adding a report

In general, here is how you work in the administrative client to define a report to the system:

1. Choose a server. On the left side of the main window, click the name of the server on which you want to define the report.
2. Select the area. First expand the areas of the server. Double click the server name or click the + (plus) to the left of the server name. Then select the area. When you define a report to the system, you typically add an application group, an application, and a folder.
   - The application group identifies database and storage management information.
   - The application identifies viewing, indexing, loading, and printing information.
   - The folder provides users the ability to search for, retrieve, view, and print report data.
3. Pick one of two ways to add an application group, an application, and a folder. For example, use one of the following methods to add an application group:
   - Add a new application group. From the File menu, select New Application Group to open the Add an Application Group dialog box.
   - Copy an existing application group. In the Name list, point to the application group that you want to copy and click the right mouse button. Select Copy from the pop-up menu to open the Add an Application Group dialog box. The fields in the dialog box contain information copied from the application group you selected. At a minimum, you need to change the Name (application group names must be unique to the server).
4. Define the properties of the application group, application, and folder.
5. When finished, add the application group, application, and folder by clicking OK in the add dialog box.

Note: To add an application group, the logon userid must be a system administrator, an application group/folder administrator, or a user with create application groups authority.

To add an application, the logon userid must be a system administrator, an application group/folder administrator, or a user with create application groups authority.

To add a folder, the logon userid must be a system administrator, an application group/folder administrator, or a user with create folders authority.

An example

This section describes how to define a sample telephone bill report to the system.
About the report
A telephone bill report typically contains hundreds of pages of line data. The report is logically segmented into statements. Users search for statements using a date and any combination of account number and customer name.

Most queries about a statement occur in the first 60 days after it is mailed to the customer. Little or no activity occurs a year after a statement is generated. For legal reasons, a statement must be maintained on the system for five years. The system should maintain index information in the most efficient way possible.

Two groups of users need to access the telephone bill reports. The customer service department is responsible for handling queries from customers. They answer questions about the statements, attach annotations to statements, and reprint and fax a replica of original statements. As part of a customer service initiative, Customer XYZ is permitted to access the system and retrieve and view their statements.

About the application group
Before adding the application group, review the database and storage management requirements.

Database requirements: Database requirements can be grouped in two categories: database tables and the database fields.

Database tables:
• A database table contains index data from one or more reports
• An annotation field is not required in the database
• The date field is the segment field for the application group

Database fields:
• Three database fields: account number, customer name, and report date
• Account number is the index, data type string, 16 bytes. However, only 13 bytes should be stored in the database, removing the - (dash) characters from the account number string.
• Customer name is a filter, data type string, 30 bytes
• Report date is a filter, data type date

Storage management requirements: The storage management requirements determine where, how, and how long OnDemand maintains the report and index data.
• Maintain a report for five years
• Copy documents to disk and maintain them for 60 days
• Copy documents to archive storage when the report is loaded into the system
• Delete a table of index data at a time

Adding the application group
Use the New Application Group command to add the application group.
1. First, point to Application Groups and click the right mouse button. From the pop-up menu, select New Application Group. The administrative client opens the Add an Application Group dialog box.
The pages of the Add an Application Group dialog box organize information about the application group into sections. The tabs show which page you are on: General, Message Logging, Storage Management, Permissions, Field Definition, and Field Information.

2. Start by completing the General page. In the Name field, type the name of the application group.

3. In the Description field, type up to 120 characters of descriptive information about the application group.

4. Based on the database requirements, accept the recommended defaults for the rest of the fields on the General page. (You can click Advanced to see the default options.)

   Figure 17 shows the completed General page.

   ![Figure 17. General page](image-url)

5. Select the Message Logging tab to specify the types of application group messages that OnDemand should save in the system log.

6. Select Retrieval, Database Queries, and Server Printing. Clear all of the other check boxes.

   Figure 18 on page 85 shows the completed Message Logging page.
7. Select the Storage Management tab to provide information that OnDemand uses to manage data stored in the application group.

8. From the Storage Set Name list, select the name of the storage set that OnDemand will use to maintain the report on disk storage and in archive storage. Select the storage set and migration policy that was defined in “Adding storage sets” on page 82.

9. Under Cache Data, select Cache Data for ___ Days and enter 60 in the space provided. OnDemand should maintain the report on disk storage for 60 days. After that time, when a user views or prints the report, OnDemand retrieves the report from archive storage.

10. Under Life of Data and Indexes, select Expire in ___ Days and enter 1825 in the space provided. This is the number of days (1825, or five years) that OnDemand should maintain index data, documents, and resources related to the report. After that number of days, OnDemand can delete the report from the system.

11. Because OnDemand should delete a table of index data at a time, from the Expiration Type list, select Segment. Figure 19 on page 86 shows the completed Storage Management page. Although the example shows the selection of an Expiration Type of Segment, the recommended selection for this field is Load. (You can click Advanced to see other, default options.)
12. Select the Permissions tab to specify the types of report and application group functions that users can perform. For example, you can let users query report data, create logical views, print and fax pages of the report, and maintain the application group. You can specify default permissions and permissions for specific groups and users. Unless you specify otherwise, the person that creates the application group is given all application group permissions; no other users can access report data or maintain the application group. For the example system, other users obtain permissions from a group. The groups were added in “Adding the customer service group” on page 78 and “Adding the Customer XYZ group” on page 79.

13. First, add the customer service group. From the User/Groups list, select +CustomerService.

14. Select the Access check box.

15. Click Add.

16. Next, add the Customer XYZ group. From the User/Groups list, select +CustomerXYZ.

17. In the Annotation area, clear the View check box. OnDemand also clears the Add check box. Customer XYZ users can view, print, fax, and copy documents but do not have permission to use the annotation tools provided by OnDemand.

18. Click Add.

Figure 20 on page 87 shows the completed Permissions page.
19. Select the Field Definition tab to define the database fields. Define three database fields for the telephone bill report:
   • Account number
   • Customer name
   • Report date

   To define a database field, type the name of the field in the Database Field Name field and click Add.

   Figure 21 shows the completed Field Definition page.

20. Select the Field Information tab to define the attributes of the database fields.

21. First, define field information for the account number field.
   • From the Type list, select Index
   • Type the string length (13)
Figure 22 shows the Field Information page for the account number field.

![Figure 22. Field Information page](image)

**Note:** IBM recommends that you always define an application ID field for the application group. An application ID field is a database field that contains values that identify an application within the application group. Figure 23 shows an example of an application ID field.

![Figure 23. Field Information page for application ID field](image)

You may not think that you need an application ID field at the time that you create your application group, if you are adding an application group that will hold only one application at the current time. However, if you decide later to add other applications to the application group (or if you want to maintain multiple versions of your application definitions) and you then need to define an application ID field for the application group, you will not be able to do so because an application ID field cannot be added after the application group is created. (All fields must be added during the original application group definition.) Also note that the application ID field can be “hidden” from users.
that do not require it to search for documents. See the online help for more information about the application ID field.

22. Next, define field information for the customer name field.
   - From the Name list, select custname
   - From the Type list, select Variable
   - In the Length field, type 30
     Figure 24 shows the Field Information page for the customer name field.

23. Next, define field information for the report date field.
   - From the Name list, select rdate
   - From the Data Type list, select Date
   - Select the Segment check box
     Figure 25 shows the Field Information page for the report date field.
24. At this point, the properties of the application group meet the requirements. Click OK in the Add an Application Group window. The administrative client adds the application group to the database and returns to the main window.

**About the application**
Before adding the application, review the viewing, indexing, and loading requirements.

**Viewing requirements:**
- Source data stored in OnDemand as AFP data
- Format data into pages and enhance the appearance with images and fonts
- Retrieve statements of one or more pages
- Define a default printer for the application. The default printer is where OnDemand sends documents when users select the server print command.

**Indexing requirements:**
- Source data is EBCDIC, code page 500
- Segment report into groups of pages, one statement in each group
- Identify the beginning of a statement using:
  - Skip-to-channel one (X’F1’)
  - PAGE 1 (X’D7C1C7C5404040F1’)
- Generate three indexes for each statement: statement date, account number, and customer name
- Collect resources

**Loading requirements:**
- Compress and store data in the most efficient method possible
- Application group database field names and index names match
- Date format is Mth d, yyyy
- Remove embedded - (dash) character from account number before storing value in the database

**Adding the application**
Use the New Application command to add the application.

1. First, point to Applications and click the right mouse button. From the pop-up menu, select New Application to open the Add an Application dialog box.
   The pages of the Add an Application dialog box organize information about the application into sections. The tabs show which page you are on: General, View Information, Indexer Information, Load Information, Logical View Fields, Logical Views, and Miscellaneous Options.
2. Start by completing the General page. In the Name field, type the name of the application.
3. In the Description field, type information about the application.
4. Click Select to open the Application Groups dialog box.
5. From the Names list, select Telephone Bill Reports.
6. Click OK.
   ![Figure 26 on page 91](image.png) shows the completed General page.
7. Select the View Information tab to specify information needed by OnDemand client programs to display the telephone bill report. This information is also used by the indexing program.

8. From the Data Type list, select Line. Note that although this example shows Line data type, most i5/OS spooled files will be either SCS or AFP.

9. Enter the correct Code Page. For Line, SCS, and SCS-Extended data types, this field determines the code page used by the OnDemand client to display the data. For Line, the default value is 500. For SCS and SCS-Extended, the default value is the code page of the server.

10. In the RECFM area, select Fixed. The report contains fixed length records, 133 bytes in length.

Figure 27 on page 92 shows the View Information page.
11. Select the Indexer Information tab.
12. From the indexer list, select OS/400 Indexer.
13. Process a sample report using the graphical indexer. In the Parameters Source area, select Sample Data.
14. Click Modify to open the Open dialog box to select a file that contains a sample of the actual report data.
15. Select OS/400 Spooled File to work with spooled files on the server. Identify how to find your spooled file by entering a user profile or output queue name, and then click Retrieve List to generate a list of spooled files to choose from. Once you select a specific spooled file, OnDemand copies that sample data to your workstation for you to use for indexing.

Figure 28 on page 93 shows the report window.
16. Define trigger number one. First, select any blank column in the first record. Click the Add a Trigger icon to open the Add a Trigger dialog box. (See online help for a description of trigger fields.)

17. In the Columns to Search area, select Carriage Control. Figure 29 shows the completed Add a Trigger dialog box for Trigger1.

18. Click OK to add the trigger.

19. Define trigger number two. First, select the string PAGE from the pop-up menu, select Trigger to open the Add a Trigger dialog box.
20. Click OK to add the trigger.

21. Define field number one. First, select the string Customer XYZ and enough blank characters to the right of the string to reserve enough space to hold the largest index value (30 characters) the field can contain. (The selected string length guide, which appears above the field, displays the number of selected characters.) Then click the right mouse button. From the pop-up menu, select Field to open the Add a Field dialog box.

22. From the Trigger list, select Trigger2.

Figure 30 shows the completed Add a Field dialog box for Field1.

23. Click OK to add the field.

24. Define field number two. First, select the string May 11, 1996. Then click the right mouse button. From the pop-up menu, select Field to open the Add a Field dialog box.

25. From the Trigger list, select Trigger2.

26. Click OK to add the field.

27. Define field number three. First, select the string 303-555-1212-95B. Then click the right mouse button. From the pop-up menu, select Field to open the Add a Field dialog box.

28. From the Trigger list, select Trigger2.

29. Click OK to add the field.

30. Define the indexes. First, clear any selected areas of the report. To define the first index, click the "Add an Index" icon to open the Add an Index dialog box.

31. From the Attribute list, select custname.

32. In the Break area, select No.

33. In the Fields list, double-click Field1.

Figure 31 on page 95 shows the Add an Index dialog box for Index1.
34. Now define the second index. From the Attribute list, select rdate.
35. In the Break area, select No.
36. In the Fields list, double-click Field2.
37. Now define the third index. From the Attribute list, select acct.
38. In the Fields list, double-click Field3. Notice that you will leave the Break setting set to Yes for this index. This will cause OnDemand to watch for a change in the value of the acct index, using the change to indicate an end to one document and the beginning of the next when breaking up the input file into separate documents. For more detail on this Break setting, see the Content Manager OnDemand for iSeries Common Server Indexing Reference.
39. Click Done to close the Add an Index dialog box.
40. Close the report window, saving the changes.
41. Select the Load Information tab to specify information that OnDemand uses to process the index data before storing it in the database.
42. In the Application Group DB Name list, select rdate. Specify the format of the date as it appears in the report.
43. From the format list, select %b %e, %Y.

Figure 31. Add an Index dialog box

Figure 32 on page 96 shows the Load Information for the report date field.
44. In the Application Group DB Name list, select acct. To conserve space in the database, OnDemand should remove the - (dash) character from index values before storing the values in the database. Also, it is best to define your numeric index fields (including date fields) so that leading, trailing, and embedded blanks, dashes, currency symbols, thousands separators, etc. are removed by OnDemand prior to being stored. Edits on these fields are sometimes strict and can cause a load to fail if non-numeric characters are found within the fields being defined.

45. In the Embedded field, type the - (dash) character. **Figure 33 on page 97** shows the Load Information for the account number field.
46. Select the Miscellaneous Options tab to provide information that OnDemand uses to print the report.

47. From the Default Server Printer list, select Customer Service printer. This is the printer that was added in “Adding server printers” on page 80. Figure 34 shows the completed Miscellaneous Options page.
At this point, the properties of the application meet the requirements. If, however, you need to use an i5/OS printer file to further define some of the server print parameters, see Appendix D, “Server printing and faxing,” on page 179 for details. Click OK in the Add an Application window. The OnDemand Administrator adds the application to the database and returns to the main window.

About the folder

Before adding the folder, review the data access requirements, the types of permissions to specify, and the search and display fields to define.

Data access requirements: The folder allows users to access the telephone bill report application group and the telephone bill report application.

Permissions: Who needs access to the folder and what types of permissions do the users need?

- Users in the customer service department can open the folder to search for and retrieve statements.
- Users at Customer XYZ can open the folder to search for and retrieve statements that contain their account number and customer name.
- Define a set of folder fields for the Customer XYZ users. The folder fields will limit access to specific statements.

Search and display fields: Define two sets of folder fields:

- One set at the folder level. These folder fields allow users in the customer service department to access any statement in the database.
- One set for the Customer XYZ group. These folder fields allow users at Customer XYZ to access specific statements.

Adding the folder

Use the New Folder command to add the folder.

1. First, point to Folders and click the right mouse button. From the pop-up menu, select New Folder to open the Add a Folder dialog box.
   
   The pages of the Add a Folder dialog box organize information about the folder into sections. The tabs show which page you are on: General, Permissions, Field Definition, Field Information, and Field Mapping.

2. Start by completing the General page. In the Name field, type the name of the folder.

3. In the Description field, type up to 120 characters of descriptive information about the folder.

4. Select the Display Document Location check box. This provides users with a visual clue about the type of media on which a statement is stored.

5. In the Application Groups list, select Telephone Bill Reports.

   Figure 35 on page 99 shows the completed General page.
6. Select the Permissions tab to specify the types of folder functions that users can perform. For example, you can let users open the folder, create private named queries, and maintain folder fields. You can specify default permissions and permissions for specific groups and users. Unless you specify otherwise, the person that creates the folder is given all folder permissions; no other users can open or maintain the folder. On the example system, other users obtain permissions from a group. Add two groups to the folder. The groups were added in “Adding the customer service group” on page 78 and “Adding the Customer XYZ group” on page 79.

7. From the Users and Group list, select +CustomerService.

8. Select the Access check box.

9. Click Add, to add the Customer Service group to the folder.

10. From the Users and Group list, select +CustomerXYZ.

11. Click Add, to add the CustomerXYZ group to the folder. Figure 36 shows the Permissions page.

Figure 35. General page

Figure 36. Permissions page
12. Select the Field Definition tab to define the folder fields. Define four folder fields to allow users to search for statements:
   • Account Number, a string field
   • Customer Name, a string field
   • Report Date, a date field
   • Other Information, a text search field

13. Complete the following steps to define a folder field:
   • In the Name field, type the name of the folder field.
   • In the Description field, type up to 120 characters of descriptive information about the folder field.
   • From the Field Type list, select the data type of the field. For the other Information field, select a data type of text search.
   • Select the Mapping Type. All of the fields in this example use the Single mapping type.
   • Click Add.

   Figure 37 shows the completed Field Definition page.

14. Select the Field Information tab to specify the properties of the folder fields. Using the *PUBLIC identifier, you can specify field information that is used by all users that can open the folder. You can also specify field information for specific users and groups. The public field information will be used unless it is overridden by field information for a specific user or group. For the example folder, do the following:
   • Specify public field information. For the Account Number, Customer Name, and Other Information fields, accept the default values. For the Report Date field, specify field information.
   • Specify field information for the CustomerXYZ group. For the Other Information and Report Date fields, accept the default values. For the Account Number and Customer Name fields, specify field information.

15. First, specify the public field information for the Report Date field. See online help for date format or time format values for the Display Fmt and Defaults Fmt fields.
   • From the Name list, select Report Date
• From the ID list, select *PUBLIC
• Select the Default check box
• From the Display Fmt list, select %b %e, %Y
• From the Defaults Fmt list, select %b %e, %Y
• In the Interval area, select Last, type a 3 (three) in the entry field and select Months

Figure 38 shows the Field Information page for the Report Date field.

16. Next, specify the field information for the CustomerXYZ group. First, make a copy of the folder fields. Click the Permissions tab.
17. From the Selected List, select +CustomerXYZ.
18. In the User/Group Fields area, click Yes.

Figure 39 shows the completed Permissions page.

19. Click the Field Information Tab.
20. Specify the Customer XYZ field information for the Account Number field.
   • From the Name list, select Account Number
   • From the ID list, select +CustomerXYZ
   • From the Default list, select Equal
   • Clear the Like check box
   • Select the Default check box
   • Select the Fixed check box
   • In the first Defaults entry field, type 1234567890123
   • Clear the Append check box
   Figure 40 shows the Field Information page for the Account Number field.

21. Next, specify the Customer XYZ field information for the Customer Name field.
   • From the Name list, select Customer Name
   • From the Default list, select Equal
   • Clear the Like check box
   • Select the Default check box
   • Select the Fixed check box
   • In the first Defaults entry field, type Customer XYZ
   • Clear the Append check box
   Figure 41 on page 103 shows the Field Information page for the Customer Name field.
22. Select the Field Mapping tab to map the folder fields to application group database fields. OnDemand uses the values that users type in folder fields to construct SQL queries. An SQL query uses the database field name.

23. Map the following folder fields to their corresponding application group fields:
   - Account Number to acct
   - Customer Name to custname
   - Report Date to rdate

   Figure 42 shows the completed Field Mapping page.

24. At this point, the properties of the folder meet the requirements. Click OK in the Add a Folder window. The administrative client adds the folder to the database and returns to the main window.

Summary
The example shows the basic requirements for adding a report to the system. Hopefully the scenario that was described and developed is similar to how you
plan to use OnDemand at your company. The example should have enough
variations to show the flexibility of OnDemand to meet a range of business and
operational requirements. Of course, there are several tasks that were not shown.
For example, logical views of the report were not created. The system log user exit
was not explored. And all of the ways to complete a given task or implement a
specific requirement were not shown. As with most administrative software, there
is more than one way to accomplish a task. Hopefully, the example showed you
the most straightforward way to get things done with the administrative client.

You can use reference information provided with the product and the online help
to find out more about how to use OnDemand. If you have questions and cannot
find the answers, contact the IBM support center. IBM also offers classes that
further explore how to administer the system. Finally, you can let IBM know how
well the information in this book was presented and if you found the book helpful.
The section titled How to Send Your Comments explains how to let IBM know.

---

**Adding a new field to an existing application group/application/folder**

In order to consume the least amount of disk space for index data, OnDemand
creates a unique index database file for each OnDemand application group, based
on the index fields defined in the application group. The index database file is
created the first time data is stored for that application group. Because of this, it is
not possible to simply add another index field later, since the database file has
already been created. However, if you find yourself needing to add an additional
index field after some of your data has already been stored, here is one technique
you could use to accomplish that same result:

1. Rename the application group, application, and folder. You might just add an X
   (for example) to the end of the name.

2. Copy the application group to a **new** application group, giving it the original
   name (so the output queue monitor can still look for this name). In the copy
   process, you can add a new database field.

3. Copy the application to a **new** application, giving it the original name, adding
   the field and index using the graphical indexer.

4. Copy the folder to a **new** folder with the original name. In the copy process,
   add a new folder field and add the **new** application group to the folder. Map
   the folder fields to the **new** application group fields. Now, you have a single
   folder which points to two application groups, one with the old set of index
   fields and one with the new field added.

The new index field will only be searchable for the new application group. But the
folder will also show all the old data, just without the new index field.

---

**Local server setup for offline administration**

OnDemand supports two types of servers. The first type of server uses TCP/IP to
communicate between the client programs and the server programs. The server
programs can run on operating systems, such as AIX®, HP-UX, i5/OS, OS/400,
Sun Solaris, Windows , z/OS® and OS/390®. Depending on the server operating
system, the databases supported by the server can be DB2®, Oracle (AIX, HP-UX,
Sun Solaris, Windows platforms only), and Microsoft® SQL server (Windows
platform only). Definitions of users, groups, applications, for example, are stored in
the database as well as the index values for the report data that is loaded into the
system.
The second type of server is a local server. The local server is self-contained (no TCP/IP communication) and is defined using files contained in a directory located on a PC rather than in a server database. The files represent the system tables that define the various objects such as users, groups, and applications.

One of the uses of a local server is to enable OnDemand administrators to work offline on administrative tasks. Another is to provide the ability to export definitions from a non-local server to a local server so the definitions can then be imported to a different non-local server. This is especially beneficial when a TCP/IP connection does not exist between two non-local servers. In either case, one of the limitations of exporting definitions from a non-local server to a local server is that the local server does not support any of the operating system-specific or database-specific parameters that are defined when using the administrative client.

When an OnDemand administrator logs on to a server, the OnDemand Administrator client determines whether the user has logged on to a local server or a non-local server. If the server is a non-local server, the operating system and the database types are determined. Based on the type of server, the operating system, and the database, default settings are established, entry fields are hidden or displayed, and values are added to or removed from selection lists. For definitions that have been exported from a non-local server to a local server, updating or viewing the definitions may not have the desired results because of the operating system differences between local and non-local servers. For example, when an application group and application are exported from an i5/OS server to a local server, the OS/400 Indexer that is specified in the application is not supported on a local server. When the application is viewed on the local server, the indexer field on the Indexer Information page will not have a value and the OS/400 Indexer will not be listed as a choice of indexers.

To correctly display the operating system- and database-specific parameters on a local server from parameters that have been exported from a non-local server, support has been added to the OnDemand Administrator client at version 7.1.0.8 and higher. Pulldowns for Operating System and Database appear on the Add a Server dialog box when you create a server with the Protocol parameter set to Local. Then, in the case of the application group and application that were exported from the i5/OS server, the OS/400 Indexer will now be selected when the application is updated or viewed from the local server.

**Note:** Although a local server can resemble a non-local server, the following are system limitations for a local server:

- The userid of a user that is defined on a local server cannot be updated.
- User and group permissions for users are not supported from the User Permissions page on Users dialog box.
- The Find function is not supported.
- Server Printers are not supported.
- Data Distribution Files and Groups are not supported.

**Note:** For a local server, the default administrative userid is admin. There is no initial password set for the admin userid on a local server.
Part 4. Loading data

This part describes how to store data in OnDemand. The OnDemand data indexing and loading programs can process many types of input data, including AFP data, line data, unformatted ASCII data, Adobe PDF files, and other types of user-defined data. You can also load compressed and uncompressed, single and multi-page TIFF images into the system. OnDemand can also process input files that contain graphics data, such as BMP, GIF, JFIF, and PCX. When you store data in OnDemand, the data indexing and loading programs extract index data from or generate index data about the input data. The index data is loaded into the OnDemand database. The input data is divided into indexed groups of pages (documents), compressed into storage objects, and copied to storage volumes. The OnDemand database is updated with the index information that allows users to search for and retrieve documents using OnDemand client programs. You can store copies of documents on disk and archive storage.
Chapter 10. Loading spooled file data

This section provides an overview of the data loading process - the process of adding the index data to the database and loading the report data and resources into OnDemand. When a load process completes, you can view the messages that were saved in the system log. To complete the data loading process, you should backup the OnDemand data on a regular basis.

Overview

You can archive the print output of your existing application programs in OnDemand without changing the print data stream or writing programs to process the data. In OnDemand, the print output of an application program is called a report. OnDemand provides programs that can index the reports, add the index data to the database, divide the input data into indexed groups of pages (documents), compress the documents, and copy the compressed documents into OnDemand. After you archive a report in OnDemand, your users can query, retrieve, and view or print pages of the report using the OnDemand client program.

