The execution of the activity is stopped and an error is returned (SQLSTATE 5U026). In the case of the UOWTOTALTIME threshold, the unit of work is rolled back.

CONTINUE
The execution of the activity is not stopped.

FORCE APPLICATION
The application is forced off the system (SQLSTATE 55032). This action can only be specified for the UOWTOTALTIME threshold.

remap-activity-action

REMAP ACTIVITY TO *service-subclass-name*
The activity is mapped to *service-subclass-name*. The execution of the activity is not stopped. This action is valid only for in-service-class and in-all-service-class thresholds like CPUTIMEINSC, SQLROWSREADINSC, DATATAGINSC IN and DATATAGINSC NOT IN and ACTIVITYTOTALRUNTIMEINALLSC thresholds (SQLSTATE 5U037). The service-subclass-name must identify an existing service subclass under the same superclass associated with the threshold (SQLSTATE 5U037). The service-subclass-name cannot be the same as the associated service subclass of the threshold (SQLSTATE 5U037).

NO EVENT MONITOR RECORD
Specifies that no threshold violation record will be written.

LOG EVENT MONITOR RECORD
Specifies that if a THRESHOLD VIOLATIONS event monitor exists and is active, a threshold violation record is written to it.

Notes

- Thresholds can be defined on different aspects of database behavior to monitor and control that behavior. When a threshold is defined on activities, unless otherwise specified, it will be enforced only during the actual execution of SQL statements, not including compilation time, and the load utility.
- The CONCURRENTWORKLOADOCCURRENCES threshold and the CONCURRENTWORKLOADACTIVITIES threshold differ in scope. CONCURRENTWORKLOADOCCURRENCES controls how many connections can map to a workload definition simultaneously, and CONCURRENTWORKLOADACTIVITIES controls how many activities each connection that is mapped to the workload definition can submit concurrently.
- Changes are written to the system catalog, but do not take effect until after a COMMIT statement, even for the connection that issues the statement.
- Only one uncommitted WLM-exclusive SQL statement at a time is allowed across all partitions. If an uncommitted WLM-exclusive SQL statement is executing, subsequent WLM-exclusive SQL statements will wait until the current WLM-exclusive SQL statement commits or rolls back.
- ***Threshold exceeded action of CONTINUE and event monitor data:*** Event monitor data is collected only once per member when a threshold condition has been exceeded. If the threshold exceeded action is CONTINUE, the activity continues executing and no further event monitor data is collected for that threshold at the affected member. For example, consider a time threshold of 10 minutes with an action of CONTINUE. After an activity exceeds the 10-minute upper bound, event monitor data is collected for the threshold at the affected member.
- ***Quiescing a service class:*** The TOTALSCPARTITIONCONNECTIONS threshold condition can be used to simulate quiescing service classes that cannot normally be quiesced (for example, the default user class, or the default system class). This is useful, because thresholds do not apply to users with DBADM authority running in the SYSDEFAULTADMWORKLOAD, whereas a quiesced service class is not available to anyone. Consequently, default service classes cannot be quiesced directly but only through a threshold that allows users with DBADM authority to join them when connected to the database using the SYSDEFAULTADMWORKLOAD.
- ***Syntax alternatives***: The following are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - DATABASE PARTITION can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - DATABASE PARTITIONS can be specified in place of MEMBERS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - TOTALDBPARTITIONCONNECTIONS can be specified in place of TOTALMEMBERCONNECTIONS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - TOTALSCPARTITIONCONNECTIONS can be specified in place of TOTALSCMEMBERCONNECTIONS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.

Examples

- *Example 1:* Create a threshold that enforces a maximum temporary table space usage of 50M (per database partition) to any activity in the database. Any activity that violates this threshold is to be stopped.

```
CREATE THRESHOLD DBMAX50MEGTEMPSPACE
  FOR DATABASE ACTIVITIES
  ENFORCEMENT MEMBER
  WHEN SQLTEMPSPACE > 50 M
  STOP EXECUTION
```

- *Example 2:* Create a second threshold to limit the default runtime of any activity in the database to a maximum of 1 hour. Any activity that violates this threshold is to be stopped.

```
CREATE THRESHOLD DBMAX1HOURRUNTIME
  FOR DATABASE
  WHEN ACTIVITYTOTALTIME > 1 HOUR
  STOP EXECUTION
```

- *Example 3:* Assume that a service superclass named BIGQUERIES was created to host queries using more temporary space than average and running longer than 1 hour. The thresholds defined inside this service class will override the values that were set in the previous example at the database level. Note how activities violating the thresholds inside this superclass are allowed to continue executing, but detailed information is collected for further analysis.

```
CREATE THRESHOLD BIGQUERIESMAX500MEGTEMPSPACE
  FOR SERVICE CLASS BIGQUERIES ACTIVITIES
  ENFORCEMENT DATABASE MEMBER
  WHEN SQLTEMPSPACE  > 500 M
  COLLECT ACTIVITY DATA WITH DETAILS AND VALUES
  CONTINUE

CREATE THRESHOLD BIGQUERIESLONGRUNNINGTIME
  FOR SERVICE CLASS BIGQUERIES ACTIVITIES
  ENFORCEMENT DATABASE
  WHEN ACTIVITYTOTALTIME   > 10 HOURS
  COLLECT ACTIVITY DATA WITH DETAILS AND VALUES
  CONTINUE
```

- *Example 4:* Assuming the existence of a workload named PAYROLL, create a threshold that enforces the maximum number of activities within the workload to be less than or equal to 10.

```
CREATE THRESHOLD MAXACTIVITIESINPAYROLL
  FOR WORKLOAD PAYROLL ACTIVITIES
  ENFORCEMENT WORKLOAD OCCURRENCE
  WHEN CONCURRENTWORKLOADACTIVITIES > 10
  STOP EXECUTION
```

- *Example 5:* Create a threshold that enforces a maximum concurrency of 2 activities in the service class BIGQUERIES.

```
CREATE THRESHOLD MAXBIGQUERIESCONCURRENCY
  FOR SERVICE CLASS BIGQUERIES  ACTIVITIES
  ENFORCEMENT DATABASE
  WHEN CONCURRENTDBCOORDACTIVITIES > 2
  STOP EXECUTION
```

- *Example 6:* Create a threshold that captures activity information for a specific statement that runs for longer than one minute, but do not cease statement execution.

```
CREATE THRESHOLD TH1
  FOR STATEMENT
  TEXT 'SELECT DISTINCT PARTS_BIN FROM STOCK WHERE PART_NUMBER = ?'
  ACTIVITIES ENFORCEMENT DATABASE
  WHEN ACTIVITYTOTALTIME > 1 MINUTE
  COLLECT ACTIVITY DATA WITH DETAILS, SECTION AND VALUES
  CONTINUE
```

CREATE TRANSFORM

The CREATE TRANSFORM statement defines transformation functions, identified by a group name, that are used to exchange structured type values with host language programs and with external functions.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

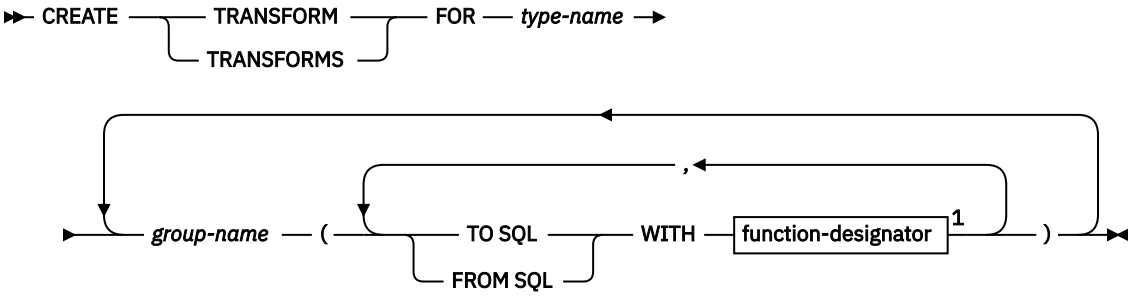
Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

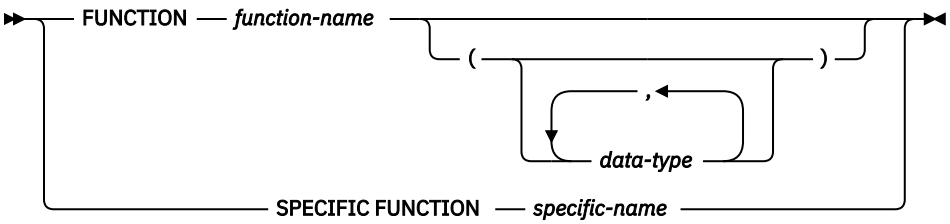
- Owner of the type identified by *type-name*, and EXECUTE privilege on every specified function

- Owner of the type identified by type-name, and EXECUTEIN privilege on the schema containing all the specified functions
- Owner of the type identified by type-name, and DATAACCESS authority on the schema containing all the specified functions
- SCHEMAADM on the schema containing the type-name
- DBADM authority

Syntax



function-designator



Notes:

[1] The same clause must not be specified more than once.

Description

TRANSFORM or TRANSFORMS
Indicates that one or more transform groups is being defined. Either version of the keyword can be specified.

FOR *type-name*
Specifies a name for the user-defined structured type for which the transform group is being defined.

In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified *type-name*. In static SQL statements the QUALIFIER precompile/bind option implicitly specifies the qualifier for an unqualified *type-name*. The *type-name* must be the name of an existing user-defined type (SQLSTATE 42704), and it must be a structured type (SQLSTATE 42809). The structured type or any other structured type in the same type hierarchy must not have transforms already defined with the given group-name (SQLSTATE 42739).

group-name
Names the transform group. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *group-name* must not identify a transform group that already exists in the catalog for the specified *type-name* (SQLSTATE 42739). The *group-name* must not begin with the characters 'SYS' (SQLSTATE 42939). At most, one of each of the FROM SQL and TO SQL function designations can be specified for any given group (SQLSTATE 42628).

TO SQL
Defines the specific function used to transform a value to the SQL user-defined structured type format. The function must have all its parameters as built-in data types and the returned type is *type-name*.

FROM SQL
Defines the specific function used to transform a value to a built in data type value representing the SQL user-defined structured type. The function must have one parameter of data type *type-name*, and return a built-in data type (or set of built-in data types).

WITH *function-designator*
Uniquely identifies the transform function.

If FROM SQL is specified, *function-designator* must identify a function that meets the following requirements:

- There is one parameter of type *type-name*.
- The return type is a built-in type, or a row whose columns all have built-in types.
- The signature specifies either LANGUAGE SQL or the use of another FROM SQL transform function that has LANGUAGE SQL.

If TO SQL is specified, *function-designator* must identify a function that meets the following requirements:

- All parameters have built-in types.
- The return type is *type-name*.
- The signature specifies either LANGUAGE SQL or the use of another TO SQL transform function that has LANGUAGE SQL.

If *function-designator* identifies a function that does not meet these requirements (according to its use as a FROM SQL or a TO SQL transform function), an error is raised (SQLSTATE 428DC).

Methods (even if specified with FUNCTION ACCESS) cannot be specified as transforms through *function-designator*. Instead, only functions that are defined by the CREATE FUNCTION statement can act as transforms (SQLSTATE 42704 or 42883).

For more information, see "Function, method, and procedure designators" on page 745.

Rules

- The one or more built-in types that are returned from the FROM SQL function should directly correspond to the one or more built-in types that are parameters of the TO SQL function. This is a logical consequence of the inverse relationship between these two functions.

Notes

- When a transform group is not specified in an application program (using the TRANSFORM GROUP precompile or bind option for static SQL, or the SET CURRENT DEFAULT TRANSFORM GROUP statement for dynamic SQL), the transform functions in the transform group 'DB2_PROGRAM' are used (if defined) when the application program is retrieving or sending host variables that are based on the user-defined structured type identified by *type-name*. When retrieving a value of data type *type-name*, the FROM SQL transform is invoked to transform the structured type to the built-in data type returned by the transform function. Similarly, when sending a host variable that will be assigned to a value of data type *type-name*, the TO SQL transform is invoked to transform the built-in data type value to the structured type value. If a user-defined transform group is not specified, or a 'DB2_PROGRAM' group is not defined (for the given structured type), an error is raised (SQLSTATE 42741).
- The built-in data type representation for a structured type host variable must be assignable:
  - from the result of the FROM SQL transform function for the structured type as defined by the specified TRANSFORM GROUP option of the precompile command (using retrieval assignment rules) and
  - to the parameter of the TO SQL transform function for the structured type as defined by the specified TRANSFORM GROUP option of the precompile command (using storage assignment rules).

If a host variable is not assignment compatible with the type required by the applicable transform function, an error is raised (for bind-in: SQLSTATE 42821; for bind-out: SQLSTATE 42806). For errors that result from string assignments, see "String Assignments".

- The transform functions identified in the default transform group named 'DB2_FUNCTION' are used whenever a user-defined function not written in SQL is invoked using the data type *type-name* as a parameter or returns type. This applies when the function does not specify the TRANSFORM GROUP clause. When invoking the function with an argument of data type *type-name*, the FROM SQL transform is executed to transform the structured type to the built-in data type returned by the transform function. Similarly, when the returns data type of the function is of data type *type-name*, the TO SQL transform is invoked to transform the built-in data type value returned from the external function program into the structured type value.
- If a structured type contains an attribute that is also a structured type, the associated transform functions must recursively expand (or assemble) all nested structured types. This means that the results or parameters of the transform functions consist only of the set of built-in types representing all base attributes of the subject structured type (including all its nested structured types). There is no "cascading" of transform functions for handling nested structured types.
- The functions identified in this statement are resolved according to the rules outlined previously at the execution of this statement. When these functions are used (implicitly) in subsequent SQL statements, they do not undergo another resolution process. The transform functions defined in this statement are recorded exactly as they are resolved in this statement.
- When attributes or subtypes of a given type are created or dropped, the transform functions for the user-defined structured type must also be changed.
- For a given transform group, the FROM SQL and TO SQL transforms can be specified in either the same *group-name* clause, in separate *group-name* clauses, or in separate CREATE TRANSFORM statements. The only restriction is that a given FROM SQL or TO SQL transform designation may not be redefined without first dropping the existing group definition. This allows you to define, for example, a FROM SQL transform for a given group first, and the corresponding TO SQL transform for the same group at a later time.

Example

Create two transform groups that associate the user-defined structured type polygon with transform functions customized for C and Java, respectively.

```
CREATE TRANSFORM FOR POLYGON
  mystruct1 (FROM SQL WITH FUNCTION myxform_sqlstruct,
             TO SQL WITH FUNCTION myxform_structsql)
  myjava1   (FROM SQL WITH FUNCTION myxform_sqljava,
             TO SQL WITH FUNCTION myxform_javasql)
```

CREATE TRIGGER

The CREATE TRIGGER statement defines a trigger in the database. Triggers can be created to support general forms of integrity or business rules. A trigger defines a set of actions that are executed with, or triggered by, an INSERT, UPDATE, or DELETE statement.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- ALTER privilege on the table on which the BEFORE or AFTER trigger is defined

- CONTROL privilege on the view on which the INSTEAD OF trigger is defined
- Owner of the view on which the INSTEAD OF trigger is defined
- ALTERIN privilege on the schema of the table or view on which the trigger is defined
- SCHEMAADM authority on the schema containing the table or view on which the trigger is defined
- DBADM authority

and one of:

- IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the trigger does not exist
- CREATEIN privilege on the schema, if the schema name of the trigger refers to an existing schema
- SCHEMAADM authority on the schema, if the schema name of the trigger refers to an existing schema
- DBADM authority

If the authorization ID of the statement does not have DATAACCESS authority, the privileges (excluding group privileges) held by the authorization ID of the statement must include all of the following authorities, as long as the trigger exists:

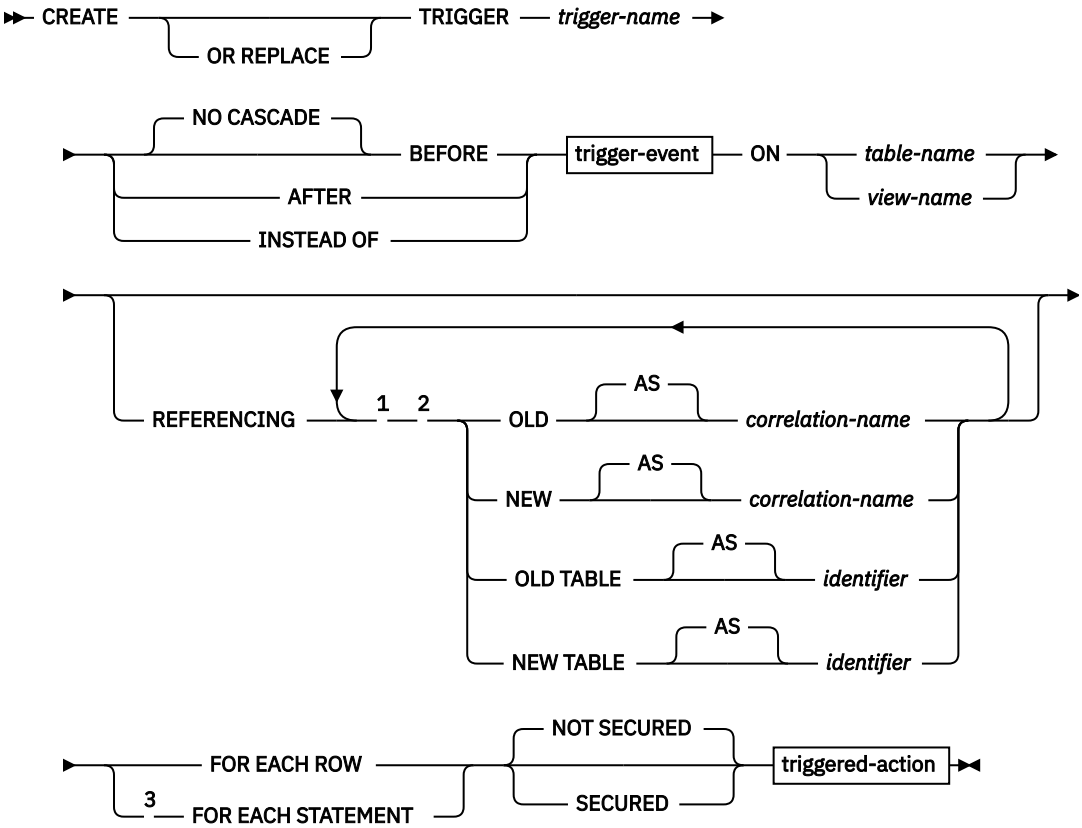
- On the table on which the trigger is defined, if any transition variables or tables are specified:
  - SELECT privilege on the table on which the trigger is defined, if any transition variables or tables are specified
  - SELECTIN privilege on the schema containing the table on which the trigger is defined, if any transition variables or tables are specified
  - CONTROL privilege on the table on which the trigger is defined, if any transition variables or tables are specified
  - DATAACCESS authority on the schema containing the table on which the trigger is defined, if any transition variables or tables are specified
  - DATAACCESS authority
- On any table or view referenced in the triggered action condition:
  - SELECT privilege on any table or view referenced in the triggered action condition
  - SELECTIN privilege on the schema containing any table or view referenced in the triggered action condition
  - CONTROL privilege on any table or view referenced in the triggered action condition
  - DATAACCESS authority on the schema containing any table or view referenced in the triggered action condition
  - DATAACCESS authority
- Necessary privileges to invoke the triggered SQL statements specified.

Group privileges are not considered for any table or view specified in the CREATE TRIGGER statement.

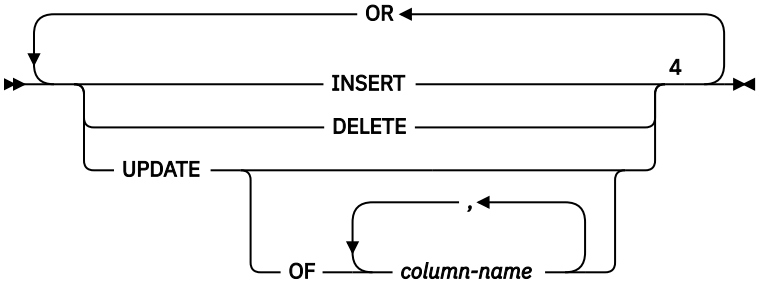
To replace an existing trigger, the authorization ID of the statement must be the owner of the existing trigger (SQLSTATE 42501).

If the SECURED option is specified, the privileges held by the authorization ID of the statement must additionally include SECADM or CREATE_SECURE_OBJECT authority (SQLSTATE 42501).

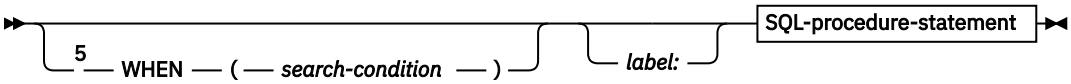
Syntax



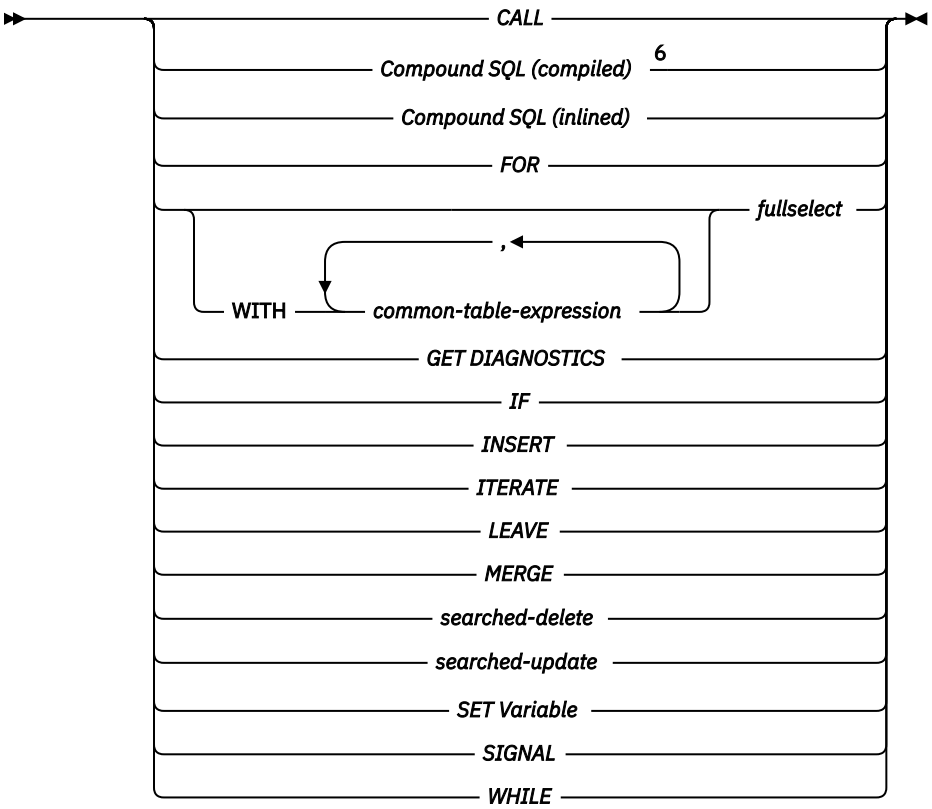
trigger-event



triggered-action



SQL-procedure-statement



Notes:

[1] OLD and NEW can only be specified once each.

[2] OLD TABLE and NEW TABLE can only be specified once each, and only for AFTER triggers or INSTEAD OF triggers.

[3] FOR EACH STATEMENT may not be specified for BEFORE triggers or INSTEAD OF triggers.

[4] A trigger event must not be specified more than once for the same operation. For example, INSERT OR DELETE is allowed, but INSERT OR INSERT is not allowed.

[5] WHEN condition may not be specified for INSTEAD OF triggers.

[6] A compound SQL (compiled) statement cannot be specified if the trigger definition includes a REFERENCING OLD TABLE clause or a REFERENCING NEW TABLE clause. A compound SQL (compiled) statement also cannot be specified for a trigger definition in a partitioned database environment.

Description

OR REPLACE

Specifies to replace the definition for the trigger if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog. This option is ignored if a definition for the trigger does not exist at the current server. This option can be specified only by the owner of the object.

trigger-name

Names the trigger. The name, including the implicit or explicit schema name, must not identify a trigger already described in the catalog (SQLSTATE 42710). If a two-part name is specified, the schema name cannot begin with "SYS" (SQLSTATE 42939).

NO CASCADE BEFORE

Specifies that the associated triggered action is to be applied before any changes caused by the actual update of the subject table are applied to the database. It also specifies that the triggered action of the trigger will not cause other triggers to be activated.

AFTER
Specifies that the associated triggered action is to be applied after the changes caused by the actual update of the subject table are applied to the database.

INSTEAD OF
Specifies that the associated triggered action replaces the action against the subject view. Only one INSTEAD OF trigger is allowed for each kind of operation on a given subject view (SQLSTATE 428FP).

trigger-event
Specifies that the triggered action associated with the trigger is to be executed whenever one of the events is applied to the subject table or subject view. Any combination of the events can be specified, but each event (INSERT, DELETE, and UPDATE) can only be specified once (SQLSTATE.42613). If multiple events are specified, the triggered action must be a compound SQL (compiled) statement (SQLSTATE 42601).

INSERT
Specifies that the triggered action associated with the trigger is to be executed whenever an INSERT operation is applied to the subject table or subject view.

DELETE
Specifies that the triggered action associated with the trigger is to be executed whenever a DELETE operation is applied to the subject table or subject view.

UPDATE
Specifies that the triggered action associated with the trigger is to be executed whenever an UPDATE operation is applied to the subject table or subject view, subject to the columns specified or implied.

If the optional *column-name* list is not specified, every column of the table or view is implied. Therefore, omission of the *column-name* list implies that the trigger will be activated by the update of any column of the table or view.

OF *column-name,...*
Each *column-name* specified must be a column of the base table (SQLSTATE 42703). If the trigger is a BEFORE trigger, the *column-name* specified cannot be a generated column other than the identity column (SQLSTATE 42989). No *column-name* can appear more than once in the *column-name* list (SQLSTATE 42711). The trigger will only be activated by the update of a column that is identified in the *column-name* list. This clause cannot be specified for an INSTEAD OF trigger (SQLSTATE 42613).

ON

table-name
Designates the subject table of the BEFORE trigger or AFTER trigger definition. The name must specify a base table or an alias that resolves to a base table (SQLSTATE 42704 or 42809). The name must not specify a catalog table (SQLSTATE 42832), a materialized query table (SQLSTATE 42997), a created temporary table, a declared temporary table (SQLSTATE 42995), or a nickname (SQLSTATE 42809).

view-name
Designates the subject view of the INSTEAD OF trigger definition. The name must specify an untyped view or an alias that resolves to an untyped view with no columns of type XML (SQLSTATE 42704 or 42809). The name must not specify a catalog view (SQLSTATE 42832). The name must not specify a view that is defined using WITH CHECK OPTION (a symmetric view), or a view on which a symmetric view has been defined, directly or indirectly (SQLSTATE 428FQ).

NOT SECURED or SECURED
Specifies whether the trigger is considered secure. The default is NOT SECURED.

NOT SECURED
Specifies the trigger is considered not secure.

SECURED
Specifies the trigger is considered secure. SECURED must be specified for a trigger whose subject table is a table on which row level or column level access control has been activated (SQLSTATE

428H8). Similarly, SECURED must be specified for a trigger that is created on a view and one or more of the underlying tables in that view definition has row level or column level access control activated (SQLSTATE 428H8).

REFERENCING

Specifies the correlation names for the *transition variables* and the table names for the *transition tables*. Correlation names identify a specific row in the set of rows affected by the triggering SQL operation. Table names identify the complete set of affected rows. Each row affected by the triggering SQL operation is available to the triggered action by qualifying columns with *correlation-names* specified as follows.

OLD AS *correlation-name*

Specifies a correlation name which identifies the row state before the triggering SQL operation.

NEW AS *correlation-name*

Specifies a correlation name which identifies the row state as modified by the triggering SQL operation and by any SET statement in a BEFORE trigger that has already executed.

The complete set of rows affected by the triggering SQL operation is available to the triggered action by using a temporary table name specified as follows.

OLD TABLE AS *identifier*

Specifies the name of a temporary table that identifies the values in the complete set of affected rows prior to the triggering SQL operation. If the trigger event is INSERT, the temporary table is empty.

NEW TABLE AS *identifier*

Specifies the name of a temporary table that identifies the state of the complete set of affected rows as modified by the triggering SQL operation and by any SET statement in a before trigger that has already been executed. If the trigger event is DELETE, the temporary table is empty.

The following rules apply to the REFERENCING clause:

- None of the OLD and NEW correlation names and the OLD TABLE and NEW TABLE names can be identical (SQLSTATE 42712).
- Only one OLD and one NEW *correlation-name* may be specified for a trigger (SQLSTATE 42613).
- Only one OLD TABLE and one NEW TABLE *identifier* may be specified for a trigger (SQLSTATE 42613).
- OLD TABLE or NEW TABLE identifiers cannot be defined in a BEFORE trigger (SQLSTATE 42898).
- A NEW transition variable can only be the target of an assignment in a BEFORE trigger. Otherwise, transition variables cannot be the target of an assignment (SQLSTATE 42703 or 42987).
- OLD or NEW correlation names cannot be defined in a FOR EACH STATEMENT trigger (SQLSTATE 42899).
- Transition tables cannot be modified (SQLSTATE 42807).
- The total of the references to the transition table columns and transition variables in the triggered-action cannot exceed the limit for the number of columns in a table or the sum of their lengths cannot exceed the maximum length of a row in a table (SQLSTATE 54040).
- The scope of each *correlation-name* and each *identifier* is the entire trigger definition.
- If the triggered-action includes a compound SQL (compiled) statement:
  - OLD TABLE or NEW TABLE identifiers cannot be defined.
  - If the operation is a DELETE operation, OLD *correlation-name* captures the value of the deleted row. If it is an UPDATE operation, it captures the value of the row before the UPDATE operation. For an insert operation, OLD *correlation-name* captures null values for each column of a row.
  - For an insert operation or an update operation, the value of NEW captures the new state of the row as provided by the original operation and as modified by any BEFORE trigger that has executed to this point. For a delete operation, NEW *correlation-name* captures null values for each column of a row. In a BEFORE DELETE trigger, any non-null values assigned to the new transition variables persist only within the trigger where the assignment occurred.

- If the triggered-action does not include a compound SQL (compiled) statement:
  - The OLD *correlation-name* and the OLD TABLE *identifier* can only be used if the trigger event is either a DELETE operation or an UPDATE operation (SQLSTATE 42898). If the operation is a DELETE operation, OLD *correlation-name* captures the value of the deleted row. If it is an UPDATE operation, it captures the value of the row before the UPDATE operation. The same applies to the OLD TABLE *identifier* and the set of affected rows.
  - The NEW *correlation-name* and the NEW TABLE *identifier* can only be used if the trigger event is either an INSERT operation or an UPDATE operation (SQLSTATE 42898). In both operations, the value of NEW captures the new state of the row as provided by the original operation and as modified by any BEFORE trigger that has executed to this point. The same applies to the NEW TABLE *identifier* and the set of affected rows.

FOR EACH ROW
Specifies that the triggered action is to be applied once for each row of the subject table or subject view that is affected by the triggering SQL operation.

FOR EACH STATEMENT
Specifies that the triggered action is to be applied only once for the whole statement. This type of trigger granularity cannot be specified for a BEFORE trigger or an INSTEAD OF trigger (SQLSTATE 42613). If specified, an UPDATE or DELETE trigger is activated, even if no rows are affected by the triggering UPDATE or DELETE statement.

triggered-action
Specifies the action to be performed when a trigger is activated. A triggered action is composed of an *SQL-procedure-statement* and by an optional condition for the execution of the *SQL-procedure-statement*.

Trigger event predicates can be used anywhere in the triggered action of a CREATE TRIGGER statement that uses a compound SQL (compiled) statement as the *SQL-procedure-statement*.

WHEN

(*search-condition*)
Specifies a condition that is true, false, or unknown. The *search-condition* provides a capability to determine whether or not a certain triggered action should be executed. The associated action is performed only if the specified search condition evaluates as true. If the WHEN clause is omitted, the associated *SQL-procedure-statement* is always performed.

The WHEN clause cannot be specified for INSTEAD OF triggers (SQLSTATE 42613).

A reference to a transition variable with an XML data type can be used only in a VALIDATED predicate.

label:
Specifies the label for an SQL procedure statement. The label must be unique within a list of SQL procedure statements, including any compound statements nested within the list. Note that compound statements that are not nested can use the same label. A list of SQL procedure statements is possible in a number of SQL control statements.

Only the FOR statement, WHILE statement, and the compound SQL statement can include a label.

SQL-procedure-statement
Specifies the SQL statement that is to be part of the triggered action. A searched update, searched delete, insert, or merge operation on nicknames inside compound SQL is not supported.

The triggered action of a BEFORE trigger on a column of type XML can invoke the XMLVALIDATE function through a SET statement, leave values of type XML unchanged, or assign them to NULL using a SET statement.

The *SQL-procedure-statement* must not contain a statement that is not supported (SQLSTATE 42987).

The *SQL-procedure-statement* cannot reference an undefined transition variable (SQLSTATE 42703), a federated object (SQLSTATE 42997), or a declared temporary table (SQLSTATE 42995). or the start and end columns of the BUSINESS_TIME period (SQLSTATE 42808).

The *SQL-procedure-statement* in a BEFORE trigger cannot:

- Contain any INSERT, DELETE, or UPDATE operations, nor invoke any routine defined with MODIFIES SQL DATA, if it is not a compound SQL (compiled).
- Contain any DELETE or UPDATE operations on the trigger subject table, nor invoke any routine containing such operations, if it is a compound SQL (compiled).
- Reference a materialized query table defined with REFRESH IMMEDIATE (SQLSTATE 42997)
- Reference a generated column other than the identity column in the NEW transition variable (SQLSTATE 42989).

Notes

- Adding a trigger to a table that already has rows in it will not cause any triggered actions to be activated. Thus, if the trigger is designed to enforce constraints on the data in the table, those constraints may not be satisfied by the existing rows.
- If the events for two triggers occur simultaneously (for example, if they have the same event, activation time, and subject tables), then the first trigger created is the first to execute. If the OR REPLACE option is used to replace a previously created trigger, the create time is changed and therefore could affect the order of trigger execution.
- If a column is added to the subject table after triggers have been defined, the following rules apply:
  - If the trigger is an UPDATE trigger that was specified without an explicit column list, then an update to the new column will cause the activation of the trigger.
  - The column will not be visible in the triggered action of any previously defined trigger.
  - The OLD TABLE and NEW TABLE transition tables will not contain this column. Thus, the result of performing a "SELECT *" on a transition table will not contain the added column.
- If a column is added to any table referenced in a triggered action, the new column will not be visible to the triggered action.
- If an object referenced in the trigger body does not exist or is marked invalid, or the definer temporarily doesn't have privileges to access the object, and if the database configuration parameter **auto_reval** is set to DEFERRED_FORCE, then the trigger will still be created successfully. The trigger will be marked invalid and will be revalidated the next time it is invoked.
- The result of a fullselect specified in a *SQL-procedure-statement* is not available inside or outside of the trigger.
- A procedure called within a triggered compound statement must not issue a COMMIT or a ROLLBACK statement (SQLSTATE 42985).
- A procedure that contains a reference to a nickname in a searched UPDATE statement, a searched DELETE statement, or an INSERT statement is not supported (SQLSTATE 25000).
- ***Table access restrictions:***: If a procedure is defined as READS SQL DATA or MODIFIES SQL DATA, no statement in the procedure can access a table that is being modified by the compound statement that invoked the procedure (SQLSTATE 57053). If the procedure is defined as MODIFIES SQL DATA, no statement in the procedure can modify a table that is being read or modified by the compound statement that invoked the procedure (SQLSTATE 57053).
- A BEFORE DELETE trigger defined on a table involved in a cycle of cascaded referential constraints should not include references to the table on which it is defined or any other table modified by cascading during the evaluation of the cycle of referential integrity constraints. The results of such a trigger are data dependent and therefore may not produce consistent results.

  In its simplest form, this means that a BEFORE DELETE trigger on a table with a self-referencing referential constraint and a delete rule of CASCADE should not include any references to the table in the *triggered-action*.

- The creation of a trigger causes certain packages to be marked invalid:
  - If an UPDATE trigger without an explicit column list is created, then packages with an update usage on the target table or view are invalidated.
  - If an UPDATE trigger with a column list is created, then packages with update usage on the target table are only invalidated if the package also has an update usage on at least one column in the *column-name* list of the CREATE TRIGGER statement.
  - If an INSERT trigger is created, packages that have an insert usage on the target table or view are invalidated.
  - If a delete trigger is created, packages that have a delete usage on the target table or view are invalidated.
- A package remains invalid until the application program is explicitly bound or rebound, or it is executed and the database manager automatically rebinds it.
- ***Inoperative triggers***: An *inoperative trigger* is a trigger that is no longer available and is therefore never activated. A trigger becomes inoperative if:
  - a privilege that the creator of the trigger is required to have for the trigger to execute is revoked
  - an object such as a table, view or alias, upon which the triggered action is dependent, is dropped
  - a view, upon which the triggered action is dependent, becomes inoperative
  - an alias that is the subject table of the trigger is dropped.

  In practical terms, an inoperative trigger is one in which a trigger definition has been dropped as a result of cascading rules for DROP or REVOKE statements. For example, when a view is dropped, any trigger with an *SQL-procedure-statement* that contains a reference to that view is made inoperative.

  When a trigger is made inoperative, all packages with statements performing operations that were activating the trigger will be marked invalid. When the package is rebound (explicitly or implicitly) the inoperative trigger is completely ignored. Similarly, applications with dynamic SQL statements performing operations that were activating the trigger will also completely ignore any inoperative triggers.

  The trigger name can still be specified in the DROP TRIGGER and COMMENT ON TRIGGER statements.

  An inoperative trigger may be re-created by issuing a CREATE TRIGGER statement using the definition text of the inoperative trigger. This trigger definition text is stored in the TEXT column of the SYSCAT.TRIGGERS catalog view. Note that there is no need to explicitly drop the inoperative trigger in order to re-create it. Issuing a CREATE TRIGGER statement with the same *trigger-name* as an inoperative trigger will cause that inoperative trigger to be replaced with a warning (SQLSTATE 01595).

  Inoperative triggers are indicated by an X in the VALID column of the SYSCAT.TRIGGERS catalog view.
- ***Errors executing triggers***: Errors that occur during the execution of triggered SQL statements are returned using SQLSTATE 09000 unless the error is considered severe. If the error is severe, the severe error SQLSTATE is returned. The SQLERRMC field of the SQLCA for non-severe error will include the trigger name, SQLCODE, SQLSTATE and as many tokens as will fit from the tokens of the failure.

  The *SQL-procedure-statement* could include a SIGNAL SQLSTATE statement or a RAISE_ERROR function. In both these cases, the SQLSTATE returned is the one specified in the SIGNAL SQLSTATE statement or the RAISE_ERROR condition.
- Creating a trigger with a schema name that does not already exist will result in the implicit creation of that schema provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- ***DB2SECURITYLABEL column***: A DB2SECURITYLABEL column can be referenced in the trigger body of a BEFORE TRIGGER but it cannot be changed in the body of a BEFORE trigger (SQLSTATE 42989).
- ***BUSINESS_TIME period columns***: The start and end columns of a BUSINESS_TIME period cannot be changed in the body of BEFORE UPDATE trigger (SQLSTATE 42808).
- ***Read-only views***: The addition of an INSTEAD OF trigger for a view affects the read only characteristic of the view. If a read-only view has a dependency relationship with an INSTEAD OF trigger, the type of

operation that is defined for the INSTEAD OF trigger defines whether the view is deletable, insertable, or updatable.

- ***Transition variable values and INSTEAD OF triggers***: The initial values for new transition variables or new transition table columns that are visible in an INSTEAD OF INSERT trigger are set as follows:
  - If a value is explicitly specified for a column in the insert operation, the corresponding new transition variable is that explicitly specified value.
  - If a value is not explicitly specified for a column in the insert operation or the DEFAULT clause is specified, the corresponding new transition variable is:
    - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger)
    - otherwise, the null value

  The initial values for new transition variables that are visible in an INSTEAD OF UPDATE trigger are set as follows:
  - If a value is explicitly specified for a column in the update operation, the corresponding new transition variable is that explicitly specified value.
  - If the DEFAULT clause is explicitly specified for a column in the update operation, the corresponding new transition variable is:
    - the default value of the underlying table column if the view column is updatable (without the INSTEAD OF trigger)
    - otherwise, the null value
  - Otherwise, the corresponding new transition variable is the existing value of the column in the row.
- ***Triggers and typed tables***: A BEFORE or AFTER trigger can be attached to a typed table at any level of a table hierarchy. If an SQL statement activates multiple triggers, the triggers will be executed in their creation order, even if they are attached to different tables in the typed table hierarchy.

  When a trigger is activated, its transition variables (OLD, NEW, OLD TABLE and NEW TABLE) may contain rows of subtables. However, they will contain only columns defined on the table to which they are attached.

  Effects of INSERT, UPDATE, and DELETE statements:
  - Row triggers: When an SQL statement is used to INSERT, UPDATE, or DELETE a table row, it activates row-triggers attached to the most specific table containing the row, and all supertables of that table. This rule is always true, regardless of how the SQL statement accesses the table. For example, when issuing an UPDATE EMP command, some of the updated rows may be in the subtable MGR. For EMP rows, the row-triggers attached to EMP and its supertables are activated. For MGR rows, the row-triggers attached to MGR and its supertables are activated.
  - Statement triggers: An INSERT, UPDATE, or DELETE statement activates statement-triggers attached to tables (and their supertables) that could be affected by the statement. This rule is always true, regardless of whether any actual rows in these tables were affected. For example, on an INSERT INTO EMP command, statement-triggers for EMP and its supertables are activated. As another example, on either an UPDATE EMP or DELETE EMP command, statement triggers for EMP and its supertables and subtables are activated, even if no subtable rows were updated or deleted. Likewise, a UPDATE ONLY (EMP) or DELETE ONLY (EMP) command will activate statement-triggers for EMP and its supertables, but not statement-triggers for subtables.

  Effects of DROP TABLE statements: A DROP TABLE statement does not activate any triggers that are attached to the table being dropped. However, if the dropped table is a subtable, all the rows of the dropped table are considered to be deleted from its supertables. Therefore, for a table T:
  - Row triggers: DROP TABLE T activates row-type delete-triggers that are attached to all supertables of T, for each row of T.
  - Statement triggers: DROP TABLE T activates statement-type delete-triggers that are attached to all supertables of T, regardless of whether T contains any rows.

Actions on Views: To predict what triggers are activated by an action on a view, use the view definition to translate that action into an action on base tables. For example:

1. An SQL statement performs UPDATE V1, where V1 is a typed view with a subview V2. Suppose V1 has underlying table T1, and V2 has underlying table T2. The statement could potentially affect rows in T1, T2, and their subtables, so statement triggers are activated for T1 and T2 and all their subtables and supertables.
2. An SQL statement performs UPDATE V1, where V1 is a typed view with a subview V2. Suppose V1 is defined as SELECT ... FROM ONLY(T1) and V2 is defined as SELECT ... FROM ONLY(T2). Since the statement cannot affect rows in subtables of T1 and T2, statement triggers are activated for T1 and T2 and their supertables, but not their subtables.
3. An SQL statement performs UPDATE ONLY(V1), where V1 is a typed view defined as SELECT ... FROM T1. The statement can potentially affect T1 and its subtables. Therefore, statement triggers are activated for T1 and all its subtables and supertables.
4. An SQL statement performs UPDATE ONLY(V1), where V1 is a typed view defined as SELECT ... FROM ONLY(T1). In this case, T1 is the only table that can be affected by the statement, even if V1 has subviews and T1 has subtables. Therefore, statement triggers are activated only for T1 and its supertables.

- ***MERGE statement and triggers***: The MERGE statement can execute update, delete, and insert operations. The applicable UPDATE, DELETE, or INSERT triggers are activated for the MERGE statement when an update, delete, or insert operation is executed.
- ***Obfuscation***: The CREATE TRIGGER statement can be submitted in obfuscated form. In an obfuscated statement, only the trigger name is readable. The rest of the statement is encoded in such a way that is not readable but can be decoded by the database server. Obfuscated statements can be produced by calling the DBMS_DDL.WRAP function.
- ***Creating a trigger with the SECURED option***: Normally users with SECADM authority do not have privileges to create database objects such as triggers or user-defined functions. Typically, they will examine the data accessed by a trigger, ensure it is secure, then grant the CREATE_SECURE_OBJECT authority to someone who has the required privileges to create the secure trigger. After the trigger is created, they will revoke the CREATE_SECURE_OBJECT authority from the trigger owner.

  The trigger is considered secure. The database manager treats the SECURED attribute as an assertion that declares the user has established an audit procedure for all activities in the trigger body. If a secure trigger references user-defined functions, the database manager assumes those functions are secure without validation. If those functions can access sensitive data, the user with SECADM authority needs to ensure those functions are allowed to access those data and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.

  A trigger must be secure if its subject table has row level or column level access control activated. Similarly, a trigger must be secure if its subject table is a view and one or more of the underlying tables in the view definition has row level or column level access control activated.
- ***Creating a trigger with the NOT SECURED option***: The CREATE TRIGGER statement returns an error if the trigger's subject table has row level or column level access control activated. Similarly, the CREATE TRIGGER statement fails if the trigger is defined on a view and one or more of the underlying tables in that view definition has row level or column level access control activated.
- ***Row and column access control that is not enforced for transition variables and transition tables***: Triggers are used for database integrity, and as such a balance between security and database integrity is needed. If row level or column level access control is activated on the subject table or an underlying table of the subject view, row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row level and column level access control that is enforced for the subject table or an underlying table of the subject view is also ignored for transition variables and transition tables that are referenced in the trigger body or are passed as arguments to user-defined functions invoked in the trigger body. To ensure there is no security concern for SQL statements in the trigger action to access sensitive data in transition variables and transition tables, the trigger must be created with the SECURED option. If a trigger is not secure, the CREATE TRIGGER statement returns an error.

- ***Considerations for implicitly hidden columns***: A transition variable exists for any column defined as implicitly hidden. In the body of a trigger, a transition variable that corresponds to an implicitly hidden column can be referenced.
- ***Rebinding dependent packages***: Every compiled trigger has a dependent package. The package can be rebound at any time by using the REBIND_ROUTINE_PACKAGE procedure. Explicitly rebinding the dependent package does not revalidate an invalid trigger. Revalidate an invalid trigger by using automatic revalidation or explicitly by using the ADMIN_REVALIDATE_DB_OBJECTS procedure. Trigger revalidation automatically rebinds the dependent package.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - OLD_TABLE can be specified in place of OLD TABLE, and NEW_TABLE can be specified in place of NEW TABLE
  - MODE DB2SQL can be specified following FOR EACH ROW or FOR EACH STATEMENT

Examples

- *Example 1:* Create two triggers that will result in the automatic tracking of the number of employees a company manages. The triggers will interact with the following tables:
  - EMPLOYEE table with these columns: ID, NAME, ADDRESS, and POSITION.
  - COMPANY_STATS table with these columns: NBEMP, NBPRODUCT, and REVENUE.

  The first trigger increments the number of employees each time a new person is hired; that is, each time a new row is inserted into the EMPLOYEE table:

```
CREATE TRIGGER NEW_HIRED
  AFTER INSERT ON EMPLOYEE
  FOR EACH ROW
  UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1
```

  The second trigger decrements the number of employees each time an employee leaves the company; that is, each time a row is deleted from the table EMPLOYEE:

```
CREATE TRIGGER FORMER_EMP
  AFTER DELETE ON EMPLOYEE
  FOR EACH ROW
  UPDATE COMPANY_STATS SET NBEMP = NBEMP - 1
```

- *Example 2:* Create a trigger that ensures that whenever a parts record is updated, the following check and (if necessary) action is taken:
  - If the on-hand quantity is less than 10% of the maximum stocked quantity, then issue a shipping request ordering the number of items for the affected part to be equal to the maximum stocked quantity minus the on-hand quantity.

  The trigger will interact with the PARTS table with these columns: PARTNO, DESCRIPTION, ON_HAND, MAX_STOCKED, and PRICE.

  ISSUE_SHIP_REQUEST is a user-defined function that sends an order form for additional parts to the appropriate company.

```
CREATE TRIGGER REORDER
  AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
  REFERENCING NEW AS N
  FOR EACH ROW
  WHEN (N.ON_HAND < 0.10 * N.MAX_STOCKED)
  BEGIN ATOMIC
  VALUES(ISSUE_SHIP_REQUEST(N.MAX_STOCKED - N.ON_HAND, N.PARTNO));
  END
```

- *Example 3:* Repeat the scenario in Example 2 except use a fullselect instead of a VALUES statement to invoke the user-defined function. This example also shows how to define the trigger as a statement

trigger instead of a row trigger. For each row in the transition table that evaluates to true for the WHERE clause, a shipping request is issued for the part.

```
CREATE TRIGGER REORDER
   AFTER UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
   REFERENCING NEW TABLE AS NTABLE
   FOR EACH STATEMENT
      BEGIN ATOMIC
         SELECT ISSUE_SHIP_REQUEST(MAX_STOCKED - ON_HAND, PARTNO)
            FROM NTABLE
         WHERE (ON_HAND < 0.10 * MAX_STOCKED);
   END
```

- *Example 4:* Create a trigger that will cause an error when an update occurs that would result in a salary increase greater than ten percent of the current salary.

```
CREATE TRIGGER RAISE_LIMIT
  AFTER UPDATE OF SALARY ON EMPLOYEE
  REFERENCING NEW AS N OLD AS O
  FOR EACH ROW
  WHEN (N.SALARY > 1.1 * O.SALARY)
        SIGNAL SQLSTATE '75000' SET MESSAGE_TEXT='Salary increase>10%'
```

- *Example 5:* Consider an application which records and tracks changes to stock prices. The database contains two tables, CURRENTQUOTE and QUOTEHISTORY.

```
Tables: CURRENTQUOTE (SYMBOL, QUOTE, STATUS)
        QUOTEHISTORY (SYMBOL, QUOTE, QUOTE_TIMESTAMP)
```

When the QUOTE column of CURRENTQUOTE is updated, the new quote should be copied, with a timestamp, to the QUOTEHISTORY table. Also, the STATUS column of CURRENTQUOTE should be updated to reflect whether the stock is:

1. rising in value;
2. at a new high for the year;
3. dropping in value;
4. at a new low for the year;
5. steady in value.

CREATE TRIGGER statements that accomplish this are as follows.

– Trigger Definition to set the status:

```
   CREATE TRIGGER STOCK_STATUS
     NO CASCADE BEFORE UPDATE OF QUOTE ON CURRENTQUOTE
     REFERENCING NEW AS NEWQUOTE OLD AS OLDQUOTE
     FOR EACH ROW
     BEGIN ATOMIC
        SET NEWQUOTE.STATUS =
          CASE
             WHEN NEWQUOTE.QUOTE >
                   (SELECT MAX(QUOTE) FROM QUOTEHISTORY
                   WHERE SYMBOL = NEWQUOTE.SYMBOL
                   AND YEAR(QUOTE_TIMESTAMP) = YEAR(CURRENT DATE) )
                THEN 'High'
             WHEN NEWQUOTE.QUOTE <
(SELECT MIN(QUOTE) FROM QUOTEHISTORY
                   WHERE SYMBOL = NEWQUOTE.SYMBOL
                   AND YEAR(QUOTE_TIMESTAMP) = YEAR(CURRENT DATE) )
                THEN 'Low'
             WHEN NEWQUOTE.QUOTE > OLDQUOTE.QUOTE
                THEN 'Rising'
             WHEN NEWQUOTE.QUOTE < OLDQUOTE.QUOTE
                THEN 'Dropping'
             WHEN NEWQUOTE.QUOTE = OLDQUOTE.QUOTE
                THEN 'Steady'
          END;
     END
```

– Trigger Definition to record change in QUOTEHISTORY table:

```
CREATE TRIGGER RECORD_HISTORY
  AFTER UPDATE OF QUOTE ON CURRENTQUOTE
  REFERENCING NEW AS NEWQUOTE
  FOR EACH ROW
  BEGIN ATOMIC
    INSERT INTO QUOTEHISTORY
      VALUES (NEWQUOTE.SYMBOL, NEWQUOTE.QUOTE, CURRENT TIMESTAMP);
  END
```

- *Example 6:*Create a trigger that overrides any changes to the location field in the employee record in the org table. This trigger would be useful if new employee records acquired when a smaller company was purchased are processed and the target location allocated to the employee is "Toronto" and the new target location is "Los Angeles". The before trigger will ensure that regardless what value the application allocates for this field, that the final resultant value is "Los Angeles".

```
CREATE TRIGGER LOCATION_TRIGGER
  NO CASCADE
   BEFORE UPDATE ON ORG
   REFERENCING
     OLD AS PRE
     NEW AS POST
   FOR EACH ROW
   WHEN (POST.LOCATION = 'Toronto')
      SET POST.LOCATION = 'Los Angeles';
   END
```

- *Example 7:* Create a BEFORE trigger that automatically validates XML documents containing new product descriptions before they are inserted into the PRODUCT table of the SAMPLE database:

```
CREATE TRIGGER NEWPROD NO CASCADE BEFORE INSERT ON PRODUCT
   REFERENCING NEW AS N
   FOR EACH ROW
   BEGIN ATOMIC
      SET (N.DESCRIPTION) = XMLVALIDATE(N.DESCRIPTION
         ACCORDING TO XMLSCHEMA ID product);
   END
```

- *Example 8:* Create a multiple-event trigger that tracks of the number and salary of employees a company manages. The triggers will interact with the following columns and tables:
  - ID, NAME, ADDRESS, SALARY, and POSITION columns in the EMPLOYEE table
  - NBEMP, NBPRODUCT, and REVENUE columns in the COMPANY_STATS table

  The trigger increments the number of employees each time a new employee is hired; decrements the number of employees each time an employee leaves the company, and raises an error when an update occurs that would result in a salary increase greater than ten percent of the current salary:

```
CREATE OR REPLACE TRIGGER HIRED
   AFTER INSERT OR DELETE OR UPDATE OF SALARY ON EMPLOYEE
   REFERENCING NEW AS N OLD AS O FOR EACH ROW
   BEGIN
      IF INSERTING THEN UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1;
      ELSEIF DELETING THEN UPDATE COMPANY_STATS SET NBEMP = NBEMP - 1;
      ELSEIF (UPDATING AND (N.SALARY > 1.1 * O.SALARY))
         THEN SIGNAL SQLSTATE '75000' SET MESSAGE_TEXT='Salary increase>10%';
      END IF;
   END;
```

- *Example 9:* Create a trigger that ensures that the following check and (if necessary) action is taken, before a parts record is updated:
  - If the on-hand quantity is less than 10% of the maximum stocked quantity, then place a new order record into the ORDER table and issue a shipping request ordering the number of items for the affected part to be equal to the maximum stocked quantity minus the on-hand quantity.

  The trigger interacts with the following columns and tables:
  - PARTNO, DESCRIPTION, ON_HAND, MAX_STOCKED, and PRICE columns in the PARTS table
  - PARTNO and PRICE columns in the ORDER table

ISSUE_SHIP_REQUEST is a user-defined SQL data modification stored procedure that sends an order form for additional parts to the supply company, and deletes the corresponding row from the ORDER table after the order form is confirmed by the supply company.

```
CREATE TRIGGER REORDER
   BEFORE UPDATE OF ON_HAND, MAX_STOCKED ON PARTS
   REFERENCING NEW AS N
   FOR EACH ROW
   WHEN (N.ON_HAND < 0.10 * N.MAX_STOCKED)
   BEGIN
      INSERT INTO ORDERS VALUES (N.MAX_STOCKED - N.ON_HAND, N.PARTNO);
      CALL ISSUE_SHIP_REQUEST(N.MAX_STOCKED - N.ON_HAND, N.PARTNO);
   END;
```

CREATE TRUSTED CONTEXT

The CREATE TRUSTED CONTEXT statement defines a trusted context at the current server.

Important: The DATA_ENCRYPT authentication type is deprecated and might be removed in a future release. To encrypt data in-transit between clients and Db2 databases, we recommend that you use the Db2 database system support of Transport Layer Security (TLS). For more information, see Encryption of data in transit

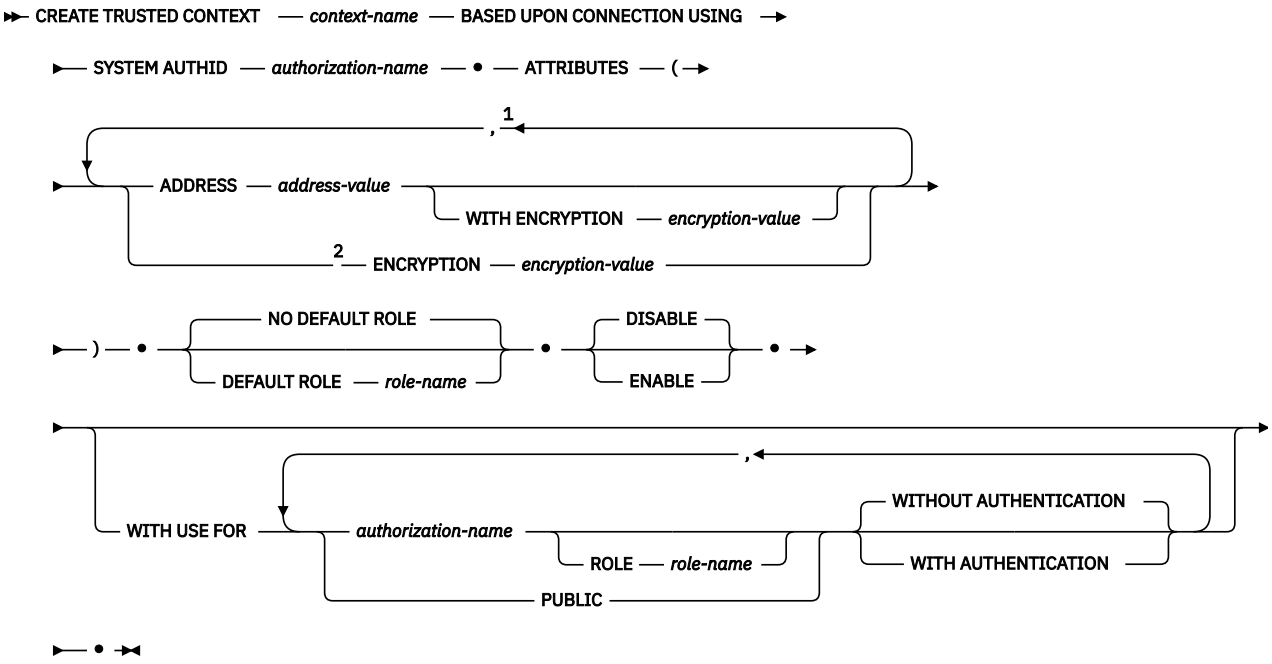
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Notes:

[1] Each combination of an attribute name and its corresponding value, as a pair, must be unique (SQLSTATE 4274D).

[2] ENCRYPTION cannot be specified more than once (SQLSTATE 42614); however, WITH ENCRYPTION can be specified for each ADDRESS that is specified.

Description

context-name
Names the trusted context. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The name must not identify a trusted context that already exists at the current server (SQLSTATE 42710). The name must not begin with the characters 'SYS' (SQLSTATE 42939).

BASED UPON CONNECTION USING SYSTEM AUTHID *authorization-name*
Specifies that the context is a connection established by system authorization ID *authorization-name*, which must not be associated with an existing trusted context (SQLSTATE 428GL). It cannot be the authorization ID of the statement (SQLSTATE 42502).

ATTRIBUTES (...)
Specifies a list of one or more connection trust attributes upon which the trusted context is defined.

ADDRESS *address-value*
Specifies the actual communication address used by the client to communicate with the database server. The only protocol supported is TCP/IP. The ADDRESS attribute can be specified multiple times, but each *address-value* pair must be unique for the set of attributes (SQLSTATE 4274D).

When establishing a trusted connection, if multiple values are defined for the ADDRESS attribute of a trusted context, a candidate connection is considered to match this attribute if the address used by the connection matches any of the defined values for the ADDRESS attribute of the trusted context.

address-value
Specifies a string constant that contains the value to be associated with the ADDRESS trust attribute. The *address-value* must be an IPv4 address, an IPv6 address, or a secure domain name.

- An IPv4 address must not contain leading spaces and is represented as a dotted decimal address. An example of an IPv4 address is 9.112.46.111. The value 'localhost' or its equivalent representation '127.0.0.1' will not result in a match; the real IPv4 address of the host must be specified instead.
- An IPv6 address must not contain leading spaces and is represented as a colon hexadecimal address. An example of an IPv6 address is 2001:0DB8:0000:0000:0008:0800:200C:417A. IPv4-mapped IPv6 addresses (for example, ::ffff:192.0.2.128) will not result in a match. Similarly, 'localhost' or its IPv6 short representation '::1' will not result in a match.
- A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is corona.torolab.ibm.com. When a domain name is converted to an IP address, the result of this conversion could be a set of one or more IP addresses. In this case, an incoming connection is said to match the ADDRESS attribute of a trusted context object if the IP address from which the connection originates matches any of the IP addresses to which the domain name was converted. When creating a trusted context object, it is advantageous to provide domain name values for the ADDRESS attribute instead of static IP addresses, particularly in Dynamic Host Configuration Protocol (DHCP) environments. With DHCP, a device can have a different IP address each time it connects to the network. So, if a static IP address is provided for the ADDRESS attribute of a trusted context object, some device might acquire a trusted connection unintentionally. Providing domain names for the ADDRESS attribute of a trusted context object avoids this problem in DHCP environments.

WITH ENCRYPTION *encryption-value*
Specifies the minimum level of encryption of the data stream or network encryption for this specific *address-value*. This *encryption-value* overrides the global ENCRYPTION attribute setting for this specific *address-value*.

encryption-value
Specifies a string constant that contains the value to be associated with the ENCRYPTION trust attribute for this specific *address-value*. The *encryption-value* must be one of the following values (SQLSTATE 42615):

- NONE, no specific level of encryption is required
- LOW, a minimum of light encryption is required; the authentication type on the database manager must be DATA_ENCRYPT if an incoming connection is to match the encryption setting for this specific address
- HIGH, Secure Sockets Layer (SSL) encryption, or equivalent, must be used for data communication between the database client and the database server if an incoming connection is to match the encryption setting for this specific address

ENCRYPTION *encryption-value*
Specifies the minimum level of encryption of the data stream or network encryption. The default is NONE.

encryption-value
Specifies a string constant that contains the value to be associated with the ENCRYPTION trust attribute for this specific *address-value*. The *encryption-value* must be one of the following values (SQLSTATE 42615):

- NONE, no specific level of encryption is required for an incoming connection to match the ENCRYPTION attribute of this trusted context object
- LOW, a minimum of light encryption is required; the authentication type on the database manager must be DATA_ENCRYPT if an incoming connection is to match the ENCRYPTION attribute of this trusted context object
- HIGH, Secure Sockets Layer (SSL) encryption, or equivalent, must be used for data communication between the database client and the database server if an incoming connection is to match the ENCRYPTION attribute of this trusted context object

The following table summarizes when a trusted context can be used, depending on the encryption used by the existing connection. If the trusted context cannot be used for the connection, a warning is returned (SQLSTATE 01679) and the SQLWARN8 field of the SQLCA is set to 'Y', indicating that the connection is a regular (non-trusted) connection.

Table 145. Encryption and trusted contexts

Encryption used by existing connection	**ENCRYPTION value for trusted context**	**Can the trusted context be used for the connection?**
No encryption	'NONE'	Yes
No encryption	'LOW'	No
No encryption	'HIGH'	No
Low encryption (DATA_ENCRYPT)	'NONE'	Yes
Low encryption (DATA_ENCRYPT)	'LOW'	Yes
Low encryption (DATA_ENCRYPT)	'HIGH'	No
High encryption (SSL)	'NONE'	Yes
High encryption (SSL)	'LOW'	Yes
High encryption (SSL)	'HIGH'	Yes

NO DEFAULT ROLE or DEFAULT ROLE *role-name*

Specifies whether or not a default role is associated with a trusted connection that is based on this trusted context. The default is NO DEFAULT ROLE.

NO DEFAULT ROLE

Specifies that the trusted context does not have a default role.

DEFAULT ROLE *role-name*

Specifies that *role-name* is the default role for the trusted context. The *role-name* must identify a role that exists at the current server (SQLSTATE 42704). This role is used with the user in a trusted connection, based on this trusted context, when the user does not have a user-specific role defined as part of the definition of the trusted context.

DISABLE or ENABLE

Specifies whether the trusted context is created in the enabled or disabled state. The default is DISABLE.

DISABLE

Specifies that the trusted context is created in the disabled state. A trusted context that is disabled is not considered when a trusted connection is established.

ENABLE

Specifies that the trusted context is created in the enabled state.

WITH USE FOR

Specifies who can use a trusted connection that is based on this trusted context.

authorization-name

Specifies that the trusted connection can be used by the specified *authorization-name*. The *authorization-name* must not be specified more than once in the WITH USE FOR clause (SQLSTATE 428GM). It must also not be the authorization ID of the statement (SQLSTATE 42502). If the definition of a trusted context allows access by both PUBLIC and a list of users, the specifications for a user override the specifications for PUBLIC. For example, assume that a trusted context is defined that allows access by both PUBLIC WITH AUTHENTICATION and JOE WITHOUT AUTHENTICATION. If the trusted context is used by JOE, authentication is not required. However, if the trusted context is used by GEORGE, authentication is required.

ROLE *role-name*

Specifies that *role-name* is the role to be used for the user when a trusted connection is using the trusted context. The *role-name* must identify a role that exists at the current server (SQLSTATE 42704). The role explicitly specified for the user overrides any default role associated with the trusted context.

PUBLIC

Specifies that a trusted connection that is based on this trusted context can be used by any user. PUBLIC must not be specified more than once (SQLSTATE 428GM). All users using such a trusted connection make use of the privileges associated with the default role for the associated trusted context. If a default role is not defined for the trusted context, there is no role associated with the users that use a trusted connection based on this trusted context.

WITHOUT AUTHENTICATION or WITH AUTHENTICATION

Specifies whether or not switching the user on a trusted connection requires authentication of the user. The default is WITHOUT AUTHENTICATION.

WITHOUT AUTHENTICATION

Specifies that switching the current user on a trusted connection to this user does not require authentication.

WITH AUTHENTICATION

Specifies that switching the current user on a trusted connection to this user requires authentication.

Rules

- A trusted context-exclusive SQL statement must be followed by a COMMIT or a ROLLBACK statement (SQLSTATE 5U021). Trusted context-exclusive SQL statements are:
  - CREATE TRUSTED CONTEXT, ALTER TRUSTED CONTEXT, or DROP (TRUSTED CONTEXT)
- A trusted context-exclusive SQL statement cannot be issued within a global transaction; for example, an XA transaction or a global transaction that is initiated as part of two-phase commit for federated transactions (SQLSTATE 51041).

Notes

- When providing an IP address as part of a trusted context definition, the address must be in the format that is in effect for the network. For example, providing an address in an IPv6 format when the network is IPv4 will not result in a match. In a mixed environment, it is advantageous to specify both the IPv4 and the IPv6 representations of the address, or better yet, to specify a secure domain name (for example, corona.torolab.ibm.com), which hides the address format details.
- ***Specifying a role in the definition of a trusted context:*** The definition of a trusted context can designate a role for a specific authorization ID, and a default role to be used for authorization IDs for which a specific role has not been specified in the definition of the trusted context. This role can be used with a trusted connection based on the trusted context, but it does not make the role available outside of a trusted connection based on the trusted context.
- When issuing a data manipulation language (DML) SQL statement using a trusted connection, the privileges held by a context-assigned role in effect for the authorization ID within the definition of the associated trusted context are considered in addition to other privileges directly held by the authorization ID of the statement, or indirectly by other roles held by the authorization ID of the statement.
- The privileges held by a context-assigned role in effect for the authorization ID within the definition of the associated trusted context are not considered for data definition language (DDL) SQL statements. For example, to create an object, the authorization ID of the statement must be able to do so without including the privileges held by the context-assigned role.
- When installing a new application that authenticates to the database server using the same credentials as an existing application on the same machine, and which takes advantage of a trusted context, the new application might also take advantage of the same trusted context object (inheriting the trusted context role, for example). This might not be the security administrator's intention. The security administrator might want to turn on the database audit facility to find out what applications are taking advantage of trusted context objects.
- Only one uncommitted trusted context-exclusive SQL statement is allowed at a time across all database partitions. If an uncommitted trusted context-exclusive SQL statement is executing, subsequent trusted context-exclusive SQL statements will wait until the current trusted context-exclusive SQL statement commits or rolls back.
- Changes are written to the system catalog, but do not take effect until they are committed, even for the connection that issues the statement.

Examples

- *Example 1:* Create a trusted context such that the current user on a trusted connection based on this trusted context can be switched to two different user IDs. When the current user of the connection is switched to user ID JOE, authentication is not required. However, authentication is required when the current user of the connection is switched to user ID BOB. Note that the trusted context has a default role called *context-role*. This implies that users working within the confines of this trusted context inherit the privileges associated with role *context-role*.

```
CREATE TRUSTED CONTEXT APPSERVER
  BASED UPON CONNECTION USING SYSTEM AUTHID WRJAIBI
  DEFAULT ROLE CONTEXT_ROLE
  ENABLE
  ATTRIBUTES (ADDRESS '9.26.113.204')
```

```
  WITH USE FOR JOE WITHOUT AUTHENTICATION
    BOB WITH AUTHENTICATION
```

- *Example 2:* Create a trusted context such that the current user of a trusted connection based on this trusted context can be switched to any user ID without authentication.

```
CREATE TRUSTED CONTEXT SECUREROLE
  BASED UPON CONNECTION USING SYSTEM AUTHID PBIRD
  ENABLE
  ATTRIBUTES (ADDRESS '9.26.113.204')
  WITH USE FOR PUBLIC WITHOUT AUTHENTICATION
```

- *Example 3:* Create a trusted context such that the current user of a trusted connection based on this trusted context can be switched to any user ID without authentication. The difference between this trusted context and the trusted context created in example 2, is that this trusted context has an additional attribute called ENCRYPTION. The ENCRYPTION attribute setting for trusted context SECUREROLEENCRYPT states that the encryption setting used by a connection must be at least "low encryption" (see Table 145 on page 1476) to match this trusted context attribute.

```
CREATE TRUSTED CONTEXT SECUREROLEENCRYPT
  BASED UPON CONNECTION USING SYSTEM AUTHID SHARPER
  ENABLE
  ATTRIBUTES (ADDRESS '9.26.113.204'
    ENCRYPTION 'LOW')
  WITH USE FOR PUBLIC WITHOUT AUTHENTICATION
```

- *Example 4:* Create a trusted context, such that connections made by user WRJAIBI from addresses 9.26.146.201 and 9.26.146.203 are trusted when no encryption is used, but a connection made by user WRJAIBI from address 9.26.146.202 requires a LOW level of encryption to be trusted.

```
CREATE TRUSTED CONTEXT WALIDLOCSENSITIVE
  BASED UPON CONNECTION USING SYSTEM AUTHID WRJAIBI
  ENABLE
  ATTRIBUTES (ADDRESS '9.26.146.201',
    ADDRESS '9.26.146.202' WITH ENCRYPTION 'LOW',
    ADDRESS '9.26.146.203'
    ENCRYPTION 'NONE')
```

CREATE TYPE

The CREATE TYPE statement defines a user-defined data type at the current server.

Five different kinds of user-defined data types can be created using this statement. Each of these types is described separately.

- Array. A user-defined data type that is an ordinary array or an associative array. The elements of an array type are based on one of the built-in data types or a user-defined type other than a cursor type or structured type.
- Cursor. A user-defined data type that is a cursor type.
- Distinct. A user-defined data type that is sourced on one of the built-in data types and can be defined to use strong type rules or weak type rules.. Functions that cast between the user-defined distinct type and the source built-in data type are generated when a strongly typed distinct type is created. Optionally, support for comparison operations to use with the strongly typed distinct type can be generated when the user-defined distinct type is created.
- Row. A user-defined data type that represents a row. It includes one or more fields with associated data types that make up a row of data.
- Structured. A user-defined data type that represents an object and associated methods. It may include zero or more attributes and may be a subtype allowing attributes to be inherited from a supertype. Some methods are generated when the user-defined structured type is created and others can be specified as part of the definition.

CREATE TYPE (array)

The CREATE TYPE (array) statement defines an array type. The elements of an array type are based on one of the built-in data types or a user-defined distinct type.

Invocation

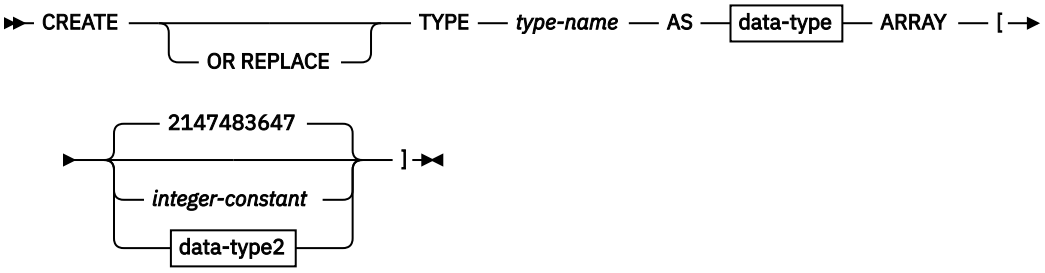
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

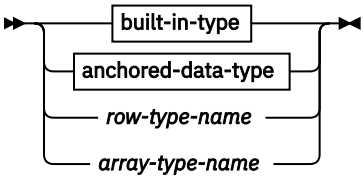
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the schema name of the array type does not refer to an existing schema
- CREATEIN privilege on the schema, if the schema name of the array type refers to an existing schema
- SCHEMAADM authority on the schema, if the schema name of the array type refers to an existing schema
- DBADM authority

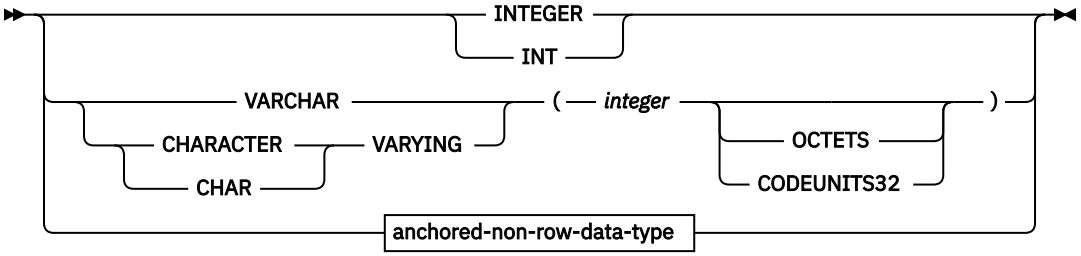
Syntax



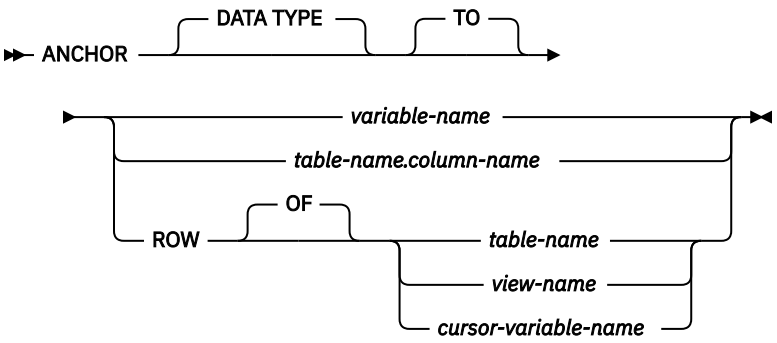
data-type



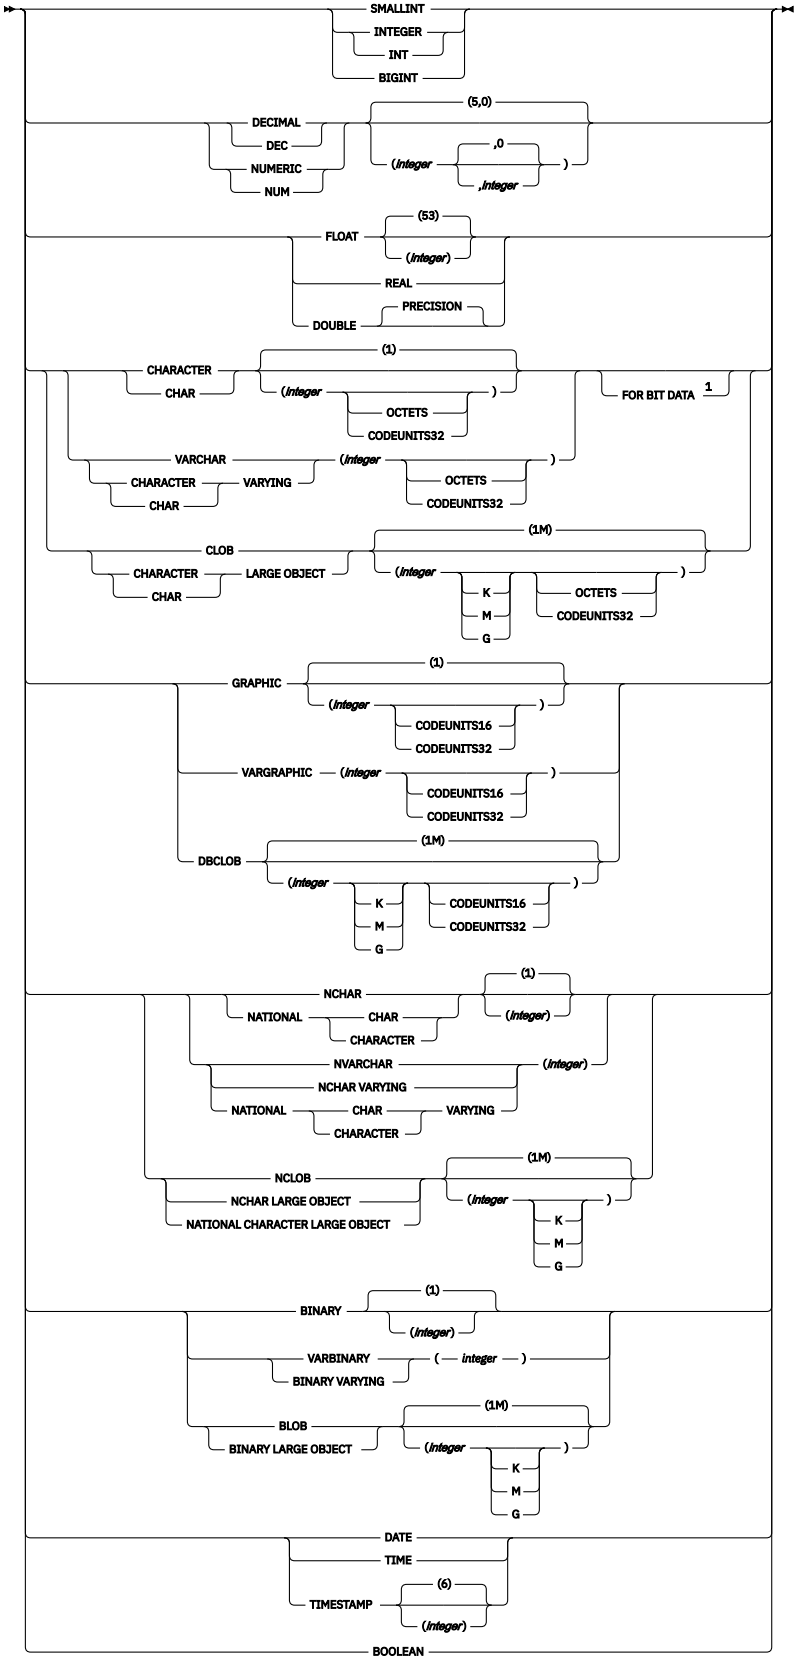
data-type2



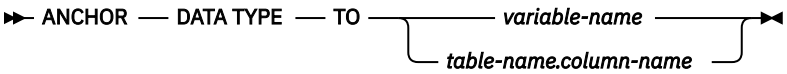
anchored-data-type



built-in-type



anchored-non-row-data-type



Notes:

[1] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

Description

OR REPLACE
Specifies to replace the definition for the data type if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that functions and methods are invalidated instead of dropped when they have parameters or a return value defined with the data type being replaced. The existing definition must not be a structured type (SQLSTATE 42809). This option is ignored if a definition for the data type does not exist at the current server.

type-name
Names the type. The name, including the implicit or explicit qualifier, must not identify any other type (built-in or user-defined) that already exists at the current server. The unqualified name must not be the same as the name of a built-in data type or VARBINARY (SQLSTATE 42918).

A number of names used as keywords in predicates are reserved for system use, and cannot be used as a *type-name* (SQLSTATE 42939). The names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators.

If a two-part *type-name* is specified, the schema name must not begin with the characters 'SYS' (SQLSTATE 42939).

data-type
Specifies the data type of the array elements.

built-in-type
Specifies a built-in data type. See "CREATE TABLE" for the description of built-in data types. Built-in types include the data types described in "CREATE TABLE", other than reference, SYSPROC.DB2SECURITYLABEL, XML, or user-defined types (SQLSTATE 429C2).

row-type-name
Specifies the name of a user-defined row type. If a *row-type-name* is specified without a schema name, the *row-type-name* is resolved by searching the schemas in the SQL path. Row types can be nested as elements in other array types with a maximum nesting level of sixteen.

array-type-name
Specifies an array type. If an *array-type-name* is specified without a schema name, the *array-type-name* is resolved by searching the schemas in the SQL path. Array types can be nested as elements in other array types with a maximum nesting level of sixteen.

anchored-data-type
Identifies another object used to determine the data type. The data type of the anchor object is bound by the same limitations that apply when specifying the data type directly, or in the case of a row, to creating a row type.

ANCHOR DATA TYPE TO
Indicates that an anchored data type is used to specify the data type.

variable-name
Identifies a global variable. The data type of the global variable is used as the data type for the array elements.

table-name.column-name
Identifies a column name of an existing table or view. The data type of the column is used as the data type for the array elements.

ROW OF *table-name* or *view-name*
Specifies a row of fields with names and data types that are based on the column names and column data types of the table identified by *table-name* or the view identified by *view-name*.The data type of the array elements is an unnamed row type.

ROW OF *cursor-variable-name*
Specifies a row of fields with names and data types that are based on the field names and field data types of the cursor variable identified by *cursor-variable-name*. The specified cursor variable must be one of the following elements (SQLSTATE 428HS):

- A global variable with a strongly typed cursor data type
- A global variable with a weakly typed cursor data type that was created or declared with a CONSTANT clause specifying a *select-statement* where all the result columns are named.

If the cursor type of the cursor variable is not strongly-typed using a named row type, the data type of the array elements is an unnamed row type.

anchored-non-row-data-type
Identifies another object used to determine the data type. The data type of the anchor object is bound by the same limitations that apply when specifying the data type directly.

ANCHOR DATA TYPE TO
Indicates that an anchored data type is used to specify the data type.

variable-name
Identifies a global variable with a data type that is an INTEGER or VARCHAR data type. The data type of the global variable is used as the data type for the array index.

table-name.column-name
Identifies a column name of an existing table or view with a data type that is an INTEGER or VARCHAR data type. The data type of the column is used as the data type for the array index.

ARRAY [*integer-constant*]
Specifies that the type is an array with a maximum cardinality of *integer-constant*. The value must be a positive integer (not zero) and less than the largest positive integer value (SQLSTATE 42820). The default is the largest positive integer value (2 147 483 647). The cardinality of an array value is determined by the highest element position assigned to the array value.

The maximum cardinality of an array on a given system is limited by the total amount of memory available to database applications. As such, although arrays of large cardinalities can be created, not all elements might be available for use.

ARRAY[*data-type2*]
Specifies that the type is an associative array that is indexed with values of data type *data-type2*. The data type must be either the INTEGER or VARCHAR data type (SQLSTATE 429C2). The values specified as the index when assigning an array element must be assignable to a value of *data-type2*. The cardinality of an array value is determined by the number of unique index values used when assigning array elements.

Rules

- ***Use of anchored data types:*** An anchored data type cannot refer to the following objects (SQLSTATE 428HS): a nickname, typed table, typed view, statistical view that is associated with an expression-based index, declared temporary table, row definition that is associated with a weakly typed cursor, object with a code page or collation that is different from the database code page or database collation.

Notes

- ***Array type usage:*** An array type can only be used as the data type of:
  - A local variable in a compound SQL (compiled) statement
  - A parameter of an SQL routine
  - A parameter of a Java procedure (non-nested ordinary arrays only)
  - The returns type of an SQL function
  - A global variable

- A variable or parameter defined with an array type can only be used in compound SQL (compiled) statements

Examples

Example 1: Create an array type named PHONENUMBERS with a maximum of 50 elements that are of the DECIMAL(10, 0) data type.

```
CREATE TYPE PHONENUMBERS AS DECIMAL(10,0)
  ARRAY[50]
```

Example 2: Create an array type named NUMBERS with the default number of elements in the schema GENERIC.

```
CREATE TYPE GENERIC.NUMBERS AS DECFLOAT(34)
  ARRAY[]
```

Example 3: Create an associative array named PERSONAL_PHONENUMBERS with elements that are DECIMAL(16, 0) that is indexed by strings like 'Home', 'Work', or 'Mom'.

```
CREATE TYPE PERSONALPHONENUMBERS AS DECIMAL(16, 0) ARRAY[VARCHAR(8)]
```

Example 4: Create an associative array type where the indexes are province, territory, or country names and the elements are capital cities:

```
CREATE TYPE CAPITALSARRAY AS VARCHAR(30) ARRAY[VARCHAR(20)]
```

Example 5: Create an associative array type for product descriptions of up to 40 characters long, where the indexes are the product numbers, which are a maximum of 12 characters long:

```
CREATE TYPE PRODUCTS AS VARCHAR(40) ARRAY[VARCHAR(12)]
```

CREATE TYPE (cursor)

The CREATE TYPE (cursor) statement defines a user-defined cursor type.

Invocation

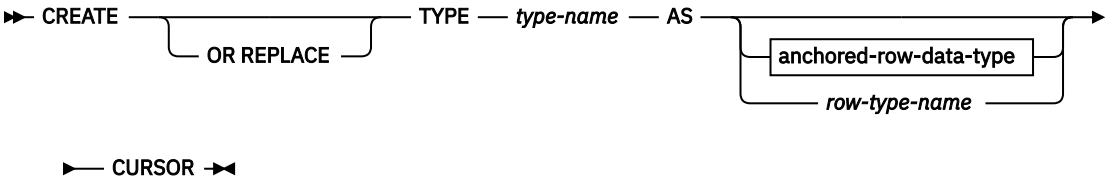
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

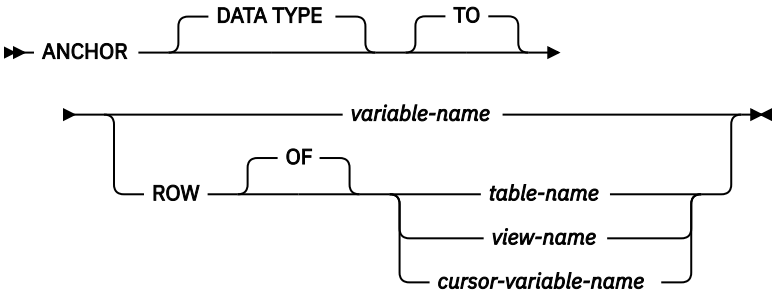
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the schema name of the cursor type does not refer to an existing schema
- CREATEIN privilege on the schema, if the schema name of the cursor type refers to an existing schema
- SCHEMAADM authority on the schema, if the schema name of the cursor type refers to an existing schema
- DBADM authority

Syntax



anchored-row-data-type



Description

OR REPLACE

Specifies to replace the definition for the data type if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that functions and methods are invalidated instead of dropped when they have parameters or a return value defined with the data type being replaced. The existing definition must not be a structured type (SQLSTATE 42809). This option is ignored if a definition for the data type does not exist at the current server.

type-name

Names the type. The name, including the implicit or explicit qualifier, must not identify any other type (built-in or user-defined) that already exists at the current server. The unqualified name must not be the same as the name of a built-in data type or BOOLEAN, BINARY or VARBINARY (SQLSTATE 42918).

A number of names used as keywords in predicates are reserved for system use, and cannot be used as a type-name (SQLSTATE 42939). The names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators. If a two-part type-name is specified, the schema name must not begin with the characters 'SYS' (SQLSTATE 42939).

anchored-row-data-type

Identifies row information from another object used to determine the row type associated with the cursor type. The data type of the anchor object has the same limitations that apply to creating a row type.

ANCHOR DATA TYPE TO

Indicates an anchored data type is used to specify the data type.

variable-name

Identifies a global variable. The data type of the referenced variable must be a row type and is used as the row type associated with the cursor type.

ROW OF *table-name* or *view-name*

Specifies a row of fields with names and data types that are based on the column names and column data types of the table identified by *table-name* or the view identified by *view-name*. The data types of the anchor object columns have the same limitations that apply to field data types. The row type associated with the cursor type is an unnamed row type.

ROW OF *cursor-variable-name*
Specifies a row of fields with names and data types that are based on the field names and field data types of the cursor variable identified by *cursor-variable-name*. The specified cursor variable must be one of the following objects (SQLSTATE 428HS):

- A global variable with a strongly typed cursor data type
- A global variable with a weakly typed cursor data type that was created or declared with a CONSTANT clause specifying a *select-statement* where all the result columns are named.

If the cursor type of the cursor variable is not strongly-typed using a named row type, the row type associated with the cursor type is an unnamed row type.

row-type-name
Specifies the row type that will be used to check the row type of the result table of the *select-statement* assigned to a variable of the cursor type. The assignment fails if the type check fails (SQLSTATE 42821). If *row-type-name* is specified without a schema name, the row type is resolved by searching the schemas in the SQL path.

Rules

- ***Use of anchored data types:*** An anchored data type cannot refer to the following objects (SQLSTATE 428HS): a nickname, typed table, typed view, statistical view that is associated with an expression-based index, declared temporary table, row definition that is associated with a weakly typed cursor, object with a code page or collation that is different from the database code page or database collation.

Notes

- ***Cursor type usage:*** A cursor type can only be used as the data type of:
  - A local variable in a compound SQL (compiled) statement
  - A parameter of an SQL routine
  - The returns type of an SQL function
  - A global variable
- A variable or parameter defined with a cursor type can only be used in compound SQL (compiled) statements
- A variable or parameter that has a strongly-typed cursor type must not be used to assign cursor values that are based on a *statement-name* instead of a *select-statement*
- A user-defined cursor type with an associated row type is a strongly-typed cursor type; otherwise, it is a weakly-typed cursor type.

Examples

- *Example 1:* Create a cursor type that can be used with any cursor.

```
CREATE TYPE EMPCURSOR AS CURSOR
```

- *Example 2:* Create a strongly-typed cursor type that is based on the row data type DEPTROW:

```
CREATE TYPE DEPTCURSOR AS DEPTROW CURSOR
```

CREATE TYPE (distinct)

The CREATE TYPE (distinct) statement defines a distinct type. The distinct type is always sourced on one of the built-in data types and can be defined to use strong type or weak type rules..

Successful execution of the statement that defines a strongly typed distinct type also generates functions to cast between the distinct type and its source type and, optionally, generates support for the comparison operators (=, <>, <, <=, >, and >=) for use with the distinct type. Successful execution of the statement that defines a weakly typed distinct type does not generate any functions.

Invocation

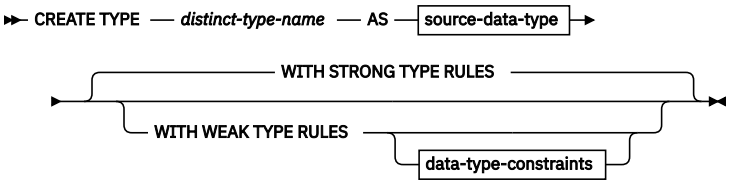
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

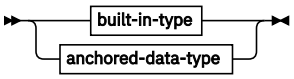
The privileges held by the authorization ID of the statement must include as least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the schema name of the distinct type does not refer to an existing schema
- CREATEIN privilege on the schema, if the schema name of the distinct type refers to an existing schema
- SCHEMAADM authority on the schema, if the schema name of the distinct type refers to an existing schema
- DBADM authority

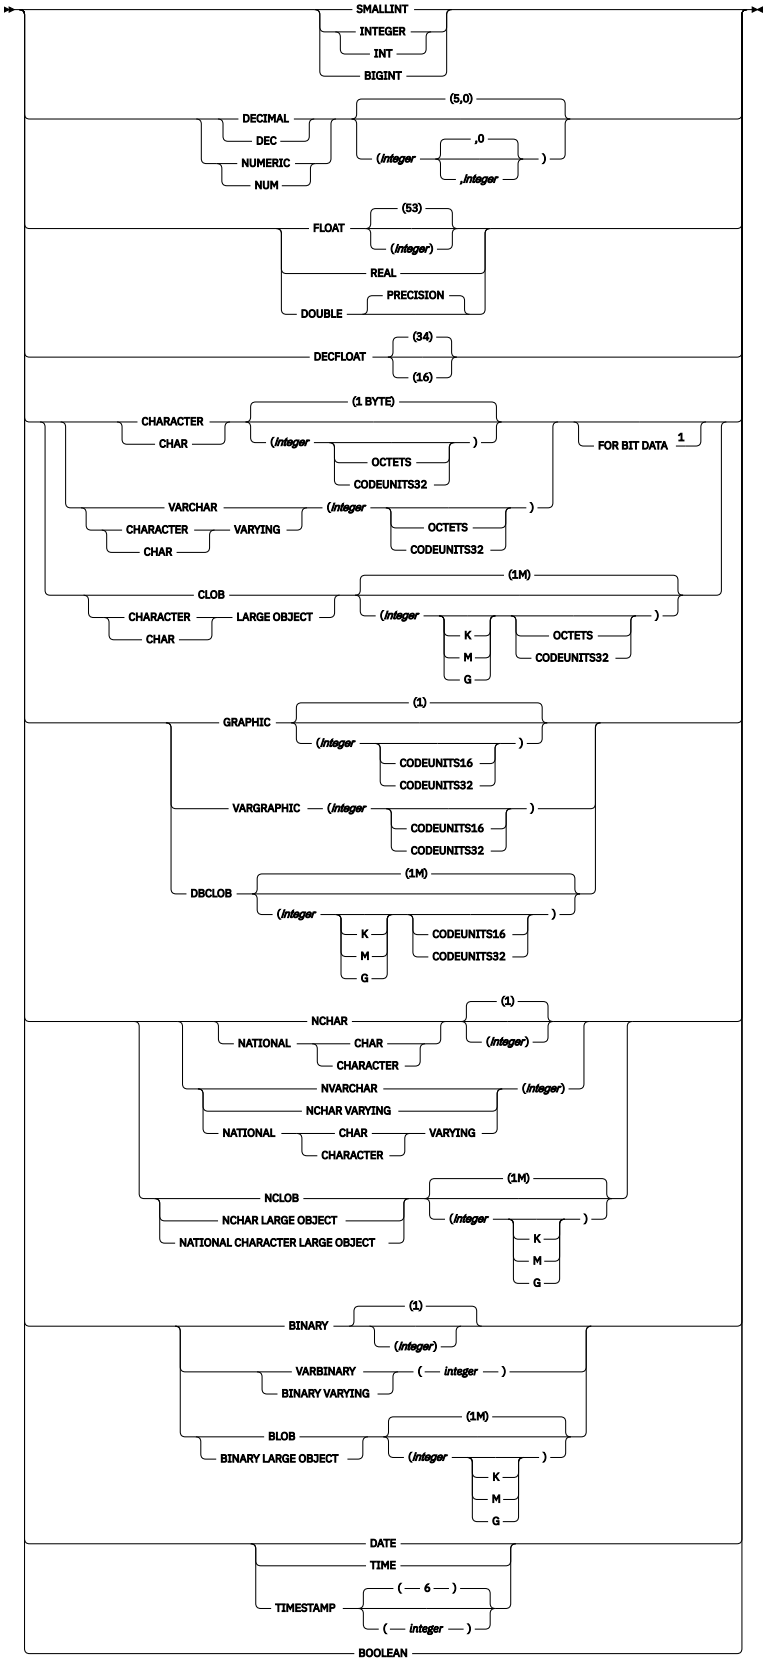
Syntax



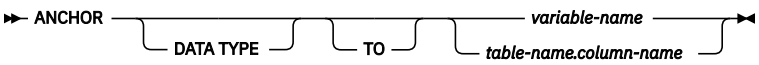
source-data-type



built-in-type



anchored-data-type



data-type-constraints

Notes:

[1] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

Description

distinct-type-name

Names the distinct type. The name, including the implicit or explicit qualifier, must not identify any other type (built-in or user-defined) that already exists at the current server. The unqualified name cannot be the same as the name of a built-in data type (SQLSTATE 42918), and cannot be ARRAY, INTERVAL, or ROWID.

In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The qualified form is a schema name followed by a period and an SQL identifier.

Several names used as keywords in predicates are reserved for system use and cannot be used as a distinct type name (SQLSTATE 42939). These names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators.

If a two-part name is specified, the schema name must not begin with the characters SYS (SQLSTATE 42939).

source-data-type

Specifies the data type used as the basis for the internal representation of the distinct type. The data type must be a built-in data type. For more information on built-in data types, see "CREATE TABLE". The source data type cannot be of type XML or an ARRAY type (SQLSTATE 42601). For portability of applications across platforms, use the following recommended data type names:

- DOUBLE or REAL instead of FLOAT
- DECIMAL instead of NUMERIC
- VARCHAR, BLOB, or CLOB instead of LONG VARCHAR
- VARGRAPHIC or DBCLOB instead of LONG VARGRAPHIC

anchored-data-type

Identifies another object used to determine the data type. The data type of the anchor object is bound by the same limitations that apply when specifying the data type directly.

ANCHOR DATA TYPE TO

Indicates that an anchored data type is used to specify the data type.

variable-name

Identifies a global variable with a data type that is a built-in type other than ROW or CURSOR. The data type of the global variable is used as the source data type for the distinct type.

table-name.column-name

Identifies a column name of an existing table or view with a data type that must be specified as a built-in-type. The data type of the column is used as the source data type for the distinct type.

WITH STRONG TYPE RULES

Specifies that strong typing rules are used for operations where this data type is an operand including assignments and comparisons. This is the default.

WITH WEAK TYPE RULES

Specifies that weak typing rules are used for operations where this data type is an operand including assignments, comparisons, and function resolution. When values of a weakly typed distinct type are used, the data type is effectively treated as the specified *source-data-type* when processing the operation.

data-type-constraints
Defines constraints on the distinct type that are applied when values are assigned or cast to the distinct type.

NOT NULL
Prevents a value with this distinct type from having a null value. If NOT NULL is not specified, a value with this distinct type can have the null value.

CHECK (*check-condition*)
Defines a data type check constraint. At any time, the check-condition must be true or unknown for every value with this data type. The *check-condition* is a form of the *search-condition* that conforms to the rules of table check constraints (SQLSTATE 426211) with the addition that the VALUE keyword is used to reference a value that is assigned or cast to the distinct type in the same way that a column name is referenced in a table check constraint. Note that the *check-condition* cannot reference global variables.

built-in-type
See "CREATE TABLE" for the description of built-in data types.

Rules

- ***Use of anchored data types:*** An anchored data type cannot refer to the following objects (SQLSTATE 428HS): a nickname, typed table, typed view, statistical view that is associated with an expression-based index, declared temporary table, row definition that is associated with a weakly typed cursor, object with a code page or collation that is different from the database code page or database collation.

Notes

- ***Privileges***: The definer of the user-defined type always receives the EXECUTE privilege WITH GRANT OPTION on all functions automatically generated for the distinct type.

  EXECUTE privilege on all functions automatically generated during the CREATE TYPE (Distinct) statement is granted to PUBLIC.
- Creating a distinct type with a schema name that does not already exist will result in the implicit creation of that schema provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- ***Additional generated functions***: When a strongly typed distinct type is created, the following functions are generated to cast to and from the source type:
  - One function to convert from the distinct type to the source type
  - One function to convert from the source type to the distinct type
  - One function to convert from INTEGER to the distinct type if the source type is SMALLINT
  - One function to convert from VARCHAR to the distinct type if the source type is CHAR
  - One function to convert from VARCHAR to the distinct type if the source type is BINARY
  - One function to convert from VARGRAPHIC to the distinct type if the source type is GRAPHIC.

  In general these functions will have the following format:

```
CREATE FUNCTION source-type-name (distinct-type-name)
  RETURNS source-type-name ...

CREATE FUNCTION distinct-type-name (source-type-name)
  RETURNS distinct-type-name ...
```

  In cases in which the source type is a parameterized type, the function to convert from the distinct type to the source type will have as function name the name of the source type without the parameters (see Table 146 on page 1492 for details). The type of the return value of this function will include the parameters given on the CREATE TYPE (Distinct) statement. The function to convert from the source

type to the distinct type will have an input parameter whose type is the source type including its parameters. For example,

```
CREATE TYPE T_SHOESIZE AS CHAR(2)

CREATE TYPE T_MILES AS DOUBLE
```

will generate the following functions:

```
FUNCTION CHAR (T_SHOESIZE) RETURNS CHAR (2)

FUNCTION T_SHOESIZE (CHAR (2))
RETURNS T_SHOESIZE

FUNCTION DOUBLE (T_MILES) RETURNS DOUBLE

FUNCTION T_MILES (DOUBLE) RETURNS T_MILES
```

The schema of the generated cast functions is the same as the schema of the distinct type. No other function with this name and with the same signature may already exist in the database (SQLSTATE 42710).

The following table gives the names of the functions to convert from the distinct type to the source type and from the source type to the distinct type for all predefined data types.

Table 146. CAST functions on distinct types

Source Type Name	Function Name	Parameter	Return-type
SMALLINT	*distinct-type-name*	SMALLINT	*distinct-type-name*
SMALLINT	*distinct-type-name*	INTEGER	*distinct-type-name*
SMALLINT	SMALLINT	*distinct-type-name*	SMALLINT
INTEGER	*distinct-type-name*	INTEGER	*distinct-type-name*
INTEGER	INTEGER	*distinct-type-name*	INTEGER
BIGINT	*distinct-type-name*	BIGINT	*distinct-type-name*
BIGINT	BIGINT	*distinct-type-name*	BIGINT
DECIMAL	*distinct-type-name*	DECIMAL (*p,s*)	*distinct-type-name*
DECIMAL	DECIMAL	*distinct-type-name*	DECIMAL (*p,s*)
NUMERIC	*distinct-type-name*	DECIMAL (*p,s*)	*distinct-type-name*
NUMERIC	DECIMAL	*distinct-type-name*	DECIMAL (*p,s*)
REAL	*distinct-type-name*	REAL	*distinct-type-name*
REAL	*distinct-type-name*	DOUBLE	*distinct-type-name*
REAL	REAL	*distinct-type-name*	REAL
FLOAT(*n*) where *n*<=24	*distinct-type-name*	REAL	*distinct-type-name*
FLOAT(*n*) where *n*<=24	*distinct-type-name*	DOUBLE	*distinct-type-name*
FLOAT(*n*) where *n*<=24	REAL	*distinct-type-name*	REAL
FLOAT(*n*) where *n*>24	*distinct-type-name*	DOUBLE	*distinct-type-name*
FLOAT(*n*) where *n*>24	DOUBLE	*distinct-type-name*	DOUBLE
FLOAT	*distinct-type-name*	DOUBLE	*distinct-type-name*
FLOAT	DOUBLE	*distinct-type-name*	DOUBLE

Table 146. CAST functions on distinct types (continued)

Source Type Name	Function Name	Parameter	Return-type
DOUBLE	*distinct-type-name*	DOUBLE	*distinct-type-name*
DOUBLE	DOUBLE	*distinct-type-name*	DOUBLE
DOUBLE PRECISION	*distinct-type-name*	DOUBLE	*distinct-type-name*
DOUBLE PRECISION	DOUBLE	*distinct-type-name*	DOUBLE
DECFLOAT	*distinct-type-name*	DECFLOAT(*n*)	*distinct-type-name*
DECFLOAT	DECFLOAT	*distinct-type-name*	DECFLOAT(*n*)
CHAR	*distinct-type-name*	CHAR (*n*)	*distinct-type-name*
CHAR	CHAR	*distinct-type-name*	CHAR (*n*)
CHAR	*distinct-type-name*	VARCHAR (*n*)	*distinct-type-name*
VARCHAR	*distinct-type-name*	VARCHAR (*n*)	*distinct-type-name*
VARCHAR	VARCHAR	*distinct-type-name*	VARCHAR (*n*)
CLOB	*distinct-type-name*	CLOB (*n*)	*distinct-type-name*
CLOB	CLOB	*distinct-type-name*	CLOB (*n*)
GRAPHIC	*distinct-type-name*	GRAPHIC (*n*)	*distinct-type-name*
GRAPHIC	GRAPHIC	*distinct-type-name*	GRAPHIC (*n*)
GRAPHIC	*distinct-type-name*	VARGRAPHIC (*n*)	*distinct-type-name*
VARGRAPHIC	*distinct-type-name*	VARGRAPHIC (*n*)	*distinct-type-name*
VARGRAPHIC	VARGRAPHIC	*distinct-type-name*	VARGRAPHIC (*n*)
DBCLOB	*distinct-type-name*	DBCLOB (*n*)	*distinct-type-name*
DBCLOB	DBCLOB	*distinct-type-name*	DBCLOB (*n*)
BINARY	*distinct-type-name*	BINARY (*n*)	*distinct-type-name*
BINARY	BINARY	*distinct-type-name*	BINARY (*n*)
BINARY	*distinct-type-name*	VARBINARY (*n*)	*distinct-type-name*
VARBINARY	*distinct-type-name*	VARBINARY (*n*)	*distinct-type-name*
VARBINARY	VARBINARY	*distinct-type-name*	VARBINARY (*n*)
BLOB	*distinct-type-name*	BLOB (*n*)	*distinct-type-name*
BLOB	BLOB	*distinct-type-name*	BLOB (*n*)
DATE	*distinct-type-name*	DATE	*distinct-type-name*
DATE	DATE	*distinct-type-name*	DATE
TIME	*distinct-type-name*	TIME	*distinct-type-name*
TIME	TIME	*distinct-type-name*	TIME
TIMESTAMP	*distinct-type-name*	TIMESTAMP(*p*	*distinct-type-name*
TIMESTAMP	TIMESTAMP	*distinct-type-name*	TIMESTAMP(*p*)
BOOLEAN	*distinct-type-name*	BOOLEAN	*distinct-type-name*

Table 146. CAST functions on distinct types (continued)

Source Type Name	Function Name	Parameter	Return-type
BOOLEAN	BOOLEAN	*distinct-type-name*	BOOLEAN

Note: NUMERIC and FLOAT are not recommended when creating a user-defined type for a portable application. DECIMAL and DOUBLE should be used instead.

The functions described in the preceding table and the comparison operator functions are the only functions that are generated automatically when distinct types are defined. Consequently, none of the built-in functions (AVG, MAX, LENGTH, and so on) are supported for strongly typed distinct types until the CREATE FUNCTION statement is used to register user-defined functions for the strongly typed distinct type, and those user-defined functions are sourced on the appropriate built-in functions. In particular, note that it is possible to register user-defined functions that are sourced on the built-in column functions.

When a strongly typed distinct type is created, system-generated comparison operators are created when the source type supports comparisons . Creation of these comparison operators will generate entries in the SYSCAT.ROUTINES catalog view for the new functions.

The schema name of the distinct type must be included in the SQL path or the FUNCPATH BIND option for successful use of these operators and cast functions in SQL statements.

- When a weakly typed distinct type is created, no additional functions need to be generated or created because the weak type rules allow a weakly typed distinct type to be used in the same context where the source type can be used.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - CREATE DISTINCT TYPE can be specified in place of CREATE TYPE
  - The LONG VARCHAR and LONG VARGRAPHIC data types and cast functions are supported but are deprecated and might be removed in a future release. The WITH COMPARISONS clause continues to not support the LONG VARCHAR and LONG VARGRAPHIC data types.
  - The WITH COMPARISONS clause, which specifies that system-generated comparison operators are to be created for comparing two instances of the distinct type, can be specified as the last clause of the statement if WITH WEAK TYPE RULES is not specified. Use WITH COMPARISONS only if it is required for compatibility with earlier versions of products in the Db2 family. If the source data type is either BLOB, CLOB, or DBCLOB and WITH COMPARISONS is specified, a warning occurs as in previous releases.
  - ALLOW NULL, or just NULL, can be specified as the opposite of NOT NULL. This is the default nullability characteristic of the distinct type if neither the ALLOW NULL clause nor the NOT NULL clause are specified. Specification of ALLOW NULL is not considered to define a data type constraint for the distinct type.

Examples

- *Example 1:* Create a strongly typed distinct type named SHOESIZE that is based on an INTEGER data type.

```
CREATE TYPE SHOESIZE AS INTEGER
```

This will also result in the creation of comparison operators (=, <>, <, <=, >, >=) and cast functions INTEGER(SHOESIZE) returning INTEGER and SHOESIZE(INTEGER) returning SHOESIZE.

- *Example 2:* Create a strongly typed distinct type named MILES that is based on a DOUBLE data type.

```
CREATE TYPE MILES AS DOUBLE
```

This will also result in the creation of comparison operators (=, <>, <, =, >, >=) and cast functions DOUBLE(MILES) returning DOUBLE and MILES(DOUBLE) returning MILES.

- *Example 3:* Create a weakly typed distinct type named BONUS that is based on an INTEGER data type and represents a percentage which cannot exceed 100.

```
CREATE TYPE BONUS AS INTEGER WITH WEAK TYPE RULES
      CHECK(VALUE >= 0 AND VALUE <= 100)
```

Because it is defined with weak type rules, comparison and cast functions are not generated for the weakly typed distinct type called BONUS.

- *Example 4:* Create a weakly typed distinct type named SALARY that is based on a DOUBLE data type which cannot be NULL and where the upper range is limited to less than one hundred thousand.

```
CREATE TYPE SALARY AS DOUBLE WITH WEAK TYPE RULES
      NOT NULL CHECK(VALUE < 100000)
```

CREATE TYPE (row)

The CREATE TYPE (row) statement defines a row type. A row type includes one or more fields with associated data types that make up a row of data.

Invocation

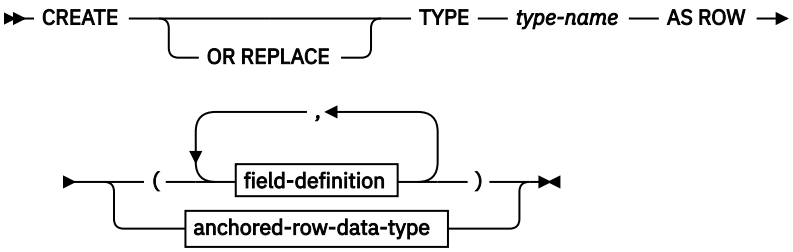
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

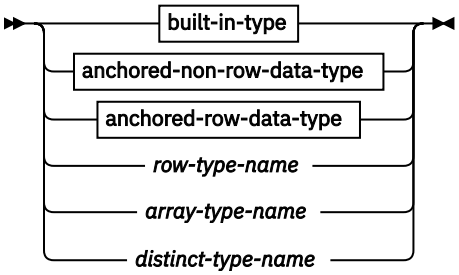
- IMPLICIT_SCHEMA authority on the database, if the schema name of the row type does not refer to an existing schema
- CREATEIN privilege on the schema, if the schema name of the row type refers to an existing schema
- SCHEMAADM authority on the schema, if the schema name of the row type refers to an existing schema
- DBADM authority

Syntax

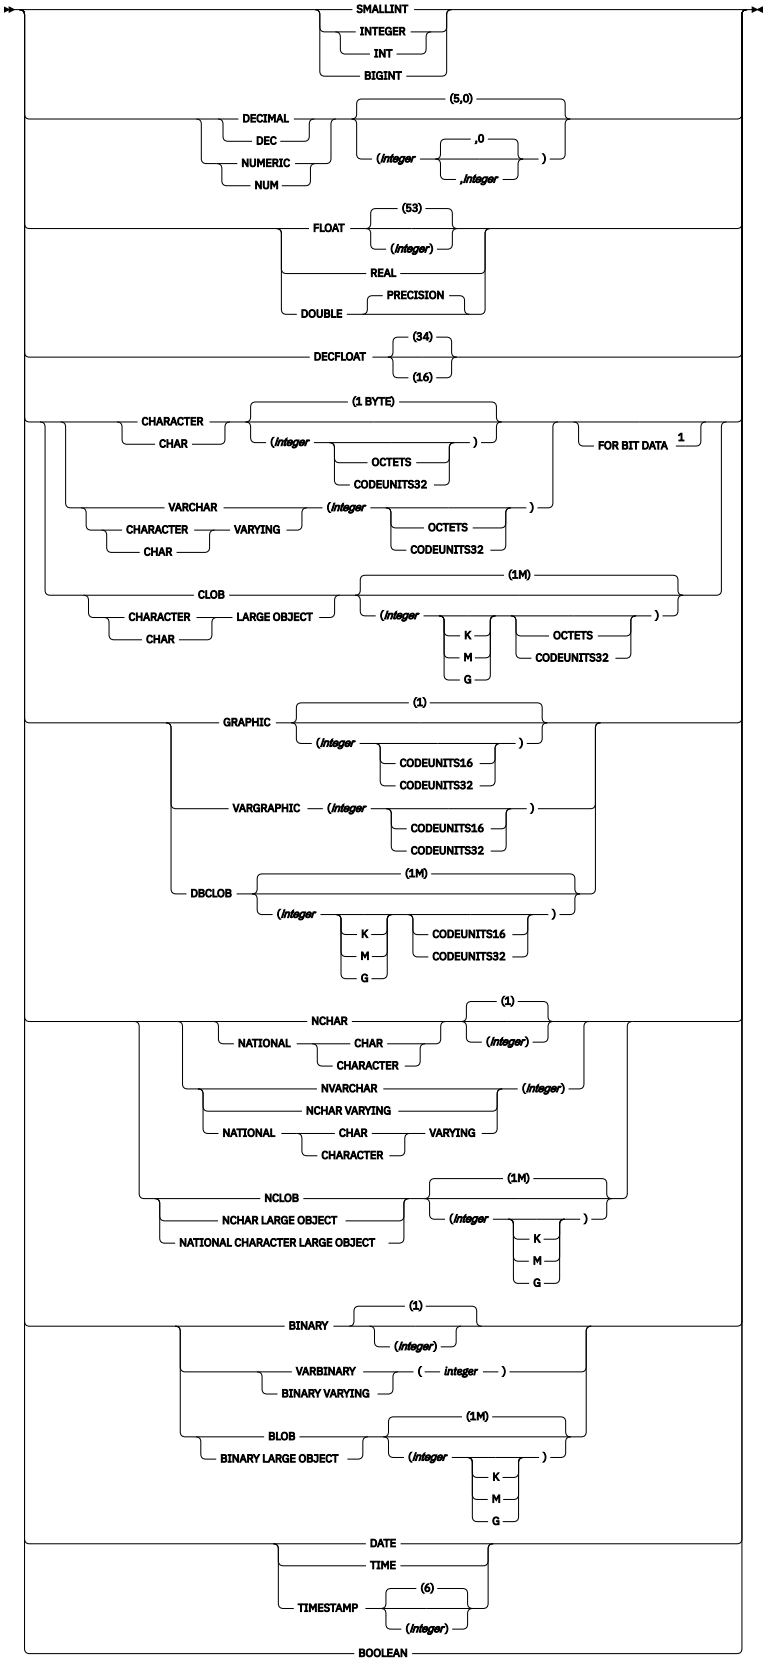


field-definition

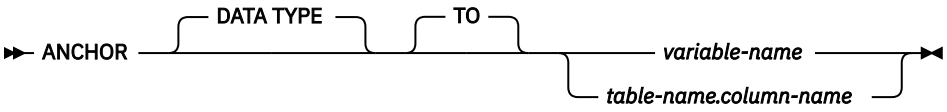
data-type



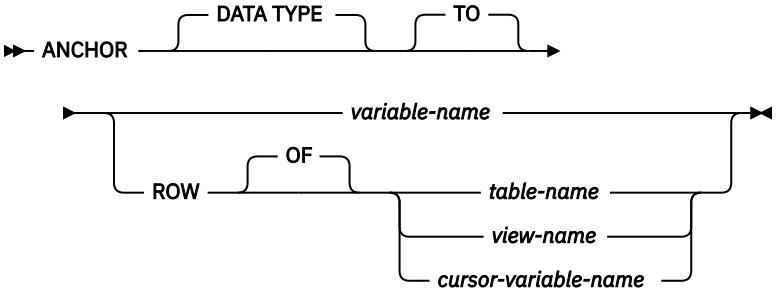
built-in type



anchored-non-row-data-type



anchored-row-data-type



Notes:

[1] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

Description

OR REPLACE
Specifies to replace the definition for the data type if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that functions and methods are invalidated instead of dropped when they have parameters or a return value defined with the data type being replaced. The existing definition must not be a structured type (SQLSTATE 42809). This option is ignored if a definition for the data type does not exist at the current server.

type-name
Names the type. The name, including the implicit or explicit qualifier, cannot identify any other type (built-in, structured, array, row, or distinct) already described in the catalog. The unqualified name cannot be the same as the name of a built-in data type (SQLSTATE 42918).

Several names used as keywords in predicates are reserved for system use, and cannot be used as a type name (SQLSTATE 42939). These names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators.

If a two-part name is specified, the schema name cannot begin with the characters SYS (SQLSTATE 42939).

field-definition
Defines the fields of the row type.

field-name
Specifies the name of a field within the row type. The name cannot be the same as any other field of this row type (SQLSTATE 42711).

data-type
Specifies the data type of the field.

built-in-type
Specifies a built-in data type. See "CREATE TABLE" for the description of built-in data types. Built-in types include the data types described in "CREATE TABLE", other than reference, SYSPROC.DB2SECURITYLABEL, XML, or user-defined types (SQLSTATE 429C2).

row-type-name
Specifies the name of a user-defined row type. If a *row-type-name* is specified without a schema name, the *row-type-name* is resolved by searching the schemas in the SQL path. Row types can be nested as field types of a row type with a maximum nesting level of sixteen.

array-type-name
Specifies an array type. If an *array-type-name* is specified without a schema name, the *array-type-name* is resolved by searching the schemas in the SQL path. Array types can be nested as field types of a row type with a maximum nesting level of sixteen.

distinct-type-name
Specifies a user-defined distinct data type. The specified distinct type cannot have any data type constraints (SQLSTATE 429C5).

anchored-non-row-data-type
Identifies another object used to determine the data type. The data type of the anchor object is has the same limitations that apply when specifying the data type directly.

ANCHOR DATA TYPE TO
Indicates that an anchored data type is used to specify the data type.

variable-name
Identifies a global variable with a data type that is a supported row field data type. The data type of the global variable is used as the data type for the field.

table-name.column-name
Identifies a column name of an existing table or view with a data type that is a built-in-type or a distinct type. The data type of the column is used as the data type for the field.

anchored-row-data-type
Identifies row information from another object to use as the fields of the row.

ANCHOR DATA TYPE TO
Indicates an anchored data type is used to specify the data type.

variable-name
Identifies a global variable. The data type of the referenced variable must be a row type.

ROW OF *table-name* or *view-name*
Specifies a row of fields with names and data types that are based on the column names and column data types of the table identified by *table-name* or the view identified by *view-name*. The data types of the anchor object columns have the same limitations that apply to field data types.

ROW OF *cursor-variable-name*
Specifies a row of fields with names and data types that are based on the field names and field data types of the cursor variable identified by *cursor-variable-name*. The specified cursor variable must be one of the following objects (SQLSTATE 428HS):

- A global variable with a strongly typed cursor data type
- A global variable with a weakly typed cursor data type that was created or declared with a CONSTANT clause specifying a *select-statement* where all the result columns are named.

Rules

- ***Use of anchored data types:*** An anchored data type cannot refer to the following objects (SQLSTATE 428HS): a nickname, typed table, typed view, statistical view that is associated with an expression-based index, declared temporary table, row definition that is associated with a weakly typed cursor, object with a code page or collation that is different from the database code page or database collation.

Notes

- ***Row type usage:*** A row type can only be used as the data type of:
  - A local variable in a compound SQL (compiled) statement
  - A parameter of an SQL routine
  - The returns type of an SQL function
  - The element of an array type

  - A user-defined cursor type
  - A global variable
- A variable or parameter defined with a row type can only be used in compound SQL (compiled) statements

Example

- Create a row type based on the columns of the DEPARTMENT table.

```
CREATE TYPE DEPTROW AS ROW (DEPTNO   VARCHAR(3),
                            DEPTNAME VARCHAR(29),
                            MGRNO    CHAR(6),
                            ADMRDEPT CHAR(3),
                            LOCATION CHAR(16))
```

CREATE TYPE (structured)

The CREATE TYPE statement defines a user-defined structured type.

A user-defined structured type can include zero or more attributes. A structured type can be a subtype allowing attributes to be inherited from a supertype. Successful execution of the statement generates methods, for retrieving and updating values of attributes. Successful execution of the statement also generates functions, for constructing instances of a structured type used in a column, for casting between the reference type and its representation type, and for supporting the comparison operators (=, <>, <, <=, >, and >=) on the reference type.

The CREATE TYPE statement also defines any method specifications for user-defined methods to be used with the user-defined structured type.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the schema name of the type does not refer to an existing schema
- CREATEIN privilege on the schema, if the schema name of the type refers to an existing schema
- SCHEMAADM authority on the schema, if the schema name of the type refers to an existing schema
- DBADM authority

If UNDER is specified, and the authorization ID of the statement is not the same as the owner of the root type of the type hierarchy, SCHEMAADM authority on the schema containing the root type is required or DBADM authority is required.

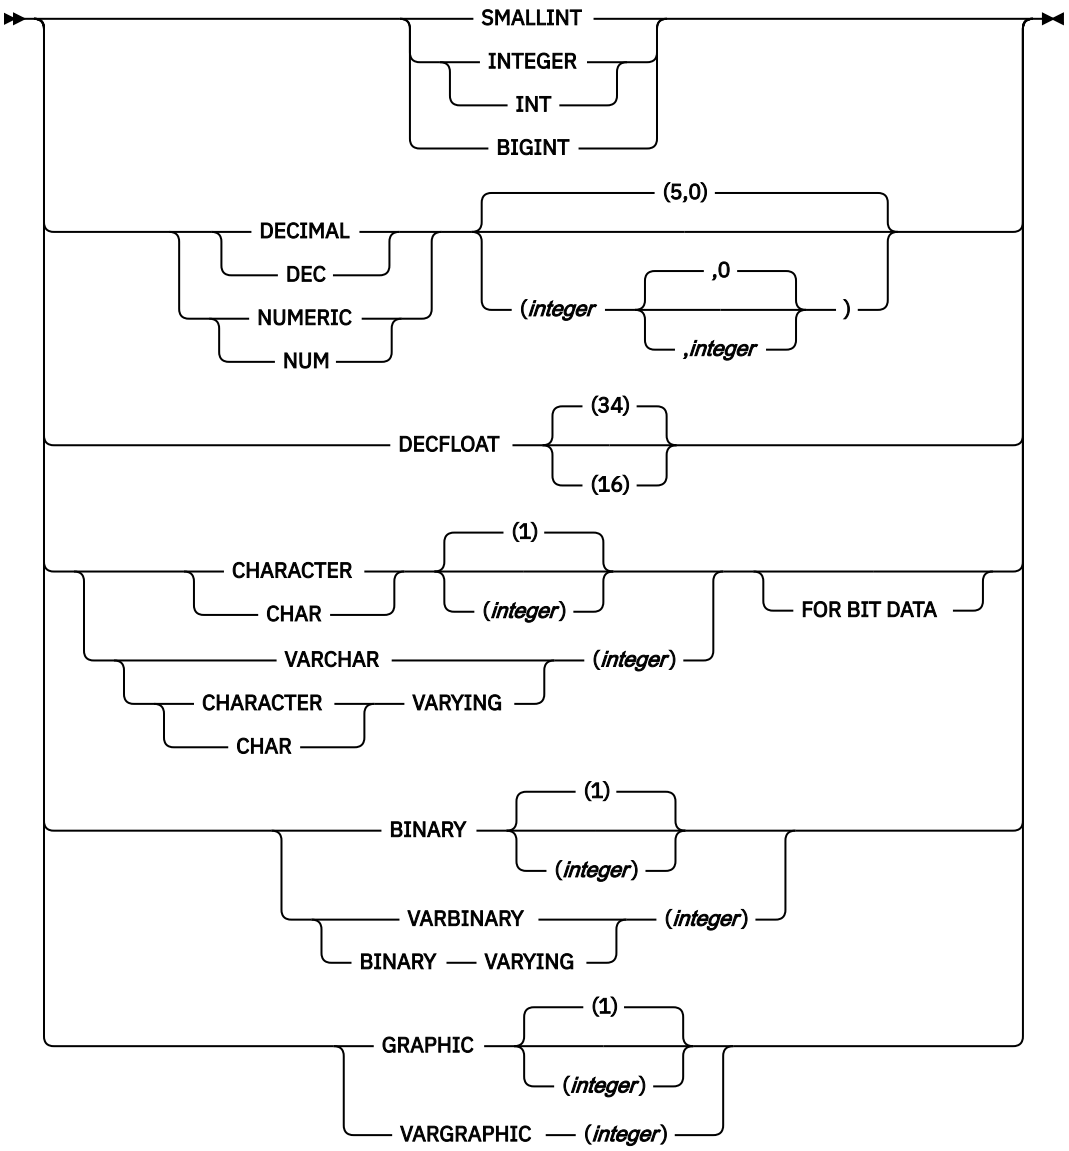
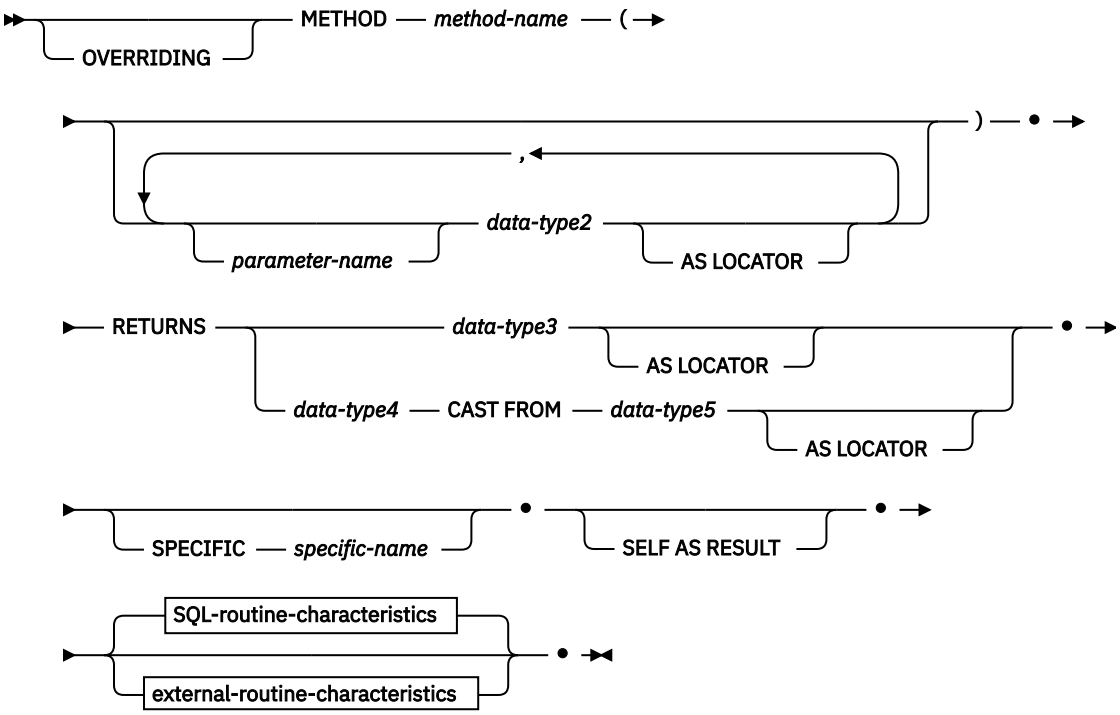
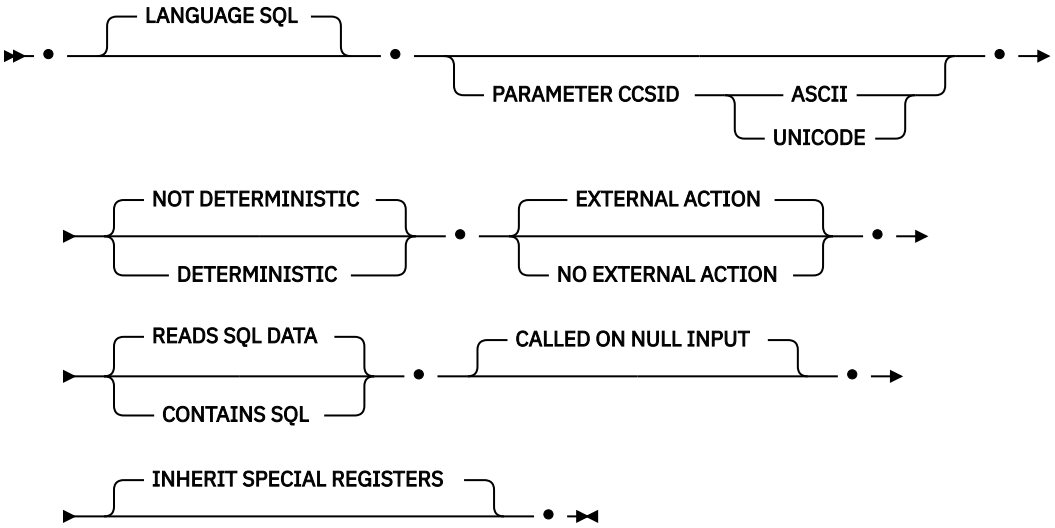
rep-type



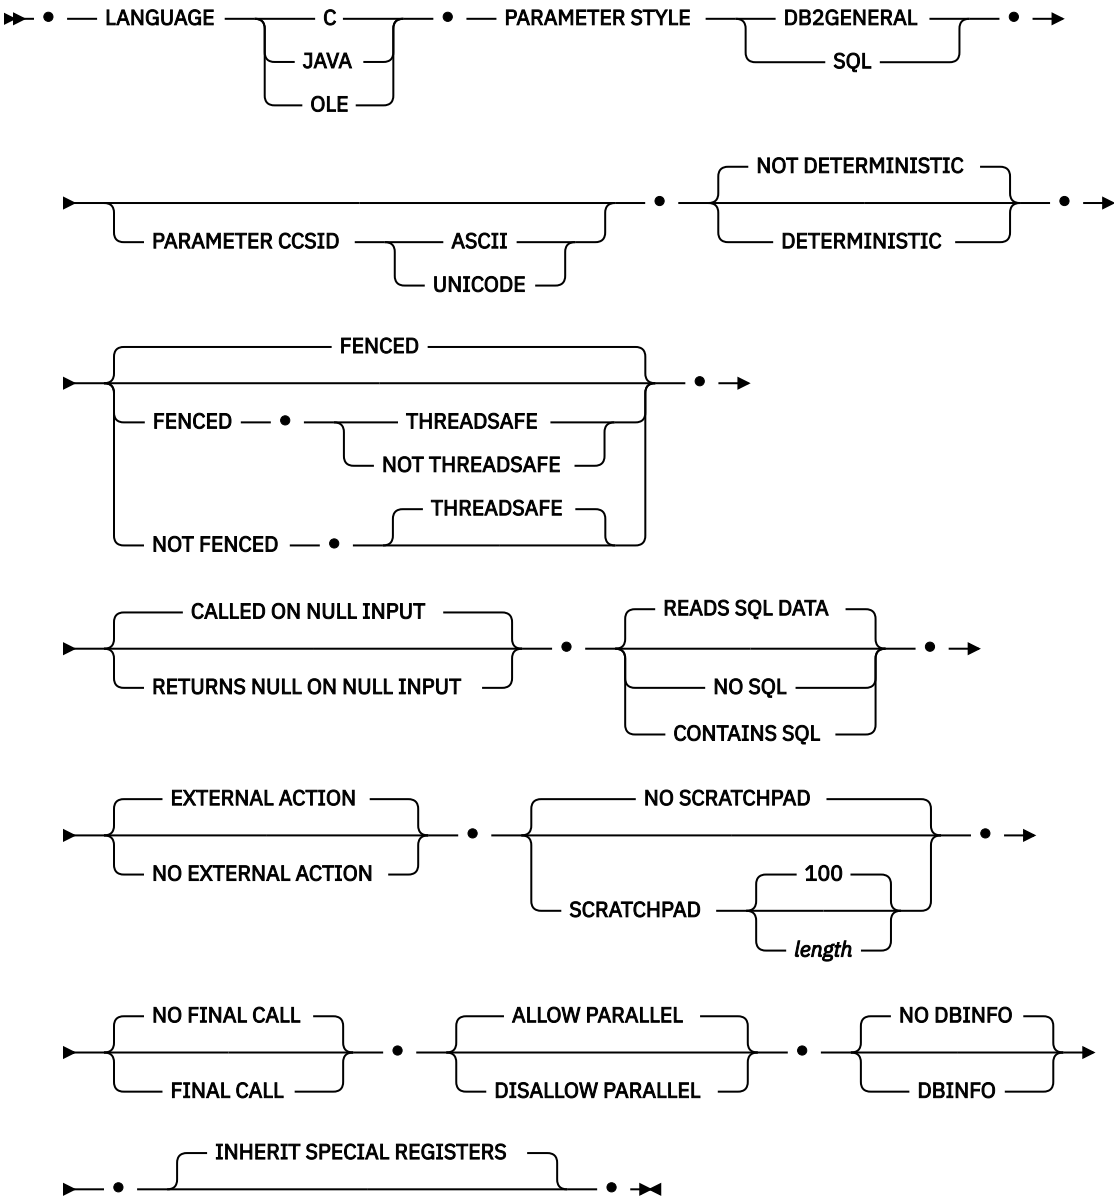
method-specification



SQL-routine-characteristics



external-routine-characteristics



Description

type-name

Names the type. The name, including the implicit or explicit qualifier, must not identify any other type (built-in, structured, or distinct) that already exists at the current server. The unqualified name must not be the same as the name of a built-in data type or BOOLEAN (SQLSTATE 42918). The unqualified name should also not be ARRAY, INTERVAL, or ROWID. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile or bind option implicitly specifies the qualifier for unqualified object names.

A number of names used as keywords in predicates are reserved for system use, and cannot be used as a *type-name* (SQLSTATE 42939). The names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators.

If a two-part *type-name* is specified, the schema name must not begin with the characters 'SYS' (SQLSTATE 42939).

UNDER *supertype-name*
Specifies that this structured type is a subtype under the specified *supertype-name*. The *supertype-name* must identify an existing structured type (SQLSTATE 42704). If *supertype-name* is specified without a schema name, the type is resolved by searching the schemas on the SQL path. The structured type includes all the attributes of the supertype followed by the additional attributes given in the *attribute-definition*.

attribute-definition
Defines the attributes of the structured type.

attribute-name
The name of an attribute. The *attribute-name* cannot be the same as any other attribute of this structured type or any supertype of this structured type (SQLSTATE 42711).

A number of names used as keywords in predicates are reserved for system use, and cannot be used as an *attribute-name* (SQLSTATE 42939). The names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators.

data-type
The data type of the attribute. It is one of the data types listed under "CREATE TABLE", other than XML or a weakly typed distinct type (SQLSTATE 42601). The data type must identify an existing data type (SQLSTATE 42704). If *data-type* is specified without a schema name, the type is resolved by searching the schemas on the SQL path. The description of various data types is given in "CREATE TABLE". If the attribute data type is a reference type, the target type of the reference must be a structured type that exists, or is created by this statement (SQLSTATE 42704).

To prevent type definitions that would, at run time, permit an instance of the type to directly or indirectly contain another instance of the same type or one of its subtypes, a type cannot be defined such that one of its attribute types directly or indirectly uses itself (SQLSTATE 428EP).

Character and graphic string data types cannot specify string units of CODEUNITS32.

lob-options
Specifies the options associated with LOB types (or distinct types based on LOB types). For a detailed description of *lob-options*, see "CREATE TABLE".

INSTANTIABLE or NOT INSTANTIABLE
Determines whether an instance of the structured type can be created. Implications of not instantiable structured types are:

- no constructor function is generated for a non-instantiable type
- a non-instantiable type cannot be used as the type of a table or view (SQLSTATE 428DP)
- a non-instantiable type can be used as the type of a column (only null values or instances of instantiable subtypes can be inserted into the column.

To create instances of a non-instantiable type, instantiable subtypes must be created. If NOT INSTANTIABLE is specified, no instance of the new type can be created.

INLINE LENGTH *integer*
This option indicates the maximum size (in bytes) of a structured type column instance to store inline with the rest of the values in the row of a table. Instances of a structured type or its subtypes, that are larger than the specified inline length, are stored separately from the base table row, similar to the way that LOB values are handled.

If the specified INLINE LENGTH is smaller than the size of the result of the constructor function for the newly-created type (32 bytes plus 10 bytes per attribute) and smaller than 292 bytes, an error results (SQLSTATE 429B2). Note that the number of attributes includes all attributes inherited from the supertype of the type.

The INLINE LENGTH for the type, whether specified or a default value, is the default inline length for columns that use the structured type. This default can be overridden at CREATE TABLE time.

INLINE LENGTH has no meaning when the structured type is used as the type of a typed table.

The default INLINE LENGTH for a structured type is calculated by the system. In the formulae that follow, the following terms are used:

short attribute
refers to an attribute with any of the following data types: SMALLINT, INTEGER, BIGINT, REAL, DOUBLE, FLOAT, DATE, or TIME. Also included are distinct types or reference types based on these types.

non-short attribute
refers to an attribute of any of the remaining data types, or distinct types based on those data types.

The system calculates the default inline length as follows:

1. Determine the added space requirements for non-short attributes using the following formula:

   *space_for_non_short_attribute*s = SUM(*attributelength* + n)

   n is defined as:

   - 0 bytes for nested structured type attributes
   - 2 bytes for non-LOB attributes
   - 9 bytes for LOB attributes

   attributelength is based on the data type specified for the attribute as shown in Table 147 on page 1506.
2. Calculate the total default inline length using the following formula:

   default_length(*structured_type*) = (*number_of_attributes* * 10) + 32 + *space_for_non-short_attributes*

   number_of_attributes is the total number of attributes for the structured type, including attributes that are inherited from its supertype. However, *number_of_attributes* does not include any attributes defined for any subtype of *structured_type*.

Table 147. Byte Counts for Attribute Data Types

Attribute Data Type	**Byte Count**
DECIMAL	The integral part of (*p* / 2) + 1, where *p* is the precision
DECFLOAT(*n*)	If *n* is 16, the byte count is 8; if *n* is 34, the byte count is 16
CHAR(*n*)	*n*
VARCHAR(*n*)	*n*
GRAPHIC(*n*)	*n* * 2
VARGRAPHIC(*n*)	*n* * 2
TIMESTAMP	10
LOB type	Each LOB attribute has a LOB descriptor in the structured type instance that points to the location of the actual value. The size of the descriptor varies according to the maximum length defined for the LOB attribute (see Table 148 on page 1507.
Distinct type	Length of the source type of the distinct type
Reference type	Length of the built-in data type on which the reference type is based
Structured type	inline_length(*attribute_type*)

Table 148. LOB Descriptor Size as a Function of the Maximum LOB Length	
Maximum LOB Length	**LOB Descriptor Size**
1024	68
8192	92
65 536	116
524 000	140
4 190 000	164
134 000 000	196
536 000 000	220
1 070 000 000	252
1 470 000 000	276
2 147 483 647	312

WITHOUT COMPARISONS
Indicates that there are no comparison functions supported for instances of the structured type.

NOT FINAL
Indicates that the structured type may be used as a supertype.

MODE DB2SQL
This clause is required and allows for direct invocation of the constructor function on this type.

WITH FUNCTION ACCESS
Indicates that all methods of this type and its subtypes, including methods created in the future, can be accessed using functional notation. This clause can be specified only for the root type of a structured type hierarchy (the UNDER clause is not specified) (SQLSTATE 42613). This clause is provided to allow the use of functional notation for those applications that prefer this form of notation over method invocation notation.

REF USING *rep-type*
Defines the built-in data type used as the representation (underlying data type) for the reference type of this structured type and all its subtypes. This clause can only be specified for the root type of a structured type hierarchy (UNDER clause is not specified) (SQLSTATE 42613). The *rep-type* cannot be a REAL, FLOAT, DECFLOAT, BLOB, CLOB, DBCLOB, array type, or structured type, and must have a length less than or equal to 32 672 bytes (SQLSTATE 42613).

If this clause is not specified for the root type of a structured type hierarchy, then REF USING VARCHAR(16) FOR BIT DATA is assumed.

CAST (SOURCE AS REF) WITH *funcname1*
Defines the name of the system-generated function that casts a value with the data type *rep-type* to the reference type of this structured type. A schema name must not be specified as part of *funcname1* (SQLSTATE 42601). The cast function is created in the same schema as the structured type. If the clause is not specified, the default value for *funcname1* is *type-name* (the name of the structured type). A function signature matching *funcname1(rep-type)* must not already exist in the same schema (SQLSTATE 42710).

CAST (REF AS SOURCE) WITH *funcname2*
Defines the name of the system-generated function that casts a reference type value for this structured type to the data type *rep-type*. A schema name must not be specified as part of *funcname2* (SQLSTATE 42601). The cast function is created in the same schema as the structured type. If the clause is not specified, the default value for *funcname2* is *rep-type* (the name of the representation type).

method-specification

Defines the methods for this type. A method cannot actually be used until it is given a body with a CREATE METHOD statement (SQLSTATE 42884).

OVERRIDING

Specifies that the method being defined overrides a method of a supertype of the type being defined. Overriding enables one to re-implement methods in subtypes, thereby providing more specific functionality. Overriding is not supported for the following types of methods:

- Table and row methods
- External methods declared with PARAMETER STYLE JAVA
- Methods that can be used as predicates in an index extension
- System-generated mutator or observer methods

Attempting to override such a method will result in an error (SQLSTATE 42745).

If a method is to be a valid overriding method, there must already exist one original method for one of the proper supertypes of the type being defined, and the following relationships must exist between the overriding method and the original method:

- The method name of the method being defined and the original method are equivalent.
- The method being defined and the original method have the same number of parameters.
- The data type of each parameter of the method being defined and the data type of the corresponding parameters of the original method are identical. This requirement excludes the implicit SELF parameter.

If such an original method does not exist, an error is returned (SQLSTATE 428FV).

The overriding method inherits the following attributes from the original method:

- Language
- Determinism indication
- External action indication
- An indication whether this method should be called if any of its arguments is the null value
- Result cast (if specified in the original method)
- SELF AS RESULT indication
- The SQL-data access or CONTAINS SQL indication
- For external methods:
  - Parameter style
  - Locator indication of the parameters and of the result (if specified in the original method)
  - FENCED, SCRATCHPAD, FINAL CALL, ALLOW PARALLEL, and DBINFO indication
  - INHERIT SPECIAL REGISTER and THREADSAFE indication

method-name

Names the method being defined. It must be an unqualified SQL identifier (SQLSTATE 42601). The method name is implicitly qualified with the schema used for CREATE TYPE.

A number of names used as keywords in predicates are reserved for system use, and cannot be used as a *method-name* (SQLSTATE 42939). The names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators.

In general, the same name can be used for more than one method if there is some difference in their signatures.

parameter-name

Identifies the parameter name. It cannot be SELF, which is the name for the implicit subject parameter of a method (SQLSTATE 42734). If the method is an SQL method, all its parameters

must have names (SQLSTATE 42629). If the method being declared overrides another method, the parameter name must be exactly the same as the name of the corresponding parameter of the overridden method; otherwise, an error is returned (SQLSTATE 428FV).

data-type2
Specifies the data type of each parameter. One entry in the list must be specified for each parameter that the method will expect to receive. No more than 90 parameters are allowed, including the implicit SELF parameter. If this limit is exceeded, an error is raised (SQLSTATE 54023).

You can specify SQL data types and abbreviations that can be specified as a column type in the CREATE TABLE statement, and that have equivalents in the language that is being used to write the method. For details on the mapping between SQL data types and host language data types, see the topic that pertains to your language from the following list of related topics.

Note: If the SQL data type in question is a structured type, there is no default mapping to a host language data type. A user-defined transform function must be used to create a mapping between the structured type and the host language data type.

DECIMAL (or NUMERIC) and decimal floating-point are invalid with LANGUAGE C and OLE (SQLSTATE 42815).

XML data types cannot be used (SQLSTATE 42815).

REF may be specified, but it does not have a defined scope. Inside the body of the method, a reference-type can be used in a path-expression only by first casting it to have a scope. Similarly, a reference returned by a method can be used in a path-expression only by first casting it to have a scope.

AS LOCATOR
For LOB types or distinct types which are based on a LOB type, the AS LOCATOR clause can be added. This indicates that a LOB locator is to be passed to the method instead of the actual value. This saves greatly in the number of bytes passed to the method, and may save as well in performance, particularly in the case where only a few bytes of the value are actually of interest to the method.

An error is raised (SQLSTATE 42601) if AS LOCATOR is specified for a type other than a LOB or a distinct type based on a LOB.

If the method is FENCED, or if LANGUAGE is SQL, the AS LOCATOR clause cannot be specified (SQLSTATE 42613).

If the method being declared overrides another method, the AS LOCATOR indication of the parameter must match exactly the AS LOCATOR indication of the corresponding parameter of the overridden method (SQLSTATE 428FV).

If the method being declared overrides another method, the FOR BIT DATA indication of each parameter must match exactly the FOR BIT DATA indication of the corresponding parameter of the overridden method. (SQLSTATE 428FV).

RETURNS
This mandatory clause identifies the method's result.

data-type3
Specifies the data type of the method's result. In this case, exactly the same considerations apply as for the parameters of methods specified in the description for data-type2.

AS LOCATOR
For LOB types or distinct types which are based on LOB types, the AS LOCATOR clause can be added. This indicates that a LOB locator is to be passed from the method instead of the actual value.

An error is raised (SQLSTATE 42601) if AS LOCATOR is specified for a type other than a LOB or a distinct type based on a LOB.

If the method is FENCED, or if LANGUAGE is SQL, the AS LOCATOR clause cannot be specified (SQLSTATE 42613).

If the method being defined overrides another method, this clause cannot be specified (SQLSTATE 428FV).

If the method overrides another method, *data-type3* must be a subtype of the data type of the result of the overridden method if this data type is a structured type; otherwise both data types must be identical (SQLSTATE 428FV).

data-type4* CAST FROM *data-type5

Specifies the data type of the method's result.

This clause is used to return a different data type to the invoking statement from the data type returned by the method code. The *data-type5* must be castable to the *data-type4* parameter. If it is not castable, an error is returned (SQLSTATE 42880).

Because the length, precision, or scale for *data-type4* can be inferred from *data-type5*, it is not necessary (but still permitted) to specify the length, precision, or scale for parameterized types specified for *data-type4*. Instead, empty parentheses can be used, such as VARCHAR(), for example. FLOAT() cannot be used (SQLSTATE 42601), because the parameter value indicates different data types (REAL or DOUBLE).

A distinct type is not valid as the type specified in *data-type5* (SQLSTATE 42815). XML is not valid as the type specified in *data-type4* or *data-type5* (SQLSTATE 42815).

The cast operation is also subject to runtime checks that might result in conversion errors being returned.

AS LOCATOR

For LOB types or distinct types which are based on LOB types, the AS LOCATOR clause can be added. This indicates that a LOB locator is to be passed from the method instead of the actual value.

An error is raised (SQLSTATE 42601) if AS LOCATOR is specified for a type other than a LOB or a distinct type based on a LOB.

If the method is FENCED, or if LANGUAGE is SQL, the AS LOCATOR clause cannot be specified (SQLSTATE 42613).

If the method being defined overrides another method, this clause cannot be specified (SQLSTATE 428FV).

If the method being defined overrides another method, the FOR BIT DATA clause cannot be specified (SQLSTATE 428FV).

SPECIFIC *specific-name*

Provides a unique name for the instance of the method that is being defined. This specific name can be used when creating the method body or dropping the method. It can never be used to invoke the method. The unqualified form of *specific-name* is an SQL identifier (with a maximum length of 18). The qualified form is a schema-name followed by a period and an SQL identifier. The name, including the implicit or explicit qualifier, must not identify another specific method name that exists at the application server; otherwise an error is raised (SQLSTATE 42710).

The *specific-name* may be the same as an existing *method-name*.

If no qualifier is specified, the qualifier that was used for *type-name* is used. If a qualifier is specified, it must be the same as the explicit or implicit qualifier of *type-name* or an error is raised (SQLSTATE 42882).

If *specific-name* is not specified, a unique name is generated by the database manager. The unique name is SQL followed by a character timestamp, SQLyymmddhhmmssxxx.

SELF AS RESULT

Identifies this method as a type-preserving method, which is defined as follows:

- The declared return type must be the same as the declared subject-type (SQLSTATE 428EQ).

- When an SQL statement is compiled and resolves to a type preserving method, the static type of the result of the method is the same as the static type of the subject argument.
- The method must be implemented in such a way that the dynamic type of the result is the same as the dynamic type of the subject argument (SQLSTATE 2200G), and the result cannot be NULL (SQLSTATE 22004).

If the method being defined overrides another method, this clause cannot be specified (SQLSTATE 428FV).

SQL-routine-characteristics
Specifies the characteristics of the method body that will be defined for this type using CREATE METHOD.

LANGUAGE SQL
This clause is used to indicate that the method is written in SQL with a single RETURN statement. The method body is specified using the CREATE METHOD statement.

PARAMETER CCSID
Specifies the encoding scheme to use for all string data passed into and out of the SQL method. If the PARAMETER CCSID clause is not specified, the default is PARAMETER CCSID UNICODE for Unicode databases, and PARAMETER CCSID ASCII for all other databases.

ASCII
Specifies that string data is encoded in the database code page. If the database is a Unicode database, PARAMETER CCSID ASCII cannot be specified (SQLSTATE 56031).

UNICODE
Specifies that character data is in UTF-8, and that graphic data is in UCS-2. If the database is not a Unicode database, PARAMETER CCSID UNICODE cannot be specified (SQLSTATE 56031).

NOT DETERMINISTIC or DETERMINISTIC
This optional clause specifies whether the method always returns the same results for given argument values (DETERMINISTIC) or whether the method depends on some state values that affect the results (NOT DETERMINISTIC). That is, a DETERMINISTIC method must always return the same result from successive invocations with identical inputs. Optimizations taking advantage of the fact that identical inputs always produce the same results are prevented by specifying NOT DETERMINISTIC. NOT DETERMINISTIC must be explicitly or implicitly specified if the body of the method accesses a special register, or calls another non-deterministic routine (SQLSTATE 428C2).

EXTERNAL ACTION or NO EXTERNAL ACTION
This optional clause specifies whether or not the method takes some action that changes the state of an object not managed by the database manager. Optimizations that assume methods have no external impacts are prevented by specifying EXTERNAL ACTION. For example: sending a message, ringing a bell, or writing a record to a file.

READS SQL DATA or CONTAINS SQL
Specifies the classification of SQL statements that the method can run. The database manager verifies that the SQL statements that the method issues are consistent with this specification.

For the classification of each statement, see "SQL statements that can be executed in routines and triggers" in Developing User-defined Routines (SQL and External).

Because the SQL statement supported is the RETURN statement, the distinction has to do with whether the expression is a subquery.

The default is READS SQL DATA.

READS SQL DATA
Specifies that the method can run statements with a data access classification of READS SQL DATA or CONTAINS SQL. The method cannot run SQL statements that modify data (SQLSTATE 42985). Nicknames cannot be referenced in the SQL statement (SQLSTATE 42997).

CONTAINS SQL
Specifies that the method can run only SQL statements with a data access classification of CONTAINS SQL. The method cannot run any SQL statements that read or modify data (SQLSTATE 42985).

CALLED ON NULL INPUT
This optional clause indicates that regardless of whether any arguments are null, the user-defined method is called. It can return a null value or a normal (non-null) value. However, responsibility for testing for null argument values lies with the method.

If the method being defined overrides another method, this clause cannot be specified (SQLSTATE 428FV).

NULL CALL can be used as a synonym for CALLED ON NULL INPUT.

INHERIT SPECIAL REGISTERS
This optional clause specifies that updatable special registers in the method will inherit their initial values from the environment of the invoking statement. For a method invoked in the select-statement of a cursor, the initial values are inherited from the environment in which the cursor is opened. For a routine invoked in a nested object (for example a trigger or view), the initial values are inherited from the runtime environment (not inherited from the object definition).

No changes to the special registers are passed back to the invoker of the function.

Non-updatable special registers, such as the datetime special registers, reflect a property of the statement currently executing, and are therefore set to their default values.

external-routine-characteristics

LANGUAGE
This mandatory clause is used to specify the language interface convention to which the user-defined method body is written.

C
This means the database manager will call the user-defined method as if it were a C function. The user-defined method must conform to the C language calling and linkage convention as defined by the standard ANSI C prototype.

JAVA
This means the database manager will call the user-defined method as a method in a Java class.

OLE
This means the database manager will call the user-defined method as if it were a method exposed by an OLE automation object. The method must conform with the OLE automation data types and invocation mechanism as described in the *OLE Automation Programmer's Reference*.

LANGUAGE OLE is only supported for user-defined methods stored in Windows 32-bit operating systems. THREADSAFE may not be specified for methods defined with LANGUAGE OLE (SQLSTATE 42613).

PARAMETER STYLE
This clause is used to specify the conventions used for passing parameters to and returning the value from methods.

DB2GENERAL
Used to specify the conventions for passing parameters to and returning the value from external methods that are defined as a method in a Java class. This can only be specified when LANGUAGE JAVA is used.

The value DB2GENRL may be used as a synonym for DB2GENERAL.

SQL
Used to specify the conventions for passing parameters to and returning the value from external methods that conform to C language calling and linkage conventions or methods

exposed by OLE automation objects. This must be specified when either LANGUAGE C or LANGUAGE OLE is used.

PARAMETER CCSID
Specifies the encoding scheme to use for all string data passed into and out of the external method. If the PARAMETER CCSID clause is not specified, the default is PARAMETER CCSID UNICODE for Unicode databases, and PARAMETER CCSID ASCII for all other databases.

ASCII
Specifies that string data is encoded in the database code page. If the database is a Unicode database, PARAMETER CCSID ASCII cannot be specified (SQLSTATE 56031).

UNICODE
Specifies that character data is in UTF-8, and that graphic data is in UCS-2. If the database is not a Unicode database, PARAMETER CCSID UNICODE cannot be specified (SQLSTATE 56031).

