

Reading a TCP/IP for VSE trace

Session E18

Leo J Langevin
Leo@E-VSE.COM

The commands – Part 1

```
DEFINE TRACE, ID=id, IP=x.x.x.x[ , PORT=xxxx ]  
SEGMENT  
DUMP TRACES  
DELETE TRACE, ID=id  
SEGMENT
```

The commands – Part 2

SUSPEND 6

REUSE OFF

DUMP GARBAGE

RESUME 6

REUSE ON

The commands – part 3 of 3

```
DEFINE MISDIRECT, ID=id, FROMIP=, TOIP=  
DELETE MISDIRECT, ID=id
```

Typical email connection

```

```

Each entry is known as an internal bus block of data, or an IBBLOCK. Each one is dumped in LIFO sequence when you issue the “DUMP TRACES” command. This, and the next 4 fullwords, (Next block in the chain, next sub-block in the chain, next retransmit in the chain, and the pointer to the garbage chain) are of no real interest.

How to find the data area

The next field points to the actual data being passed to the stack, which is several bytes of header information followed by the actual data. The Email client doesn't see the header information. That is for the stack to use. You can also see that the start address for this datagram is X'01489C00' and there is a total length of X'1A2', which tells us that the last address should be X'01489DA2'. We also see that the actual data is only X'72' long, so X'1489DA2' - X'72' = X'1489D30', which is where the actual data that is passed to the application begins. And as you can see, the datagram also tells use where the actual data begins.

After the unique half-word identifier, we see three full-words. The first is the IP address where this datagram originated. The second is the destination IP address. We then have 1-byte of filler followed by the type of protocol being used. The value is: 1=ICMP, 2=IGMP, 6=TCP, or 17 (X'11')=UDP. As you can see in this example, we were doing a TCP connection. The next half-word is the length of actual data being sent to the application, which, in this case is X'86' or 134 bytes. If we subtract that value from the previous X'1A8' (114), which was the total of the data + the header, we get 20 bytes, or the 5-full-word IP header that is being passed with the actual data.

Port Info

Type	Source port	Dest port		
01489C00	C9C2C2D2	00000000	00000000	00000000

01489DA0	0D0A			

Next is a pair of half-words, giving the port number of the source and the destination. This information is also included in the data header. The data is coming from an SMTP server at port X'19' or 25 (the standard SMTP port), while the VSE client is using port X'101C' or 4124. (This number is always very high and decrements). Now the next byte tells us what this datagram is doing. In our example, it is a 12, or X'0C'. (see next slide) This means that it is an inbound TCP datagram, coming from outside of VSE to VSE.

Datagram type list (decimal)

- 1=Raw1
- 2=Raw2
- 3=Prepare1
- 4=Prepare2
- 5=IPBlock (link)

TIMERS

Data Length

We'll skip over the internal block pointers and get to the next field that we pass to each IP, which is the unique sequence number of this datagram. The next full-word is the address where the data that the application sees actually begins. The next pair of full-words is the MAC address of the device on VSE that is being used, and an assorted other hardware related bytes. The four double-words that are highlighted are the retransmission time, garbage time, departure time, and arrival time. This is in STCK format. As you can see in this example, this datagram arrived and moments later a copy of it was marked for the garbage collector, which handles time-outs and the like. This datagram arrived fine.

So what do we know so far?

- This is a TCP connection with an incoming datagram coming from port 25, which is the standard SMTP server port.
- It can from another computer with a different IP address, but within the same subnet.
- It is sending 112 bytes of data (which we can see in ASCII).
- Since it's an SMTP server, it is likely talking to an SMTP client.
- This client is running on VSE and is listening on port 4124.

Now let's look at the incoming datagram without the IBBLOCK headers, but with the application header and data only.

Looking at the data and header

Here is the header...

```
01489D10 8006CBA7 82010565 82010516 0019101C |...xb...b.....|.....e.....| 00342D10

```

The data obviously gives us some important clues concerning what is actually going on, telling us some server information as part of the handshaking, but let's focus on the 20 bytes of header information.

Taking the header apart – part 1

Header: X'0019101C23BFFB4F00721A0A501822387D410000'

Let's look at the layout:

Source port:	X'0019'	(25)
Destination port:	X'101C'	(4124)
Sequence number:	X'23BFFB4F'	(Current block pos. in the overall msg)
Acknowledgment #:	X'00721A0A'	(Expected next sequence #. Last # + 1)

There isn't too much that you can use there that you couldn't get elsewhere. But let's look at the next full-word.

Header: X'0019101C23BFFB4F00721A0A501822387D410000'

X'2238' is the window size, or the maximum amount of data to send at any one time.

Taking the header apart – part 2

Header: X'0019101C23BFFB4F00721A0A501822387D410000'

X'5018' is B'**0101** 000000 **011000**'

Now, the first 4 bits (**0101**) indicates the number of full-words in the TCP header. (B'0101="5", and $5*4 = 20$ bytes). The next 6 bits (000000) are reserved. The next 6 bits, however, contain actual protocol flags. In this case, it's B'**011000**'. These flags (in order of their position) are:

URGENT (Off) – Often ignored by most stacks

ACK (On) – This is in response to a previous request.

PUSH (On) – Send data right away. Don't buffer it. We want immediate acknowledgment.

RESET (OFF) – Used to break the connection.

SYNCHRONIZE NUMBERS (OFF) - Used when establishing connection

FINISH (OFF) – If on, it's the end of transmission.

The last pair of half-words contains a checksum value and an URGENT

Final things to note in a trace:

- Only look at datagrams that are relevant to your task. If the DEST/SOURCE IP addresses don't match, ignore them.
- If the port number is fairly low, it indicates a standard protocol, and if it's not what you expect, discard that too.
- Only trace what you need to trace.
- Compare the SOURCE/DEST IP address to the VSE IP address in order to determine direction of flow.
- Use EBCDIC/ASCII info to the right for a quick diagnosis.
- If a connection breaks, first check if it ever successfully connected, and check the FIN setting.
- Some traffic, such as "keep alive" will come through at regular intervals.
- If you see an eye catcher for "/MAILBOX", this is Microsoft message flooding, and it can be ignored.
- Utility to make it easier?