The OnDemand data indexing and loading programs process input files that reside on the OnDemand server. If you generate your reports on another system, then you would typically transfer the reports to the OnDemand server and use the data indexing and loading programs to process them. When you index a report that contains AFP data, you must make sure that the data indexing program can access the resources required by the report. Resources include page segments and fonts. If the resources are not already on the OnDemand server, you must transfer them before loading the report.

You can create up to 32 index fields for each type of report that you define to OnDemand, providing many ways for users to query information contained in a report. The number of index fields that you define depends on the organization of the data in the report. For example, when you index a report that contains logical items, such as policies and statements, you might define index fields for the date, customer name, customer number, balance due, transaction number, and amount. When you index a report that contains transaction data, such as a general ledger, you might define index fields for the date and transaction number. After you determine what index fields you need and define them to the system, OnDemand extracts the index values from a report during the load process and stores them in records that are added to the database.

OnDemand compresses report data into storage objects, using information that you specify in the application. Depending on how you configure storage management for your application groups, OnDemand can automatically copy the report to disk and archive storage.

The load process saves messages in the system log each time that you load an input file into the system. You can open the System Log folder and view the messages for information such as the name of the input file, the indexing information, and the number of rows that were added to the database.
Preparing to load reports

There are a number of things to consider when preparing to load reports.

Storage space
When you initially configure an OnDemand system, you calculate the total amount of disk, optical, and tape storage required to hold the OnDemand database, database log files and reports. You also need to plan for the temporary space needed by OnDemand programs. The amount of storage space that you need on your system is usually a factor of how much data that you plan to store in OnDemand, how long you need OnDemand to maintain the data, the compression ratio that you can expect to achieve on the report data, and the number of copies of reports that you need the system to maintain. If you plan to index your reports on the OnDemand server, then you must allocate temporary space for the data indexing program. Temporary space is also required for the data loading program.

The IBM Content Manager OnDemand for iSeries Common Server: Planning and Installation Guide provides information, formulas, and worksheets that can help you calculate your storage requirements.

Defining the application group
When you archive reports in OnDemand, the ADDRPTOND command adds index data to the database and compresses report data into storage objects and copies the storage objects into OnDemand. The index data and the storage objects are associated with an application group. As part of defining a report to OnDemand, you must specify the application group that OnDemand uses to maintain the data. The application group specifies the database fields that hold the index data and the storage management information that determines where OnDemand maintains the report data and how long it maintains the index data and the report data. You can use the OnDemand administrative client to define an application group. See the online help for the administrative client for more information about defining database fields and specifying storage management information for application groups.

If you plan to maintain a copy of your reports in archive storage, then the application group must specify a migration policy and storage set that identify your storage management requirements.

Defining the application
Most customers define an application for each different report (or source of data) that they plan to archive in OnDemand. When you create an application, you specify information about the report, such as:
- The application group in which you want to store the report
- Physical information about the report, including the type of data found in the report
- The indexing parameters
- The processing that OnDemand should do to the index data before adding it to the database

You can use the OnDemand administrative client to define an application. See the online help for the administrative client for more information about defining applications.
Loading reports

You can load reports into OnDemand in a number of different ways, depending on your application requirements.

Running the ADDRPTOND command

The ADDRPTOND command is the primary OnDemand data indexing and loading command. The ADDRPTOND command determines if the input data needs to be indexed, and if it does, calls the indexing program. The ADDRPTOND command then processes the index data, adding it to the database, optionally compresses the report data into storage objects, and copies the storage objects to storage volumes.

You run the ADDRPTOND command each time that you want to load a report or set of reports into the system. You can either run the command from the command line or use the OnDemand output queue monitor to periodically check for input data to process. See “Using an output queue monitor” below for more detail.

**Note:** The OnDemand server job must be running, otherwise the ADDRPTOND command will fail.

Using an output queue monitor

You can use the Start Monitor for OnDemand (STRMONOND) command to start a monitor program for any output queue to receive spooled files for processing. The monitor continuously checks an output queue for spooled files, and allows OnDemand to capture the spooled files as they arrive.

**IBM recommends using the monitors in a batch environment only.**

You generally define and then manually store reports with the ADDRPTOND command during testing. Then, when the report is ready for production, you can automate storage with the OnDemand monitor—if you use the *SPLFNAME, *FORMTYPE, *USERDATA, *JOBNAME, or *USRDFNxxxx spooled file attribute of the report to match the application group and application names you defined to OnDemand.

The spooled files must be in ready status (RDY) on the output queue that you are monitoring. The first time a Monitor is started for an output queue, OnDemand will create a data queue and attach it to the output queue being monitored. If there are spooled files already in that queue, the monitor will not detect them. If this happens, place these spooled files on hold, then release them. The Monitor should then detect and process them. This should only be necessary the first time a Monitor job is started for a particular output queue.

To begin capturing reports automatically when a spooled file arrives in a particular output queue, you can issue the STRMONRDAR command. The monitor runs continuously until the End time or Number of hours occurs. You can also use the End Monitor for OnDemand (ENDMONOND) command to stop processing.

The default job name for the monitor job is MONOUTQ. After the job has ended, the job log can be found with the User data (USRDTA) spooled file attribute set to MONOUTQ. For every spooled file that the monitor has processed, there will either be a successful load (message number 87) or a failure (message number 88) indicated in the System Log.
The monitor processes any spooled files that arrive in the named output queue in RDY (Ready) status. Spooled files with any other status are not affected by the monitor, and remain in the output queue until they are deleted or moved.

When a Common Server monitor job is active, the job status displayed by the Work with Active Jobs (WRKACTJOB) command changes a number of times during processing. The monitor job has a status of RUN when it is preparing to process a document (such as determining parameter values or running an exit program). It then spawns several jobs and goes to a status of TIMW while those jobs do the actual archiving. When the processing is complete, the status changes back to RUN while the monitor checks what needs to be done next. If there are no additional documents that are ready to be archived the monitor job goes into a DEQW status until the next document is ready to be archived or a request to end the monitor job is received.

You may wish to add the STRMONOND command to your system startup program so the monitor(s) start each time you IPL the system.

When starting an OnDemand output queue monitor (using the STRMONOND command) from a job scheduler, you may be unsure of what job description to use. In most cases, STRMONOND will work best using the QOND400 job description. You may have special system needs that require the use of your own job description, but these two IBM-supplied job descriptions will work successfully for many customers.

See the online help for more information about these commands and their parameters.

**Important:** The OnDemand server job must be running, otherwise the spooled files will fail to load.

**Indexing reports**

You must generate index data for a report before you load the report into OnDemand. If the report contains AFP data, then you need to store the AFP resources in OnDemand. The resources are required to display and reprint pages of a report that contains AFP data. There are several programs provided with OnDemand to help you generate index data for your reports:

- **OnDemand OS/400 Indexer** - You can use the OS/400 Indexer to specify indexing parameters for SCS, SCS-Extended, Advanced Function Presentation (AFP), and Line spooled files.
- **OnDemand PDF Indexer** - You can use the PDF Indexer to specify indexing parameters for Adobe PDF input files.
- **OnDemand Generic Indexer** - You can use the Generic Indexer to specify index data for a wide variety other types of input files.

For details about indexing data, including how to use other indexers, see the IBM Content Manager OnDemand for iSeries Common Server: Indexing Reference.

**Processing the input data**

After a report has been indexed, the ADDRPTOND command can process the index file to prepare the index data for loading into the database and prepare the report data and resource group files for the storage managers to load on storage volumes.
Processing index data

The index data is processed by the ADDRPTOND command before the index data is added to the database. The ADDRPTOND command extracts information from the application group and the application and performs the following processing:

- Determines the database field information from the application group.
- Determines the preprocessing information from the application, if needed.
- After preprocessing the index file, the ADDRPTOND command creates the database rows:
  - One row for every group of indexed pages in a report that contains a sorted transaction value
  - One row for every indexed item in a report that contains logical items, such as policies and statements
- Determines the postprocessing information from the Postprocessor Parameters specified on the Load Information tab of the application. For example, the ADDRPTOND command may need to drop duplicate index records. You specify exactly what processing you want the command to do when you define the application.
- Passes the index rows to the database manager. The rows consist of fields that contain the index values that the indexing program extracted from the report and other fields generated by OnDemand. An index row contains:
  - One column for each field defined in the application group
  - One or more columns of OnDemand control information

Processing reports and resources

The ADDRPTOND command divides the input data into indexed groups of pages (documents) and compresses the documents into storage objects. Dividing a report into groups of pages improves the efficiency of queries and can improve the time required to retrieve and display the report. Compression improves the efficiency of the storage manager. In this step, the ADDRPTOND command:

- Determines the compression information from the application.
- Determines the storage management information from the application group. The storage management information determines the storage locations, such as disk storage and archive storage.
- Locates the AFP resources called for in the input data. If the resources are not available, the load will fail and the System Log will be updated with message number 88, indicating the failure. An ADDRPT joblog will contain error messages.
- Compresses the documents into storage objects. OnDemand compresses report data into approximately 100 KB blocks (a default value) and places the blocks into a storage object. OnDemand uses a 10 MB storage object (a default value) to improve storage efficiency and performance. Compressed data does not span storage objects. OnDemand assigns unique file names to the storage objects and sequentially numbers them within an application group.

Loading index data

The ADDRPTOND command works with the database manager to add the index data to the database. Depending on the database organization that you specified when you defined the application group, OnDemand either creates a new table each time that you load a report or adds the index data to an existing database table.
OnDemand uses a segment table as a high level index to the index data for an application group. Each row in the segment table identifies a specific table of application group index data. The fields in the segment table identify the application group and the dates found in a table. The dates represent the earliest and latest dates that can be found in that segment of application group index data. OnDemand can use the segment table to limit a query to a specific table of application group index data.

The database manager updates the segment table if the beginning date in the report is earlier than a date already stored in the table.

OnDemand limits the size of a table to improve performance and storage management. The number of rows in a table can be specified when you define the application group. The default size of a table is ten million rows. The database manager automatically closes a table and opens a new table when this threshold is reached. When closing a table, the database manager updates the segment table with the latest ending date found in the table.

### Loading storage objects

The ADDRPTOND command calls the storage manager to copy storage objects to disk and archive storage. The storage manager extracts information from the application group to determine where and when to copy the storage objects.

OnDemand uses an object called a storage set to determine the locations that can hold report data. A storage set and its associated migration policy (of the exact same name) point to one or more storage locations. A storage set can write data to one and only one storage location at a time (the active storage level).

### Disk storage

The primary purpose of disk storage is for short-term, high-speed retrieval of report data.

If you configure your application groups to copy data to disk storage, then the disk storage manager copies the storage object to disk. The Cache Data for xx Days setting on the Storage Management page determines whether OnDemand copies documents to disk storage.

### Archive storage

A storage set can identify an archive storage media such as optical or tape. OnDemand uses its archive storage manager to maintain storage objects in archive storage for long-term storage and for backup copies of reports.

The storage manager can copy the storage object to archive storage when the report is initially loaded into the system or at a later time, depending on how you configure your application groups. Most customers configure the system to copy report data to disk and archive storage at the same time.

### Resources

OnDemand always stores resources (such as AFP overlays or page segments) on disk, to provide fast retrieval when a user selects an item for viewing. OnDemand saves only one copy of a resource on the system, even if several reports use the
same resource. When processing a resource group file, the ADDRPOND command checks the resource identifier to determine if the resource is already present on the system.

Verifying processing

When you add a report into the system, the ADDRPOND command saves a copy of the messages generated during the load process in the system log. After a load process completes, you can open the System Log folder and view the messages. Message number 87 indicates a successful load; message number 88 indicates a failure, and should produce an ADDRPOND job log that contains additional error messages. The System Log message reference the load program named ARSLOAD and include the date and time that the load process started and completed, the name of the input file, and the number of rows that were added to the database. For example:

arsload: Processing file br1010a
arsload: Fri Mar 29 12:37:23 MST 1996 Indexing started, 394419060 bytes to process
arsload: Fri Mar 29 12:41:33 MST 1996 Indexing completed
arsload: Fri Mar 29 12:41:35 MST 1996 Load Started, 394419060 bytes to load
Resource br1010a.res matches the resource 2
OnDemand Load ID = >6850-25-0-15FAA-9577-9577<
Loaded 130000 rows into the database
arsload: Fri Mar 29 13:05:14 MST 1996 Load Completed
arsload: Processing successful for file br1010a

You can verify the number of rows that OnDemand added to the database:

- For a report that contains transaction data that you have divided into indexed groups of pages, the number of pages in the report divided by the number of pages in an indexed group of pages should equal the number of rows added to the database. For example, if a report contains 150,010 pages and there are 100 pages in an indexed group of pages, then OnDemand should have added 1,501 rows to the database.
- For a report that contains logical items, such as statements and policies, the number of rows added to the database should equal the number of indexed items in the report. For example, if a report contains 1,000 statements, OnDemand should have added 1,000 rows to the database.

The OnDemand Load ID represents the data that the ADDRPOND command stored in the system during a load process. The Load ID can be used to identify a specific load process. For example, you can run the RMVRPOND command and specify the Load ID to delete the index data and documents that were created when the ADDRPOND command processed an input file. Table 6 lists the fields in a Load ID.

Table 6. OnDemand Load ID

<table>
<thead>
<tr>
<th>Load ID Field</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>6850</td>
<td>Application group identifier</td>
</tr>
<tr>
<td>25</td>
<td>Primary node identifier</td>
</tr>
<tr>
<td>0</td>
<td>Secondary node identifier</td>
</tr>
<tr>
<td>15FAA</td>
<td>The load identifier within the application group</td>
</tr>
<tr>
<td>9577</td>
<td>The earliest date in the report (relative to 1/1/1970)</td>
</tr>
<tr>
<td>9577</td>
<td>The latest date in the report (relative to 1/1/1970)</td>
</tr>
</tbody>
</table>
Backing up databases

After you load reports into OnDemand, we recommend that you create a backup copy of the OnDemand data.

- When you backup the OnDemand database, you protect control information and index data that OnDemand and the database manager need to support the system.

- When you backup the OnDemand data in IFS, you protect your data that resides on disk that may not have been copied to archive media yet.

We recommend that you backup the data at least once a week, and more often if you load reports every day.

See Chapter 5, “Backup and recovery,” on page 23 for details about OnDemand backup and recovery.
Chapter 11. Loading image files

Overview

OnDemand provides support for storing and retrieving letters and other types of correspondence. The most straightforward way to store this type of information is to transform a printed copy of a letter into an image file using a scanner and image capture software. In addition to scanning the letter and saving it as an image file, you must create index data for the letter. You can then use the ARSLOAD program to load the index data into the database and store the letter file on the system. Your users can then query, retrieve, and view, print or send copies of the letter using one of the OnDemand client programs.

OnDemand provides the Generic Indexer so that you can index input files that contain data other than AFP data, line data, and PDF. You specify the index data for the input files that you want to index with the Generic Indexer in a parameter file. The parameter file contains the index field names and values and identifies the input files that you want to process. You can create up to 32 index fields for each input file that you want to load into the system, providing many ways for users to query and retrieve the letters. The number of index fields that you define usually depends on how your users retrieve documents from the system. In the example that follows, index fields were defined for the date on the letter, the name of the person that sent the letter, the company name, and the subject of the letter.

This section describes how to use a scanner and image capture software to create the image files. Before you can load the image files into the system, you must define an application group to manage the storage of the letters, an application to specify the physical and logical properties of the letters, and a folder to let users search for and retrieve the letters.

Defining the application group

When you load an input file into the system, OnDemand updates the database with the index data that you provide and stores the indexed groups of pages as documents in cache storage and archive storage. The application group contains the information that OnDemand uses to store and maintain the index data and the documents on the system. This section provides information about some of the key properties of the application group. You can use the OnDemand administrative client to define an application group.

Database Organization

The Database Organization determines how OnDemand organizes the index data that is stored in the application group.

Accept the default Database Organization of Multiple Loads per Database Table and Table Size of its maximum number of rows. Each time that a letter (input file) is loaded into the system, OnDemand adds one row to a database table. When a table reaches its maximum number of rows, OnDemand closes the table and creates a new table. OnDemand always adds index records to the open table; the closed tables can be queried.
Expiration Type

The Expiration Type determines how OnDemand deletes index data and documents from the application group.

Accept the default Expiration Type of Load. This means that OnDemand deletes the index data and documents from one load process (one or more input files) at a time from the application group. Depending on the number of input files processed during a load process, one or more letters (input files) may be deleted at a time. For example, if you create a parameter file for the Generic Indexer that contains index data for several input files, then OnDemand will delete all of the index data and documents from the application group at the same time.

Permissions

Application group permissions determine the users that can access information stored in the application group and determine the users that can do other types of tasks related to the application group.

Under the *PUBLIC identifier, specify the Access permission so that all of the users defined to the server can access data stored in the application group.

Field Definition

The Field Definition page is where you define the database fields for the application group. When you load an input file into the system, OnDemand stores the index data that is specified in the parameter file into fields in records that are added to the database. When a user searches for letters, OnDemand compares the search criteria entered by the user with index data in the application group.

Define the following database fields. The fields allow users to locate letters based on different criteria, such as the date of the letter, the name of the person that sent the letter, and the subject of the letter.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ldate</td>
<td>The date on the letter. Defined as a date field.</td>
</tr>
<tr>
<td>name</td>
<td>The person that sent the letter. Defined as a string field that contains variable length data.</td>
</tr>
<tr>
<td>company</td>
<td>The person’s company. Defined as a string field that contains variable length data.</td>
</tr>
<tr>
<td>subject</td>
<td>The subject of the letter. Defined as a string field that contains variable length data.</td>
</tr>
</tbody>
</table>

Defining the application

Most customers define an application for each different source of input data that they plan to load into OnDemand. This section provides information about some of the key properties of the application. You can use the OnDemand administrative client to define an application.

Application Group

You must assign an application to an application group. Assign the application to the application group that was created in “Defining the application group” on page 117.
Data Format

The Data Format determines the kind of data that is found in the documents that are stored on the system. If the type of the data that is found in the original input file is different than the type of the data that is found in the documents that are stored on the system, then you should specify the type of the data that will be stored in OnDemand. (In this example, the type of the data is the same, a TIFF image.) Selected TIFF as the Data Type. When saving the scanned image of a letter, save the data as a TIFF image.

Indexer

The indexer determines the indexing program that OnDemand uses to index and convert input data. Select Generic as the indexer. To store TIFF images in the system, you must index them with the Generic Indexer program that is provided with OnDemand.

Data Compression

The Data Compression determines whether OnDemand compresses the input files.

Selected Disable, so that OnDemand does not attempt to compress the input files. In this example, the scanned image files are created as compressed TIFF images. Therefore, it is not necessary for the system to compress them. If you need to create scanned image files as uncompressed TIFF images, you should select one of the compression methods so that the system can compress the input files to improve storage efficiency and retrieval performance.

Defining the folder

You must define a folder so that users can search for and retrieve the input files that you load into OnDemand. This section provides information about some of the key properties of the folder. You can use the OnDemand administrative client to define a folder.

Application Group

A folder can be used to search one or more application groups. Select the application group that was created in "Defining the application group" on page 117. When users open the folder, they can search for and retrieve the input files that were loaded into the application group.

Permissions

Folder permissions determine the users that can open the folder and determine the users that can do other types of tasks related to the folder.

Under the *PUBLIC identifier, specify the Access permission so that all users defined to the library server can open the folder.

Field Definition

The Field Definition page is where you define the search fields for the folder. The search fields contain the search criteria entered by the user. For most folders, you probably want to define a search field for each field that you defined for the application group.
Define the following fields. The fields allow users to locate letters based on different criteria, such as the date of the letter, the name of the person that sent the letter, and the subject of the letter.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Letter Date</td>
<td>The date on the letter.</td>
</tr>
<tr>
<td>From</td>
<td>The person that sent the letter.</td>
</tr>
<tr>
<td>Company</td>
<td>The person’s company.</td>
</tr>
<tr>
<td>Subject</td>
<td>The subject of the letter.</td>
</tr>
</tbody>
</table>

**Field Mapping**

The Field Mapping page is where you map, or associate, the folder fields to the application group fields. This is how you specify that the search criteria that a user enters in a particular folder field should be used to search a specific application group field. Map each of the folder fields to their corresponding application group fields. For example, map the folder field named Letter Date to the application group field named Ldate.

**Accessing the image files**

The ARSLOAD program runs on the OnDemand server and is the primary OnDemand program for loading images and other user-defined data. The files that you want to load into the system by using the ARSLOAD program must be stored on the server or you must provide network access to the files.

In the example, the files were copied from a PC to the server as binary files with a file type of TIF.

Store the input files on the server in the location from which you plan to run the ARSLOAD program. Otherwise, you must specify the full path name of the input files in the Generic index file.

**Creating index data**

You must create index data for your input files before you can load them into OnDemand. If the input data is other than AFP, line, or PDF, then you must use the Generic Indexer to load it into the system. You specify index data for the Generic Indexer using a parameter file. You should use a standard text editor to create the parameter file. [Figure 43 on page 121](#) shows an example of a parameter file that can be used by the Generic Indexer to process image files. See the *IBM Content Manager OnDemand for iSeries Common Server: Indexing Reference* for more information about the Generic Indexer and the parameter file.
Save the parameter file as LETTERS.IND on the server in the directory from which you plan to run the ARSLOAD program.

Configuring the ARSLOAD program

**Note:** The OnDemand server job must be running, otherwise the ARSLOAD program will fail.

The ARSLOAD program is the primary OnDemand data indexing and loading program for image files. The ARSLOAD program determines if the input data needs to be indexed, and if so, it calls the indexing program. The ARSLOAD program then processes the index data, loading it into the database, optionally
compresses the input data into storage objects, and copies the storage objects to storage volumes. See "ARSLOAD" on page 211 for more information about running the ARSLOAD program within QSHELL, including the parameters that you can specify to process input files.

You typically run the ARSLOAD program each time that you want to load a file or set of files into the system. You can either run the ARSLOAD program from the command line or configure it to run periodically to check for input data to process. To support a low volume scanning operation, most customers run the ARSLOAD program from the command line using QSHELL. For example:

arsload -n -g Letters letters

Specify the following parameters to the ARSLOAD program:

- **-n** Do not delete the input files.
- **-g Letters** The name of the application group to load.
- **letters** The name of the input file to process.

In the example, the ARSLOAD program must locate the input file LETTERS.INO in the current directory. The input file contains the index information that was created in "Creating index data” on page 120 (which is a parameter file for the Generic Indexer). The image files must be in the same directory.

### Processing the input data

The ARSLOAD program processes the parameter file, loads the index data into the database, and loads the image files into OnDemand.

### Processing index data

The ARSLOAD program processes the parameters that were specified on the command line and the indexing parameter file before loading the index data into the database. The ARSLOAD program extracts information from the application group and the application and performs the following processing:

- Determines the database field information from the application group
- Determines the data type and other information from the application
- Creates one database row for each group that was specified in the parameter file. One group was specified for each image file.
- Passes the index rows to the database manager. The rows contain the index values and other fields generated by OnDemand. An index row contains:
  - One column for each field that was defined for the application group
  - One or more columns of OnDemand control information

### Processing the image files

The ARSLOAD program processes each image file that was specified in the parameter file. The ARSLOAD program extracts information from the application group and the application and performs the following processing:

- Determines the compression information from the application
- Determines the storage management information from the application group.
  The storage management information determines the storage locations, such as disk and archive storage.
• Stores the image files in storage objects. OnDemand uses a 10 MB storage object (the default value) to improve storage efficiency and performance. OnDemand assigns unique names to the storage objects and sequentially numbers them within an application group.

**Verifying processing**

The ARSLOAD program saves a copy of the messages that were generated during a load process in the system log. (In the System Log folder, search for message number 87 for a successful load or 88 for an unsuccessful load.) After a load process completes, you can open the System Log folder and review the messages. The information in the messages includes the date and time that the load process started and completed, the name of the input file(s), and the number of rows that were added to the database. For example:

```
arsload: Processing file >letters<
arsload: Mon Dec 18 13:04:37 MST 1995 Indexing started,
       116017 bytes to process
OnDemand Load ID = >6927-0-0-1FAA-0-0<
Loaded 4 rows into the database
arsload: Mon Dec 18 13:05:14 MST 1995 Loading Completed
arsload: Processing successful for file >letters<
```

You can verify the number of rows that OnDemand added to the database. In the example, the number of rows added to the database should equal the number of groups (and image files) that was specified in the parameter file.