This clause cannot be specified with LANGUAGE OLE (SQLSTATE 42613).

DETERMINISTIC or NOT DETERMINISTIC
This optional clause specifies whether the method always returns the same results for given argument values (DETERMINISTIC) or whether the method depends on some state values that affect the results (NOT DETERMINISTIC). That is, a DETERMINISTIC method must always return the same result from successive invocations with identical inputs. Optimizations taking advantage of the fact that identical inputs always produce the same results are prevented by specifying NOT DETERMINISTIC. An example of a type that is non-deterministic is one that references special registers, global variables, or non-deterministic functions in a way that affects the result type.

FENCED or NOT FENCED
This clause specifies whether the method is considered "safe" to run in the database manager operating environment's process or address space (NOT FENCED), or not (FENCED).

If a method is registered as FENCED, the database manager protects its internal resources (data buffers, for example) from access by the method. Most methods will have the option of running as FENCED or NOT FENCED. In general, a method running as FENCED will not perform as well as a similar one running as NOT FENCED.

CAUTION: Use of NOT FENCED for methods that were not adequately coded, reviewed, and tested can compromise the integrity of your database. The database engine takes some precautions against many of the common types of inadvertent failures that might occur, but cannot guarantee complete integrity when NOT FENCED methods are used.

Only FENCED can be specified for a method with LANGUAGE OLE or NOT THREADSAFE (SQLSTATE 42613).

If the method is FENCED and has the NO SQL option, the AS LOCATOR clause cannot be specified (SQLSTATE 42613).

Either SYSADM authority, DBADM authority, or a special authority (CREATE_NOT_FENCED_ROUTINE) is required to register a method as NOT FENCED.

THREADSAFE or NOT THREADSAFE
Specifies whether the method is considered "safe" to run in the same process as other routines (THREADSAFE), or not (NOT THREADSAFE).

If the method is defined with LANGUAGE other than OLE:

- If the method is defined as THREADSAFE, the database manager can invoke the method in the same process as other routines. In general, to be threadsafe, a method should not use any global or static data areas. Most programming references include a discussion of writing threadsafe routines. Both FENCED and NOT FENCED methods can be THREADSAFE.
- If the method is defined as NOT THREADSAFE, the database manager will never invoke the method in the same process as another routine.

For FENCED methods, THREADSAFE is the default if the LANGUAGE is JAVA. For all other languages, NOT THREADSAFE is the default. If the method is defined with LANGUAGE OLE, THREADSAFE may not be specified (SQLSTATE 42613).

For NOT FENCED methods, THREADSAFE is the default. NOT THREADSAFE cannot be specified (SQLSTATE 42613).

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT
This optional clause may be used to avoid a call to the external method if any of the non-subject arguments is null.

If RETURNS NULL ON NULL INPUT is specified, and if at execution time any one of the method's arguments is null, the method is not called and the result is the null value.

If CALLED ON NULL INPUT is specified, then regardless of the number of null arguments, the method is called. It can return a null value or a normal (non-null) value. However, responsibility for testing for null argument values lies with the method.

The value NULL CALL may be used as a synonym for CALLED ON NULL INPUT for backwards and family compatibility. Similarly, NOT NULL CALL may be used as a synonym for RETURNS NULL ON NULL INPUT.

There are two cases in which this specification is ignored:

- If the subject argument is null, in which case the method is not executed and the result is null
- If the method is defined to have no parameters, in which case this null argument condition cannot occur.

READS SQL DATA, NO SQL, CONTAINS SQL
Specifies the classification of SQL statements that the method can run. The database manager verifies that the SQL statements that the method issues are consistent with this specification.

For the classification of each statement, see "SQL statements that can be executed in routines and triggers" in Developing User-defined Routines (SQL and External).

The default is READS SQL DATA.

READS SQL DATA
Specifies that the method can run statements with a data access classification of READS SQL DATA or CONTAINS SQL (SQLSTATE 38002 or 42985). The method cannot run SQL statements that modify data (SQLSTATE 38003 or 42985).

NO SQL
Specifies that the method can run only SQL statements with a data access classification of NO SQL (SQLSTATE 38001).

CONTAINS SQL
Specifies that the method can run only SQL statements with a data access classification of CONTAINS SQL (SQLSTATE 38004 or 42985). The method cannot run any SQL statements that read or modify data (SQLSTATE 38003 or 42985).

EXTERNAL ACTION or NO EXTERNAL ACTION
This optional clause specifies whether or not the method takes some action that changes the state of an object not managed by the database manager. Optimizations that assume methods have no external impacts are prevented by specifying EXTERNAL ACTION.

NO SCRATCHPAD or SCRATCHPAD *length*
This optional clause may be used to specify whether a scratchpad is to be provided for an external method. It is strongly recommended that methods be re-entrant, so a scratchpad provides a means for the method to "save state" from one call to the next.

If SCRATCHPAD is specified, then at the first invocation of the user-defined method, memory is allocated for a scratchpad to be used by the external method. This scratchpad has the following characteristics:

- *length*, if specified, sets the size in bytes of the scratchpad and must be between 1 and 32 767 (SQLSTATE 42820). The default value is 100.
- It is initialized to all X'00''s.
- Its scope is the SQL statement. There is one scratchpad per reference to the external method in the SQL statement.

So, if method X in the following statement is defined with the SCRATCHPAD keyword, three scratchpads would be assigned.

```
SELECT A, X..(A) FROM TABLEB
   WHERE X..(A) > 103 OR X..(A) < 19
```

If ALLOW PARALLEL is specified or defaulted to, then the scope is different from the one shown previously. If the method is executed on multiple database partitions, a scratchpad would be assigned on each database partition where the method is processed, for each reference to the method in the SQL statement. Similarly, if the query is executed with intrapartition parallelism enabled, more than three scratchpads may be assigned.

The scratchpad is persistent. Its content is preserved from one external method call to the next. Any changes made to the scratchpad by the external method on one call will be present on the next call. The database manager initializes scratchpads at the beginning of execution of each SQL statement. The database manager may reset scratchpads at the beginning of execution of each subquery. The system issues a final call before resetting a scratchpad if the FINAL CALL option is specified.

The scratchpad can be used as a central point for system resources (memory, for example) which the external method might acquire. The method could acquire the memory on the first call, keep its address in the scratchpad, and refer to it in subsequent calls.

In such a case where system resource is acquired, the FINAL CALL keyword should also be specified; this causes a special call to be made at end-of-statement to allow the external method to free any system resources acquired.

If SCRATCHPAD is specified, then on each invocation of the user-defined method, an additional argument is passed to the external method which addresses the scratchpad.

If NO SCRATCHPAD is specified, then no scratchpad is allocated or passed to the external method.

NO FINAL CALL or FINAL CALL

This optional clause specifies whether a final call is to be made to an external method. The purpose of such a final call is to enable the external method to free any system resources it has acquired. It can be useful in conjunction with the SCRATCHPAD keyword in situations where the external method acquires system resources such as memory and anchors them in the scratchpad.

If FINAL CALL is specified, then at execution time, an additional argument is passed to the external method which specifies the type of call. The types of calls are:

- Normal call: SQL arguments are passed and a result is expected to be returned.
- First call: the first call to the external method for this specific reference to the method in this specific SQL statement. The first call is a normal call.
- Final call: a final call to the external method to enable the method to free up resources. The final call is not a normal call. This final call occurs at the following times:
  - End-of-statement: this case occurs when the cursor is closed for cursor-oriented statements, or when the statement is through executing otherwise.
  - End-of-transaction: This case occurs when the normal end-of-statement does not occur. For example, the logic of an application may for some reason bypass the close of the cursor.

  If a commit operation occurs while a cursor defined as WITH HOLD is open, a final call is made at the subsequent close of the cursor or at the end of the application.

If NO FINAL CALL is specified, then no "call type" argument is passed to the external method, and no final call is made.

ALLOW PARALLEL or DISALLOW PARALLEL

This optional clause specifies whether, for a single reference to the method, the invocation of the method can be parallelized. In general, the invocations of most scalar methods should be parallelizable, but there may be methods (such as those depending on a single copy of a scratchpad) that cannot. If either ALLOW PARALLEL or DISALLOW PARALLEL are specified for a method, then this specification will be accepted.

The following questions should be considered in determining which keyword is appropriate for the method:

- Are all the method invocations completely independent of each other? If YES, then specify ALLOW PARALLEL.
- Does each method invocation update the scratchpad, providing value(s) that are of interest to the next invocation (the incrementing of a counter, for example)? If YES, then specify DISALLOW PARALLEL or accept the default.
- Is there some external action performed by the method which should happen only on one database partition? If YES, then specify DISALLOW PARALLEL or accept the default.
- Is the scratchpad used, but only so that some expensive initialization processing can be performed a minimal number of times? If YES, then specify ALLOW PARALLEL.

In any case, the body of every external method should be in a directory that is available on every database partition.

The syntax diagram indicates that the default value is ALLOW PARALLEL. However, the default is DISALLOW PARALLEL if one or more of the following options is specified in the statement:

- NOT DETERMINISTIC
- EXTERNAL ACTION
- SCRATCHPAD
- FINAL CALL

NO DBINFO or DBINFO

This optional clause specifies whether certain specific information known by the database manager will be passed to the method as an additional invocation-time argument (DBINFO), or not (NO DBINFO).NO DBINFO is the default. DBINFO is not supported for LANGUAGE OLE (SQLSTATE 42613). If the method being defined overrides another method, this clause cannot be specified (SQLSTATE 428FV).

If DBINFO is specified, a structure that contains the following information is passed to the method:

- Database name - the name of the currently connected database.
- Application ID - unique application ID which is established for each connection to the database.
- Application Authorization ID - the application runtime authorization ID, regardless of the nested methods in between this method and the application.
- Code page - identifies the database code page.
- Schema name - under the exact same conditions as for Table name, contains the name of the schema; otherwise blank.
- Table name - if and only if the method reference is either the right side of a SET clause in an UPDATE statement, or an item in the VALUES list of an INSERT statement, contains the unqualified name of the table being updated or inserted; otherwise blank.
- Column name - under the exact same conditions as for Table name, contains the name of the column being updated or inserted; otherwise blank.
- Database version/release - identifies the version, release and modification level of the database server invoking the method.
- Platform - contains the server's platform type.
- Table method result column numbers - not applicable to methods.

INHERIT SPECIAL REGISTERS

This optional clause specifies that special registers in the method will inherit their initial values from the calling statement. For cursors, the initial values are inherited from the time that the cursor is opened.

No changes to the special registers are passed back to the caller of the method.

Some special registers, such as the datetime special registers, reflect a property of the statement currently executing, and are therefore never inherited from the caller.

Notes

- Creating a structured type with a schema name that does not already exist will result in the implicit creation of that schema provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- A structured subtype defined with no attributes defines a subtype that inherits all its attributes from the supertype. If neither an UNDER clause nor any other attribute is specified, then the type is a root type of a type hierarchy without any attributes.
- The addition of a new subtype to a type hierarchy may cause packages to be invalidated. A package may be invalidated if it depends on a supertype of the new type. Such a dependency is the result of the use of a TYPE predicate or a TREAT specification.
- A structured type may have no more than 4082 attributes (SQLSTATE 54050).
- A method specification is not allowed to have the same signature as a function (comparing the first parameter-type of the function with the subject-type of the method).
- No original method may override another method, or be overridden by an original method (SQLSTATE 42745). Furthermore, a function and a method cannot be in an overriding relationship. This means that if the function were considered to be a method with its first parameter as subject S, it must not override another method in any supertype of S, and it must not be overridden by another method in any subtype of S (SQLSTATE 42745).
- Creation of a structured type automatically generates a set of functions and methods for use with the type. All the functions and methods are generated in the same schema as the structured type. If the signature of the generated function or method conflicts with or overrides the signature of an existing function in this schema, the statement fails (SQLSTATE 42710). The generated functions or methods cannot be dropped without dropping the structured type (SQLSTATE 42917). The following functions and methods are generated:
  - Functions
    - Reference Comparisons

      Six comparison functions with names =, <>, <, <=, >, >= are generated for the reference type REF(*type-name*). Each of these functions takes two parameters of type REF(*type-name*) and returns true, false, or unknown. The comparison operators for REF(*type-name*) are defined to have the same behavior as the comparison operators for the underlying data type of REF(*type-name*). (All references in a type hierarchy have the same reference representation type. This enables REF(S) and REF(T) to be compared, provided that S and T have a common supertype. Because uniqueness of the OID column is enforced only within a table hierarchy, it is possible that a value of REF(T) in one table hierarchy may be "equal" to a value of REF(T) in another table hierarchy, even though they reference different rows.)

      The scope of the reference type is not considered in the comparison.

    - Cast functions

      Two cast functions are generated to cast between the generated reference type REF(*type-name*) and the underlying data type of this reference type.

      - The name of the function to cast from the underlying type to the reference type is the implicit or explicit *funcname1*.

        The format of this function is:

```
CREATE FUNCTION funcname1 (rep-type)
  RETURNS REF(type-name) ...
```

- The name of the function to cast from the reference type to the underlying type of the reference type is the implicit or explicit *funcname2*.

  The format of this function is:

```
CREATE FUNCTION funcname2 ( REF(type-name) )
  RETURNS rep-type ...
```

For some rep-types, there are additional cast functions generated with *funcname1* to handle casting from constants.

- If *rep-type* is SMALLINT, the additional generated cast function has the format:

```
CREATE FUNCTION funcname1 (INTEGER)
  RETURNS REF(type-name)
```

- If *rep-type* is CHAR(n), the additional generated cast function has the format:

```
CREATE FUNCTION funcname1 ( VARCHAR(n))
  RETURNS REF(type-name)
```

- If *rep-type* is GRAPHIC(n), the additional generated cast function has the format:

```
CREATE FUNCTION funcname1 (VARGRAPHIC(n))
  RETURNS REF(type-name)
```

The schema name of the structured type must be included in the SQL path for successful use of these operators and cast functions in SQL statements.

- Constructor function

  The constructor function is generated to allow a new instance of the type to be constructed. This new instance will have null for all attributes of the type, including attributes that are inherited from a supertype.

  The format of the generated constructor function is:

```
CREATE FUNCTION type-name ( )
  RETURNS type-name
 ...
```

If NOT INSTANTIABLE is specified, no constructor function is generated.

– Methods

- Observer methods

  An observer method is defined for each attribute of the structured type. For each attribute, the observer method returns the type of the attribute. If the subject is null, the observer method returns a null value of the attribute type.

  For example, the attributes of an instance of the structured type ADDRESS can be observed using `C1..STREET`, `C1..CITY`, `C1..COUNTRY`, and `C1..CODE`.

  The method signature of the generated observer method is as if the following statement had been executed:

```
CREATE TYPE  type-name
   ...
  METHOD attribute-name()
    RETURNS attribute-type
```

  where *type-name* is the structured type name.

- Mutator methods

A type-preserving mutator method is defined for each attribute of the structured type. Use mutator methods to change attributes within an instance of a structured type. For each attribute, the mutator method returns a copy of the subject modified by assigning the argument to the named attribute of the copy.

For example, an instance of the structured type ADDRESS can be mutated using `C1..CODE('M3C1H7')`. If the subject is null, the mutator method raises an error (SQLSTATE 2202D).

The method signature of the generated mutator method is as if the following statement had been executed:

```
CREATE TYPE  type-name
        ...
     METHOD attribute-name (attribute-type)
        RETURNS type-name
```

If the attribute data type is SMALLINT, REAL, CHAR, or GRAPHIC, an additional mutator method is generated in order to support mutation using constants:

- If *attribute-type* is SMALLINT, the additional mutator supports an argument of type INTEGER.
- If *attribute-type* is REAL, the additional mutator supports an argument of type DOUBLE.
- If *attribute-type* is CHAR, the additional mutator supports an argument of type VARCHAR.
- If *attribute-type* is GRAPHIC, the additional mutator supports an argument of type VARGRAPHIC.

- If the structured type is used as a column type, the length of an instance of the type can be no more than 1 GB in length at runtime (SQLSTATE 54049).

- When creating a new subtype for an existing structured type (for use as a column type), any transform functions already written in support of existing related structured types should be re-examined and updated as necessary. Whether the new type is in the same hierarchy as a given type, or in the hierarchy of a nested type, it is likely that the existing transform function associated with this type will need to be modified to include some or all of the new attributes introduced by the new subtype. Generally speaking, because it is the set of transform functions associated with a given type (or type hierarchy) that enables UDF and client application access to the structured type, the transform functions should be written to support *all* of the attributes in a given composite hierarchy (that is, including the transitive closure of all subtypes and their nested structured types).

  When a new subtype of an existing type is created, all packages dependent on methods that are defined in supertypes of the type being created, and that are eligible for overriding, are invalidated.
- ***Table access restrictions***: If a method is defined as READS SQL DATA, no statement in the method can access a table that is being modified by the statement which invoked the method (SQLSTATE 57053). For example, suppose the method BONUS() is defined as READS SQL DATA. If the statement UPDATE DEPTINFO SET SALARY = SALARY + EMP..BONUS() is invoked, no SQL statement in the BONUS method can read from the EMPLOYEE table.
- ***Privileges***: The definer of the user-defined type always receives the EXECUTE privilege WITH GRANT OPTION on all methods and functions automatically generated for the structured type. The EXECUTE privilege is not granted on any methods explicitly specified in the CREATE TYPE statement until a method body is defined using the CREATE METHOD statement. The definer of the user-defined type does have the right to drop the method specification using the ALTER TYPE statement. EXECUTE privilege on all methods and functions automatically generated during the CREATE TYPE (structured) statement is granted to PUBLIC.

  When an external method is used in an SQL statement, the method definer must have the EXECUTE privilege on any packages used by the method or EXECUTEIN privilege on the schema containing the packages used by the method.
- In a partitioned database environment, the use of SQL in external user-defined functions or methods is not supported (SQLSTATE 42997).
- Only routines defined as NO SQL can be used to define an index extension (SQLSTATE 428F8).

- A Java routine defined as NOT FENCED will be invoked as if it had been defined as FENCED THREADSAFE.
- ***EXTERNAL ACTION methods***: If an EXTERNAL ACTION method is invoked in other than the outermost select list, the results are unpredictable since the number of times the method is invoked will vary depending on the access plan used.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - NOT VARIANT can be specified in place of DETERMINISTIC
  - VARIANT can be specified in place of NOT DETERMINISTIC
  - NULL CALL can be specified in place of CALLED ON NULL INPUT
  - NOT NULL CALL can be specified in place of RETURNS NULL ON NULL INPUT
  - PARAMETER STYLE DB2SQL can be specified in place of PARAMETER STYLE SQL

  The following syntax is accepted as the default behavior for external methods:
  - ASUTIME NO LIMIT
  - NO COLLID
  - PROGRAM TYPE SUB
  - STAY RESIDENT NO
  - CCSID UNICODE in a Unicode database
  - CCSID ASCII in a non-Unicode database if PARAMETER CCSID UNICODE is not specified

  The following syntax is accepted as the default behavior for SQL methods:
  - CCSID UNICODE in a Unicode database
  - CCSID ASCII in a non-Unicode database

Examples

- *Example 1:* Create a type for department.

```
CREATE TYPE DEPT AS
   (DEPT_NAME     VARCHAR(20),
      MAX_EMPS INT)
      REF USING INT
   MODE DB2SQL
```

- *Example 2:* Create a type hierarchy consisting of a type for employees and a subtype for managers.

```
CREATE TYPE EMP AS
  (NAME      VARCHAR(32),
  SERIALNUM INT,
  DEPT      REF(DEPT),
  SALARY    DECIMAL(10,2))
  MODE DB2SQL

CREATE TYPE MGR UNDER EMP AS
  (BONUS     DECIMAL(10,2))
  MODE DB2SQL
```

- *Example 3:* Create a type hierarchy for addresses. Addresses are intended to be used as types of columns. The inline length is not specified, so a default length is calculated. Encapsulate within the address type definition an external method that calculates how close this address is to a given input address. Create the method body using the CREATE METHOD statement.

```
CREATE TYPE address_t AS
  (STREET     VARCHAR(30),
  NUMBER     CHAR(15),
  CITY       VARCHAR(30),
  STATE      VARCHAR(10))
  NOT FINAL
```

```
    MODE DB2SQL
      METHOD SAMEZIP (addr address_t)
      RETURNS INTEGER
      LANGUAGE SQL
      DETERMINISTIC
      CONTAINS SQL
      NO EXTERNAL ACTION,

      METHOD DISTANCE (address_t)
      RETURNS FLOAT
      LANGUAGE C
      DETERMINISTIC
      PARAMETER STYLE SQL
      NO SQL
      NO EXTERNAL ACTION

  CREATE TYPE germany_addr_t UNDER address_t AS
    (FAMILY_NAME VARCHAR(30))
    NOT FINAL
    MODE DB2SQL

  CREATE TYPE us_addr_t UNDER address_t AS
    (ZIP VARCHAR(10))
    NOT FINAL
    MODE DB2SQL
```

- *Example 4:* Create a type that has nested structured type attributes.

```
  CREATE TYPE PROJECT AS
    (PROJ_NAME  VARCHAR(20),
     PROJ_ID    INTEGER,
     PROJ_MGR   MGR,
     PROJ_LEAD  EMP,
     LOCATION   ADDR_T,
     AVAIL_DATE DATE)
     MODE DB2SQL
```

CREATE TYPE MAPPING

The CREATE TYPE MAPPING statement defines a mapping between data types.

The mapping can be defined between the following data types:

- The data type of a column in a data source table or view that is going to be defined to a federated database
- A corresponding data type that is already defined to the federated database

The mapping can associate the federated database data type with a data type at:

- A specified data source
- A range of data sources; for example, all data sources of a particular type and version

A data type mapping must be created only if an existing one is not adequate.

If multiple type mappings are applicable when creating a nickname or creating a table (transparent DDL), the most recent one is applied.

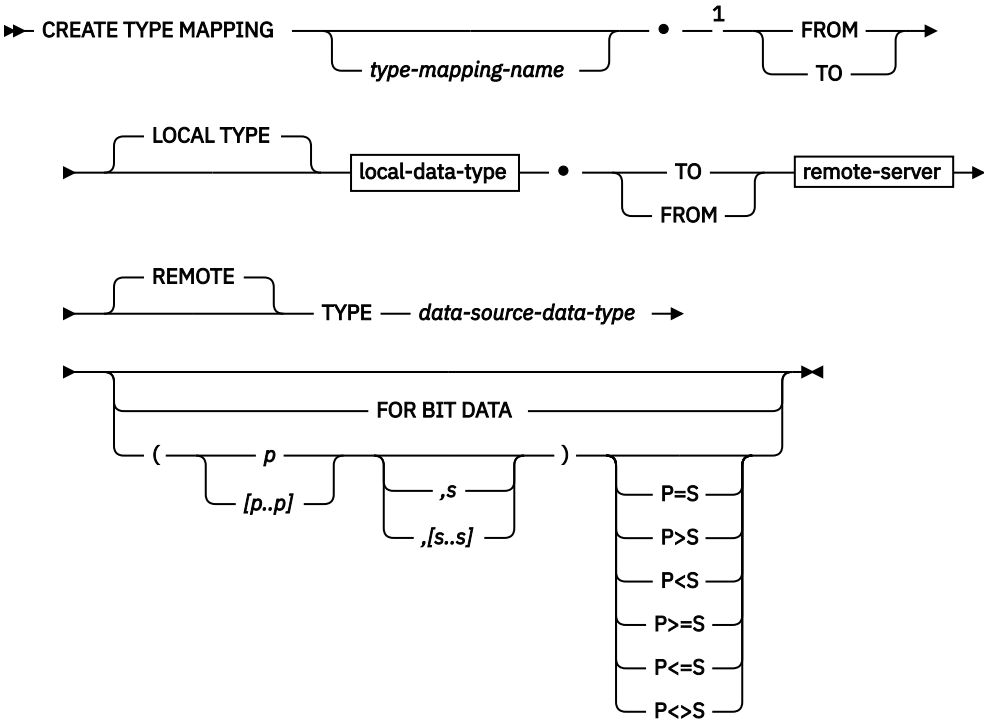
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

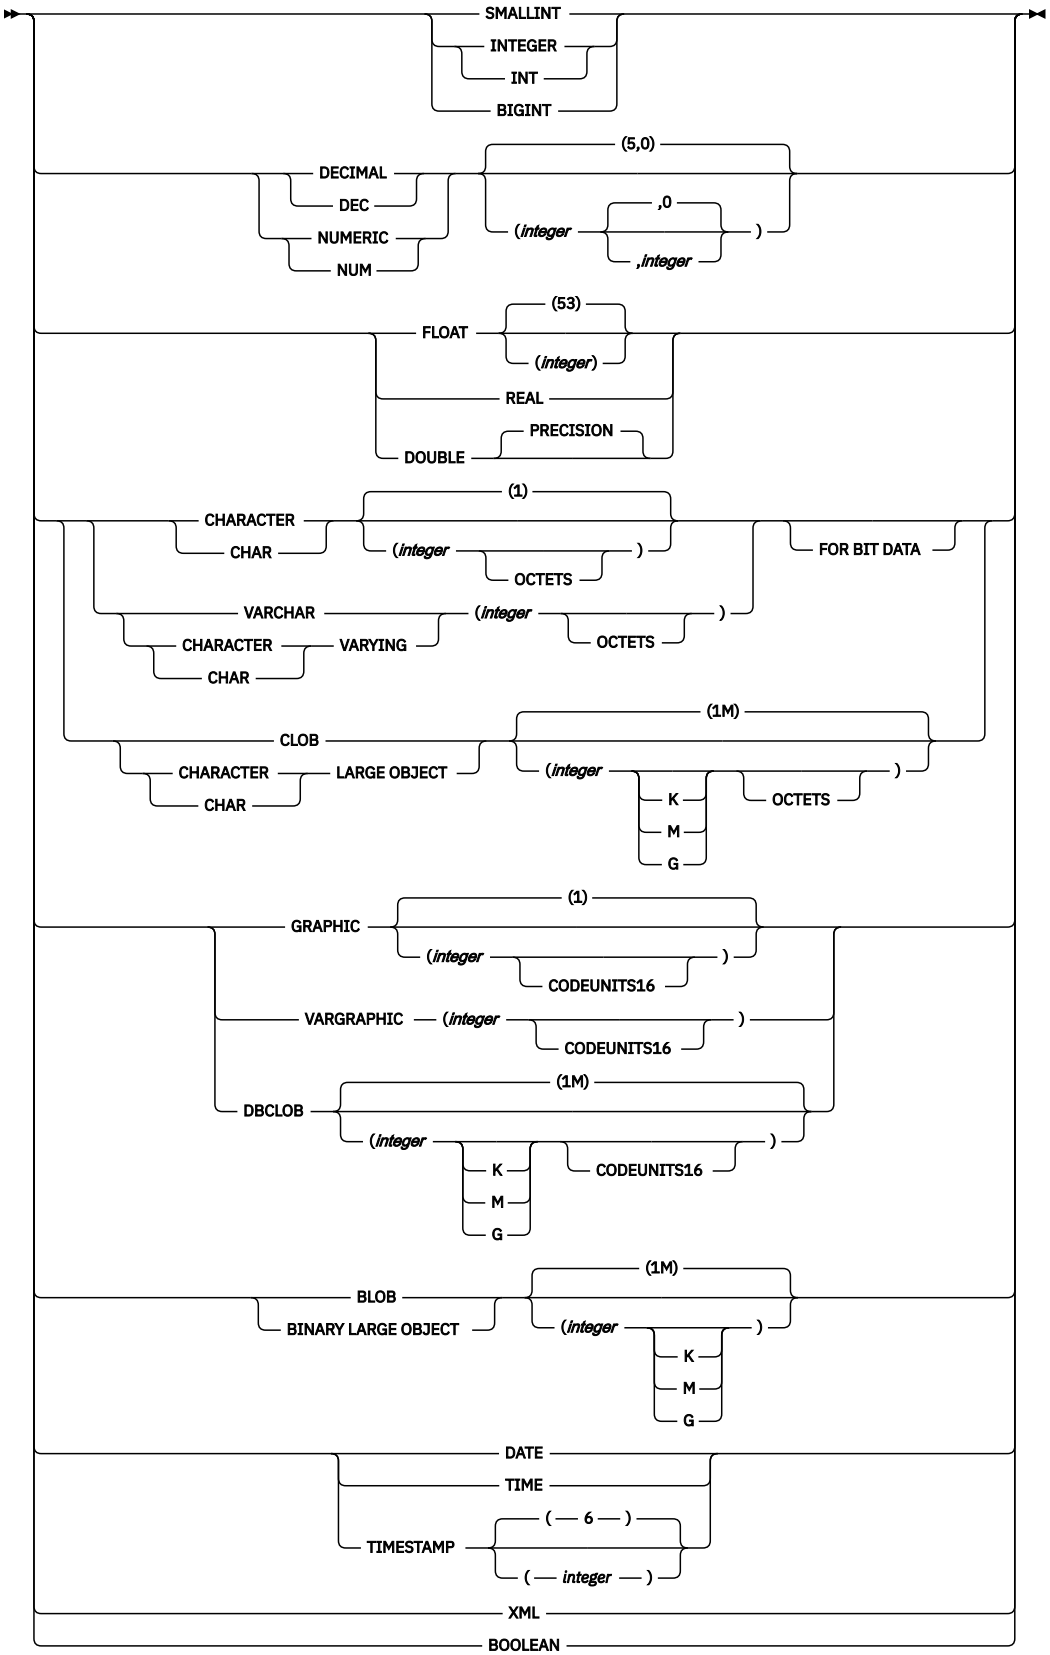
The privileges held by the authorization ID of the statement must include DBADM authority.

Syntax

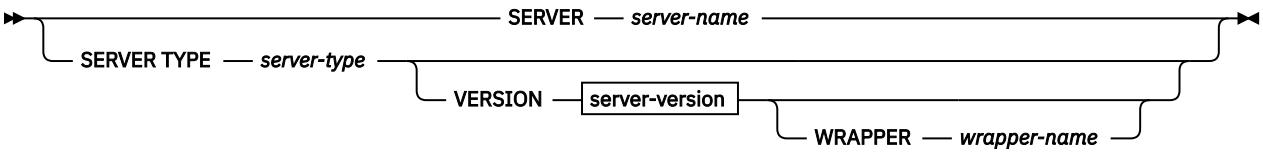


local-data-type

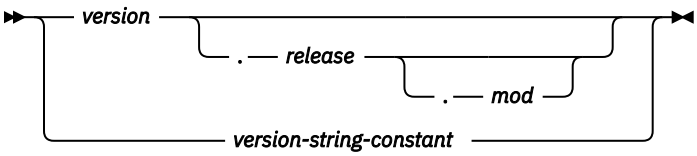
built-in-type



remote-server



server-version



Notes:

[1] Both a TO and a FROM keyword must be present in the CREATE TYPE MAPPING statement.

Description

type-mapping-name
Names the data type mapping. The name must not identify a data type mapping that is already described in the catalog. A unique name is generated if *type-mapping-name* is not specified.

FROM or TO
Specifies a reverse or forward type mapping.

FROM
Specifies a forward type mapping when followed by *local-data-type* or a reverse type mapping when followed by *remote-server*.

TO
Specifies a forward type mapping when followed by *remote-server* or a reverse type mapping when followed by *local-data-type*.

local-data-type
Identifies a data type that is defined to a federated database. If *local-data-type* is specified without a schema name, the type name is resolved by searching the schemas in the SQL path.

Empty parentheses can be used for the parameterized data types. A parameterized data type is any one of the data types that can be defined with a specific length, scale, or precision. If empty parentheses are specified in a forward type mapping, such as, for example, CHAR(), the length is determined from the column length on the remote table. If empty parentheses are specified in a reverse type mapping, the type mapping is applied to the data type with any length. If you omit parentheses altogether, the default length for the data type is used.

FLOAT() cannot be used (SQLSTATE 42601), because the parameter value indicates different data types (REAL or DOUBLE). NUMBER() cannot be used (SQLSTATE 42601), because the parameter value indicates different data types (DECFLOAT or DECIMAL).

DECFLOAT can be accepted only as the *local-data-type* by Oracle wrapper, Db2 wrapper for IBM Db2 Version 9.5 or later.

The *local-data-type* cannot be a user-defined type (SQLSTATE 42611).

built-in-type
See "CREATE TABLE" for the description of built-in data types.

SERVER *server-name*
Names the data source to which *data-source-data-type* is defined.

SERVER TYPE *server-type*
Identifies the type of data source to which *data-source-data-type* is defined.

VERSION
Identifies the version of the data source to which *data-source-data-type* is defined.

version
Specifies the version number. The value must be an integer.

release
Specifies the number of the release of the version denoted by *version*. The value must be an integer.

mod
Specifies the number of the modification of the release denoted by *release*. The value must be an integer.

version-string-constant
Specifies the complete designation of the version. The *version-string-constant* can be a single value (for example, '8i'); or it can be the concatenated values of *version*, *release* and, if applicable, *mod* (for example, '8.0.3').

WRAPPER *wrapper-name*
Specifies the name of the wrapper that the federated server uses to interact with data sources of the type and version denoted by *server-type* and *server-version*.

TYPE *data-source-data-type*
Specifies the data source data type that is being mapped to or from the local data type.

Empty parentheses can be used for the parameterized data types. If empty parentheses are specified in a forward type mapping, such as, for example, CHAR(), the type mapping is applied to the data type with any length. If empty parentheses are specified in a reverse type mapping, the length is determined from the column length specified in the transparent DDL. If you omit parentheses altogether, the default length for the data type is used.

The *data-source-data-type* must be a built-in data type. User-defined types are not allowed.

If *server-name* is specified with a type mapping, or existing servers are affected by the type mapping, *data-source-data-type*, *p*, and *s* are verified when creating the type mapping (SQLSTATE 42611).

p
If *p* is specified, only the data type whose length or precision equals *p* is affected by the type mapping.

[p1..p2]
For forward type mapping only. For a decimal data type, *p1* and *p2* specify the minimum and maximum number of digits that a value can have. For string data types, *p1* and *p2* specify the minimum and maximum number of characters that a value can have. In all cases, the maximum must equal or exceed the minimum; and both numbers must be valid with respect to the data type.

s
If *s* is specified, only the data type whose scale equals *s* is affected by the type mapping.

[s1..s2]
For forward type mapping only. For a decimal data type, *s1* and *s2* specify the minimum and maximum number of digits allowed to the right of the decimal point. The maximum must equal or exceed the minimum, and both numbers must be valid with respect to the data type.

P [operand] S
For a decimal data type, P *[operand]* S specifies a comparison between the precision and the number of digits allowed to the right of the decimal point. For example, the operand = indicates that the type mapping is applied if the precision and the number of digits allowed in the decimal fraction are the same.

FOR BIT DATA
Indicates whether *data-source-data-type* is for bit data. These keywords are required if the data source type column contains binary values. The database manager will determine this attribute if it is not specified for a character data type.

Notes

- A CREATE TYPE MAPPING statement within a given unit of work (UOW) cannot be processed (SQLSTATE 55007) under either of the following conditions:
  - The statement references a single data source, and the UOW already includes one of the following:
    - A SELECT statement that references a nickname for a table or view within this data source
    - An open cursor on a nickname for a table or view within this data source
    - Either an INSERT, DELETE, or UPDATE statement issued against a nickname for a table or view within this data source
  - The statement references a category of data sources (for example, all data sources of a specific type and version), and the UOW already includes one of the following:
    - A SELECT statement that references a nickname for a table or view within one of these data sources
    - An open cursor on a nickname for a table or view within one of these data sources
    - Either an INSERT, DELETE, or UPDATE statement issued against a nickname for a table or view within one of these data sources
- When multiple type mappings are applicable, the most recent one will be used. You can retrieve the creation time for a type mapping by querying the CREATE_TIME column of the SYSCAT.TYPEMAPPINGS catalog view.
- BINARY and VARBINARY types are not supported in a Federated system.

Examples

1. Create a forward type mapping between the Oracle data type DATE and the data type SYSIBM.DATE. For all of the nicknames that are created after this mapping is defined, Oracle columns of data type DATE will map to Db2 columns of data type DATE.

```
CREATE TYPE MAPPING MY_ORACLE_DATE
  FROM LOCAL TYPE SYSIBM.DATE
  TO SERVER TYPE ORACLE
  REMOTE TYPE DATE
```

2. Create a forward type mapping between data type SYSIBM.DECIMAL(10,2) and the Oracle data type NUMBER([10..38],2) at data source ORACLE1. If there is a column in the Oracle table of data type NUMBER(11,2), it will be mapped to a column of data type DECIMAL(10,2), because 11 is between 10 and 38.

```
CREATE TYPE MAPPING MY_ORACLE_DEC
  FROM LOCAL TYPE SYSIBM.DECIMAL(10,2)
  TO SERVER ORACLE1
  REMOTE TYPE NUMBER([10..38],2)
```

3. Create a forward type mapping between data type SYSIBM.VARCHAR(*p*) and the Oracle data type CHAR(*p*) at data source ORACLE1 (*p* is any length). If there is a column in the Oracle table of data type CHAR(10), it will be mapped to a column of data type VARCHAR(10).

```
CREATE TYPE MAPPING MY_ORACLE_CHAR
  FROM LOCAL TYPE SYSIBM.VARCHAR()
  TO SERVER ORACLE1
  REMOTE TYPE CHAR()
```

4. Create a reverse type mapping between the Oracle data type NUMBER(10,2) at data source ORACLE2 and data type SYSIBM.DECIMAL(10,2). If you use transparent DDL to create an Oracle table and specify a column of data type DECIMAL(10,2), the Oracle table will be created with a column of data type NUMBER(10,2).

```
CREATE TYPE MAPPING MY_ORACLE_DEC
  TO LOCAL TYPE SYSIBM.DECIMAL(10,2)
  FROM SERVER ORACLE2
  REMOTE TYPE NUMBER(10,2)
```

CREATE USAGE LIST

The CREATE USAGE LIST statement defines a usage list. A usage list is a database object for monitoring all unique sections (DML statements) that have referenced a particular table or index during their execution.

Invocation

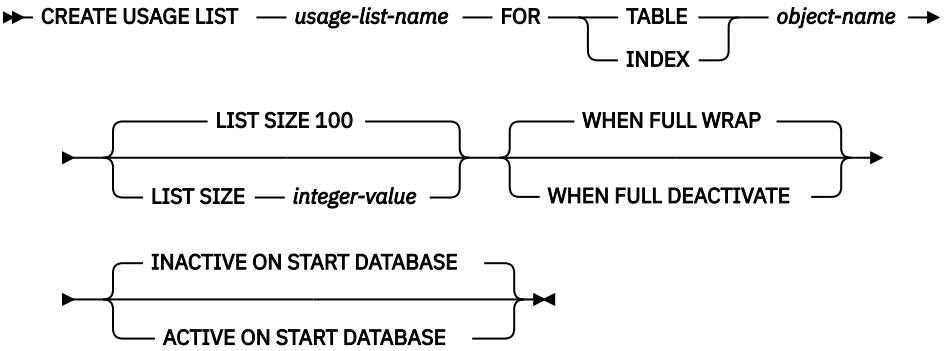
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include one of the following privileges:

- DBADM authority
- SQLADM authority

Syntax



Description

usage-list-name
Names the usage list. The *usage-list-name*, including the implicit or explicit qualifier, must not identify a usage list that is described in the catalog (SQLSTATE 42710). If the usage list is explicitly qualified with a schema name, the schema name must not begin with the characters 'SYS' (SQLSTATE 42939).

TABLE *object-name*
Designates the table for which the usage list is defined. The *object-name*, including the implicit or explicit qualifier, must specify a table defined in the catalog (SQLSTATE 42704). The name must not specify an alias, catalog table, created temporary table, hierarchy table, detached table, nickname, typed table, or view (SQLSTATE 42809). If the table is explicitly qualified with a schema name, the schema name must not begin with the characters 'SYS' (SQLSTATE 42939).

INDEX *object-name*
Designates the index for which the usage list is defined. The *object-name*, including the implicit or explicit qualifier, must specify an index defined in the catalog (SQLSTATE 42704). Indexes defined on tables other than untyped tables or materialized query tables are not supported (SQLSTATE 42809). The name must specify a physical index; Block Indexes (BLOK), Clustering indexes (CLUS), Dimension block indexes (DIM), Regular indexes (REG), and Physical indexes over XML column (XVIP). All other index types are not supported (SQLSTATE 42809). If the index is explicitly qualified with a schema name, the schema name must not begin with the characters 'SYS' (SQLSTATE 42939).

LIST SIZE *integer-value*
Specifies that the size of this list is *integer-value* entries. The minimum size that can be specified is 10 and the maximum is 5000 (SQLSTATE 428B7). The default size is 100 entries.

WHEN FULL
Specifies what action is performed when an active usage list becomes full. The default is to wrap when the list becomes full.

WRAP
Specifies that the usage list wraps and replaces the oldest entries.

DEACTIVATE
Specifies that the usage list deactivates.

INACTIVE ON START DATABASE
Specifies that the usage list is not activated for monitoring whenever the database is activated. Collection must be explicitly started using the SET USAGE LIST statement. This clause is the default.

ACTIVE ON START DATABASE
Specifies that the usage list is automatically activated for monitoring whenever the database is activated.

Notes

- ***Tracking sections with unique keys:*** A usage list keep tracks of all unique sections (DML statements only) that have referenced a particular object. References are aggregated within the list with the unique key of executable ID, representing the section doing the reference, and the monitor interval ID at the time of the reference. Each list entry keeps a count of section executions related to that entry and a set of statistics outlining the affect that the section had on the object across those executions.
- ***Usage list release time:*** A usage list is set to released when the CREATE USAGE LIST statement is committed.
- ***Memory allocation:*** Memory is allocated the first time that the object for which the usage list is defined is referenced by a section.
- ***Memory allocation in a partitioned database environment or Db2 pureScale environment***: If the state of a usage list for a partitioned table or index is set to active, memory is allocated for each data partition when the data partition is first referenced by the section. Similarly, in a partitioned database environment or Db2 pureScale environment, memory is allocated at each active member. If a member is unavailable at the time of activation, then the memory is allocated when the member is next activated (if the state of the usage list is still set to active). This also applies when a member is added to the cluster.
- ***State of the usage list when specifying WHEN FULL DEACTIVATE:*** If the usage list was created with the clause WHEN FULL DEACTIVATE, then the state of the usage list at each member is set to inactive independently. Similarly, for partitioned tables and indexes, the state of the usage list for each data partition is set to inactive independently.
- ***Implicit reactivation of an active usage list:*** If the state of an INACTIVE ON START DATABASE usage list is set to active in a partitioned database environment or Db2 pureScale environment, then its behavior is similar to the ACTIVE ON START DATABASE clause until the state of the usage list is explicitly set to inactive or the instance is recycled. That is, if the state of a usage list is active when a database member is deactivated or offline, and that database member is subsequently reactivated, the usage list for this member is also implicitly reactivated.
- ***Inactive usage lists remain inactive upon database member reactivation:*** If the state of an ACTIVE ON START DATABASE usage list is set to inactive in a partitioned database environment or Db2 pureScale environment, then its behavior is similar to the INACTIVE ON START DATABASE clause until the state of the usage list is explicitly set to active or the instance is recycled. That is, if the state of a usage list is inactive when a database member is deactivated or offline, and that database member is subsequently reactivated, the state of the usage list for this member will remain inactive.
- ***Multiple usage lists:*** Multiple usage lists can be created for the same table or index, however, it is recommended that only one of them be activated. Activating all of them affects database performance and memory usage.
- ***Activating and deactivating usage lists:*** See the Notes section for the SET USAGE LIST STATE statement regarding activation and deactivation of the usage list.

- ***Usage list size considerations:*** When the state of a usage list is set to active, the memory for the usage list is allocated from the monitor heap. At the maximum list size setting, the usage list is approximately 2MB. For partitioned tables or indexes, memory is allocated for each data partition. For example, if a partitioned table has three data partitions defined, approximately 6MB of memory is allocated. Therefore, activating multiple usage lists imposes more memory requirements on the monitor heap. It is therefore suggested that a reasonable list size is selected, or that you set the **mon_heap_sz** configuration parameter to AUTOMATIC so that the database manager manages the monitor heap size.
- ***Performance considerations:*** To maintain high performance, create usage lists such that they are limited to the amount required to gather the information you need. Each usage list requires system memory; system performance can degrade as additional usage lists are activated.

Examples

- *Example 1*: Create a usage list USL_ACC for table SAYYID.ACCOUNTS with a default list size of 100 entries.

```
CREATE USAGE LIST USL_ACC FOR TABLE SAYYID.ACCOUNTS
```

- *Example 2*: Create a usage list USL_SHOPPING_IND for index BIRD.SHOPPINGIND with a list of 50 entries that wraps when the list becomes full.

```
CREATE USAGE LIST USL_SHOPPING_IND FOR INDEX BIRD.SHOPPINGIND
   LISTSIZE 50
   WHEN FULL WRAP
```

- *Example 3*: Create a usage list USL_PAYROLL for table MIKE.PAYROLL with a list size of 200 entries which will deactivate when the list becomes full and will automatically start collecting whenever the database is activated.

```
CREATE USAGE LIST USL_PAYROLL FOR TABLE MIKE.PAYROLL
   LISTSIZE 200
   WHEN FULL DEACTIVATE
   ACTIVE ON START DATABASE
```

- *Example 4*: Create a usage list USL_EMP for partitioned table JACOBO.EMPLOYEES with a list size of 500 entries which will deactivate when the list becomes full.

```
CREATE USAGE LIST USL_EMP FOR TABLE JACOBO.EMPLOYEES
   LIST SIZE 500
   WHEN FULL DEACTIVATE
```

  When the usage list is activated for monitoring, then a list of 500 entries will be allocated for each data partition.

- *Example 5*: Create a usage list USL_PARTS for table SHAKTI.PARTS with a list size of 20 entries that will be activated manually on database activation and will wrap when it becomes full.

```
CREATE USAGE LIST USL_PARTS FOR TABLE SHAKTI.PARTS
   LIST SIZE 20
   INACTIVE ON START DATABASE
   WHEN FULL WRAP
```

CREATE USER MAPPING

The CREATE USER MAPPING statement defines a mapping between an authorization ID that uses a federated database and the authorization ID and password to use at a specified data source.

Invocation

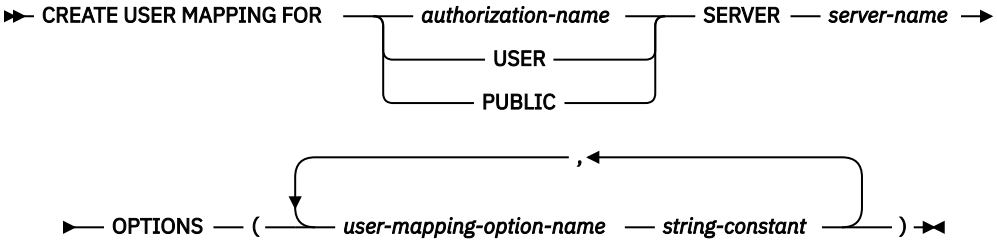
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

If the authorization ID of the statement is different from the authorization name that is being mapped to the data source, the privileges held by the authorization ID of the statement must include DBADM authority. Otherwise, if the authorization ID and the authorization name match, no authorities or privileges are required.

When creating a public user mapping, the privileges held by the authorization ID of the statement must include DBADM authority.

Syntax



Description

authorization-name
Specifies the authorization name under which a user or application connects to a federated database. The *authorization_name* is mapped to the REMOTE_AUTHID user mapping option.

USER
The value in the USER special register. When USER is specified, the authorization ID issuing the CREATE USER MAPPING statement is mapped to the REMOTE_AUTHID user mapping option.

PUBLIC
Specifies that any valid authorization ID for the local federated database will be mapped to the data source authorization ID that is specified in the REMOTE_AUTHID user option.

SERVER *server-name*
Names the server object for the data source that the *authorization-name* can access. The *server-name* is the local name for the remote server that is registered with the federated database.

OPTIONS
Specify configuration options for the user mapping to be created. Which options you can specify depends on the data source of the object for which a user mapping is being created. For a list of data sources and the user mapping options that apply to each, see Data source options. Each option value is a character string constant that must be enclosed in single quotation marks.

Notes

- User mappings are required only for the following data sources: the Db2 family of products, Documentum, Informix, Microsoft SQL Server, ODBC, Oracle, Sybase, and Teradata.
- The REMOTE_PASSWORD option is always required for a user mapping.
- Public user mappings and non-public user mappings cannot coexist on the same federated server. This means that if you have created public user mappings, you will not be able to create non-public user mappings on the same federated server. The reverse is also true, if you have created non-public user mappings, you will not be able to create public user mappings on the same federated server.
- **Syntax alternatives:** The following syntax is supported for compatibility with previous versions of Db2:
  - ADD can be specified before *user-mapping-option-name string-constant*.

Example

```
CREATE USER MAPPING FOR <db2inst1>
   SERVER <server_name>
   OPTIONS (
      REMOTE_AUTHID '<admin>',
      REMOTE_PASSWORD '<password>);
```

where

- *db2inst1* specifies the local authorization ID in the Db2 instance. You should use the keyword USER or PUBLIC, or the Db2 instance name. USER is for current Db2 user, PUBLIC is for all Db2 users.
- *server_name* specifies the server definition name that you defined in the **CREATE SERVER** statement for the JDBC data source. The user mapping is paired with the server statement.
- *admin* specifies the remote user ID for the remote data source (for example, MySQL). The value is case-sensitive unless you set the **FOLD_ID** server parameter to "U" or "L" in the **CREATE SERVER** statement.
- *password* specifies the remote password for the remote data source (for example, MySQL). The value is case-sensitive unless you set the **FOLD_PW** server option to "U" or "L" in the CREATE SERVER statement.

CREATE VARIABLE

The CREATE VARIABLE statement defines a session global variable.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the variable does not exist
- CREATEIN privilege on the schema, if the schema name of the variable refers to an existing schema
- SCHEMAADM authority on the schema, if the schema name of the variable refers to an existing schema
- DBADM authority

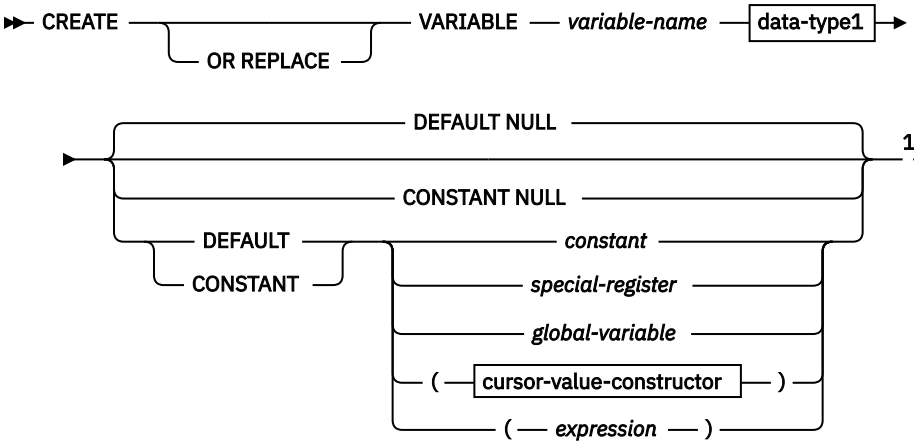
and any privileges that are necessary to execute the default expression.

To execute this statement with a *cursor-value-constructor* that uses a *select-statement*, the privileges held by the authorization ID of the statement must include the privileges necessary to execute the *select-statement*. See the Authorization section in "SQL queries".

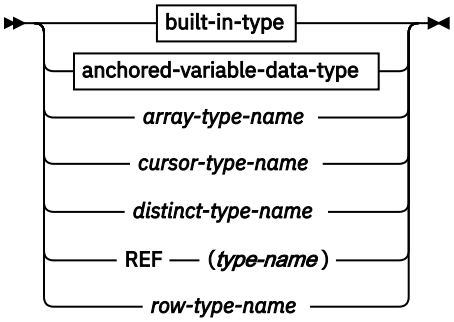
Group privileges are not considered when checking authorization for objects referenced in the statement

To replace an existing variable, the authorization ID of the statement must be the owner of the existing variable (SQLSTATE 42501).

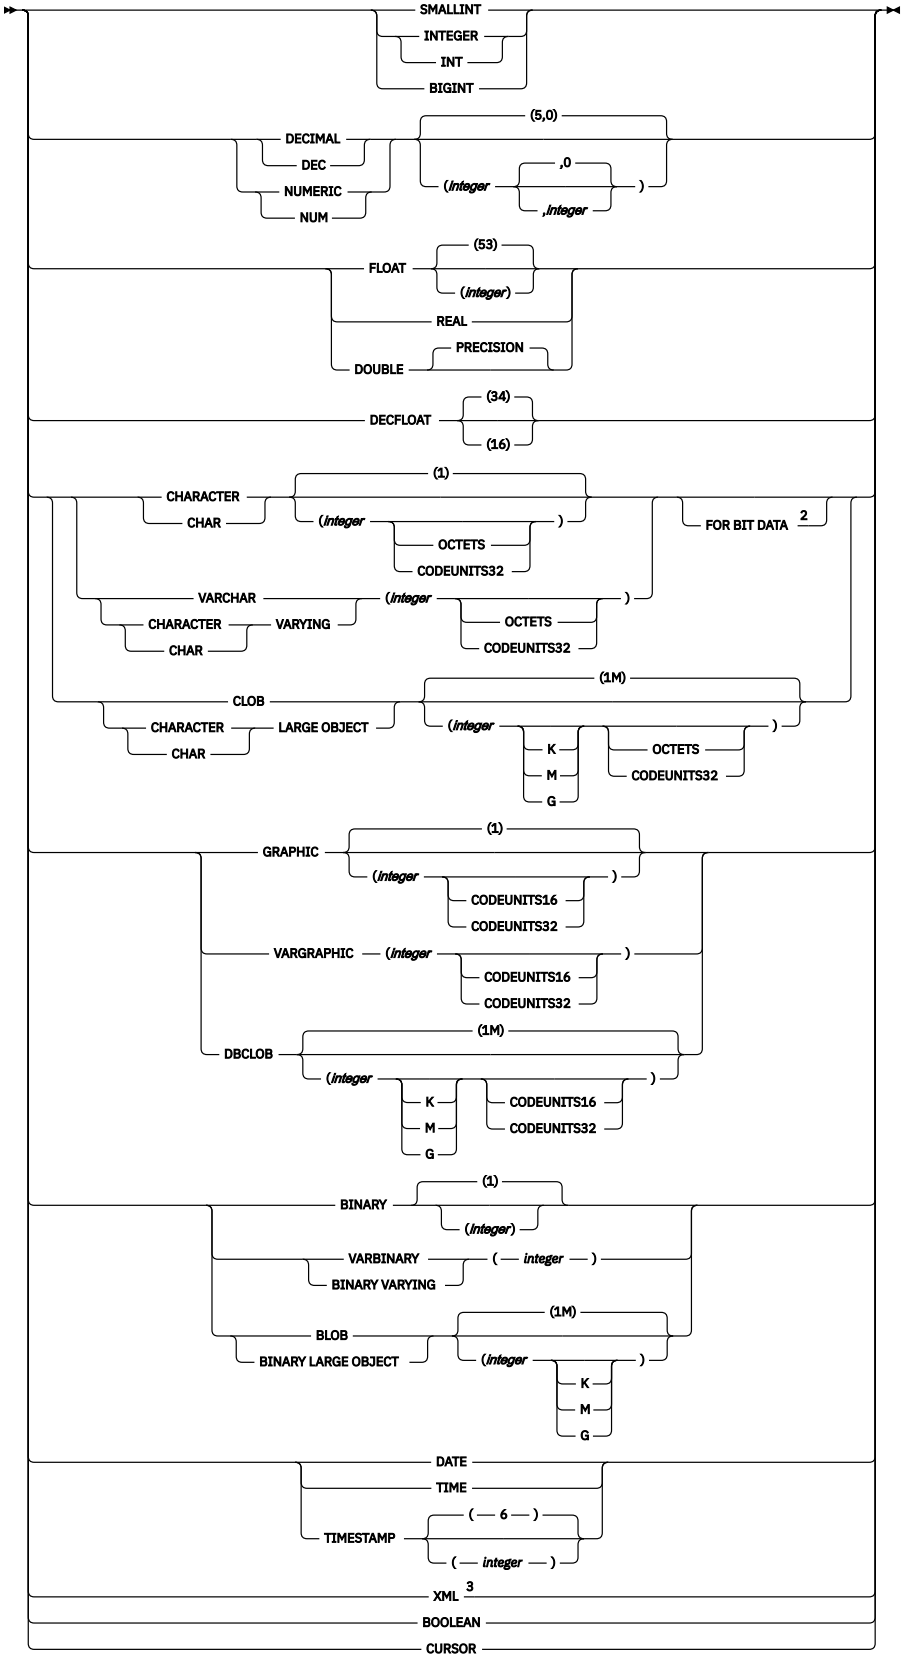
Syntax



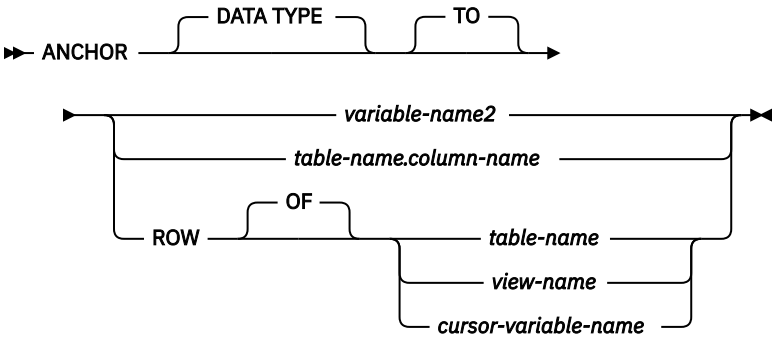
data-type1



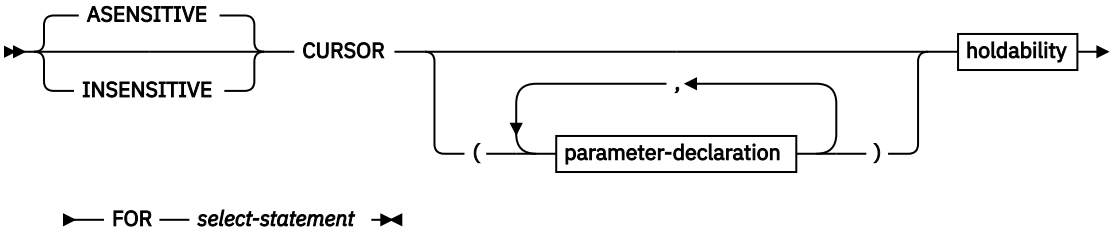
built-in-type



anchored-variable-data-type

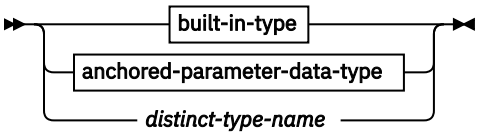


cursor-value-constructor

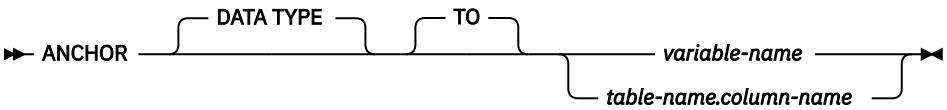


parameter-declaration

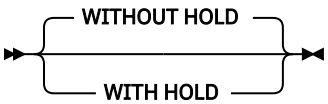
data-type2



anchored-parameter-data-type



holdability



Notes:

[1] If *data-type1* specifies a CURSOR built-in type or *cursor-type-name*, only NULL or *cursor-value-constructor* can be specified. Only DEFAULT NULL can be explicitly specified for *array-type-name* or *row-type-name*.

[2] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

[3] For version 10.1, you can use the XML data type only as a parameter data type in a cursor value constructor. For version 10.1 Fix Pack 1 or later fix pack releases, you can also use the XML data type to create global variables.

Description

OR REPLACE

Specifies to replace the definition for the variable if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that privileges that were granted on the variable are not affected. This option is ignored

if a definition for the variable does not exist at the current server. This option can be specified only by the owner of the object.

variable-name
Names the global variable. The name, including an implicit or explicit qualifier, must not identify a global variable that already exists at the current server (SQLSTATE 42710). If a qualifier is not specified, the current schema is implicitly assigned. If the global variable name is explicitly qualified with a schema name, the schema name must not begin with the characters "SYS" (SQLSTATE 42939).

data-type1
Specifies the data type of the global variable. A structured type cannot be specified (SQLSTATE 42611).

built-in-type
Specifies a built-in data type. BOOLEAN and CURSOR cannot be specified for a table. For version 10.1, an XML data type cannot be specified (SQLSTATE 42611). The XML data type support starts in version 10.1 Fix Pack 1. For a more complete description of each built-in data type, see "CREATE TABLE".

FOR BIT DATA can be specified as part of character string data types.

BOOLEAN
For a Boolean.

CURSOR
For a reference to an underlying cursor.

anchored-variable-data-type
Identifies another object used to determine the data type of the global variable. The data type of the anchor object has the same limitations that apply to specifying the data type directly, or in the case of a row, to creating a row type.

ANCHOR DATA TYPE TO
Indicates an anchored data type is used to specify the data type.

variable-name2
Identifies a global variable. The data type of the referenced variable is used as the data type for the global variable.

table-name.column-name
Identifies a column name of an existing table or view. The data type of the column is used as the data type for the global variable.

ROW OF *table-name* or *view-name*
Specifies that the global variable is a row of fields with names and data types that are based on the column names and column data types of the table identified by *table-name* or the view identified by *view-name*. The data type of the global variable is an unnamed row type.

ROW OF *cursor-variable-name*
Specifies a row of fields with names and data types that are based on the field names and field data types of the cursor variable identified by *cursor-variable-name*. The specified cursor variable must be one of the following elements (SQLSTATE 428HS):

- A global variable with a strongly typed cursor data type
- A global variable with a weakly typed cursor data type that was created or declared with a CONSTANT clause specifying a select-statement where all the result columns are named.

If the cursor type of the cursor variable is not strongly-typed using a named row type, the data type of the global variable is an unnamed row type.

array-type-name
Specifies the name of a user-defined array type. If *array-type-name* is specified without a schema name, the array type is resolved by searching the schemas in the SQL path.

cursor-type-name
Specifies the name of a cursor type. If *cursor-type-name* is specified without a schema name, the cursor type is resolved by searching the schemas in the SQL path.

distinct-type-name
Specifies the name of a distinct type. The length, precision, and scale of the declared variable are, respectively, the length, precision, and scale of the source type of the distinct type. If *distinct-type-name* is specified without a schema name, the distinct type is resolved by searching the schemas in the SQL path.

REF (*type-name*)
Specifies a reference type. If a type name is specified without a schema name, the *type-name* is resolved by searching the schemas in the SQL path.

row-type-name
Specifies the name of a user-defined row type. The fields of the variable are the fields of the row type. If *row-type-name* is specified without a schema name, the row type is resolved by searching the schemas in the SQL path.

DEFAULT or CONSTANT
Specifies a value for the global variable when it is first referenced. The DEFAULT or CONSTANT clause value is determined on this first reference. If neither is specified, the default for the global variable is the null value. Only DEFAULT NULL can be explicitly specified if *array-type-name* or *row-type-name* is specified.

DEFAULT
Defines the default for the global variable. The default value must be assignment-compatible with the data type of the variable.

CONSTANT
Specifies that the global variable has a fixed value that cannot be changed. A global variable that is defined using CONSTANT cannot be used as the target of any assignment operation. The fixed value must be assignment-compatible with the data type of the variable.

NULL
Specifies NULL as the default for the global variable. If *row-type-name* is specified, the value for the global variable is a row where each field has the null value.

constant
Specifies the value of a constant as the default for the global variable. If *data-type1* specifies a CURSOR built-in type or *cursor-type-name*, *constant* cannot be specified (SQLSTATE 42601).

special-register
Specifies the value of a special register as the default for the global variable. If *data-type1* specifies a CURSOR built-in type or *cursor-type-name*, *special-register* cannot be specified (SQLSTATE 42601).

global-variable
Specifies the value of a global variable as the default for the global variable. If *data-type1* specifies a CURSOR built-in type or *cursor-type-name*, *global-variable* cannot be specified (SQLSTATE 42601).

cursor-value-constructor
A *cursor-value-constructor* specifies the *select-statement* that is associated with the global variable. The assignment of a *cursor-value-constructor* to a cursor variable defines the underlying cursor of that cursor variable.

ASENSITIVE or INSENSITIVE
Specifies whether the cursor is asensitive or insensitive to changes. See "DECLARE CURSOR" for more information. The default is ASENSITIVE.

ASENSITIVE
Specifies that the cursor should be as sensitive as possible to insert, update, or delete operations made to the rows underlying the result table, depending on how the *select-statement* is optimized. This option is the default.

INSENSITIVE
Specifies that the cursor does not have sensitivity to insert, update, or delete operations that are made to the rows underlying the result table. If INSENSITIVE is specified, the cursor is read-only and the result table is materialized when the cursor is opened. As a result, the size of the result table, the order of the rows, and the values for each row do not change after the cursor is opened. The SELECT statement cannot contain a FOR UPDATE clause, and the cursor cannot be used for positioned updates or deletes.

(parameter-declaration, ...)
Specifies the input parameters of the cursor, including the name and the data type of each parameter.

parameter-name
Names the parameter for use as an SQL variable within *select-statement*. The name cannot be the same as any other parameter name for the cursor. Names should also be chosen to avoid any column names that could be used in *select-statement*, since column names are resolved before parameter names.

data-type2
Specifies the data type of the cursor parameter used within *select-statement*.

built-in-type
Specifies a built-in data type. For a more complete description of each built-in data type, see "CREATE TABLE". The BOOLEAN and CURSOR built-in types cannot be specified (SQLSTATE 429BB).

anchored-parameter-data-type
Identifies another object used to determine the data type of the cursor parameter. The data type of the anchor object is bound by the same limitations that apply when specifying the data type directly.

ANCHOR DATA TYPE TO
Indicates an anchored data type is used to specify the data type.

variable-name
Identifies a global variable. The data type of the referenced variable is used as the data type for the cursor parameter.

table-name.column-name
Identifies a column name of an existing table or view. The data type of the column is used as the data type for the cursor parameter.

distinct-type-name
Specifies the name of a distinct type. If *distinct-type-name* is specified without a schema name, the distinct type is resolved by searching the schemas in the SQL path.

holdability
Specifies whether the cursor is prevented from being closed as a consequence of a commit operation. See "DECLARE CURSOR" for more information. The default is WITHOUT HOLD.

WITHOUT HOLD
Does not prevent the cursor from being closed as a consequence of a commit operation.

WITH HOLD
Maintains resources across multiple units of work. Prevents the cursor from being closed as a consequence of a commit operation.

select-statement
Specifies the SELECT statement of the cursor. See "select-statement" for more information.

statement-name
Specifies the prepared *select-statement* of the cursor. See "PREPARE" for an explanation of prepared statements. The target cursor variable must not have a data type that is a strongly-typed user-defined cursor type (SQLSTATE 428HU).

expression
Specifies the value of an expression as the default for the global variable. The expression can be any expression of the type described in "Expressions". The expression must be assignment-compatible with the data type of the variable. The maximum size of the expression is 64K. The default expression must not modify SQL data (SQLSTATE 428FL) or perform external action (SQLSTATE 42845). If *data-type1* specifies a CURSOR built-in type or *cursor-type-name*, *expression* cannot be specified (SQLSTATE 42601).

Rules

- ***Use of anchored data types:*** An anchored data type cannot refer to the following objects (SQLSTATE 428HS): a nickname, typed table, typed view, statistical view that is associated with an expression-based index, declared temporary table, row definition that is associated with a weakly typed cursor, object with a code page or collation that is different from the database code page or database collation.

Notes

- Session global variables have a session scope. This means that, although they are available to all sessions that are active on the database, their value is private for each session.
- ***Contexts for array, Boolean, cursor, and row global variables:*** Global variables that are array variables, Boolean variables, or row variables can only be used in compound SQL (compiled) statements or SET variable statements. Global variables that are cursor variables can only be used in compound SQL (compiled) statements.
- ***Create with errors:*** If an object referenced in the default expression does not exist or is marked invalid, or the definer temporarily doesn't have privileges to access the object, and if the database configuration parameter **auto_reval** is not set to DISABLED, then the variable will still be created successfully. The variable will be marked invalid and will be revalidated the next time it is invoked.
- ***Scope of global variable values:*** The values for session global variables persist until they are updated in the current session, the global variable is dropped or altered, or the application session ends. The value is unaffected by COMMIT or ROLLBACK statements. The default value for a global variable can be not deterministic and dependent on when the default value is calculated for the global variable (for example, a reference to the time of day, or a reference to some data stored in a table).

  A technique commonly used, especially for performance, is for an application or product to manage a set of connections and route transactions to an arbitrary connection. In these situations, the non-default value of a global variable or the not deterministic initial default value for a global variable should only be relied on until the end of the transaction. Examples of where this type of situation can occur include applications that: use XA protocols, use connection pooling, use the connection concentrator, and use HADR to achieve failover.
- ***Privileges to use a global variable:*** An attempt to read from or to write to a global variable created by this statement requires that the authorization ID attempting this action hold the appropriate privilege on the global variable. The definer of the variable is implicitly granted all privileges on the variable.
- ***Setting of the default value:*** A created global variable is instantiated to its default value when it is first referenced within its given scope. Note that if a global variable is referenced in a statement, it is instantiated independently of the control flow for that statement.
- ***Using a newly created session global variable:*** If a global variable is created within a session, it cannot be used by other sessions until the unit of work has committed. However, the new global variable can be used within the session that created the variable before the unit of work commits.

Examples

- *Example 1:* Create a session global variable to indicate what printer to use for the session.

```
CREATE VARIABLE MYSCHEMA.MYJOB_PRINTER VARCHAR(30)
  DEFAULT 'Default printer'
```

- *Example 2:* Create a session global variable to indicate the department where an employee works.

```
CREATE VARIABLE SCHEMA1.GV_DEPTNO INTEGER
  DEFAULT ((SELECT DEPTNO FROM HR.EMPLOYEES
    WHERE EMPUSER = SESSION_USER))
```

- *Example 3:* Create a session global variable to indicate the security level of the current user.

```
CREATE VARIABLE SCHEMA2.GV_SECURITY_LEVEL INTEGER
  DEFAULT (GET_SECURITY_LEVEL (SESSION_USER))
```

- *Example 4:* Create a session global variable as a cursor on the STAFF table that returns the names of each employee for the specified job type. Order the results by the department number.

```
CREATE VARIABLE STAFFJOBS CURSOR
  CONSTANT (CURSOR (WHICHJOB CHAR(5))
  FOR SELECT NAME, DEPT FROM STAFF WHERE JOB = WHICHJOB
    ORDER BY DEPT)
```

- *Example 5:* Create a global variable of the XML data type:

```
CREATE VARIABLE MYSCHEMA.CUSTOMER_HISTORY_VAR XML
```

CREATE VIEW

The CREATE VIEW statement defines a view on one or more tables, views or nicknames.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the view does not exist
- CREATEIN privilege on the schema, if the schema name of the view refers to an existing schema
- SCHEMAADM authority on the schema, if the schema name of the view refers to an existing schema
- DBADM authority

and at least one of the following authorities for each table, view, or nickname identified in any fullselect:

- CONTROL privilege on that table, view, or nickname
- SELECT privilege on that table, view, or nickname
- SELECTIN privilege on the schema containing the table, view, or nickname
- DATAACCESS authority on the schema containing the table, view, or nickname
- DATAACCESS authority

If creating a subview:

- The authorization ID of the statement must be the same as the definer of the root table of the table hierarchy, or
- The privileges held by the authorization ID must include SCHEMAADM authority on the schema containing the root table of the table hierarchy
- The privileges held by the authorization ID must include DBADM authority

and

- The authorization ID of the statement must have SELECT WITH GRANT privilege on the underlying table of the subview, or the superview must not have SELECT privilege granted to any user other than the view definer, or
- ACCESSCTRL authority on the database or ACCESSCTRL authority on the schema containing the underlying table of the subview, and one of the following authorities:
  - SELECT privilege on the underlying table of the subview
  - SELECTIN privilege on the schema containing the underlying table of the subview
  - DATAACCESS authority on the schema containing the underlying table of the subview
  - DATAACCESS authority

If WITH ROW MOVEMENT is specified, the privileges held by the authorization ID of the statement must include at least one of the following authorities:

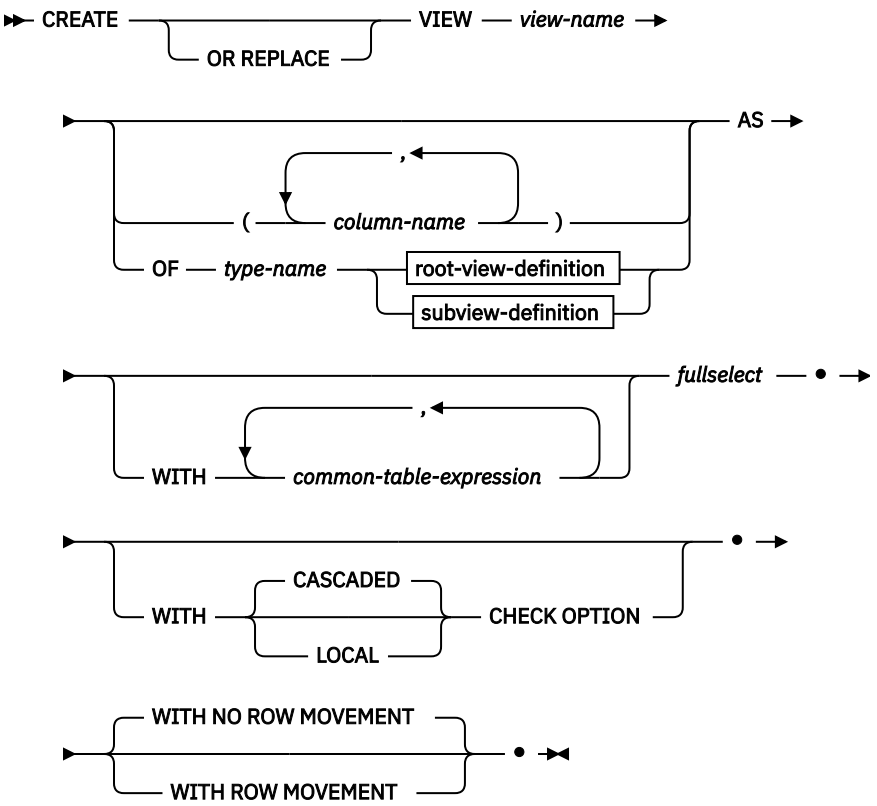
- UPDATE privilege on that table or view
- UPDATEIN privilege on the schema containing that table or view
- DATAACCESS authority on the schema containing that table or view
- DATAACCESS authority

Group privileges are not considered for any table or view specified in the CREATE VIEW statement.

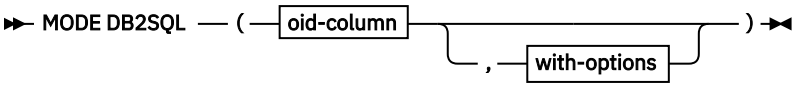
Privileges are not considered when defining a view on a federated database nickname. Authorization requirements of the data source for the table or view referenced by the nickname are applied when the query is processed. The authorization ID of the statement can be mapped to a different remote authorization ID.

To replace an existing view, the authorization ID of the statement must be the owner of the existing view (SQLSTATE 42501).

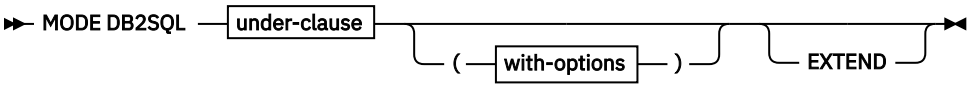
Syntax



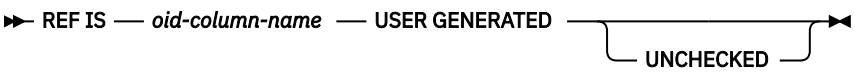
root-view-definition



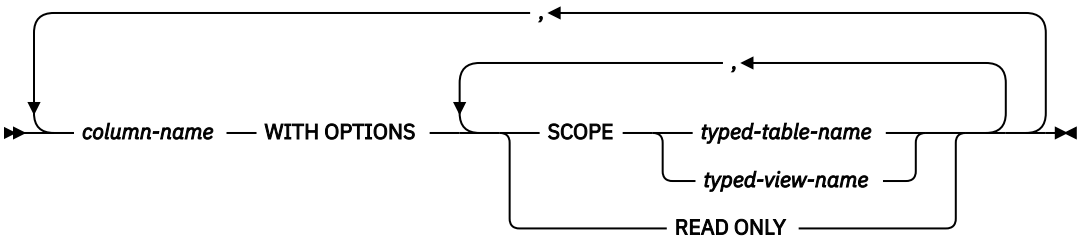
subview-definition



oid-column



with-options



under-clause

Description

OR REPLACE
Specifies to replace the definition for the view if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that privileges that were granted on the view are not affected. This option is ignored if a definition for the view does not exist at the current server. This option can be specified only by the owner of the object.

view-name
Names the view. The name, including the implicit or explicit qualifier, must not identify a table, view, nickname or alias described in the catalog. The qualifier must not be SYSIBM, SYSCAT, SYSFUN, or SYSSTAT (SQLSTATE 42939).

The name can be the same as the name of an inoperative view (see Inoperative views). In this case the new view specified in the CREATE VIEW statement will replace the inoperative view. The user will get a warning (SQLSTATE 01595) when an inoperative view is replaced. No warning is returned if the application was bound with the bind option SQLWARN set to NO.

column-name
Names the columns in the view. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the fullselect. Each *column-name* must be unique and unqualified. If a list of column names is not specified, the columns of the view inherit the names of the columns of the result table of the fullselect.

A list of column names must be specified if the result table of the fullselect has duplicate column names or an unnamed column (SQLSTATE 42908). An unnamed column is a column derived from a constant, function, expression, or set operation that is not named using the AS clause of the select list.

OF *type-name*
Specifies that the columns of the view are based on the attributes of the structured type identified by *type-name*. If *type-name* is specified without a schema name, the type name is resolved by searching the schemas on the SQL path (defined by the FUNCPATH preprocessing option for static SQL and by the CURRENT PATH register for dynamic SQL). The type name must be the name of an existing

user-defined type (SQLSTATE 42704) and it must be a structured type that is instantiable (SQLSTATE 428DP).

MODE DB2SQL
This clause is used to specify the mode of the typed view. This is the only valid mode currently supported.

UNDER *superview-name*
Indicates that the view is a subview of *superview-name*. The superview must be an existing view (SQLSTATE 42704) and the view must be defined using a structured type that is the immediate supertype of *type-name* (SQLSTATE 428DB). The schema name of *view-name* and *superview-name* must be the same (SQLSTATE 428DQ). The view identified by *superview-name* must not have any existing subview already defined using *type-name* (SQLSTATE 42742).

The columns of the view include the object identifier column of the superview with its type modified to be REF(*type-name*), followed by columns based on the attributes of *type-name* (remember that the type includes the attributes of its supertype).

INHERIT SELECT PRIVILEGES
Any user or group holding a SELECT privilege on the superview will be granted an equivalent privilege on the newly created subview. The subview definer is considered to be the grantor of this privilege.

OID-column
Defines the object identifier column for the typed view.

REF IS *OID-column-name* USER GENERATED
Specifies that an object identifier (OID) column is defined in the view as the first column. An OID is required for the root view of a view hierarchy (SQLSTATE 428DX). The view must be a typed view (the OF clause must be present) that is not a subview (SQLSTATE 42613). The name for the column is defined as *OID-column-name* and cannot be the same as the name of any attribute of the structured type *type-name* (SQLSTATE 42711). The first column specified in *fullselect* must be of type REF(*type-name*) (you may need to cast it so that it has the appropriate type). If UNCHECKED is not specified, it must be based on a not nullable column on which uniqueness is enforced through an index (primary key, unique constraint, unique index, or OID-column). This column will be referred to as the *object identifier column* or *OID column*. The keywords USER GENERATED indicate that the initial value for the OID column must be provided by the user when inserting a row. Once a row is inserted, the OID column cannot be updated (SQLSTATE 42808).

UNCHECKED
Defines the object identifier column of the typed view definition to assume uniqueness even though the system can not prove this uniqueness. This is intended for use with tables or views that are being defined into a typed view hierarchy where the user knows that the data conforms to this uniqueness rule but it does not comply with the rules that allow the system to prove uniqueness. UNCHECKED option is mandatory for view hierarchies that range over multiple hierarchies or legacy tables or views By specifying UNCHECKED, the user takes responsibility for ensuring that each row of the view has a unique OID. If the user fails to ensure this property, and a view contains duplicate OID values, then a path-expression or DEREF operator involving one of the non-unique OID values may result in an error (SQLSTATE 21000).

with-options
Defines additional options that apply to columns of a typed view.

***column-name* WITH OPTIONS**
Specifies the name of the column for which additional options are specified. The *column-name* must correspond to the name of an attribute defined in (not inherited by) the *type-name* of the view. The column must be a reference type (SQLSTATE 42842). It cannot correspond to a column that also exists in the superview (SQLSTATE 428DJ). A column name can only appear in one WITH OPTIONS SCOPE clause in the statement (SQLSTATE 42613).

SCOPE
Identifies the scope of the reference type column. A scope must be specified for any column that is intended to be used as the left operand of a dereference operator or as the argument of the DEREF function.

Specifying the scope for a reference type column may be deferred to a subsequent ALTER VIEW statement (if the scope is not inherited) to allow the target table or view to be defined, usually in the case of mutually referencing views and tables. If no scope is specified for a reference type column of the view and the underlying table or view column was scoped, then the underlying column's scope is inherited by the reference type column. The column remains unscoped if the underlying table or view column did not have a scope. See "Notes" on page 1546 for more information about scope and reference type columns.

typed-table-name
The name of a typed table. The table must already exist or be the same as the name of the table being created (SQLSTATE 42704). The data type of *column-name* must be REF(*S*), where *S* is the type of *typed-table-name* (SQLSTATE 428DM). No checking is done of any existing values in *column-name* to ensure that the values actually reference existing rows in *typed-table-name*.

typed-view-name
The name of a typed view. The view must already exist or be the same as the name of the view being created (SQLSTATE 42704). The data type of *column-name* must be REF(*S*), where *S* is the type of *typed-view-name* (SQLSTATE 428DM). No checking is done of any existing values in *column-name* to ensure that the values actually reference existing rows in *typed-view-name*.

READ ONLY
Identifies the column as a read-only column. This option is used to force a column to be read-only so that subview definitions can specify an expression for the same column that is implicitly read-only.

AS
Identifies the view definition.

WITH *common-table-expression*
Defines a common table expression for use with the fullselect that follows. A common table expression cannot be specified when defining a typed view.

fullselect
Defines the view. At any time, the view consists of the rows that would result if the SELECT statement were executed. The data type of the columns of the view cannot be a distinct type with data type constraints, array type, cursor type, or row type. The fullselect must not reference host variables, parameter markers, or declared temporary tables. However, a parameterized view can be created as an SQL table function.

The fullselect cannot include an SQL data change statement in the FROM clause (SQLSTATE 428FL).

If a view is created by using a 'SELECT *' statement, the view is not updated when a new column is added to the base table.

For Typed Views and Subviews: The *fullselect* must conform to the following rules otherwise an error is returned (SQLSTATE 428EA unless otherwise specified).

- The fullselect must not include references to the DBPARTITIONNUM or HASHEDVALUE functions, non-deterministic functions, or functions defined to have external action.
- The body of the view must consist of a single subselect, or a UNION ALL of two or more subselects. Let each of the subselects participating directly in the view body be called a *branch* of the view. A view may have one or more branches.
- The FROM-clause of each branch must consist of a single table or view (not necessarily typed), called the *underlying* table or view of that branch.
- The underlying table or view of each branch must be in a separate hierarchy (that is, a view cannot have multiple branches with their underlying tables or views in the same hierarchy).
- None of the branches of a typed view definition may specify GROUP BY or HAVING.
- If the view body contains UNION ALL, the root view in the hierarchy must specify the UNCHECKED option for its OID column.

For a hierarchy of views and subviews: Let BR1 and BR2 be any branches that appear in the definitions of views in the hierarchy. Let T1 be the underlying table or view of BR1, and let T2 be the underlying table or view of BR2. Then:

- If T1 and T2 are not in the same hierarchy, then the root view in the view hierarchy must specify the UNCHECKED option for its OID column.
- If T1 and T2 are in the same hierarchy, then BR1 and BR2 must contain predicates or ONLY-clauses that are sufficient to guarantee that their row-sets are disjoint.

For typed subviews defined using EXTEND AS: For every branch in the body of the subview:

- The underlying table of each branch must be a (not necessarily proper) subtable of some underlying table of the immediate superview.
- The expressions in the SELECT list must be assignable to the non-inherited columns of the subview (SQLSTATE 42854).

For typed subviews defined using AS without EXTEND:

- For every branch in the body of the subview, the expressions in the SELECT-list must be assignable to the declared types of the inherited and non-inherited columns of the subview (SQLSTATE 42854).
- The OID-expression of each branch over a given hierarchy in the subview must be equivalent (except for casting) to the OID-expression in the branch over the same hierarchy in the root view.
- The expression for a column not defined (implicitly or explicitly) as READ ONLY in a superview must be equivalent in all branches over the same underlying hierarchy in its subviews.

WITH CHECK OPTION

Specifies the constraint that every row that is inserted or updated through the view must conform to the definition of the view. A row that does not conform to the definition of the view is a row that does not satisfy the search conditions of the view.

WITH CHECK OPTION must not be specified if any of the following conditions is true:

- The view is read-only (SQLSTATE 42813). If WITH CHECK OPTION is specified for an updatable view that does not allow inserts, the constraint applies to updates only.
- The view references the DBPARTITIONNUM or HASHEDVALUE function, a non-deterministic function, or a function with external action (SQLSTATE 42997).
- A nickname is the update target of the view.
- A view that has an INSTEAD OF trigger defined on it is the update target of the view (SQLSTATE 428FQ).

If WITH CHECK OPTION is omitted, the definition of the view is not used in the checking of any insert or update operations that use the view. Some checking might still occur during insert or update operations if the view is directly or indirectly dependent on another view that includes WITH CHECK OPTION. Because the definition of the view is not used, rows might be inserted or updated through the view that do not conform to the definition of the view.

CASCADED

The WITH CASCADED CHECK OPTION constraint on a view *V* means that *V* inherits the search conditions as constraints from any updatable view on which *V* is dependent. Furthermore, every updatable view that is dependent on *V* is also subject to these constraints. Thus, the search conditions of *V* and each view on which *V* is dependent are ANDed together to form a constraint that is applied for an insert or update of *V* or of any view dependent on *V*.

LOCAL

The WITH LOCAL CHECK OPTION constraint on a view *V* means the search condition of *V* is applied as a constraint for an insert or update of *V* or of any view that is dependent on *V*.

The difference between CASCADED and LOCAL is shown in the following example. Consider the following updatable views (substituting for Y from column headings of the table that follows):

```
V1 defined on table T
V2 defined on V1 WITH Y CHECK OPTION
```

```
V3 defined on V2
V4 defined on V3 WITH Y CHECK OPTION
V5 defined on V4
```

The following table shows the search conditions against which inserted or updated rows are checked:

	Y is LOCAL	**Y is CASCADED**
V1 checked against:	no view	no view
V2 checked against:	V2	V2, V1
V3 checked against:	V2	V2, V1
V4 checked against:	V2, V4	V4, V3, V2, V1
V5 checked against:	V2, V4	V4, V3, V2, V1

Consider the following updatable view which shows the impact of the WITH CHECK OPTION using the default CASCADED option:

```
CREATE VIEW V1 AS SELECT COL1 FROM T1 WHERE COL1 > 10

CREATE VIEW V2 AS SELECT COL1 FROM V1 WITH CHECK OPTION

CREATE VIEW V3 AS SELECT COL1 FROM V2 WHERE COL1 < 100
```

The following INSERT statement using *V1* will succeed because *V1* does not have a WITH CHECK OPTION and *V1* is not dependent on any other view that has a WITH CHECK OPTION.

```
INSERT INTO V1 VALUES(5)
```

The following INSERT statement using *V2* will result in an error because *V2* has a WITH CHECK OPTION and the insert would produce a row that did not conform to the definition of *V2*.

```
INSERT INTO V2 VALUES(5)
```

The following INSERT statement using *V3* will result in an error even though it does not have WITH CHECK OPTION because *V3* is dependent on *V2* which does have a WITH CHECK OPTION (SQLSTATE 44000).

```
INSERT INTO V3 VALUES(5)
```

The following INSERT statement using *V3* will succeed even though it does not conform to the definition of *V3* (*V3* does not have a WITH CHECK OPTION); it does conform to the definition of *V2* which does have a WITH CHECK OPTION.

```
INSERT INTO V3 VALUES(200)
```

WITH NO ROW MOVEMENT or WITH ROW MOVEMENT

Specifies the action to take for an updatable UNION ALL view when a row is updated in a way that violates a check constraint on the underlying table. The default is WITH NO ROW MOVEMENT.

WITH NO ROW MOVEMENT

Specifies that an error (SQLSTATE 23513) is to be returned if a row is updated in a way that violates a check constraint on the underlying table.

WITH ROW MOVEMENT

Specifies that an updated row is to be moved to the appropriate underlying table, even if it violates a check constraint on that table.

Row movement involves deletion of the rows that violate the check constraint, and insertion of those rows back into the view. The WITH ROW MOVEMENT clause can only be specified for UNION ALL views whose columns are all updatable (SQLSTATE 429BJ). If a row is inserted (perhaps after trigger activation) into the same underlying table from which it was deleted, an error is returned (SQLSTATE 23524). A view defined using the WITH ROW MOVEMENT clause must not

contain nested UNION ALL operations, except in the outermost fullselect (SQLSTATE 429BJ). A view defined using the WITH ROW MOVEMENT clause, cannot contain any references to a system-period temporal table, application-period temporal table, or bitemporal table.

Notes

- Creating a view with a schema name that does not already exist will result in the implicit creation of that schema provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- View columns inherit the NOT NULL WITH DEFAULT attribute from the base table or view except when columns are derived from an expression. When a row is inserted or updated into an updatable view, it is checked against the constraints (primary key, referential integrity, and check) if any are defined on the base table.
- A new view cannot be created if it uses an inoperative view in its definition. (SQLSTATE 51024).
- If an object referenced in the view body does not exist or is marked invalid, or the definer temporarily doesn't have privileges to access the object, and if the database configuration parameter **auto_reval** is set to DEFERRED_FORCE, then the view will still be created successfully. The view will be marked invalid and will be revalidated the next time it is referenced.
- This statement does not support declared temporary tables (SQLSTATE 42995).
- ***Views based on column-organized tables:***
  - Creating a typed view on column-organized tables is not supported.
  - The WITH CHECK OPTION clause cannot be specified if a column-organized table is part of the view definition.
- ***Deletable views:*** A view is *deletable* if an INSTEAD OF trigger for the delete operation has been defined for the view, or if all of the following conditions are true:
  - Each FROM clause of the outer fullselect identifies only one base table (with no OUTER clause), deletable view (with no OUTER clause), deletable nested table expression, or deletable common table expression (cannot identify a nickname). Also, any period-specification specified for the base table or deletable view does not reference the SYSTEM_TIME period.
  - The outer fullselect does not include a VALUES clause
  - The outer fullselect does not include a GROUP BY clause or HAVING clause
  - The outer fullselect does not include aggregate functions in the select list
  - The outer fullselect does not include SET operations (UNION, EXCEPT or INTERSECT) with the exception of UNION ALL
  - The base tables in the operands of a UNION ALL must not be the same table and each operand must be deletable
  - The select list of the outer fullselect does not include DISTINCT
- ***Updatable views:*** A column of a view is *updatable* if an INSTEAD OF trigger for the update operation has been defined for the view, or if all of the following conditions are true:
  - The view is deletable (independent of an INSTEAD OF trigger for delete), the column resolves to a column of a base table (not using a dereference operation), and the READ ONLY option is not specified
  - All the corresponding columns of the operands of a UNION ALL have exactly matching data types (including length or precision and scale) and matching default values if the fullselect of the view includes a UNION ALL

  A view is updatable if *any* column of the view is updatable.
- ***Insertable views***: A view is insertable if an INSTEAD OF trigger for the insert operation has been defined for the view, or at least one column of the view is updatable (independent of an INSTEAD OF trigger for update), and the fullselect of the view does not include UNION ALL.

A given row can be inserted into a view (including a UNION ALL) if, and only if, it fulfills the check constraints of exactly one of the underlying base tables.

To insert into a view that includes non-updatable columns, those columns must be omitted from the column list.

- ***Read-only views***: A view is *read-only* if it is *not* deletable, updatable, or insertable.

  The READONLY column in the SYSCAT.VIEWS catalog view indicates if a view is read-only without considering period specifications or INSTEAD OF triggers.
- Common table expressions and nested table expressions follow the same set of rules for determining whether they are deletable, updatable, insertable, or read-only.
- ***Special registers for temporal support:*** The values of the CURRENT TEMPORAL SYSTEM_TIME and CURRENT TEMPORAL BUSINESS_TIME special registers have no impact on the query expression that defines a view while it is being defined. When a view is used in an SQL statement, the values of the CURRENT TEMPORAL SYSTEM_TIME and CURRENT TEMPORAL BUSINESS_TIME special registers for the session processing the SQL statement are applied to the view.
- ***Inoperative views:*** An *inoperative view* is a view that is no longer available for SQL statements. A view becomes inoperative if:
  - A privilege, upon which the view definition is dependent, is revoked.
  - An object such as a table, nickname, alias or function, upon which the view definition is dependent, is dropped.
  - A view, upon which the view definition is dependent, becomes inoperative.
  - A view that is the superview of the view definition (the subview) becomes inoperative.

  In practical terms, an inoperative view is one in which the view definition has been unintentionally dropped. For example, when an alias is dropped, any view defined using that alias is made inoperative. All dependent views also become inoperative and packages dependent on the view are no longer valid.

  Until the inoperative view is explicitly re-created or dropped, a statement using that inoperative view cannot be compiled (SQLSTATE 51024) with the exception of the CREATE ALIAS, CREATE VIEW, DROP VIEW, and COMMENT ON TABLE statements. Until the inoperative view has been explicitly dropped, its qualified name cannot be used to create another table or alias (SQLSTATE 42710).

  An inoperative view may be re-created by issuing a CREATE VIEW statement using the definition text of the inoperative view. This view definition text is stored in the TEXT column of the SYSCAT.VIEWS catalog. When recreating an inoperative view, it is necessary to explicitly grant any privileges required on that view by others, due to the fact that all authorization records on a view are deleted if the view is marked inoperative. Note that there is no need to explicitly drop the inoperative view in order to re-create it. Issuing a CREATE VIEW statement with the same *view-name* as an inoperative view will cause that inoperative view to be replaced, and the CREATE VIEW statement will return a warning (SQLSTATE 01595).

  Inoperative views are indicated by an X in the VALID column of the SYSCAT.VIEWS catalog view and an X in the STATUS column of the SYSCAT.TABLES catalog view.
- ***Privileges***: The definer of a view always receives the SELECT privilege on the view as well as the right to drop the view. The definer of a view will get CONTROL privilege on the view only if the definer has CONTROL privilege on every base table, view, or nickname identified in the fullselect, or if the definer has each of the following authorities:
  - ACCESSCTRL or SECADM on the database or ACCESSCTRL on the schema containing every base table, view, or nickname identified in the fullselect
  - DATAACCESS on the database or DATAACCESS on the schema containing every base table, view, or nickname identified in the fullselect
  - DBADM or SCHEMAADM on the schema containing every base table, view, or nickname identified in the fullselect

The definer of the view is granted INSERT, UPDATE, column level UPDATE or DELETE privileges on the view if the view is not read-only and the definer has the corresponding privileges on the underlying objects.

For a view defined WITH ROW MOVEMENT, the definer acquires the UPDATE privilege on the view only if the definer has the UPDATE privilege on all columns of the view, as well as INSERT and DELETE privileges on all underlying tables or views.

The definer of a view only acquires privileges if the privileges from which they are derived exist at the time the view is created. The definer must have these privileges either directly or because PUBLIC has these privilege. Privileges are not considered when defining a view on a federated server nickname. However, when using a view on a nickname, the user's authorization ID must have valid select privileges on the table or view that the nickname references at the data source. Otherwise, an error is returned. Privileges held by groups of which the view definer is a member, are not considered.

When a subview is created, the SELECT privileges held on the immediate superview are automatically granted on the subview.

- ***Scope and REF columns***: When selecting a reference type column in the fullselect of a view definition, consider the target type and scope that is required.
  - If the required target type and scope is the same as the underlying table or view, the column can simply be selected.
  - If the scope needs to be changed, use the WITH OPTIONS SCOPE clause to define the required scope table or view.
  - If the target type of the reference needs to be changed, the column must be cast first to the representation type of the reference and then to the new reference type. The scope in this case can be specified in the cast to the reference type or using the WITH OPTIONS SCOPE clause. For example, assume you select column Y defined as REF(TYP1) SCOPE TAB1. You want this to be defined as REF(VTYP1) SCOPE VIEW1. The select list item would be as follows:

    ```
    CAST(CAST(Y AS VARCHAR(16) FOR BIT DATA) AS REF(VTYP1) SCOPE VIEW1)
    ```

- ***Identity columns:*** A column of a view is considered an identity column, if the element of the corresponding column in the fullselect of the view definition is the name of an identity column of a table, or the name of a column of a view which directly or indirectly maps to the name of an identity column of a base table.

  In all other cases, the columns of a view will not get the identity property. For example:
  - the select-list of the view definition includes multiple instances of the name of an identity column (that is, selecting the same column more than once)
  - the view definition involves a join
  - a column in the view definition includes an expression that refers to an identity column
  - the view definition includes a UNION

  When inserting into a view for which the select list of the view definition directly or indirectly includes the name of an identity column of a base table, the same rules apply as if the INSERT statement directly referenced the identity column of the base table.
- ***Federated views:*** A federated view is a view that includes a reference to a nickname somewhere in the fullselect. The presence of such a nickname changes the authorization model used for the view when the view is subsequently referenced in a query.

  When the view is created, no privilege checking is done to determine whether the view definer has access to the underlying data source table or view of a nickname. Privilege checking of references to tables or views at the federated database are handled as usual, requiring the view definer to have at least SELECT privilege on such objects.

  When a federated view is subsequently referenced in a query, the nicknames result in queries against the data source, and the authorization ID that issued the query (or the remote authorization ID to which it maps) must have the necessary privileges to access the data source table or view. The authorization

ID that issues the query referencing the federated view is not required to have any additional privileges on tables or views (non-federated) that exist at the federated server.

- ***ROW MOVEMENT, triggers and constraints:*** When a view that is defined using the WITH ROW MOVEMENT clause is updated, the sequence of trigger and constraints operations is as follows:
  1. BEFORE UPDATE triggers are activated for all rows being updated, including rows that will eventually be moved.
  2. The update operation is processed.
  3. Constraints are processed for all updated rows.
  4. AFTER UPDATE triggers (both row-level and statement-level) are activated in creation order, for all rows that satisfy the constraints after the update operation. Because this is an UPDATE statement, all UPDATE statement-level triggers are activated for all underlying tables.
  5. BEFORE DELETE triggers are activated for all rows that did not satisfy the constraints after the update operation (these are the rows that are to be moved).
  6. The delete operation is processed.
  7. Constraints are processed for all deleted rows.
  8. AFTER DELETE triggers (both row-level and statement-level) are activated in creation order, for all deleted rows. Statement-level triggers are activated for only those tables that are involved in the delete operation.
  9. BEFORE INSERT triggers are activated for all rows being inserted (that is, the rows being moved). The new transition tables for the BEFORE INSERT triggers contain the input data provided by the user. Such triggers cannot contain an UPDATE, a DELETE, or an INSERT operation, or invoke any routine containing such operations (SQLSTATE 42987).
  10. The insert operation is processed.
  11. Constraints are processed for all inserted rows.
  12. AFTER INSERT triggers (both row-level and statement-level) are activated in creation order, for all inserted rows. Statement-level triggers are activated for only those tables that are involved in the insert operation.
- ***Nested UNION ALL views:*** A view defined with UNION ALL and based, either directly or indirectly, on a view that is also defined with UNION ALL cannot be updated if either view is defined using the WITH ROW MOVEMENT clause (SQLSTATE 429BK).
- ***Considerations for implicitly hidden columns:*** It is possible that the result table of the fullselect will include a column of the base table that is defined as implicitly hidden. This can occur when the implicitly hidden column is explicitly referenced in the fullselect of the view definition. However, the corresponding column of the view does not inherit the implicitly hidden attribute. Columns of a view cannot be defined as hidden.
- ***Subselect***: The *isolation-clause* cannot be specified in the *fullselect* (SQLSTATE 42601).
- ***Obfuscation***: The CREATE VIEW statement can be submitted in obfuscated form. In an obfuscated statement, only the view name is readable. The rest of the statement is encoded in such a way that is not readable but can be decoded by the database server. Obfuscated statements can be produced by calling the DBMS_DDL.WRAP function.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products.
  - The FEDERATED keyword can be specified between the keywords CREATE and VIEW. The FEDERATED keyword is ignored, however, because a warning is no longer returned if federated objects are used in the view definition.

Examples

- *Example 1:* Create a view named MA_PROJ upon the PROJECT table that contains only those rows with a project number (PROJNO) starting with the letters 'MA'.

```
CREATE VIEW MA_PROJ  AS SELECT *
  FROM PROJECT
   WHERE SUBSTR(PROJNO, 1, 2) = 'MA'
```

- *Example 2:* Create a view as in example 1, but select only the columns for project number (PROJNO), project name (PROJNAME) and employee in charge of the project (RESPEMP).

```
CREATE VIEW MA_PROJ
  AS SELECTPROJNO, PROJNAME, RESPEMP
  FROM PROJECT
  WHERE SUBSTR(PROJNO, 1, 2) = 'MA'
```

- *Example 3:* Create a view as in example 2, but, in the view, call the column for the employee in charge of the project IN_CHARGE.

```
CREATE VIEW MA_PROJ
  (PROJNO, PROJNAME, IN_CHARGE)
  AS SELECTPROJNO, PROJNAME, RESPEMP
  FROM PROJECT
  WHERE SUBSTR(PROJNO, 1, 2) = 'MA'
```

  Note: Even though only one of the column names is being changed, the names of all three columns in the view must be listed in the parentheses that follow MA_PROJ.

- *Example 4:* Create a view named PRJ_LEADER that contains the first four columns (PROJNO, PROJNAME, DEPTNO, RESPEMP) from the PROJECT table together with the last name (LASTNAME) of the person who is responsible for the project (RESPEMP). Obtain the name from the EMPLOYEE table by matching EMPNO in EMPLOYEE to RESPEMP in PROJECT.

```
CREATE VIEW PRJ_LEADER
  AS SELECT PROJNO, PROJNAME, DEPTNO, RESPEMP, LASTNAME
  FROM PROJECT, EMPLOYEE
  WHERE RESPEMP = EMPNO
```

- *Example 5:* Create a view as in example 4, but in addition to the columns PROJNO, PROJNAME, DEPTNO, RESPEMP, and LASTNAME, show the total pay (SALARY + BONUS + COMM) of the employee who is responsible. Also select only those projects with mean staffing (PRSTAFF) greater than one.

```
CREATE VIEW PRJ_LEADER
(PROJNO, PROJNAME, DEPTNO, RESPEMP, LASTNAME, TOTAL_PAY )
AS SELECT PROJNO, PROJNAME, DEPTNO, RESPEMP, LASTNAME, SALARY+BONUS+COMM
  FROM PROJECT, EMPLOYEE
  WHERE RESPEMP = EMPNO
  AND PRSTAFF > 1
```

  Specifying the column name list could be avoided by naming the expression SALARY+BONUS+COMM as TOTAL_PAY in the fullselect.

```
CREATE VIEW PRJ_LEADER
  AS SELECT PROJNO, PROJNAME, DEPTNO, RESPEMP,
              LASTNAME, SALARY+BONUS+COMM AS TOTAL_PAY
    FROM PROJECT, EMPLOYEE
    WHERE RESPEMP = EMPNO AND PRSTAFF > 1
```

- *Example 6:* Given the set of tables and views shown in the following figure:

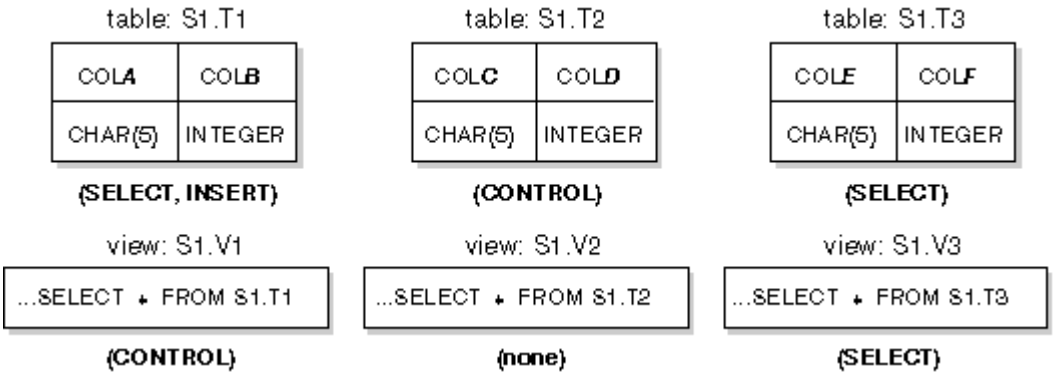


Figure 5. Tables and Views for Example 6

User ZORPIE (who does not have ACCESSCTRL, DATAACCESS, or DBADM authority) has the privileges shown in parentheses for each object:

1. ZORPIE will get CONTROL privilege on the view that she creates with:

   ```
   CREATE VIEW VA AS SELECT * FROM S1.V1
   ```

   because she has CONTROL on S1.V1. (CONTROL on S1.V1 must have been granted to ZORPIE by someone with ACCESSCTRL or SECADM authority.) It does not matter which, if any, privileges she has on the underlying base table.
2. ZORPIE will not be allowed to create the view:

   ```
   CREATE VIEW VB AS SELECT * FROM S1.V2
   ```

   because she has neither CONTROL nor SELECT on S1.V2. It does not matter that she has CONTROL on the underlying base table (S1.T2).
3. ZORPIE will get CONTROL privilege on the view that she creates with:

   ```
   CREATE VIEW VC (COLA, COLB, COLC, COLD)
     AS SELECT * FROM S1.V1, S1.T2
     WHERE COLA = COLC
   ```

   because the fullselect of ZORPIE.VC references view S1.V1 and table S1.T2 and she has CONTROL on both of these. Note that the view VC is read-only, so ZORPIE does not get INSERT, UPDATE or DELETE privileges.
4. ZORPIE will get SELECT privilege on the view that she creates with:

   ```
   CREATE VIEW VD (COLA,COLB, COLE, COLF)
     AS SELECT * FROM S1.V1, S1.V3
     WHERE COLA = COLE
   ```

   because the fullselect of ZORPIE.VD references the two views S1.V1 and S1.V3, one on which she has only SELECT privilege, and one on which she has CONTROL privilege. She is given the lesser of the two privileges, SELECT, on ZORPIE.VD.
5. ZORPIE will get INSERT, UPDATE and DELETE privilege WITH GRANT OPTION and SELECT privilege on the view VE in the following view definition.

   ```
   CREATE VIEW VE
      AS SELECT * FROM S1.V1
     WHERE COLA > ANY
            (SELECT COLE FROM S1.V3)
   ```

   ZORPIE's privileges on VE are determined primarily by her privileges on S1.V1. Since S1.V3 is only referenced in a subquery, she only needs SELECT privilege on S1.V3 to create the view VE. The definer of a view only gets CONTROL on the view if they have CONTROL on all objects referenced in the view definition. ZORPIE does not have CONTROL on S1.V3, consequently she does not get CONTROL on VE.

CREATE WORK ACTION SET

The CREATE WORK ACTION SET statement defines a work action set and work actions within the work action set.

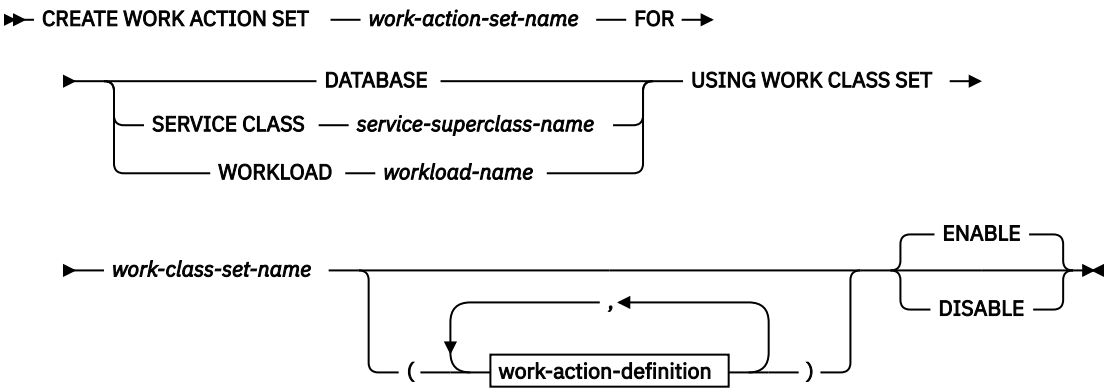
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

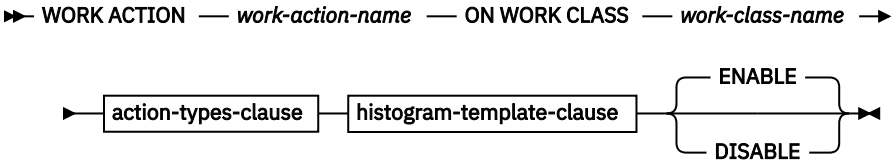
Authorization

The privileges held by the authorization ID of the statement must include WLMADM or DBADM authority.

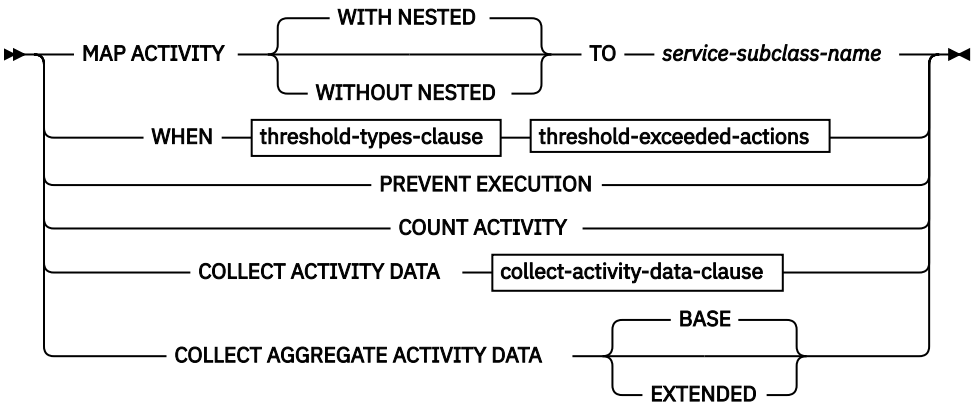
Syntax



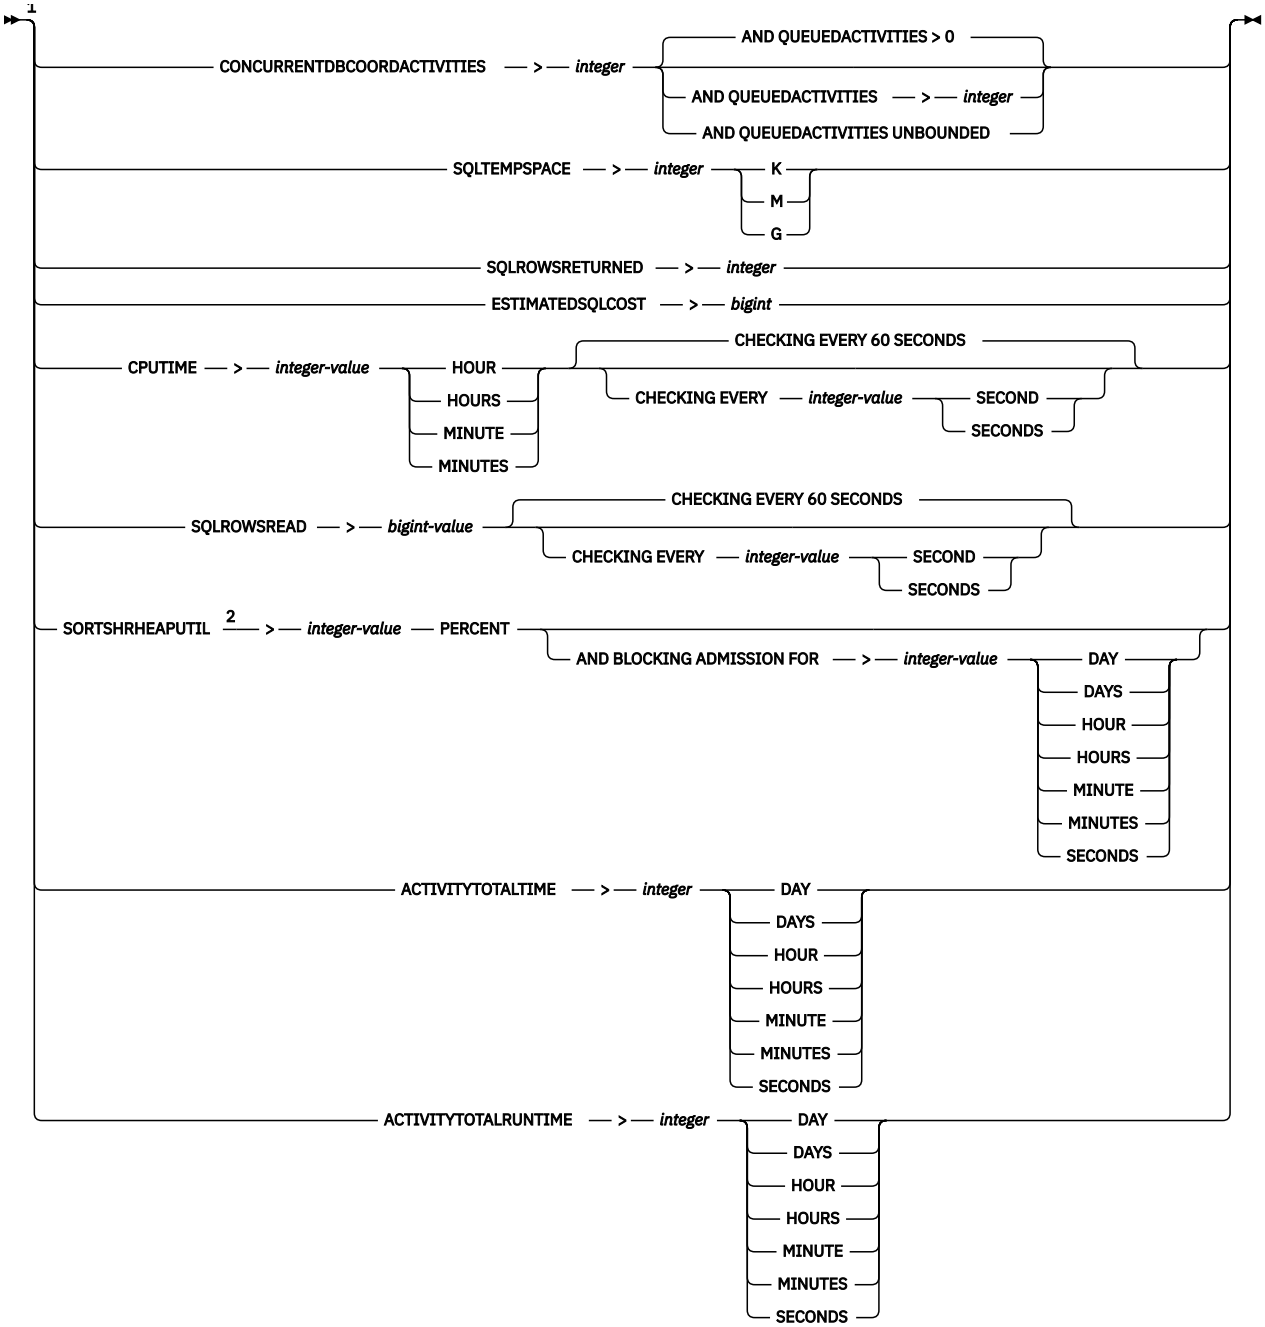
work-action-definition



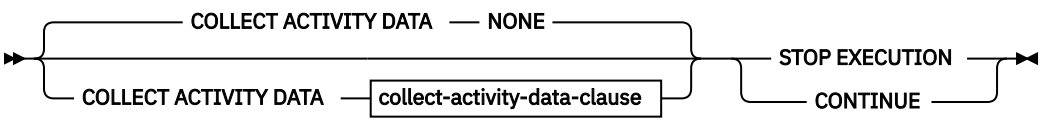
action-types-clause



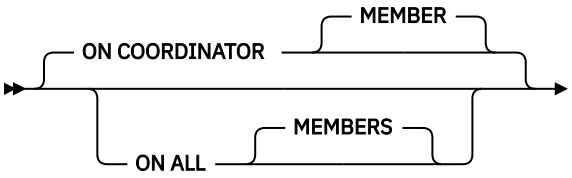
threshold-types-clause

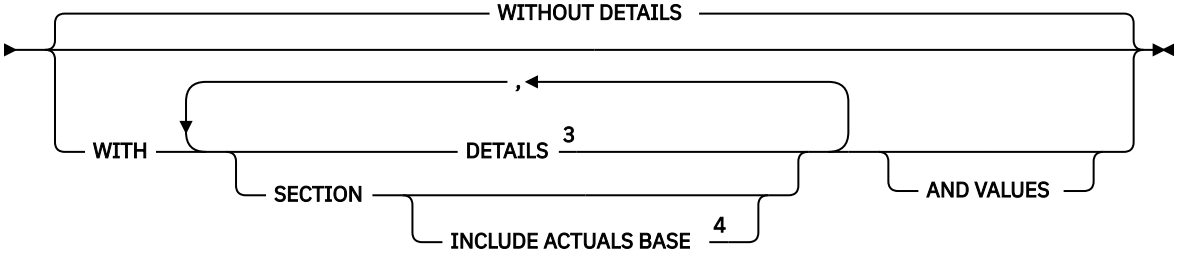


threshold-exceeded-actions

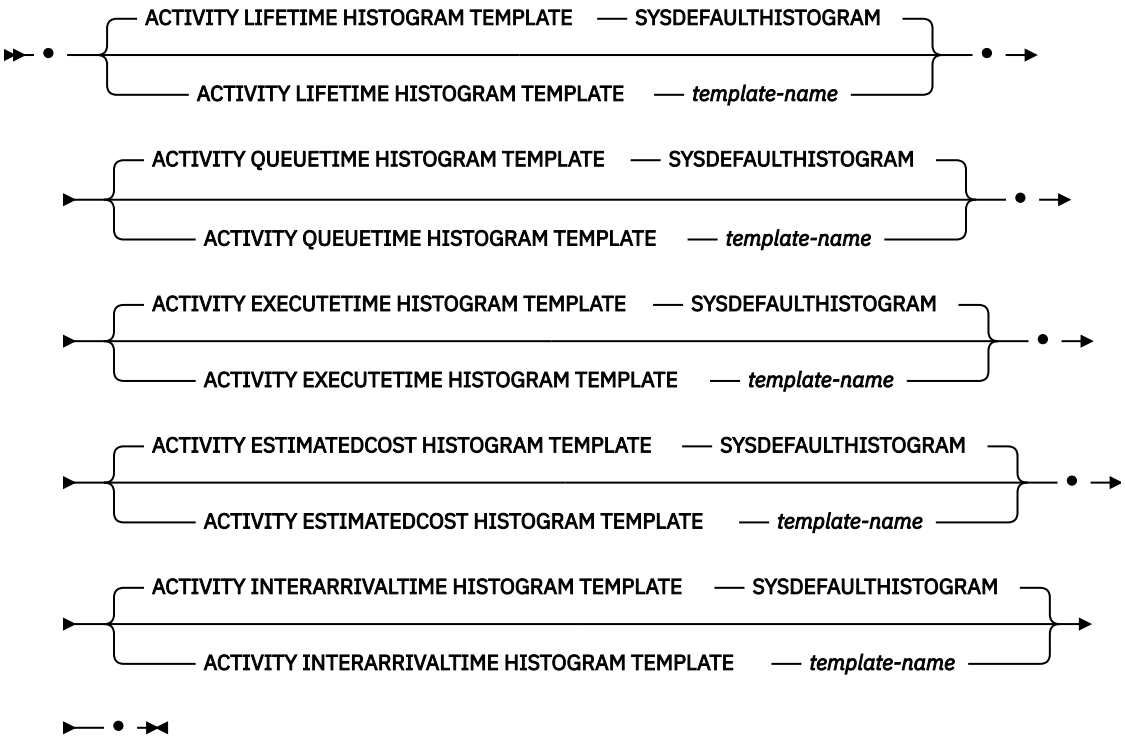


collect-activity-data-clause





histogram-template-clause



Notes:

[1] Only one work action of the same threshold type can be applied to a single work class at a time.
[2] This feature is available in Db2 Version 11.5 Mod Pack 2 and later versions.
[3] The DETAILS keyword is the minimum to be specified, followed by the option separated by a comma.
[4] This clause does not apply to thresholds.

Description

work-action-set-name
Names the work action set. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *work-action-set-name* must not identify a work action set that already exists at the current server (SQLSTATE 42710). The name must not begin with the characters 'SYS' (SQLSTATE 42939).

FOR
Specifies the database manager object to which the actions in this work action set will apply. Each database manager object can have only one work action set defined for it (SQLSTATE 5U017).

DATABASE
The actions in this work action set are to apply to the database. If DATABASE is specified, the MAP ACTIVITY action cannot be specified (SQLSTATE 5U034).

SERVICE CLASS *service-superclass-name*
The actions in this work action set are to apply to *service-superclass-name*. If SERVICE CLASS is specified, threshold actions cannot be specified (SQLSTATE 5U034). The *service-superclass-name* must exist at the current server (SQLSTATE 42704). The *service-superclass-name* must not be a service subclass and cannot be any of the following classes (SQLSTATE 5U032):

- The system service class (SYSDEFAULTSYSTEMCLASS)
- The maintenance service class (SYSDEFAULTMAINTENANCECLASS)
- The default user service class (SYSDEFAULTUSERCLASS)

WORKLOAD *workload-name*
The actions in this work action set are to apply to workload *workload-name*. If WORKLOAD is specified, the MAP ACTIVITY action cannot be specified (SQLSTATE 5U034). The *workload-name* must exist at the current server (SQLSTATE 42704). The *workload-name* cannot be the SYSDEFAULTADMWORKLOAD (SQLSTATE 5U032).

USING WORK CLASS SET *work-class-set-name*
Specifies the work class set containing the work classes that will classify database activities on which to perform actions. The *work-class-set-name* must exist at the current server (SQLSTATE 42704).

work-action-definition
Specifies the definition of the work action.

WORK ACTION *work-action-name*
Names the work action. The *work-action-name* must not identify a work action that already exists at the current server under this work action set (SQLSTATE 42710). The *work-action-name* cannot begin with 'SYS' (SQLSTATE 42939).

ON WORK CLASS *work-class-name*
Specifies the work class that identifies the database activities to which this work action will apply. The *work-class-name* must exist in the *work-class-set-name* at the current server (SQLSTATE 42704).

MAP ACTIVITY
Specifies a work action of mapping the activity. This action can only be specified if the object for which this work action set is defined is a service superclass (SQLSTATE 5U034).

WITH NESTED or WITHOUT NESTED
Specifies whether or not activities that are nested under this activity are mapped to the service subclass. The default is WITH NESTED.

WITH NESTED
All database activities that have a nesting level of zero that are classified under the work class, and all database activities nested under this activity, are mapped to the service subclass; that is, activities with a nesting level greater than zero are run under the same service class as activities with a nesting level of zero.

WITHOUT NESTED
Only database activities that have a nesting level of zero that are classified under the work class are mapped to the service subclass. Database activities that are nested under this activity are handled according to their activity type.

TO *service-subclass-name*
Specifies the service subclass to which activities are to be mapped. The *service-subclass-name* must already exist in the *service-superclass-name* at the current server (SQLSTATE 42704). The *service-subclass-name* cannot be the default service subclass, SYSDEFAULTSUBCLASS (SQLSTATE 5U018).

WHEN
Specifies the threshold that will be applied to the database activity that is associated with the work class for which this work action is defined. A threshold can only be specified if the database

manager object for which this work action set is defined is a database or a workload (SQLSTATE 5U034). None of these thresholds apply to internal database activities initiated by the database manager or to database activities generated by administrative SQL routines.

threshold-types-clause
For a description of valid threshold types, see "CREATE THRESHOLD" statement.

threshold-exceeded-actions
For a description of valid threshold-exceeded actions, see "CREATE THRESHOLD" statement.

PREVENT EXECUTION
Specifies that none of the database activities associated with the work class for which this work action is defined will be allowed to run (SQLSTATE 5U033).

COUNT ACTIVITY
Specifies that all of the database activities associated with the work class for which this work action is defined are to be run and that each time one is run, the counter for the work class will be incremented.

COLLECT ACTIVITY DATA
Specifies that data about each activity associated with the work class for which this work action is defined is to be sent to any active activities event monitor when the activity completes. The default is COLLECT ACTIVITY DATA WITHOUT DETAILS.

collect-activity-data-clause

ON COORDINATOR MEMBER
Specifies that the activity data is to be collected only at the coordinator member of the activity.

ON ALL MEMBERS
Specifies that activity data is to be collected at all members where the activity is processed. On remote members, a record for the activity may be captured multiple times as the activity comes and goes on those members. If the AND VALUES clause is specified, activity input values will be collected only for the members of the coordinator.

WITHOUT DETAILS
Specifies that data about each activity that executes in the service class should be sent to any active activities event monitor, when the activity completes execution. Details about statement, compilation environment, and section environment data are not sent.

WITH

DETAILS
Specifies that statement and compilation environment data is to be sent to any active activities event monitor, for those activities that have them. Section environment data is not sent.

SECTION
Specifies that statement, compilation environment, section environment data, and section actuals are to be sent to any active activities event monitor for those activities that have them. DETAILS must be specified if SECTION is specified. Section actuals will be collected on any member where the activity data is collected.

INCLUDE ACTUALS BASE
Specifies that section actuals should also be collected on any partition where the activity data is collected. For section actuals to be collected, either INCLUDE ACTUALS clause must be specified or the **section_actuals** database configuration parameter must be set.

The effective setting for the collection of section actuals is the combination of the INCLUDE ACTUALS clause, the **section_actuals** database configuration parameter, and the <collectsectionactuals> setting specified on the WLM_SET_CONN_ENV routine. For example, if INCLUDE ACTUALS BASE is

specified, yet the **section_actuals** database configuration parameter value is NONE and <collectsectionactuals> is set to NONE, then the effective setting for the collection of section actuals is BASE.

BASE specifies that the following should be enabled and collected during the activity's execution:

- Basic operator cardinality counts
- Statistics for each object referenced (DML statements only)

AND VALUES
Specifies that input data values are to be sent to any active activities event monitor, for those activities that have them. This data does not include SQL statements that are compiled by using the REOPT ALWAYS bind option.

COLLECT AGGREGATE ACTIVITY DATA
Specifies that aggregate activity data is to be captured for activities that are associated with the work class for which this work action is defined and sent to the statistics event monitor, if one is active. This information is collected periodically on an interval that is specified by the **wlm_collect_int** database configuration parameter. The default is COLLECT AGGREGATE ACTIVITY DATA BASE. This clause cannot be specified for a work action defined in a work action set that is applied to a database.

BASE
Specifies that basic aggregate activity data should be captured for activities associated with the work class for which this work action is defined and sent to the statistics event monitor, if one is active. Basic aggregate activity data includes:

- Estimated activity cost high watermark
- Rows returned high watermark
- Temporary table space usage high watermark. Only activities that have an SQLTEMPSPACE threshold applied to them participate in this high watermark.
- Activity life time histogram
- Activity queue time histogram
- Activity execution time histogram

EXTENDED
Specifies that all aggregate activity data should be captured for activities associated with the work class for which this work action is defined and sent to the statistics event monitor, if one is active. This includes all basic aggregate activity data plus:

- Activity data manipulation language (DML) estimated cost histogram
- Activity DML inter-arrival time histogram

ENABLE or DISABLE
Specifies whether or not the work action is to be considered when database activities are submitted. The default is ENABLE.

ENABLE
Specifies that the work action is enabled and will be considered when database activities are submitted.

DISABLE
Specifies that the work action is disabled and will not be considered when database activities are submitted.

ENABLE or DISABLE
Specifies whether or not the work action set is to be considered when database activities are submitted. The default is ENABLE.

ENABLE
Specifies that the work action set is enabled and will be considered when database activities are submitted.

DISABLE
Specifies that the work action set is disabled and will not be considered when database activities are submitted.

histogram-template-clause
Specifies histogram templates to use when collecting aggregate activity data for activities associated with the work class to which this work action is assigned. Aggregate activity data is only collected for the work class when the work action type is COLLECT AGGREGATE ACTIVITY DATA.

ACTIVITY LIFETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the duration, in milliseconds, of database activities running during a specific interval. The database activities are those associated with the work class to which this work action is assigned. This time includes both time queued and time executing. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY QUEUETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities are queued during a specific interval. The database activities are those associated with the work class to which this work action is assigned. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY EXECUTETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities are executing during a specific interval. The database activities are those associated with the work class to which this work action is assigned. This time does not include the time spent queued. Activity execution time is collected in this histogram at each member where the activity executes. On the activity's coordinator member, this is the end-to-end execution time (that is, the life time less the time spent queued). On non-coordinator members, this is the time that these members spend working on behalf of the activity. During the execution of a given activity, the database manager might present work to a non-coordinator member more than once, and each time the non-coordinator member will collect the execution time for that occurrence of the activity. Therefore, the counts in the execution time histogram might not represent the actual number of unique activities that executed on a member. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY ESTIMATEDCOST HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the estimated cost, in timerons, of DML activities associated with the work class to which this work action is assigned. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option.

ACTIVITY INTERARRIVALTIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, between the arrival of one DML activity and the arrival of the next DML activity, for any activity associated with the work class to which this work action is assigned. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option.

Rules

- A workload management (WLM)-exclusive SQL statement must be followed by a COMMIT or a ROLLBACK statement (SQLSTATE 5U021). WLM-exclusive SQL statements are:
  - CREATE HISTOGRAM TEMPLATE, ALTER HISTOGRAM TEMPLATE, or DROP (histogram template)

  - CREATE SERVICE CLASS, ALTER SERVICE CLASS, or DROP (service class)
  - CREATE THRESHOLD, ALTER THRESHOLD, or DROP (threshold)
  - CREATE WORK ACTION SET, ALTER WORK ACTION SET, or DROP (work action set)
  - CREATE WORK CLASS SET, ALTER WORK CLASS SET, or DROP (work class set)
  - CREATE WORKLOAD, ALTER WORKLOAD, or DROP (workload)
  - GRANT (workload privileges) or REVOKE (workload privileges)
- A WLM-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.

Notes

- Changes are written to the system catalog, but do not take effect until they are committed, even for the connection that issues the statement.
- Only one uncommitted WLM-exclusive SQL statement at a time is allowed across all partitions. If an uncommitted WLM-exclusive SQL statement is executing, subsequent WLM-exclusive SQL statements will wait until the current WLM-exclusive SQL statement commits or rolls back.
- ***Syntax alternatives***: The following are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - DATABASE PARTITION can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - DATABASE PARTITIONS can be specified in place of MEMBERS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
- The enforcement scope is determined automatically based on the threshold type. For CONCURRENTDBCOORDACTIVITIES type thresholds, the environment is also used to determine the enforcement scope where it defaults to the DATABASE enforcement scope in environments other than Db2 pureScale, and the MEMBER enforcement scope in Db2 pureScale environments.

Examples

- *Example 1:* Create a work action set named DATABASE_ACTIONS to apply to all database activities. Use the LARGE_QUERIES work class set and define the following work actions. Work action ONE_CONCURRENT_QUERY has a threshold action that allows one concurrent query to run on the system at a time for queries that fall within the LARGE_ESTIMATED_COST work class. If that threshold is exceeded, the database manager is to queue the activity, but is not to allow more than one database activity to be queued at a time. If the queue threshold is exceeded, the database activity is not to be allowed to run. Work action TWO_CONCURRENT_QUERIES has a threshold action that allows two concurrent queries to execute at the same time for queries that fall within the LARGE_CARDINALITY work class, and allows no more than two to be queued. If more than two queries are to be queued, the database activity is to continue putting the queries in the queue and is to collect the database activity data in the activities event monitor, if one is active.

```
CREATE WORK ACTION SET DATABASE_ACTIONS
  FOR DATABASE USING WORK CLASS SET LARGE_QUERIES
    (WORK ACTION ONE_CONCURRENT_QUERY ON WORK CLASS LARGE_ESTIMATED_COST
     WHEN CONCURRENTDBCOORDACTIVITIES > 1 AND QUEUEDACTIVITIES > 1
       STOP EXECUTION,
     WORK ACTION TWO_CONCURRENT_QUERIES ON WORK CLASS LARGE_CARDINALITY
     WHEN CONCURRENTDBCOORDACTIVITIES > 2 AND QUEUEDACTIVITIES > 2
       COLLECT ACTIVITY DATA CONTINUE)
```

- *Example 2:* Create a work action set named ADMIN_APPS_ACTIONS with one work action named MAP_SELECTS that is to apply to database activities that run under service superclass ADMIN_APPS. The work action is to map all database activity that falls within the SELECT_CLASS work class to service subclass SELECTS_SERVICE_CLASS, which is in the DML_SELECTS work class set.

```
CREATE WORK ACTION SET ADMIN_APPS_ACTIONS
  FOR SERVICE CLASS ADMIN_APPS USING
```

```
        WORK CLASS SET DML_SELECTS
          (WORK ACTION MAP_SELECTS ON WORK CLASS SELECT_CLASS
           MAP ACTIVITY TO SELECTS_SERVICE_CLASS)
```

CREATE WORK CLASS SET

The CREATE WORK CLASS SET statement defines a work class set.

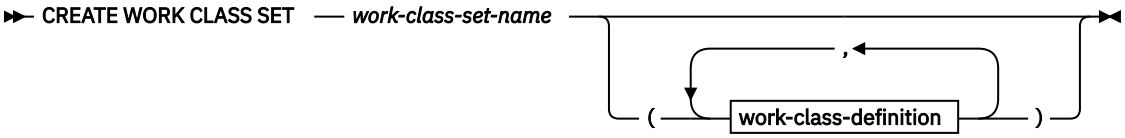
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

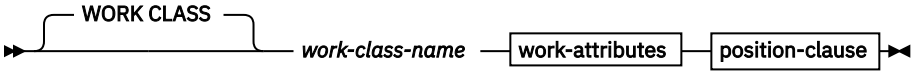
Authorization

The privileges held by the authorization ID of the statement must include WLMADM or DBADM authority.

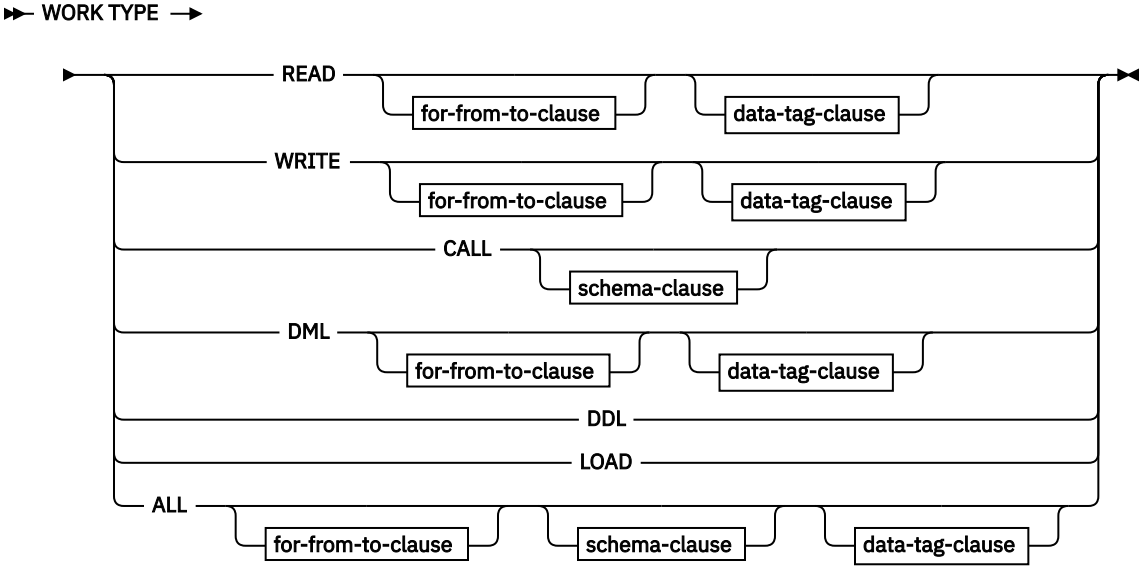
Syntax



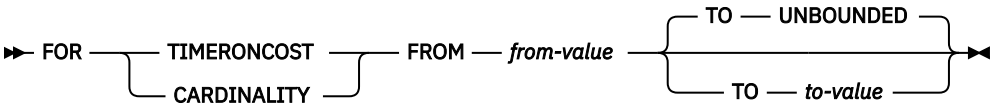
work-class-definition



work-attributes



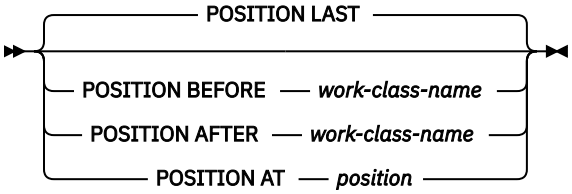
for-from-to-clause



data-tag-clause

schema-clause

position-clause



Description

work-class-set-name
Names the work class set. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *work-class-set-name* must not identify a work class set that already exists at the current server (SQLSTATE 42710). The name must not begin with the characters 'SYS' (SQLSTATE 42939).

work-class-definition
Specifies the definition of the work class.

WORK CLASS *work-class-name*
Names the work class. The *work-class-name* must not identify a work class that already exists within the work class set at the current server (SQLSTATE 42710). The *work-class-name* cannot begin with 'SYS' (SQLSTATE 42939).

work-attributes
The attributes of the database activity must match all of the attributes specified in this work class if that activity is to be associated with this work class.

WORK TYPE
Specifies the type of database activity.

READ
This activity includes the following statements:

- All SELECT or SELECT INTO statements that do not contain a DELETE, INSERT, MERGE, or UPDATE statement, and all VALUES INTO statements
- All XQuery statements

WRITE
This activity includes the following statements:

- UPDATE
- DELETE
- INSERT
- MERGE
- All SELECT statements that contain a DELETE, INSERT, or UPDATE statement, and all VALUES INTO statements

CALL
Includes the CALL statement. A CALL statement is considered for a work class with a work type of CALL or ALL.

DML
Includes the statements listed under READ and WRITE.

DDL
This activity includes the following statements:

- ALTER

- CREATE
- COMMENT
- DECLARE GLOBAL TEMPORARY TABLE
- DROP
- FLUSH PACKAGE CACHE
- GRANT
- REFRESH TABLE
- RENAME
- REVOKE
- SET INTEGRITY

LOAD
Db2 load operations.

ALL
All recognized workload management (WLM) activity that falls under any one of the keywords previously listed within the description for WORK TYPE.

FOR
Indicates the type of information that is being specified in the FROM *from-value* TO *to-value* clause. The FOR clause is only used for the following work types:

- ALL
- DML
- READ
- WRITE

TIMERONCOST
The estimated cost of the work, in timerons. This value is used to determine whether the work falls within the range specified in the FROM *from-value* TO *to-value* clause.

CARDINALITY
The estimated cardinality of the work. This value is used to determine whether the work falls within the range specified in the FROM *from-value* TO *to-value* clause.

FROM *from-value* TO UNBOUNDED or FROM *from-value* TO *to-value*
Specifies the range of either timeron value (for estimated cost) or cardinality within which the database activity must fall if it is to be part of this work class. The range is inclusive of *from-value* and *to-value*. If this clause is not specified for the work class, all work that falls within the specified work type will be included (that is, the default is FROM 0 TO UNBOUNDED). This range is only used for the following work types:

- ALL
- DML
- READ
- WRITE

FROM *from-value* TO UNBOUNDED
The *from-value* must be zero or a positive DOUBLE value (SQLSTATE 5U019). The range has no upper bound.

FROM *from-value* TO *to-value*
The *from-value* must be zero or a positive DOUBLE value and the *to-value* must be a positive DOUBLE value. The *from-value* must be smaller than or equal to the *to-value* (SQLSTATE 5U019).

DATA TAG LIST CONTAINS *integer-constant*
Specifies the value of the tag given to any data which the database activity might touch if it is to be part of this work class. If the clause is not specified for the work class, all work that falls

within the specified work type, regardless of what data it might touch, will be included (that is, the default is to ignore the data tag). This clause is used only if the work type is READ, WRITE, DML, or ALL and the database activity is a DML statement. Valid values for *integer-constant* are integers from 1 to 9.

schema-clause

ROUTINES IN SCHEMA *schema-name*
Specifies the schema name of the procedure that the CALL statement will be calling. This clause is only used if the work type is CALL or ALL and the database activity is a CALL statement. If no value is specified, all schemas are included.

position-clause

POSITION
Specifies where this work class is to be placed within the work class set, which determines the order in which work classes are evaluated. When performing work class assignment at run time, the database manager first determines the work class set that is associated with the object, either the database or a service superclass. The first matching work class within that work class set is then selected. If this keyword is not specified, the work class is placed in the last position.

LAST
Specifies that the work class is to be placed last in the ordered list of work classes within the work class set. This is the default.

BEFORE *work-class-name*
Specifies that the work class is to be placed before work class *work-class-name* in the list. The *work-class-name* must identify a work class in the work class set that exists at the current server (SQLSTATE 42704).

AFTER *work-class-name*
Specifies that the work class is to be placed after work class *work-class-name* in the list. The *work-class-name* must identify a work class in the work class set that exists at the current server (SQLSTATE 42704).

AT *position*
Specifies the absolute position at which the work class is to be placed within the work class set in the ordered list of work classes. This value can be any positive integer (not zero) (SQLSTATE 42615). If *position* is greater than the number of existing work classes plus one, the work class is placed at the last position within the work class set.

Rules

- A workload management (WLM)-exclusive SQL statement must be followed by a COMMIT or a ROLLBACK statement (SQLSTATE 5U021). WLM-exclusive SQL statements are:
  - CREATE HISTOGRAM TEMPLATE, ALTER HISTOGRAM TEMPLATE, or DROP (HISTOGRAM TEMPLATE)
  - CREATE SERVICE CLASS, ALTER SERVICE CLASS, or DROP (SERVICE CLASS)
  - CREATE THRESHOLD, ALTER THRESHOLD, or DROP (THRESHOLD)
  - CREATE WORK ACTION SET, ALTER WORK ACTION SET, or DROP (WORK ACTION SET)
  - CREATE WORK CLASS SET, ALTER WORK CLASS SET, or DROP (WORK CLASS SET)
  - CREATE WORKLOAD, ALTER WORKLOAD, or DROP (WORKLOAD)
  - GRANT (Workload Privileges) or REVOKE (Workload Privileges)
- A WLM-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.

Notes

- Changes are written to the system catalog, but do not take effect until they are committed, even for the connection that issues the statement.

- Only one uncommitted WLM-exclusive SQL statement at a time is allowed across all partitions. If an uncommitted WLM-exclusive SQL statement is executing, subsequent WLM-exclusive SQL statements will wait until the current WLM-exclusive SQL statement commits or rolls back.

Examples

- *Example 1:* Create a work class set named LARGE_QUERIES that has a set of work classes representing all DML with an estimated cost greater than 9999 and an estimated cardinality greater than 1000.

```
CREATE WORK CLASS SET LARGE_QUERIES
  (WORK CLASS LARGE_ESTIMATED_COST WORK TYPE DML
   FOR TIMERONCOST FROM 9999 TO UNBOUNDED,
   WORK CLASS LARGE_CARDINALITY WORK TYPE DML
   FOR CARDINALITY FROM 1000 TO UNBOUNDED)
```

- *Example 2:* Create a work class set named DML_SELECTS that has a work class representing all DML SELECT statements that do not contain a DELETE, INSERT, MERGE, or UPDATE statement.

```
CREATE WORK CLASS SET DML_SELECTS
  (WORK CLASS SELECT_CLASS WORK TYPE READ)
```

CREATE WORKLOAD

The CREATE WORKLOAD statement defines a workload.

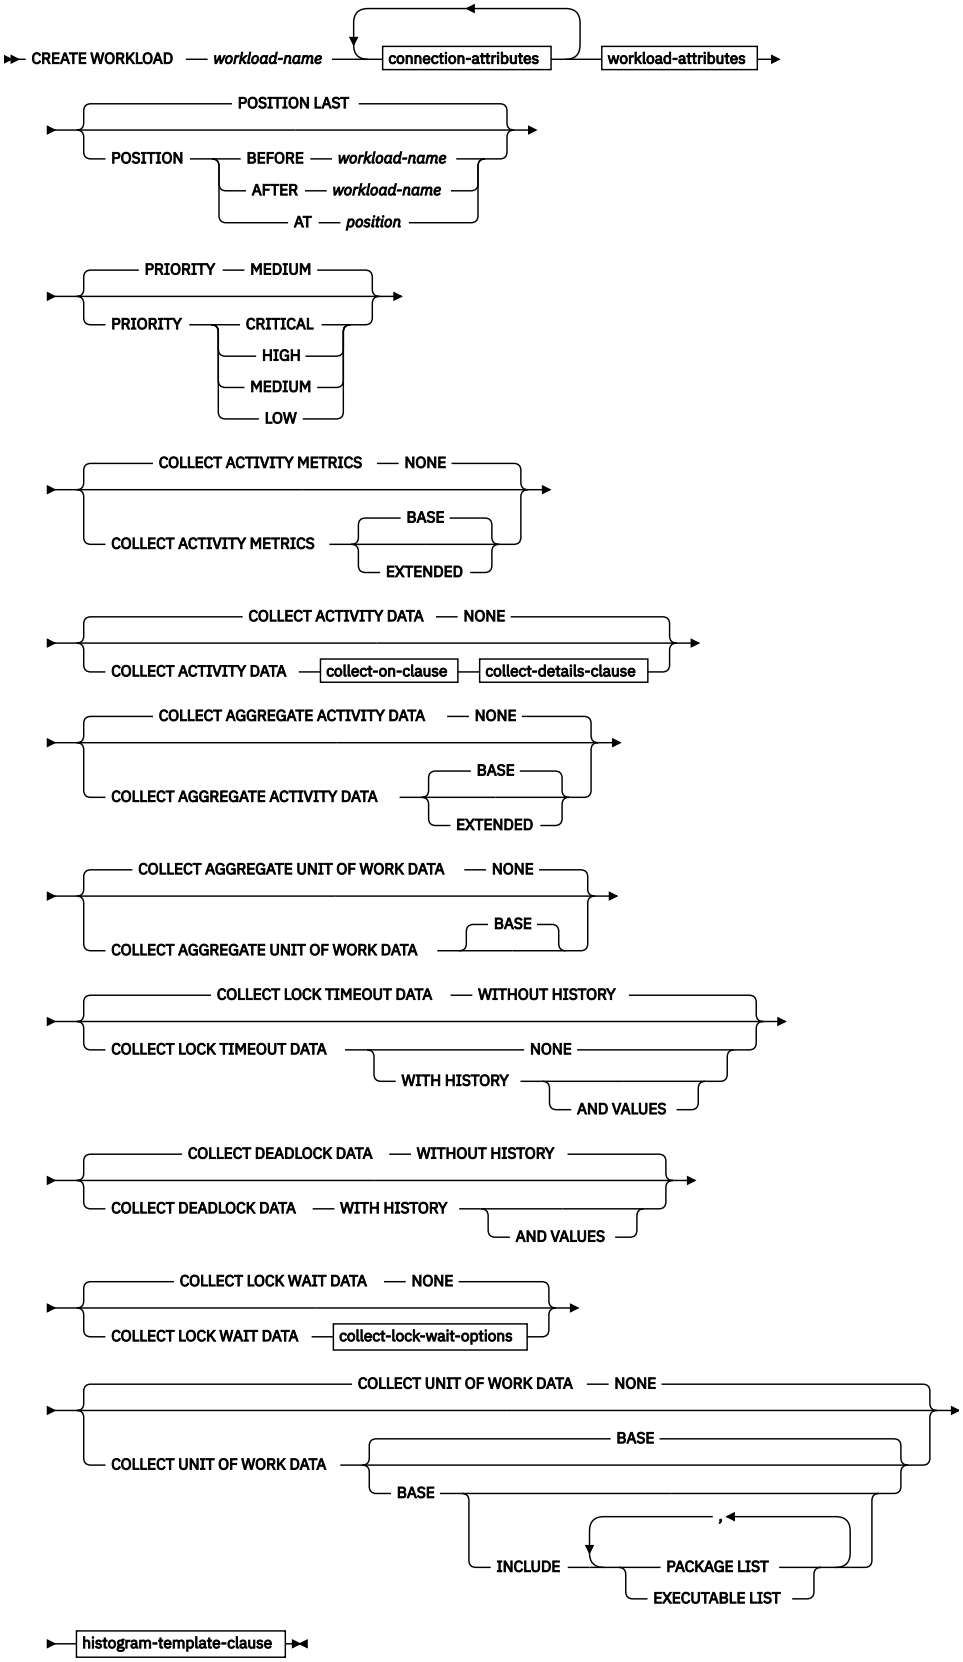
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

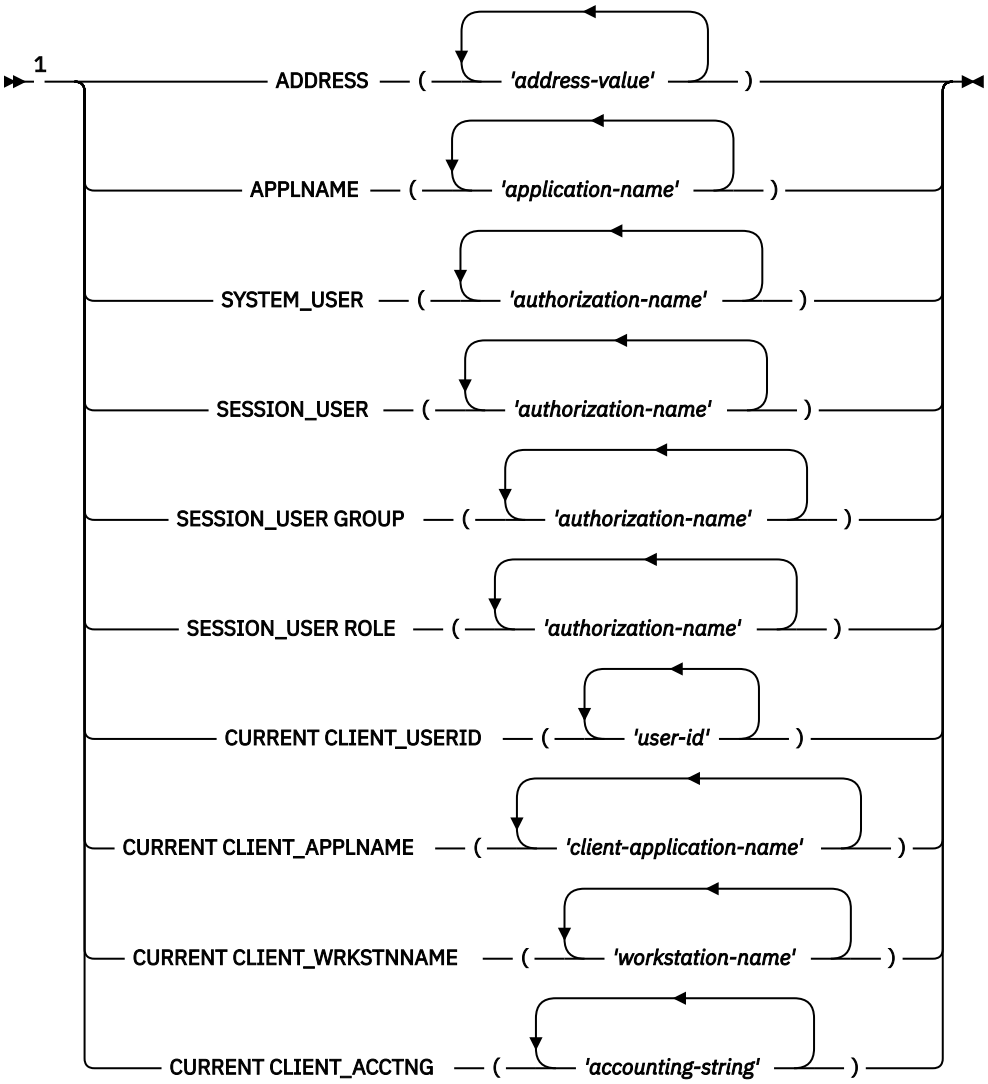
Authorization

The privileges held by the authorization ID of the statement must include WLMADM or DBADM authority.

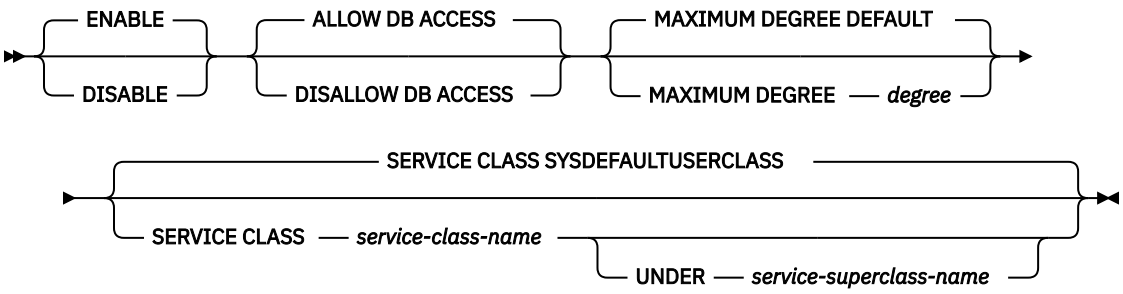
Syntax



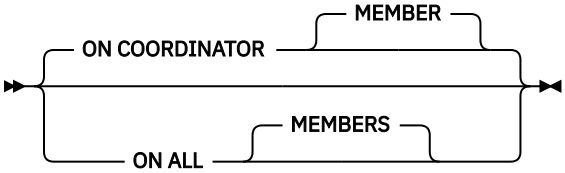
connection-attributes



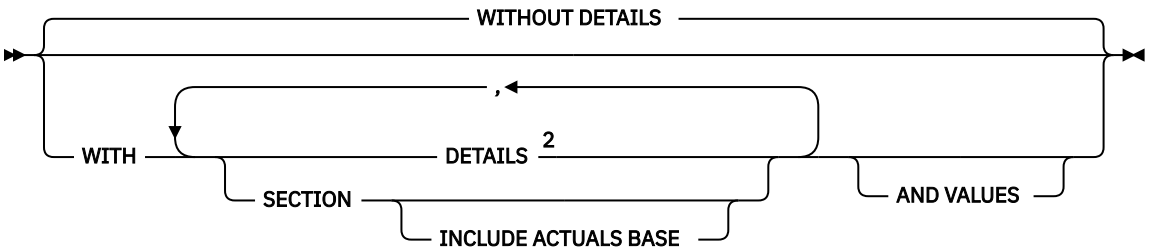
workload-attributes



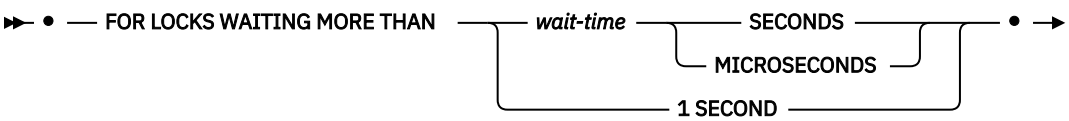
collect-on-clause

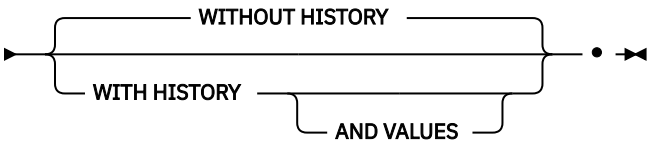


collect-details-clause

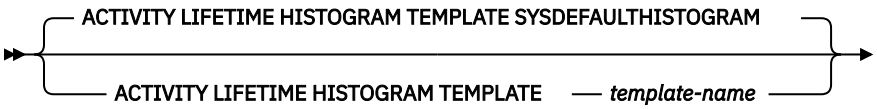


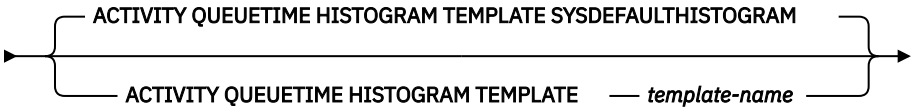
collect-lock-wait-options

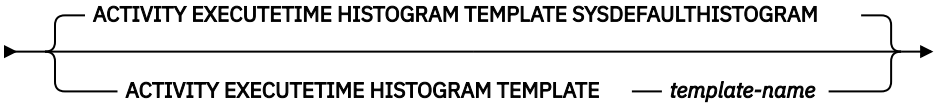


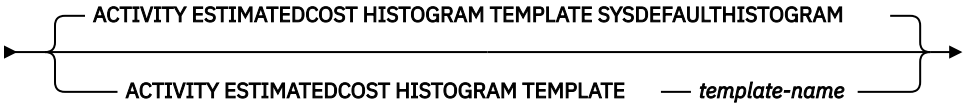


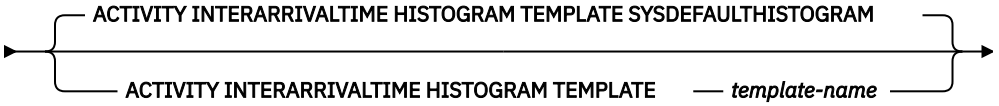
histogram-template-clause

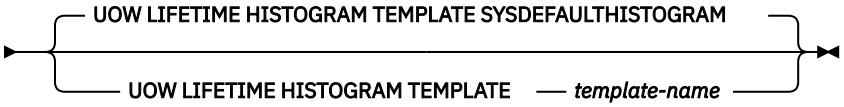












Notes:

[1] Each connection attribute clause can only be specified once.

[2] The DETAILS keyword is the minimum to be specified, followed by the option separated by a comma.

Description

workload-name
Names the workload. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *workload-name* must not identify a workload that already exists at the current server (SQLSTATE 42710). The name must not begin with the characters 'SYS' (SQLSTATE 42939).

connection-attributes
The attributes of the connection must match all attributes specified in this workload definition if it is to be associated with this workload when the connection is established. If a list of values is specified for a connection attribute in the workload definition, the corresponding attribute of the connection must match at least one of the values in the list. If a connection attribute is not specified in the workload definition, the connection can have any value for the corresponding connection attribute.

Note: All connection attributes are case sensitive, except for ADDRESS.

ADDRESS ('*address-value*', ...)
Specifies one or more IPv4 addresses, IPv6 addresses, or secure domain names for the ADDRESS connection attribute. An address value cannot appear more than once in the list (SQLSTATE 42713). The only supported protocol is TCP/IP. Each address value must be an IPv4 address, an IPv6 address, or a secure domain name.

An IPv4 address must not contain leading spaces and is represented as a dotted decimal address. An example of an IPv4 address is `192.0.2.1`. The value `localhost` or its equivalent representation `127.0.0.1` will not result in a match; the real IPv4 address of the host must be specified instead. An IPv6 address must not contain leading spaces and is represented as a colon hexadecimal address. An example of an IPv6 address is `2001:0DB8:0000:0000:0008:0800:200C:417A`. IPv4-mapped IPv6 addresses (`::ffff:192.0.2.1`, for example) will not result in a match. Similarly, `localhost` or its IPv6 short representation `::1` will not result in a match. A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is `corona.example.com`. When a domain name is converted to an IP address, the result of this conversion could be a set of one or more IP addresses. In this case, an incoming connection is said to match the ADDRESS attribute of a workload object if the IP address from which the connection originates matches any of the IP addresses to which the domain name was converted.

When creating a workload object, you should specify domain name values for the ADDRESS attribute instead of static IP addresses, particularly in Dynamic Host Configuration Protocol (DHCP) environments where a device can have a different IP address each time it connects to the network.

APPLNAME ('*application-name*', ...)
Specifies one or more applications for the APPLNAME connection attribute. An application name cannot appear more than once in the list (SQLSTATE 42713). If *application-name* does not contain a single asterisk character (*), is equivalent to the value shown in the "Application name" field in system monitor output and in output from the LIST APPLICATIONS command. If *application-name* does contain a single asterisk character (*), the value is used as an expression to represent a set of application names, where the asterisk (*) represents a string of zero or more characters. If the expression needs to include an asterisk character in the application name, use a sequence of two asterisk characters (**).

SYSTEM_USER ('*authorization-name*', ...)
Specifies one or more authorization IDs for the SYSTEM USER connection attribute. An authorization ID cannot appear more than once in the list (SQLSTATE 42713).

SESSION_USER ('*authorization-name*', ...)
Specifies one or more authorization IDs for the SESSION USER connection attribute. An authorization ID cannot appear more than once in the list (SQLSTATE 42713).

SESSION_USER GROUP ('*authorization-name*', ...)
Specifies one or more authorization IDs for the SESSION_USER GROUP connection attribute. An authorization ID cannot appear more than once in the list (SQLSTATE 42713).

SESSION_USER ROLE ('*authorization-name*', ...)
Specifies one or more authorization IDs for the SESSION_USER ROLE connection attribute. The roles of a session authorization ID in this context refer to all the roles that are available to the session authorization ID, regardless of how the roles were obtained. An authorization ID cannot appear more than once in the list (SQLSTATE 42713).

CURRENT CLIENT_USERID ('*user-id*', ...)
Specifies one or more client user IDs for the CURRENT CLIENT_USERID connection attribute. A client user ID cannot appear more than once in the list (SQLSTATE 42713). If *user-id* contains a single asterisk character (*), the value is used as an expression to represent a set of user IDs, where the asterisk (*) represents a string of zero or more characters. If the expression needs to include an asterisk character in the user ID, use a sequence of two asterisk characters (**).

CURRENT CLIENT_APPLNAME ('*client-application-name*', ...)
Specifies one or more applications for the CURRENT CLIENT_APPLNAME connection attribute. An application name cannot appear more than once in the list (SQLSTATE 42713). If *client-application-name* does not contain a single asterisk character (*), is equivalent to the value shown in the "TP Monitor client application name" field in system monitor output. If *client-application-name* does contain a single asterisk character (*), the value is used as an expression to represent a set of application names, where the asterisk (*) represents a string of zero or more characters. If the expression needs to include an asterisk character in the application name, use a sequence of two asterisk characters (**).

CURRENT CLIENT_WRKSTNNAME ('*workstation-name*', ...)
Specifies one or more client workstation names for the CURRENT CLIENT_WRKSTNNAME connection attribute. A client workstation name cannot appear more than once in the list (SQLSTATE 42713). If *workstation-name* contains a single asterisk character (*), the value is used as an expression to represent a set of workstation names, where the asterisk (*) represents a string of zero or more characters. If the expression needs to include an asterisk character in the workstation name, use a sequence of two asterisk characters (**).

CURRENT CLIENT_ACCTNG ('*accounting-string*', ...)
Specifies one or more client accounting strings for the CURRENT CLIENT_ACCTNG connection attribute. A client accounting string cannot appear more than once in the list (SQLSTATE 42713). If *accounting-string* contains a single asterisk character (*), the value is used as an expression to represent a set of accounting strings, where the asterisk (*) represents a string of zero or more characters. If the expression needs to include an asterisk character in the accounting string, use a sequence of two asterisk characters (**).

workload-attributes
Specifies attributes of the workload.

ENABLE or DISABLE
Specifies whether or not this workload will be considered when a workload is chosen. The default is ENABLE.

ENABLE
Specifies that the workload is enabled and will be considered when a workload is chosen.

DISABLE
Specifies that the workload is disabled and will not be considered when a workload is chosen.

ALLOW DB ACCESS or DISALLOW DB ACCESS
Specifies whether or not a workload occurrence associated with this workload is allowed access to the database. The default is ALLOW DB ACCESS.

ALLOW DB ACCESS
Specifies that workload occurrences associated with this workload are allowed access to the database.

DISALLOW DB ACCESS
Specifies that workload occurrences associated with this workload are not allowed access to the database. The next unit of work associated with this workload will be rejected (SQLSTATE 5U020). Workload occurrences that are already running are allowed to complete.

MAXIMUM DEGREE
Specifies the maximum runtime degree of parallelism for this workload. The default is DEFAULT.

DEFAULT
If DB2_WORKLOAD=ANALYTICS, this setting enables intrapartition parallelism for this workload. Otherwise, this setting specifies that this workload inherits the intrapartition parallelism setting from the database manager configuration parameter **intra_parallel**. When **intra_parallel** is set to NO, this workload runs with intrapartition parallelism disabled. When **intra_parallel** is set to YES, this workload runs with intrapartition parallelism enabled. This workload does not specify a maximum runtime degree for assigned applications. Therefore, the actual runtime degree is determined as the lower of the value of **max_querydegree** configuration parameter, the MAXIMUM DEGREE set on the query service class, the value set by SET RUNTIME DEGREE command, and the SQL statement compilation degree.

degree
Specifies the maximum degree of parallelism for this workload. Valid values are 1 to 32,767. With value 1, the associated requests run with intrapartition parallelism disabled. With value 2 to 32,767, the associated requests run with intrapartition parallelism enabled. The actual runtime degree is determined as the lower of this *degree*, the MAXIMUM DEGREE set on the query service class, the value of **max_querydegree** configuration parameter, the value set by SET RUNTIME DEGREE command and the SQL statement compilation degree.

Note: A MAXIMUM DEGREE value greater than 1 will not enable intrapartition parallelism unless the shared sort heap is available.

SERVICE CLASS *service-class-name*
Specifies that requests associated with this workload are to be executed in the service class *service-class-name*. The *service-class-name* must identify a service class that exists at the current server (SQLSTATE 42704). The *service-class-name* cannot be 'SYSDEFAULTSUBCLASS', 'SYSDEFAULTSYSTEMCLASS', or 'SYSDEFAULTMAINTENANCECLASS' (SQLSTATE 5U032). The default is SYSDEFAULTUSERCLASS.

UNDER *service-superclass-name*
This clause is used when specifying a service subclass. The *service-superclass-name* identifies the service superclass of *service-class-name*. The *service-superclass-name* must identify a service superclass that exists at the current server (SQLSTATE 42704). The *service-superclass-name* cannot be 'SYSDEFAULTSYSTEMCLASS' or 'SYSDEFAULTMAINTENANCECLASS' (SQLSTATE 5U032).

POSITION
Specifies where this workload is to be placed within the ordered list of workloads. At run time, this list is searched in order for the first workload that matches the required connection attributes. The default is LAST.

LAST
Specifies that the workload is to be last in the list, before the default workloads SYSDEFAULTUSERWORKLOAD and SYSDEFAULTADMWORKLOAD.

BEFORE *relative-workload-name*
Specifies that the workload is to be placed before workload *relative-workload-name* in the list. The *relative-workload-name* must identify a workload that exists at the current server (SQLSTATE 42704). The BEFORE option cannot be specified if *relative-workload-name* is 'SYSDEFAULTUSERWORKLOAD' or 'SYSDEFAULTADMWORKLOAD' (SQLSTATE 42832).

AFTER *relative-workload-name*
Specifies that the workload is to be placed after workload *relative-workload-name* in the list. The *relative-workload-name* must identify a workload that exists at the current server (SQLSTATE 42704). The AFTER option cannot be specified if *relative-workload-name* is 'SYSDEFAULTUSERWORKLOAD' or 'SYSDEFAULTADMWORKLOAD' (SQLSTATE 42832).

AT *position*
Specifies the absolute position at which the workload is to be placed in the list. This value can be any positive integer (not zero) (SQLSTATE 42615). If *position* is greater than the

number of existing workloads plus one, the workload is placed at the last position, just before SYSDEFAULTUSERWORKLOAD and SYSDEFAULTADMWORKLOAD.

PRIORITY
Specifies the priority of the work from this workload compared to that of the work in other workloads in the same service superclass. Within a service superclass priority is used to prioritize more important jobs over less important jobs. Work scheduling across superclasses does not use the priority for scheduling, but instead uses only resource-based scheduling.

COLLECT ACTIVITY METRICS
Specifies that monitor metrics should be collected for an activity submitted by an occurrence of the workload. The default is COLLECT ACTIVITY METRICS NONE.

Note: The effective activity metrics collection setting is the combination of the attribute specified by the COLLECT ACTIVITY METRICS clause on the workload submitting the activity, and the **mon_act_metrics** database configuration parameter. If either the workload attribute or the configuration parameter has a value other than NONE, metrics will be collected for the activity.

NONE
Specifies that no metrics will be collected for any activity submitted by an occurrence of the workload.

BASE
Specifies that basic metrics will be collected for any activity submitted by an occurrence of the workload.

EXTENDED
Specifies that basic metrics will be collected for any activity submitted by an occurrence of the workload. In addition, specifies that the values for the following monitor elements should be determined with additional granularity:

- **total_section_time**
- **total_section_proc_time**
- **total_routine_user_code_time**
- **total_routine_user_code_proc_time**
- **total_routine_time**

COLLECT ACTIVITY DATA
Specifies that data about each activity associated with this workload is to be sent to any active activities event monitor when the activity completes. The default is COLLECT ACTIVITY DATA NONE.

collect-on-clause
Specifies where the activity data is to be collected. The default is ON COORDINATOR MEMBER.

ON COORDINATOR MEMBER
Specifies that activity data is to be collected only at the coordinator member of the activity.

ON ALL MEMBERS
Specifies that activity data is to be collected at all members where the activity is processed. On remote members, a record for the activity may be captured multiple times as the activity comes and goes on those members. If the AND VALUES clause is specified, activity input values will be collected only for the members of the coordinator.

NONE
Specifies that activity data is not collected for each activity that is associated with this workload.

collect-details-clause
Specifies what type of activity data is to be collected. The default is WITHOUT DETAILS.

WITHOUT DETAILS
Specifies that data about each activity that is associated with this workload is to be sent to any active activities event monitor, when the activity completes execution. Details about statement, compilation environment, and section environment data are not sent.

WITH

DETAILS
Specifies that statement and compilation environment data is to be sent to any active activities event monitor, for those activities that have them. Section environment data is not sent.

SECTION
Specifies that statement, compilation environment, section environment data, and section actuals are to be sent to any active activities event monitor for those activities that have them. DETAILS must be specified if SECTION is specified. Section actuals will be collected on any member where the activity data is collected.

INCLUDE ACTUALS BASE
Specifies that section actuals should also be collected on any partition where the activity data is collected. For section actuals to be collected, either INCLUDE ACTUALS clause must be specified or the **section_actuals** database configuration parameter must be set.

The effective setting for the collection of section actuals is the combination of the INCLUDE ACTUALS clause, the **section_actuals** database configuration parameter, and the <collectsectionactuals> setting specified on the WLM_SET_CONN_ENV routine. For example, if INCLUDE ACTUALS BASE is specified, yet the **section_actuals** database configuration parameter value is NONE and <collectsectionactuals> is set to NONE, then the effective setting for the collection of section actuals is BASE.

BASE specifies that the following should be enabled and collected during the activity's execution:

- Basic operator cardinality counts
- Statistics for each object referenced (DML statements only)

AND VALUES
Specifies that input data values are to be sent to any active activities event monitor, for those activities that have them. This data does not include SQL statements that are compiled by using the REOPT ALWAYS bind option.

COLLECT AGGREGATE ACTIVITY DATA
Specifies that aggregate activity data about the activities associated with this workload is to be sent to the statistics event monitor, if one is active. This information is collected periodically on an interval that is specified by the **wlm_collect_int** database configuration parameter. The default when COLLECT AGGREGATE ACTIVITY DATA is not specified is COLLECT AGGREGATE ACTIVITY DATA NONE. The default when COLLECT AGGREGATE ACTIVITY DATA is specified is COLLECT AGGREGATE ACTIVITY DATA BASE.

BASE
Specifies that basic aggregate activity data about the activities associated with this workload is to be sent to the statistics event monitor, if one is active. Basic aggregate activity data includes:

- Activity CPU time high watermark
- Activity execution time histogram
- Activity life time histogram
- Activity queue time histogram
- Activity rows read high watermark
- Estimated activity cost high watermark
- Rows returned high watermark
- Temporary table space usage high watermark. Only activities that have an SQLTEMPSPACE threshold applied to them participate in this high watermark.

EXTENDED
Specifies that all aggregate activity data about the activities associated with this workload is to be sent to the statistics event monitor, if one is active. This includes all basic aggregate activity data plus:

- Activity data manipulation language (DML) estimated cost histogram
- Activity DML inter-arrival time histogram

NONE
Specifies that no aggregate activity data is to be collected for this workload.

COLLECT AGGREGATE UNIT OF WORK DATA
Specifies that aggregate unit of work data about the units of work associated with this workload is to be sent to the statistics event monitor, if one is active. This information is collected periodically on an interval that is specified by the **wlm_collect_int** database configuration parameter. The default when COLLECT AGGREGATE UNIT OF WORK DATA is not specified is COLLECT AGGREGATE UNIT OF WORK DATA NONE.

BASE
Specifies that basic aggregate unit of work data about the units of work associated with this workload is to be sent to the statistics event monitor, if one is active. Basic aggregate unit of work includes:

- Unit of work lifetime histogram

NONE
Specifies that no aggregate unit of work data is to be collected for this workload.

COLLECT LOCK TIMEOUT DATA
Specifies that data about lock timeout events that occur within this workload is sent to the applicable event monitor when the lock event occurs. The lock timeout data is collected on all members. The default is COLLECT LOCK TIMEOUT DATA WITHOUT HISTORY. This setting works in conjunction with the **mon_locktimeout** database configuration parameter setting. The setting that produces the most detailed output is honored.

WITHOUT HISTORY
Specifies that data about lock events that occur within this workload is sent to any active locking event monitor when the lock event occurs. Past activity history and input values are not sent to the event monitor.

NONE
Specifies that lock timeout data for the workload is not collected at any member.

WITH HISTORY
Specifies to collect past activity history in the current unit of work for all of this type of lock events. The activity history buffer will wrap after the maximum size limit is used.

The default limit on the number of past activities to be kept by any one application is 250. If the number of past activities is greater than the limit, only the newest activities are reported. This default value can be overridden using the registry variable DB2_MAX_INACT_STMTS to specify a different value. You can choose a different value for the limit to increase or reduce the amount of system monitor heap used for past activity information.

AND VALUES
Specifies that input data values are to be sent to any active locking event monitor for those activities that have them. These data values will not include LOB data, LONG VARCHAR data, LONG VARGRAPHIC data, structured type data, or XML data. For SQL statements compiled using the REOPT ALWAYS bind option, there will be no REOPT compilation or statement execution data values provided in the event information.

COLLECT DEADLOCK DATA
Specifies that data about deadlock events that occur within this workload is sent to any active locking event monitor when the lock event occurs. The deadlock data is collected on all members. The default

is COLLECT DEADLOCK DATA WITHOUT HISTORY. This setting is only honored if the **mon_deadlock** database configuration parameter is not set to NONE.

WITHOUT HISTORY
Specifies that data about lock events that occur within this workload is sent to any active locking event monitor when the lock event occurs. Past activity history and input values are not sent to the event monitor.

WITH HISTORY
Specifies to collect past activity history in the current unit of work for all of this type of lock events. The activity history buffer will wrap after the maximum size limit is used.

The default limit on the number of past activities to be kept by any one application is 250. If the number of past activities is greater than the limit, only the newest activities are reported. This default value can be overridden using the registry variable DB2_MAX_INACT_STMTS to specify a different value. You can choose a different value for the limit to increase or reduce the amount of system monitor heap used for past activity information.

AND VALUES
Specifies that input data values are to be sent to any active locking event monitor for those activities that have them. These data values will not include LOB data, LONG VARCHAR data, LONG VARGRAPHIC data, structured type data, or XML data. For SQL statements compiled using the REOPT ALWAYS bind option, there will be no REOPT compilation or statement execution data values provided in the event information.

COLLECT LOCK WAIT DATA
Specifies that data about lock wait events that occur within this workload is sent to any active locking event monitor when the lock has not been acquired within *wait-time*. The default is COLLECT LOCK WAIT DATA NONE with a default *wait-time* value of 0 microseconds. This setting works in conjunction with the **mon_lockwait** and **mon_lw_thresh** database configuration parameters. The setting that produces the most detailed output is honored.

NONE
Specifies that the lock wait event for the workload is not collected at any member.

FOR LOCKS WAITING MORE THAN *wait-time* (SECONDS | MICROSECONDS) | 1 SECOND
Specifies that data about lock wait events that occur within this workload is sent to any active locking event monitor when the lock has not been acquired within *wait-time*.

This value can be any non-negative integer. Use a valid duration keyword to specify an appropriate unit of time for *wait-time*. The minimum valid value for the *wait-time* parameter is 1000 microseconds.

WITH HISTORY
Specifies to collect past activity history in the current unit of work for all of this type of lock events. The activity history buffer will wrap after the maximum size limit is used.

The default limit on the number of past activities to be kept by any one application is 250. If the number of past activities is greater than the limit, only the newest activities are reported. This default value can be overridden using the registry variable DB2_MAX_INACT_STMTS to specify a different value. You can choose a different value for the limit to increase or reduce the amount of system monitor heap used for past activity information.

AND VALUES
Specifies that input data values are to be sent to any active locking event monitor for those activities that have them. These data values will not include LOB data, LONG VARCHAR data, LONG VARGRAPHIC data, structured type data, or XML data. For SQL statements compiled using the REOPT ALWAYS bind option, there will be no REOPT compilation or statement execution data values provided in the event information.

COLLECT UNIT OF WORK DATA
Specifies that data about each transaction associated with this workload is to be sent to the unit of work event monitor, if any are active, when the unit of work ends. The default, when COLLECT UNIT OF WORK DATA is not specified, is COLLECT UNIT OF WORK DATA NONE. The default, when COLLECT

UNIT OF WORK DATA is specified, is COLLECT UNIT OF WORK DATA BASE. If the **mon_uow_data** database configuration parameter is set to BASE, it takes precedence over the COLLECT UNIT OF WORK DATA parameter. A value of NONE for the **mon_uow_data** indicates that the COLLECT UNIT OF WORK DATA parameters of individual workloads is used.

NONE
Specifies that no unit of work data for transactions associated with this workload is sent to the unit of work event monitor. The default is COLLECT UNIT OF WORK DATA NONE.

BASE
Specifies that base level of data for transactions associated with this workload is sent to the unit of work event monitors.

Some of the information reported in a unit of work event are system level request metrics. The collection of these metrics is controlled independently from the collection of the unit of work data. The request metrics are controlled with the COLLECT REQUEST METRICS clause on superclass, or using the **mon_req_metrics** database configuration parameter. The service super class which the workload is associated with, or the service super class of the service subclass which the workload is associated with, must have the collection of request metrics enabled in order for the request metrics to be present in the unit of work event. If the request metrics collection is not enabled, the value of the request metrics will be zero.

INCLUDE PACKAGE LIST
Specifies that base level of data and the package list for transactions associated with this workload are sent to the unit of work event monitor.

The size of the collected package list is determined by the value of the **mon_pkglist_sz** database configuration parameter. If this value is 0, then the package list is not collected even if the PACKAGE LIST option is specified.

In a partitioned database environment, the package list is only available on the coordinator member. The BASE level will be collected on remote members.

Some of the information reported in a unit of work event are system level request metrics. The collection of these metrics is controlled independently from the collection of the unit of work data. The request metrics are controlled with the COLLECT REQUEST METRICS clause on superclass, or using the **mon_req_metrics** database configuration parameter. The service super class which the workload is associated with, or the service super class of the service subclass which the workload is associated with, must have the collection of request metrics enabled in order for the request metrics to be present in the unit of work event. If the request metrics collection is not enabled, the value of the request metrics will be zero.

INCLUDE EXECUTABLE LIST
Specifies that executable ID list will be collected for a unit of work together with base level of data and sent to the unit of work event monitor.

histogram-template-clause
Specifies the histogram templates to use when collecting aggregate activity data for activities executing in the workload.

ACTIVITY LIFETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the duration, in milliseconds, of database activities running in the workload during a specific interval. This time includes both time queued and time executing. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY QUEUETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities running in the workload are queued during a specific interval. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY EXECUTETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities running in the workload are executing during a specific interval. This time does not include the time spent queued. Activity execution time is collected in this histogram at the coordinator member only. The time does not include idle time. Idle time is the time between the execution of requests belonging to the same activity when no work is being done. An example of idle time is the time between the end of opening a cursor and the start of fetching from that cursor. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option. Only activities at nesting level 0 are considered for inclusion in the histogram.

ACTIVITY ESTIMATEDCOST HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the estimated cost, in timerons, of DML activities running in the workload. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option. Only activities at nesting level 0 are considered for inclusion in the histogram.

ACTIVITY INTERARRIVALTIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, between the arrival of one DML activity into this workload and the arrival of the next DML activity into this workload. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option.

UOW LIFETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the duration, in milliseconds, of units of work running in the workload during a specific interval. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE UNIT OF WORK DATA clause is specified with the BASE option.

Rules

- A workload management (WLM)-exclusive SQL statement must be followed by a COMMIT or a ROLLBACK statement (SQLSTATE 5U021). WLM-exclusive SQL statements are:
  - CREATE HISTOGRAM TEMPLATE, ALTER HISTOGRAM TEMPLATE, or DROP (HISTOGRAM TEMPLATE)
  - CREATE SERVICE CLASS, ALTER SERVICE CLASS, or DROP (SERVICE CLASS)
  - CREATE THRESHOLD, ALTER THRESHOLD, or DROP (THRESHOLD)
  - CREATE WORK ACTION SET, ALTER WORK ACTION SET, or DROP (WORK ACTION SET)
  - CREATE WORK CLASS SET, ALTER WORK CLASS SET, or DROP (WORK CLASS SET)
  - CREATE WORKLOAD, ALTER WORKLOAD, or DROP (WORKLOAD)
  - GRANT (Workload Privileges) or REVOKE (Workload Privileges)
- A WLM-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.

Notes

- Changes are written to the system catalog, but do not take effect until they are committed, even for the connection that issues the statement.
- Only one uncommitted WLM-exclusive SQL statement at a time is allowed across all partitions. If an uncommitted WLM-exclusive SQL statement is executing, subsequent WLM-exclusive SQL statements will wait until the current WLM-exclusive SQL statement commits or rolls back.
- When a database connection is established, the database manager looks for a matching workload based on the connection attributes that were specified in the POSITION clause (in order of specification). If a matching workload is found, the database manager checks whether the current session user has USAGE

privilege on that workload. If the session user does not have USAGE privilege on the workload, the database manager looks for the next matching workload. If the session user has USAGE privilege on this workload, the connection is associated with the workload. If a matching workload is not found, the connection is associated with the default user workload, SYSDEFAULTUSERWORKLOAD. If the session user does not have USAGE privilege on SYSDEFAULTUSERWORKLOAD, an error is returned (SQLSTATE 42501).

- The workload association is re-evaluated at the beginning of each new unit of work if the database manager detects one of the following conditions.
  - The connection attributes have changed. This can happen if any of the following events has occurred:
    - The set client information API (`sqleseti`) has been invoked and it changed the connection attributes that were included in the workload definition. Note that although the client information can be set by the end user so that it could initiate a workload re-evaluation, the workload remapping itself cannot happen if the session user does not have the USAGE privilege on the workload.
    - The SET SESSION AUTHORIZATION statement has been invoked and it changed the current session user.
    - The roles that are available to a session user have changed.
  - A workload is created.
  - A workload is dropped.
  - A workload is altered.
  - The USAGE privilege on a workload is granted to a user, group, or role.
  - The USAGE privilege on a workload is revoked from a user, group, or role.

  If the workload re-evaluation results in no workload reassignment, the current workload occurrence continues to run; that is, a new workload occurrence will not be started.
- A connection cannot be reassigned to a different workload when an activity is still active. Examples of such activities are a load operation, an executing procedure, or statements that maintain resources across multiple units of work, such as an open WITH HOLD cursor. The current workload occurrence continues to run until all executing activities complete. Workload reassignment occurs at the beginning of the next unit of work.
- After a service class has been referenced by a workload, it cannot be dropped until it is no longer referenced by any workload. Either of the following actions can be taken to remove a service class reference from a workload:
  - Alter the workload to change the service class name
  - Drop the workload
- After a role has been referenced by a workload, it cannot be dropped until it is no longer referenced by any workload. Either of the following actions can be taken to remove a role reference from a workload:
  - Alter the workload to remove the role
  - Drop the workload
- ***Privileges***: The USAGE privilege is not granted to any user, group, or role when a workload is created. To enable use of a workload, grant USAGE privilege on that workload to a user, a group, or a role using the GRANT USAGE ON WORKLOAD statement.
- ***Syntax alternatives***: The following are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - DATABASE PARTITION can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - DATABASE PARTITIONS can be specified in place of MEMBERS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - COLLECT UNIT OF WORK DATA PACKAGE LIST can be specified in place of COLLECT UNIT OF WORK DATA BASE INCLUDE PACKAGE LIST.

Examples

- *Example 1:* Create a workload named CAMPAIGN for requests that are submitted by a session user belonging to group FINANCE. These requests are to be executed in the default user service class SYSDEFAULTUSERCLASS.

```
CREATE WORKLOAD CAMPAIGN
  SESSION_USER GROUP ('FINANCE')
```

- *Example 2:* Create a workload named PAYROLL for a session user with role HR that has the CURRENT CLIENT_APPLNAME special register set to SALARYSYS. Units of work associated with this workload are to be executed in service class MEDIUMSC that is under the service superclass HRSC. When a workload is chosen at run time, this workload should be evaluated only after the workload CAMPAIGN has been evaluated and determined to not match.

```
CREATE WORKLOAD PAYROLL
  SESSION_USER ROLE ('HR')
  CURRENT CLIENT_APPLNAME ('SALARYSYS') SERVICE CLASS MEDIUMSC
  UNDER HRSC POSITION AFTER CAMPAIGN
```

- *Example 3:* An occurrence of workload CAMPAIGN (from example 1) is currently running on the system. Create a workload named NEWCAMPAIGN, also for requests that are submitted by a session user belonging to group FINANCE, but only those requests submitted through application DB2BP.EXE. Requests associated with this workload are to be executed in service class MARKETINGSC. NEWCAMPAIGN should be evaluated before CAMPAIGN.

```
CREATE WORKLOAD NEWCAMPAIGN
  SESSION_USER GROUP ('FINANCE')
  APPLNAME ('DB2BP.EXE') SERVICE CLASS MARKETINGSC
  POSITION BEFORE CAMPAIGN
```

  The running workload occurrence of CAMPAIGN continues to run until the current unit of work completes, at which time a workload re-evaluation takes place, and the connection could then be remapped to workload NEWCAMPAIGN.

- *Example 4:* Create a workload named REPORTS for requests that are submitted through application appl1, appl2, or appl3 by system user BOB or MARY.

```
CREATE WORKLOAD REPORTS
  APPLNAME ('appl1', 'appl2', 'appl3')
  SYSTEM_USER ('BOB', 'MARY')
```

- *Example 5:* Assuming a lock event monitor called PAYROLL exists and is active, create lock event records with statement history for lock timeout events that occur within the workload EMPLOYEES.

```
CREATE WORKLOAD EMPLOYEES
  APPLNAME ("app1", "app2")
  COLLECT LOCK TIMEOUT DATA WITH HISTORY
```

- *Example 6:* Assuming a lock event monitor called PAYROLL exists and is active, create lock event records for only deadlock and lock timeout events that occur within the workload FINANCE on all partitions.

```
CREATE WORKLOAD FINANCE
  APPLNAME ("app1", "app2")
  COLLECT DEADLOCK DATA
  COLLECT LOCK TIMEOUT DATA
```

- *Example 7:* Assuming a lock event monitor called PAYROLL exists and is active, create lock event records with statement history and values for deadlock events that occur within the workload MANAGERS.

```
CREATE WORKLOAD MANAGERS
  APPLNAME ("app1", "app2")
  COLLECT DEADLOCK DATA WITH HISTORY AND VALUES
```

- *Example 8:* Assuming a lock event monitor called PAYROLL exists and is active, create lock event records with statement history for locks that are acquired after waiting 5000 milliseconds within the MANAGERS workload.

```
CREATE WORKLOAD MANAGERS
  APPLNAME ("app1", "app2")
  COLLECT LOCK WAIT DATA FOR LOCKS WAITING MORE THAN 5 SECONDS WITH HISTORY
```

- *Example 9*: Create a workload named ACCRECS for all accounts receivable applications that share a similar name (*accrec01, accrec02 ... accrec15*) and assign them to the service class ACCOUNTNGSC. Application names are identified through the APPLNAME connection attribute with the help of a wild card (*) and do not need to be specified individually.

```
CREATE WORKLOAD ACCRECS
  SESSION_USER GROUP ('ACCOUNTING')
  APPLNAME ('accrec*')
  SERVICE CLASS ACCOUNTNGSC
```

- *Example 10:* Create a workload named CAMPAIGN for requests submitted through the application appl1, and have unit of work data collected and sent to any active unit of work event monitors.

```
CREATE WORKLOAD CAMPAIGN
  APPLNAME ('appl1')
  COLLECT UNIT OF WORK DATA BASE
```

- *Example 11:* The following statements show how you can specify the different address value formats supported by the ADDRESS connection attribute when creating a workload.
  - To specify a secure domain name:

```
CREATE WORKLOAD DOMAINWORKLOAD
  ADDRESS ('aviator.example.com')
```

  - To specify a IPv4 address value:

```
CREATE WORKLOAD IPWORKLOAD1
  ADDRESS ('192.0.2.11')
```

  - To specify a IPv6 address value (long format):

```
CREATE WORKLOAD IPWORKLOAD2
  ADDRESS ('2001:db8:519:13:204:acff:fe57:6135')
```

  - To specify a IPv6 address value (short format):

```
CREATE WORKLOAD IPWORKLOAD3
  ADDRESS ('2001:db8::202:55ff:fe9a:6eee')
```

CREATE WRAPPER

The CREATE WRAPPER statement registers a wrapper with a federated server. A wrapper is a mechanism by which a federated server can interact with certain types of data sources.

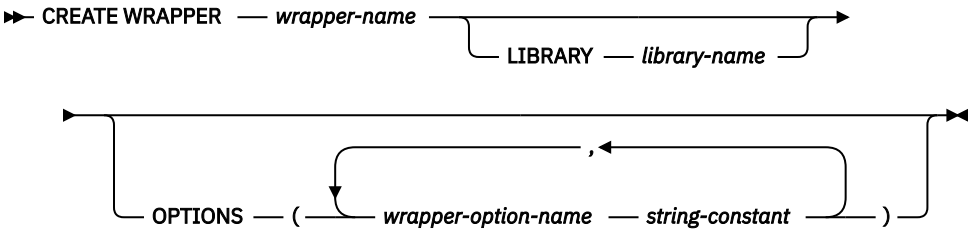
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include DBADM authority.

Syntax



Description

wrapper-name
Names the wrapper. It can be:

- A predefined name. If a predefined name is specified, the federated server automatically assigns a default value to *library-name*.
- A user-supplied name. If a user-supplied name is provided, it is necessary to also specify the appropriate *library-name* to be used with that wrapper and operating system.

LIBRARY *library-name*
The name of the file that contains the wrapper library module. This option is required when a user-supplied wrapper name is used, and cannot be specified when a predefined wrapper name is used. The library name must be enclosed in single quotation marks.

The library name can be specified either as an absolute path name or as a base name (without the path). If a base name is specified, the library must reside in the following subdirectory of your database's installation path:

Operating system	Subdirectory for the wrapper library module
Linux AIX	`lib`
Windows	`bin`

OPTIONS
Specify configuration options for the wrapper to be created. Which options you can specify depends on the data source of the object for which a wrapper is being created. For a list of data sources and the wrapper options that apply to each, see Data source options. Each option value is a character string constant that must be enclosed in single quotation marks.

Notes

- **Syntax alternatives:** The following syntax is supported for compatibility with previous versions of Db2:
  - ADD can be specified before *wrapper-option-name string-constant*.

Examples

1. Register the NET8 wrapper on a federated server to access Oracle data sources. *NET8* is the predefined name for the wrapper that you can use to access Oracle data sources.

```
CREATE WRAPPER NET8
```

2. Register a wrapper on a Db2 federated server that uses the Linux operating system to access ODBC data sources. Assign the name *odbc* to the wrapper that is being registered in the federated database.

The full path of the library that contains the ODBC Driver Manager is defined in the wrapper option *MODULE '/usr/lib/odbc.so'*.

```
CREATE WRAPPER odbc OPTIONS (MODULE '/usr/lib/odbc.so')
```

3. Register a wrapper on a Db2 federated server that uses the Windows operating system to access ODBC data sources. The library name for the ODBC wrapper is *'db2rcodbc.dll'*.

```
CREATE WRAPPER odbc LIBRARY 'db2rcodbc.dll'
```

DECLARE CURSOR

The DECLARE CURSOR statement defines a cursor.

Invocation

Although an interactive SQL facility might provide an interface that gives the appearance of interactive execution, this statement can only be embedded within an application program. It is not an executable statement and cannot be dynamically prepared.

When invoked using the command line processor, additional options can be specified.

For more information, refer to "Using command line SQL statements and XQuery statements" in *Command Reference*.

Authorization

The term "SELECT statement of the cursor" is used to specify the authorization rules. The SELECT statement of the cursor is one of the following statements:

- The prepared select-statement identified by *statement-name*
- The specified *select-statement*

The privileges held by the authorization ID of the statement must include the privileges necessary to execute the *select-statement*. See the Authorization section in "SQL queries".

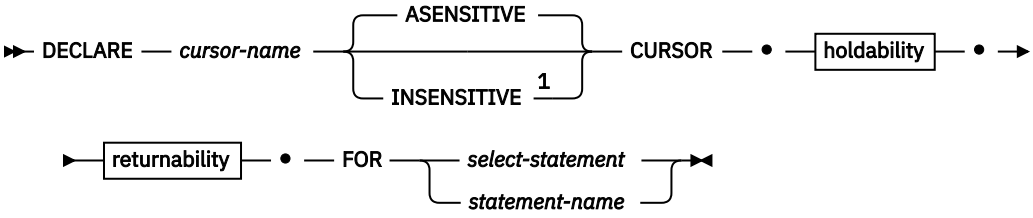
If *statement-name* is specified:

- The authorization ID of the statement is the runtime authorization ID.
- The authorization check is performed when the SELECT-statement is prepared.
- The cursor cannot be opened unless the SELECT-statement is in a prepared state.

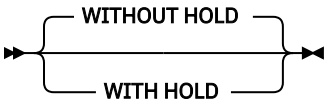
If *select-statement* is specified:

- GROUP privileges are not checked.
- The authorization ID of the statement is the authorization ID specified during program preparation.

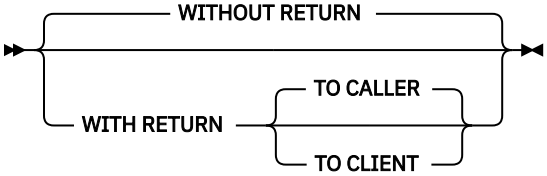
Syntax



holdability



returnability



Notes:

[1] This option can be used only in the context of a compound SQL (compiled) statement

Description

cursor-name
Specifies the name of the cursor created when the source program is run. The name must not be the same as the name of another cursor declared in the source program. The cursor must be opened before use.

ASENSITIVE or INSENSITIVE
Specifies whether the cursor is asensitive or insensitive to changes.

ASENSITIVE
Specifies that the cursor should be as sensitive as possible to insert, update, or delete operations made to the rows underlying the result table, depending on how the *select-statement* is optimized. This option is the default.

INSENSITIVE
Specifies that the cursor does not have sensitivity to insert, update, or delete operations that are made to the rows underlying the result table. If INSENSITIVE is specified, the cursor is read-only and the result table is materialized when the cursor is opened. As a result, the size of the result table, the order of the rows, and the values for each row do not change after the cursor is opened. The SELECT statement cannot contain a FOR UPDATE clause, and the cursor cannot be used for positioned updates or deletes.

WITHOUT HOLD or WITH HOLD
Specifies whether or not the cursor should be prevented from being closed as a consequence of a commit operation.

WITHOUT HOLD
Does not prevent the cursor from being closed as a consequence of a commit operation. This is the default.

WITH HOLD
Maintains resources across multiple units of work. The effect of the WITH HOLD cursor attribute is as follows:

- For units of work ending with COMMIT:
  - Open cursors defined WITH HOLD remain open. The cursor is positioned before the next logical row of the results table.

    If a DISCONNECT statement is issued after a COMMIT statement for a connection with WITH HOLD cursors, the held cursors must be explicitly closed or the connection will be assumed to have performed work (simply by having open WITH HELD cursors even though no SQL statements were issued) and the DISCONNECT statement will fail.
  - All locks are released, except locks protecting the current cursor position of open WITH HOLD cursors. The locks held include the locks on the table, and for parallel environments, the locks

on rows where the cursors are currently positioned. Locks on packages and dynamic SQL sections (if any) are held.

  - Valid operations on cursors defined WITH HOLD immediately following a COMMIT request are:
    - FETCH: Fetches the next row of the cursor.
    - CLOSE: Closes the cursor.
  - UPDATE and DELETE CURRENT OF CURSOR are valid only for rows that are fetched within the same unit of work.
  - LOB locators are freed.
  - The set of rows modified by:
    - A data change statement
    - Routines that modify SQL data embedded within open WITH HOLD cursors

    is committed.
- For units of work ending with ROLLBACK:
  - All open cursors are closed.
  - All locks acquired during the unit of work are released.
  - LOB locators are freed.
- For special COMMIT case:
  - Packages can be recreated either explicitly, by binding the package, or implicitly, because the package has been invalidated and then dynamically recreated the first time it is referenced. All held cursors are closed during package rebind. This might result in errors during subsequent execution.

WITHOUT RETURN or WITH RETURN

Specifies whether or not the result table of the cursor is intended to be used as a result set that will be returned from a procedure.

WITHOUT RETURN

Specifies that the result table of the cursor is not intended to be used as a result set that will be returned from a procedure.

WITH RETURN

Specifies that the result table of the cursor is intended to be used as a result set that will be returned from a procedure. WITH RETURN is relevant only if the DECLARE CURSOR statement is contained with the source code for a procedure. In other cases, the precompiler might accept the clause, but it has no effect.

Within an SQL procedure, cursors declared using the WITH RETURN clause that are still open when the SQL procedure ends, define the result sets from the SQL procedure. All other open cursors in an SQL procedure are closed when the SQL procedure ends. Within an external procedure (one not defined using LANGUAGE SQL), the default for all cursors is WITH RETURN TO CALLER. Therefore, all cursors that are open when the procedure ends will be considered result sets. Cursors that are returned from a procedure cannot be declared as scrollable cursors.

TO CALLER

Specifies that the cursor can return a result set to the caller. For example, if the caller is another procedure, the result set is returned to that procedure. If the caller is a client application, the result set is returned to the client application.

TO CLIENT

Specifies that the cursor can return a result set to the client application. This cursor is invisible to any intermediate nested procedures. If a function, method, or trigger called the procedure either directly or indirectly, result sets cannot be returned to the client and the cursor will be closed after the procedure finishes.

select-statement
Identifies the SELECT statement of the cursor. The *select-statement* must not include parameter markers, but can include references to host variables. The declarations of the host variables must precede the DECLARE CURSOR statement in the source program.

statement-name
The SELECT statement of the cursor is the prepared SELECT statement identified by the *statement-name* when the cursor is opened. The *statement-name* must not be identical to a *statement-name* specified in another DECLARE CURSOR statement of the source program.

For an explanation of prepared SELECT statements, see "PREPARE".

Notes

- A program called from another program, or from a different source file within the same program, cannot use the cursor that was opened by the calling program.
- Unnested procedures, with LANGUAGE other than SQL, will have WITH RETURN TO CALLER as the default behavior if DECLARE CURSOR is specified without a WITH RETURN clause, and the cursor is left open in the procedure. This provides compatibility with procedures from previous versions that allow procedures to return result sets to applicable client applications. To avoid this behavior, close all cursors opened in the procedure.
- If the SELECT statement of a cursor contains CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP, all references to these special registers will yield the same respective datetime value on each FETCH. This value is determined when the cursor is opened.
- For more efficient processing of data, the database manager can block data for read-only cursors when retrieving data from a remote server. The use of the FOR UPDATE clause helps the database manager decide whether a cursor is updatable or not. Updatability is also used to determine the access path selection as well. If a cursor is not going to be used in a Positioned UPDATE or DELETE statement, it should be declared as FOR READ ONLY.
- A cursor in the open state designates a result table and a position relative to the rows of that table. The table is the result table specified by the SELECT statement of the cursor.
- A cursor is *deletable* if each of the following conditions is true:
  - Each FROM clause of the outer fullselect identifies only one base table or deletable view (cannot identify a nested or common table expression or a nickname) without use of the OUTER clause
  - The outer fullselect does not include a VALUES clause
  - The outer fullselect does not include a GROUP BY clause or HAVING clause
  - The outer fullselect does not include column functions in the select list
  - The outer fullselect does not include SET operations (UNION, EXCEPT, or INTERSECT) with the exception of UNION ALL
  - The outer fullselect does not contain a FOR SYSTEM_TIME period specification.
  - The select list of the outer fullselect does not include DISTINCT
  - The outer fullselect does not include an ORDER BY clause (even if the ORDER BY clause is nested in a view), and the FOR UPDATE clause has not been specified
  - The select-statement does not include a FOR READ ONLY clause
  - The FROM clause of the outer fullselect does not include a *data-change-table-reference*
  - One or more of the following conditions is true:
    - The FOR UPDATE clause is specified
    - The cursor is statically defined, unless the STATICREADONLY bind option is YES
    - The LANGLEVEL bind option is MIA or SQL92E

  A column in the select list of the outer fullselect associated with a cursor is *updatable* if each of the following conditions is true:

- The cursor is deletable
- The column resolves to a column of the base table
- The LANGLEVEL bind option is MIA, SQL92E or the select-statement includes the FOR UPDATE clause (the column must be specified explicitly or implicitly in the FOR UPDATE clause)

A cursor is *read-only* if it is not deletable.

A cursor is *ambiguous* if each of the following conditions is true:

- The select-statement is dynamically prepared
- The select-statement does not include either the FOR READ ONLY clause or the FOR UPDATE clause
- The LANGLEVEL bind option is SAA1
- The cursor otherwise satisfies the conditions of a deletable cursor

An ambiguous cursor is considered read-only if the BLOCKING bind option is ALL, otherwise it is considered updatable.

- Cursors in procedures that are called by application programs written using CLI can be used to define result sets that are returned directly to the client application. Cursors in SQL procedures can also be returned to a calling SQL procedure only if they are defined using the WITH RETURN clause.
- Cursors declared in routines that are invoked directly or indirectly from a cursor declared WITH HOLD, do not inherit the WITH HOLD option. Thus, unless the cursor in the routine is explicitly defined WITH HOLD, a COMMIT in the application will close it.

  Consider the following application and two UDFs:

```
Application:

   DECLARE APPCUR CURSOR WITH HOLD FOR SELECT UDF1() ...
   OPEN APPCUR
   FETCH APPCUR ...
   COMMIT

UDF1:

   DECLARE UDF1CUR CURSOR FOR SELECT UDF2() ...
   OPEN UDF1CUR
   FETCH UDF1CUR ...

UDF2:

   DECLARE UDF2CUR CURSOR WITH HOLD FOR SELECT UDF2() ...
   OPEN UDF2CUR
   FETCH UDF2CUR ...
```

  After the application fetches cursor APPCUR, all three cursors are open. When the application issues the COMMIT statement, APPCUR remains open, because it was declared WITH HOLD. In UDF1, however, the cursor UDF1CUR is closed, because it was not defined with the WITH HOLD option. When the cursor UDF1CUR is closed, all routine invocations in the corresponding select-statement complete (receiving a final call, if so defined). UDF2 completes, which causes UDF2CUR to close.

Examples

Example 1: The DECLARE CURSOR statement associates the cursor name C1 with the results of the SELECT.

```
  EXEC SQL DECLARE C1 CURSOR FOR
    SELECT DEPTNO, DEPTNAME, MGRNO
    FROM DEPARTMENT
    WHERE ADMRDEPT = 'A00';
```

Example 2: Assume that the EMPLOYEE table has been altered to add a generated column, WEEKLYPAY, that calculates the weekly pay based on the yearly salary. Declare a cursor to retrieve the system-generated column value from a row to be inserted.

```
EXEC SQL DECLARE C2 CURSOR FOR
  SELECT E.WEEKLYPAY
  FROM NEW TABLE
    (INSERT INTO EMPLOYEE
     (EMPNO, FIRSTNME, MIDINIT, LASTNAME, EDLEVEL, SALARY)
     VALUES('000420', 'Peter', 'U', 'Bender', 16, 31842) AS E;
```

DECLARE GLOBAL TEMPORARY TABLE

The DECLARE GLOBAL TEMPORARY TABLE statement defines a temporary table for the current session.

The declared temporary table description does not appear in the system catalog. It is not persistent and cannot be shared with other sessions. Each session that defines a declared global temporary table of the same name has its own unique description of the temporary table. When the session terminates, the rows of the table are deleted, and the description of the temporary table is dropped.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

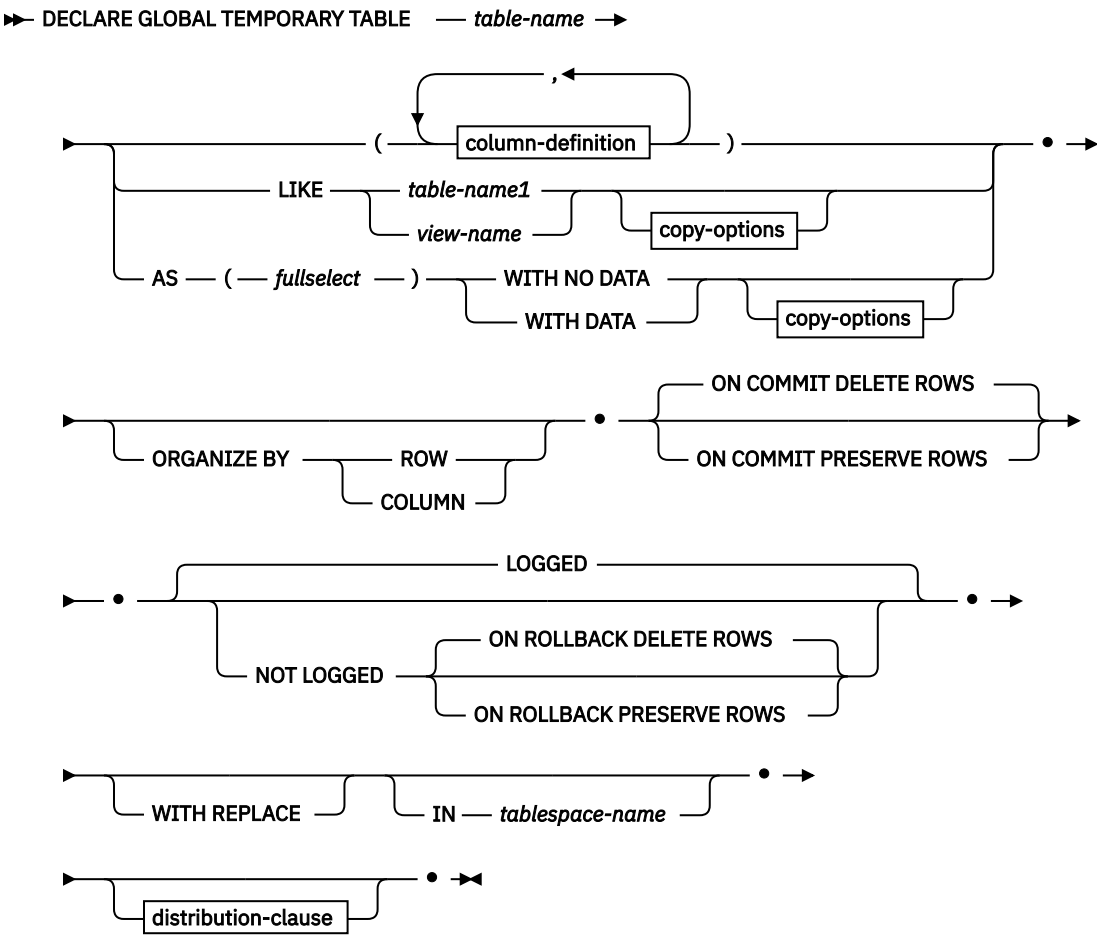
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- USE privilege on the USER TEMPORARY table space
- DBADM authority
- SYSADM authority
- SYSCTRL authority

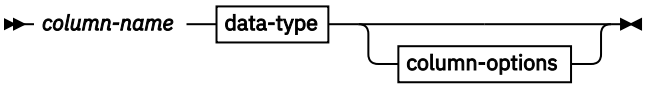
When defining a table using LIKE or a fullselect, the privileges held by the authorization ID of the statement must also include at least one of the following authorities on each identified table or view:

- SELECT privilege on the table or view
- SELECTIN privilege on the schema containing the table or view
- CONTROL privilege on the table or view
- DATAACCESS authority on the schema containing the table or view
- DATAACCESS authority

Syntax

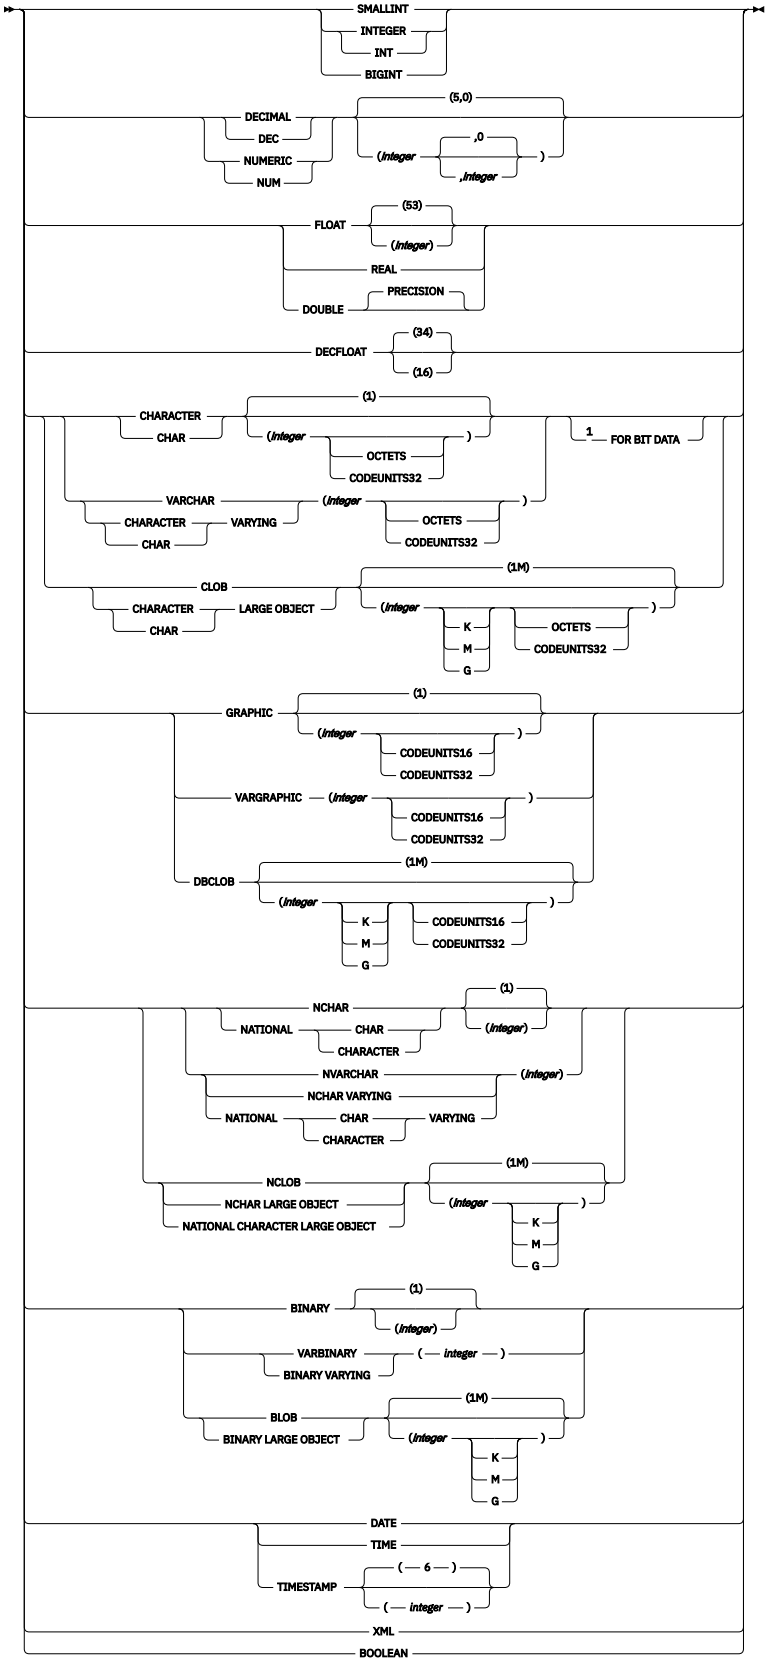


column-definition

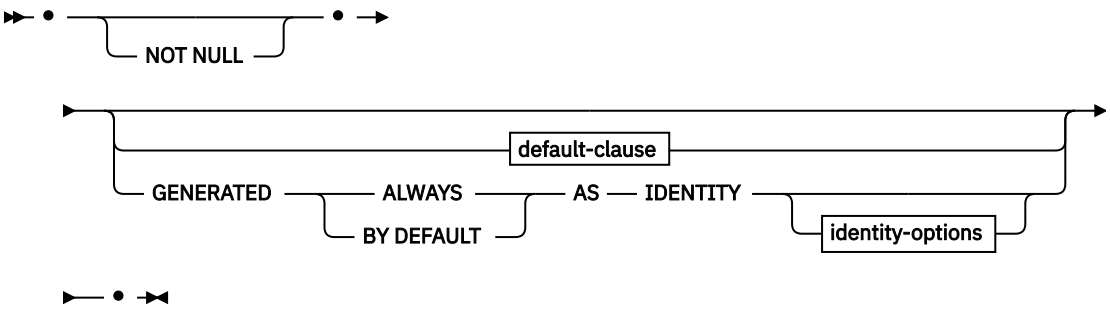


data-type

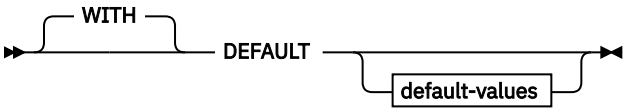
built-in-type



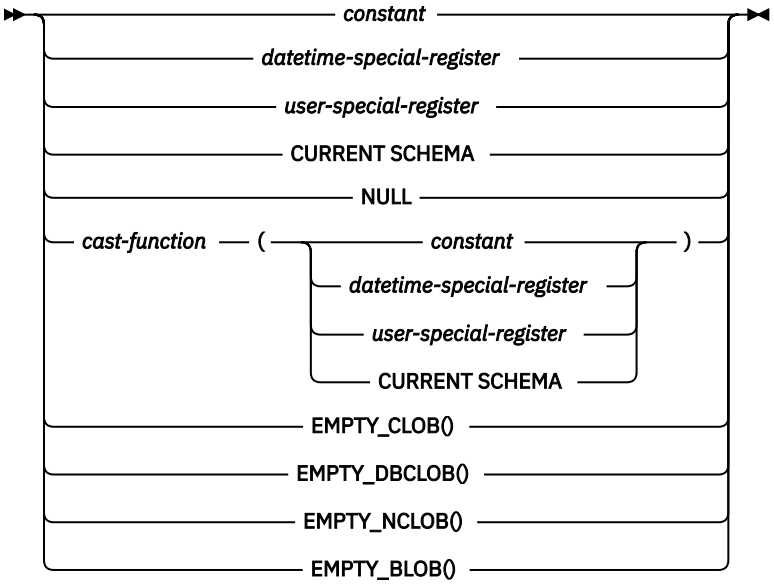
column-options



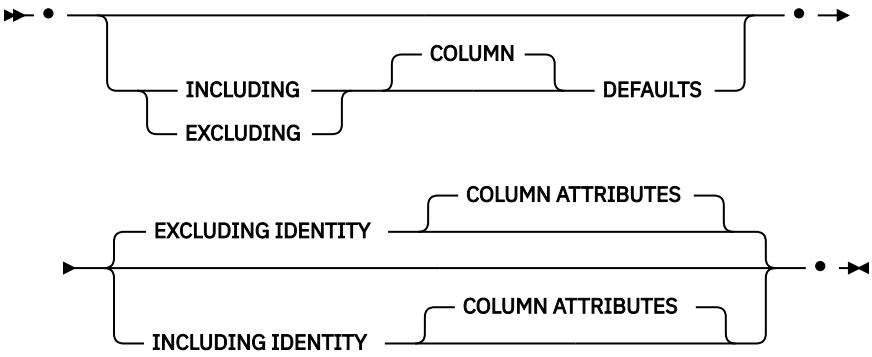
default-clause



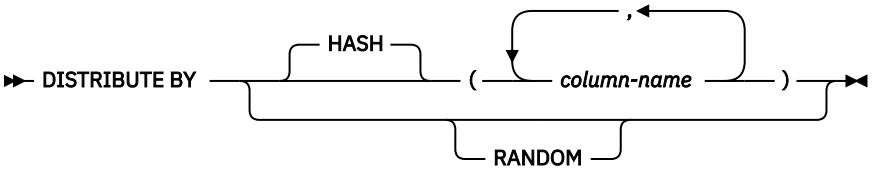
default-values



copy-options



distribution-clause



Notes:

[1] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

Description

table-name
Names the temporary table. The qualifier, if specified explicitly, must be SESSION, otherwise an error is returned (SQLSTATE 428EK). If the qualifier is not specified, SESSION is implicitly assigned.

Each session that defines a declared temporary table with the same *table-name* has its own unique description of that declared temporary table. The WITH REPLACE clause must be specified if *table-name* identifies a declared temporary table that already exists in the session (SQLSTATE 42710).

It is possible that a table, view, alias, or nickname already exists in the catalog, with the same name and the schema name SESSION. In this case:

- A declared temporary table *table-name* may still be defined without any error or warning
- Any references to SESSION.*table-name* will resolve to the declared temporary table rather than the SESSION.*table-name* already defined in the catalog.

column-definition
Defines the attributes of a column of the temporary table.

column-name
Names a column of the table. The name cannot be qualified, and the same name cannot be used for more than one column of the table (SQLSTATE 42711).

A row-organized table can have the following attributes:

- A 4K page size with a maximum of 500 columns, where the byte counts of the columns must not be greater than 4005.
- An 8K page size with a maximum of 1012 columns, where the byte counts of the columns must not be greater than 8101.
- A 16K page size with a maximum of 1012 columns, where the byte counts of the columns must not be greater than 16,293.
- A 32K page size with a maximum of 1012 columns, where the byte counts of the columns must not be greater than 32,677.

A column-organized table can have a maximum of 1012 columns, regardless of its page size. The byte count of each column must not exceed 32,677. Extended row size support does not apply to column-organized tables.

A created temporary table cannot have a row-begin column, row-end column, or a transaction-start-ID column.

For more details, see "Row Size" in “CREATE TABLE ” on page 1351.

data-type
Specifies the data type of the column

built-in-type
Specifies a built-in data type. See "CREATE TABLE" for a description of *built-in-type*.

A SYSPROC.DB2SECURITYLABEL data type cannot be specified for a declared temporary table.

column-options
Defines additional options related to the columns of the table.

NOT NULL
Prevents the column from containing null values. For specification of null values, see NOT NULL in “CREATE TABLE ” on page 1351.

default-clause
Specifies a default value for the column.

WITH
An optional keyword.

DEFAULT
Provides a default value in the event a value is not supplied on INSERT or is specified as DEFAULT on INSERT or UPDATE. If a default value is not specified following the DEFAULT keyword, the default value depends on the data type of the column as shown in "ALTER TABLE".

If the column is based on a column of a typed table, a specific default value must be specified when defining a default. A default value cannot be specified for the object identifier column of a typed table (SQLSTATE 42997).

If a column is defined using a distinct type, then the default value of the column is the default value of the source data type cast to the distinct type.

If a column is defined using a structured type, the *default-clause* cannot be specified (SQLSTATE 42842).

Omission of DEFAULT from a *column-definition* results in the use of the null value as the default for the column. If such a column is defined NOT NULL, then the column does not have a valid default.

default-values
Specific types of default values that can be specified are as follows.

constant
Specifies the constant as the default value for the column. The specified constant must:

- represent a value that could be assigned to the column in accordance with the rules of assignment
- not be a floating-point constant unless the column is defined with a floating-point data type
- be a numeric constant or a decimal floating-point special value if the data type of the column is a decimal floating-point. Floating-point constants are first interpreted as DOUBLE and then converted to decimal floating-point if the target column is DECFLOAT. For DECFLOAT(16) columns, decimal constants having precision greater than 16 digits will be rounded using the rounding modes specified by the CURRENT DECFLOAT ROUNDING MODE special register.
- not have nonzero digits beyond the scale of the column data type if the constant is a decimal constant (for example, 1.234 cannot be the default for a DECIMAL(5,2) column)
- be expressed with no more than 254 bytes including the quote characters, any introducer character such as the X for a hexadecimal constant, and characters from the fully qualified function name and parentheses when the constant is the argument of a *cast-function*

datetime-special-register
Specifies the value of the datetime special register (CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP) at the time of INSERT, UPDATE, or LOAD as the default for the column. The data type of the column must be the data type that corresponds to the special register specified (for example, data type must be DATE when CURRENT DATE is specified).

user-special-register
Specifies the value of the user special register (CURRENT USER, SESSION_USER, SYSTEM_USER) at the time of INSERT, UPDATE, or LOAD as the default for the column. The data type of the column must be a character string with a length not less than the length attribute of a user special register. Note that USER can be specified in place of SESSION_USER and CURRENT_USER can be specified in place of CURRENT USER.

CURRENT SCHEMA
Specifies the value of the CURRENT SCHEMA special register at the time of INSERT, UPDATE, or LOAD as the default for the column. If CURRENT SCHEMA is specified, the data type of the column must be a character string with a length greater than or equal to the length attribute of the CURRENT SCHEMA special register.

NULL
Specifies NULL as the default for the column. If NOT NULL was specified, DEFAULT NULL may be specified within the same column definition but will result in an error on any attempt to set the column to the default value.

cast-function
This form of a default value can only be used with columns defined as a distinct type, BLOB or datetime (DATE, TIME or TIMESTAMP) data type. For distinct type, with the exception of distinct types based on BLOB or datetime types, the name of the function must match the name of the distinct type for the column. If qualified with a schema name, it must be the same as the schema name for the distinct type. If not qualified, the schema name from function resolution must be the same as the schema name for the distinct type. For a distinct type based on a datetime type, where the default value is a constant, a function must be used and the name of the function must match the name of the source type of the distinct type with an implicit or explicit schema name of SYSIBM. For other datetime columns, the corresponding datetime function may also be used. For a BLOB or a distinct type based on BLOB, a function must be used and the name of the function must be BLOB with an implicit or explicit schema name of SYSIBM.

constant
Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type or for the data type if not a distinct type. If the *cast-function* is BLOB, the constant must be a string constant.

datetime-special-register
Specifies CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP. The source type of the distinct type of the column must be the data type that corresponds to the specified special register.

user-special-register
Specifies CURRENT USER, SESSION_USER, or SYSTEM_USER. The data type of the source type of the distinct type of the column must be a string data type with a length of at least 8 bytes. If the *cast-function* is BLOB, the length attribute must be at least 8 bytes.

CURRENT SCHEMA
Specifies the value of the CURRENT SCHEMA special register. The data type of the source type of the distinct type of the column must be a character string with a length greater than or equal to the length attribute of the CURRENT SCHEMA special register. If the cast-function is BLOB, the length attribute must be at least 8 bytes.

EMPTY_CLOB(), EMPTY_DBCLOB(), or EMPTY_BLOB()
Specifies a zero-length string as the default for the column. The column must have the data type that corresponds to the result data type of the function.

If the value specified is not valid, an error is returned (SQLSTATE 42894).

IDENTITY and *identity-options*
For specification of identity columns, see IDENTITY and *identity-options* in "CREATE TABLE".

LIKE *table-name1* or *view-name* or *nickname*
Specifies that the columns of the table have exactly the same name and description as the columns of the identified table (*table-name1*), view (*view-name*), or nickname (*nickname*). The name specified after LIKE must identify a table, view, or nickname that exists in the catalog or a declared temporary table. A typed table or typed view cannot be specified (SQLSTATE 428EC). A protected table cannot

be specified (SQLSTATE 42962).A table that has a column defined as IMPLICITLY HIDDEN cannot be specified (SQLSTATE 560AE).

The use of LIKE is an implicit definition of *n* columns, where *n* is the number of columns in the identified table (including implicitly hidden columns), view, or nickname. The implicit definition depends on what is identified after LIKE.

- If a table is identified, then the implicit definition includes the column name, data type and nullability characteristic of each of the columns of *table-name1*. If EXCLUDING COLUMN DEFAULTS is not specified, then the column default is also included.
- If a view is identified, then the implicit definition includes the column name, data type, and nullability characteristic of each of the result columns of the fullselect defined in *view-name*. The data types of the view columns must be data types that are valid for columns of a table.
- If a nickname is identified, then the implicit definition includes the column name, data type, and nullability characteristic of each column of *nickname*.
- If a random distribution table using the random by generation method is identified, then the **RANDOM_DISTRIBUTION_KEY** column used for generation of random distribution values is not included. Unless the new table being created shares the same table distribution.

Column default and identity column attributes may be included or excluded, based on the *copy-attributes* clauses. The implicit definition does not include any other attributes of the identified table, view, or nickname. Thus the new table does not have any unique constraints, foreign key constraints, triggers, indexes, table partitioning keys, or distribution keys. The table is created in the table space implicitly or explicitly specified by the IN clause, and the table has any other optional clause only if the optional clause is specified.

When a table is identified in the LIKE clause and that table contains a ROW CHANGE TIMESTAMP column, the corresponding column of the new table inherits only the data type of the ROW CHANGE TIMESTAMP column. The new column is not considered to be a generated column.

If row or column level access control (RCAC) is enforced for *table-name1*, RCAC is not inherited by the new table.

AS (*fullselect*)
Specifies that, for each column in the derived result table of the *fullselect*, a corresponding column is to be defined for the table. Each defined column adopts the following attributes from its corresponding column of the result table (if applicable to the data type):

- Column name
- Column description
- Data type, length, precision, and scale
- Nullability

The following attributes are not included (although the default value and identity attributes can be included by using the *copy-options*):

- Default value
- Identity attributes
- Hidden attribute
- ROW CHANGE TIMESTAMP
- Any other optional attributes of the tables or views referenced in the fullselect

The following restrictions apply:

- Every select list element must have a unique name (SQLSTATE 42711). The AS clause can be used in the select clause to provide unique names.
- The fullselect cannot refer to host variables or include parameter markers.
- The data types of the result columns of the fullselect must be data types that are valid for columns of a table.

- If row or column level access control (RCAC) is activated for any table that is specified in the fullselect, RCAC is not cascaded to the new table.

WITH NO DATA | WITH DATA
Determines whether to fill the columns of the table with data:

WITH NO DATA
Do not execute the fullselect. It is used only to define the table, which is not populated with the results of the query.

WITH DATA
Execute the fullselect and populate the table with the results of the query.

copy-options
These options specify whether to copy additional attributes of the source result table definition (table, view, or fullselect).

INCLUDING COLUMN DEFAULTS
Column defaults for each updatable column of the source result table definition are copied. Columns that are not updatable will not have a default defined in the corresponding column of the created table.

If LIKE *table-name1* is specified, and *table-name1* identifies a base table, created temporary table, or declared temporary table, then INCLUDING COLUMN DEFAULTS is the default.

EXCLUDING COLUMN DEFAULTS
Column defaults are not copied from the source result table definition.

This clause is the default, except when LIKE *table-name* is specified and *table-name* identifies a base table, created temporary table, or declared temporary table.

INCLUDING IDENTITY COLUMN ATTRIBUTES
If available, identity column attributes (START WITH, INCREMENT BY, and CACHE values) are copied from the source's result table definition. It is possible to copy these attributes if the element of the corresponding column in the table, view, or fullselect is the name of a column of a table, or the name of a column of a view which directly or indirectly maps to the column name of a base table or created temporary table with the identity property. In all other cases, the columns of the new temporary table will not get the identity property. For example:

- The select list of the fullselect includes multiple instances of the name of an identity column (that is, selecting the same column more than once)
- The select list of the fullselect includes multiple identity columns (that is, it involves a join)
- The identity column is included in an expression in the select list
- The fullselect includes a set operation (union, except, or intersect).

EXCLUDING IDENTITY COLUMN ATTRIBUTES
Identity column attributes are not copied from the source result table definition.

ORGANIZE BY
Specifies how the data is organized in the data pages of the table:

ROW
The data is stored by row in the data pages of the table. Each data page stores the data for one or more rows of the table.

COLUMN
The data is stored by column in the data pages of the table. Each data page stores data for one column of the table.

The default is determined by the value of the dft_table_org database configuration parameter.

ON COMMIT
Specifies the action taken on the global temporary table when a COMMIT operation is performed. The default is DELETE ROWS.

DELETE ROWS
All rows of the table will be deleted if no WITH HOLD cursor is open on the table.

PRESERVE ROWS
Rows of the table will be preserved.

LOGGED or NOT LOGGED
Specifies whether operations for the table are logged. The default is LOGGED.

LOGGED
Specifies that insert, update, or delete operations against the table as well as the creation or dropping of the table are to be logged.

NOT LOGGED
Specifies that insert, update, or delete operations against the table are not to be logged, but that the creation or dropping of the table is to be logged. During a ROLLBACK (or ROLLBACK TO SAVEPOINT) operation:

- If the table had been created within a unit of work (or savepoint), the table is dropped
- If the table had been dropped within a unit of work (or savepoint), the table is recreated, but without any data

ON ROLLBACK
Specifies the action that is to be taken on the not logged global temporary table when a ROLLBACK (or ROLLBACK TO SAVEPOINT) operation is performed. The default is DELETE ROWS.

DELETE ROWS
If the table data has been changed, all the rows will be deleted.

PRESERVE ROWS
Rows of the table will be preserved.

Note: Declared global temporary tables using NOT LOGGED ON ROLLBACK PRESERVE ROWS cannot be column-organized.

WITH REPLACE
Indicates that, in the case that a declared temporary table already exists with the specified name, the existing table is replaced with the temporary table defined by this statement (and all rows of the existing table are deleted).

When WITH REPLACE is not specified, then the name specified must not identify a declared temporary table that already exists in the current session (SQLSTATE 42710).

IN *tablespace-name*
Identifies the table space in which the declared temporary table will be instantiated. The table space must exist and be a USER TEMPORARY table space (SQLSTATE 42838), over which the authorization ID of the statement has USE privilege (SQLSTATE 42501). If this clause is not specified, a table space for the table is determined by choosing the USER TEMPORARY table space with the smallest sufficient page size over which the authorization ID of the statement has USE privilege. When more than one table space qualifies, preference is given according to who was granted the USE privilege:

1. The authorization ID
2. A group to which the authorization ID belongs
3. PUBLIC

If more than one table space still qualifies, the final choice is made by the database manager. When no USER TEMPORARY table space qualifies, an error is raised (SQLSTATE 42727).

Determination of the table space can change when:

- Table spaces are dropped or created
- USE privileges are granted or revoked

The sufficient page size of a table is determined by either the byte count of the row or the number of columns. For more details, see "Row Size" in “CREATE TABLE ” on page 1351.

distribution-clause

Specifies the database partitioning or the way the data is distributed across multiple database partitions.

DISTRIBUTE BY HASH (*column-name*, ...)

Specifies the use of the default hashing function on the specified columns, called a *distribution key*, as the distribution method across database partitions. The *column-name* must be an unqualified name that identifies a column of the table (SQLSTATE 42703). The same column must not be identified more than once (SQLSTATE 42709). No column whose data type is BLOB, CLOB, DBCLOB, XML, distinct type based on any of these types, or structured type can be used as part of a distribution key (SQLSTATE 42962).

If this clause is not specified, and the table resides in a multiple partition database partition group with multiple database partitions, a default distribution key is automatically defined.

If none of the columns satisfies the requirements for a default distribution key, the table is created without one. Such tables are allowed only in table spaces that are defined on single-partition database partition groups.

For tables in table spaces that are defined on single-partition database partition groups, any collection of columns with data types that are valid for a distribution key can be used to define the distribution key. If this clause is not specified, no distribution key is created.

DISTRIBUTE BY RANDOM

Specifies that the database manager will select a distribution key to spread data evenly across all database partitions of the database partitioning group. Data distribution is accomplished by using a *random by generation* method. In this method, the database manager will include a column in the table to generate and store a generated value to use in the hashing function. The column will be created with the **IMPLICITLY HIDDEN** clause so that it does not appear in queries unless explicitly included. The value of the column will be automatically generated as new rows are added to the table. By default, the column name is **RANDOM_DISTRIBUTION_KEY**. If it collides with the existing column, a non-conflicting name will be generated by the database manager.

Notes

- A user temporary table space must exist before a declared temporary table can be declared (SQLSTATE 42727).
- ***Referencing a declared temporary table:*** The description of a declared temporary table does not appear in the database catalog (SYSCAT.TABLES); therefore, it is not persistent and is not shareable across database connections. This means that each session that defines a declared temporary table called *table-name* has its own possibly unique description of that declared global temporary table.

  In order to reference the declared temporary table in an SQL statement (other than the DECLARE GLOBAL TEMPORARY TABLE statement), the table must be explicitly or implicitly qualified by the schema name SESSION. If *table-name* is not qualified by SESSION, declared temporary tables are not considered when resolving the reference.

  A reference to SESSION.*table-name* in a connection that has not declared a declared temporary table by that name will attempt to resolve from persistent objects in the catalog. If no such object exists, an error occurs (SQLSTATE 42704).
- When binding a package that has static SQL statements that refer to tables implicitly or explicitly qualified by SESSION, those statements will not be bound statically. When these statements are invoked, they will be incrementally bound, regardless of the VALIDATE option chosen while binding the package. At runtime, each table reference will be resolved to a declared temporary table, if it exists, or a created temporary table, or permanent table. If none exist, an error will be raised (SQLSTATE 42704).
- ***Privileges:*** When a declared temporary table is defined, the definer of the table is granted all table privileges on the table, including the ability to drop the table. Additionally, these privileges are granted to PUBLIC. (None of the privileges are granted with the GRANT option, and none of the privileges appear in the catalog table.) This enables any SQL statement in the session to reference a declared temporary table that has already been defined in that session.

- ***Instantiation and termination:*** For the following explanations, P denotes a session and T is a declared temporary table in the session P:
  - An empty instance of T is created as a result of the DECLARE GLOBAL TEMPORARY TABLE statement that is executed in P.
  - Any SQL statement in P can make reference to T and any reference to T in P is a reference to that same instance of T.
  - If a DECLARE GLOBAL TEMPORARY TABLE statement is specified within the SQL procedure compound statement (defined by BEGIN and END), the scope of the declared temporary table is the connection, not just the compound statement, and the table is known outside of the compound statement. The table is not implicitly dropped at the END of the compound statement. A declared temporary table cannot be defined multiple times by the same name in other compound statements in that session, unless the table has been explicitly dropped.
  - Assuming that the ON COMMIT DELETE ROWS clause was specified implicitly or explicitly, then when a commit operation terminates a unit of work in P, and there is no open WITH HOLD cursor in P that is dependent on T, the commit includes the operation DELETE FROM SESSION.T.
  - When a rollback operation terminates a unit of work or a savepoint in P, and that unit of work or savepoint includes a modification to SESSION.T:
    - If NOT LOGGED was specified, all rows from SESSION.T are deleted unless ON ROLLBACK PRESERVE ROWS was also specified
    - If NOT LOGGED was not specified, the changes to T are undone
  - If NOT LOGGED was specified and an INSERT, UPDATE or DELETE statement fails during execution (as opposed to a compilation error), all rows from SESSION.T are deleted.
  - When a rollback operation terminates a unit of work or a savepoint in P, and that unit of work or savepoint includes the declaration of SESSION.T, then the rollback includes the operation DROP SESSION.T.
  - If a rollback operation terminates a unit of work or a savepoint in P, and that unit of work or savepoint includes the drop of a declared temporary table SESSION.T, then the rollback will undo the drop of the table. If NOT LOGGED was specified, then the table will also have been emptied.
  - When the application process that declared T terminates or disconnects from the database, T is dropped and its instantiated rows are destroyed.
  - When the connection to the server at which T was declared terminates, T is dropped and its instantiated rows are destroyed.
- ***Restrictions on the use of declared temporary tables:*** Declared temporary tables cannot:
  - Be specified in an ALTER, COMMENT, GRANT, LOCK, RENAME or REVOKE statement (SQLSTATE 42995).
  - Be referenced in an AUDIT, CREATE ALIAS, or CREATE VIEW statement (SQLSTATE 42995).
  - Be specified in referential constraints (SQLSTATE 42995).
- Data row compression is enabled for a declared temporary table. When the database manager determines that there is a performance gain, table row data including XML documents stored inline in the base table object will be compressed. However, data compression of the XML storage object of a declared temporary table is not supported.
- Index compression is enabled for indexes that are created on declared temporary tables.
- Index compression is enabled by default for indexes that are created on declared temporary tables. Compression will be shown as on, but indexes will not be compressed if the correct license (IBM Db2 Storage Optimization Feature) is not applied.
- ***Syntax alternatives***: The following alternatives are non-standard. They are supported for compatibility with earlier product versions or with other database products.
  - DEFINITION ONLY can be specified in place of WITH NO DATA.
  - The PARTITIONING KEY clause or DISTRIBUTE ON clause can be specified in place of the DISTRIBUTE BY clause.

– When specifying the value of the datetime special register, NOW() can be specified in place of CURRENT_TIMESTAMP.
– In a CHAR or VARCHAR column definition, you do not need to specify the CCSID explicitly; the correct CCSID will be used automatically. However, if you do specify the CCSID explicitly, it must correspond to the type of database being used:
  - `CCSID ASCII` for a non-unicode database
  - `CCSID UNICODE` for a unicode database

Examples

- *Example 1:* Define a declared temporary table with column definitions for an employee number, salary, bonus, and commission.

```
DECLARE GLOBAL TEMPORARY TABLE SESSION.TEMP_EMP
   (EMPNO  CHAR(6) NOT NULL,
    SALARY DECIMAL(9, 2),
    BONUS  DECIMAL(9, 2),
    COMM   DECIMAL(9, 2)) ON COMMIT PRESERVE ROWS
```

- *Example 2:* Assume that base table USER1.EMPTAB exists and that it contains three columns, one of which is an identity column. Declare a temporary table that has the same column names and attributes (including identity attributes) as the base table.

```
DECLARE GLOBAL TEMPORARY TABLE TEMPTAB1
   LIKE USER1.EMPTAB
   INCLUDING IDENTITY
   ON COMMIT PRESERVE ROWS
```

  In this example, SESSION is used as the implicit qualifier for TEMPTAB1.

Compatibility for Netezza Performance Server (NPS) temporary tables

If you need to declare a temporary table, it is recommended that you use a DECLARE GLOBAL TEMPORARY TABLE statement. However, to provide compatibility with IBM Netezza SQL, a CREATE TEMPORARY TABLE statement can be used instead.

Unlike a DECLARE GLOBAL TEMPORARY TABLE statement, the table name specified by a CREATE TEMPORARY TABLE statement can be qualified with a schema name other than SESSION. The default schema is the current schema. For a schema other than SESSION:

- In order to be able to reference a declared temporary table within STATIC SQL, the package must be bound with VALIDATE RUN.
- The session's ability to use the package cache might be impeded as a consequence.
- The schema name cannot begin with SYS (SQLSTATE 42939).

The qualified name of the temporary table must not identify a table, view, nickname, or alias that is described in the catalog (SQLSTATE 42710).

A CREATE TEMPORARY TABLE statement can include the following additional syntax elements, which correspond to those of DECLARE GLOBAL TEMPORARY TABLE:

- A list of column definitions.
- A DISTRIBUTE BY HASH clause. For compatibility reasons, DISTRIBUTE ON HASH can be specified as an alternative.
- A DISTRIBUTE BY HASH clause. For compatibility reasons, DISTRIBUTE BY RANDOM can be specified as an alternative.
- An AS *fullselect* clause. Note that the fullselect can be enclosed in parentheses.

The following two statements are equivalent and achieve the same result:

```
CREATE TEMPORARY TABLE table_name (column_definition) AS fullselect
```

```
DECLARE GLOBAL TEMPORARY TABLE table_name (column_definition) AS (fullselect) WITH DATA
  ON COMMIT PRESERVE ROWS LOGGED
```

DELETE

The DELETE statement deletes rows from a table, nickname, or view, or the underlying tables, nicknames, or views of the specified fullselect.

Deleting a row from a nickname deletes the row from the data source object to which the nickname refers. Deleting a row from a view deletes the row from the table on which the view is based if no INSTEAD OF trigger is defined for the delete operation on this view. If such a trigger is defined, the trigger will be executed instead.

There are two forms of this statement:

- The *Searched* DELETE form is used to delete one or more rows (optionally determined by a search condition).
- The *Positioned* DELETE form is used to delete exactly one row (as determined by the current position of a cursor).

Invocation

A DELETE statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

To execute either form of this statement, the privileges held by the authorization ID of the statement must include at least one of the following authorities:

- DELETE privilege on the table, view, or nickname from which rows are to be deleted
- CONTROL privilege on the table, view, or nickname from which rows are to be deleted
- DELETEIN privilege on the schema containing the table, view or nickname from which rows are to be deleted
- Schema DATAACCESS authority on the schema containing the table table, view or nickname from which rows are to be deleted
- DATAACCESS authority

To execute a Searched DELETE statement, the privileges held by the authorization ID of the statement must also include at least one of the following authorities for each table, view, or nickname referenced by a subquery:

- SELECT privilege
- CONTROL privilege
- SELECTIN privilege on the schema containing the table, view, or nickname
- Schema DATAACCESS authority on the schema containing the table, view, or nickname
- DATAACCESS authority

If the package used to process the statement is precompiled with SQL92 rules (option LANGLEVEL with a value of SQL92E or MIA), and the searched form of a DELETE statement includes a reference to a column of the table or view in the *search-condition*, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

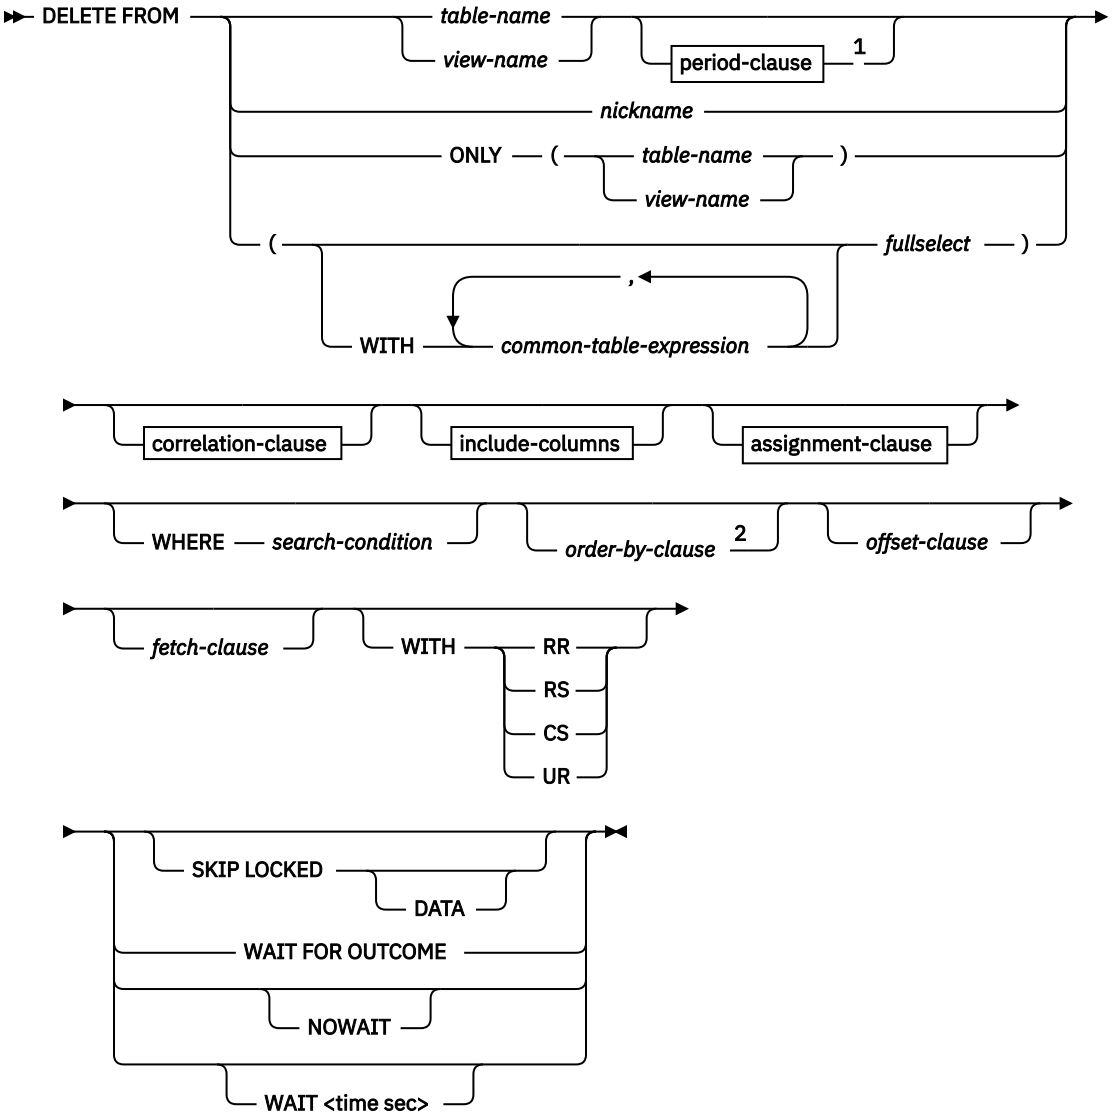
- SELECT privilege
- CONTROL privilege
- SELECTIN privilege on the schema containing the table, view, or nickname
- Schema DATAACCESS authority on the schema containing the table or view
- DATAACCESS authority

If the specified table or view is preceded by the ONLY keyword, the privileges held by the authorization ID of the statement must also include the SELECT privilege for every subtable or subview of the specified table or view.

Group privileges are not checked for static DELETE statements.

If the target of the delete operation is a nickname, the privileges on the object at the data source are not considered until the statement is executed at the data source. At this time, the authorization ID that is used to connect to the data source must have the privileges required for the operation on the object at the data source. The authorization ID of the statement can be mapped to a different authorization ID at the data source.

Syntax (searched-delete)



Notes:

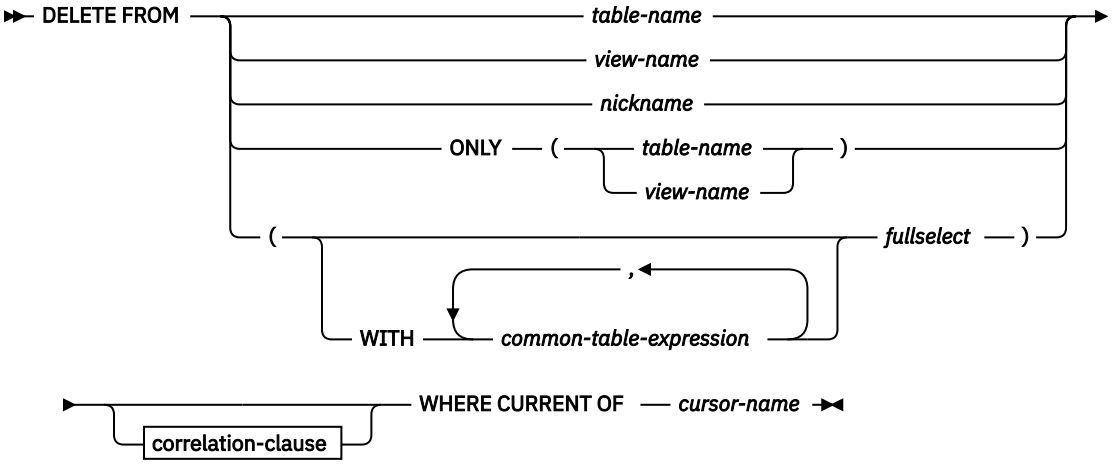
[1] If the *period-clause* is specified, neither the *offset-clause* nor the *fetch-clause* can be specified (SQLSTATE 42601).

[2] If the *order-by-clause* is specified, either the *offset-clause* or *fetch-clause* must also be specified (SQLSTATE 42601).

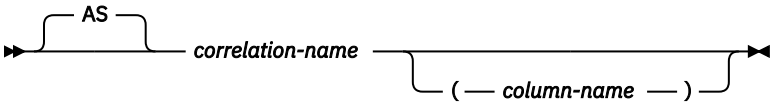
period-clause

include-columns

Syntax (positioned-delete)



correlation-clause



Description

FROM *table-name*, *view-name*, *nickname*, or *(fullselect)*

Identifies the object of the delete operation. The name must identify one of the following objects:

- A table or view that exists in the catalog at the current server
- A table or view at a remote server specified using a remote-object-name

The object must not be a catalog table, a catalog view, a system-maintained materialized query table, or a read-only view.

If *table-name* is a typed table, rows of the table or any of its proper subtables may get deleted by the statement.

If *view-name* is a typed view, rows of the underlying table or underlying tables of the view's proper subviews may get deleted by the statement. If *view-name* is a regular view with an underlying table that is a typed table, rows of the typed table or any of its proper subtables may get deleted by the statement.

If the object of the delete operation is a fullselect, the fullselect must be deletable, as defined in the "Deletable views" Notes item in the description of the CREATE VIEW statement.

For additional restrictions related to temporal tables and use of a view or fullselect as the target of the delete operation, see "Considerations for a system-period temporal table" and "Considerations for an application-period temporal table" in the Notes section.

Only the columns of the specified table can be referenced in the WHERE clause. For a positioned DELETE, the associated cursor must also have specified the table or view in the FROM clause without using ONLY.

FROM ONLY (*table-name*)
Applicable to typed tables, the ONLY keyword specifies that the statement should apply only to data of the specified table and rows of proper subtables cannot be deleted by the statement. For a positioned DELETE, the associated cursor must also have specified the table in the FROM clause using ONLY. If *table-name* is not a typed table, the ONLY keyword has no effect on the statement.

FROM ONLY (*view-name*)
Applicable to typed views, the ONLY keyword specifies that the statement should apply only to data of the specified view and rows of proper subviews cannot be deleted by the statement. For a positioned DELETE, the associated cursor must also have specified the view in the FROM clause using ONLY. If *view-name* is not a typed view, the ONLY keyword has no effect on the statement.

period-clause
Specifies that a period clause applies to the target of the delete operation.

If the target of the delete operation is a view, the following conditions apply to the view:

- The FROM clause of the outer fullselect of the view definition must include a reference, directly or indirectly, to an application-period temporal table (SQLSTATE 42724M).
- An INSTEAD OF DELETE trigger must not be defined for the view (SQLSTATE 428HY).

FOR PORTION OF BUSINESS_TIME
Specifies that the delete only applies to row values for the portion of the period in the row that is specified by the period clause. The BUSINESS_TIME period must exist in the table (SQLSTATE 4274M). FOR PORTION OF BUSINESS_TIME must not be specified if the value of the CURRENT TEMPORAL BUSINESS_TIME special register is not NULL when the BUSTIMESENSITIVE bind option is set to YES (SQLSTATE 428HY).

FROM *value1* TO *value2*
Specifies that the delete applies to rows for the period specified from *value1* up to *value2*. No rows are deleted if *value1* is greater than or equal to *value2*, or if *value1* or *value2* is the null value (SQLSTATE 02000).

For the period specified with FROM *value1* TO *value2*, the BUSINESS_TIME period in a row in the target of the delete is in any of the following states:

- **Overlaps the beginning** of the specified period if the value of the begin column is less than *value1* and the value of the end column is greater than *value1*.
- **Overlaps the end**of the specified period if the value of the end column is greater than or equal to *value2* and the value of the begin column is less than *value2*.
- Is **fully contained** within the specified period if the value for the begin column for BUSINESS_TIME is greater than or equal to *value1* and the value for the corresponding end column is less than or equal to *value2*.
- Is **partially contained** in the specified period if the row overlaps the beginning of the specified period or the end of the specified period, but not both.
- **Fully overlaps** the specified period if the period in the row overlaps the beginning and end of the specified period.
- Is **not contained** in the period if both columns of BUSINESS_TIME are less than or equal to *value1* or greater than or equal to *value2*.

If the BUSINESS_TIME period in a row is not contained in the specified period, the row is not deleted. Otherwise, the delete is applied based on how the values in the columns of the BUSINESS_TIME period overlap the specified period as follows:

- If the BUSINESS_TIME period in a row is fully contained within the specified period, the row is deleted.
- If the BUSINESS_TIME period in a row is partially contained in the specified period and overlaps the beginning of the specified period:
  - The row is deleted.

- A row is inserted using the original values from the row, except that the end column is set to *value1*.

- If the BUSINESS_TIME period in a row is partially contained in the specified period and overlaps the end of the specified period:
  - The row is deleted.
  - A row is inserted using the original values from the row, except that the begin column is set to *value2*.
- If the BUSINESS_TIME period in a row fully overlaps the specified period:
  - The row is deleted.
  - A row is inserted using the original values from the row, except that the end column is set to *value1*.
  - An additional row is inserted using the original values from the row, except that the begin column is set to *value2*.

value1* and *value2
Each expression must return a value that has a date data type, timestamp data type, or a valid data type for a string representation of a date or timestamp (SQLSTATE 428HY). The result of each expression must be comparable to the data type of the columns of the specified period (SQLSTATE 42884). See the comparison rules described in "Assignments and comparisons".

Each expression can contain any of the following supported operands (SQLSTATE 428HY):

- Constant
- Special register
- Variable. For details, refer to "References to variables" in the "Identifiers" topic, in *SQL Reference Volume 1* .
- Scalar function whose arguments are supported operands (though user-defined functions and non-deterministic functions cannot be used)
- CAST specification where the cast operand is a supported operand
- Expression using arithmetic operators and operands

correlation-clause
Can be used within the *search-condition* to designate a table, view, nickname, or fullselect. For a description of *correlation-clause*, see "table-reference" in the description of "Subselect".

include-columns
Specifies a set of columns that are included, along with the columns of *table-name* or *view-name*, in the intermediate result table of the DELETE statement when it is nested in the FROM clause of a fullselect. The *include-columns* are appended at the end of the list of columns that are specified for *table-name* or *view-name*.

INCLUDE
Specifies a list of columns to be included in the intermediate result table of the DELETE statement.

column-name
Specifies a column of the intermediate result table of the DELETE statement. The name cannot be the same as the name of another include column or a column in *table-name* or *view-name* (SQLSTATE 42711).

data-type
Specifies the data type of the include column. The data type must be one that is supported by the CREATE TABLE statement.

assignment-clause
See the description of *assignment-clause* under the UPDATE statement. The same rules apply. The *include-columns* are the only columns that can be set using the *assignment-clause* (SQLSTATE 42703).

WHERE
Specifies a condition that selects the rows to be deleted. The clause can be omitted, a search condition specified, or a cursor named. If the clause is omitted, all rows of the table or view are deleted.

search-condition
Each *column-name* in the search condition, other than in a subquery must identify a column of the table or view.

The *search-condition* is applied to each row of the table, view, or nickname, and the deleted rows are those for which the result of the *search-condition* is true.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the *search condition* is applied to a row, and the results used in applying the *search condition*. In actuality, a subquery with no correlated references is executed once, whereas a subquery with a correlated reference may have to be executed once for each row. If a subquery refers to the object table of a DELETE statement or a dependent table with a delete rule of CASCADE or SET NULL, the subquery is completely evaluated before any rows are deleted.

CURRENT OF *cursor-name*
Identifies a cursor that is defined in a DECLARE CURSOR statement of the program. The DECLARE CURSOR statement must precede the DELETE statement.

The table, view, or nickname named must also be named in the FROM clause of the SELECT statement of the cursor, and the result table of the cursor must not be read-only. (For an explanation of read-only result tables, see "DECLARE CURSOR".)

When the DELETE statement is executed, the cursor must be positioned on a row: that row is the one deleted. After the deletion, the cursor is positioned before the next row of its result table. If there is no next row, the cursor is positioned after the last row.

order-by-clause
Specifies the order of the rows for application of the *offset-clause* and *fetch-clause*. Specify an *order-by-clause* to ensure a predictable order for determining the set of rows to be deleted based on the *offset-clause* and *fetch-clause*. For details on the *order-by-clause*, see “order-by-clause” on page 703.

offset-clause
Limits the effect of the delete by skipping a subset of the qualifying rows. For details on the *offset-clause*, refer to “offset-clause” on page 706.

fetch-clause
Limits the effect of the delete to a subset of the qualifying rows. For details on the *fetch-clause*, refer to “fetch-clause” on page 705.

WITH
Specifies the isolation level used when locating the rows to be deleted.

RR
Repeatable Read

RS
Read Stability

CS
Cursor Stability

UR
Uncommitted Read

The default isolation level of the statement is the isolation level of the package in which the statement is bound. The WITH clause has no effect on nicknames, which always use the default isolation level of the statement.

SKIP LOCKED DATA
The SKIP LOCKED DATA clause specifies that rows are skipped when incompatible locks that would block the progress of the statement are held on the rows by other transactions. These rows can belong to any accessed table addressed in the statement, including tables accessed in a subquery.

This clause applies when the isolation level is CS or RS and is ignored when an isolation level of UR or RR is in effect. It applies to row and block level locks.

Invocation

SKIP LOCKED DATA is ignored if it is specified when WITH RR or WITH UR. The default isolation level of the statement depends on the isolation of the package or plan with which the statement is bound, and whether the result table is read-only. If the default isolation level of the statement is Repeatable Read or Uncommitted Read, then SKIP LOCKED DATA is ignored.

NOWAIT / WAIT <time sec>

Attention: The following feature is available in Db2 11.5.6 and later versions.

The NOWAIT and WAIT clauses specify the number of seconds to wait for a lock before returning an error indicating that a lock cannot be obtained.

When using the WAIT clause, `<time sec>` is an integer between `-1` and `32767`.

Note: For `NOWAIT` and `WAIT 0`, locks are not waited for. If no lock is available at the time of the request, a `-911` error is returned.

When a WAIT value of `-1` is specified, lock timeout detection is turned off. In this situation a lock is waited for (if one is not available at the time of the request) until either of the following events occur:

- The lock is granted.
- A deadlock occurs.

Use of the NOWAIT and WAIT clauses overwrites the value of the LOCKTIMEOUT database configuration variable and the value of the CURRENT LOCK TIMEOUT special register for this delete statement. This means that adding the NOWAIT/WAIT clause with a wait time value of **t** has the same effect as executing the delete statement with a LOCKTIMEOUT value or CURRENT LOCK TIMEOUT value of **t**.

While the NOWAIT and WAIT clauses are not allowed for positioned updates and deletes, you can use them in the declaration of the cursor. When used in the cursor declaration, the specified wait time value is inherited by the statements that use this cursor.

Rules

- ***Triggers:*** DELETE statements may cause triggers to be executed. A trigger may cause other statements to be executed, or may raise error conditions based on the deleted rows. If a DELETE statement on a view causes an INSTEAD OF trigger to fire, referential integrity will be checked against the updates performed in the trigger, and not against the underlying tables of the view that caused the trigger to fire.
- ***Referential integrity:*** If the identified table or the base table of the identified view is a parent, the rows selected for delete must not have any dependents in a relationship with a delete rule of RESTRICT, and the DELETE must not cascade to descendent rows that have dependents in a relationship with a delete rule of RESTRICT.

  If the delete operation is not prevented by a RESTRICT delete rule, the selected rows are deleted. Any rows that are dependents of the selected rows are also affected:

  – The nullable columns of the foreign keys of any rows that are their dependents in a relationship with a delete rule of SET NULL are set to the null value.

  – Any rows that are their dependents in a relationship with a delete rule of CASCADE are also deleted, and the preceding rules apply, in turn, to those rows.

  The delete rule of NO ACTION is checked to enforce that any non-null foreign key refers to an existing parent row after the other referential constraints have been enforced.
- ***Security policy:*** If the identified table or the base table of the identified view is protected with a security policy, the session authorization ID must have the label-based access control (LBAC) credentials that allow:

- Write access to all protected columns (SQLSTATE 42512)
- Read and write access to all of the rows that are selected for deletion (SQLSTATE 42519)

Notes

- If an error occurs during the execution of a multiple row DELETE, no changes are made to the database.
- Unless appropriate locks already exist, one or more exclusive locks are acquired during the execution of a successful DELETE statement. Issuing a COMMIT or ROLLBACK statement will release the locks. Until the locks are released by a commit or rollback operation, the effect of the delete operation can only be perceived by:
  - The application process that performed the deletion
  - Another application process using isolation level UR.

  The locks can prevent other application processes from performing operations on the table.
- If an application process deletes a row on which any of its cursors are positioned, those cursors are positioned before the next row of their result table. Let C be a cursor that is positioned before row R (as a result of an OPEN, a DELETE through C, a DELETE through some other cursor, or a searched DELETE). In the presence of INSERT, UPDATE, and DELETE operations that affect the base table from which R is derived, the next FETCH operation referencing C does not necessarily position C on R. For example, the operation can position C on R', where R' is a new row that is now the next row of the result table.
- SQLERRD(3) in the SQLCA shows the number of rows that qualified for the delete operation. In the context of an SQL procedure statement, the value can be retrieved using the ROW_COUNT variable of the GET DIAGNOSTICS statement. SQLERRD(5) in the SQLCA shows the number of rows affected by referential constraints and by triggered statements. It includes rows that were deleted as a result of a CASCADE delete rule and rows in which foreign keys were set to the null value as the result of a SET NULL delete rule. With regards to triggered statements, it includes the number of rows that were inserted, updated, or deleted.
- If an error occurs that prevents deleting all rows matching the search condition and all operations required by existing referential constraints, no changes are made to the table and the error is returned.
- For nicknames, the external server option `iud_app_svpt_enforce` poses an additional limitation. Refer to the Federated documentation for more information.
- For some data sources, the SQLCODE -20190 may be returned on a delete against a nickname because of potential data inconsistency. Refer to the Federated documentation for more information.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - The FROM keyword can be omitted.
- **Considerations for a system-period temporal table:** The target of the DELETE statement must not be a fullselect that references a view in the FROM clause followed by a period specification for SYSTEM_TIME if the view is defined with the WITH CHECK OPTION and the view definition includes a WHERE clause containing one of the following syntax elements (SQLSTATE 51046):
  - A subquery that references a system-period temporal table (directly or indirectly)
  - An invocation of an SQL routine that has a package associated with it
  - An invocation of an external routine with a data access indication other than NO SQL

  If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value, an underlying target of the UPDATE statement must not be a system-period temporal table (SQLSTATE 51046), and the target of the DELETE statement must not be a view defined with the WITH CHECK OPTION if the view definition includes a WHERE clause containing one of the following syntax elements (SQLSTATE 51046):
  - A subquery that references a system-period temporal table (directly or indirectly)
  - An invocation of an SQL routine that has a package associated with it

– An invocation of an external routine with a data access indication other than NO SQL

If the DELETE statement has a search condition containing a correlated subquery that references historical rows (explicitly referencing the name of the history table name or implicitly through the use of a period specification in the FROM clause), the deleted rows that are stored as historical rows are potentially visible for delete operations for the rows subsequently processed for the statement.

The mass delete algorithm is not used for a DELETE statement for a table defined as a system-period temporal table that does not contain a search condition.

- **Considerations for a history table:** When a row of a system-period temporal table is deleted, a historical copy of the row is inserted into the corresponding history table and the end timestamp of the historical row is captured in the form of a system determined value that corresponds to the time of the data change operation. The database manager assigns the value that is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. The database manager ensures uniqueness of the generated values for an end column in a history table across transactions. The timestamp value might be adjusted to ensure that rows inserted into the history table have the end timestamp value greater than the begin timestamp value which can happen when a conflicting transaction is updating the same row in the system-period temporal table (SQLSTATE 01695). The database configuration parameter **systime_period_adj** must be set to Yes for this adjustment in the timestamp value to occur otherwise and error is returned (SQLSTATE 57062).

  For a delete operation, the adjustment only affects the value for the end column in the history table that corresponds to the row-end column in the associated system-period temporal table. Take these adjustments into consideration on subsequent references to the table when there is a search for the transaction start time in the row-begin column and row-end column for the SYSTEM_TIME period of the associated system-period temporal table.
- **Considerations for an application-period temporal table:** The target of the DELETE statement must not be a fullselect that references a view in the FROM clause followed by a period specification for BUSINESS_TIME if the view is defined with the WITH CHECK OPTION and the view definition includes a WHERE clause containing one of the following syntax elements (SQLSTATE 51046):

  – A subquery that references an application-period temporal table (directly or indirectly)

  – An invocation of an SQL routine that has a package associated with it

  – An invocation of an external routine with a data access indication other than NO SQL

  If the CURRENT TEMPORAL BUSINESS_TIME special register is set to a non-null value, the target of the DELETE statement must not be a view defined with the WITH CHECK option if the view definition includes a WHERE clause containing one of the following syntax elements (SQLSTATE 51046):

  – A subquery that references an application-period temporal table (directly or indirectly)

  – An invocation of an SQL routine that has a package associated with it

  – An invocation of an external routine with a data access indication other than NO SQL

  A DELETE statement for an application-period temporal table that contains a FOR PORTION OF BUSINESS_TIME clause indicates between which two points in time that the deletes are effective. When FOR PORTION OF BUSINESS_TIME is specified and the period value for a row, specified by the values of the row-begin column and row-end column, is only partially contained in the period specified from *value1* up to *value2*, the row is deleted and one or two rows are automatically inserted to represent the portion of the row that is not deleted. New values are generated for each generated column in an application-period temporal table for each row that is automatically inserted as a result of a delete operation on the table. If a generated column is defined as part of a unique or primary key, parent key in a referential constraint, or unique index, it is possible that an automatic insert will violate a constraint or index in which case an error is returned.

  When an application-period temporal table is the target of an DELETE statement, the value in effect for the CURRENT TEMPORAL BUSINESS_TIME special register is not the null value, and the BUSTIMESENSITIVE bind option is set to YES, the following additional predicates are implicit:

```
    bt_begin <= CURRENT TEMPORAL BUSINESS_TIME
AND bt_end > CURRENT TEMPORAL BUSINESS_TIME
```

where bt_begin and bt_end are the begin and end columns of the BUSINESS_TIME period of the target table of the DELETE statement.

- **Considerations for application-period temporal tables and triggers:** When a row is deleted and the FOR PORTION OF BUSINESS_TIME clause is specified, additional rows may be implicitly inserted to reflect any portion of the row that was not deleted. Any existing delete triggers are activated for the rows deleted, and any existing insert triggers are activated for rows that are implicitly inserted.

Examples

- *Example 1:* Delete department (DEPTNO) 'D11' from the DEPARTMENT table.

```
DELETE FROM DEPARTMENT
  WHERE DEPTNO = 'D11'
```

- *Example 2:* Delete all the departments from the DEPARTMENT table (that is, empty the table).

```
DELETE FROM DEPARTMENT
```

- *Example 3:* Delete from the EMPLOYEE table any sales rep or field rep who didn't make a sale in 1995.

```
DELETE FROM EMPLOYEE
  WHERE LASTNAME NOT IN
    (SELECT SALES_PERSON
      FROM SALES
      WHERE YEAR(SALES_DATE)=1995)
      AND JOB IN ('SALESREP','FIELDREP')
```

-
- *Example 4:* Delete all the duplicate employee rows from the EMPLOYEE table. An employee row is considered to be a duplicate if the last names match. Keep the employee row with the smallest first name in lexical order.

```
DELETE FROM
  (SELECT ROWNUMBER() OVER (PARTITION BY LASTNAME ORDER BY FIRSTNME)
    FROM EMPLOYEE) AS E(RN)
    WHERE RN > 1
```

DESCRIBE

The DESCRIBE statement obtains information about an object.

There are two types of information that can be obtained with this statement. Each of these is described separately.

- Input parameter markers of a prepared statement. Gets information about the input parameter markers in a prepared statement. This information is put into a descriptor.
- The output of a prepared statement. Gets information about a prepared statement or information about the select list columns in a prepared SELECT statement. This information is put into a descriptor.

DESCRIBE INPUT

The DESCRIBE INPUT statement obtains information about the input parameter markers of a prepared statement.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax

Description

statement-name
Identifies the prepared statement. When the DESCRIBE INPUT statement is executed, the name must identify a statement that has been prepared by the application process at the current server.

For a CALL statement, the information returned describes the input parameters, defined as IN or INOUT, of the procedure. Input parameter markers are always considered nullable, regardless of usage.

INTO *descriptor-name*
Identifies an SQL descriptor area (SQLDA). Before the DESCRIBE INPUT statement is executed, the following variable in the SQLDA must be set:

SQLN
Specifies the number of SQLVAR occurrences provided in the SQLDA. SQLN must be set to a value greater than or equal to zero before the DESCRIBE INPUT statement is executed.

When the DESCRIBE INPUT statement is executed, the database manager assigns values to the variables of the SQLDA as follows:

SQLDAID
The first 6 bytes are set to 'SQLDA ' (that is, 5 letters followed by the space character).

The seventh byte, defined as SQLDOUBLED, is set based on the parameter markers described:

- If the SQLDA contains two SQLVAR entries for every input parameter, the seventh byte is set to '2'. This technique is used to accommodate LOB or structured type input parameters.
- Otherwise, the seventh byte is set to the space character.

The seventh byte is set to the space character if there is not enough room in the SQLDA to contain the description of all input parameter markers.

The eighth byte is set to the space character.

SQLDABC
Length of the SQLDA in bytes.

SQLD
The number of IN and INOUT parameters of the procedure.

SQLVAR
If the value of SQLD is 0, or greater than the value of SQLN, no values are assigned to occurrences of SQLVAR.

If the value of SQLD is *n*, where *n* is greater than 0 but less than or equal to the value of SQLN, values are assigned to the first *n* occurrences of SQLVAR. The values describe parameter markers for the input parameters of the procedure. The first occurrence of SQLVAR describes the first input parameter marker, the second occurrence of SQLVAR describes the second input parameter marker, and so on.

Base SQLVAR

SQLTYPE
A code showing the data type of the parameter and whether or not it can contain null values.

SQLLEN
A length value depending on the data type of the parameter. SQLLEN is 0 for LOB data types.

SQLNAME
The sqlname is derived as follows:

- If the SQLVAR corresponds to a parameter marker that is in the parameter list of a procedure and is not part of an expression, sqlname contains the name of the parameter if one was specified on the CREATE PROCEDURE statement.
- If the SQLVAR corresponds to a named parameter marker, sqlname contains the name of the parameter marker.
- Otherwise, sqlname contains an ASCII numeric literal value that represents the SQLVAR's position within the SQLDA.

Secondary SQLVAR
These variables are only used if the number of SQLVAR entries are doubled to accommodate LOB, distinct type, structured type, or reference type parameters.

SQLLONGLEN
The length attribute of a BLOB, CLOB, or DBCLOB parameter.

SQLDATATYPE_NAME
For any user-defined type (distinct or structured) parameter, the database manager sets this to the fully qualified user-defined type name. For a reference type parameter, the database manager sets this to the fully qualified user-defined type name of the target type of the reference. Otherwise, schema name is SYSIBM and the type name is the name in the TYPENAME column of the SYSCAT.DATATYPES catalog view.

Notes

- **Preparing the SQLDA:** Before the DESCRIBE INPUT statement is executed, the SQLDA must be allocated and the value of SQLN must be set to a value greater than or equal to zero to indicate how many occurrences of SQLVAR are provided in the SQLDA. Enough storage must be allocated to contain SQLN occurrences. To obtain the description of the input parameter markers in the prepared statement, the number of occurrences of SQLVAR must not be less than the number of input parameter markers. Furthermore, if the input parameter markers include LOBs or structured types, the number of occurrences of SQLVAR should be two times the number of input parameter markers.
- Code page conversions between extended UNIX code (EUC) code pages and DBCS code pages, or between Unicode and non-Unicode code pages, can result in expansion or contraction of character lengths.
- If a structured type is being selected, but no FROM SQL transform is defined (either because no TRANSFORM GROUP was specified using the CURRENT DEFAULT TRANSFORM GROUP special register (SQLSTATE 428EM), or because the named group does not have a FROM SQL transform function defined (SQLSTATE 42744), an error is returned.
- **Allocating the SQLDA:** Three of the possible ways to allocate the SQLDA are as follows:

  First Technique: Allocate an SQLDA with enough occurrences of SQLVAR to accommodate any select list that the application will have to process. If the table contains any LOB, distinct type, structured type, or reference type columns, the number of SQLVARs should be double the maximum number of columns; otherwise the number should be the same as the maximum number of columns. Having done the allocation, the application can use this SQLDA repeatedly.

  This technique uses a large amount of storage that is never deallocated, even when most of this storage is not used for a particular select list.

  Second Technique: Repeat the following two steps for every processed select list:

  1. Execute a DESCRIBE INPUT statement with an SQLDA that has no occurrences of SQLVAR; that is, an SQLDA for which SQLN is zero. The value returned for SQLD is the number of columns in the result table. This is either the required number of occurrences of SQLVAR or half the required number. Because there were no SQLVAR entries, a warning with SQLSTATE 01005 will be issued. If the SQLCODE accompanying that warning is equal to one of +237, +238 or +239, the number of SQLVAR entries should be double the value returned in SQLD. (The return of these positive

SQLCODEs assumes that the SQLWARN bind option setting was YES (return positive SQLCODEs). If SQLWARN was set to NO, +238 is still returned to indicate that the number of SQLVAR entries must be double the value returned in SQLD.)

2. Allocate an SQLDA with enough occurrences of SQLVAR. Then execute the DESCRIBE statement again, using this new SQLDA.

This technique allows better storage management than the first technique, but it doubles the number of DESCRIBE INPUT statements.

Third Technique: Allocate an SQLDA that is large enough to handle most, and perhaps all, select lists but is also reasonably small. Execute DESCRIBE INPUT and check the SQLD value. Use the SQLD value for the number of occurrences of SQLVAR to allocate a larger SQLDA, if necessary.

This technique is a compromise between the first two techniques. Its effectiveness depends on a good choice of size for the original SQLDA.

Example

Execute a DESCRIBE INPUT statement with an SQLDA that has enough SQLVAR occurrences to describe any number of input parameters a prepared statement might have. Assume that five parameter markers at most will need to be described and that the input data does not contain LOBs.

```
    /* STMT1_STR contains INSERT statement with VALUES clause */
EXEC SQL PREPARE STMT1_NAME FROM :STMT1_STR;
... /* code to set SQLN to 5 and to allocate the SQLDA        */
EXEC SQL DESCRIBE INPUT STMT1_NAME INTO :SQLDA;
.
.
.
```

This example uses the first technique described under "Allocating the SQLDA" in "DESCRIBE OUTPUT".

DESCRIBE OUTPUT

The DESCRIBE OUTPUT statement obtains information about a prepared statement.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax

Description

statement-name

Identifies the prepared statement. When the DESCRIBE OUTPUT statement is executed, the name must identify a statement that has been prepared by the application process at the current server.

If the prepared statement is a SELECT or VALUES INTO statement, the information returned describes the columns in its result table. If the prepared statement is a CALL statement, the information returned describes the output parameters, defined as OUT or INOUT, of the procedure.

INTO *descriptor-name*

Identifies an SQL descriptor area (SQLDA). Before the DESCRIBE OUTPUT statement is executed, the following variable in the SQLDA must be set:

SQLN

Specifies the number of SQLVAR occurrences provided in the SQLDA. SQLN must be set to a value greater than or equal to zero before the DESCRIBE OUTPUT statement is executed.

When the DESCRIBE OUTPUT statement is executed, the database manager assigns values to the variables of the SQLDA as follows:

SQLDAID

The first 6 bytes are set to 'SQLDA ' (that is, 5 letters followed by the space character).

The seventh byte, defined as SQLDOUBLED, is set based on the results columns or parameter markers described:

- If the SQLDA contains two SQLVAR entries for every column or output parameter, the seventh byte is set to '2'. This technique is used to accommodate LOB, distinct type, structured type, or reference type columns, or output parameters.
- Otherwise, the seventh byte is set to the space character.

The seventh byte is set to the space character if there is not enough room in the SQLDA to contain the description of all result columns or output parameter markers.

The eighth byte is set to the space character.

SQLDABC

Length of the SQLDA in bytes.

SQLD

If the prepared statement is a SELECT, SQLD is set to the number of columns in its result table. If the prepared statement is a CALL statement, SQLD is set to the number of OUT and INOUT parameters of the procedure. Otherwise, SQLD is set to 0.

SQLVAR

If the value of SQLD is 0, or greater than the value of SQLN, no values are assigned to occurrences of SQLVAR.

If the value of SQLD is *n*, where *n* is greater than 0 but less than or equal to the value of SQLN, values are assigned to SQLTYPE, SQLLEN, SQLNAME, SQLLONGLEN, and SQLDATATYPE_NAME for the first *n* occurrences of SQLVAR. These values describe either columns of the result table or parameter markers for the output parameters of the procedure. The first occurrence of SQLVAR describes the first column or output parameter marker, the second occurrence of SQLVAR describes the second column or output parameter marker, and so on.

Base SQLVAR

SQLTYPE

A code showing the data type of the column or parameter and whether or not it can contain null values.

SQLLEN

A length value depending on the data type of the column or parameter. SQLLEN is 0 for LOB data types.

SQLNAME

The sqlname is derived as follows:

- If the SQLVAR corresponds to a derived column for a simple column reference in the select list of a select-statement, sqlname is the name of the column.
- If the SQLVAR corresponds to a parameter marker that is in the parameter list of a procedure and is not part of an expression, sqlname contains the name of the parameter if one was specified on CREATE PROCEDURE.

- Otherwise sqlname contains an ASCII numeric literal value that represents the SQLVAR's position within the SQLDA.

Secondary SQLVAR
These variables are only used if the number of SQLVAR entries is doubled to accommodate LOB, distinct type, structured type, or reference type columns or parameters.

SQLLONGLEN
The length attribute of a BLOB, CLOB, or DBCLOB column or parameter.

SQLDATATYPE_NAME
For any user-defined type (distinct or structured) column or parameter, the database manager sets this to the fully qualified user-defined type name. For a reference type column or parameter, the database manager sets this to the fully qualified user-defined type name of the target type of the reference. Otherwise, schema name is SYSIBM and the type name is the name in the TYPENAME column of the SYSCAT.DATATYPES catalog view.

Notes

- Before the DESCRIBE OUTPUT statement is executed, the value of SQLN must be set to indicate how many occurrences of SQLVAR are provided in the SQLDA and enough storage must be allocated to contain SQLN occurrences. For example, to obtain the description of the columns of the result table of a prepared SELECT statement, the number of occurrences of SQLVAR must not be less than the number of columns.
- If a LOB of a large size is expected, then remember that manipulating this large object will affect application memory. Given this condition, consider using locators or file reference variables. Modify the SQLDA after the DESCRIBE OUTPUT statement is executed but before allocating storage so that an SQLTYPE of SQL_TYP_xLOB is changed to SQL_TYP_xLOB_LOCATOR or SQL_TYP_xLOB_FILE with corresponding changes to other fields such as SQLLEN. Then allocate storage based on SQLTYPE and continue.
- Code page conversions between extended UNIX code (EUC) code pages and DBCS code pages, or between Unicode and non-Unicode code pages, can result in the expansion and contraction of character lengths.
- If a structured type is being selected, but no FROM SQL transform is defined (either because no TRANSFORM GROUP was specified using the CURRENT DEFAULT TRANSFORM GROUP special register (SQLSTATE 428EM), or because the named group does not have a FROM SQL transform function defined (SQLSTATE 42744), an error is returned.
- **Allocating the SQLDA:** Three of the possible ways to allocate the SQLDA are as follows:

  First Technique: Allocate an SQLDA with enough occurrences of SQLVAR to accommodate any select list that the application will have to process. If the table contains any LOB, distinct type, structured type, or reference type columns, the number of SQLVARs should be double the maximum number of columns; otherwise the number should be the same as the maximum number of columns. Having done the allocation, the application can use this SQLDA repeatedly.

  This technique uses a large amount of storage that is never deallocated, even when most of this storage is not used for a particular select list.

  Second Technique: Repeat the following two steps for every processed select list:

  1. Execute a DESCRIBE OUTPUT statement with an SQLDA that has no occurrences of SQLVAR; that is, an SQLDA for which SQLN is zero. The value returned for SQLD is the number of columns in the result table. This is either the required number of occurrences of SQLVAR or half the required number. Because there were no SQLVAR entries, a warning with SQLSTATE 01005 will be issued. If the SQLCODE accompanying that warning is equal to one of +237, +238 or +239, the number of SQLVAR entries should be double the value returned in SQLD. (The return of these positive SQLCODEs assumes that the SQLWARN bind option setting was YES (return positive SQLCODEs). If SQLWARN was set to NO, +238 is still returned to indicate that the number of SQLVAR entries must be double the value returned in SQLD.)

2. Allocate an SQLDA with enough occurrences of SQLVAR. Then execute the DESCRIBE OUTPUT statement again, using this new SQLDA.

This technique allows better storage management than the first technique, but it doubles the number of DESCRIBE OUTPUT statements.

Third Technique: Allocate an SQLDA that is large enough to handle most, and perhaps all, select lists but is also reasonably small. Execute DESCRIBE and check the SQLD value. Use the SQLD value for the number of occurrences of SQLVAR to allocate a larger SQLDA, if necessary.

This technique is a compromise between the first two techniques. Its effectiveness depends on a good choice of size for the original SQLDA.

- ***Considerations for implicitly hidden columns:*** A DESCRIBE OUTPUT statement returns only information about an implicitly hidden column if the column is explicitly specified as part of the SELECT list of the final result table of the query being described. If implicitly hidden columns are not part of the result table of a query, a DESCRIBE OUTPUT statement that returns information about that query will not contain information about any implicitly hidden columns.

Example

In a C program, execute a DESCRIBE OUTPUT statement with an SQLDA that has no occurrences of SQLVAR. If SQLD is greater than zero, use the value to allocate an SQLDA with the necessary number of occurrences of SQLVAR and then execute a DESCRIBE statement using that SQLDA.

```
EXEC SQL  BEGIN DECLARE SECTION;
  char  stmt1_str[200];
EXEC SQL  END DECLARE SECTION;
EXEC SQL  INCLUDE SQLDA;
EXEC SQL  DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;

... /* code to prompt user for a query, then to generate */
    /* a select-statement in the stmt1_str            */
EXEC SQL  PREPARE STMT1_NAME FROM :stmt1_str;

... /* code to set SQLN to zero and to allocate the SQLDA */
EXEC SQL  DESCRIBE STMT1_NAME INTO :sqlda;

... /* code to check that SQLD is greater than zero, to set */
    /* SQLN to SQLD, then to re-allocate the SQLDA          */
EXEC SQL  DESCRIBE STMT1_NAME INTO :sqlda;

... /* code to prepare for the use of the SQLDA             */
    /* and allocate buffers to receive the data             */
EXEC SQL  OPEN DYN_CURSOR;

... /* loop to fetch rows from result table                 */
EXEC SQL  FETCH DYN_CURSOR USING DESCRIPTOR :sqlda;
.
.
.
```

DISCONNECT

The DISCONNECT statement destroys one or more connections when there is no active unit of work (that is, after a commit or rollback operation).

If a single connection is the target of the DISCONNECT statement, the connection is destroyed only if the database has participated in an existing unit of work, regardless of whether there is an active unit of work. For example, if several other databases have done work, but the target in question has not, it can still be disconnected without destroying the connection.

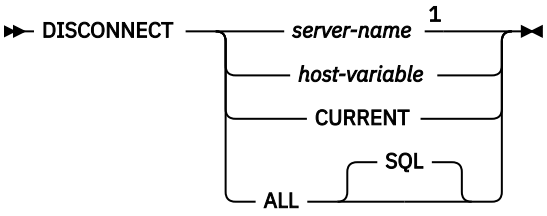
Invocation

Although an interactive SQL facility might provide an interface that gives the appearance of interactive execution, this statement can only be embedded within an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax



Notes:

[1] Note that an application server named CURRENT or ALL can only be identified by a host variable.

Description

server-name* or *host-variable

Identifies the application server by the specified *server-name* or a *host-variable* which contains the *server-name*.

If a *host-variable* is specified, it must be a character string variable with a length attribute that is not greater than 8, and it must not include an indicator variable. The *server-name* that is contained within the *host-variable* must be left-aligned and must not be delimited by quotation marks.

Note that the *server-name* is a database alias identifying the application server. It must be listed in the application requester's local directory.

The specified database-alias or the database-alias contained in the host variable must identify an existing connection of the application process. If the database-alias does not identify an existing connection, an error (SQLSTATE 08003) is raised.

CURRENT

Identifies the current connection of the application process. The application process must be in the connected state. If not, an error (SQLSTATE 08003) is raised.

ALL

Indicates that all existing connections of the application process are to be destroyed. An error or warning does not occur if no connections exist when the statement is executed. The optional keyword SQL is included to be consistent with the syntax of the RELEASE statement.

Rules

- Generally, the DISCONNECT statement cannot be executed while within a unit of work. If attempted, an error (SQLSTATE 25000) is raised. The exception to this rule is if a single connection is specified to be disconnected and the database has not participated in an existing unit of work. In this case, it does not matter if there is an active unit of work when the DISCONNECT statement is issued.
- The DISCONNECT statement cannot be executed at all in the Transaction Processing (TP) Monitor environment (SQLSTATE 25000). It is used when the SYNCPOINT precompiler option is set to TWOPHASE.

Notes

- If the DISCONNECT statement is successful, each identified connection is destroyed.

  If the DISCONNECT statement is unsuccessful, the connection state of the application process and the states of its connections are unchanged.
- If DISCONNECT is used to destroy the current connection, the next executed SQL statement should be CONNECT or SET CONNECTION.

- Type 1 CONNECT semantics do not preclude the use of DISCONNECT. However, though DISCONNECT CURRENT and DISCONNECT ALL can be used, they will not result in a commit operation like a CONNECT RESET statement would do.

  If *server-name* or *host-variable* is specified in the DISCONNECT statement, it must identify the current connection because Type 1 CONNECT only supports one connection at a time. Generally, DISCONNECT will fail if within a unit of work with the exception noted in "Rules".
- Resources are required to create and maintain remote connections. Thus, a remote connection that is not going to be reused should be destroyed as soon as possible.
- Connections can also be destroyed during a commit operation because the connection option is in effect. The connection option could be AUTOMATIC, CONDITIONAL, or EXPLICIT, which can be set as a precompiler option or through the SET CLIENT API at run time. For information about the specification of the DISCONNECT option, see "Distributed relational databases".

Examples

- *Example 1:* The SQL connection to IBMSTHDB is no longer needed by the application. The following statement should be executed after a commit or rollback operation to destroy the connection.

```
EXEC SQL DISCONNECT IBMSTHDB;
```

- *Example 2:* The current connection is no longer needed by the application. The following statement should be executed after a commit or rollback operation to destroy the connection.

```
EXEC SQL DISCONNECT CURRENT;
```

- *Example 3:* The existing connections are no longer needed by the application. The following statement should be executed after a commit or rollback operation to destroy all the connections.

```
EXEC SQL DISCONNECT ALL;
```

DROP

The DROP statement deletes an object. Any objects that are directly or indirectly dependent on that object are either deleted or made inoperative. Whenever an object is deleted, its description is deleted from the catalog, and any packages that reference the object are invalidated.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

When dropping objects that allow two-part names, the privileges held by the authorization ID of the statement must include at least one of the following authorities:

- DROPIN privilege on the schema for the object
- Owner of the object, as recorded in the OWNER column of the catalog view for the object
- CONTROL privilege on the object (applicable only to indexes, index specifications, nicknames, packages, tables, and views)
- Owner of the user-defined type, as recorded in the OWNER column of the SYSCAT.DATATYPES catalog view (applicable only when dropping a method that is associated with a user-defined type)
- SCHEMAADM authority on the schema for the object
- DBADM authority

When dropping a table or view hierarchy, the privileges held by the authorization ID of the statement must include one of the previously mentioned privileges for each of the tables or views in the hierarchy.

When dropping an audit policy, the privileges held by the authorization ID of the statement must include SECADM authority.

When dropping a buffer pool, database partition group, storage group, or table space, the privileges held by the authorization ID of the statement must include SYSADM or SYSCTRL authority.

When dropping a data type mapping, function mapping, server definition, or wrapper, the privileges held by the authorization ID of the statement must include DBADM authority.

When dropping an event monitor the privilege held by the authorization ID of the statement must include SQLADM or DBADM authority.

When dropping a role, the privileges held by the authorization ID of the statement must include SECADM authority.

When dropping a row permission or a column mask, the privileges held by the authorization ID of the statement must include SECADM authority.

When dropping a schema, the privileges held by the authorization ID of the statement must include DBADM authority, or be the schema owner, as recorded in the OWNER column of the SYSCAT.SCHEMATA catalog view.

When dropping a security label, a security label component, or a security policy, the privileges held by the authorization ID of the statement must include SECADM authority.

When dropping a service class, work action set, work class set, workload, threshold, or histogram template, the privileges held by the authorization ID of the statement must include WLMADM or DBADM authority.

When dropping a system-period temporal table, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

- Privileges to drop the associated history table
- Administrative authority

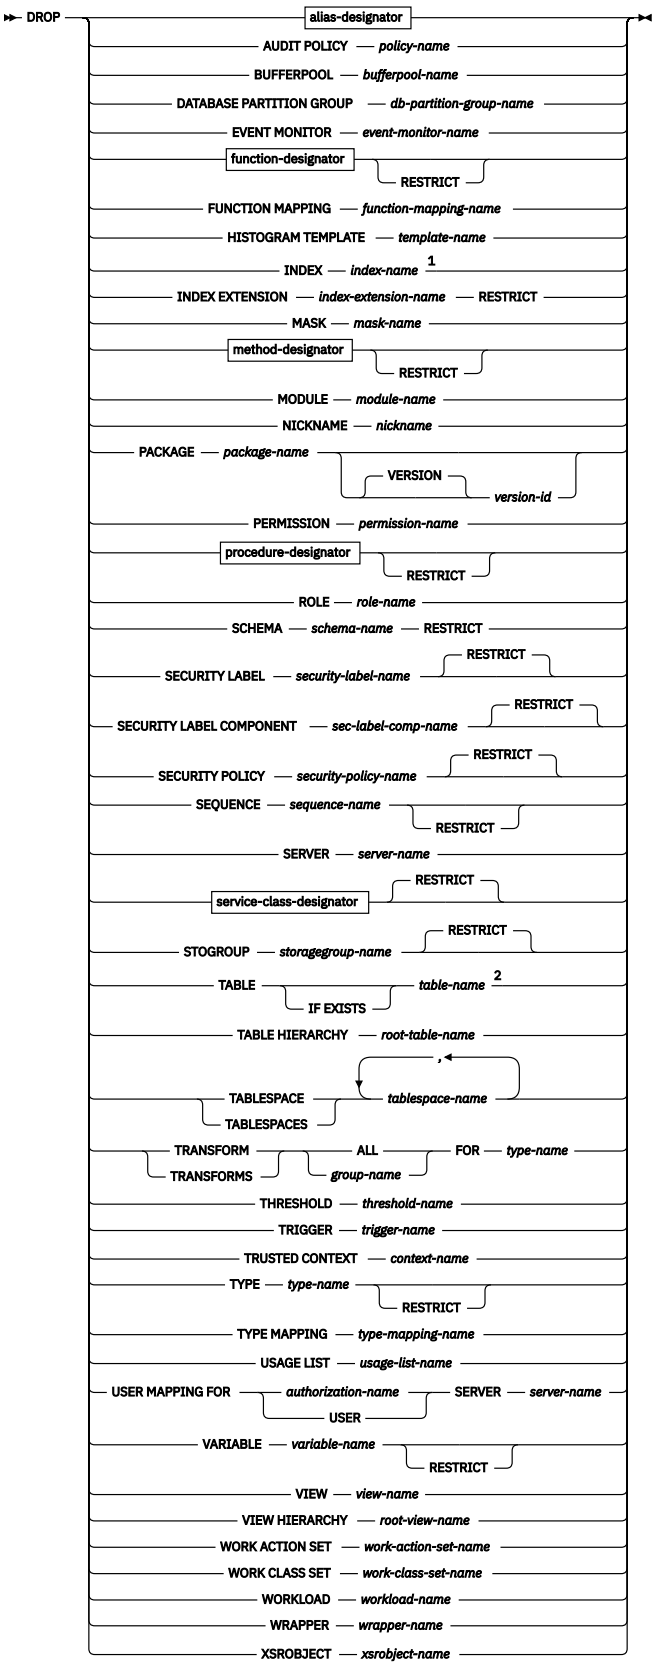
When dropping a transform, the privileges held by the authorization ID of the statement must include DBADM authority, or must be the owner of *type-name*.

When dropping a trusted context, the privileges held by the authorization ID of the statement must include SECADM authority.

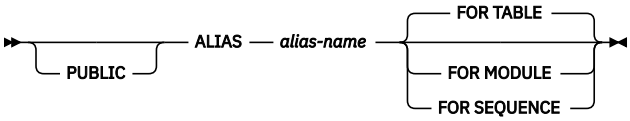
When dropping an event monitor or usage list the privilege held by the authorization ID of the statement must include SQLADM or DBADM authority.

When dropping a user mapping, the privileges held by the authorization ID of the statement must include DBADM authority, if this authorization ID is different from the federated database authorization name within the mapping. Otherwise, if the authorization ID and the authorization name match, no authorities or privileges are required.

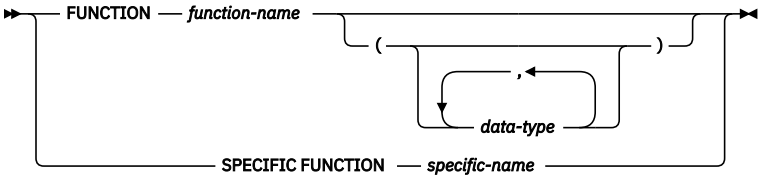
Syntax



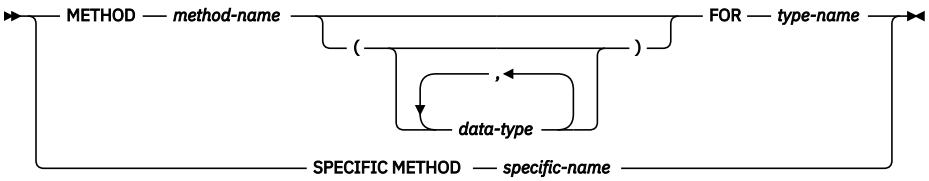
alias-designator



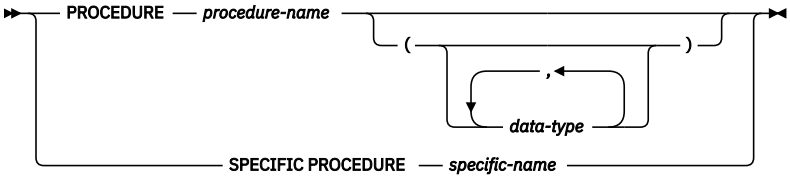
function-designator



method-designator



procedure-designator



service-class-designator

Notes:

[1] *Index-name* can be the name of either an index or an index specification.

[2] For compatibility with Netezza, you can change the order of IF EXISTS and *table-name*.

Description

alias-designator

ALIAS *alias-name*

Identifies the alias that is to be dropped. The *alias-name* must identify an alias that is described in the catalog (SQLSTATE 42704). The specified alias is deleted.

FOR TABLE, FOR MODULE, or FOR SEQUENCE

Specifies the object type for the alias.

FOR TABLE

The alias is for a table, view, or nickname.

FOR MODULE

The alias is for a module.

FOR SEQUENCE

The alias is for a sequence.

All views and triggers that reference the alias are made inoperative. This includes alias references in both the ON clause of the CREATE TRIGGER statement and within the triggered SQL statements. Any materialized query table or staging table that references the alias is dropped.

If PUBLIC is specified, the *alias-name* must identify a public alias (SQLSTATE 428EK) that exists at the current server (SQLSTATE 42704).

If the alias is referenced in the definition of a row permission or a column mask, the alias cannot be dropped (SQLSTATE 42893).

AUDIT POLICY *policy-name*
Identifies the audit policy that is to be dropped. The *policy-name* must identify an audit policy that exists at the current server (SQLSTATE 42704). The audit policy must not be associated with any database objects (SQLSTATE 42893). The specified audit policy is deleted from the catalog.

BUFFERPOOL *bufferpool-name*
Identifies the buffer pool that is to be dropped. The *bufferpool-name* must identify a buffer pool that is described in the catalog (SQLSTATE 42704). There can be no table spaces assigned to the buffer pool (SQLSTATE 42893). The IBMDEFAULTBP buffer pool cannot be dropped (SQLSTATE 42832).

Buffer pool memory is released immediately. Disk storage may not be released until the next connection to the database.

DATABASE PARTITION GROUP *db-partition-group-name*
Identifies the database partition group that is to be dropped. The *db-partition-group-name* parameter must identify a database partition group that is described in the catalog (SQLSTATE 42704). This is a one-part name.

Dropping a database partition group drops all table spaces defined in the database partition group. All existing database objects with dependencies on the tables in the table spaces (such as packages, referential constraints, and so on) are dropped or invalidated (as appropriate), and dependent views and triggers are made inoperative.

IBMCATGROUP, IBMDEFAULTGROUP, and IBMTEMPGROUP database partition groups cannot be dropped (SQLSTATE 42832).

If a DROP DATABASE PARTITION GROUP statement is issued against a database partition group that is currently undergoing a data redistribution, the drop database partition group operation fails, and an error is returned (SQLSTATE 55038). However, a partially redistributed database partition group can be dropped. A database partition group can become partially redistributed if a REDISTRIBUTE DATABASE PARTITION GROUP command does not execute to completion. This can happen if it is interrupted by either an error or a FORCE APPLICATION ALL command. (For a partially redistributed database partition group, the REDISTRIBUTE_PMAP_ID in the SYSCAT.DBPARTITIONGROUPS catalog is not -1.)

EVENT MONITOR *event-monitor-name*
Identifies the event monitor that is to be dropped. The *event-monitor-name* must identify an event monitor that is described in the catalog (SQLSTATE 42704).

If the identified event monitor is active, an error is returned (SQLSTATE 55034); otherwise, the event monitor is deleted. Note that if an event monitor has been previously activated using the SET EVENT MONITOR STATE statement, and the database has been deactivated and subsequently reactivated, use the SET EVENT MONITOR STATE statement to deactivate the event monitor before issuing the DROP statement.

If there are event files in the target path of a WRITE TO FILE event monitor that is being dropped, the event files are not deleted. However, if a new event monitor that specifies the same target path is created, the event files are deleted.

When dropping WRITE TO TABLE event monitors, table information is removed from the SYSCAT.EVENTTABLES catalog view, but the tables themselves are not dropped.

function-designator
Identifies an instance of a user-defined function (either a complete function or a function template) that is to be dropped. For more information, see "Function, method, and procedure designators" on page 745.

The function instance specified must be a user-defined function described in the catalog. The following functions cannot be dropped:

- A function implicitly generated by a CREATE TYPE statement (SQLSTATE 42917)

- A function that is in the SYSIBM, SYSFUN, SYSIBMADM, or the SYSPROC schema (SQLSTATE 42832)
- A function that is referenced in the definition of a row permission or a column mask (SQLSTATE 42893)
- A function that is referenced in a generated column expression or a check constraint (SQLSTATE 42893)

RESTRICT
The RESTRICT keyword enforces the rule that the function is not to be dropped if any of the following dependencies exists:

- Another function is sourced on the function.
- Another routine uses the function.
- A view uses the function.
- A trigger uses the function.
- A materialized query table uses the function in its definition.

The restrict rule is enforced by default for the same dependencies as in version 9.5 if the **auto_reval** database configuration parameter is set to disabled.

In this case, the following considerations apply:

- Other objects can be dependent upon a function. All such dependencies must be removed before the function can be dropped, with the exception of packages which are marked inoperative. An attempt to drop a function with such dependencies will result in an error (SQLSTATE 42893). See the "Rules" section for a list of these dependencies. If the function can be dropped, it is dropped.
- Any package dependent on the specific function being dropped is marked as inoperative. Such a package is not implicitly rebound. It must either be rebound by use of the BIND or REBIND command, or it must be re-prepared by use of the PREP command.

FUNCTION MAPPING *function-mapping-name*
Identifies the function mapping that is to be dropped. The *function-mapping-name* must identify a user-defined function mapping that is described in the catalog (SQLSTATE 42704). The function mapping is deleted from the database.

Default function mappings cannot be dropped, but can be disabled by using the CREATE FUNCTION MAPPING statement. Dropping a user-defined function mapping that was created to override a default function mapping reinstates the default function mapping.

Packages having a dependency on a dropped function mapping are invalidated.

HISTOGRAM TEMPLATE *template-name*
Identifies the histogram template that is to be dropped. The *template-name* must identify a histogram template that exists at the current server (SQLSTATE 42704). The *template-name* cannot be SYSDEFAULTHISTOGRAM (SQLSTATE 42832). The histogram template cannot be dropped if a service class or a work action is dependent on it (SQLSTATE 42893). The specified histogram template is deleted from the catalog.

INDEX *index-name*
Identifies the index or index specification that is to be dropped. The *index-name* must identify an index or index specification that is described in the catalog (SQLSTATE 42704). It cannot be an index that is required by the system for a primary key or unique constraint, for a replicated materialized query table, or for an XML column (SQLSTATE 42917). The specified index or index specification is deleted.

Modification state indexes (also known as mod state indexes) can be dropped, even though they are classified as system indexes. Dropping modification state indexes is supported in order to facilitate rollback to an earlier fix pack level. If a modification state index exists when dropping the last user index on a table, the modification state index is implicitly dropped.

Packages having a dependency on a dropped index or index specification are invalidated.

INDEX EXTENSION *index-extension-name* RESTRICT
Identifies the index extension that is to be dropped. The *index-extension-name* must identify an index extension that is described in the catalog (SQLSTATE 42704). The RESTRICT keyword enforces the rule that no index can be defined that depends on this index extension definition (SQLSTATE 42893).

MASK *mask-name*
Identifies the column mask to drop. The name must identify a column mask that exists at the current server (SQLSTATE 42704).

method-designator
Identifies a method body that is to be dropped. For more information, see "Function, method, and procedure designators" on page 745. The method body specified must be a method described in the catalog (SQLSTATE 42704). Method bodies that are implicitly generated by the CREATE TYPE statement cannot be dropped.

DROP METHOD deletes the body of a method, but the method specification (signature) remains as a part of the definition of the subject type. After dropping the body of a method, the method specification can be removed from the subject type definition by ALTER TYPE DROP METHOD.

RESTRICT
The RESTRICT keyword enforces the rule that the method is not to be dropped if any of the following dependencies exists:

- A function is sourced on the method.
- Another routine uses the method.
- A view uses the method.
- A trigger uses the method.
- A materialized query table uses the method in its definition.

The restrict rule is enforced by default for the same dependencies as in version 9.5 if the **auto_reval** database configuration parameter is set to disabled.

In this case, the following considerations apply:

- Other objects can be dependent upon a method. All such dependencies must be removed before the method can be dropped, with the exception of packages which will be marked inoperative if the drop is successful. An attempt to drop a method with such dependencies will result in an error (SQLSTATE 42893). If the method can be dropped, it will be dropped.
- Any package dependent on the specific method being dropped is marked as inoperative. Such a package is not implicitly re-bound. Either it must be re-bound by use of the BIND or REBIND command, or it must be re-prepared by use of the PREP command.

If the specific method being dropped overrides another method, all packages dependent on the overridden method - and on methods that override this method in supertypes of the specific method being dropped - are invalidated.

MODULE *module-name*
Identifies the module that is to be dropped. The *module-name* must identify a module that exists at the current server (SQLSTATE 42704). The specified name must not be an alias for a module (SQLSTATE 560CT). The specified module is dropped from the schema, including all module objects. All privileges on the module are also dropped.

If the module is referenced in the definition of a row permission or a column mask, the module cannot be dropped (SQLSTATE 42893).

NICKNAME *nickname*
Identifies the nickname that is to be dropped. The nickname must be listed in the catalog (SQLSTATE 42704). The nickname is deleted from the database.

All information about the columns and indexes associated with the nickname is deleted from the catalog. Any materialized query tables that are dependent on the nickname are dropped. Any index specifications that are dependent on the nickname are dropped. Any views that are dependent on the nickname are marked inoperative. Any packages that are dependent on the dropped

index specifications or inoperative views are invalidated. The data source table that the nickname references is not affected.

If an SQL function or method is dependent on a nickname, that nickname cannot be dropped (SQLSTATE 42893).

PACKAGE *package-name*
Identifies the package that is to be dropped. The package name must identify a package that is described in the catalog (SQLSTATE 42704). The specified package is deleted. If the package being dropped is the only package identified by *package-name* (that is, there are no other versions), all privileges on the package are also deleted.

VERSION *version-id*
Identifies which package version is to be dropped. If a value is not specified, the version defaults to the empty string. If multiple packages with the same package name but different versions exist, only one package version can be dropped in one invocation of the DROP statement. Delimit the version identifier with double quotation marks when it:

- Is generated by the VERSION(AUTO) precompiler option
- Begins with a digit
- Contains lowercase or mixed-case letters

If the statement is invoked from an operating system command prompt, precede each double quotation mark delimiter with a back slash character to ensure that the operating system does not strip the delimiters.

PERMISSION *permission-name*
Identifies the row permission to drop. The name must identify a row permission that exists at the current server (SQLSTATE 42704). The name must not identify the default row permission that was created implicitly by the database manager (SQLSTATE 42917).

procedure-designator
Identifies an instance of a procedure that is to be dropped. For more information, see "Function, method, and procedure designators" on page 745. The procedure instance specified must be a procedure described in the catalog. It is not possible to drop a procedure that is in the SYSIBM, SYSFUN, SYSIBMADM, or the SYSPROC schema (SQLSTATE 42832).

RESTRICT
The RESTRICT keyword prevents the procedure from being dropped if a trigger definition or an SQL routine definition contains a CALL identifying the procedure.

The restrict rule is enforced by default for the same dependencies as in version 9.5 if the following conditions are met:

- The **auto_reval** database configuration parameter is set to disabled
- An inlined trigger definition, inlined SQL function definition, or inlined SQL method definition contains a CALL statement identifying the procedure

It is not possible to drop a procedure that is in the SYSIBM, SYSFUN, or the SYSPROC schema (SQLSTATE 42832).

ROLE *role-name*
Identifies the role that is to be dropped. The *role-name* must identify a role that already exists at the current server (SQLSTATE 42704). The *role-name* must not identify a role, or a role that contains *role-name*, if the role has either EXECUTE privilege on a routine or USAGE privilege on a sequence, and an SQL object other than a package is dependent on the routine or sequence (SQLSTATE 42893). The owner of the SQL object is either *authorization-name* or any user who is a member of *authorization-name*, where *authorization-name* is a role.

A DROP ROLE statement fails (SQLSTATE 42893) if any of the following conditions are true for the role to be dropped:

- A workload exists such that one of the values for the connection attribute SESSION_USER ROLE is *role-name*

- A trusted context using *role-name* exists

The specified role is deleted from the catalog.

SCHEMA *schema-name* RESTRICT
Identifies the particular schema to be dropped. The *schema-name* must identify a schema that is described in the catalog (SQLSTATE 42704).

RESTRICT
The RESTRICT keyword enforces the rule that no objects can be defined in the specified schema for the schema to be deleted from the database (SQLSTATE 42893).

SECURITY LABEL *security-label-name*
Identifies the security label to be dropped. The name must be qualified with a security policy (SQLSTATE 42704) and must identify a security label that exists at the current server (SQLSTATE 42704).

RESTRICT
This option, which is the default, prevents the security label from being dropped if any of the following dependencies exist (SQLSTATE 42893):

- One or more authorization IDs currently hold the security label for read access
- One or more authorization IDs currently hold the security label for write access
- The security label is currently being used to protect one or more columns

SECURITY LABEL COMPONENT *sec-label-comp-name*
Identifies the security label component to be dropped. The *sec-label-comp-name* must identify a security label component that is described in the catalog (SQLSTATE 42704).

RESTRICT
This option, which is the default, prevents the security label component from being dropped if any of the following dependencies exist (SQLSTATE 42893):

- One or more security policies that include the security label component are currently defined

SECURITY POLICY *security-policy-name*
Identifies the security policy to be dropped. The *security-policy-name* must identify a security policy that exists at the current server (SQLSTATE 42704).