The OnDemand Load ID represents the data that the ARSLOAD program stored into the system during a load process. The Load ID can be used to identify a specific load process. For example, you can run the RMVRPTOND command and specify the Load ID to delete the index data and documents that were created when the ARSLOAD program processed a Generic Indexer parameter file.
Chapter 12. Loading user-defined data

OnDemand provides support for storing and retrieving almost any type of data. For example, OnDemand provides support for AFP, Line, PDF, GIF, JFIF (JPEG), PCX, and TIFF data. However, OnDemand is not limited to maintaining these types of data. OnDemand provides the User-Defined data type to support almost any other type of data that you want to store in the system. For example, you can configure the system to process Lotus® WordPro documents, so that when a user retrieves one of the files from the system, OnDemand automatically starts Lotus WordPro to open the document.

To store user-defined data on the system, you must create index data for the input files and you must register the file type of the input file with OnDemand. The file type determines the program that is started to open a file when a user retrieves one of the files from the system. The file type must also be registered with the client operating system. If your OnDemand system supports client programs that run under different operating systems, then you must register the specified file type on all of the client operating systems.

OnDemand provides the Generic Indexer so that you can index user-defined data. You specify the index data for the input files that you want to index with the Generic Indexer in a parameter file. The parameter file contains the index field names and values and identifies the input files that you want to process. You can create up to 32 index fields for each input file that you want to load into the system, providing many ways for users to query and retrieve documents. The number of index fields that you define usually depends on how your users retrieve documents from the system. For example, you might want to define index fields for the date, author, and subject or purpose of the user-defined data.

Before you can load user-defined data into the system, you must define an application group to manage the storage of the files, an application to specify the physical and logical attributes of the input files, and a folder to let users search for and retrieve the files. This section contains an example that shows how to define Lotus WordPro files to OnDemand. It provides an overview of defining the application group, application, and folder. For details and a comprehensive example of defining input data to OnDemand, see Part 3, “Using iSeries Navigator for OnDemand administration,” on page 27.

Defining the application group

When you load an input file into the system, OnDemand updates the database with the index data that you provide and stores the indexed groups of pages as documents in cache storage and archive storage. The application group contains the information that OnDemand uses to store and maintain the index data and the documents on the system. This section provides information about some of the key properties of the application group. You can use the OnDemand administrative client to define an application group.

Database organization

The Database Organization determines how OnDemand organizes the index data that is stored in the application group.
Accept the default Database Organization of Multiple Loads per Database Table and Table Size of its maximum number of rows. Each time that a Lotus WordPro file is loaded into the system, OnDemand adds one row to a database table. When a table reaches its maximum number of rows, OnDemand closes the table and creates a new table. OnDemand always adds index records to the open table; closed tables can be queried.

**Expiration type**

The Expiration Type determines how OnDemand deletes index data and documents from the application group.

Accept the default Expiration Type of Load. This means that OnDemand deletes the index data and documents from one load process (one or more input files) at a time from the application group. Depending on the number of input files processed during a load process, one or more Lotus WordPro files may be deleted at a time. For example, if you create a parameter file for the Generic Indexer that contains index data for several input files, OnDemand will delete all of the index data and documents from the application group at the same time.

**Permissions**

Application group permissions determine the users that can access information stored in the application group and determine the users that can do other types of tasks related to the application group.

Under the *PUBLIC identifier, specify the Access permission so that all of the users defined to the server can access data stored in the application group.

**Field definition**

The Field Definition page is where you define the database fields for the application group. When you load an input file into the system, OnDemand stores the index data that is specified in the parameter file into fields in records that are added to the database. When a user queries the system, OnDemand compares the search criteria entered by the user with index data in the application group.

Define the following database fields. The fields allow users to locate files based on different criteria, such as the date, author, and subject of the file.

- **fdate** The date associated with the file. For example, the date the file was created or the date the file was published. Defined as a date field.
- **author** The author of the file. Defined as a string field that contains variable length data.
- **subject** The subject or purpose of the file. Defined as a string field that contains variable length data.

**Defining the application**

Most customers define an application for each different source of input data that they plan to load into OnDemand. This section provides information about some of the key properties of the application. You can use the OnDemand administrative client to define an application.
Application Group

You must assign the application to an application group. Assign the application to the application group that was created in “Defining the application group” on page 125.

Data Format

The Data Format determines the kind of data that is found in the documents that are stored on the system. If the type of the data that is found in the original input file is different than the type of the data that is found in the documents that are stored on the system, then you should specify the type of the data that will be stored in OnDemand.

Because there is not a supplied Data Format for Lotus WordPro files, you must select User Defined from the Data Type list.

File Extension

When you select User Defined from the Data Type list, you must also enter a value in the File Extension. The File Extension determines the program that is started to open a user-defined file when it is retrieved from the system. In the example, type the characters LWP, for Lotus WordPro.

The File Extension that you specify must also be registered on the client operating system. See your operating system information for help with registering file extensions.

Indexer

The indexer determines the indexing program that OnDemand uses to index and convert input data. Select Generic as the indexer. To store user-defined files on the system, you must index them with the Generic Indexer program provided with OnDemand.

Data Compression

The Data Compression determines whether OnDemand compresses the input files.

On the Load Information page, accept the default Data Compression of 0077 so that OnDemand will compress input files before storing them on the server. Resources are not supported with user-defined input data.

Defining the folder

You must define a folder so that users can search for and retrieve the input files that you load into OnDemand. This section provides information about some of the key properties of the folder. You can use the OnDemand administrative client to define a folder.

Application Group

A folder can be used to search one or more application groups. Select the application group that was created in “Defining the application group” on page 125. When users open the folder, they can search for and retrieve the Lotus WordPro files that were loaded into the application group.
Permissions

Folder permissions determine the users that can open the folder and determine the users that can do other types of tasks related to the folder.

Under the *PUBLIC identifier, specify the Access permission so that all users defined to the server can open the folder.

Folder fields

The Field Definition page is where you define the search fields for the folder. The search fields contain the search criteria entered by the user. For most folders, you probably want to define a search field for each field that you defined for the application group.

Define the following folder fields. The fields allow users to locate files based on different criteria, such as the date, the author, and the subject.

- **File Date**: The date associated with the file. For example, the date the file was created or the date that the file was published.
- **Author**: The person that created the file.
- **Subject**: The subject or purpose of the file.

Field Mapping

The Field Mapping page is where you map, or associate, the folder fields to the application group fields. This is how you specify that the search criteria that a user enters in a particular folder field should be used to search a specific application group field. Map each of the folder fields to their corresponding application group fields. For example, map the folder field named File Date to the application group field named fdate.

Accessing the input files

The ARSLOAD program runs on the OnDemand server and is the primary data loading program for user-defined data. The files that you want to load into the system by using the ARSLOAD program must be stored on the server or you must provide network access to the files.

In the example, the files were copied from a PC to the server as binary files with a file type of LWP.

Store the input files on the server in the location from which you plan to run the ARSLOAD program. Otherwise, you must specify the full path name of the input files in the Generic index file.

Creating the index data

You must create index data for your input files before you can load them into the system. If the input data is other than AFP, line, or PDF, then you must use the Generic Indexer to load it into the system. You must specify index data for the Generic Indexer using a parameter file. You should use a standard text editor to create the parameter file. Figure 44 on page 129 shows an example of a parameter file that can be used by the Generic Indexer to process the Lotus WordPro files. See the IBM Content Manager OnDemand for iSeries Common Server: Indexing Reference for more information about the Generic Indexer and the parameter file.
Save the parameter file as LWP.IND on the server in the directory from which you plan to run the ARSLOAD program.

**Configuring the ARSLOAD program**

**Note:** The OnDemand server job must be running, otherwise the ARSLOAD program will fail.

The ARSLOAD program is the primary OnDemand data indexing and loading program for user-defined data. The ARSLOAD program determines if the input data needs to be indexed, and if so, it calls the indexing program. The ARSLOAD program then processes the index data, loading it into the database, optionally compresses the input data into storage objects, and copies the storage objects to storage volumes. See "ARSLOAD" on page 211 for more information about running the ARSLOAD program within QSHELL, including the parameters that you can specify to process input data.

You typically run the ARSLOAD program each time that you want to load a file or set of files into the system. You can either run the ARSLOAD program from the
command line or configure it to run as a daemon (UNIX® servers) or service (Windows servers) to periodically check for input data to process. To store a few WordPro files at a time, most customers run the ARSLOAD program from the command line using QSHELL. For example:

```
arsload -n -g 'Lotus WordPro Documents' lwp
```

Specify the following parameters to the ARSLOAD program:

- `n` Do not delete the input files.
- `-g 'Lotus WordPro Documents'` The name of the application group to load.
- `lwp` The name of the input file to process.

In the example, the ARSLOAD program must locate the input file `lwp.IND` in the current directory. The input file contains the index information that was created in "Creating the index data" on page 128 (which is a parameter file for the Generic Indexer). Because the full path name of the input file was not specified, they must reside in the same directory.

**Processing the input data**

The ARSLOAD program processes the parameter file, loads the index data into the database, and loads the Lotus WordPro files into OnDemand.

**Processing index data**

The ARSLOAD program processes the parameters that were specified on the command line and the indexing parameter file before loading the index data into the database. The ARSLOAD program extracts information from the application group and the application and performs the following processing:

- Determines the database field information from the application group
- Determines the data type and other information from the application
- Creates one database row for each group that was specified in the parameter file. One group was specified for each Lotus WordPro file.
- Passes the index rows to the database manager. The rows contain the index values and other fields generated by OnDemand. An index row contains:
  - One column for each field that was defined for the application group
  - One or more columns of OnDemand control information

**Processing the Lotus WordPro files**

The ARSLOAD program processes each Lotus WordPro file that was specified in the parameter file. The ARSLOAD program extracts information from the application group and the application and performs the following processing:

- Determines the compression information from the application
- Determines the storage management information from the application group. The storage management information determines the storage locations, such as disk and archive storage.
- Stores the Lotus WordPro files in storage objects. OnDemand uses a 10 MB storage object (the default value) to improve storage efficiency and performance. OnDemand assigns unique names to the storage objects and sequentially numbers them within an application group.
Verifying processing

The ARSLOAD program saves a copy of the messages that were generated during a load process in the system log. After a load process completes, you can open the System Log folder and review the messages. Search for message number 87 for a successful load or 88 for an unsuccessful load. The information in the messages includes the date and time that the load process started and completed, the name of the input file, and the number of rows that were added to the database. For example:

arsload: Processing file >lwp<
arsload: Mon Dec 18 14:14:47 MST 1995 Indexing started,
      5116017 bytes to process
OnDemand Load ID = >6927-0-0-4FAA-0-0<
Loaded 4 rows into the database
arsload: Mon Dec 18 14:25:11 MST 1995 Loading Completed
arsload: Processing successful for file >lwp<

You can verify the number of rows that OnDemand added to the database. In the example, the number of rows added to the database should equal the number of groups (and Lotus WordPro files) that were specified in the parameter file.

The OnDemand Load ID represents the data that the ARSLOAD program stored into the system during a load process. The Load ID can be used to identify a specific load process. For example, you can run the RMVRPTOND command and specify the Load ID to delete the index data and documents that were created when the ARSLOAD program processed a Generic Indexer parameter file.
Chapter 13. Restarting a load process

The ADDRPTOND command will terminate if an unrecoverable error occurs during index, database, or storage manager processing. Termination processing includes setting a return code and saving error messages in the system log.

To start problem determination, open the System Log folder and view the messages that the command generated during the load process. The message log will contain normal processing messages, return codes, and error messages, such as message number 87 for a successful load or 88 for an unsuccessful load. See Appendix B, “System log messages,” on page 147 or IBM Content Manager OnDemand: Messages and Codes, SC27-1379 for other possible messages.

If the command failed during indexing, correct the problem and then restart the load process from the beginning. Common causes of problems during indexing include invalid input files or indexing parameter files and insufficient temporary space. Note: The messages in the system log will actually refer to a program named ARSLOAD.

If the command failed during database processing or storage manager processing:
• Determine and correct the problem.
• If a Load ID is listed in the message log that the ADDRPTOND command saved in the system log, then you can use the RMVRPTOND command to unload the data. See Chapter 14, “Deleting a report,” on page 135 for information about unloading data from OnDemand.
• Restart the load process from the beginning.
Chapter 14. Deleting a report

You can use the RMVRPTOND command to delete the index data and documents that the ADDRPTOND command stored in the system during a load process. To use the delete command, you must specify the application group name and Load ID that the ADDRPTOND command generated during the load process. The Load ID represents the index data that was added to the database and the storage objects that were copied to disk and archive storage. The Load ID can be found in the message that the ADDRPTOND command saved in the System Log. If there is more than one Load ID listed in the System Log, then you should use the last Load ID listed in the log.

See online help for RMVRPTOND for more information about the command and parameters.

When the RMVRPTOND command completes, you should open the System Log folder to view the messages that were generated during the delete process. The messages will reference a program named ARSADMIN.

Note: The OnDemand server job must be running, otherwise the RMVRPTOND command will fail.
Part 5. Server administration

This part describes errors and alerts, system logging, how to find the server job and its attributes, and how to restart journaling.
Chapter 15. Managing the server

This chapter provides information for a number of topics related to the OnDemand server.

Errors and alerts

During normal processing, OnDemand programs, including the client programs, generate messages. OnDemand saves the messages in the OnDemand System Log and sends a copy of each message to the System Log user exit program. OnDemand assigns a severity to each message. Messages that are assigned a severity of alert or error are also sent to the i5/OS QSYSOPR message queue and logged in the server joblog. Additionally, when a user runs a query that requires a table of index data that has been migrated to archive storage, OnDemand sends a message to QSYSOPR and the joblog.

OnDemand provides the System Logging facility to help you identify and resolve any alerts and errors that you may receive. You can open the System Log folder to display the messages that are saved in the System Log. See “System logging facility” for more information; see Appendix B, “System log messages,” on page 147 or IBM Content Manager OnDemand: Messages and Codes, SC27-1379 for a listing of message numbers and text.

System logging facility

OnDemand provides a logging facility to help administrators track OnDemand activity and monitor the system. When you enable logging for system events, user events, and application group events, OnDemand stores the messages that are generated by the various OnDemand programs in the System Log. You can use the OnDemand client program to search for and filter messages by time stamp, severity, message number, and user name.

Searching for and viewing messages

To search for and view the messages that are stored in the System Logging facility, log on to OnDemand with an OnDemand client program and open the System Log folder. Enter search criteria in one or more of the search fields. When you choose the Search command, OnDemand retrieves the messages from the database that match the search criteria that you specified.

You can specify a date and time value to search for and retrieve messages. You can also specify other search criteria, such as:

Userid
The OnDemand userid

Account
Accounting information; the information specified in the Account field for the user.

Log Id
Each time that a client logs on to the server, OnDemand assigns a number to that session. All messages that are generated during that session include the same Log Id.

Severity
OnDemand assigns a severity to each message: Alert, Error, Warning, Info, and Debug
Depending on the type of message in the System Log, you may be able to view other information that is related to or associated with the message. For example:

- You can display the message log that was generated during a load process by selecting an ARSLOAD message and then choosing the View all Selected command. You might see ARSLOAD messages after issuing the ADDRPTOND command. While most processes do not generate other information that can be stored in the System Log, you could write a user exit program to process the messages and generate your own information about the events. For example, you could write a user exit program to generate a report that lists the number of users that are logged on to the system in 30 minute increments. OnDemand provides a System Log user exit so that you can process any message that is stored in the System Log and take the action that you require. See below for more information about the System Log user exit.
- Other messages in the System Log do not provide additional records or other data associated with an event. For example, the Logon and Logoff events each generate a single message, with no additional information that you can view.

<table>
<thead>
<tr>
<th>Msg Num</th>
<th>The message number that is assigned by OnDemand</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message</td>
<td>The text of the message that OnDemand uses to restrict a search. For example, if you type Login, OnDemand searches for and displays the messages issued by the Logon to a Server command.</td>
</tr>
</tbody>
</table>

**System Log user exit**

When you enable logging for system, user, and application group events, OnDemand sends a copy of each message that is generated by the system to the System Log user exit program. The System Log user exit program is named ARSL0G and resides in the OnDemand library named QRDARS.

The System Log user exit program that is provided by IBM does not perform any functions. However, you can replace the program that is provided by IBM with your own program that does user-defined processing. For example, you could create a program that checks for certain message numbers or severity and takes whatever action you deem appropriate.

You configure OnDemand to send messages to the System Log user exit by selecting User Exit Logging options with the System Parameters command. See the online help for the administrative client for more information about the User Exit Logging options and the System Parameters command.

See the IBM Content Manager OnDemand for iSeries Common Server Planning and Installation Guide for more information about the System Log user exit.

**Monitoring users**

The OnDemand server generates System Log messages to help you track the number of users that are logged on to the server:

- OnDemand stores message number 201 in the System Log approximately every 30 minutes if at least one activity is detected. This message contains the current number of users that are logged on to the server.
• OnDemand stores message number 202 in the System Log every time that the number of concurrent users exceeds the previous maximum number of concurrent users. The number of concurrent users is reset each time that you restart the OnDemand server processes.

How to find or change the server job and its attributes for a particular instance

The name of the server job for a particular server matches the name of the OnDemand instance for which it is running. For example, the server job name is QUSROND for the default OnDemand instance named QUSROND. You can use the command WRKACTJOB JOB(QUSROND) to find this default server job.

In addition, Common Server spawns many QSQSRVR jobs during its processes. To determine which specific QSQSRVR job to view if you have encountered a problem with an OnDemand process, look at the instance joblog (for example, the joblog for the QUSROND job described above) and compare the time stamps of the error messages to the time stamps of the QSQSRVR joblogs to determine which spawned QSQSRVR job or jobs would be related to the particular process you are investigating.

Server jobs are started using a job description by the name of the instance (which must be found in the QUSRDRARS library). If a job description by that name is not found in QUSRDRARS, then job description QOND400 in library QRDARS is used (and can be changed if necessary).

The job description controls the following attributes of the server job:
• JOBQ
• JOBPTY
• OUTPTY
• PRTDEV
• OUTQ
• INLLIBL
• LOG
• LOGCLPGM
• INQMSGRPY
• HOLD
• DATE
• SWS
• JOBMMSGQM
• JOBMMSGQFL

For example, if you wanted to change the job queue that instance TEST used, you would create a job description called TEST in library QUSRDRARS that specified the job queue you wanted to use. This alternate job queue could be used to send the server jobs to a different subsystem than the default.
Controlling the run priority of instance server jobs

The run priority of Common Server instance server jobs is by default set by the *ANY routing entry in the QSYSWRK subsystem description. Normally this defaults to priority 50. (It depends on the class that is specified for the *ANY routing entry in subsystem QSYSWRK.) If you wish to change this for all instance server jobs, you may add a routing entry to the QSYSWRK subsystem description using the Add Routing Entry (ADDTGE) command as follows:

```
ADDTGE SBSD(QSYS/QSYSWRK) SEONBR(nnnn) CMPVAL('QRLMSERVER') +
PGM(QSYS/QCMD) CLS(class)
```

Where:
nnnn is an unused routing sequence number in the QSYSWRK subsystem, which is lower than the *ANY routing entry sequence number.
class is the name of a i5/OS class object (OBJTYPE(*CLS)) that contains the attributes you want to use.

For example:

```
ADDTGE SBSD(QSYS/QSYSWRK) SEONBR(1000) CMPVAL('QRLMSERVER') +
PGM(QSYS/QCMD) CLS(QSYS/QSYSCLS35)
```

The system ships with the following classes that you might consider using:

- QSYS/QSYSCLS25 (Run priority of 25)
- QSYS/QSYSCLS35 (Run priority of 35)

If you want to specify a different run priority, for example 45, then you need to create your own class. An example command that does this is:

```
CRTCLS CLS(QGPL/ONDSVR45) RUNPTY(45) TIMESLICE(2000) +
PURGE(*YES) DFTWAIT(30) CPUTIME(*NOMAX) +
MAXTMPSTG(*NOMAX) +
TEXT('OnDemand Common Server run priority 45 class')
```

After creating the class, specify it as the class name in the routing entry for QRLMSERVER in subsystem QSYSWRK.

Restarting journaling

If you receive a message on the server indicating that journaling needs to be started for your OnDemand database files, issue the following command from a command line while signed on with sufficient authority:

```
CALL QRLCSTRJ PARM(RLC)
```

The parameter value (RLC) must be entered in uppercase.
Appendix A. Command reference

This part contains reference information about the OnDemand server commands. The commands are presented in alphabetical order. Each command contains a description of its purpose. See the online help text for details about the command parameters.

OnDemand server commands

These commands require that you be signed on to the server with a user profile that is also defined as a user in OnDemand. For commands that specify an application or application group name, if the value to be entered contains lower case letters, blanks, or special characters, it must be enclosed in apostrophes.

ADDRPTOND

The Add Report to OnDemand (ADDRPTOND) command allows you to load reports in OnDemand. During this process the report is broken into segments, indexed, compressed, and stored on disk for retrieval and later migration to optical or tape media if desired. Input can be in the form of a spooled file (*SPLF), a database file (*FILE), or a stream file (*STMF). Important: Set the proper locale before issuing this command. See the chapter entitled “Defining a locale” in the IBM Content Manager OnDemand for iSeries Common Server: Planning and Installation Guide for important details.

After the ADDRTOND command has run, message number 87 will appear in the System Log if the loading of data was successful; message 88 will appear if the data loading failed.

ENDMONOND

The End Monitor for OnDemand (ENDMONOND) command allows you to end a currently active monitor for an output queue.

FNDKEYOND

The Find Key for OnDemand (FNDKEYOND) command allows you to search for a particular document that is available through the folder specified in the FOLDER parameter. The OnDemand client is launched to view the results of the search. The key fields entered must exist in the folder. This is intended as an API to launch the OnDemand client from a green screen application. See Appendix C, “5250 host connection to client viewer,” on page 175 for more details.

PRTRPTOND

The Print Report from OnDemand (PRTRPTOND) command prints the specified report in its entirety.

If a printer name is specified for the PRINTER parameter, then OnDemand will use the first record found in the ARSPRT file (in your instance library) with a printer name that contains the string you entered anywhere in the name.

For example, if you enter PRINTER1 for the PRINTER parameter and your ARSPRT file has these four records (in this order), OnDemand would send your output to the first one in the following list:
• Printer1 in the printer room
• PRINTER1
• Printer123
• XPrinter1

If *OUTQ is specified for the PRINTER parameter, then you must also enter an output queue name and library. OnDemand will use the printer associated with the first record found in the ARSPRT file (in your instance library) with an output queue name that contains the library name/output queue name you entered. If no match is found and if *LIBL is entered as your output queue library name, OnDemand will use the printer associated with the first record found in the ARSPRT file (in your instance library) with an output queue name that matches (with no library specified).

For example, if you enter QUSROND/MYOUTQ for the OUTQ parameter and your ARSPRT file has these four records (in this order), OnDemand would send your output to the printer name associated with the first output queue in the following list:
• QUSROND/MYOUTQ
• MYOUTQ
• AMYOUTQ
• TEST/MYOUTQ

**PRTTXTOND**

The Print Text for OnDemand (PRTTXTOND) command allows you to print all or part of a spooled file in a text-only format. This allows the report administrator to see what the report looks like to ADDRPTOND when it is indexed. Using this output (spooled file name QPRLMTXT), the administrator can determine how to index the report.

**RMVRPTOND**

The Remove Report from OnDemand (RMVRPTOND) command removes the specified report from OnDemand.

**STRASMOND**

The Start Archived Storage Mgmt (STRASMOND) command starts the Archived Storage Management (ASM) process which manages the movement of data within the ASM defined levels. This function can be canceled with a controlled cancel option if enough time is allowed to end what it is currently processing.

**Notes:**

1. This command must only be run in batch (SBMJOB parameter set to *YES). Running this command interactively (with SBMJOB(*NO)) may cause SQL errors.

2. By default, the QUSROND default instance is used, and will produce the desired results for most systems. If you need to run the STRASMOND command for multiple instances, you must issue the command separately for each instance. Note that if you initiate the archive storage manager by running the STRDSMOND command with RUNASM(*YES), then the instance name is passed from the disk storage manager and no further specifications are needed.

3. The report that is produced when ASM is run has a spooled file name of QPRLCASM1. The report provides of list of actions that the ASM process
performed. This report should be checked each time ASM is run to ensure that processing of the data completed successfully. If a failed condition is found, it is important to check the joblog for the STRASMOND job to determine the cause of the failure.

4. See “Hints and tips” on page 39 for information about resetting optical volume statistics such as bytes used and the volume full flag if you feel any of your optical volumes may have incorrect values set.

5. The LOGSTS and SNDFAILMSG parameters have been removed from the STRASMOND command at Version 5 Release 4 and should be removed from any CL programs or job scheduler entries that may currently specify them.

**STRDSMOND**

The Start Disk Storage Management (STRDSMOND) command starts the Disk Storage Management (DSM) task which manages the movement of OnDemand data on disk and between disk and the Archived Storage Manager (ASM). DSM also controls the expiration of data in OnDemand. This function can be canceled with a controlled cancel option if enough time is allowed to end what it is currently processing. While it may be possible to run multiple STRDSMOND commands for different application groups within the same instance or different instances, it is not recommended.