RESTRICT
This option, which is the default, prevents the security policy from being dropped if any of the following dependencies exist (SQLSTATE 42893):

- One or more tables are associated with this security policy
- One or more authorization IDs hold an exemption on one of the rules in this security policy
- One or more security labels are defined for this security policy

SEQUENCE *sequence-name*
Identifies the particular sequence that is to be dropped. The *sequence-name*, along with the implicit or explicit schema name, must identify an existing sequence at the current server. If no sequence by this name exists in the explicitly or implicitly specified schema, an error is returned (SQLSTATE 42704).

RESTRICT
The RESTRICT keyword prevents the sequence from being dropped if any of the following dependencies exist:

- A trigger exists such that a NEXT VALUE or PREVIOUS VALUE expression in the trigger body specifies the sequence (SQLSTATE 42893).
- An SQL routine exists such that a NEXT VALUE expression in the routine body specifies the sequence (SQLSTATE 42893).

The restrict rule is enforced by default for the same dependencies as in version 9.5 if the following conditions are met:

- The **auto_reval** database configuration parameter is set to disabled
- An inlined trigger definition, inlined SQL function definition, or inlined SQL method definition references the sequence

SERVER ***server-name***
Identifies the data source whose definition is to be dropped from the catalog. The *server-name* must identify a data source that is described in the catalog (SQLSTATE 42704). The definition of the data source is deleted.

All nicknames for tables and views residing at the data source are dropped. Any index specifications dependent on these nicknames are dropped. Any user-defined function mappings, user-defined type mappings, and user mappings that are dependent on the dropped server definition are also dropped. All packages dependent on the dropped server definition, function mappings, nicknames, and index specifications are invalidated. All federated procedures that are dependent on the server definition are also dropped.

service-class-designator

SERVICE CLASS ***service-class-name***
Identifies the service class to be dropped. The *service-class-name* must identify a service class that is described in the catalog (SQLSTATE 42704). To drop a service subclass, the *service-superclass-name* must be specified using the UNDER clause.

UNDER ***service-superclass-name***
Specifies the service superclass of the service subclass when dropping a service subclass. The *service-superclass-name* must identify a service superclass that is described in the catalog (SQLSTATE 42704).

RESTRICT
This keyword enforces the rule that the service class is not to be dropped if any of the following dependencies exists:

- The service class is a service subclass and there is a work action mapping to the service class (SQLSTATE 5U031). The work action must first be dropped.
- The service class is the target of a REMAP ACTIVITY action in a threshold (SQLSTATE 5U031). Alter the threshold to set a different service subclass as the target of the REMAP ACTIVITY action or drop the threshold.
- The service class is not disabled (SQLSTATE 5U031). The service class must first be disabled.

RESTRICT is the default behavior.

STOGROUP ***storagegroup-name***

Identifies the storage group that is to be dropped; *storagegroup-name* must identify a storage group that exists at the current server (SQLSTATE 42704). This is a one-part name.

RESTRICT
The RESTRICT keyword prevents the storage group from being dropped if a table space exists that uses the storage group (SQLSTATE 42893). RESTRICT is the default behavior.

The current default storage group cannot be dropped (SQLSTATE 42893). A new default can be designated using the ALTER STOGROUP statement.

The DROP STOGROUP statement cannot be executed while a database partition server is being added (SQLSTATE 55071).

TABLE ***table-name***

Identifies the base table, created temporary table, or declared temporary table that is to be dropped. The *table-name* must identify a table that is described in the catalog or, if it is a declared temporary table, the *table-name* must be qualified by the schema name SESSION and exist in the application (SQLSTATE 42704). The subtables of a typed table are dependent on their supertables. All subtables must be dropped before a supertable can be dropped (SQLSTATE 42893). The *table-name* must

not identify a catalog table (SQLSTATE 42832), or a history table associated with a system-period temporal table (SQLSTATE 42893). The specified table is deleted from the database.

All indexes, primary keys, foreign keys, row permissions (including the default row permission), column masks, check constraints, materialized query tables, and staging tables that are defined on the table are dropped. All views and triggers that reference the table are made inoperative, including both the table referenced in the ON clause of the CREATE TRIGGER statement and all tables referenced within the triggered SQL statements. All packages which depend on any object dropped or marked inoperative will be invalidated. This includes packages dependent on any supertables above the subtable in the hierarchy. Any referenced columns for which the dropped table is defined as the scope of the reference become unscoped.

Packages are not dependent on declared temporary tables, and therefore are not invalidated when such a table is dropped. Packages are, however, dependent on created temporary tables, and are invalidated when such a table is dropped.

In a federated system, a remote table that was created using transparent DDL can be dropped. Dropping a remote table also drops the nickname associated with that table, and invalidates any packages that are dependent on that nickname.

When a subtable is dropped from a table hierarchy, the columns associated with the subtable are no longer accessible although they continue to be considered with respect to limits on the number of columns and size of the row. Dropping a subtable has the effect of deleting all the rows of the subtable from the supertables. This may result in activation of triggers or referential integrity constraints defined on the supertables.

When a created temporary table or declared temporary table is dropped, and its creation preceded the active unit of work or savepoint, then the table will be functionally dropped and the application will not be able to access the table. However, the table will still reserve some space in its table space and will prevent that USER TEMPORARY table space from being dropped or the database partition group of the USER TEMPORARY table space from being redistributed until the unit of work is committed or savepoint is ended. Dropping a created temporary table or declared temporary table causes the data in the table to be destroyed, regardless of whether DROP is committed or rolled back.

If *table-name* is a system-period temporal table, any associated history table and any indexes defined on the history table are also dropped. To drop a system-period temporal table, the privilege set must also contain the authorization required to drop the history table (SQLSTATE 42501).

A history table associated with a system-period temporal table cannot be explicitly dropped using the DROP statement (SQLSTATE 42893). A history table is implicitly dropped when the associated system-period temporal table is dropped.

A table cannot be dropped if it has the RESTRICT ON DROP attribute.

A newly detached table is initially inaccessible. This prevents the table from being read, modified, or dropped until the SET INTEGRITY statement can be run to incrementally refresh MQTs or to complete any processing for foreign key constraints. After the SET INTEGRITY statement executes against all dependent tables, the table is fully accessible, its detached attribute is reset, and it can be dropped.

When a table is dropped, all row permissions, including the default row permission, and column masks that are created for the table are also dropped.

If the table is referenced in the definition of a row permission or a column mask, the table cannot be dropped (SQLSTATE 42893).

IF EXISTS

Specifies that no error message is shown if the specified table name does not exist in the current database and schema.

Unless other conditions or dependencies prevent the drop operation, a successful message is returned even if no table is dropped. The condition for the failure is ignored if the table does not exist.

TABLE HIERARCHY *root-table-name*

Identifies the typed table hierarchy that is to be dropped. The *root-table-name* must identify a typed table that is the root table in the typed table hierarchy (SQLSTATE 428DR). The typed table identified by *root-table-name* and all of its subtables are deleted from the database.

All indexes, materialized query tables, staging tables, primary keys, foreign keys, and check constraints referencing the dropped tables are dropped. All views and triggers that reference the dropped tables are made inoperative. All packages depending on any object dropped or marked inoperative will be invalidated. Any reference columns for which one of the dropped tables is defined as the scope of the reference become unscoped.

Unlike dropping a single subtable, dropping the table hierarchy does not result in the activation of delete triggers of any tables in the hierarchy nor does it log the deleted rows.

TABLESPACE or TABLESPACES *tablespace-name*

Identifies the table spaces that are to be dropped; *tablespace-name* must identify a table space that is described in the catalog (SQLSTATE 42704). This is a one-part name. *tablespace-name* must not identify a table space that contains a history table unless the system-period temporal table with which it is associated is also being dropped (SQLSTATE 42893).

The table spaces will not be dropped (SQLSTATE 55024) if there is any table that stores at least one of its parts in a table space being dropped, and has one or more of its parts in another table space that is not being dropped (these tables would need to be dropped first), or if any table that resides in the table space has the RESTRICT ON DROP attribute.

Objects whose names are prefixed with 'SYS' are built-in objects and, with the exception of the SYSTOOLSPACE and SYSTOOLSTMPSPACE table spaces, cannot be dropped (SQLSTATE 42832).

A SYSTEM TEMPORARY table space cannot be dropped (SQLSTATE 55026) if it is the only temporary table space that exists in the database. A USER TEMPORARY table space cannot be dropped if there is an instance of a created temporary table or a declared temporary table created in it (SQLSTATE 55039). Even if a created temporary table has been dropped, the USER TEMPORARY table space will still be considered to be in used until all instances of the created temporary table are dropped. Instances of a created temporary table are dropped when the session terminates or when the created temporary table is referenced in the session. Even if a declared temporary table has been dropped, the USER TEMPORARY table space will still be considered to be in use until the unit of work containing the DROP TABLE statement has been committed.

Dropping a table space drops all objects that are defined in the table space. All existing database objects with dependencies on the table space, such as packages, referential constraints, and so on, are dropped or invalidated (as appropriate), and dependent views and triggers are made inoperative.

Containers that were created by a user are not deleted. Any directories in the path of the container name that were created by the database manager during CREATE TABLESPACE execution are deleted. All containers that are below the database directory are deleted. When the DROP TABLESPACE statement is committed, the DMS file containers or SMS containers for the specified table space are deleted, if possible. If the containers cannot be deleted (because they are being kept open by another agent, for example), the files are truncated to zero length. After all connections are terminated, or the DEACTIVATE DATABASE command is issued, these zero-length files are deleted.

THRESHOLD *threshold-name*

Identifies the threshold that is to be dropped. The *threshold-name* must identify a threshold that exists at the current server (SQLSTATE 42704). This is a one-part name. Thresholds with a queue, for example TOTALSCPARTITIONCONNECTIONS and CONCURRENTDBCOORDACTIVITIES, must be disabled before they can be dropped (SQLSTATE 5U025). The specified threshold is deleted from the catalog.

TRIGGER *trigger-name*

Identifies the trigger that is to be dropped. The *trigger-name* must identify a trigger that is described in the catalog (SQLSTATE 42704). The specified trigger is deleted.

Dropping triggers causes certain packages to be marked invalid.

If *trigger-name* specifies an INSTEAD OF trigger on a view, another trigger may depend on that trigger through an update against the view.

TRANSFORM ALL FOR *type-name*
Indicates that all transforms groups defined for the user-defined data type *type-name* are to be dropped. The transform functions referenced in these groups are not dropped. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The *type-name* must identify a user-defined type described in the catalog (SQLSTATE 42704).

If there are not transforms defined for *type-name*, an error is returned (SQLSTATE 42740).

DROP TRANSFORM is the inverse of CREATE TRANSFORM. It causes the transform functions associated with certain groups, for a given data type, to become undefined. The functions formerly associated with these groups still exist and can still be called explicitly, but they no longer have the transform property, and are no longer invoked implicitly for exchanging values with the host language environment.

The transform group is not dropped if there is a user-defined function (or method) written in a language other than SQL that has a dependency on one of the group's transform functions defined for the user-defined type *type-name* (SQLSTATE 42893). Such a function has a dependency on the transform function associated with the referenced transform group defined for type *type-name*. Packages that depend on a transform function associated with the named transform group are marked inoperative.

TRANSFORMS *group-name* FOR *type-name*
Indicates that the specified transform group for the user-defined data type *type-name* is to be dropped. The transform functions referenced in this group are not dropped. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The *type-name* must identify a user-defined type described in the catalog (SQLSTATE 42704), and the *group-name* must identify an existing transform group for *type-name*.

TRIGGER *trigger-name*
Identifies the trigger that is to be dropped. The *trigger-name* must identify a trigger that is described in the catalog (SQLSTATE 42704). The specified trigger is deleted.

Dropping triggers causes certain packages to be marked invalid.

If *trigger-name* specifies an INSTEAD OF trigger on a view, another trigger may depend on that trigger through an update against the view.

TRUSTED CONTEXT *context-name*
Identifies the trusted context that is to be dropped. The *context-name* must identify a trusted context that exists at the current server (SQLSTATE 42704). If the trusted context is dropped while trusted connections for this context are active, those connections remain trusted until they terminate or until the next reuse attempt. If an attempt is made to switch the user on these trusted connections, an error is returned (SQLSTATE 42517). The specified trusted context is deleted from the catalog.

TYPE *type-name*
Identifies the user-defined type to be dropped. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. For a structured type, the associated reference type is also dropped. The *type-name* must identify a user-defined type described in the catalog.

RESTRICT
The type is not dropped (SQLSTATE 42893) if any of the following conditions are true:

- The type is used as the type of a column of a table or view.
- The type has a subtype.

- The type is a structured type used as the data type of a typed table or a typed view.
- The type is an attribute of another structured type.
- There exists a column of a table whose type might contain an instance of *type-name*. This can occur if *type-name* is the type of the column or is used elsewhere in the column's associated type hierarchy. More formally, for any type T, T cannot be dropped if there exists a column of a table whose type directly or indirectly uses *type-name*.
- The type is the target type of a reference-type column of a table or view, or a reference-type attribute of another structured type.
- The type, or a reference to the type, is a parameter type or a return value type of a function or method.
- The type is a parameter type or is used in the body of an SQL procedure.
- The type, or a reference to the type, is used in the body of an SQL function or method, but it is not a parameter type or a return value type.
- The type is used in a check constraint, trigger, view definition, or index extension.

If RESTRICT is not specified, the behavior is the same as RESTRICT, except for functions and methods that use the type.

The restrict rule is enforced by default for the same dependencies as in version 9.5 if the **auto_reval** database configuration parameter is set to disabled.

Functions that use the type: If the user-defined type can be dropped, then for every function, F (with specific name SF), that has parameters or a return value of the type being dropped or a reference to the type being dropped, the following DROP FUNCTION statement is effectively executed:

```
DROP SPECIFIC FUNCTION SF
```

It is possible that this statement also would cascade to drop dependent functions. If all of these functions are also in the list to be dropped because of a dependency on the user-defined type, the drop of the user-defined type will succeed (otherwise it fails with SQLSTATE 42893).

Methods that use the type: If the user-defined type can be dropped, then for every method, M of type T1 (with specific name SM), that has parameters or a return value of the type being dropped or a reference to the type being dropped, the following statements are effectively executed:

```
DROP SPECIFIC METHOD SM
ALTER TYPE T1 DROP SPECIFIC METHOD SM
```

The existence of objects that are dependent on these methods may cause the DROP TYPE operation to fail.

All packages that are dependent on methods defined in supertypes of the type being dropped, and that are eligible for overriding, are invalidated.

If the type is referenced in the definition of a row permission or a column mask, the type cannot be dropped (SQLSTATE 42893).

TYPE MAPPING *type-mapping-name*
Identifies the user-defined data type mapping to be dropped. The *type-mapping-name* must identify a data type mapping that is described in the catalog (SQLSTATE 42704). The data type mapping is deleted from the database.

No additional objects are dropped.

USAGE LIST *usage-list-name*
Identifies the usage list that is to be dropped. The *usage-list-name*, including the implicit or explicit qualifier, must identify a usage list that is described in the catalog (SQLSTATE 42704). Memory allocated for the usage list is released and is not under transactional control.

USER MAPPING FOR *authorization-name* | USER SERVER *server-name*
Identifies the user mapping to be dropped. This mapping associates an authorization name that is used to access the federated database with an authorization name that is used to access a data

source. The first of these two authorization names is either identified by the *authorization-name* or referenced by the special register USER. The *server-name* identifies the data source that the second authorization name is used to access.

The *authorization-name* must be listed in the catalog (SQLSTATE 42704). The *server-name* must identify a data source that is described in the catalog (SQLSTATE 42704). The user mapping is deleted.

No additional objects are dropped.

VARIABLE *variable-name*
Identifies the global variable that is to be dropped. The *variable-name* must identify a global variable that exists at the current server (SQLSTATE 42704).

If the variable is referenced in the definition of a row permission or a column mask, the variable cannot be dropped (SQLSTATE 42893).

RESTRICT
The RESTRICT keyword prevents the global variable from being dropped if it is referenced in an SQL routine definition, trigger definition, or view definition (SQLSTATE 42893).

The restrict rule is enforced by default for the same dependencies as in version 9.5 if the following conditions are met:

- The **auto_reval** database configuration parameter is set to disabled
- An inlined trigger definition, inlined SQL function definition, inlined SQL method definition, or view references the variable

VIEW *view-name*
Identifies the view that is to be dropped. The *view-name* must identify a view that is described in the catalog (SQLSTATE 42704). The subviews of a typed view are dependent on their superviews. All subviews must be dropped before a superview can be dropped (SQLSTATE 42893).

The specified view is deleted. The definition of any view or trigger that is directly or indirectly dependent on that view is marked inoperative. Any materialized query table or staging table that is dependent on any view that is marked inoperative is dropped. Any packages dependent on a view that is dropped or marked inoperative will be invalidated. This includes packages dependent on any superviews above the subview in the hierarchy. Any reference columns for which the dropped view is defined as the scope of the reference become unscoped.

If the view is referenced in the definition of a row permission or a column mask, the view cannot be dropped (SQLSTATE 42893).

VIEW HIERARCHY *root-view-name*
Identifies the typed view hierarchy that is to be dropped. The *root-view-name* must identify a typed view that is the root view in the typed view hierarchy (SQLSTATE 428DR). The typed view identified by *root-view-name* and all of its subviews are deleted from the database.

The definition of any view or trigger that is directly or indirectly dependent on any of the dropped views is marked inoperative. Any packages dependent on any view or trigger that is dropped or marked inoperative will be invalidated. Any reference columns for which a dropped view or view marked inoperative is defined as the scope of the reference become unscoped.

WORK ACTION SET *work-action-set-name*
Identifies the work action set that is to be dropped. The *work-action-set-name* must identify a work action set that exists at the current server (SQLSTATE 42704). All work actions that are contained by the *work-action-set-name* are also dropped.

WORK CLASS SET *work-class-set-name*
Identifies the work class set that is to be dropped. The *work-class-set-name* must identify a work class set that exists at the current server (SQLSTATE 42704). All work classes that are contained by the *work-class-set-name* are also dropped.

WORKLOAD *workload-name*
Identifies the workload that is to be dropped. This is a one-part name. The *workload-name* must identify a workload that exists at the current server (SQLSTATE 42704). SYSDEFAULTUSERWORKLOAD or SYSDEFAULTADMWORKLOAD cannot be dropped (SQLSTATE 42832). A workload must be disabled and must not have active workload occurrences associated with it before it can be dropped (SQLSTATE 5U023). To drop a workload with an associated threshold (SQLSTATE 5U031), you must drop the threshold first. The specified workload is deleted from the catalog.

WRAPPER *wrapper-name*
Identifies the wrapper to be dropped. The *wrapper-name* must identify a wrapper that is described in the catalog (SQLSTATE 42704). The wrapper is deleted.

All server definitions, user-defined function mappings, and user-defined data type mappings that are dependent on the wrapper are dropped. All user-defined function mappings, nicknames, user-defined data type mappings, and user mappings that are dependent on the dropped server definitions are also dropped. Any index specifications dependent on the dropped nicknames are dropped, and any views dependent on these nicknames are marked inoperative. All packages dependent on the dropped objects and inoperative views are invalidated. All federated procedures that are dependent on the dropped server definitions are also dropped.

XSROBJECT *xsrobject-name*
Identifies the XSR object to be dropped. The *xsrobject-name* must identify an XSR object that is described in the catalog (SQLSTATE 42704).

Check constraints that reference the XSR object are dropped. All triggers and views referencing the XSR object are marked inoperative. Packages having a dependency on a dropped XSR object are invalidated.

In a partitioned database environment, you can issue this statement against an XSR object by connecting to any partition.

Rules

Dependencies: Table 149 on page 1632 shows the dependencies that objects have on each other. Not all dependencies are explicitly recorded in the catalog. For example, there is no record of the constraints on which a package has dependencies. Four different types of dependencies are shown:

R
Restrict semantics. The underlying object cannot be dropped as long as the object that depends on it exists.

C
Cascade semantics. Dropping the underlying object causes the object that depends on it (the depending object) to be dropped as well. However, if the depending object cannot be dropped because it has a Restrict dependency on some other object, the drop of the underlying object will fail.

X
Inoperative semantics. Dropping the underlying object causes the object that depends on it to become inoperative. It remains inoperative until a user takes some explicit action.

A
Automatic invalidation and revalidation semantics. Dropping the underlying object causes the object that depends on it to become invalid. The database manager attempts to revalidate the invalid object.

A package used by a function or a method, or by a procedure that is called directly or indirectly from a function or method, will only be automatically revalidated if the routine is defined as MODIFIES SQL DATA. If the routine is not MODIFIES SQL DATA, an error is returned (SQLSTATE 56098).

In general, the database manager attempts to revalidate the invalid objects the next time the object is used. However, in situations when **auto_reval** is set to IMMEDIATE, the impacted dependent objects will be revalidated immediately after they become invalid. Those situations are:

- ALTER TABLE ... ALTER COLUMN

- ALTER TABLE ... DROP COLUMN
- ALTER TABLE ... RENAME COLUMN
- ALTER TYPE ... ADD ATTRIBUTE
- ALTER TYPE ... DROP ATTRIBUTE
- Any CREATE statement that specifies "OR REPLACE"

Some of the dependencies shown in Table 149 on page 1632 change to "A" (Automatic Invalidation/ Revalidation semantics) when the database configuration parameter **auto_reval** is set to IMMEDIATE or DEFERRED. Table 150 on page 1638 summarizes the dependent objects that are impacted. Objects listed in the "Impacted Dependent Objects" column will be invalidated when the corresponding statement listed in the "Statement" column is executed.

Some DROP statement parameters and objects are not shown in Table 149 on page 1632 because they would result in blank rows or columns:

- EVENT MONITOR, PACKAGE, PROCEDURE, SCHEMA, TYPE MAPPING, and USER MAPPING DROP statements do not have object dependencies.
- Alias, buffer pool, distribution key, privilege, and procedure object types do not have DROP statement dependencies.
- A DROP SERVER, DROP FUNCTION MAPPING, or DROP TYPE MAPPING statement in a given unit of work (UOW) cannot be processed under either of the following conditions:
  - The statement references a single data source, and the UOW already includes a SELECT statement that references a nickname for a table or view within this data source (SQLSTATE 55006).
  - The statement references a category of data sources (for example, all data sources of a specific type and version), and the UOW already includes a SELECT statement that references a nickname for a table or view within one of these data sources (SQLSTATE 55006).

1

This dependency is implicit in depending on a table with these constraints, triggers, or a distribution key.

2

If a package has an INSERT, UPDATE, or DELETE statement acting upon a view, then the package has an insert, update or delete usage on the underlying base table of the view. In the case of UPDATE, the package has an update usage on each column of the underlying base table that is modified by the UPDATE.

If a package has a statement acting on a typed view, creating or dropping any view in the same view hierarchy will invalidate the package.

3

If a package, materialized query table, staging table, view, or trigger uses an alias, it becomes dependent both on the alias and the object that the alias references. If the alias is in a chain, a dependency is created on each alias in the chain.

Aliases themselves are not dependent on anything. It is possible for an alias to be defined on an object that does not exist.

4

A user-defined type T can depend on another user-defined type B, if T:

- names B as the data type of an attribute
- has an attribute of REF(B)
- has B as a supertype.

5

If the user-defined type is referenced as a function parameter type or return type, then the type will be dropped and its catalog data will be maintained due to the routine parameter dependency. A value 'X' in the VALID column of the SYSCAT.DATATYPES catalog view indicates this dropped type. Its catalog data will be deleted by a DROP FUNCTION statement if the DROP FUNCTION statement also dropped the last routine parameter dependency on this type, or will be deleted by a CREATE TYPE statement with the same schema name, module name, and type name. If the user-defined type is a structured type, any methods that are associated with the type are also dropped.

6

Dropping a table space or a list of table spaces causes all the tables that are completely contained within the given table space or list to be dropped. However, if a table spans table spaces (indexes, long columns, or data partitions in different table spaces) and those table spaces are not in the list being dropped, the table spaces cannot be dropped as long as the table exists.

7

A function can depend on another specific function if the depending function names the base function in a SOURCE clause. A function or method can also depend on another specific function or method if the depending routine is written in SQL and uses the base routine in its body. An external method, or an external function with a structured type parameter or returns type will also depend on one or more transform functions.

8

Only loss of SELECT privilege will cause a materialized query table to be dropped or a view to become inoperative. If the view that is made inoperative is included in a typed view hierarchy, all of its subviews also become inoperative.

9

If a package has an INSERT, UPDATE, or DELETE statement acting on table T, then the package has an insert, update or delete usage on T. In the case of UPDATE, the package has an update usage on each column of T that is modified by the UPDATE.

If a package has a statement acting on a typed table, creating or dropping any table in the same table hierarchy will invalidate the package.

10

Dependencies do not exist at the column level because privileges on columns cannot be revoked individually.

If a package, trigger or view includes the use of OUTER(*Z*) in the FROM clause, there is a dependency on the SELECT privilege on every subtable or subview of *Z*. Similarly, if a package, trigger, or view includes the use of DEREF(*Y*) where *Y* is a reference type with a target table or view *Z*, there is a dependency on the SELECT privilege on every subtable or subview of *Z*.

11

A materialized query table is dependent on the underlying tables or nicknames specified in the fullselect of the table definition.

Cascade semantics apply to dependent materialized query tables.

A subtable is dependent on its supertables up to the root table. A supertable cannot be dropped until all of its subtables are dropped.

A history table is dependent on the system-period temporal table with which it is associated. Cascade semantics apply to the history table when the system-period temporary table on which depends is dropped.

12

A package can depend on structured types as a result of using the TYPE predicate or the subtype-treatment expression (TREAT *expression* AS *data-type*). The package has a dependency on the subtypes of each structured type specified in the right side of the TYPE predicate, or the right side of the TREAT expression. Dropping or creating a structured type that alters the subtypes on which the package is dependent causes invalidation.

All packages that are dependent on methods defined in supertypes of the type being dropped, and that are eligible for overriding, are invalidated.

13

A check constraint or trigger is dependent on a type if the type is used anywhere in the constraint or trigger. There is no dependency on the subtypes of a structured type used in a TYPE predicate within a check constraint or trigger.

14

A view is dependent on a type if the type is used anywhere in the view definition (this includes the type of typed view). There is no dependency on the subtypes of a structured type used in a TYPE predicate within a view definition.

15

A subview is dependent on its superview up to the root view. A superview cannot be dropped until all its subviews are dropped. Refer to [16] for additional view dependencies.

16

A trigger or view is also dependent on the target table or target view of a dereference operation or DEREF function. A trigger or view with a FROM clause that includes OUTER(*Z*) is dependent on all the subtables or subviews of *Z* that existed at the time the trigger or view was created.

17

A typed view can depend on the existence of a unique index to ensure the uniqueness of the object identifier column.

18

A table may depend on a user defined data type (distinct or structured) because the type is:

- used as the type of a column
- used as the type of the table
- used as an attribute of the type of the table
- used as the target type of a reference type that is the type of a column of the table or an attribute of the type of the table
- directly or indirectly used by a type that is the column of the table.

19

Dropping a server cascades to drop the function mappings and type mappings created for that named server.

20

If the distribution key is defined on a table in a multiple partition database partition group, the distribution key is required.

21

If a dependent OLE DB table function has "R" dependent objects (see DROP FUNCTION), then the server cannot be dropped.

22

An SQL function or method can depend on the objects referenced by its body.

23

When an attribute A of type TA of *type-name* T is dropped, the following DROP statements are effectively executed:

```
Mutator method: DROP METHOD A (TA) FOR T
Observer method: DROP METHOD A () FOR T
ALTER TYPE T
  DROP METHOD A(TA)
  DROP METHOD A()
```

24

A table may depend on an attribute of a user-defined structured data type in the following cases:

1. The table is a typed table that is based on *type-name* or any of its subtypes.
2. The table has an existing column of a type that directly or indirectly refers to *type-name*.

25

A REVOKE of SELECT privilege on a table or view that is used in the body of an SQL function or method body causes an attempt to drop the function or method body, if the function or method body defined no longer has the SELECT privilege. If such a function or method body is used in a view, trigger, function, or method body, it cannot be dropped, and the REVOKE is restricted as a result. Otherwise, the REVOKE cascades and drops such functions.

26

A trigger depends on an INSTEAD OF trigger when it modifies the view on which the INSTEAD OF trigger is defined, and the INSTEAD OF trigger fires.

27

A method declaration of an original method that is overridden by other methods cannot be dropped (SQLSTATE 42893).

28

If the method of the method body being created is declared to override another method, all packages dependent on the overridden method, and on methods that override this method in supertypes of the method being created, are invalidated.

29

When a new subtype of an existing type is created, all packages dependent on methods that are defined in supertypes of the type being created, and that are eligible for overriding (for example, no mutators or observers), are invalidated.

30

If the specific method of the method body being dropped is declared to override another method, all packages dependent on the overridden method, and on methods that override this method in supertypes of the specific method being dropped, are invalidated.

31

Cached dynamic SQL has the same semantics as packages.

32

When a remote base table is dropped using the DROP TABLE statement, both the nickname and the remote base table are dropped.

33

A primary key or unique keys that are not referenced by a foreign key do not restrict the altering of a nickname local name or local type.

34

An XSROBJECT can become inoperative for decomposition as a result of changes to a table that is associated with the XML schema for decomposition. Changes that could impact decomposition are: dropping the table or dropping a column of the table, or changing a column of the table. The decomposition status of the XML schema can be reset by issuing an ALTER XSROBJECT statement to enable or disable decomposition for the XML schema.

35

- A service class cannot be dropped if any workload is mapped to it (SQLSTATE 5U031).
- A service subclass cannot be dropped if any work action is mapped to it (SQLSTATE 5U031).
- A service subclass cannot be explicitly dropped if it is the target of a threshold REMAP action (SQLSTATE 5U031).

Dropping a service superclass cascades to drop any thresholds, work action sets and service subclasses defined for the service class.

36

A work class set cannot be dropped until the work action set that is defined on it has been dropped.

37

Once the index or table is dropped, its usage list will be invalidated in the catalog. Revalidation will take place on the next activation of the list or it can be explicitly revalidated using the procedure ADMIN_REVALIDATE_DB_OBJECTS.

38

Revoking a privilege is restricted if it causes an object to be dropped or invalidated, and a permission or mask depends on it. For example, if you have a view which depends on a table, and a permission or mask that references the view, REVOKE SELECT on the table invalidates the view, but causes an error.

39

Packages are invalidated when a table on which the enabled permission is defined has row level access control activated on the table. Packages are not affected when dropping a permission that is disabled or is defined on a table with row access control deactivated.

40

Packages are invalidated when a table on which the enabled permission is defined has row level access control activated on the table. Packages are not affected when dropping a permission that is disabled or is defined on a table with row access control deactivated.

*Table 150. Dependent Objects Impacted by **auto_reval***

Statement	Impacted Dependent Objects
ALTER NICKNAME (altering the local name or the local type)	Anchor Type, Function, Method, Procedure, User Defined Type, Variable, View
ALTER TABLE ALTER COLUMN	Anchor Type, Function, Method, Procedure, Trigger[4], User Defined Type, Variable, View, XSROBJECT
ALTER TABLE DROP COLUMN[2]	Anchor Type, Function, Method, Index, Procedure, Trigger[4], User Defined Type, Variable, View, XSROBJECT
ALTER TABLE RENAME COLUMN[1, 3]	Anchor Type, Function, Method, Index, Procedure, Trigger[4], User Defined Type, Variable, View, XSROBJECT
ALTER TYPE ADD ATTRIBUTE	View
ALTER TYPE DROP ATTRIBUTE	View
DROP ALIAS	Anchor Type, Function, Method, Procedure, Trigger, User Defined Type, Variable, View

*Table 150. Dependent Objects Impacted by **auto_reval** (continued)*

Statement	Impacted Dependent Objects
DROP FUNCTION (ALTER MODULE DROP FUNCTION)	Function, Function Mapping, Index Extension, Method, Procedure, Trigger, Variable, View
DROP METHOD	Function, Function Mapping, Index Extension, Method, Procedure, Trigger, Variable, View
DROP NICKNAME	Anchor Type, Function, Method, Procedure, Trigger, User Defined Type, Variable, View
DROP PROCEDURE (ALTER MODULE DROP PROCEDURE)	Function, Method, Procedure, Trigger
DROP SEQUENCE	Function, Method, Procedure, Trigger, Variable, View
DROP TABLE	Anchor Type, Function, Method, Procedure, Trigger[4], User Defined Type, Variable, View, XSROBJECT
DROP TABLE HIERARCHY	Function, Method, Procedure, Trigger, Variable, View
DROP TRIGGER	Trigger
DROP TYPE (ALTER MODULE DROP TYPE)	Anchor Type, Cursor Type, Function, Method, Procedure, Index Extension, Trigger, User Defined Type, Variable, View
DROP VARIABLE (ALTER MODULE DROP VARIABLE)	Anchor Type, Function, Function Mapping, Method, Procedure, Trigger, User Defined Type, Variable, View
DROP VIEW	Anchor Type, Function, Method, Procedure, Trigger[4], User Defined Type, Variable, View
DROP VIEW HIERARCHY	Function, Procedure, Trigger, Variable, View
DROP XSROBJECT	Trigger, View
RENAME TABLE	Anchor Type, Function, Method, Procedure, Trigger[4], User Defined Type, Variable, View, XSROBJECT
REVOKE a privilege	Function, Method, Procedure, Trigger, Variable, View
CREATE OR REPLACE ALIAS[1]	Function, Trigger, Procedure, Variable, View
CREATE OR REPLACE VIEW[1]	Anchor Type, Function, Method, Procedure, Trigger[4], User Defined Type, Variable, View
CREATE OR REPLACE FUNCTION[1]	Function, Function Mapping, Index Extension, method, Procedure, Variable, View
CREATE OR REPLACE PROCEDURE[1]	Function, Method, Procedure, Trigger
CREATE OR REPLACE NICKNAME[1]	Function, method, Procedure, Variable, View
CREATE OR REPLACE SEQUENCE[1]	Function, Method, Procedure, Trigger, Variable, View
CREATE OR REPLACE VARIABLE[1]	Function, Method, Procedure, Trigger, User Defined Type, Variable, View
CREATE OR REPLACE TRIGGER[1]	Trigger

1

Immediate revalidation semantics apply for these statements (for the CREATE statements, only if OR REPLACE is specified) regardless of the setting of the **auto_reval** database configuration parameter.

2

The dependent objects listed will be revalidated the next time the object is used, except for the following objects, which will be revalidated immediately as part of the statement:

- ANCHOR TYPE
- CURSOR TYPE
- VIEW (where the select list consists only of SELECT *, and does not contain any explicitly defined view columns).

For an immediate view revalidation, the list of column names for the select list will be re-established during revalidation.

3

The dependent objects listed will be revalidated the next time the object is used except for the following objects, which will be revalidated immediately as part of the statement:

- User Defined Type
- VIEW (where the select list consists only of SELECT *, and does not contain any explicitly defined view columns).

For an immediate view revalidation, the list of column names for the select list will be re-established during revalidation.

4

If the dependency is because the trigger is defined on the table or view, then the inoperative semantics from Table 1 continue to apply. If the dependency is because the trigger body references the table or view, then automatic invalidation and revalidation semantics apply.

The DROP DATABASE PARTITION GROUP statement might fail (SQLSTATE 55071) if an add database partition server request is either pending or in progress. This statement might also fail (SQLSTATE 55077) if a new database partition server is added online to the instance and not all applications are aware of the new database partition server.

Notes

- It is valid to drop a user-defined function while it is in use. Also, a cursor can be open over a statement which contains a reference to a user-defined function, and while this cursor is open the function can be dropped without causing the cursor fetches to fail.
- If a package which depends on a user-defined function is executing, it is not possible for another authorization ID to drop the function until the package completes its current unit of work. At that point, the function is dropped and the package becomes inoperative. The next request for this package results in an error indicating that the package must be explicitly rebound.
- The removal of a function body (this is very different from dropping the function) can occur while an application which needs the function body is executing. This may or may not cause the statement to fail, depending on whether the function body still needs to be loaded into storage by the database manager on behalf of the statement.
- In addition to the dependencies recorded for any explicitly specified UDF, the following dependencies are recorded when transforms are implicitly required:
  1. When the structured type parameter or result of a function or method requires a transform, a dependency is recorded for the function or method on the required TO SQL or FROM SQL transform function.
  2. When an SQL statement included in a package requires a transform function, a dependency is recorded for the package on the designated TO SQL or FROM SQL transform function.

  Since these describe the only circumstances under which dependencies are recorded due to implicit invocation of transforms, no objects other than functions, methods, or packages can have a dependency on implicitly invoked transform functions. On the other hand, explicit calls to transform functions (in views and triggers, for example) do result in the usual dependencies of these other types of objects on

transform functions. As a result, a DROP TRANSFORM statement may also fail due to these "explicit" type dependencies of objects on the transform(s) being dropped (SQLSTATE 42893).

- Since the dependency catalogs do not distinguish between depending on a function as a transform versus depending on a function by explicit function call, it is suggested that explicit calls to transform functions are not written. In such an instance, the transform property on the function cannot be dropped, or packages will be marked inoperative, simply because they contain explicit invocations in an SQL expression.
- System created sequences for IDENTITY columns cannot be dropped using the DROP SEQUENCE statement.
- When a sequence is dropped, all privileges on the sequence are also dropped and any packages that refer to the sequence are invalidated.
- For relational nicknames, the DROP NICKNAME statement within a given unit of work (UOW) cannot be processed under either of the following conditions (SQLSTATE 55007):
  - A nickname referenced in this statement has a cursor open on it in the same UOW
  - Either an INSERT, DELETE, or UPDATE statement is already issued in the same UOW against the nickname that is referenced in this statement
- For non-relational nicknames, the DROP NICKNAME statement within a given unit of work (UOW) cannot be processed under any of the following conditions (SQLSTATE 55007):
  - A nickname referenced in this statement has a cursor open on it in the same UOW
  - A nickname referenced in this statement is already referenced by a SELECT statement in the same UOW
  - Either an INSERT, DELETE, or UPDATE statement has already been issued in the same UOW against the nickname that is referenced in this statement
- A DROP SERVER statement (SQLSTATE 55006), or a DROP FUNCTION MAPPING or DROP TYPE MAPPING statement (SQLSTATE 55007) within a given unit of work (UOW) cannot be processed under either of the following conditions:
  - The statement references a single data source, and the UOW already includes one of the following items:
    - A SELECT statement that references a nickname for a table or view within this data source
    - An open cursor on a nickname for a table or view within this data source
    - Either an INSERT, DELETE, or UPDATE statement issued against a nickname for a table or view within this data source
  - The statement references a category of data sources (for example, all data sources of a specific type and version), and the UOW already includes one of the following items:
    - A SELECT statement that references a nickname for a table or view within one of these data sources
    - An open cursor on a nickname for a table or view within one of these data sources
    - Either an INSERT, DELETE, or UPDATE statement issued against a nickname for a table or view within one of these data sources
- The DROP WORKLOAD statement does not take effect until it is committed, even for the connection that issues the statement.
- Only one of these statements can be issued by any application at a time, and only one of these statements is allowed within any one unit of work. Each statement must be followed by a COMMIT or a ROLLBACK statement before another one of these statements can be issued (SQLSTATE 5U021).
  - CREATE HISTOGRAM TEMPLATE, ALTER HISTOGRAM TEMPLATE, or DROP (HISTOGRAM TEMPLATE)
  - CREATE SERVICE CLASS, ALTER SERVICE CLASS, or DROP (SERVICE CLASS)
  - CREATE THRESHOLD, ALTER THRESHOLD, or DROP (THRESHOLD)
  - CREATE WORK ACTION, ALTER WORK ACTION, or DROP (WORK ACTION)
  - CREATE WORK CLASS, ALTER WORK CLASS, or DROP (WORK CLASS)

  - CREATE WORKLOAD, ALTER WORKLOAD, or DROP (WORKLOAD)
  - GRANT (Workload Privileges) or REVOKE (Workload Privileges)
- ***Soft invalidation:*** After the drop or change of a database object done by the following statements, active access to the dropped or changed object continues until the access is complete.
  - ALTER FUNCTION
  - ALTER MODULE ... DROP FUNCTION
  - ALTER MODULE ... DROP VARIABLE
  - ALTER TABLE ... DETACH PARTITION
  - ALTER VIEW
  - DROP ALIAS
  - DROP FUNCTION
  - DROP TRIGGER
  - DROP VARIABLE
  - DROP VIEW
  - All of the CREATE OR REPLACE statements except CREATE OR REPLACE SEQUENCE.

  This is the case when the database registry variable *DB2_DLL_SOFT_INVALID* is set to ON. When it is set to OFF, the drop or change of these objects will only complete after all active access to the object to be dropped or changed is complete.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - NODEGROUP can be specified in place of DATABASE PARTITION GROUP
  - DISTINCT TYPE *type-name* can be specified in place of TYPE *type-name*
  - DATA TYPE *type-name* can be specified in place of TYPE *type-name*
  - SYNONYM can be specified in place of ALIAS
  - PROGRAM can be specified in place of PACKAGE
- **Invalidation of packages and dynamically cached statements after dropping row permissions or column masks:** If row level access control is activated on the table, dropping an enabled row permission defined for that table invalidates all packages and dynamically cached statements that reference that same table. If column level access control is activated on the table, dropping an enabled column mask defined for that table invalidates all packages and dynamically cached statements that reference that same table. There is no invalidation for dropping disabled masks or permissions.
- **Circular dependency:** Circular dependency exists in the following example:

```
CREATE PERMISSION RP1 ON T1 FOR ROWS
     WHERE C1>(SELECT MAX(C1) FROM T2)
ENFORCED FOR ALL ACCESS
ENABLE;

CREATE PERMISSION RP2 ON T2 FOR ROWS
     WHERE C1>(SELECT MAX(C1) FROM T1)
ENFORCED FOR ALL ACCESS
ENABLE
```

  The DROP TABLE T1 and DROP TABLE T2 statements fail because **RP1** depends on **T2** and **RP2** depends on **T1**. The user with the SECADM authority should drop one of the row permissions first then issue the **DROP TABLE** statement.

Examples

1. Drop table TDEPT.

```
DROP TABLE TDEPT
```

2. Drop the view VDEPT.

```
DROP VIEW VDEPT
```

3. The authorization ID HEDGES attempts to drop an alias.

```
DROP ALIAS A1
```

   The alias HEDGES.A1 is removed from the catalogs.

4. Hedges attempts to drop an alias, but specifies T1 as the alias-name, where T1 is the name of an existing table (not the name of an alias).

```
DROP ALIAS T1
```

   This statement fails (SQLSTATE 42809).

5. Drop the BUSINESS_OPS database partition group. To drop the database partition group, the two table spaces (ACCOUNTING and PLANS) in the database partition group must first be dropped.

```
DROP TABLESPACE ACCOUNTING
DROP TABLESPACE PLANS
DROP DATABASE PARTITION GROUP BUSINESS_OPS
```

6. Pellow wants to drop the CENTER function, which he created in his PELLOW schema, using the signature to identify the function instance to be dropped.

```
DROP FUNCTION CENTER (INT,FLOAT)
```

7. McBride wants to drop the FOCUS92 function, which she created in the PELLOW schema, using the specific name to identify the function instance to be dropped.

```
DROP SPECIFIC FUNCTION PELLOW.FOCUS92
```

8. Drop the function ATOMIC_WEIGHT from the CHEM schema, where it is known that there is only one function with that name.

```
DROP FUNCTION CHEM.ATOMIC_WEIGHT
```

9. Drop the trigger SALARY_BONUS, which caused employees under a specified condition to receive a bonus to their salary.

```
DROP TRIGGER SALARY_BONUS
```

10. Drop the distinct data type named shoesize, if it is not currently in use.

```
DROP TYPE SHOESIZE
```

11. Drop the SMITHPAY event monitor.

```
DROP EVENT MONITOR SMITHPAY
```

12. Drop the schema from Example 2 under CREATE SCHEMA using RESTRICT. Notice that the table called PART must be dropped first.

```
DROP TABLE PART
DROP SCHEMA INVENTRY RESTRICT
```

13. Macdonald wants to drop the DESTROY procedure, which he created in the EIGLER schema, using the specific name found in the system catalog to identify the procedure to be dropped.

```
DROP SPECIFIC PROCEDURE  EIGLER.SQL100506102825100
```

14. Drop the procedure OSMOSIS from the BIOLOGY schema, where it is known that there is only one procedure with that name.

```
DROP PROCEDURE BIOLOGY.OSMOSIS
```

15. User SHAWN used one authorization ID to access the federated database and another to access the database at an Oracle data source called ORACLE1. A mapping was created between the two authorizations, but SHAWN no longer needs to access the data source. Drop the mapping.

```
DROP USER MAPPING FOR  SHAWN SERVER ORACLE1
```

16. An index of a data source table that a nickname references has been deleted. Drop the index specification that was created to let the optimizer know about this index.

```
DROP INDEX INDEXSPEC
```

17. Drop the MYSTRUCT1 transform group.

```
DROP TRANSFORM MYSTRUCT1 FOR POLYGON
```

18. Drop the method BONUS for the EMP data type in the PERSONNEL schema.

```
DROP METHOD BONUS (SALARY DECIMAL(10,2)) FOR PERSONNEL.EMP
```

19. Drop the sequence ORG_SEQ, with restrictions.

```
DROP SEQUENCE ORG_SEQ
```

20. A remote table EMPLOYEE was created in a federated system using transparent DDL. Access to the table is no longer needed. Drop the remote table EMPLOYEE.

```
DROP TABLE EMPLOYEE
```

21. Drop the function mapping BONUS_CALC and reinstate the default function mapping (if one exists).

```
DROP FUNCTION MAPPING BONUS_CALC
```

22. Drop the security label component LEVEL.

```
DROP SECURITY LABEL COMPONENT LEVEL
```

23. Drop the security label EMPLOYEESECLABEL of the security policy DATA_ACCESS.

```
DROP SECURITY LABEL DATA_ACCESS.EMPLOYEESECLABEL
```

24. Drop the security policy DATA_ACCESS.

```
DROP SECURITY POLICY DATA_ACCESS
```

25. Drop the security label component GROUPS.

```
DROP SECURITY LABEL COMPONENT GROUPS
```

26. Drop the XML schema EMPLOYEE located in the SQL schema HR.

```
DROP XSROBJECT HR.EMPLOYEE
```

27. Drop service subclass DOGSALES under service superclass PETSALES.

```
DROP SERVICE CLASS DOGSALES UNDER PETSALES
```

28. Drop service superclass PETSALES, which has no user-defined service subclasses. The default subclass for service class PETSALES is automatically dropped.

```
DROP SERVICE CLASS PETSALES
```

29. DROP permission P1.

```
DROP PERMISSION P1
```

30. DROP mask M1.

```
DROP MASK M1
```

31. Drop a storage group named TEST_SG.

```
DROP STOGROUP TEST_SG
```

32. Drop the usage list MON_PAYROLL

```
DROP USAGE LIST MON_PAYROLL
```

END DECLARE SECTION

The END DECLARE SECTION statement marks the end of a host variable declare section.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in REXX.

Authorization

None required.

Syntax

Description

The END DECLARE SECTION statement can be coded in the application program wherever declarations can appear according to the rules of the host language. It indicates the end of a host variable declaration section. A host variable section starts with a BEGIN DECLARE SECTION statement.

The BEGIN DECLARE SECTION and the END DECLARE SECTION statements must be paired and may not be nested.

Host variable declarations can be specified by using the SQL INCLUDE statement. Otherwise, a host variable declaration section must not contain any statements other than host variable declarations.

Host variables referenced in SQL statements must be declared in a host variable declare section in all host languages, other than REXX. Furthermore, the declaration of each variable must appear before the first reference to the variable.

Variables declared outside a declare section should not have the same name as variables declared within a declare section.

EXECUTE

The EXECUTE statement executes a prepared SQL statement.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

For each global variable used as an *expression* in the USING clause or in the expression for an *array-index*, the privileges held by the authorization ID of the statement must include one of the following authorities:

- READ privilege on the global variable that is not defined in a module
- EXECUTE privilege on the module of the global variable that is defined in a module
- EXECUTEIN privilege on the schema containing the module of the global variable that is defined in a module
- DATAACCESS authority on the schema containing the module of the global variable that is defined in a module

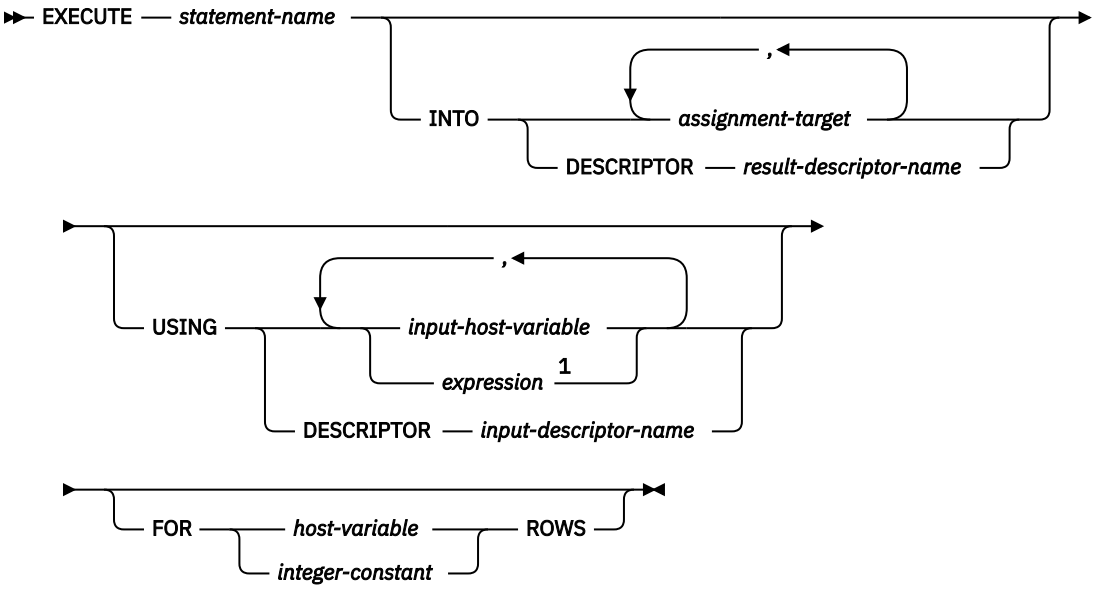
For each global variable used as an *assignment-target*, the privileges held by the authorization ID of the statement must include one of the following authorities:

- WRITE privilege on the global variable that is not defined in a module
- EXECUTE privilege on the module of the global variable that is defined in a module
- EXECUTEIN privilege on the schema containing the module of the global variable that is defined in a module
- DATAACCESS authority on the schema containing the module of the global variable that is defined in a module

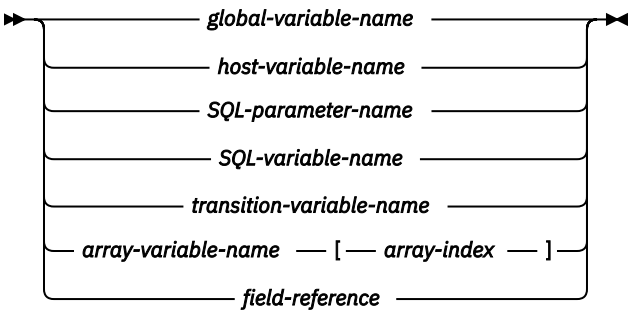
For statements where authorization checking is performed at statement execution time (DDL, GRANT, and REVOKE statements), the privileges held by the authorization ID of the statement must include those required to execute the SQL statement specified by the PREPARE statement. The authorization ID of the statement might be affected by the DYNAMICRULES bind option.

For statements where authorization checking is performed at statement preparation time (DML), no further authorization checking is performed on the SQL statement specified by the PREPARE statement.

Syntax



assignment-target



Notes:

[1] An expression other than *host-variable* can only be used when the EXECUTE statement is used within a compound SQL (compiled) statement.

Description

statement-name
Identifies the prepared statement to be executed. The *statement-name* must identify a statement that was previously prepared, and the prepared statement cannot be a SELECT statement.

INTO
Introduces a list of targets which are used to receive values from output parameter markers in the prepared statement. Each assignment to a target is made in sequence through the list. If an error occurs on any assignment, the value is not assigned to the target, and no more values are assigned to targets. Any values that have already been assigned to targets remain assigned.

For a dynamic CALL statement, parameter markers appearing in OUT and INOUT arguments to the procedure are output parameter markers. If any output parameter markers appear in the statement, the INTO clause must be specified (SQLSTATE 07007).

assignment-target
Identifies one or more targets for the assignment of output values. The first value in the result row is assigned to the first target in the list, the second value to the second target, and so on.

If the data type of an *assignment-target* is a row type, then there must be exactly one *assignment-target* specified (SQLSTATE 428HR), the number of columns must match the number of fields in the row type, and the data types of the columns of the fetched row must be assignable to the corresponding fields of the row type (SQLSTATE 42821).

If the data type of an *assignment-target* is an array element, then there must be exactly one *assignment-target* specified.

global-variable-name
Identifies the global variable that is the assignment target.

host-variable-name
Identifies the host variable that is the assignment target. For LOB output values, the target can be a regular host variable (if it is large enough), a LOB locator variable, or a LOB file reference variable.

SQL-parameter-name
Identifies the routine parameter that is the assignment target.

SQL-variable-name
Identifies the SQL variable that is the assignment target. SQL variables must be declared before they are used.

transition-variable-name
Identifies the column to be updated in the transition row. A *transition-variable-name* must identify a column in the subject table of a trigger, optionally qualified by a correlation name that identifies the new value.

array-variable-name
Identifies an SQL variable, SQL parameter, or global variable of an array type.

array-index
An expression that specifies which element in the array will be the target of the assignment. For an ordinary array, the *array-index* expression must be assignable to INTEGER (SQLSTATE 428H1) and cannot be the null value. Its value must be between 1 and the maximum cardinality defined for the array (SQLSTATE 2202E). For an associative array, the *array-index* expression must be assignable to the index data type of the associative array (SQLSTATE 428H1) and cannot be the null value.

field-reference
Identifies the field within a row type value that is the assignment target. The *field-reference* must be specified as a qualified *field-name* where the qualifier identifies the row value in which the field is defined.

DESCRIPTOR *result-descriptor-name*
Identifies an output SQLDA that must contain a valid description of host variables.

Before the EXECUTE statement is processed, the user must set the following fields in the input SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA
- SQLDABC to indicate the number of bytes of storage allocated for the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables.

The SQLDA must have enough storage to contain all SQLVAR occurrences. Therefore, the value in SQLDABC must be greater than or equal to 16 + SQLN*(N), where N is the length of an SQLVAR occurrence.

If LOB or structured data type output data must be accommodated, there must be two SQLVAR entries for every output parameter marker.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN.

USING
Introduces a list of variables or expressions for which values are substituted for the input parameter markers in the prepared statement.

For a dynamic CALL statement, parameter markers appearing in IN and INOUT arguments to the procedure are input parameter markers. For all other dynamic statements, all the parameter markers are input parameter markers. If any input parameter markers appear in the statement, the USING clause must be specified (SQLSTATE 07004).

***input-host-variable*, ...**
Identifies a host variable that is declared in the program in accordance with the rules for declaring host variables. The number of variables must be the same as the number of input parameter markers in the prepared statement. The *n*th variable corresponds to the *n*th parameter marker in the prepared statement. Locator variables and file reference variables, where appropriate, can be provided as the source of values for parameter markers.

expression
Identifies an expression to be used as the input for the corresponding input parameter marker in the prepared statement. An expression other than a *host-variable* can only be specified when the EXECUTE statement is issued within a compound SQL (compiled) statement.

DESCRIPTOR *input-descriptor-name*
Identifies an input SQLDA that must contain a valid description of host variables.

Before the EXECUTE statement is processed, the user must set the following fields in the input SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA

- SQLDABC to indicate the number of bytes of storage allocated for the SQLDA
- SQLD to indicate the number of variables used in the SQLDA when processing the statement
- SQLVAR occurrences to indicate the attributes of the variables.

The SQLDA must have enough storage to contain all SQLVAR occurrences. Therefore, the value in SQLDABC must be greater than or equal to 16 + SQLN*(N), where N is the length of an SQLVAR occurrence.

If LOB or structured data type input data must be accommodated, there must be two SQLVAR entries for every parameter marker.

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN.

FOR host-variable or integer-constant ROWS

Specifies the number of rows of source data. The values for the insert or merge operation are specified in the USING clause.

host-variable or integer-constant is assigned to an integral value k. If host-variable is specified, it must be of type integer or short and must not include an indicator variable. k must be in the range 2 to 32767. If FOR host-variable or integer-constant ROWS is not provided, the SQL will be executed with array of size 1.

Notes

- Before the prepared statement is executed, each input parameter marker is effectively replaced by the value of its corresponding variable or expression. For a typed parameter marker, the attributes of the target variable or expression are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable or expression are determined according to the context of the parameter marker.

  Let V denote an input variable or expression that corresponds to parameter marker P. The value of V is assigned to the target variable for P in accordance with the rules for assigning a value to a column. Thus:

  – V must be compatible with the target.
  – If V is a string, its length must not be greater than the length attribute of the target.
  – If V is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
  – If the attributes of V are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.

  When the prepared statement is executed, the value used in place of P is the value of the target variable for P or the result of the target expression for P. For example, if V is CHAR(6) and the target is CHAR(8), the value used in place of P is the value of V padded with two blanks.
- For a dynamic CALL statement, after the prepared statement is executed, the returned value of each OUT and INOUT argument is assigned to the assignment target corresponding to the output parameter marker used for the argument. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are those specified by the definition of the parameter of the procedure.

  Let V denote an output assignment target that corresponds to parameter marker P, which is used for argument A of a procedure. The value of A is assigned to V in accordance with the rules for retrieving a value from a column. Thus:

  – V must be compatible with A.
  – If V is a string, its length must not be less than the length of A, or the value of A will be truncated.
  – If V is a number, the maximum absolute value of its integral part must not be less than the absolute value of the integral part of A.
  – If the attributes of V are not identical to the attributes of A, the value of A is converted to conform to the attributes of V.

- ***Dynamic SQL statement caching:*** The information required to execute dynamic and static SQL statements is placed in the database package cache when static SQL statements are first referenced or when dynamic SQL statements are first prepared. This information stays in the package cache until it becomes invalid, the cache space is required for another statement, or the database is shut down.

  When an SQL statement is executed or prepared, the package information relevant to the application issuing the request is loaded from the system catalog into the package cache. The actual executable section for the individual SQL statement is also placed into the cache: static SQL sections are read in from the system catalog and placed in the package cache when the statement is first referenced; dynamic SQL sections are placed directly in the cache after they have been created. Dynamic SQL sections can be created by an explicit statement, such as PREPARE or EXECUTE IMMEDIATE. Once created, sections for dynamic SQL statements may be recreated by an implicit prepare of the statement by the system if the original section has been deleted for space management reasons, or has become invalid due to changes in the environment.

  Each SQL statement is cached at the database level and can be shared among applications. Static SQL statements are shared among applications using the same package; dynamic SQL statements are shared among applications using the same compilation environment, and the exact same statement text. The text of each SQL statement issued by an application is cached locally within the application for use if an implicit prepare is required. Each PREPARE statement in the application program can cache one statement. All EXECUTE IMMEDIATE statements in an application program share the same space, and only one cached statement exists for all these EXECUTE IMMEDIATE statements at a time. If the same PREPARE or any EXECUTE IMMEDIATE statement is issued multiple times with a different SQL statement each time, only the last statement will be cached for reuse. The optimal use of the cache is to issue a number of different PREPARE statements once at the start of the application, and then to issue an EXECUTE or OPEN statement as required.

  When dynamic SQL statements are cached, a statement can be reused over multiple units of work without needing to prepare the statement again, unless the SQL statements prepared in a package are bound with the `KEEPDYNAMIC NO` option. The system recompiles the statement if necessary when environment changes occur.

  The following events are examples of environment or data object changes that can cause cached dynamic statements to be implicitly prepared on the next PREPARE, EXECUTE, EXECUTE IMMEDIATE, or OPEN request:

  - ALTER FUNCTION
  - ALTER METHOD
  - ALTER NICKNAME
  - ALTER PROCEDURE
  - ALTER SERVER
  - ALTER TABLE
  - ALTER TABLESPACE
  - ALTER TYPE
  - CREATE FUNCTION
  - CREATE FUNCTION MAPPING
  - CREATE INDEX
  - CREATE METHOD
  - CREATE PROCEDURE
  - CREATE TABLE
  - CREATE TEMPORARY TABLESPACE
  - CREATE TRIGGER
  - CREATE TYPE
  - DROP (all objects)

- RUNSTATS on any table or index
- Any action that causes a view to become inoperative
- UPDATE of statistics in any system catalog table
- SET CURRENT DEGREE
- SET PATH
- SET QUERY OPTIMIZATION
- SET SCHEMA
- SET SERVER OPTION

The following list outlines the behavior that can be expected from cached dynamic SQL statements:

- *PREPARE Requests:* Subsequent preparations of the same statement do not incur the cost of compiling the statement if the section is still valid. The cost and cardinality estimates for the current cached section are returned. These values might differ from the values returned from any previous PREPARE for the same SQL statement. You do not need to issue a PREPARE statement subsequent to a COMMIT or ROLLBACK statement, unless the statement is associated with a package that was bound with `KEEPDYNAMIC NO`.
- *EXECUTE Requests:* EXECUTE statements may occasionally incur the cost of implicitly preparing the statement if it has become invalid since the original PREPARE. If a section is implicitly prepared, it will use the current environment and not the environment of the original PREPARE statement.
- *EXECUTE IMMEDIATE Requests:* Subsequent EXECUTE IMMEDIATE statements for the same statement will not incur the cost of compiling the statement if the section is still valid.
- *OPEN Requests:* OPEN requests for dynamically defined cursors may occasionally incur the cost of implicitly preparing the statement if it has become invalid since the original PREPARE statement. If a section is implicitly prepared, it will use the current environment and not the environment of the original PREPARE statement.
- *FETCH Requests:* No behavior changes should be expected.
- *ROLLBACK:* Only those dynamic SQL statements prepared or implicitly prepared during the unit of work affected by the rollback operation are invalidated. Inactive dynamic SQL statements associated with a package bound with `KEEPDYNAMIC NO` are removed from the application SQL context after a ROLLBACK opeation and must be explicitly prepared again before the application can execute them. Dynamic SQL statements are still cached at the database level, so a subsequent PREPARE request does not incur the cost of compiling the statement if the section is still valid.
- *COMMIT:* Dynamic SQL statements are not be invalidated, but any acquired locks are be freed. Cursors not defined with the `WITH HOLD` option are closed and their locks freed. Open cusors defined with the `WITH HOLD` option hold onto their package and section locks to protect the active section both during and after commit processing. Dynamic SQL statements bound with the `KEEPDYNAMIC NO` option are not in a prepared state after a transaction boundary and must be explicitly prepared again before the application can execute them. SELECT statements prepared for an open cursor defined with the `WITH HOLD` option remain in a prepared state until a transaction boundary is hit where the cursor is closed. Inactive dynamic SQL statements associated with a package bound with `KEEPDYNAMIC NO` are removed from the application SQL context after a commit operation and must be explicitly prepared again before the application can execute them.

If an error occurs during an implicit prepare, an error will be returned for the request causing the implicit prepare (SQLSTATE 56098).

- For Embedded SQL applications, the `db2dsdriver.cfg` keyword **Anonyblksqlexec** and Db2 registry variable **DB2_ANONYMOUS_ESQL_EXECUTION_BLOCK** allow you to use INPUT and OUTPUT parameters in both the USING and INTO clauses, to get correct values in output.

  For example, when the variable is set to TRUE or 1 (or the keyword set to 1), you can specify INPUT and OUTPUT parameters in both the USING and INTO clauses:

```
EXEC SQL EXECUTE db2strm1 INTO
:h_name_in INDICATOR:h_name_in_ind,
```

```
:h_name_out INDICATOR:h_name_out_ind USING
:h_name_in, :h_name_out;
```

If the **DB2_ANONYMOUS_ESQL_EXECUTION_BLOCK** variable is not set, or set to FALSE or 0 (or the keyword set to 0), you can specify only INPUT parameters in the USING clause and only OUTPUT parameters in the INTO clause.

Attention: The **Anonyblksqlexec** keyword and **DB2_ANONYMOUS_ESQL_EXECUTION_BLOCK** registry variable are available in Db2 11.5.6 and later versions.

Examples

Example 1: In this C example, an INSERT statement with parameter markers is prepared and executed. Host variables h1 - h4 correspond to the format of TDEPT.

```
strcpy (s,"INSERT INTO TDEPT VALUES(?,?,?,?)");
EXEC SQL PREPARE DEPT_INSERT FROM :s;
  .
  .
(Check for successful execution and put values into :h1, :h2, :h3, :h4)
  .
  .
EXEC SQL EXECUTE DEPT_INSERT USING :h1, :h2,
:h3, :h4;
```

Example 2: This EXECUTE statement uses an SQLDA.

```
EXECUTE S3 USING DESCRIPTOR :sqlda3
```

Example 3: Given a procedure to award an employee a bonus:

```
CREATE PROCEDURE GIVE_BONUS (IN EMPNO INTEGER,
                             IN DEPTNO INTEGER,
                             OUT CHECK INTEGER,
                             INOUT BONUS DEC(6,0))
...
```

Dynamically call the procedure from a C application. The procedure takes the following host variables as input:

- *employee*, the ID number of the employee
- *dept*, the department number
- *bonus*, the bonus to be awarded to the employee

The procedure returns the following values to the host variables:

- *check_no*, the ID number from the check
- *bonus*, the actual bonus amount (after any adjustments)

```
strcpy (s, "CALL GIVE_BONUS(?, ?, ?, ?)");
EXEC SQL PREPARE DO_BONUS FROM :s;
  .
  .
/* Check for successful execution and put values into
   :employee, :dept, and :bonus */
  .
  .
EXEC SQL EXECUTE DO_BONUS INTO :check_no, :bonus
                          USING :employee, :dept, :bonus;
  .
  .
/* Check for successful execution and process the
   values returned in :check_no and :bonus */
```

EXECUTE IMMEDIATE

The EXECUTE IMMEDIATE statement prepares an executable form of an SQL statement from a character string form of the statement, and executes the SQL statement.

EXECUTE IMMEDIATE combines the basic functions of the PREPARE and EXECUTE statements. It can be used to prepare and execute SQL statements that contain neither host variables nor parameter markers.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

The authorization rules are those defined for the specified SQL statement.

The authorization ID of the statement might be affected by the DYNAMICRULES bind option.

Syntax

Description

expression
An expression returning the statement string to be executed. The expression must return a character-string type that is less than the maximum statement size of 2 097 152 bytes. Note that a CLOB(2097152) can contain a maximum size statement, but a VARCHAR cannot.

The statement string must be one of the following SQL statements:

- ALTER
- CALL
- COMMENT
- COMMIT
- Compound SQL (compiled)
- Compound SQL (inlined)
- CREATE
- DECLARE GLOBAL TEMPORARY TABLE
- DELETE
- DROP
- EXPLAIN
- FLUSH EVENT MONITOR
- FLUSH PACKAGE CACHE
- GRANT
- INSERT
- LOCK TABLE
- MERGE
- REFRESH TABLE
- RELEASE SAVEPOINT
- RENAME
- REVOKE

- ROLLBACK
- SAVEPOINT
- SET COMPILATION ENVIRONMENT
- SET CURRENT DECFLOAT ROUNDING MODE
- SET CURRENT DEFAULT TRANSFORM GROUP
- SET CURRENT DEGREE
- SET CURRENT EXPLAIN MODE
- SET CURRENT EXPLAIN SNAPSHOT
- SET CURRENT FEDERATED ASYNCHRONY
- SET CURRENT IMPLICIT XMLPARSE OPTION
- SET CURRENT ISOLATION
- SET CURRENT LOCALE LC_MESSAGES
- SET CURRENT LOCALE LC_TIME
- SET CURRENT LOCK TIMEOUT
- SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION
- SET CURRENT MDC ROLLOUT MODE
- SET CURRENT OPTIMIZATION PROFILE
- SET CURRENT QUERY OPTIMIZATION
- SET CURRENT REFRESH AGE
- SET CURRENT TEMPORAL BUSINESS_TIME
- SET CURRENT TEMPORAL SYSTEM_TIME
- SET ENCRYPTION PASSWORD
- SET EVENT MONITOR STATE (only if DYNAMICRULES run behavior is in effect for the package)
- SET INTEGRITY
- SET PASSTHRU
- SET PATH
- SET ROLE (only if DYNAMICRULES run behavior is in effect for the package)
- SET SCHEMA
- SET SERVER OPTION
- SET SESSION AUTHORIZATION
- SET SQL_CCFLAGS
- SET USAGE LIST STATE (only if DYNAMICRULES run behavior is in effect for the package)
- SET variable
- TRANSFER OWNERSHIP (only if DYNAMICRULES run behavior is in effect for the package)
- TRUNCATE (only if DYNAMICRULES run behavior is in effect for the package)
- UPDATE

The statement string must not include parameter markers or references to host variables, and must not begin with EXEC SQL. It must not contain a statement terminator, with the exception of compound SQL statements which can contain semi-colons (;) to separate statements within the compound block. A compound SQL statement is used within some CREATE and ALTER statements which, therefore, can also contain semi-colons.

When an EXECUTE IMMEDIATE statement is executed, the specified statement string is parsed and checked for errors. If the SQL statement is invalid, it is not executed, and the error condition that prevents its execution is reported in the SQLCA. If the SQL statement is valid, but an error occurs during its execution, that error condition is reported in the SQLCA.

Notes

- Statement caching affects the behavior of an EXECUTE IMMEDIATE statement.

Example

Use C program statements to move an SQL statement to the host variable *qstring* (char[80]), and prepare and execute whatever SQL statement is in the host variable qstring.

```
if ( strcmp(accounts,"BIG") == 0 )
  strcpy (qstring,"INSERT INTO WORK_TABLE SELECT *
    FROM EMP_ACT WHERE ACTNO < 100");
else
  strcpy (qstring,"INSERT INTO WORK_TABLE SELECT *
    FROM EMP_ACT WHERE ACTNO >= 100");
  .
  .
  .
EXEC SQL  EXECUTE IMMEDIATE :qstring;
```

EXPLAIN

The EXPLAIN statement captures information about the access plan chosen for the supplied explainable statement and places this information into the explain tables.

An *explainable statement* can either be a valid XQuery statement or one of the following SQL statements: CALL, Compound SQL (Dynamic), DELETE, INSERT, MERGE, REFRESH, SELECT, SELECT INTO, SET INTEGRITY, UPDATE, VALUES, or VALUES INTO.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

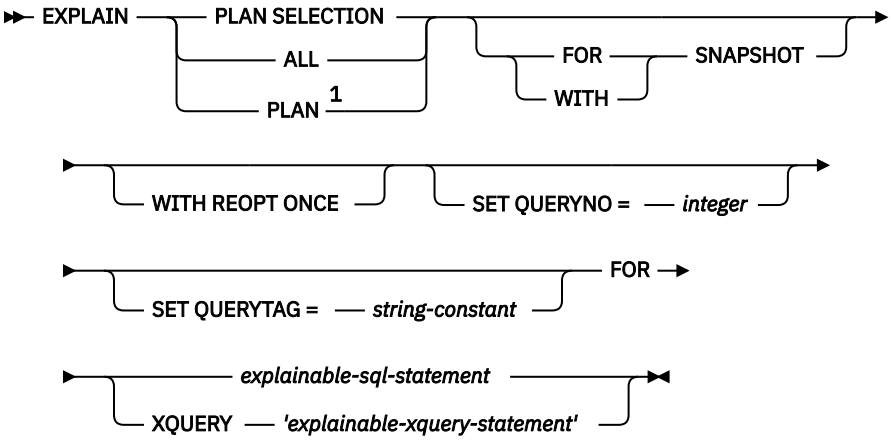
The statement to be explained is not executed.

Authorization

The authorization ID of the statement must hold at least one of the following authorizations:

- DATAACCESS authority which allows an INSERT, UPDATE, DELETE, or SELECT statement.
- DATAACCESS authority on the schema containing the explain tables
- INSERT privilege on the explain tables and at least one of the following authorizations:
  - All the privileges that are necessary to execute the explainable statement that is specified in the EXPLAIN statement (for example, if a DELETE statement is used as the explainable statement, the authorization rules for the DELETE statement are applied when the DELETE statement is explained)
  - EXPLAIN authority
  - SQLADM authority
  - DBADM authority

Syntax



Notes:

[1] The PLAN option is supported only for syntax toleration of existing Db2 for z/OS EXPLAIN statements. There is no PLAN table. Specifying PLAN is equivalent to specifying PLAN SELECTION.

Description

PLAN SELECTION
Indicates that the information from the plan selection phase of query compilation is to be inserted into the explain tables.

ALL
Specifying ALL is equivalent to specifying PLAN SELECTION.

PLAN
The PLAN option provides syntax toleration for existing database applications from other systems. Specifying PLAN is equivalent to specifying PLAN SELECTION.

FOR SNAPSHOT
This clause indicates that only an explain snapshot is to be taken and placed into the SNAPSHOT column of the EXPLAIN_STATEMENT table. No other explain information is captured other than that present in the EXPLAIN_INSTANCE and EXPLAIN_STATEMENT tables.

WITH SNAPSHOT
This clause indicates that, in addition to the regular explain information, an explain snapshot is to be taken.

The default behavior of the EXPLAIN statement is to only gather regular explain information and not the explain snapshot.

default (neither FOR SNAPSHOT nor WITH SNAPSHOT specified)
Puts explain information into the explain tables.

WITH REOPT ONCE
This clause indicates that the specified *explainable statement* is to be reoptimized using the values for host variables, parameter markers, special registers, or global variables that were previously used to reoptimize this statement with REOPT ONCE. The explain tables will be populated with the new access plan. If the user has DBADM authority, or the database registry variable DB2_VIEW_REOPT_VALUES is set to YES, the EXPLAIN_PREDICATE table will also be populated with the values if they are used to reoptimize the statement.

SET QUERYNO = *integer*
Associates *integer*, via the QUERYNO column in the EXPLAIN_STATEMENT table, with the *explainable statement*. The integer value supplied must be a positive value.

If this clause is not specified for a dynamic EXPLAIN statement, a default value of one (1) is assigned. For a static EXPLAIN statement, the default value assigned is the statement number assigned by the precompiler.

SET QUERYTAG = *string-constant*

Associates *string-constant*, via the QUERYTAG column in the EXPLAIN_STATEMENT table, with the *explainable statement*. *string-constant* can be any character string up to 20 bytes in length. If the value supplied is less than 20 bytes in length, the value is padded on the right with blanks to the required length.

If this clause is not specified for an EXPLAIN statement, blanks are used as the default value.

FOR *explainable-sql-statement*

Specifies the SQL statement to be explained. This statement can be any valid CALL, Compound SQL (Dynamic), DELETE, INSERT, MERGE, REFRESH, SELECT, SELECT INTO, SET INTEGRITY, UPDATE, VALUES, or VALUES INTO SQL statement. If the EXPLAIN statement is embedded in a program, the *explainable-sql-statement* can contain references to host variables (these variables must be defined in the program). Similarly, if EXPLAIN is being dynamically prepared, the *explainable-sql-statement* can contain parameter markers.

The *explainable-sql-statement* must be a valid SQL statement that could be prepared and executed independently of the EXPLAIN statement. It cannot be a statement name or host variable. SQL statements referring to cursors defined through CLP are not valid for use with this statement.

To explain dynamic SQL within an application, the entire EXPLAIN statement must be dynamically prepared.

FOR XQUERY *'explainable-xquery-statement'*

Specifies the XQUERY statement to be explained. This statement can be any valid XQUERY statement.

If the EXPLAIN statement is embedded in a program, the *'explainable-xquery-statement'* can contain references to host variables, provided that the host variables are not used in the top level XQUERY statement, but are passed in through an XMLQUERY function, by an XMLEXISTS predicate, or by an XMLTABLE function. The host variables must be defined in the program.

Similarly, if EXPLAIN is being dynamically prepared, the *'explainable-xquery-statement'* can contain parameter markers, provided that the same restrictions as for passing host variables are followed.

Alternatively, the Db2 XQUERY function db2-fn:sqlquery can be used to embed SQL statements with references to host variables and parameter markers.

The *'explainable-xquery-statement'* must be a valid XQUERY statement that could be prepared and executed independently of the EXPLAIN statement. Query statements referring to cursors defined through CLP are not valid for use with this statement.

Notes

- The Explain facility uses the following IDs as the schema when qualifying explain tables that it is populating:
  - The session authorization ID for dynamic SQL
  - The statement authorization ID for static SQL

  The schema can be associated with a set of explain tables, or aliases that point to a set of explain tables under a different schema. If no explain tables are found under the schema, the Explain facility checks for explain tables under the SYSTOOLS schema and attempts to use those tables.
- The following table shows the interaction of the snapshot keywords and the explain information.

Keyword Specified	Capture Explain Information?
none	Yes
FOR SNAPSHOT	No
WITH SNAPSHOT	Yes

If neither the FOR SNAPSHOT nor the WITH SNAPSHOT clause is specified, an explain snapshot is not taken.

- The explain tables must be created by the user before invocation of the EXPLAIN statement. The information generated by this statement is stored in the explain tables, in the schema that is designated at the time the statement is compiled.
- If any errors occur during the compilation of the *explainable statement* supplied, then no information is stored in the explain tables.
- The access plan generated for the *explainable statement* is not saved and thus, cannot be invoked at a later time. The explain information for the *explainable statement* is inserted when the EXPLAIN statement itself is compiled.
- For a static EXPLAIN query statement, the information is inserted into the explain tables at bind time and during an explicit rebind. During precompilation, the static EXPLAIN statements are commented out in the modified application source file. At bind time, the EXPLAIN statements are stored in the SYSCAT.STATEMENTS catalog. When the package is run, the EXPLAIN statement is not executed. Note that the section numbers for all statements in the application will be sequential and will include the EXPLAIN statements. An alternative to using a static EXPLAIN statement is to use a combination of the EXPLAIN and EXPLSNAP BIND or PREP options. Static EXPLAIN statements can be used to cause the explain tables to be populated for one specific static query statement out of many; simply prefix the target statement with the appropriate EXPLAIN statement syntax and bind the application without using either of the explain BIND or PREP options. The EXPLAIN statement can also be used when it is advantageous to set the QUERYNO or QUERYTAG field at the time of the actual explain invocation.
- Static EXPLAIN statements in an SQL procedure are evaluated when the procedure is compiled.
- For an incremental bind EXPLAIN query statement, the explain tables are populated when the EXPLAIN statement is submitted for compilation. When the package is run, the EXPLAIN statement performs no processing (though the statement will be successful). When populating the explain tables, the explain table qualifier and authorization ID used during population will be those of the package owner. The EXPLAIN statement can also be used when it is advantageous to set the QUERYNO or QUERYTAG field at the time of the actual explain invocation.
- For dynamic EXPLAIN statements, the explain tables are populated at the time the EXPLAIN statement is submitted for compilation. An EXPLAIN statement can be prepared with the PREPARE statement but, if executed, will perform no processing (though the statement will be successful). An alternative to issuing dynamic EXPLAIN statements is to use a combination of the CURRENT EXPLAIN MODE and CURRENT EXPLAIN SNAPSHOT special registers to explain dynamic query statements. The EXPLAIN statement should be used when it is advantageous to set the QUERYNO or QUERYTAG field at the time of the actual EXPLAIN invocation.
- If the REOPT bind option is set to ONCE, and either the CURRENT EXPLAIN MODE or the CURRENT EXPLAIN SNAPSHOT special register is set to REOPT, the execution of static and dynamic query statements containing host variables, special registers, parameter markers, or global variables will cause explain information to be captured for the statement only when the statement is reoptimized. Alternatively, if the REOPT bind option is set to ALWAYS, explain information will be captured every time these statements are executed.

Examples

- *Example 1:* Explain a simple SELECT statement and tag with QUERYNO = 13.

```
EXPLAIN PLAN SET QUERYNO = 13
  FOR SELECT C1
  FROM T1
```

- *Example 2:* Explain a simple SELECT statement and tag with QUERYTAG = 'TEST13'.

```
EXPLAIN PLAN SELECTION SET QUERYTAG = 'TEST13'
  FOR SELECT C1
  FROM T1
```

- *Example 3:* Explain a simple SELECT statement and tag with QUERYNO = 13 and QUERYTAG = 'TEST13'.

```
EXPLAIN PLAN SELECTION SET QUERYNO = 13 SET QUERYTAG = 'TEST13'
  FOR SELECT C1
  FROM T1
```

- *Example 4:* Attempt to get explain information when explain tables do not exist.

```
EXPLAIN ALL FOR SELECT C1
  FROM T1
```

  This statement will fail because the explain tables have not been defined (SQLSTATE 42704).

- *Example 5:* The following statement will succeed if it is found in the package cache and has already been compiled using REOPT ONCE.

```
EXPLAIN ALL WITH REOPT ONCE FOR SELECT C1
  FROM T1
  WHERE C1 = :<host variable>
```

- *Example 6:* The following example uses the db2-fn:xmlcolumn function, which takes the case- sensitive name of an XML column as an argument and returns an XML sequence that is the concatenation of XML column values.

  Consider a table called BUSINESS.CUSTOMER with an XML column called INFO. A simple XQuery that returns all documents from the INFO column is :

```
EXPLAIN PLAN SELECTION
   FOR XQUERY 'db2-fn:xmlcolumn ("BUSINESS.CUSTOMER.INFO")'
```

  If a column value is null, then the resulting return sequence for that row will be empty.

FETCH

The FETCH statement positions a cursor on the next row of its result table and assigns the values of that row to target variables.

Invocation

Although an interactive SQL facility might provide an interface that gives the appearance of interactive execution, this statement can only be embedded within an application program. It is an executable statement that cannot be dynamically prepared. When invoked using the command line processor, the syntax following *cursor-name* is optional and different from the SQL syntax.

For more information, refer to "Using command line SQL statements and XQuery statements" in *Command Reference*.

Authorization

For each global variable used as a *cursor-variable-name* or in the expression for an *array-index*, the privileges held by the authorization ID of the statement must include one of the following:

- READ privilege on the global variable that is not defined in a module
- EXECUTE privilege on the module of the global variable that is defined in a module
- EXECUTEIN privilege on the schema containing the module of the global variable that is defined in a module
- DATAACCESS authority on the schema containing the module of the global variable that is defined in a module

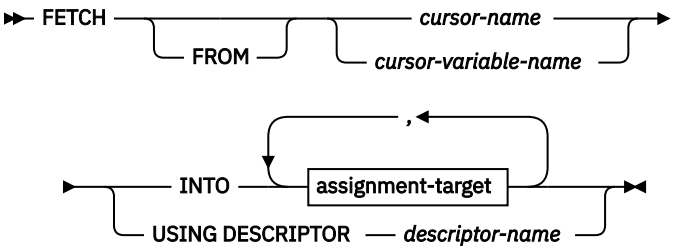
For each global variable used as an *assignment-target*, the privileges held by the authorization ID of the statement must include one of the following:

- WRITE privilege on the global variable that is not defined in a module

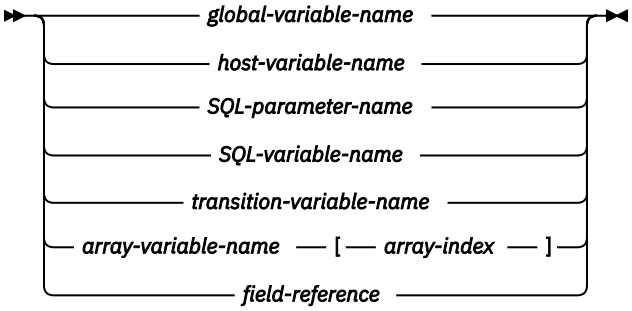
- EXECUTE privilege on the module of the global variable that is defined in a module
- EXECUTEIN privilege on the schema containing the module of the global variable that is defined in a module
- DATAACCESS authority on the schema containing the module of the global variable that is defined in a module

For the authorization required to use a cursor, see "DECLARE CURSOR".

Syntax



assignment-target



Description

cursor-variable-name

Identifies the cursor to be used in the fetch operation. The cursor-variable-name must identify a cursor variable that is in scope. When the FETCH statement is executed, the underlying cursor of the *cursor-variable-name* must be in the open state. A FETCH statement using a *cursor-variable-name* can only be used within a compound SQL (compiled) statement.

INTO *assignment-target*

Identifies one or more targets for the assignment of output values. The first value in the result row is assigned to the first target in the list, the second value to the second target, and so on. Each assignment to an *assignment-target* is made in sequence through the list. If an error occurs on any assignment, the value is not assigned to the target, and no more values are assigned to targets. Any values that have already been assigned to targets remain assigned.

When the data type of every *assignment-target* is not a row type, then the value 'W' is assigned to the SQLWARN3 field of the SQLCA if the number of *assignment-targets* is less than the number of result column values.

If the data type of an *assignment-target* is a row type, then there must be exactly one *assignment-target* specified (SQLSTATE 428HR), the number of columns must match the number of fields in the row type, and the data types of the columns of the fetched row must be assignable to the corresponding fields of the row type (SQLSTATE 42821).

If the data type of an *assignment-target* is an array element, then there must be exactly one *assignment-target* specified.

global-variable-name
Identifies the global variable that is the assignment target.

host-variable-name
Identifies the host variable that is the assignment target. For LOB output values, the target can be a regular host variable (if it is large enough), a LOB locator variable, or a LOB file reference variable.

SQL-parameter-name
Identifies the parameter that is the assignment target.

SQL-variable-name
Identifies the SQL variable that is the assignment target. SQL variables must be declared before they are used.

transition-variable-name
Identifies the column to be updated in the transition row. A *transition-variable-name* must identify a column in the subject table of a trigger, optionally qualified by a correlation name that identifies the new value.

array-variable-name
Identifies an SQL variable, SQL parameter, or global variable of an array type.

[array-index]
An expression that specifies which element in the array will be the target of the assignment. For an ordinary array, the *array-index* expression must be assignable to INTEGER (SQLSTATE 428H1) and cannot be the null value. Its value must be between 1 and the maximum cardinality defined for the array (SQLSTATE 2202E). For an associative array, the *array-index* expression must be assignable to the index data type of the associative array (SQLSTATE 428H1) and cannot be the null value.

field-reference
Identifies the field within a row type value that is the assignment target. The *field-reference* must be specified as a qualified *field-name* where the qualifier identifies the row value in which the field is defined.

USING DESCRIPTOR *descriptor-name*
Identifies an SQLDA that must contain a valid description of zero or more host variables.

Before the FETCH statement is processed, the user must set the following fields in the SQLDA:

- SQLN to indicate the number of SQLVAR occurrences provided in the SQLDA.
- SQLDABC to indicate the number of bytes of storage allocated for the SQLDA.
- SQLD to indicate the number of variables used in the SQLDA when processing the statement.
- SQLVAR occurrences to indicate the attributes of the variables.

The SQLDA must have enough storage to contain all SQLVAR occurrences. Therefore, the value in SQLDABC must be greater than or equal to 16 + SQLN*(N), where N is the length of an SQLVAR occurrence.

If LOB or structured type result columns need to be accommodated, there must be two SQLVAR entries for every select-list item (or column of the result table).

SQLD must be set to a value greater than or equal to zero and less than or equal to SQLN.

The *n*th variable described in the SQLDA corresponds to the *n*th column of the result table of the cursor. The data type of each variable must be compatible with its corresponding column.

Each assignment to a variable is made according to specific rules. If the number of variables is less than the number of values in the row, the SQLWARN3 field of the SQLDA is set to 'W'. Note that there is no warning if there are more variables than the number of result columns. If an assignment error occurs, the value is not assigned to the variable, and no more values are assigned to variables. Any values that have already been assigned to variables remain assigned.

Notes

- ***Cursor position:*** An open cursor has three possible positions:
  - Before a row
  - On a row
  - After the last row.

  A cursor can only be on a row as a result of a FETCH statement. If the cursor is currently positioned on or after the last row of the result table:
  - SQLCODE is set to +100, and SQLSTATE is set to '02000'.
  - The cursor is positioned after the last row.
  - Values are not assigned to assignment targets.

  If the cursor is currently positioned before a row, it will be repositioned on that row, and values will be assigned to targets as specified by the INTO or USING clause.

  If the cursor is currently positioned on a row other than the last row, it will be repositioned on the next row and values of that row will be assigned to targets as specified by the INTO or USING clause.

  If a cursor is on a row, that row is called the current row of the cursor. A cursor referenced in an UPDATE or DELETE statement must be positioned on a row.

  It is possible for an error to occur that makes the state of the cursor unpredictable.
- When retrieving into LOB locators in situations where it is not necessary to retain the locator across FETCH statements, it is good practice to issue a FREE LOCATOR statement before issuing the next FETCH statement, as locator resources are limited.
- It is possible that a warning may not be returned on a FETCH. It is also possible that the returned warning applies to a previously fetched row. This occurs as a result of optimizations such as the use of system temporary tables or pushdown operators.
- Statement caching affects the behavior of an EXECUTE IMMEDIATE statement.
- Db2 CLI supports additional fetching capabilities. For instance, when a cursor's result table is read-only, the SQLFetchScroll() function can be used to position the cursor at any spot within that result table.
- For an updatable cursor, a lock is obtained on a row when it is fetched.
- If the cursor definition contains an SQL data change statement or invokes a routine that modifies SQL data, an error during the fetch operation does not cause the modified rows to be rolled back, even if the error results in the cursor being closed.

Examples

- *Example 1:* In this C example, the FETCH statement fetches the results of the SELECT statement into the program variables dnum, dname, and mnum. When no more rows remain to be fetched, the not found condition is returned.

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO FROM TDEPT
    WHERE ADMRDEPT = 'A00';

EXEC SQL OPEN C1;

while (SQLCODE==0) {
    EXEC SQL FETCH C1 INTO :dnum, :dname, :mnum;
}

EXEC SQL CLOSE C1;
```

- *Example 2:* This FETCH statement uses an SQLDA.

```
FETCH CURS USING DESCRIPTOR :sqlda3
```

FLUSH BUFFERPOOLS

The FLUSH BUFFERPOOLS statement writes the dirty pages from all the local buffer pools for a particular database synchronously to disk.

In Db2 pureScale environments, the dirty pages in the group buffer pool are also written synchronously to disk.

This statement is not under transaction control.

The FLUSH BUFFERPOOLS statement can be used in the following ways:

- To reduce the recovery window of a database in the event of a failure
- To reduce the size of logs written to a backup image before database operations such as online backups
- To minimize the recovery time of a split-mirror database

Invocation

The statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include SQLADM, DBADM, SYSMAINT, SYSCTRL, or SYSADM authority.

Syntax

Description

ALL
Flushes the dirty pages from all the buffer pools (local and group).

Notes

- **Dirty pages processing:** Only the dirty pages that are in the buffer pools when the statement begins processing are written to disk. Any dirty pages that are added to the buffer pools before the statement finishes processing are not written to disk.
- **Syntax alternatives:** BUFFERPOOL can be specified in place of BUFFERPOOLS.

FLUSH EVENT MONITOR

The FLUSH EVENT MONITOR statement writes current database monitor values for all active monitor types associated with event monitor *event-monitor-name* to the event monitor I/O target.

A partial event record is available at any time for event monitors that have low record generation frequency (such as a database event monitor). Such records are noted in the event monitor log with a *partial record* identifier.

When an event monitor is flushed, its active internal buffers are written to the event monitor output object.

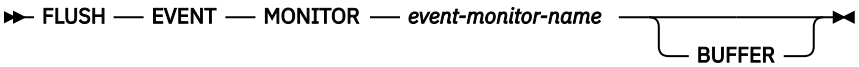
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include SQLADM or DBADM authority.

Syntax



Description

event-monitor-name
Name of the event monitor. This is a one-part name. It is an ordinary identifier.

BUFFER
Indicates that the event monitor buffers are to be written out. If BUFFER is specified, then a partial record is not generated. Only the data already present in the event monitor buffers are written out.

Notes

- Flushing out the event monitor will not cause the event monitor values to be reset. This means that the event monitor record that would have been generated if no flush was performed, will still be generated when the normal monitor event is triggered.
- The FLUSH EVENT MONITOR statement does not cause events to be generated and written for the UNIT OF WORK event monitor.

FLUSH FEDERATED CACHE

The FLUSH FEDERATED CACHE statement flushes the federated cache, allowing fresh metadata to be obtained the next time an SQL statement is issued against the remote table or view using a federated three part name.

When an SQL statement is issued against a remote table or view using a federated three part name, if the remote table or view is being referenced for the first time, the metadata and statistics for the remote object are retrieved and stored in a federated cache.

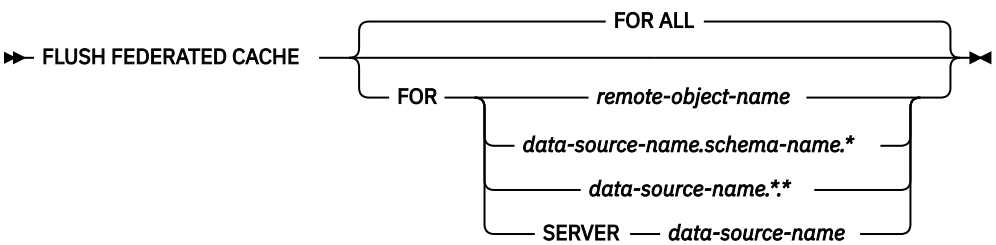
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include either SQLADM or DBADM authority.

Syntax



Description

FOR ALL
Flushes the federated cache information for all objects from all data sources. This is the default.

FOR *remote-object-name*
Flushes the federated cache information for a specific remote table or view.

FOR *data-source-name.schema-name.**
Flushes the federated cache information for all objects in the schema identified by *schema-name* from the specific data source identified by *data-source-name*.

FOR *data-source-name.*.**
Flushes the federated cache information for all objects from the specific data source identified by *data-source-name*.

FOR SERVER *data-source-name*
Flushes the federated cache information for all objects from the specific data source identified by *data-source-name*.

Notes

- **Package invalidation:** Flushing the federated cache causes packages with a dependency on the three-part name to be invalidated. This action could have a performance impact since the invalidated packages need to be recompiled whenever statements from the package are executed.
- **View invalidation:** Flushing the federated cache will not cause the views depending on the three part name to be invalidated. The next time the view is used, it will implicitly revalidate the view. If there are changes to the remote object, it is possible that the statement using the view could return an error.

Examples

- *Example 1*: Flush the federated cache information for the remote-table-name *t1* in the remote-schema-name *rschema* on the data source *rudb*.

```
FLUSH FEDERATED CACHE FOR rudb.rschema.t1
```

- *Example 2*: Flush the federated cache information for all objects in the remote-schema-name *rschema* on the data source *rudb*.

```
FLUSH FEDERATED CACHE FOR rudb.rschema.*
```

- *Example 3*: Flush the federated cache information for all objects from the data source *rudb*.

```
FLUSH FEDERATED CACHE FOR rudb.*.*
```

An alternative to this syntax is as follows:

```
FLUSH FEDERATED CACHE FOR SERVER rudb
```

FLUSH OPTIMIZATION PROFILE CACHE

Multiple statements can be compiled using the same optimization profile.

To make optimization profile processing more efficient, the optimization profile is processed the first time it is used to optimize a statement, and the output is stored in the optimization profile cache. Subsequent references to the optimization profile use the processed version in the optimization profile cache.

An optimization profile should be removed from the optimization profile cache when the version stored in SYSTOOLS.OPT_PROFILE has been updated. When the old version is removed from the cache, the new version will be used upon optimization of subsequent statements that use the optimization profile.

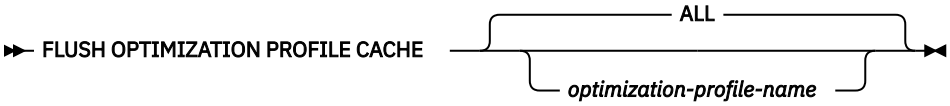
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include either SQLADM or DBADM authority (SQLSTATE 42502).

Syntax



Description

optimization-profile-name
Specifies the name of the optimization profile to be flushed from the optimization profile cache. If the name specified is unqualified, the value of the CURRENT DEFAULT SCHEMA register is used as the implicit qualifier.

ALL
Specifies that all profiles on all active database partitions be flushed from the optimization profile cache.

Notes

- The FLUSH OPTIMIZATION PROFILE CACHE statement removes all or a single optimization profile from the optimization profile cache. It also causes the logical invalidation of any cached dynamic SQL statements that were prepared with that optimization profile.
- New access plans for any invalidated dynamic plans are regenerated when the next request for the same SQL statement is made.
- Packages that reference an optimization profile removed from the optimization profile cache by this statement must be explicitly bound again to allow new access plans to be generated.

Examples

- *Example 1:* The optimization profile "Rick"."Foo" is flushed from the optimization profile cache.

```
SET CURRENT SCHEMA = '"Rick"'
FLUSH OPTIMIZATION PROFILE CACHE "Foo"
```

- *Example 2:* The optimization profile JOHN.ALL is removed from the optimization profile cache.

```
SET CURRENT SCHEMA = '"Rick"'
FLUSH OPTIMIZATION PROFILE CACHE JOHN.ALL
```

Messages

- No errors are issued if the optimization profile cache is empty or if the specified optimization profiles (specified explicitly or implicitly) do not exist in the optimization profile cache.

FLUSH PACKAGE CACHE

The FLUSH PACKAGE CACHE statement invalidates cached dynamic SQL statements in the package cache. This invalidation causes the next request for any SQL statement that matches an invalidated cached dynamic SQL statement to be compiled instead of reused from the package cache.

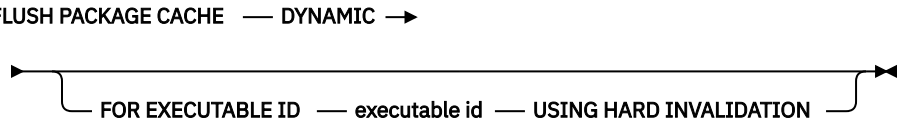
Invocation

This statement can be embedded in an application program or issued by using dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

The privileges that are held by the authorization ID of the statement must include SQLADM or DBADM authority.

Syntax



FOR EXECUTABLE ID executable id
An input argument of type VARCHAR(32) FOR BIT DATA that contains the executable ID used to identify the section to be removed from the package cache. The executable ID cannot represent a static section (4274L). If the executable ID does not map to a currently cached entry, no action will be taken and an error will be returned (4274L).

USING HARD INVALIDATION
Specifies that, if the identified package cache entries to be invalidated are currently being used, the FLUSH PACKAGE CACHE statement will wait until the entry is no longer being used before completing the invalidation.

Notes

- This statement affects all cached dynamic SQL entries in the package cache on all active database partitions.
- As cached dynamic SQL statements are invalidated, the package cache memory that is used for the cached entry is freed if the entry is not in use when the FLUSH PACKAGE CACHE statement runs. Entries are not evicted during the FLUSH PACKAGE CACHE statement if the FOR EXECUTABLE ID clause is used. If the entry still remains in the cache after the statement is executed, the VALID element for that entry will indicate that it is invalid and subsequent requests for that statement will cause a new compilation.
- Any cached dynamic SQL statement currently in use is allowed to continue to exist in the package cache until it is no longer needed by the current user. The next new user of the same statement will force an implicit prepare of the statement, and the new user will run the new version of the cached dynamic SQL statement.

Examples

To mark all cached dynamic SQL entries invalid to force them to be prepared again:

```
FLUSH PACKAGE CACHE DYNAMIC
```

To force a specific cached entry out of the cache, find the target executable ID:

```
select section_type, executable_id, substr(stmt_text, 1, 30) as stmt_text from table
(mon_get_pkg_cache_stmt(null, null, null, -1)) where stmt_text like 'VALUES (17+30)%'

SECTION_TYPE EXECUTABLE_ID
```

```
STMT_TEXT
------------ ------------------------------------------------------------------
------------------------------
D            x'00000001000000000000000000000001000000000002201902201551126783 01' VALUES
(17+30)

  1 record(s) selected.
```

And then issue the command to force it out:

```
flush package cache dynamic for executable id
x'00000001000000000000000000000001000000000002201902201551126783 01' using hard invalidation
DB20000I  The SQL command completed successfully.
```

FLUSH AUTHENTICATION CACHE

The FLUSH AUTHENTICATION CACHE statement flushes the Db2 authentication cache of all entries, allowing fresh entries to be cached. Running this statement will perform the flush on all database members in which the cache is present.
When the Db2 authentication cache is active, each new authentication request made with a username and password is compared against existing, valid entries in the cache. If a match is found, the authentication request is deemed to be successful and processing continues. If a match is not found, the authentication request is processed and, if successful, the result is placed as a new entry in the cache.

Invocation

This statement can be issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include either SECADM or DBADM authority.

Syntax

Description

FOR ALL
Flushes the authentication cache information for all users. This is the default.

Example

- Flush the authentication cache information for all entries with the following command:

```
FLUSH AUTHENTICATION CACHE
```

FOR

The FOR statement executes a statement or group of statements for each row of a table.

Invocation

This statement can be embedded in an:

- SQL procedure definition
- Compound SQL (compiled) statement

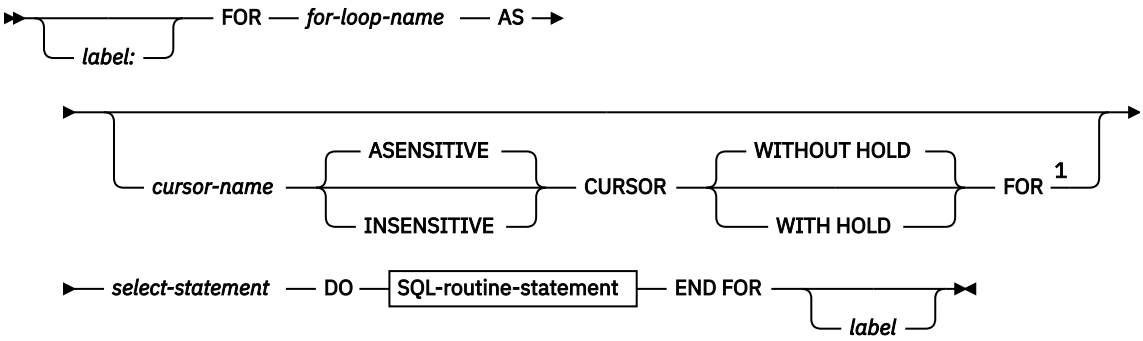
- Compound SQL (inlined) statement

The compound statements can be embedded in an SQL procedure definition, SQL function definition, or SQL trigger definition. It is not an executable statement and cannot be dynamically prepared.

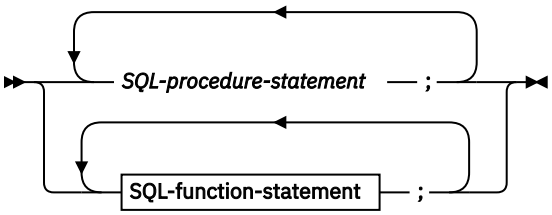
Authorization

No privileges are required to invoke the FOR statement. However, the authorization ID of the statement must hold the necessary privileges to invoke the SQL statements that are embedded in the FOR statement. For the authorization required to use a cursor, see "DECLARE CURSOR".

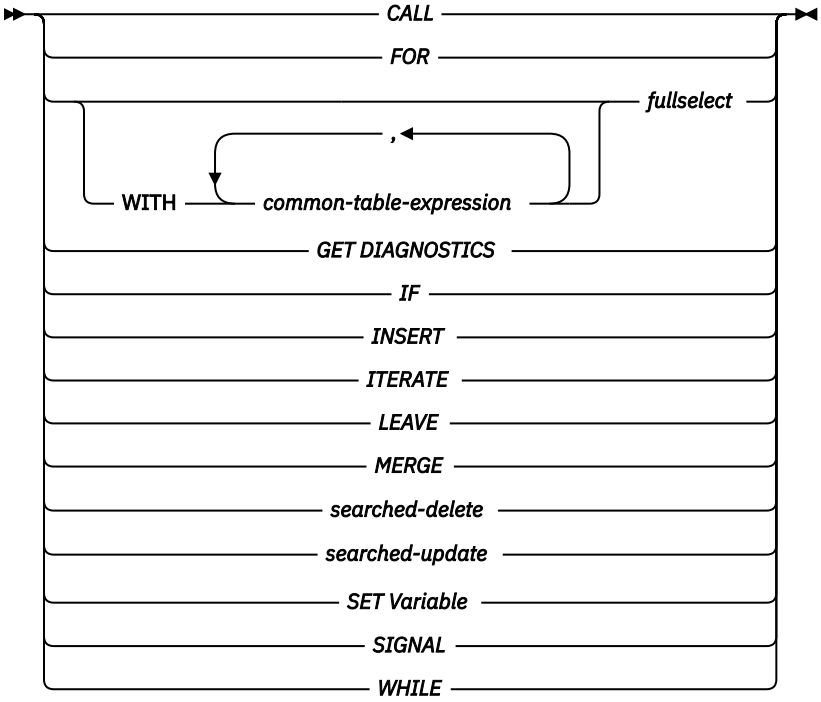
Syntax



SQL-routine-statement



SQL-function-statement



Notes:

[1] This option can only be used in the context of an SQL procedure or a compound SQL (compiled) statement.

Description

label
Specifies the label for the FOR statement. If the beginning label is specified, that label can be used in LEAVE and ITERATE statements. If the ending label is specified, it must be the same as the beginning label.

for-loop-name
Specifies a label for the implicit compound statement generated to implement the FOR statement. It follows the rules for the label of a compound statement except that it cannot be used with an ITERATE or LEAVE statement within the FOR statement. The *for-loop-name* is used to qualify the column names returned by the specified *select-statement*.

cursor-name
Names the cursor that is used to select rows from the result table of the SELECT statement. If not specified, the database manager generates a unique cursor name. For a description of ASENSITIVE, INSENSITIVE, WITHOUT HOLD, or WITH HOLD, see "DECLARE CURSOR".

select-statement
Specifies the SELECT statement of the cursor. All columns in the select list must have a name and there cannot be two columns with the same name.

In a trigger, function, method, or compound SQL (inlined) statement, the *select-statement* must consist of only a *fullselect* with optional common table expressions.

SQL-procedure-statement
Specifies one or more statements to be invoked for each row of the table. *SQL-procedure-statement* is only applicable when in the context of an SQL procedure or within a compound SQL (compiled) statement. See *SQL-procedure-statement* in "Compound SQL (compiled)" statement.

SQL-function-statement
Specifies one or more statements to be invoked for each row of the table. A searched-update, searched-delete, or INSERT operation on nicknames is not supported. *SQL-function-statement* is only applicable when in the context of an SQL function or SQL method.

Rules

- The select list must consist of unique column names and the objects specified in the *select-statement* must exist when the procedure is created, or the object must be created in a previous SQL procedure statement.
- The cursor specified in a for-statement cannot be referenced outside the for-statement and cannot be specified in an OPEN, FETCH, or CLOSE statement.

Example

In the following example, the for-statement is used to iterate over the entire `employee` table. For each row in the table, the SQL variable `fullname` is set to the last name of the employee, followed by a comma, the first name, a blank space, and the middle initial. Each value for `fullname` is inserted into table `tnames`.

```
BEGIN ATOMIC
  DECLARE fullname CHAR(40);
  FOR vl AS
    SELECT firstnme, midinit, lastname FROM employee
      DO
      SET fullname = lastname CONCAT ','
        CONCAT firstnme CONCAT ' ' CONCAT midinit;
      INSERT INTO tnames VALUES (fullname);
  END FOR;
END
```

FREE LOCATOR

The FREE LOCATOR statement removes the association between a large object locator variable and its value.

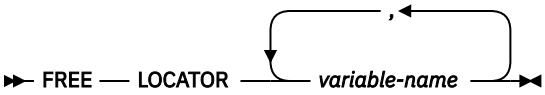
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

LOCATOR *variable-name, ...*

Identifies one or more large object locator variables that must be declared in accordance with the rules for declaring locator variables.

The locator-variable must currently have a locator assigned to it. That is, a locator must have been assigned during this unit of work (by a CALL, FETCH, SELECT INTO, or VALUES INTO statement) and must not subsequently have been freed (by a FREE LOCATOR statement); otherwise, an error is returned (SQLSTATE 0F001).

If more than one locator is specified, all locators that can be freed will be freed, regardless of errors detected in other locators in the list.

Example

In a COBOL program, free the BLOB locator variables TKN-VIDEO and TKN-BUF and the CLOB locator variable LIFE-STORY-LOCATOR.

```
EXEC SQL
FREE LOCATOR :TKN-VIDEO, :TKN-BUF, :LIFE-STORY-LOCATOR
END-EXEC.
```

GET DIAGNOSTICS

The GET DIAGNOSTICS statement is used to obtain current execution environment information including information about the previous SQL statement (other than a GET DIAGNOSTICS statement) that was executed. Some of the information available through the GET DIAGNOSTICS statement is also available in the SQLCA.

Invocation

This statement can be embedded in an:

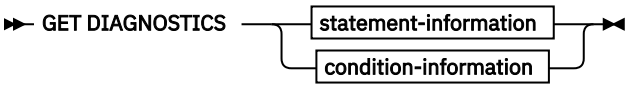
- SQL procedure definition
- Compound SQL (compiled) statement
- Compound SQL (inlined) statement

The compound statements can be embedded in an SQL procedure definition, SQL function definition, or SQL trigger definition. It is not an executable statement and cannot be dynamically prepared.

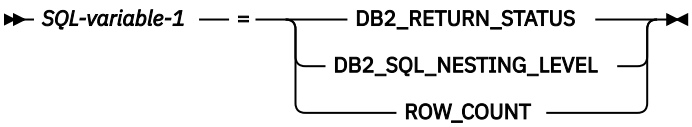
Authorization

None required.

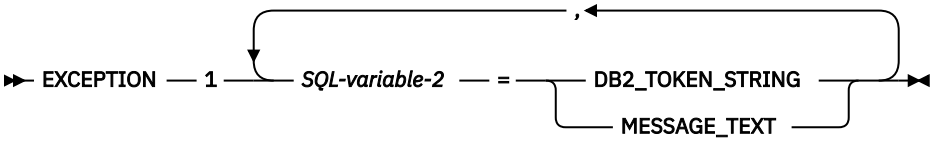
Syntax



statement-information



condition-information



Description

statement-information

Returns information about the last SQL statement executed.

SQL-variable-1

Identifies the variable that is the assignment target. The variable must not be a global variable. SQL variables can be defined in a compound statement. The data type of the variable must be compatible with the data type as specified in Table 151 on page 1673.

DB2_RETURN_STATUS

Identifies the status value returned from the procedure associated with the previously executed SQL statement, provided that the statement was a CALL statement invoking a procedure that returns a status. If the previous statement is not such a statement, then the value returned has no meaning and could be any integer.

DB2_SQL_NESTING_LEVEL

Identifies the current level of nesting or recursion in effect when the GET DIAGNOSTICS statement was executed. Each level of nesting corresponds to a nested or recursive invocation of a compiled SQL function, compiled SQL procedure, compiled trigger, or dynamically prepared compound SQL (compiled) statement. If the GET DIAGNOSTICS statement is executed outside of a level of nesting, the value zero is returned. This option can be specified only in the context of a compiled SQL function, compiled SQL procedure, compiled trigger, or compound SQL (compiled) statement (SQLSTATE 42601).

ROW_COUNT

Identifies the number of rows associated with the previous SQL statement. If the previous SQL statement is a DELETE, INSERT, or UPDATE statement, ROW_COUNT identifies the number of rows that qualified for the operation. If the previous statement is a PREPARE statement, ROW_COUNT identifies the *estimated* number of result rows in the prepared statement.

condition-information

Specifies that the error or warning information for the previously executed SQL statement is to be returned. If information about an error is needed, the GET DIAGNOSTICS statement must be the first statement specified in the handler that will handle the error. If information about a warning is needed, and if the handler will get control of the warning condition, the GET DIAGNOSTICS statement must be the first statement specified in that handler. If the handler will *not* get control of the warning condition, the GET DIAGNOSTICS statement must be the next statement executed. This option can only be specified in the context of an SQL Procedure (SQLSTATE 42601).

SQL-variable-2
Identifies the variable that is the assignment target. The variable must not be a global variable. SQL variables can be defined in a compound statement. The data type of the variable must be compatible with the data type as specified in Table 151 on page 1673.

DB2_TOKEN_STRING
Identifies any error or warning message tokens returned from the previously executed SQL statement. If the statement completed with an SQLCODE of zero, or if the SQLCODE had no tokens, an empty string is returned for a VARCHAR variable or blanks are returned for a CHAR variable.

MESSAGE_TEXT
Identifies any error or warning message text returned from the previously executed SQL statement. The message text is returned in the language of the database server where the statement is processed. If the statement completed with an SQLCODE of zero, an empty string is returned for a VARCHAR variable or blanks are returned for a CHAR variable.

Notes

- The GET DIAGNOSTICS statement does not change the contents of the diagnostics area (SQLCA). If an SQLSTATE or SQLCODE special variable is declared in the SQL procedure, these are set to the SQLSTATE or SQLCODE returned from issuing the GET DIAGNOSTICS statement.
- **Data types for items**: The following table shows the SQL data type for each diagnostic item. When a diagnostic item is assigned to a variable, the data type of the variable must be compatible with the data type of the requested diagnostic item.

Table 151. Data types for GET DIAGNOSTICS items

Type of information	Item	Data type
Statement information	DB2_RETURN_STATUS	INTEGER
Statement information	DB2_SQL_NESTING_LEVEL	INTEGER
Statement information	ROW_COUNT	DECIMAL(31,0)
Condition information	DB2_TOKEN_STRING	VARCHAR(1000)
Condition information	MESSAGE_TEXT	VARCHAR(32672)

- ***Syntax alternatives***: The following are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - RETURN_STATUS can be specified in place of DB2_RETURN_STATUS.

Examples

- *Example 1*: In an SQL procedure, execute a GET DIAGNOSTICS statement to determine how many rows were updated.

```
CREATE PROCEDURE sqlprocg (IN deptnbr VARCHAR(3))
   LANGUAGE SQL
   BEGIN
      DECLARE SQLSTATE CHAR(5);
      DECLARE rcount INTEGER;
      UPDATE CORPDATA.PROJECT
         SET PRSTAFF = PRSTAFF + 1.5
         WHERE DEPTNO = deptnbr;
      GET DIAGNOSTICS rcount = ROW_COUNT;
-- At this point, rcount contains the number of rows that were updated.
...
   END
```

- *Example 2*: Within an SQL procedure, handle the returned status value from the invocation of a procedure called TRYIT that could either explicitly RETURN a positive value indicating a user failure, or

encounter SQL errors that would result in a negative return status value. If the procedure is successful, it returns a value of zero.

```
CREATE PROCEDURE TESTIT ()
   LANGUAGE SQL
   A1:BEGIN
      DECLARE RETVAL INTEGER DEFAULT 0;
      ...
      CALL TRYIT;
      GET DIAGNOSTICS RETVAL = DB2_RETURN_STATUS;
      IF RETVAL <> 0 THEN
         ...
         LEAVE A1;
      ELSE
         ...
      END IF;
   END A1
```

GOTO

The GOTO statement is used to branch to a user-defined label within an SQL procedure.

Invocation

This statement can only be embedded in an SQL procedure. It is not an executable statement and cannot be dynamically prepared.

Authorization

None required.

Syntax

Description

label

Specifies a labelled statement where processing is to continue. The labelled statement and the GOTO statement must be in the same scope:

- If the GOTO statement is defined in a FOR statement, *label* must be defined inside the same FOR statement, excluding a nested FOR statement or nested compound statement
- If the GOTO statement is defined in a compound statement, *label* must be defined inside the same compound statement, excluding a nested FOR statement or nested compound statement
- If the GOTO statement is defined in a handler, *label* must be defined in the same handler, following the other scope rules
- If the GOTO statement is defined outside of a handler, *label* must not be defined within a handler.

If *label* is not defined within a scope that the GOTO statement can reach, an error is returned (SQLSTATE 42736).

Notes

- It is recommended that the GOTO statement be used sparingly. This statement interferes with normal processing sequences, thus making a routine more difficult to read and maintain. Before using a GOTO statement, determine whether another statement, such as IF or LEAVE, can be used in place, to eliminate the need for a GOTO statement.

Example

In the following compound statement, the parameters *rating* and *v_empno* are passed into the procedure, which then returns the output parameter *return_parm* as a date duration. If the employee's time in service with the company is less than 6 months, the GOTO statement transfers control to the end of the procedure, and *new_salary* is left unchanged.

```
CREATE PROCEDURE adjust_salary
  (IN v_empno CHAR(6),
  IN rating INTEGER,
  OUT return_parm DECIMAL (8,2))
  MODIFIES SQL DATA
  LANGUAGE SQL
  BEGIN
    DECLARE new_salary DECIMAL (9,2);
    DECLARE service DECIMAL (8,2);
      SELECT SALARY, CURRENT_DATE - HIREDATE
        INTO new_salary, service
        FROM EMPLOYEE
        WHERE EMPNO = v_empno;
      IF service < 600
        THEN GOTO EXIT;
      END IF;
      IF rating = 1
        THEN SET new_salary = new_salary + (new_salary * .10);
      ELSEIF rating = 2
        THEN SET new_salary = new_salary + (new_salary * .05);
      END IF;
      UPDATE EMPLOYEE
        SET SALARY = new_salary
        WHERE EMPNO = v_empno;
      EXIT: SET return_parm = service;
END
```

GRANT (database authorities)

This form of the GRANT statement grants authorities that apply to the entire database (rather than privileges that apply to specific objects within the database).

Invocation

This statement can be embedded in an application program or issued by using dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

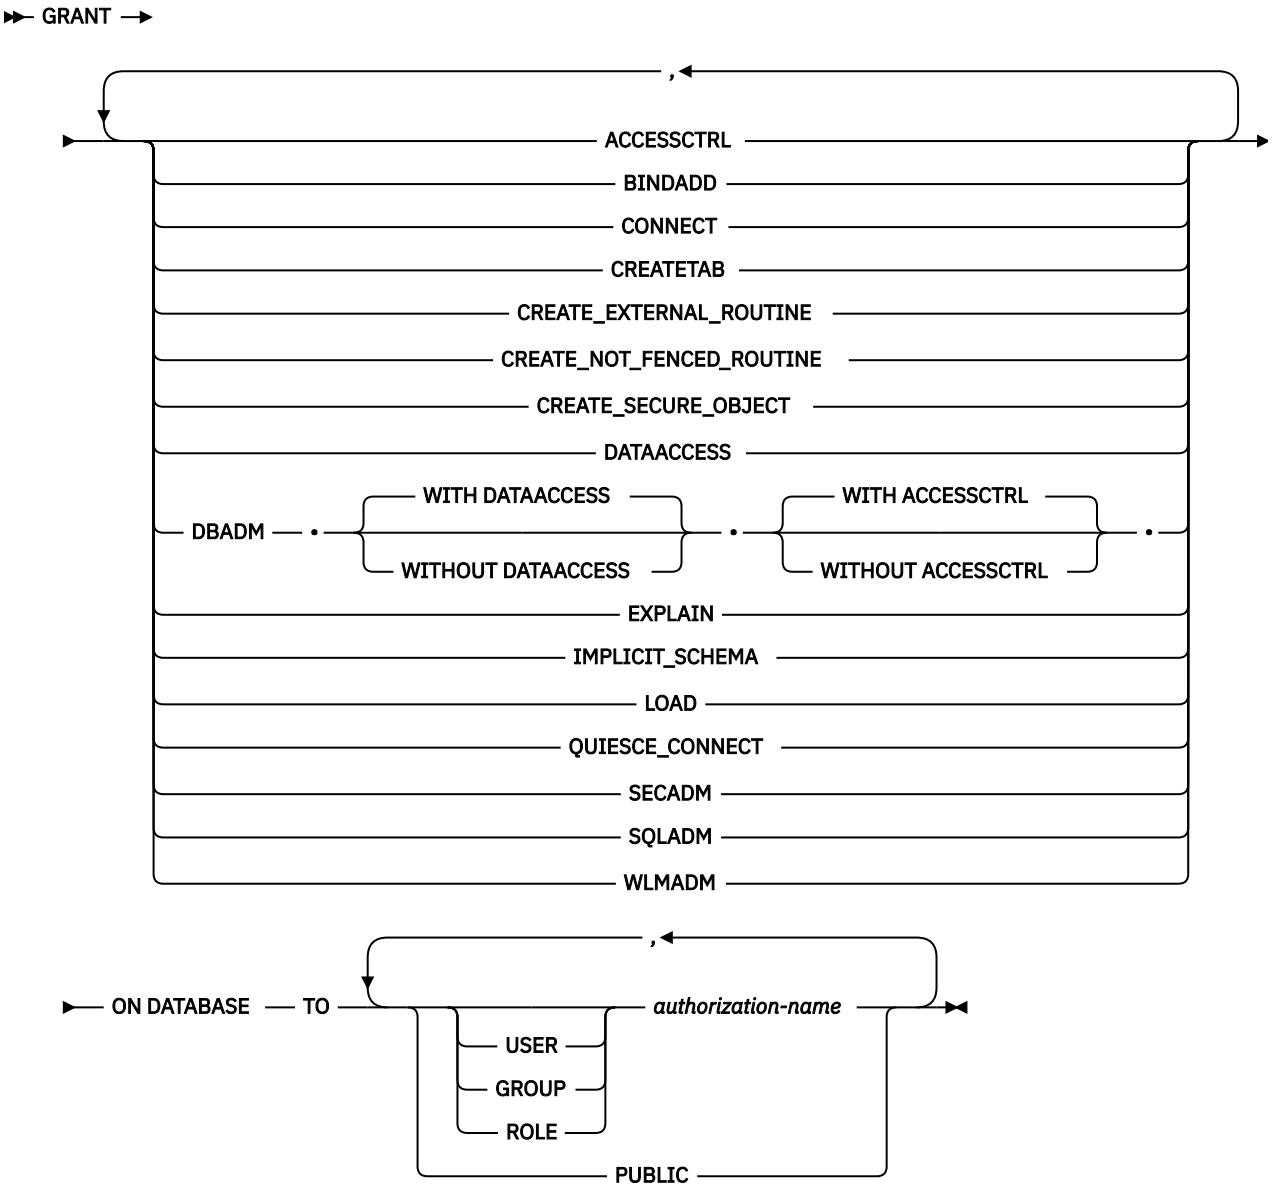
Authorization

To grant ACCESSCTRL, CREATE_SECURE_OBJECT, DATAACCESS, DBADM, or SECADM authority, SECADM authority is needed.

Note: In Db2 11.5.7 and later, to grant CREATE_EXTERNAL_ROUTINE authority, SYSADM authority is needed. If the DB2_ALTERNATE_AUTHZ_BEHAVIOUR registry variable is set and contains the value EXTERNAL_ROUTINE_DBAUTH, then SYSADM, SECADM, or ACCESSCTRL authority is needed.
Also, in Db2 11.5.7 and later, to grant CREATE_NOT_FENCED_ROUTINE authority, SYSADM authority is needed. If the DB2_ALTERNATE_AUTHZ_BEHAVIOUR registry variable is set and contains the value NOT_FENCED_ROUTINE_DBAUTH, then SYSADM, SECADM, or ACCESSCTRL authority is needed.

To grant other authorities ACCESSCTRL or SECADM authority is needed.

Syntax



Description

ACCESSCTRL

Grants the access control authority. The ACCESSCTRL authority allows the holder to:

- Grant and revoke the following database authorities: BINDADD, CONNECT, CREATETAB, CREATE_EXTERNAL_ROUTINE, CREATE_NOT_FENCED_ROUTINE, EXPLAIN, IMPLICIT_SCHEMA, LOAD, QUIESCE_CONNECT, SQLADM, WLMADM
- Grant and revoke all object level privileges.

The ACCESSCTRL authority cannot be granted to PUBLIC (SQLSTATE 42508).

BINDADD

Grants the authority to create packages. The creator of a package automatically has the CONTROL privilege on that package and retains this privilege even if the BINDADD authority is later revoked.

CONNECT

Grants the authority to access the database.

CREATETAB
Grants the authority to create base tables. The creator of a base table automatically has the CONTROL privilege on that table. The creator retains this privilege even if the CREATETAB authority is later revoked.

No explicit authority is needed for view creation. A view can be created at any time if the authorization ID of the statement that is used to create the view has either CONTROL or SELECT privilege on each base table of the view.

CREATE_EXTERNAL_ROUTINE
Grants the authority to register external routines. Care must be taken that routines so registered do not have adverse side effects. (For more information, see the description of the THREADSAFE clause in “CREATE PROCEDURE (external) ” on page 1292).

After an external routine has been registered, it continues to exist, even if CREATE_EXTERNAL_ROUTINE is later revoked.

CREATE_NOT_FENCED_ROUTINE
Grants the authority to register routines that run in the database manager's process. Care must be taken that routines so registered do not have adverse side effects. (For more information, see the description of the FENCED clause on the “CREATE PROCEDURE (external) ” on page 1292).

After a routine is registered as not fenced, it continues to run in this manner, even if CREATE_NOT_FENCED_ROUTINE is later revoked.

CREATE_EXTERNAL_ROUTINE is automatically granted to an *authorization-name* that is granted CREATE_NOT_FENCED_ROUTINE authority.

CREATE_SECURE_OBJECT
Grants the authority to create secure triggers and secure functions. Grants the authority to alter the secure attribute of such objects as well.

DATAACCESS
Grants the authority to access data. The DATAACCESS authority allows the holder to:

- Select, insert, update, delete, and load data.
- Run any package.
- Run any routine (except audit routines).

The DATAACCESS authority cannot be granted to PUBLIC (SQLSTATE 42508).

DBADM
Grants the database administrator authority. A database administrator holds nearly all privileges on nearly all objects in the database. The only exceptions are those privileges that are part of the access control, data access, and security administrator authorities. DBADM cannot be granted to PUBLIC.

EXPLAIN
Grants the authority to explain statements. The EXPLAIN authority allows the holder to explain, prepare, and describe dynamic and static SQL statements without requiring access to data.

IMPLICIT_SCHEMA
Grants the authority to implicitly create a schema.

LOAD
Grants the authority to load in this database. This authority gives a user the right to use the LOAD utility in this database. DATAACCESS and DBADM also have this authority by default. However, if a user only has LOAD authority (not DATAACCESS), the user is also needs to have table-level privileges. In addition to LOAD privilege, the user needs to have:

- INSERT privilege on the table for LOAD with mode INSERT, TERMINATE (to terminate a previous LOAD INSERT), or RESTART (to restart a previous LOAD INSERT).
- INSERT and DELETE privilege on the table for LOAD with mode REPLACE, TERMINATE (to terminate a previous LOAD REPLACE), or RESTART (to restart a previous LOAD REPLACE).
- INSERT privilege on the exception table, if such a table is used as part of LOAD.

QUIESCE_CONNECT
Grants the authority to access the database while it is quiesced.

SECADM
Grants the security administrator authority. The authority allows the holder to:

- Create and drop security objects such as audit policies, roles, security labels, security label components, security policies, and trusted contexts.
- Grant and revoke authorities, exemptions, privileges, roles, and security labels.
- Grant and revoke the SETSESSIONUSER privilege.
- Run TRANSFER OWNERSHIP on objects that are owned by others.

The SECADM authority cannot be granted to PUBLIC (SQLSTATE 42508).

SQLADM
Grants the authority to manage SQL statement execution. The SQLADM authority allows the holder to:

- Create, drop, flush, and set event monitors.
- Explain, prepare, and describe dynamic and static SQL statements without requiring access to data.
- Flush optimization profile cache
- Flush package cache
- Execute the runstats utility.
- Create, alter, drop, and set usage lists.

WLMADM
Grants the authority to manage workloads. The WLMADM authority allows the holder to:

- Create, drop, and alter service classes, thresholds, work action sets, work class sets, or workloads.

TO
Specifies to whom the authorities are granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Grants the authorities to a set of users (authorization IDs).

Rules

- For each *authorization-name* specified, if neither USER, GROUP, or ROLE is specified, then:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database, and as either GROUP or USER according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).

- If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
- If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.
- If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.

Notes

- ACCESSCTRL, CREATE_SECURE_OBJECT, DATAACCESS, DBADM, or SECADM authorities cannot be granted to the special group PUBLIC. Therefore, granting ACCESSCTRL, CREATE_SECURE_OBJECT, DBADM, DATAACCESS, or SECADM authority to a role *role-name* fails if *role-name* is granted to PUBLIC either directly or indirectly (SQLSTATE 42508).
  - Role *role-name* is granted directly to PUBLIC if the following statement has been issued:

    ```
    GRANT ROLE role-name TO PUBLIC
    ```

  - Role *role-name* is granted indirectly to PUBLIC if the following statements have been issued:

    ```
    GRANT ROLE role-name TO ROLE role-name2
    GRANT ROLE role-name2 TO PUBLIC
    ```

- ***Syntax alternatives***: The following are supported for compatibility with previous versions of Db2 and with other database products.
  - CREATE_NOT_FENCED can be specified in place of CREATE_NOT_FENCED_ROUTINE.
  - SYSTEM can be specified in place of DATABASE.
- ***Privileges granted to a group***: A privilege that is granted to a group is not used for authorization checking on:
  - Static DML statements in a package
  - A base table while processing a CREATE VIEW statement
  - A base table while processing a CREATE TABLE statement for a materialized query table
  - Create SQL routine
  - Create trigger
- WITH GRANT OPTION is ignored when granting database authorities.

Examples

- *Example 1:* Give the users WINKEN, BLINKEN, and NOD the authority to connect to the database.

  ```
  GRANT CONNECT ON DATABASE TO USER WINKEN, USER BLINKEN, USER NOD
  ```

- *Example 2:* Grant BINDADD authority on the database to a group named D024. Both a group and a user called D024 exist in the system.

  ```
  GRANT BINDADD ON DATABASE TO GROUP D024
  ```

  Observe that, the GROUP keyword must be specified; otherwise, an error will occur since both a user and a group named D024 exist. Any member of the D024 group will be allowed to bind packages in the database, but the D024 user will not be allowed (unless this user is also a member of the group D024, had been granted BINDADD authority previously, or BINDADD authority had been granted to another group of which D024 was a member).

- *Example 3:* Give user Walid security administrator authority.

  ```
  GRANT SECADM ON DATABASE TO USER Walid
  ```

- *Example 4:* A user with SECADM authority grants the CREATE_SECURE_OBJECT authority to user Haytham.

```
GRANT CREATE_SECURE_OBJECT ON DATABASE TO USER HAYTHAM
```

GRANT (exemption)

This form of the GRANT statement grants to a user, group, or role an exemption on an access rule for a specified label-based access control (LBAC) security policy.

When the user holding the exemption accesses data in a table protected by that security policy the indicated rule will not be enforced when deciding if they can access the data.

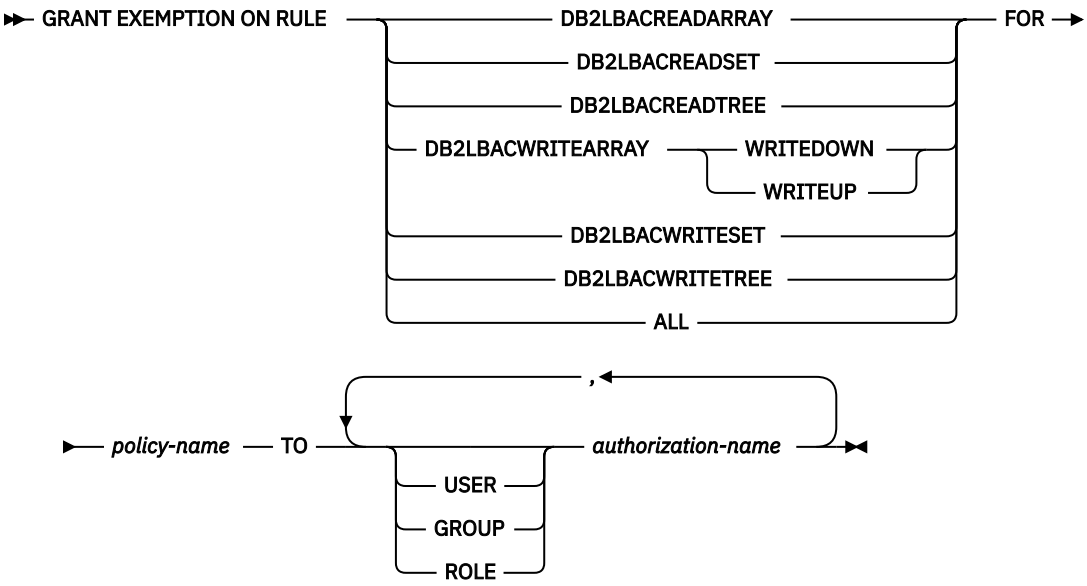
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Description

EXEMPTION ON RULE
Grants an exemption on an access rule.

DB2LBACREADARRAY
Grants an exemption on the predefined DB2LBACREADARRAY rule.

DB2LBACREADSET
Grants an exemption on the predefined DB2LBACREADSET rule.

DB2LBACREADTREE
Grants an exemption on the predefined DB2LBACREADTREE rule.

DB2LBACWRITEARRAY
Grants an exemption on the predefined DB2LBACWRITEARRAY rule.

WRITEDOWN
Specifies that the exemption only applies to write down.

WRITEUP
Specifies that the exemption only applies to write up.

DB2LBACWRITESET
Grants an exemption on the predefined DB2LBACWRITESET rule.

DB2LBACWRITETREE
Grants an exemption on the predefined DB2LBACWRITETREE rule.

ALL
Grants an exemption on all of the predefined rules.

FOR *policy-name*
Identifies the security policy for which the exemption is being granted. The exemption will only be effective for tables that are protected by this security policy. The name must identify a security policy already described in the catalog (SQLSTATE 42704).

TO
Specifies to whom the exemption is granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database, and as either GROUP or USER according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.
  - If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.
- If the security policy is not defined to consider access through groups or roles, any exemption granted to a group or role is ignored when access is attempted.

Notes

- By default when a security policy is created, only exemptions granted to an individual user are considered. To have groups or roles considered for the security policy, you must issue the ALTER SECURITY POLICY statement and specify USE GROUP AUTHORIZATION or USE ROLE AUTHORIZATION as applicable.

Examples

- *Example 1:* Grant an exemption on access rule DB2LBACREADSET for security policy DATA_ACCESS to user WALID.

```
GRANT EXEMPTION ON RULE DB2LBACREADSET FOR DATA_ACCESS TO USER WALID
```

- *Example 2:* Grant an exemption on access rule DB2LBACWRITEARRAY with the WRITEDOWN option for security policy DATA_ACCESS to user BOBBY.

```
GRANT EXEMPTION ON RULE DB2LBACWRITEARRAY WRITEDOWN
  FOR DATA_ACCESS TO USER BOBBY
```

- *Example 3:* Grant an exemption on access rule DB2LBACWRITEARRAY with the WRITEUP option for security policy DATA_ACCESS to user BOBBY.

```
GRANT EXEMPTION ON RULE DB2LBACWRITEARRAY WRITEUP
  FOR DATA_ACCESS TO USER BOBBY
```

GRANT (global variable privileges)

This form of the GRANT statement grants one or more privileges on a created global variable.

Invocation

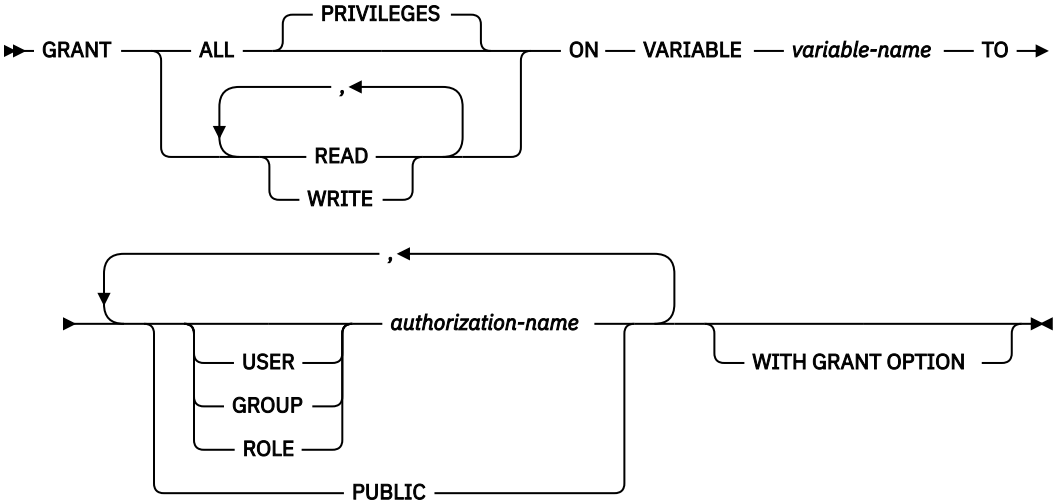
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- The WITH GRANT OPTION for each identified privilege on the global variable
- ACCESSCTRL authority on the schema containing the global variable
- ACCESSCTRL or SECADM authority

Syntax



Description

ALL PRIVILEGES
Grants all privileges on the specified global variable.

READ
Grants the privilege to read the value of the specified global variable.

WRITE
Grants the privilege to assign a value to the specified global variable.

ON VARIABLE *variable-name*
Identifies the global variable on which one or more privileges are to be granted. The *variable-name*, including an implicit or explicit qualifier, must identify a global variable that exists at the current server and is not a module variable (SQLSTATE 42704).

TO
Specifies to whom the privileges are granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group.

ROLE
Specifies that the *authorization-name* identifies an existing role at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles. The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Grants the specified privileges to a set of users (authorization IDs).

WITH GRANT OPTION
Allows the specified *authorization-name* to grant the privileges to others. If the WITH GRANT OPTION clause is omitted, the specified *authorization-name* cannot grant the privileges to others unless that authority has been received from some other source.

Rules

- For each *authorization-name* specified, if none of the keywords USER, GROUP, or ROLE is specified:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database and as either GROUP or USER in the operating system, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as both USER and GROUP according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as USER only according to the security plug-in in effect, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined as GROUP only according to the security plug-in in effect, GROUP is assumed.
  - If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.

Notes

- ***Privileges granted to a group***: A privilege that is granted to a group is not used for authorization checking on:
  - Static DML statements in a package

- A base table while processing a CREATE VIEW statement
- A base table while processing a CREATE TABLE statement for a materialized query table
- Create SQL routine
- Create trigger

Example

Grant the READ and WRITE privilege on global variable MYSCHEMA.MYJOB_PRINTER to user ZUBIRI.

```
GRANT READ, WRITE ON VARIABLE MYSCHEMA.MYJOB_PRINTER TO ZUBIRI
```

GRANT (index privileges)

This form of the GRANT statement grants the CONTROL privilege on indexes.

Invocation

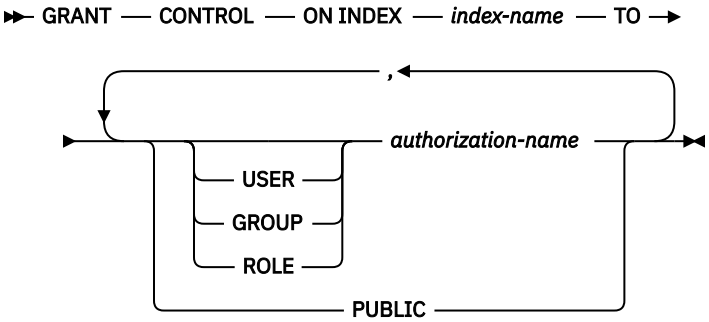
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The authorization ID privileges of the statement on the schema containing the index must include one of the following:

- ACCESSCTRL authority
- SECADM authority
- Schema ACCESSCTRL authority

Syntax



Description

CONTROL
Grants the privilege to drop the index. This is the CONTROL authority for indexes, which is automatically granted to creators of indexes.

ON INDEX *index-name*
Identifies the index for which the CONTROL privilege is to be granted.

TO
Specifies to whom the privileges are granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Grants the privileges to a set of users (authorization IDs). For more information, see "Authorization, privileges and object ownership".

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database, and as either GROUP or USER according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.
  - If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.

Notes

- ***Privileges granted to a group***: A privilege that is granted to a group is not used for authorization checking on:
  - Static DML statements in a package
  - A base table while processing a CREATE VIEW statement
  - A base table while processing a CREATE TABLE statement for a materialized query table
  - Create SQL routine
  - Create trigger
- WITH GRANT OPTION is ignored when granting index privileges

Example

Grant CONTROL privilege on the DEPTIDX index to the user whose ID is KIESLER:

```
GRANT CONTROL ON INDEX DEPTIDX TO USER KIESLER
```

GRANT (module privileges)

This form of the GRANT statement grants privileges on a module.

Invocation

This statement can be embedded in an application program or issued by using dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges that are held by the authorization ID of the statement must include at least one of the following authorities:

- The WITH GRANT OPTION for EXECUTE on the module.
- ACCESSCTRL authority on the schema that contains the module.
- ACCESSCTRL or SECADM authority.

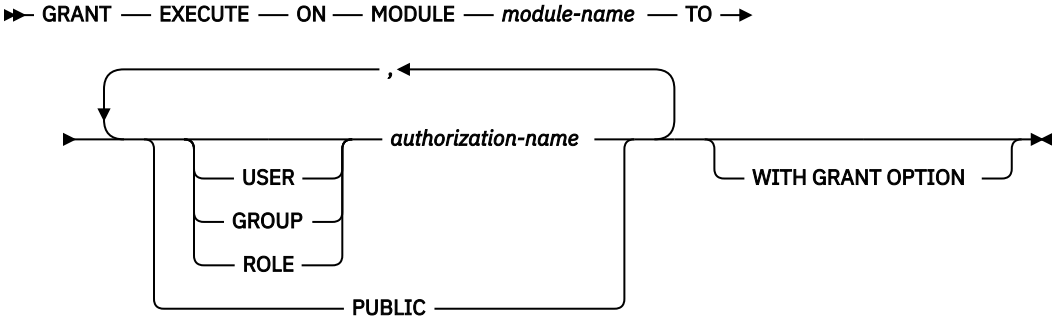
Note: In Db2 11.5.7 and later, the needed authorities are different if the module is SYSIBMADM.UTL_DIR. In this case, the authorities that are held by the authorization ID of the statement must include at least one of the following options:

- The WITH GRANT OPTION for EXECUTE on the module.
- SYSADM authority.

If the module on which the privilege is granted is SYSIBMADM.UTL_DIR, and the DB2_ALTERNATE_AUTHZ_BEHAVIOUR registry variable is set to UTL_DIR_DBAUTH, then the privileges that are held by the authorization ID of the statement are different. In this case, the needed privileges must include at least one of the following options:

- The WITH GRANT OPTION for EXECUTE on the module
- ACCESSCTRL authority on the schema that contains the module.
- SYSADM, ACCESSCTRL, or SECADM authority

Syntax



Description

EXECUTE

Grants the privilege to reference published module objects and run the following operations:

- Run any published routines defined in the module.
- Read from and write to any published global variables defined in the module.
- Reference any published user-defined types defined in the module.
- Reference any published conditions defined in the module.

ON MODULE ***module-name***
Identifies the module on which the privilege is granted. The module-name must identify a module that exists at the current server (SQLSTATE 42704).

TO
Indicates to whom the privilege is granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name,...
Lists one or more authorization IDs.

PUBLIC
Grants the privilege to a set of users (authorization IDs). For more information, see "Authorization, privileges and object ownership".

WITH GRANT OPTION
Allows the specified *authorization-name*s to grant the EXECUTE privilege to other users. If WITH GRANT OPTION is omitted, the specified *authorization-name*s cannot grant the EXECUTE privilege to others unless they receive that authority from some other source.

Notes

Privileges that are granted to a group

- A privilege that is granted to a group is not used for authorization checking on any of the following items:
  - Static DML statements in a package.
  - A base table that is actively processing a CREATE VIEW statement.
  - A base table that is actively processing a CREATE TABLE statement for a materialized query table.
  - Create SQL routine.
  - Create trigger.

Example

Grant the EXECUTE privilege on module MYMODA to user JONES:

```
GRANT EXECUTE
  ON MODULE MYMODA
    TO JONES
```

GRANT (package privileges)

This form of the GRANT statement grants privileges on a package.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

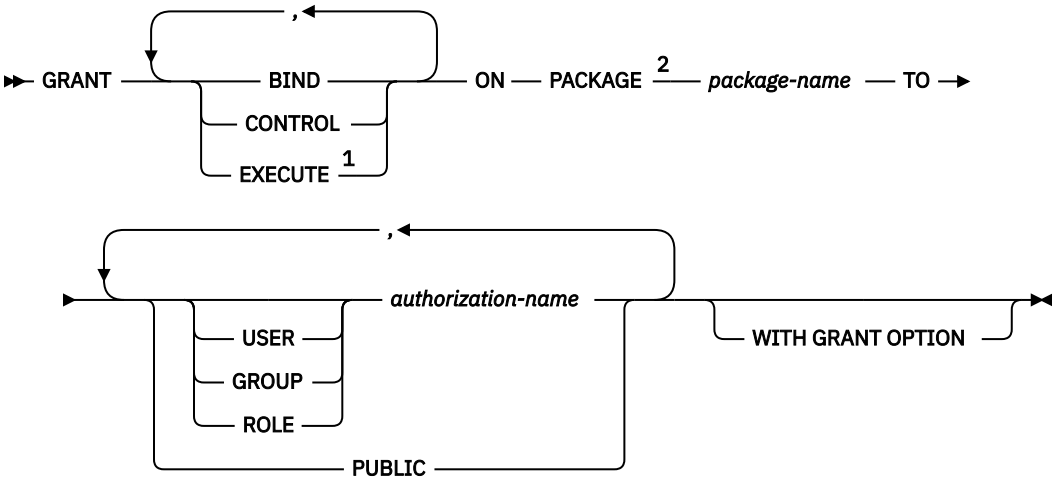
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CONTROL privilege on the referenced package
- The WITH GRANT OPTION for each identified privilege on *package-name*
- ACCESSCTRL on the schema containing the package
- ACCESSCTRL or SECADM authority

One of the following authorities is required to grant the CONTROL privilege:

- ACCESSCTRL
- SECADM
- ACCESSCTRL authority on the schema containing the package

Syntax



Notes:

[1] RUN can be used as a synonym for EXECUTE.
[2] PROGRAM can be used as a synonym for PACKAGE.

Description

BIND

Grants the privilege to bind a package. The BIND privilege allows a user to re-issue the BIND command against that package, or to issue the REBIND command. It also allows a user to create a new version of an existing package.

In addition to the BIND privilege, a user must hold the necessary privileges on each table referenced by static DML statements contained in a program. This is necessary, because authorization on static DML statements is checked at bind time.

CONTROL

Grants the privilege to rebind, drop, or execute the package, and extend package privileges to other users. The CONTROL privilege for packages is automatically granted to creators of packages. A package owner is the package binder, or the ID specified with the OWNER option at bind/precompile time.

BIND and EXECUTE are automatically granted to an *authorization-name* that is granted CONTROL privilege.

CONTROL grants the ability to grant the previously mentioned privileges (except for CONTROL) to others.

EXECUTE

Grants the privilege to execute the package.

ON PACKAGE *package-name*
Specifies the name of the package on which privileges are to be granted. The granting of a package privilege applies to all versions of the package (that is, to all packages that share the same package name and package schema).

TO
Specifies to whom the privileges are granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Grants the privileges to a set of users (authorization IDs). For more information, see "Authorization, privileges and object ownership".

WITH GRANT OPTION
Allows the specified *authorization-name* to GRANT the privileges to others.

If the specified privileges include CONTROL, the WITH GRANT OPTION applies to all of the applicable privileges except for CONTROL (SQLSTATE 01516).

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database, and as either GROUP or USER according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.
  - If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.

Notes

- Package privileges apply to all versions of a package (that is, all packages that share the same package ID and package schema). It is not possible to restrict access to only one version. Because CONTROL privilege is implicitly granted to the binder of a package, if two different users bind two versions of a package, then both users will implicitly be granted access to each other's package.
- ***Privileges granted to a group***: A privilege that is granted to a group is not used for authorization checking on:
  - Static DML statements in a package
  - A base table while processing a CREATE VIEW statement

- A base table while processing a CREATE TABLE statement for a materialized query table
- Create SQL routine
- Create trigger

Examples

- *Example 1:* Grant the EXECUTE privilege on PACKAGE CORPDATA.PKGA to PUBLIC.

```
GRANT EXECUTE
  ON PACKAGE CORPDATA.PKGA
  TO PUBLIC
```

- *Example 2:* GRANT EXECUTE privilege on package CORPDATA.PKGA to a user named EMPLOYEE. There is neither a group nor a user called EMPLOYEE.

```
GRANT EXECUTE ON PACKAGE
  CORPDATA.PKGA TO EMPLOYEE
```

or

```
GRANT EXECUTE ON PACKAGE
  CORPDATA.PKGA TO USER EMPLOYEE
```

GRANT (role)

This form of the GRANT statement grants roles to users, groups, or to other roles.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

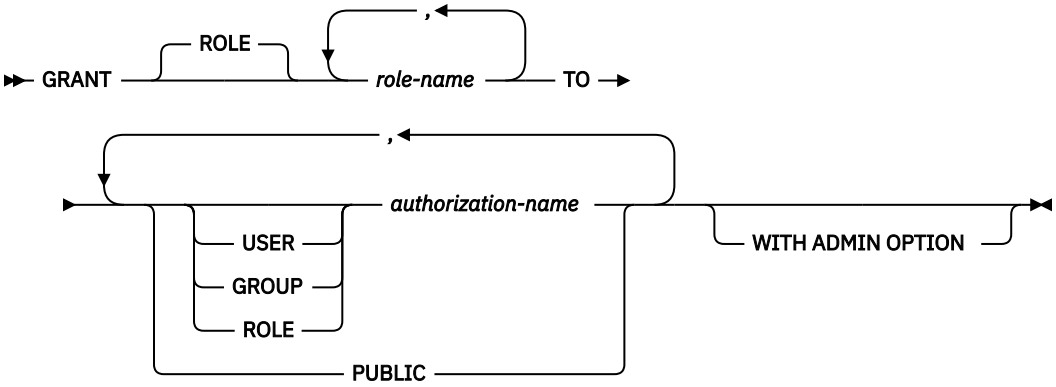
Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- The WITH ADMIN OPTION on the role
- SECADM authority

SECADM authority is required to grant the WITH ADMIN OPTION to an *authorization-name*.

Syntax



Description

ROLE *role-name*,...
Identifies one or more roles to be granted. Each *role-name* must identify an existing role at the current server (SQLSTATE 42704).

TO
Specifies to whom the role is granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group.

ROLE
Specifies that the *authorization-name* identifies an existing role at the current server (SQLSTATE 42704).

***authorization-name*,...**
Lists the authorization IDs of one or more users, groups, or roles. The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Grants the specified roles to a set of users (authorization IDs).

WITH ADMIN OPTION
Allows the specified *authorization-name* to grant or revoke the *role-name* to or from others, or to associate a comment with the role. It does not allow the specified *authorization-name* to drop the role.

Rules

- For each *authorization-name* specified, if none of the keywords USER, GROUP, or ROLE is specified:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database and as either GROUP or USER in the operating system, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as both USER and GROUP according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as USER only according to the security plug-in in effect, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined as GROUP only according to the security plug-in in effect, GROUP is assumed.
  - If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.
- Hierarchies of roles can be built by granting one role to another role. However, cycles are not allowed (SQLSTATE 428GF). For example, if role R1 is granted to another role R2, then role R2 (or some other role R*n* that contains R2) cannot be granted back to R1, because this would produce a cycle.
- The USER, GROUP, or ROLE names must not begin with the characters 'SYS' and must not be 'ACCESSCTRL', 'DATAACCESS', 'DBADM', 'NONE', 'NULL', 'PUBLIC', 'SECADM', 'SQLADM', 'SCHEMAADM', or 'WLMADM' (SQLSTATE 42939).

Notes

- When role R1 is granted to another role R2, then R2 contains R1.
- DBADM authority cannot be granted to PUBLIC. Therefore:
  - Granting role R1 to PUBLIC fails (SQLSTATE 42508) if role R1 holds DBADM authority either directly or indirectly.

- Role R1 holds DBADM authority directly if the following statement has been issued:

```
GRANT DBADM ON DATABASE TO ROLE R1
```

- Role R1 holds DBADM authority indirectly if the following statements have been issued:

```
GRANT DBADM ON DATABASE TO ROLE R2
GRANT ROLE R2 TO ROLE R1
```

– Granting role R1, which holds DBADM authority, to role R2 fails (SQLSTATE 42508) if role R2 is granted to PUBLIC either directly or indirectly.

- Role R2 is granted to PUBLIC directly if the following statement has been issued:

```
GRANT ROLE R2 TO PUBLIC
```

- Role R2 is granted to PUBLIC indirectly if the following statements have been issued:

```
GRANT ROLE R2 TO ROLE R3
GRANT ROLE R3 TO PUBLIC
```

- No schema-level authority (SCHEMAADM, schema ACCESSCTRL, schema DATAACCESS, schema LOAD) can be granted to PUBLIC.
- ***Privileges granted to a group***: A privilege that is granted to a group is not used for authorization checking on:
  – Static DML statements in a package
  – A base table while processing a CREATE VIEW statement
  – A base table while processing a CREATE TABLE statement for a materialized query table
  – Create SQL routine
  – Create trigger

Examples

- *Example 1:* Grant role INTERN to role DOCTOR and role DOCTOR to role SPECIALIST.

```
GRANT ROLE INTERN TO ROLE DOCTOR
GRANT ROLE DOCTOR TO ROLE SPECIALIST
```

- *Example 2:* Grant role INTERN to PUBLIC.

```
GRANT ROLE INTERN TO PUBLIC
```

- *Example 3:* Grant role SPECIALIST to user BOB and group TORONTO.

```
GRANT ROLE SPECIALIST TO USER BOB, GROUP TORONTO
```

GRANT (routine privileges)

This form of the GRANT statement grants privileges on a routine (function, method, or procedure) that is not defined in a module.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

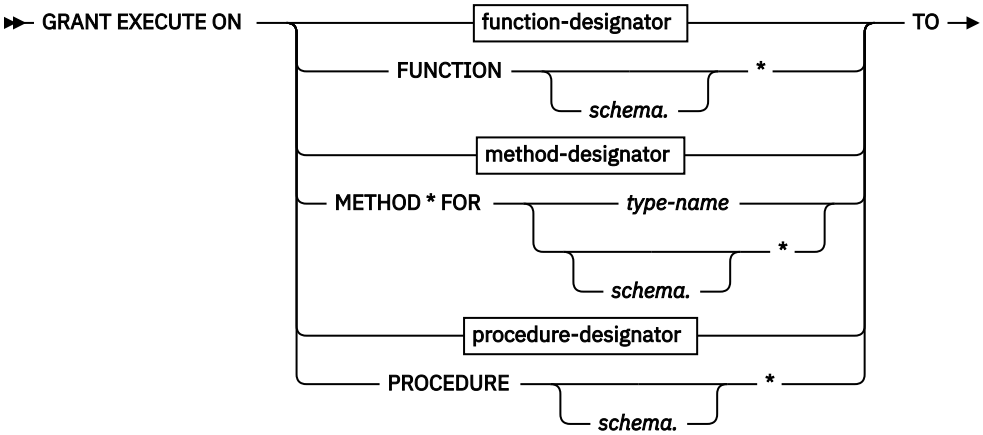
- The WITH GRANT OPTION for EXECUTE on the routine
- ACCESSCTRL authority on the schema containing the routine
- ACCESSCTRL or SECADM authority

To grant all routine EXECUTE privileges in the schema or type, the privileges held by the authorization ID of the statement must include at least one of the following authorities:

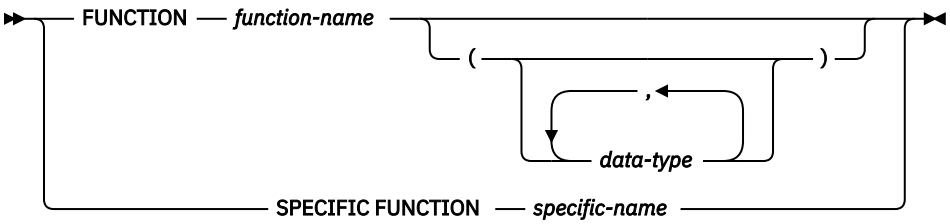
- The WITH GRANT OPTION for EXECUTE on all existing and future routines (of the specified type) in the specified schema
- ACCESSCTRL authority on the schema containing all the routines
- ACCESSCTRL or SECADM authority

SECADM authority is required to grant EXECUTE privilege on audit routines and the SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY procedure. EXECUTE privilege WITH GRANT OPTION cannot be granted for these routines (SQLSTATE 42501). EXECUTE privilege cannot be granted to PUBLIC on the SET_MAINT_MODE_RECORD_NO_TEMPORALHISTORY procedure (SQLSTATE 42501).

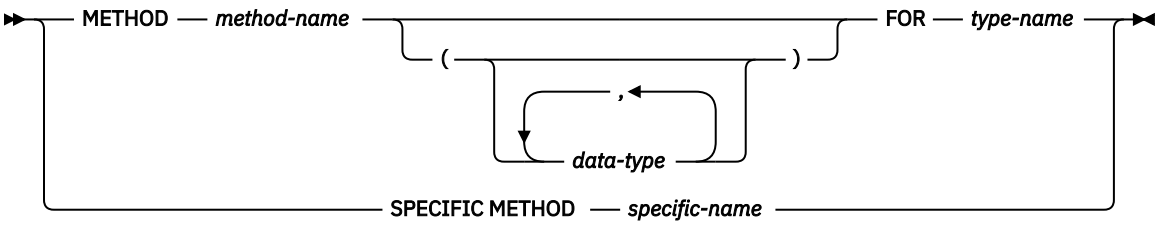
Syntax



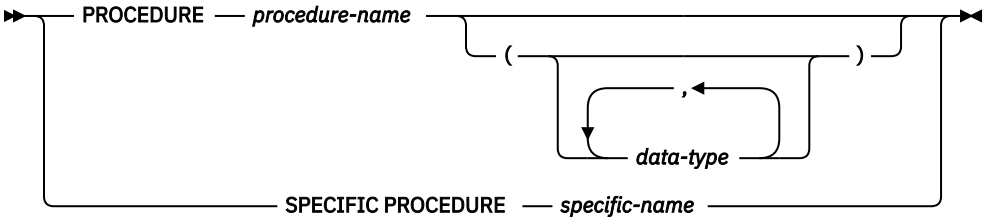
function-designator



method-designator



procedure-designator



Description

EXECUTE
Grants the privilege to run the identified user-defined function, method, or procedure.

function-designator
Uniquely identifies the function on which the privilege is granted. For more information, see "Function, method, and procedure designators" on page 745.

FUNCTION *schema*.*
Identifies all the functions in the schema, including any functions that may be created in the future. In dynamic SQL statements, if a schema is not specified, the schema in the CURRENT SCHEMA special register will be used. In static SQL statements, if a schema is not specified, the schema in the QUALIFIER precompile/bind option will be used.

method-designator
Uniquely identifies the method on which the privilege is granted. For more information, see "Function, method, and procedure designators" on page 745.

METHOD *
Identifies all the methods for the type *type-name*, including any methods that may be created in the future.

FOR *type-name*
Names the type in which the specified method is found. The name must identify a type already described in the catalog (SQLSTATE 42704). In dynamic SQL statements, the value of the CURRENT SCHEMA special register is used as a qualifier for an unqualified type name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified type names. An asterisk (*) can be used in place of *type-name* to identify all types in the schema, including any types that may be created in the future.

procedure-designator
Uniquely identifies the procedure on which the privilege is granted. For more information, see "Function, method, and procedure designators" on page 745.

PROCEDURE *schema*.*
Identifies all the procedures in the schema, including any procedures that may be created in the future. In dynamic SQL statements, if a schema is not specified, the schema in the CURRENT SCHEMA special register will be used. In static SQL statements, if a schema is not specified, the schema in the QUALIFIER precompile/bind option will be used.

TO
Specifies to whom the EXECUTE privilege is granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

PUBLIC
Grants the EXECUTE privilege to a set of users (authorization IDs).

WITH GRANT OPTION
Allows the specified *authorization-name*s to GRANT the EXECUTE privilege to others.

If the WITH GRANT OPTION is omitted, the specified *authorization-name* can only grant the EXECUTE privilege to others if they:

- have SYSADM or DBADM authority or
- received the ability to grant the EXECUTE privilege from some other source.

Rules

- It is not possible to grant the EXECUTE privilege on a function or method defined with schema 'SYSIBM' or 'SYSFUN' (SQLSTATE 42832).
- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database, and as either GROUP or USER according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.
  - If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.
- In general, the GRANT statement will process the granting of privileges that the authorization ID of the statement is allowed to grant, returning a warning (SQLSTATE 01007) if one or more privileges was not granted. If the package used for processing the statement was precompiled with LANGLEVEL set to SQL92E or MIA, and no privileges were granted, a warning is returned (SQLSTATE 01007). If the grantor has no privileges on the object of the grant operation, an error is returned (SQLSTATE 42501).

Notes

- Privileges for a routine defined in a module are granted at the module level using the GRANT (module privileges) statement. The EXECUTE privilege on the module allows access to all objects in the module.
- ***Privileges granted to a group***: A privilege that is granted to a group is not used for authorization checking on:
  - Static DML statements in a package
  - A base table while processing a CREATE VIEW statement
  - A base table while processing a CREATE TABLE statement for a materialized query table
  - Create SQL routine

– Create trigger

Examples

- *Example 1:* Grant the EXECUTE privilege on function CALC_SALARY to user JONES. Assume that there is only one function in the schema with function name CALC_SALARY.

```
GRANT EXECUTE ON FUNCTION CALC_SALARY TO JONES
```

- *Example 2:* Grant the EXECUTE privilege on procedure VACATION_ACCR to all users at the current server.

```
GRANT EXECUTE ON PROCEDURE VACATION_ACCR TO PUBLIC
```

- *Example 3:* Grant the EXECUTE privilege on function DEPT_TOTALS to the administrative assistant and give the assistant the ability to grant the EXECUTE privilege on this function to others. The function has the specific name DEPT85_TOT. Assume that the schema has more than one function named DEPT_TOTALS.

```
GRANT EXECUTE ON SPECIFIC FUNCTION DEPT85_TOT
  TO ADMIN_A WITH GRANT OPTION
```

- *Example 4:* Grant the EXECUTE privilege on function NEW_DEPT_HIRES to HR (Human Resources). The function has two input parameters of type INTEGER and CHAR(10), respectively. Assume that the schema has more than one function named NEW_DEPT_HIRES.

```
GRANT EXECUTE ON FUNCTION NEW_DEPT_HIRES (INTEGER, CHAR(10)) TO HR
```

- *Example 5:* Grant the EXECUTE privilege on method SET_SALARY of type EMPLOYEE to user JONES.

```
GRANT EXECUTE ON METHOD SET_SALARY FOR EMPLOYEE TO JONES
```

GRANT (schema privileges and authorities)

This form of the GRANT statement grants privileges and authorities on a schema.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

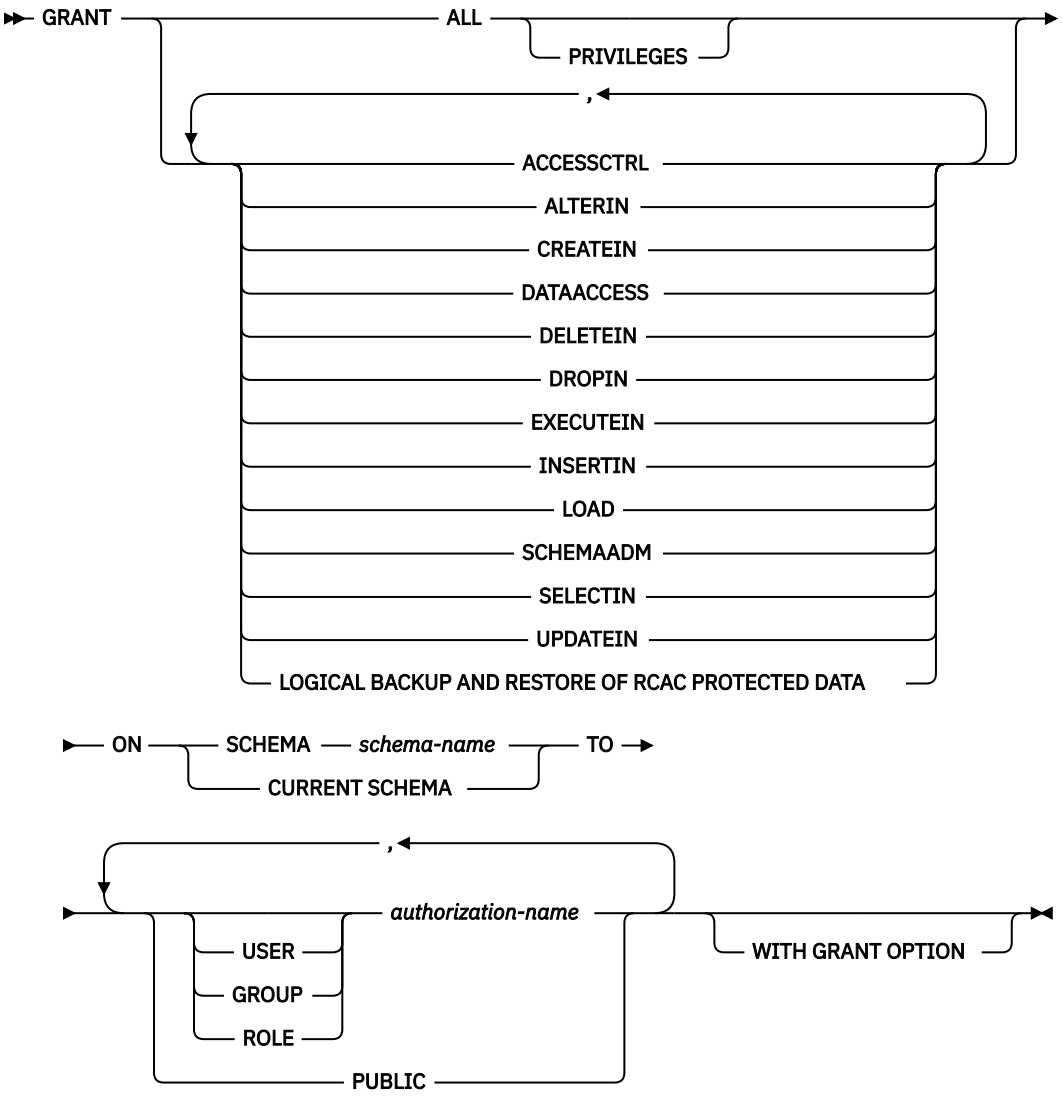
- The WITH GRANT OPTION for each identified privilege on *schema-name*
- ACCESSCTRL authority on *schema-name*
- ACCESSCTRL or SECADM authority

Exceptions:

- Only an authorization ID with ACCESSCTRL or SECADM can grant the following privileges on schema names starting with SYS:
  - SELECTIN privilege on SYSCAT, SYSFUN, SYSSTAT or any schema names starting with SYSIBM (SQLSTATE 42501).
  - SELECTIN, CREATEIN and DROPIN privileges on SYSPROC, SYSPUBLIC or SYSTOOLS schemas. Granting CREATEIN privilege allows the user to create a public alias. Granting DROPIN privilege allows the user to drop any public alias.

- No user can grant any other privileges or authorities on schema names starting with SYS (SQLSTATE 42501).
- Only a user with SECADM or database ACCESSCTRL authority can grant schema ACCESSCTRL authority.
- No schema authorities (SCHEMAADM, ACCESSCTRL, DATAACCESS, and LOAD) can be granted to PUBLIC directly or indirectly

Syntax



Description

ALL or ALL PRIVILEGES

Grants all of the following schema privileges on the schema that is named in the ON clause:

- ALTERIN
- CREATEIN
- DELETEIN
- DROPIN
- EXECUTEIN
- INSERTIN
- SELECTIN

- UPDATEIN

If ALL is not specified, one or more of the keywords in the list of privileges must be specified.

ACCESSCTRL
Grants the access control authority on the schema. The schema ACCESSCTRL authority allows the holder to:

- Grant and revoke the following privileges:
  - READ, WRITE on global variables defined in the schema
  - BIND privileges on packages defined in the schema
  - CONTROL privileges on packages and modules defined in the schema
  - USAGE privilege on XSR objects defined in the schema
- Grant and revoke all schema level privileges and authorities except for schema ACCESSCTRL itself.

The schema ACCESSCTRL authority cannot be granted to PUBLIC (SQLSTATE 42508).

For more information, see Schema access control authority (ACCESSCTRL).

ALTERIN
Grants the privilege to alter or comment on all objects in the schema. The owner of an explicitly created schema automatically receives ALTERIN privilege.

CREATEIN
Grants the privilege to create objects in the schema. Other authorities or privileges required to create the object (such as CREATETAB) are still required. The owner of an explicitly created schema automatically receives CREATEIN privilege. An implicitly created schema has CREATEIN privilege automatically granted to PUBLIC.

DATAACCESS
Grants the authority to access data in the schema. The schema DATAACCESS authority allows the holder to do the following:

- Select, insert, update, delete, and load data from tables or views defined in the schema
- Execute any package defined in the schema
- Execute any routine, except audit routines, defined in the schema

The schema DATAACCESS authority cannot be granted to PUBLIC (SQLSTATE 42508).

For more information, see Schema data access authority (DATAACCESS).

DELETEIN

Grants the privilege to delete data in the table objects in the schema. The owner of the schema (explicitly or implicitly created) does not automatically receive DELETEIN privilege.

DROPIN
Grants the privilege to drop all objects in the schema. The owner of an explicitly created schema automatically receives DROPIN privilege.

EXECUTEIN
Grants the privilege to execute all existing and future user-defined functions, methods, procedures, packages, or modules defined in the schema. The owner of the schema (explicitly or implicitly created) does not automatically receive EXECUTEIN privilege.

INSERTIN

Grants the privilege to insert rows and to run the IMPORT utility on all existing and future tables or views defined in the schema. The owner of the schema (explicitly or implicitly created) does not automatically receive INSERTIN privilege.

LOAD
Grants the authority to load in this schema. This authority gives a user the right to use the LOAD utility in this schema. SCHEMAADM has this authority by default. However, if a user only has schema

LOAD authority (not schema DATAACCESS), the user is also required to have table-level privileges. In addition to schema LOAD privilege, the user is required to have:

- INSERT privilege on the table or INSERTIN privilege on the schema of the table for LOAD with mode INSERT, TERMINATE (to terminate a previous LOAD INSERT), or RESTART (to restart a previous LOAD INSERT)
- INSERT and DELETE privilege on the table or INSERTIN and DELETEIN privilege on the schema of the table for LOAD with mode REPLACE, TERMINATE (to terminate a previous LOAD REPLACE), or RESTART (to restart a previous LOAD REPLACE)
- INSERT privilege on the exception table or INSERTIN privilege on the schema of the exception table, if such a table is used as part of LOAD

Schema LOAD authority cannot be granted to PUBLIC (SQLSTATE 42508).

For more information, see Schema load authority (LOAD).

SCHEMAADM

Grants the schema administrator authority. A schema administrator holds nearly all privileges on nearly all objects in the schema. The only exceptions are those privileges that are part of the access control, and schema data access.

SCHEMAADM authority cannot be granted to PUBLIC (SQLSTATE 42508).

For more information, see Schema administration authority (SCHEMAADM).

SELECTIN

Grants the privilege to select from all existing and future tables or views defined in the schema. The owner of the schema (explicitly or implicitly created) does not automatically receive SELECTIN privilege.

UPDATEIN

Grants the privilege to use the UPDATE statement on all existing and future tables or updatable views defined in the schema. The owner of the schema (explicitly or implicitly created) does not automatically receive UPDATEIN privilege.

LOGICAL BACKUP AND RESTORE OF RCAC PROTECTED DATA

Grants users the privilege to allow a schema-level **db_backup** and **db_restore** scripts to access RCAC protected data.

The schema **LOGICAL BACKUP AND RESTORE OF RCAC PROTECTED DATA** authority cannot be granted to PUBLIC (SQLSTATE 42508).

ON

SCHEMA *schema-name*

Specifies the name of the schema on which the authorities are to be granted. Authorities cannot be granted on any schema beginning with the SYS prefix (SQLSTATE 42501).

CURRENT SCHEMA

Specifies that the authorities will be granted on the schema described by the DB2® special register CURRENT SCHEMA. Authorities cannot be granted on any schema beginning with the SYS prefix (SQLSTATE 42501).

TO

Specifies to whom the privileges are granted.

USER

Specifies that the *authorization-name* identifies a user.

GROUP

Specifies that the *authorization-name* identifies a group name.

ROLE

Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Grants the privileges to a set of users (authorization IDs). For more information, see "Authorization, privileges and object ownership".

WITH GRANT OPTION
Allows the specified *authorization-name*s to GRANT the privileges to others.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database, and as either GROUP or USER according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.
  - If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.
- In general, the GRANT statement will process the granting of privileges that the authorization ID of the statement is allowed to grant, returning a warning (SQLSTATE 01007) if one or more privileges was not granted. If no privileges were granted, an error is returned (SQLSTATE 42501). (If the package used for processing the statement was precompiled with LANGLEVEL set to SQL92E for MIA, a warning is returned (SQLSTATE 01007), unless the grantor has no privileges on the object of the grant operation.)

Notes

- **Grant on SYSPUBLIC:** You can grant privileges on the reserved schema SYSPUBLIC. Granting CREATEIN privilege allows you to create a public alias, and granting DROPIN privilege allows you to drop a public alias. Granting SELECTIN allows you to select from tables defined in the schema.
- The following authorities cannot be granted to the special group PUBLIC:
  - SCHEMAADM on the schema
  - ACCESSCTRL on the schema
  - DATAACCESS on the schema
  - LOAD on the schema

  Granting any of these authorities to a role that is granted to PUBLIC, either directly or indirectly, will fail (SQLSTATE 42508).
  - Role role-name is granted directly to PUBLIC if the following statement has been issued:

    ```
    GRANT ROLE role-name TO PUBLIC
    ```

  - Role role-name is granted indirectly to PUBLIC if the following statements have been issued:

    ```
    GRANT ROLE role-name TO ROLE role-name2
    ```

    ```
    GRANT ROLE role-name2 TO PUBLIC
    ```

- ***Privileges granted to a group***: An authority that is granted to a group is not used for authorization checking on:
  - Static DML statements in a package
  - A base table while processing a CREATE VIEW statement
  - A base table while processing a CREATE TABLE statement for a materialized query table
  - Create SQL routine
  - Create trigger
- WITH GRANT OPTION is ignored when granting schema authorities (SCHEMAADM, ACCESSCTRL, DATAACCESS, LOAD)

Examples

- *Example 1:* Grant user JSINGLETON to the ability to create objects in schema CORPDATA.

```
GRANT CREATEIN ON SCHEMA CORPDATA TO JSINGLETON
```

- *Example 2:* Grant user IHAKES the ability to create and drop objects in schema CORPDATA.

```
GRANT CREATEIN, DROPIN ON SCHEMA CORPDATA TO IHAKES
```

GRANT (security label)

This form of the GRANT statement grants a label-based access control (LBAC) security label to a user, group, or role for read access, write access, or for both read and write access.

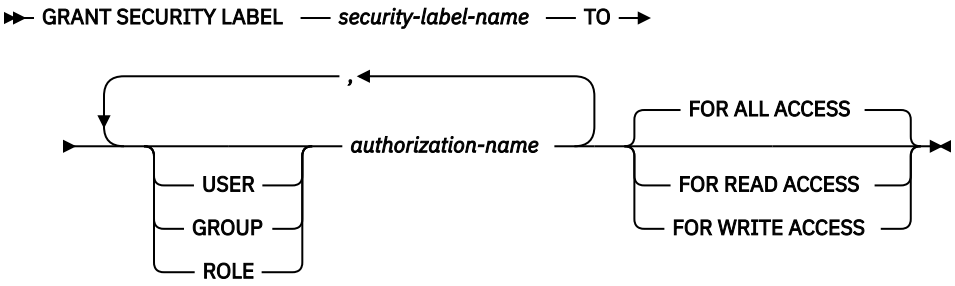
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Description

SECURITY LABEL *security-label-name*
Grants the security label *security-label-name*. The name must be qualified with a security policy (SQLSTATE 42704) and must identify a security label that exists at the current server (SQLSTATE 42704).

TO
Specifies to whom the specified security label is granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

FOR ALL ACCESS
Indicates that the security label is to be granted for both read access and write access.

FOR READ ACCESS
Indicates that the security label is to be granted for read access only.

FOR WRITE ACCESS
Indicates that the security label is to be granted for write access only.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database, and as either GROUP or USER according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.
  - If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.
- For any given security policy, an *authorization-name* can be granted at most one security label from that policy for read access and one for write access. If the grantee already holds a security label for the type of access (read or write) indicated and that is part of the security policy that qualifies *security-label-name*, an error is returned (SQLSTATE 428GR).
- If the security policy is not defined to consider access through groups or roles, any security label granted to a group or role is ignored when access is attempted.
- If an *authorization-name* holds different security labels for read access and write access, the security labels must meet the following criteria (SQLSTATE 428GQ):
  - If any component in the security labels is of type ARRAY then the value for that component must be the same in both security labels.
  - If any component in the security labels is of type SET then every element in the value for that component in the write security label must also be part of the value for that component in the read security label.
  - If any component in the security labels is of type TREE then every element in the value for that component in the write security label must be the same as or a descendent of one of the elements in the value for that same component in the read security label.

Notes

- By default when a security policy is created, only security labels granted to an individual user are considered. To have groups or roles considered for the security policy, you must issue the ALTER

SECURITY POLICY statement and specify USE GROUP AUTHORIZATION or USE ROLE AUTHORIZATION as applicable.

Example

The following statement grants two security labels to user GUYLAINE. The security label EMPLOYEESECLABELREAD is granted for read access and the security label EMPLOYEESECLABELWRITE is granted for write access. Both security labels are part of the security policy DATA_ACCESS.

```
GRANT SECURITY LABEL DATA_ACCESS.EMPLOYEESECLABELREAD
  TO USER GUYLAINE FOR READ ACCESS

GRANT SECURITY LABEL DATA_ACCESS.EMPLOYEESECLABELWRITE
  TO USER GUYLAINE FOR WRITE ACCESS
```

The same user is now granted the security label BEGINNER for both read and write access. This does not cause an error, because BEGINNER is part of the security policy CLASSPOLICY, and the security labels already held are part of the security policy DATA_ACCESS.

```
GRANT SECURITY LABEL CLASSPOLICY.BEGINNER
  TO USER GUYLAINE FOR ALL ACCESS
```

GRANT (sequence privileges)

This form of the GRANT statement grants privileges on a sequence.

Invocation

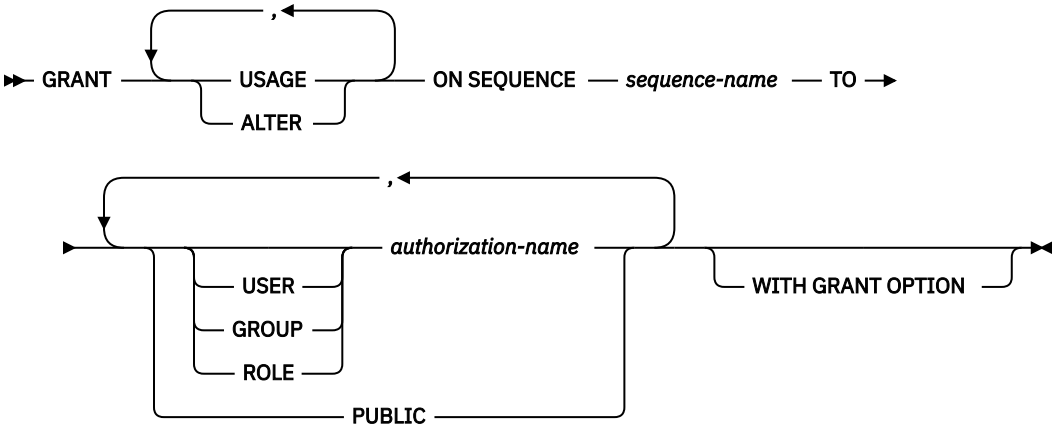
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- The WITH GRANT OPTION for each identified privilege on *sequence-name*
- ACCESSCTRL authority on the schema containing the sequence-name
- ACCESSCTRL or SECADM authority

Syntax



Description

USAGE
Grants the privilege to reference a sequence using *nextval-expression* or *prevval-expression*.

ALTER
Grants the privilege to alter sequence properties using the ALTER SEQUENCE statement.

ON SEQUENCE *sequence-name*
Identifies the sequence on which the specified privileges are to be granted. The sequence name, including an implicit or explicit schema qualifier, must uniquely identify an existing sequence at the current server. If no sequence by this name exists, an error (SQLSTATE 42704) is returned.

TO
Specifies to whom the specified privileges are granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

PUBLIC
Grants the specified privileges to a set of users (authorization IDs).

WITH GRANT OPTION
Allows the specified *authorization-name* to grant the specified privileges to others.

If the WITH GRANT OPTION is omitted, the specified *authorization-name* can only grant the specified privileges to others if they:

- have SYSADM or DBADM authority or
- received the ability to grant the specified privileges from some other source.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database, and as either GROUP or USER according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.
  - If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.
- In general, the GRANT statement will process the granting of privileges that the authorization ID of the statement is allowed to grant, returning a warning (SQLSTATE 01007) if one or more privileges is not granted. If no privileges are granted, an error is returned (SQLSTATE 42501). (If the package used for processing the statement was precompiled with LANGLEVEL set to SQL92E or MIA, a warning is returned (SQLSTATE 01007), unless the grantor has no privileges on the object of the grant operation.)

Notes

- ***Privileges granted to a group***: A privilege that is granted to a group is not used for authorization checking on:
  - Static DML statements in a package
  - A base table while processing a CREATE VIEW statement
  - A base table while processing a CREATE TABLE statement for a materialized query table
  - Create SQL routine
  - Create trigger

Examples

- *Example 1:* Grant any user the USAGE privilege on a sequence called ORG_SEQ.

```
GRANT USAGE ON SEQUENCE ORG_SEQ TO PUBLIC
```

- *Example 2:* Grant user BOBBY the ability to alter a sequence called GENERATE_ID, and to grant this privilege to others.

```
GRANT ALTER ON SEQUENCE GENERATE_ID TO BOBBY WITH GRANT OPTION
```

GRANT (server privileges)

This form of the GRANT statement grants the privilege to access and use a specified data source in pass-through mode.

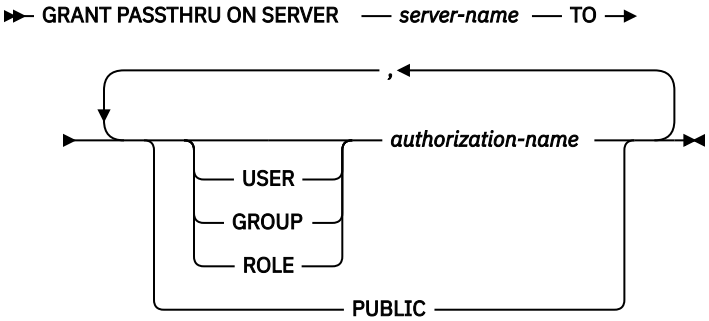
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include ACCESSCTRL or SECADM authority.

Syntax



Description

server-name
Names the data source for which the privilege to use in pass-through mode is being granted. *server-name* must identify a data source that is described in the catalog.

TO

Specifies to whom the privilege is granted.

USER

Specifies that the *authorization-name* identifies a user.

GROUP

Specifies that the *authorization-name* identifies a group name.

ROLE

Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name,...

Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC

Grants to a set of users (authorization IDs) the privilege to pass through to *server-name*. For more information, see "Authorization, privileges and object ownership".

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database, and as either GROUP or USER according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.
  - If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.

Examples

- *Example 1:* Give R. Smith and J. Jones the privilege to pass through to data source SERVALL. Their authorization IDs are RSMITH and JJONES.

```
GRANT PASSTHRU ON SERVER SERVALL
  TO USER RSMITH,
  USER JJONES
```

- *Example 2:* Grant the privilege to pass through to data source EASTWING to a group whose authorization ID is D024. There is a user whose authorization ID is also D024.

```
GRANT PASSTHRU ON SERVER EASTWING TO GROUP D024
```

The GROUP keyword must be specified; otherwise, an error will occur because D024 is a user's ID as well as the specified group's ID (SQLSTATE 56092). Any member of group D024 will be allowed to pass through to EASTWING. Therefore, if user D024 belongs to the group, this user will be able to pass through to EASTWING.

GRANT (SETSESSIONUSER privilege)

This form of the GRANT statement grants the SETSESSIONUSER privilege to one or more authorization IDs. The privilege allows the holder to use the SET SESSION AUTHORIZATION statement to set the session authorization to one of a set of specified authorization IDs.

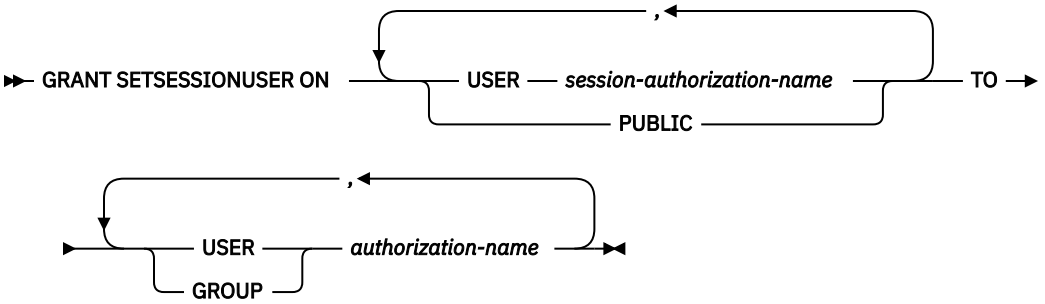
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Description

SETSESSIONUSER ON
Grants the privilege to assume the identity of a new authorization ID.

USER *session-authorization-name*
Specifies the authorization ID that the *authorization-name* will be able to assume, using the SET SESSION AUTHORIZATION statement. The *session-authorization-name* must identify a user, not a group.

PUBLIC
Specifies that the grantee will be able to assume any valid authorization ID, using the SET SESSION AUTHORIZATION statement.

TO
Specifies to whom the privilege is granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group.

authorization-name,...
Lists the authorization IDs of one or more users or groups.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

Rules

- For each *authorization-name* specified, if neither USER nor GROUP is specified, then:

- If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
- If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).
- If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
- If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.

Notes

- ***Privileges granted to a group***: A privilege that is granted to a group is not used for authorization checking on:
  - Static DML statements in a package
  - A base table while processing a CREATE VIEW statement
  - A base table while processing a CREATE TABLE statement for a materialized query table
  - Create SQL routine
  - Create trigger

Examples

- *Example 1:* The following statement grants user PAUL the ability to set the session authorization to user WALID and therefore to execute statements as WALID.

```
GRANT SETSESSIONUSER ON USER WALID
  TO USER PAUL
```

- *Example 2:* The following statement grants user GUYLAINE the ability to set the session authorization to user BOBBY. It also grants her the ability to set the session authorization to users RICK and KEVIN.

```
GRANT SETSESSIONUSER ON USER BOBBY, USER RICK, USER KEVIN
  TO USER GUYLAINE
```

- *Example 3:* The following statement grants user WALID and everyone in the groups ADMINS and ACCTG the ability to set the session authorization to any user.

```
GRANT SETSESSIONUSER ON PUBLIC TO USER WALID, GROUP ADMINS, ACCTG
```

GRANT (table space privileges)

This form of the GRANT statement grants privileges on a table space.

Invocation

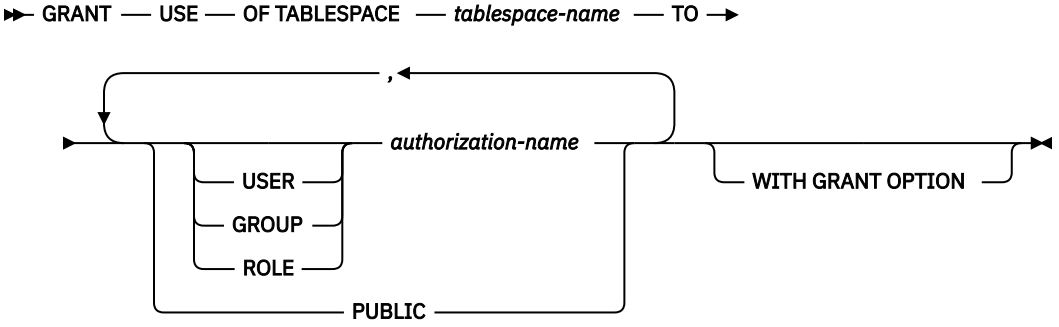
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- The WITH GRANT OPTION for use of the table space
- ACCESSCTRL, SECADM, SYSADM, or SYSCTRL authority

Syntax



Description

USE
Grants the privilege to specify or default to the table space when creating a table. The creator of a table space automatically receives USE privilege with grant option.

OF TABLESPACE *tablespace-name*
Identifies the table space on which the USE privilege is to be granted. The table space cannot be SYSCATSPACE (SQLSTATE 42838) or a system temporary table space (SQLSTATE 42809).

TO
Specifies to whom the USE privilege is granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Grants the USE privilege to a set of users (authorization IDs).

WITH GRANT OPTION
Allows the specified *authorization-name* to GRANT the USE privilege to others.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database, and as either GROUP or USER according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.

– If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.

Example

Grant user BOBBY the ability to create tables in table space PLANS and to grant this privilege to others.

```
GRANT USE OF TABLESPACE PLANS TO BOBBY WITH GRANT OPTION
```

GRANT (table, view, or nickname privileges)

This form of the GRANT statement grants privileges on a table, view, or nickname.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

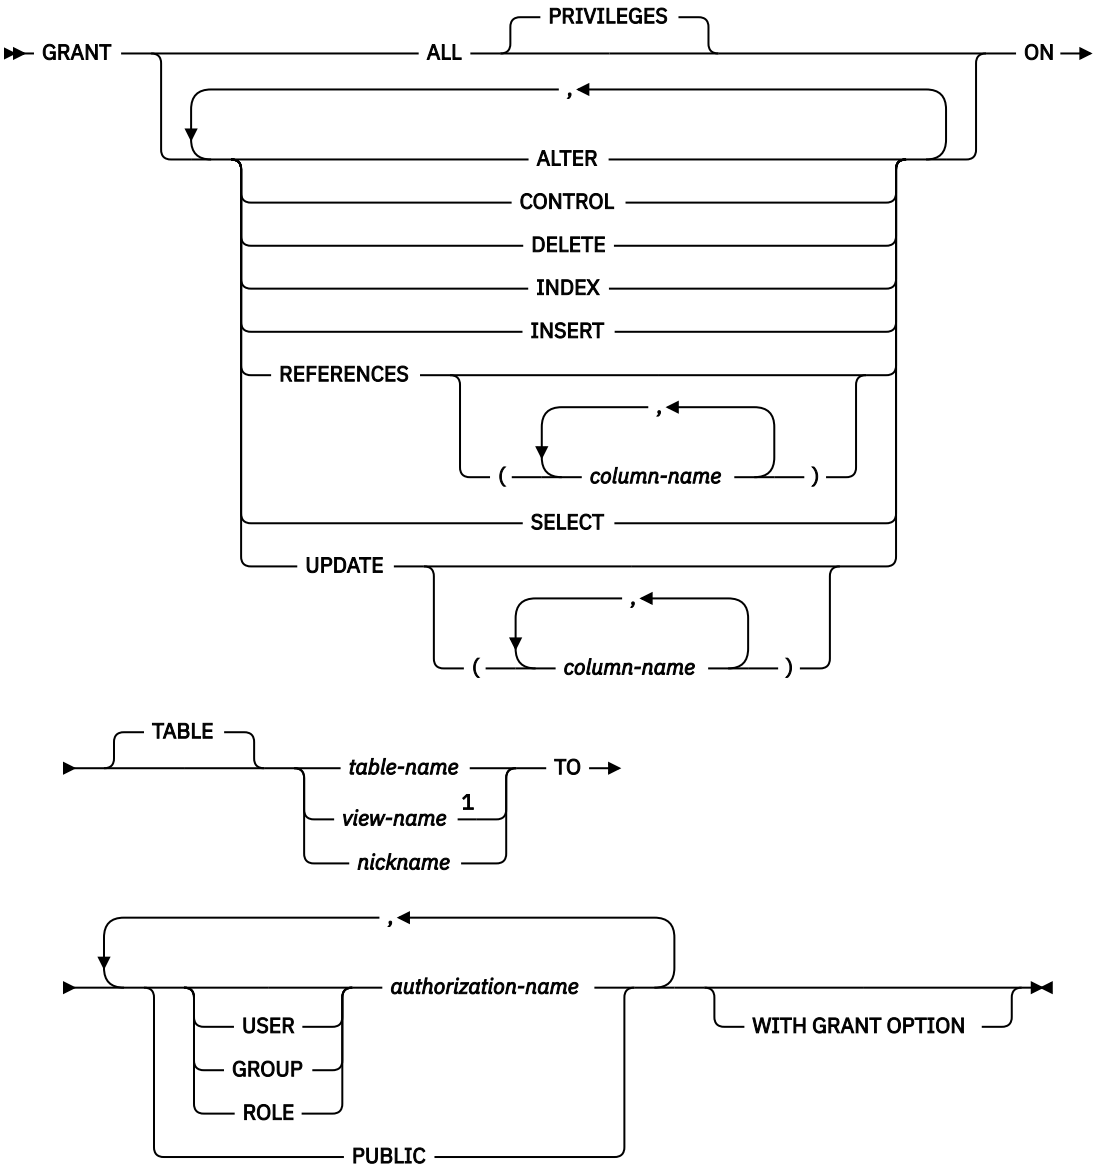
Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CONTROL privilege on the referenced table, view, or nickname
- The WITH GRANT OPTION for each identified privilege. If ALL is specified, the authorization ID must have some grantable privilege on the identified table, view, or nickname
- ACCESSCTRL authority on the schema containing the identified table, view, or nickname
- ACCESSCTRL or SECADM authority

ACCESSCTRL authority on the schema, ACCESSCTRL authority on the database, or SECADM authority is required to grant the CONTROL privilege. ACCESSCTRL authority on the database or SECADM authority is required to grant privileges on catalog tables and views.

Syntax



Notes:

[1] ALTER, INDEX, and REFERENCES privileges are not applicable to views.

Description

ALL or ALL PRIVILEGES

Grants all the appropriate privileges, except CONTROL, on the base table, view, or nickname named in the ON clause.

If the authorization ID of the statement has CONTROL privilege on the table, view, or nickname, or ACCESSCTRL or SECADM authority, then all the privileges applicable to the object (except CONTROL) are granted. Otherwise, the privileges granted are all those grantable privileges that the authorization ID of the statement has on the identified table, view, or nickname.

If ALL is not specified, one or more of the keywords in the list of privileges must be specified.

ALTER

Grants the privilege to:

- Add columns to a base table definition.

- Create or drop a primary key or unique constraint on a base table.
- Create or drop a foreign key on a base table.

  The REFERENCES privilege on each column of the parent table is also required.
- Create or drop a check constraint on a base table.
- Create a trigger on a base table.
- Add, reset, or drop a column option for a nickname.
- Change a nickname column name or data type.
- Add or change a comment on a base table or a nickname.

CONTROL
Grants:

- All of the appropriate privileges in the list, that is:
  - ALTER, CONTROL, DELETE, INSERT, INDEX, REFERENCES, SELECT, and UPDATE to base tables
  - CONTROL, DELETE, INSERT, SELECT, and UPDATE to views
  - ALTER, CONTROL, INDEX, and REFERENCES to nicknames
- The ability to grant the previously mentioned privileges (except for CONTROL) to others.
- The ability to drop the base table, view, or nickname.

  This ability cannot be extended to others on the basis of holding CONTROL privilege. The only way that it can be extended is by granting the CONTROL privilege itself and that can only be done by an authorization ID with ACCESSCTRL or SECADM authority.
- The ability to execute the RUNSTATS utility on the table and indexes.
- The ability to execute the REORG utility on the table.
- The ability to issue the SET INTEGRITY statement against a base table, materialized query table, or staging table.

The definer of a base table, materialized query table, staging table, or nickname automatically receives the CONTROL privilege.

The definer of a view automatically receives the CONTROL privilege if the definer holds the CONTROL privilege on all tables, views, and nicknames identified in the fullselect.

DELETE
Grants the privilege to delete rows from the table or updatable view.

INDEX
Grants the privilege to create an index on a table, or an index specification on a nickname. This privilege cannot be granted on a view. The creator of an index or index specification automatically has the CONTROL privilege on the index or index specification (authorizing the creator to drop the index or index specification). In addition, the creator retains the CONTROL privilege even if the INDEX privilege is revoked.

INSERT
Grants the privilege to insert rows into the table or updatable view and to run the IMPORT utility.

REFERENCES
Grants the privilege to create and drop a foreign key referencing the table as the parent.

If the authorization ID of the statement has one of:

- ACCESSCTRL or SECADM authority
- CONTROL privilege on the table
- REFERENCES WITH GRANT OPTION on the table

then the grantee(s) can create referential constraints using all columns of the table as parent key, even those added later using the ALTER TABLE statement. Otherwise, the privileges granted are all

those grantable column REFERENCES privileges that the authorization ID of the statement has on the identified table.

The privilege can be granted on a nickname, although foreign keys cannot be defined to reference nicknames.

REFERENCES (*column-name*,...)
Grants the privilege to create and drop a foreign key using only those columns specified in the column list as a parent key. Each *column-name* must be an unqualified name that identifies a column of the table identified in the ON clause. Column level REFERENCES privilege cannot be granted on typed tables, typed views, or nicknames (SQLSTATE 42997).

SELECT
Grants the privilege to:

- Retrieve rows from the table or view.
- Create views on the table.
- Run the EXPORT utility against the table or view.

UPDATE
Grants the privilege to use the UPDATE statement on the table or updatable view identified in the ON clause.

If the authorization ID of the statement has one of:

- ACCESSCTRL or SECADM authority
- CONTROL privilege on the table or view
- UPDATE WITH GRANT OPTION on the table or view

then the grantee(s) can update all updatable columns of the table or view on which the grantor has with grant privilege as well as those columns added later using the ALTER TABLE statement. Otherwise, the privileges granted are all those grantable column UPDATE privileges that the authorization ID of the statement has on the identified table or view.

UPDATE (*column-name*,...)
Grants the privilege to use the UPDATE statement to update only those columns specified in the column list. Each *column-name* must be an unqualified name that identifies a column of the table or view identified in the ON clause. Column level UPDATE privilege cannot be granted on typed tables, typed views, or nicknames (SQLSTATE 42997).

ON TABLE *table-name* or *view-name* or *nickname*
Specifies the table, view, or nickname on which privileges are to be granted.

No privileges may be granted on an inoperative view or an inoperative materialized query table (SQLSTATE 51024). No privileges may be granted on a declared temporary table (SQLSTATE 42995).

TO
Specifies to whom the privileges are granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

A privilege that is granted to a group is not used for authorization checking:

- On static DML statements in a package
- On a base table while processing a CREATE VIEW statement

- On a base table while processing a CREATE TABLE statement for a materialized query table

Table privileges granted to groups only apply to statements that are dynamically prepared. For example, if the INSERT privilege on the PROJECT table has been granted to group D204 but not UBIQUITY (a member of D204) UBIQUITY could issue the statement:

```
EXEC SQL EXECUTE IMMEDIATE :INSERT_STRING;
```

where the content of the string is:

```
INSERT INTO PROJECT (PROJNO, PROJNAME, DEPTNO, RESPEMP)
VALUES ('AD3114', 'TOOL PROGRAMMING', 'D21', '000260');
```

but could not precompile or bind a program with the statement:

```
EXEC SQL INSERT INTO PROJECT (PROJNO, PROJNAME, DEPTNO, RESPEMP)
VALUES ('AD3114', 'TOOL PROGRAMMING', 'D21', '000260');
```

PUBLIC
Grants the privileges to a set of users (authorization IDs). For more information, see "Authorization, privileges and object ownership". (Previous restrictions on the use of privileges granted to PUBLIC for static SQL statements and the CREATE VIEW statement have been removed.)

WITH GRANT OPTION
Allows the specified *authorization-name*s to GRANT the privileges to others.

If the specified privileges include CONTROL, the WITH GRANT OPTION applies to all the applicable privileges except for CONTROL (SQLSTATE 01516).

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database, and as either GROUP or USER according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.
  - If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.
- In general, the GRANT statement will process the granting of privileges that the authorization ID of the statement is allowed to grant, returning a warning (SQLSTATE 01007) if one or more privileges was not granted. If no privileges were granted, an error is returned (SQLSTATE 42501). (If the package used for processing the statement was precompiled with LANGLEVEL set to SQL92E or MIA, a warning is returned (SQLSTATE 01007), unless the grantor has no privileges on the object of the grant operation.) If CONTROL privilege is specified, privileges will only be granted if the authorization ID of the statement has ACCESSCTRL or SECADM authority (SQLSTATE 42501).

Notes

- Privileges may be granted independently at every level of a table hierarchy. A user with a privilege on a supertable may affect the subtables. For example, an update specifying the supertable *T* may show up as a change to a row in the subtable *S* of *T* done by a user with UPDATE privilege on *T* but without UPDATE privilege on *S*. A user can only operate directly on the subtable if the necessary privilege is held on the subtable.

- Granting nickname privileges has no effect on data source object (table or view) privileges. Typically, data source privileges are required for the table or view that a nickname references when attempting to retrieve data.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. The following syntax is tolerated and ignored:
  - PUBLIC AT ALL LOCATIONS
- WITH GRANT OPTION is ignored when granting table or view (CONTROL) privilege

Examples

1. Grant all privileges on the table WESTERN_CR to PUBLIC.

```
GRANT ALL ON WESTERN_CR
   TO PUBLIC
```

2. Grant the appropriate privileges on the CALENDAR table so that users PHIL and CLAIRE can read it and insert new entries into it. Do not allow them to change or remove any existing entries.

```
GRANT SELECT, INSERT ON CALENDAR
   TO USER  PHIL, USER CLAIRE
```

3. Grant all privileges on the COUNCIL table to user FRANK and the ability to extend all privileges to others.

```
GRANT ALL ON COUNCIL
   TO USER FRANK WITH GRANT OPTION
```

4. GRANT SELECT privilege on table CORPDATA.EMPLOYEE to a user named JOHN. There is a user called JOHN and no group called JOHN.

```
GRANT SELECT ON CORPDATA.EMPLOYEE TO JOHN
```

   or

```
GRANT SELECT
  ON CORPDATA.EMPLOYEE TO USER JOHN
```

5. GRANT SELECT privilege on table CORPDATA.EMPLOYEE to a group named JOHN. There is a group called JOHN and no user called JOHN.

```
GRANT SELECT ON CORPDATA.EMPLOYEE TO JOHN
```

   or

```
GRANT SELECT ON CORPDATA.EMPLOYEE TO GROUP JOHN
```

6. GRANT INSERT and SELECT on table T1 to both a group named D024 and a user named D024.

```
GRANT INSERT, SELECT ON TABLE T1
  TO GROUP D024, USER D024
```

   In this case, both the members of the D024 group and the user D024 would be allowed to INSERT into and SELECT from the table T1. Also, there would be two rows added to the SYSCAT.TABAUTH catalog view.

7. GRANT INSERT, SELECT, and CONTROL on the CALENDAR table to user FRANK. FRANK must be able to pass the privileges on to others.

```
GRANT CONTROL ON TABLE CALENDAR
  TO FRANK WITH GRANT OPTION
```

   The result of this statement is a warning (SQLSTATE 01516) that CONTROL was not given the WITH GRANT OPTION. Frank now has the ability to grant any privilege on CALENDAR including INSERT

and SELECT as required. FRANK cannot grant CONTROL on CALENDAR to other users unless he has ACCESSCTRL or SECADM authority.

8. User JON created a nickname for an Oracle table that had no index. The nickname is ORAREM1. Later, the Oracle DBA defined an index for this table. User SHAWN now wants Db2 to know that this index exists, so that the optimizer can devise strategies to access the table more efficiently. SHAWN can inform Db2 of the index by creating an index specification for ORAREM1. Give SHAWN the index privilege on this nickname, so that he can create the index specification.

```
GRANT INDEX ON NICKNAME ORAREM1
  TO USER SHAWN
```

GRANT (workload privileges)

This form of the GRANT statement grants the USAGE privilege on a workload.

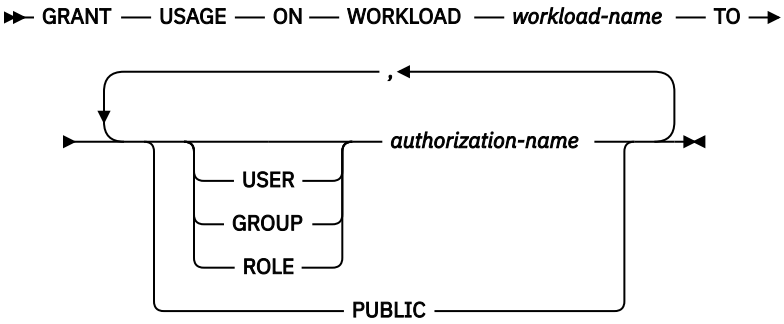
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include ACCESSCTRL, SECADM, or WLMADM authority.

Syntax



Description

USAGE
Grants the privilege to use a workload. Units of work that are submitted by a user will only be mapped to a workload on which the user has USAGE privilege. A user with SYSADM or DBADM authority automatically has USAGE privilege on any workload that exists at the current server.

ON WORKLOAD *workload-name*
Identifies the workload on which the USAGE privilege is to be granted. This is a one-part name. The *workload-name* must identify a workload that exists at the current server (SQLSTATE 42704). The name cannot be 'SYSDEFAULTADMWORKLOAD' (SQLSTATE 42832).

TO
Specifies to whom the USAGE privilege is granted.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group.

ROLE
Specifies that the *authorization-name* identifies an existing role at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles. The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Grants the USAGE privilege to a set of users (authorization IDs).

Rules

- For each *authorization-name* specified, if none of the keywords USER, GROUP, or ROLE is specified:
  - If the security plug-in in effect for the instance cannot determine the status of the *authorization-name*, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as ROLE in the database and as either GROUP or USER in the operating system, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as both USER and GROUP according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
  - If the *authorization-name* is defined as USER only according to the security plug-in in effect, or if it is undefined, USER is assumed.
  - If the *authorization-name* is defined as GROUP only according to the security plug-in in effect, GROUP is assumed.
  - If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.

Notes

- The GRANT statement does not take effect until it is committed, even for the connection that issues the statement.
- If the database is created with the RESTRICT option, the USAGE privilege of the default user workload, SYSDEFAULTUSERWORKLOAD, must be granted explicitly by a user that has DBADM authority. If the database is created without the RESTRICT option, the USAGE privilege of SYSDEFAULTUSERWORKLOAD is granted to PUBLIC at database creation time.

Example

Grant user LISA the ability to use the workload CAMPAIGN.

```
GRANT USAGE ON WORKLOAD CAMPAIGN TO USER LISA
```

GRANT (XSR object privileges)

This form of the GRANT statement grants USAGE privilege on an XSR object.

Invocation

The GRANT statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if the DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

One of the following authorities is required:

- ACCESSCTRL or SECADM authority
- ACCESSCTRL authority on the schema containing the XSR object

- Owner of the XSR object, as recorded in the OWNER column of the SYSCAT.XSROBJECTS catalog view

Syntax

Description

ON XSROBJECT *xsrobject-name*
This name identifies the XSR object for which the USAGE privilege is granted. The *xsrobject-name*, including the implicit or explicit schema qualifier, must uniquely identify an existing XSR object at the current server. If no XSR object by this name exists, an error is returned (SQLSTATE 42704).

TO PUBLIC
Grants the USAGE privilege to a set of users (authorization IDs).

Example

Grant every user the usage privilege on the XML schema MYSCHEMA:

```
GRANT USAGE ON XSROBJECT MYSCHEMA TO PUBLIC
```

IF

The IF statement selects an execution path based on the evaluation of a condition.

Invocation

This statement can be embedded in an:

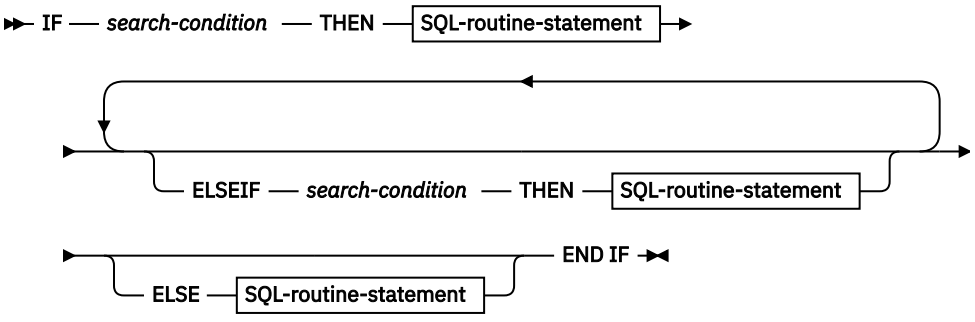
- SQL procedure definition
- Compound SQL (compiled) statement
- Compound SQL (inlined) statement

The compound statements can be embedded in an SQL procedure definition, SQL function definition, or SQL trigger definition. It is not an executable statement and cannot be dynamically prepared.

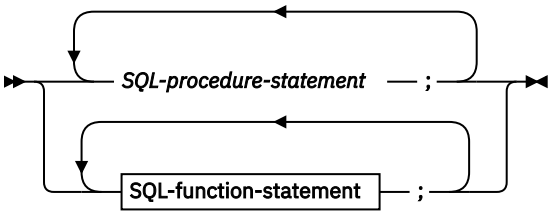
Authorization

Group privileges are not considered because this statement cannot be dynamically prepared.

Syntax



SQL-routine-statement



Description

search-condition
Specifies the condition for which an SQL statement should be invoked. If the condition is unknown or false, processing continues to the next search condition, until either a condition is true or processing reaches the ELSE clause.

SQL-procedure-statement
Specifies the statement to be invoked if the preceding *search-condition* is true. *SQL-procedure-statement* is only applicable when in the context of an SQL procedure or a compound SQL (compiled) statement. See *SQL-procedure-statement* in "Compound SQL (compiled)" statement.

SQL-function-statement
Specifies the statement to be invoked if the preceding *search-condition* is true. *SQL-function-statement* is only applicable when in the context of a compound SQL (inlined) statement, an SQL trigger, an SQL function, or an SQL method. See *SQL-function-statement* in "FOR".

Example

The following SQL procedure accepts two IN parameters: an employee number *employee_number* and an employee rating *rating*. Depending on the value of *rating*, the `employee` table is updated with new values in the `salary` and `bonus` columns.

```
CREATE PROCEDURE UPDATE_SALARY_IF
  (IN employee_number CHAR(6), INOUT rating SMALLINT)
  LANGUAGE SQL
  BEGIN
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE EXIT HANDLER FOR not_found
      SET rating = -1;
    IF rating = 1
      THEN UPDATE employee
      SET salary = salary * 1.10, bonus = 1000
      WHERE empno = employee_number;
    ELSEIF rating = 2
      THEN UPDATE employee
      SET salary = salary * 1.05, bonus = 500
      WHERE empno = employee_number;
    ELSE UPDATE employee
      SET salary = salary * 1.03, bonus = 0
      WHERE empno = employee_number;
    END IF;
  END
```

INCLUDE

The INCLUDE statement inserts declarations into a source program.

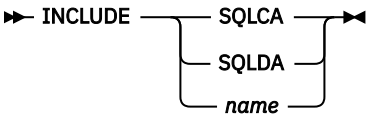
Invocation

This statement can only be embedded in an application program. It is not an executable statement.

Authorization

None required.

Syntax



Description

SQLCA
Indicates the description of an SQL communication area (SQLCA) is to be included.

SQLDA
Indicates the description of an SQL descriptor area (SQLDA) is to be included.

name
Identifies an external file containing text that is to be included in the source program being precompiled. It can be an SQL identifier without a file name extension or a literal enclosed by single quotation marks (' '). An SQL identifier assumes the filename extension of the source file being precompiled. If a file name extension is not provided by a literal enclosed by quotation marks, none is assumed.

Notes

- When a program is precompiled, the INCLUDE statement is replaced by source statements. Thus, the INCLUDE statement should be specified at a point in the program such that the resulting source statements are acceptable to the compiler.
- The external source file must be written in the host language specified by *name*. If it is greater than 18 bytes or contains characters that are not allowed in an SQL identifier, it must be enclosed by single quotation marks. INCLUDE *name* statements may be nested though not cyclical (for example, if A and B are modules and A contains an INCLUDE *name* statement, then it is not valid for A to call B and then B to call A).
- When the LANGLEVEL precompile option is specified with the SQL92E value, INCLUDE SQLCA should not be specified. SQLSTATE and SQLCODE variables may be defined within the host variable declare section.

Example

Include an SQLCA in a C program.

```
EXEC SQL INCLUDE SQLCA;

EXEC SQL DECLARE C1 CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO FROM TDEPT
    WHERE ADMRDEPT = 'A00';

EXEC SQL OPEN C1;

while (SQLCODE==0) {
  EXEC SQL FETCH C1 INTO :dnum, :dname, :mnum;

(Print results)

}

EXEC SQL CLOSE C1;
```

INSERT

The INSERT statement inserts rows into a table, nickname, or view, or the underlying tables, nicknames, or views of the specified fullselect.

Inserting a row into a nickname inserts the row into the data source object to which the nickname refers. Inserting a row into a view also inserts the row into the table on which the view is based, if no INSTEAD OF trigger is defined for the insert operation on this view. If such a trigger is defined, the trigger will be executed instead.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- INSERT privilege on the target table, view, or nickname
- CONTROL privilege on the target table, view, or nickname
- INSERTIN privilege on the schema containing the target table, view, or nickname
- DATAACCESS authority on the schema containing the target table, view, or nickname
- DATAACCESS authority

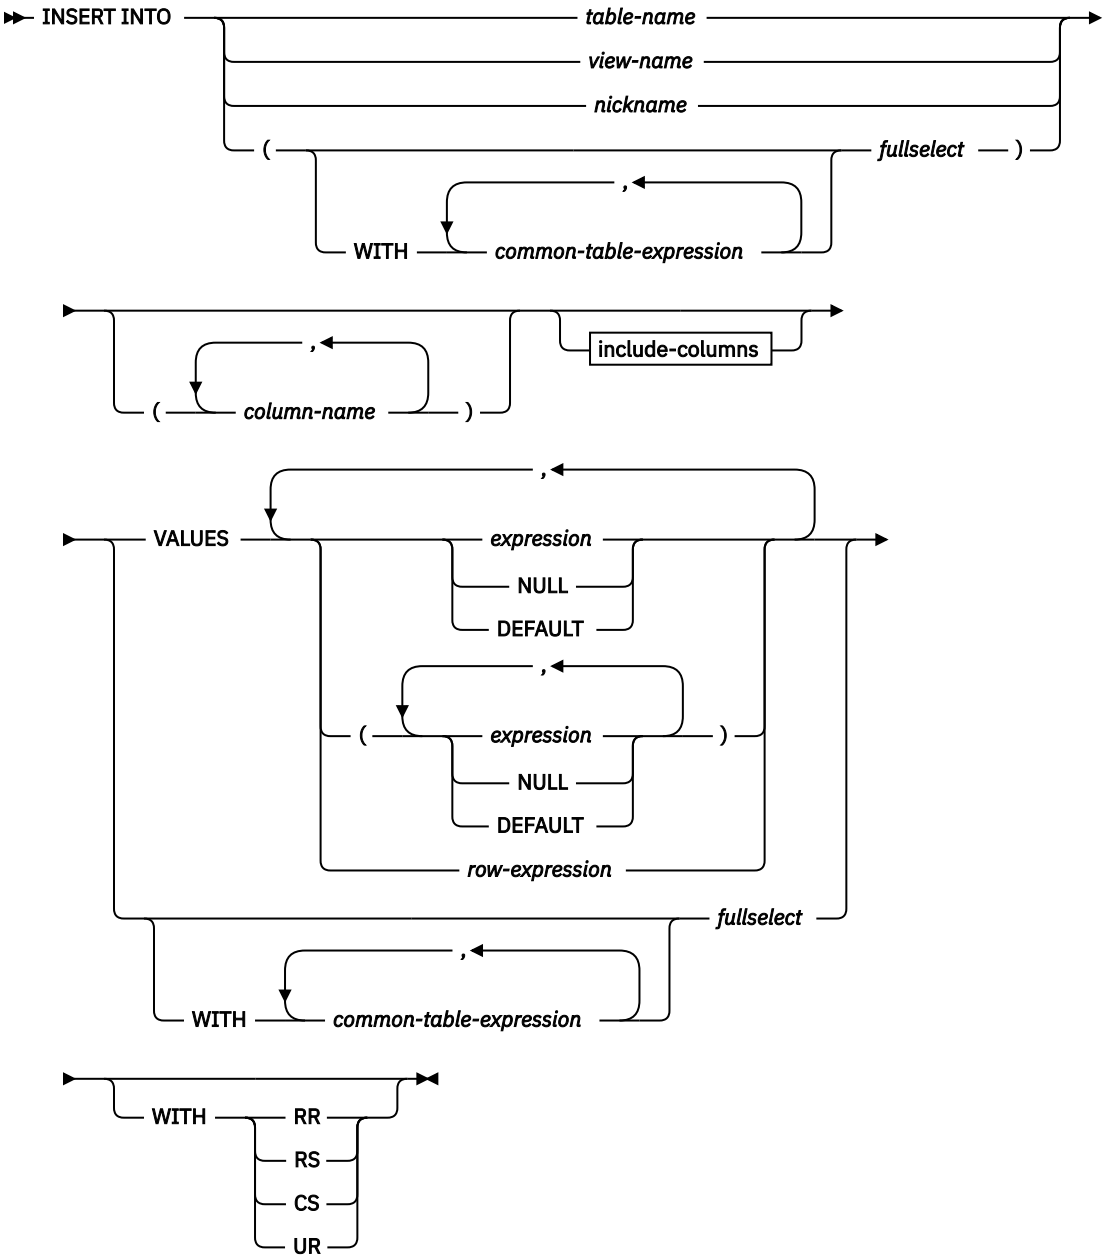
In addition, for each table, view, or nickname referenced in any fullselect used in the INSERT statement, the privileges held by the authorization ID of the statement must include at least one of the following authorities:

- SELECT privilege
- CONTROL privilege
- SELECTIN privilege on the schema containing the table, view or nickname
- DATAACCESS authority on the schema containing the table, view, or nickname
- DATAACCESS authority

GROUP privileges are not checked for static INSERT statements.

If the target of the insert operation is a nickname, the privileges on the object at the data source are not considered until the statement is executed at the data source. At this time, the authorization ID that is used to connect to the data source must have the privileges required for the operation on the object at the data source. The authorization ID of the statement can be mapped to a different authorization ID at the data source.

Syntax



include-columns

Description

INTO *table-name*, *view-name*, *nickname*, or *(fullselect)*

Identifies the object of the insert operation. The name must identify one of the following objects:

- A table, view or nickname that exists at the application server
- A table or view at a remote server specified using a remote-object-name

The object must not be a catalog table, a system-maintained materialized query table, a view of a catalog table, or a read-only view, unless an INSTEAD OF trigger is defined for the insert operation

on the subject view. Rows inserted into a nickname are placed in the data source object to which the nickname refers.

If the object of the insert operation is a fullselect, the fullselect must be insertable, as defined in the "Insertable views" Notes item in the description of the CREATE VIEW statement.

If the object of the insert operation is a nickname, the extended indicator variable values of DEFAULT and UNASSIGNED must not be used (SQLSTATE 22539).

If no INSTEAD OF trigger exists for the insert operation on this view, a value cannot be inserted into a view column that is derived from the following elements:

- A constant, expression, or scalar function
- The same base table column as some other column of the view

If the object of the insert operation is a view with such columns, a list of column names must be specified, and the list must not identify these columns.

A row can be inserted into a view or a fullselect that is defined using a UNION ALL if the row satisfies the check constraints of exactly one of the underlying base tables. If a row satisfies the check constraints of more than one table, or no table at all, an error is returned (SQLSTATE 23513).

A row cannot be inserted into a view or a fullselect that is defined using a UNION ALL if any base table of the view contains a before trigger and the before trigger contains an UPDATE, a DELETE, or an INSERT operation, or invokes any routine containing such operations (SQLSTATE 42987).

(*column-name*,...)
Specifies the columns for which insert values are provided. Each name must identify a column of the specified table, view, or nickname, or a column in the fullselect. The same column must not be identified more than once. If extended indicator variables are not enabled, a column that cannot accept inserted values (for example, a column based on an expression) must not be identified.

Omission of the column list is an implicit specification of a list in which every column of the table (that is not implicitly hidden) or view, or every item in the select-list of the fullselect is identified in left-to-right order. This list is established when the statement is prepared and, therefore, does not include columns that were added to a table after the statement was prepared.

include-columns
Specifies a set of columns that are included, along with the columns of *table-name* or *view-name*, in the intermediate result table of the INSERT statement when it is nested in the FROM clause of a fullselect. The *include-columns* are appended at the end of the list of columns that are specified for *table-name* or *view-name*.

INCLUDE
Specifies a list of columns to be included in the intermediate result table of the INSERT statement. This clause can only be specified if the INSERT statement is nested in the FROM clause of a fullselect.

column-name
Specifies a column of the intermediate result table of the INSERT statement. The name cannot be the same as the name of another include column or a column in *table-name* or *view-name* (SQLSTATE 42711).

data-type
Specifies the data type of the include column. The data type must be one that is supported by the CREATE TABLE statement.

VALUES
Introduces one or more rows of values to be inserted.

Each row specified in the VALUES clause must be assignable to the implicit or explicit column list and the columns identified in the INCLUDE clause, unless a row variable is used. When a row value list in parentheses is specified, the first value is inserted into the first column in the list, the second value into the second column, and so on. When a row expression is specified, the number of fields in the row type must match the number of names in the implicit or explicit column list.

expression
An *expression* can be any expression defined in the "Expressions" topic. If *expression* is a row type, it must not appear in parentheses. If *expression* is a variable, the host variable can include an indicator variable or in the case of a host structure, an indicator array, enabled for extended indicator variables. If extended indicator variables are enabled, the extended indicator variable values of default (-5) or unassigned (-7) must not be used (SQLSTATE 22539) if either of the following statements is true:

- The expression is more complex than a single host variable with explicit casts
- The target column has data type of structured type

NULL
Specifies the null value and should only be specified for nullable columns.

DEFAULT
Specifies that the default value is to be used. The result of specifying DEFAULT depends on how the column was defined, as follows:

- If the column was defined as a generated column based on an expression, the column value is generated by the system, based on that expression.
- If the IDENTITY clause is used, the value is generated by the database manager.
- If the ROW CHANGE TIMESTAMP clause is used, the value for each inserted row is generated by the database manager as a timestamp that is unique for the table partition within the database partition.
- If the WITH DEFAULT clause is used, the value inserted is as defined for the column (see *default-clause* in "CREATE TABLE").
- If the NOT NULL clause is used and the GENERATED clause is not used, or the WITH DEFAULT clause is not used or DEFAULT NULL is used, the DEFAULT keyword cannot be specified for that column (SQLSTATE 23502).
- When inserting into a nickname, the DEFAULT keyword will be passed through the INSERT statement to the data source only if the data source supports the DEFAULT keyword in its query language syntax.

row-expression
Specifies any row expression of the type described in "Row expressions" that does not include a column name. The number of fields in the row must match the target of the insert and each field must be assignable to the corresponding column.

WITH *common-table-expression*
Defines a common table expression for use with the fullselect that follows.

fullselect
Specifies a set of new rows in the form of the result table of a fullselect. There may be one, more than one, or none. If the result table is empty, SQLCODE is set to +100 and SQLSTATE is set to '02000'.

When the base object of the INSERT and the base object of the fullselect or any subquery of the fullselect, are the same table, the fullselect is completely evaluated before any rows are inserted.

The number of columns in the result table must equal the number of names in the column list. The value of the first column of the result is inserted in the first column in the list, the second value in the second column, and so on.

If the expression that specifies the value of a result column is a variable, the host variable can include an indicator variable enabled for extended indicator variables. If extended indicator variables are enabled, and the expression is more than a single host variable, or a host variable being explicitly cast, then the extended indicator variable values of default or unassigned must not be used (SQLSTATE 22539). The effects of default or unassigned values apply to the corresponding target columns of the *fullselect*.

WITH
Specifies the isolation level at which the statement is executed.

RR
Repeatable Read

RS
Read Stability

CS
Cursor Stability

UR
Uncommitted Read

The default isolation level of the statement is the isolation level of the package in which the statement is bound. The WITH clause has no effect on nicknames, which always use the default isolation level of the statement.

Rules

- ***Triggers:*** INSERT statements may cause triggers to be executed. A trigger may cause other statements to be executed, or may raise error conditions based on the inserted values. If an insert operation into a view causes an INSTEAD OF trigger to fire, validity, referential integrity, and constraints will be checked against the updates that are performed in the trigger, and not against the view that caused the trigger to fire, or its underlying tables.
- ***Default values:*** The value inserted in any column that is not in the column list is either the default value of the column or null. Columns that do not allow null values and are not defined with NOT NULL WITH DEFAULT must be included in the column list. Similarly, if you insert into a view, the value inserted into any column of the base table that is not in the view is either the default value of the column or null. Hence, all columns of the base table that are not in the view must have either a default value or allow null values. The only value that can be inserted into a generated column defined with the GENERATED ALWAYS clause is DEFAULT (SQLSTATE 428C9).
- ***Length:*** If the insert value of a column is a number, the column must be a numeric column with the capacity to represent the integral part of the number. If the insert value of a column is a string, the column must either be a string column with a length attribute at least as great as the length of the string, or a datetime column if the string represents a date, time, or timestamp.
- ***Assignment:*** Insert values are assigned to columns in accordance with specific assignment rules.
- ***Validity:*** If the table named, or the base table of the view named, has one or more unique indexes, each row inserted into the table must conform to the constraints imposed by those indexes. If a view whose definition includes WITH CHECK OPTION is named, each row inserted into the view must conform to the definition of the view. For an explanation of the rules governing this situation, see "CREATE VIEW".
- ***Referential integrity:*** For each constraint defined on a table, each non-null insert value of the foreign key must be equal to a primary key value of the parent table.
- ***Check constraint:*** Insert values must satisfy the check conditions of the check constraints defined on the table. An INSERT to a table with check constraints defined has the constraint conditions evaluated once for each row that is inserted.
- ***XML values:*** A value that is inserted into an XML column must be a well-formed XML document (SQLSTATE 2200M).
- ***Security policy:*** If the identified table or the base table of the identified view is protected with a security policy, the session authorization ID must have the label-based access control (LBAC) credentials that allow:
  - Write access to all protected columns for which a data value is explicitly provided (SQLSTATE 42512)
  - Write access for any explicit value provided for a DB2SECURITYLABEL column for security policies that were created with the RESTRICT NOT AUTHORIZED WRITE SECURITY LABEL option (SQLSTATE 23523)

  The session authorization ID must also have been granted a security label for write access for the security policy if an implicit value is used for a DB2SECURITYLABEL column (SQLSTATE 23523), which can happen when:

  - A value for the DB2SECURITYLABEL column is not explicitly provided
  - A value for the DB2SECURITYLABEL column is explicitly provided but the session authorization ID does not have write access for that value, and the security policy is created with the OVERRIDE NOT AUTHORIZED WRITE SECURITY LABEL option
- **Extended indicator variable usage**: If enabled, negative indicator variable values outside the range of -1 through -7 must not be input (SQLSTATE 22010). Also, if enabled, the default and unassigned extended indicator variable values must not appear in contexts in which they are not supported (SQLSTATE 22539).
- **Extended indicator variables**: In an INSERT statement, a value of unassigned has the effect of setting the column to its default value.

  If the target column is a column defined as GENERATED ALWAYS, then it must be assigned the DEFAULT keyword, or the extended indicator variable-based values of default or unassigned (SQLSTATE 428C9).

Notes

- After execution of an INSERT statement, the value of the third variable of the SQLERRD(3) portion of the SQLCA indicates the number of rows that were passed to the insert operation. In the context of an SQL procedure statement, the value can be retrieved using the ROW_COUNT variable of the GET DIAGNOSTICS statement. SQLERRD(5) contains the count of all triggered insert, update and delete operations.
- Unless appropriate locks already exist, one or more exclusive locks are acquired at the execution of a successful INSERT statement. Until the locks are released, an inserted row can only be accessed by:
  - The application process that performed the insert.
  - Another application process using isolation level UR through a read-only cursor, SELECT INTO statement, or subselect used in a subquery.
- For further information about locking, see the description of the COMMIT, ROLLBACK, and LOCK TABLE statements.
- If an application is running against a partitioned database, and it is bound with option INSERT BUF, then INSERT with VALUES statements which are not processed using EXECUTE IMMEDIATE may be buffered. It is assumed that such an INSERT statement is being processed inside a loop in the application's logic. Rather than execute the statement to completion, it attempts to buffer the new row values in one or more buffers. As a result the actual insertions of the rows into the table are performed later, asynchronous with the application's INSERT logic. Be aware that this asynchronous insertion may cause an error related to an INSERT to be returned on some other SQL statement that follows the INSERT in the application.

  This has the potential to dramatically improve INSERT performance, but is best used with clean data, due to the asynchronous nature of the error handling.
- When a row is inserted into a table that has an identity column, a value is generated for the identity column.
  - For a GENERATED ALWAYS identity column, the value is always generated.
  - For a GENERATED BY DEFAULT column, if a value is not explicitly specified (with a VALUES clause, or subselect), a value is generated.

  The first value generated is the value of the START WITH specification for the identity column.
- When a value is inserted for a user-defined distinct type identity column, the entire computation is done in the source type, and the result is cast to the distinct type before the value is actually assigned to the column. (There is no casting of the previous value to the source type before the computation.)
- When inserting into a GENERATED ALWAYS identity column, a value is always generated for the column, and users must not specify a value at insertion time. If a GENERATED ALWAYS identity column is listed in the column-list of the INSERT statement, with a non-DEFAULT value in the VALUES clause, an error occurs (SQLSTATE 428C9).

For example, assuming that EMPID is defined as an identity column that is GENERATED ALWAYS, then the command:

```
INSERT INTO T2 (EMPID, EMPNAME, EMPADDR)
  VALUES (:hv_valid_emp_id, :hv_name, :hv_addr)
```

will result in an error.

- When inserting into a GENERATED ALWAYS ROW CHANGE TIMESTAMP column, a value is always generated for the column, and users must not specify a value at insertion time (SQLSTATE 428C9) . The value generated is unique for each row inserted on the database partition.
- When inserting into a GENERATED BY DEFAULT column, you can specify an actual value for the column within the VALUES clause, or from a subselect. However, when a value is specified in the VALUES clause, the database manager does not perform any verification of the value. To guarantee uniqueness of IDENTITY column values, a unique index on the identity column must be created.

  When inserting into a table with a GENERATED BY DEFAULT identity column, without specifying a column list, the VALUES clause can specify the DEFAULT keyword to represent the value for the identity column. In such cases, the value for the identity column will be generated.

  ```
  INSERT INTO T2 (EMPID, EMPNAME, EMPADDR)
    VALUES (DEFAULT, :hv_name, :hv_addr)
  ```

  In this example, EMPID is defined as an identity column, and thus the value inserted into this column is generated by the database manager.
- The rules for inserting into an identity column with a subselect are similar to those for an insert with a VALUES clause. A value for an identity column may only be specified if the identity column is defined as GENERATED BY DEFAULT.

  For example, assume T1 and T2 are tables with the same definition, both containing columns *intcol1* and *identcol2* (both are type INTEGER and the second column has the identity attribute). Consider the following insert:

  ```
  INSERT INTO T2
    SELECT *
    FROM T1
  ```

  This example is logically equivalent to:

  ```
  INSERT INTO T2 (intcol1,identcol2)
    SELECT intcol1, identcol2
    FROM T1
  ```

  In both cases, the INSERT statement is providing an explicit value for the identity column of T2. This explicit specification can be given a value for the identity column, but the identity column in T2 must be defined as GENERATED BY DEFAULT. Otherwise, an error will result (SQLSTATE 428C9).

  If there is a table with a column defined as a GENERATED ALWAYS identity, it is still possible to propagate all other columns from a table with the same definition. For example, given the example tables T1 and T2 described previously, the intcol1 values from T1 to T2 can be propagated with the following SQL:

  ```
  INSERT INTO T2 (intcol1)
    SELECT intcol1
    FROM T1
  ```

  Note that, because identcol2 is not specified in the column-list, it will be filled in with its default (generated) value.
- When inserting a row into a single column table where the column is defined as a GENERATED ALWAYS identity column or a ROW CHANGE TIMESTAMP column, it is possible to specify a VALUES clause with the DEFAULT keyword. In this case, the application does not provide any value for the table, and the database manager generates the value for the identity or ROW CHANGE TIMESTAMP column.

```
INSERT INTO IDTABLE
  VALUES(DEFAULT)
```

Assuming the same single column table for which the column has the identity attribute, to insert multiple rows with a single INSERT statement, the following INSERT statement could be used:

```
INSERT INTO IDTABLE
  VALUES (DEFAULT), (DEFAULT), (DEFAULT), (DEFAULT)
```

- When a value for an identity column is generated, that generated value is consumed; the next time that a value is needed, a new value is generated. This is true even when an INSERT statement involving an identity column fails or is rolled back.

  For example, assume that a unique index has been created on the identity column. If a duplicate key violation is detected in generating a value for an identity column, an error occurs (SQLSTATE 23505) and the value generated for the identity column is considered to be consumed. This can occur when the identity column is defined as GENERATED BY DEFAULT and the system tries to generate a new value, but the user has explicitly specified values for the identity column in previous INSERT statements. Reissuing the same INSERT statement in this case can lead to success. The next value for the identity column will be generated, and it is possible that this next value will be unique, and that this INSERT statement will be successful.
- If the maximum value for the identity column is exceeded (or minimum value for a descending sequence) in generating a value for an identity column, an error occurs (SQLSTATE 23522). In this situation, the user would have to DROP and CREATE a new table with an identity column having a larger range (that is, change the data type or increment value for the column to allow for a larger range of values).

  For example, an identity column may have been defined with a data type of SMALLINT, and eventually the column runs out of assignable values. To redefine the identity column as INTEGER, the data would need to be unloaded, the table would have to be dropped and recreated with a new definition for the column, and then the data would be reloaded. When the table is redefined, it needs to specify a START WITH value for the identity column such that the next value generated will be the next value in the original sequence. To determine the end value, issue a query using MAX of the identity column (for an ascending sequence), or MIN of the identity column (for a descending sequence), before unloading the data.
- **Extended indicator variables and insert triggers**: No change in the activation of insert triggers results from use of extended indicator variables. If all columns in the implicit or explicit column list have been assigned to an extended indicator variable-based value of unassigned or default, an insert where all columns have their respective default values is attempted, and if successful, the insert trigger is activated.
- **Extended indicator variables and deferred error checks**: When extended indicator variables are enabled, validation that would otherwise be done in statement preparation, to recognize an insert into a non-updatable column, is deferred until statement execution. Whether an error should be reported can be determined only during execution.
- **Inserting into tables with row-begin, row-end, or transaction start-ID columns**: When a row is inserted into a table with these generated columns (for instance, a system-period temporal table), the database manager assigns values to the following columns:
  - A row-begin column is assigned a value that is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row-begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. The database manager ensures uniqueness of the generated values for a row-begin column across transactions. If multiple rows are inserted within a single SQL transaction, the values for the row-begin column are the same for all the rows and are unique from the values generated for the column for another transaction.
  - A row-end column is assigned the maximum value for the data type of the column (9999-12-30-00.00.00.000000000000).

  - A transaction start-ID column is assigned a unique timestamp value per transaction or the null value. The null value is assigned to the transaction start-ID column if the column is nullable. Otherwise, the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row-begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. If multiple rows are inserted within a single SQL transaction, the values for the transaction start-ID column are the same for all the rows and are unique from the values generated for the column for another transaction.
- **Inserting into a system-period temporal table**: When a row is inserted into a system-period temporal table, the database manager assigns values to columns as indicated for tables with row-begin, row-end, or transaction start-ID columns. Also, when a row is inserted, no rows are added to the history table associated with the system-period temporal table.
- **Inserting into application-period temporal tables**: An error is returned when a row is inserted into an application-period temporal table and the following conditions are met:
  - The application-period temporal table has either a primary key or unique constraint with the BUSINESS_TIME WITHOUT OVERLAPS clause defined, or a unique index with the BUSINESS_TIME WITHOUT OVERLAPS clause defined.
  - The period defined by the begin and end columns of the BUSINESS_TIME period overlap the period defined by the begin and end columns of the BUSINESS_TIME period for another row that matches the other columns of the same unique constraint or unique index.
- **Considerations for an INSERT without a column list**: An INSERT statement without a column list does not include implicitly hidden columns. Columns that are defined as implicitly hidden and not null must have a defined default value.

Examples

- *Example 1:* Insert a new department with the following specifications into the DEPARTMENT table:
  - Department number (DEPTNO) is 'E31'
  - Department name (DEPTNAME) is 'ARCHITECTURE'
  - Managed by (MGRNO) a person with number '00390'
  - Reports to (ADMRDEPT) department 'E01'.

```
INSERT INTO DEPARTMENT
  VALUES ('E31', 'ARCHITECTURE', '00390', 'E01')
```

- *Example 2:* Insert a new department into the DEPARTMENT table as in example 1, but do not assign a manager to the new department.

```
INSERT INTO DEPARTMENT (DEPTNO, DEPTNAME, ADMRDEPT )
  VALUES ('E31', 'ARCHITECTURE', 'E01')
```

- *Example 3:* Insert two new departments using one statement into the DEPARTMENT table as in example 2, but do not assign a manager to the new department.

```
INSERT INTO DEPARTMENT (DEPTNO, DEPTNAME, ADMRDEPT)
  VALUES ('B11', 'PURCHASING', 'B01'),
         ('E41', 'DATABASE ADMINISTRATION', 'E01')
```

- *Example 4:* Create a temporary table MA_EMP_ACT with the same columns as the EMP_ACT table. Load MA_EMP_ACT with the rows from the EMP_ACT table with a project number (PROJNO) starting with the letters 'MA'.

```
CREATE TABLE MA_EMP_ACT
         ( EMPNO CHAR(6)  NOT NULL,
          PROJNO CHAR(6)  NOT NULL,
          ACTNO SMALLINT  NOT NULL,
          EMPTIME DEC(5,2),
          EMSTDATE DATE,
          EMENDATE  DATE )
INSERT INTO MA_EMP_ACT
```

```
  SELECT * FROM EMP_ACT
    WHERE SUBSTR(PROJNO, 1, 2) = 'MA'
```

- *Example 5:* Use a C program statement to add a skeleton project to the PROJECT table. Obtain the project number (PROJNO), project name (PROJNAME), department number (DEPTNO), and responsible employee (RESPEMP) from host variables. Use the current date as the project start date (PRSTDATE). Assign a null value to the remaining columns in the table.

```
EXEC SQL INSERT INTO PROJECT (PROJNO, PROJNAME, DEPTNO, RESPEMP, PRSTDATE)
  VALUES (:PRJNO, :PRJNM, :DPTNO, :REMP, CURRENT DATE);
```

- *Example 6:* Specify an INSERT statement as the *data-change-table-reference* within a SELECT statement. Define an extra include column whose values are specified in the VALUES clause, which is then used as an ordering column for the inserted rows.

```
SELECT INORDER.ORDERNUM
  FROM NEW TABLE (INSERT INTO ORDERS(CUSTNO)INCLUDE (INSERTNUM INTEGER)
    VALUES(:CNUM1, 1), (:CNUM2, 2)) InsertedOrders
  ORDER BY INSERTNUM;
```

- *Example 7:* Use a C program statement to add a document to the DOCUMENTS table. Obtain values for the document ID (DOCID) column and the document data (XMLDOC) column from a host variable that binds to an SQL TYPE IS XML AS BLOB_FILE.

```
EXEC SQL INSERT INTO DOCUMENTS
  (DOCID, XMLDOC) VALUES (:docid, :xmldoc)
```

- *Example 8:* For the following INSERT statements, assume that table SALARY_INFO is defined with three columns, and that the last column is an implicitly hidden ROW CHANGE TIMESTAMP column. In the following statement, the implicitly hidden column is explicitly referenced in the column list and a value is provided for it in the VALUES clause.

```
INSERT INTO SALARY_INFO (LEVEL, SALARY, UPDATE_TIME)
  VALUES (2, 30000, CURRENT TIMESTAMP)
```

  The following INSERT statement uses an implicit column list. An implicit column list does not include implicitly hidden columns, so the VALUES clause only contains values for the other two columns.

```
INSERT INTO SALARY_INFO VALUES (2, 30000)
```

  In this case, the UPDATE_TIME column must be defined to have a default value, and that default value is used for the row that is inserted.

ITERATE

The ITERATE statement causes the flow of control to return to the beginning of a labelled loop.

Invocation

This statement can be embedded in an:

- SQL procedure definition
- Compound SQL (compiled) statement
- Compound SQL (inlined) statement

The compound statements can be embedded in an SQL procedure definition, SQL function definition, or SQL trigger definition. It is not an executable statement and cannot be dynamically prepared.

Authorization

None required.

Syntax

Description

label
Specifies the label of the FOR, LOOP, REPEAT, or WHILE statement to which the database server passes the flow of control.

Example

This example uses a cursor to return information for a new department. If the *not_found* condition handler was invoked, the flow of control passes out of the loop. If the value of *v_dept* is 'D11', an ITERATE statement passes the flow of control back to the top of the LOOP statement. Otherwise, a new row is inserted into the DEPARTMENT table.

```
CREATE PROCEDURE ITERATOR()
  LANGUAGE SQL
  BEGIN
    DECLARE v_dept CHAR(3);
    DECLARE v_deptname VARCHAR(29);
    DECLARE v_admdept CHAR(3);
    DECLARE at_end INTEGER DEFAULT 0;
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE c1 CURSOR FOR
      SELECT deptno, deptname, admrdept
      FROM department
      ORDER BY deptno;
    DECLARE CONTINUE HANDLER FOR not_found
      SET at_end = 1;
    OPEN c1;
    ins_loop:
    LOOP
      FETCH c1 INTO v_dept, v_deptname, v_admdept;
      IF at_end = 1 THEN
        LEAVE ins_loop;
      ELSEIF v_dept = 'D11' THEN
        ITERATE ins_loop;
      END IF;
      INSERT INTO department (deptno, deptname, admrdept)
      VALUES ('NEW', v_deptname, v_admdept);
    END LOOP;
    CLOSE c1;
  END
```

LEAVE

The LEAVE statement transfers program control out of a loop or a compound statement.

Invocation

This statement can be embedded in an:

- SQL procedure definition
- Compound SQL (compiled) statement
- Compound SQL (inlined) statement

The compound statements can be embedded in an SQL procedure definition, SQL function definition, or SQL trigger definition. It is not an executable statement and cannot be dynamically prepared.

Authorization

None required.

Syntax

Description

label
Specifies the label of the compound, FOR, LOOP, REPEAT, or WHILE statement to exit.

Notes

- When a LEAVE statement transfers control out of a compound statement, all open cursors in the compound statement, except cursors that are used to return result sets, are closed.

Example

This example contains a loop that fetches data for cursor *c1*. If the value of SQL variable *at_end* is not zero, the LEAVE statement transfers control out of the loop.

```
CREATE PROCEDURE LEAVE_LOOP(OUT counter INTEGER)
  LANGUAGE SQL
  BEGIN
    DECLARE v_counter INTEGER;
    DECLARE v_firstnme VARCHAR(12);
    DECLARE v_midinit CHAR(1);
    DECLARE v_lastname VARCHAR(15);
    DECLARE at_end SMALLINT DEFAULT 0;
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE c1 CURSOR FOR
      SELECT firstnme, midinit, lastname
        FROM employee;
    DECLARE CONTINUE HANDLER for not_found
      SET at_end = 1;
    SET v_counter = 0;
    OPEN c1;
    fetch_loop:
    LOOP
      FETCH c1 INTO v_firstnme, v_midinit, v_lastname;
      IF at_end <> 0 THEN LEAVE fetch_loop;
      END IF;
      SET v_counter = v_counter + 1;
    END LOOP fetch_loop;
    SET counter = v_counter;
    CLOSE c1;
  END
```

LOCK TABLE

The LOCK TABLE statement prevents concurrent application processes from using or changing a table. The lock is released when the unit of work issuing the LOCK TABLE statement either commits or terminates.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

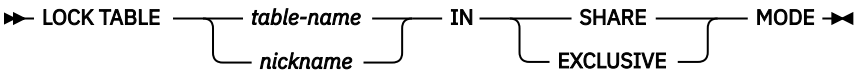
Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- SELECT privilege on the table
- SELECTIN privilege on the schema containing the table
- CONTROL privilege on the table

- DATAACCESS authority on the schema containing the table
- DATAACCESS authority

Syntax



Description

table-name* or *nickname
Identifies the table or nickname. The *table-name* must identify a table that exists at the application server, but it must not identify a catalog table, a created temporary table, or a declared temporary table (SQLSTATE 42995). If the *table-name* is a typed table, it must be the root table of the table hierarchy (SQLSTATE 428DR). When a nickname is specified, the database manager will lock the underlying object (that is, a table or view) of the data source to which the nickname refers.

IN SHARE MODE
Prevents concurrent application processes from executing any but read-only operations on the table.

IN EXCLUSIVE MODE
Prevents concurrent application processes from executing any operations on the table. Note that EXCLUSIVE MODE does not prevent concurrent application processes that are running at isolation level Uncommitted Read (UR) from executing read-only operations on the table.

Notes

- Locking is used to prevent concurrent operations. A lock is not necessarily acquired during execution of the LOCK TABLE statement if a suitable lock already exists. The lock that prevents concurrent operations is held at least until termination of the unit of work.
- In a partitioned database, if the LOCK TABLE statement is interrupted, the table may be locked on some database partitions but not on others. If this occurs, either issue another LOCK TABLE statement to complete the locking on all database partitions, or issue a COMMIT or ROLLBACK statement to release the current locks.
- This statement affects all database partitions in the database partition group.
- For partitioned tables, the only lock acquired for the LOCK TABLE statement is at the table level; no data partition locks are acquired.

Example

Obtain a lock on the table EMP. Do not allow other programs to read or update the table.

```
LOCK TABLE EMP IN EXCLUSIVE MODE
```

LOOP

The LOOP statement repeats the execution of a statement or a group of statements.

Invocation

This statement can be embedded in an:

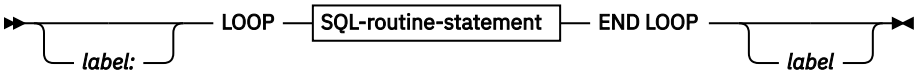
- SQL procedure definition
- Compound SQL (compiled) statement
- Compound SQL (inlined) statement

The compound statements can be embedded in an SQL procedure definition, SQL function definition, or SQL trigger definition. It is not an executable statement and cannot be dynamically prepared.

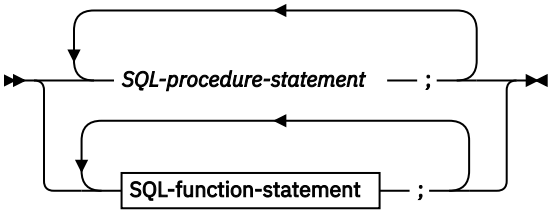
Authorization

No privileges are required to invoke the LOOP statement. However, the authorization ID of the statement must hold the necessary privileges to invoke the SQL statements that are embedded in the LOOP statement.

Syntax



SQL-routine-statement



Description

label
Specifies the label for the LOOP statement. If the beginning label is specified, that label can be specified on LEAVE and ITERATE statements. If the ending label is specified, a matching beginning label must be specified.

SQL-procedure-statement
Specifies the SQL statements that are to be invoked in the loop. *SQL-procedure-statement* is only applicable when in the context of an SQL procedure or Compound SQL (compiled) statement. See *SQL-procedure-statement* in "Compound SQL (compiled)" statement.

SQL-function-statement
Specifies the SQL statements that are to be invoked in the loop. *SQL-function-statement* is only applicable when in the context of an SQL function, SQL method, or Compound SQL (inlined) statement. See *SQL-function-statement* in "FOR".

Example

This procedure uses a LOOP statement to fetch values from the `employee` table. Each time the loop iterates, the OUT parameter *counter* is incremented and the value of *v_midinit* is checked to ensure that the value is not a single space (' '). If *v_midinit* is a single space, the LEAVE statement passes the flow of control outside of the loop.

```
CREATE PROCEDURE LOOP_UNTIL_SPACE(OUT counter INTEGER)
  LANGUAGE SQL
  BEGIN
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE v_firstnme VARCHAR(12);
    DECLARE v_midinit CHAR(1);
    DECLARE v_lastname VARCHAR(15);
    DECLARE c1 CURSOR FOR
      SELECT firstnme, midinit, lastname
        FROM employee;
    DECLARE CONTINUE HANDLER FOR NOT FOUND
      SET counter = -1;
    OPEN c1;
    fetch_loop:
    LOOP
      FETCH c1 INTO v_firstnme, v_midinit, v_lastname;
      IF v_midinit = ' ' THEN
```

```
          LEAVE fetch_loop;
        END IF;
        SET v_counter = v_counter + 1;
      END LOOP fetch_loop;
      SET counter = v_counter;
      CLOSE c1;
    END
```

MERGE

The MERGE statement updates a target (a table or view, or the underlying tables or views of a fullselect) using data from a source (result of a table reference).

Rows in the target that match the source can be deleted or updated as specified, and rows that do not exist in the target can be inserted. Updating, deleting or inserting a row in a view updates, deletes or inserts the row in the tables on which the view is based.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- If an insert operation is specified, INSERT privilege on the table or view or INSERTIN privilege on the schema containing the table or view; if a delete operation is specified, DELETE privilege on the table or view or DELETEIN privilege on the schema containing the table or view; and if an update operation is specified, either:
  - UPDATE privilege on the table or view
  - UPDATE privilege on each column that is to be updated
  - UPDATEIN privilege on the schema containing the table or view
- CONTROL privilege on the table
- DATAACCESS authority on the schema containing the table or view
- DATAACCESS authority

The privileges held by the authorization ID of the statement must also include at least one of the following authorities:

- SELECT privilege on every table or view identified in the *table-reference*
- SELECTIN privilege on the schema containing the tables or views identified in the table-reference
- CONTROL privilege on the tables or views identified in the *table-reference*
- DATAACCESS authority on the schema containing the tables or views identified in the table-reference
- DATAACCESS authority

If *search-condition*, *insert-operation*, or *assignment-clause* includes a subquery, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

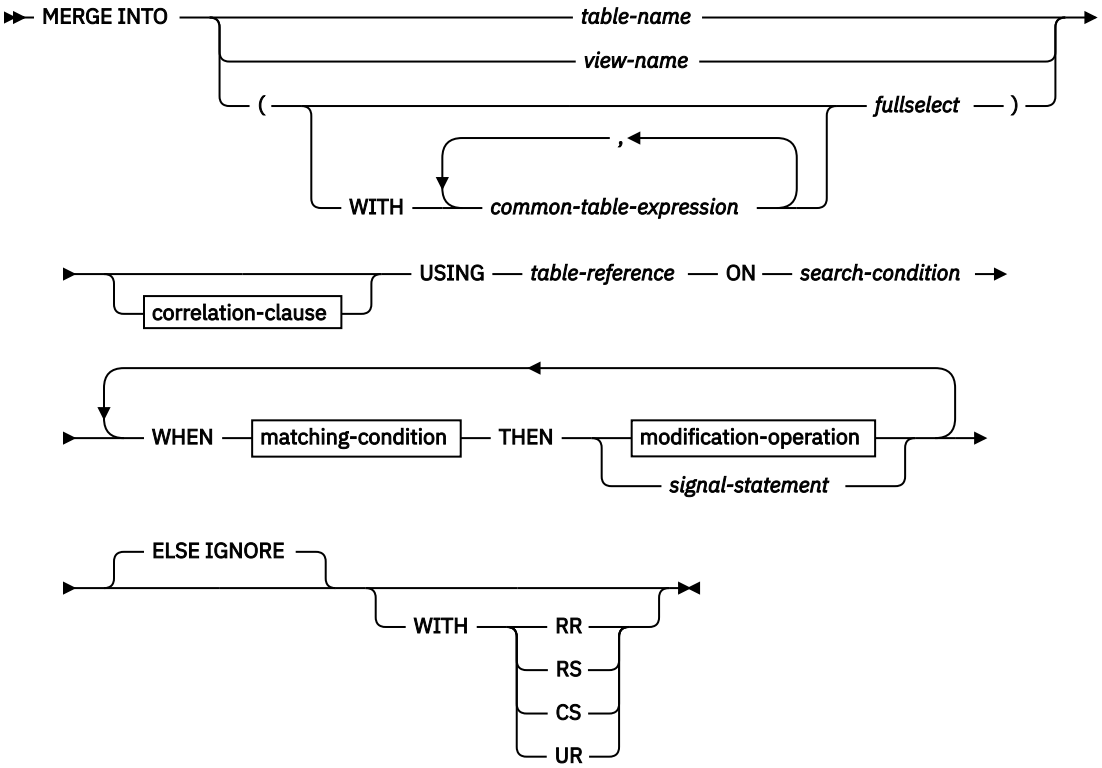
- SELECT privilege on every table or view identified in the subquery
- SELECTIN privilege on the schema containing the table or view identified in the subquery
- CONTROL privilege on the tables or views identified in the subquery
- DATAACCESS authority on the schema containing the table or view identified in the subquery
- DATAACCESS authority

If a *row-fullselect* is included in the assignment, the privileges held by the authorization ID of the statement must include at least one of the following authorities for each referenced table, view, or nickname:

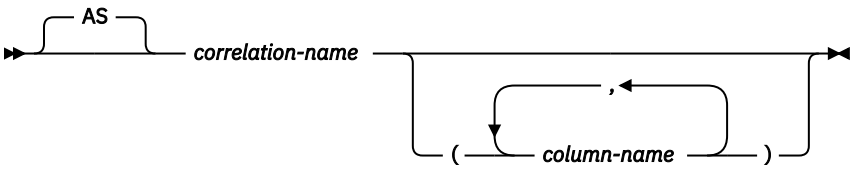
- SELECT privilege
- SELECTIN privilege on the schema containing the table, view or nickname referenced
- CONTROL privilege
- DATAACCESS authority on the schema containing the table, view or nickname referenced
- DATAACCESS authority

If an expression that refers to a function is specified, the privilege set must include any authority that is necessary to execute the function.

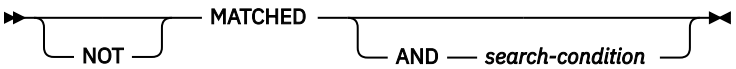
Syntax



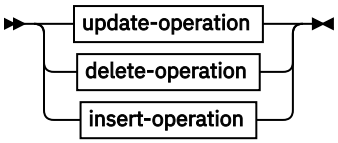
correlation-clause



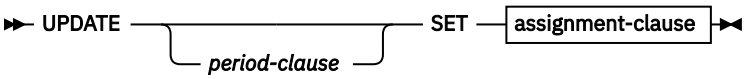
matching-condition



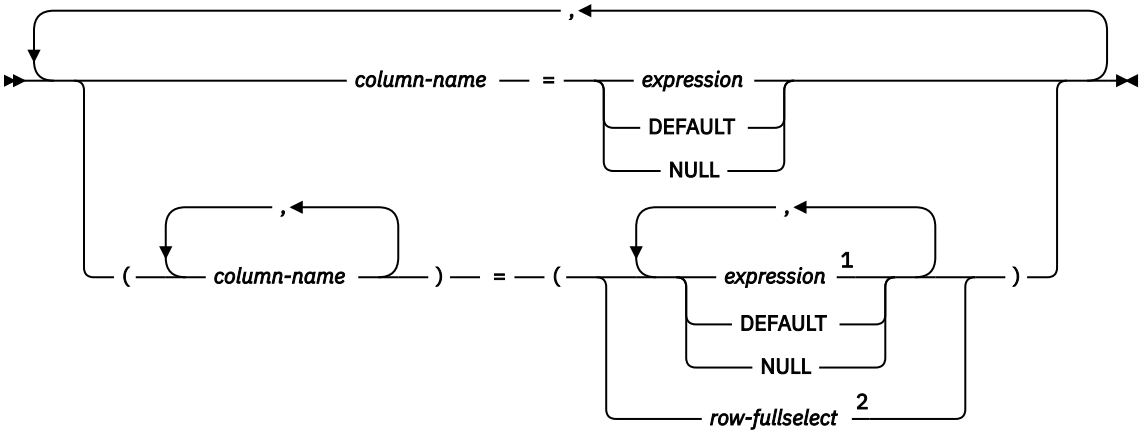
modification-operation



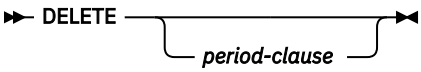
update-operation



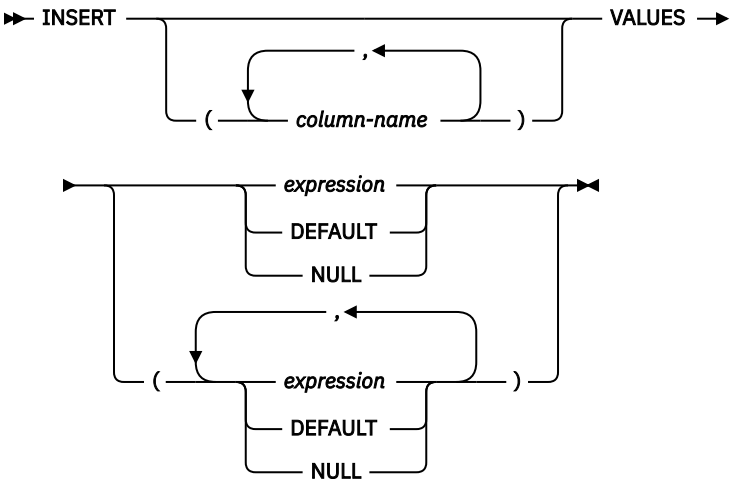
assignment-clause



delete-operation



insert-operation



period-clause

Notes:

[1] The number of expressions, NULLs, and DEFAULTs must match the number of column names.
[2] The number of columns in the select list must match the number of column names.

Description

table-name*, *view-name*, or *(fullselect)

Identifies the target of the update, delete, or insert operations of the merge. The name must identify a table or view that exists at the current server, but it must not identify a catalog table, a system-maintained materialized query table, a view of a catalog table, a read-only view, or a view that directly or indirectly contains a WHERE clause that references a subquery or a routine defined with NOT DETERMINISTIC or EXTERNAL ACTION (SQLSTATE 42807).

If the target of the merge operation is a fullselect, the fullselect must be updatable, deletable, or insertable as defined in the "Updatable views", "Deletable views", or "Insertable views" Notes items in the description of the CREATE VIEW statement.

You cannot use a *period-clause* in an update-operation or a delete-operation if the target of the merge operation is a union-all view or a fullselect.

You cannot use a nickname (a reference to a remote, federated table) as the target table.

correlation-clause
Can be used within *search-condition* or on the right side of an *assignment-clause* to designate a table, view, or fullselect. For a description of *correlation-clause*, see "table-reference" in the description of "Subselect".

USING *table-reference*
Specifies a set of rows as a result table to be merged into the target. If the result table is empty, a warning is returned (SQLSTATE 02000).

ON *search-condition*
Logically, a right join is performed between the target table and the *table-reference* using the ON *search-condition*. For those rows of the join result table where the search condition is true, the specified update or delete operation is performed. For those rows of the join result table where the result of the search condition is not true, the specified insert operation is performed.

The *search-condition* has the following restrictions (SQLSTATE 42972 unless otherwise noted):

- It cannot contain any subqueries, scalar or otherwise
- It cannot include any dereference operations or the DEREF function where the reference value is other than the object identifier column
- It cannot include an SQL function
- It cannot include an XMLQUERY or XMLEXISTS expression
- Any column that is referenced in an expression of the *search-condition* must be a column of the target table, view, or *table-reference*
- Any function that is referenced in an expression of the *join-condition* of a full outer join must be deterministic and have no external action
- It cannot be include an aggregate function (SQLSTATE 42903)

If the *search-condition* is false or unknown for every row in *table-reference*, a warning is returned (SQLSTATE 02000).

WHEN *matching-condition*
Specifies the condition under which the *modification-operation* or the *signal-statement* is executed. Each *matching-condition* is evaluated in order of specification. Rows for which the *matching-condition* evaluates to true are not considered in subsequent matching conditions.

MATCHED
Indicates the operation to be performed on the rows where the ON search condition is true. Only UPDATE, DELETE, or *signal-statement* can be specified after THEN.

AND *search-condition*
Specifies a further search condition to be applied against the rows that matched the ON search condition for the operation to be performed after THEN.

NOT MATCHED
Indicates the operation to be performed on the rows where the ON search condition is false or unknown. Only INSERT or *signal-statement* can be specified after THEN.

AND *search-condition*
Specifies a further search condition to be applied against the rows that did not match the ON search condition for the operation to be performed after THEN. This search condition applies only to rows that did not match ON *search condition*; if AND search condition references columns from the target table a syntax error might be returned (SQL0206N).

THEN *modification-operation*

Specifies the operation to execute when the *matching-condition* evaluates to true.

update-operation

Specifies the update operation to be executed for the rows where the *matching-condition* evaluates to true.

UPDATE

Introduces the update operation.

period-clause

Specifies that a period clause is applied to the update operation in the MERGE statement. For more information about the effects of a period clause specified in the context of an update operation, see the UPDATE statement topic.

SET

Introduces the assignment of values to column names.

assignment-clause

Specifies a list of column updates.

column-name

Identifies a column to be updated. The *column-name* must identify a column of the specified table or view, but not a view column derived from a scalar function, constant, or expression. A column must not be specified more than once (SQLSTATE 42701).

A view column derived from the same column as another column of the view can be updated, but both columns cannot be updated in the same MERGE statement (SQLSTATE 42701).

expression

Indicates the new value of the column. The *expression* must not include an aggregate function except when it occurs within a scalar fullselect (SQLSTATE 42903).

An *expression* can contain references to columns of the *table-name* or *view-name*. For each row that is updated, the value of such a column in an expression is the value of the column in the row before the row is updated.

If *expression* is a reference to a single column of the source table, the source table column value may have been specified with an extended indicator variable value. The effects of such indicator variables apply to the corresponding target columns of the *assignment-clause*.

If *expression* is a single host variable, or a host variable being explicitly cast, the host variable can include an indicator variable that is enabled for extended indicator variables.

When extended indicator variables are enabled, the extended indicator variable values of default (-5) or unassigned (-7) must not be used (SQLSTATE 22539) if either of the following statements is true:

- The expression is more complex than a single host variable with explicit casts
- The target column has data type of structured type

DEFAULT

The default value assigned to the column. DEFAULT can be specified only for columns that have a default value. For information about default values of data types, see the description of the DEFAULT clause in the "CREATE TABLE" statement.

DEFAULT must be specified for a column that was defined as GENERATED ALWAYS. A valid value can be specified for a column that was defined as GENERATED BY DEFAULT.

NULL
Specifies the null value as the new value of the column. Specify NULL only for nullable columns (SQLSTATE 23502).

row-fullselect
Specifies a fullselect that returns a single row. The result column values are assigned to each corresponding *column-name*. If the fullselect returns no rows, the null value is assigned to each column; an error occurs if any column to be updated is not nullable. An error also occurs if there is more than one row in the result.

A *row-fullselect* can contain references to columns of the target table of the MERGE statement. For each row that is updated, the value of such a column in an expression is the value of the column in the row before the row is updated. An error is returned if there is more than one row in the result (SQLSTATE 21000).

delete-operation
Specifies the delete operation to be executed for the rows where the *matching-condition* evaluates to true.

DELETE
Introduces the delete operation.

period-clause
Specifies that a period clause is applied to the delete operation in the MERGE statement. For more information about the effects of a period clause specified in the context of a delete operation, see the DELETE statement topic.

insert-operation
Specifies the insert operation to be executed for the rows where the *matching-condition* evaluates to true.

INSERT
Introduces a list of column names and row value expressions to be used for the insert operation.

The number of values for the row in the row value expression must equal the number of names in the insert column list. The first value is inserted in the first column in the list, the second value in the second column, and so on.

(*column-name,...*)
Specifies the columns for which the insert values are provided. Each name must identify a column of the table or view. The same column must not be identified more than once (SQLSTATE 42701). A view column that cannot accept insert values must not be identified. A value cannot be inserted into a view column that is derived from:

- A constant, expression, or scalar function
- The same base table column as some other column of the view

If the object of the operation is a view with such columns, a list of column names must be specified, and the list must not identify these columns.

Omission of the column list is an implicit specification of a list in which every column of the table (that is not defined as implicitly hidden) or view is identified in left-to-right order. This list is established when the statement is prepared, and therefore does not include columns that were added to a table after the statement was prepared.

VALUES
Introduces one or more rows of values to be inserted.

expression
Any expression that does not include a column name (SQLSTATE 42703).

If *expression* is a reference to a single column of the source table, the source table column value may have been specified with an extended indicator variable value. The effects of such indicator variables apply to the corresponding target columns of the *insert-operation*.

If *expression* is a single host variable, or a host variable being explicitly cast, the host variable can include an indicator variable (or in the case of a host structure, an indicator array) that is enabled for extended indicator variables.

When extended indicator variables are enabled, the extended indicator variable values of default (-5) or unassigned (-7) must not be used (SQLSTATE 22539) if either of the following statements is true:

- The expression is more complex than a single host variable with explicit casts
- The target column has data type of structured type

DEFAULT
The default value assigned to the column. DEFAULT can be specified only for columns that have a default value. For information about default values of data types, see the description of the DEFAULT clause in the "CREATE TABLE" statement.

DEFAULT must be specified for a column that was defined as GENERATED ALWAYS. A valid value can be specified for a column that was defined as GENERATED BY DEFAULT.

NULL
Specifies the null value as the value of the column. Specify NULL only for nullable columns (SQLSTATE 23502).

signal-statement
Specifies the SIGNAL statement that is to be executed to return an error when the *matching-condition* evaluates to true.

ELSE IGNORE
Specifies that no action is to be taken for the rows where no *matching-condition* evaluates to true. If all rows of *table-reference* are ignored, a warning is returned (SQLSTATE 02000).

WITH
Specifies the isolation level at which the MERGE statement is executed.

RR
Repeatable Read

RS
Read Stability

CS
Cursor Stability

UR
Uncommitted Read

The default isolation level of the statement is the isolation level of the package in which the statement is bound.

Rules

- More than one *modification-operation* (UPDATE SET, DELETE, or *insert-operation*), or *signal-statement* can be specified in a single MERGE statement.
- Each row in the target can only be operated on once. A row in the target can only be identified as MATCHED with one row in the result table of the *table-reference* (SQLSTATE 21506). A nested SQL operation (RI or trigger except INSTEAD OF trigger) cannot specify the target table (or a table within the same table hierarchy) as a target of an UPDATE, DELETE, INSERT, or MERGE statement (SQLSTATE 27000).
- ***Security policy:*** If the identified target table or the base table of the identified target view is protected with a security policy, the session authorization ID must have the label-based access control (LBAC) credentials that allow the following types of access.

– For the update operation:
  - Write access to all protected columns that are being updated (SQLSTATE 42512)
  - Write access for any explicit value provided for a DB2SECURITYLABEL column for security policies that were created with the RESTRICT NOT AUTHORIZED WRITE SECURITY LABEL option (SQLSTATE 23523)
  - Read and write access to all rows that are being updated (SQLSTATE 42519)

  The session authorization ID must also have been granted a security label for write access for the security policy if an implicit value is used for a DB2SECURITYLABEL column (SQLSTATE 23523), which can happen when:
  - The DB2SECURITYLABEL column is not included in the list of columns that are to be updated (and so it will be implicitly updated to the security label for write access of the session authorization ID)
  - A value for the DB2SECURITYLABEL column is explicitly provided but the session authorization ID does not have write access for that value, and the security policy is created with the OVERRIDE NOT AUTHORIZED WRITE SECURITY LABEL option

– For the delete operation:
  - Write access to all protected columns (SQLSTATE 42512)
  - Read and write access to all of the rows that are selected for deletion (SQLSTATE 42519)

– For the insert operation:
  - Write access to all protected columns for which a data value is explicitly provided (SQLSTATE 42512)
  - Write access for any explicit value provided for a DB2SECURITYLABEL column for security policies that were created with the RESTRICT NOT AUTHORIZED WRITE SECURITY LABEL option (SQLSTATE 23523)

  The session authorization ID must also have been granted a security label for write access for the security policy if an implicit value is used for a DB2SECURITYLABEL column (SQLSTATE 23523), which can happen when:
  - A value for the DB2SECURITYLABEL column is not explicitly provided
  - A value for the DB2SECURITYLABEL column is explicitly provided but the session authorization ID does not have write access for that value, and the security policy is created with the OVERRIDE NOT AUTHORIZED WRITE SECURITY LABEL option

- ***INSTEAD OF triggers***: If a view is specified as the target of the MERGE statement, either no INSTEAD OF triggers should be defined for the view, or an INSTEAD OF trigger should be defined for each of the update, delete, and insert operations (SQLSTATE 428FZ).
- **Extended indicator variable usage**: If enabled, negative indicator variable values outside the range of -1 through -7 must not be input (SQLSTATE 22010). Also, if enabled, the default and unassigned extended indicator variable values must not appear in contexts in which they are not supported (SQLSTATE 22539).
- **Extended indicator variables in the *assignment-clause***: An *expression* that is a reference to a single column of the source table, a single host variable, or a host variable being explicitly cast can result in assigning an extended indicator variable-based value. Assigning the extended indicator variable-based value of unassigned has the effect of leaving the target column set to its current value, as if it had not been specified in the statement. Assigning the extended indicator variable-based value of default assigns the default value of the column. For information on default values of data types, see the description of the DEFAULT clause in “CREATE TABLE ” on page 1351.

  If a target column is not updatable (for example, a column in a view that is defined as an expression), then it must be assigned the extended indicator variable-based value of unassigned (SQLSTATE 42808).

  If the target column is a column defined as GENERATED ALWAYS, then it must be assigned the DEFAULT keyword, or the extended indicator variable-based values of default or unassigned (SQLSTATE 428C9).

The *assignment-clause* must not assign all target columns to an extended indicator variable-based value of unassigned (SQLSTATE 22540).

- **Extended indicator variables in the *insert-operation***: An *expression* that is a reference to a single column of the source table, a single host variable, or a host variable being explicitly cast can result in inserting an extended indicator variable-based value. In *insert-operation*, a value of unassigned has the effect of setting the column to its default value.

  If a target column is not updatable, then it must be assigned the extended indicator variable-based value of unassigned (SQLSTATE 42808), unless it is a column defined as GENERATED ALWAYS. If the target column is a column defined as GENERATED ALWAYS, then it must be assigned the DEFAULT keyword, or the extended indicator variable-based values of default or unassigned (SQLSTATE 428C9).

For other rules that affect the update, insert, or delete operation portion of the MERGE statement, see the "Rules" section of the corresponding statement description.

Notes

- ***Order of processing***:
  1. Determine the set of rows to be processed from the source and target. If CURRENT TIMESTAMP is used in this statement, only one clock reading is done for the whole statement.
  2. Use the ON clause to classify these rows as either MATCHED or NOT MATCHED.
  3. Evaluate any *matching-condition* in the WHEN clauses.
  4. Evaluate any *expression* in any *assignment-clause* and *insert-operation*.
  5. Execute each *signal-statement*.
  6. Apply each *modification-operation* to the applicable rows in the order of specification. The constraints and triggers activated by each *modification-operation* are executed for the *modification-operation*. Statement-level triggers are activated even if no rows satisfy the *modification-operation*. Each *modification-operation* can affect the triggers and referential constraints of each subsequent *modification-operation*.
- ***Statement level atomicity***: If an error occurs during execution of the MERGE statement, the whole statement is rolled back.
- ***Number of rows updated***: When a MERGE statement completes execution, the value of the ROW_COUNT item for GET DIAGNOSTICS and SQLERRD(3) in the SQLCA is the number of rows operated on by the MERGE statement, excluding rows identified by the ELSE IGNORE clause. The value in SQLERRD(3) does not include the number of rows that were operated on as a result of constraints or triggers. The value in SQLERRD(5) includes the number of these rows.
- ***Inserted row cannot also be updated***: No attempt is made to update a row in the target that did not already exist before the MERGE statement was executed; that is, there are no updates of rows that were inserted by the MERGE statement.
- **Extended indicator variables and update triggers**: If a target column has been assigned with an extended indicator variable-based value of unassigned, that column is not considered to have been updated. That column is treated as if it had not been specified in the OF *column-name* list of any update trigger defined on the target table.
- **Extended indicator variables and insert triggers**: No change in the activation of insert triggers results from the use of extended indicator variables. If all columns in the implicit or explicit column list have been assigned to an extended indicator variable-based value of unassigned or default, an insert where all columns have their respective default values is attempted. If the insert is successful, the insert trigger is activated.
- **Extended indicator variables and deferred error checks**: When extended indicator variables are enabled, validation that would otherwise be done in statement preparation to recognize an insert into, or update of, a non-updatable column, is deferred until statement execution. Whether an error should be reported can be determined only during execution.
- **Considerations for system-period temporal tables**: When MERGE is processed for a system-period temporal table, the rows are impacted in the same way as if the specific data change operations

had been invoked. See UPDATE statement, DELETE statement, and INSERT statement topics for more information.

- **Considerations for application-period temporal tables and triggers**; When a row is deleted and the FOR PORTION OF BUSINESS_TIME clause is specified, additional rows may be implicitly inserted to reflect any portion of the row that was not deleted. Any existing delete triggers are activated for the rows deleted, and any existing insert triggers are activated for rows that are implicitly inserted. When a row is updated and the FOR PORTION OF BUSINESS_TIME clause is specified, additional rows may be implicitly inserted to reflect any portion of the row that was not updated. Any existing update triggers are activated for the rows updated, and any existing insert triggers are activated for rows that are implicitly inserted.
- **Considerations for a MERGE without a column list in the insert-operation**: A MERGE statement without a column list specified as part of the insert-operation does not include implicitly hidden columns. Columns that are defined as implicitly hidden and not null must have a defined default value.

Examples

- *Example 1:* For activities whose description has been changed, update the description in the archive table. For new activities, insert into the archive table. The archive and activities table both have activity as a primary key.

```
MERGE INTO archive ar
USING (SELECT activity, description FROM activities) ac
ON (ar.activity = ac.activity)
WHEN MATCHED THEN
   UPDATE SET
      description = ac.description
WHEN NOT MATCHED THEN
   INSERT
      (activity, description)
      VALUES (ac.activity, ac.description)
```

- *Example 2:* Using the shipment table, merge rows into the inventory table, increasing the quantity by part count in the shipment table for rows that match; else insert the new *partno* into the inventory table.

```
MERGE INTO inventory AS in
USING (SELECT partno, description, count FROM shipment
       WHERE shipment.partno IS NOT NULL) AS sh
ON (in.partno = sh.partno)
WHEN MATCHED THEN
   UPDATE SET
      description = sh.description,
      quantity = in.quantity + sh.count
WHEN NOT MATCHED THEN
   INSERT
      (partno, description, quantity)
      VALUES (sh.partno, sh.description, sh.count)
```

- *Example 3:* Using the transaction table, merge rows into the account table, updating the balance from the set of transactions against an account ID and inserting new accounts from the consolidated transactions where they do not already exist.

```
MERGE INTO account AS a
USING (SELECT id, sum(amount) sum_amount FROM transaction
       GROUP BY id) AS t
ON a.id = t.id
WHEN MATCHED THEN
   UPDATE SET
      balance = a.balance + t.sum_amount
WHEN NOT MATCHED THEN
   INSERT
      (id, balance)
      VALUES (t.id, t.sum_amount)
```

- *Example 4:* Using the transaction_log table, merge rows into the employee_file table, updating the phone and office with the latest transaction_log row based on the transaction time, and inserting the latest new employee_file row where the row does not already exist.

```
MERGE INTO employee_file AS e
USING (SELECT empid, phone, office
       FROM (SELECT empid, phone, office,
             ROW_NUMBER() OVER (PARTITION BY empid
             ORDER BY transaction_time DESC) rn
             FROM transaction_log) AS nt
             WHERE rn = 1) AS t
ON e.empid = t.empid
WHEN MATCHED THEN
   UPDATE SET
      (phone, office) =
      (t.phone, t.office)
WHEN NOT MATCHED THEN
   INSERT
      (empid, phone, office)
      VALUES (t.empid, t.phone, t.office)
```

- *Example 5:* Using dynamically supplied values for an employee row, update the master employee table if the data corresponds to an existing employee, or insert the row if the data is for a new employee. The following example is a fragment of code from a C program.

```
hv1 =
"MERGE INTO employee AS t
USING TABLE(VALUES(CAST (? AS CHAR(6)), CAST (? AS VARCHAR(12)),
                   CAST (? AS CHAR(1)), CAST (? AS VARCHAR(15)),
                   CAST (? AS SMALLINT), CAST (? AS INTEGER)))
                   s(empno, firstnme, midinit, lastname, edlevel, salary)
ON t.empno = s.empno
WHEN MATCHED THEN
   UPDATE SET
      salary = s.salary
WHEN NOT MATCHED THEN
   INSERT
      (empno, firstnme, midinit, lastname, edlevel, salary)
      VALUES (s.empno, s.firstnme, s.midinit, s.lastname, s.edlevel,
              s.salary)";
EXEC SQL PREPARE s1 FROM :hv1;
EXEC SQL EXECUTE s1 USING '000420', 'SERGE', 'K', 'FIELDING', 18, 39580;
```

- *Example 6:* Update the list of activities organized by Group A in the archive table. Delete all outdated activities and update the activities information (description and date) in the archive table if they have been changed. For new upcoming activities, insert into the archive. Signal an error if the date of the activity is not known. The date of the activities in the archive table must be specified. Each group has an activities table. For example, activities_groupA contains all activities that they organize, and the archive table contains all upcoming activities organized by different groups in a company. The archive table has (group, activity) as the primary key, and date is not nullable. All activities tables have activity as the primary key. The last_modified column in the archive is defined with CURRENT TIMESTAMP as the default value.

```
MERGE INTO archive ar
USING (SELECT activity, description, date, last_modified
       FROM activities_groupA) ac
ON (ar.activity = ac.activity) AND ar.group = 'A'
WHEN MATCHED AND ac.date IS NULL THEN
   SIGNAL SQLSTATE '70001'
      SET MESSAGE_TEXT =
         ac.activity CONCAT ' cannot be modified. Reason: Date is not known'
WHEN MATCHED AND ac.date < CURRENT DATE THEN
   DELETE
WHEN MATCHED AND ar.last_modified < ac.last_modified THEN
   UPDATE SET
      (description, date, last_modified) = (ac.description, ac.date, DEFAULT)
WHEN NOT MATCHED AND ac.date IS NULL THEN
   SIGNAL SQLSTATE '70002'
      SET MESSAGE_TEXT =
         ac.activity CONCAT ' cannot be inserted. Reason: Date is not known'
WHEN NOT MATCHED AND ac.date >= CURRENT DATE THEN
   INSERT
      (group, activity, description, date)
```

```
        VALUES ('A', ac.activity, ac.description, ac.date)
  ELSE IGNORE
```

OPEN

The OPEN statement opens a cursor so that it can be used to fetch rows from its result table.

Invocation

Although an interactive SQL facility might provide an interface that gives the appearance of interactive execution, this statement can only be embedded within an application program. It is an executable statement that cannot be dynamically prepared. When invoked using the command line processor, some options cannot be specified.

For more information, refer to "Using command line SQL statements and XQuery statements" in *Command Reference*.

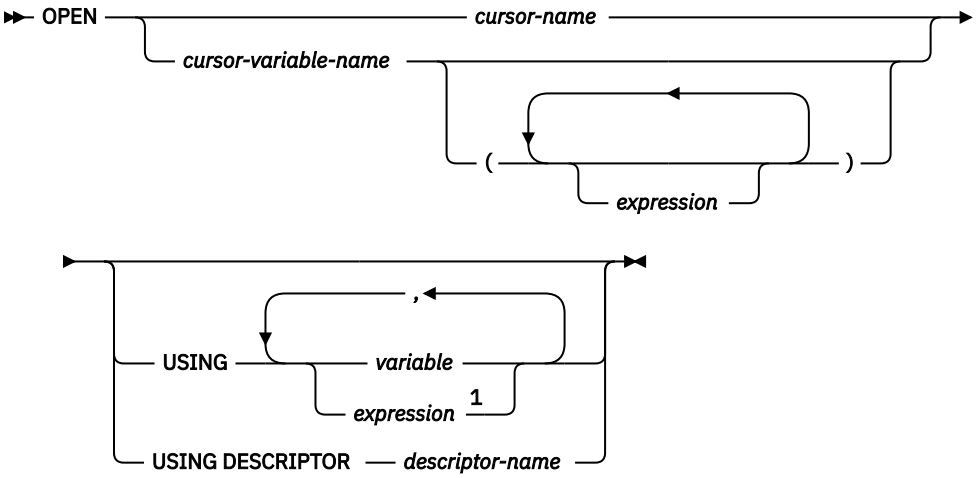
Authorization

If the *cursor-variable-name* references a global variable, then the privileges held by the authorization ID of the statement must include one of the following authorities:

- READ privilege on the global variable that is not defined in a module
- EXECUTE privilege on the module of the global variable that is defined in a module
- EXECUTEIN privilege on the schema containing the module of the global variable that is defined in a module
- DATAACCESS authority on the schema containing the module of the global variable that is defined in a module

Group privileges are not considered because this statement cannot be dynamically prepared.

Syntax



Notes:

[1] An expression other than a variable can only be used in compiled compound statements.

Description

cursor-name

Names a cursor that is defined in a DECLARE CURSOR statement that was stated earlier in the program. If *cursor-name* identifies a cursor in an SQL procedure declared as WITH RETURN TO CLIENT that is already in the open state, the existing open cursor becomes a result set cursor that is no longer accessible using cursor-name and a new cursor is opened that becomes accessible using

cursor-name. Otherwise, when the OPEN statement is executed, the cursor identified by *cursor-name* must be in the closed state.

The DECLARE CURSOR statement must identify a SELECT statement, in one of the following ways:

- Including the SELECT statement in the DECLARE CURSOR statement
- Including a *statement-name* that names a prepared SELECT statement.

The result table of the cursor is derived by evaluating the SELECT statement. The evaluation uses the current values of any special registers, global variables, or PREVIOUS VALUE expressions specified in the SELECT statement, and the current values of any host variables specified in the SELECT statement or the USING clause of the OPEN statement. The rows of the result table may be derived during the execution of the OPEN statement, and a temporary table may be created to hold them; or they may be derived during the execution of subsequent FETCH statements. In either case, the cursor is placed in the open state and positioned before the first row of its result table. If the table is empty, the state of the cursor is effectively "after the last row".

cursor-variable-name

Names a cursor variable. The value of the cursor variable must not be null (SQLSTATE 34000). A cursor variable that is directly or indirectly assigned a cursor value constructor can be used only in an OPEN statement that is in the same scope as the assignment (SQLSTATE 51044). If the cursor value constructor assigned to the cursor variable specified a *statement-name*, the OPEN statement must be in the same scope where that *statement-name* was explicitly or implicitly declared (SQLSTATE 51044).

When the OPEN statement is executed, the underlying cursor of the cursor variable must be in the closed state. The result table of the underlying cursor is derived by evaluating the SELECT statement or dynamic statement associated with the cursor variable. The evaluation uses the current values of any special registers, global variables, or PREVIOUS VALUE expressions specified in the SELECT statement, and the current values of any variables specified in the SELECT statement or the USING clause of the OPEN statement. The rows of the result table may be derived during the execution of the OPEN statement, and a temporary table may be created to hold them; or they may be derived during the execution of subsequent FETCH statements. In either case, the cursor is placed in the open state and positioned before the first row of its result table. If the table is empty, the state of the cursor is effectively "after the last row".

An OPEN statement using a *cursor-variable-name* can only be used within a compound SQL (compiled) statement.

(expression, ...)

Specifies the arguments associated with the named parameters of a parameterized cursor variable. The *cursor-value-constructor* assigned to the cursor variable must include a list of parameters with the same number of parameters as the number of arguments specified (SQLSTATE 07006 or 07004). The data type and value of the *n*th expression must be assignable to the *n*th parameter (SQLSTATE 07006 or 22018).

USING

Introduces the values that are substituted for the parameter markers or variables in the statement of the cursor. For an explanation of parameter markers, see "PREPARE".

If a *statement-name* is specified in the DECLARE CURSOR statement or the cursor value constructor associated with the cursor variable that includes parameter markers, USING must be used. If the prepared statement does not include parameter markers, USING is ignored.

If a *select-statement* is specified in the DECLARE CURSOR statement or the non-parameterized cursor value constructor associated with the cursor variable, USING may be used to override the variable values.

variable

Identifies a variable or a host structure declared in the program in accordance with the rules for declaring variables and host variables. The number of variables must be the same as the number of parameter markers in the prepared statement. The *n*th variable corresponds to the *n*th parameter

marker in the prepared statement. Where appropriate, locator variables and file reference variables can be provided as the source of values for parameter markers.

expression
Specifies values to associate with parameter markers using expressions. An OPEN statement that specifies expressions in the USING clause can only be used within a compound SQL (compiled) statement (SQLSTATE 42601). The number of expressions must be the same as the number of parameter markers in the prepared statement (SQLSTATE 07001). The *n*th expression corresponds to the *n*th parameter marker in the prepared statement. The data type and value of the nth expression must be assignable to the type associated with the nth parameter marker (SQLSTATE 07006).

Rules

- When the SELECT statement of the cursor is evaluated, each parameter marker in the statement is effectively replaced by its corresponding host variable. For a typed parameter marker, the attributes of the target variable are those specified by the CAST specification. For an untyped parameter marker, the attributes of the target variable are determined according to the context of the parameter marker.
- Let V denote a host variable that corresponds to parameter marker P. The value of V is assigned to the target variable for P in accordance with the rules for assigning a value to a column. Thus:
  - V must be compatible with the target.
  - If V is a string, its length (excluding trailing blanks for strings that are not long strings) must not be greater than the length attribute of the target.
  - If V is a number, the absolute value of its integral part must not be greater than the maximum absolute value of the integral part of the target.
  - If the attributes of V are not identical to the attributes of the target, the value is converted to conform to the attributes of the target.

  When the SELECT statement of the cursor is evaluated, the value used in place of P is the value of the target variable for P. For example, if V is CHAR(6), and the target is CHAR(8), the value used in place of P is the value of V padded with two blanks.
- The USING clause is intended for a prepared SELECT statement that contains parameter markers. However, it can also be used when the SELECT statement of the cursor is part of the DECLARE CURSOR statement or the non-parameterized cursor value constructor associated with the cursor variable. In this case the OPEN statement is executed as if each host variable in the SELECT statement were a parameter marker, except that the attributes of the target variables are the same as the attributes of the host variables in the SELECT statement. The effect is to override the values of the host variables in the SELECT statement of the cursor with the values of the host variables specified in the USING clause. A variable value override must not be used when opening a parameterized cursor variable since the SELECT statement will not include any other variables.
- SQL data change statements and routines that modify SQL data embedded in the cursor definition are completely executed, and the result set is stored in a temporary table when the cursor opens. If statement execution is successful, the SQLERRD(3) field contains the sum of the number of rows that qualified for insert, update, and delete operations. If an error occurs during execution of an OPEN statement involving a cursor that contains a data change statement within a fullselect, the results of that data change statement are rolled back.

  Explicit rollback of an OPEN statement, or rollback to a savepoint before an OPEN statement, closes the cursor. If the cursor definition contains a data change statement within the FROM clause of a fullselect, the results of the data change statement are rolled back.

  Changes to rows in a table that is targeted by a data change statement nested within a SELECT statement or a SELECT INTO statement are processed when the cursor opens, and are not undone if an error occurs during a fetch operation against that cursor.

Notes

- ***Closed state of cursors:*** All cursors in a program are in the closed state when the program is initiated and when it initiates a ROLLBACK statement.

  All cursors, except open cursors declared WITH HOLD, are in a closed state when a program issues a COMMIT statement.

  A cursor can also be in the closed state because a CLOSE statement was executed or an error was detected that made the position of the cursor unpredictable.

  The underlying cursor of a cursor variable is closed if the cursor variable goes out of scope and there are no other cursor variables that referenced that underlying cursor.
- To retrieve rows from the result table of a cursor, execute a FETCH statement when the cursor is open. The only way to change the state of a cursor from closed to open is to execute an OPEN statement.
- ***Effect of materialized result tables:*** In some cases, such as when the cursor is not read only, the result rows of a cursor are derived during the execution of FETCH statements. In other cases, the materialized result table method is used instead. With the materialized result table method the entire result table is transferred to a temporary buffer during the execution of the OPEN statement. When a temporary buffer is used, the results of a program can differ in these ways:
  - An error can occur during OPEN that would otherwise not occur until some later FETCH statement.
  - INSERT, UPDATE, and DELETE statements executed in the same transaction while the cursor is open cannot affect the result table.
  - Any NEXT VALUE expressions in the SELECT statement are evaluated for every row of the result table during OPEN.

  Conversely, if a temporary buffer is not used, INSERT, UPDATE, and DELETE statements executed while the cursor is open can affect the result table if issued from the same unit of work, and any NEXT VALUE expressions in the SELECT statement are evaluated as each row is fetched. This result table can also be affected by operations executed by the same unit of work, and the effect of such operations is not always predictable. For example, if cursor C is positioned on a row of its result table defined as SELECT * FROM T, and a new row is inserted into T, the effect of that insert on the result table is not predictable because its rows are not ordered. Thus a subsequent FETCH C may or may not retrieve the new row of T.
- Statement caching affects cursors declared open by the OPEN statement.
- ***Opening the same cursor multiple times:*** A cursor in an SQL procedure declared as WITH RETURN TO CLIENT can be opened even when a cursor with the same name is already in the open state. In this case, the existing open cursor becomes a result set cursor and is no longer accessible by its cursor name. A new cursor is opened and becomes accessible by the cursor name. Closing the new cursor does not make the cursor that was previously accessible by that name accessible by the cursor name again. The cursors that become result set cursors in this way cannot be accessed at the server and can be processed only at the client.
- When an SQL procedure, or an external stored procedure that uses non-blocking cursors, opens a cursor with return but does not fetch any rows from it, the access plan of the cursor query might not be evaluated. The query is evaluated when a row is fetched from the procedure's result set by the caller or client.

Examples

Example 1: Write the embedded statements in a COBOL program that will:

1. Define a cursor C1 that is to be used to retrieve all rows from the DEPARTMENT table for departments that are administered by (ADMRDEPT) department 'A00'.
2. Place the cursor C1 before the first row to be fetched.

```
EXEC SQL  DECLARE C1 CURSOR FOR
                SELECT DEPTNO, DEPTNAME, MGRNO
                  FROM DEPARTMENT
                  WHERE ADMRDEPT = 'A00'
END-EXEC.
```

```
EXEC SQL  OPEN C1
END-EXEC.
```

Example 2: Code an OPEN statement to associate a cursor DYN_CURSOR with a dynamically defined select-statement in a C program. Assuming two parameter markers are used in the predicate of the select-statement, two host variable references are supplied with the OPEN statement to pass integer and varchar(64) values between the application and the database. (The related host variable definitions, PREPARE statement, and DECLARE CURSOR statement are also shown in this example.)

```
EXEC SQL  BEGIN DECLARE SECTION;
  static short    hv_int;
  char            hv_vchar64[65];
  char            stmt1_str[200];
EXEC SQL  END DECLARE SECTION;

EXEC SQL  PREPARE STMT1_NAME FROM :stmt1_str;
EXEC SQL  DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;

EXEC SQL  OPEN DYN_CURSOR USING :hv_int, :hv_vchar64;
```

Example 3: Code an OPEN statement as in example 2, but in this case the number and data types of the parameter markers in the WHERE clause are not known.

```
EXEC SQL  BEGIN DECLARE SECTION;
  char    stmt1_str[200];
EXEC SQL  END DECLARE SECTION;
EXEC SQL  INCLUDE SQLDA;

EXEC SQL  PREPARE STMT1_NAME FROM :stmt1_str;
EXEC SQL  DECLARE DYN_CURSOR CURSOR FOR STMT1_NAME;

EXEC SQL  OPEN DYN_CURSOR USING DESCRIPTOR :sqlda;
```

Example 4: Create a procedure that does the following operations:

1. Assigns a cursor to the output cursor variable
2. Opens the cursor

```
CREATE PROCEDURE PROC1 (OUT P1 CURSOR)LANGUAGE SQL
BEGIN
SET P1=CURSOR FOR SELECT DEPTNO, DEPTNAME, MGRNO FROM DEPARTMENT WHERE
ADMRDEPT='A00'; --
OPEN P1; --
END;
```

PIPE

The PIPE statement is used to return a row from a compiled table function.

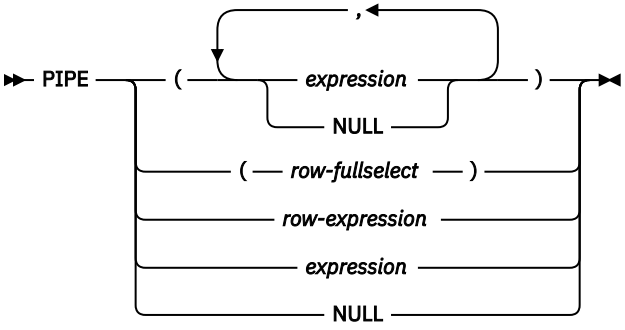
Invocation

This statement can be embedded in a compound SQL (compiled) statement of an SQL table function. It is not an executable statement and cannot be dynamically prepared.

Authorization

No privileges are required to invoke the PIPE statement. However, the authorization ID of the statement must hold the necessary privileges to invoke any expression that is embedded in the PIPE statement.

Syntax



Description

(*expression, ...*)
Specifies a row value is returned from the function. The number of expressions (or NULL keywords) in the list must match the RETURNS data type of the function and the value of each expression must be assignable to the corresponding column or field in the RETURNS data type of the function.

row-fullselect
Specifies a fullselect that returns a single row with the number of columns corresponding to the number of columns or fields in the RETURNS data type of the function. The value in each column of the row returned by the fullselect must be assignable to the corresponding column or field in the RETURNS data type of the function. If the result of the row fullselect is no rows, null values are returned.

row-expression
Specifies the row value is returned from the function. The number of fields in the row must match the RETURNS data type of the function and each field in the row must be assignable to the corresponding field in the RETURNS data type of the function. If the *row-expression* and the RETURNS data type are user-defined row types, the type names must be the same (SQLSTATE 42821).

expression
Specifies a scalar value is returned from the function. The RETURNS data type of the table function must have a single column and the expression value must be assignable to that column.

NULL
Specifies that a null value is returned from the function. A null value is returned for each column or row field.

Notes

- **Locally declared procedures:** The PIPE statement cannot be used within a procedure that is locally declared in the compound SQL (compiled) statement of an SQL table function.
- **Similar terms:** An SQL table function that uses a PIPE statement is sometimes referred to as a *pipelined* function.

Example

Create a table function called NEXT52 that returns a week number and date for the same day of the week for the next 52 weeks, along with the associated ISO week number.

```
CREATE OR REPLACE FUNCTION NEXT52 (START_TS TIMESTAMP)
   RETURNS TABLE (WEEKNUM SMALLINT, WEEKNUM_DATE DATE, ISO_WEEK SMALLINT)
BEGIN
   DECLARE WN INTEGER DEFAULT 1;
   DECLARE WND DATE;
   SET WND = START_TS;
   WHILE (WN < 53) DO
      SET WND = WND + 7 DAYS;
      PIPE (WN, WND, WEEK_ISO(WND));
      SET WN = WN + 1;
```

```
   END WHILE;
   RETURN;
END
```

PREPARE

The PREPARE statement is used by application programs to dynamically prepare an SQL statement for execution. The PREPARE statement creates an executable SQL statement, called a *prepared statement*, from a character string form of the statement, called a *statement string*.

Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

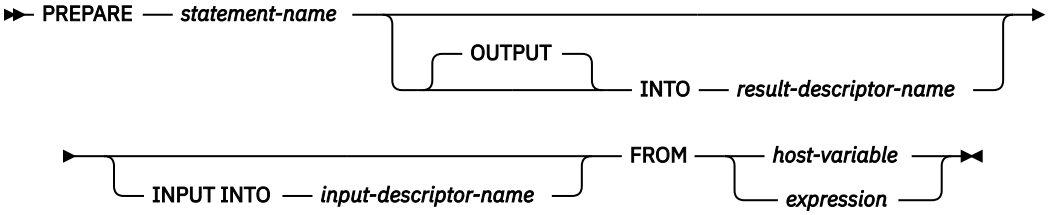
For statements where authorization checking is performed at statement preparation time (DML), the privileges held by the authorization ID of the statement must include those required to execute the SQL statement specified by the PREPARE statement. The authorization ID of the statement might be affected by the DYNAMICRULES bind option.

For statements where authorization checking is performed at statement execution time (DDL, GRANT, and REVOKE statements), no authorization is required to use this statement; however, the authorization is checked when the prepared statement is executed.

For statements involving tables that are protected with a security policy, the rules associated with the security policy are always evaluated at statement execution time.

If the authorization ID of the statement holds EXPLAIN, SQLADM, or DBADM authority, the user may prepare any statement; however, the ability to execute the statement is re-checked at statement execution time.

Syntax



Description

statement-name
Names the prepared statement. If the name identifies an existing prepared statement, that previously prepared statement is destroyed. The name must not identify a prepared statement that is the SELECT statement of an open cursor.

OUTPUT INTO
If OUTPUT INTO is used, and the PREPARE statement executes successfully, information about the output parameter markers in the prepared statement is placed in the SQLDA specified by *result-descriptor-name*.

result-descriptor-name
Specifies the name of an SQLDA. (The DESCRIBE statement may be used as an alternative to this clause.)

INPUT INTO

If INPUT INTO is used, and the PREPARE statement executes successfully, information about the input parameter markers in the prepared statement is placed in the SQLDA specified by *input-descriptor-name*. Input parameter markers are always considered nullable, regardless of usage.

input-descriptor-name

Specifies the name of an SQLDA. (The DESCRIBE statement may be used as an alternative to this clause.)

FROM

Introduces the statement string. The statement string is the value of the specified host variable.

host-variable

Specifies a host variable that is described in the program in accordance with the rules for declaring character string variables. It must be a fixed-length or varying-length character-string variable that is less than the maximum statement size of 2 097 152 bytes. Note that a CLOB(2097152) can contain a maximum size statement, but a VARCHAR cannot.

expression

An expression specifying the statement string. The expression must return a fixed-length or varying-length character-string type that is less than the maximum statement size of 2 097 152 bytes.

Rules

- ***Rules for statement strings:*** The statement string must be an executable statement that can be dynamically prepared. It must be one of the following SQL statements:
  - ALTER
  - CALL
  - COMMENT
  - COMMIT
  - Compound SQL (compiled)
  - Compound SQL (inlined)
  - CREATE
  - DECLARE GLOBAL TEMPORARY TABLE
  - DELETE
  - DROP
  - EXPLAIN
  - FLUSH EVENT MONITOR
  - FLUSH PACKAGE CACHE
  - GRANT
  - INSERT
  - LOCK TABLE
  - MERGE
  - REFRESH TABLE
  - RELEASE SAVEPOINT
  - RENAME
  - REVOKE
  - ROLLBACK
  - SAVEPOINT
  - select-statement
  - SET COMPILATION ENVIRONMENT

- SET CURRENT DECFLOAT ROUNDING MODE
- SET CURRENT DEFAULT TRANSFORM GROUP
- SET CURRENT DEGREE
- SET CURRENT EXPLAIN MODE
- SET CURRENT EXPLAIN SNAPSHOT
- SET CURRENT FEDERATED ASYNCHRONY
- SET CURRENT IMPLICIT XMLPARSE OPTION
- SET CURRENT ISOLATION
- SET CURRENT LOCALE LC_MESSAGES
- SET CURRENT LOCALE LC_TIME
- SET CURRENT LOCK TIMEOUT
- SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION
- SET CURRENT MDC ROLLOUT MODE
- SET CURRENT OPTIMIZATION PROFILE
- SET CURRENT QUERY OPTIMIZATION
- SET CURRENT REFRESH AGE
- SET CURRENT TEMPORAL BUSINESS_TIME
- SET CURRENT TEMPORAL SYSTEM_TIME
- SET ENCRYPTION PASSWORD
- SET EVENT MONITOR STATE (only if DYNAMICRULES run behavior is in effect for the package)
- SET INTEGRITY
- SET PASSTHRU
- SET PATH
- SET ROLE (only if DYNAMICRULES run behavior is in effect for the package)
- SET SCHEMA
- SET SERVER OPTION
- SET SESSION AUTHORIZATION
- SET SQL_CCFLAGS
- SET USAGE LIST STATE (only if DYNAMICRULES run behavior is in effect for the package)
- SET variable
- TRANSFER OWNERSHIP (only if DYNAMICRULES run behavior is in effect for the package)
- TRUNCATE (only if DYNAMICRULES run behavior is in effect for the package)
- UPDATE

Notes

- ***Parameter markers:*** Although a statement string cannot include references to host variables, it can include *parameter markers*. These can be replaced by the values of host variables when the prepared statement is executed. In the case of a CALL statement, a parameter marker can also be used for OUT and INOUT arguments to the procedure. After the CALL is executed, the returned value for the argument will be assigned to the host variable corresponding to the parameter marker.

  A parameter marker is a question mark (?) or a colon followed by a name (:name) that is used where a host variable could be used if the statement string were a static SQL statement. For an explanation of how parameter markers are replaced by values, see "OPEN" and "EXECUTE".

  If the parameter marker is named, the name can include letters, numbers, and the symbols @, #, $, and _. The name is not folded to upper case.

Named parameter markers have the same syntax as host variables, but the two are not interchangeable. A host variable has a value and is used directly in a static SQL statement. A named parameter marker is a placeholder for a value in a dynamic SQL statement and the value is provided when the statement is executed.

There are two types of parameter markers:

Typed parameter marker
A parameter marker that is specified along with its target data type. It has the general form:

```
   CAST(? AS data-type)
```

This notation is not a function call, but a "promise" that the type of the parameter at run time will be of the data type specified or some data type that can be converted to the specified data type. For example, in:

```
  UPDATE EMPLOYEE
SET LASTNAME = TRANSLATE(CAST(? AS VARCHAR(12))
WHERE EMPNO = ?
```

the value of the argument of the TRANSLATE function will be provided at run time. The data type of that value will either be VARCHAR(12), or some type that can be converted to VARCHAR(12).

Untyped parameter marker
A parameter marker that is specified without its target data type. It has the form of a single question mark. The data type of an untyped parameter marker is provided by context. For example, the untyped parameter marker in the predicate of the previous update statement is the same as the data type of the EMPNO column.

Typed parameter markers can be used in dynamic SQL statements wherever a host variable is supported and the data type is based on the promise made in the CAST function.

Untyped parameter markers can be used in dynamic SQL statements as long as the data type of the parameter marker can be derived based on the context in the SQL statement (SQLSTATE 42610).

The following example results in an error since in the first context, *c1* would resolve to a string data type, but in the second context, *c1* would resolve to a numeric data type:

```
SELECT 'Hello' || c1, 5 + c1 FROM (VALUES(?)) AS T(c1)
```

However, the following statement is successful since the parameter marker associated with the derived column, *c1*, would resolve to a numeric data type for both contexts:

```
SELECT 7 + c1, 5 + c1 FROM (VALUES(?)) AS T(c1)
```

See "Determining data types of untyped expressions" for the rules for typing an untyped parameter marker.

- When a PREPARE statement is executed, the statement string is parsed and checked for errors. If the statement string is invalid, the error condition is reported in the SQLCA. Any subsequent EXECUTE or OPEN statement that references this statement will also receive the same error (due to an implicit prepare done by the system) unless the error has been corrected.
- Prepared statements can be referred to in the following kinds of statements, with the restrictions shown:

In...
The prepared statement...

DESCRIBE
can be any statement

DECLARE CURSOR
must be SELECT

EXECUTE
must *not* be SELECT

- A prepared statement can be executed many times. Indeed, if a prepared statement is not executed more than once and does not contain parameter markers, it is more efficient to use the EXECUTE IMMEDIATE statement rather than the PREPARE and EXECUTE statements.
- All prepared statements created by a unit of work remain in a prepared state until the application terminates, with the following exceptions:
  - A statement that is prepared within a package bound with KEEPDYNAMC NO and which is not used by an open cursor declared with the WITH HOLD option is no longer in a prepared state when the unit of work ends.
  - A dynamic statement that is bound with KEEPDYNAMIC NO and which is used by an open cursor declared with the WITH HOLD option is in a prepared state until the next unit of work boundary where the cursor is closed.

Examples

Example 1: Prepare and execute a non-select-statement in a COBOL program. Assume the statement is contained in a host variable HOLDER and that the program will place a statement string into the host variable based on some instructions from the user. The statement to be prepared does not have any parameter markers.

```
EXEC SQL  PREPARE STMT_NAME FROM :HOLDER
END-EXEC.
EXEC SQL  EXECUTE STMT_NAME
END-EXEC.
```

Example 2: Prepare and execute a non-select-statement as in example 1, except code it for a C program. Also assume the statement to be prepared can contain any number of parameter markers.