**Note:** If you run STRDSMOND for a specific application group (rather than the default of *ALL) and you set the Run ASM (RUNASM) parameter to *YES, be aware that ASM will run for ALL application groups, even though you have named a specific application group for DSM to use. You can, however, name a specific Policy for ASM to process, if desired. Also note that when you specify RUNASM(*YES), OnDemand will initiate a separate batch job for ASM.

**STRIMPOND**

The Start Import into OnDemand (STRIMPOND) command allows you to import data into OnDemand. This command is used only if you have migrated your index data to an alternate media (such as optical or tape), which is not recommended, but may be necessary in some cases.

**STRMONOND**

The Start Monitor for OnDemand (STRMONOND) command allows you to specify the name of an output queue or IFS directory to monitor. When a spooled file is added to the output queue or a file is added to an IFS directory, the spooled file is automatically processed by ADDRPTOND. **Important:** Set the proper locale before issuing this command. See the chapter entitled “Defining a locale” in the IBM Content Manager OnDemand for iSeries Common Server: Planning and Installation Guide for important details.

The application and application group names for spooled files are determined using spooled file attributes such as spooled file name or user data (or a number of others). You can alter these values that OnDemand uses for application and application group by using the output queue monitor user exit program as described in Appendix E, “API and user exit reference,” on page 183.

The application and application group names for PC files are determined by the PC file name itself. The monitor can use any one of the first four parts of the file
name. For example, a file name of CHECKSTMTS.BIGSTMTS.data might be used to archive an application named CHECKSTMTS into an application group named BIGSTMTS.

After the STRMONOND command has processed an input file, message number 87 will appear in the System Log if the loading of data was successful; message 88 will appear if the data loading failed.

You can end the monitor by:
• Specifying a method for the monitor to end automatically.
• Running the ENDMONOND command
• Ending the monitor job using the ENDJOB command. Specify OPTION(*CNTRLD) and DELAY(999999). The job will end as soon as the monitor finishes processing the current file.
Appendix B. System log messages

Overview

This section contains many of the most common messages found in the System Log, which is searchable by using the OnDemand client. For a complete list of System Log messages, see IBM Content Manager OnDemand Messages and Codes, SC27-1379.

You should always keep the system logs. (See the application group and folder titled System Log.) The System Log is the only place where the Load Identifier for archived data is maintained. Every time data is loaded into OnDemand, message number 87 is placed in the system log and the Load Identifier is recorded as part of the message. The Load Identifier is also called the Report ID and is a required parameter (RPTID) for the Remove Report from OnDemand (RMVRPTOND) and Print Report from OnDemand (PRTRPTOND) commands. When installed, the System Log application group is defined to never expire and IBM recommends that you do not change that setting. If you do change the setting, you should only expire the System Log data after all other application groups have expired their data. In other words, the value in the Expire in x Days field under Life of Data and Indexes on the Storage Management tab of the System Log application group should always be larger than the same value in any other application group. If any other application group is using the Never Expire setting, you should not change the System Log application group setting from the default. If you do, you will be unable to use the RMVRPTOND or the PRTRPTOND commands for some of the data stored in those other application groups.

Message reference

The format of the message identifier is ARSnnmnt, where:

ARS The message prefix for OnDemand messages.

nnnn Represents the message number.

mnt Represents the type of message and indicates the severity of the message. Can be one of the following letters:

A An alert message is a warning for an administrator to take action to avoid performance and reliability problems.

D A debug message contains information that an administrator can use to help service and development resolve problems.

E Error message when an OnDemand server program fails.

I Informational message that the OnDemand server issues when a program completes successfully. These messages can assist in providing an audit trail.

W Warning message that the OnDemand server issues when the results of a program might be in question.

The messages that are written to the OnDemand System Log do not contain the ARS prefix and the type suffix. For example, the message that is associated with
the failure of a load process would be written as 88 to the system log, while it is listed as ARS0088E in this publication. However, 88 and ARS0088E are one and the same message.

In this publication, the messages and explanations are listed according to the four-digit message numbers (for example, 0088).

</tr>
<tr>
<td></td>
<td>SM Error: ASM FAILED TO RETRIEVE OBJECT, RC=2, Reason=0, File=arssmsms.c, Line=789</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>User response: See the messages and codes publication of the storage manager product that you are using with OnDemand for information about the SM Error, RC, and Reason.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
ARS0021E  Unable to store data to cache because there is no cache defined
Explanation: There are no cache storage filesystems defined on the system. See your Planning and Installing book for information about defining cache storage filesystems.
User response: Define and configure one or more cache storage filesystems. Then restart the server and resubmit the command.

ARS0023E  Object >object_name< in Application Group >appl_grp_name< not found in cache, no other storage defined
Explanation: The object no longer exists in the OnDemand cache and no other storage manager was defined to store the data. The data was expired. Depending on how the application group index expiration was configured, the index information will also expire in the future.
Example:
Object >IFAAA< in Application Group >LOANS< not found in cache, no other storage defined
Srvr->rdr400m.raleigh.ibm.com 10.37.63.53<-
User response: Verify the storage management configuration on the system and verify the storage management settings for the specified application group.

ARS0024E  Object >object_name< in Application Group >appl_grp_name< not found in node >node_name<
Explanation: The object cannot be found in the specified storage node. The data has expired from the storage node.
Example:
Object >2FAA< in Application Group >JIF< not found in node >PriForever< Srvr->everest.ibm.com<-
User response: Verify the storage management settings for the specified application group.

ARS0025E  Unable to store data because the cache is full
Explanation: The cache storage filesystems are full.
User response: Add or extend the cache storage filesystems. Then restart the server and resubmit the command.

ARS0026E  Unable to perform action because this server is cache only and does not support the Storage Management Subsystem
Explanation: The system is configured for cache only. However, the storage node definitions are pointing to a storage manager that is not configured.
User response: Either define and configure the storage manager or change the storage node to be cache only. Then restart the server and resubmit the command.

ARS0027E  Unable to load the TSM dynamic load library
Explanation: The command failed when attempting to load the Tivoli Storage Manager dynamic load library.
User response: Verify that Tivoli Storage Manager is correctly installed and configured. Then restart the server and resubmit the command.

ARS0030I  Login: hostname
Explanation: A client successfully logged on to the server. This message is for your information only.
Example:
Login: dyna.raleigh.ibm.com 9.34.172.252
User response: No action is required.
ARS0031W  Failed login: hostname
Explanation:  A client failed when attempting to log on to the server.
Example:  
Failed login: stled32.stl.ibm.com 9.112.32.132
User response:  Verify the user ID, password, and server selection. Passwords might be case sensitive. Then resubmit the command.

ARS0032I  Logoff
Explanation:  A client logged off from the server. This message is for your information only.
User response:  No action is required.

ARS0033I  Logoff Timeout
Explanation:  The server forced a client to log off from the server because the client did not perform an action on the server within the interval of time that is specified by the Inactivity Time Out value.
User response:  Log off from the server and log back on to the server. Then resubmit the command. A system administrator can increase the inactivity time out value for this or any other server in the OnDemand administrative client. See the online help in the OnDemand administrative client for more information.

ARS0034I  User Add: Userid(user_name) Id(uid)
Explanation:  The specified user was added to the system. This message is for your information only.
Example:  
User Add: Userid(TBROWN) Id(3)
User response:  No action is required.

ARS0035I  User Delete: Userid(user_name) Id(uid)
Explanation:  The specified user was deleted from the system. This message is for your information only.
Example:  
User Delete: Userid(SBOWMAN) Id(5)
User response:  No action is required.

ARS0036I  User Update: Userid(user_name) Id(uid)
Explanation:  The specified user was updated. This message is for your information only.
Example:  
User Update: Userid(TBROWN) Id(3)
User response:  No action is required.

ARS0037I  User Update with new Password: Userid(user_name) Id(uid)
Explanation:  The specified user’s password was successfully updated. This message is for your information only.
Example:  
User Update with new Password: Userid(QONDADM) Id(1)
User response:  No action is required.
ARS0038W  User Failed Update with new Password: Userid(user_name) Id(uid)
Explanation: An attempt to update the specified user's password failed.

Example:
User Failed Update with new Password: Userid(QONDADM) Id(1)
User response: Verify the user ID and the new password and then resubmit the command.

ARS0039I  Group Add: Group(group_name) Id(gid)
Explanation: The specified group was added to the system. This message is for your information only.

Example:
Group Add: Group(SUPPORT) Id(80102)
User response: No action is required.

ARS0040I  Group Delete: Group(group_name) Id(gid)
Explanation: The specified group was deleted from the system. This message is for your information only.

Example:
Group Delete: Group(Accounting) Id(80021)
User response: No action is required.

ARS0041I  Group Update: Group(group_name) Id(gid)
Explanation: The specified group was updated. This message is for your information only.

Example:
Group Update: Group(ACCOUNTING) Id(80001)
User response: No action is required.

ARS0042I  User to Group Add: User(user_name) Id(uid), Group(group_name) Id(gid)
Explanation: The specified user was added to the specified group. This message is for your information only.

Examples:
User to Group Add: User(Accounting) Id(80021), Group(D:\7107\arc\admin\Arsadmin.cpp) Id(3047)
User to Group Add: User(CALLEN) Id(4), Group(Accounting) Id(80021)
User response: No action is required.

ARS0043I  User to Group Delete: User(user_name) Id(uid), Group(group_name) Id(gid)
Explanation: The specified user was deleted from the specified group. This message is for your information only.

Example:
User to Group Delete: User(CALLEN) Id(4), Group(Accounting) Id(80021)
User response: No action is required.

ARS0044I  Folder Add: Name(folder_name) Fid(fid)
Explanation: The specified folder was added to the system. This message is for your information only.

Example:
Folder Add: Name(CHKSTMTS1R) Fid(5015)
User response: No action is required.
ARS0045I  Folder Delete: Fid(fid)
Explanation:  The specified folder was deleted from the system. This message is for your information only.
Examples:
Folder Delete: Fid(TENANT)
Folder Delete: Fid(5487)
User response:  No action is required.

ARS0046I  Folder Update: Name(folder_name) Fid(fid)
Explanation:  The specified folder was updated. This message is for your information only.
Example:
Folder Update: Name(Check Statements Folder) Fid(5064)
User response:  No action is required.

ARS0047I  ApplGroup to Folder Add: Agid(agid) Aid(aid) Fid(fid)
Explanation:  The specified application group was added to the specified folder. This message is for your information only.
Example:
ApplGroup to Folder Add: Agid(5028) Aid(0) Fid(5030)
User response:  No action is required.

ARS0048I  ApplGroup to Folder Delete: Agid(agid) Aid(aid) Fid(fid)
Explanation:  The specified application group was deleted from the specified folder. This message is for your information only.
User response:  No action is required.

ARS0049I  ApplGroup to Folder Update: Agid(agid) Fid(fid)
Explanation:  The specified application group was updated in the specified folder. This message is for your information only.
User response:  No action is required.

ARS0050I  Id to Folder Add: Id(id) Fid(fid)
Explanation:  Permissions were added to the specified folder for the user or group with the specified ID. This message is for your information only.
Example:
Id to Folder Add: Id(2) Fid(5015)
User response:  No action is required.

ARS0051I  Id to Folder Delete: Id(id) Fid(fid)
Explanation:  Permissions were deleted from the specified folder for the user or group with the specified ID. This message is for your information only.
User response:  No action is required.

ARS0059I  Appl to ApplGroup Add: Name(appl_name) Aid(aid) Agid(agid)

Explanation: The specified application was added to the specified application group. This message is for your information only.

Example:
Appl to ApplGroup Add: Name(CHECKSTMTS) Aid(5514) Agid(5512)

User response: No action is required.

ARS0060I  Appl to ApplGroup Delete: Aid(aid) Agid(agid)

Explanation: The specified application was deleted from the specified application group. This message is for your information only.

Example:
Appl to ApplGroup Delete: Aid(PATBILLS) Agid(5044)

User response: No action is required.

ARS0061I  Appl to ApplGroup Update: Name(appl_name) Aid(aid) Agid(agid)

Explanation: The specified application was updated in the specified application group. This message is for your information only.

Example:
Appl to ApplGroup Update: Name(CHECKSTMTS) Aid(5063) Agid(5062)

User response: No action is required.

ARS0062I  Id to Appl Add: Id(id) Aid(aid) Agid(agid)

Explanation: Logical views were added to the specified application for the user with the specified ID. This message is for your information only.

Example:
Id to Appl Add: Id(17) Aid(5057) Agid(5056)

User response: No action is required.

ARS0063I  Id to Appl Delete: Id(id) Aid(aid) Agid(agid)

Explanation: Logical views were deleted from the specified application for the user with the specified ID. This message is for your information only.

User response: No action is required.

ARS0064I  Id to Appl Update: Id(id) Aid(aid) Agid(agid)

Explanation: Logical views were updated in the specified application for the user with the specified ID. This message is for your information only.

Example:
Id to Appl Update: Id(10) Aid(5027) Agid(5024)

User response: No action is required.

ARS0065I  ApplGroup Query: Name(appl_GRP_name) Agid(agid) Sql(sql) SqlR(sql_restrict) TextSearch(text_search_str) AnnColor(ann_color) AnnText(ann_text)

Explanation: A query was run against the specified application group. This message is for your information only.

Example:
ApplGroup Query: Name(QPJOBLOG) Agid(5081) Sql(WHERE jobdate BETWEEN 11470 AND 11654 ) SqlR()

**User response:** No action is required.

ARS0104E  popen failed for command >command<. errno=errno

Explanation: The server was unable to handle the request. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: If the problem persists, contact your IBM Service Representative.

ARS0105E  pclose failed for command >command<. errno=errno

Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: If the problem persists, contact your IBM Service Representative.

ARS0106E  Unlink failed for file >file<. errno=errno

Explanation: The specified file does not exist or the OnDemand instance owner does not have permission to access it. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

Example:
Unlink failed for file >/QIBM/USERDATA/ONDEMAND/QUSROND/CACHE/retr/KCA/RES/1FAA1<. errno=3025 Srvr->rdr400m.raleigh.ibm.com 10.37.63.53<-

User response: Verify that the file exists, and that the OnDemand instance owner has permission to access it. If the problem persists, contact your IBM Service Representative.

ARS0107E  Unknown file or directory in cache >path_name<

Explanation: An unexpected error occurred during the execution of this program.

Example:
Unknown file/dir in cache >/arscache1/everest< Srvr->rdr400m.raleigh.ibm.com 10.37.63.53<-

User response: If the problem persists, contact your IBM Service Representative.

ARS0108E  Unable to validate library server

Explanation: The library and object servers failed to validate that they belong to the same OnDemand instance.

Example:
Unable to validate library server Srvr->RDR400M.RALEIGH.IBM.COM<-

User response: Verify that the OnDemand instance is properly configured. Restart the servers. If the problem persists, contact your IBM Service Representative.

ARS0109I  Cache Expiration: Internal Date(internal_date) MinPct(minimum_percentage) MaxPct(maximum_percentage) Server(server)

Explanation: The ARSMAINT program has started to expire data from cache storage. This message is for your information only.

Example:
Cache Expiration: Internal Date(11850) MinPct(0) MaxPct(0) Server(RDR400M.RALEIGH.IBM.COM)

User response: No action is required.

ARS0110I  Cache Migration: Internal Date(internal_date) Server(server)

Explanation: The ARSMAINT program has started to migrate data to archive storage. This message is for your information only.

User response: No action is required.
ARS0111E Unable to determine the link for the file >file_name<. errno=errno

Explanation: The OnDemand server was unable to access the specified file. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: Refer to errno.h for additional information. If the problem persists, contact your IBM Service Representative.

ARS0112E Unable to change permissions on the file >file_name<. errno=errno

Explanation: The OnDemand server was unable to access the specified file. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: Refer to errno.h for additional information. If the problem persists, contact your IBM Service Representative.

ARS0113E Cache Migration Failed: ApplGroup(appl_grp_name) Agid(agid) ObjName(object_name) Date(date) Server(server)

Explanation: The ARSMAINT program failed when attempting to migrate data to archive storage.

User response: See the OnDemand System Log for other messages that are associated with the migration. If the problem persists, contact your IBM Service Representative.

ARS0114E Unable to open file >file_name<. errno=errno

Explanation: The command failed when attempting to open the specified file. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: Verify that the file exists and that the file permissions are correct. Then resubmit the command. If the problem persists, contact your IBM Service Representative.

ARS0115E Unable to seek within file >file_name< from offset to length. errno=errno

Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: If the problem persists, contact your IBM Service Representative.

ARS0116E Unable to stat file >file_name<. errno=errno

Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: If the problem persists, contact your IBM Service Representative.

ARS0117E Offset off and length len is larger than the size of the file >file_name< of size bytes

Explanation: An unexpected error occurred during the execution of this program.

Example:
Offset **UNK** and length **UNK** is larger than the size of the file **UNK** of **UNK** bytes
Srvr->rdr400m.raleigh.ibm.com 10.37.63.53<-

User response: If the problem persists, contact your IBM Service Representative.

ARS0118E Unable to read from file >file_name<. errno=errno

Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: If the problem persists, contact your IBM Service Representative.
ARS0119E  Unable to write to file >file_name<. errno=errno

Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

Example:
Unable to write to file >/arscache1/13585/SL/DOC/1502FAA<. errno=28 Srvr->everest.ibm.com<-

User response: If the problem persists, contact your IBM Service Representative.

ARS0120E  Unable to lock the file >file_name<. errno=errno

Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: If the problem persists, contact your IBM Service Representative.

ARS0121E  Unable to close the file >file_name<. errno=errno

Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: If the problem persists, contact your IBM Service Representative.

ARS0122E  Unable to stat filesystem >filesystem_name<. errno=errno

Explanation: The ARSMAINT program failed when attempting to run statistics on the specified filesystem. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: Verify that the filesystem exists and verify the filesystem permissions. Then resubmit the command. If the problem persists, contact your IBM Service Representative.

ARS0123E  Filesystem Stats Name(filesystem_name) Data(percent_full%) Inodes(inode_percent_full%)

Explanation: The ARSMAINT program has started to run statistics on the specified filesystem. This message is for your information only.

Example:
Filesystem Stats Name(/arscache1) Data(84%) Inodes(1%) Srvr->everest.ibm.com 9.99.999.999<-

User response: No action is required.

ARS0124E  Unable to create symbolic link from file >symbolic_name< to >file_name<. errno=errno

Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

Example:
Unable to create symbolic link from file >/QIBM/USERDATA/ONDEMAND/ONDPERFORM/CACHE/ONDPERFORM/retr/SL/APPEND< to >/QIBM/USERDATA/ONDEMAND/ONDPERFORM/CACHE/ONDPERFORM/21667/SL/DOC/9FAA<. errno=3457 Srvr->RDR400M.RALEIGH.IBM.COM<-

User response: If the problem persists, contact your IBM Service Representative.

ARS0125E  ApplGroup Document Expire: Name(appl_grp_name) Agid(agid) Cnt(documents_expired)

Explanation: The ARSMAINT program is using the document expiration method to delete items from an application group. This message is for your information only.

Example:
ApplGroup Document Expire: Name(sp-00021) Agid(15197) Cnt(14)

User response: No action is required.
ARS0127I  ApplGroup Load Expire: Name(appl_grp_name) LoadId(agid-pri_nid-sec_nid-name-start_date-stop_date)

Explanation: The ARSMAINT program is using the load expiration method to delete items from an application group. This message is for your information only.

Example:
ApplGroup Load Expire: Name(CHKSTMTS1R) LoadId(5017-2-0-756FAA-11311-11311)

User response: No action is required.

ARS0128I  ApplGroup Segment Expire: Name(appl_grp_name) Agid(agid) Seg(segment_name)

Explanation: The ARSMAINT program is using the segment expiration method to delete items from an application group. This message is for your information only.

Example:
ApplGroup Segment Expire: Name(test-ebcdic-cc-trc) Agid(15757) Seg(YJF1)

User response: No action is required.

ARS0129A  Filesystem Full Name(filesystem_name) Data(percent_full%%) Inodes(inode_percent_full%%)

Explanation: The cache storage filesystem is almost full.

User response: Either extend the existing cache storage filesystem or add new cache storage filesystems. Then restart the server.

ARS0130E  No logical place to store object >object_name<

Explanation: The command failed when attempting to store the object because there are no cache storage filesystems defined to the system or the archive storage manager is not properly configured.

User response: To use cache storage, define and configure OnDemand cache storage filesystems. To use archive storage, install and configure the archive storage manager. Then restart the server and resubmit the command.

ARS0131E  No logical place to retrieve object >object_name<

Explanation: The command failed when attempting to retrieve the object because there are no cache storage filesystems defined to the system or the archive storage manager is not properly configured.

User response: To use cache storage, define and configure OnDemand cache storage filesystems. To use archive storage, install and configure the archive storage manager. Then restart the server and resubmit the command.

ARS0132I  Printer Options Add: Name(printer_opts_name)

Explanation: Printer options have been added. This message is for your information only.

User response: No action is required.

ARS0133I  Id Printer Options Add: Id(id) Name(printer_opts_name)

Explanation: Printer options have been added for the user with the specified ID. This message is for your information only.

Example:
Id Prt Options Add: Id(12) Name(rosa)

User response: No action is required.
ARS0134I  Printer Options Delete: Name(printer_opts_name)
Explanation: Printer options have been deleted. This message is for your information only.
User response: No action is required.

ARS0135I  Id Printer Options Delete: Id(id) Name(printer_opts_name)
Explanation: This message is for your information only.
User response: No action is required.

ARS0136I  Printer Options Update: Name(printer_opts_name)
Explanation: This message is for your information only.
User response: No action is required.

ARS0137I  Id Printer Options Update: Id(id) Name(printer_opts_name)
Explanation: This message is for your information only.
User response: No action is required.

ARS0138E  BulkPrint Failed
Explanation: The server print function failed.
Example:
BulkPrint Failed Srvr->everest.ibm.com 9.99.999.999<-
User response: See the OnDemand System Log for other messages that are associated with the server print function. If the problem persists, contact your IBM Service Representative.

ARS0139E  Unable to exec program >command<. errno=errno
Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.
User response: If the problem persists, contact your IBM Service Representative.

ARS0140E  Unable to fork. errno=errno, File=file, Line=line
Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.
User response: If the problem persists, contact your IBM Service Representative.

ARS0141E  Ran out of load-id naming conventions. Increase the size of the Application Group Object Size.
Explanation: The system was unable to create new object names because it exceeded the number of available object names for this application group. The object size controls how much space is allotted for objects in an application group.
User response: Increase the object size on the application group’s Advanced Storage Management page in the OnDemand administrative client. Then resubmit the command.

ARS0142E  Connection cannot be established for the >hostname< server
Explanation: The client was unable to connect to the specified server.
Example:
Connection cannot be established for the >PRODUCTION< server. Srvr->everest.ibm.com<-

164  Common Server Administration Guide
User response: Verify that the server is available, that it is properly configured, and that the required programs are running. Then resubmit the command.

ARS0143E Unable to create stream communications. errno=errno
Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.
User response: If the problem persists, contact your IBM Service Representative.

ARS0144E Unable to create socket communications. errno=errno
Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.
User response: If the problem persists, contact your IBM Service Representative.

ARS0145E The communication layer was unable to send data. errno=errno
Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.
User response: If the problem persists, contact your IBM Service Representative.

ARS0146E The communication layer was unable to receive data. errno=errno
Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.
User response: If the problem persists, contact your IBM Service Representative.

ARS0147E Unable to initialize server environment. rc=rc
Explanation: An unexpected error occurred during the execution of this program.
User response: Check the configuration files ars.ini and ars.cfg to make sure filesystem paths and parameters are correct. If the problem persists, contact your IBM Service Representative.

ARS0148E Unable to initialize server communications. rc=rc
Explanation: A communication error has occurred. Either the OnDemand server was already started, TCP/IP was not started, or there is a configuration problem. The ARSS0CK* debug parameter in ars.cfg can help you troubleshoot TCP/IP errors.
User response: Check to see that the server is running and that TCP/IP is started. Use the ARSS0CK* debug parameter to help you identify possible TCP/IP errors. If the problem persists, contact your IBM Service Representative.

ARS0150E Unable to allocate enough memory. File=file, Line=line
Explanation: The system was unable to allocate enough memory.
User response: If the problem persists, contact your IBM Service Representative.

ARS0151E Unable to initialize server database system parameters. Contact your system administrator.
Explanation: The command failed when attempting to initialize the database.
User response: Verify that the OnDemand instance and the database are properly configured. Then resubmit the command.
ARS0152E  The command &lt;command&gt; can only be run by the owner of the command.
Explanation: The command failed when attempting to run the specified command.
User response: Log on to the system as the owner of the command and resubmit the command.