```
EXEC SQL  PREPARE STMT_NAME FROM :holder;
EXEC SQL  EXECUTE STMT_NAME USING DESCRIPTOR :insert_da;
```

Assume that the following statement is to be prepared:

```
INSERT INTO DEPT VALUES(?, ?, ?, ?)
```

The columns in the DEPT table are defined as follows:

```
DEPT_NO   CHAR(3) NOT NULL, -- department number
DEPTNAME  VARCHAR(29), -- department name
MGRNO     CHAR(6), -- manager number
ADMRDEPT  CHAR(3)  -- admin department number
```

To insert department number G01 named COMPLAINTS, which has no manager and reports to department A00, the structure INSERT_DA should have the values in Table 152 on page 1756 before issuing the EXECUTE statement.

Table 152. Required values for the INSERT_DA structure

SQLDA field	**Value**
SQLDAID	SQLDA
SQLDABC	192 (See note 1.)
SQLN	4
SQLD	4
SQLTYPE	452
SQLLEN	3
SQLDATA	*pointer to* G01
SQLIND	(See note 2.)

Table 152. Required values for the INSERT_DA structure (continued)	
SQLDA field	**Value**
SQLNAME	
SQLTYPE SQLLEN SQLDATA SQLIND SQLNAME	449 29 *pointer to* COMPLAINTS *pointer to* 0
SQLTYPE SQLLEN SQLDATA SQLIND SQLNAME	453 6 (See note 3.) *pointer to* -1
SQLTYPE SQLLEN SQLDATA SQLIND SQLNAME	453 3 *pointer to* A00 *pointer to* 0
Note: 1. This value is for a PREPARE done from a 32-bit application. If the PREPARE was done in a 64-bit application, then SQLDABC would have the value 240. 2. The value in SQLIND for this SQLVAR is ignored because the SQLTYPE identifies a non-nullable data type. 3. The value in SQLDATA for this SQLVAR is ignored because the value of SQLIND indicates this is a null value.	

REFRESH TABLE

The REFRESH TABLE statement refreshes the data in a materialized query table.

Invocation

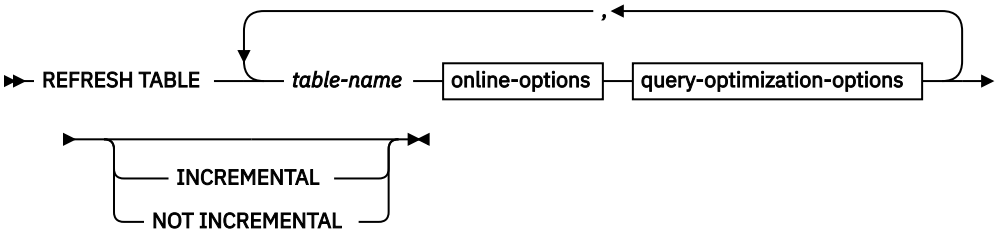
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

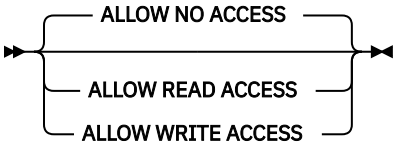
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CONTROL privilege on the table
- DATAACCESS authority on the schema containing the materialized query table
- DATAACCESS authority

Syntax



online-options



query-optimization-options

Description

table-name

Identifies the table to be refreshed.

The name, including the implicit or explicit schema, must identify a table that already exists at the current server. The table must allow the REFRESH TABLE statement (SQLSTATE 42809). This includes materialized query tables defined with:

- REFRESH IMMEDIATE
- REFRESH DEFERRED

online-options

Specifies the accessibility of the table while it is being processed.

ALLOW NO ACCESS
Specifies that no other users can access the table while it is being refreshed, except if they are using the Uncommitted Read isolation level.

ALLOW READ ACCESS
Specifies that other users have read-only access to the table while it is being refreshed.

ALLOW WRITE ACCESS
Specifies that other users have read and write access to the table while it is being refreshed.

To prevent a rollback of the entire statement because of a lock timeout when using the ALLOW READ ACCESS or the ALLOW WRITE ACCESS option, it is recommended that you issue a SET CURRENT LOCK TIMEOUT statement (specifying the WAIT option) before executing the REFRESH TABLE statement, and to reset the special register to its previous value afterwards. Note, however, that the CURRENT LOCK TIMEOUT register only impacts a specific set of lock types, not all lock types.

query-optimization-options

Specifies the query optimization options for the refresh of REFRESH DEFERRED materialized query tables.

ALLOW QUERY OPTIMIZATION USING REFRESH DEFERRED TABLES WITH REFRESH AGE ANY
Specifies that when the CURRENT REFRESH AGE special register is set to 'ANY', the refresh of *table-name* will allow REFRESH DEFERRED materialized query tables to be used to optimize the query that is used to refresh *table-name*. If *table-name* is not a REFRESH DEFERRED materialized

query table, an error is returned (SQLSTATE 428FH). REFRESH IMMEDIATE materialized query tables are always considered for query optimization.

INCREMENTAL
Specifies an incremental refresh for the table by considering only the delta portion (if any) of its underlying tables or the content of an associated staging table (if one exists and its contents are consistent). If such a request cannot be satisfied (that is, the system detects that the materialized query table definition needs to be fully recomputed), an error (SQLSTATE 55019) is returned.

NOT INCREMENTAL
Specifies a full refresh for the table by recomputing the materialized query table definition.

If neither INCREMENTAL nor NOT INCREMENTAL is specified, the system will determine whether incremental processing is possible; if not, full refresh will be performed. If a staging table is present for the materialized query table that is to be refreshed, and incremental processing is not possible because the staging table is in a pending state, an error is returned (SQLSTATE 428A8). Full refresh will be performed if the staging table or the materialized query table is in an inconsistent state; otherwise, the contents of the staging table will be used for incremental processing.

Rules

- If REFRESH TABLE is issued on a materialized query table that references one or more nicknames, the authorization ID of the statement must have authority to select from the tables at the data source or from all schemas of the tables at the data source (SQLSTATE 42501).
- The NOT INCREMENTAL clause must be used if REFRESH TABLE is issued on a system-maintained column-organized MQT.

Notes

- When the statement is used to refresh a REFRESH IMMEDIATE materialized query table whose underlying tables have been loaded, attached, or detached, the system might choose to incrementally refresh the materialized query table with the delta portions of its underlying tables. When the statement is used to refresh a REFRESH DEFERRED materialized query table with a supporting staging table, the system might choose to incrementally refresh the materialized query table with the delta portions of its underlying tables that have been captured in the staging table. However, there are some situations in which this optimization is not possible, and a full refresh (that is, a recomputation of the materialized query table definition) is necessary to ensure data integrity. You can explicitly request incremental maintenance by specifying the INCREMENTAL option; if this optimization is not possible, the system returns an error (SQLSTATE 55019).
- If the ALLOW QUERY OPTIMIZATION USING REFRESH DEFERRED TABLES WITH REFRESH AGE ANY option is used, ensure that the refresh order is correct for REFRESH DEFERRED materialized query tables. For example, consider two materialized query tables, MQT1 and MQT2, whose materialized queries share the same underlying tables. The materialized query for MQT2 can be calculated using MQT1, instead of the underlying tables. If separate statements are used to refresh these two materialized query tables, and MQT2 is refreshed first, the system might choose to use the contents of MQT1, which have not yet been refreshed, to refresh MQT2. In this case, MQT1 would contain current data, but MQT2 could still contain stale data, even though both were refreshed at almost the same time. The correct refresh order, if two REFRESH statements are used instead of one, is to refresh MQT1 first.
- If the materialized query table has an associated staging table, the staging table is pruned when the refresh is successfully performed.
- Any label-based access control on the base tables or on the materialized query table does not interfere with the refresh process. The refresh happens as if label-based access control were not present. The automatic protection that is associated with the materialized query table when it is created ensures that the data from the base tables remains protected when it is passed into the materialized query table.
- For materialized query table only, SET INTEGRITY FOR *mqt_name* IMMEDIATE CHECKED is the same as REFRESH TABLE *mqt_name*.

- **Refresh use of materialized query tables:** Materialized query tables are not used to evaluate the *select-statement* during the processing of the REFRESH TABLE statement.
- **Refresh isolation level:** The isolation level used to evaluate the *select-statement* is the isolation level specified on the *isolation-level* clause of the *select-statement*. Or, if the *isolation-level* clause was not specified, the isolation level of the materialized query table recorded when CREATE TABLE or ALTER TABLE was issued is used to evaluate the *select-statement*.
- Consider the statement:

  ```
  SET INTEGRITY FOR T IMMEDIATE CHECKED
  ```

  In the following scenarios, neither the INCREMENTAL check option for T nor an incremental refresh of T---if T is a materialized query table (MQT) or a staging table---is supported:

  – New constraints have been added to T while it is in set integrity pending state
  – When a LOAD REPLACE operation against T, it parents, or its underlying tables has taken place
  – When the NOT LOGGED INITIALLY WITH EMPTY TABLE option has been activated after the last integrity check on T, its parents, or its underlying tables
  – The cascading effect of full processing, when any parent of T (or underlying table, if T is a materialized query table or a staging table) has been checked for integrity non-incrementally
  – If the table space containing the table or its parent (or underlying table of a materialized query table or a staging table) has been rolled forward to a point in time, and the table and its parent (or underlying table if the table is a materialized query table or a staging table) reside in different table spaces
  – T is an MQT, and a LOAD REPLACE or LOAD INSERT operation directly into T has taken place after the last refresh
- Incremental processing will be used whenever the situation allows it, because it is more efficient. The INCREMENTAL option is not needed in most cases. It is needed, however, to ensure that integrity checks are indeed processed incrementally. If the system detects that full processing is needed to ensure data integrity, an error is returned (SQLSTATE 55019).
- If the conditions for full processing described in the previous bullet are not satisfied, the system will perform an incremental refresh (if it is a materialized query table) when the user does not specify the NOT INCREMENTAL option for the statement `SET INTEGRITY FOR T IMMEDIATE CHECKED`.

RELEASE (connection)

The RELEASE (Connection) statement places one or more connections in the release-pending state.

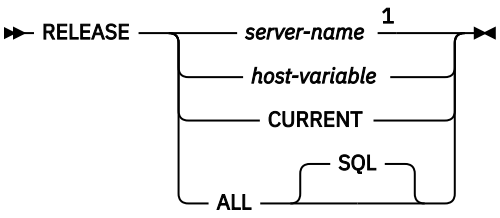
Invocation

Although an interactive SQL facility might provide an interface that gives the appearance of interactive execution, this statement can only be embedded within an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax



Notes:

[1] Note that an application server named CURRENT or ALL can only be identified by a host variable or a delimited identifier.

Description

server-name* or *host-variable

Identifies the application server by the specified *server-name* or a *host-variable* which contains the *server-name*.

If a *host-variable* is specified, it must be a character string variable with a length attribute that is not greater than 8, and it must not include an indicator variable. The *server-name* that is contained within the *host-variable* must be left-aligned and must not be delimited by quotation marks.

Note that the *server-name* is a database alias identifying the application server. It must be listed in the application requester's local directory.

The specified database-alias or the database-alias contained in the host variable must identify an existing connection of the application process. If the database-alias does not identify an existing connection, an error (SQLSTATE 08003) is raised.

CURRENT

Identifies the current connection of the application process. The application process must be in the connected state. If not, an error (SQLSTATE 08003) is raised.

ALL or ALL SQL

Identifies all existing connections of the application process. This form of the RELEASE statement places all existing connections of the application process in the release-pending state. All connections will therefore be destroyed during the next commit operation. An error or warning does not occur if no connections exist when the statement is executed.

Examples

- *Example 1:* The SQL connection to IBMSTHDB is no longer needed by the application. The following statement will cause it to be destroyed during the next commit operation:

```
EXEC SQL RELEASE IBMSTHDB;
```

- *Example 2:* The current connection is no longer needed by the application. The following statement will cause it to be destroyed during the next commit operation:

```
EXEC SQL RELEASE CURRENT;
```

- *Example 3:* If an application has no need to access the databases after a commit but will continue to run for a while, then it is better not to tie up those connections unnecessarily. The following statement can be executed before the commit to ensure all connections will be destroyed at the commit:

```
EXEC SQL RELEASE ALL;
```

RELEASE SAVEPOINT

The RELEASE SAVEPOINT statement is used to indicate that the application no longer wishes to have the named savepoint maintained. After this statement has been invoked, rollback to the savepoint is no longer possible.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

Description

savepoint-name
Specifies the savepoint that is to be released. Any savepoints nested within the named savepoint are also released. Rollback to that savepoint, or any savepoint nested within it, is no longer possible. If the named savepoint does not exist in the current savepoint level (see the "Rules" section in the description of the SAVEPOINT statement), an error is returned (SQLSTATE 3B001). The specified *savepoint-name* cannot begin with 'SYS' (SQLSTATE 42939).

Notes

- The name of the savepoint that was released can now be reused in another SAVEPOINT statement, regardless of whether the UNIQUE keyword was specified on an earlier SAVEPOINT statement specifying this same savepoint name.

Example

Release a savepoint named SAVEPOINT1.

```
RELEASE SAVEPOINT SAVEPOINT1
```

RENAME

The RENAME statement renames an existing table or index.

Invocation

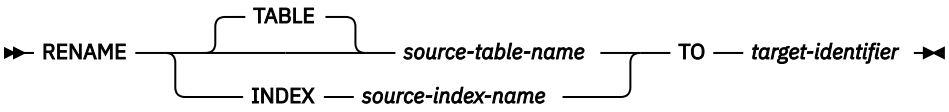
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CONTROL privilege on the table or index
- Ownership of the table or index, as recorded in the OWNER column of the SYSCAT.TABLES catalog view for a table, and the SYSCAT.INDEXES catalog view for an index
- ALTERIN privilege on the schema
- SCHEMAADM authority on the schema
- DBADM authority

Syntax



Description

TABLE *source-table-name*

Names the existing table that is to be renamed. The name, including the schema name, must identify a table that already exists in the database (SQLSTATE 42704). It must not be the name of a catalog table (SQLSTATE 42832), a materialized query table, a typed table (SQLSTATE 42997), a created temporary table, a declared global temporary table (SQLSTATE 42995), a nickname, or an object other than a table or an alias (SQLSTATE 42809). The TABLE keyword is optional.

The name must not identify a table that is referenced in a row permission definition or a column mask definition (SQLSTATE 42917).

INDEX *source-index-name*

Names the existing index that is to be renamed. The name, including the schema name, must identify an index that already exists in the database (SQLSTATE 42704). It must not be the name of an index on a created temporary table or a declared global temporary table (SQLSTATE 42995). The schema name must not be SYSIBM, SYSCAT, SYSFUN, or SYSSTAT (SQLSTATE 42832).

target-identifier

Specifies the new name for the table or index without a schema name. The schema name of the source object is used to qualify the new name for the object. The qualified name must *not* identify a table, view, alias, or index that already exists in the database (SQLSTATE 42710).

Rules

When renaming a table, the source table must not:

- Be referenced in any existing materialized query table definitions
- Be referenced in any existing statistical view definition. This includes the system-generated statistical view that is created as part of index creation which includes an expression-based key.

  Note: With the release of Db2 11.5.7, renaming of tables with an index having an expression-based key is possible, if the expression does not contain qualified names.
- Be the subject table of an existing trigger
- Be a parent or dependent table in any referential integrity constraints
- Be the scope of any existing reference column
- Be referenced in a spatial registration with Spatial Extender. Unregister the spatial column or columns, and then reregister them after the rename is completed.
- Be referenced by an XSR object that has been enabled for decomposition

An error (SQLSTATE 42986) is returned if the source table violates one or more of these conditions.

When renaming an index:

- The source index must not be a system-generated index for an implementation table on which a typed table is based (SQLSTATE 42858).

Notes

- CHECK constraints with three part names are not supported and will return SQL0750. Use only the column name instead.
- Catalog entries are updated to reflect the new table or index name.

- *All* authorizations associated with the source table or index name are *transferred* to the new table or index name (the authorization catalog tables are updated appropriately).
- Indexes defined over the source table are *transferred* to the new table (the index catalog tables are updated appropriately).
- RENAME TABLE invalidates any packages that are dependent on the source table. RENAME INDEX invalidates any packages that are dependent on the source index.
- If an alias is used for the *source-table-name*, it must resolve to a table name. The alias is not changed by the RENAME statement and continues to refer to the old table name. The table is renamed within its original schema
- A table with primary key or unique constraints can be renamed if none of the primary key or unique constraints are referenced by any foreign key.

Examples

- *Example 1*: Change the name of the EMP table to EMPLOYEE.

```
RENAME TABLE EMP TO EMPLOYEE
RENAME TABLE ABC.EMP TO EMPLOYEE
```

- *Example 2*: Change the name of the index NEW-IND to IND.

```
RENAME INDEX NEW-IND TO IND
RENAME INDEX ABC.NEW-IND TO IND
```

RENAME STOGROUP

The RENAME STOGROUP statement renames an existing storage group.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include either SYSCTRL or SYSADM authority.

Syntax

Description

source-storagegroup-name
Identifies the storage group to rename; *source-storagegroup-name* must identify a storage group that exists at the current server (SQLSTATE 42704). This is a one-part name.

target-storagegroup-name
Names the storage group. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *target-storagegroup-name* must not identify a storage group that already exists in the catalog (SQLSTATE 42710). The *target-storagegroup-name* must not begin with the characters 'SYS' (SQLSTATE 42939).

Rules

- The RENAME STOGROUP statement cannot be executed while a database partition server is being added (SQLSTATE 55071).

RENAME TABLESPACE

The RENAME TABLESPACE statement renames an existing table space.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include either SYSCTRL or SYSADM authority.

Syntax

Description

source-tablespace-name
Specifies the existing table space that is to be renamed, as a one-part name. It is an SQL identifier (either ordinary or delimited). The table space name must identify a table space that already exists in the catalog (SQLSTATE 42704).

target-tablespace-name
Specifies the new name for the table space, as a one-part name. It is an SQL identifier (either ordinary or delimited). The new table space name must *not* identify a table space that already exists in the catalog (SQLSTATE 42710), and it cannot start with 'SYS' (SQLSTATE 42939).

Rules

- The SYSCATSPACE table space cannot be renamed (SQLSTATE 42832).
- Any table spaces with "rollforward pending" or "rollforward in progress" states cannot be renamed (SQLSTATE 55039)

Notes

- Renaming a table space will update the minimum recovery time of a table space to the point in time when the rename took place. This implies that a roll forward at the table space level must be to at least this point in time.
- The new table space name must be used when restoring a table space from a backup image, where the rename was done after the backup was created.

Example

Change the name of the table space USERSPACE1 to DATA2000:

```
RENAME TABLESPACE USERSPACE1 TO DATA2000
```

REPEAT

The REPEAT statement executes a statement or group of statements until a search condition is true.

Invocation

This statement can be embedded in an:

- SQL procedure definition
- Compound SQL (compiled) statement
- Compound SQL (inlined) statement

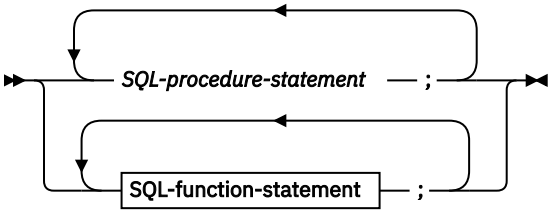
The compound statements can be embedded in an SQL procedure definition, SQL function definition, or SQL trigger definition. It is not an executable statement and cannot be dynamically prepared.

Authorization

No privileges are required to invoke the REPEAT statement. However, the authorization ID of the statement must hold the necessary privileges to invoke the SQL statements and search condition that are embedded in the REPEAT statement.

Syntax

SQL-routine-statement



Description

label
Specifies the label for the REPEAT statement. If the beginning label is specified, that label can be specified on LEAVE and ITERATE statements. If an ending label is specified, a matching beginning label also must be specified.

SQL-procedure-statement
Specifies the SQL statements to execute within the loop. *SQL-procedure-statement* is only applicable when in the context of an SQL procedure or a compound SQL (compiled) statement. See *SQL-procedure-statement* in "Compound SQL (compiled)" statement.

SQL-function-statement
Specifies the SQL statements to execute within the loop. *SQL-function-statement* is only applicable when in the context of an SQL trigger, SQL function, or SQL method. See *SQL-function-statement* in "FOR".

search-condition
The *search-condition* is evaluated after each execution of the REPEAT loop. If the condition is true, the loop will exit. If the condition is unknown or false, the looping continues.

Example

A REPEAT statement fetches rows from a table until the *not_found* condition handler is invoked.

```
CREATE PROCEDURE REPEAT_STMT(OUT counter INTEGER)
  LANGUAGE SQL
  BEGIN
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE v_firstnme VARCHAR(12);
    DECLARE v_midinit CHAR(1);
    DECLARE v_lastname VARCHAR(15);
    DECLARE at_end SMALLINT DEFAULT 0;
    DECLARE not_found CONDITION FOR SQLSTATE '02000';
    DECLARE c1 CURSOR FOR
      SELECT firstnme, midinit, lastname
        FROM employee;
    DECLARE CONTINUE HANDLER FOR not_found
      SET at_end = 1;
    OPEN c1;
    fetch_loop:
    REPEAT
      FETCH c1 INTO v_firstnme, v_midinit, v_lastname;
      SET v_counter = v_counter + 1;
      UNTIL at_end > 0
    END REPEAT fetch_loop;
    SET counter = v_counter;
    CLOSE c1;
  END
```

RESIGNAL

The RESIGNAL statement is used within a condition handler to resignal the condition that activated the handler, or to raise an alternate condition so that it can be processed at a higher level. It causes an exception, warning, or not found condition to be returned, along with optional message text.

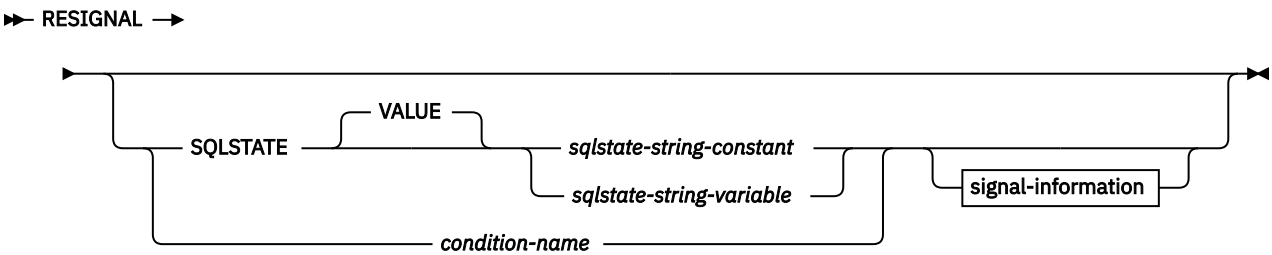
Invocation

This statement can only be embedded in a condition handler within a compound SQL (compiled) statement. The compound SQL (compiled) statement can be embedded in an SQL procedure definition, SQL function definition, or SQL trigger definition.

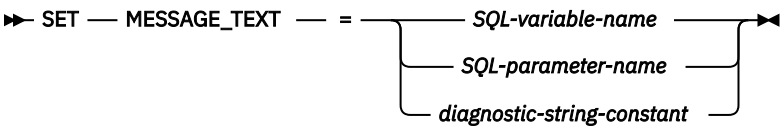
Authorization

If a module condition is referenced, the privileges held by the authorization ID of the statement must include EXECUTE privilege on the module or EXECUTEIN privilege or DATAACCESS on the schema containing the module.

Syntax



signal-information



Description

SQLSTATE VALUE *sqlstate-string-constant*

The specified string constant represents an SQLSTATE. It must be a character string constant with exactly 5 characters that follow the rules for SQLSTATEs:

- Each character must be from the set of digits ("0" through "9") or non-accented upper case letters ("A" through "Z")
- The SQLSTATE class (first two characters) cannot be "00", since this represents successful completion.

If the SQLSTATE does not conform to these rules, an error is raised (SQLSTATE 428B3).

SQLSTATE VALUE

Specifies the SQLSTATE that will be returned. Any valid SQLSTATE value can be used. The specified value must follow the rules for SQLSTATEs:

- Each character must be from the set of digits ("0" through "9") or upper case letters ("A" through "Z") without diacritical marks
- The SQLSTATE class (first two characters) cannot be "00", since this represents successful completion.

If the SQLSTATE does not conform to these rules, an error is returned.

sqlstate-string-constant

The *sqlstate-string-constant* must be a character string constant with exactly 5 characters.

sqlstate-string-variable

The specified SQL variable or SQL parameter must be of data type CHAR(5) and must not be the null value.

condition-name

Specifies the name of a condition that will be returned. The *condition-name* must be declared within the compound-statement or identify a condition that exists at the current server.

SET MESSAGE_TEXT =

Specifies a string that describes the error or warning. The string is returned in the `sqlerrmc` field of the SQLCA. If the actual string is longer than 70 bytes, it is truncated without warning.

SQL-variable-name

Identifies an SQL variable, declared within the compound statement, that contains the message text.

SQL-parameter-name

Identifies an SQL parameter, defined for the routine, that contains the message text. The SQL parameter must be defined as a CHAR or VARCHAR data type.

diagnostic-string-constant

Specifies a character string constant that contains the message text.

Notes

- If a RESIGNAL statement is issued without specifying an SQLSTATE clause or a *condition-name*, the identical condition that invoked the handler is returned. The SQLSTATE, SQLCODE and the SQLCA associated with the condition are unchanged.
- If a RESIGNAL statement is issued using a *condition-name* that has no associated SQLSTATE value and the condition is not handled, SQLSTATE 45000 is returned and the SQLCODE is set to -438. Note that such a condition will not be handled by a condition handler for SQLSTATE 45000 that is within the scope of the routine issuing the RESIGNAL statement.
- If a RESIGNAL statement is issued using an SQLSTATE value or a *condition-name* with an associated SQLSTATE value, the SQLCODE returned is based on the SQLSTATE value as follows:
  - If the specified SQLSTATE class is either "01" or "02" a warning or not found condition is returned and the SQLCODE is set to +438.

  - Otherwise, an exception condition is returned and the SQLCODE is set to -438.
- A RESIGNAL statement has the indicated fields of the SQLCA set as follows:
  - `sqlerrd` fields are set to zero
  - `sqlwarn` fields are set to blank
  - `sqlerrmc` is set to the first 70 bytes of MESSAGE_TEXT
  - `sqlerrml` is set to the length of `sqlerrmc`, or to zero if no SET MESSAGE_TEXT clause is specified
  - `sqlerrp` is set to ROUTINE
- Refer to the "Notes" section under "SIGNAL statement" for further information about SQLSTATE values.

Example

This example detects a division by zero error. The IF statement uses a SIGNAL statement to invoke the *overflow* condition handler. The condition handler uses a RESIGNAL statement to return a different SQLSTATE value to the client application.

```
CREATE PROCEDURE divide ( IN numerator INTEGER,
                          IN denominator INTEGER,
                          OUT result INTEGER)
LANGUAGE SQL
BEGIN
  DECLARE overflow CONDITION FOR SQLSTATE '22003';
  DECLARE CONTINUE HANDLER FOR overflow
    RESIGNAL SQLSTATE '22375';
  IF denominator = 0 THEN
    SIGNAL overflow;
  ELSE
    SET result = numerator / denominator;
  END IF;
END
```

RETURN

The RETURN statement is used to return from a routine. For SQL functions or methods, it returns the result of the function or method. For an SQL procedure, it optionally returns an integer status value.

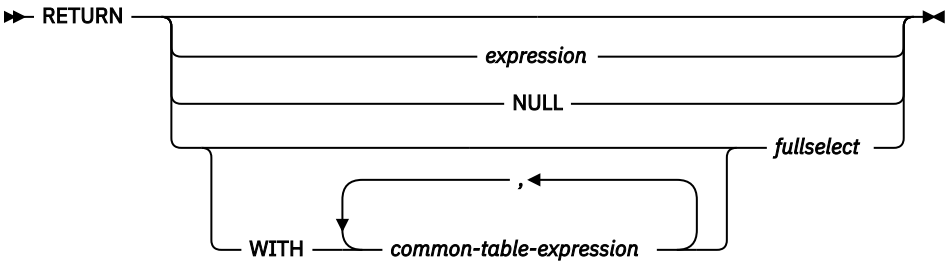
Invocation

This statement can be embedded in an SQL function, SQL method, or SQL procedure. It is not an executable statement and cannot be dynamically prepared.

Authorization

No privileges are required to invoke the RETURN statement. However, the authorization ID of the statement must hold the necessary privileges to invoke any expression or fullselect that is embedded in the RETURN statement.

Syntax



Description

expression
Specifies a value that is returned from the routine:

- If the routine is a function or method other than a compiled table function, one of *expression*, NULL, or *fullselect* must be specified (SQLSTATE 42631) and the data type of the result must be assignable to the RETURNS type of the routine (SQLSTATE 42866).
- If the routine is an inlined table function, a scalar expression (other than a scalar fullselect) cannot be specified (SQLSTATE 428F1). If the routine is a compiled table function, an expression cannot be specified.
- If the routine is a procedure, the data type of *expression* must be INTEGER (SQLSTATE 428F2). A procedure cannot return NULL or a *fullselect*.

NULL
Specifies that the function or method returns a null value of the data type defined in the RETURNS clause. NULL cannot be specified for a RETURN from a table function, row function, or procedure.

WITH *common-table-expression*
Defines a common table expression for use with the *fullselect* that follows.

fullselect
Specifies the row or rows to be returned for the function. The number of columns in the *fullselect* must match the number of columns in the function result (SQLSTATE 42811). In addition, the static column types of the *fullselect* must be assignable to the declared column types of the function result, using the rules for assignment to columns (SQLSTATE 42866).

The *fullselect* cannot be specified for a RETURN from a procedure or a compiled table function.

If the routine is a scalar function or method, then the *fullselect* must return one column (SQLSTATE 42823) and, at most, one row (SQLSTATE 21000).

If the routine is a row function, it must return, at most, one row (SQLSTATE 21505). However, one or more columns can be returned.

If the routine is an inlined table function, it can return zero or more rows with one or more columns. If the fullselect has zero result rows, no row is returned to the result table by the RETURN statement.

Rules

- The execution of an SQL function or method must end with a RETURN statement (SQLSTATE 42632).
- In an SQL table function using a compound SQL (compiled) statement, an *expression*, NULL, or *fullselect*cannot be specified. Rows are returned from the function using the PIPE statement and the RETURN statement is required as the last statement to execute when the function exits (SQLSTATE 2F005).
- In an SQL table or row function using a compound SQL (inlined) statement, the only RETURN statement allowed is the one at the end of the compound statement. (SQLSTATE 429BD).

Notes

- When a value is returned from a procedure, the caller can access the value:
  - using the GET DIAGNOSTICS statement to retrieve the DB2_RETURN_STATUS when the SQL procedure was called from another SQL procedure
  - using the parameter bound for the return value parameter marker in the escape clause CALL syntax (?=CALL...) in a CLI application
  - directly from the `sqlerrd[0]` field of the SQLCA, after processing the CALL of an SQL procedure. This field is only valid if the SQLCODE is zero or positive (assume a value of -1 otherwise).

Example

Use a RETURN statement to return from an SQL procedure with a status value of zero if successful, and -200 if not.

```
BEGIN
...
  GOTO FAIL;
...
  SUCCESS: RETURN 0;
  FAIL: RETURN -200;
END
```

REVOKE (database authorities)

This form of the REVOKE statement revokes authorities that apply to the entire database.

Invocation

This statement can be embedded in an application program or issued by using dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

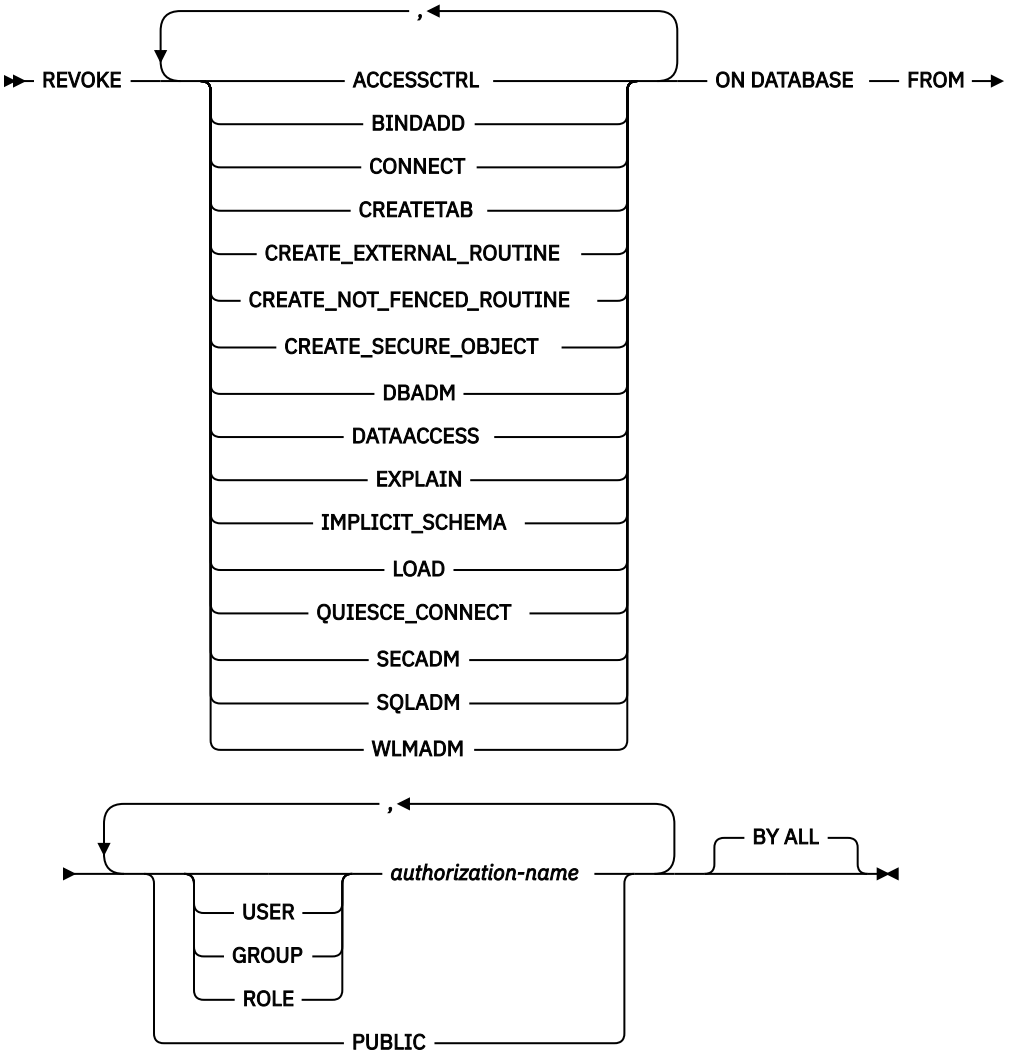
Authorization

To revoke ACCESSCTRL, CREATE_SECURE_OBJECT, DATAACCESS, DBADM, or SECADM authority, SECADM authority is needed.

Note: In Db2 11.5.7 and later, to revoke CREATE_EXTERNAL_ROUTINE or CREATE_NOT_FENCED_ROUTINE authority, SYSADM, SECADM or ACCESSCTRL authority is needed.

To revoke other authorities, ACCESSCTRL or SECADM authority is needed.

Syntax



Description

ACCESSCTRL
Revokes the authority to grant and revoke most database authorities and object privileges.

BINDADD
Revokes the authority to create packages. The creator of a package automatically has the CONTROL privilege on that package and retains this privilege even if the creator's BINDADD authority is later revoked.

The BINDADD authority cannot be revoked from an *authorization-name* holding DBADM authority without also revoking the DBADM authority.

CONNECT
Revokes the authority to access the database.

Revoking the CONNECT authority from a user does not affect any privileges that were granted to that user on objects in the database. If the user is again granted the CONNECT authority, all previously held privileges are still valid (assuming they were not explicitly revoked).

The CONNECT authority cannot be revoked from an *authorization-name* holding DBADM authority without also revoking the DBADM authority (SQLSTATE 42504).

CREATETAB
Revokes the authority to create tables. The creator of a table automatically has the CONTROL privilege on that table, and retains this privilege even if the creator's CREATETAB authority is later revoked.

The CREATETAB authority cannot be revoked from an *authorization-name* holding DBADM authority without also revoking the DBADM authority (SQLSTATE 42504).

CREATE_EXTERNAL_ROUTINE
Revokes the authority to register external routines. When an external routine is registered, it continues to exist, even if CREATE_EXTERNAL_ROUTINE is later revoked from the authorization ID that registered the routine.

CREATE_EXTERNAL_ROUTINE authority cannot be revoked from an *authorization-name* holding DBADM or CREATE_NOT_FENCED_ROUTINE authority without also revoking DBADM or CREATE_NOT_FENCED_ROUTINE authority (SQLSTATE 42504).

CREATE_NOT_FENCED_ROUTINE
Revokes the authority to register routines that run in the database manager's process. When a routine is registered as not fenced, it continues to run in this manner, even if CREATE_NOT_FENCED_ROUTINE is later revoked from the authorization ID that registered the routine.

CREATE_NOT_FENCED_ROUTINE authority cannot be revoked from an *authorization-name* holding DBADM authority without also revoking the DBADM authority (SQLSTATE 42504).

CREATE_SECURE_OBJECT
Revokes the authority to create secure triggers and secure functions. Revokes the authority to alter the secure attribute of such objects as well.

DATAACCESS
Revokes the authority to access data.

DBADM
Revokes the DBADM authority.

DBADM authority cannot be revoked from PUBLIC (because it cannot be granted to PUBLIC).

CAUTION: Revoking DBADM authority does not automatically revoke any privileges that were held by the authorization-name on objects in the database.

EXPLAIN
Revokes the authority to explain, prepare, and describe static and dynamic statements without requiring access to data.

IMPLICIT_SCHEMA
Revokes the authority to implicitly create a schema. It does not affect the ability to create objects in existing schemas or to process a CREATE SCHEMA statement.

IMPLICIT_SCHEMA authority cannot be revoked from an *authorization-name* holding DBADM authority without also revoking the DBADM authority (SQLSTATE 42504).

LOAD
Revokes the authority to LOAD in this database.

QUIESCE_CONNECT
Revokes the authority to access the database while it is quiesced.

SECADM
Revokes the authority to administer database security.

SQLADM
Revokes the authority to monitor and tune SQL statements.

WLMADM
Revokes the authority to manage workload manager objects.

FROM
Indicates from whom the authorities are revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name.

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user that is issuing the statement (SQLSTATE 42502).

PUBLIC
Revokes the authorities from PUBLIC.

BY ALL
Revokes each named privilege from all named users who were explicitly granted those privileges, regardless of who granted them. This behavior is the default.

Rules

Security administrator mandatory: The database must have at least one authorization ID of type USER with the SECADM authority. The SECADM authority cannot be revoked from every user authorization ID (SQLSTATE 42523).

- For each *authorization-name* specified, if USER, GROUP, or ROLE is not specified, then:
  - For all rows for the specified object in the SYSCAT.DBAUTH catalog view where the grantee is *authorization-name*:
    - USER is assumed if all rows have a GRANTEETYPE of 'U'.
    - GROUP is assumed if all rows have a GRANTEETYPE of 'G'.
    - ROLE is assumed if all rows have a GRANTEETYPE of 'R'.
    - An error is returned (SQLSTATE 56092) if all rows do not have the same value for GRANTEETYPE.

Notes

- Revoking a specific privilege does not necessarily revoke the ability to complete a task. A user can proceed with a task if other privileges are held by PUBLIC, a group, or a role, or if the user holds a higher-level authority, such as DBADM.
- *Syntax alternatives*: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products.
  - CREATE_NOT_FENCED can be specified in place of CREATE_NOT_FENCED_ROUTINE.
  - SYSTEM can be specified in place of DATABASE.
  - NOT INCLUDING DEPENDENT PRIVILEGES can be specified as a syntax alternative.

Examples

- *Example 1:* Given that USER6 is only a user and not a group, revoke the privilege to create tables from the user USER6.

```
REVOKE CREATETAB ON DATABASE FROM USER6
```

- *Example 2:* Revoke BINDADD authority on the database from a group named D024. Two rows exist in the SYSCAT.DBAUTH catalog view for this grantee; one with a GRANTEETYPE of U and one with a GRANTEETYPE of G.

```
REVOKE BINDADD ON DATABASE FROM GROUP D024
```

In this case, the GROUP keyword must be specified; otherwise, an error occurs (SQLSTATE 56092).

- *Example 3:* Revoke security administrator authority from user Walid.

```
REVOKE SECADM ON DATABASE FROM USER Walid
```

- *Example 4:* A user with SECADM authority revokes the CREATE_SECURE_OBJECT authority from user Haytham.

```
REVOKE CREATE_SECURE_OBJECT ON DATABASE FROM USER HAYTHAM
```

REVOKE (exemption)

This form of the REVOKE statement revokes an exemption to a label-based access control (LBAC) access rule.

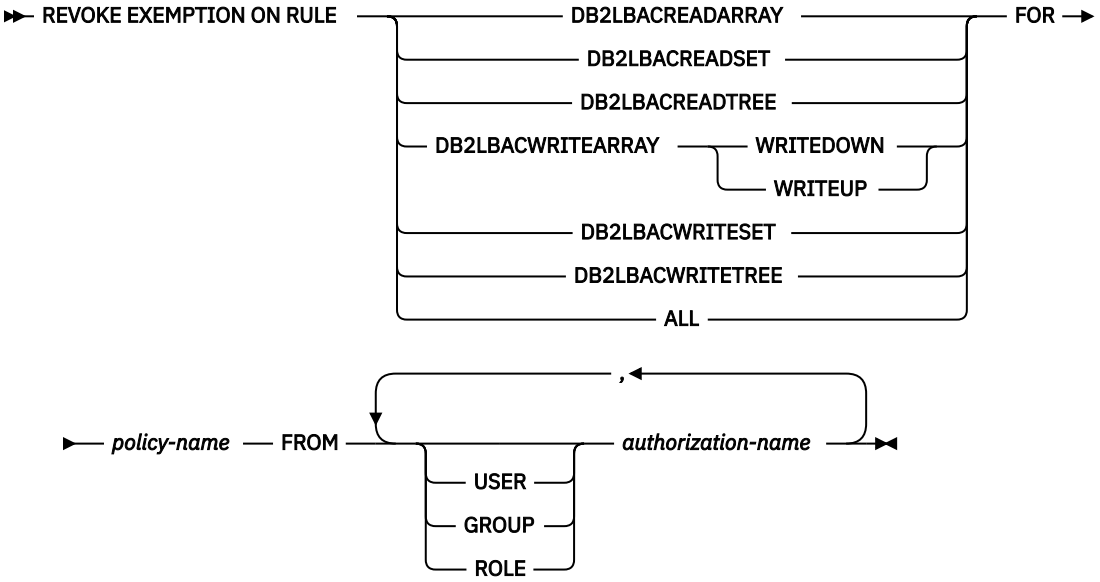
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Description

EXEMPTION ON RULE
Revokes the exemption on an access rule.

DB2LBACREADARRAY
Revokes an exemption on the predefined DB2LBACREADARRAY rule.

DB2LBACREADSET
Revokes an exemption on the predefined DB2LBACREADSET rule.

DB2LBACREADTREE
Revokes an exemption on the predefined DB2LBACREADTREE rule.

DB2LBACWRITEARRAY
Revokes an exemption on the predefined DB2LBACWRITEARRAY rule.

WRITEDOWN
Specifies that the exemption only applies to write down.

WRITEUP
Specifies that the exemption only applies to write up.

DB2LBACWRITESET
Revokes an exemption on the predefined DB2LBACWRITESET rule.

DB2LBACWRITETREE
Revokes an exemption on the predefined DB2LBACWRITETREE rule.

ALL
Revokes the exemptions on all of the predefined rules.

FOR *policy-name*
Specifies the name of the security policy on which exemptions are to be revoked.

FROM
Specifies from whom the exemption is revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name.

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - For all rows for the specified object in the SYSCAT.SECURITYPOLICYEXEMPTIONS catalog view where the grantee is *authorization-name*:
    - If all rows have a GRANTEETYPE of 'U', USER is assumed.
    - If all rows have a GRANTEETYPE of 'G', GROUP is assumed.
    - If all rows have a GRANTEETYPE of 'R', ROLE is assumed.
    - If all rows do not have the same value for GRANTEETYPE, an error is returned (SQLSTATE 56092).

Examples

- *Example 1:* Revoke the exemption on access rule DB2LBACREADSET for security policy DATA_ACCESS from user WALID.

```
REVOKE EXEMPTION ON RULE DB2LBACREADSET FOR DATA_ACCESS
  FROM USER WALID
```

- *Example 2:* Revoke an exemption on access rule DB2LBACWRITEARRAY with the WRITEDOWN option for security policy DATA_ACCESS from user BOBBY.

```
REVOKE EXEMPTION ON RULE DB2LBACWRITEARRAY WRITEDOWN
  FOR DATA_ACCESS FROM USER BOBBY
```

- *Example 3:* Revoke an exemption on access rule DB2LBACWRITEARRAY with the WRITEUP option for security policy DATA_ACCESS from user BOBBY.

```
REVOKE EXEMPTION ON RULE DB2LBACWRITEARRAY WRITEUP
  FOR DATA_ACCESS FROM USER BOBBY
```

REVOKE (global variable privileges)

This form of the REVOKE statement revokes one or more privileges on a created global variable.

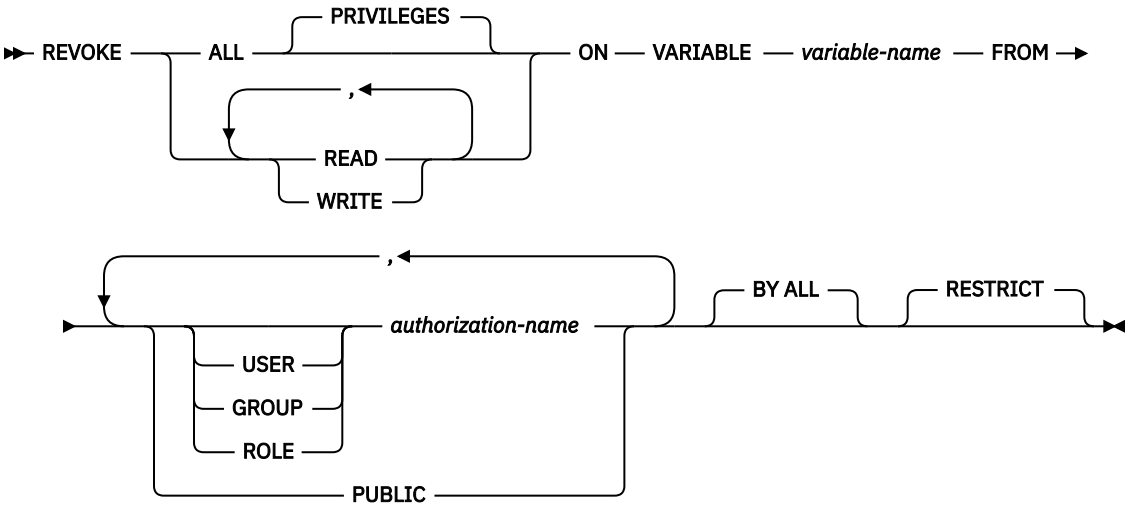
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include database ACCESSCTRL or SECADM authority or ACCESSCTRL authority on the schema containing the global variable.

Syntax



Description

ALL PRIVILEGES
Revokes all privileges held by an *authorization-name* for the specified global variable. If ALL is not specified, READ or WRITE must be specified. READ or WRITE must not be specified more than once.

READ
Revokes the privilege to read the value of the specified global variable.

WRITE
Revokes the privilege to assign a value to the specified global variable.

ON VARIABLE *variable-name*
Identifies the global variable on which one or more privileges are to be revoked. The *variable-name* must identify a global variable that exists at the current server and is not a module variable (SQLSTATE 42704).

FROM
Specifies from whom the privileges are revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group.

ROLE
Specifies that the *authorization-name* identifies an existing role at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles. The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Revokes the specified privileges from PUBLIC.

BY ALL
Revokes each specified privilege from all named users who were explicitly granted those privileges, regardless of who granted them. This is the default behavior.

RESTRICT
Specifies that the statement is to fail if any objects depend on the privileges being revoked. This is the default behavior.

Rules

- For each *authorization-name* specified, if none of the keywords USER, GROUP, or ROLE is specified, then for all rows for the specified object in the SYSCAT.VARIABLEAUTH catalog view where the grantee is *authorization-name*:
  - If GRANTEETYPE is 'U', USER is assumed.
  - If GRANTEETYPE is 'G', GROUP is assumed.
  - If GRANTEETYPE is 'R', ROLE is assumed.
  - If GRANTEETYPE does not have the same value, an error is returned (SQLSTATE 56092.
- If any SQL function, SQL method, procedure, view, trigger, or another global variable contains a global variable and depends on the privilege being revoked, the revoke operation will fail (SQLSTATE 42893).

Notes

- If the READ privilege on a global variable is revoked, packages with a dependency to write the value of the global variable (for example, by the SET statement) are not affected, because writing to a global variable is controlled by the WRITE privilege on that global variable.
- If the WRITE privilege on a global variable is revoked, packages with a dependency to read the value of the global variable are not affected, because reading from a global variable is controlled by the READ privilege on that global variable.
- Revoking a privilege does not necessarily impair the ability to perform the action. A user might be able to proceed if the required privilege is held through membership in a different group or role, or by PUBLIC.

Example

Revoke the WRITE privilege on global variable MYSCHEMA.MYJOB_PRINTER from user ZUBIRI.

```
REVOKE WRITE ON VARIABLE MYSCHEMA.MYJOB_PRINTER FROM ZUBIRI
```

REVOKE (index privileges)

This form of the REVOKE statement revokes the CONTROL privilege on an index.

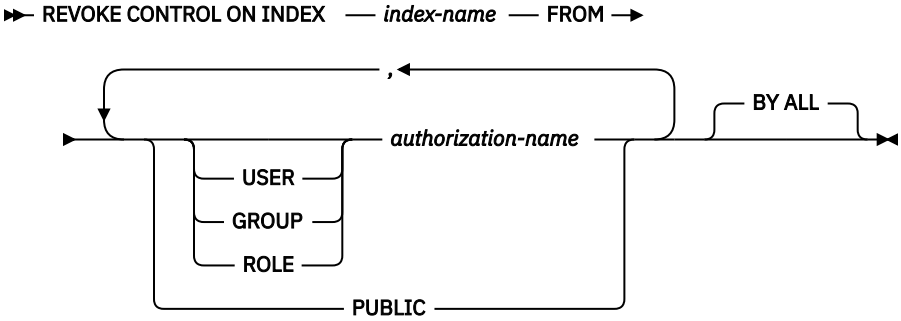
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include ACCESSCTRL or SECADM authority or ACCESSCTRL authority on the schema containing the index.

Syntax



Description

CONTROL
Revokes the privilege to drop the index. This is the CONTROL privilege for indexes, which is automatically granted to creators of indexes.

ON INDEX *index-name*
Specifies the name of the index on which the CONTROL privilege is to be revoked.

FROM
Indicates from whom the privileges are revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name.

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Revokes the privileges from PUBLIC.

BY ALL
Revokes the privilege from all named users who were explicitly granted that privilege, regardless of who granted it. This is the default behavior.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - For all rows for the specified object in the SYSCAT.INDEXAUTH catalog view where the grantee is *authorization-name*:
    - If all rows have a GRANTEETYPE of 'U', USER is assumed.
    - If all rows have a GRANTEETYPE of 'G', GROUP is assumed.
    - If all rows have a GRANTEETYPE of 'R', ROLE is assumed.
    - If all rows do not have the same value for GRANTEETYPE, an error is returned (SQLSTATE 56092).

Notes

- Revoking a specific privilege does not necessarily revoke the ability to perform the action. A user can proceed with a task if other privileges are held by PUBLIC, a group, or a role, or if the user holds authorities such as ALTERIN on the schema of an index.

Examples

- *Example 1:* Given that USER4 is only a user and not a group, revoke the privilege to drop an index DEPTIDX from the user USER4.

```
REVOKE CONTROL ON INDEX DEPTIDX FROM KIESLER
```

- *Example 2:* Revoke the privilege to drop an index LUNCHITEMS from the user CHEF and the group WAITERS.

```
REVOKE CONTROL ON INDEX LUNCHITEMS
  FROM USER CHEF, GROUP WAITERS
```

REVOKE (module privileges)

This form of the REVOKE statement revokes the privilege on a module.

Invocation

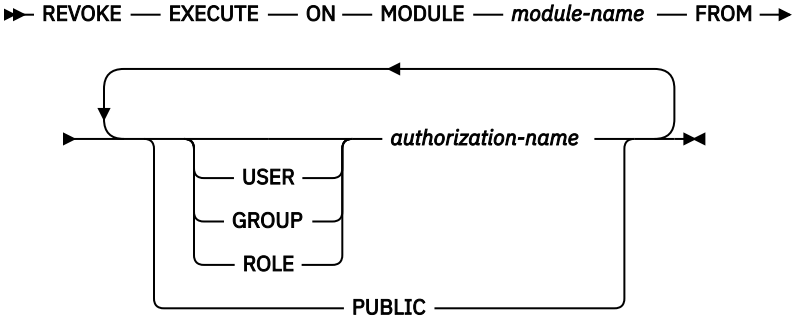
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include ACCESSCTRL or SECADM authority or ACCESSCTRL authority on the schema containing the module.

Note: In Db2 11.5.7 and later, the needed authorities are different if the module is SYSIBMADM.UTL_DIR. In this case, the authorities that are held by the authorization ID of the statement must include at least one of ACCESSCTRL, SECADM, or SYSADM.

Syntax



Description

EXECUTE

Revokes the privilege to reference published module objects. This includes revoking the privilege to:

- Execute any published routine defined in the module.
- Read from and write to any published global variables defined in the module.
- Reference any published user-defined types defined in the module.

- Reference any published conditions defined in the module.

ON MODULE ***module-name***
Identifies the module on which the privilege is revoked. The *module-name* must identify a module that exists at the current server (SQLSTATE 42704).

FROM
Indicates from whom the privilege is revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name
Lists one or more authorization IDs. The same *authorization-name* must not be specified more than once

PUBLIC
Grants the privilege to a set of users (authorization IDs). For more information, see "Authorization, privileges and object ownership".

Example

The following example demonstrate how to revoke the EXECUTE privilege from a module named *myModa* from user *jones*

```
REVOKE EXECUTE ON MODULE MYMODA FROM JONES
```

REVOKE (package privileges)

This form of the REVOKE statement revokes CONTROL, BIND, and EXECUTE privileges against a package.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

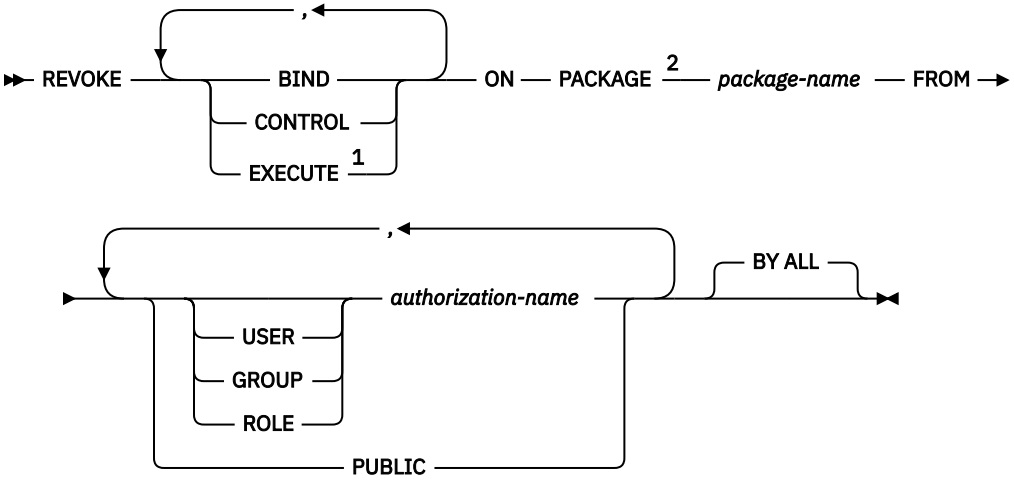
Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CONTROL privilege on the referenced package
- ACCESSCTRL on the schema containing the package
- ACCESSCTRL or SECADM authority

ACCESSCTRL or SECADM authority or ACCESSCTRL authority on the schema containing the package is required to revoke the CONTROL privilege.

Syntax



Notes:

[1] RUN can be used as a synonym for EXECUTE.
[2] PROGRAM can be used as a synonym for PACKAGE.

Description

BIND
Revokes the privilege to execute BIND or REBIND on-or to add a new version of- the referenced package.

The BIND privilege cannot be revoked from an *authorization-name* that holds CONTROL privilege on the package, without also revoking the CONTROL privilege.

CONTROL
Revokes the privilege to drop the package and to extend package privileges to other users.

Revoking CONTROL does not revoke the other package privileges.

EXECUTE
Revokes the privilege to execute the package.

The EXECUTE privilege cannot be revoked from an *authorization-name* that holds CONTROL privilege on the package without also revoking the CONTROL privilege.

ON PACKAGE *package-name*
Specifies the name of the package on which privileges are to be revoked. The revoking of a package privilege applies to all versions of the package.

FROM
Indicates from whom the privileges are revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name.

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Revokes the privileges from PUBLIC.

BY ALL
Revokes each named privilege from all named users who were explicitly granted those privileges, regardless of who granted them. This is the default behavior.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - For all rows for the specified object in the SYSCAT.PACKAGEAUTH catalog view where the grantee is *authorization-name*:
    - If all rows have a GRANTEETYPE of 'U', USER is assumed.
    - If all rows have a GRANTEETYPE of 'G', GROUP is assumed.
    - If all rows have a GRANTEETYPE of 'R', ROLE is assumed.
    - If all rows do not have the same value for GRANTEETYPE, an error is returned (SQLSTATE 56092).

Notes

- Revoking a specific privilege does not necessarily revoke the ability to perform the action. A user can proceed with a task if other privileges are held by PUBLIC, a group, or a role, or if the user holds privileges such as ALTERIN or SCHEMAADM on the schema of a package.

Examples

- *Example 1:* Revoke the EXECUTE privilege on package CORPDATA.PKGA from PUBLIC.

```
REVOKE EXECUTE
  ON PACKAGE CORPDATA.PKGA
  FROM PUBLIC
```

- *Example 2:* Revoke CONTROL authority on the RRSP_PKG package for the user FRANK and for PUBLIC.

```
REVOKE CONTROL
  ON PACKAGE RRSP_PKG
  FROM USER FRANK, PUBLIC
```

REVOKE (role)

This form of the REVOKE statement revokes roles from users, groups, or other roles.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

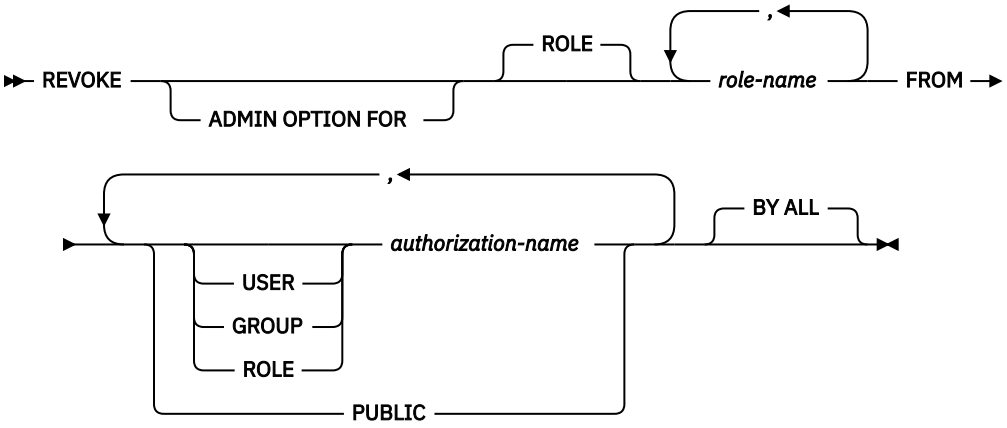
Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- The WITH ADMIN OPTION on the role
- SECADM authority

SECADM authority is required to revoke the ADMIN OPTION FOR *role-name* from an *authorization-name* or to revoke a *role-name* from an *authorization-name* that has the WITH ADMIN OPTION on that role.

Syntax



Description

ADMIN OPTION FOR
Revokes the WITH ADMIN OPTION on *role-name*. The WITH ADMIN OPTION on *role-name* must be held by *authorization-name* or by PUBLIC, if PUBLIC is specified (SQLSTATE 42504). If the ADMIN OPTION FOR clause is specified, only the WITH ADMIN OPTION on ROLE *role-name* is revoked, not the role itself.

ROLE *role-name*
Specifies the role that is to be revoked. The *role-name* must identify an existing role at the current server (SQLSTATE 42704) that has been granted to *authorization-name* or to PUBLIC, if PUBLIC is specified (SQLSTATE 42504).

FROM
Specifies from whom the role is revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group.

ROLE
Specifies that the *authorization-name* identifies an existing role at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles. The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Revokes the specified roles from PUBLIC.

BY ALL
Revokes the *role-name* from each specified *authorization-name* that was explicitly granted that role, regardless of who granted it. This is the default behavior.

Rules

- For each *authorization-name* specified, if none of the keywords USER, GROUP, or ROLE is specified, then for all rows for the specified object in the SYSCAT.ROLEAUTH catalog view where the grantee is *authorization-name*:
  - If GRANTEETYPE is 'U', USER is assumed.
  - If GRANTEETYPE is 'G', GROUP is assumed.
  - If GRANTEETYPE is 'R', ROLE is assumed.

  - If GRANTEETYPE does not have the same value, an error is returned (SQLSTATE 56092.
- The *role-name* must not identify a role, or a role that contains *role-name*, if the role has either EXECUTE privilege on a routine or USAGE privilege on a sequence, and an SQL object other than a package is dependent on the routine or sequence (SQLSTATE 42893). The owner of the SQL object is either *authorization-name* or any user that is a member of *authorization-name*, where *authorization-name* is a role.

Notes

- If a role is revoked from an *authorization-name* or from PUBLIC, all privileges that the role held are no longer available to the *authorization-name* or to PUBLIC through that role.
- Revoking a role does not necessarily revoke the ability to perform a particular action by way of a privilege that was granted to that role. A user might still be able to proceed if other privileges are held by PUBLIC, by a group to which the user belongs, by another role granted to the user, or if the user has a higher level authority, such as DBADM.

Examples

- *Example 1:* Revoke the role INTERN from the role DOCTOR and the role DOCTOR from the role SPECIALIST.

```
REVOKE ROLE INTERN FROM ROLE DOCTOR
REVOKE ROLE DOCTOR FROM ROLE SPECIALIST
```

- *Example 2:* Revoke the role INTERN from PUBLIC.

```
REVOKE ROLE INTERN FROM PUBLIC
```

- *Example 3:* Revoke the role SPECIALIST from user BOB and group TORONTO.

```
REVOKE ROLE SPECIALIST FROM USER BOB, GROUP TORONTO BY ALL
```

REVOKE (routine privileges)

This form of the REVOKE statement revokes privileges on a routine (function, method, or procedure) that is not defined in a module.

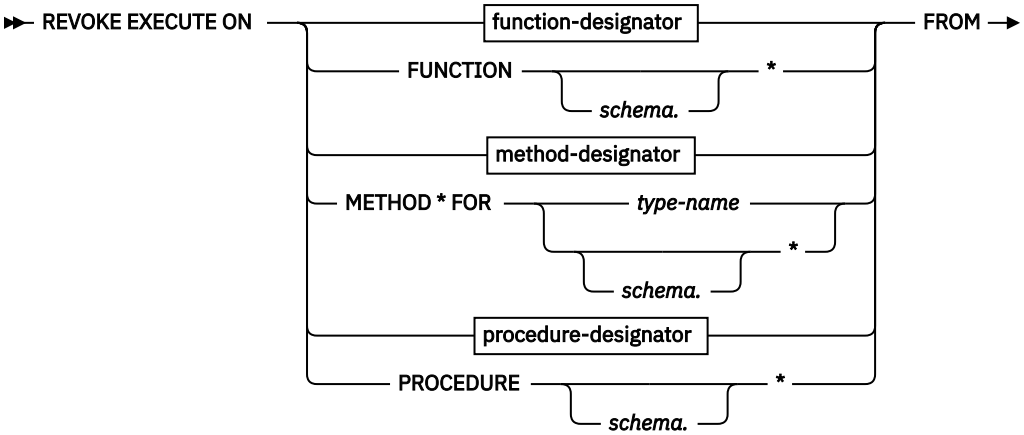
Invocation

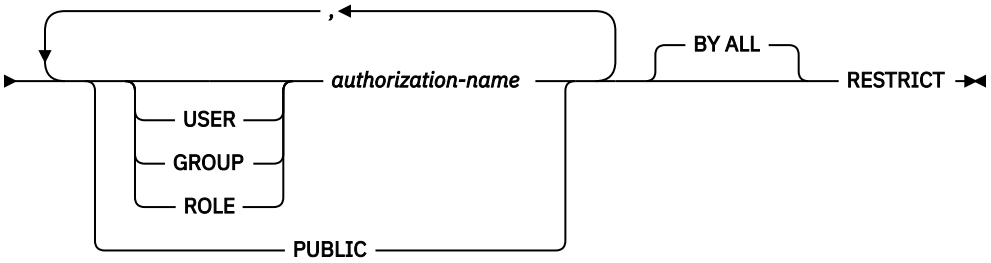
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

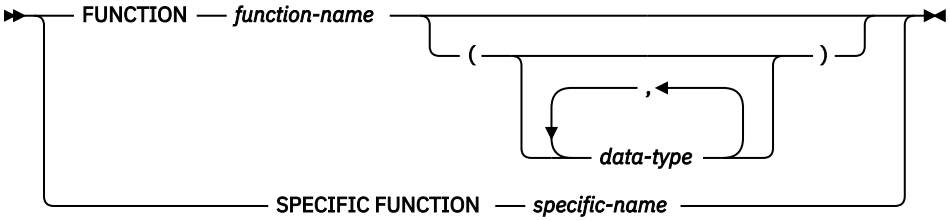
The privileges held by the authorization ID of the statement must include ACCESSCTRL or SECADM authority or ACCESSCTRL authority on the schema containing the routine.

Syntax

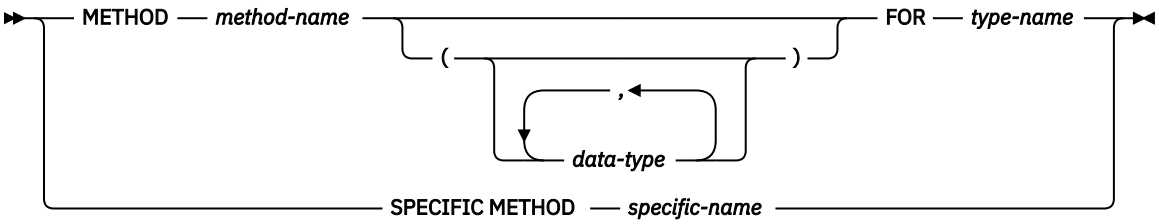




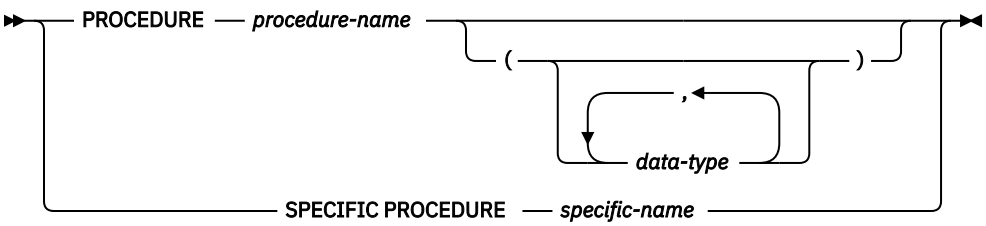
function-designator



method-designator



procedure-designator



Description

EXECUTE

Revokes the privilege to run the identified user-defined function, method, or procedure.

function-designator
Uniquely identifies the function from which the privilege is revoked. For more information, see "Function, method, and procedure designators" on page 745.

FUNCTION *schema.**
Identifies the explicit grant for all the existing and future functions in the schema. Revoking the *schema*.* privilege does not revoke any privileges that were granted on a specific function. In dynamic SQL statements, if a schema is not specified, the schema in the CURRENT SCHEMA special register will be used. In static SQL statements, if a schema is not specified, the schema in the QUALIFIER precompile/bind option will be used.

method-designator
Uniquely identifies the method from which the privilege is revoked. For more information, see "Function, method, and procedure designators" on page 745.

METHOD *
Identifies the explicit grant for all the existing and future methods for the type *type-name*. Revoking the * privilege does not revoke any privileges that were granted on a specific method.

FOR *type-name*
Names the type in which the specified method is found. The name must identify a type already described in the catalog (SQLSTATE 42704). In dynamic SQL statements, the value of the CURRENT SCHEMA special register is used as a qualifier for an unqualified type name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified type names. An asterisk (*) can be used in place of *type-name* to identify the explicit grant on all existing and future methods for all existing and future types in the schema. Revoking the privilege using an asterisk for method and *type-name* does not revoke any privileges that were granted on a specific method or on all methods for a specific type.

procedure-designator
Uniquely identifies the procedure from which the privilege is revoked. For more information, see "Function, method, and procedure designators" on page 745.

PROCEDURE *schema.**
Identifies the explicit grant for all the existing and future procedures in the schema. Revoking the *schema*.* privilege does not revoke any privileges that were granted on a specific procedure. In dynamic SQL statements, if a schema is not specified, the schema in the CURRENT SCHEMA special register will be used. In static SQL statements, if a schema is not specified, the schema in the QUALIFIER precompile/bind option will be used.

FROM
Specifies from whom the EXECUTE privilege is revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name.

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Revokes the EXECUTE privilege from PUBLIC.

BY ALL
Revokes the EXECUTE privilege from all named users who were explicitly granted the privilege, regardless of who granted it. This is the default behavior.

RESTRICT

Specifies that the EXECUTE privilege cannot be revoked if both of the following conditions are true (SQLSTATE 42893):

- The specified routine is used in a view, trigger, constraint, index extension, SQL function, SQL method, aggregate interface function, transform group, or is referenced as the SOURCE of a sourced function.
- The loss of the EXECUTE privilege would cause the owner of the view, trigger, constraint, index extension, SQL function, SQL method, aggregate interface function, transform group, or sourced function to no longer be able to execute the specified routine.

Rules

- It is not possible to revoke the EXECUTE privilege on a function or method defined with schema 'SYSIBM' or 'SYSFUN' (SQLSTATE 42832).
- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - For all rows for the specified object in the SYSCAT.ROUTINEAUTH catalog view where the grantee is *authorization-name*:
    - If all rows have a GRANTEETYPE of 'U', USER is assumed.
    - If all rows have a GRANTEETYPE of 'G', GROUP is assumed.
    - If all rows have a GRANTEETYPE of 'R', ROLE is assumed.
    - If all rows do not have the same value for GRANTEETYPE, an error is returned (SQLSTATE 56092).

Notes

- If a package depends on a routine (function, method, or procedure), and the EXECUTE privilege on that routine is revoked from PUBLIC, a user, or a role, the package becomes inoperative if the routine is a function or a method, and the package becomes invalid if the routine is a procedure, unless the package owner still holds the EXECUTE privilege on the routine. The package owner can still hold the EXECUTE privilege if:
  - The package owner was explicitly granted the EXECUTE privilege
  - The package owner is a member of a role that holds the EXECUTE privilege
  - The EXECUTE privilege was granted to PUBLIC
  - The EXECUTEIN privilege was granted to PUBLIC

  Because group privileges are not considered for static packages, the package becomes inoperative (in the case of a function or a method) or invalid (in the case of a procedure) even if a group to which the package owner belongs holds the EXECUTE privilege.

Examples

- *Example 1:* Revoke the EXECUTE privilege on function CALC_SALARY from user JONES. Assume that there is only one function in the schema with function name CALC_SALARY.

```
REVOKE EXECUTE ON FUNCTION CALC_SALARY FROM JONES RESTRICT
```

- *Example 2:* Revoke the EXECUTE privilege on procedure VACATION_ACCR from all users at the current server.

```
REVOKE EXECUTE ON PROCEDURE VACATION_ACCR FROM PUBLIC RESTRICT
```

- *Example 3:* Revoke the EXECUTE privilege on function NEW_DEPT_HIRES from HR (Human Resources). The function has two input parameters of type INTEGER and CHAR(10), respectively. Assume that the schema has more than one function named NEW_DEPT_HIRES.

```
REVOKE EXECUTE ON FUNCTION NEW_DEPT_HIRES (INTEGER, CHAR(10))
  FROM HR RESTRICT
```

- *Example 4:* Revoke the EXECUTE privilege on method SET_SALARY for type EMPLOYEE from user Jones.

```
REVOKE EXECUTE ON METHOD SET_SALARY FOR EMPLOYEE FROM JONES RESTRICT
```

REVOKE (schema privileges and authorities)

This form of the REVOKE statement revokes the privileges and authorities on a schema.

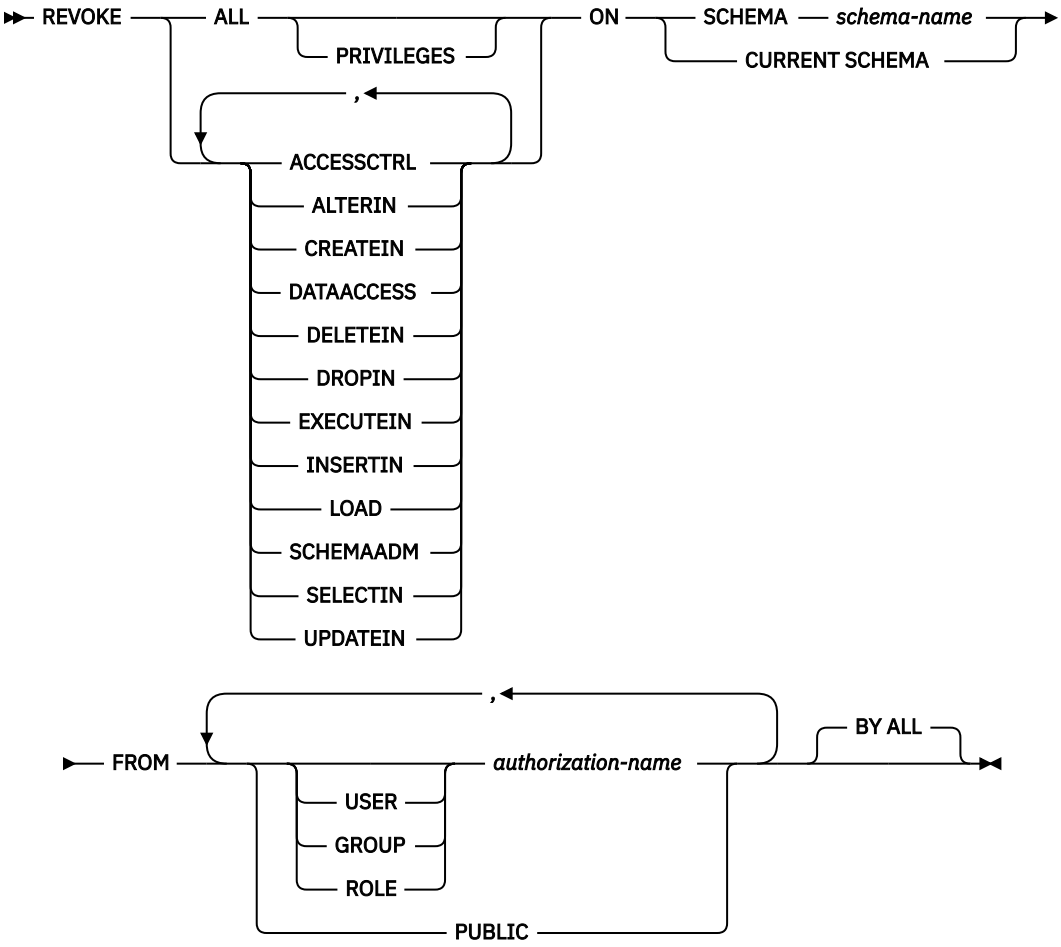
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

- The privileges held by the authorization ID of the statement must include ACCESSCTRL or SECADM authority or ACCESSCTRL authority on the schema-name.
- To revoke schema ACCESSCTRL, the authorization must have SECADM or database ACCESSCTRL authority.

Syntax



Description

ALL or ALL PRIVILEGES
Revoke all of the following schema privileges on the schema that is named in the ON clause:

- ALTERIN
- CREATEIN
- DELETEIN
- DROPIN
- EXECUTEIN
- INSERTIN
- SELECTIN
- UPDATEIN

If ALL is not specified, one or more of the keywords in the list of privileges must be specified.

ACCESSCTRL
Revokes the authority to grant and revoke schema-level privileges. For more information, see Schema access control authority (ACCESSCTRL).

ALTERIN
Revokes the privilege to alter or comment on objects in the schema.

CREATEIN
Revokes the privilege to create objects in the schema.

DATAACCESS
Revokes the authority to access data in the schema. For more information, see Schema data access authority (DATAACCESS).

DELETEIN
Revokes the privilege to delete all objects in the schema.

DROPIN
Revokes the privilege to drop objects in the schema.

EXECUTEIN
Revokes the privilege to execute user-defined functions, methods, procedures, packages, and modules defined in the schema.

INSERTIN
Revokes the privilege to insert data in to all objects in the schema.

LOAD
Revokes the authority to load in this schema. For more information, see Schema load authority (LOAD).

SCHEMAADM
Revokes the schema administrator authority. For more information, see Schema administration authority (SCHEMAADM).

SELECTIN
Revokes the privilege to select from all objects in the schema.

UPDATEIN
Revokes the privilege to update all objects in the schema.

ON

SCHEMA *schema-name*
Specifies the name of the schema on which privileges are to be revoked.

CURRENT SCHEMA
Specifies that the privileges will be revoked from the schema described by the DB2® special register CURRENT SCHEMA.

FROM
Indicates from whom the privileges are revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name.

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Revokes the privileges from PUBLIC.

BY ALL
Revokes each named privilege from all named users who were explicitly granted those privileges, regardless of who granted them. This is the default behavior.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:

- If the security plug-in in effect for the instance cannot determine the status of the authorization-name, an error is returned (SQLSTATE 56092).
- If the *authorization-name* is defined as ROLE in the database, and as either GROUP or USER according to the security plug-in in effect, an error is returned (SQLSTATE 56092).
- If the *authorization-name* is defined according to the security plug-in in effect as both USER and GROUP, an error is returned (SQLSTATE 56092).
- If the *authorization-name* is defined according to the security plug-in in effect as USER only, or if it is undefined, USER is assumed.
- If the *authorization-name* is defined according to the security plug-in in effect as GROUP only, GROUP is assumed.
- If the *authorization-name* is defined in the database as ROLE only, ROLE is assumed.

Notes

- Revoking a specific privilege does not necessarily revoke the ability to perform the action. A user can proceed with a task if other privileges are held by PUBLIC, a group, or a role, or if the user holds a higher level authority such as DBADM.

Examples

- *Example 1:* Given that USER4 is only a user and not a group, revoke the privilege to create objects in schema DEPTIDX from the user USER4.

```
REVOKE CREATEIN ON SCHEMA DEPTIDX FROM USER4
```

- *Example 2:* Revoke the privilege to drop objects in schema LUNCH from the user CHEF and the group WAITERS.

```
REVOKE DROPIN ON SCHEMA LUNCH
  FROM USER CHEF, GROUP WAITERS
```

REVOKE (security label)

This form of the REVOKE statement revokes a label-based access control (LBAC) security label.

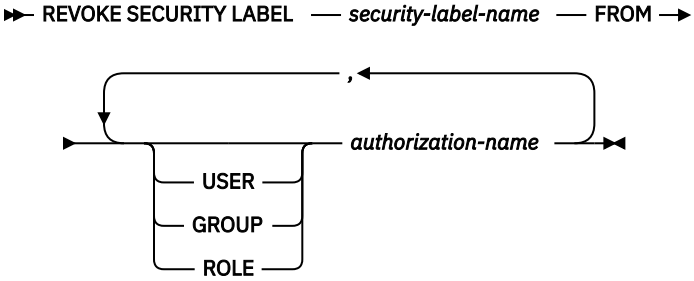
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Description

SECURITY LABEL *security-label-name*
Revokes the security label *security-label-name*. The name must be qualified with a security policy (SQLSTATE 42704) and must identify a security label that exists at the current server (SQLSTATE 42704), and that is held by *authorization-name* (SQLSTATE 42504).

FROM
Specifies from whom the specified security label is revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name. The role name must exist at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - For all rows for the specified object in the SYSCAT.SECURITYLABELACCESS catalog view where the grantee is *authorization-name*:
    - If all rows have a GRANTEETYPE of 'U', USER is assumed.
    - If all rows have a GRANTEETYPE of 'G', GROUP is assumed.
    - If all rows have a GRANTEETYPE of 'R', ROLE is assumed.
    - If all rows do not have the same value for GRANTEETYPE, an error is returned (SQLSTATE 56092).

Example

Revoke the security label EMPLOYEESECLABEL, which is part of the security policy DATA_ACCESS, from user WALID.

```
REVOKE SECURITY LABEL DATA_ACCESS.EMPLOYEESECLABEL
  FROM USER WALID
```

REVOKE (sequence privileges)

This form of the REVOKE statement revokes privileges on a sequence.

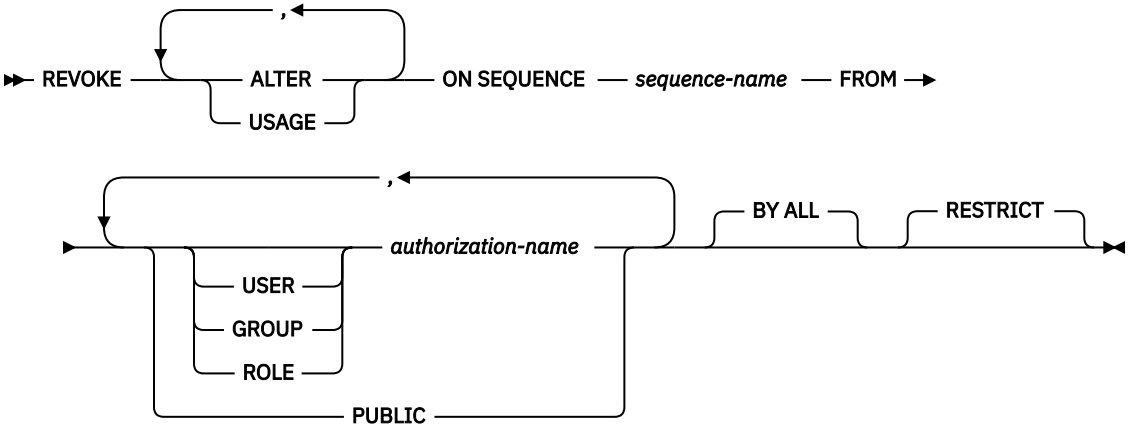
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared. However, if the bind option DYNAMICRULES BIND applies, the statement cannot be dynamically prepared (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include ACCESSCTRL or SECADM authority or ACCESSCTRL authority on the schema containing the sequence-name.

Syntax



Description

ALTER
Revokes the privilege to change the properties of a sequence or to restart sequence number generation using the ALTER SEQUENCE statement.

USAGE
Revokes the privilege to reference a sequence using *nextval-expression* or *prevval-expression*.

ON SEQUENCE *sequence-name*
Identifies the sequence on which the specified privileges are to be revoked. The sequence name, including an implicit or explicit schema qualifier, must uniquely identify an existing sequence at the current server. If no sequence by this name exists, an error is returned (SQLSTATE 42704).

FROM
Specifies from whom the privileges are revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name.

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Revokes the specified privileges from PUBLIC.

BY ALL
Revokes each specified privilege from all named users who were explicitly granted those privileges, regardless of who granted them. This is the default behavior.

RESTRICT
This optional keyword indicates that the statement will fail if any objects depend on the privilege being revoked.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:

– For all rows for the specified object in the SYSCAT.SEQUENCEAUTH catalog view where the grantee is *authorization-name*:
  - If all rows have a GRANTEETYPE of 'U', USER is assumed.
  - If all rows have a GRANTEETYPE of 'G', GROUP is assumed.
  - If all rows have a GRANTEETYPE of 'R', ROLE is assumed.
  - If all rows do not have the same value for GRANTEETYPE, an error is returned (SQLSTATE 56092).

Notes

- Revoking a privilege on a sequence from the authorization ID under which a package was bound will cause the package to become invalid if the authorization ID does not continue to hold the privilege on the sequence through different means; for example, through membership in a role that holds the privilege.
- Revoking a specific privilege does not necessarily remove the ability to perform an action. A user can proceed if other privileges are held by PUBLIC or by a group to which the user belongs, or if the user has a higher level of authority, such as DBADM.

Examples

- *Example 1:* Revoke the USAGE privilege on a sequence called GENERATE_ID from user ENGLES. There is one row in the SYSCAT.SEQUENCEAUTH catalog view for this sequence and grantee, and the GRANTEETYPE value is U.

```
REVOKE USAGE ON SEQUENCE GENERATE_ID FROM ENGLES
```

- *Example 2:* Revoke alter privileges on sequence GENERATE_ID that were previously granted to all local users. (Grants to specific users are not affected.)

```
REVOKE ALTER ON SEQUENCE GENERATE_ID FROM PUBLIC
```

- *Example 3:* Revoke all privileges on sequence GENERATE_ID from users PELLOW and MLI, and from group PLANNERS.

```
REVOKE ALTER, USAGE ON SEQUENCE GENERATE_ID
  FROM USER PELLOW, USER MLI, GROUP PLANNERS
```

REVOKE (server privileges)

This form of the REVOKE statement revokes the privilege to access and use a specified data source in pass-through mode.

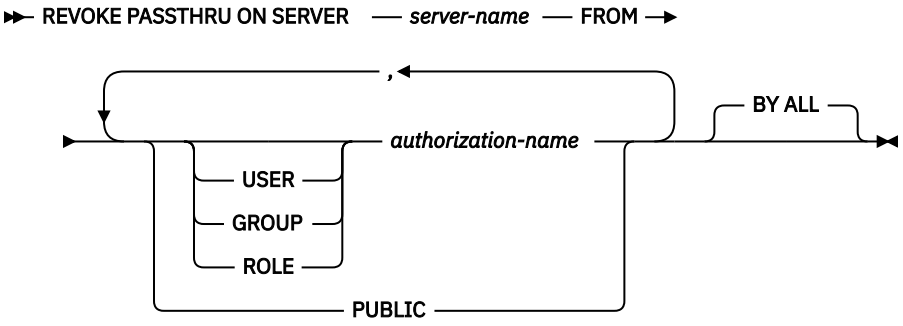
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include ACCESSCTRL or SECADM authority.

Syntax



Description

SERVER *server-name*
Names the data source for which the privilege to use in pass-through mode is being revoked. *server-name* must identify a data source that is described in the catalog.

FROM
Specifies from whom the privilege is revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name.

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Revokes from PUBLIC the privilege to pass through to *server-name*.

BY ALL
Revokes the privilege from all named users who were explicitly granted that privilege, regardless of who granted it. This is the default behavior.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - For all rows for the specified object in the SYSCAT.PASSTHRUAUTH catalog view where the grantee is *authorization-name*:
    - If all rows have a GRANTEETYPE of 'U', USER is assumed.
    - If all rows have a GRANTEETYPE of 'G', GROUP is assumed.
    - If all rows have a GRANTEETYPE of 'R', ROLE is assumed.
    - If all rows do not have the same value for GRANTEETYPE, an error is returned (SQLSTATE 56092).

Examples

- *Example 1:* Revoke USER6's privilege to pass through to data source MOUNTAIN.

```
REVOKE PASSTHRU ON SERVER MOUNTAIN FROM USER USER6
```

- *Example 2:* Revoke group D024's privilege to pass through to data source EASTWING.

```
REVOKE PASSTHRU ON SERVER EASTWING FROM GROUP D024
```

The members of group D024 will no longer be able to use their group ID to pass through to EASTWING. But if any members have the privilege to pass through to EASTWING under their own user IDs, they will retain this privilege.

REVOKE (SETSESSIONUSER privilege)

This form of the REVOKE statement revokes one or more SETSESSIONUSER privileges from one or more authorization IDs.

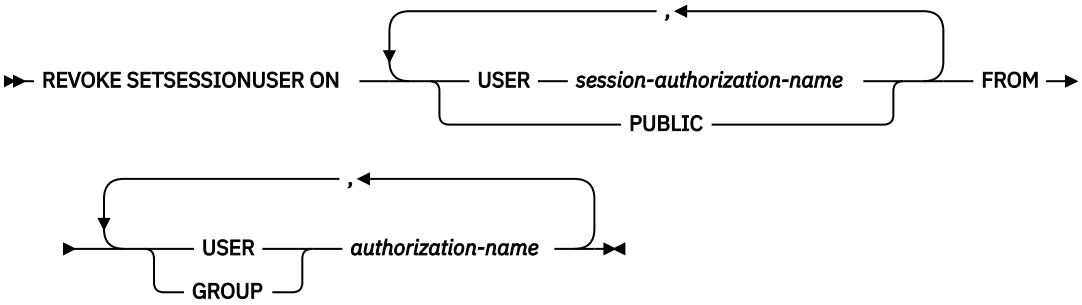
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Description

SETSESSIONUSER ON
Revokes the privilege to assume the identity of a new authorization ID.

USER *session-authorization-name*
Specifies the authorization ID that the *authorization-name* is able to assume, using the SET SESSION AUTHORIZATION statement. The *session-authorization-name* must identify a user that the *authorization-name* can assume, not a group (SQLSTATE 42504).

PUBLIC
Specifies that all privileges to set the session authorization will be revoked.

FROM
Specifies from whom the privilege is revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

authorization-name,...
Lists the authorization IDs of one or more users or groups.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

Examples

- *Example 1:* User PAUL holds the privilege to set the session authorization to WALID and therefore to execute SQL statements as user WALID. The following statement revokes that privilege.

```
REVOKE SETSESSIONUSER ON USER WALID
  FROM USER PAUL
```

- *Example 2:* User GUYLAINE holds the privilege to set the session authorization to BOBBY, RICK, or KEVIN and therefore to execute SQL statements as BOBBY, RICK, or KEVIN. The following statement revokes the privilege to use two of those authorization IDs. After this statement executes, GUYLAINE will only be able to set the session authorization to KEVIN.

```
REVOKE SETSESSIONUSER ON USER BOBBY, USER RICK
  FROM USER GUYLAINE
```

- *Example 3:* The group ACCTG and user WALID can set session authorization to any authorization ID. The following statement revokes that privilege from both ACCTG and WALID.

```
REVOKE SETSESSIONUSER ON PUBLIC
  FROM USER WALID, GROUP ACCTG
```

REVOKE (table space privileges)

This form of the REVOKE statement revokes the USE privilege on a table space.

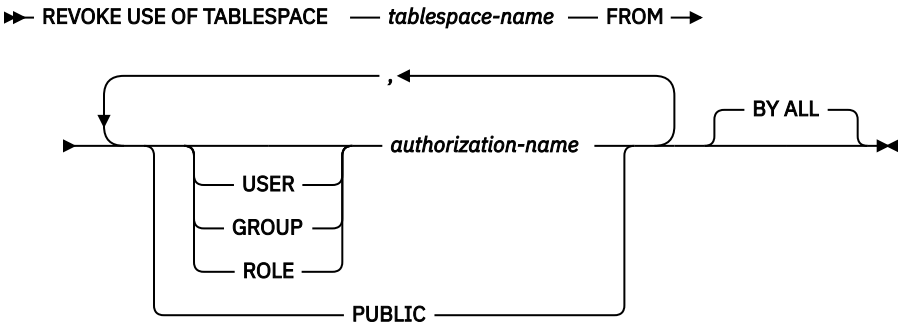
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include ACCESSCTRL, SECADM, SYSCTRL, or SYSADM authority.

Syntax



Description

USE
Revokes the privilege to specify or default to the table space when creating a table.

OF TABLESPACE *tablespace-name*
Specifies the table space on which the USE privilege is to be revoked. The table space cannot be SYSCATSPACE (SQLSTATE 42838) or a SYSTEM TEMPORARY table space (SQLSTATE 42809).

FROM
Indicates from whom the USE privilege is revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name.

authorization-name
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Revokes the USE privilege from PUBLIC.

BY ALL
Revokes the privilege from all named users who were explicitly granted that privilege, regardless of who granted it. This is the default behavior.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - For all rows for the specified object in the SYSCAT.TBSPACEAUTH catalog view where the grantee is *authorization-name*:
    - If all rows have a GRANTEETYPE of 'U', USER is assumed.
    - If all rows have a GRANTEETYPE of 'G', GROUP is assumed.
    - If all rows have a GRANTEETYPE of 'R', ROLE is assumed.
    - If all rows do not have the same value for GRANTEETYPE, an error is returned (SQLSTATE 56092).

Notes

- Revoking the USE privilege does not necessarily revoke the ability to create tables in that table space. A user may still be able to create tables in that table space if the USE privilege is held by PUBLIC or a group, or if the user has a higher level authority, such as DBADM.

Example

Revoke the privilege to create tables in table space PLANS from the user BOBBY.

```
REVOKE USE OF TABLESPACE PLANS FROM USER BOBBY
```

REVOKE (table, view, or nickname privileges)

This form of the REVOKE statement revokes privileges on a table, view, or nickname.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

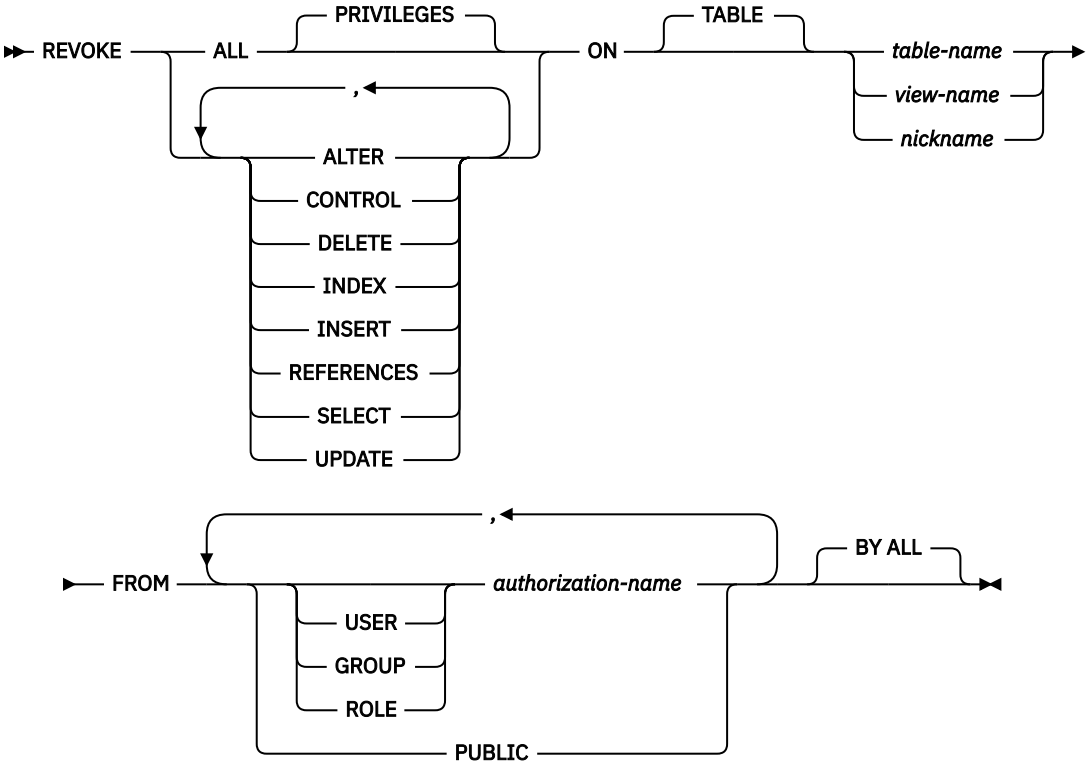
Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CONTROL privilege on the referenced table, view, or nickname
- ACCESSCTRL authority on the schema containing the identified table, view, or nickname
- ACCESSCTRL or SECADM authority

Schema ACCESSCTRL, ACCESSCTRL or SECADM authority is required to revoke the CONTROL privilege. ACCESSCTRL or SECADM authority is required to revoke privileges on catalog tables and views.

Syntax



Description

ALL or ALL PRIVILEGES
Revokes all privileges (except CONTROL) held by an authorization-name for the specified tables, views, or nicknames.

If ALL is not used, one or more of the keywords listed in the option stack (ALTER through UPDATE) must be used. Each keyword revokes the privilege described, but only as it applies to the tables, views, or nicknames named in the ON clause. The same keyword must not be specified more than once.

ALTER
Revokes the privilege to add columns to the base table definition; create or drop a primary key or unique constraint on the table; create or drop a foreign key on the table; add/change a comment on the table, view, or nickname; create or drop a check constraint; create a trigger; add, reset, or drop a column option for a nickname; or, change nickname column names or data types.

CONTROL
Revokes the ability to drop the table, view, or nickname, and the ability to execute the RUNSTATS utility on the table and indexes.

Revoking CONTROL privilege from an *authorization-name* does not revoke other privileges granted to the user on that object.

DELETE
Revokes the privilege to delete rows from the table, updatable view, or nickname.

INDEX
Revokes the privilege to create an index on the table or an index specification on the nickname. The creator of an index or index specification automatically has the CONTROL privilege over the index or index specification (authorizing the creator to drop the index or index specification). In addition, the creator retains this privilege even if the INDEX privilege is revoked.

INSERT
Revokes the privileges to insert rows into the table, updatable view, or nickname, and to run the IMPORT utility.

REFERENCES
Revokes the privilege to create or drop a foreign key referencing the table as the parent. Any column level REFERENCES privileges are also revoked.

SELECT
Revokes the privilege to retrieve rows from the table or view, to create a view on a table, and to run the EXPORT utility against the table or view.

Revoking SELECT privilege may cause some views to be marked inoperative. (For information about inoperative views, see "CREATE VIEW".)

UPDATE
Revokes the privilege to update rows in the table, updatable view, or nickname. Any column level UPDATE privileges are also revoked.

ON TABLE *table-name* or *view-name* or *nickname*
Specifies the table, view, or nickname on which privileges are to be revoked. The *table-name* cannot be a declared temporary table (SQLSTATE 42995).

FROM
Indicates from whom the privileges are revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group name.

ROLE
Specifies that the *authorization-name* identifies a role name.

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles.

The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Revokes the privileges from PUBLIC.

BY ALL
Revokes each named privilege from all named users who were explicitly granted those privileges, regardless of who granted them. This is the default behavior.

Rules

- For each *authorization-name* specified, if neither USER, GROUP, nor ROLE is specified, then:
  - For all rows for the specified object in the SYSCAT.TABAUTH and SYSCAT.COLAUTH catalog views where the grantee is *authorization-name*:
    - If all rows have a GRANTEETYPE of 'U', USER is assumed.
    - If all rows have a GRANTEETYPE of 'G', GROUP is assumed.
    - If all rows have a GRANTEETYPE of 'R', ROLE is assumed.
    - If all rows do not have the same value for GRANTEETYPE, an error is returned (SQLSTATE 56092).

Notes

- If a privilege is revoked from the *authorization-name* that is the owner of the view (as recorded in the OWNER column in SYSCAT.VIEWS), that privilege is also revoked from any dependent views.
- If the owner of the view loses a SELECT privilege on some object on which the view definition depends (or an object upon which the view definition depends is dropped, or made inoperative in the case of another view), the view will be made inoperative.

  However, if a user who holds ACCESSCTRL or SECADM authority explicitly revokes all privileges on the view from the owner, then the record of the OWNER will not appear in SYSCAT.TABAUTH but nothing will happen to the view - it remains operative.
- Privileges on inoperative views cannot be revoked.
- A package might become invalid when the authorization ID under which the package was bound loses a privilege on an object on which the package depends. The privilege can be lost in one of the following ways:
  - The privilege is revoked from the authorization ID
  - The privilege is revoked from a role of which the authorization ID is a member
  - The privilege is revoked from PUBLIC

  A package remains invalid until a bind or rebind operation on the application is successfully executed, or the application is executed and the database manager successfully rebinds the application (using information stored in the catalogs). Packages marked invalid due to a revoke may be successfully rebound without any additional grants.

  For example, if a package owned by USER1 contains a SELECT from table T1, and the SELECT privilege on table T1 is revoked from USER1, the package will be marked invalid. If SELECT authority is granted again, or if the user holds DBADM authority, the package is successfully rebound when executed.

  Another example is a package owned by USER1, who is a member of role R1. The package contains a SELECT from table T1, and the SELECT privilege on table T1 is revoked from role R1. The package will be marked invalid, assuming USER1 does not hold the SELECT privilege on table T1 by other means.
- Packages, triggers or views that include the use of OUTER(*Z*) in the FROM clause, are dependent on having SELECT privilege on every subtable or subview of *Z*. Similarly, packages, triggers, or views that include the use of DEREF(*Y*) where *Y* is a reference type with a target table or view *Z*, are dependent on having SELECT privilege on every subtable or subview of *Z*. Such packages might become invalid, and such triggers or views made inoperative when the authorization ID under which the packages were bound, or the owner of the triggers or views loses the SELECT privilege. The SELECT privilege can be lost in one of the following ways:
  - SELECT privilege is revoked from the authorization ID
  - SELECT privilege is revoked from a role of which the authorization ID is a member
  - SELECT privilege is revoked from PUBLIC
- Table, view, or nickname privileges cannot be revoked from an *authorization-name* with CONTROL on the object without also revoking the CONTROL privilege (SQLSTATE 42504).
- Revoking a specific privilege does not necessarily revoke the ability to perform the action. A user can proceed with a task if other privileges are held by PUBLIC, a group, or a role, or if the user holds privileges such as ALTERIN on the schema of a table or a view.
- If the owner of the materialized query table loses a SELECT privilege on a table on which the materialized query table definition depends (or a table upon which the materialized query table definition depends is dropped), the materialized query table will be dropped.

  However, if a user who holds SECADM or ACCESSCTRL authority explicitly revokes all privileges on the materialized query table from the owner, then the record in SYSTABAUTH for the OWNER will be deleted, but nothing will happen to the materialized query table - it remains operative.
- Revoking nickname privileges has no affect on data source object (table or view) privileges.

- Revoking the SELECT privilege for a table or view that is directly or indirectly referenced in an SQL function or method body may fail if the SQL function or method body cannot be dropped because some other object is dependent on it (SQLSTATE 42893).
- Revoking the SELECT privilege causes an SQL function or method body to be dropped when:
  - The owner of the SQL function or method body loses the SELECT privilege on some object on which the SQL function or method body definition depends; note that the privilege can be lost because of a revoke from PUBLIC or from a role of which the owner is a member
  - An object on which the SQL function or method body definition depends is dropped

  However, the revoke fails if another object depends on the function or method (SQLSTATE 42893).
- **Revoking WITH GRANT OPTION:** The only way to revoke the WITH GRANT OPTION is to revoke the privilege itself and then grant it again without specifying WITH GRANT OPTION.
- **Revoking column privileges:** The only way to revoke column privileges is to revoke the privilege from the entire table itself and then grant it again for each column.

Examples

- *Example 1:* Revoke SELECT privilege on table EMPLOYEE from user ENGLES. There is one row in the SYSCAT.TABAUTH catalog view for this table and grantee and the GRANTEETYPE value is U.

```
REVOKE SELECT
  ON TABLE EMPLOYEE
  FROM ENGLES
```

- *Example 2:* Revoke update privileges on table EMPLOYEE previously granted to all local users. Note that grants to specific users are not affected.

```
REVOKE UPDATE
  ON EMPLOYEE
  FROM PUBLIC
```

- *Example 3:* Revoke all privileges on table EMPLOYEE from users PELLOW and MLI and from group PLANNERS.

```
REVOKE ALL
  ON EMPLOYEE
  FROM USER PELLOW, USER MLI, GROUP PLANNERS
```

- *Example 4:* Revoke SELECT privilege on table CORPDATA.EMPLOYEE from a user named JOHN. There is one row in the SYSCAT.TABAUTH catalog view for this table and grantee and the GRANTEETYPE value is U.

```
REVOKE SELECT
  ON CORPDATA.EMPLOYEE FROM JOHN
```

  or

```
REVOKE SELECT
  ON CORPDATA.EMPLOYEE FROM USER JOHN
```

  Note that an attempt to revoke the privilege from GROUP JOHN would result in an error, since the privilege was not previously granted to GROUP JOHN.
- *Example 5:* Revoke SELECT privilege on table CORPDATA.EMPLOYEE from a group named JOHN. There is one row in the SYSCAT.TABAUTH catalog view for this table and grantee and the GRANTEETYPE value is G.

```
REVOKE SELECT
  ON CORPDATA.EMPLOYEE FROM JOHN
```

  or

```
REVOKE SELECT
  ON CORPDATA.EMPLOYEE FROM GROUP JOHN
```

- *Example 6:* Revoke user SHAWN's privilege to create an index specification on nickname ORAREM1.

```
REVOKE INDEX
  ON ORAREM1 FROM USER SHAWN
```

REVOKE (workload privileges)

This form of the REVOKE statement revokes the USAGE privilege on a workload.

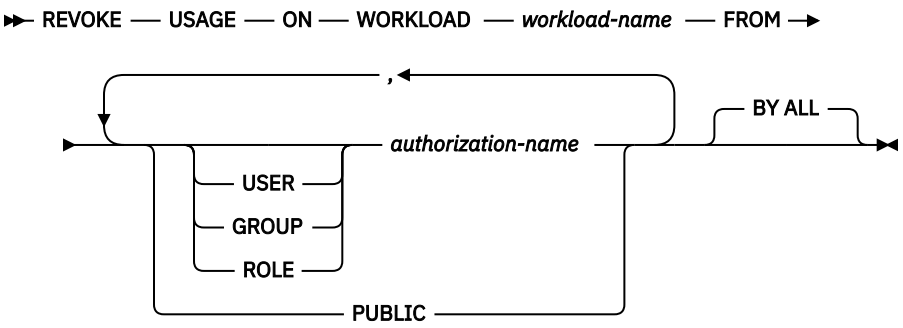
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include ACCESSCTRL, SECADM, or WLMADM authority.

Syntax



Description

USAGE
Revokes the privilege to use a workload.

ON WORKLOAD *workload-name*
Identifies the workload on which the USAGE privilege is to be revoked. This is a one-part name. The *workload-name* must identify a workload that exists at the current server (SQLSTATE 42704). The name cannot be 'SYSDEFAULTADMWORKLOAD' (SQLSTATE 42832).

FROM
Specifies from whom the USAGE privilege is revoked.

USER
Specifies that the *authorization-name* identifies a user.

GROUP
Specifies that the *authorization-name* identifies a group.

ROLE
Specifies that the *authorization-name* identifies an existing role at the current server (SQLSTATE 42704).

authorization-name,...
Lists the authorization IDs of one or more users, groups, or roles. The list of authorization IDs cannot include the authorization ID of the user issuing the statement (SQLSTATE 42502).

PUBLIC
Revokes the USAGE privilege from PUBLIC.

BY ALL
Revokes the USAGE privilege from all named users who were explicitly granted that privilege, regardless of who granted it. This is the default behavior.

Rules

- For each *authorization-name* specified, if none of the keywords USER, GROUP, or ROLE is specified, then for all rows for the specified object in the SYSCAT.WORKLOADAUTH catalog view where the grantee is *authorization-name*:
  - If GRANTEETYPE is 'U', USER is assumed.
  - If GRANTEETYPE is 'G', GROUP is assumed.
  - If GRANTEETYPE is 'R', ROLE is assumed.
  - If GRANTEETYPE does not have the same value, an error is returned (SQLSTATE 56092.

Notes

- The REVOKE statement does not take effect until it is committed, even for the connection that issues the statement.

Example

Revoke the privilege to use the workload CAMPAIGN from user LISA.

```
REVOKE USAGE ON WORKLOAD CAMPAIGN FROM USER LISA
```

REVOKE (XSR object privileges)

This form of the REVOKE statement revokes USAGE privilege on an XSR object.

Invocation

The REVOKE statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if the DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

One of the following authorities is required:

- ACCESSCTRL or SECADM authority or ACCESSCTRL authority on the schema containing the XSR object

Syntax

Description

ON XSROBJECT *xsrobject-name*
This name identifies the XSR object for which the USAGE privilege is revoked. The *xsrobject-name*, including the implicit or explicit schema qualifier, must uniquely identify an existing XSR object at the current server. If no XSR object by this name exists in the specified schema, an error is raised (SQLSTATE 42704).

FROM PUBLIC
Revokes the USAGE privilege from PUBLIC.

BY ALL
Revokes each named privilege from all users who were explicitly granted those privileges, regardless of who granted them. This is the default behavior.

Example

Revoke usage privileges on the XML schema MYSCHEMA from PUBLIC:

```
REVOKE USAGE ON XSROBJECT MYSCHEMA FROM PUBLIC
```

ROLLBACK

The ROLLBACK statement is used to back out of the database changes that were made within a unit of work or a savepoint.

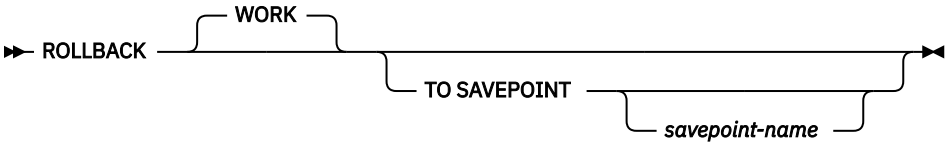
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

The unit of work in which the ROLLBACK statement is executed is terminated and a new unit of work is initiated. All changes made to the database during the unit of work are backed out.

The following statements, however, are not under transaction control, and changes made by them are independent of the ROLLBACK statement:

- SET CONNECTION
- SET ENCRYPTION PASSWORD
- SET EVENT MONITOR STATE
- SET PASSTHRU

  Note: Although the SET PASSTHRU statement is not under transaction control, the passthru session initiated by the statement is under transaction control.
- SET SERVER OPTION
- SET variable
- Assignments to updatable special registers

The generation of sequence and identity values is not under transaction control. Values generated and consumed by the *nextval-expression* or by inserting rows into a table that has an identity column are independent of issuing the ROLLBACK statement. Also, issuing the ROLLBACK statement does not affect the value returned by the *prevval-expression*, nor the IDENTITY_VAL_LOCAL function.

Modification of the values of global variables is not under transaction control. ROLLBACK statements do not affect the values assigned to global variables.

TO SAVEPOINT
Specifies that a partial rollback (ROLLBACK TO SAVEPOINT) is to be performed. If no savepoint is active in the current savepoint level (see the "Rules" section in the description of the SAVEPOINT statement), an error is returned (SQLSTATE 3B502). After a successful rollback, the savepoint continues to exist, but any nested savepoints are released and no longer exist. The nested savepoints, if any, are considered to have been rolled back and then released as part of the rollback to the current savepoint. If a *savepoint-name* is not provided, rollback occurs to the most recently set savepoint within the current savepoint level.

If this clause is omitted, the ROLLBACK statement rolls back the entire transaction. Furthermore, savepoints within the transaction are released.

savepoint-name
Specifies the savepoint that is to be used in the rollback operation. The specified *savepoint-name* cannot begin with 'SYS' (SQLSTATE 42939). After a successful rollback operation, the named savepoint continues to exist. If the savepoint name does not exist, an error (SQLSTATE 3B001) is returned. Data and schema changes made since the savepoint was set are undone.

Notes

- All locks held are released on a ROLLBACK of the unit of work. All open cursors are closed. All LOB locators are freed.
- Executing a ROLLBACK statement does not affect either the SET statements that change special register values or the RELEASE statement.
- If the program terminates abnormally, the unit of work is implicitly rolled back.
- Statement caching is affected by the rollback operation.
- The impact on cursors resulting from a ROLLBACK TO SAVEPOINT depends on the statements within the savepoint
  - If the savepoint contains DDL on which a cursor is dependent, the cursor is marked invalid. Attempts to use such a cursor results in an error (SQLSTATE 57007).
  - Otherwise:
    - If the cursor is referenced in the savepoint, the cursor remains open and is positioned before the next logical row of the result table. (A FETCH must be performed before a positioned UPDATE or DELETE statement is issued.)
    - Otherwise, the cursor is not affected by the ROLLBACK TO SAVEPOINT (it remains open and positioned).
- Dynamic SQL statements prepared in a package bound with the `KEEPDYNAMIC YES` option are kept in the SQL context after a ROLLBACK statement. The statement might be implicitly prepared again, as a result of DDL operations that are rolled back within the unit of work.
- Inactive dynamic SQL statements prepared in a package bound with `KEEPDYNAMIC NO` are removed from the SQL context after a rollback operation. The statement must be prepared again before it can be executed in a new transaction.
- The following dynamic SQL statements may be active during ROLLBACK:
  - ROLLBACK statement
  - CALL statements under which the ROLLBACK statement was executed
- A ROLLBACK TO SAVEPOINT operation will drop any created temporary tables created within the savepoint. If a created temporary table is modified within the savepoint and that table has been defined as not logged, then all rows in the table are deleted.
- A ROLLBACK TO SAVEPOINT operation will drop any declared temporary tables declared within the savepoint. If a declared temporary table is modified within the savepoint and that table has been defined as not logged, then all rows in the table are deleted.

- All locks are retained after a ROLLBACK TO SAVEPOINT statement.
- All LOB locators are preserved following a ROLLBACK TO SAVEPOINT operation.

Example

Delete the alterations made since the last commit point or rollback.

```
ROLLBACK WORK
```

SAVEPOINT

Use the SAVEPOINT statement to set a savepoint within a transaction.

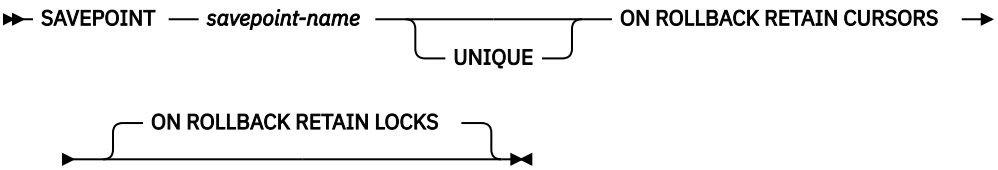
Invocation

This statement can be imbedded in an application program (including a procedure) or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

savepoint-name
Specifies the name of a savepoint. The specified *savepoint-name* cannot begin with 'SYS' (SQLSTATE 42939). If a savepoint by this name has already been defined as UNIQUE within this savepoint level, an error is returned (SQLSTATE 3B501).

UNIQUE
Specifies that the application does not intend to reuse this savepoint name while the savepoint is active within the current savepoint level. If *savepoint-name* already exists within this savepoint level, an error is returned (SQLSTATE 3B501).

ON ROLLBACK RETAIN CURSORS
Specifies system behavior upon rollback to this savepoint with respect to open cursor statements processed after the SAVEPOINT statement. This clause indicates that, whenever possible, the cursors are unaffected by a rollback to savepoint operation. For situations where the cursors are affected by the rollback to savepoint, see "ROLLBACK".

ON ROLLBACK RETAIN LOCKS
Specifies system behavior upon rollback to this savepoint with respect to locks acquired after the setting of the savepoint. Locks acquired since the savepoint are not tracked, and are not rolled back (released) upon rollback to the savepoint.

Rules

- Savepoint-related statements must not be used within trigger definitions (SQLSTATE 42987).
- A new savepoint level starts when one of the following events occurs:
  - A new unit of work (UOW) starts.

  - A procedure defined with the NEW SAVEPOINT LEVEL clause is called.
  - An atomic compound SQL statement starts.
- A savepoint level ends when the event that caused its creation is finished or removed. When a savepoint level ends, all savepoints contained within it are released. Any open cursors, DDL actions, or data modifications are inherited by the parent savepoint level (that is, the savepoint level within which the one that just ended was created), and are subject to any savepoint-related statements issued against the parent savepoint level.
- The following rules apply to actions within a savepoint level:
  - Savepoints can only be referenced within the savepoint level in which they are established. You cannot release, destroy, or roll back to a savepoint established outside of the current savepoint level.
  - All active savepoints established within the current savepoint level are automatically released when the savepoint level ends.
  - The uniqueness of savepoint names is only enforced within the current savepoint level. The names of savepoints that are active in other savepoint levels can be reused in the current savepoint level without affecting those savepoints in other savepoint levels.

Notes

- Once a SAVEPOINT statement has been issued, insert, update, or delete operations on nicknames are not allowed.
- Omitting the UNIQUE clause specifies that *savepoint-name* can be reused within the savepoint level by another savepoint. If a savepoint of the same name already exists within the savepoint level, the existing savepoint is destroyed and a new savepoint with the same name is created at the current point in processing. The new savepoint is considered to be the last savepoint established by the application. Note that the destruction of a savepoint through the reuse of its name by another savepoint simply destroys that one savepoint and does not release any savepoints established after the destroyed savepoint. These subsequent savepoints can only be released by means of the RELEASE SAVEPOINT statement, which releases the named savepoint and all savepoints established after the named savepoint.
- If the UNIQUE clause is specified, *savepoint-name* can only be reused after an existing savepoint with the same name has been released.
- Within a savepoint, if a utility, SQL statement, or database command performs intermittent commits during processing, the savepoint will be implicitly released.
- If the SET INTEGRITY statement is rolled back within the savepoint, dynamically prepared statement names are still valid, although the statement might be implicitly prepared again.
- If inserts are buffered (that is, the application was precompiled with the INSERT BUF option), the buffer will be flushed when SAVEPOINT, ROLLBACK, or RELEASE TO SAVEPOINT statements are issued.

Example

Perform a rollback operation for nested savepoints. First, create a table named DEPARTMENT. Insert a row before starting SAVEPOINT1; insert another row and start SAVEPOINT2; then, insert a third row and start SAVEPOINT3.

```
CREATE TABLE DEPARTMENT (
  DEPTNO   CHAR(6),
  DEPTNAME VARCHAR(20),
  MGRNO    INTEGER)

  INSERT INTO DEPARTMENT VALUES ('A20', 'MARKETING', 301)

  SAVEPOINT SAVEPOINT1 ON ROLLBACK RETAIN CURSORS

  INSERT INTO DEPARTMENT VALUES ('B30', 'FINANCE', 520)

  SAVEPOINT SAVEPOINT2 ON ROLLBACK RETAIN CURSORS

  INSERT INTO DEPARTMENT VALUES ('C40', 'IT SUPPORT', 430)
```

```
    SAVEPOINT SAVEPOINT3 ON ROLLBACK RETAIN CURSORS
    INSERT INTO DEPARTMENT VALUES ('R50', 'RESEARCH', 150)
```

At this point, the DEPARTMENT table exists with rows A20, B30, C40, and R50. If you now issue:

```
  ROLLBACK TO SAVEPOINT SAVEPOINT3
```

row R50 is no longer in the DEPARTMENT table. If you then issue:

```
  ROLLBACK TO SAVEPOINT SAVEPOINT1
```

the DEPARTMENT table still exists, but the rows inserted since SAVEPOINT1 was established (B30 and C40) are no longer in the table.

SELECT

The SELECT statement is a form of query

The SELECT statement can be embedded in an application program or issued interactively.

SELECT INTO

The SELECT INTO statement produces a result table consisting of at most one row, and assigns the values in that row to host variables.

If the table is empty, the statement assigns +100 to SQLCODE and '02000' to SQLSTATE and does not assign values to the host variables. If more than one row satisfies the search condition, statement processing is terminated, and an error occurs (SQLSTATE 21000).

Invocation

This statement can be embedded only in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- SELECT privilege on the table, view, or nickname
- CONTROL privilege on the table, view, or nickname
- SELECTIN privilege on the schema containing the table, view, or nickname
- DATAACCESS authority on the schema containing the table, view, or nickname
- DATAACCESS authority

For each global variable used as an assignment target, the privileges held by the authorization ID of the statement must include one of the following authorities:

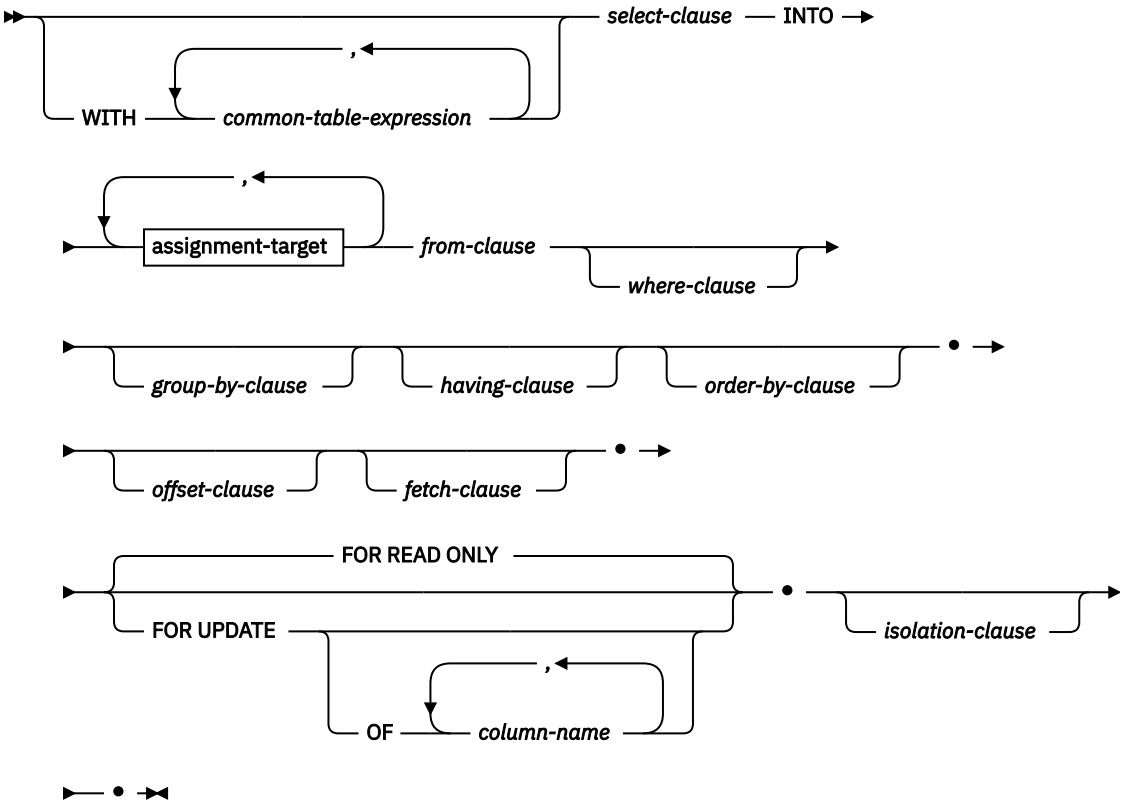
- WRITE privilege on the global variable that is not defined in a module
- EXECUTE privilege on the module of the global variable that is defined in a module
- EXECUTEIN privilege on the schema containing the module of the global variable that is defined in a module
- DATAACCESS authority on the schema containing the module of the global variable that is defined in a module

GROUP privileges are not checked for static SELECT INTO statements.

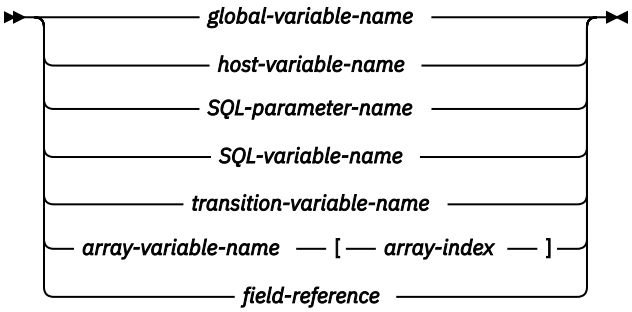
If the target of the SELECT INTO statement is a nickname, privileges on the object at the data source are not considered until the statement is executed at the data source. At this time, the authorization ID

that is used to connect to the data source must have the privileges that are required for the operation on the object at the data source. The authorization ID of the statement can be mapped to a different authorization ID at the data source.

Syntax



assignment-target



Description

For a description of the *common-table-expression*, *select-clause*, *from-clause*, *where-clause*, *group-by-clause*, *having-clause*, *order-by-clause*, *offset-clause*, *fetch-clause*, and *isolation-clause*, see "subselect" in the *SQL Reference Volume 1*.

INTO *assignment-target*

Identifies one or more targets for the assignment of output values.

The first value in the result row is assigned to the first target in the list, the second value to the second target, and so on. Each assignment to an *assignment-target* is made in sequence through the list. If an error occurs on any assignment, no value is assigned to any *assignment-target*.

When the data type of every *assignment-target* is not a row type, then the value 'W' is assigned to the SQLWARN3 field of the SQLCA if the number of *assignment-targets* is less than the number of result column values.

If the data type of an *assignment-target* is a row type, then there must be exactly one *assignment-target* specified (SQLSTATE 428HR), the number of columns must match the number of fields in the row type, and the data types of the columns of the fetched row must be assignable to the corresponding fields of the row type (SQLSTATE 42821).

If the data type of an *assignment-target* is an array element, then there must be exactly one *assignment-target* specified.

global-variable-name
Identifies the global variable that is the assignment target.

host-variable-name
Identifies the host variable that is the assignment target. For LOB output values, the target can be a regular host variable (if it is large enough), a LOB locator variable, or a LOB file reference variable.

SQL-parameter-name
Identifies the parameter that is the assignment target.

SQL-variable-name
Identifies the SQL variable that is the assignment target. SQL variables must be declared before they are used.

transition-variable-name
Identifies the column to be updated in the transition row. A *transition-variable-name* must identify a column in the subject table of a trigger, optionally qualified by a correlation name that identifies the new value.

array-variable-name
Identifies an SQL variable, SQL parameter, or global variable of an array type.

[array-index]
An expression that specifies which element in the array will be the target of the assignment. For an ordinary array, the *array-index* expression must be assignable to INTEGER (SQLSTATE 428H1) and cannot be the null value. Its value must be between 1 and the maximum cardinality defined for the array (SQLSTATE 2202E). For an associative array, the *array-index* expression must be assignable to the index data type of the associative array (SQLSTATE 428H1) and cannot be the null value.

field-reference
Identifies the field within a row type value that is the assignment target. The *field-reference* must be specified as a qualified *field-name* where the qualifier identifies the row value in which the field is defined.

FOR READ ONLY or FOR UPDATE
Indicates the intended use for the selected row. The default is FOR READ ONLY.

FOR READ ONLY
Specifies that the selected row will not be locked for update.

FOR UPDATE
Specifies that the selected row from the underlying table will be locked to facilitate updating the row later on in the transaction, similar to the locking done for the select statement of a cursor which includes the FOR UPDATE clause.

FOR UPDATE must not be specified if the result table of the SELECT INTO statement is read-only (SQLSTATE 42829).

If *column-name* values are listed, these columns must be updatable (SQLSTATE 42829).

Note that listing columns has only documentary effect and does not limit subsequent searched update statements from modifying other columns.

Rules

- Global variables cannot be assigned inside triggers that are not defined using a compound SQL (compiled) statement, functions that are not defined using a compound SQL (compiled) statement, methods, or compound SQL (inlined) statements (SQLSTATE 428GX).

Notes

- **Syntax alternatives:** For consistency with SQL queries:
  - FOR FETCH ONLY can be specified in place of FOR READ ONLY

Examples

- *Example 1:* This C example puts the maximum salary in the EMP table into the host variable MAXSALARY.

```
EXEC SQL SELECT MAX(SALARY)
  INTO :MAXSALARY
  FROM EMP;
```

- *Example 2:* This C example puts the row for employee 528671 (from the EMP table) into host variables.

```
EXEC SQL SELECT * INTO :h1, :h2, :h3, :h4
  FROM EMP
  WHERE EMPNO = '528671';
```

- *Example 3:* This SQLJ example puts the row for employee 528671 (from the EMP table) into host variables. That row will later be updated using a searched update, and should be locked when the query executes.

```
#sql { SELECT * INTO :FIRSTNAME, :LASTNAME, :EMPNO, :SALARY
  FROM EMP
  WHERE EMPNO = '528671'
  FOR UPDATE };
```

- *Example 4:* This C example puts the maximum salary in the EMP table into the global variable GV_MAXSALARY.

```
EXEC SQL SELECT MAX(SALARY)
  INTO GV_MAXSALARY
  FROM EMP;
```

SET COMPILATION ENVIRONMENT

The SET COMPILATION ENVIRONMENT statement changes the current compilation environment in the connection to match the values contained in the compilation environment provided by an event monitor.

The compilation environment contains information like schema, isolation level, query degree or function path under which a SQL statement has been compiled (prepared). It allows you to run and explain SQL statements within a given environment. You can run the **db2caem** command or the **db2support** command with the **-compenv** parameter to specify a file containing a BLOB data type with the compilation environment. Follow these steps to create the file:

1. Set the environment (for example, to **SET CURRENT SCHEMA**, **CHANGE ISOLATION**, **SET CURRENT DEGREE**, or **SET PATH**.
2. Run a SQL statement
3. Export the compilation environment into the `lob` file in directory `lobs`:

```
EXPORT TO compenv.ixf OF IXF LOBS TO lobs
SELECT COMP_ENV_DESC
FROM TABLE (MON_GET_PKG_CACHE_STMT('d', null, null, -1)) AS tf
WHERE STMT_TEXT = '' ;
```

4. Use compilation environment BLOB file for other SQL statements for **db2caem** and **db2support** and specify:

```
-compenv lobs/compenv.ixf.001.lob
```

For more information, see COMPILATION_ENV table function

This statement changes the values of one or more special registers; these changes, in turn, will affect the compilation of any subsequent dynamic SQL statement.

This statement is not under transaction control.

Invocation

The statement can be embedded in an application program. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

Description

host-variable
A variable of type BLOB containing a compilation environment provided by an event monitor. It cannot be set to null. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 42815). If the format of the compilation environment is incorrect, an error is returned, and the connection settings remain unmodified (SQLSTATE 51040).

Notes

- To reset the compilation environment to the original default values, terminate and then restart the connection. You can achieve the same effect by issuing this statement within an SQL routine, so that any special register changes are not reflected in the connection upon return from that routine.
- Use the COMPILATION_ENV table function to look at the individual elements that are contained within the compilation environment.

Example

Set the current session's compilation environment to the values contained in a compilation environment that was previously captured by a deadlock event monitor. A deadlock event monitor that is created specifying the WITH DETAILS HISTORY option will capture the compilation environment for dynamic SQL statements. This captured environment is what is accepted as input to the statement.

```
SET COMPILATION ENVIRONMENT = :hv1
```

SET CONNECTION

The SET CONNECTION statement changes the state of a connection from dormant to current, making the specified location the current server.

This statement is not under transaction control.

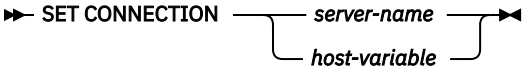
Invocation

Although an interactive SQL facility might provide an interface that gives the appearance of interactive execution, this statement can only be embedded within an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax



Description

server-name* or *host-variable

Identifies the application server by the specified *server-name* or a *host-variable* which contains the *server-name*.

If a *host-variable* is specified, it must be a character string variable with a length attribute that is not greater than 8, and it must not include an indicator variable. The *server-name* that is contained within the *host-variable* must be left-aligned and must not be delimited by quotation marks.

Note that the *server-name* is a database alias identifying the application server. It must be listed in the application requester's local directory.

The *server-name* or the *host-variable* must identify an existing connection of the application process. If they do not identify an existing connection, an error (SQLSTATE 08003) is raised.

If SET CONNECTION is to the current connection, the states of all connections of the application process are unchanged.

Successful Connection

If the SET CONNECTION statement executes successfully:

- No connection is made. The CURRENT SERVER special register is updated with the specified *server-name*.
- The previously current connection, if any, is placed into the dormant state (assuming a different *server-name* is specified).
- The CURRENT SERVER special register and the SQLCA are updated in the same way as documented under "CONNECT (Type 1)".

Unsuccessful Connection

If the SET CONNECTION statement fails:

- No matter what the reason for failure, the connection state of the application process and the states of its connections are unchanged.
- As with an unsuccessful Type 1 CONNECT, the SQLERRP field of the SQLCA is set to the name of the module that detected the error.

Notes

- The use of type 1 CONNECT statements does not preclude the use of SET CONNECTION, but the statement will always fail (SQLSTATE 08003), unless the SET CONNECTION statement specifies the current connection, because dormant connections cannot exist.
- The SQLRULES(DB2) connection option (see "Options that Govern Distributed Unit of Work Semantics") does not preclude the use of SET CONNECTION, but the statement is unnecessary, because type 2 CONNECT statements can be used instead.

- When a connection is used, made dormant, and then restored to the current state in the same unit of work, that connection reflects its last use by the application process with regard to the status of locks, cursors, and prepared statements.

Example

Execute SQL statements at IBMSTHDB, execute SQL statements at IBMTOKDB, and then execute more SQL statements at IBMSTHDB.

```
EXEC SQL CONNECT TO IBMSTHDB;
/* Execute statements referencing objects at IBMSTHDB */
```

```
EXEC SQL CONNECT TO IBMTOKDB;
/* Execute statements referencing objects at IBMTOKDB */
```

```
EXEC SQL SET CONNECTION IBMSTHDB;
/* Execute statements referencing objects at IBMSTHDB */
```

Note that the first CONNECT statement creates the IBMSTHDB connection, the second CONNECT statement places it in the dormant state, and the SET CONNECTION statement returns it to the current state.

SET CURRENT DECFLOAT ROUNDING MODE

The SET CURRENT DECFLOAT ROUNDING MODE statement verifies that the specified rounding mode is the value that is currently set for the CURRENT DECFLOAT ROUNDING MODE special register.

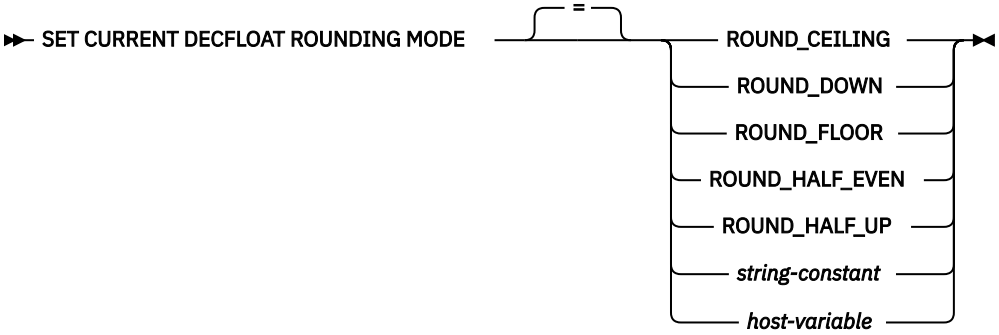
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

ROUND_CEILING
Round the value toward positive infinity. If all of the discarded digits are zero or if the sign is negative, the result is unchanged (except for the removal of the discarded digits). Otherwise, the result coefficient is incremented by 1.

ROUND_DOWN
Round the value toward 0 (truncation). The discarded digits are ignored.

ROUND_FLOOR
Round the value toward negative infinity. If all of the discarded digits are zero or if the sign is positive, the result is unchanged (except for the removal of the discarded digits). Otherwise, the sign is negative and the result coefficient is incremented by 1.

ROUND_HALF_EVEN
Round the value to the nearest value. If the values are equidistant, round the value so that the final digit is even. If the discarded digits represent more than half of the value of a number in the next left position, the result coefficient is incremented by 1. If they represent less than half, the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise, the result coefficient is unaltered if its rightmost digit is even, or incremented by 1 if its rightmost digit is odd (to make an even digit).

ROUND_HALF_UP
Round the value to the nearest value. If the values are equidistant, round the value up. If the discarded digits represent half or more than half of the value of a number in the next left position, the result coefficient is incremented by 1. Otherwise, the discarded digits are ignored.

string-constant
A character string constant with a maximum length of 15 bytes, after trailing blanks have been removed. The value must be a left-aligned string that specifies one of the five rounding mode keywords (case insensitive).

host-variable
A variable of type CHAR or VARCHAR. The value of the host variable must be a left-aligned string that specifies one of the five rounding mode keywords (case insensitive). The actual length of the contents of *host-variable* must not be greater than 15 bytes, after trailing blanks have been removed. The value must be padded on the right with blanks when using a fixed-length character host variable. The host variable cannot be set to the null value.

Rules

- The specified rounding mode value must be the same as the value of the CURRENT DECFLOAT ROUNDING MODE special register (SQLSTATE 42815).

Notes

- This statement does not change the value of the CURRENT DECFLOAT ROUNDING MODE special register on a Db2 server. However, when the statement is processed by a Db2 for z/OS server or a Db2 for IBM i server, it can be used to change the value of the CURRENT DECFLOAT ROUNDING MODE special register on that server.

Example

The following statement verifies whether the specified rounding mode value for the client matches the rounding mode value that is currently set on the server.

```
SET CURRENT DECFLOAT ROUNDING MODE = ROUND_CEILING
```

SET CURRENT DEFAULT TRANSFORM GROUP

The SET CURRENT DEFAULT TRANSFORM GROUP statement changes the value of the CURRENT DEFAULT TRANSFORM GROUP special register.

This statement is not under transaction control.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

Description

group-name
Specifies a one-part name that identifies a transform group defined for all structured types. This name can be referenced in subsequent statements (or until the special register value is changed again using another SET CURRENT DEFAULT TRANSFORM GROUP statement).

The name must be an SQL identifier (either ordinary or delimited). No validation that the *group-name* is defined for any structured type is made when the special register is set. Only when a structured type is specifically referenced is the definition of the named transform group checked for validity.

Rules

- If the value specified does not conform to the rules for a *group-name*, an error is raised (SQLSTATE 42815)
- The TO SQL and FROM SQL functions defined in the *group-name* transform group are used for exchanging user-defined structured type data with a host program.

Usage notes

- The initial value of the CURRENT DEFAULT TRANSFORM GROUP special register is the empty string.

Example

Set the default transform group to MYSTRUCT1. The TO SQL and FROM SQL functions defined in the MYSTRUCT1 transform group will be used for exchanging user-defined structured type variables with the current host program.

```
SET CURRENT DEFAULT TRANSFORM GROUP = MYSTRUCT1
```

SET CURRENT DEGREE

The SET CURRENT DEGREE statement assigns a value to the CURRENT DEGREE special register.

This statement is not under transaction control.

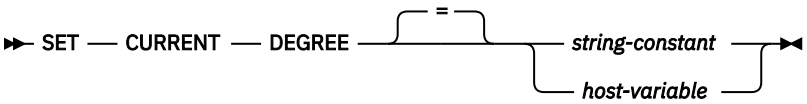
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

The value of CURRENT DEGREE is replaced by the value of the string constant or host variable. The value must be a character string that is not longer than 5 bytes. The value must be the character string representation of an integer between 1 and 32 767 inclusive or 'ANY'.

If the value of CURRENT DEGREE represented as an integer is 1 when an SQL statement is dynamically prepared, the execution of that statement will not use intrapartition parallelism.

If the value of CURRENT DEGREE is a number when an SQL statement is dynamically prepared, the execution of that statement can involve intrapartition parallelism with the specified degree.

If the value of CURRENT DEGREE is 'ANY' when an SQL statement is dynamically prepared, the execution of that statement can involve intrapartition parallelism using a degree determined by the database manager.

host-variable
The *host-variable* must be of data type CHAR or VARCHAR and the length must not exceed 5. If a longer field is provided, an error will be returned (SQLSTATE 42815). If the actual value provided is larger than the replacement value specified, the input must be padded on the right with blanks. Leading blanks are not allowed (SQLSTATE 42815). All input values are treated as being case-insensitive. If a *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 42815).

string-constant
The *string-constant* length must not exceed 5.

Notes

- The degree of intrapartition parallelism for static SQL statements can be controlled using the DEGREE option of the PREP or BIND command.
- The actual runtime degree of intrapartition parallelism will be the lower of:
  - Maximum query degree (**max_querydegree**) configuration parameter
  - Application runtime degree
  - SQL statement compilation degree
  - MAXIMUM DEGREE service class option
  - MAXIMUM DEGREE workload option
- The **intra_parallel** database manager configuration parameter must be on to use intrapartition parallelism. If it is set to off, the value of this register will be ignored and the statement will not use intrapartition parallelism for the purpose of optimization (SQLSTATE 01623).
- The value in the CURRENT DEGREE special register and the **intra_parallel** setting can be overridden in a workload by setting the MAXIMUM DEGREE workload attribute.
- If the DB2_WORKLOAD system environment variables is set to ANALYTICS and MAXIMUM DEGREE for the workload is set to DEFAULT, the value of the **intra_parallel** setting for the workload is overridden to ON.
- Some SQL statements cannot use intrapartition parallelism.

Examples

- *Example 1:* The following statement sets the CURRENT DEGREE to inhibit intrapartition parallelism.

```
SET CURRENT DEGREE = '1'
```

- *Example 2:* The following statement sets the CURRENT DEGREE to allow intrapartition parallelism.

```
SET CURRENT DEGREE = 'ANY'
```

SET CURRENT EXPLAIN MODE

The SET CURRENT EXPLAIN MODE statement changes the value of the CURRENT EXPLAIN MODE special register. It is not under transaction control.

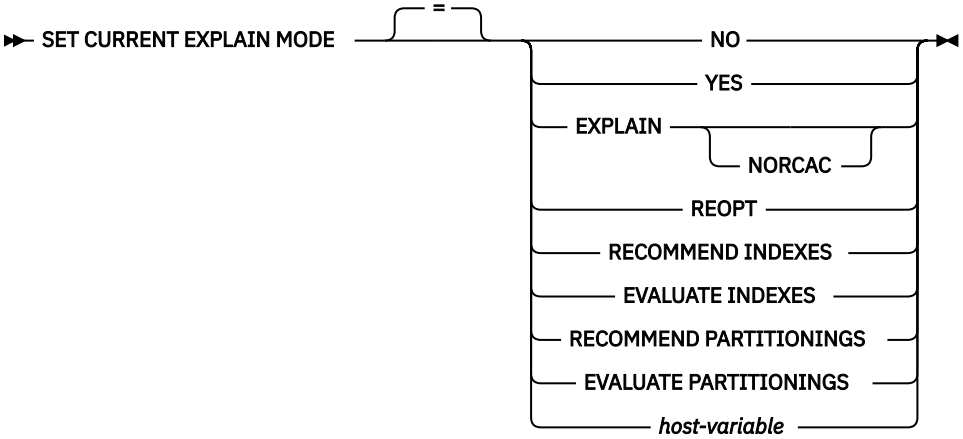
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

NO
Disables the Explain facility. No Explain information is captured. NO is the initial value of the special register.

YES
Enables the Explain facility and causes Explain information to be inserted into the Explain tables for eligible dynamic SQL statements. All dynamic SQL statements are compiled and executed normally.

EXPLAIN
Enables the Explain facility and causes Explain information to be captured for any eligible dynamic SQL statement that is prepared. However, dynamic statements are not executed.

EXPLAIN NORCAC
Enables the Explain facility and causes Explain information to be captured for any eligible dynamic SQL statement that is prepared as if row or column access control (RCAC) was not activated. Dynamic statements are not executed. When this explain mode is set, explain facility would explain the plan as if RCAC was not present.

REOPT
Enables the Explain facility and causes Explain information to be captured for a static or dynamic SQL statement during statement reoptimization at execution time; that is, when actual values for the host variables, special registers, global variables, or parameter markers are available.

RECOMMEND INDEXES
Enables the SQL compiler to recommend indexes. All queries that are executed in this explain mode will populate the ADVISE_INDEX table with recommended indexes. In addition, Explain information will be captured in the Explain tables to reveal how the recommended indexes are used, but the statements are neither compiled nor executed.

EVALUATE INDEXES
Enables the SQL compiler to evaluate virtual recommended indexes for dynamic queries. Queries executed in this explain mode will be compiled and optimized using fabricated statistics based on the virtual indexes. The statements are not executed. The indexes to be evaluated are read from the ADVISE_INDEX table if the USE_INDEX column contains "Y". Existing non-unique indexes can also be ignored by setting the USE_INDEX column to "I" and the EXISTS column to "Y". If a combination of USE_INDEX="I" and EXISTS="N" is given then index evaluation for the query will continue normally but the index in question will not be ignored.

RECOMMEND PARTITIONINGS
Specifies that the compiler is to recommend the best database partition for each table that is accessed by a specific query. The best database partitions are then written to an ADVISE_PARTITION table. The query is not executed.

EVALUATE PARTITIONINGS
Specifies that the compiler is to obtain the estimated performance of a query using the virtual database partitions specified in the ADVISE_PARTITION table.

host-variable
The *host-variable* must be of data type CHAR or VARCHAR and the length must not exceed 254. If a longer field is provided, an error will be returned (SQLSTATE 42815). The value specified must be NO, YES, EXPLAIN, RECOMMEND INDEXES, or EVALUATE INDEXES. If the actual value provided is larger than the replacement value specified, the input must be padded on the right with blanks. Leading blanks are not allowed (SQLSTATE 42815). All input values are treated as being case-insensitive. If a *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 42815).

Notes

- The Explain facility uses the following IDs as the schema when qualifying Explain tables that it is populating:
  - The session authorization ID for dynamic SQL
  - The statement authorization ID for static SQL

  The schema can be associated with a set of Explain tables, or aliases that point to a set of Explain tables under a different schema. If no Explain tables are found under the schema, the Explain facility checks for Explain tables under the SYSTOOLS schema and attempts to use those tables.
- Explain information for static SQL statements can be captured by using the **EXPLAIN** option of the **PREP** or **BIND** command. If the ALL value of the **EXPLAIN** option is specified, and the CURRENT EXPLAIN MODE register value is NO, explain information will be captured for dynamic SQL statements at run time. If the value of the CURRENT EXPLAIN MODE register is not NO, the value of the **EXPLAIN** bind option is ignored.
- RECOMMEND INDEXES and EVALUATE INDEXES are special modes which can only be set with the SET CURRENT EXPLAIN MODE statement. These modes cannot be set using **PREP** or **BIND** options, and they do not work with the SET CURRENT EXPLAIN SNAPSHOT statement.
- If the Explain facility is activated, the current authorization ID must have INSERT privilege for the Explain tables, or an error (SQLSTATE 42501) is raised.

- When SQL statements are explained from a routine, the routine must be defined with an SQL data access indicator of MODIFIES SQL DATA (SQLSTATE 42985).
- If the special register is set to REOPT, and the SQL statement does not qualify for reoptimization at execution time (that is, if the statement does not have input variables, or if the **REOPT** bind option is set to NONE), then no Explain information will be captured. If the **REOPT** bind option is set to ONCE, Explain information will be captured only once when the statement is initially reoptimized. After the statement is cached, no further Explain information will be acquired for this statement on subsequent executions.
- If the Explain facility is enabled, the **REOPT** bind option is set to ONCE, and you attempt to execute an SQL statement that is already cached, the statement will be compiled and reoptimized with the current values of the input variables, and the Explain tables will be populated accordingly. The newly generated access plan for this statement will not be cached or executed. Other applications that are concurrently executing this cached statement will continue to execute, and new requests to execute this statement will pick up the already cached access plan.
- A value of REOPT for the CURRENT EXPLAIN MODE and CURRENT EXPLAIN SNAPSHOT special registers will override the value of the **EXPLAIN** and **EXPLSNAP** bind options at bind time if a static or dynamic SQL statement has input variables, and the **REOPT** bind option is set to ONCE or ALWAYS.
- Row and column level access control (RCAC) defined on the EXPLAIN tables is enforced for user access to these tables just like any other regular tables. However, row and column level access control on the EXPLAIN tables is not enforced when the database itself is populating those EXPLAIN tables. This is considered internal housekeeping and is not subject to RCAC, much like internal SQL.

Example

The following statement sets the CURRENT EXPLAIN MODE special register, so that Explain information will be captured for any subsequent eligible dynamic SQL statements and the statement will not be executed.

```
SET CURRENT EXPLAIN MODE = EXPLAIN
```

SET CURRENT EXPLAIN SNAPSHOT

The SET CURRENT EXPLAIN SNAPSHOT statement changes the value of the CURRENT EXPLAIN SNAPSHOT special register.

This statement is not under transaction control.

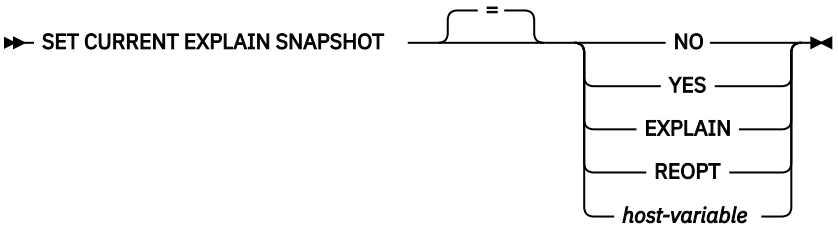
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

NO
Disables the Explain snapshot facility. No snapshot is taken. NO is the initial value of the special register.

YES
Enables the Explain snapshot facility, creating a snapshot of the internal representation for each eligible dynamic SQL statement. This information is inserted in the SNAPSHOT column of the EXPLAIN_STATEMENT table.

EXPLAIN
Enables the Explain snapshot facility, creating a snapshot of the internal representation for each eligible dynamic SQL statement that is prepared. However, dynamic statements are not executed.

REOPT
Enables the Explain facility and causes Explain information to be captured for a static or dynamic SQL statement during statement reoptimization at execution time; that is, when actual values for the host variables, special registers, global variables, or parameter markers are available.

host-variable
The *host-variable* must be of data type CHAR or VARCHAR and the length of its contents must not exceed 8. If a longer field is provided, an error will be returned (SQLSTATE 42815). The value contained in this register must be either NO, YES, or EXPLAIN. If the actual value provided is larger than the replacement value specified, the input must be padded on the right with blanks. Leading blanks are not allowed (SQLSTATE 42815). All input values are treated as being case-insensitive. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 42815).

Notes

- The Explain facility uses the following IDs as the schema when qualifying Explain tables that it is populating:
  - The session authorization ID for dynamic SQL
  - The statement authorization ID for static SQL

  The schema can be associated with a set of Explain tables, or aliases that point to a set of Explain tables under a different schema. If no Explain tables are found under the schema, the Explain facility checks for Explain tables under the SYSTOOLS schema and attempts to use those tables.
- Explain snapshots for static SQL statements can be captured by using the EXPLSNAP option of the PREP or BIND command. If the ALL value of the EXPLSNAP option is specified, and the CURRENT EXPLAIN SNAPSHOT register value is NO, Explain snapshots will be captured for dynamic SQL statements at run time. If the value of the CURRENT EXPLAIN SNAPSHOT register is not NO, the EXPLSNAP option is ignored.
- If the Explain snapshot facility is activated, the current authorization ID must have INSERT privilege for the Explain tables or an error (SQLSTATE 42501) is raised.
- When SQL statements are explained from a routine, the routine must be defined with an SQL data access indicator of MODIFIES SQL DATA (SQLSTATE 42985).
- If the special register is set to REOPT, and the SQL statement does not qualify for reoptimization at execution time (that is, if the statement does not have input variables, or if the REOPT bind option is set to NONE), then no Explain information will be captured. If the REOPT bind option is set to ONCE, Explain snapshot information will be captured only once when the statement is initially reoptimized. After the statement is cached, no further Explain information will be acquired for this statement on subsequent executions.
- If the Explain facility is enabled, the REOPT bind option is set to ONCE, and you attempt to execute a reoptimizable SQL statement that is already cached, the statement will be compiled and reoptimized with the current values of the input variables, and the Explain snapshot will be captured accordingly. The newly generated access plan for this statement will not be cached or executed. Other applications

that are concurrently executing this cached statement will continue to execute, and new requests to execute this statement will pick up the already cached access plan.

- The value REOPT for the CURRENT EXPLAIN MODE and CURRENT EXPLAIN SNAPSHOT special registers will override the value of the EXPLAIN and EXPLSNAP bind options at bind time if a static or dynamic SQL statement has input variables, and the REOPT bind option is set to ONCE or ALWAYS.

Examples

- *Example 1:* The following statement sets the CURRENT EXPLAIN SNAPSHOT special register, so that an Explain snapshot will be taken for any subsequent eligible dynamic SQL statements and the statement will be executed.

```
SET CURRENT EXPLAIN SNAPSHOT = YES
```

- *Example 2:* The following example retrieves the current value of the CURRENT EXPLAIN SNAPSHOT special register into the host variable called SNAP.

```
EXEC SQL VALUES (CURRENT EXPLAIN SNAPSHOT) INTO :SNAP;
```

SET CURRENT FEDERATED ASYNCHRONY

The SET CURRENT FEDERATED ASYNCHRONY statement assigns a value to the CURRENT FEDERATED ASYNCHRONY special register.

This statement is not under transaction control.

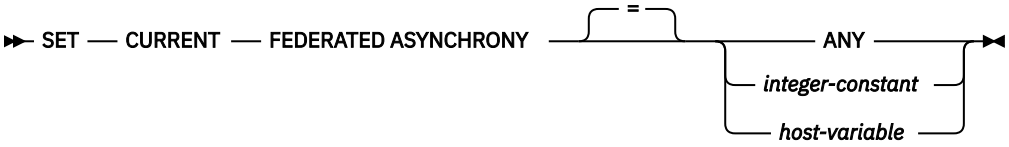
Invocation

The statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

ANY
Specifies a CURRENT FEDERATED ASYNCHRONY value of -1, which means that the execution of statements can involve asynchrony using a degree that is determined by the database manager.

integer-constant
Specifies an integer value between 0 and 32 767, inclusive. The execution of statements can involve asynchrony using the specified degree. If the value is 0 when an SQL statement is dynamically prepared, the execution of that statement will not use asynchrony.

host-variable
A variable of type INTEGER. The value must be between 0 and 32 767, inclusive, or -1 (representing ANY). If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 42815).

Notes

- The degree of asynchrony for static SQL statements can be controlled using the FEDERATED_ASYNCHRONY option of the PREP or BIND command.
- The initial value of the CURRENT FEDERATED ASYNCHRONY special register is determined by the **federated_async** database manager configuration parameter if the dynamic statement is issued through the command line processor (CLP). The initial value is determined by the FEDERATED_ASYNCHRONY bind option if the dynamic statement is part of an application that is being bound.

Examples

- *Example 1:* The following statement disables asynchrony by setting the value of the CURRENT FEDERATED ASYNCHRONY special register to 0.

```
SET CURRENT FEDERATED ASYNCHRONY = 0
```

- *Example 2:* The following statement sets the degree of asynchrony to 5.

```
SET CURRENT FEDERATED ASYNCHRONY 5
```

- *Example 3:* The following statement sets the value of the CURRENT FEDERATED ASYNCHRONY special register to -1, which specifies that the database manager is to determine the degree of asynchrony.

```
SET CURRENT FEDERATED ASYNCHRONY ANY
```

SET CURRENT IMPLICIT XMLPARSE OPTION

The SET CURRENT IMPLICIT XMLPARSE OPTION statement changes the value of the CURRENT IMPLICIT XMLPARSE OPTION special register.

This statement is not under transaction control.

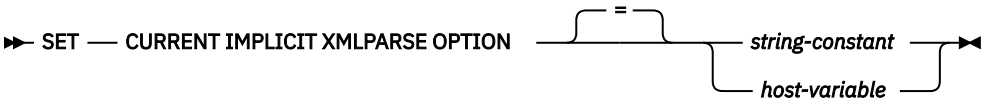
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

string-constant
A character string constant. The value must be a left-aligned string that is either 'PRESERVE WHITESPACE' or 'STRIP WHITESPACE' (case insensitive) with no additional blank characters between the keywords.

host-variable
A variable of type CHAR or VARCHAR. The value of the host variable must be a left-aligned string that is either 'PRESERVE WHITESPACE' or 'STRIP WHITESPACE' (case insensitive) with no additional blank

characters between the keywords. The value must be padded on the right with blanks when using a fixed-length character *host-variable*. The host variable cannot be set to null.

Notes

- The initial value of the CURRENT IMPLICIT XMLPARSE OPTION special register is 'STRIP WHITESPACE'.
- Both dynamic and static SQL statements are affected by this special register.

Example

Set the value of the CURRENT IMPLICIT XMLPARSE OPTION special register to 'PRESERVE WHITESPACE'.

```
SET CURRENT IMPLICIT XMLPARSE OPTION = 'PRESERVE WHITESPACE'
```

SET CURRENT ISOLATION

The SET CURRENT ISOLATION statement assigns a value to the CURRENT ISOLATION special register.

This statement is not under transaction control.

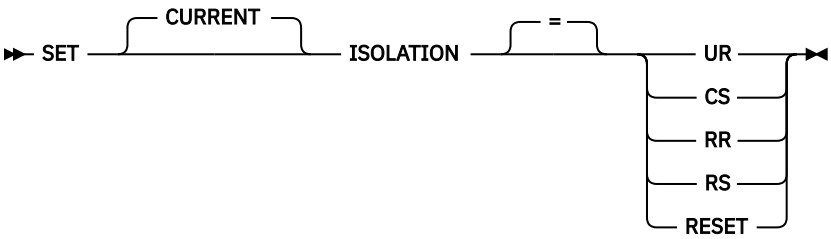
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

The value of the CURRENT ISOLATION special register is replaced by the specified value or set to blanks if RESET is specified.

Notes

- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products.
  - TO can be specified in place of the equal sign (=)
  - DIRTY READ can be specified in place of UR
  - READ UNCOMMITTED can be specified in place of UR
  - READ COMMITTED is recognized and upgraded to CS
  - CURSOR STABILITY can be specified in place of CS
  - REPEATABLE READ can be specified in place of RR
  - SERIALIZABLE can be specified in place of RR

SET CURRENT LOCALE LC_MESSAGES

The SET CURRENT LOCALE LC_MESSAGES statement changes the value of the CURRENT LOCALE LC_MESSAGES special register.

This statement is not under transaction control.

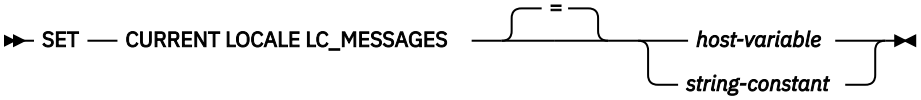
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

The CURRENT LOCALE LC_MESSAGES special register identifies the locale that is used by EVMON_UPGRADE_TABLES, as well as monitoring routines in the **monreport** module. EVMON_UPGRADE_TABLES and the monitoring routines use the value of CURRENT LOCALE LC_MESSAGES to determine in which language the result set text output should be returned. User-defined routines that are coded to return messages could also use the value of CURRENT LOCALE LC_MESSAGES to determine what language to use for message text.

host-variable
A variable of type CHAR or VARCHAR. It cannot be set to null.

string-constant
A character string constant.

Notes

- ***Initial value:*** The initial value of the CURRENT LOCALE LC_MESSAGES special register is `'en_US'`.
- ***Language availability:*** If the language for the locale is not available to the database manager, messages will be returned in English.
- ***Code page compatibility:*** The language for the locale specified must be supported by the code page of the output parameter or returns type of a routine that uses the special register to determine what language to return message text information in. If the database is not a Unicode database (and the routine was not created with PARAMETER CCSID UNICODE) and some characters in the language for the locale cannot be represented in the database code page, substitution characters will be returned as a result of code page conversion.
- ***Potential future use:*** In a future release, the value of the CURRENT LOCALE LC_MESSAGES special register might be used for other areas of the database environment that involve messages.
- ***Valid locales and naming:*** For information about valid locales and their naming, see "Locale names for SQL and XQuery" in the *Globalization Guide*.

Examples

- *Example 1:* The following statement sets the CURRENT LOCALE LC_MESSAGES special register to the English (Canada) locale using the latest version of Common Locale Data Repository (CLDR) available in the database manager.

```
SET CURRENT LOCALE LC_MESSAGES = 'en_CA'
```

- *Example 2:* The following statement sets the CURRENT LOCALE LC_MESSAGES special register to the French (France) locale using Common Locale Data Repository (CLDR) version 1.5. The CONNECTION routine in the **monreport** module is then invoked to have its output returned in French.

```
SET CURRENT LOCALE LC_MESSAGES = 'CLDR 1.5:fr_FR'
CALL MONREPORT.CONNECTION
```

- *Example 3:* Assume that the user-defined procedure XYZ.STORELOCATOR takes a zip code or postal code input. It returns a result set of stores of the XYZ company within a 30 minute drive from the zip code or postal code given as input. If the zip code or postal code is not in the correct format, an error message is returned that indicates what the problem is with the format. The procedure is coded to be able to return the error message in the language determined from the value of the CURRENT LOCALE LC_MESSAGES special register. The following statement sets the CURRENT LOCALE LC_MESSAGES special register to the Spanish (Mexico) locale. The store locator user-defined procedure is then invoked and any error messages will be returned in Spanish.

```
SET CURRENT LOCALE LC_MESSAGES = 'es_MX'
CALL XYZ.STORELOCATOR(:ZIP, :STATUSMSG)
```

SET CURRENT LOCALE LC_TIME

The SET CURRENT LOCALE LC_TIME statement changes the value of the CURRENT LOCALE LC_TIME special register. It is not under transaction control.

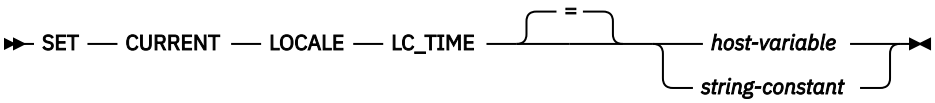
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

The CURRENT LOCALE LC_TIME special register is used by the DAYNAME, MONTHNAME, NEXT_DAY, ROUND, ROUND_TIMESTAMP, TIMESTAMP_FORMAT, TRUNCATE, TRUNC_TIMESTAMP and VARCHAR_FORMAT functions when the *locale-name* argument is not explicitly specified.

host-variable
A variable of type CHAR or VARCHAR. It cannot be set to null.

string-constant
A character string constant.

Notes

- ***Initial Value:*** The initial value of the CURRENT LOCALE LC_TIME special register is 'en_US'.
- ***Potential future use:*** In a future release the value of the CURRENT LOCALE LC_TIME special register might be used by other scalar functions and for other areas of the database environment that involve datetime values.
- ***Valid locales and naming:*** For information on valid locales and their naming,, see "Locale names for SQL and XQuery" in the *Globalization Guide* .

Examples

- *Example 1:* The following statement sets the CURRENT LOCALE LC_TIME special register to the English (Canada) locale using the latest version of Common Locale Data Repository (CLDR) available in the database manager.

```
SET CURRENT LOCALE LC_TIME = 'en_CA'
```

- *Example 2:* The following statement sets the CURRENT LOCALE LC_TIME special register to the French (France) locale using Common Locale Data Repository (CLDR) version 1.8.1. The MONTHNAME scalar function is then invoked with a single argument of '2008-11-10-00.00.00.000000'.

```
SET CURRENT LOCALE LC_TIME = 'CLDR181_fr_FR'
VALUES MONTHNAME( '2008-11-10-00.00.00.000000' )
```

  returns:

```
'novembre'
```

SET CURRENT LOCK TIMEOUT

The SET CURRENT LOCK TIMEOUT statement changes the value of the CURRENT LOCK TIMEOUT special register.

This statement is not under transaction control.

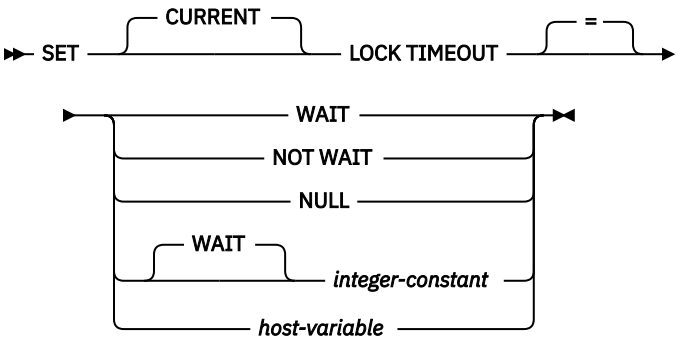
Invocation

The statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

The specified value must be an integer between -1 and 32767, inclusive (SQLSTATE 428B7), or the null value.

WAIT
Specifies a CURRENT LOCK TIMEOUT value of -1, which means that the database manager is to wait until a lock is released, or a deadlock is detected (SQLSTATE 40001 or 57033).

NOT WAIT
Specifies a CURRENT LOCK TIMEOUT value of 0, which means that the database manager is not to wait for locks that cannot be obtained, and an error (SQLSTATE 40001 or 57033) will be returned.

NULL
Specifies that the CURRENT LOCK TIMEOUT value is to be unset, and that the value of the **locktimeout** database configuration parameter is to be used when waiting for a lock. The value that is returned for the special register will change as the value of **locktimeout** changes.

WAIT *integer-constant*
Specifies an integer value between -1 and 32767. A value of -1 is equivalent to specifying the WAIT keyword without an integer value. A value of 0 is equivalent to specifying the NOT WAIT clause. If the value is between 1 and 32767, the database manager will wait that number of seconds (if a lock cannot be obtained) before an error (SQLSTATE 40001 or 57033) is returned.

host-variable
A variable of type INTEGER. The value must be between -1 and 32767. If *host-variable* has an associated indicator variable, and the value of that indicator variable specifies a null value, the CURRENT LOCK TIMEOUT value is unset. This is equivalent to specifying the NULL keyword.

Notes

- An updated value of the special register takes effect immediately upon successful execution of this statement. Because the special register value that is to be used during statement execution is fixed at the beginning of statement execution, an updated value of the CURRENT LOCK TIMEOUT special register will only be returned by statements that start execution after the SET LOCK TIMEOUT statement has completed successfully.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with Informix database products. These alternatives are non-standard and should not be used.
  - MODE can be specified in place of TIMEOUT.
  - TO can be specified in place of the equals (=) operator.

Examples

- *Example 1:* Set the lock timeout value to wait for 30 seconds before returning an error.

```
SET CURRENT LOCK TIMEOUT 30
```

- *Example 2:* Unset the lock timeout value, so that the **locktimeout** database configuration parameter value will be used instead.

```
SET CURRENT LOCK TIMEOUT NULL
```

SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

The SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION statement changes the value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register.

This statement is not under transaction control.

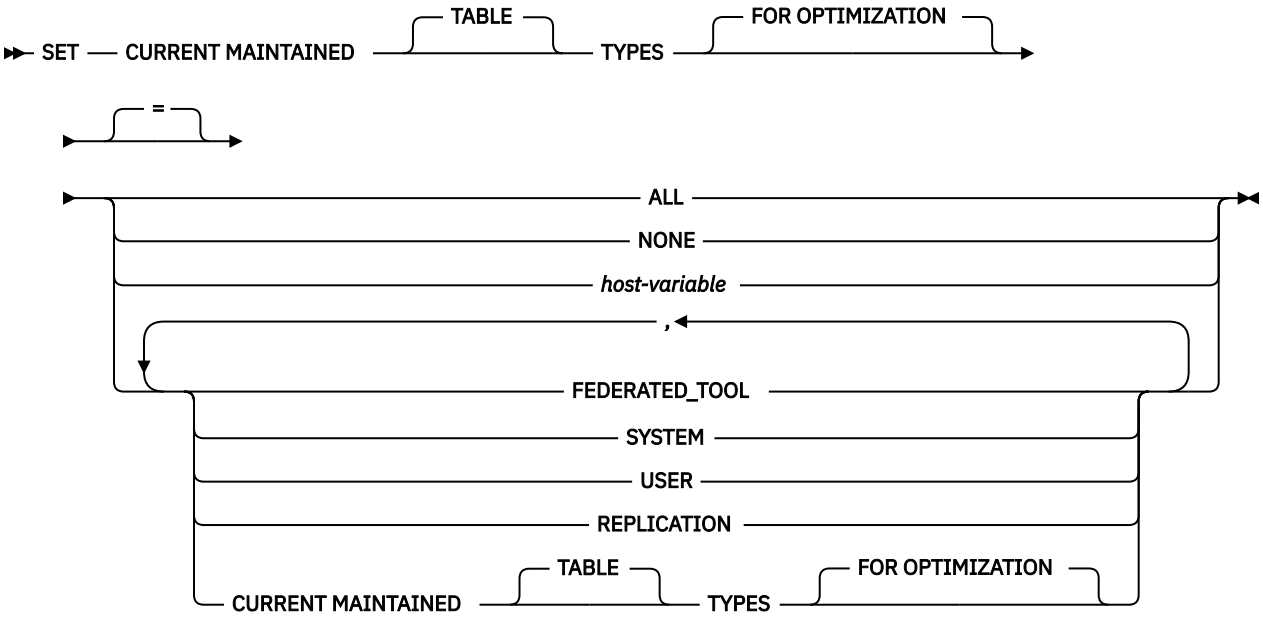
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

ALL
Specifies that all possible types of maintained tables controlled by this special register, now and in the future, are to be considered when optimizing the processing of dynamic SQL queries.

NONE
Specifies that none of the object types that are controlled by this special register are to be considered when optimizing the processing of dynamic SQL queries.

FEDERATED_TOOL
Specifies that refresh-deferred materialized query tables that are maintained by a federated tool can be considered to optimize the processing of dynamic SQL queries, provided the value of the CURRENT QUERY OPTIMIZATION special register is 2 or greater than 5.

SYSTEM
Specifies that system-maintained refresh-deferred materialized query tables can be considered to optimize the processing of dynamic SQL queries. (Immediate materialized query tables are always available.)

USER
Specifies that user-maintained refresh-deferred materialized query tables can be considered to optimize the processing of dynamic SQL queries.

REPLICATION
Specifies that shadow tables can be considered to help optimize the processing of dynamic SQL queries.

CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION
The value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register before this statement executes.

host-variable
A variable of type CHAR or VARCHAR. The length of the contents of the host variable must not exceed 254 bytes (SQLSTATE 42815). It cannot be set to null. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 42815).

The characters of *host-variable* must be left-aligned. The contents of *host-variable* must be a string that is a comma-separated list of keywords matching what can be specified as keywords for the special register. These keywords must be specified in the exact case intended, because there is no conversion to uppercase characters. The value must be padded on the right with blanks if its length is less than that of the host variable.

Notes

- The initial value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register is determined by the **dft_mttb_types** database configuration parameter, which has a default value of SYSTEM.
- You must set the CURRENT REFRESH AGE special register to a value other than 0 for the specified table types to be considered during optimization of the processing of dynamic SQL queries.
- If the value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register includes anything other than REPLICATION or NONE, the value of the CURRENT REFRESH AGE special register must be either 0 or 99999999999999 (ANY).

Examples

- *Example 1:* Set the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register.

```
SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION = SYSTEM, USER
```

- *Example 2:* Retrieve the current value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register into a host variable called CURMAINTYPES.

```
EXEC SQL VALUES (CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION)
  INTO :CURMAINTYPES
```

- *Example 3:* Set the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register to have no value.

```
SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION = NONE
```

SET CURRENT MDC ROLLOUT MODE

The SET CURRENT MDC ROLLOUT MODE statement assigns a value to the CURRENT MDC ROLLOUT MODE special register. The value specifies the type of rollout cleanup that is to be performed on qualifying DELETE statements for multidimensional clustering (MDC) tables.

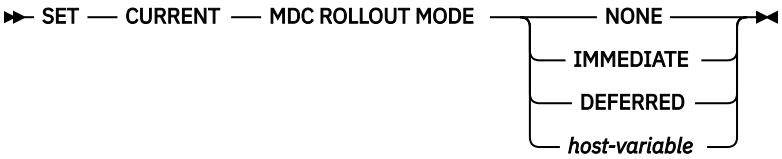
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

NONE
Specifies that MDC rollout optimization during delete operations is not to be used. The DELETE statement is processed in the same way as a DELETE statement that does not qualify for rollout.

IMMEDIATE
Specifies that MDC rollout optimization is to be used if the DELETE statement qualifies. If the table has RID indexes, the indexes are updated immediately during delete processing. The deleted blocks are available for reuse after the transaction commits.

DEFERRED
Specifies that MDC rollout optimization is to be used if the DELETE statement qualifies. If the table has RID indexes, index updates are deferred until after the transactions commits. With this option, delete processing is faster and uses less log space, but the deleted blocks are not available for reuse until after the index updates are complete.

host-variable
A variable of type VARCHAR. The length of *host-variable* must be less than or equal to 17 bytes (SQLSTATE 42815). The value of the host variable must be a left-aligned string that is one of 'NONE', 'IMMEDIATE', or 'DEFERRED' (case insensitive). If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 42815).

Notes

- Subsequent DELETE statements that are eligible for rollout processing respect the setting of the CURRENT MDC ROLLOUT MODE special register. Currently executing sections are not affected by a change to this special register.
- The effects of executing the SET CURRENT MDC ROLLOUT MODE statement are not rolled back if the unit of work in which the statement is executed is rolled back.
- After you run a SET CURRENT MDC ROLLOUT MODE statement, the behavior of MDC table rollout changes. The behavior of MDC table rollouts returns to the configuration set by the registry variable **DB2_MDC_ROLLOUT** when one of the following situations occur:
  - The connection/session to the database is terminated.
  - A CONNECT RESET is entered.
  - A SET CURRENT MDC ROLLOUT MODE NONE is entered.
- The DEFERRED mode is not supported on a data partitioned MDC table with partitioned RID indexes. Only the NONE and IMMEDIATE modes are supported. The cleanup rollout type will be IMMEDIATE if the **DB2_MDC_ROLLOUT** registry variable is set to DEFER, or if the CURRENT MDC ROLLOUT MODE special register is set to DEFERRED to override the **DB2_MDC_ROLLOUT** setting.

  If only nonpartitioned RID indexes exist on the MDC table, deferred index cleanup rollout is supported.

Example

Specify deferred cleanup behavior for the next DELETE statement that qualifies for rollout processing.

```
SET CURRENT MDC ROLLOUT MODE IMMEDIATE
```

SET CURRENT OPTIMIZATION PROFILE

The SET CURRENT OPTIMIZATION PROFILE statement assigns a value to the CURRENT OPTIMIZATION PROFILE special register. The value specifies the optimization profile the optimizer should use when preparing dynamic DML statements.

This statement is not under transaction control.

When the statement is evaluated, the name of the optimization profile is checked for validity, but the profile is not processed until the optimizer encounters a dynamic DML statement.

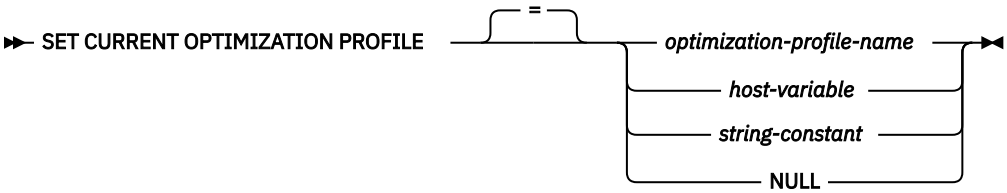
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

optimization-profile-name

The two-part name of the optimization profile. The name can be specified with a literal, host variable, or special register. The name specified is the name entered into the CURRENT OPTIMIZATION PROFILE special register.

If the specified optimization-profile-name is unqualified, the value of the CURRENT DEFAULT SCHEMA register is used as the implicit qualifier. The default value of the special register is null.

host-variable

A variable of type CHAR or VARCHAR that includes the name of the optimization profile. A host variable that includes a null indicator indicates that the value of the OPTPROFILE bind option is to be used if that value is specified for the current package. A host variable of zero length, or of white space only, indicates that no optimization profile is to be used.

The host variable must meet the following characteristics:

- The content of the string is a single or two-part identifier (separated by a period), with no leading blanks.
- The identifier or identifiers can be delimited or non-delimited.
- The content of the string is not folded to upper case.
- Lower case and special characters cannot be used in non-delimited strings.
- If the first character is a double quotation mark, a closing double quotation mark must either precede a period or be the last non-blank character in the string.
- If the first character following a period is a double quotation mark, then a double quotation mark must be the last non-blank character in the string.
- If the identifier is delimited, then to include double quotation marks in the identifier, specify the character twice.

- Any period that is not inside a delimited identifier is treated as a separator, and only one period separator can exist in the string.

string-constant
Specifies a constant as a character string that is the name of the optimization profile. The content of a string constant must meet the same characteristics as a host variable.

NULL
Sets the CURRENT OPTIMIZATION PROFILE register to null.

Table 153 on page 1835 provides examples of string literals and identifiers that might be used to assign the register as per the optimization profile naming rules. The value in the SCHEMA and NAME column represent an optimization profile name as it might appear in the OPT_PROFILE table. The valid string literals column shows string literals that match the optimization profile named by the corresponding SCHEMA and NAME column values. The valid identifiers column shows identifiers that would identify that same optimization profile.

Table 153. Examples of string literals and identifiers

SCHEMA	NAME	Valid string literals	Valid identifiers
SIMMEN	BIG_PROF	'BIG_PROF' 'SIMMEN.BIG_PROF' '"BIG_PROF"' '"SIMMEN"."BIG_PROF"'	BIG_PROF SIMMEN.BIG_PROF "BIG_PROF" "SIMMEN"."BIG_PROF"
SIMMEN	low_profile	'"low_profile"' 'SIMMEN."low_profile"' '"SIMMEN"."low_profile"'	"low_profile" SIMMEN."low_profile" "SIMMEN"."low_profile"
eliaz	DBA3	'DBA3' '"DBA3"' '"eliaz".DBA3' '"eliaz"."DBA3"'	DBA3 "eliaz".DBA3 "eliaz"."DBA3"
SNOW	PROFILE1.0	'"PROFILE1.0"' 'SNOW."PROFILE1.0"' '"SNOW"."PROFILE1.0"'	"PROFILE1.0" SNOW."PROFILE1.0" "SNOW"."PROFILE1.0"

Notes

- If the value of the register specifies the name of an existing optimization profile, the specified optimization profile is used when preparing subsequent dynamic DML statements.
- If the value of the register is null, the optimization profile specified by the OPTPROFILE bind option, if any, is used when preparing subsequent dynamic DML statements.
- If the value of the register is null, and the OPTPROFILE bind option is not set, no optimization profile is used when preparing subsequent dynamic DML statements.
- If the value of the register is the empty string, then no optimization profile is used when preparing subsequent dynamic DML statements, regardless of whether the OPTPROFILE bind option is set.
- Subsequent changes to CURRENT DEFAULT SCHEMA do not have any effect on the optimization profile. The CURRENT OPTIMIZATION PROFILE register value is set with the two part name that is in effect at the time SET CURRENT OPTIMIZATION PROFILE statement is evaluated. Only another SET CURRENT OPTIMIZATION PROFILE statement can change the optimization profile that is used.

Examples

- *Example 1:* The optimization profile RICK.FOO is used for statements 1, 2, and 3. TOM.FOO is used for statement 4.

```
SET CURRENT SCHEMA = 'RICK'
SET CURRENT OPTIMIZATION PROFILE = 'FOO'
   statement 1
   statement 2
SET CURRENT SCHEMA = 'TOM'
   statement 3
SET CURRENT OPTIMIZATION PROFILE = 'FOO'
   statement 4
```

- *Example 2:* An application with the following statements was bound with the options OPTPROFILE("Foo") and QUALIFIER("John"). The optimization profile KAAREL.BAR is used for statement 1 and optimization profile "John"."Foo" is used for statement 2.

```
SET CURRENT SCHEMA = 'KAAREL'
SET CURRENT OPTIMIZATION PROFILE = 'BAR'
   statement 1
SET CURRENT SCHEMA = "Tom"
SET CURRENT OPTIMIZATION PROFILE NULL
   statement 2
```

- *Example 3:* The empty string is a special value that indicates that no optimization profile is to be used. Optimization profile "Hamid"."Foo" is used for statement 1 and no optimization profile is used for statement 2.

```
SET CURRENT OPTIMIZATION PROFILE = '"Hamid"."Foo"'
   statement 1
SET CURRENT OPTIMIZATION PROFILE = ''
   statement 2
```

SET CURRENT PACKAGE PATH

The SET CURRENT PACKAGE PATH statement assigns a value to the CURRENT PACKAGE PATH special register.

This statement is not under transaction control.

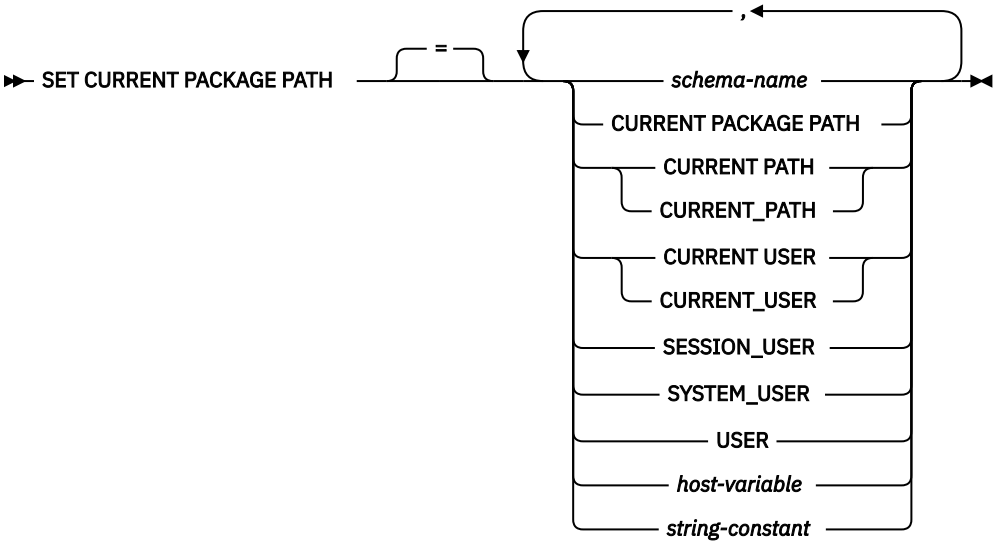
Invocation

This statement can only be embedded in an application program. It is an executable statement that cannot be dynamically prepared.

Authorization

None required.

Syntax



Description

schema-name
Identifies a schema. The name must not be a delimited identifier that is empty or that contains only blanks (SQLSTATE 42815).

CURRENT PACKAGE PATH
The value of the CURRENT PACKAGE PATH special register before this statement executes.

CURRENT PATH
The value of the CURRENT PATH special register.

CURRENT USER
The value of the CURRENT USER special register.

SESSION_USER
The value of the SESSION_USER special register.

SYSTEM_USER
The value of the SYSTEM_USER special register.

USER
The value of the USER special register.

host-variable
Contains one or more schema names, separated by commas. The host variable must:

- Be a character-string variable (CHAR or VARCHAR). The actual length of the contents of the host variable must not exceed the length of the CURRENT PACKAGE PATH special register.
- Not be the null value. If an indicator variable is provided, its value must not indicate a null value.
- Contain an empty or blank string, or one or more schema names separated by commas.
- Be padded on the right with blanks if the actual length of the host variable is greater than the content.
- Not contain CURRENT PACKAGE PATH, CURRENT PATH, CURRENT_PATH, CURRENT USER, CURRENT_USER, SESSION_USER, SYSTEM_USER, PATH, or USER.
- Not contain a delimited identifier that is empty or that contains only blanks.

string-constant
Specifies a character string constant that contains zero, one, or more schema names that are separated by commas. The string constant must:

- Have a length that does not exceed the maximum length of the CURRENT PACKAGE PATH special register.
- Not contain CURRENT PACKAGE PATH, CURRENT PATH, CURRENT_PATH, CURRENT USER, CURRENT_USER, SESSION_USER, SYSTEM_USER, PATH, or USER.
- Not contain a delimited identifier that is empty or that contains only blanks.

Rules

- If the same schema appears more than once in the list, the first occurrence of the schema is used (SQLSTATE 01625).
- The number of schemas that can be specified is limited by the total length of the CURRENT PACKAGE PATH special register. The special register string is built by taking each specified schema name and removing trailing blanks, delimiting the name with double quotation marks, and separating the schema names with commas. The length of the resulting list cannot exceed the maximum length of the special register (SQLSTATE 0E000).
- A schema name that does not conform to the rules for an ordinary identifier (for example, a schema name that contains lowercase characters or characters that cannot be specified in an ordinary identifier), must be specified as a delimited schema name, and must not be specified within a host variable or string constant.
- To indicate that the current value of a special register (specified as a single keyword) is to be used in the package path, specify the name of the special register as a keyword. If the name of the special register is specified as a delimited identifier instead (for example, "USER"), it is interpreted as a schema name of that value ('USER').
- The following rules are used to determine whether a value specified in a SET CURRENT PACKAGE PATH statement is a variable or a schema name:
  - If *name* is the same as a parameter or SQL variable in the SQL procedure, *name* is interpreted as a parameter or SQL variable, and the value in *name* is assigned to the package path.
  - If *name* is not the same as a parameter or SQL variable in the SQL procedure, *name* is interpreted as a schema name, and the value in *name* is assigned to the package path.

Notes

- ***Transaction considerations:*** The SET CURRENT PACKAGE PATH statement is not a commitable operation. ROLLBACK has no effect on the CURRENT PACKAGE PATH special register.
- ***Existence checking of schemas:*** No validation that the specified schemas exist is made at the time that the CURRENT PACKAGE PATH special register is set. For example, a schema that is misspelled is not detected, which could affect the way subsequent SQL operates. At package execution time, authorization to a matching package is checked, and if this authorization check fails, an error is returned (SQLSTATE 42501).
- ***Contents of host variable or string constant:*** The contents of a host variable or a string constant are interpreted as a list of schema names. If multiple schema names are specified, they must be separated by commas. Each schema name in the list must conform to the rules for forming an ordinary identifier, or be specified as a delimited identifier. The contents of the host variable or string constant are not folded to uppercase.
- ***Restrictions specific to embedded SQL for COBOL applications:*** A maximum of ten literal (non-host variable) values can appear on the right side of a SET CURRENT PACKAGE PATH statement. Such values can have a maximum length of 130 (non-delimited) or 128 (delimited).

Examples

- *Example 1:* Set the CURRENT PACKAGE PATH special register to the following list of schemas: MYPKGS, 'ABC E', SYSIBM

```
SET CURRENT PACKAGE PATH = MYPKGS, 'ABC E', SYSIBM
```

The following statement sets a host variable to the value of the resulting list:

```
SET :hvpklist = CURRENT PACKAGE PATH
```

The value of the host variable is: "MYPKGS", "ABC E", "SYSIBM".

- *Example 2:* Set the CURRENT PACKAGE PATH special register to the following list of schemas: "SCH4","SCH5", where :hvar1 contains 'SCH4,SCH5'.

```
SET CURRENT PACKAGE PATH :hvar1
```

The value of the CURRENT PACKAGE PATH special register after this statement executes is: "SCH4","SCH5".

- *Example 3:* Set the CURRENT PACKAGE PATH special register to the following list of schemas: "SCH1","SCH#2","SCH3","SCH4","SCH5", where :hvar1 contains 'SCH4,SCH5'.

```
SET CURRENT PACKAGE PATH = SCH1,'SCH#2',"SCH3",:hvar1
```

The value of the CURRENT PACKAGE PATH special register after this statement executes is: "SCH1","SCH#2","SCH3","SCH4","SCH5".

- *Example 4:* Clear the CURRENT PACKAGE PATH special register.

```
SET CURRENT PACKAGE PATH = ''
```

- *Example 5:* Temporarily append the "SCH_PROD" schema (contained in the :prodschema host variable) and the "SCH_PROD2" schema (contained in the :prod2schema host variable) to the end of the CURRENT PACKAGE PATH special register for execution of the SUMMARIZE procedure. Then, switch the CURRENT PACKAGE PATH special register back to its previous value.

```
SET :oldCPP = CURRENT PACKAGE PATH

SET CURRENT PACKAGE PATH = CURRENT PACKAGE PATH,:prodschema,:prod2schema

CALL SUMMARIZE(:V1,:V2)

SET CURRENT PACKAGE PATH = :oldCPP
```

- *Example 6:* Set the CURRENT PACKAGE PATH special register to a list of delimited schema names: "MY.SCHEMA" (imbedded period), "OLD SCHEMA" (imbedded blank). Use a single host variable containing both delimited identifiers:

```
hv = '"MY.SCHEMA", "OLD SCHEMA"'

SET CURRENT PACKAGE PATH = :hv
```

or use a single string constant containing both delimited identifiers:

```
SET CURRENT PACKAGE PATH = '"MY.SCHEMA", "OLD SCHEMA"'
```

or use a list of delimited schemas:

```
SET CURRENT PACKAGE PATH = 'MY.SCHEMA', 'OLD SCHEMA'
```

SET CURRENT PACKAGESET

The SET CURRENT PACKAGESET statement sets the schema name (collection identifier) that will be used to select the package to use for subsequent SQL statements.

This statement is not under transaction control.

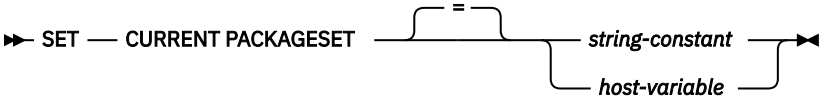
Invocation

This statement can be embedded only in an application program. It is an executable statement that cannot be dynamically prepared. This statement is not supported in REXX.

Authorization

None required.

Syntax



Description

string-constant
A character string constant. If the value exceeds 128 bytes, only the first 128 bytes are used.

host-variable
A variable of type CHAR or VARCHAR. It cannot be set to null. If the value exceeds 128 bytes, only the first 128 bytes are used.

Notes

- This statement allows an application to specify the schema name used when selecting a package for an executable SQL statement. The statement is processed at the client and does not flow to the application server.
- The COLLECTION bind option can be used to create a package with a specified schema name.
- Unlike Db2 for z/OS, the SET CURRENT PACKAGESET statement is implemented without support for a special register called CURRENT PACKAGESET.

Examples

- *Example 1*: Assume an application called TRYIT is precompiled by user ID PRODUSA, making "PRODUSA" the default schema name in the bind file. The application is then bound twice with different bind options. The following command line processor commands were used:

```
CONNECT TO SAMPLE USER PRODUSA
BIND TRYIT.BND DATETIME USA
CONNECT TO SAMPLE USER PRODEUR
BIND TRYIT.BND DATETIME EUR COLLECTION 'PRODEUR'
```

  This creates two packages called TRYIT. The first bind command created the package in the schema named "PRODUSA". The second bind command created the package in the schema named "PRODEUR" based on the COLLECTION option.

- *Example 2*: Assume the application TRYIT contains the following statements:

```
EXEC SQL CONNECT TO SAMPLE;
.
.
EXEC SQL SELECT HIREDATE INTO :HD FROM EMPLOYEE WHERE EMPNO='000010'; 1
.
.
EXEC SQL SET CURRENT PACKAGESET 'PRODEUR';                            2
.
.
EXEC SQL SELECT HIREDATE INTO :HD FROM EMPLOYEE WHERE EMPNO='000010'; 3
```

1
This statement will run using the PRODUSA.TRYIT package because it is the default package for the application. The date is therefore returned in USA format.

2
This statement sets the schema name to "PRODEUR" for package selection.

3

This statement will run using the PRODEUR.TRYIT package as a result of the SET CURRENT PACKAGESET statement. The date is therefore returned in EUR format.

SET CURRENT QUERY OPTIMIZATION

The SET CURRENT QUERY OPTIMIZATION statement assigns a value to the CURRENT QUERY OPTIMIZATION special register. The value specifies the current class of optimization techniques enabled when preparing dynamic SQL statements.

This statement is not under transaction control.

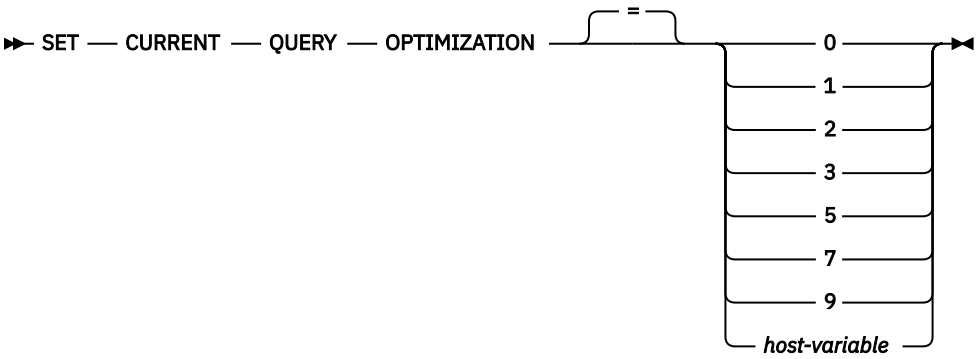
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

optimization-class

optimization-class can be specified either as an integer constant or as the name of a host variable that will contain the appropriate value at run time. An overview of the classes follows.

0

Specifies that a minimal amount of optimization is performed to generate an access plan. This class is most suitable for simple dynamic SQL access to well-indexed tables.

1

Specifies that optimization roughly comparable to Db2 Version 1 is performed to generate an access plan.

2

Specifies a level of optimization higher than that of Db2 Version 1, but at significantly less optimization cost than levels 3 and higher, especially for very complex queries.

3

Specifies that a moderate amount of optimization is performed to generate an access plan.

5

Specifies a significant amount of optimization is performed to generate an access plan. For complex dynamic SQL queries, heuristic rules are used to limit the amount of time spent selecting an access plan. Where possible, queries will use materialized query tables instead of the underlying base tables.

7
Specifies a significant amount of optimization is performed to generate an access plan. Similar to 5 but without the heuristic rules.

9
Specifies a maximal amount of optimization is performed to generate an access plan. This can greatly expand the number of possible access plans that are evaluated. This class should be used to determine if a better access plan can be generated for very complex and very long-running queries using large tables. Explain and performance measurements can be used to verify that a better plan has been generated.

host-variable
The data type is INTEGER. The value must be in the range 0 to 9 (SQLSTATE 42815) but should be 0, 1, 2, 3, 5, 7, or 9. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 42815).

Notes

- When the CURRENT QUERY OPTIMIZATION register is set to a particular value, a set of query rewrite rules are enabled, and certain optimization variables take on particular values. This class of optimization techniques is then used during preparation of dynamic SQL statements.
- In general, changing the optimization class impacts the execution time of the application, the compilation time, and resources required. Most statements will be adequately optimized using the default query optimization class. Lower query optimization classes, especially classes 1 and 2, may be appropriate for dynamic SQL statements for which the resources consumed by the dynamic *PREPARE* are a significant portion of those required to execute the query. Higher optimization classes should be chosen only after considering the additional resources that may be consumed and verifying that a better access plan has been generated.
- Query optimization classes must be in the range 0 to 9. Classes outside this range will return an error (SQLSTATE 42815). Unsupported classes within this range will return a warning (SQLSTATE 01608) and will be replaced with the next lowest query optimization class. For example, a query optimization class of 6 will be replaced by 5.
- Dynamically prepared statements use the class of optimization that was set by the most recently executed SET CURRENT QUERY OPTIMIZATION statement. In cases where a SET CURRENT QUERY OPTIMIZATION statement has not yet been executed, the query optimization class is determined by the value of the **dft_queryopt** database configuration parameter.
- Statically bound statements do not use the CURRENT QUERY OPTIMIZATION special register; therefore this statement has no effect on them. The QUERYOPT option is used during preprocessing or binding to specify the required class of optimization for statically bound statements. If QUERYOPT is not specified then, the default value specified by the **dft_queryopt** database configuration parameter is used.
- The results of executing the SET CURRENT QUERY OPTIMIZATION statement are not rolled back if the unit of work in which it is executed is rolled back.

Examples

- *Example 1:* This example shows how the highest degree of optimization can be selected.

```
SET CURRENT QUERY OPTIMIZATION 9
```

- *Example 2:* The following example shows how the CURRENT QUERY OPTIMIZATION special register can be used within a query.

  Using the SYSCAT.PACKAGES catalog view, find all plans that were bound with the same setting as the current value of the CURRENT QUERY OPTIMIZATION special register.

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT PKGNAME, PKGSCHEMA FROM SYSCAT.PACKAGES
  WHERE QUERYOPT = CURRENT QUERY OPTIMIZATION
```

SET CURRENT REFRESH AGE

The SET CURRENT REFRESH AGE statement changes the value of the CURRENT REFRESH AGE special register.

This statement is not under transaction control.

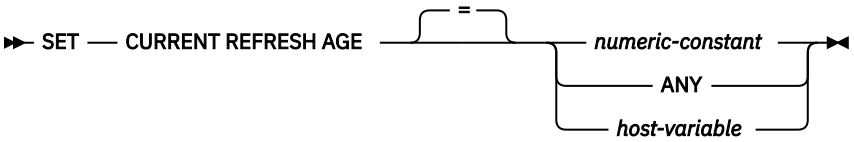
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

numeric-constant
A DECIMAL(20,6) value that represents a time stamp duration.The value must be 0 - 99999999999999 or a valid time stamp within that range. The valid format for the range is *yyyymmddhhmmss.nnnnnn*, where:

- *yyyy* is the number of years and can have a value of 0 - 9999.
- *mm* is the number of months and can have a value of 0 - 11.
- *dd* is the number of days and can have a value of 0 - 30.
- *hh* is the number of hours and can have a value of 0 - 23.
- *mm* is the number of minutes and can have a value of 0 - 59.
- *ss* is the number of seconds and can have a value of 0 - 59.
- *nnnnnn* is the number of fractional seconds. The fractional seconds portion of the value is ignored and therefore can be any value.

You do not have to include the leading zeros for the entire value or the trailing fractional seconds. However, individual elements that have another element to the left must include the zeros. For example, to represent 1 hour, 7 minutes, and 5 seconds, use 10705.

If materialized query tables that are affected by the CURRENT REFRESH AGE special register are maintained by USER, SYSTEM, or FEDERATED_TOOL, the only valid numeric values are 0 and 99999999999999. For further details, see the "Notes" section.

ANY
A short form 99999999999999. See the description of the *numeric-constant* parameter.

host-variable
A variable of type DECIMAL(20,6) or another type that is assignable to DECIMAL(20,6). You cannot set the *host-variable* parameter to null. If the host variable has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 42815). The *host-variable* parameter must conform to the same constraints as the *numeric-constant* parameter.

Notes

- The initial value of the CURRENT REFRESH AGE special register is determined by the **dft_refresh_age** database configuration parameter, which has a default value of 0.
- Be careful when setting the CURRENT REFRESH AGE special register to a value other than 0. A table type that you specify for the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register might not represent the values of the underlying base table. If such a table is used to optimize the processing of a query, the query result might not accurately represent the data in the underlying table. This might be reasonable if you know that the underlying data has not changed, or if you are willing to accept a degree of error in the results, based on your knowledge of the cached data.
- The CURRENT REFRESH AGE special register value of 99999999999999 cannot be used in time stamp arithmetic operations, because the result would be outside the valid range for dates (SQLSTATE 22008).
- The CURRENT REFRESH AGE special register affects the materialized query tables that you define as REFRESH DEFERRED MAINTAINED BY USER, REFRESH DEFERRED MAINTAINED BY REPLICATION, and REFRESH DEFERRED MAINTAINED BY SYSTEM. The CURRENT REFRESH AGE special register affects these materialized query tables as follows:
  - If the value of the CURRENT REFRESH AGE special register is 0, the materialized query tables are not used to optimize the processing of a query.
  - If the value of the CURRENT REFRESH AGE special register is 99999999999999, the materialized query tables can be used to help optimize the processing of a query if both the following criteria are met:
    - The value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register includes these tables.
    - The value of the CURRENT QUERY OPTIMIZATION special register is 2 or a value that is greater than or equal to 5.
  - If the value of the CURRENT REFRESH AGE special register is a value other than 0 or 99999999999999, only shadow tables are affected by this special register setting can be used to optimize the processing of a query, but only if both the following criteria are met:
    - The value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register is REPLICATION.
    - The value of the CURRENT QUERY OPTIMIZATION special register is 2 or a value that is greater than or equal to 5.
- The CURRENT REFRESH AGE special register has no effect on whether REFRESH IMMEDIATE MAINTAINED BY SYSTEM materialized query tables or REFRESH DEFERRED MAINTAINED BY FEDERATED_TOOL materialized query tables are used to optimize the processing of a query.

  REFRESH IMMEDIATE MAINTAINED BY SYSTEM materialized query tables can always be used to optimize the processing of a query if the value of the CURRENT QUERY OPTIMIZATION special register is 2 or a value that is greater than or equal to 5.

  REFRESH DEFERRED MAINTAINED BY FEDERATED_TOOL materialized query tables are used for optimization if both the following criteria are met:
  - The value of the CURRENT QUERY OPTIMIZATION special register is 2 or a value that is greater than or equal to 5.
  - The value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register is ALL or includes FEDERATED_TOOL.

Examples

- *Example 1:* The following statement sets the CURRENT REFRESH AGE special register:

```
SET CURRENT REFRESH AGE ANY
```

- *Example 2:* The following command retrieves the value of the CURRENT REFRESH AGE special register into a host variable called CURMAXAGE.

```
EXEC SQL VALUES (CURRENT REFRESH AGE) INTO  :CURMAXAGE;
```

SET CURRENT SQL_CCFLAGS

The SET CURRENT SQL_CCFLAGS statement changes the value of the CURRENT SQL_CCFLAGS special register.

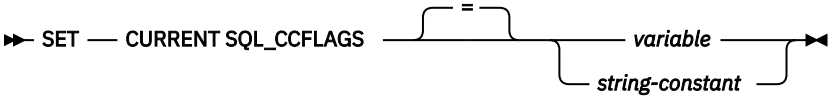
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

variable
Specifies a variable that contains one or more name and value pairs that are separated by commas.

The variable must have the following characteristics (SQLSTATE 42815):

- The data type must be CHAR or VARCHAR. The actual length of the contents of the variable must not exceed the maximum length of the special register.
- It must be a string of blanks, an empty string, or include one or more name and value pairs where the name is separated from the value by the colon character. The name must be a valid ordinary identifier. The value associated with a name must be a BOOLEAN constant, an INTEGER constant, or the keyword NULL.
- It must be padded on the right with blanks if using a fixed-length character variable.
- It can include extra blanks at the beginning or ending of the string, around the comma character, or around the colon character. The blanks are ignored.
- It must not be the null value.

string-constant
Specifies a character string constant that contains one or more name and value pairs that are separated by commas.

The string constant must have the following characteristics (SQLSTATE 42815):

- It must be a character string constant. The length of the constant must not exceed the maximum length of the special register.
- It must be a string of blanks, an empty string or include one or more name and value pairs where the name is separated from the value by the colon character. The name must be a valid ordinary identifier. The value associated with a name must be a BOOLEAN constant, an INTEGER constant, or the keyword NULL.
- It can include extra blanks at the beginning or ending of the string, around the comma character, or around the colon character. The blanks are ignored.

Notes

- If a duplicate name appears in the content for the CURRENT SQL_FLAGS special register, then only the last (furthest to the right) value is used. The special register value will include only a single occurrence of the duplicated name with the value that is used. Concatenating a duplicated name with a different value to the CURRENT SQL_CCFLAGS value can be used to override some conditional compilation values while retaining other values.
- When the CURRENT SQL_CCFLAGS is retrieved, the returned string includes the unique name and value pairs in uppercase characters with multiple pairs separated by a comma and a blank. The pairs are in the order they were specified, with a duplicate name appearing only where it first occurred, but reflecting the value from where it last occurred.
- The CURRENT SQL_CCFLAGS special register can be set to the default defined for the database by retrieving the VALUE column from SYSIBMADM.DBCFG where NAME='sql_ccflags' into a variable and then assigning that variable to the special register.
- ***Transaction considerations:*** The SET SQL_CCFLAGS statement is not a committable operation. ROLLBACK has no effect on CURRENT SQL_CCFLAGS.

Examples

- *Example 1*: Define a conditional compilation value for the session to indicate that the server is Db2 9.7 and that debug is false.

```
SET CURRENT SQL_CCFLAGS 'db2v97:true, debug:false'
```

- *Example 2*: Extend the existing CURRENT SQL_CCFLAGS to set debug to true and define the tracing level.

```
BEGIN
  DECLARE LIST VARCHAR(1024);
  SET LIST = CASE WHEN (CURRENT SQL_CCFLAGS = ' ')
              THEN 'tracelvl:3,debug:true'
              ELSE CURRENT SQL_CCFLAGS
                   concat ',tracelvl:3,debug:true'
              END;
  SET CURRENT SQL_CCFLAGS = LIST;
END
```

A CASE expression is used in the assignment to handle the possibility that the CURRENT SQL_CCFLAGS special register does not include any conditional compilation values, resulting in a leading comma in the value of the variable LIST.

A query of the CURRENT SQL_CCFLAGS special register after the execution of the statement in Example 1 and the compound statement in this example would return:

```
DB2V97:TRUE, DEBUG:TRUE, TRACELVL:3
```

Even though the conditional compilation value for DEBUG appeared twice in the variable LIST, it appears only once in the special register value where it would have first appeared.

SET CURRENT TEMPORAL BUSINESS_TIME

The SET CURRENT TEMPORAL BUSINESS_TIME statement changes the value of the CURRENT TEMPORAL BUSINESS_TIME special register.

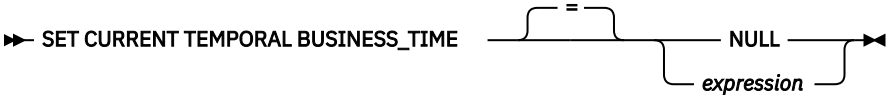
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

NULL
Specifies the null value.

expression
Each expression can contain any of the following supported operands (SQLSTATE 428HY):

- Constant
- Special register
- Variable. For details, refer to "References to variables" in the "Identifiers" topic, in *SQL Reference Volume 1* .
- Built-in scalar function whose arguments are supported operands. User-defined functions and non-deterministic functions are not supported in this context.
- CAST specification where the cast operand is a supported operand
- Expression using arithmetic operator and operands

Notes

- ***Transaction considerations:*** The SET CURRENT TEMPORAL BUSINESS_TIME statement is not a committable operation. ROLLBACK has no effect on CURRENT TEMPORAL BUSINESS_TIME.
- ***Effects on other special registers:*** The setting of the CURRENT TEMPORAL BUSINESS_TIME special register does not have any effect on the values of other special registers, specifically the CURRENT DATE and CURRENT TIMESTAMP special registers.

Examples

- *Example 1:* Set the CURRENT TEMPORAL BUSINESS_TIME special register to the previous month.

```
SET CURRENT TEMPORAL BUSINESS_TIME = CURRENT TIMESTAMP - 1 MONTH
```

- *Example 2:* Set the CURRENT TEMPORAL BUSINESS_TIME special register to the null value.

```
SET CURRENT TEMPORAL BUSINESS_TIME = NULL
```

SET CURRENT TEMPORAL SYSTEM_TIME

The SET CURRENT TEMPORAL SYSTEM_TIME statement changes the value of the CURRENT TEMPORAL SYSTEM_TIME special register.

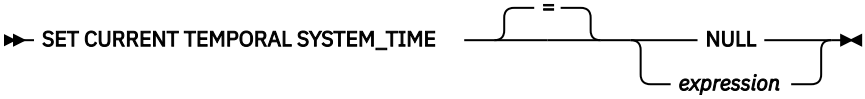
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

NULL
Specifies the null value.

expression
Each expression can contain any of the following supported operands (SQLSTATE 428HY):

- Constant
- Special register
- Variable (host variable, SQL variable, SQL parameter, transition variable, global variable)
- Built-in scalar function whose arguments are supported operands. User-defined functions and non-deterministic functions are not supported in this context.
- CAST specification where the cast operand is a supported operand
- Expression using arithmetic operator and operands

Notes

- ***Transaction considerations:*** The SET CURRENT TEMPORAL SYSTEM_TIME statement is not a committable operation. ROLLBACK has no effect on CURRENT TEMPORAL SYSTEM_TIME.
- ***Effects on other special registers:*** The setting of the CURRENT TEMPORAL SYSTEM_TIME special register does not have any effect on the values of other special registers, specifically the CURRENT DATE and CURRENT TIMESTAMP special registers.

Examples

- *Example 1:* Set the CURRENT TEMPORAL SYSTEM_TIME special register to the previous month.

```
SET CURRENT TEMPORAL SYSTEM_TIME = CURRENT TIMESTAMP - 1 MONTH
```

- *Example 2:* Set the CURRENT TEMPORAL SYSTEM_TIME special register to the null value.

```
SET CURRENT TEMPORAL SYSTEM_TIME = NULL
```

SET ENCRYPTION PASSWORD

The SET ENCRYPTION PASSWORD statement sets the password to be used by the ENCRYPT, DECRYPT_BIN and DECRYPT_CHAR functions. The password is not tied to database authentication, and is used for data encryption and decryption only.

This statement is not under transaction control.

Important: The SET ENCRYPTION PASSWORD statement is deprecated and might not appear in future releases.

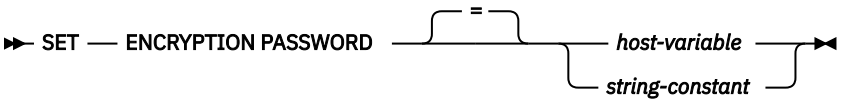
Invocation

The statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

The encryption password can be used by the ENCRYPT, DECRYPT_BIN, and DECRYPT_CHAR built-in functions for password-based encryption. The length of the password must be between 6 and 127 bytes and all characters must be specified in the exact case intended, because there is no automatic conversion to uppercase characters. To maintain the best level of security on your system, it is recommended that you use a host variable or dynamic parameter markers to specify the password, rather than using a literal string in your SET ENCRYPTION PASSWORD statement.

host-variable
A variable of type CHAR or VARCHAR. The length of the *host-variable* must be between 6 and 127 bytes (SQLSTATE 428FC). It cannot be set to null. All characters are specified in the exact case intended, as there is no conversion to uppercase characters.

string-constant
A character string constant. The length must be between 6 and 127 bytes (SQLSTATE 428FC).

Notes

- The initial value of the ENCRYPTION PASSWORD is the empty string.
- The *host-variable* or *string-constant* is transmitted to the database server using normal database mechanisms.

Example

The following example shows how you can set the ENCRYPTION PASSWORD special register in an embedded SQL application using parameter markers. It is strongly recommended that this special register is always set up using parameter markers in your applications.

```
EXEC SQL BEGIN DECLARE SECTION;
      char hostVarSetEncPassStmt[200];
      char hostVarPassword[128];
EXEC SQL END DECLARE SECTION;

/* prepare the statement with a parameter marker */
strcpy(hostVarSetEncPassStmt, "SET ENCRYPTION PASSWORD = ?");
EXEC SQL PREPARE hostVarSetEncPassStmt FROM :hostVarSetEncPassStmt;

/* execute the statement for hostVarPassword = 'Gre89Ea' */
strcpy(hostVarPassword, "Gre89Ea");
EXEC SQL EXECUTE hostVarSetEncPassStmt USING :hostVarPassword;
```

SET EVENT MONITOR STATE

The SET EVENT MONITOR STATE statement activates or deactivates an event monitor. The current state of an event monitor (active or inactive) is determined by using the EVENT_MON_STATE built-in function.

The SET EVENT MONITOR STATE statement is not under transaction control.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include DBADM or SQLADM authority.

Syntax

Description

event-monitor-name
Identifies the event monitor to activate or deactivate. The name must identify an event monitor that exists in the catalog (SQLSTATE 42704).

new-state
new-state can be specified either as an integer constant or as the name of a host variable that will contain the appropriate value at run time. The following values can be specified:

0
Indicates that the specified event monitor should be deactivated.

1
Indicates that the specified event monitor should be activated. The event monitor should not already be active; otherwise a warning (SQLSTATE 01598) is issued.

host-variable
The data type is INTEGER. The value specified must be 0 or 1 (SQLSTATE 42815). If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 42815).

Rules

- Although an unlimited number of event monitors may be defined, a maximum of 128 event monitors can be active simultaneously on each database partition. In a multiple partition database environment, a maximum of 32 GLOBAL event monitors can be active simultaneously on each database.
- In order to activate an event monitor, the transaction in which the event monitor was created must have been committed (SQLSTATE 55033). This rule prevents (in one unit of work) creating an event monitor, activating the monitor, then rolling back the transaction.
- If the number or size of the event monitor files exceeds the values specified for MAXFILES or MAXFILESIZE on the CREATE EVENT MONITOR statement, an error (SQLSTATE 54031) is raised.

- If the target path of the event monitor (that was specified on the CREATE EVENT MONITOR statement) is already in use by another event monitor, an error (SQLSTATE 51026) is raised.

Notes

- Activating a non-WLM event monitor performs a reset of any counters associated with it. The reset of counters does not occur when activating WLM, locking, and unit of work event monitors.
- When a WRITE TO TABLE event monitor is started using SET EVENT MONITOR STATE, it updates the EVMON_ACTIVATES column of the SYSCAT.EVENTMONITORS catalog view. If the unit of work in which the set operation was performed is rolled back for any reason, that catalog update is lost. When the event monitor is restarted, it will reuse the EVMON_ACTIVATES value that was rolled back.
- If the database partition on which the event monitor is to run is not active, event monitor activation occurs when that database partition next activates.
- After an event monitor is activated, it behaves like an autostart event monitor until that event monitor is explicitly deactivated or the instance is recycled. That is, if an event monitor is active when a database partition is deactivated, and that database partition is subsequently reactivated, the event monitor is also explicitly reactivated.
- If an activity event monitor is active when the database deactivates, any backlogged activity records in the queue are discarded. To ensure that you obtain all activity event monitor records and that none are discarded, explicitly deactivate the activity event monitor first before deactivating the database. When an activity event monitor is explicitly deactivated, all backlogged activity records in the queue are processed before the event monitor deactivates.

Examples

- *Example 1:* Activate an event monitor named SMITHPAY.

```
SET EVENT MONITOR SMITHPAY STATE = 1
```

- *Example 2:* Assume that MYSAMPLE is a multiple partition database with two database partitions, 0 and 2. Partition 2 is not yet active.

```
On database partition 0:

   CONNECT TO MYSAMPLE;
   CREATE EVENT MONITOR MYEVMON ON DBPARTITIONNUM 2;
   SET EVENT MONITOR MYEVMON STATE 1;
```

  MYEVMON automatically activates whenever MYSAMPLE activates on database partition 2. This occurs until **SET EVENT MONITOR** MYEVMON **STATE** 0 is issued, or partition 2 is stopped.

SET INTEGRITY

The SET INTEGRITY statement is used to set the integrity pending state on tables, place tables into full access state, and prune the contents of one or more staging tables.

The following operations can be performed with the SET INTEGRITY statement:

- Bring one or more tables out of set integrity pending state (previously known as "check pending state") by performing required integrity processing on those tables.
- Bring one or more tables out of set integrity pending state without performing required integrity processing on those tables.
- Place one or more tables in set integrity pending state.
- Place one or more tables into full access state.
- Prune the contents of one or more staging tables.

When the statement is used to perform integrity processing for a table after it has been loaded or attached, the system can incrementally process the table by checking only the appended portion for constraints violations. If the subject table is a materialized query table or a staging table, and load, attach,

or detach operations are performed on its underlying tables, the system can incrementally refresh the materialized query table or incrementally propagate to the staging table with only the delta portions of its underlying tables. However, there are some situations in which the system will not be able to perform such optimizations and will instead perform full integrity processing to ensure data integrity. Full integrity processing is done by checking the entire table for constraints violations, recomputing a materialized query table's definition, or marking a staging table as inconsistent. The latter implies that a full refresh of its associated materialized query table is required. There is also a situation in which you might want to explicitly request incremental processing by specifying the INCREMENTAL option.

The SET INTEGRITY statement is under transaction control.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges required to execute the SET INTEGRITY statement depend on the purpose, as outlined in the following list.

- Bringing tables out of set integrity pending state and performing the required integrity processing.

  The privileges held by the authorization ID of the statement must include at least one of the following:

  – CONTROL privilege on:

    - The tables on which integrity processing is performed and, if exception tables are provided for one or more of those tables, INSERT privilege on the exception tables or INSERTIN privilege on the schema containing the exception tables
    - All descendent foreign key tables, descendent immediate materialized query tables, and descendent immediate staging tables that will implicitly be placed in set integrity pending state by the statement

  – LOAD authority on the database or LOAD authority on the schema containing the table (with conditions). The following conditions must all be met before LOAD authority can be considered as providing valid privileges:

    - The required integrity processing does not involve the following actions:
      - Refreshing a materialized query table
      - Propagating to a staging table
      - Updating a generated or identity column
    - If exception tables are provided for one or more tables, the required access is granted for the duration of the integrity processing to the tables on which integrity processing is performed, and to the associated exception tables. That is:
      - SELECT and DELETE privilege on each table on which integrity processing is performed, or SELECTIN and DELETEIN privilege on the schema containing the table on which integrity processing is performed and
      - INSERT privilege on the exception tables or INSERTIN privilege on the schema containing the exception tables

  – DATAACCESS authority on the relevant schema

  – DATAACCESS authority

- Bringing tables out of set integrity pending state without performing the required integrity processing.

  The privileges held by the authorization ID of the statement must include at least one of the following:

  - CONTROL privilege on the tables that are being processed; CONTROL privilege on each descendent foreign key table, descendent immediate materialized query table, and descendent immediate staging table that will implicitly be placed in set integrity pending state by the statement
  - LOAD authority on the database or LOAD authority on the relevant schema
  - DATAACCESS authority or DATAACCESS authority on the relevant schema
  - DBADM authority or SCHEMAADM authority on the relevant schema
- Placing tables in set integrity pending state.

  The privileges held by the authorization ID of the statement must include at least one of the following:
  - CONTROL privilege on:
    - The specified tables, and
    - The descendent foreign key tables that will be placed in set integrity pending state by the statement, and
    - The descendent immediate materialized query tables that will be placed in set integrity pending state by the statement, and
    - The descendent immediate staging tables that will be placed in set integrity pending state by the statement
  - LOAD authority on the database or LOAD authority on the relevant schema
  - DATAACCESS authority or DATAACCESS authority on the relevant schema
  - DBADM authority or SCHEMAADM authority on the relevant schema
- Place a table into the full access state.

  The privileges held by the authorization ID of the statement must include at least one of the following:
  - CONTROL privilege on the tables that are placed into the full access state
  - LOAD authority on the database or LOAD authority on the relevant schema
  - DATAACCESS authority or DATAACCESS authority on the relevant schema
  - DBADM authority or SCHEMAADM authority on the relevant schema
- Prune a staging table.

  The privileges held by the authorization ID of the statement must include at least one of the following:
  - CONTROL privilege on the table being pruned
  - DATAACCESS authority or DATAACCESS authority on the relevant schema

Description

FOR *table-name*
Identifies one or more tables for integrity processing. It must be a table described in the catalog and must not be a view, catalog table, or typed table.

OFF
Specifies that the tables are placed in set integrity pending state. Only very limited activity is allowed on a table that is in set integrity pending state.

access-mode-clause
Specifies the readability of the table while it is in set integrity pending state.

NO ACCESS
Specifies that the table is to be put in set integrity pending no access state, which does not allow read or write access to the table.

READ ACCESS
Specifies that the table is to be put in set integrity pending read access state, which allows read access to the non-appended portion of the table. This option is not allowed on a table that is in set integrity pending no access state (SQLSTATE 428FH).

cascade-clause
Specifies whether the set integrity pending state of the table referenced in the SET INTEGRITY statement is to be immediately cascaded to descendent tables.

CASCADE IMMEDIATE
Specifies that the set integrity pending state is to be immediately extended to descendent tables.

to-descendent-types
Specifies the type of descendent tables to which the set integrity pending state is immediately cascaded.

TO ALL TABLES
Specifies that the set integrity pending state is to be immediately cascaded to all descendent tables of the tables in the invocation list. Descendent tables include all descendent foreign key tables, immediate staging tables, and immediate materialized query tables that are descendants of the tables in the invocation list, or descendants of descendent foreign key tables.

Specifying TO ALL TABLES is equivalent to specifying TO FOREIGN KEY TABLES, TO MATERIALIZED QUERY TABLES, and TO STAGING TABLES, all in the same statement.

TO MATERIALIZED QUERY TABLES
If only TO MATERIALIZED QUERY TABLES is specified, the set integrity pending state is to be immediately cascaded only to descendent immediate materialized query tables. Other descendent tables might later be put in set integrity pending state, if necessary, when the table is brought out of set integrity pending state. If both TO FOREIGN KEY TABLES and TO MATERIALIZED QUERY TABLES are specified, the set integrity pending state will be immediately cascaded to all descendent foreign key tables, all descendent immediate materialized query tables of the tables in the invocation list, and to all immediate materialized query tables that are descendants of the descendent foreign key tables.

TO FOREIGN KEY TABLES
Specifies that the set integrity pending state is to be immediately cascaded to descendent foreign key tables. Other descendent tables might later be put in set integrity pending state, if necessary, when the table is brought out of set integrity pending state.

TO STAGING TABLES
Specifies that the set integrity pending state is to be immediately cascaded to descendent staging tables. Other descendent tables might later be put in set integrity pending state, if necessary, when the table is brought out of set integrity pending state. If both TO FOREIGN KEY TABLES and TO STAGING TABLES are specified, the set integrity pending state will be immediately cascaded to all descendent foreign key tables, all descendent immediate staging tables of the tables in the invocation list, and to all immediate staging tables that are descendants of the descendent foreign key tables.

CASCADE DEFERRED
Specifies that only the tables in the invocation list are to be put in set integrity pending state. The states of the descendent tables will remain unchanged. Descendent foreign key tables might later be implicitly put in set integrity pending state when their parent tables are checked for constraints violations. Descendent immediate materialized query tables and descendent immediate staging tables might be implicitly put in set integrity pending state when one of their underlying tables is checked for integrity violations. A query of a table that is in the set integrity pending state might succeed if an eligible materialized query table that is not in the set integrity pending state is accessed by the query instead of the specified table.

If *cascade-clause* is not specified, the set integrity pending state is immediately cascaded to all descendent tables.

IMMEDIATE CHECKED
Specifies that the table is to be taken out of set integrity pending state by performing required integrity processing on the table. This is done in accordance with the information set in the STATUS and CONST_CHECKED columns of the SYSCAT.TABLES catalog view. That is:

- The value in the STATUS column must be "C" (the table is in set integrity pending state), or an error is returned (SQLSTATE 51027), unless the table is a descendent foreign key table, descendent materialized query table, or descendent staging table of a table that is specified in the list, is in set integrity pending state, and whose intermediate ancestors are also in the list.
- If the table being checked is in set integrity pending state, the value in CONST_CHECKED indicates which integrity options are to be checked.

When the table is taken out of set integrity pending state, its descendent tables are, if necessary, put in set integrity pending state. A warning to indicate that descendent tables have been put in set integrity pending state is returned (SQLSTATE 01586).

If the table is a system-maintained materialized query table, the data is checked against the query and refreshed as necessary. (IMMEDIATE CHECKED cannot be used for user-maintained materialized query tables or shadow tables.) If the table is a staging table, the data is checked against its query definition and propagated as necessary.

When the integrity of a child table is checked:

- None of its parents can be in set integrity pending state, or
- Each of its parents must be checked for constraints violations in the same SET INTEGRITY statement

When an immediate materialized query table is refreshed, or deltas are propagated to a staging table:

- None of its underlying tables can be in set integrity pending state, or
- Each of its underlying tables must be checked in the same SET INTEGRITY statement

Otherwise, an error is returned (SQLSTATE 428A8).

table-checked-options

online-options
Specifies the accessibility of the table while it is being processed.

ALLOW NO ACCESS
Specifies that no other users can access the table while it is being processed, except if they are using the Uncommitted Read isolation level.

ALLOW READ ACCESS
Specifies that other users have read-only access to the table while it is being processed.

ALLOW WRITE ACCESS
Specifies that other users have read and write access to the table while it is being processed.

GENERATE IDENTITY
Specifies that if the table includes an identity column, the values are generated by the SET INTEGRITY statement. By default, when the GENERATE IDENTITY option is specified, only attached rows will have their identity column values generated by the SET INTEGRITY statement. The NOT INCREMENTAL option must be specified in conjunction with the GENERATE IDENTITY option to have the SET INTEGRITY statement generate identity column values for all rows in the table, including attached rows, loaded rows, and existing rows. If the GENERATE IDENTITY option is not specified, the current identity column values for all rows in the table are left unchanged. When the table is a system-period temporal table, GENERATE IDENTITY with the NOT INCREMENTAL option is allowed only if you first issue an ALTER TABLE statement with the DROP VERSIONING clause (SQLSTATE 428FH).

query-optimization-options
Specifies the query optimization options for the maintenance of REFRESH DEFERRED materialized query tables.

ALLOW QUERY OPTIMIZATION USING REFRESH DEFERRED TABLES WITH REFRESH AGE ANY
Specifies that when the CURRENT REFRESH AGE special register is set to "ANY", the maintenance of *table-name* will allow REFRESH DEFERRED materialized query tables to be used to optimize the query that maintains *table-name*. If *table-name* is not a REFRESH DEFERRED materialized query table, an error is returned (SQLSTATE 428FH). REFRESH IMMEDIATE materialized query tables are always considered during query optimization.

check-options

incremental-options

INCREMENTAL
Specifies the application of integrity processing on the appended portion (if any) of the table. If such a request cannot be satisfied (that is, the system detects that the whole table needs to be checked for data integrity), an error is returned (SQLSTATE 55019).

NOT INCREMENTAL
Specifies the application of integrity processing on the whole table. If the table is a materialized query table, the materialized query table definition is recomputed. If the table has at least one constraint defined on it, this option causes full processing of descendent foreign key tables and descendent immediate materialized query tables. If the table is a staging table, it is set to an inconsistent state.

If the *incremental-options* clause is not specified, the system determines whether incremental processing is possible; if not, the whole table is checked.

FORCE GENERATED
If the table includes generated by expression columns, the values are computed on the basis of the expression and stored in the column. If this option is not specified, the current values are compared to the computed value of the expression, as though an equality check constraint were in effect. If the table is processed for integrity incrementally, generated columns are computed only for the appended portion. When the table is a system-period temporal table, the FORCE GENERATED option is allowed only if you first issue an ALTER TABLE statement with the DROP VERSIONING clause (SQLSTATE 428FH).

PRUNE
This option can be specified for staging tables only. Specifies that the content of the staging table is to be pruned, and that the staging table is to be set to an inconsistent state. If any table in the *table-name* list is not a staging table, an error is returned (SQLSTATE 428FH). If the INCREMENTAL check option is also specified, an error is returned (SQLSTATE 428FH).

FULL ACCESS
Specifies that the table is to become fully accessible after the SET INTEGRITY statement executes.

When an underlying table (that has dependent immediate materialized query tables or dependent immediate staging tables) in the invocation list is incrementally processed, the underlying table is put in no data movement state, as required, after the SET INTEGRITY statement executes. When all incrementally refreshable dependent immediate materialized query tables and staging tables are taken out of set integrity pending state, the underlying table is automatically brought out of the no data movement state into the full access state. If the FULL ACCESS option is specified with the IMMEDIATE CHECKED option, the underlying table is put directly in full access state (bypassing the no data movement state). In Db2 Version 9.7. Fix Pack 1 and later, specifying the FULL ACCESS option only removes the dependency between the dependent tables and underlying table. The underlying table continues to be unavailable until the data partition detach process is completed by the asynchronous partition detach task.

Dependent immediate materialized query tables that have not been refreshed might undergo a full recomputation in the subsequent REFRESH TABLE statement, and dependent immediate staging tables that have not had the appended portions of the table propagated to them might be flagged as inconsistent.

When an underlying table in the invocation list requires full processing, or does not have dependent immediate materialized query tables, or dependent immediate staging tables, the underlying table is put directly into full access state after the SET INTEGRITY statement executes, regardless of whether the FULL ACCESS option was specified.

exception-clause

FOR EXCEPTION
Specifies that any row that is in violation of a constraint being checked is to be moved to an exception table. Even if errors are detected, the table is taken out of set integrity pending state. A warning to indicate that one or more rows have been moved to the exception tables is returned (SQLSTATE 01603).

If the FOR EXCEPTION option is not specified and any constraints are violated, only the first detected violation is returned (SQLSTATE 23514). If there is a violation in any table, all of the tables are left in set integrity pending state.

It is recommended to always use the FOR EXCEPTION option when checking for constraints violations to prevent a rollback of the SET INTEGRITY statement if a violation is found.

When the table specified after the IN keyword is a system-period temporal table, the FOR EXCEPTION option is allowed only if you first issue an ALTER TABLE statement with the DROP VERSIONING clause (SQLSTATE 428FH).

IN *table-name*
Specifies the table from which rows that violate constraints are to be moved. There must be one exception table specified for each table being checked. This clause cannot be specified for a materialized query table or a staging table (SQLSTATE 428A7).

USE *table-name*
Specifies the exception table into which error rows are to be moved.

FULL ACCESS
If the FULL ACCESS option is specified as the only operation of the statement, the table is placed into the full access state without being rechecked for integrity violations. However, dependent immediate materialized query tables that have not been refreshed might require a full recomputation in subsequent REFRESH TABLE statements, and dependent immediate staging tables that have not had the delta portions of the table propagated to them might be changed to incomplete state. This option can only be specified for a table that is in the no data movement state or the no access state, but not in the set integrity pending state (SQLSTATE 428FH).

PRUNE
This option can be specified for staging tables only. Specifies that the content of the staging table is to be pruned, and that the staging table is to be set to an inconsistent state. If any table in the *table-name* list is not a staging table, an error is returned (SQLSTATE 428FH).

table-unchecked-options

integrity-options
Used to define the types of required integrity processing that are to be bypassed when the table is taken out of the set integrity pending state.

ALL
The table will be immediately taken out of set integrity pending state without any of its required integrity processing being performed.

FOREIGN KEY
Required foreign key constraints checking will not be performed when the table is brought out of set integrity pending state.

CHECK
Required check constraints checking will not be performed when the table is brought out of set integrity pending state.

MATERIALIZED QUERY
Required refreshing of a materialized query table will not be performed when the table is brought out of set integrity pending state.

GENERATED COLUMN
Required generated column constraints checking will not be performed when the table is brought out of set integrity pending state.

STAGING
Required propagation of data to a staging table will not be performed when the table is brought out of set integrity pending state.

If no other types of integrity processing are required on the table after a specific type of integrity processing has been marked as bypassed, the table is immediately taken out of set integrity pending state.

FULL ACCESS
Specifies that the tables are to become fully accessible after the SET INTEGRITY statement executes.

When an underlying table in the invocation list is incrementally processed, and it has dependent immediate materialized query tables or dependent immediate staging tables, the underlying table is placed, as required, in the no data movement state after the SET INTEGRITY statement executes. When all incrementally refreshable dependent immediate materialized query tables and staging tables have been taken out of set integrity pending state, the underlying table is automatically brought out of the no data movement state into the full access state. If the

FULL ACCESS option is specified with the IMMEDIATE UNCHECKED option, the underlying table is placed directly in full access state (it bypasses the no data movement state). Dependent immediate materialized query tables that have not been refreshed might undergo a full recomputation in the subsequent REFRESH TABLE statement, and dependent immediate staging tables that have not had the appended portions of the table propagated to them might be flagged as inconsistent.

In Db2 V9.7. Fix Pack 1 and later, specifying the FULL ACCESS option only removes the dependency between the dependent tables and underlying table. The underlying table continues to be unavailable until the data partition detach process is completed by the asynchronous partition detach task.

When an underlying table in the invocation list requires full processing, or does not have dependent immediate materialized query tables, or dependent immediate staging tables, the underlying table is placed directly in full access state after the SET INTEGRITY statement executes, regardless of whether the FULL ACCESS option has been specified.

If the FULL ACCESS option has been specified with the IMMEDIATE UNCHECKED option, and the statement does not bring the table out of set integrity pending state, an error is returned (SQLSTATE 428FH).

IMMEDIATE UNCHECKED
Specifies one of the following:

- The table is to be brought out of set integrity pending state immediately without any required integrity processing.
- The table is to have one or more types of required integrity processing bypassed when the table is brought out of set integrity pending state by a subsequent SET INTEGRITY statement using the IMMEDIATE CHECKED option.

Consider the data integrity implications of this option before using it. See the "Notes" section.

Notes

- The following restrictions apply to the SMP parallelization of set integrity checking:
  - SMP parallelization of set integrity checking is not enabled by default. The **DB2_EXTENDED_OPTIMIZATION** registry variable with the PRLSI option must be set in order to enable it.
  - The CURRENT DEGREE special register should be used to ensure an appropriate degree of parallelism.
  - SMP parallelization is not supported in MPP environments.
  - SMP parallelization is not supported for INCREMENTAL checking or set integrity after attach.
  - SMP parallelization is not supported when any of the following are involved:
    - Materialized query tables or staging tables
    - Identity or generated columns
  - Parallelization will be limited when there are multiple tables referenced or self-references involved. The constraint and referential checking will be parallelized for one table at the most. The checks for the table with the most expensive constraint checking will be the one which may be parallelized. However, if a table has multiple self-references, some or all of its constraint checking may not be parallelized.
  - Exception handling will not be parallelized.
- Effects on tables in one of the restricted set integrity-related states:
  - Use of INSERT, UPDATE, or DELETE is disallowed on a table that is in read access state or in no access state. Furthermore, any statement that requires this type of modification to a table that is in such a state will be rejected. For example, deletion of a row in a parent table that cascades to a dependent table that is in the no access state is not allowed.

- Use of SELECT is disallowed on a table that is in the no access state. Furthermore, any statement that requires read access to a table that is in the no access state will be rejected.
- New constraints added to a table are normally enforced immediately. However, if the table is in set integrity pending state, the checking of any new constraints is deferred until the table is taken out of set integrity pending state. If the table is in set integrity pending state, addition of a new constraint places the table into set integrity pending no access state, because validity of data is at risk.
- The CREATE INDEX statement cannot reference any table that is in read access state or in no access state. Similarly, an ALTER TABLE statement to add a primary key or a unique constraint cannot reference any table that is in read access state or in no access state.
- The import utility is not allowed to operate on a table that is in read access state or in no access state.
- The export utility is not allowed to operate on a table that is in no access state, but is allowed to operate on a table that is in read access state. If a table is in read access state, the export utility will only export the data that is in the non-appended portion.
- Operations (like REORG, REDISTRIBUTE, update distribution key, update multidimensional clustering key, update range clustering key, update table partitioning key, and so on) that might involve data movement within a table are not allowed on a table that is in any of the following states: read access, no access, or no data movement.
- The load, backup, restore, update statistics, runstats, reorgchk, list history, and rollforward utilities are allowed on a table that is in any of the following states: full access, read access, no access, or no data movement.
- The ALTER TABLE, COMMENT, DROP TABLE, CREATE ALIAS, CREATE TRIGGER, CREATE VIEW, GRANT, REVOKE, and SET INTEGRITY statements can reference a table that is in any of the following states: full access, read access, no access, or no data movement. However, they might cause the table to be put into no access state.
- Packages, views, and any other objects that depend on a table that is in no access state will return an error when the table is accessed at run time. Packages that depend on a table that is in read access state will return an error when an insert, update, or delete operation is attempted on the table at run time.
- The ALL or GENERATED COLUMN option cannot be specified with the IMMEDIATE UNCHECKED option if the table's database partitioning key, table-partitioning key, multidimensional clustering key, or range-clustering key references a generated column whose expression was altered through an ALTER TABLE statement.

The removal of violating rows by the SET INTEGRITY statement is not a delete event. Therefore, triggers are never activated by a SET INTEGRITY statement. Similarly, updating generated columns using the FORCE GENERATED option does not activate triggers.

- Warning about the use of the IMMEDIATE UNCHECKED clause:
  - This clause is intended to be used by utility programs, and its use by application programs is not recommended. If there is data in the table that does not meet the integrity specifications that were defined for the table, and the IMMEDIATE UNCHECKED option is used, incorrect query results might be returned.

    The fact that the table was taken out of the set integrity pending state without performing the required integrity processing will be recorded in the catalog (the respective byte in the CONST_CHECKED column in the SYSCAT.TABLES view will be set to "U"). This indicates that the user has assumed responsibility for data integrity with respect to the specific constraints. This value remains unchanged until either:

    - The table is put back into set integrity pending state (by referencing the table in a SET INTEGRITY statement with the OFF option), at which time "U" values in the CONST_CHECKED column are changed to "W" values, indicating that the user had previously assumed responsibility for data integrity, and the system needs to verify the data.
    - All unchecked constraints for the table are dropped.

The "W" state differs from the "N" state in that it records the fact that integrity was previously checked by the user, but not yet by the system. If the user issues the SET INTEGRITY ... IMMEDIATE CHECKED statement with the NOT INCREMENTAL option, the system rechecks the whole table for data integrity (or performs a full refresh on a materialized query table), and then changes the "W" state to the "Y" state. If IMMEDIATE UNCHECKED is specified, or if NOT INCREMENTAL is not specified, the "W" state is changed back to the "U" state to record the fact that some data has still not been verified by the system. In the latter case (when the NOT INCREMENTAL is not specified), a warning is returned (SQLSTATE 01636).

If an underlying table's integrity has been checked using the IMMEDIATE UNCHECKED clause, the "U" values in the CONST_CHECKED column of the underlying table will be propagated to the corresponding CONST_CHECKED column of:

- Dependent immediate materialized query tables
- Dependent deferred materialized query tables
- Dependent staging tables

For a dependent immediate materialized query table, this propagation is done whenever the underlying table is brought out of set integrity pending state, and whenever the materialized query table is refreshed. For a dependent deferred materialized query table, this propagation is done whenever the materialized query table is refreshed. For dependent staging tables, this propagation is done whenever the underlying table is brought out of set integrity pending state. These propagated "U" values in the CONST_CHECKED columns of dependent materialized query tables and staging tables record the fact that these materialized query tables and staging tables depend on some underlying table whose required integrity processing has been bypassed using the IMMEDIATE UNCHECKED option.

For a materialized query table, the "U" value in the CONST_CHECKED column that was propagated by the underlying table will remain until the materialized query table is fully refreshed and none of its underlying tables have a "U" value in their corresponding CONST_CHECKED column. After such a refresh, the "U" value in the CONST_CHECKED column for the materialized query table will be changed to "Y".

For a staging table, the "U" value in the CONST_CHECKED column that was propagated by the underlying table will remain until the corresponding deferred materialized query table of the staging table is refreshed. After such a refresh, the "U" value in the CONST_CHECKED column for the staging table will be changed to "Y".

– If a child table and its parent table are checked in the same SET INTEGRITY statement with the IMMEDIATE CHECKED option, and the parent table requires full checking of its constraints, the child table will have its foreign key constraints checked, independently of whether or not the child table has a "U" value in the CONST_CHECKED column for foreign key constraints.

- If the table is data partitioned and there are nonpartitioned indexes (except the XML column path index) to maintain, IMMEDIATE UNCHECKED behavior when a single target table is specified is the same as IMMEDIATE CHECKED behavior with the ALLOW WRITE ACCESS option: all integrity processing is performed and any resulting errors are returned. If the statement references more than one target table, an error is returned (SQLSTATE 428FH).
- After appending data using LOAD INSERT or ALTER TABLE ATTACH, the SET INTEGRITY statement with the IMMEDIATE CHECKED option checks the table for constraints violations. The system determines whether incremental processing on the table is possible. If so, only the appended portion is checked for integrity violations. If not, the system checks the whole table for integrity violations.
- Consider the statement:

```
SET INTEGRITY FOR T IMMEDIATE CHECKED
```

In the following scenarios, neither the INCREMENTAL check option for T nor an incremental refresh of T---if T is a materialized query table (MQT) or a staging table---is supported:

– New constraints have been added to T while it is in set integrity pending state

– When a LOAD REPLACE operation against T, it parents, or its underlying tables has taken place

  - When the NOT LOGGED INITIALLY WITH EMPTY TABLE option has been activated after the last integrity check on T, its parents, or its underlying tables
  - The cascading effect of full processing, when any parent of T (or underlying table, if T is a materialized query table or a staging table) has been checked for integrity non-incrementally
  - If the table space containing the table or its parent (or underlying table of a materialized query table or a staging table) has been rolled forward to a point in time, and the table and its parent (or underlying table if the table is a materialized query table or a staging table) reside in different table spaces
  - T is an MQT, and a LOAD REPLACE or LOAD INSERT operation directly into T has taken place after the last refresh
- Incremental processing will be used whenever the situation allows it, because it is more efficient. The INCREMENTAL option is not needed in most cases. It is needed, however, to ensure that integrity checks are indeed processed incrementally. If the system detects that full processing is needed to ensure data integrity, an error is returned (SQLSTATE 55019).
- If the conditions for full processing described in the previous bullet are not satisfied, the system will attempt to check only the appended portion for integrity, or perform an incremental refresh (if it is a materialized query table) when the user does not specify the NOT INCREMENTAL option for the statement `SET INTEGRITY FOR T IMMEDIATE CHECKED`.
- If an error occurs during integrity processing, all the effects of the processing (including deleting from the original and inserting into the exception tables) will be rolled back.
- If a SET INTEGRITY statement issued with the FORCE GENERATED option fails because of a lack of log space, increase available active log space and reissue the SET INTEGRITY statement. Alternatively, use the SET INTEGRITY statement with the GENERATED COLUMN and IMMEDIATE UNCHECKED options to bypass generated column checking for the table. Then, issue a SET INTEGRITY statement with the IMMEDIATE CHECKED option and without the FORCE GENERATED option to check the table for other integrity violations (if applicable) and to bring it out of set integrity pending state. After the table is out of the set integrity pending state, the generated columns can be updated to their default (generated) values by assigning them to the keyword DEFAULT in an UPDATE statement. This is accomplished by using either multiple searched update statements based on ranges (each followed by a commit), or a cursor-based approach using intermittent commits. A "with hold" cursor should be used if locks are to be retained after intermittent commits using the cursor-based approach.
- A table that was put into set integrity pending state using the CASCADE DEFERRED option of the SET INTEGRITY statement or the LOAD command, or through the ALTER TABLE statement with the ATTACH clause, and that is checked for integrity violations using the IMMEDIATE CHECKED option of the SET INTEGRITY statement, will have its descendent foreign key tables, descendent immediate materialized query tables, and descendent immediate staging tables put in set integrity pending state, as required:
  - If the entire table is checked for integrity violations, its descendent foreign key tables, descendent immediate materialized query tables, and descendent immediate staging tables will be put in set integrity pending state.
  - If the table is checked for integrity violations incrementally, its descendent immediate materialized query tables and staging tables will be put in set integrity pending state, and its descendent foreign key tables will remain in their original states.
  - If the table requires no checking at all, its descendent immediate materialized query tables, descendent staging tables, and descendent foreign key tables will remain in their original states.
- A table that was put in set integrity pending state using the CASCADE DEFERRED option (of the SET INTEGRITY statement or the LOAD command), and that is brought out of set integrity pending state using the IMMEDIATE UNCHECKED option of the SET INTEGRITY statement, will have its descendent foreign key tables, descendent immediate materialized query tables, and descendent immediate staging tables put in set integrity pending state, as required:
  - If the table has been loaded using the REPLACE mode, its descendent foreign key tables, descendent immediate materialized query tables, and descendent immediate staging tables will be put in set integrity pending state.

  - If the table has been loaded using the INSERT mode, its descendent immediate materialized query tables and staging tables will be put in set integrity pending state, and its descendent foreign key tables will remain in their original states.
  - If the table has not been loaded, its descendent immediate materialized query tables, descendent staging tables, and its descendent foreign key tables will remain in their original states.
- SET INTEGRITY is usually a long running statement. In light of this, to reduce the risk of a rollback of the entire statement because of a lock timeout, you can issue the SET CURRENT LOCK TIMEOUT statement with the WAIT option before executing the SET INTEGRITY statement, and then reset the special register to its previous value after the transaction commits. Note, however, that the CURRENT LOCK TIMEOUT special register only impacts a specific set of lock types.
- If you use the ALLOW QUERY OPTIMIZATION USING REFRESH DEFERRED TABLES WITH REFRESH AGE ANY option, ensure that the maintenance order is correct for REFRESH DEFERRED materialized query tables. For example, consider two materialized query tables, MQT1 and MQT2, whose materialized queries share the same underlying tables. The materialized query for MQT2 can be calculated using MQT1, instead of the underlying tables. If separate statements are used to maintain these two materialized query tables, and MQT2 is maintained first, the system might choose to use the contents of MQT1, which has not yet been maintained, to maintain MQT2. In this case, MQT1 would contain current data, but MQT2 could still contain stale data, even though both were maintained at almost the same time. The correct maintenance order, if two SET INTEGRITY statements are used instead of one, is to maintain MQT1 first.
- When using the SET INTEGRITY statement to perform integrity processing on a base table that has been loaded or attached, it is recommended that you process its dependent REFRESH IMMEDIATE materialized query tables and its PROPAGATE IMMEDIATE staging tables in the same SET INTEGRITY statement to avoid putting these dependent tables in set integrity pending no access state at the end of SET INTEGRITY processing. Note that for base tables that have a large number of dependent REFRESH IMMEDIATE materialized query tables and PROPAGATE IMMEDIATE staging tables, memory constraints might make it impossible to process all of the dependents in the same statement as the base table.
- If the FORCE GENERATED or the GENERATE IDENTITY option is specified, and the column that is generated is part of a unique index, the SET INTEGRITY statement returns an error (SQLSTATE 23505) and rolls back if it detects duplicate keys in the unique index. This error is returned even if there is an exception table for the table being processed.

  This scenario can occur under the following circumstances:

  - The SET INTEGRITY statement runs after a LOAD command against the table, and the GENERATEDOVERRIDE or the IDENTITYOVERRIDE file type modifier is specified during the load operation. To prevent this scenario, it is recommended that you use the GENERATEDIGNORE or the GENERATEDMISSING file type modifier instead of GENERATEDOVERRIDE, and that you use the IDENTITYIGNORE or the IDENTITYMISSING modifier instead of IDENTITYOVERRIDE. Using the recommended modifiers will prevent the need for any generated by expression column or identity column processing during SET INTEGRITY statement execution.
  - The SET INTEGRITY statement is run after an ALTER TABLE statement that alters the expression of a generated by expression column.

  To bring a table out of the set integrity pending state after encountering such a scenario:

  - Do not use the FORCE GENERATED or the GENERATE IDENTITY option to regenerate the column values. Instead, use the IMMEDIATE CHECKED option in conjunction with the FOR EXCEPTION option to move any rows that violate the generated column expression to an exception table. Then, re-insert the rows into the table from the exception table, which will generate the correct expression and perform unique key checking. This prevents having to reprocess the entire table, because only those rows that violated the generated column expression will need to be processed again.
  - If the table being processed has attached partitions, detach those partitions before performing the actions that are described in the previous bullet. Then, re-attach the partitions and execute a SET INTEGRITY statement to process integrity on the attached partitions separately.
- If a protected table is specified for the SET INTEGRITY statement along with an exception table, all of the following table criteria must be met; otherwise, an error is returned (SQLSTATE 428A5):

  - The tables must be protected by the same security policy.
  - If a column in the protected table has data type DB2SECURITYLABEL, the corresponding column in the exception table must also have data type DB2SECURITYLABEL.
  - If a column in the protected table is protected by a security label, the corresponding column in the exception table must also be protected by the same security label.
- Rows that violate the integrity being checked in a system-period temporal table cannot be moved to an exception table. If the violating rows must be moved to an exception table, the table must be altered to drop versioning before issuing the SET INTEGRITY statement with the FOR EXCEPTION clause.
- ***Syntax alternatives***: The following are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - SET CONSTRAINTS can be specified in place of SET INTEGRITY
  - SUMMARY can be specified in place of MATERIALIZED QUERY

Examples

- *Example 1:* The following is an example of a query that provides information about the set integrity pending state and the set integrity-related access restriction states of tables. SUBSTR is used to extract individual bytes of the CONST_CHECKED column of SYSCAT.TABLES. The first byte represents foreign key constraints; the second byte represents check constraints; the fifth byte represents materialized query table integrity; the sixth byte represents generated column constraints; the seventh byte represents staging table integrity; and the eighth byte represents data partitioning constraints. STATUS gives the set integrity pending state, and ACCESS_MODE gives the set integrity-related access restriction state.

```
SELECT TABNAME, STATUS, ACCESS_MODE,
  SUBSTR(CONST_CHECKED,1,1) AS FK_CHECKED,
  SUBSTR(CONST_CHECKED,2,1) AS CC_CHECKED,
  SUBSTR(CONST_CHECKED,5,1) AS MQT_CHECKED,
  SUBSTR(CONST_CHECKED,6,1) AS GC_CHECKED,
  SUBSTR(CONST_CHECKED,7,1) AS STG_CHECKED,
  SUBSTR(CONST_CHECKED,8,1) AS DP_CHECKED
FROM SYSCAT.TABLES
```

- *Example 2:* Put the PARENT table in set integrity pending no access state, and immediately cascade the set integrity pending state to its descendants.

```
SET INTEGRITY FOR PARENT OFF
  NO ACCESS CASCADE IMMEDIATE
```

- *Example 3:* Put the PARENT table in set integrity pending read access state without immediately cascading the set integrity pending state to its descendants.

```
SET INTEGRITY FOR PARENT OFF
  READ ACCESS CASCADE DEFERRED
```

- *Example 4:* Check integrity for a table named FACT_TABLE. If there are no integrity violations detected, the table is brought out of set integrity pending state. If any integrity violations are detected, the entire statement is rolled back, and the table remains in set integrity pending state.

```
SET INTEGRITY FOR FACT_TABLE IMMEDIATE CHECKED
```

- *Example 5:* Check integrity for the SALES and PRODUCTS tables, and move the rows that violate integrity into exception tables named SALES_EXCEPTIONS and PRODUCTS_EXCEPTIONS. Both the SALES and PRODUCTS tables are brought out of set integrity pending state, whether or not there are any integrity violations.

```
SET INTEGRITY FOR SALES, PRODUCTS IMMEDIATE CHECKED
  FOR EXCEPTION IN SALES USE SALES_EXCEPTIONS,
  IN PRODUCTS USE PRODUCTS_EXCEPTIONS
```

- *Example 6:* Enable FOREIGN KEY constraint checking in the MANAGER table, and CHECK constraint checking in the EMPLOYEE table, to be bypassed with the IMMEDIATE UNCHECKED option.

```
SET INTEGRITY FOR MANAGER FOREIGN KEY,
  EMPLOYEE CHECK IMMEDIATE UNCHECKED
```

- *Example 7:* Add a check constraint and a foreign key to the EMP_ACT table, using two ALTER TABLE statements. The SET INTEGRITY statement with the OFF option is used to put the table in set integrity pending state, so that the constraints are not checked immediately upon execution of the two ALTER TABLE statements. The single SET INTEGRITY statement with the IMMEDIATE CHECKED option is used to check both of the added constraints during a single pass through the table.

```
SET INTEGRITY FOR EMP_ACT OFF;
ALTER TABLE EMP_ACT ADD CHECK
  (EMSTDATE <= EMENDATE);
ALTER TABLE EMP_ACT ADD FOREIGN KEY
  (EMPNO) REFERENCES EMPLOYEE;
SET INTEGRITY FOR EMP_ACT IMMEDIATE CHECKED
  FOR EXCEPTION IN EMP_ACT USE EMP_ACT_EXCEPTIONS
```

- *Example 8:* Update generated columns with the correct values.

```
SET INTEGRITY FOR SALES IMMEDIATE CHECKED
  FORCE GENERATED
```

- *Example 9:* Append (using LOAD INSERT) from different sources into an underlying table (SALES) of a REFRESH IMMEDIATE materialized query table (SALES_SUMMARY). Check SALES incrementally for data integrity, and refresh SALES_SUMMARY incrementally. In this scenario, integrity checking for SALES and refreshing of SALES_SUMMARY are incremental, because the system chooses incremental processing. The ALLOW READ ACCESS option is used on the SALES table to allow concurrent reads of existing data while integrity checking of the loaded portion of the table is taking place.

```
LOAD FROM 2000_DATA.DEL OF DEL
  INSERT INTO SALES ALLOW READ ACCESS;
LOAD FROM 2001_DATA.DEL OF DEL
  INSERT INTO SALES ALLOW READ ACCESS;
SET INTEGRITY FOR SALES ALLOW READ ACCESS IMMEDIATE CHECKED
  FOR EXCEPTION IN SALES USE SALES_EXCEPTIONS;
REFRESH TABLE SALES_SUMMARY;
```

- *Example 10:* Attach a new partition to a data partitioned table named SALES. Incrementally check for constraints violations in the attached data of the SALES table and incrementally refresh the dependent SALES_SUMMARY table. The ALLOW WRITE ACCESS option is used on both tables to allow concurrent updates while integrity checking is taking place.

```
ALTER TABLE SALES
  ATTACH PARTITION STARTING (100) ENDING (200)
  FROM SOURCE;
SET INTEGRITY FOR SALES ALLOW WRITE ACCESS, SALES_SUMMARY ALLOW WRITE ACCESS
  IMMEDIATE CHECKED FOR EXCEPTION IN SALES
  USE SALES_EXCEPTIONS;
```

- *Example 11:* Detach a partition from a data partitioned table named SALES. Incrementally refresh the dependent SALES_SUMMARY table.

```
ALTER TABLE SALES
  DETACH PARTITION 2000_PART INTO ARCHIVE_TABLE;
SET INTEGRITY FOR SALES_SUMMARY
  IMMEDIATE CHECKED;
```

- *Example 12:* Bring a new user-maintained materialized query table out of set integrity pending state.

```
CREATE TABLE YEARLY_SALES
  AS (SELECT YEAR, SUM(SALES)AS SALES
  FROM FACT_TABLE GROUP BY YEAR)
  DATA INITIALLY DEFERRED REFRESH DEFERRED MAINTAINED BY USER

SET INTEGRITY FOR YEARLY_SALES
  ALL IMMEDIATE UNCHECKED
```

- *Example 13:* Attach a new partition to a data partitioned table named SALES. Assume that this table has no nonpartitioned user indexes. Assume also that data integrity checking, including range validation and other constraints checking, has already been done (through application logic that is independent of the data server). Optimize the data roll-in process by using the SET INTEGRITY ... ALL IMMEDIATE UNCHECKED statement to skip range and constraints violation checking.

```
ALTER TABLE SALES
  ATTACH PARTITION STARTING (300) ENDING (400)
  FROM SOURCE_TABLE;
SET INTEGRITY FOR SALES ALL IMMEDIATE UNCHECKED;
```

  The SALES table is brought out of SET INTEGRITY pending state, and the new data is available for applications to use immediately.
- *Example 14*: Setting the **DB2_EXTENDED_OPTIMIZATION** registry variable with the option is done by running:

```
db2set DB2_EXTENDED_OPTIMIZATION=
```

SET PASSTHRU

The SET PASSTHRU statement opens and closes a session for submitting a data source's native SQL directly to that data source.

The statement is not under transaction control.

Invocation

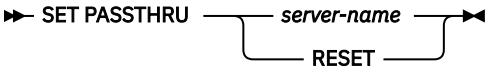
This statement can be issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must provide authorization to:

- Pass through to the data source
- Satisfy security measures at the data source

Syntax



Description

server-name
Names the data source for which a pass-through session is to be opened. *server-name* must identify a data source that is described in the catalog.

RESET
Closes a pass-through session.

Notes

- The following restrictions apply to Microsoft SQL Server, Sybase, and Oracle data sources:
  - User-defined transactions cannot be used for Microsoft SQL Server and Sybase data sources in pass-through mode, because Microsoft SQL Server and Sybase restrict which SQL statements can be specified within a user-defined transaction. Because SQL statements that are processed in pass-

through mode are not parsed by the database manager, it is not possible to detect whether the user specified an SQL statement that is permitted within a user-defined transaction.

- The COMPUTE clause is not supported on Microsoft SQL Server and Sybase data sources.
- DDL statements are not subject to transaction semantics on Microsoft SQL Server, Oracle and Sybase data sources. The operation, when complete, is automatically committed by Microsoft SQL Server, Oracle or Sybase. If a rollback occurs, the DDL is not rolled back.

Examples

- *Example 1:* Start a pass-through session to data source BACKEND.

```
strcpy (PASS_THRU,"SET PASSTHRU BACKEND");
EXEC SQL EXECUTE IMMEDIATE :PASS_THRU;
```

- *Example 2:* Start a pass-through session with a PREPARE statement.

```
strcpy (PASS_THRU,"SET PASSTHRU BACKEND");
EXEC SQL PREPARE STMT FROM :PASS_THRU;
EXEC SQL EXECUTE STMT;
```

- *Example 3:* End a pass-through session.

```
strcpy (PASS_THRU_RESET,"SET PASSTHRU RESET");
EXEC SQL EXECUTE IMMEDIATE :PASS_THRU_RESET;
```

- *Example 4:* Use the PREPARE and EXECUTE statements to end a pass-through session.

```
strcpy (PASS_THRU_RESET,"SET PASSTHRU RESET");
EXEC SQL PREPARE STMT FROM :PASS_THRU_RESET;
EXEC SQL EXECUTE STMT;
```

- *Example 5:* Open a session to pass through to a data source, create a clustered index for a table at this data source, and close the pass-through session.

```
strcpy (PASS_THRU,"SET PASSTHRU BACKEND");
EXEC SQL EXECUTE IMMEDIATE :PASS_THRU;
EXEC SQL PREPARE STMT                 pass-through mode
  FROM "CREATE UNIQUE
        CLUSTERED INDEX TABLE_INDEX
        ON USER2.TABLE              table is not an
        WITH IGNORE DUP KEY";        alias
EXEC SQL EXECUTE STMT;
strcpy (PASS_THRU_RESET,"SET PASSTHRU RESET");
EXEC SQL EXECUTE IMMEDIATE :PASS_THRU_RESET;
```

SET PATH

The SET PATH statement changes the value of the CURRENT PATH special register.

This statement is not under transaction control.

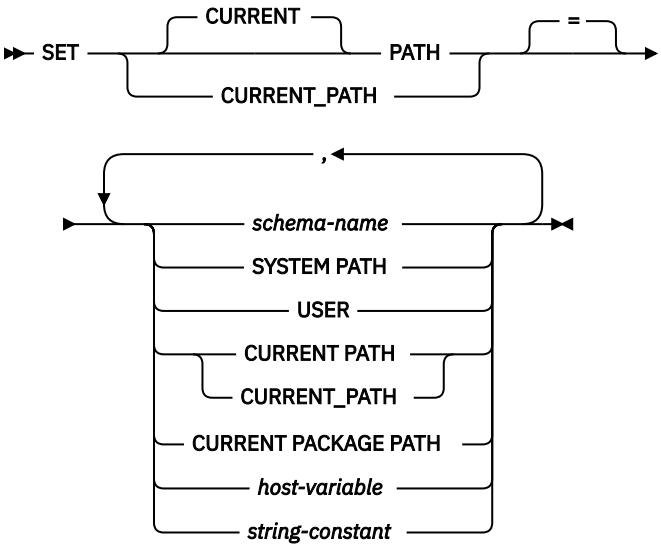
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

schema-name
This one-part name identifies a schema that exists at the application server. No validation that the schema exists is made at the time that the path is set. If a *schema-name* is, for example, misspelled, the error will not be caught, and it could affect the way subsequent SQL operates.

SYSTEM PATH
This value is the same as specifying the schema names *"SYSIBM","SYSFUN","SYSPROC","SYSIBMADM"*.

USER
The value of the USER special register.

CURRENT PATH
The value of the CURRENT PATH special register before this statement executes.

CURRENT PACKAGE PATH
The value of the CURRENT PACKAGE PATH special register.

host-variable
A variable of type CHAR or VARCHAR. The length of the contents of the *host-variable* must not exceed 128 bytes (SQLSTATE 42815). It cannot be set to null. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 42815).

The characters of the *host-variable* must be left-aligned. When specifying the *schema-name* with a *host-variable*, all characters must be specified in the exact case intended as there is no conversion to uppercase characters.

string-constant
A character string constant with a maximum length of 128 bytes.

Rules

- A schema name cannot appear more than once in the SQL path (SQLSTATE 42732).
- The schema name SYSPUBLIC cannot be specified in the SQL path (SQLSTATE 42815).
- The number of schemas that can be specified is limited by the total length of the CURRENT PATH special register. The special register string is built by taking each schema name specified and removing trailing blanks, delimiting with double quotation marks, doubling quotation marks within the schema name as necessary, and then separating each schema name by a comma. The length of the resulting string cannot exceed 2048 bytes (SQLSTATE 42907).

Notes

- The initial value of the CURRENT PATH special register is "SYSIBM","SYSFUN","SYSPROC","SYSIBMADM","X" where X is the value of the USER special register.
- The schema SYSIBM does not need to be specified. If it is not included in the SQL path, it is implicitly assumed as the first schema (in this case, it is not included in the CURRENT PATH special register).
- The CURRENT PATH special register specifies the SQL path used to resolve function names, procedure names, data type names, global variable names, and module object names in dynamic SQL statements. The FUNCPATH bind option specifies the SQL path to be used for resolving function names, procedure names, data type names, global variable names, and module object names in static SQL statements.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - CURRENT FUNCTION PATH can be specified in place of CURRENT PATH

Examples

- *Example 1:* The following statement sets the CURRENT PATH special register.

```
SET PATH = FERMAT, "McDrw #8", SYSIBM
```

- *Example 2:* The following example retrieves the current value of the CURRENT PATH special register into the host variable called CURPATH.

```
EXEC SQL VALUES (CURRENT PATH) INTO :CURPATH;
```

  The value would be "FERMAT","McDrw #8","SYSIBM" if set by the previous example.

SET ROLE

The SET ROLE statement verifies that the authorization ID of the session is a member of a specific role. An authorization ID acquires membership in a role when the role is granted to the authorization ID, or to a group or role in which the authorization ID is a member.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

None required.

Syntax

Description

role-name

Specifies a role in whose membership the authorization ID of the session is to be verified. The *role-name* must identify an existing role at the current server (SQLSTATE 42704). If the authorization ID of the session is not a member of *role-name*, an error is returned (SQLSTATE 42501).

Notes

- All roles that have been granted to an authorization ID are used for authorization checking. The SET ROLE statement does not affect which roles are used for this authorization checking. Use the GRANT ROLE and REVOKE ROLE statements to change the roles in which an authorization ID has membership.

Examples

- *Example 1:* User WALID has been granted the role EDITOR, but not the role AUTHOR. Verify that WALID is a member of the EDITOR role.

```
SET ROLE EDITOR
```

- *Example 2:* Verify that WALID is not a member of the AUTHOR role. The following statement returns an error (SQLSTATE 42501).

```
SET ROLE AUTHOR
```

SET SCHEMA

The SET SCHEMA statement changes the value of the CURRENT SCHEMA special register.

This statement is not under transaction control. If the package is bound with the DYNAMICRULES BIND option, this statement does not affect the qualifier used for unqualified database object references.

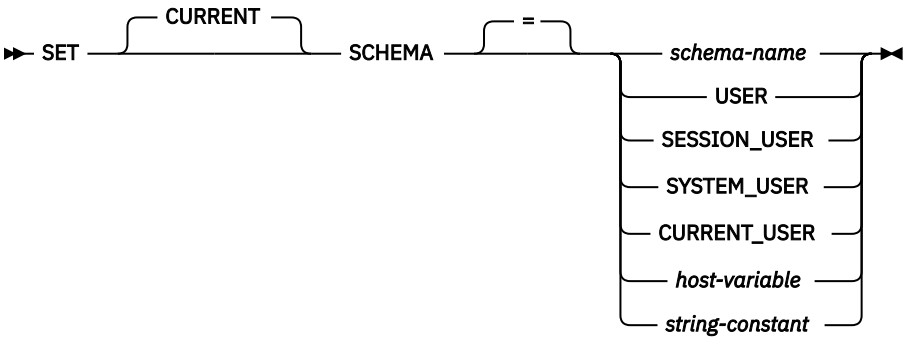
Invocation

The statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

schema-name
This one-part name identifies a schema that exists at the application server. The length must not exceed 128 bytes (SQLSTATE 42815). No validation that the schema exists is made at the time that the schema is set. If a *schema-name* is misspelled, the error will not be caught, and that could affect the way that subsequent SQL statements execute.

USER
The value in the USER special register.

SESSION_USER
The value in the SESSION_USER special register.

SYSTEM_USER
The value in the SYSTEM_USER special register.

CURRENT_USER
The value in the CURRENT_USER special register.

host-variable
A variable of type CHAR or VARCHAR. The length of the contents of the *host-variable* must not exceed 128 bytes (SQLSTATE 42815). It cannot be set to null. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 42815).

The characters of the *host-variable* must be left-aligned. When specifying the *schema-name* with a *host-variable*, all characters must be specified in the exact case intended as there is no conversion to uppercase characters.

string-constant
A character string constant with a maximum length of 128 bytes.

Rules

- If the value specified does not conform to the rules for a *schema-name*, an error (SQLSTATE 3F000) is raised.
- The value of the CURRENT SCHEMA special register is used as the schema name in all dynamic SQL statements, with the exception of the CREATE SCHEMA statement, where an unqualified reference to a database object exists.
- The QUALIFIER bind option specifies the schema name for use as the qualifier for unqualified database object names in static SQL statements.

Notes

- The initial value of the CURRENT SCHEMA special register is equivalent to USER.
- Setting the CURRENT SCHEMA special register does not affect the CURRENT PATH special register. Hence, the CURRENT SCHEMA will not be included in the SQL path and functions, procedures and user-defined type resolution may not find these objects. To include the current schema value in the SQL path, whenever the SET SCHEMA statement is issued, also issue the SET PATH statement including the schema name from the SET SCHEMA statement.
- CURRENT SQLID is accepted as a synonym for CURRENT SCHEMA and the effect of a SET CURRENT SQLID statement will be identical to that of a SET CURRENT SCHEMA statement. No other effects, such as statement authorization changes, will occur.

Examples

- *Example 1:* The following statement sets the CURRENT SCHEMA special register.

```
SET SCHEMA RICK
```

- *Example 2:* The following example retrieves the current value of the CURRENT SCHEMA special register into the host variable called CURSCHEMA.
-

```
EXEC SQL VALUES (CURRENT SCHEMA) INTO :CURSCHEMA;
```

The value would be RICK, set by the previous example.

SET SERVER OPTION

The SET SERVER OPTION statement specifies a server option setting that is to remain in effect while a user or application is connected to the federated database. When the connection ends, this server option's previous setting is reinstated.

This statement is not under transaction control.

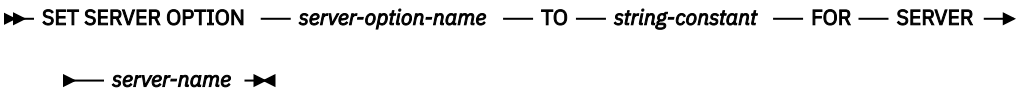
Invocation

This statement can be issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax



Description

server-option-name
Names the server option that is to be set.

TO *string-constant*
Specifies the setting for *server-option-name* as a character string constant.

SERVER *server-name*
Names the data source to which *server-option-name* applies. It must be a server described in the catalog.

Notes

- Server option names can be entered in uppercase or lowercase.
- One or more SET SERVER OPTION statements can be submitted when a user or application connects to the federated database. The statement (or statements) must be specified at the start of the first unit of work that is processed after the connection is established.
- SYSCAT.SERVEROPTIONS will not be updated based on a SET SERVER OPTION statement, because this change only affects the current connection.
- For static SQL, using the SET SERVER OPTION statement affects only the execution of the static SQL statement. Using the SET SERVER OPTION statement has no effect on the plans that are generated by the optimizer.

Examples

- *Example 1:* An Oracle data source called ORASERV is defined to a federated database called DJDB. ORASERV is configured to disallow plan hints. However, the DBA would like plan hints to be enabled for a test run of a new application. When the run is over, plan hints will be disallowed again.

```
CONNECT TO DJDB;
strcpy(stmt,"set server option plan_hints to 'Y' for server oraserv");
EXEC SQL EXECUTE IMMEDIATE :stmt;
strcpy(stmt,"select c1 from ora_t1 where c1 > 100"); /*Generate plan hints*/
EXEC SQL PREPARE s1 FROM :stmt;
EXEC SQL DECLARE c1 CURSOR FOR s1;
```

```
EXEC SQL OPEN c1;
EXEC SQL FETCH c1 INTO :hv;
```

- *Example 2:* You have set the server option PASSWORD to 'Y' (validating passwords at the data source) for all Oracle 8 data sources. However, for a particular session in which an application is connected to the federated database in order to access a specific Oracle 8 data source-one defined to the federated database DJDB as ORA8A-passwords will not need to be validated.

```
CONNECT TO DJDB;
strcpy(stmt,"set server option password to 'N' for server ora8a");
EXEC SQL PREPARE STMT_NAME FROM :stmt;
EXEC SQL EXECUTE STMT_NAME FROM :stmt;
strcpy(stmt,"select max(c1) from ora8a_t1");
EXEC SQL PREPARE STMT_NAME FROM :stmt;
EXEC SQL DECLARE c1 CURSOR FOR STMT_NAME;
EXEC SQL OPEN c1; /*Does not validate password at ora8a*/
EXEC SQL FETCH c1 INTO :hv;
```

SET SESSION AUTHORIZATION

The SET SESSION AUTHORIZATION statement changes the value of the SESSION_USER special register.

The statement is not under transaction control. The SET SESSION AUTHORIZATION statement is intended to provide support for a single user assuming different authorization IDs on the same connection, and should not be used for scenarios in which different users reuse the same connection, commonly referred to as connection pooling.

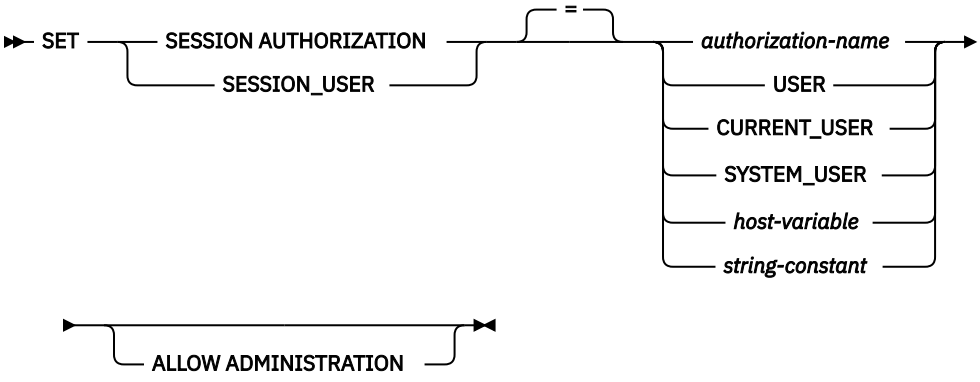
Invocation

The statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include SETSESSIONUSER on the authorization ID value to which the special register is being set.

Syntax



Description

authorization-name
Specifies the authorization ID that is to be used as the new value for the SESSION_USER special register.

USER
The value in the USER special register.

CURRENT_USER
The value in the CURRENT USER special register.

SYSTEM_USER
The value in the SYSTEM_USER special register.

host-variable
A variable of type CHAR or VARCHAR. The length of the contents of *host-variable* must not exceed 128 bytes (SQLSTATE 28000). It cannot be set to null. If *host-variable* has an associated indicator variable, the value of that indicator variable must not indicate a null value (SQLSTATE 28000).

The characters of *host-variable* must be left-aligned. When specifying *authorization-name* with a host variable, all characters must be specified in uppercase, because there is no conversion to uppercase characters.

string-constant
A character string constant with a maximum length of 128 bytes.

ALLOW ADMINISTRATION
Specifies that SQL schema statements can be specified before this statement in the same unit of work.

Rules

- The value specified for the SESSION_USER special register must conform to the rules for an authorization ID of type USER (SQLSTATE 42602).
- The OWNER bind option specifies the authorization ID that is to be used for static SQL statements.
- This statement can only be issued as the first statement (other than a SET special register statement) in a new unit of work without any open WITH HOLD cursors (SQLSTATE 25001). This restriction includes any PREPARE request for a statement other than a SET special register statement.
- The value of the SESSION_USER special register is used as the authorization ID for all dynamic SQL statements in a package bound with the DYNAMICRULES(RUN) bind option. (This includes INVOKERUN and DEFINERUN when the package is not used by a routine). If a package is using owner, invoker, or definer authorization based on the DYNAMICRULES option, this statement has no effect on dynamic SQL statements issued from within that package.

Notes

- The SET SESSION AUTHORIZATION statement lets you change the session authorization ID. The session authorization ID represents the current user of the connection and is the authorization ID that the database manager considers for all authorization checking relative to dynamic SQL within a DYNAMICRULES run package. The SESSION_USER special register can be used to see the current value of this session authorization ID.
- The initial value of the SESSION_USER special register for a new connection is the same as the value of the SYSTEM_USER special register.
- The group information for the session authorization ID specified in this statement is acquired at the time of statement execution.
- Setting the SESSION_USER special register does not effect either the CURRENT SCHEMA or the CURRENT PATH special register.
- If any error occurs during the setting of the SESSION_USER special register, the register reverts to its previous value.
- This statement should not be used to allow multiple, different users to reuse the same connection, because each user will inherit the ability to change the value of the SESSION_USER special register that the original connection owner had. This statement is dependent upon the value of SYSTEM_USER for privileges checking, and the initial connection authorization ID is not changed by the SET SESSION AUTHORIZATION statement. Moreover, the following behaviors impacting connection reuse are not addressed by this statement:

  - The CONNECT privilege is not checked for the new authorization ID
  - The content of any updatable special register is not reset; in particular, the content of the ENCRYPTION PASSWORD special register is not modified and is available to the new authorization ID for encryption or decryption
  - The content of any declared global temporary table is not affected, and is accessible to the new authorization ID
  - Any existing links to remote servers are not reset
- If the ALLOW ADMINISTRATION clause is specified, the following types of statements or operations can precede the SET SESSION AUTHORIZATION statement:
  - Data definition language (DDL), including the definition of savepoints and the declaration of global temporary tables, but not including SET INTEGRITY
  - GRANT and REVOKE statements
  - LOCK TABLE statement
  - COMMIT and ROLLBACK statements
  - SET of special registers
  - SET of global variables

Examples

- *Example 1:* The following statement sets the SESSION_USER special register.

```
SET SESSION_USER = RAJIV
```

- *Example 2:* Set the session authorization ID (the SESSION_USER special register) to be the value of the system authorization ID, which is the ID that established the connection on which the statement has been issued.

```
SET SESSION AUTHORIZATION SYSTEM_USER
```

SET USAGE LIST STATE

The SET USAGE LIST STATE statement manages the state of a usage list and the associated data and memory.

This statement is not under transaction control.

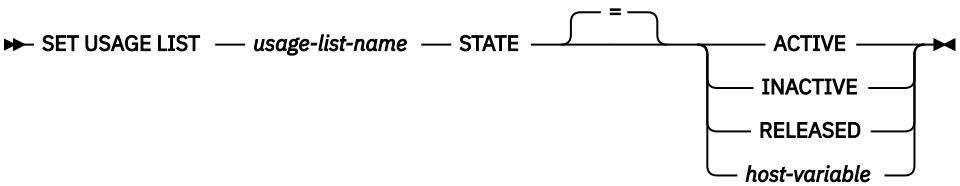
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include DBADM or SQLADM authority.

Syntax



Description

usage-list-name
Identifies the usage list. The *usage-list-name*, including the implicit or explicit qualifier, must identify a usage list that is described in the catalog (SQLSTATE 42704).

ACTIVE
Indicates that the usage list is activated for monitoring. Memory for the usage list is allocated when the table or index is first referenced by a section. If the usage list is for a partitioned table or index then the memory is allocated when the data partition is first referenced by a section. In a partitioned database environment or Db2 pureScale environment, memory is allocated at each member. If the usage list is already in the ACTIVE state then a warning is returned (SQLSTATE 01598).

On activation, the data in the usage list is removed and collection starts from the beginning of the list.

INACTIVE
Indicates that the usage list is deactivated for monitoring. If the state of a usage list is already set to INACTIVE then this keyword is ignored. If the state of the usage list for a partitioned table or index is set to INACTIVE, then the state of the usage list for each data partition is set to INACTIVE. If the state is already INACTIVE then this keyword is ignored. Similarly, in a partitioned database environment or Db2 pureScale environment, the state of the usage list for each member is set to INACTIVE. If the state is already INACTIVE then this keyword is ignored.

Data collected in the list is not removed when the state of the usage list is set to INACTIVE.

RELEASED
Indicates that the memory associated with a usage list is released. If the state of the usage list for a partitioned table or index is set to RELEASED, then the memory associated with each data partition is released. In a partitioned database environment or Db2 pureScale environment, the memory associated with each member is released.

Notes

- ***Determining current state***: The current state of a usage list is determined by using the MON_GET_USAGE_LIST_STATUS built-in function.
- ***Considerations for Db2 pureScale or partitioned database environments***: If a usage list for a partitioned table or index is activated, memory is allocated for each data partition. Similarly, in a partitioned database environment or Db2 pureScale environment, memory is allocated at each active member.
- ***Memory allocation for unavailable members***: If a member is unavailable at the time of activation, then the memory associated with the usage list for this member is allocated when the member is next activated (if the state of the usage list is still active). This also applies when a member is added to the cluster.
- ***Memory allocation for data partitions that are being added or attached***: For data partitions that are being added or attached, the memory associated with the usage list for this newly added or attached data partition is allocated when the next section that references the partitioned table or index is executed.
- ***Setting INACTIVE independently***: If the usage list was created with the property, WHEN FULL DEACTIVATE, then the state of the usage list for each data partition or member is set to INACTIVE independently.
- ***Implicit reactivation of an active usage list***: If the state of an INACTIVE ON START DATABASE usage list is set to ACTIVE in a partitioned database environment or Db2 pureScale environment, then its behavior is similar to ACTIVE ON START DATABASE until the usage list is explicitly deactivated or the instance is recycled. That is, if state of the usage list is active when a database member is deactivated or offline, and that database member is subsequently reactivated, the usage list for this member is implicitly reactivated.
- ***Definition of released state***: A usage list is considered to be in the released state if it is defined and has not been activated (explicitly or automatically) or has been released using the SET USAGE LIST STATE

statement. Usage lists in the state released are not returned by the MON_GET_USAGE_LIST_STATUS table function.

- ***Activation pending, active, and failed states***: If a usage list is activated (explicitly or automatically) then the state of the usage list is set to activation pending and the memory is allocated when the table or index is first referenced by the section. At this point the state of the usage list is set to active. If the memory for the usage list cannot be allocated, then the state of the usage list is set to failed and it must be explicitly activated using the SET USAGE LIST STATE statement.
- ***Inactive usage lists remain inactive upon database member reactivation***: If the state of an ACTIVE ON START DATABASE usage list is set to INACTIVE in a partitioned database environment or Db2 pureScale environment, then its behavior is similar to INACTIVE ON START DATABASE until the usage list is explicitly activated or the instance is recycled. That is, if the state of a usage list is inactive when a database member is deactivated or offline, and that database member is subsequently reactivated, the state of the usage list for this member will remain inactive.
- ***Activating, deactivating, or releasing a usage list for a partitioned table or index***: If a usage list for a partitioned table or index is activated, deactivated, or released then the state change applies to each data partition. Similarly, in a partitioned database environment or Db2 pureScale environment, the state change applies to each member.
- ***Usage list size considerations***: When activated, the memory associated with the usage list is allocated from the monitor heap. At the maximum list size setting, the usage list is approximately 2MB. For partitioned tables or indexes, memory is allocated for each data partition. For example, if a partitioned table has three data partitions defined, the total memory allocated is approximately 6MB. Therefore, activating multiple usage lists imposes more memory requirements on the monitor heap. It is therefore suggested that a reasonable list size is selected or that you set the **mon_heap_sz** configuration parameter to AUTOMATIC so that the database manager manages the monitor heap size.
- ***Data collection when a usage list is set to INACTIVE***: Data collected in the list is not removed when the state of the usage list is set to INACTIVE.
- ***Data access and memory***: The data in the list is still accessible (using MON_GET_TABLE_USAGE_LIST and MON_GET_INDEX_USAGE_LIST table functions) provided that the memory for the list is allocated.
- ***Releasing memory***: The memory associated with the usage list is released when one of the following events occurs:
  - The usage list is dropped.
  - The table or index on which the usage list is defined is dropped. The memory that is associated with the usage is released for all data partitions. In a partitioned database environment or Db2 pureScale environment, the memory that is associated with the usage list is released for all active members.
  - When a data partition is detached from a partitioned table or index. Only the memory associated with the data partition is released.
  - When a database member is deactivated. Only the memory associated with the member is released.
  - When the entire instance or database is deactivated. Usage list data does not persist when the database is deactivated and restarted.
  - When memory associated with the usage list is explicitly released using the SET USAGE LIST STATE statement.

SET variable

The SET variable statement assigns values to variables.

This statement is not under transaction control.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared.

Authorization

To reference a transition variable, the privileges held by the authorization ID of the trigger creator must include at least one of the following authorities:

- UPDATE privilege on any columns referenced on the left side of the assignment or UPDATEIN privilege on the schema containing the tables having the columns referenced on the left side of the assignment
- SELECT privilege on any columns referenced on the right side or SELECTIN privilege on the schema containing the tables having the columns referenced on the right side
- CONTROL privilege on the table (subject table of the trigger)
- DATAACCESS authority on the schema containing the table
- DATAACCESS authority

If a global variable is referenced in the right side of the assignment statement, the privileges held by the authorization ID of the statement must include one of the following authorities:

- READ privilege on the global variable that is not defined in a module
- EXECUTE privilege on the module of the global variable that is defined in a module
- EXECUTEIN privilege on the schema containing the module of the global variable that is defined in a module
- DATAACCESS authority on the schema containing the module of the global variable that is defined in a module

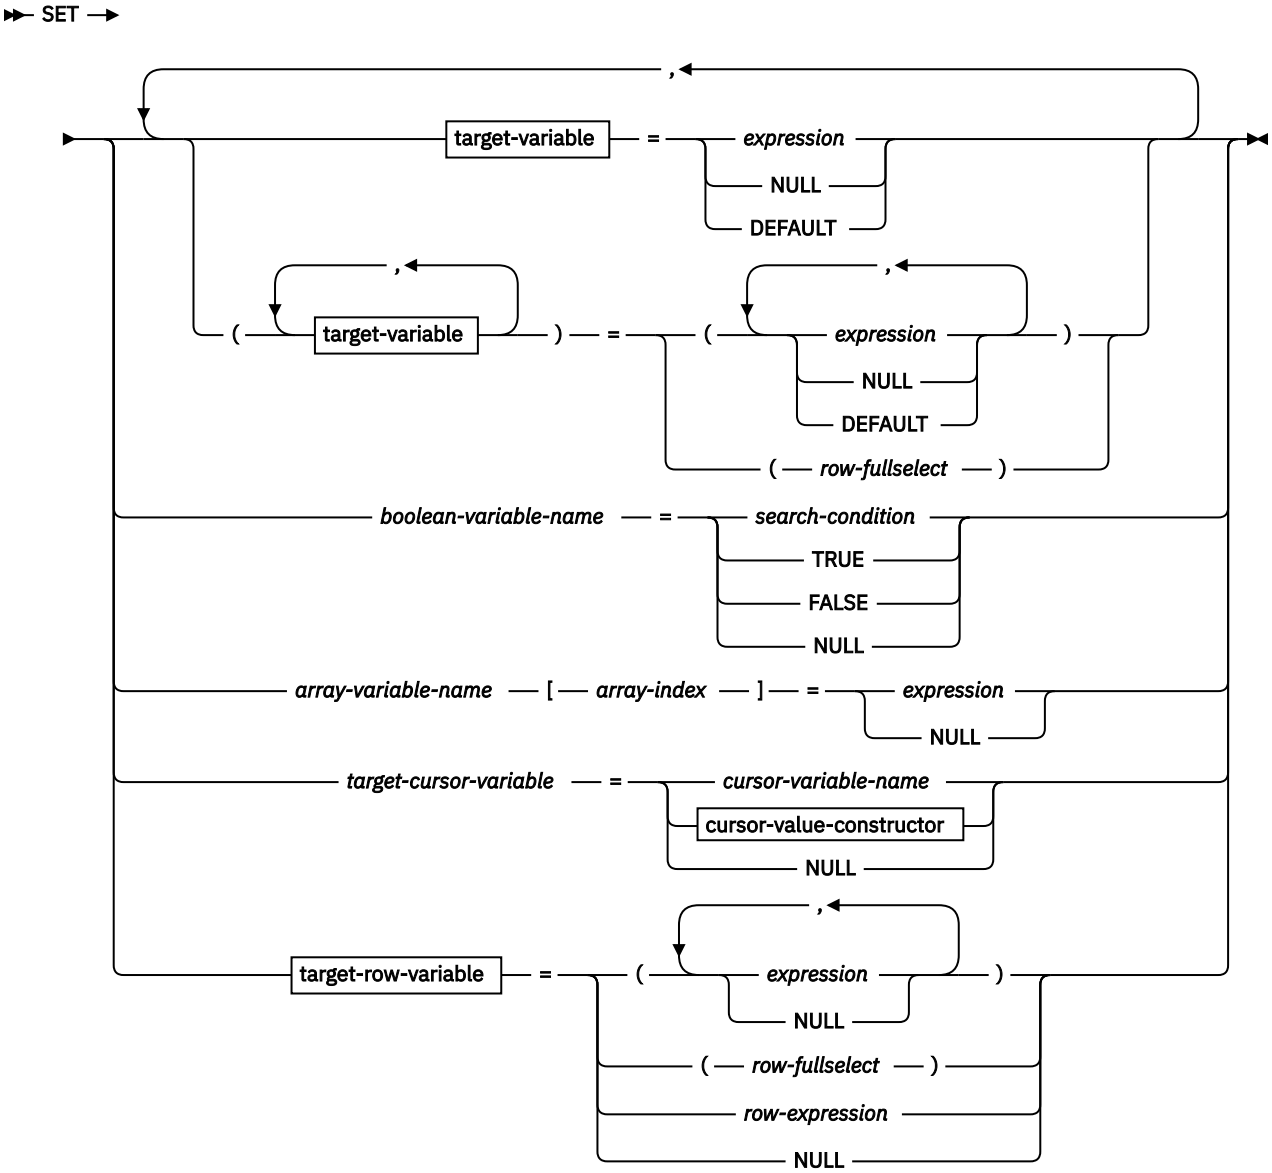
If a global variable is assigned a value in the left side of the assignment statement, the privileges held by the authorization ID of the statement must include one of the following authorities:

- WRITE privilege on the global variable that is not defined in a module
- EXECUTE privilege on the module of the global variable that is defined in a module
- EXECUTEIN privilege on the schema containing the module of the global variable that is defined in a module
- DATAACCESS authority on the schema containing the module of the global variable that is defined in a module

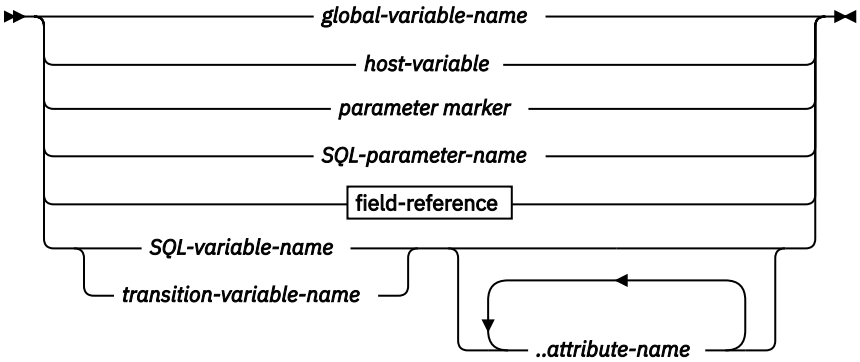
To execute this statement with a *row-fullselect* as the right side of the assignment, the privileges held by the authorization ID of the statement must include the privileges necessary to execute the *row-fullselect*. See the Authorization section in "SQL queries".

To execute this statement with a *cursor-value-constructor* that uses a *select-statement*, the privileges held by the authorization ID of the statement must include the privileges necessary to execute the *select-statement*. See the Authorization section in "SQL queries".

Syntax

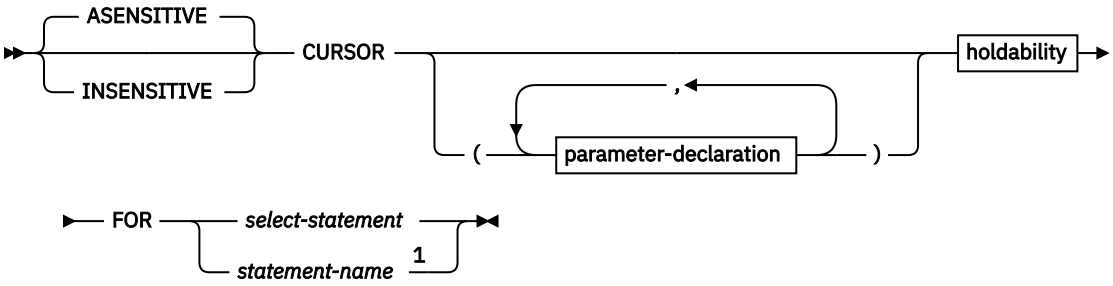


target-variable



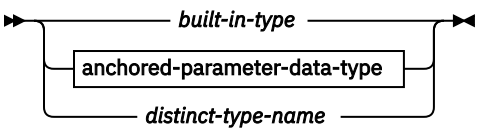
field-reference

cursor-value-constructor

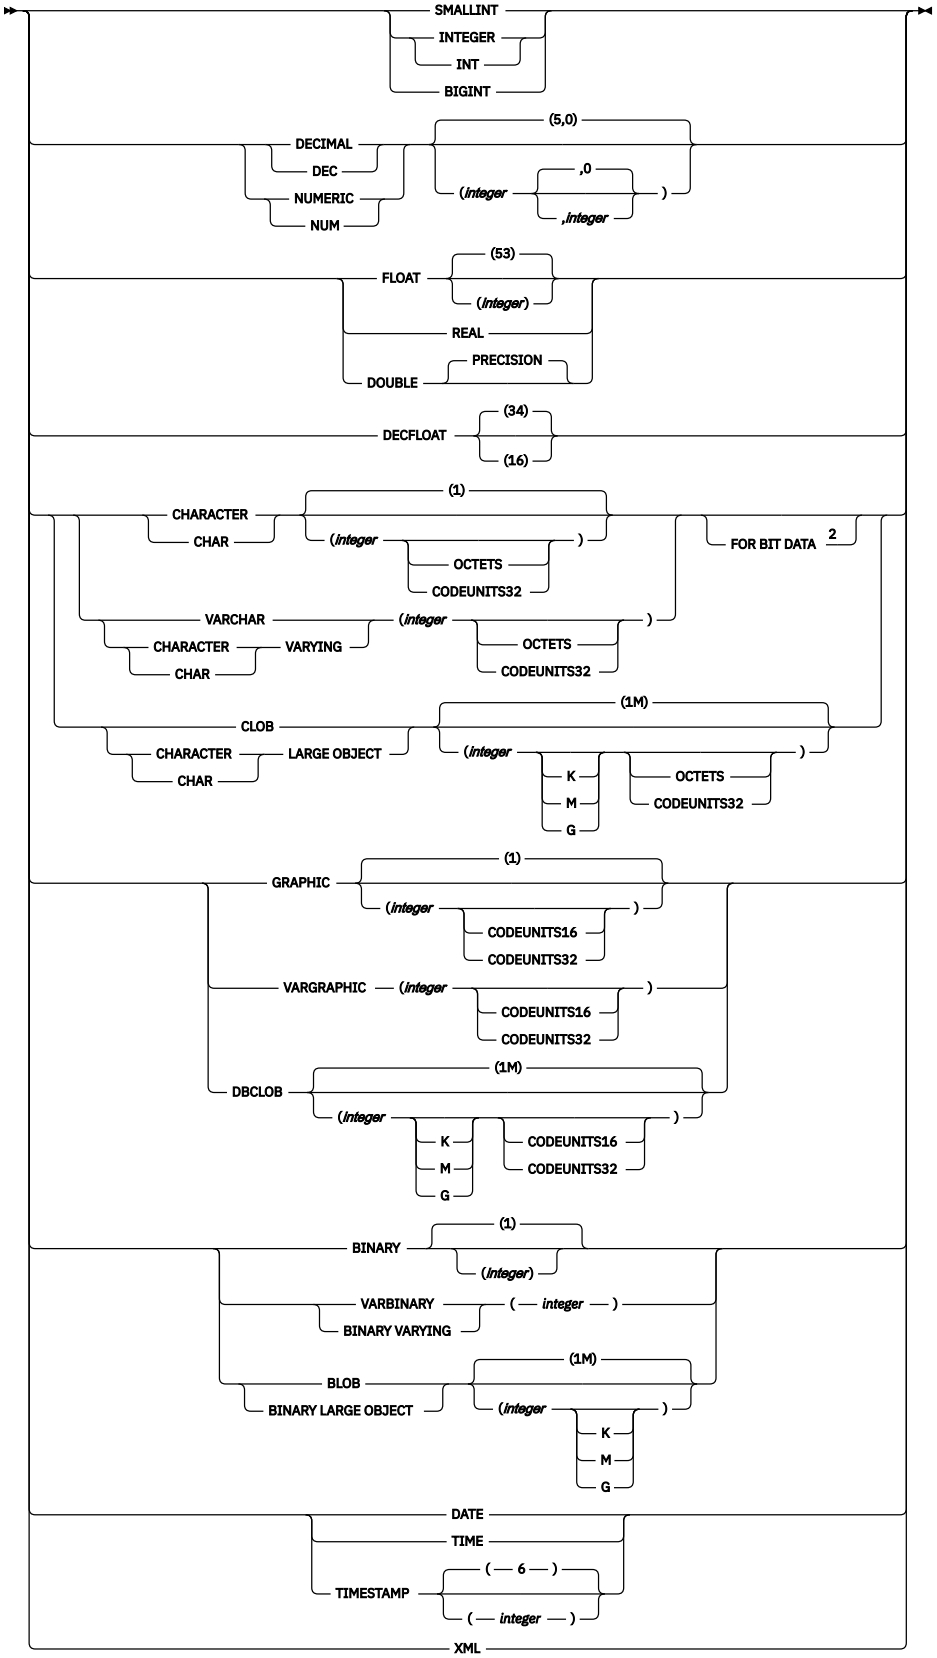


parameter-declaration

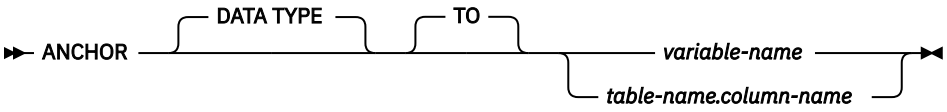
data-type



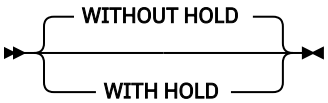
built-in-type



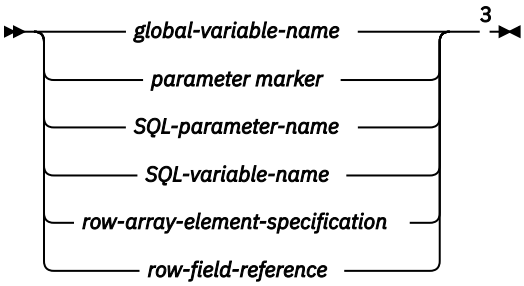
anchored-parameter-data-type



holdability



target-row-variable



Notes:

[1] *statement-name* cannot be specified if *parameter-declaration* is specified.

[2] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

[3] The data type must be a row type.

Description

target-variable

Identifies the target variable of the assignment. A *target-variable* representing the same variable must not be specified more than once (SQLSTATE 42701).

global-variable-name

Identifies the global variable that is the assignment target. The *global-variable-name* must identify a global variable that exists at the current server (SQLSTATE 42704).

host-variable

Identifies the host variable that is the assignment target.

parameter-marker

Identifies the parameter marker that is the assignment target.

SQL-parameter-name

Identifies the parameter that is the assignment target. The parameter must be specified in *parameter-declaration* in the CREATE PROCEDURE statement.

field-reference

Identifies the field within a row type value that is the assignment target.

row-variable-name

The name of a variable with a data type that is a row type.

field-name

The name of a field within the row type.

SQL-variable-name

Identifies the SQL variable that is the assignment target. SQL variables must be declared before they are used.

transition-variable-name
Identifies the column to be updated in the transition row. A *transition-variable-name* must identify a column in the subject table of a trigger, optionally qualified by a correlation name that identifies the new value (SQLSTATE 42703).

..attribute-name
Specifies the attribute of a structured type that is set (referred to as an *attribute assignment*). The *SQL-variable-name* or *transition-variable-name* specified must be defined with a user-defined structured type (SQLSTATE 428DP). The *..attribute-name* must be an attribute of the structured type (SQLSTATE 42703). An assignment that does not involve the *..attribute-name* clause is referred to as a *conventional assignment*.

expression
Indicates the new value of the target of the assignment. The expression is any expression of the type described in "Expressions". The expression cannot include an aggregate function except when it occurs within a scalar fullselect (SQLSTATE 42903). In the context of a CREATE TRIGGER statement, an *expression* can contain references to OLD and NEW transition variables. The transition variables must be qualified by the *correlation-name* (SQLSTATE 42702).

NULL
Specifies the null value. If the target of the assignment is a row variable, each field is assigned the null value. NULL cannot be the value in an attribute assignment unless it was specifically cast to the data type of the attribute (SQLSTATE 429B9).

DEFAULT
Specifies that the default value should be used.

In SQL procedures, the DEFAULT clause can be specified only for static SQL statements. The exception is that the DEFAULT clause can be specified when *target-variable* is a global variable in a dynamic SQL statement.

If *target-variable* is a column, the value inserted depends on how the column was defined in the table.

- If the column was defined using the WITH DEFAULT clause, the value is set to the default defined for the column (see *default-clause* in "ALTER TABLE").
- If the column was defined using the IDENTITY clause, the value is generated by the database manager.
- If the column was defined without specifying the WITH DEFAULT clause, the IDENTITY clause, or the NOT NULL clause, the value is NULL.
- If the column was defined using the NOT NULL clause and:
  - The IDENTITY clause is not used or
  - The WITH DEFAULT clause was not used or
  - DEFAULT NULL was used

  the DEFAULT keyword cannot be specified for that column (SQLSTATE 23502).

If *target-variable* is an SQL variable, the value inserted is the default, as specified or implied in the variable declaration.

If *target-variable* is a global variable, the value inserted is the default, as specified in the variable creation.

If *target-variable* is an SQL variable or an SQL parameter in an SQL procedure, a host variable, or a parameter marker, the DEFAULT keyword cannot be specified (SQLSTATE 42608).

row-fullselect
A fullselect that returns a single row with the number of columns corresponding to the number of target variables or fields in the row variable specified for assignment. The values are assigned to each corresponding target variable or field. If the result of the row fullselect is no rows, null values are assigned to the target variables in the list or, in an assignment to a row variable, a single null is assigned. In the context of a CREATE TRIGGER statement, a *row-fullselect* can contain references to OLD and NEW transition variables, which must be qualified by their *correlation-name* to specify which

transition variable is to be used (SQLSTATE 42702). An error is returned if there is more than one row in the result (SQLSTATE 21000).

boolean-variable-name
Identifies an SQL variable or parameter or a global variable. The variable or parameter must be of Boolean type (SQLSTATE 428H0). The SET statement must be issued within a compound SQL (compiled) statement (SQLSTATE 428H2).

search-condition
A search condition whose result is true, false, or unknown. A result of unknown is returned as the Boolean value NULL.

TRUE
Specifies the Boolean value TRUE.

FALSE
Specifies the Boolean value FALSE.

NULL
Specifies the Boolean value NULL.

array-variable-name
Identifies an SQL variable, SQL parameter, or global variable of an array type (SQLSTATE 428H0).

[*array-index*]
An expression that specifies which element in the array will be the target of the assignment. For an ordinary array, the array-index must be assignable to INTEGER (SQLSTATE 22018 or 428H1). Its value must be between 1 and the maximum cardinality defined for the array and cannot be the null value (SQLSTATE 2202E).

For an associative array, the array index expression must be assignable to the index data type of the associative array (SQLSTATE 22018 or 428H1) and cannot be the null value (SQLSTATE 2202E).

target-cursor-variable
Identifies a cursor variable. The data type of *target-cursor-variable* must be a cursor type (SQLSTATE 42821).

cursor-variable-name
Identifies a cursor variable of the same cursor type as *target-cursor-variable*.

cursor-value-constructor
A *cursor-value-constructor* specifies the *select-statement* that is associated with the target variable. The assignment of a *cursor-value-constructor* to a cursor variable defines the underlying cursor of that cursor variable.

ASENSITIVE or INSENSITIVE
Specifies whether the cursor is asensitive or insensitive to changes. See "DECLARE CURSOR" for more information. The default is ASENSITIVE.

ASENSITIVE
Specifies that the cursor should be as sensitive as possible to inserts, updates, or deletes made to the rows underlying the result table, depending on how the *select-statement* is optimized. ASENSITIVE is the default.

INSENSITIVE
Specifies that the cursor does not have sensitivity to inserts, updates, or deletes that are made to the rows underlying the result table. If INSENSITIVE is specified, the cursor is read-only and the result table is materialized when the cursor is opened. As a result, the size of the result table, the order of the rows, and the values for each row do not change after the cursor is opened. The SELECT statement cannot contain a FOR UPDATE clause, and the cursor cannot be used for positioned updates or deletes.

(parameter-declaration, ...)
Specifies the input parameters of the cursor, including the name and the data type of each parameter. Named input parameters can be specified only if *select-statement* is also specified in *cursor-value-constructor* (SQLSTATE 428HU).

parameter-name
Names the cursor parameter for use as an SQL variable within *select-statement*. The name cannot be the same as any other parameter name for the cursor. Names should also be chosen to avoid any column names that could be used in *select-statement*, since column names are resolved before parameter names.

data-type
Specifies the data type of the cursor parameter used within *select-statement*. Structured types, and reference types cannot be specified (SQLSTATE 429BB).

built-in-type
Specifies a built-in data type. For a more complete description of each built-in data type, see "CREATE TABLE".

anchored-parameter-data-type
Identifies another object used to determine the data type of the cursor parameter. The data type of the anchor object is bound by the same limitations that apply when specifying the data type directly.

ANCHOR DATA TYPE TO
Indicates an anchored data type is used to specify the data type.

variable-name
Identifies a local SQL variable, an SQL parameter, or a global variable. The data type of the referenced variable is used as the data type for the cursor parameter.

table-name.column-name
Identifies a column name of an existing table or view. The data type of the column is used as the data type for the cursor parameter.

distinct-type-name
Specifies the name of a distinct type. If *distinct-type-name* is specified without a schema name, the distinct type is resolved by searching the schemas in the SQL path.

holdability
Specifies whether the cursor is prevented from being closed as a consequence of a commit operation. See "DECLARE CURSOR" for more information. The default is WITHOUT HOLD.

WITHOUT HOLD
Does not prevent the cursor from being closed as a consequence of a commit operation.

WITH HOLD
Maintains resources across multiple units of work. Prevents the cursor from being closed as a consequence of a commit operation.

select-statement
Specifies the SELECT statement of the cursor. See "select-statement" for more information. If *parameter-declaration* is included in *cursor-value-constructor*, then *select-statement* must not include any local SQL variables or routine SQL parameters (SQLSTATE 42704).

statement-name
Specifies the prepared *select-statement* of the cursor. See "PREPARE" for an explanation of prepared statements. The target cursor variable must not have a data type that is a strongly-typed user-defined cursor type (SQLSTATE 428HU). Named input parameters must not be specified in *cursor-value-constructor* if *statement-name* is specified (SQLSTATE 428HU).

target-row-variable
Identifies the target row variable of the assignment. The data type must be of a row type.

row-expression
Specifies the new row value for the target of the assignment. It can be any row expression of the type described in "Row expression". The number of fields in the row must match the target of the assignment and each field in the row must be assignable to the corresponding field in the target of the assignment. If the source and the target values are a user-defined row type, the type names must be the same (SQLSTATE 42821).

Rules

- The number of values to be assigned from expressions, NULLs, DEFAULTs, or the *row-fullselect* must match the number of *target-variables* specified for assignment (SQLSTATE 42802).
- A SET variable statement cannot assign an SQL variable and a transition variable in one statement (SQLSTATE 42997).
- Global variables cannot be assigned inside triggers that are not defined using a compound SQL (compiled) statement, functions that are not defined using a compound SQL (compiled) statement, methods, or compound SQL (inlined) statements (SQLSTATE 428GX).
- If the value being assigned is an array resulting from an array constructor or from ARRAY_AGG, the base types of the array and of the target variable must be identical (SQLSTATE 42821).
- ***Use of anchored data types:*** An anchored data type cannot refer to the following objects (SQLSTATE 428HS): a nickname, typed table, typed view, statistical view that is associated with an expression-based index, declared temporary table, row definition that is associated with a weakly typed cursor, object with a code page or collation that is different from the database code page or database collation.
- ***Assignments involving cursor variables:*** Assignments that reference a cursor variable that set it to the value of a cursor value constructor can only be used in compound SQL (compiled) statements. Any OPEN statement using a cursor variable must occur within the same scope as the assignment (SQLSTATE 51044).

Notes

- Values are assigned to target variables according to specific assignment rules.
- ***Assignment statement in SQL procedures:*** Assignment statements in SQL procedures must conform to the SQL assignment rules. String assignments use retrieval assignment rules.
- ***Assignments of array elements:*** If the assignment is of the form `SET A[idx] = rhs`, where A is an array variable name, `idx` is an expression used as the array-index, and `rhs` is an expression of the same type as the array element, then:

  1. If array A is the null value, set A to the empty array.
  2. Let C be the cardinality of array A.
  3. If A is an ordinary array:
     - If `idx` is less than or equal to C, the value in the position identified by `idx` is replaced by the value of `rhs`.
     - If `idx` is greater than C, then:
       - The value in position *i*, for *i* greater than C and less than `idx`, is set to the null value.
       - The value in position `idx` is set to the value of `rhs`.
       - The cardinality of A is set to `idx`.
  4. If A is an associative array:
     - If `idx` matches an existing array index value, the element value with array index `idx` is replaced by the value of `rhs`.
     - If `idx` does not match any existing array index value, then:
       - The cardinality of A is incremented by `1`
       - The new element value is set to `rhs` with associated array index value `idx`.
  5. If `idx` is less than or equal to C, the value in the position identified by `idx` is replaced by the value of `rhs`.
  6. If `idx` is greater than C, then:
     a. The value in position *i*, for *i* greater than C and less than `idx`, is set to the null value.
     b. The value in position `idx` is set to the value of `rhs`.
     c. The cardinality of A is set to `idx`.

- If a variable has been declared with an identifier that matches the name of a special register (such as PATH), the variable must be delimited to prevent unintentional assignment to the special register (for example, `SET "PATH" = 1;` for a variable called PATH that has been declared as an integer).
- If more than one assignment is included, each *expression* and *row-fullselect* is evaluated before the assignments are performed. Thus, references to target variables in an expression or row fullselect are always the value of the target variable before any assignment in the single SET statement.
- When an identity column defined as a distinct type is updated, the entire computation is done in the source type, and the result is cast to the distinct type before the value is actually assigned to the column. (There is no casting of the previous value to the source type before the computation.)
- To have the database manager generate a value on a SET statement for an identity column, use the DEFAULT keyword:

```
SET NEW.EMPNO = DEFAULT
```

  In this example, NEW.EMPNO is defined as an identity column, and the value used to update this column is generated by the database manager.
- For more information about consuming values of a generated sequence for an identity column, and for information about exceeding the maximum value for an identity column, see "INSERT".

Examples

- *Example 1:* Set the salary column of the row for which the trigger action is currently executing to 50000.

```
SET NEW_VAR.SALARY = 50000;
```

  Or:

```
SET (NEW_VAR.SALARY) = (50000);
```

- *Example 2:* Set the salary and the commission column of the row for which the trigger action is currently executing to 50000 and 8000, respectively.

```
SET NEW_VAR.SALARY = 50000, NEW_VAR.COMM = 8000;
```

  Or:

```
SET (NEW_VAR.SALARY, NEW_VAR.COMM) = (50000, 8000);
```

- *Example 3:* Set the salary and the commission column of the row for which the trigger action is currently executing to the average salary and commission of employees in the department that is associated with the updated row.

```
SET (NEW_VAR.SALARY, NEW_VAR.COMM)
   = (SELECT AVG(SALARY), AVG(COMM)
        FROM EMPLOYEE E
        WHERE E.WORKDEPT = NEW_VAR.WORKDEPT);
```

- *Example 4:* Set the salary and the commission column of the row for which the trigger action is currently executing to 10000 and the original value of salary (that is, before the SET statement was executed), respectively.

```
SET NEW_VAR.SALARY = 10000, NEW_VAR.COMM = NEW_VAR.SALARY;
```

  Or:

```
SET (NEW_VAR.SALARY, NEW_VAR.COMM) = (10000, NEW_VAR.SALARY);
```

- *Example 5:* Increase the SQL variable P_SALARY by 10 percent.

```
SET P_SALARY = P_SALARY + (P_SALARY * .10)
```

- *Example 6:* Set the SQL variable P_SALARY to the null value.

```
SET P_SALARY = NULL
```

- *Example 7:* Assign numbers 2.71828183 and 3.1415926 to the first and tenth elements of the array variable SPECIALNUMBERS. After the first assignment, the cardinality of P_PHONENUMBERS is 1. After the second assignment, the cardinality is 10, and elements 2 to 9 have been implicitly assigned the null value.

```
SET SPECIALNUMBERS[1] = 2.71828183;

SET SPECIALNUMBERS[10] = 3.14159265;
```

- *Example 8:* Given a table named SECURITY.USERS, which has a row for every user that could connect to the database, assign the current time and the authorization level to the global variables USERINFO.GV_CONNECT_TIME and USERINFO.GV_AUTH_LEVEL, respectively.

```
SET USERINFO.GV_CONNECT_TIME = CURRENT TIMESTAMP,
  USERINFO.GV_AUTH_LEVEL = (
    SELECT AUTHLEVEL FROM SECURITY.USERS
      WHERE USERID = CURRENT USER)
```

- *Example 9:* Assign values to associative array variable, CAPITALS, which has been declared as the array type CAPITALSARRAY.

```
SET CAPITALS['British Columbia'] = 'Victoria';
SET CAPITALS['Alberta'] = 'Edmonton';
SET CAPITALS['Manitoba'] = 'Winnipeg';
SET CAPITALS['Canada'] = 'Ottawa';
```

  When populating the CAPITALS array, the array indexes are province, territory, and country names specified by strings and the associated array elements are capital cities, also specified by strings.

- *Example 10:* Assign easy to remember names as indexes for personal phone numbers stored in the array variable PHONELIST of array type PERSONAL_PHONENUMBERS.

```
SET PHONELIST['Home'] = '4163053745';
SET PHONELIST['Work'] = '4163053746';
SET PHONELIST['Mom']  = '4164789683';
```

SIGNAL

The SIGNAL statement is used to signal an error or warning condition. It causes an error or warning to be returned with the specified SQLSTATE, along with optional message text.

Invocation

This statement can be embedded in an:

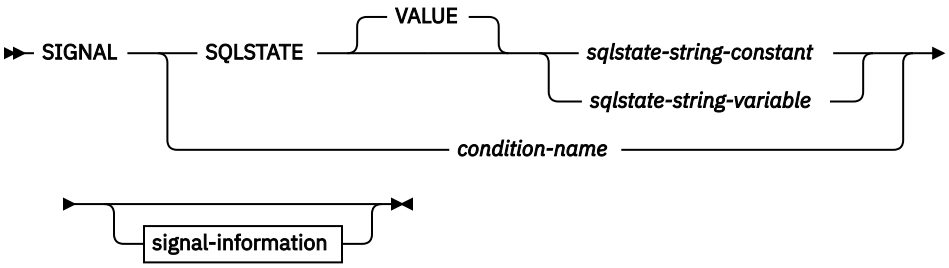
- SQL procedure definition
- Compound SQL (compiled) statement
- Compound SQL (inlined) statement

The compound statements can be embedded in an SQL procedure definition, SQL function definition, or SQL trigger definition. It is not an executable statement and cannot be dynamically prepared.

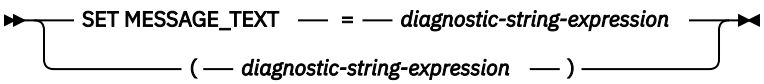
Authorization

If a module condition is referenced, the privileges held by the authorization ID of the statement must include EXECUTE privilege on the module or EXECUTEIN privilege or DATAACCESS authority on the schema containing the module.

Syntax



signal-information



Description

SQLSTATE VALUE

Specifies the SQLSTATE that will be returned. Any valid SQLSTATE value can be used. The specified value must follow the rules for SQLSTATEs:

- Each character must be from the set of digits ("0" through "9") or upper case letters ("A" through "Z") without diacritical marks
- The SQLSTATE class (first two characters) cannot be "00", since this represents successful completion.

In the context of a compound SQL (inlined) statement, a MERGE statement, or as the only statement in a trigger body, the following rules must also be applied:

- The SQLSTATE class (first two characters) cannot be "01" or "02", since these are not error classes.
- If the SQLSTATE class starts with the numbers "0" through "6" or the letters "A" through "H", then the subclass (the last three characters) must start with a letter in the range of "I" through "Z".
- If the SQLSTATE class starts with the numbers "7", "8", "9", or the letters "I" through "Z", then the subclass can be any of "0" through "9" or "A" through "Z".

If the SQLSTATE does not conform to these rules, an error is returned.

sqlstate-string-constant

The *sqlstate-string-constant* must be a character string constant with exactly 5 characters.

sqlstate-string-variable

The specified SQL variable or SQL parameter must be of data type CHAR(5) and must not be the null value.

condition-name

Specifies the name of a condition that will be returned. The condition-name must be declared within the compound-statement or identify a condition that exists at the current server (SQLSTATE 42373).

SET MESSAGE_TEXT =

Specifies a string that describes the error or warning. The string is returned in the SQLERRMC field of the SQLCA. If the actual string is longer than 70 bytes, it is truncated without warning.

diagnostic-string-expression

A literal string, or a local variable or parameter that describes the error condition. If the string is longer than 70 bytes, it is truncated.

(*diagnostic-string-expression*)

An expression of type CHAR or VARCHAR that returns a character string of up to 70 bytes to describe the error condition. If the string is longer than 70 bytes, it is truncated. This option is only provided within the scope of a CREATE TRIGGER statement for compatibility with previous versions of Db2. Regular use of this option is not recommended.