ARS0153E  Unable to change directory to &lt;directory_name&gt;.  errno=errno
Explanation: The system failed when attempting to change to the specified directory. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.
User response: Verify that the directory exists and verify the directory permissions. Then resubmit the command.

ARS0154E  Unable to establish server communications with network.  rc=rc
Explanation: A communication error has occurred. Either the OnDemand server was already started, TCP/IP was not started, or there is a configuration problem. The ARS50CK debug parameter in ars.cfg can help you troubleshoot TCP/IP errors.
User response: If the problem persists, contact your IBM Service Representative.

ARS0155E  Server is unable to communicate to receive client requests.  rc=rc
Explanation: A TCP/IP failure has occurred.
User response: Check to see if TCP/IP is running. Stop and restart the OnDemand Server. If the problem persists, contact your IBM Service Representative.

ARS0156E  Server is unable to communicate request with SubSrvr
Explanation: A TCP/IP failure has occurred.
User response: Check to see if TCP/IP is running. Stop and restart the OnDemand Server. If the problem persists, contact your IBM Service Representative.

ARS0157E  SubSrvr is unable to communicate request with Server
Explanation: A TCP/IP failure has occurred.
User response: Check to see if TCP/IP is running. Stop and restart the OnDemand Server. If the problem persists, contact your IBM Service Representative.

ARS0158E  Server is unable to initialize database connection.  rc=rc
Explanation: The server failed when attempting to initialize the database.
User response: Verify that the database is running and that you can connect to it. See the OnDemand System Log for other messages that are associated with database initialization. If the problem persists, contact your IBM Service Representative.

ARS0159E  Server is unable to terminate database connection properly.  rc=rc
Explanation: The server failed when attempting to terminate the database connection.
User response: Verify that the database is running and that you can connect to it. See the OnDemand System Log for other messages that are associated with database initialization. If the problem persists, contact your IBM Service Representative.

ARS0160E  Unable to load module &lt;function_name&gt;.  rc=rc
Explanation: The system failed when attempting to load the specified dynamic load library. Permissions on the dynamic load library need to be at least read and execute. On a UNIX system, the load module must also exist in the server exits directory (/usr/1pp/ars/bin/exits). On a Windows system, the load module must also exist in the server bin directory (usually C:\Program Files\IBM\OnDemand for WinNT\bin).
Example: Unable to load module /usr/lpp/ars/exits/arsusxct. rc=2 Srvr->everest.ibm.com 9.99.999.999<-

User response: Verify that the dynamic load library exists and verify the file permissions. Then resubmit the command.

ARS0161E The userexit >userexit_name< failed. rc=rc

Explanation: The specified user exit program failed. Permissions on the user exit program need to be at least read and execute. On a UNIX system, the exit module must also exist in the server exits directory (/usr/lpp/ars/bin/exits). On a Windows system, the exit module must also exist in the server bin directory (usually C:\Program Files\IBM\OnDemand for WinNT\bin).

Example: The userexit >QRDARS/ARSUSEC< failed. rc=3 Srvr->RDR400M.RALEIGH.IBM.COM<-

User response: Verify that the user exit program functions properly outside of the OnDemand environment. Then resubmit the command.

ARS0162E Unable to determine codepage. Check configuration file ars.cfg for ARS_CODEPAGE variable

Explanation: The command failed when attempting to determine the code page.

User response: Verify that the OnDemand instance is configured correctly and then resubmit the command.

ARS0163E Unable to initialize converter from (codepage,codeset) input_codepage,input_codeset to (codepage,codeset) output_codepage,output_codeset. rc=rc

Explanation: The system was unable to initialize the converter. The required iconv conversion tables are not available.

User response: Check the server's locale directory to make sure the specified conversion tables exist.

ARS0164I ApplGroup Segment Maintenance: Name(appl_grp_name) Agid(agid) SegName(segment_name) Action(action) Time(time)

Explanation: The ARSMAINT program collected statistics on the specified table. This message is for your information only.

Example: ApplGroup Segment Maintenance: Name(ERN-TEST001) Agid(15912) SegName(WLF1) Action(15) Time(0.195)

User response: No action is required.

ARS0165I ApplGroup Segment Expire Maintenance: Name(appl_grp_name) Agid(agid) SegName(segment_name)

Explanation: The ARSMAINT program expired the specified segment from the specified application group. This message is for your information only.

Example: ApplGroup Segment Expire Maintenance: Name(!UDB-index-expire) Agid(15404) SegName(MFF1)

User response: No action is required.

ARS0166I ApplGroup Segment Export: Name(appl_grp_name) Agid(agid) SegName(segment_name) Time(time)

Explanation: The ARSMAINT program migrated the specified segment from the database to archive storage. This message is for your information only.

Example: ApplGroup Segment Export: Name(test-testdocs-lwp) Agid(15673) SegName(VIF1FAA) Time(2.364)

User response: No action is required.
ARS0171I  •  ARS0174I

ARS0167I  ApplGroup Segment Import: Name(appl_grp_name) Agid(agrid) SegName(segment_name) Time(time)
Explanation:  The ARSADMIN program imported the specified segment from archive storage to the database. This message is for your information only.
Example:  
ApplGroup Segment Export: Name(test-testdocs-lwp) Agid(15673) SegName(VIF1FAA) Time(2.364)
User response:  No action is required.

ARS0168E  ApplGroup Segment Not Available: Name(appl_grp_name) Agid(agrid) SegName(segment_name)
Explanation:  The specified segment was required to perform a query, however, the segment was not found in the database.
Example:  
ApplGroup Segment Not Available: Name(!UDB-index-migration) Agid(15365) SegName(WEF2)
User response:  Ask an administrator to import the specified segment from the archive storage to the database. Then resubmit the command.

ARS0169E  ApplGroup Segment Migration Failed: Name(appl_grp_name) Agid(agrid) SegName(segment_name). rc=rc
Explanation:  The command failed when attempting to migrate a segment.
User response:  See the OnDemand System Log for other messages that are associated with the migration. If the problem persists, contact your IBM Service Representative.

ARS0171E  ApplGroup Segment Exists: Name(appl_grp_name) Agid(agrid) SegName(segment_name). rc=rc
Explanation:  The command did not import the segment because the segment already exists in the database.
User response:  Verify the name of the segment and the name and ID of the application group. Then resubmit the command.

ARS0172E  Filesystem >filesystem_name< is not unique. It is common with filesystem >common_filesystem_name<
Explanation:  Duplicate filesystem names were used in the ars.dbfs configuration file. Filesystem names must be unique.
User response:  Change the filesystem configuration so that it contains only unique filesystem names. Then restart the server and resubmit the command.

ARS0173I  Annotation Update: Name(appl_grp_name) Agid(agrid)
Explanation:  An annotation was updated. This message is for your information only.
Example:  
Annotation Update: Name(CHECKSDB) Agid(5025)
User response:  No action is required.

ARS0174I  Annotation Id Update: Id(id) Name(appl_grp_name) Agid(agrid)
Explanation:  This message is for your information only.
User response:  No action is required.
## ARS0175E

**User >user_name< does not have permission to perform the specified action. File=file, Line=line**

**Explanation:** The specified user does not have the permissions that are required to perform the action.

**User response:** Update the user to provide the user with permission to perform the action and then resubmit the command. Otherwise, resubmit the command with a different user ID.

## ARS0176E

**BulkTextSearch Failed**

**Explanation:** The command failed when attempting a text search.

**User response:** See the OnDemand System Log for other messages that are associated with the text search. If the problem persists, contact your IBM Service Representative.

## ARS0178E

**System call failed for command >command<. errno=errno**

**Explanation:** The OnDemand server failed trying to execute the command. The `errno` value is provided in `/usr/include/sys/errno.h` on UNIX systems and might provide additional information.

**User response:** Refer to `errno.h` for additional information. If the problem persists, contact your IBM Service Representative.

## ARS0179E

**License Server Failed. rc=rc**

**Explanation:** A licensing problem has occurred.

**User response:** If the problem persists, contact your IBM Service Representative.

## ARS0180E

**License Server was unable to initialize the license management system. rc=rc**

**Explanation:** An unexpected error occurred during the execution of this program.

**User response:** If the problem persists, contact your IBM Service Representative.

## ARS0181E

**License Server failed during termination of the license management system. rc=rc**

**Explanation:** An unexpected error occurred during the execution of this program.

**User response:** If the problem persists, contact your IBM Service Representative.

## ARS0182E

**License Server was unable to acquire a license from the license management system. cnt=count, rc=rc**

**Explanation:** An unexpected error occurred during the execution of this program.

**User response:** If the problem persists, contact your IBM Service Representative.

## ARS0183E

**License Server was unable to release a license from the license management system. rc=rc**

**Explanation:** An unexpected error occurred during the execution of this program.

**User response:** If the problem persists, contact your IBM Service Representative.

## ARS0184E

**License Server was unable to reactivate a license from the license management system. rc=rc**

**Explanation:** An unexpected error occurred during the execution of this program.

**User response:** If the problem persists, contact your IBM Service Representative.

## ARS0185E

**OnDemand license limit has been exceeded, currently current_licenses running only entitled_licenses are entitled. Please contact an IBM Service Representative.**

**Explanation:** The number of concurrent users exceeds the number of entitled licenses for concurrent users.

**User response:** Verify the number of client licenses that your organization is authorized to use. Verify the
configuration of the client licenses for concurrent users. If the problem persists, contact your IBM Service Representative.

ARS0186I  OnDemand started with a license limit of entitled_licenses

Explanation: The number of configured entitled licenses for concurrent users is displayed when the OnDemand Library Server starts.

Example:
OnDemand started with a license limit of 50

User response: No action is required.

ARS0187I  Unable to establish thread server connection. rc=rc

Explanation: An unexpected error occurred during the execution of this program.

User response: If the problem persists, contact your IBM Service Representative.

ARS0188I  Unable to create thread. rc=rc

Explanation: An unexpected error occurred during the execution of this program.

User response: If the problem persists, contact your IBM Service Representative.

ARS0189E  Unable to create pipe communications. errno=errno

Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: If the problem persists, contact your IBM Service Representative.

ARS0190E  System command failed >command<. errno=errno

Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: If the problem persists, contact your IBM Service Representative.

ARS0191I  Segment >segment_name< unknown in System Migration

Explanation: The command failed when attempting to find the specified segment in the OnDemand System Migration application group.

User response: Verify the migration parameters, including the name of the segment and the name of the application group. Then resubmit the command. If the problem persists, contact your IBM Service Representative.

ARS0192E  Unable to create file >file_name<. errno=errno

Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.

User response: If the problem persists, contact your IBM Service Representative.

ARS0193E  Unable to query System Migration Application Group. rc=rc

Explanation: An unexpected error occurred during the execution of this program.

User response: If the problem persists, contact your IBM Service Representative.
ARS0194E   Unable to open directory >directory_name<.  errno=errno
Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.
User response: If the problem persists, contact your IBM Service Representative.

ARS0195E   Unable to close directory >directory_name<.  errno=errno
Explanation: An unexpected error occurred during the execution of this program. The errno value is provided in /usr/include/sys/errno.h on UNIX systems and might provide additional information.
Example: Unable to close directory >**UNK**<.  err=(**UNK**) Srvr->everest.ibm.com 9.99.999.999<-
User response: If the problem persists, contact your IBM Service Representative.

ARS0196I   Cache Expiration: ApplGroup(appl_grp_name) Agid(agid) ObjName(object_name) Date(date) Server(server)
Explanation: The ARSMAINT program expired the specified storage object from the specified application group. This message is for your information only.
Example: Cache Expiration: ApplGroup(CHKSTMTS1R) Agid(5013) ObjName(95FAAA) Date(11401) Server(RDR400M.RALEIGH.IBM.COM)  Srvr->rdr400m.raleigh.ibm.com 10.36.173.225<-
User response: No action is required.

ARS0197I   Cache Migration: ApplGroup(appl_grp_name) Agid(agid) ObjName(object_name) Date(date) Server(server)
Explanation: The ARSMAINT program migrated the specified storage object from cache storage to archive storage. This message is for your information only.
Example: Cache Migration: ApplGroup(System Log) Agid(9263) ObjName(1534FAA) Date(11073) Server(libraryserver)  Srvr->everest.ibm.com 9.99.999.999<-
User response: No action is required.

ARS0198E   Invalid ownership and/or permissions on cache file/directory >path_name<
Explanation: The ownership or permissions for the specified cache storage file or directory are not correct. Cache filesystems have specific permissions for directories, which are described in discussed in your Planning and Installing.
Example: Invalid ownership and/or permissions on cache file/dir >/arscache1<  Srvr->everest.ibm.com<-
User response: Verify the ownership and permissions for the cache storage filesystems and then resubmit the command. If the problem persists, contact your IBM Service Representative.

ARS0199E   Unexpected empty directory in cache >directory_name<
Explanation: The cache directory is empty.
User response: Verify the configuration of the cache storage filesystems and resubmit the command. If the problem persists, contact your IBM Service Representative.
ARS0200E  CD-ROM Creation Failed: Volume(volume)

Explanation: The command failed when attempting to create the specified CD-ROM.

Example:
CD-ROM Creation Failed: Volume(1290)

User response: See the OnDemand System Log for other messages that are associated with the CD-ROM creation process. If the problem persists, contact your IBM Service Representative.

ARS0201I  Concurrent Licenses: Current(current_licenses), Maximum Allowed(entitled_licenses)

Explanation: The server generates this message approximately every 30 minutes to display the number of concurrent users on the system (at the time that the message was generated). This message also displays the maximum number of concurrent users that are allowed on the system.

Example:
Concurrent Licenses: Current(8), Maximum Allowed(50)

User response: No action is required.

ARS0202I  Concurrent Licenses: Maximum Achieved(maximum_licenses), Maximum Allowed(entitled_licenses)

Explanation: The server generates this message each time that the number of concurrent users on the system exceeds the last reported maximum number of concurrent users on the system. This message also displays the maximum number of concurrent users that are allowed on the system. The counter for the maximum number of concurrent users is reset to zero each time that the OnDemand library server is restarted.

Example:
Concurrent Licenses: Maximum Achieved(12), Maximum Allowed(50)

User response: No action is required.

ARS0203I  ApplGroup Load: Name(appl_grp_name) LoadId(load_id) File(file) InputSize(input_size) OutputSize(output_size)

Explanation: ARSLOAD has finished loading. This message is for your information only.

Example:
ApplGroup Load: Name( ) LoadId( ) File( ) Inputsize( ) OutputSize( )

User response: No action is required.

ARS0204I  Printer Add: Name(printer_name) Queue(queue) Pid(pid)

Explanation: The specified printer was added to the specified queue. This message is for your information only.

Example:
Printer Add: Name(QPRINT2) Queue(QGPL/QPRINT2) Pid(5098)

User response: No action is required.

ARS0205I  Printer Delete: Name(printer_name) Queue(queue) Pid(pid) IdName(id_name) Id(id)

Explanation: The specified printer was deleted from OnDemand. This message is for your information only.

Example:
Printer Delete: Name(QPRINT) Queue(QGPL/QPRINT) Pid(5193) IdName() Id(0)

User response: No action is required.
ARS0206I  User ID Add: User(name) Id(id), User(owner_name) Id(owner_id), Perms(permissions)
Explanation: The specified user ID was added with the specified permissions. This message is for your information only.

User response: No action is required.

ARS0207I  User ID Delete: User(name) Id(id), User(owner_name) Id(owner_id)
Explanation: The specified user ID was deleted. This message is for your information only.

Example:
User Id Delete: User(HOMER) Id(998), User(Ulysses) Id(74)
User response: No action is required.

ARS0208I  User ID Update: User(name) Id(id), User(owner_name) Id(owner_id), Perms(permissions)
Explanation: The specified user ID was updated as shown. This message is for your information only.

User response: No action is required.

ARS0209I  User ID Add: User(name) Id(id), Group(owner_name) Id(owner_id), Perms(permissions)
Explanation: The specified user ID was added to the specified group with the specified permissions. This message is for your information only.

Example:
User Id Add: User(BUZZ) Id(20), Group(noaccess) Id(80041), Perms(3)
User response: No action is required.

ARS0210I  User ID Delete: User(name) Id(id), Group(owner_name) Id(owner_id)
Explanation: The specified user was deleted from OnDemand. This message is for your information only.

User response: No action is required.

ARS0211I  User ID Update: User(name) Id(id), Group(owner_name) Id(owner_id), Perms(permissions)
Explanation: The specified user was added to the specified group. This message is for your information only.

User response: No action is required.

ARS0212I  BulkTextSearch: Time(time)
Explanation: The search was completed in the length of time indicated. This message is for your information only.

Example:
BulkTextSearch: Time(2.752)  Srvr->RDR400M.RALEIGH.IBM.COM<-

BULK DOCUMENT RETRIEVAL
Application Group  Agid Flds->Handle
----------------------------------------------------------------
PATINFO01  5014  ->7FAAA,3852,968,0,3272,0x4E,0x4F,0,1,0

User response: No action is required.
Appendix C. 5250 host connection to client viewer

This section describes the OnDemand 5250 Host Connection, which allows an i5/OS application to send information to the OnDemand client workstation viewer program (the viewer). The intent is to provide a mechanism by which a 5250 line-of-business application can use the viewer to display documents from the OnDemand database. This is done with little or no interaction between the user and the viewer.

This function is comprised of two parts:

- The FNDKEYOND or FNDKEYRDAR command, which the line-of-business application will invoke. The FNDKEYOND command is a part of Option 10 (Common Server) of OnDemand for iSeries, and is used to retrieve documents archived using the OnDemand Common Server feature. The output of the FNDKEYOND command MUST be displayed using the workstation viewer. FNDKEYRDAR is a part of Option 1 (Spool File Archive) of OnDemand for iSeries, and it is used to retrieve documents archived using the OnDemand Spool File Archive feature. The output of the FNDKEYRDAR command may be displayed using the workstation viewer, or may be displayed on a non-programmable terminal or in a terminal emulation session. The references to FNDKEYRDAR which follow assume that its output is being directed to the workstation viewer. One or both of these commands may be used, depending on which options of OnDemand (Spool File Archive or Common Server) are installed. In the following paragraphs, FNDKEYxxxx means either FNDKEYOND or FNDKEYRDAR.
- A companion program that resides on the workstation, which is the interface between the FNDKEYxxxx command and the viewer.

Operational and environmental considerations

For this function to operate correctly, you must address several operational and environmental considerations. This section will describe these considerations.

Workstation installation tasks

For the FNDKEYxxxx command to operate correctly, the workstation companion program, QRLROCD.EXE, must be running on the workstation when the FNDKEYxxxx command is run on the server. This program is found in the OnDemand install directory, usually C:\Program Files\IBM\OnDemand32. The following paragraphs describe a suggested approach for simplifying the startup of this program.

After the OnDemand client software is installed on your workstation, you should establish a shortcut which points to the QRLROCD.EXE program. This shortcut can be placed on the workstation desktop, in the startup folder or in any other place which meets your needs. Placing the shortcut in your startup folder will start the program automatically when you start your workstation. This is appropriate if you use this interface frequently. If you end the program and need to restart it, or if you have no need for the program to be started automatically, you may want to place a shortcut on the desktop.

In most cases, you will only need to start the companion program once. If, however, the workstation is attached to multiple OnDemand server systems, or if
both FNDKEYOND and FNDKEYRDAR output will be displayed by the viewer, you may need to start the program multiple times. In this case, you should create a shortcut for each one, for reasons explained below in the section labeled Multiple OnDemand servers in the network. Follow the directions in the sections below, depending on your configuration. The term “multiple OnDemand server systems” refers to a network where either of the following is true:

- there are two or more OnDemand server systems from which you need to view FNDKEYxxxx output concurrently using the viewer
- there is one OnDemand server, but the results of both FNDKEYOND and FNDKEYRDAR commands will be displayed concurrently by the viewer

**One OnDemand server in the network**

If you will be using either FNDKEYOND or FNDKEYRDAR (but not both), and there is only one OnDemand server where the command will be used, you may allow the command and the companion program to use the default port number (3005). In this case, it is not necessary to modify the shortcut to specify a different port. Please skip to the section titled Other workstation considerations. If the above does not describe your configuration, please continue with the next section.

**Multiple OnDemand servers in the network**

If you intend to display the results of both the FNDKEYOND and FNDKEYRDAR commands with the viewer, or if there are multiple OnDemand servers where either of these commands may be run, a separate workstation companion program must be started on the workstation for each different combination of system and command. For example, if FNDKEYRDAR and FNDKEYOND will be run on a single system, two of the companion programs should be started. The same applies when FNDKEYOND is run from two systems.

Each instance of the companion program must be configured to use a different port. After you have created the shortcuts you need, you should alter the properties of the shortcuts to specify a port number and, optionally, a system name. The system name, if specified, will appear as the window title for the viewer which the shortcut will start.

To specify a port and system for a shortcut, right-click the shortcut. From the pop-up menu, select Properties. On the Shortcut tab, you will see an entry box labeled Target. This should contain the path for the QRLROCD.EXE program. At the end of the path, after QRLROCD.EXE, add at least one space, followed by:

```
/p=nnnn /s=systemName
```

where nnnn is the port number and systemName is the name of the OnDemand server.

**Example:**

```
....\qrlrocd.exe /p=3006 /s=ACCOUNTING
```

You may also use uppercase P and S (\qrlrocd.exe /P=3007 /S=BILLING ).

After adding the port and system parameters, press OK to save the new properties of the shortcut. You also should change the title which displays beneath the shortcut to something meaningful, such as “OnDemand Viewer for ACCOUNTING reports”. 
Make a note of the port numbers and system names you have specified for the shortcuts. It will be necessary to configure the server systems so that FNDKEYxxxx will use the matching port numbers instead of the default. This is discussed in the section “Server Configuration” below.

Other workstation considerations
For FNDKEYxxxx output to be displayed correctly using the OnDemand viewer, the FNDKEYxxxx program on the server system must be able to determine the TCP/IP address of the workstation. You should access your line-of-business applications which invoke FNDKEYxxxx through a terminal emulation session. The connection method for the session should be TCP/IP. If the FNDKEYxxxx command is run in a job attached to this session, the address of the workstation can be determined by the FNDKEYxxxx command, and nothing further needs to be done.

If the emulation session does not use TCP/IP, the FNDKEYxxxx command searches for the presence of a data area, located in QUSRDRARS library, which has the same name as the device name associated with the emulation session. If the data area exists, the command looks for a non-blank value in positions 1-15 of the data area and uses this value as the workstation IP (Internet Protocol) address. It is the responsibility of the user to ensure that this data area exists and contains the IP address. You can use the CRTDTAARA and CHGDTAARA commands for this purpose.

If the FNDKEYOND command detects errors when sending the search request to the workstation companion program, it will assign a three-digit error code and will display this information in message RDR2882. If the FNDKEYRDAR command detects errors, see the IBM Content Manager OnDemand for iSeries Common Server Administration Guide for an explanation of the errors.

Table 7 lists the error codes and their meanings for exception RDR2882.

<table>
<thead>
<tr>
<th>Error code</th>
<th>Error description</th>
</tr>
</thead>
<tbody>
<tr>
<td>002</td>
<td>Environment error. A connection could not be established with the workstation companion program because the workstation IP address could not be determined.</td>
</tr>
<tr>
<td>091</td>
<td>The TCP/IP socket could not be created.</td>
</tr>
<tr>
<td>092</td>
<td>Connect failed for TCP/IP socket. The most likely cause is that the workstation companion program is not running, or there is a port number mismatch between the FNDKEYxxxx command and the companion program.</td>
</tr>
<tr>
<td>093</td>
<td>Socket Close operation failed.</td>
</tr>
</tbody>
</table>

Server Configuration
The information in this section is pertinent only if you created more than one shortcut. If you created only one shortcut, the FNDKEYxxxx commands will function correctly using the default port number, and nothing further needs to be done.

If you created more than one shortcut, you should also have specified different port numbers for the shortcuts. Since the FNDKEYxxxx commands must use the same port numbers which you specified on the shortcuts, it is necessary to configure these commands on the server systems to use the specified ports.
The FNDKEYxxxx commands check for the existence of a data area named QRLMFKPORT, in library QUSRRDARS. If this data area does not exist, the commands will use the default port number (3005). If the data area exists, the FNDKEYxxxx commands will use the port number found in the data area contents. The first five characters of the data area contents represent the port number which the FNDKEYOND command should use. The next five characters represent the port number for the FNDKEYRDAR command. To create this data area, enter the following:

```csh
CRTDTAARA QUSRRDARS/QRLMFKPORT TYPE(*CHAR) LEN(10) VALUE( 'AAAAABBBBB' )
```

whereAAAAA is the FNDKEYOND port number andBBBBB is the FNDKEYRDAR port number.

For example, to specify that FNDKEYOND, on this system, should use port 3007 and that FNDKEYRDAR should use 3008, specify `VALUE('0300703008')`. It is important that each five-position number be right-justified, with leading zeros if necessary. If you will not use both commands from the same system, enter 00000 for the port number corresponding to the command you will not use.

If there are multiple OnDemand servers in your network (or you will use FNDKEYOND and FNDKEYRDAR commands on one or more systems), and there are workstations which will display FNDKEYxxxx output from these systems, you must configure the FNDKEYxxxx commands on these systems to use a different port number. Some examples are shown below:

- If you have one OnDemand server, but both FNDKEYOND and FNDKEYRDAR commands will be used on this system, you need to create the data area. In this case, you can allow one of the commands to use the default port, and the other command should use a different port. For example, if you specify `VALUE('0300503006')`, FNDKEYOND will use port 3005, and FNDKEYRDAR will use 3006. Make sure that your shortcuts are modified to specify these port numbers.
- If FNDKEYxxxx will be run from multiple servers in your network, create the data area on the systems where it is necessary to change the port assignments for the FNDKEYxxxx commands. For example, on SYSTEMA, specify `VALUE('0300503006')`, and on SYSTEMB specify `VALUE('0300703008')`. It is imperative that these commands on multiple systems in the network use different port numbers.
Appendix D. Server printing and faxing

Using an i5/OS printer file to define server print parameters

You can use an i5/OS printer file to define some of the server print parameters in your Common Server application definition by specifying the following in the Print Parameters field on the Print Options tab of your application:

PRTF=LIBRARY/PRINTERFILENAME

where LIBRARY is the name of the library that contains your printer file and PRINTERFILENAME is the name of the printer file.

Notes:
1. The entire line must be entered in uppercase.
2. The printer file cannot be an externally-described printer file. If necessary, you will need to create a printer file that has the same characteristics (LPI, CPI, page size, overlays, and so on), but that does not specify a source file (keyword SRCFILE) on the CRTPRTF command.

This printer file specification is also used when faxing from the server to produce the temporary i5/OS spooled file which is then faxed.

The following parameters, even though specified in the printer file identified in the PRTF parameter, are overridden as shown in Table 8:

Table 8. Parameter Overrides

<table>
<thead>
<tr>
<th>Printer file parameter</th>
<th>Changed to</th>
<th>Where specified</th>
<th>When specified</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEVTYPE</td>

</tr>
</tbody>
</table>

Server fax setup

When defining a printer for use with server fax functions, a Server Queue Name is required in the printer definition within the OnDemand Administrator. You can either specify the name of a library/output queue or *NONE. If *NONE is specified, the output is temporarily spooled to QUSRRDARS/QRDARS400 output queue before it is sent to fax using the QRLMSFAX program. If you enter a library/output queue name, then OnDemand will use that output queue to temporarily spool the data.

If you use the SNDFAX command in the QRLMSFAX program (which is the default as shipped), the restrictions in Table 10 on page 219 apply to the fax information. If you use a different server fax product, see “Facsimile user exit program” on page 219.

Appendix E. API and user exit reference

API reference

This section contains reference information about the OnDemand server Application Programming Interfaces (APIs).

The APIs contained in this reference include APIs for various OnDemand functions beyond the standard command set described in Appendix A, “Command reference,” on page 143. The APIs are presented in alphabetical order. Each API contains a description of its purpose and syntax (including descriptions of the parameters that can be used). Examples and general information about using the APIs have also been included.

Note: These APIs require that you be signed on to the server with a user profile that is also defined as a user in OnDemand.

Using quotes when executing the APIs

When you execute an OnDemand program from the i5/OS command line interactively, in batch using the SBMJOB command or the QSHELL environment and you specify parameter values that contain a null (blank) character or some other special character (such as the parenthesis), you must delimit the parameter value with double quote characters. For example, when executing the ARSDOC GET program from the i5/OS command line and you specify the -o parameter to specify one or more application group field names, each field name is enclosed with parenthesis and the entire string must be surrounded by double quote characters, for example: -o "(sdate)(student)". Please see the operating system documentation for more information about the use of quotes when executing the APIs. Note that if the same string is included in a parameter file using the -F parameter on the ARSDOC GET command, it would be enclosed in brackets and the double quotes are not required, for example: [-o (sdate)(student)].

Using the QSHELL environment

All ARSxxxxx API programs must be executed using the QSHELL environment. QSHELL is a command interpreter that allows i5/OS to execute AIX commands on i5/OS. These commands can also be run from a script file. More information about QSHELL can be found at http://www.as400.ibm.com/developer/qshell/. Currently, option 30 for 5722-SS1 (i5/OS) installs the QSHELL interpreter. The QSHELL environment is started by the QSH or STRQSH i5/OS command.

Multiple ARSxxxxx programs may be issued in one QSHELL session. After the completion of a QSHELL command, a $ is displayed. This notifies the user that the QSHELL command has completed. This does not mean that the command actually ran successfully and performed the desired function.

All command examples assume that the QSHELL environment has been started and the ARSxxxxx programs are in a directory specified in the PATH variable. OnDemand places a symbolic link to the commands in the /usr/bin directory during installation. To exit the QSHELL environment, press the F3 key.

The -v parameter will provide detailed program logging information. The -u parameter specifies a valid OnDemand user that exists with the proper authority to
perform the functions requested. The -p parameter specifies the OnDemand password for the OnDemand user specified in the -u parameter. The userid and password are not normally needed when running these programs in i5/OS. By default, the current i5/OS user profile and password are used as the OnDemand userid. If your i5/OS user profile does not exist in OnDemand, you must specify a valid OnDemand userid and password to use these programs.

The -h is the OnDemand instance name where the program is to execute. For the purposes of this document, the administrative user name will be testadmin, the password will be ondemand and the host name is QUSROND. User testadmin must have the appropriate authority to perform the function being requested by the ARSxxxxxxx command.

**Calling QSHELL commands from an i5/OS command line**

When executing the ARSxxxxxxx programs from an i5/OS command line, the i5/OS QSH command is used. When embedded single quotes exist within the program parameter, they must be doubled. For example:

```
QSH CMD('arsdoc get ...... "-i WHERE Account#='1234567" "....-u testadmin -p ondemand")
```

Since the QSHELL environment will log messages to the terminal, you will want to control this by setting environment variable QIBM_QSH_CMD_OUTPUT. This variable will control where the messages are logged. This does not interfere with the messages that get logged to the OnDemand System Log. The QSHELL environment logging can be sent to the terminal session, to a file in the IFS directory structure, or you can choose not to log the messages. The ADDENVVVAR, CHGENVVAR, RMVENVVAR and WRKENVVAR commands can be used to manipulate the QSHELL environment. The environment parameters can be set for the entire system and for the job. In most cases, you will not want to change the environment parameter at the system level, because it will affect all users of QSHELL on the system.

- Set the job environment to log messages to the terminal
  `ADDENVVVAR EnVVar(QIBM_QSH_CMD_OUTPUT) VALUE(STDOUT) LEVEL(*JOB)`

- Set the system environment to not log messages.
  `ADDENVVVAR EnVVar(QIBM_QSH_CMD_OUTPUT) VALUE(NONE) LEVEL(*SYS)`

- Set the job environment to log messages to the a file in the IFS. mydirectory must exist in the IFS.
  `ADDENVVVAR EnVVar(QIBM_QSH_CMD_OUTPUT) VALUE('FILE=/mydirectory/QSHELL_output') LEVEL(*JOB)`

The following is an example of the messages that might be displayed to the terminal or logged in the output file.

```
OnDemand Load Id = >5013-1-0-85FAA-11359-11359<  
Loaded 4 rows into the database  
Document compression type used - OD77. Bytes Stored = >10240<
```

Message QSH0005 will be issued in the joblog when running the QSH command. The message text is "Command ended normally with exit status &1". The possible statuses returned are shown in Table 11 on page 185.
Table 11. Message QSH0005 status codes

**How to read a syntax diagram**

A syntax diagram shows you how to specify an API program so that the operating system can correctly interpret what you type.

Read a syntax diagram from left to right and from top to bottom, following the horizontal line (the main path). If the line ends with an arrowhead, the API syntax is continued and the next line starts with an arrowhead. Facing arrowheads mark the end of the API syntax.

When you type an API from the syntax, be sure to include punctuation, such as commas and equal signs.

Parameters are classified as keywords or variables:

- Keywords represent constants and are shown (in syntax) in uppercase letters; however, you can enter keywords in either uppercase or lowercase.
- Variables represent names or values you supply and are shown (in syntax) in lowercase letters; however, you can enter variables in either uppercase or lowercase unless the syntax directions explicitly state the case restrictions. An example of a variable is a file name.

A parameter can be a combination of a keyword and a variable.

Required parameters are displayed on the main path.

```
+---+------+
|   | PRIOR |
```

Optional parameters are displayed below the main path.

```
+---+-----+
|   | OPT  |
```

A stack of parameters, with the first parameter displayed on the main path, shows that you must choose one of the parameters.

```
+---+-----+
|   | OPC  |
```

Appendix E. API and user exit reference 185
A stack of parameters, with the first parameter displayed below the main path, shows that you can choose one of the parameters.

An arrow returning to the left, above the path, shows that items can be repeated following these conventions:
- If the repeat arrow contains a break, the item can be repeated in a list with the items separated by blank spaces.

You can repeat items from parameter stacks following the stack conventions for required and optional parameters described previously.

Some syntax diagrams contain parameter stacks within other parameter stacks. You can only repeat items from stacks according to the conventions described previously. That is, if an inner stack does not have a repeat arrow above it but an outer stack does, you can choose only one parameter from the inner stack and combine it with any parameter from the outer stack, and that combination can be repeated. For example, the following diagram shows that you could combine parameter choice2a with parameter choice2 and then you can repeat that combination again (choice2 plus choice2a).

Some APIs are preceded by an optional path parameter.

If you do not supply the path parameter, the system searches the current directory for the API. If the API is not in the current directory, the system continues to search for the API using the directories defined in the PATH environment variable.
Some APIs in this section have several formats that accomplish the same task. These APIs appear (in syntax) similar to the following:

```
PROGRAM FORM1
PROGRAM FORM2
```

The description of the API directs you to the correct format to use.

ARSDATE

Purpose
The ARSDATE program allows you to display the OnDemand internal database value for a given date and time string or display the date and time string for a given OnDemand internal database value.

Syntax
```
arsdate [-a] [-i] [-g] [-h hours] [-n minutes] [-s seconds]
[-d days] [-m months] [-y years] [-f "format"]
```

```
internalValue
"dateString"
```

Description
The ARSDATE program can be used to display the OnDemand internal database value for a given date and time string or display the date and time string for a given OnDemand internal database value.

Values whose data types are Date, Time, Date/Time, or Date/Time (TZ) are represented in an internal form that is transparent to the casual user of OnDemand. Casual users enter these values the same way that they appear in a report. However, to search the database with an SQL string, a user must enter the internal form of the value. The ARSDATE program lists the internal value of a date or time string.

Parameters
- `-a` Use to display database values and date strings for Date fields. For example, to display the database value for the date 9/1/99, enter:
  
  `arsdate -a 9/1/99`

  The ARSDATE program returns:
  
  `9/1/99 -> 10836`
To display the date string for the database value 10836 in the default date format, enter:

```
arsdate -a 10836
```

The ARSDATE program returns:

```
10836 -&gt; 9/1/99
```

**-i**

Use to display database values and date and time strings for Date/Time fields. The time part of a Date/Time field is not adjusted for the local time zone. You typically use the -i parameter to find out one of two things:

- Given a date and time printed on a report, what value did OnDemand store in a Date/Time database field? You can use the result to search a Date/Time field with an SQL string.
- Given a value stored in a Date/Time database field, what would be the date and time printed on a report?

**-t**

Use to display database values and time strings for Time fields. The time is not adjusted for the local time zone. For example, to display the database value for the time 04:00:00, enter:

```
arsdate -t 04:00:00
```

The ARSDATE program returns:

```
04:00:00 -&gt; 4800
```

To display the time string for the database value 4800, enter:

```
arsdate -t 4800
```

The ARSDATE program returns:

```
4800 -&gt; 04:00:00
```

**-z**

Use to display database values and date and time strings for Date/Time (TZ) fields. The time part of a Date/Time (TZ) field is adjusted for the local time zone. If you run the ARSDATE program with the -z parameter on systems in different time zones and you specify the same date and time value, the result will be different. For example, suppose that you need to determine the value stored in a Date/Time (TZ) field for "09/01/99 04:00:00". The API:

```
arsdate -z "09/01/99 04:00:00"
```

When run on a server in the Eastern time zone will return:

```
09/01/00 04:00:99 -&gt; 936172800
```

If you run the same API on a server in the Mountain time zone, then result will be:

```
09/01/00 04:00:99 -&gt; 936180000
```

A typical use of the -z parameter is to determine a database value with which to search the system log. You can use the result to search the Date/Time (TZ) field of the system log with an SQL string. For example, suppose a user in New York logs on to a server in Denver. To retrieve the log on messages with an SQL string, you must specify the date and time part of the query using the local time of the client that is running the query. If the user
logged on to the server at 4 a.m. Eastern time, then a query that is run in Denver must specify 2 a.m. to retrieve the message.

- **g** Display the current system date.
- **d days** Add the specified number of days to the specified internal value.
- **h hours** Add the specified number of hours to the specified internal value.
- **m months** Add the specified number of months to the specified internal value.
- **n minutes** Add the specified number of minutes to the specified internal value.
- **s seconds** Add the specified number of seconds to the specified internal value.
- **y years** Add the specified number of years to the specified internal value.
- **f ”format”** Determines the format of the date and time string that OnDemand displays.

<table>
<thead>
<tr>

</tbody>
</table>

**internalValue** The internal date and time value from the OnDemand database. Enter one or more internal values when you want to display formatted date strings.
"dateString" The date and time string. Enter one or more strings when you want to display internal date values.

Examples
1. The following example shows how to determine the database value for the specified date and time string. The data type of the database field is Date/Time.

arsdate -i "09/01/99 04:00:00"

09/01/99 04:00:00 -> 936158400

In the example, you could use the database value to search a Date/Time field in the database with an SQL string. For example:

arsdoc get -i "WHERE somedate=936158400" ...

2. The following example shows how to determine the date and time string for the specified database value. The data type of the database field is Date/Time. The result is shown using the default display format.

arsdate -i 936158400

936158400 -> 09/01/99 04:00:00

3. The following example shows how to determine the database value for the specified date and time string. The data type of the database field is Date/Time (TZ). The ARSDATE program adjusts the time part of the result for the local time zone. For Mountain time zone:

arsdate -z "09/01/99 04:00:00"

09/01/99 04:00:00 -> 936180000

If you were to run the same API on a server in the Eastern time zone, the result would be:

arsdate -z "09/01/99 04:00:00"

09/01/99 04:00:00 -> 936172800

Notes
1. When displaying the date string for a given internal value, by default, the ARSDATE program displays the date string using the mm/dd/yy format. If you want the ARSDATE program to display the date string using a different format, then you must specify the date format with the -f parameter. For example:

arsdate 10907

10907 -> 11/11/99

arsdate -f "%m/%d/%Y" 10907

10907 -> 11/11/1999

2. When displaying the internal value for a given date string, by default, the ARSDATE program expects you to specify the date string using the mm/dd/yy format. If you want to specify the date string using a different format, then you must specify the date format with the -f parameter. For example:

arsdate 11/12/99

11/12/99 -> 10908

arsdate 11/12/1999

11/12/1999 -> -1 (Error)
arsdate -f "%m/%d/%Y" 11/12/1999

11/12/1999 -> 10908

3. Unless you specify otherwise, the upper limit of the year part of a date is 2069. To process dates beyond December 31, 2069, you must specify the -f parameter and a four-digit year format. For example:

arsdate -f %m/%d/%Y 112500

112500 -> 01/05/2278

The ARSDATE program will fail if you specify an internal value beyond the year 2069 and you do not specify a four-digit year format with the -f parameter.

**IFS location**

/usr/bin/arsdate

The executable program.

**ARSDOC**

**Purpose**

The ARSDOC program is a multi-purpose document processing program. You can use the ARSDOC program to query the server and generate a list of items that match a query, retrieve documents from the system, add, delete, and update documents, and send documents to a server printer. You can run the ARSDOC program from the command line or from a program.

**Description and syntax**

The ARSDOC program provides the following functions:

- ADD
- DELETE
- GET
- PRINT
- QUERY
- UPDATE

For each function, you can specify all of the required options on the command line or you can specify the name of a parameter file that contains the options. The syntax of each function is listed twice: first, when you specify the options on the command line; second, when you specify a parameter file.

**ADD function:** Use to store data in OnDemand by specifying the folder, application group, application, and database fields and values. **Important:** Set the proper locale before issuing the ARSDOC ADD API. See the chapter entitled “Defining a locale” in the IBM Content Manager OnDemand for iSeries Common Server: Planning and Installation Guide for important details. If you specify the -O parameter, then you do not have to specify all of the database fields (however, you must always specify date and time fields). When you specify the -O parameter, the ARSDOC program stores a default value in any database field that you omit. The default value for string fields is an empty string. The default value for numeric fields is 0 (zero). Numeric fields include integer and decimal (floating point) fields. When adding a document, you can specify the document data in one of three ways:

- A document file
• An SQL query that contains clauses, database field names, index values, and operators that identifies an existing document
• A public named query that identifies an existing document

When you specify an SQL query or public named query, you are creating a database row that points to an existing document that has been identified by the query.

When you use the ADD function to add a row for an existing document, the row must be added to the application group that contains the document. The application group must be specified with the -g parameter and must be one of the application groups referenced by the folder named with the -f parameter.

**Important:** The ADD function will fail unless the Database Organization for the application group named with the -g parameter is Multiple Loads per Database Table and the Expiration Type is Segment or Document.

```
arsdoc add -a application -f folder -g applGroup -h host

-n dbfield=value -0 D -p password

-i sqlQuery -o docfilename -q namedQuery

-S startdate,enddate -u userid
```

When you use the parameter file option, you must specify the -F, -h, -p, -u, and -v parameters on the command line. All other parameters must be specified in the parameter file. The following diagram shows the syntax of the ADD function when you use the parameter file option:

```
arsdoc add -a application -f folder -g applGroup -h host

-p password -u userid

-v
```

The syntax of the parameter file for the ADD function is:

```
[ -a application ] [ -f folder ]

-g applGroup
-G applGroup
```
DELETE function: Use to delete documents from OnDemand. To identify the documents that you want to delete, you must enter an SQL query or specify the name of a public named query. The SQL query must contain clauses, database field names, index values, and operators. The DELETE function deletes all documents that match the query.

```bash
arsdoc delete -f folder -G applGroup -h host
-<i>sqlQuery
-<q>namedQuery -p password
-<S>startdate,enddate -u userid -v
```

When you use the parameter file option, you must specify the -F, -h, -p, -u, and -v parameters on the command line. All other parameters must be specified in the parameter file. The following diagram shows the syntax of the DELETE function when you use the parameter file option:

```bash
arsdoc delete -F parmfile -h host -p password -u userid
```

The syntax of the parameter file for the DELETE function is:

```plaintext
[<f>folder]
[<G>applGroup]
[<i>sqlQuery]
[<q>namedQuery]
[<S>startdate,enddate]
```

GET function: Use to retrieve documents and resources from the system. The GET function can also generate and save generic index data for the documents that match the query. You must identify the name of the OnDemand library server. You must specify the application group or folder that you want to search. To query the database, you can enter an SQL query or specify the name of a public named query. The SQL query must contain clauses, database field names, index values,
and operators. By default, the ARSDOC program sends a copy of the documents that match the query to the display (interactive) or the joblog (batch). You can also choose to write the output to a file. To retrieve documents in a sorted order, you must specify the -n parameter.

```
arsdoc get [-a] [-c] [-d dir] [-f folder] [-g]

- G applGroup - h host - i sqlQuery - q namedQuery - L max# - n

- N - o name - p password - s seconds

- S startdate, enddate - , format - u userid - v

- x loadId - X loadId
```

When you use the parameter file option, you must specify the -F, -h, -p, -s, -u, and -v parameters on the command line. All other parameters must be specified in the parameter file. The following diagram shows the syntax of the GET function when you use the parameter file option:

```
arsdoc get -F parm_file - h host - p password - s seconds

- u userid - v
```

The syntax of the parameter file for the GET function is:

```
[---a---] [---c---] [---d directory---] [---f folder---]

[---g---] [---G applGroup---] [---i sqlQuery---]

[---l max#---] [---n---] [---N---] [---o name---]

[---S startdate, enddate---, format---] [---x loadId---]

[---X loadId---]
```

**PRINT function:** Use to send documents to an OnDemand server printer. You must name the OnDemand library server and the folder that you want to search and specify the query to run. The items that match the query are sent to the server printer named with the -P parameter. The server printer must be defined to OnDemand using the administrative client. To query the database, you can enter an SQL query or specify the name of a public named query. The SQL query must contain clauses, database field names, index values, and operators. You can limit
the number of documents sent to the printer by using the -L parameter and specifying the maximum number of documents that should be retrieved, regardless of the number of documents that match the query. You can limit the number of database tables searched, and possibly increase the performance of a query, by specifying the -S parameter and specifying a start date and an end date. The PRINT function does not currently support server fax.

```
arsdoc print [-f folder] [-G applGroup] -h host

-1 sqlQuery [-q namedQuery] [-L max#] [-p password] [-P printer]

[-S startdate,enddate] [-v format] [-u userid] [-v]
```

When you use the parameter file option, you must specify the -F, -h, -p, -u, and -v parameters on the command line. All other parameters must be specified in the parameter file. The following diagram shows the syntax of the PRINT function when you use the parameter file option:

```
arsdoc print -F parmfile -h host

[-p password] [-u userid]
```

The syntax of the parameter file for the PRINT function is:

```
[[-f folder] [-G applGroup]] [-l sqlQuery] [-q namedQuery]

[-L max#] [-P printer]

[-S startdate,enddate] [-v format]
```

**QUERY function**: Use to generate a list of items that match a query. You must specify the name of the OnDemand library server and the folder that you want to search and specify the query to run. To query the database, you can enter an SQL query or specify the name of a public named query. The SQL query must contain clauses, database field names, index values, and operators. The data that is retrieved from the server is sorted by using the Sort field from the Field Information page for the folder. By default, the ARSDOC program sends the list of items that match the SQL query to the display (interactive) or the joblog (batch). You can choose to write the output to a file.

```
arsdoc query [-d directory] [-D] [-e delimiter] [-f folder]
```
When you use the parameter file option, you must specify the -F, -h, -p, -u, and -v parameters on the command line. All other parameters must be specified in the parameter file. The following shows the syntax of the QUERY function when you use the parameter file option:

```bash
arsdoc query -F parm_file -h host -p password -u userid
```

The syntax of the parameter file for the QUERY function is:

```bash
[--d directory] [--D] [--e delimiter]
[--f folder] [--G applGroup] [--H]
[--i sqlQuery] [--q namedQuery] [--I] [--L max#] [--n]
[--N "(dbfield)"
[--o outputFile]
[--S startdate,enddate,format]
[--x loadId]
```

**UPDATE function**: Use to update documents. You must name the application group to update and specify one or more application group fields and their values. To identify the documents that you want to update, you must enter an SQL query or specify the name of a public named query. The SQL query must contain clauses, database field names, index values, and operators. The UPDATE function updates all of the rows that match the query. It does not change the actual document data.
When you use the parameter file option, you must specify the -F, -h, -p, -u, and -v parameters on the command line. All other parameters must be specified in the parameter file. The following shows the syntax of the UPDATE function when you use the parameter file option:

```
arsdoc update -F parm_file -h host [-p password] [-u userid] -v
```

The syntax of the parameter file for the UPDATE function is:

```
[folder] [g applGroup] [G applGroup] [sqlQuery] [NamedQuery] [dbfield=value] [startdate,enddate] [format] [-u userid] [-v]
```

### Parameters

**-a**

For the GET function, when retrieving AFP documents, specify this parameter to include resources with the documents that are retrieved. If documents from the same application have different resource groups, then the ARSDOC program creates separate output files for each resource group.

For the ADD function, you must specify the name of the OnDemand application. The application must belong to the application group named with the -g (or -G) parameter.

**-c**

For the GET function, use to concatenate all of the documents that match the query into one output file. Name the output file with...
the -o parameter. However, even if you do specify the -c parameter, the ARSDOC program creates separate output files when any of the following conditions occur:

- If more than one application group is referenced by the folder. The ARSDOC program creates one output file for each application group that contains items that match the query.
- If more than one application is contained in an application group. The ARSDOC program creates one output file for each application that contains items that match the query.
- If documents from the same application have different resource groups, the ARSDOC program creates separate output files for each resource group.

For example, if a folder references two application groups, then the following specification:

-o student -c

Can result in file names such as:

student.516
student.517

Where 516 and 517 are application group identifiers. One file is created for each application group. Each file contains all of the items that match the query for that particular application group.

-d directory
The name of the directory where the ARSDOC program writes the output files. The directory must exist before the ARSDOC program attempts to save the output files.

-D
For the QUERY function, appends the document handle information to the end of each output record. The document handle information consists of the following ten values, in the order listed:

Document name
Offset
Length
Compressed object offset
Compressed object length
Annotation type
Compression type
Resource ID
Primary node ID
Secondary node ID

The values are separated by a delimiter. The default delimiter is the comma character. You can specify a different delimiter with the -e parameter.

You cannot specify the -H, -n, or -N parameters when you specify the -D parameter.

-e delimiter
For the QUERY function, determines the character that separates the database field values in the output. By default, OnDemand separates values in the output with a comma.

-f folder
The name of the OnDemand folder. The folder name must be
specified exactly as it appears in OnDemand. The case of the folder
name is significant. For example, to query the OnDemand System
Log folder, you must enter:

    -f "System Log"

If you are using a parameter file, then you must specify the -f
parameter in the parameter file. If you are not using a parameter
file and you do not specify the -f parameter, then the ARSDOC
program prompts you for the folder name when you run the
program.

For the GET and QUERY functions, you can omit the -f parameter
and specify the -G parameter to search a specific application
group.

For the UPDATE function, if the folder that is specified with the -f
parameter contains only one application group, then you can omit
the -g or -G parameter (you do not have to specify the name of the
application group).

When you specify the -X parameter, you cannot specify the -f
parameter.

**Note:** The following information applies only when an application
group name is not provided.

A folder can be used to search one or more application
groups. Because the ARSDOC program generates a single
SQL query to search all of the application groups, the
properties of the database fields must be the same for each
application group. The properties include the field name,
type, and length. For example, suppose that you define the
following application groups and fields:

<table>
<thead>
<tr>
<th>Application Group</th>
<th>Field Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>Student Bills</td>
<td>name, account, billDate</td>
</tr>
<tr>
<td>Student Grades</td>
<td>name, account, gradeDate</td>
</tr>
<tr>
<td>Student Transcripts</td>
<td>name, account, transcriptDate</td>
</tr>
</tbody>
</table>

You cannot query the application groups using the ARSDOC
program because the name of the date field is not the same
for each application group. However, if you were to define
the application groups and fields as follows:

<table>
<thead>
<tr>
<th>Application Group</th>
<th>Field Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>Student Bills</td>
<td>name, account, studentDate</td>
</tr>
<tr>
<td>Student Grades</td>
<td>name, account, studentDate</td>
</tr>
<tr>
<td>Student Transcripts</td>
<td>name, account, studentDate</td>
</tr>
</tbody>
</table>

Then you could query the application groups using the
ARSDOC program because the names of the database fields
are the same for each application group.

**-F parmFile** Specifies the name of the file that contains the actions to run and
other parameters, values, and options. You typically specify this
option when you want to perform more than one action.
Parameters and values specified in the parameter file must be enclosed by the left and right bracket characters.

An action (one or more input lines) can contain a maximum of 32767 characters (bytes).

You can use the \ (backslash) character to continue the parameters of an action to two or more lines.

A parameter file can contain blank lines and comment lines. A comment line contains the # character in the first column.

For the GET function, use to generate Generic Indexer data for the items that match the query. See the IBM Content Manager OnDemand for iSeries Common Server: Indexing Reference for details about the Generic Indexer.

When you specify the -g parameter, you must specify the -c, -N, and -o parameters. However, you cannot specify database field names with the -o parameter.

The ARSDOC program uses the following convention to name the output files that are generated with the -g parameter:

-o.res_id.appl_group.appl.type

Where:

- o is the value specified with the -o parameter
- res_id is the resource group identifier. A resource group identifier always starts at 1 (one) and is incremented by one for each version of the resource group.
- appl_group is the name of the application group
- appl is the name of the application
- type is the file type:
  - out identifies a document file
  - ind identifies a generic index file
  - res identifies a resource file

In general, the number of files generated is dependent on the number of application groups in a folder, the number of applications in an application group, and the number of versions of resource groups in an application.

For the ADD and UPDATE functions, specifies the name of the OnDemand application group. The application group that you specify will be searched from the folder named with the -f parameter. For the UPDATE function, if the folder that is specified with the -f parameter contains only one application group, then you can omit the -g parameter (you do not have to specify the name of the application group).

-G applGroup Use to specify the name of the application group.

Note: For the UPDATE function, if the folder that is specified with the -f parameter contains only one application group, then you can omit the -G parameter (you do not have to specify the name of the application group).

For ADD: When the database query is run to retrieve the document that contains the data that is to be used in the add
function, the search is limited to the specified application group, even if the folder named with the -f parameter can be used to search more than one application group. This ensures that only documents in the specified application group can be used for the add function. You can specify the name of the application group with the -g parameter or the -G parameter.

For DELETE: The -G parameter is an optional parameter. If specified, then the database query that is run to determine the document(s) to delete is limited to the specified application group. The addition of the -G parameter allows you to delete documents from a specific application group in folders that can search more than one application group. If you do not specify the -G parameter, then the query runs against all of the application groups that can be searched from the folder. You can omit the -f parameter and specify the -G parameter to search a specific application group. The -G parameter is required if you specify the -X parameter.

For GET: Specifies the application group to query and retrieve documents from. The -G parameter lets you retrieve documents from a specific application group from a folder that can search more than one application group. If you do not specify the -G parameter, then the query runs against all of the application groups that can be searched from the folder. You can omit the -f parameter and specify the -G parameter to search a specific application group. The -G parameter is required if you specify the -X parameter.

For PRINT: The -G parameter is an optional parameter. If specified, then the database query that is run to determine the document(s) to print is limited to the specified application group. The addition of the -G parameter allows you to print documents from a specific application group in folders that can search more than one application group. If you do not specify the -G parameter, then the query runs against all of the application groups that can be searched from the folder. You can omit the -f parameter and specify the -G parameter to search a specific application group. The -G parameter is required if you specify the -X parameter.

For QUERY: Specifies the application group to search. The -G parameter lets you search a specific application group from folders that can search more than one application group. If you do not specify the -G parameter, then the query runs against all of the application groups that can be searched from the folder. You can omit the -f parameter and specify the -G parameter to search a specific application group. The -G parameter is required if you specify the -X parameter.

For UPDATE: When the database query is run to determine the document(s) to update, the search is limited to the specified application group, even if the folder named with the -f parameter can search more than one application group. This guarantees that only documents in the specified application group can be updated. You can specify the name of the application group with the -g parameter or the -G parameter.

You can use the -G parameter with the -i parameter to query folders that can search more than one application group. For example, a folder contains three application groups; you want to query only one of the application groups. Use the -G parameter to specify the name of the application group that you want to query. Use the -i parameter to specify the application group’s database field names. You can also use the -G and -i parameters when the
application groups have different database field names. The following example shows how to search a folder and three application groups that have different database field names:

```
arsdoc get -f "Student Information" -G loans
   -i "WHERE number LIKE '123456' AND loanDate = 10593"
arsdoc get -f "Student Information" -G grades
   -i "WHERE number LIKE '123456' AND gradeDate = 10593"
arsdoc get -f "Student Information" -G transcripts
   -i "WHERE number LIKE '123456' AND transDate = 10593"
```

You can use the -G parameter with the -q parameter to query folders that can search more than one application group. When you specify the -G parameter and you specify a public named query with the -q parameter, the ARSDOC program queries the application group named with the -G parameter instead of the application group specified in the named query. (If you do not specify the -G parameter, then the query runs against the application group specified in the named query. If the named query does not identify an application group, then the query runs against all of the application groups that can be searched from the folder.)

- **h instance**  
  The instance name. This is a required parameter.

- **H**  
  For the QUERY function, specify this parameter to generate a header record in the output. The default header record contains the application group field names. By default, the field names are delimited with the comma character. You can specify a delimiter of your choice with the -e parameter.

  You can use the -H parameter to generate output that contains only the application group database field names. To do so, specify the -H parameter without specifying the -i or -q parameters. (You also must not specify the -L, -n or -N parameters.) The ARSDOC program writes the database field names to the specified output file, or to the display (interactive) or the joblog (batch).

- **i sqlQuery**  
  A valid SQL query, that includes the names of one or more application group database fields, index values, and operators. OnDemand does not validate the string that you enter. Please see the DB2 Universal Database™ for iSeries: SQL Reference for an overview of SQL concepts and details about how to construct a query.

  **Note:** If you specify the -q or the -X parameters, then you cannot specify the -i parameter.

For the DELETE or UPDATE functions, if more than one document meets the search criteria, then multiple documents will be deleted or updated. For an update, all of the documents will be updated with the same values.

To construct a query with a database field of type date, you must use the OnDemand internal format of the date. That is, the number of days since January 1, 1970. You can use the ARSDATE program to list the internal format for a given date string. For example, the following shows how to use the ARSDATE program to obtain the internal date for July 21, 1995:

```
arsdate -a 7/21/95
```
The ARSDATE program displays:

7/21/95 -> 9333

You would then enter 9333 as the index value for the date field.

-I

For the QUERY function, appends the Load ID to the end of each output record. The Load ID is separated from the database field values by a delimiter. The default delimiter is the comma character. You can specify a different delimiter with the -e parameter. You cannot specify the -H, -n, or -N parameters when you specify the -I parameter.

To use the -I parameter, the user running the query must have permission to access the System Log application group and folder.

If the Load ID is not found in the system log, then the string Load ID could not be found is appended to the end of the output record.

Note: The Load ID for a document is determined by searching the system log. Searching the system log can be very time consuming, depending on the number of records stored in the system log. The system log is searched for each document that matches the query.

-L max#

For the GET and PRINT functions, determines the maximum number of items retrieved from OnDemand, regardless of the number of items that match the query.

For the QUERY function, determines the number of items included in the hit list, regardless of the number of items that match the query.

-n

For the GET function, specify to retrieve items one at a time from the server. By default, the ARSDOC program uses a bulk retrieval method for high-speed retrieval of items from the server.

Note: Specify the -n parameter if a sort order has been defined in the folder and it is a requirement that the documents be retrieved in the order specified by the sort order. For more information about the sort order, see the online help on the Field Information page for the folder.

For the QUERY function, use to number the items in the output file. If you specify this option, the ARSDOC program will sequentially number each line in the output file, beginning with 1 (one).

For the ADD and UPDATE functions, use to specify the application group database field names and their values using the form -n dbfield=value. Note:

- Specify a null (blank) field value by using single quotes within double quotes. For example: -n middle=""'"
- Specify a string field value that contains a null (blank) or other special character by enclosing the field value in single quotes within double quotes. For example: -n name="Sally Smith"

You can specify one or more field names and their values (by specifying the -n parameter one time for each database field name and its value). When adding a document, you must specify all of the application group fields unless you specify the -O parameter.
When updating a document, you can specify one or more fields and their values. For a date field, you must specify the value using the Display Format from the Field Information page under folders.

**-N**

For the GET function, when querying a folder that searches more than one application group or a folder that searches an application group that contains more than one application, specify this parameter to add the resource identifier, application group name, and application name to the output file name. When you specify the **-N** parameter, you must specify the **-c** parameter. If you specify the **-g** parameter to generate generic index data, you must specify the **-N** parameter.

If the folder searches more than one application group or an application group contains more than one application and you do not specify the **-N** parameter, then the ARSDOC program adds the application group or application identifier to the output file name. For example, the following specification:

- **-o student -c**

Can result in output file names such as:

- `student.516`
- `student.517`

Where 516 and 517 are application group identifiers. However, when you specify the **-N** parameter, the ARSDOC program uses the resource identifier, application group name, and application name to name the output file. For example, the following specification:

- **-o student -c -N**

Can result in output file names such as:

- `student.1.BILLS.1995`
- `student.1.BILLS.1996`

Where 1 is the resource identifier, BILLS is the application group name, and 1995 and 1996 are application names.

The number of index files created is dependent on the number of application groups in a folder, the number of applications in an application group, and the number of resource groups in an application.

For the QUERY function, determines the application group fields that the ARSDOC program writes to the output file and the field names that appear in the header record. By default, the ARSDOC program writes all fields to the output file. You can specify one or more application group field names using the form `-N(dbfield)...(dbfield)`. Each field name that you specify must be delimited with parenthesis. When you run a query from the command line, you must delimit the entire string in double quote characters. For example, `-N"(dbfield1)(dbfield2)"`.

**-o name**

For the GET function, use to write documents to one or more files and identify a user-defined string used to generate unique file names. For example, the following specification:

- **-o student -c**
Can result in the following output file name:

```
student
```

You can concatenate one or more of the database field names that you specify with the -i parameter to generate a unique file name. For example, the following specification:

```
-o "(sdate)(student)"
-i "WHERE sdate='971025' AND student='001200340056'"
```

Can result in the file name:

```
971025.001200340056
```

When you use database field names to generate a unique file name:

- OnDemand verifies that the field names that you specify are valid for the application groups that can be searched by the folder specified with the -f parameter.
- If the field name that you specify is a date field, the output format of the date is determined by the Format on the Load Information page under applications.
- The field names must be delimited with parenthesis.
- You can specify the fields in any order. The order that you specify determines the file name that the ARSDOC program generates.
- You cannot use a field name to represent a directory name. For example:

```
-o "(field_1)/(field_2)"
```

Is not valid.

- You cannot specify the -c parameter to concatenate items in one output file. Each item that matches the query is stored in a separate output file.

If more than one item matches a query and you do not generate a unique file name using database field names, concatenate items in a single file with the -c parameter, or specify the -g parameter, then the ARSDOC program generates a unique file name for each item that matches the query by adding a .n extension to the file name. Where n is the number of the item that matched the query. For example, if you specify:

```
-o statements
```

And two items match the query, the ARSDOC program creates the following files:

```
statements.1
statements.2
```

You must specify the -o parameter when you specify the -c parameter.

For the QUERY function, determines the file name of the output file in which the ARSDOC program writes the list of items that match the query.
For the ADD function, determines the name of the input file that contains the document to be added. The value that you specify is not checked for valid characters. You can specify a full path name, including the forward slash characters as part of a directory path. When adding a document, you can provide the input data by specifying the name of the input file that contains the data with the -o parameter, an SQL query with the -i parameter, or a public named query with the -q parameter. Only one document can be added at a time.

-O For the ADD function, you must specify this parameter if you intend to omit one or more database fields. However, you can never omit date or time fields. When you specify the -O parameter, the ARSDOC program stores a default value in any other database field that you omit. The default value for string fields is an empty string. The default value for numeric fields is 0 (zero). Numeric fields include integer and decimal fields.

-p password The password of the OnDemand user that you named with the -u parameter. If there is no password assigned to the user that you specify, use double quotes to show a null password. That is, specify -p "". If you omit the -p parameter and do specify a userid with the -u parameter, then the ARSDOC program prompts you to enter the password when you run the program. If there is no password assigned to the user that you specify, press the Enter key when prompted. If you omit -u and -p parameters, OnDemand will use the i5/OS user profile of the user issuing ARSDOC as the OnDemand userid.

-P printer For the PRINT function, identifies the OnDemand server printer to which you want to send the documents that match the query.

-q namedQuery The name of a public named query for the folder named with the -f parameter. A named query is a set of search criteria previously saved on the server that can be recalled by name to search a folder. A named query is typically defined to search a folder for a specific document or set of documents.

Note: If you specify the -i or the -X parameters, then you cannot specify the -q parameter.

-s seconds For the GET function, determines the number of seconds that the ARSDOC program waits between query requests when you specify more than one query with the -F parameter. If you do not specify this option, then the ARSDOC program does not wait between query requests. That is, the default is 0 (zero) seconds.

-S startdate,enddate[,format]
Provides a date range that the ARSDOC program uses to limit a search to specific tables. When you specify this parameter, the ARSDOC program searches only tables that contain a segment within the specified date range.

You can optionally specify a date format. See "ARSDATE” on page 187 for a list of the standard date formats. An example of a date range with a date format is:
-S "01011990,12311990,%m%d%Y"
If you do not specify a date format, then the date values must be specified by using the Display Format that is set on the Field Information page in the folder. An example of a date range without a date format is:

-S "01011990,12311990"

Notes:
1. For most queries, you should always specify the -S parameter and specify a date range. Doing so limits the range of a query and can significantly improve the performance of a query.
2. For the ADD function, if you specify the -o parameter, you cannot specify the -S parameter.
3. For the GET and QUERY functions, if you specify the -X parameter, you cannot specify the -S parameter.
4. For all functions, if you specify the -q parameter, you cannot specify the -S parameter.

-u userid
The OnDemand user that is permitted to perform the specified function. The ARSDOC program verifies that the userid that you specify is a valid OnDemand user for the server that you name with the -h parameter, that the userid is permitted to open the folder that you name with the -f parameter, and that the userid has permission in application groups to perform the specified function. If you omit the -u parameter, the current user profile of the job running ARSDOC is used as the OnDemand userid. If that user profile does not match an OnDemand userid, then ARSDOC prompts you to enter the userid.

-v
Enables verbose mode, which displays all messages (informational and error). By default, the ARSDOC program displays error messages.

-x loadId
For the GET function, specify to limit the documents that can be retrieved to the set of documents that were loaded into the system under the specified loadId.

For the QUERY function, specify to limit the query to the set of documents that were loaded into the system under the specified loadId.

When you specify the -x parameter, use the -f and -G parameters as follows:
• Specify the -f parameter to search all application groups. You can specify the search using the -i parameter or the -q parameter.
• Specify the -G parameter to search a specific application group. You must specify the search using the -i parameter.
• Specify both the -f parameter and the -G parameter. The ARSDOC program will verify that the application group can be searched from the folder.

When you specify the -x parameter, you cannot specify the -X parameter.

-X loadId
For the GET function, specify the -X parameter to retrieve documents by using the index file that was generated for the specified loadId.
For the QUERY function, specify the -X parameter to build a hit list from the index file that was generated for the specified loadId.

When you specify the -X parameter, you must specify the -G parameter and name the application group.

When you specify the -X parameter, you cannot specify the -x parameter, or the -i, -q, -S, and -f parameters.

Examples

1. The following shows how to use the GET function to retrieve documents and save them in a file in the current directory.

```bash
arsdoc get -h rockies -f "Student Information" -o student
   -c -S 1/1/97,12/31/97 -i "WHERE student='001200340056'" -v
```

The ARSDOC program saves all of the documents that match the query in the following output file:

```
student
```

2. The following shows how to use the GET function and a parameter file to run more than one query at a time. The parameter file is in the current directory. The output files are saved in the current directory.

```bash
arsdoc get -h rockies -F parmfile -v
```

The parameter file contains two queries:

```
[-f "Student Information"] [-S 1/1/97,12/31/97] [-o (student)(type)] \ 
[-i "WHERE student='123420010056' AND type='B' OR type='G' OR type='T'"
[-f "Student Information"] [-S 1/1/97,12/31/97] [-o (student)(type)] \ 
[-i "WHERE student='123450011917' AND type='B' OR type='G' OR type='T'"
```

Assuming that documents exist for all of the specified types, the ARSDOC program creates the following output files:

```
123420010056.Bills
123420010056.Grades
123420010056.Transcripts
123450011917.Bills
123450011917.Grades
123450011917.Transcripts
```

3. The following shows how to use the GET function to retrieve documents, write the documents to a file, and generate and save generic index data for the documents that match the query. The example shows how to specify the name of a public named query that is valid for the specified folder.

```bash
arsdoc get -h rockies -f "Student Information"
   -a -c -g -o student -q "3rd yr students GPA>3.5" -N -v
```

The number of output files that the ARSDOC program generates is a factor of the number of application groups queried, the applications contained in the application groups, whether the data is AFP, and if so, the versions of resource groups in each application. At a minimum, for AFP data with one version of the resource group and one application group, the ARSDOC program generates three output files. For example:

```
student.1.Student Information.TRANSCRIPTS.ind
student.1.Student Information.TRANSCRIPTS.out
student.1.Student Information.TRANSCRIPTS.res
```
For AFP data, if there is more than one version of the resource group per application, then the ARSDOC program can generate additional output files. For example:

```
student.1.Student Information.TRANSCRIPTS.ind
student.1.Student Information.TRANSCRIPTS.out
student.1.Student Information.TRANSCRIPTS.res
student.2.Student Information.TRANSCRIPTS.ind
student.2.Student Information.TRANSCRIPTS.out
student.2.Student Information.TRANSCRIPTS.res
```

If the application group contains more than one application, then the ARSDOC program can generate additional output files. For example:

```
student.1.Student Information.BILLS.ind
student.1.Student Information.BILLS.out
student.1.Student Information.BILLS.res
student.1.Student Information.GRADES.ind
student.1.Student Information.GRADES.out
student.1.Student Information.GRADES.res
```

4. The following shows how to use the QUERY function to generate a list of items and save the list in a file in the current directory.

```
arsdoc query -h rockies -f "Student Information"
-o query1.out -H -S 1/1/97,12/31/97
-i "WHERE student='0012-0034-0056' AND type='B' OR type='G' OR type='T'" -v
```

5. The following shows how to use the QUERY function and a parameter file to run more than one query at a time. The parameter file is in the current directory. The output files are saved in the current directory.

```
arsdoc query -h rockies -F parfile -v
```

The parameter file contains three queries:

```
[-f "Student Information"] [-i "WHERE type='B'"] [-o "query2.out"] \ [-S 1/1/97,12/31/97] [-H] [-N (student)(id)(p_date)]

[-f "Student Information"] [-i "WHERE type='G'"] [-o "query3.out"] \ [-S 1/1/97,12/31/97] [-H] [-N (student)(id)(p_date)]

[-f "Student Information"] [-i "WHERE type='T'"] [-o "query4.out"] \ [-S 1/1/97,12/31/97] [-H] [-N (student)(id)(p_date)]
```

6. The following example shows how to use the QUERY function to search a specific application group:

```
arsdoc query -h rockies -i "where Date_Taken BETWEEN 9863 AND 11531"
-G load-scanned-images-jpeg -o jpeg -v
```

7. The following example shows how to use the QUERY function to add a document to the Credit Card Statements folder:

```
arsdoc add -h rockies -o/newdata/crd.dat
-n "crd_date=01/21/98" -n "account='000-000-000'"
-n balance=123.45 -n "name='John Watpole'"
-f "Credit Card Statements" -g CRD -a CRD -v
```

8. The following example shows how to use the UPDATE function to update a document in the Credit Card Statements folder, changing the balance from 123.45 to 0.00:

```
arsdoc update -h rockies
-s Student Information.TRANSCRIPTS.out
-i "where account='000-000-000' and name='John Watpole'"
-n "balance=0.00" -S 1/1/97,12/31/97
-f "Credit Card Statements" -g CRD -v
```

9. The following example shows how to use the DELETE function to delete a document from the Credit Card Statements folder:
arsdoc delete -h rockies
   -i "where account='000-000-000' and name='John Watpole'"
   -f "Credit Card Statements" -S 1/1/97,12/31/97 -v

10. The following example shows how to use the PRINT function to send the
documents that match a query to a server printer:
    arsdoc print -h rockies -P svrprt1
       -i "where account='000-000-000' and name='John Watpole'"
       -f "Credit Card Statements" -S 1/1/97,12/31/97 -v

11. You can use the ARSDOC program to add an index that points to an existing
document. For example, assume that you loaded a bank statement for account
number 000-000-000, date 5/23/97, and account name Joe Smith. You want to
add a new index, but point to the existing statement. The new index uses the
same account number and date, but contains a different account name (for
example, Sally Smith). After adding the index, if a query is run with account
name Joe Smith or Sally Smith, the same bank statement will be retrieved. To
add an index for an existing document:
    arsdoc add -h rockies
       -i "where sdate=10005 and account='000-000-000' and name='Joe Smith'"
       -n "sdate=5/23/97" -n "account=000-000-000" -n "name='Sally Smith'"
       -f "Credit Card Statements" -S 1/1/97,6/31/97 -v

12. The following example shows how to use the QUERY function to limit a
search to the documents that were loaded into the system under a specific
load ID. For example, assume that the specified folder could be used to search
several application groups; each application group contains more than one
application; there are 500,000 documents in the application groups. By using
the -x parameter, the query will be limited to the set of documents that was
loaded into the system under the specified load ID. Without the -x parameter,
the query is run against all 500,000 documents.
    arsdoc query -h rockies -x 19867-025-0-3FAA-10136-10136
       -f load-scanned-images -q query -o out -v

13. The following example shows how to use the QUERY function to limit a
search to the documents that were loaded into the system under a specific
load ID. In the example, the load ID, application group name, and query
string are provided. The search is limited to the application group and only
those documents that were loaded into the system under the specified load ID.
    arsdoc query -h rockies -x 19867-025-0-3FAA-10136-10136
       -i "where Date_Taken BETWEEN 9863 AND 11531" -G load-scanned-images-jpeg
          -o jpeg -v

14. The following example shows how to use the QUERY function to limit a
search to the documents that were loaded into the system under a specific
load ID. In the example, the load ID, folder name, application group name,
and named query are provided. The search is limited to the application group
and only those documents that were loaded into the system under the
specified load ID. Because a folder was specified, a named query can be used.
(If an application group name is specified and a folder name is not specified,
a named query cannot be used, because a named query is associated with a
folder.)
    arsdoc query -h rockies -x 19867-025-0-3FAA-10136-10136
       -f load_scanned-images -q query -G load-scanned-images-jpeg -o jpeg -v

15. The following example shows how to use the GET function and an index file
to retrieve documents from the system. The index file was generated for the
set of documents that was loaded into the system under the specified load ID.
When using the -X parameter, the database is not queried; rather, documents
are retrieved based on the information in the index file.
Notes
The ADD function will fail unless the Database Organization for the application group named with the -g parameter is Multiple Loads per Database Table and the Expiration Type is Segment or Document.

The ADD function can be run without providing an input document from a file or by retrieving an existing document from the system. This means that you can add database field values without adding a document. To add database field values without adding a document, do not specify the -o, -i, or -q parameters; specify the database field names and their values using one or more -n parameters.

The ARSDOC program can print the PTF version number and the ARSDOC GET function can print the number of documents that were queried and retrieved and print a status message for each document that is retrieved. To enable the messages, you must specify the -v parameter. The following shows an example of the new messages:

12/08/02 10:33:36: arsdoc get -u admin -h instance -q 000-000-000 -f CC Stmts -o test -v -c
12/08/02 10:33:36: Attempting login for userid 'admin' on server 'instance' ...
12/08/02 10:33:37: Login successful
12/08/02 10:33:37: Searching for folder 'CC Stmts' ...
12/08/02 10:33:38: Search successful
12/08/02 10:33:38: Searching for documents in 'CC Stmts' ...
12/08/02 10:33:40: Search successful
12/08/02 10:33:40: 2 document(s) have been queried. Retrieving 2 document(s).
12/08/02 10:33:41: (1): Retrieving document for userid 'admin' ...
12/08/02 10:33:41: Document successfully retrieved and stored in file 'test'
12/08/02 10:33:42: (2): Retrieving document for userid 'admin' ...
12/08/02 10:33:42: Document successfully retrieved and stored in file 'test'
12/08/02 10:33:45: arsdoc completed.

IFS location
/usr/bin/arsdoc The executable program.

ARSLOAD

Purpose
The ARSLOAD program can be used to process the input files (not spooled files) that you want to load into the system. The ARSLOAD program determines if the input data needs to be indexed, and if so, calls the appropriate indexing program. The ARSLOAD program calls the storage manager programs to load report data on
storage volumes and the database manager to update the OnDemand database with the index information that was extracted from or specified for the input file. **Important:** Set the proper locale before issuing the ARSLOAD API. See the chapter entitled “Defining a locale” in the *IBM Content Manager OnDemand for iSeries Common Server: Planning and Installation Guide* for important details.

**Syntax**

```
arsload -a application -A applID -c indexDir -d dataDir
-E -f -g applGroup -G applGroupID -h hostname -i
-I instance -j parmFile -n -p password
-t seconds -u userid -U filename -V -X
```

**Description**

The ARSLOAD program is the main OnDemand data indexing and loading program. The ARSLOAD program calls the indexing program if the input data needs to be indexed, creates input files for the storage manager, and updates the OnDemand database. The ARSLOAD program saves processing messages in the system log. You can open the System Log folder and list the messages that were generated when an input file was processed.

You typically configure the ARSLOAD program to run as a monitor to periodically check specified IFS directories for input files to process.

The ARSLOAD program can use the following sources for input files to process:
- one or more file systems specified with one or more `-d` parameters,
- one or more load file names.

If you omit the load file name, the ARSLOAD program will run in monitor mode and attempt to load input data from the directories that are specified by the `-d` parameter. If you omit the load file name and do not specify the monitor mode parameter (`-d`), the ARSLOAD program will issue a usage note and exit. **Note:** When running the ARSLOAD program in monitor mode, the `.ARD` and `.PDF` file name extensions are required to initiate a load process.
When you run the ARSLOAD program, you must provide the userid and password of an OnDemand user with administrator authority for the application group into which the input data will be loaded. There are several ways that you can provide the userid and password:

- Do not specify the -u and -p parameters. In this case, the current user profile of the job that is running ARSLOAD is used as the OnDemand userid. This is the recommended method.
- Specify the -u and -p parameters each time that you run the ARSLOAD program.
- Specify the -U parameter each time that you run the ARSLOAD program to name a file that contains the userid and password of a user with administrator authority for the application group.

**Parameters**

- **a application**  
  The name of the application to load. If the application group contains more than one application, then you must identify the application to load. Otherwise, the load will fail. If you plan to automate the loading of files into different application groups and applications, then use the -A parameter to specify the part of the file name that identifies the name of the application.

- **A applID**  
  Determines the part of the file name that identifies the application to load. If the application group contains more than one application, then you must identify the application to load; otherwise, the load will fail.

You typically use this parameter when you run the ARSLOAD program as a monitor to automate the loading of files into different application groups and applications. For example, a file transmitted from an OS/390 or z/OS system might use the following file naming convention:

```
MVS.JOBNAME.DATASET.FORM.YYYYDDD.HHMMSST.ARD
```

**Important:** The .ARD file name extension is required to initiate a load process.

- Unless you specify otherwise, the ARSLOAD program uses the FORM part of the file name to identify the application group to load. You can use the -G parameter to specify a different part of the file name that identifies the application group (MVS™, JOBNAME, or DATASET). For example, arsload -G JOBNAME.
- If the application group to load contains more than one application (source of data), then you must identify the application to load; otherwise, the load will fail. When you run the ARSLOAD program, you can use the -A parameter to specify the part of the file name that identifies the application (MVS, JOBNAME, DATASET, or FORM). For example, to use the DATASET part of the file name to identify the application, run the ARSLOAD program with the -A DATASET parameter.

- **c indexDir**  
  The directory in which OnDemand temporarily stores data created by the indexing program. The default location is the directory from which the ARSLOAD program was invoked.

- **d dataDir**  
  The directory that contains input files to process.
OS/390 or z/OS download utility; .PDF files are created by Acrobat Distiller). The case of the file type extension is not significant.

You can specify this parameter one or more times. The ARSLOAD program will search for input files to load in each of the directories that you specify. **Note:** To specify more than one directory, specify the `-d` parameter multiple times. In the following example:

```
arsload ... -d dir1 -d dir2 -d dir3 ...
```

The ARSLOAD program will search for input files in the `dir1`, `dir2`, and `dir3` directories.

**-E**

When specified, the user-written program that is associated with the ARSUUPDT exit point is to be invoked. If the `-E` parameter is not specified, the user-written program is not invoked. The user-written program may be used to modify some of the parameters that are used by OnDemand when document data is being loaded by the ARSLOAD program, such as the name of the application group, application, or storage node into which the data will be loaded. For more information, see “Report Specifications Archive Definition Exit” in IBM Content Manager OnDemand for iSeries Common Server: Planning and Installing.

**-f**

Use to unload the data if the load process fails. If the database manager step fails, then OnDemand should remove any index data that was added to the database. If the storage manager step fails, then OnDemand should remove any storage objects that were copied to storage volumes.

**Note:** If an input file fails to load, you should review the message log that was created during the load process. You can retrieve a message log from the system log. If the message log contains a Load ID, then it means that for some reason, OnDemand stored at least some of the input data in the application group. Before you attempt to reload the input data, you must remove the data that was created during the failed load process by using the RMVRPTOND command. See Chapter 14, “Deleting a report,” on page 135 for help with removing the data that is created when a file is loaded into the system.

**-g applGroup**

The name of the application group to load. This parameter is required if you specify the `loadFilename` parameter. This parameter is optional if you specify the `-d` parameter. If you specify the `-d` parameter, then by default, the ARSLOAD program uses the FORMS part of the file name to determine the name of the application group to load. If you plan to automate the loading of files into different application groups and applications, then you should use the `-G` parameter to specify the part of the file name that identifies the application group to load.

**-G applGroupID**

Determines the part of the file name used to identify the name of the application group to load.

You typically use this parameter when you run the ARSLOAD program as a monitor to automate the loading of input files into
different application groups and applications. For example, a file transmitted by an OS/390 or z/OS download utility might use the following naming convention:

MVS.JOBNAME.DATASET.FORM.YYYYDDD.HHMMSST.ARD

**Important:** The .ARD file name extension is required to initiate a load process.

- Unless you specify otherwise, the ARSLOAD program uses the FORM part of the file name to identify the application group to load. You can use the -G parameter to specify a different part of the file name that identifies the application group (MVS, JOBNAME, or DATASET). For example, arsload -G JOBNAME.

- If the application group to load contains more than one application (source of data), then you must identify the application to load; otherwise, the load will fail. When you run the ARSLOAD program, you can use the -A parameter to specify the part of the file name that identifies the application (MVS, JOBNAME, DATASET, or FORM). For example, to use the DATASET part of the file name to identify the application, run the ARSLOAD program with the -A DATASET parameter.

  - **-h hostname** The TCP/IP address, fully-qualified host name, or host name alias of the iSeries system on which the OnDemand server is running.

  - **-i** Use to run the data indexing program only; do not copy report data to storage volumes or add the index data to the database.

  - **-l instance** The name of the OnDemand instance that you want to process. The name of the default instance on the iSeries is QUSROND. You must specify the -l parameter and name the instance, if you are running more than one instance on the same iSeries system and you want to process an instance other than the default instance (QUSROND).

  - **-j parmFile** Use to specify the name of a parameter file that contains additional indexing parameters.

    When you specify the -j parameter and name a parameter file, the ARSLOAD program adds the indexing parameters from the specified parameter file to the indexing parameters that it extracts from the application. (Indexing parameters are typically specified on the Indexing Information page in the application definition.) If an indexing parameter appears in both the application and the parameter file that you specify, unexpected results may occur.

    The following shows an example of a file that contains additional indexing parameters to be processed by ACIF.

    FORMDEF=F1ABB880
    PAGEDEF=P1ABB880
    USERLIB=/usr/acif/resources/sapku11

    - **-n** Determines whether OnDemand deletes the input files when the ARSLOAD program ends.

      - If you specify the -n parameter, then OnDemand does not delete the input files when the ARSLOAD program ends.

      - If you do not specify the -n parameter, then OnDemand deletes the input files when the ARSLOAD program ends.
In either case, if the ARSLOAD program fails in the load step because of a device or system problem, then you can restart the load step after you correct the problem by using the intermediate files that were created by the ARSLOAD program. The ARSLOAD program stores the intermediate files in the directory named with the -c parameter (or the current directory, if you did not specify the -c parameter). The intermediate files have the same file name as the original input file.

-p password  The password for the user specified with the -u parameter. If the user is not assigned a password, enter a null password (that is, specify -p ")

-t seconds  Determines the polling time in seconds. This is the interval of time in which the ARSLOAD program checks the input directories for input files to process. The default value is 600 seconds, which means that the ARSLOAD program checks the input directories every ten minutes.

-u userid  The userid of an OnDemand user with administrator authority for the application group. The user must have permission to add documents to the application group.

If you omit the -u and -p parameters, then the current user profile for the job is used for the OnDemand userid. If that user profile does not match an OnDemand userid, then OnDemand attempts to obtain the userid and password from the value of the -U parameter. If the ARSLOAD program cannot locate or use the file named with the -U parameter, then it attempts to log on to OnDemand and access the application group with a userid of QONDADM and no password.

-U filename  See -u for an explanation.

Important: After you configure the file named with the -U parameter, remember to change the password any time that you change the user’s password in OnDemand. Otherwise the load will fail. The ARSLOAD program can accept an expired password. However, the ARSLOAD program will fail if you specify an incorrect password.

-v  Enables verbose mode, which displays all messages (informational and error). By default, the ARSLOAD program displays error messages.

-X indexer  Allows you to override the indexing program that was specified on the Indexer Information page for the application. The possible values are 4 and 6. Specify -X 4 to use the OS/400 Indexer. Specify -X 6 to use the OnDemand Generic Indexer.

You must specify an indexing program if the input contains index data in a format other than the one supported by the indexing program that was specified for the application. For example, assume that you defined an application and specified the OS/400 Indexer as the indexing program. Later, you used the ARSDOC program to extract documents from an application group. The ARSDOC program generates index data that is in the Generic Indexer format. To load the index data into the application, you must specify:
arsload -X 6 . . .

filename Specifies an input file to process.
You may specify the names of one or more input files to process. If you specify more than one input file, separate the file names with a blank character.
The ARSLOAD program concatenates the following file type extensions to the file name that you specify: IND, OUT, and RES
• The IND file contains the index data
• The OUT file contains the report data
• The RES file contains the resource data
For example, if you specify arsload -g BILLS po3510, then the ARSLOAD program looks for the following files:
• po3510.ind
• po3510.out
• po3510.res
If the ARSLOAD program does not find a file with the IND file type extension, it automatically calls the indexer specified in the application to index the input file.

If you omit an input file name, the ARSLOAD program will run in monitor mode and attempt to load input data from the directories that are specified by the -d parameter. Any files with a file type extension of ARD or PDF will be processed. If you omit an input file name and do not specify the monitor mode parameter (-d), the ARSLOAD program will issue a usage note and exit.

Examples
1. The following shows how to run the ARSLOAD program to check the specified directory for input files to process. The input files must have a file type extension of ARD or PDF. The ARSLOAD program stores temporary work files in the location specified by the -c parameter. In this example, the ARSLOAD program uses the FORM part of the file name to determine the application group to load, and the application group contains only one application. The ARSLOAD program logs on to OnDemand and accesses the application group with the current user profile.
   arsload -c /arsacif/acif1 -d /arsacif/acif2
2. The following shows how to run the ARSLOAD program to check the specified directory for input files to process. The input files must have a file type extension of ARD or PDF. The ARSLOAD program stores temporary work files in the location specified by the -c parameter. In this example, the ARSLOAD program uses the JOBNAME part of the file name to determine the application group to load and the DATASET part of the file name to determine the application to load. The ARSLOAD program logs on to OnDemand and accesses the application group with the current user profile.
   arsload -c /arsacif/acif1 -d /arsacif/acif2 -A DATASET -G JOBNAME
3. The following shows how to run the ARSLOAD program to load the specified file into the specified application group. The ARSLOAD program logs on to OnDemand and accesses the application group with the userid and password provided with the -u and -p parameters.
   arsload -g BILLS -u bob -p secret P03510
4. The following shows how to run the ARSLOAD program to load several input files into the specified application group. The application group name contains an embedded blank character, and must be quoted. The ARSLOAD program logs on to OnDemand and accesses the application group with the userid and password provided with the -u and -p parameters.

   arsload -g "ABC Credit" -u bob -p secret RW7505 RW8505

5. The following shows how to run the ARSLOAD program to load the specified file into the specified application group. The TCP/IP address of the OnDemand library server is specified. This format of the command can be used to load input files from an object server and store the index data on the library server. The ARSLOAD program logs on to OnDemand and accesses the application group with the userid and password from the file named with the -U parameter.

   arsload -g "BILLS" -h "9.99.111.222" -U userpw.cfg ARSPOMST

Notes
An input file cannot exceed 4 GB in size.

The OnDemand server job must be running, otherwise the ARSLOAD program will fail.

IFS location
/usr/bin/arsload The executable program.

User exit reference

Output queue monitor user exit program
The output queue monitor function (started by the STRMONOND command or by using a monitor definition in iSeries Navigator) automatically processes spooled files from selected output queues. When a spooled file is selected from an output queue to be processed, OnDemand first checks for a user exit program in the monitor job’s library list with a name that matches the spooled file attribute that the monitor chose for the application name (*SPLFNAME, *FORMTYPE, *USERDATA, *JOBNAME, *USRDFNOPT1, *USRDFNOPT2, *USRDFNOPT3, *USRDFNOPT4, or *USRDFNDTA). If a program is found, it is called, allowing the application name or application group name to be changed as needed. Then OnDemand uses the new name as it looks for an application definition to use. If a user exit program is not found, OnDemand looks for an application name that matches the original spooled file attribute.

When OnDemand calls the user exit, it passes several parameters, only two of which should be changed. These two changeable fields are:

- Application group (60 bytes)
- Application (60 bytes)

You can design an output queue monitor user exit program to alter the application group name or application name that the monitor finds as it processes the particular spooled files in the output queue. For example, if the monitor finds PGM123 in the User Data spooled file attribute of the spooled file, but you want OnDemand to use the application name of INVOICES, you can write your user exit program as the example shows:

CHANGE APPNAME TO 'INVOICES'
There is a sample monitor output queue user exit program in source file QSAMPLES2 in libraries QRDARS and QUSRDRARS. (Any program source code that you modify should not be placed in QRDARS because that library is replaced during software upgrades. However, QUSRDRARS library is not replaced and can be used for your modified source.) IBM recommends that you copy this source code into a backup member in case you need to go back to the original sample as shipped from IBM.

**Facsimile user exit program**

The facsimile user exit program is designed to enable OnDemand server fax functions to work with iSeries facsimile (fax) software other than Facsimile Support from IBM. To accomplish this, modify and recompile the QRLMSFAX program source code to change the command that is issued when an end user requests a server fax during report retrieval. Simply change the line in the program that issues the SNDFAFX command to use the command for the fax software you have installed on your system. (You could also call a program if no command is available.)

An end-user requesting a server fax causes the QRLMSFAX program to be called. If you do not change and recompile it, the standard program will run (which issues the Facsimile Support command). If you do change and recompile the QRLMSFAX program, then the changed program will run (which will issue your facsimile command).

The sample CL source code for this program (member name QRLMSFAX) can be found in source file QSAMPLES2 in libraries QRDARS and QUSRDRARS. (Any program source code that you modify should not be placed in QRDARS because that library is replaced during software upgrades. However, QUSRDRARS library is not replaced and can be used for your modified source.) IBM recommends that you copy this source code into a backup member in case you need to go back to the original function as shipped from IBM. When you recompile your program, be sure to preserve the QRLMSFAX program name and place the compiled program back in QRDARS library to replace the program that is shipped by IBM.
Appendix F. Automating ARSLOAD data loading

This section provides information to help you configure the ARSLOAD data loading API.

ARSLOAD

The ARSLOAD program is the main OnDemand data loading and indexing API. You can configure the ARSLOAD API to monitor specific IFS directories for report data. If the data needs to be indexed, then the ARSLOAD program calls the indexing program that is specified in the OnDemand application. The ARSLOAD program then works with the database manager to load the index data into the database and works with the storage manager to load the report data and resources on to storage volumes.

Note: The OnDemand server job must be running, otherwise the ARSLOAD program will fail.

Automating ARSLOAD

The following shows an example of the ARSLOAD API.

arsload -v -c /arsacif/acif4 -d /arsacif/acif1 -d /arsacif/acif2 -d /arsacif/acif3

In the example, the ARSLOAD program checks for data in the specified directories every ten minutes (the default polling time). If data needs to be indexed, then the ARSLOAD program stores the index data in the specified index directory.

You must verify the names of the directories. Replace the strings /arsacif/acif1, /arsacif/acif2, /arsacif/acif3, and /arsacif/acif4 with the names of directories that are valid on the server that you are configuring.

Important: The ARSLOAD program uses a particular part of the input file name to determine the application group to load. You can use the -G parameter to specify a different part of the file name to identify the application group to load. If the application group contains more than one application, then you must identify the application to load. Otherwise, the load will fail. You can use the -A parameter to specify the part of the file name that identifies the application.

If a userid and password are not specified on the ARSLOAD program, the current i5/OS userid is used. See Appendix E, “API and user exit reference,” on page 183 for more information about the ARSLOAD program and its userid and password parameters.

After indexing the data, the ARSLOAD program deletes the input files, unless you specify otherwise. Any output or error messages that are generated by the ARSLOAD program are written to the System Log. You can open the System Log folder and retrieve any messages that were generated by the ARSLOAD program. For example, you may see message number 87 for a successful load or message 88 for a failed load.
Appendix G. Alternative to starting the administrative client

Starting the Administrator

If you do not need to work with the OnDemand administrative functions that are supported directly thru the OnDemand iSeries Navigator component (such as tape volumes, tape devices, optical volumes, optical storage groups, disk pool storage groups, monitor definitions, or migration policies), you can go directly to the OnDemand Administrator by following the instructions below:

1. Click Start.
2. Select Programs, then choose IBM OnDemand32.
3. Click OnDemand32 Administrator.
4. When you start the Administrator, OnDemand opens the administrator window that contains a menu bar, toolbar, navigator pane, list pane, and status bar. Figure 45 shows the administrator window.

![OnDemand Administrator](image)

*Figure 45. Administrator main window*

**Administrator start up parameters**

OnDemand provides parameters that you can specify as properties that the operating system uses when you start the Administrator program. The parameters can be used, for example, to automate the logon process and to select the areas that appear in the navigator pane. Table 13 lists the start up parameters for the Administrator.

<table>

<td>Identifies the OnDemand user. Use with the /S and /P parameters to log on to a specific server, without displaying the Logon dialog box. If the logon is not successful, OnDemand opens the Logon dialog box to allow the user to log on to the system.</td>
<td>/U admin</td>
</tr>
</tbody>
</table>

### Changing start up parameters

To change start up parameters:

1. Click Start.
2. From the pop-up menu, select Explore.
3. Under Start Menu, expand Programs.
4. Select IBM OnDemand32.
5. In the list pane, point to OnDemand32 Administrator and click the right mouse button.
6. From the pop-up menu, select Properties.
7. Click the Shortcut tab.
8. In the Target field, enter the startup parameters. Make sure that you enter any startup parameters after the string:

   "D:\Program Files\IBM\OnDemand32\ARSADM32.EXE"
   /1 D:\Program Files\IBM\OnDemand32\LOCALE\ENU"

9. Click OK.
The next time that you start the administrative client, Windows uses the start up parameters and values that you specified.

**Examples**

The following program properties could be used to set up the Administrator so that when a person starts the program, the name Customer Service is displayed in the title bar of the administrator window.

```
"D:\Program Files\IBM\OnDemand32\ARSADM32.EXE"
   /I D:\Program Files\IBM\OnDemand32\LOCALE\ENU /T "Customer Service"
```

The following program properties could be used to set up the Administrator so that when a person starts the program, OnDemand displays only users and folders in the navigator pane. When the user selects folders, OnDemand displays only the Permissions and Field Information pages.

```
"D:\Program Files\IBM\OnDemand32\ARSADM32.EXE"
   /I D:\Program Files\IBM\OnDemand32\LOCALE\ENU /I /D 2
```

The following program properties could be used to set up the Administrator so that when a person starts the program, OnDemand attempts to log on to the specified server, without displaying the Logon dialog box. If the logon attempt is not successful, then OnDemand opens the Logon dialog box to allow the user to log on to the system.

```
"D:\Program Files\IBM\OnDemand32\ARSADM32.EXE"
   /I D:\Program Files\IBM\OnDemand32\LOCALE\ENU /S peak /U admin /P pw
```
Appendix H. Accessibility features

The OnDemand product includes a number of features that make the product more accessible for people with disabilities. These features include:

- Features that facilitate keyboard input and navigation
- Features that enhance display properties
- Options for audio and visual alert cues
- Compatibility with assistive technologies
- Compatibility with accessibility features of the operating system
- Accessible documentation formats

Keyboard input and navigation

Keyboard input

The OnDemand clients can be operated using only the keyboard. Menu items and controls provide access keys that allow users to activate a control or select a menu item directly from the keyboard. These keys are self-documenting, in that the access keys are underlined on the control or menu where they appear.

Keyboard focus

In Windows-based systems, the position of the keyboard focus is highlighted, indicating which area of the window is active and where the user’s keystrokes will have an effect.

Features for accessible display

The OnDemand clients have a number of features that enhance the user interface and improve accessibility for users with low vision. These accessibility enhancements include support for high-contrast settings and customizable font properties.

High-contrast mode

The OnDemand clients support the high-contrast-mode option that is provided by the operating system. This feature assists users who require a higher degree of contrast between background and foreground colors.

Font settings

In Windows-based systems, the user can specify display settings that determine the color, size, and font for the text in menus and dialog windows. The OnDemand client allows the user to select the font for the document list.

Non-dependence on color

Users do not need to distinguish between colors in order to use any of the functions in this product.
Alternative alert cues

In Windows-based systems, the SoundSentry feature can be used to provide visual feedback for general application and system alerts such as warning beeps.

Compatibility with assistive technologies

The OnDemand clients are compatible with screen reader applications such as Narrator and Via Voice. The OnDemand clients have the properties required for these accessibility applications to make onscreen information available to blind users.

Accessible documentation

Documentation for the OnDemand product is available in HTML format. This allows users to view documentation according to the display preferences set in their browsers. It also allows the use of screen readers and other assistive technologies.
Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area.