Notes

- If a SIGNAL statement is issued using a *condition-name* that has no associated SQLSTATE value and the condition is not handled, SQLSTATE 45000 is returned and the SQLCODE is set to -438. Note that such a condition will not be handled by a condition handler for SQLSTATE 45000 that is within the scope of the routine issuing the SIGNAL statement.
- If a SIGNAL statement is issued using an SQLSTATE value or a *condition-name* with an associated SQLSTATE value, the SQLCODE returned is based on the SQLSTATE value as follows:
  - If the specified SQLSTATE class is either "01" or "02", a warning or not found condition is returned and the SQLCODE is set to +438.
  - Otherwise, an exception condition is returned and the SQLCODE is set to -438.
- A SIGNAL statement has the indicated fields of the SQLCA set as follows:
  - `sqlerrd` fields are set to zero
  - `sqlwarn` fields are set to blank
  - `sqlerrmc` is set to the first 70 bytes of MESSAGE_TEXT
  - `sqlerrml` is set to the length of `sqlerrmc`, or to zero if no SET MESSAGE_TEXT clause is specified
  - `sqlerrp` is set to ROUTINE
- SQLSTATE values are composed of a two-character class code value, followed by a three-character subclass code value. Class code values represent classes of successful and unsuccessful execution conditions.

  Any valid SQLSTATE value can be used in the SIGNAL statement. However, it is recommended that programmers define new SQLSTATEs based on ranges reserved for applications. This prevents the unintentional use of an SQLSTATE value that might be defined by the database manager in a future release.
  - SQLSTATE classes that begin with the characters "7" through "9", or "I" through "Z" may be defined. Within these classes, any subclass may be defined.
  - SQLSTATE classes that begin with the characters "0" through "6", or "A" through "H" are reserved for the database manager. Within these classes, subclasses that begin with the characters "0" through "H" are reserved for the database manager. Subclasses that begin with the characters "I" through "Z" may be defined.

Example

An SQL procedure for an order system that signals an application error when a customer number is not known to the application. The ORDERS table includes a foreign key to the CUSTOMER table, requiring that the CUSTNO exist before an order can be inserted.

```
CREATE PROCEDURE SUBMIT_ORDER
  (IN ONUM INTEGER, IN CNUM INTEGER,
   IN PNUM INTEGER, IN QNUM INTEGER)
   SPECIFIC SUBMIT_ORDER
   MODIFIES SQL DATA
  LANGUAGE SQL
  BEGIN
    DECLARE EXIT HANDLER FOR SQLSTATE VALUE '23503'
      SIGNAL SQLSTATE '75002'
        SET MESSAGE_TEXT = 'Customer number is not known';
    INSERT INTO ORDERS (ORDERNO, CUSTNO, PARTNO, QUANTITY)
      VALUES (ONUM, CNUM, PNUM, QNUM);
  END
```

TRANSFER OWNERSHIP

The TRANSFER OWNERSHIP statement transfers ownership of a database object.

Invocation

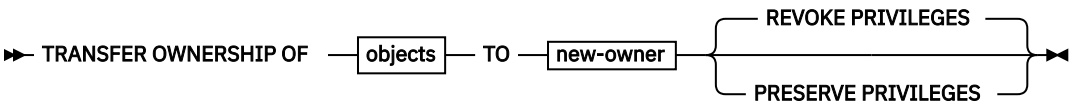
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

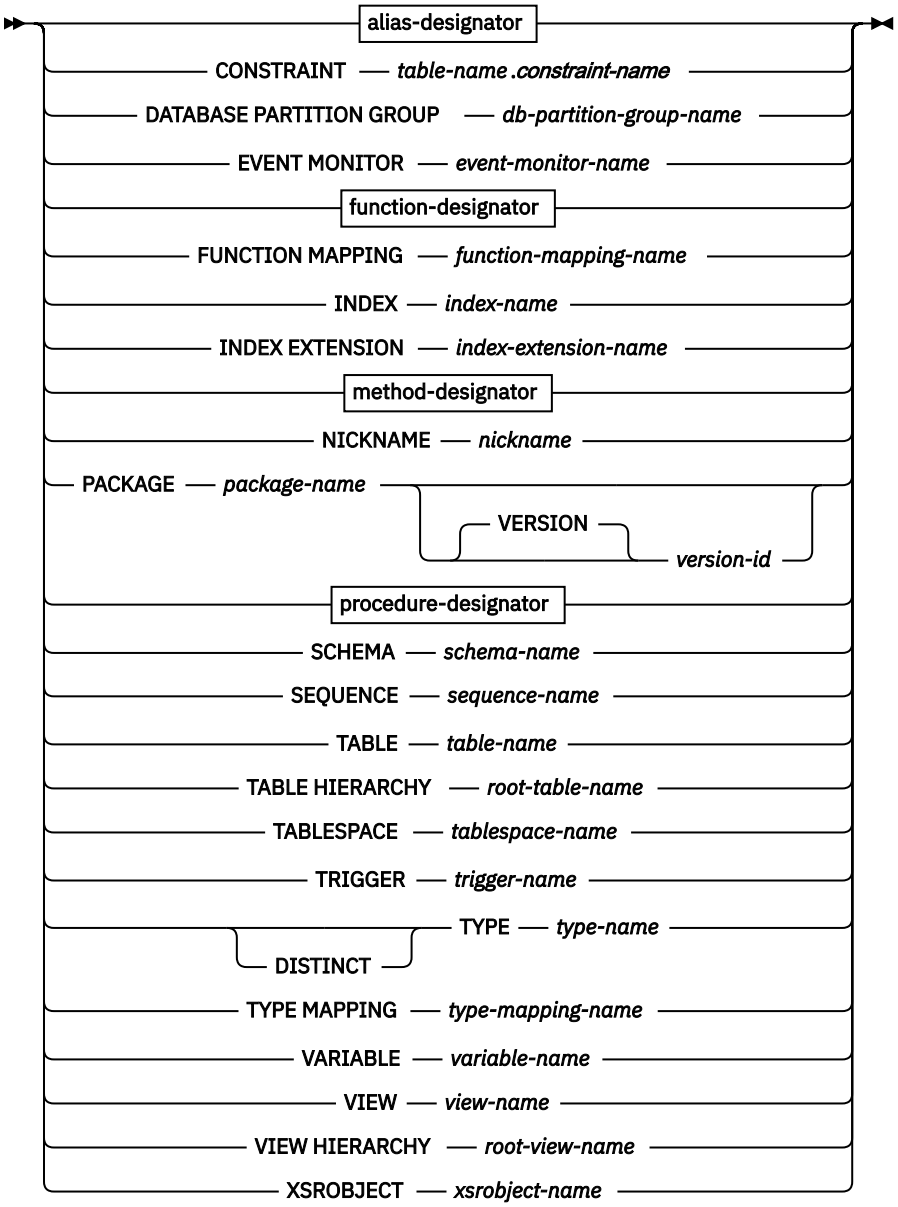
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- Ownership of the object
- SECADM authority

Syntax

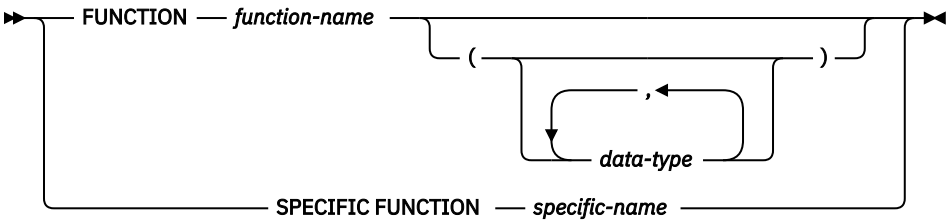


objects

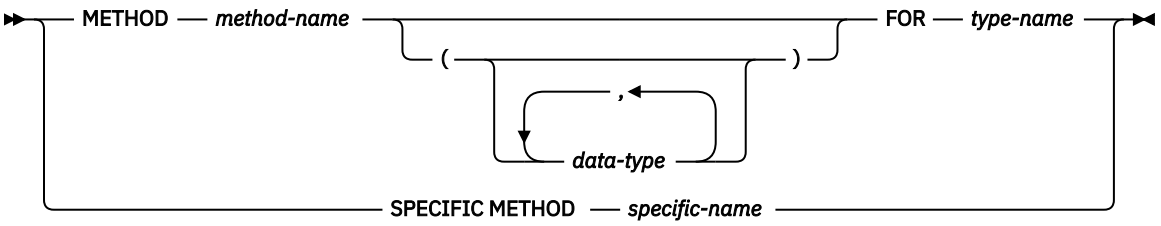


alias-designator

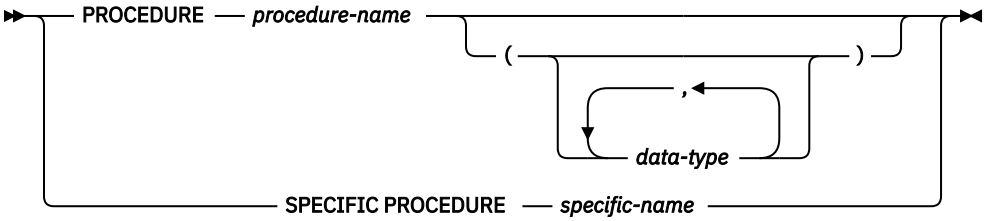
function-designator



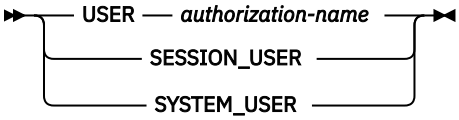
method-designator



procedure-designator



new-owner



Description

alias-designator

ALIAS *alias-name*
Identifies the alias that is to have its ownership transferred. The *alias-name* must identify an alias that is described in the catalog (SQLSTATE 42704). If PUBLIC is specified, the *alias-name* must identify a public alias that exists at the current server (SQLSTATE 42704).

FOR TABLE, or FOR SEQUENCE
Specifies the object type for the alias.

FOR TABLE
The alias is for a table, view, or nickname. When ownership of the alias is transferred, the value in the OWNER column for the alias in the SYSCAT.TABLES catalog view is replaced with the authorization ID of the new owner.

FOR SEQUENCE
The alias is for a sequence. When ownership of the alias is transferred, the value in the OWNER column for the alias in the SYSCAT.SEQUENCES catalog view is replaced with the authorization ID of the new owner.

CONSTRAINT *table-name.constraint-name*
Identifies the constraint that is to have its ownership transferred. The *table-name.constraint-name* combination must identify a constraint and the table that it constrains. The *constraint-name* must identify a constraint that is described in the catalog (SQLSTATE 42704).

When ownership of the constraint is transferred, the value in the OWNER column for the constraint in the SYSCAT.TABCONST catalog view is replaced with the authorization ID of the new owner.

- If the constraint is a FOREIGN KEY constraint, the OWNER column in the SYSCAT.REFERENCES catalog view is replaced with the authorization ID of the new owner.
- If the constraint is a PRIMARY KEY or UNIQUE constraint, the OWNER column in the SYSCAT.INDEXES catalog view for the index that was created implicitly for this constraint is replaced with the authorization ID of the new owner. If the index existed, and it is reused in this case, the owner of the index is not changed.

DATABASE PARTITION GROUP *db-partition-group-name*
Identifies the database partition group that is to have its ownership transferred. The *db-partition-group-name* must identify a database partition group that is described in the catalog (SQLSTATE 42704).

When ownership of the database partition group is transferred, the value in the OWNER column for the database partition group in the SYSCAT.DBPARTITIONGROUPS catalog view is replaced with the authorization ID of the new owner.

EVENT MONITOR *event-monitor-name*
Identifies the event monitor that is to have its ownership transferred. The *event-monitor-name* must identify an event monitor that is described in the catalog (SQLSTATE 42704).

When ownership of the event monitor is transferred, the value in the OWNER column for the event monitor in the SYSCAT.EVENTMONITORS catalog view is replaced with the authorization ID of the new owner.

If the identified event monitor is active, an error is returned (SQLSTATE 429BT).

If there are event files in the target path of a WRITE TO FILE event monitor whose ownership is being transferred, the event files are not deleted.

When ownership of WRITE TO TABLE event monitors is transferred, table information in the SYSCAT.EVENTTABLES catalog view is retained.

function-designator
Identifies the function that is to have its ownership transferred. For more information, see "Function, method, and procedure designators" on page 745. The specified function instance must be a user-defined function or function template that is described in the catalog. Ownership of functions that are implicitly generated by CREATE TYPE statements cannot be transferred (SQLSTATE 429BT).

When ownership of the function is transferred, the value in the OWNER column for the function in the SYSCAT.ROUTINES catalog view is replaced with the authorization ID of the new owner. Transferring ownership of an SQL function that has an associated package also implicitly transfers ownership of the package to the new owner.

SPECIFIC FUNCTION *specific-name*
Identifies the particular user-defined function that is to have its ownership transferred, using the specific name either specified or defaulted to at function creation time. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile or bind option implicitly specifies the qualifier for unqualified object names. The *specific-name* must identify a specific function instance in the named or implied schema; otherwise, an error is returned (SQLSTATE 42704).

When ownership of the specific function is transferred, the value in the OWNER column for the specific function in the SYSCAT.ROUTINES catalog view is replaced with the authorization ID of the new owner.

FUNCTION MAPPING *function-mapping-name*
Identifies the function mapping that is to have its ownership transferred. The *function-mapping-name* must identify a function mapping that is described in the catalog (SQLSTATE 42704).

When ownership of the function mapping is transferred, the value in the OWNER column for the function mapping in the SYSCAT.FUNCMAPPINGS catalog view is replaced with the authorization ID of the new owner.

INDEX *index-name*
Identifies the index or index specification that is to have its ownership transferred. The *index-name* must identify an index or index specification that is described in the catalog (SQLSTATE 42704).

When ownership of the index is transferred, the value in the OWNER column for the index in the SYSCAT.INDEXES catalog view is replaced with the authorization ID of the new owner.

Ownership of an index cannot be transferred if the table on which the index is defined is a global temporary table (SQLSTATE 429BT).

INDEX EXTENSION ***index-extension-name***
Identifies the index extension that is to have its ownership transferred. The *index-extension-name* must identify an index extension that is described in the catalog (SQLSTATE 42704).

When ownership of the index extension is transferred, the value in the OWNER column for the index extension in the SYSCAT.INDEXEXTENSIONS catalog view is replaced with the authorization ID of the new owner.

method-designator
Identifies the method that is to have its ownership transferred. For more information, see "Function, method, and procedure designators" on page 745. The method body specified must be a method that is described in the catalog (SQLSTATE 42704). The ownership of methods that are implicitly generated by the CREATE TYPE statement cannot be transferred (SQLSTATE 429BT).

When ownership of the method is transferred, the value in the OWNER column for the method in the SYSCAT.ROUTINES catalog view is replaced with the authorization ID of the new owner.

NICKNAME ***nickname***
Identifies the nickname that is to have its ownership transferred. The *nickname* must be a nickname that is described in the catalog (SQLSTATE 42704).

When ownership of the nickname is transferred, the value in the OWNER column for the nickname in the SYSCAT.TABLES catalog view is replaced with the authorization ID of the new owner.

PACKAGE ***package-name***
Identifies the package that is to have its ownership transferred. The package name must identify a package that is described in the catalog (SQLSTATE 42704).

VERSION ***version-id***
Identifies which package version is to have its ownership transferred. If a value is not specified, the version defaults to the empty string, and the ownership of this package is transferred. If multiple packages with the same package name but different versions exist, only the ownership of the package whose *version-id* is specified in the TRANSFER OWNERSHIP statement is transferred. Delimit the version identifier with double quotation marks when it:

- Is generated by the VERSION(AUTO) precompiler option
- Begins with a digit
- Contains lowercase or mixed-case letters

If the statement is invoked from an operating system command prompt, precede each double quotation mark delimiter with a back slash character to ensure that the operating system does not strip the delimiters.

When ownership of the package is transferred, the value in the BOUNDBY column for the package in the SYSCAT.PACKAGES catalog view is replaced with the authorization ID of the new owner.

The ownership of packages that are associated with SQL procedures, compiled SQL functions or compiled triggers cannot be transferred (SQLSTATE 429BT).

procedure-designator
Identifies the procedure that is to have its ownership transferred. For more information, see "Function, method, and procedure designators" on page 745. The procedure instance specified must be a procedure that is described in the catalog.

When ownership of the procedure is transferred, the value in the OWNER column for the procedure in the SYSCAT.ROUTINES catalog view is replaced with the authorization ID of the new owner.

Transferring ownership of an SQL procedure that has an associated package also implicitly transfers ownership of the package to the new owner.

SPECIFIC PROCEDURE ***specific-name***
Identifies the particular procedure that is to have its ownership transferred, using the specific name either specified or defaulted to at procedure creation time. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In

static SQL statements, the QUALIFIER precompile or bind option implicitly specifies the qualifier for unqualified object names. The *specific-name* must identify a specific procedure instance in the named or implied schema; otherwise, an error is returned (SQLSTATE 42704).

When ownership of the specific procedure is transferred, the value in the OWNER column for the specific procedure in the SYSCAT.ROUTINES catalog view is replaced with the authorization ID of the new owner.

SCHEMA *schema-name*
Identifies the schema that is to have its ownership transferred. The *schema-name* must identify a schema that is described in the catalog (SQLSTATE 42704).

When ownership of the schema is transferred, the value in the OWNER column and the DEFINER column for the schema in the SYSCAT.SCHEMATA catalog view is replaced with the authorization ID of the new owner.

Ownership of built-in schemas (where the definer is SYSIBM) cannot be transferred (SQLSTATE 42832).

SEQUENCE *sequence-name*
Identifies the sequence that is to have its ownership transferred. The *sequence-name* must identify a sequence that is described in the catalog (SQLSTATE 42704).

When ownership of the sequence is transferred, the value in the OWNER column for the schema in the SYSCAT.SEQUENCES catalog view is replaced with the authorization ID of the new owner.

TABLE *table-name*
Identifies the table that is to have its ownership transferred. The *table-name* must identify a table that exists in the database (SQLSTATE 42704) and must not identify a declared temporary table (SQLSTATE 42995).

When ownership of the table is transferred:

- The value in the OWNER column for the table in the SYSCAT.TABLES catalog view is replaced with the authorization ID of the new owner.
- The value in the OWNER column for all dependent objects on the table in the SYSCAT.TABDEP catalog view is replaced with the authorization ID of the new owner.

Ownership of subtables in a table hierarchy cannot be transferred (SQLSTATE 429BT).

In a federated system, ownership of a remote table that was created using transparent DDL can be transferred. Transferring the ownership of a remote table will not transfer ownership of the nickname that is associated with the table. Ownership of such a nickname can be transferred explicitly using the TRANSFER OWNERSHIP statement.

TABLE HIERARCHY *root-table-name*
Identifies the typed table that is the root table in a typed table hierarchy that is to have its ownership transferred. The *root-table-name* must identify a typed table that is the root table in the typed table hierarchy (SQLSTATE 428DR), and must refer to a typed table that exists in the database (SQLSTATE 42704).

When ownership of the table hierarchy is transferred:

- The value in the OWNER column for the root table and all of its subtables in the SYSCAT.TABLES catalog view is replaced with the authorization ID of the new owner.
- The value in the OWNER column for all dependent objects on the table and all of its subtables in the SYSCAT.TABDEP catalog view is replaced with the authorization ID of the new owner.

TABLESPACE *tablespace-name*
Identifies the table space that is to have its ownership transferred. The *tablespace-name* must identify a table space that is described in the catalog (SQLSTATE 42704).

When ownership of the table space is transferred, the value in the OWNER column for the table space in the SYSCAT.TABLESPACES catalog view is replaced with the authorization ID of the new owner.

TRIGGER *trigger-name*
Identifies the trigger that is to have its ownership transferred. The *trigger-name* must identify a trigger that is described in the catalog (SQLSTATE 42704).

When ownership of the trigger is transferred, the value in the OWNER column for the trigger in the SYSCAT.TRIGGERS catalog view is replaced with the authorization ID of the new owner. Transferring ownership of a compiled trigger also implicitly transfers ownership of the associated package to the new owner.

TYPE *type-name*
Identifies the user-defined type that is to have its ownership transferred. The *type-name* must identify a type that is described in the catalog (SQLSTATE 42704). If DISTINCT is specified, *type-name* must identify a distinct type that is described in the catalog (SQLSTATE 42704).

In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile or bind option implicitly specifies the qualifier for unqualified object names.

When ownership of the type is transferred, the value in the OWNER column for the type in the SYSCAT.DATATYPES catalog view is replaced with the authorization ID of the new owner.

TYPE MAPPING *type-mapping-name*
Identifies the user-defined data type mapping that is to have its ownership transferred. The *type-mapping-name* must identify a data type mapping that is described in the catalog (SQLSTATE 42704).

When ownership of the type mapping is transferred, the value in the OWNER column for the type mapping in the SYSCAT.TYPEMAPPINGS catalog view is replaced with the authorization ID of the new owner.

VARIABLE *variable-name*
Indicates that the object whose ownership is to be transferred is a created global variable. The *variable-name* must identify a global variable that exists at the current server (SQLSTATE 42704).

When the global variable is transferred, the value in the OWNER column for the global variable in the SYSCAT.VARIABLES catalog view is replaced with the authorization ID of the new owner.

VIEW *view-name*
Identifies the view that is to have its ownership transferred. The *view-name* must identify a view that exists in the database (SQLSTATE 42704).

When ownership of the view is transferred:

- The value in the OWNER column for the view in the SYSCAT.VIEWS catalog view is replaced with the authorization ID of the new owner.
- The value in the OWNER column for all dependent objects on the view in the SYSCAT.TABDEP catalog view is replaced with the authorization ID of the new owner.

The ownership of a subview in a view hierarchy cannot be transferred (SQLSTATE 429BT).

VIEW HIERARCHY *root-view-name*
Identifies the typed view that is the root view in a typed view hierarchy that is to have its ownership transferred. The *root-view-name* must identify a typed view that is the root view in the typed view hierarchy (SQLSTATE 428DR), and must refer to a typed view that exists in the database (SQLSTATE 42704).

When ownership of the view hierarchy is transferred:

- The value in the OWNER column for the root view and all of its subviews in the SYSCAT.VIEWS catalog view is replaced with the authorization ID of the new owner.
- The value in the OWNER column for all dependent objects on the view and all of its subviews in the SYSCAT.TABDEP catalog view is replaced with the authorization ID of the new owner.

XSROBJECT *xsrobject-name*
Identifies the XSR object that is to have its ownership transferred. The *xsrobject-name* must identify an XSR object that is described in the catalog (SQLSTATE 42704).

When ownership of the XSR object is transferred, the value in the OWNER column for the XSR object in the SYSCAT.XSROBJECTS catalog view is replaced with the authorization ID of the new owner.

USER *authorization-name*
Specifies the authorization ID to which ownership of the object is being transferred.

SESSION_USER
Specifies that the value of the SESSION_USER special register is to be used as the authorization ID to which ownership of the object is being transferred.

SYSTEM_USER
Specifies that the value of the SYSTEM_USER special register is to be used as the authorization ID to which ownership of the object is being transferred.

REVOKE PRIVILEGES
Indicates that the old owner of an object will lose all privileges on the object being transferred. This is the default option.

PRESERVE PRIVILEGES
Specifies that the current owner of an object that is to have its ownership transferred will continue to hold any existing privileges on the object after the transfer. For example, any privileges that were granted to the creator of a view when that view was created continue to be held by the original owner even after ownership has been transferred to another user.

Rules

- Ownership of most built-in objects (where the owner is SYSIBM) cannot be transferred (SQLSTATE 42832). However, you can transfer ownership of implicitly created schema objects that have SYSIBM in the OWNER column and do not have SYSIBM in the DEFINER column.
- Ownership of schemas whose name starts with 'SYS' cannot be transferred (SQLSTATE 42832).
- Ownership of the following objects cannot be explicitly transferred (SQLSTATE 429BT):
  - Subtables in a table hierarchy (they are transferred with the root hierarchy table)
  - Subviews in a view hierarchy (they are transferred with the root hierarchy view)
  - Indexes that are defined on global temporary tables
  - Methods or functions that are implicitly generated when a user-defined type is created
  - Module aliases and modules
  - Packages that depend on SQL procedures (they are transferred with the SQL procedure)
  - Event monitors that are active (they can be transferred when they are not active)
- An authorization ID that has SECADM authority cannot transfer the ownership of an object to itself, if it is not already the owner of the object (SQLSTATE 42502).
- Transfer of ownership on a variable or sequence with REVOKE PRIVILEGES will fail if any objects depend on the privileges being revoked (SQLSTATE 42893).
- Transfer of ownership on a function with REVOKE PRIVILEGES on a routine will fail if both of the following conditions are true (SQLSTATE 42893)
  - The specified routine is used in a view, trigger, constraint, index extension, SQL function, SQL method, transform group, or is referenced as the SOURCE of a sourced function.
  - The loss of the EXECUTE privilege would cause the owner of the view, trigger, constraint, index extension, SQL function, SQL method, transform group, or sourced function to no longer be able to execute the specified routine.
- Transfer of ownership on a module, table, view, nickname, or routine with REVOKE PRIVILEGES will cause any dependent view, MQT, function, trigger, and package to marked inoperative or invalid unless the old owner has the revoked privileges through a database authority or schema authority or through a group, role, or PUBLIC.

Notes

- All privileges that the current owner has that were granted as part of the creation of the object are transferred to the new owner. If the current owner has had a privilege on the object revoked, and that privilege was subsequently granted back, the privilege is not transferred. For implicitly created schema objects that have not already been transferred, the new owner is granted CREATEIN, DROPIN, and ALTERIN on the schema and can also grant only these privileges to other users.
- When the ownership of a database object is transferred, the new owner must have the set of privileges on the base objects, as indicated by the object's dependencies, that are required to maintain the object's existence unchanged. The new owner does not need the privileges required to create the object if those privileges are not required to maintain the object's existence.

  For example:

  – Consider a view with SELECT and INSERT dependencies on an underlying table. The privileges held by the new owner of the view must include at least SELECT (with or without the GRANT OPTION) and INSERT (with or without the GRANT OPTION) for the ownership transfer to be successful. If the dependencies were SELECT WITH GRANT OPTION and INSERT WITH GRANT OPTION, the privileges held by the new owner of the view must include at least SELECT WITH GRANT OPTION and INSERT WITH GRANT OPTION.
  – Consider a view with a dependency on a routine. The privileges held by the new owner of the view must include at least EXECUTE on the dependent routine.
  – Consider a trigger with a dependency on a table. The privileges held by the new owner of the trigger must include the same set of privileges on the table that are indicated by the trigger's dependencies. ALTER privilege on the table on which the trigger is defined is not required.

  The following table lists the catalog views that describe the objects on which other database objects depend.

Table 154. Catalog Views that Describe Objects on which Other Objects Depend

Database Object	**Catalog View**
CONSTRAINT	SYSCAT.CONSTDEP
FUNCTION	SYSCAT.ROUTINEDEP; SYSCAT.ROUTINES (for a sourced function)
INDEX	SYSCAT.INDEXDEP
INDEX EXTENSION	SYSCAT.INDEXEXTENSIONDEP
METHOD	SYSCAT.ROUTINEDEP
PACKAGE	SYSCAT.PACKAGEDEP
PROCEDURE	SYSCAT.ROUTINEDEP
TABLE	SYSCAT.TABDEP
TRIGGER	SYSCAT.TRIGDEP
VIEW	SYSCAT.TABDEP
XSROBJECT	SYSCAT.XSROBJECTDEP

  If ownership of a database object that depends on another object is to be transferred successfully, the new owner of the database object must hold certain privileges on the dependent object of that dependency:

  – If the dependent object is a sequence, the new owner must have the USAGE privilege on that sequence.
  – If the dependent object is a function, method, or procedure, the new owner must have the EXECUTE privilege on that function, method, or procedure.

  - If the dependent object is a package, the new owner must have the EXECUTE privilege on that package.
  - If the dependent object is an XSR object, the new owner must have the USAGE privilege on that XSR object.

  For any other dependent object of a dependency, use the TABAUTH column in the appropriate catalog view to determine what privileges the new owner must hold.
- If an attempt is made to transfer ownership of an object to its owner, a warning is returned (SQLSTATE 01676).
- Ownership of the following database objects cannot be transferred, because these objects have no owner: audit policies, buffer pools, roles, security labels, security label components, security policies, servers, transformation functions, trusted contexts, user mappings, and wrappers. Note that there is no OWNER column in the SYSCAT.AUDITPOLICIES, SYSCAT.BUFFERPOOLS, SYSCAT.CONTEXTS, SYSCAT.ROLES, SYSCAT.SECURITYLABELS, SYSCAT.SECURITYLABELCOMPONENTS, SYSCAT.SECURITYPOLICIES, SYSCAT.SERVERS, SYSCAT.TRANSFORMS, SYSCAT.USEROPTIONS, and SYSCAT.WRAPPERS catalog views.
- The schema name of an object whose ownership was transferred does not automatically change.
- ***Syntax alternatives***: For consistency with other SQL statements:
  - NODEGROUP can be specified in place of DATABASE PARTITION GROUP
  - SYNONYM can be specified in place of ALIAS

Examples

- *Example 1:* Transfer ownership of table T1 to PAUL.

```
TRANSFER OWNERSHIP OF TABLE WALID.T1
  TO USER PAUL PRESERVE PRIVILEGES
```

  The value in the OWNER column for the table WALID.T1 in the SYSCAT.TABLES catalog view is replaced with 'PAUL'. Paul is implicitly granted the following privileges on table WALID.T1 (assuming that the previous owner of the table did not lose any privileges on it): CONTROL and ALTER, DELETE, INDEX, INSERT, SELECT, UPDATE, REFERENCE (WITH GRANT OPTION).
- *Example 2:* Assume that JOHN creates tables T1 and T2, and that MIKE holds SELECT privilege on tables JOHN.T1 and JOHN.T2. MIKE creates view V1 that depends on tables JOHN.T1 and JOHN.T2. Transfer ownership of view V1 to HENRY, who has DBADM authority.

```
TRANSFER OWNERSHIP OF VIEW V1
  TO USER HENRY PRESERVE PRIVILEGES
```

  The value in the OWNER column for the view V1 in the SYSCAT.VIEWS catalog view is replaced with 'HENRY'. A new row is added to SYSCAT.TABAUTH with the following values: GRANTOR = 'SYSIBM', GRANTEE = 'HENRY', and TABNAME = 'V1'.
- *Example 3:* Assume that HENRY, who holds DBADM authority, creates a trigger TR1 that depends on table T1. Transfer ownership of trigger TR1 to WALID, who does not hold DBADM authority.

```
TRANSFER OWNERSHIP OF TRIGGER TR1
  TO USER WALID PRESERVE PRIVILEGES
```

  Ownership of the trigger is transferred successfully, even though Walid does not hold DBADM authority.
- *Example 4:* Assume that JOHN creates tables T1 and T2, and that MIKE holds SELECT privilege on table JOHN.T1 and CONTROL privilege on table JOHN.T2. PAUL holds SELECT privilege on tables JOHN.T1 and JOHN.T2. MIKE creates view V1 that depends on tables JOHN.T1 and JOHN.T2. The view has an

entry for the SELECT privilege in SYSCAT.TABAUTH and two SELECT dependencies in SYSCAT.TABDEP for tables JOHN.T1 and JOHN.T2. Transfer ownership of view V1 to PAUL, who is a regular user.

```
TRANSFER OWNERSHIP OF VIEW V1
  TO USER PAUL PRESERVE PRIVILEGES
```

Ownership of the view is transferred successfully, even though Paul does not hold CONTROL privilege on table JOHN.T2. Paul only needs SELECT privilege on tables JOHN.T1 and JOHN.T2 to maintain the view's existence. (The view only has SELECT privilege because Paul did not hold CONTROL privilege on both tables when the view was created and, as a result, he was not granted CONTROL on the view.) The value in the OWNER column for the view V1 in the SYSCAT.VIEWS catalog view is replaced with 'PAUL'. The value in the OWNER column for the view V1 in the SYSCAT.TABDEP catalog view is replaced with 'PAUL'. A new row is added to SYSCAT.TABAUTH with the following values: GRANTOR = 'SYSIBM', GRANTEE = 'PAUL', and TABNAME = 'V1'.

- *Example 5:* Assume that JOHN creates table T1, and that PUBLIC holds SELECT privilege on JOHN.T1. PAUL holds SELECT privilege on JOHN.T1 explicitly, and creates view V1 that depends on table JOHN.T1. Transfer ownership of view V1 to MIKE, who is not a DBADM, but who holds the required privileges to acquire view ownership through the special group PUBLIC.

  ```
  TRANSFER OWNERSHIP OF VIEW V1
    TO USER MIKE PRESERVE PRIVILEGES
  ```

  Ownership of the view is transferred successfully, because Mike holds SELECT privilege on table JOHN.T1 through PUBLIC. The value in the OWNER column for the view V1 in the SYSCAT.VIEWS catalog view is replaced with 'MIKE'. The value in the OWNER column for the view V1 in the SYSCAT.TABDEP catalog view is replaced with 'MIKE'. A new row is added to SYSCAT.TABAUTH with the following values: GRANTOR = 'SYSIBM', GRANTEE = 'MIKE', and TABNAME = 'V1'.
- *Example 6:* Similar to example 5, assume that JOHN creates table T1, and that role R1 holds SELECT privilege on JOHN.T1. PAUL holds SELECT privilege on JOHN.T1 explicitly, and creates view V1 that depends on table JOHN.T1. Transfer ownership of view V1 to MIKE, who is not a DBADM, but who holds the required privileges through membership in role R1 to acquire view ownership.

  ```
  TRANSFER OWNERSHIP OF VIEW V1
    TO USER MIKE PRESERVE PRIVILEGES
  ```

  Ownership of the view is transferred successfully, because Mike holds SELECT privilege on table JOHN.T1 through membership in role R1. The value in the OWNER column for the view V1 in the SYSCAT.VIEWS catalog view is replaced with 'MIKE'. The value in the OWNER column for the view V1 in the SYSCAT.TABDEP catalog view is replaced with 'MIKE'. A new row is added to SYSCAT.TABAUTH with the following values: GRANTOR = 'SYSIBM', GRANTEE = 'MIKE', and TABNAME = 'V1'.

TRUNCATE

The TRUNCATE statement deletes all of the rows from a table.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities for the table, and all subtables of a table hierarchy:

- DELETE privilege on the table to be truncated
- DELETEIN privilege on the schema containing the table
- CONTROL privilege on the table to be truncated

- DATAACCESS authority on the schema containing the table
- DATAACCESS authority

To ignore any DELETE triggers that are defined on the table, the privileges held by the authorization ID of the statement must include at least one of the following authorities for the table, and all subtables of a table hierarchy:

- ALTER privilege on the table
- ALTERIN privilege on the schema containing the table and all subtables of a table hierarchy
- CONTROL privilege on the table
- SCHEMAADM authority on the schema containing the table and all subtables of a table hierarchy
- DBADM authority

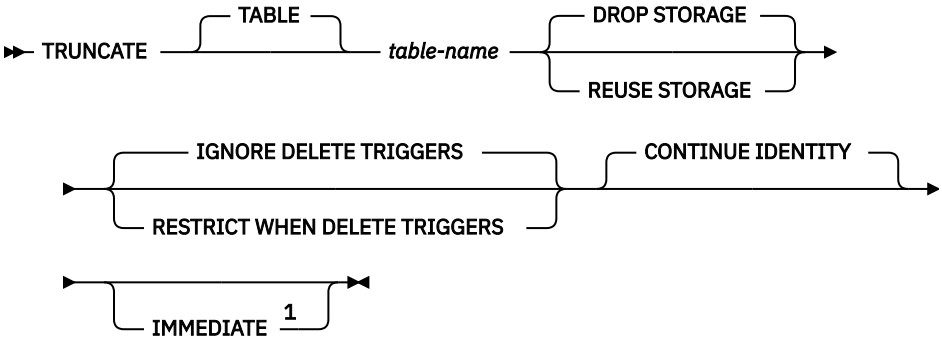
To truncate a table that is protected by a security policy, the privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CONTROL privilege on the table
- DBADM authority

To truncate a table that has row access control activated, the authorization ID of the statement must include at least one of the following authorities:

- CONTROL privilege on the table
- DBADM authority

Syntax



Notes:

[1] IMMEDIATE is optional only for column-organized tables.

Description

table-name
Identifies the table to be truncated. The name must identify a table that exists at the current server (SQLSTATE 42704), but it cannot be a catalog table (SQLSTATE 42832), a nickname (SQLSTATE 42809), a view, a subtable, a staging table, a system-maintained materialized query table, a system-period temporal table (SQLSTATE 428HZ), or a range-clustered table (SQLSTATE 42807).

If *table-name* is the root table of a table hierarchy, all tables in the table hierarchy will be truncated.

DROP STORAGE or REUSE STORAGE
Specifies whether to drop or reuse the existing storage that is allocated for the table. The default is DROP STORAGE.

DROP STORAGE
All storage allocated for the table is released and made available. If this option is specified (implicitly or explicitly), an online backup would be blocked.

REUSE STORAGE
All storage allocated for the table will continue to be allocated for the table, but the storage will be considered empty. This option is only applicable to tables in DMS table spaces and is ignored otherwise.

IGNORE DELETE TRIGGERS or RESTRICT WHEN DELETE TRIGGERS
Specifies what to do when delete triggers are defined on the table. The default is IGNORE DELETE TRIGGERS.

IGNORE DELETE TRIGGERS
Any delete triggers that are defined for the table are not activated by the truncation operation.

RESTRICT WHEN DELETE TRIGGERS
An error is returned if delete triggers are defined on the table (SQLSTATE 428GJ).

CONTINUE IDENTITY
If an identity column exists for the table, the next identity column value generated continues with the next value that would have been generated if the TRUNCATE statement had not been executed.

IMMEDIATE
Specifies that the truncate operation is processed immediately and cannot be undone. The statement must be the first statement in a transaction (SQLSTATE 25001).

The truncated table is immediately available for use in the same unit of work. Although a ROLLBACK statement is allowed to execute after a TRUNCATE statement, the truncate operation is not undone, and the table remains in a truncated state. For example, if another data change operation is done on the table after the TRUNCATE IMMEDIATE statement and then the ROLLBACK statement is executed, the truncate operation will not be undone, but all other data change operations are undone.

The IMMEDIATE clause can be excluded only for column organized tables.

If IMMEDIATE is not specified for column organized tables, the TRUNCATE statement does not need to be the first statement in the work unit and you can use a ROLLBACK statement to undo the truncate operation.

Attention: The IMMEDIATE clause is optional only in Db2 Version 11.5 Mod Pack 2 and later versions.

Rules

- ***Referential Integrity:*** The table, and all tables in a table hierarchy, must not be a parent table in an enforced referential constraint (SQLSTATE 428GJ). A self-referencing RI constraint is permitted.
- ***Partitioned tables:*** The table must not be in set integrity pending state due to being altered to attach a data partition (SQLSTATE 55019). The table needs to be checked for integrity before executing the TRUNCATE statement. The table must not have any logically detached partitions (SQLSTATE 55057). The asynchronous partition detach task must complete before executing the TRUNCATE statement.
- ***Exclusive Access:*** No other session can have a cursor open on the table, or a lock held on the table (SQLSTATE 25001).
- ***WITH HOLD cursors:*** The current session cannot have a WITH HOLD cursor open on the table (SQLSTATE 25001).

Notes

- ***Table statistics:*** The statistics for the table are not changed by the TRUNCATE statement.
- ***Number of rows deleted:*** SQLERRD(3) in the SQLCA is set to -1 for the truncate operation. The number of rows that were deleted from the table is not returned.
- On column-organized tables, the following rules apply to the IMMEDIATE clause when it is optional:
  - If you do not specify the IMMEDIATE option, the TRUNCATE statement is processed and can be undone.
  - The TRUNCATE statement can be anywhere within the transaction scope.

- The TRUNCATE statement can be undone before the transaction completes.
- The truncated table can be used immediately in the same unit of work.
- A ROLLBACK statement can be executed after a TRUNCATE statement without the IMMEDIATE option is processed. The TRUNCATE operation is then undone.
- For example, if another data change operation is done on the table after the TRUNCATE statement without the IMMEDIATE option is processed, and if then the ROLLBACK statement is executed, the TRUNCATE operation is also undone.
- The storage is automatically asynchronously reclaimed after the transaction completes.
- The truncate operation will perform in a similar way to a mass delete operation. The number of rows that are deleted from the table is returned at SQLERRD(4).
- The SQLWARN(5) value is 'W' because the underlying DELETE statement does not include a WHERE clause.

Examples

- *Example 1:* Empty an unused inventory table regardless of any existing triggers and return its allocated space.

```
TRUNCATE TABLE INVENTORY
  IGNORE DELETE TRIGGERS
  DROP STORAGE
  IMMEDIATE
```

- *Example 2:* Empty an unused inventory table regardless of any existing delete triggers but preserve its allocated space for later reuse.

```
TRUNCATE TABLE INVENTORY
   REUSE STORAGE
   IGNORE DELETE TRIGGERS
   IMMEDIATE
```

- *Example 3:* If IMMEDIATE is not specified for column organized tables, the TRUNCATE statement does not have to be the first statement in the work unit, and you can use a ROLLBACK statement to undo the truncate operation.

```
SELECT COUNT(*) FROM TAB10;
TRUNCATE TABLE TAB10;
SELECT COUNT(*) FROM TAB10;
ROLLBACK;
```

  Note that the truncate statement without IMMEDIATE is not the first statement in the work unit, and that the truncate statement without IMMEDIATE can be rolled back.

UPDATE

The UPDATE statement updates the values of specified columns in rows of a table, view or nickname, or the underlying tables, nicknames, or views of the specified fullselect.

Updating a row of a view updates a row of its base table, if no INSTEAD OF trigger is defined for the update operation on this view. If such a trigger is defined, the trigger will be executed instead. Updating a row using a nickname updates a row in the data source object to which the nickname refers.

The forms of this statement are:

- The *Searched* UPDATE form is used to update one or more rows (optionally determined by a search condition).
- The *Positioned* UPDATE form is used to update exactly one row (as determined by the current position of a cursor).

Invocation

An UPDATE statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- UPDATE privilege on the target table, view, or nickname
- UPDATE privilege on each of the columns that are to be updated, including the columns of the BUSINESS_TIME period if a period-clause is specified
- UPDATEIN privilege on schema of the target table, view or nickname
- CONTROL privilege on the target table, view, or nickname
- DATAACCESS on the schema containing the target table, view, or nickname
- DATAACCESS authority

If a *row-fullselect* is included in the assignment, the privileges held by the authorization ID of the statement must include at least one of the following authorities for each referenced table, view, or nickname:

- SELECT privilege
- SELECTIN privilege on the schema containing the referenced table, view, or nickname
- CONTROL privilege
- DATAACCESS on the schema containing the referenced table, view, or nickname
- DATAACCESS authority

For each table, view, or nickname referenced by a subquery, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

- SELECT privilege
- SELECTIN privilege on the schema containing the table, view or nickname
- CONTROL privilege
- DATAACCESS on the schema containing the table, view or nickname
- DATAACCESS authority

If the package used to process the statement is precompiled with SQL92 rules (option LANGLEVEL with a value of SQL92E or MIA), and the searched form of an UPDATE statement includes a reference to a column of the table, view, or nickname in the right side of the *assignment-clause*, or anywhere in the *search-condition*, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

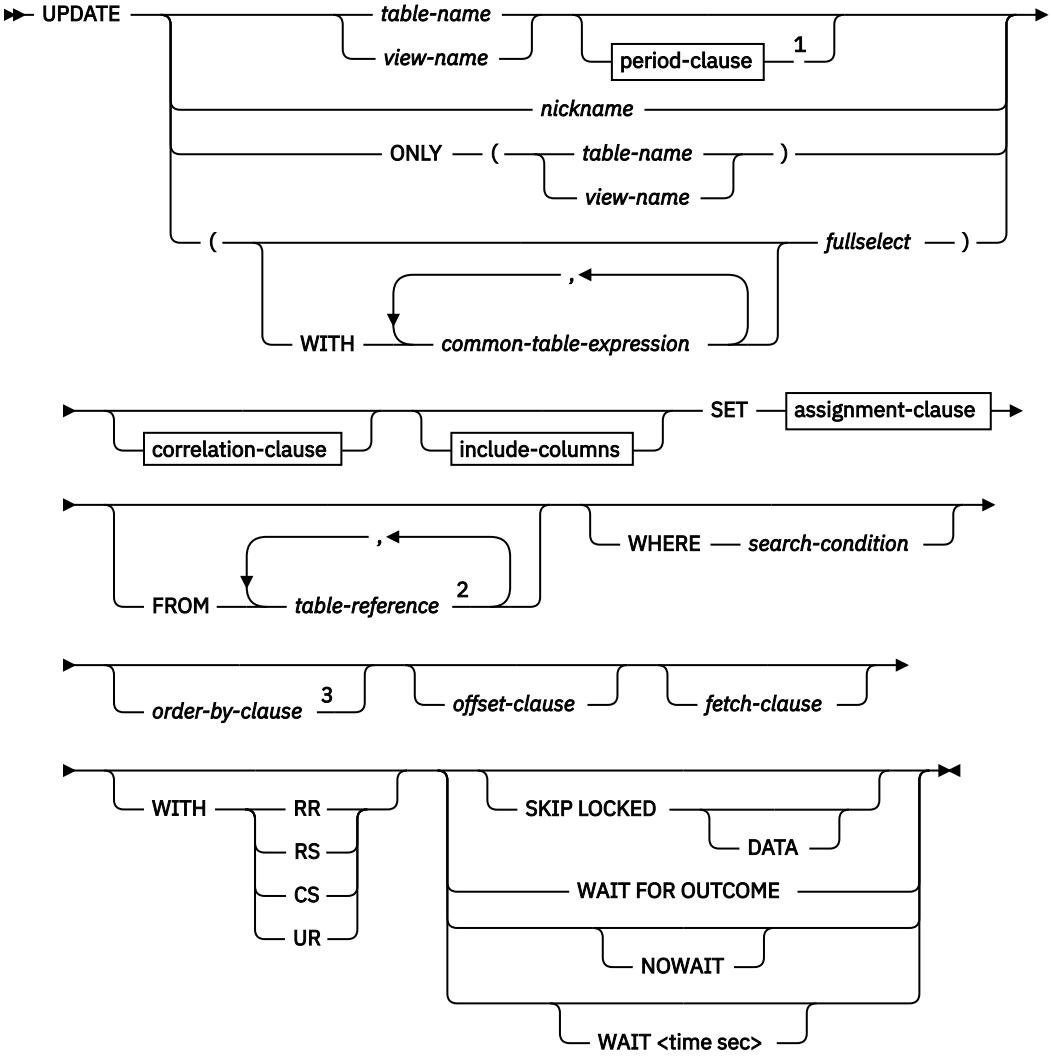
- SELECT privilege
- CONTROL privilege
- SELECTIN privilege on the schema containing the table, view, or nickname
- DATAACCESS on the schema containing the table, view or nickname
- DATAACCESS authority

If the specified table or view is preceded by the ONLY keyword, the privileges held by the authorization ID of the statement must also include the SELECT privilege for every subtable or subview of the specified table or view, or SELECTIN privilege on the schema containing the subtables or subviews of the specified table or view.

GROUP privileges are not checked for static UPDATE statements.

If the target of the update operation is a nickname, privileges on the object at the data source are not considered until the statement is executed at the data source. At this time, the authorization ID that is used to connect to the data source must have the privileges that are required for the operation on the object at the data source. The authorization ID of the statement can be mapped to a different authorization ID at the data source.

Syntax (searched-update)



Notes:

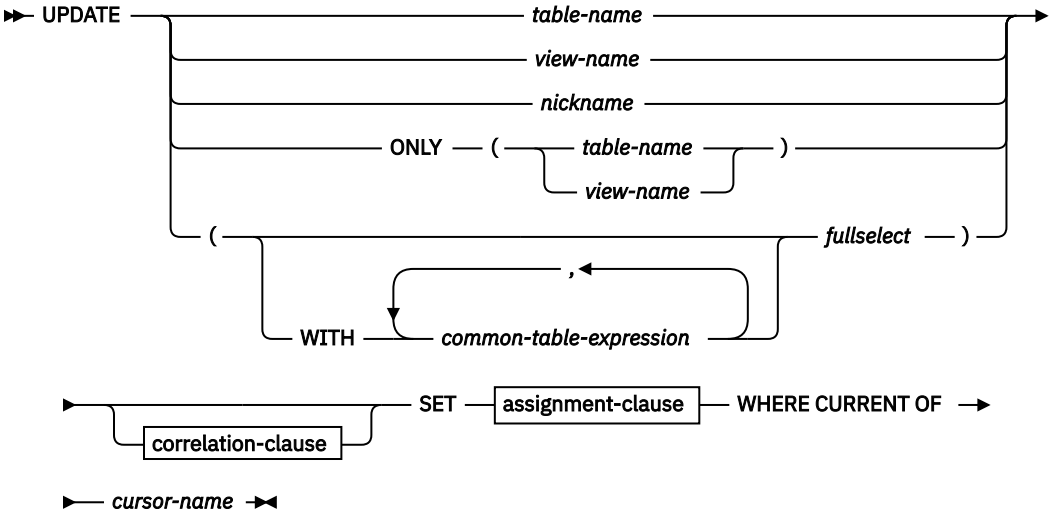
[1] If the *period-clause* is specified, neither the *offset-clause* nor the *fetch-clause* can be specified (SQLSTATE 42601).

[2] The specified table-reference cannot be an *analyze_table-expression* (that is, the result of a data mining model) or a *data-change-table-reference* (that is, the result of a nested UPDATE, DELETE, or INSERT statement) (SQLSTATE 42601).

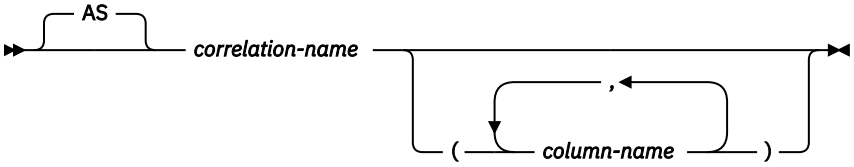
[3] If the *order-by-clause* is specified, either the *offset-clause* or *fetch-clause* must also be specified (SQLSTATE 42601).

period-clause

Syntax (positioned-update)

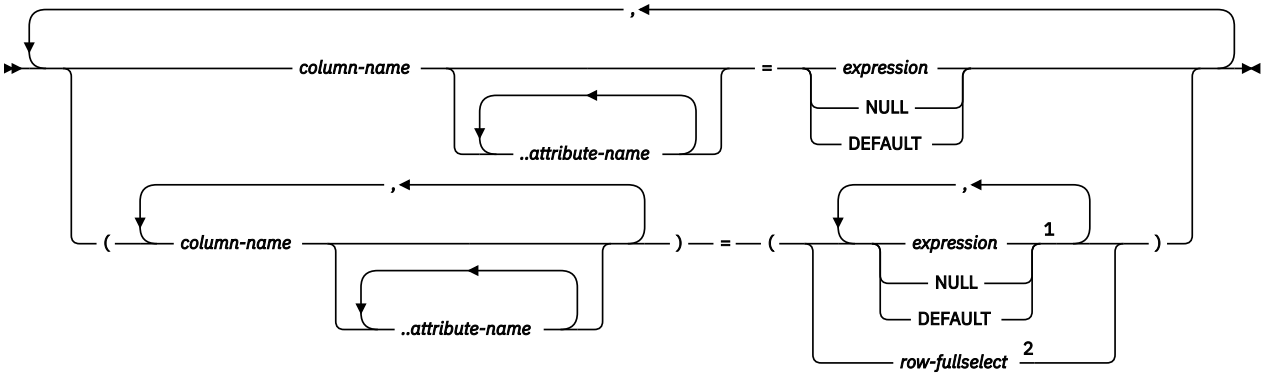


correlation-clause



include-columns

assignment-clause



Notes:

[1] The number of expressions, NULLs and DEFAULTs must match the number of column names.
[2] The number of columns in the select list must match the number of column names.

Description

table-name*, *view-name*, *nickname*, or *(fullselect)

Identifies the object of the update operation. The name must identify one of the following objects:

- A table, view, or nickname described in the catalog at the current server
- A table or view at a remote server specified using a remote-object-name

The object must not be a catalog table, a view of a catalog table (unless it is one of the updatable SYSSTAT views), a system-maintained materialized query table, or a read-only view that has no INSTEAD OF trigger defined for its update operations.

If *table-name* is a typed table, rows of the table or any of its proper subtables may get updated by the statement. Only the columns of the specified table may be set or referenced in the WHERE clause. For a positioned UPDATE, the associated cursor must also have specified the same table, view or nickname in the FROM clause without using ONLY.

If the object of the update operation is a fullselect, the fullselect must be updatable, as defined in the "Updatable views" Notes item in the description of the CREATE VIEW statement.

If the object of the update operation is a nickname, the extended indicator variable values of DEFAULT and UNASSIGNED must not be used (SQLSTATE 22539).

For additional restrictions related to temporal tables and use of a view or *fullselect* as the target of the update operation, see "Considerations for a system-period temporal table" and "Considerations for an application-period temporal table" in the Notes section of this topic.

ONLY (*table-name*)
Applicable to typed tables, the ONLY keyword specifies that the statement should apply only to data of the specified table and rows of proper subtables cannot be updated by the statement. For a positioned UPDATE, the associated cursor must also have specified the table in the FROM clause using ONLY. If *table-name* is not a typed table, the ONLY keyword has no effect on the statement.

ONLY (*view-name*)
Applicable to typed views, the ONLY keyword specifies that the statement should apply only to data of the specified view and rows of proper subviews cannot be updated by the statement. For a positioned UPDATE, the associated cursor must also have specified the view in the FROM clause using ONLY. If *view-name* is not a typed view, the ONLY keyword has no effect on the statement.

period-clause
Specifies that a period clause applies to the target of the update operation. If the target of the update operation is a view, the following conditions apply to the view:

- The FROM clause of the outer fullselect of the view definition must include a reference, directly or indirectly, to an application-period temporal table (SQLSTATE 42724M).
- An INSTEAD OF UPDATE trigger must not be defined for the view (SQLSTATE 428HY).

FOR PORTION OF BUSINESS_TIME
Specifies that the update only applies to row values for the portion of the period in the row that is specified by the period clause. The BUSINESS_TIME period must exist in the table (SQLSTATE 4274M).

FROM *value1* TO *value2*
Specifies that the update applies to rows for the period specified from *value1* up to *value2*. No rows are updated if *value1* is greater than or equal to *value2*, or if *value1* or *value2* is the null value (SQLSTATE 02000).

For the period specified with FROM *value1* TO *value2*, the BUSINESS_TIME period in a row in the target of the update is in any of the following states:

- **Overlaps the beginning** of the specified period if the value of the begin column is less than *value1* and the value of the end column is greater than *value1*.
- **Overlaps the end** of the specified period if the value of the end column is greater than or equal to *value2* and the value of the begin column is less than *value2*.
- Is **fully contained** within the specified period if the value for the begin column for BUSINESS_TIME is greater than or equal to *value1* and the value for the corresponding end column is less than or equal to *value2*.
- Is **partially contained** in the specified period if the row overlaps the beginning of the specified period or the end of the specified period, but not both.

- **Fully overlaps** the specified period if the period in the row overlaps the beginning and end of the specified period.
- Is **not contained** in the period if both columns of BUSINESS_TIME are less than or equal to *value1* or greater than or equal to *value2*.

If the BUSINESS_TIME period in a row is not contained in the specified period, the row is not updated. Otherwise, the update is applied based on how the values in the columns of the BUSINESS_TIME period overlap the specified period as follows:

- If the BUSINESS_TIME period in a row is fully contained within the specified period, the row is updated and the values of the begin column and end column of BUSINESS_TIME are unchanged.
- If the BUSINESS_TIME period in a row is partially contained in the specified period and overlaps the beginning of the specified period:
  - The row is updated. In the updated row, the value of the begin column is set to *value1* and the value of the end column is the original value of the end column.
  - A row is inserted using the original values from the row, except that the end column is set to *value1*.
- If the BUSINESS_TIME period in a row is partially contained in the specified period and overlaps the end of the specified period:
  - The row is updated. In the updated row, the value of the begin column is the original value of the begin column and the end column is set to *value2*.
  - A row is inserted using the original values from the row, except that the begin column is set to *value2*.
- If the BUSINESS_TIME period in a row fully overlaps the specified period:
  - The row is updated. In the updated row the value of the begin column is set to *value1* and the value of the end column is set to *value2*.
  - A row is inserted using the original values from the row, except that the end column is set to *value1*.
  - An additional row is inserted using the original values from the row, except that the begin column is set to *value2*.

value1* and *value2

Each expression must return a value that has a date data type, timestamp data type, or a valid data type for a string representation of a date or timestamp (SQLSTATE 428HY). The result of each expression must be comparable to the data type of the columns of the specified period (SQLSTATE 42884). See the comparison rules described in "Assignments and comparisons".

Each expression can contain any of the following supported operands (SQLSTATE 428HY):

- Constant
- Special register
- Variable. For details, refer to "References to variables" in the "Identifiers" topic, in *SQL Reference Volume 1* .
- Scalar function whose arguments are supported operands (though user-defined functions and non-deterministic functions cannot be used)
- CAST specification where the cast operand is a supported operand
- Expression using arithmetic operators and operands

correlation-clause

Can be used within *search-condition* or *assignment-clause* to designate a table, view, nickname, or fullselect. For a description of *correlation-clause*, see "table-reference" in the description of "Subselect".

include-columns
Specifies a set of columns that are included, along with the columns of *table-name* or *view-name*, in the intermediate result table of the UPDATE statement when it is nested in the FROM clause of a fullselect. The *include-columns* are appended at the end of the list of columns that are specified for *table-name* or *view-name*.

INCLUDE
Specifies a list of columns to be included in the intermediate result table of the UPDATE statement.

column-name
Specifies a column of the intermediate result table of the UPDATE statement. The name cannot be the same as the name of another include column or a column in *table-name* or *view-name* (SQLSTATE 42711).

data-type
Specifies the data type of the include column. The data type must be one that is supported by the CREATE TABLE statement.

SET
Introduces the assignment of values to column names.

assignment-clause

column-name
Identifies a column to be updated. If extended indicator variables are not enabled, the *column-name* must identify an updatable column of the specified table, view, or nickname, or identify an INCLUDE column. The object ID column of a typed table is not updatable (SQLSTATE 428DZ). A column must not be specified more than once, unless it is followed by *..attribute-name* (SQLSTATE 42701).

If it specifies an INCLUDE column, the column name cannot be qualified.

For a Positioned UPDATE:

- If the *update-clause* was specified in the *select-statement* of the cursor, each column name in the *assignment-clause* must also appear in the *update-clause*.
- If the *update-clause* was not specified in the *select-statement* of the cursor and LANGLEVEL MIA or SQL92E was specified when the application was precompiled, the name of any updatable column may be specified.
- If the *update-clause* was not specified in the *select-statement* of the cursor and LANGLEVEL SAA1 was specified either explicitly or by default when the application was precompiled, no columns may be updated.

..attribute-name
Specifies the attribute of a structured type that is set (referred to as an *attribute assignment*. The *column-name* specified must be defined with a user-defined structured type (SQLSTATE 428DP). The attribute-name must be an attribute of the structured type of *column-name* (SQLSTATE 42703). An assignment that does not involve the *..attribute-name* clause is referred to as a *conventional assignment*.

expression
Indicates the new value of the column. The expression is any expression of the type described in "Expressions". The expression cannot include an aggregate function except when it occurs within a scalar fullselect (SQLSTATE 42903).

An *expression* may contain references to columns of the target table of the UPDATE statement. For each row that is updated, the value of such a column in an expression is the value of the column in the row before the row is updated.

An expression cannot contain references to an INCLUDE column. If *expression* is a single host variable, the host variable can include an indicator variable that is enabled for extended indicator variables. If extended indicator variables are enabled, the extended indicator variable values of

default (-5) or unassigned (-7) must not be used (SQLSTATE 22539) if either of the following statements is true:

- The expression is more complex than a single host variable with explicit casts
- The target column has data type of structured type

NULL
Specifies the null value and can only be specified for nullable columns (SQLSTATE 23502). NULL cannot be the value in an attribute assignment (SQLSTATE 429B9) unless it is specifically cast to the data type of the attribute.

DEFAULT
Specifies that the default value should be used based on how the corresponding column is defined in the table. The value that is inserted depends on how the column was defined.

- If the column was defined as a generated column based on an expression, the column value will be generated by the system, based on the expression.
- If the column was defined using the IDENTITY clause, the value is generated by the database manager.
- If the column was defined using the WITH DEFAULT clause, the value is set to the default defined for the column (see *default-clause* in "ALTER TABLE").
- If the column was defined using the NOT NULL clause and the GENERATED clause was not used, or the WITH DEFAULT clause was not used, or DEFAULT NULL was used, the DEFAULT keyword cannot be specified for that column (SQLSTATE 23502).
- If the column was defined using the ROW CHANGE TIMESTAMP clause, the value is generated by the database manager.

The only value that a generated column defined with the GENERATED ALWAYS clause can be set to is DEFAULT (SQLSTATE 428C9).

The DEFAULT keyword cannot be used as the value in an attribute assignment (SQLSTATE 429B9).

The DEFAULT keyword cannot be used as the value in an assignment for update on a nickname where the data source does not support DEFAULT syntax.

row-fullselect
Specifies a fullselect that returns a single row. The result column values are assigned to each corresponding *column-name*. If the fullselect returns no rows, the null value is assigned to each column; an error occurs if any column to be updated is not nullable. An error also occurs if there is more than one row in the result.

A *row-fullselect* may contain references to columns of the target table of the UPDATE statement. For each row that is updated, the value of such a column in an expression is the value of the column in the row before the row is updated. An error is returned if there is more than one row in the result (SQLSTATE 21000).

FROM

Specifies a list of source tables that supply values for assignment to target table columns. The source tables are implicitly inner joined with the target table with the WHERE clause specifying the join condition. The rows in the target table that satisfy the WHERE condition are updated with the values from the source table rows.

When an UPDATE statement specifies a FROM clause:

- The target of the update operation cannot be a nickname.
- The source for the update operation cannot be an *analyze_table-expression* (that is, the result of a data mining model) or a *data-change-table-reference* (that is, the result of a nested UPDATE, DELETE, or INSERT statement).

For a description of *table-reference*, see “table-reference” on page 644.

WHERE
Introduces a condition that indicates what rows are updated. You can omit the clause, give a search condition, or name a cursor. If the clause is omitted, all rows of the table, view or nickname are updated.

search-condition
Each *column-name* in the search condition, other than in a subquery, must name a column of the table, view or nickname. When the search condition includes a subquery in which the same table is the base object of both the UPDATE and the subquery, the subquery is completely evaluated before any rows are updated.

The search-condition is applied to each row of the table, view or nickname and the updated rows are those for which the result of the search-condition is true.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a row, and the results used in applying the search condition. In actuality, a subquery with no correlated references is executed only once, whereas a subquery with a correlated reference may have to be executed once for each row.

CURRENT OF *cursor-name*
Identifies the cursor to be used in the update operation. The *cursor-name* must identify a declared cursor, explained in "DECLARE CURSOR". The DECLARE CURSOR statement must precede the UPDATE statement in the program.

The specified table, view, or nickname must also be named in the FROM clause of the SELECT statement of the cursor, and the result table of the cursor must not be read-only. (For an explanation of read-only result tables, see "DECLARE CURSOR".)

When the UPDATE statement is executed, the cursor must be positioned on a row; that row is updated.

This form of UPDATE cannot be used (SQLSTATE 42828) if the cursor references:

- A view on which an INSTEAD OF UPDATE trigger is defined
- A view that includes an OLAP function in the select list of the fullselect that defines the view
- A view that is defined, either directly or indirectly, using the WITH ROW MOVEMENT clause

order-by-clause
Specifies the order of the rows for application of the *offset-clause* and *fetch-clause*. Specify an *order-by-clause* to ensure a predictable order for determining the set of rows to be updated based on the *offset-clause* and *fetch-clause*. For details on the *order-by-clause*, see “order-by-clause” on page 703.

offset-clause
Limits the effect of the update by skipping a subset of the qualifying rows. For details on the *offset-clause*, refer to “offset-clause” on page 706.

fetch-clause
Limits the effect of the update to a subset of the qualifying rows. For details on the *fetch-clause*, refer to “fetch-clause” on page 705.

WITH
Specifies the isolation level at which the UPDATE statement is executed.

RR
Repeatable Read

RS
Read Stability

CS
Cursor Stability

UR
Uncommitted Read

The default isolation level of the statement is the isolation level of the package in which the statement is bound. The WITH clause has no effect on nicknames, which always use the default isolation level of the statement.

SKIP LOCKED DATA

The SKIP LOCKED DATA clause specifies that rows are skipped when incompatible locks that would block the progress of the statement are held on the rows by other transactions. These rows can belong to any accessed table addressed in the statement, including tables accessed in a subquery. This clause applies when the isolation level is CS or RS and is ignored when an isolation level of UR or RR is in effect. It applies to row and block level locks.

Invocation

SKIP LOCKED DATA is ignored if it is specified when WITH RR or WITH UR. The default isolation level of the statement depends on the isolation of the package or plan with which the statement is bound, and whether the result table is read-only. If the default isolation level of the statement is Repeatable Read or Uncommitted Read, then SKIP LOCKED DATA is ignored.

NOWAIT / WAIT <time sec>

Attention: The following feature is available in Db2 11.5.6 and later versions.

The NOWAIT and WAIT clauses specify the number of seconds to wait for a lock before returning an error indicating that a lock cannot be obtained.

When using the WAIT clause, `<time sec>` is an integer between `-1` and `32767`.

Note: For `NOWAIT` and `WAIT 0`, locks are not waited for. If no lock is available at the time of the request, a `-911` error is returned.

When a WAIT value of `-1` is specified, lock timeout detection is turned off. In this situation a lock is waited for (if one is not available at the time of the request) until either of the following events occur:

- The lock is granted.
- A deadlock occurs.

Use of the NOWAIT and WAIT clauses overwrites the value of the LOCKTIMEOUT database configuration variable and the value of the CURRENT LOCK TIMEOUT special register for this update statement. This means that adding the NOWAIT/WAIT clause with a wait time value of **t** has the same effect as executing the update statement with a LOCKTIMEOUT value or CURRENT LOCK TIMEOUT value of **t**.

While the NOWAIT and WAIT clauses are not allowed for positioned updates and deletes, you can use them in the declaration of the cursor. When used in the cursor declaration, the specified wait time value is inherited by the statements that use this cursor.

Rules

- ***Triggers:*** UPDATE statements may cause triggers to be executed. A trigger may cause other statements to be executed, or may raise error conditions based on the update values. If an update operation on a view causes an INSTEAD OF trigger to fire, validity, referential integrity, and constraints will be checked against the updates that are performed in the trigger, and not against the view that caused the trigger to fire, or its underlying tables.
- ***Assignment***: Update values are assigned to columns according to specific assignment rules.
- ***Validity***: The updated row must conform to any constraints imposed on the table (or on the base table of the view) by any unique index on an updated column.

  If a view is used that is not defined using WITH CHECK OPTION, rows can be changed so that they no longer conform to the definition of the view. Such rows are updated in the base table of the view and no longer appear in the view.

  If a view is used that is defined using WITH CHECK OPTION, an updated row must conform to the definition of the view. For an explanation of the rules governing this situation, see "CREATE VIEW".

- ***Check constraint***: Update value must satisfy the check-conditions of the check constraints defined on the table.

  An UPDATE to a table with check constraints defined has the constraint conditions for each column updated evaluated once for each row that is updated. When processing an UPDATE statement, only the check constraints referring to the updated columns are checked.
- ***Referential integrity***: The value of the parent unique keys cannot be changed if the update rule is RESTRICT and there are one or more dependent rows. However, if the update rule is NO ACTION, parent unique keys can be updated as long as every child has a parent key by the time the update statement completes. A non-null update value of a foreign key must be equal to a value of the primary key of the parent table of the relationship.
- ***XML values:*** When an XML column value is updated, the new value must be a well-formed XML document (SQLSTATE 2200M).
- ***Security policy:*** If the identified table or the base table of the identified view is protected with a security policy, the session authorization ID must have the label-based access control (LBAC) credentials that allow:
  - Write access to all protected columns that are being updated (SQLSTATE 42512)
  - Write access for any explicit value provided for a DB2SECURITYLABEL column for security policies that were created with the RESTRICT NOT AUTHORIZED WRITE SECURITY LABEL option (SQLSTATE 23523)
  - Read and write access to all rows that are being updated (SQLSTATE 42519)

  The session authorization ID must also have been granted a security label for write access for the security policy if an implicit value is used for a DB2SECURITYLABEL column (SQLSTATE 23523), which can happen when:
  - The DB2SECURITYLABEL column is not included in the list of columns that are to be updated (and so it will be implicitly updated to the security label for write access of the session authorization ID)
  - A value for the DB2SECURITYLABEL column is explicitly provided but the session authorization ID does not have write access for that value, and the security policy is created with the OVERRIDE NOT AUTHORIZED WRITE SECURITY LABEL option
- **Extended indicator variable usage**: If enabled, indicator variable values other than 0 (zero) through -7 must not be input (SQLSTATE 22010). Also, if enabled, the default and unassigned extended indicator variable values must not appear in contexts in which they are not supported (SQLSTATE 22539).
- **Extended indicator variables**: In the *assignment-clause* of an UPDATE statement, an *expression* that is a reference to a single host variable, or a host variable being explicitly cast can result in assigning an extended indicator variable value. Assigning an extended indicator variable-based value of unassigned has the effect of leaving the target column set to its current value, as if it had not been specified in the statement. Assigning an extended indicator variable-based value of default assigns the default value of the column. For information about default values of data types, see the description of the DEFAULT clause in “CREATE TABLE ” on page 1351.

  If a target column is not updatable (for example, a column in a view that is defined as an expression), then it must be assigned the extended indicator variable-based value of unassigned (SQLSTATE 42808).

  If the target column is a column defined as GENERATED ALWAYS, then it must be assigned the DEFAULT keyword, or the extended indicator variable-based values of default or unassigned (SQLSTATE 428C9).

  The UPDATE statement must not assign all target columns to an extended indicator variable-based value of unassigned (SQLSTATE 22540).

Notes

- If an update value violates any constraints, or if any other error occurs during the execution of the UPDATE statement, no rows are updated. The order in which multiple rows are updated is undefined.

- An update to a view defined using the WITH ROW MOVEMENT clause could cause a delete operation and an insert operation against the underlying tables of the view. For details, see the description of the CREATE VIEW statement.
- When an UPDATE statement completes execution, the value of SQLERRD(3) in the SQLCA is the number of rows that qualified for the update operation. In the context of an SQL procedure statement, the value can be retrieved using the ROW_COUNT variable of the GET DIAGNOSTICS statement. The SQLERRD(5) field contains the number of rows inserted, deleted, or updated by all activated triggers.
- Unless appropriate locks already exist, one or more exclusive locks are acquired by the execution of a successful UPDATE statement. Until the locks are released, the updated row can only be accessed by the application process that performed the update (except for applications using the Uncommitted Read isolation level). For further information on locking, see the descriptions of the COMMIT, ROLLBACK, and LOCK TABLE statements.
- When updating the column distribution statistics for a typed table, the subtable that first introduced the column must be specified.
- Multiple attribute assignments on the same structured type column occur in the order specified in the SET clause and, within a parenthesized set clause, in left-to-right order.
- An attribute assignment invokes the mutator method for the attribute of the user-defined structured type. For example, the assignment `st..a1=x` has the same effect as using the mutator method in the assignment `st = st..a1(x)`.
- While a given column may be a target column in only one conventional assignment, a column may be a target column in multiple attribute assignments (but only if it is not also a target column in a conventional assignment).
- When an identity column defined as a distinct type is updated, the entire computation is done in the source type, and the result is cast to the distinct type before the value is actually assigned to the column. (There is no casting of the previous value to the source type before the computation.)
- To have a generated value on a SET statement for an identity column, use the DEFAULT keyword:

  ```
  SET NEW.EMPNO = DEFAULT
  ```

  In this example, NEW.EMPNO is defined as an identity column, and the value used to update this column is generated.
- For more information about consuming values of a generated sequence for an identity column, or about exceeding the maximum value for an identity column, see "INSERT".
- With partitioned tables, an UPDATE WHERE CURRENT OF *cursor-name* operation can move a row from one data partition to another. After this occurs, the cursor is no longer positioned on the row, and no further UPDATE WHERE CURRENT OF *cursor-name* modifications to that row are possible. The next row in the cursor can be fetched, however.
- For a column defined using the ROW CHANGE TIMESTAMP clause, the value is always changed on update of the row. If the column is not specified in the SET list explicitly, the database manager still generates a value for that row. The value is unique for each table partition within the database partition and is set to the approximate timestamp corresponding to the row update.
- **Extended indicator variables and update triggers**: If a target column has been assigned with an extended indicator variable-based value of unassigned, that column is not considered to have been updated. That column is treated as if it had not been specified in the OF *column-name* list of any update trigger defined on the target table.
- **Extended indicator variables and deferred error checks**: When extended indicator variables are enabled, validation that would otherwise be done in statement preparation, to recognize an update of a non-updatable column, is deferred until statement execution, except for column level update privilege checking of static UPDATE statements. Whether an error should be reported can be determined only during execution based on the indicator value. The checking of column level update privilege for static UPDATE statements continues to be performed during bind processing even when extended indicator variables are enabled.

- **Considerations for a system-period temporal table:** The target of the UPDATE statement must not be a fullselect that references a view in the FROM clause followed by a period specification for SYSTEM_TIME if the view is defined with the WITH CHECK OPTION and the view definition includes a WHERE clause containing one of the following syntax elements (SQLSTATE 51046):
  - A subquery that references a system-period temporal table (directly or indirectly)
  - An invocation of an SQL routine that has a package associated with it
  - An invocation of an external routine with a data access indication other than NO SQL

  If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value, an underlying target of the UPDATE statement must not be a system-period temporal table (SQLSTATE 51046), and the target of the UPDATE statement must not be a view defined with the WITH CHECK OPTION if the view definition includes a WHERE clause containing one of the following syntax elements (SQLSTATE 51046):
  - A subquery that references a system-period temporal table (directly or indirectly)
  - An invocation of an SQL routine that has a package associated with it
  - An invocation of an external routine with a data access indication other than NO SQL

  When a row of a system-period temporal table is updated, the database manager updates the values of the row-begin and transaction-start-ID columns as follows:
  - A row-begin column is assigned a value that is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. The database manager ensures uniqueness of the generated values for a row-begin column across transactions. The timestamp value might be adjusted to ensure that rows inserted into an associated history table have the end timestamp value greater than the begin timestamp value which can happen when a conflicting transaction is updating the same row in the system-period temporal table. The database configuration parameter **systime_period_adj** must be set to Yes for this adjustment in the timestamp value to occur. If multiple rows are updated within a single SQL transaction and an adjustment is not needed, the values for the row-begin column are the same for all the rows and are unique from the values generated for the column for another transaction.
  - A transaction start-ID column is assigned a unique timestamp value per transaction or the null value The null value is assigned to the transaction start-ID column if the column is nullable and there is a row-begin column in the table for which the value did not need to be adjusted. Otherwise, the value is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. If multiple rows are updated within a single SQL transaction, the values for the transaction start-ID column are the same for all the rows and are unique from the values generated for the column for another transaction.

  If the UPDATE statement has a search condition containing a correlated subquery that references historical rows (explicitly referencing the name of the history table name or implicitly through the use of a period specification in the FROM clause), the old version of the updated rows that are inserted as historical rows (into the history table if any) are potentially visible to update operations for the rows subsequently processed for the statement.

  The target of an UPDATE statement cannot be a fullselect that references a view in the FROM clause followed by a period specification for SYSTEM_TIME if both of the following conditions are true (SQLSTATE 51046):
  - The view is defined with the WITH CHECK OPTION.
  - The view definition includes a WHERE clause containing one of the following syntax elements:
    - A subquery that references a system-period temporal table (directly or indirectly).
    - An invocation of an SQL routine that has a package associated with it.
    - An invocation of an external routine with a data access indication other than NO SQL.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value, the underlying target (direct or indirect) of the UPDATE statement cannot be a system-period temporal table (SQLSTATE 51046).

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value, the target of an UPDATE statement cannot be a view defined with the WITH CHECK OPTION if the view definition includes a WHERE clause containing one of the following syntax elements (SQLSTATE 51046):

- A subquery that references a system-period temporal table (directly or indirectly).
- An invocation of an SQL routine that has a package associated with it.
- An invocation of an external routine with a data access indication other than NO SQL.

- **Considerations for a history table:** When a row of a system-period temporal table is updated, a historical copy of the row is inserted into the corresponding history table and the end timestamp of the historical row is captured in the form of a system determined value that corresponds to the time of the data change operation. The database manager assigns the value that is generated using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row begin or transaction start-ID column in a table, or a row in a system-period temporal table is deleted. The database manager ensures uniqueness of the generated values for an end column in a history table across transactions. The timestamp value might be adjusted to ensure that rows inserted into the history table have the end timestamp value greater than the begin timestamp value which can happen when a conflicting transaction is updating the same row in the system-period temporal table (SQLSTATE 01695). The database configuration parameter **systime_period_adj** must be set to Yes for this adjustment in the timestamp value to occur.

  For an update operation, the adjustment only affects the value for the end column corresponding to the row-end column in the history table associated with the system-period temporal table. Take these adjustments into consideration on subsequent references to the table whether there is a search for the transaction start time in the values for the columns corresponding to the row-begin and row-end columns of the period in the associated system-period temporal table.
- **Considerations for an application-period temporal table:** The target of the UPDATE statement must not be a fullselect that references a view in the FROM clause followed by a period specification for BUSINESS_TIME if the view is defined with the WITH CHECK OPTION and the view definition includes a WHERE clause containing one of the following syntax elements (SQLSTATE 51046):

  - A subquery that references an application-period temporal table (directly or indirectly)
  - An invocation of an SQL routine that has a package associated with it
  - An invocation of an external routine with a data access indication other than NO SQL

  If the CURRENT TEMPORAL BUSINESS_TIME special register is set to a non-null value, the target of the UPDATE statement must not be a view defined with the WITH CHECK option if the view definition includes a WHERE clause containing one of the following syntax elements (SQLSTATE 51046):

  - A subquery that references an application-period temporal table (directly or indirectly)
  - An invocation of an SQL routine that has a package associated with it
  - An invocation of an external routine with a data access indication other than NO SQL

  An UPDATE statement for an application-period temporal table that contains a FOR PORTION OF BUSINESS_TIME clause indicates between which two points in time that the specified updates are effective. When FOR PORTION OF BUSINESS_TIME is specified and the period value for a row, specified by the values of the row-begin column and row-end column, is only partially contained in the period specified from *value1* up to *value2*, the row is updated and one or two rows are automatically inserted to represent the portion of the row that is not changed. New values are generated for each generated column in an application-period temporal table for each row that is automatically inserted as a result of an update operation on the table. If a generated column is defined as part of a unique or primary key, parent key in a referential constraint, or unique index, it is possible that an automatic insert will violate a constraint or index in which case an error is returned.

  When a row is inserted into an application-period temporal table that has either a primary key or unique constraint with the BUSINESS_TIME WITHOUT OVERLAPS clause defined, or a unique index with

the BUSINESS_TIME WITHOUT OVERLAPS clause defined, if the period defined by the begin and end columns of the BUSINESS_TIME period overlap the period defined by the begin and end columns of the BUSINESS_TIME period for another row with the same unique constraint or unique index in the table, an error is returned.

The target of an UPDATE statement cannot be a fullselect that references a view in the FROM clause followed by a period specification for BUSINESS_TIME if both of the following conditions are true (SQLSTATE 51046):

– The view is defined with the WITH CHECK OPTION.
– The view definition includes a WHERE clause containing one of the following syntax elements:
  - A subquery that references an application-period temporal table (directly or indirectly).
  - An invocation of an SQL routine that has a package associated with it.
  - An invocation of an external routine with a data access indication other than NO SQL.

If the CURRENT TEMPORAL BUSINESS_TIME special register is set to a non-null value, the target of an UPDATE statement cannot be a view defined with the WITH CHECK OPTION if the view definition includes a WHERE clause containing one of the following syntax elements (SQLSTATE 51046):

– A subquery that references an application-period temporal table (directly or indirectly).
– An invocation of an SQL routine that has a package associated with it.
– An invocation of an external routine with a data access indication other than NO SQL.

When an application-period temporal table is the target of an UPDATE statement, the value in effect for the CURRENT TEMPORAL BUSINESS_TIME special register is not the null value, and the BUSTIMESENSITIVE bind option is set to YES, the following additional predicates are implicit:

```
    bt_begin <= CURRENT TEMPORAL BUSINESS_TIME
AND bt_end > CURRENT TEMPORAL BUSINESS_TIME
```

where `bt_begin` and `bt_end` are the begin and end columns of the BUSINESS_TIME period of the target table of the UPDATE statement.

- **Considerations for application-period temporal tables and triggers:** When a row is updated and the FOR PORTION OF BUSINESS_TIME clause is specified, additional rows may be implicitly inserted to reflect any portion of the row that was not updated. Any existing update triggers are activated for the rows updated, and any existing insert triggers are activated for rows that are implicitly inserted.

Examples

- *Example 1:* Change the job (JOB) of employee number (EMPNO) '000290' in the EMPLOYEE table to 'LABORER'.

```
UPDATE EMPLOYEE
   SET JOB = 'LABORER'
   WHERE EMPNO = '000290'
```

- *Example 2:* Increase the project staffing (PRSTAFF) by 1.5 for all projects that department (DEPTNO) 'D21' is responsible for in the PROJECT table.

```
UPDATE PROJECT
   SET PRSTAFF = PRSTAFF + 1.5
   WHERE DEPTNO = 'D21'
```

- *Example 3:* All the employees except the manager of department (WORKDEPT) 'E21' have been temporarily reassigned. Indicate this by changing their job (JOB) to the null value and their pay (SALARY, BONUS, COMM) values to zero in the EMPLOYEE table.

```
UPDATE EMPLOYEE
  SET JOB=NULL, SALARY=0, BONUS=0, COMM=0
  WHERE WORKDEPT = 'E21' AND JOB <> 'MANAGER'
```

This statement could also be written as follows.

```
UPDATE EMPLOYEE
  SET (JOB, SALARY, BONUS, COMM) = (NULL, 0, 0, 0)
  WHERE WORKDEPT = 'E21' AND JOB <> 'MANAGER'
```

- *Example 4:* Update the salary and the commission column of the employee with employee number 000120 to the average of the salary and of the commission of the employees of the updated row's department, respectively.

```
UPDATE (SELECT EMPNO, SALARY, COMM,
  AVG(SALARY) OVER (PARTITION BY WORKDEPT),
  AVG(COMM) OVER (PARTITION BY WORKDEPT)
  FROM EMPLOYEE E) AS E(EMPNO, SALARY, COMM, AVGSAL, AVGCOMM)
SET (SALARY, COMM) = (AVGSAL, AVGCOMM)
WHERE EMPNO = '000120'
```

  The previous statement is semantically equivalent to the following statement, but requires only one access to the EMPLOYEE table, whereas the following statement specifies the EMPLOYEE table twice.

```
UPDATE EMPLOYEE EU
  SET (EU.SALARY, EU.COMM)
  =
(SELECT AVG(ES.SALARY), AVG(ES.COMM)
  FROM EMPLOYEE ES
  WHERE ES.WORKDEPT = EU.WORKDEPT)
  WHERE EU.EMPNO = '000120'
```

- *Example 5:* In a C program display the rows from the EMPLOYEE table and then, if requested to do so, change the job (JOB) of certain employees to the new job keyed in.

```
EXEC SQL  DECLARE C1 CURSOR FOR
               SELECT *
                 FROM EMPLOYEE
                 FOR UPDATE OF JOB;

EXEC SQL  OPEN C1;

EXEC SQL  FETCH C1 INTO ...     ;
if ( strcmp (change, "YES") == 0 )
  EXEC SQL  UPDATE EMPLOYEE
              SET JOB = :newjob
              WHERE CURRENT OF C1;

EXEC SQL  CLOSE C1;
```

- *Example 6:* These examples mutate attributes of column objects.

  Assume that the following types and tables exist:

```
CREATE TYPE POINT AS (X INTEGER, Y INTEGER)
  NOT FINAL WITHOUT COMPARISONS
  MODE DB2SQL
```

```
CREATE TYPE CIRCLE AS (RADIUS INTEGER, CENTER POINT)
  NOT FINAL WITHOUT COMPARISONS
  MODE DB2SQL
```

```
CREATE TABLE CIRCLES (ID INTEGER, OWNER VARCHAR(50), C CIRCLE
```

  The following example updates the CIRCLES table by changing the OWNER column and the RADIUS attribute of the CIRCLE column where the ID is 999:

```
UPDATE CIRCLES
  SET OWNER = 'Bruce'
    C..RADIUS = 5
  WHERE ID = 999
```

  The following example transposes the X and Y coordinates of the center of the circle identified by 999:

```
UPDATE CIRCLES
  SET C..CENTER..X = C..CENTER..Y,
```

```
    C..CENTER..Y = C..CENTER..X
  WHERE ID = 999
```

The following example is another way of writing both of the previous statements. This example combines the effects of both of the previous examples:

```
UPDATE CIRCLES
  SET (OWNER,C..RADIUS,C..CENTER..X,C..CENTER..Y) =
    ('Bruce',5,C..CENTER..Y,C..CENTER..X)
  WHERE ID = 999
```

- *Example 7:* Update the XMLDOC column of the DOCUMENTS table with DOCID '001' to the character string that is selected and parsed from the XMLTEXT table.

```
UPDATE DOCUMENTS SET XMLDOC =
  (SELECT XMLPARSE(DOCUMENT C1 STRIP WHITESPACE)
    FROM XMLTEXT WHERE TEXTID = '001')
WHERE DOCID = '001'
```

- *Example 8:* A new location column has been added to the project table. Update the project location with the location of the department handling the project.

```
UPDATE PROJECT P
   SET P.LOCATION = D.LOCATION
   FROM DEPARTMENT D
   WHERE P.DEPTNO = D.DEPTNO;
```

- *Example 9:* Update the estimated project staffing to the max staffing required for all activities within the project.

```
UPDATE PROJECT P
   SET P.PRSTAFF = S.ACSTAFF
   FROM (SELECT PROJNO, MAX(ACSTAFF) ACSTAFF FROM PROJACT GROUP BY PROJNO) S
   WHERE P.PROJNO = S.PROJNO AND
         P.PROJNAME = 'PAYROLL PROGRAMMING';
```

- *Example 10:* Update an employee's work department to the project department he is assigned to.

```
UPDATE EMPLOYEE E
   SET E.WORKDEPT = P.DEPTNO
   FROM PROJECT P JOIN EMPPROJACT EP ON P.PROJNO = EP.PROJNO
   WHERE E.EMPNO = EP.EMPNO AND
         E.FIRSTNME = 'PHILIP' AND E.LASTNAME = 'SMITH';
```

VALUES

The VALUES statement is a form of query.

The VALUES statement can be embedded in an application program or issued interactively.

VALUES INTO

The VALUES INTO statement produces a result table consisting of at most one row, and assigns the values in that row to host variables.

Invocation

This statement can be embedded only in an application program. It is an executable statement that cannot be dynamically prepared.

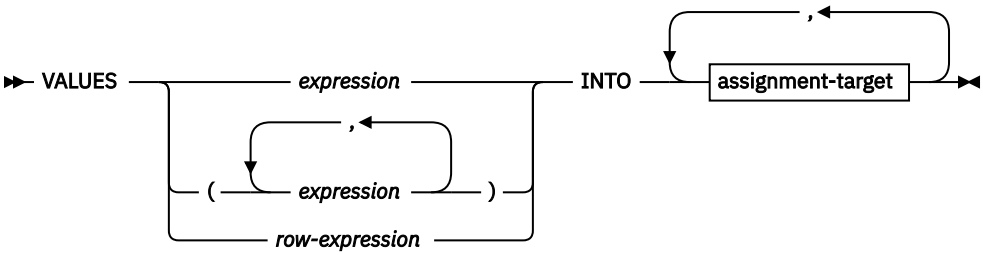
Authorization

The privileges held by the authorization ID of the statement must include any privileges that are necessary to execute each *expression* and *row-expression*.

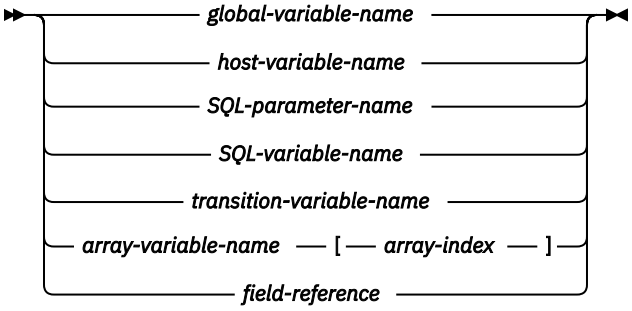
For each global variable used as an *assignment-target*, the privileges held by the authorization ID of the statement must include one of the following authorities:

- WRITE privilege on the global variable that is not defined in a module
- EXECUTE privilege on the module of the global variable that is defined in a module
- EXECUTEIN privilege on the schema containing the module of the global variable that is defined in a module
- DATAACCESS authority on the schema containing the module of the global variable that is defined in a module

Syntax



assignment-target



Description

VALUES

Introduces a single row consisting of one or more columns.

expression

An expression that defines a single value of a one column result table.

(expression,...)

One or more expressions that define the values for one or more columns of the result table.

row-expression

Specifies the new row of values. The *row-expression* is any row expression of the type described in "Row expressions". The *row-expression* must not include a column name.

INTO *assignment-target*

Identifies one or more targets for the assignment of output values.

The first value in the result row is assigned to the first target in the list, the second value to the second target, and so on. Each assignment to an *assignment-target* is made in sequence through the list. If an error occurs on any assignment, no value is assigned to any *assignment-target*.

When the data type of every *assignment-target* is not a row type, then the value 'W' is assigned to the SQLWARN3 field of the SQLCA if the number of *assignment-targets* is less than the number of result column values.

If the data type of an *assignment-target* is a row type, then there must be exactly one *assignment-target* specified (SQLSTATE 428HR), the number of columns must match the number of fields in the row type, and the data types of the columns of the fetched row must be assignable to the corresponding fields of the row type (SQLSTATE 42821).

If the data type of an *assignment-target* is an array element, then there must be exactly one *assignment-target* specified.

global-variable-name
Identifies the global variable that is the assignment target.

host-variable-name
Identifies the host variable that is the assignment target. For LOB output values, the target can be a regular host variable (if it is large enough), a LOB locator variable, or a LOB file reference variable.

SQL-parameter-name
Identifies the name parameter that is the assignment target.

SQL-variable-name
Identifies the SQL variable that is the assignment target. SQL variables must be declared before they are used.

transition-variable-name
Identifies the column to be updated in the transition row. A *transition-variable-name* must identify a column in the subject table of a trigger, optionally qualified by a correlation name that identifies the new value.

array-variable-name
Identifies an SQL variable, SQL parameter, or global variable of an array type.

[array-index]
An expression that specifies which element in the array will be the target of the assignment. For an ordinary array, the *array-index* expression must be assignable to INTEGER (SQLSTATE 428H1) and cannot be the null value. Its value must be between 1 and the maximum cardinality defined for the array (SQLSTATE 2202E). For an associative array, the *array-index* expression must be assignable to the index data type of the associative array (SQLSTATE 428H1) and cannot be the null value.

field-reference
Identifies the field within a row type value that is the assignment target. The *field-reference* must be specified as a qualified *field-name* where the qualifier identifies the row value in which the field is defined.

Rules

- Global variables cannot be assigned inside triggers that are not defined using a compound SQL (compiled) statement, functions that are not defined using a compound SQL (compiled) statement, methods, or compound SQL (inlined) statements (SQLSTATE 428GX).

Examples

- *Example 1:* This C example retrieves the value of the CURRENT PATH special register into a host variable.

```
EXEC SQL VALUES(CURRENT PATH)
         INTO :hvl;
```

- *Example 2:* This C example retrieves a portion of a LOB field into a host variable, exploiting the LOB locator for deferred retrieval.

```
EXEC SQL VALUES (substr(:locator1,35))
         INTO :details;
```

- *Example 3:* This C example retrieves the value of the SESSION_USER special register into a global variable.

```
EXEC SQL VALUES(SESSION_USER)
  INTO GV_SESS_USER;
```

WHENEVER

The WHENEVER statement specifies the action to be taken when a specified exception condition occurs.

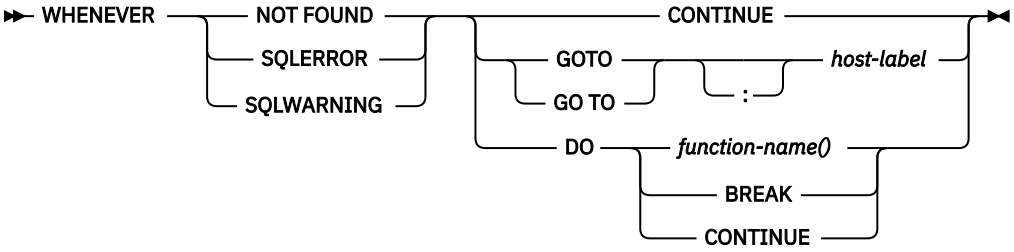
Invocation

This statement can only be embedded in an application program. It is not an executable statement. The statement is not supported in REXX.

Authorization

None required.

Syntax



Description

The NOT FOUND, SQLERROR, or SQLWARNING clause is used to identify the type of exception condition.

NOT FOUND
Identifies any condition that results in an SQLCODE of +100 or an SQLSTATE of '02000'.

SQLERROR
Identifies any condition that results in a negative SQLCODE.

SQLWARNING
Identifies any condition that results in a warning condition (SQLWARN0 is 'W'), or that results in a positive SQL return code other than +100.

The CONTINUE or GO TO clause is used to specify what is to happen when the identified type of exception condition exists.

CONTINUE
Causes the next sequential instruction of the source program to be executed.

GOTO or GO TO *host-label*
Causes control to pass to the statement identified by host-label. For host-label, substitute a single token, optionally preceded by a colon. The form of the token depends on the host language.

DO
Causes additional action in the form of a function call, `break` statement, or `continue` statement to take place.

function-name()
Specifies the C function that is to be called. The function must have a void return value and cannot accept any arguments. The function name must end with set of parentheses "(" and ")". The name of the function is limited to 255 bytes.

The function name resolution takes place during the compilation of the C and C++ embedded SQL application. The database precompiler does not resolve the function name.

BREAK
Specifies the C `break` statement. The C `break` statement exits the`do`, `for`, `switch`, or `while` statement block.

CONTINUE
Specifies the C `continue` statement. The C `continue` statement passes control to the next iteration of the do, `for`, `switch`, or `while` statement block.

Notes

There are three types of WHENEVER statements:

- WHENEVER NOT FOUND
- WHENEVER SQLERROR
- WHENEVER SQLWARNING

Every executable SQL statement in a program is within the scope of one implicit or explicit WHENEVER statement of each type. The scope of a WHENEVER statement is related to the listing sequence of the statements in the program, not their execution sequence.

An SQL statement is within the scope of the last WHENEVER statement of each type that is specified before that SQL statement in the source program. If a WHENEVER statement of some type is not specified before an SQL statement, that SQL statement is within the scope of an implicit WHENEVER statement of that type in which CONTINUE is specified.

If the WHENEVER statement is not used, the default action is to continue processing if an error, warning, or exception condition occurs during execution.

The WHENEVER statement must be used before the SQL statements that you want to affect. Otherwise, the precompiler does not know that additional error-handling code is required for the executable SQL statements. You can have any combination of the three basic forms active at any time. The order in which you declare the three forms is not significant.

To avoid an infinite looping situation, ensure that you undo the WHENEVER handling before any SQL statements are executed inside the handler. You can undo the WHENEVER handling by using the WHENEVER SQLERROR CONTINUE statement.

The WHENEVER statement support for use of the DO *function-name()*, DO BREAK, or DO CONTINUE syntax is available in Version 9.7 Fix Pack 6 and later.

Example

In the following C example, if an error is produced, go to HANDLERR. If a warning code is produced, continue with the normal flow of the program. If no data is returned, go to ENDDATA.

```
   EXEC SQL WHENEVER SQLERROR GOTO HANDLERR;
   EXEC SQL WHENEVER SQLWARNING CONTINUE;
   EXEC SQL WHENEVER NOT FOUND GO TO ENDDATA;
```

The C example for use of the DO *function-name()*, DO BREAK, or DO CONTINUE syntax are:

```
/* DO function_name */
EXEC SQL WHENEVER SQLERROR DO perform_error_action();
EXEC SQL WHENEVER SQLWARNING DO perform_warning_action();
EXEC SQL WHENEVER NOT FOUND DO perform_notfound_action();

/* DO BREAK */
EXEC SQL WHENEVER SQLERROR DO BREAK;
EXEC SQL WHENEVER SQLWARNING DO BREAK;
EXEC SQL WHENEVER NOT FOUND DO BREAK;

/* DO CONTINUE */
EXEC SQL WHENEVER SQLERROR DO CONTINUE;
EXEC SQL WHENEVER SQLWARNING DO CONTINUE;
EXEC SQL WHENEVER NOT FOUND DO CONTINUE;
```

WHILE

The WHILE statement repeats the execution of a statement or group of statements while a specified condition is true.

Invocation

This statement can be embedded in an:

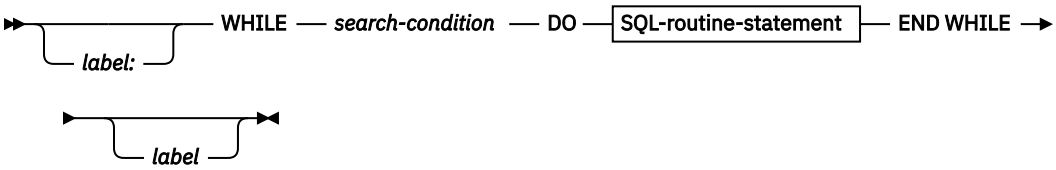
- SQL procedure definition
- Compound SQL (compiled) statement
- Compound SQL (inlined) statement

The compound statements can be embedded in an SQL procedure definition, SQL function definition, or SQL trigger definition. It is not an executable statement and cannot be dynamically prepared.

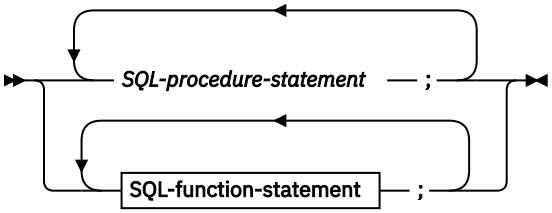
Authorization

No privileges are required to invoke the WHILE statement. However, the authorization ID of the statement must hold the necessary privileges to invoke the SQL statements and search condition that are embedded in the WHILE statement.

Syntax



SQL-routine-statement



Description

label
Specifies the label for the WHILE statement. If the beginning label is specified, it can be specified in LEAVE and ITERATE statements. If the ending label is specified, it must be the same as the beginning label.

search-condition
Specifies a condition that is evaluated before each execution of the loop. If the condition is true, the SQL-procedure-statements in the loop are processed.

SQL-procedure-statement
Specifies the SQL statements to execute within the loop. *SQL-procedure-statement* is only applicable when in the context of an SQL procedure or compound SQL (compiled) statement. See *SQL-procedure-statement* in "Compound SQL (compiled)" statement.

SQL-function-statement
Specifies the SQL statements to execute within the loop. *SQL-function-statement* is only applicable in an SQL function or a compound SQL (inlined) statement which can be embedded in an SQL trigger, SQL function or SQL method. See *SQL-function-statement* in "FOR".

Example

This example uses a WHILE statement to iterate through FETCH and SET statements. While the value of SQL variable *v_counter* is less than half of number of employees in the department identified by the IN parameter *deptNumber*, the WHILE statement continues to perform the FETCH and SET statements. When the condition is no longer true, the flow of control leaves the WHILE statement and closes the cursor.

```
CREATE PROCEDURE DEPT_MEDIAN
  (IN deptNumber SMALLINT, OUT medianSalary DOUBLE)
  LANGUAGE SQL
  BEGIN
    DECLARE v_numRecords INTEGER DEFAULT 1;
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE c1 CURSOR FOR
      SELECT CAST(salary AS DOUBLE)
        FROM staff
        WHERE DEPT = deptNumber
        ORDER BY salary;
    DECLARE EXIT HANDLER FOR NOT FOUND
      SET medianSalary = 6666;
    SET medianSalary = 0;
    SELECT COUNT(*) INTO v_numRecords
      FROM staff
      WHERE DEPT = deptNumber;
    OPEN c1;
    WHILE v_counter < (v_numRecords / 2 + 1) DO
      FETCH c1 INTO medianSalary;
      SET v_counter = v_counter + 1;
    END WHILE;
    CLOSE c1;
  END
```

Catalog views

The database manager creates and maintains two sets of catalog views that are defined on top of the base system catalog tables.

- SYSCAT views are read-only catalog views that are found in the SYSCAT schema. The RESTRICT option on CREATE DATABASE statement determines how SELECT privilege is granted. When the RESTRICT option is not specified, SELECT privilege is granted to PUBLIC.
- SYSSTAT views are updatable catalog views that are found in the SYSSTAT schema. The updatable views contain statistical information that is used by the optimizer. The values in some columns in these views can be changed to test performance. (Before changing any statistics, it is recommended that the RUNSTATS command be invoked so that all the statistics reflect the current state.)

Applications should be written to the SYSCAT and SYSSTAT views rather than the base catalog tables.

All the catalog views are created at database creation time. The catalog views cannot be explicitly created or dropped. In a Unicode database, the catalog views are created with IDENTITY collation. In non-Unicode databases, the catalog views are created with the database collation. The views are updated during normal operation in response to SQL data definition statements, environment routines, and certain utilities. Data in the catalog views is available through normal SQL query facilities. The catalog views (with the exception of some updatable catalog views) cannot be modified using normal SQL data manipulation statements.

An object table, statistical view, column, or index object appears in a user's updatable SYSSTAT catalog view only if that user holds explicit CONTROL privilege on the object, or holds explicit DATAACCESS authority. An object table or statistical view also appears in a user's updatable SYSSTAT.TABLES catalog view if the user is a direct or indirect member of a role that has CONTROL privilege on the object, or a role that has DATAACCESS authority. Role privileges and authorities are not considered when determining the objects that appear in the other SYSSTAT catalog views. A routine object appears in a user's updatable SYSSTAT.ROUTINES catalog view if that user owns the routine or holds explicit SQLADM authority. Group privileges and authorities are not considered when determining the objects that appear in a user's updatable SYSSTAT catalog views.

The order of columns in the views may change from release to release. To prevent this from affecting programming logic, specify the columns in a select list explicitly, and avoid using SELECT *. Columns have consistent names based on the types of objects that they describe.

Table 155. Samples of consistent column names for objects they describe

Described Object	**Column Names**
Table	TABSCHEMA, TABNAME
Index	INDSCHEMA, INDNAME
Index extension	IESCHEMA, IENAME
View	VIEWSCHEMA, VIEWNAME
Constraint	CONSTSCHEMA, CONSTNAME
Control	CONTROLSCHEMA, CONTROLNAME, CONTROLID
Trigger	TRIGSCHEMA, TRIGNAME
Package	PKGSCHEMA, PKGNAME
Type	TYPESCHEMA, TYPENAME, TYPEID
Function	ROUTINESCHEMA, ROUTINEMODULENAME, ROUTINENAME, ROUTINEID
Method	ROUTINESCHEMA, ROUTINEMODULENAME, ROUTINENAME, ROUTINEID
Procedure	ROUTINESCHEMA, ROUTINEMODULENAME, ROUTINENAME, ROUTINEID
Column	COLNAME
Schema	SCHEMANAME
Table Space	TBSPACE
Database partition group	DBPGNAME
Audit policy	AUDITPOLICYNAME, AUDITPOLICYID
Buffer pool	BPNAME
Event Monitor	EVMONNAME
Condition	CONDSCHEMA, CONDMODULENAME, CONDNAME, CONDMODULEID
Data source	SERVERNAME, SERVERTYPE, SERVERVERSION
Global variable	VARSCHEMA, VARMODULENAME, VARNAME, VARMODULEID
Histogram template	TEMPLATENAME, TEMPLATEID
Module	MODULESCHEMA, MODULENAME, MODULEID
Period	PERIODNAME
Role	ROLENAME, ROLEID
Security label	SECLABELNAME, SECLABELID
Security policy	SECPOLICYNAME, SECPOLICYID
Sequence	SEQSCHEMA, SEQNAME
Threshold	THRESHOLDNAME, THRESHOLDID

Table 155. Samples of consistent column names for objects they describe (continued)	
Described Object	**Column Names**
Trusted context	CONTEXTNAME, CONTEXTID
Usage list	USAGELISTSCHEMA, USAGELISTNAME, USAGELISTID
Work action	ACTIONNAME, ACTIONID
Work action set	ACTIONSETNAME, ACTIONSETID
Work class	WORKCLASSNAME, WORKCLASSID
Work class set	WORKCLASSSETNAME, WORKCLASSSETID
Workload	WORKLOADID, WORKLOADNAME
Wrapper	WRAPNAME
Alteration Timestamp	ALTER_TIME
Creation Timestamp	CREATE_TIME

Road map to the catalog views

This topic lists the catalog views, grouped by object or functionality.

[1] The following catalog views for functions, methods, and procedures defined in Db2 Version 7.1 and earlier are still available:

```
Functions:  SYSCAT.FUNCTIONS, SYSCAT.FUNCDEP, SYSCAT.FUNCPARMS
Methods:    SYSCAT.FUNCTIONS, SYSCAT.FUNCDEP, SYSCAT.FUNCPARMS
Procedures: SYSCAT.PROCEDURES, SYSCAT.PROCPARMS
```

However, these views have not been updated since Db2 Version 7.1. Use the SYSCAT.ROUTINES, SYSCAT.ROUTINEDEP, or SYSCAT.ROUTINEPARMS catalog view instead.

Table 157. Road map to the updatable catalog views

Description	Catalog View
columns	“SYSSTAT.COLUMNS ” on page 2116
detailed column group statistics	“SYSSTAT.COLGROUPDIST ” on page 2115 “SYSSTAT.COLGROUPDISTCOUNTS ” on page 2115 “SYSSTAT.COLGROUPS ” on page 2116
detailed column statistics	“SYSSTAT.COLDIST ” on page 2114
indexes	“SYSSTAT.INDEXES ” on page 2118
routines[1]	“SYSSTAT.ROUTINES ” on page 2122
tables	“SYSSTAT.TABLES ” on page 2123

[1] The SYSSTAT.FUNCTIONS catalog view still exists for updating the statistics for functions and methods. This view, however, does not reflect any changes since Db2 Version 7.1.

SYSCAT.ATTRIBUTES

Each row represents an attribute that is defined for a user-defined structured data type. Includes inherited attributes of subtypes.

Table 158. SYSCAT.ATTRIBUTES Catalog View

Column Name	Data Type	Nullable	Description
TYPESCHEMA	VARCHAR (128)		Schema name of the structured data type that includes the attribute.
TYPEMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the structured data type belongs. The null value if not a module structured data type.
TYPENAME	VARCHAR (128)		Unqualified name of the structured data type that includes the attribute.
ATTR_NAME	VARCHAR (128)		Attribute name.
ATTR_TYPESCHEMA	VARCHAR (128)		Schema name of the data type of an attribute.
ATTR_TYPEMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the data type of an attribute belongs. The null value if not a module attribute.
ATTR_TYPENAME	VARCHAR (128)		Unqualified name of the data type of an attribute.
TARGET_TYPESCHEMA	VARCHAR (128)	Y	Schema name of the target row type. Applies to reference types only; null value otherwise.
TARGET_TYPEMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the target row type belongs. The null value if not a module row type. Applies to reference types only; null value otherwise.
TARGET_TYPENAME	VARCHAR (128)	Y	Unqualified name of the target row type. Applies to reference types only; null value otherwise.

Table 158. SYSCAT.ATTRIBUTES Catalog View (continued)

Column Name	Data Type	Nullable	Description
SOURCE_TYPESCHEMA	VARCHAR (128)		For inherited attributes, the schema name of the data type with which the attribute was first defined. For non-inherited attributes, this column is the same as TYPESCHEMA.
SOURCE_TYPEMODULENAME	VARCHAR (128)	Y	For inherited attributes, the unqualified name of the module to which the data type with which the attribute was first defined belongs. For non-inherited attributes, this column is the same as TYPEMODULEID. The null value if not a module data type.
SOURCE_TYPENAME	VARCHAR (128)		For inherited attributes, the unqualified name of the data type with which the attribute was first defined. For non-inherited attributes, this column is the same as TYPENAME.
ORDINAL	SMALLINT		Position of the attribute in the definition of the structured data type, starting with 0.
LENGTH	INTEGER		Length of the attribute data type. 0 if the attribute is a user-defined type.
SCALE	SMALLINT		Scale if the attribute data type is DECIMAL or distinct type based on DECIMAL; the number of digits of fractional seconds if the attribute data type is TIMESTAMP or distinct type based on TIMESTAMP; 0 otherwise.
TYPESTRINGUNITS	VARCHAR (11)	Y	In a Unicode database, the string units that apply to a character string or graphic string data type. Otherwise, the null value.
STRINGUNITSLENGTH	INTEGER	Y	In a Unicode database, the declared number of string units for a character string or graphic string data type. Otherwise, the null value.
CODEPAGE	SMALLINT		For string types, denotes the code page; 0 indicates FOR BIT DATA; 0 for non-string types.
COLLATIONSCHEMA	VARCHAR (128)	Y	For string types, the schema name of the collation for the attribute; the null value otherwise.
COLLATIONNAME	VARCHAR (128)	Y	For string types, the unqualified name of the collation for the attribute; the null value otherwise.
LOGGED	CHAR (1)		Applies to LOB types only; blank otherwise. • N = Changes are not logged • Y = Changes are logged

Table 158. SYSCAT.ATTRIBUTES Catalog View (continued)

Column Name	Data Type	Nullable	Description
COMPACT	CHAR (1)		Applies to LOB types only; blank otherwise. • N = Stored in non-compact format • Y = Stored in compact format
DL_FEATURES	CHAR (10)		This column is no longer used and will be removed in a future release.
JAVA_FIELDNAME	VARCHAR (256)	Y	Reserved for future use.
ENVSTRINGUNITS	VARCHAR (11)		Default string units when the object was created.

SYSCAT.AUDITPOLICIES

Each row represents an audit policy.

Table 159. SYSCAT.AUDITPOLICIES Catalog View

Column Name	Data Type	Nullable	Description
AUDITPOLICYNAME	VARCHAR (128)		Name of the audit policy.
AUDITPOLICYID	INTEGER		Identifier for the audit policy.
CREATE_TIME	TIMESTAMP		Time at which the audit policy was created.
ALTER_TIME	TIMESTAMP		Time at which the audit policy was last altered.
AUDITSTATUS	CHAR (1)		Status for the AUDIT category. • B = Both • F = Failure • N = None • S = Success
CONTEXTSTATUS	CHAR (1)		Status for the CONTEXT category. • B = Both • F = Failure • N = None • S = Success
VALIDATESTATUS	CHAR (1)		Status for the VALIDATE category. • B = Both • F = Failure • N = None • S = Success

Table 159. SYSCAT.AUDITPOLICIES Catalog View (continued)

Column Name	Data Type	Nullable	Description
CHECKINGSTATUS	CHAR (1)		Status for the CHECKING category. • B = Both • F = Failure • N = None • S = Success
SECMAINTSTATUS	CHAR (1)		Status for the SECMAINT category. • B = Both • F = Failure • N = None • S = Success
OBJMAINTSTATUS	CHAR (1)		Status for the OBJMAINT category. • B = Both • F = Failure • N = None • S = Success
SYSADMINSTATUS	CHAR (1)		Status for the SYSADMIN category. • B = Both • F = Failure • N = None • S = Success
EXECUTESTATUS	CHAR (1)		Status for the EXECUTE category. • B = Both • F = Failure • N = None • S = Success
EXECUTEWITHDATA	CHAR (1)		Host variables and parameter markers logged with EXECUTE category. • N = No • Y = Yes
ERRORTYPE	CHAR (1)		The audit error type. • A = Audit • N = Normal
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.AUDITUSE

Each row represents an audit policy that is associated with an object.

Table 160. SYSCAT.AUDITUSE Catalog View

Column Name	Data Type	Nullable	Description
AUDITPOLICYNAME	VARCHAR (128)		Name of the audit policy.
AUDITPOLICYID	INTEGER		Identifier for the audit policy.
OBJECTTYPE	CHAR (1)		The type of object with which this audit policy is associated. • S = MQT • T = Table • g = Authority • i = Authorization ID • x = Trusted context • Blank = Database
SUBOBJECTTYPE	CHAR (1)		If OBJECTTYPE is 'i', this is the type that the authorization ID represents. • G = Group • R = Role • U = User • Blank = Not applicable
OBJECTSCHEMA	VARCHAR (128)		Schema name of the object for which the audit policy is in use. OBJECTSCHEMA is null if OBJECTTYPE identifies an object to which a schema does not apply.
OBJECTNAME	VARCHAR (128)		Unqualified name of the object for which this audit policy is in use.
AUDITEXCEPTIONENABLED	CHAR (1)		Reserved for future use.

SYSCAT.BUFFERPOOLDBPARTITIONS

Each row represents a combination of a buffer pool and a member, in which the size of the buffer pool on that member is different from its default size for other members in the same database partition group (as represented in SYSCAT.BUFFERPOOLS).

Table 161. SYSCAT.BUFFERPOOLDBPARTITIONS Catalog View

Column Name	Data Type	Nullable	Description
BUFFERPOOLID	INTEGER		Internal buffer pool identifier.
DBPARTITIONNUM	SMALLINT		Member number.
NPAGES	INTEGER		Number of pages in this buffer pool on this member.

SYSCAT.BUFFERPOOLEXCEPTIONS

Each row represents a combination of a buffer pool and a member, in which the size of the buffer pool on that member is different from its default size for other members in the same database partition group (as represented in SYSBUFFERPOOLS).

Table 162. SYSCAT.BUFFERPOOLEXCEPTIONS Catalog View

Column Name	Data Type	Nullable	Description
BUFFERPOOLID	INTEGER		Internal buffer pool identifier.
MEMBER	SMALLINT		Member number.
NPAGES	INTEGER		The number of pages in this buffer pool on this member.

SYSCAT.BUFFERPOOLS

Each row represents the configuration of a buffer pool on one database partition group of a database, or on all database partitions of a database.

Table 163. SYSCAT.BUFFERPOOLS Catalog View

Column Name	Data Type	Nullable	Description
BPNAME	VARCHAR (128)		Name of the buffer pool.
BUFFERPOOLID	INTEGER		Identifier for the buffer pool.
DBPGNAME	VARCHAR (128)	Y	Name of the database partition group (the null value if the buffer pool exists on all database partitions in the database).
NPAGES	INTEGER		Default number of pages in this buffer pool on database partitions in this database partition group. -1(Computed) and -2(Automatic).
PAGESIZE	INTEGER		Page size for this buffer pool on database partitions in this database partition group.
ESTORE	INTEGER		Always 'N'. Extended storage no longer applies.
NUMBLOCKPAGES	INTEGER		Number of pages of the buffer pool that are to be in a block-based area. A block-based area of the buffer pool is only used by prefetchers doing a sequential prefetch.
BLOCKSIZE	INTEGER		Number of pages in a *block*.
NGNAME[1]	VARCHAR (128)	Y	Name of the database partition group (the null value if the buffer pool exists on all database partitions in the database).

Note:

1. The NGNAME column is included for backwards compatibility. See DBPGNAME.

SYSCAT.CASTFUNCTIONS

Each row represents a cast function, not including built-in cast functions.

Table 164. SYSCAT.CASTFUNCTIONS Catalog View

Column Name	Data Type	Nullable	Description
FROM_TYPESCHEMA	VARCHAR (128)		Schema name of the data type of the parameter.
FROM_TYPEMODULENAME	VARCHAR (128)		Unqualified name of the module to which the data type of the parameter belongs. The null value if not a module data type.
FROM_TYPENAME	VARCHAR (128)		Name of the data type of the parameter.
FROM_TYPEMODULEID	INTEGER	Y	Identifier for the module to which the data type of the parameter belongs. The null value if not a module data type.
TO_TYPESCHEMA	VARCHAR (128)		Schema name of the data type of the result after casting.
TO_TYPEMODULENAME	VARCHAR (128)		Unqualified name of the module to which the data type of the result after casting belongs. The null value if not a module data type.
TO_TYPENAME	VARCHAR (128)		Name of the data type of the result after casting.
TO_TYPEMODULEID	INTEGER	Y	Identifier for the module to which the data type of the result after casting belongs. The null value if not a module data type.
FUNCSCHEMA	VARCHAR (128)		Schema name of the function.
FUNCMODULENAME	VARCHAR (128)		Unqualified name of the module to which the function belongs. The null value if not a module function.
FUNCNAME	VARCHAR (128)		Unqualified name of the function.
SPECIFICNAME	VARCHAR (128)		Name of the routine instance (might be system-generated).
FUNCMODULEID	INTEGER	Y	Identifier for the module to which the function belongs. The null value if not a module function.
ASSIGN_FUNCTION	CHAR (1)		• N = Not an assignment function • Y = Implicit assignment function

SYSCAT.CHECKS

Each row represents a check constraint or a derived column in a materialized query table. For table hierarchies, each check constraint is recorded only at the level of the hierarchy where the constraint was created.

Table 165. SYSCAT.CHECKS Catalog View

Column Name	Data Type	Nullable	Description
CONSTNAME	VARCHAR (128)		Name of the check constraint.
OWNER	VARCHAR (128)		Authorization ID of the owner of the constraint.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
TABSCHEMA	VARCHAR (128)		Schema name of the table to which this constraint applies.
TABNAME	VARCHAR (128)		Name of the table to which this constraint applies.
CREATE_TIME	TIMESTAMP		Time at which the constraint was defined. Used in resolving functions that are part of this constraint. Functions that were created after the constraint was defined are not chosen.
QUALIFIER	VARCHAR (128)		Value of the default schema at the time of object definition. Used to complete any unqualified references.
TYPE	CHAR (1)		Type of check constraint: • C = Check constraint • F = Functional dependency • O = Constraint is an object property • S = System-generated check constraint for a GENERATED ALWAYS column
FUNC_PATH	CLOB (2K)		SQL path in effect when the constraint was defined.
TEXT	CLOB (2M)		Text of the check condition or definition of the derived column.[1]
PERCENTVALID	SMALLINT		Number of rows for which the informational constraint is valid, expressed as a percentage of the total.
COLLATIONSCHEMA	VARCHAR (128)		Schema name of the collation for the constraint.

Table 165. SYSCAT.CHECKS Catalog View (continued)

Column Name	Data Type	Nullable	Description
COLLATIONNAME	VARCHAR (128)		Unqualified name of the collation for the constraint.
COLLATIONSCHEMA_ORDERBY	VARCHAR (128)		Schema name of the collation for ORDER BY clauses in the constraint.
COLLATIONNAME_ORDERBY	VARCHAR (128)		Unqualified name of the collation for ORDER BY clauses in the constraint.
DEFINER[2]	VARCHAR (128)		Authorization ID of the owner of the constraint.
ENVSTRINGUNITS	VARCHAR (11)		Default string units when the object was created.

Note:

1. In the catalog view, the text of the check condition is always shown in the database code page and can contain substitution characters. The check constraint will always be applied in the code page of the target table, and will not contain any substitution characters when applied. (The check constraint will be applied based on the original text in the code page of the target table, which might not include the substitution characters.)
2. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.COLAUTH

Each row represents a user, group, or role that has been granted one or more privileges on a column.

Table 166. SYSCAT.COLAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of a privilege.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user
GRANTEE	VARCHAR (128)		Holder of a privilege.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
TABSCHEMA	VARCHAR (128)		Schema name of the table or view on which the privilege is held.
TABNAME	VARCHAR (128)		Unqualified name of the table or view on which the privilege is held.
COLNAME	VARCHAR (128)		Name of the column to which this privilege applies.
COLNO	SMALLINT		Column number of this column within the table (starting with 0).

Table 166. SYSCAT.COLAUTH Catalog View (continued)

Column Name	Data Type	Nullable	Description
PRIVTYPE	CHAR (1)		• R = Reference privilege • U = Update privilege
GRANTABLE	CHAR (1)		• G = Privilege is grantable • N = Privilege is not grantable

Note:

1. Privileges can be granted by column, but can be revoked only on a table-wide basis.

SYSCAT.COLCHECKS

Each row represents a column that is referenced by a check constraint or by the definition of a materialized query table. For table hierarchies, each check constraint is recorded only at the level of the hierarchy where the constraint was created.

Table 167. SYSCAT.COLCHECKS Catalog View

Column Name	Data Type	Nullable	Description
CONSTNAME	VARCHAR (128)		Name of the check constraint.
TABSCHEMA	VARCHAR (128)		Schema name of the table containing the referenced column.
TABNAME	VARCHAR (128)		Unqualified name of the table containing the referenced column.
COLNAME	VARCHAR (128)		Name of the column.
USAGE	CHAR (1)		• D = Column is the child in a functional dependency • P = Column is the parent in a functional dependency • R = Column is referenced in the check constraint • S = Column is a source in the system-generated column check constraint that supports a materialized query table • T = Column is a target in the system-generated column check constraint that supports a materialized query table

SYSCAT.COLDIST

Each row represents the *n*th most frequent value of some column, or the *n*th quantile (cumulative distribution) value of the column. Applies to columns of real tables only (not views). No statistics are recorded for inherited columns of typed tables.

Table 168. SYSCAT.COLDIST Catalog View

Column Name	Data Type	Nullable	Description
TABSCHEMA	VARCHAR (128)		Schema name of the table to which the statistics apply.

Table 168. SYSCAT.COLDIST Catalog View (continued)

Column Name	Data Type	Nullable	Description
TABNAME	VARCHAR (128)		Unqualified name of the table to which the statistics apply.
COLNAME	VARCHAR (128)		Name of the column to which the statistics apply.
TYPE	CHAR (1)		• F = Frequency value • Q = Quantile value
SEQNO	SMALLINT		If TYPE = "F", *n* in this column identifies the *n*th most frequent value. If TYPE = "Q", *n* in this column identifies the *n*th quantile value.
COLVALUE[1]	VARCHAR (254)	Y	Data value as a character literal or a null value.
VALCOUNT[2]	BIGINT		If TYPE = "F", VALCOUNT is the number of occurrences of COLVALUE in the column. If TYPE = "Q", VALCOUNT is the number of rows whose value is less than or equal to COLVALUE.
DISTCOUNT[3]	BIGINT	Y	If TYPE = "Q", this column records the number of distinct values that are less than or equal to COLVALUE (the null value if unavailable).

Note:

1. In the catalog view, the value of COLVALUE is always shown in the database code page and can contain substitution characters. However, the statistics are gathered internally in the code page of the column's table, and will therefore use actual column values when applied during query optimization.
2. VALCOUNT is estimated, regardless of the sampling method that is used for collecting statistics. VALCOUNT might not be estimated if the given column is a leading column of an index that is defined on the table.
3. DISTCOUNT is collected only for columns that are the first key column in an index.

SYSCAT.COLGROUPCOLS

Each row represents a column that makes up a column group.

Table 169. SYSCAT.COLGROUPCOLS Catalog View

Column Name	Data Type	Nullable	Description
COLGROUPID	INTEGER		Identifier for the column group.
COLNAME	VARCHAR (128)		Name of the column in the column group.
TABSCHEMA	VARCHAR (128)		Schema name of the table for the column in the column group.
TABNAME	VARCHAR (128)		Unqualified name of the table for the column in the column group.
ORDINAL	SMALLINT		Ordinal number of the column in the column group.

SYSCAT.COLGROUPDIST

Each row represents the value of the column in a column group that makes up the *n*th most frequent value of the column group or the *n*th quantile value of the column group.

Table 170. SYSCAT.COLGROUPDIST Catalog View

Column Name	Data Type	Nullable	Description
COLGROUPID	INTEGER		Identifier for the column group.
TYPE	CHAR (1)		• F = Frequency value • Q = Quantile value
ORDINAL	SMALLINT		Ordinal number of the column in the column group.
SEQNO	SMALLINT		If TYPE = 'F', *n* in this column identifies the *n*th most frequent value. If TYPE = 'Q', *n* in this column identifies the *n*th quantile value.
COLVALUE[1]	VARCHAR (254)		Data value as a character literal or a null value.

Note:

1. In the catalog view, the value of COLVALUE is always shown in the database code page and can contain substitution characters. However, the statistics are gathered internally in the code page of the column's table, and will therefore use actual column values when applied during query optimization.

SYSCAT.COLGROUPDISTCOUNTS

Each row represents the distribution statistics that apply to the *n*th most frequent value of a column group or the *n*th quantile of a column group.

Table 171. SYSCAT.COLGROUPDISTCOUNTS Catalog View

Column Name	Data Type	Nullable	Description
COLGROUPID	INTEGER		Identifier for the column group.
TYPE	CHAR (1)		• F = Frequency value • Q = Quantile value
SEQNO	SMALLINT		Sequence number *n* representing the *n*th TYPE value.
VALCOUNT	BIGINT		If TYPE = "F", VALCOUNT is the number of occurrences of COLVALUE for the column group with this SEQNO. If TYPE = "Q", VALCOUNT is the number of rows whose value is less than or equal to COLVALUE for the column group with this SEQNO.
DISTCOUNT	BIGINT		If TYPE = "Q", this column records the number of distinct values that are less than or equal to COLVALUE for the column group with this SEQNO (the null value if unavailable).

SYSCAT.COLGROUPS

Each row represents a column group and statistics that apply to the entire column group.

Table 172. SYSCAT.COLGROUPS Catalog View

Column Name	Data Type	Nullable	Description
COLGROUPSCHEMA	VARCHAR (128)		Schema name of the column group.
COLGROUPNAME	VARCHAR (128)		Unqualified name of the column group.
COLGROUPID	INTEGER		Identifier for the column group.
COLGROUPCARD	BIGINT		Cardinality of the column group.
NUMFREQ_VALUES	SMALLINT		Number of frequent values collected for the column group.
NUMQUANTILES	SMALLINT		Number of quantiles collected for the column group.

SYSCAT.COLIDENTATTRIBUTES

Each row represents an identity column that is defined for a table.

Table 173. SYSCAT.COLIDENTATTRIBUTES Catalog View

Column Name	Data Type	Nullable	Description
TABSCHEMA	VARCHAR (128)		Schema name of the table or view that contains the column.
TABNAME	VARCHAR (128)		Unqualified name of the table or view that contains the column.
COLNAME	VARCHAR (128)		Name of the column.
START	DECIMAL (31,0)	Y	Start value of the sequence. The null value if the sequence is an alias.
INCREMENT	DECIMAL (31,0)	Y	Increment value. The null value if the sequence is an alias.
MINVALUE	DECIMAL (31,0)	Y	Minimum value of the sequence. The null value if the sequence is an alias.
MAXVALUE	DECIMAL (31,0)	Y	Maximum value of the sequence. The null value if the sequence is an alias.
CYCLE	CHAR (1)		Indicates whether or not the sequence can continue to generate values after reaching its maximum or minimum value. • N = Sequence cannot cycle • Y = Sequence can cycle • Blank = Sequence is an alias.
CACHE	INTEGER		Number of sequence values to pre-allocate in memory for faster access. 0 indicates that values of the sequence are not to be preallocated. In a partitioned database, this value applies to each database partition. -1 if the sequence is an alias.

Table 173. SYSCAT.COLIDENTATTRIBUTES Catalog View (continued)

Column Name	Data Type	Nullable	Description
ORDER	CHAR (1)		Indicates whether or not the sequence numbers must be generated in order of request. • N = Sequence numbers are not required to be generated in order of request • Y = Sequence numbers must be generated in order of request • Blank = Sequence is an alias.
NEXTCACHEFIRSTVALUE	DECIMAL (31,0)	Y	The first value available to be assigned in the next cache block. If no caching, the next value available to be assigned.
SEQID	INTEGER		Identifier for the sequence or alias.

SYSCAT.COLOPTIONS

Each row contains column-specific option values.

Table 174. SYSCAT.COLOPTIONS Catalog View

Column Name	Data Type	Nullable	Description
TABSCHEMA	VARCHAR (128)		Schema name of the nickname.
TABNAME	VARCHAR (128)		Nickname for the column for which options are set.
COLNAME	VARCHAR (128)		Local column name.
OPTION	VARCHAR (128)		Name of the column option.
SETTING	CLOB (32K)		Value.

SYSCAT.COLUMNS

Each row represents a column defined for a table, view, or nickname.

Table 175. SYSCAT.COLUMNS Catalog View

Column Name	Data Type	Nullable	Description
TABSCHEMA	VARCHAR (128)		Schema name of the table, view, or nickname that contains the column.
TABNAME	VARCHAR (128)		Unqualified name of the table, view, or nickname that contains the column.
COLNAME	VARCHAR (128)		Name of the column.
COLNO	SMALLINT		Number of this column in the table (starting with 0).
TYPESCHEMA	VARCHAR (128)		Schema name of the data type for the column.
TYPENAME	VARCHAR (128)		Unqualified name of the data type for the column.

Table 175. SYSCAT.COLUMNS Catalog View (continued)

Column Name	Data Type	Nullable	Description
LENGTH	INTEGER		Maximum length of the data; 0 for distinct types. The LENGTH column indicates precision for DECIMAL fields, and indicates the number of bytes of storage required for decimal floating-point columns; that is, 8 and 16 for DECFLOAT(16) and DECFLOAT(34), respectively.
SCALE	SMALLINT		Scale if the column type is DECIMAL or number of digits of fractional seconds if the column type is TIMESTAMP; 0 otherwise.
TYPESTRINGUNITS	VARCHAR (11)	Y	In a Unicode database, the string units that apply to a character string or graphic string data type. Otherwise, the null value.
STRINGUNITSLENGTH	INTEGER	Y	In a Unicode database, the declared number of string units for a character string or graphic string data type. Otherwise, the null value.
DEFAULT	CLOB (64K)	Y	Default value for the column of a table expressed as a constant, special register, or cast-function appropriate for the data type of the column. Can also be the keyword NULL. Values might be converted from what was specified as a default value. For example, date and time constants are shown in ISO format, cast-function names are qualified with schema names, and identifiers are delimited. Null value if a DEFAULT clause was not specified or the column is a view column.
NULLS	CHAR (1)		Nullability attribute for the column. • N = Column is not nullable • Y = Column is nullable The value can be "N" for a view column that is derived from an expression or function. Nevertheless, such a column allows null values when the statement using the view is processed with warnings for arithmetic errors.
CODEPAGE	SMALLINT		Code page used for data in this column; 0 if the column is defined as FOR BIT DATA or is not a string type.
COLLATIONSCHEMA	VARCHAR (128)	Y	For string types, the schema name of the collation for the column; the null value otherwise.
COLLATIONNAME	VARCHAR (128)	Y	For string types, the unqualified name of the collation for the column; the null value otherwise.

Table 175. SYSCAT.COLUMNS Catalog View (continued)

Column Name	Data Type	Nullable	Description
LOGGED	CHAR (1)		Applies only to columns whose type is LOB or distinct based on LOB; blank otherwise. • N = Column is not logged • Y = Column is logged
COMPACT	CHAR (1)		Applies only to columns whose type is LOB or distinct based on LOB; blank otherwise. • N = Column is not compacted • Y = Column is compacted in storage
COLCARD	BIGINT		Number of distinct values in the column; -1 if statistics are not collected; -2 for inherited columns and columns of hierarchy tables.
HIGH2KEY[1]	VARCHAR (254)	Y	Second-highest data value. Representation of numeric data changed to character literals. Empty if statistics are not collected. Empty for inherited columns and columns of hierarchy tables.
LOW2KEY[1]	VARCHAR (254)	Y	Second-lowest data value. Representation of numeric data changed to character literals. Empty if statistics are not collected. Empty for inherited columns and columns of hierarchy tables.
AVGCOLLEN	INTEGER		Average space in bytes when the column is stored in database memory or a temporary table. For LOB data types that are not inlined, LONG data types, and XML documents, the value used to calculate the average column length is the length of the data descriptor. An extra byte is required if the column is nullable; -1 if statistics have not been collected; -2 for inherited columns and columns of hierarchy tables. Note: The average space required to store the column on disk may be different than the value represented by this statistic.
KEYSEQ	SMALLINT	Y	The column's numerical position within the table's primary key. The null value for columns of subtables and hierarchy tables.
PARTKEYSEQ	SMALLINT	Y	The column's numerical position within the table's distribution key; 0 or the null value if the column is not in the distribution key. The null value for columns of subtables and hierarchy tables.
NQUANTILES	SMALLINT		Number of quantile values recorded in SYSCAT.COLDIST for this column; -1 if statistics are not gathered; -2 for inherited columns and columns of hierarchy tables.

Table 175. SYSCAT.COLUMNS Catalog View (continued)

Column Name	Data Type	Nullable	Description
NMOSTFREQ	SMALLINT		Number of most-frequent values recorded in SYSCAT.COLDIST for this column; -1 if statistics are not gathered; -2 for inherited columns and columns of hierarchy tables.
NUMNULLS	BIGINT		Number of null values in the column; -1 if statistics are not collected.
TARGET_TYPESCHEMA	VARCHAR (128)	Y	Schema name of the target row type, if the type of this column is REFERENCE; null value otherwise.
TARGET_TYPENAME	VARCHAR (128)	Y	Unqualified name of the target row type, if the type of this column is REFERENCE; null value otherwise.
SCOPE_TABSCHEMA	VARCHAR (128)	Y	Schema name of the scope (target table), if the type of this column is REFERENCE; null value otherwise.
SCOPE_TABNAME	VARCHAR (128)	Y	Unqualified name of the scope (target table), if the type of this column is REFERENCE; null value otherwise.
SOURCE_TABSCHEMA	VARCHAR (128)	Y	For columns of typed tables or views, the schema name of the table or view in which the column was first introduced. For non-inherited columns, this is the same as TABSCHEMA. The null value for columns of non-typed tables and views.
SOURCE_TABNAME	VARCHAR (128)	Y	For columns of typed tables or views, the unqualified name of the table or view in which the column was first introduced. For non-inherited columns, this is the same as TABNAME. The null value for columns of non-typed tables and views.
DL_FEATURES	CHAR (10)	Y	This column is no longer used and will be removed in a future release.
SPECIAL_PROPS	CHAR (8)	Y	Applies to REFERENCE type columns only; blanks otherwise. Each byte position is defined as follows: • 1 = Object identifier (OID) column ("Y" for yes; "N" for no) • 2 = User-generated or system-generated ("U" for user; "S" for system) Bytes 3 through 8 are reserved for future use.

Table 175. SYSCAT.COLUMNS Catalog View (continued)

Column Name	Data Type	Nullable	Description
HIDDEN	CHAR (1)		Type of hidden column. • I = Column is defined as IMPLICITLY HIDDEN • S = System-managed hidden column • Blank = Column is not hidden
INLINE_LENGTH	INTEGER		Maximum size in bytes of the internal representation of an instance of an XML document, a structured type, or a LOB data type, that can be stored in the base table; 0 when not applicable.
PCTINLINED	SMALLINT		Percentage of inlined data for columns with VARCHAR, VARGRAPHIC, LOB, or XML data types. -1 if statistics have not been collected or the column data type does not support storing data outside the row. Also -1 for VARCHAR and VARGRAPHIC column if the table is organized by column or the table is organized by row and the row size of the table does not exceed the maximum record length for the page size of the table space.
IDENTITY	CHAR (1)		• N = Not an identity column • Y = Identity column
ROWCHANGETIMESTAMP	CHAR (1)		• N = Not a row change timestamp column • Y = Row change timestamp column
GENERATED	CHAR (1)		Type of generated column. • A = Column value is always generated • D = Column value is generated by default • Blank = Column is not generated
TEXT	CLOB (2M)	Y	For columns defined as generated as expression, this field contains the text of the generated column expression, starting with the keyword AS.
COMPRESS	CHAR (1)		• O = Compress off • S = Compress system default values
AVGDISTINCTPERPAGE	DOUBLE	Y	For future use.
PAGEVARIANCERATIO	DOUBLE		Reserved for future use.
SUB_COUNT	SMALLINT		Average number of sub-elements in the column. Applicable to character string columns only.

Table 175. SYSCAT.COLUMNS Catalog View (continued)

Column Name	Data Type	Nullable	Description
SUB_DELIM_LENGTH	SMALLINT		Average length of the delimiters that separate each sub-element in the column. Applicable to character string columns only.
AVGCOLLENCHAR	INTEGER		Average number of characters (based on the collation in effect for the column) required for the column; -1 if the data type of the column is long, LOB, or XML or if statistics have not been collected; -2 for inherited columns and columns of hierarchy tables.
IMPLICITVALUE[2]	VARCHAR (254)	Y	For a column that was added to a table after the table was created, stores the default value at the time the column was added. For a column that was defined when the table was created, stores the null value.
SECLABELNAME	VARCHAR (128)	Y	Name of the security label that is associated with the column if it is a protected column; the null value otherwise.
ROWBEGIN	CHAR (1)		• N = Not a row begin column • Y = Row begin column
ROWEND	CHAR (1)		• N = Not a row end column • Y = Row end column
TRANSACTIONSTARTID	CHAR (1)		• N = Not a transaction start ID column • Transaction start ID column
RANDDISTKEY	CHAR (1)		• N = Column of a table not using random distribution with random by generation method or not the distribution key • Y = Distribution key of a random distribution table that uses random by generation method
PCTENCODED	SMALLINT		Percentage of values that are encoded as a result of compression for a column in a column-organized table; -1 if the table is not organized by column or if statistics are not collected; -2 for inherited columns and columns of hierarchy tables.
AVGENCODEDCOLLEN	DOUBLE		Average space in bytes when the column is stored in database memory, taking into account that some of the column values might be compressed; -1 if the table is not organized by column or if statistics are not collected; -2 for inherited columns and columns of hierarchy tables.
QUALIFIER	VARCHAR (128)	Y	Reserved for future use.

Table 175. SYSCAT.COLUMNS Catalog View (continued)

Column Name	Data Type	Nullable	Description
FUNC_PATH	CLOB (2K)	Y	Reserved for future use.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. In the catalog view, the values of HIGH2KEY and LOW2KEY are always shown in the database code page and can contain substitution characters. However, the statistics are gathered internally in the code page of the column's table, and will therefore use actual column values when applied during query optimization.
2. Attaching a data partition is allowed unless IMPLICITVALUE for a specific column is a non-null value for both the source column and the target column, and the values do not match. In this case, you must drop the source table and then re-create it. A column can have a non-null value in the IMPLICITVALUE field if one of the following conditions is met:
   - The column is created as the result of an ALTER TABLE...ADD COLUMN statement
   - The IMPLICITVALUE field is propagated from a source table during attach
   - The IMPLICITVALUE field is inherited from a source table during detach
   - The IMPLICITVALUE field is set during database upgrade from Version 8 to Version 9, where it is determined to be an added column, or might be an added column. If the database is not certain whether the column is added or not, it is treated as added. An added column is a column that was created as the result of an ALTER TABLE...ADD COLUMN statement.

   To avoid these inconsistencies during non-migration scenarios, it is recommended that you always create the tables that you are going to attach with all the columns already defined. That is, never use the ALTER TABLE statement to add columns to a table before attaching it.

SYSCAT.COLUSE

Each row represents a column that is referenced in the DIMENSIONS clause of a CREATE TABLE statement.

Table 176. SYSCAT.COLUSE Catalog View

Column Name	Data Type	Nullable	Description
TABSCHEMA	VARCHAR (128)		Schema name of the table containing the column.
TABNAME	VARCHAR (128)		Unqualified name of the table containing the column.
COLNAME	VARCHAR (128)		Name of the column.
DIMENSION	SMALLINT		Dimension number, based on the reverse order of dimensions specified in the DIMENSIONS clause (initial position is 1). For a composite dimension, this value will be the same for each component of the dimension.
COLSEQ	SMALLINT		Numeric position of the column in the dimension to which it belongs (initial position is 1). The value is 1 for the single column in a noncomposite dimension.

Table 176. SYSCAT.COLUSE Catalog View (continued)

Column Name	Data Type	Nullable	Description
TYPE	CHAR (1)		Type of dimension. • C = Clustering or multidimensional clustering • P = Partitioning

SYSCAT.CONDITIONS

Each row represents a condition defined in a module.

Table 177. SYSCAT.CONDITIONS Catalog View

Column Name	Data Type	Nullable	Description
CONDSCHEMA	VARCHAR (128)		Schema name of the condition.
CONDMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the condition belongs.
CONDNAME	VARCHAR (128)		Unqualified name of the condition.
CONDID	INTEGER		Identifier for the condition.
CONDMODULEID	INTEGER	Y	Identifier of the module to which the condition belongs.
SQLSTATE	CHAR (5)	Y	SQLSTATE value associated with the condition.
OWNER	VARCHAR (128)		Authorization ID of the owner of the condition.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
CREATE_TIME	TIMESTAMP		Time at which the condition was created.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.CONSTDEP

Each row represents a dependency of a constraint on some other object. The constraint depends on the object of type BTYPE of name BNAME, so a change to the object affects the constraint.

Table 178. SYSCAT.CONSTDEP Catalog View

Column Name	Data Type	Nullable	Description
CONSTNAME	VARCHAR (128)		Unqualified name of the constraint.
TABSCHEMA	VARCHAR (128)		Schema name of the table to which the constraint applies.
TABNAME	VARCHAR (128)		Unqualified name of the table to which the constraint applies.

Table 178. SYSCAT.CONSTDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
BTYPE	CHAR (1)		Type of object on which the constraint depends. Possible values are: • F = Routine • I = Index • R = User-defined structured type • u = Module alias
BSCHEMA	VARCHAR (128)		Schema name of the object on which the constraint depends.
BMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the object on which a dependency belongs. The null value if not a module object.
BNAME	VARCHAR (128)		Unqualified name of the object on which the constraint depends.
BMODULEID	INTEGER	Y	Identifier for the module of the object on which the constraint depends.

SYSCAT.CONTEXTATTRIBUTES

Each row represents a trusted context attribute.

Table 179. SYSCAT.CONTEXTATTRIBUTES Catalog View

Column Name	Data Type	Nullable	Description
CONTEXTNAME	VARCHAR (128)		Name of the trusted context.
ATTR_NAME	VARCHAR (128)		Name of the attribute. One of: • ADDRESS • ENCRYPTION
ATTR_VALUE	VARCHAR (128)		Value of the attribute.
ATTR_OPTIONS	VARCHAR (128)	Y	If ATTR_NAME is 'ADDRESS', specifies the level of encryption required for this specific address. A null value indicates that the global ENCRYPTION attribute applies.

SYSCAT.CONTEXTS

Each row represents a trusted context.

Table 180. SYSCAT.CONTEXTS Catalog View

Column Name	Data Type	Nullable	Description
CONTEXTNAME	VARCHAR (128)		Name of the trusted context.
CONTEXTID	INTEGER		Identifier for the trusted context.
SYSTEMAUTHID	VARCHAR (128)		The system authorization ID associated with the trusted context.
DEFAULTCONTEXTROLE	VARCHAR (128)	Y	The default role for the context.

Table 180. SYSCAT.CONTEXTS Catalog View (continued)

Column Name	Data Type	Nullable	Description
CREATE_TIME	TIMESTAMP		Time at which the trusted context was created.
ALTER_TIME	TIMESTAMP		Time at which the trusted context was last altered.
ENABLED	CHAR (1)		Trusted context state. • N = Disabled • Y = Enabled
AUDITPOLICYID	INTEGER	Y	Identifier for the audit policy.
AUDITPOLICYNAME	VARCHAR (128)	Y	Name of the audit policy.
AUDITEXCEPTIONENABLED	CHAR (1)		Reserved for future use.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.CONTROLDEP

Each row represents a dependency of a row permission or column mask on some other object.

Table 181. SYSCAT.CONTROLDEP Catalog View

Column Name	Data Type	Nullable	Description
DSCHEMA	VARCHAR (128)		Schema name of the row permission or column mask.
DNAME	VARCHAR (128)		Unqualified name of the row permission or column mask.
DTYPE	CHAR (1)		Type of the depending object. • y = Row Permission • 2 = Column Mask

Table 181. SYSCAT.CONTROLDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
BTYPE	CHAR (1)		Type of object on which there is a dependency: • A = Table alias • C = Column • F = Routine • H = Hierarchy table • I = Index • L = Detached table • S = Materialized query table • T = Table (not typed) • U = Typed table • V = View (not typed) • W = Typed view • m = Module • s = Statistical Table • u = Module alias • v = Global variable
BSCHEMA	VARCHAR (128)		Schema name of the object on which there is a dependency.
BMODULENAME	VARCHAR (128)	Y	Unqualified name for the module of the object on which the control depends. The null value if not a module object.
BNAME	VARCHAR (128)		Unqualified name of the object on which there is a dependency.
BMODULEID	INTEGER	Y	Identifier for the module of the object on which the control depends.
BCOLNAME	VARCHAR (128)	Y	If BTYPE = 'C', the column name on which there is a dependency; the null value otherwise.

SYSCAT.CONTROLS

Each row represents a row permission or column mask.

Table 182. SYSCAT.CONTROLS Catalog View

Column Name	Data Type	Nullable	Description
CONTROLSCHEMA	VARCHAR (128)		Schema of the row permission or column mask.
CONTROLNAME	VARCHAR (128)		Name of the row permission or column mask.
OWNER	VARCHAR (128)		Owner of the row permission or column mask.

Table 182. SYSCAT.CONTROLS Catalog View (continued)

Column Name	Data Type	Nullable	Description
OWNERTYPE	CHAR (1)		• S = System • U = User
TABSCHEMA	VARCHAR (128)		Schema of the table on which the row permission or column mask is defined.
TABNAME	VARCHAR (128)		Name of the table on which the row permission or column mask is defined.
COLNAME	VARCHAR (128)		Column name on which the column mask is defined. Blank if this is a row permission.
CONTROLID	INTEGER		Identifier of the control.
CONTROLTYPE	CHAR (1)		• C = Column mask • R = Row permission
ENFORCED	CHAR (1)		• A = All access
IMPLICIT	CHAR (1)		• N = The row permission was explicitly created or this is a column mask • Y = The row permission was implicitly created
ENABLE	CHAR (1)		• N = Not enabled • Y = Enabled
VALID	CHAR (1)		• N = The control is invalid • Y = The control is valid
RULETEXT	CLOB (2M)		The source text of the search condition or case expression portion of the CREATE PERMISSION or CREATE MASK statement.
TABCORRELATION	VARCHAR (128)		The correlation name of the table on which the row permission or column mask is defined. Blank if not specified.
QUALIFIER	VARCHAR (128)		Value of the default schema at the time of object definition. Used to complete any unqualified references.
FUNC_PATH	CLOB (2K)		SQL path in effect when the control was defined.
COLLATIONSCHEMA	VARCHAR (128)		Schema name of the collation for the control.
COLLATIONNAME	VARCHAR (128)		Unqualified name of the collation for the control.

Table 182. SYSCAT.CONTROLS Catalog View (continued)

Column Name	Data Type	Nullable	Description
COLLATIONSCHEMA_ORDERBY	VARCHAR (128)		Schema name of the collation for the ORDER BY clauses in the control.
COLLATIONNAME_ORDERBY	VARCHAR (128)		Unqualified name of the collation for the ORDER BY clauses in the control.
CREATE_TIME	TIMESTAMP		Time at which the row permission or column mask was created.
ALTER_TIME	TIMESTAMP		Time at which the row permission or column mask was last altered.
ENVSTRINGUNITS	VARCHAR (11)		Default string units when the object was created.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.DATAPARTITIONEXPRESSION

Each row represents an expression for that part of the table partitioning key.

Table 183. SYSCAT.DATAPARTITIONEXPRESSION Catalog View

Column Name	Data Type	Nullable	Description
TABSCHEMA	VARCHAR (128)		Schema name of the partitioned table.
TABNAME	VARCHAR (128)		Unqualified name of the partitioned table.
DATAPARTITIONKEYSEQ	INTEGER		Expression key part sequence ID, starting from 1.
DATAPARTITIONEXPRESSION	CLOB (32K)		Expression for this entry in the sequence, in SQL syntax.
NULLSFIRST	CHAR (1)		• N = Null values in this expression compare high • Y = Null values in this expression compare low

SYSCAT.DATAPARTITIONS

Each row represents a data partition. Note that the data partition statistics represent one database partition if the table is created on multiple database partitions.

Table 184. SYSCAT.DATAPARTITIONS Catalog View

Column Name	Data Type	Nullable	Description
DATAPARTITIONNAME	VARCHAR (128)		Name of the data partition.
TABSCHEMA	VARCHAR (128)		Schema name of the table to which this data partition belongs.
TABNAME	VARCHAR (128)		Unqualified name of the table to which this data partition belongs.
DATAPARTITIONID	INTEGER		Identifier for the data partition.

Table 184. SYSCAT.DATAPARTITIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
TBSPACEID	INTEGER	Y	Identifier for the table space in which this data partition is stored. The null value when STATUS is 'I'.
PARTITIONOBJECTID	INTEGER	Y	Identifier for the data partition within the table space.
LONG_TBSPACEID	INTEGER	Y	Identifier for the table space in which long data is stored. The null value when STATUS is 'I'.
ACCESS_MODE	CHAR (1)		Access restriction state of the data partition. These states only apply to objects that are in set integrity pending state or to objects that were processed by a SET INTEGRITY statement. Possible values are: • D = No data movement • F = Full access • N = No access • R = Read-only access
STATUS	VARCHAR (32)		• A = Data partition is newly attached • D = Data partition is detached and detached dependents are to be incrementally maintained with respect to the content of this partition • I = Detached data partition whose entry in the catalog is maintained only during asynchronous index cleanup; rows with a STATUS value of 'I' are removed when all index records referring to the detached partition have been deleted • L = Data partition is logically detached • Empty string = Data partition is visible (normal status) Bytes 2 through 32 are reserved for future use.
SEQNO	INTEGER		Data partition sequence number (starting from 0).
LOWINCLUSIVE	CHAR (1)		• N = Low key value is not inclusive • Y = Low key value is inclusive
LOWVALUE	VARCHAR (512)		Low key value (a string representation of an SQL value) for this data partition.
HIGHINCLUSIVE	CHAR (1)		• N = High key value is not inclusive • Y = High key value is inclusive
HIGHVALUE	VARCHAR (512)		High key value (a string representation of an SQL value) for this data partition.

Table 184. SYSCAT.DATAPARTITIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
CARD	BIGINT		Total number of rows in the data partition; -1 if statistics are not collected.
OVERFLOW	BIGINT		Total number of overflow records in the data partition; -1 if statistics are not collected.
NPAGES	BIGINT		Total number of pages on which the rows of the data partition exist; -1 if statistics are not collected.
FPAGES	BIGINT		Total number of pages in the data partition; -1 if statistics are not collected.
ACTIVE_BLOCKS	BIGINT		Total number of active blocks in the data partition, or -1. Applies to multidimensional clustering (MDC) tables only.
INDEX_TBSPACEID	INTEGER		Identifier for the table space which holds all partitioned indexes for this data partition.
AVGROWSIZE	SMALLINT		Average length (in bytes) of both compressed and uncompressed rows in this data partition; -1 if statistics are not collected.
PCTROWSCOMPRESSED	REAL		Compressed rows as a percentage of the total number of rows in the data partition; -1 if statistics are not collected.
PCTPAGESAVED	SMALLINT		Approximate percentage of pages saved in the data partition as a result of row compression. This value includes overhead bytes for each user data row in the data partition, but does not include the space that is consumed by dictionary overhead; -1 if statistics are not collected.
AVGCOMPRESSEDROWSIZE	SMALLINT		Average length (in bytes) of compressed rows in this data partition; -1 if statistics are not collected.
AVGROWCOMPRESSIONRATIO	REAL		For compressed rows in the data partition, this is the average compression ratio by row; that is, the average uncompressed row length divided by the average compressed row length; -1 if statistics are not collected.
STATS_TIME	TIMESTAMP	Y	Time at which any change was last made to recorded statistics for this object. Null if statistics are not collected.

Table 184. SYSCAT.DATAPARTITIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
LASTUSED	DATE		Date when the data partition was last used by any DML statement or the LOAD command. If the table is not partitioned, only the LASTUSED value in SYSCAT.TABLES is updated. This column is not updated when the data partition is used on an HADR standby database. The default value is '0001-01-01'. This value is updated asynchronously not more than once within a 24 hour period and might not reflect usage within the last 15 minutes.
COLDICT_EXISTS	CHAR(1)		Indicates the existence and status of a column compression dictionary for a column-organized table. Possible values are: • A = Common dictionary exists on all members of the table's database partition group • N = Common dictionary does not exist • S = Common dictionary exists on some members of the table's database partition group • X = Not applicable
COLDICT_CREATE_TIME	TIMESTAMP	Y	Time at which the column compression dictionary was created. Null if COLDICT_EXISTS is 'N' or 'X'.
COLDICT_ALTER_TIME	TIMESTAMP	Y	Time at which the column compression dictionary was last altered. At the time of dictionary creation, this value matches the value of COLDICT_CREATE_TIME. Null if COLDICT_EXISTS is 'N' or 'X'.

SYSCAT.DATATYPEDEP

Each row represents a dependency of a user-defined data type on some other object.

Table 185. SYSCAT.DATATYPEDEP Catalog View

Column Name	Data Type	Nullable	Description
TYPESCHEMA	VARCHAR (128)		Schema name of the data type.
TYPEMODULENAME	VARCHAR (128)	Y	Module name of the data type.
TYPENAME	VARCHAR (128)		Unqualified name of the data type.
TYPEMODULEID	INTEGER	Y	Identifier for the module of the data type.

Table 185. SYSCAT.DATATYPEDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
BTYPE	CHAR (1)		Type of object on which there is a dependency. Possible values are: • A = Table alias • F = Routine • G = Global temporary table • H = Hierarchy table • I = Index • N = Nickname • R = User-defined data type • S = Materialized query table • T = Table (not typed) • U = Typed table • V = View (not typed) • W = Typed view • m = Module • q = Sequence alias • u = Module alias • v = Global variable • * = Anchored to the row of a base table
BSCHEMA	VARCHAR (128)		Schema name of the object on which there is a dependency.
BMODULENAME	VARCHAR (128)	Y	Module name of the object on which there is a dependency.
BNAME	VARCHAR (128)		Unqualified name of the object on which there is a dependency.
BMODULEID	INTEGER	Y	Identifier for the module of the object on which there is a dependency.
TABAUTH	SMALLINT	Y	If BTYPE = 'S', 'T', 'U', 'V', 'W', or 'v', encodes the privileges on the table or view that are required by the dependent data type; the null value otherwise.

SYSCAT.DATATYPES

Each row represents a built-in or user-defined data type.

Table 186. SYSCAT.DATATYPES Catalog View

Column Name	Data Type	Nullable	Description
TYPESCHEMA	VARCHAR (128)		Schema name of the data type if TYPEMODULEID is null; otherwise schema name of the module to which the data type belongs.

Table 186. SYSCAT.DATATYPES Catalog View (continued)

Column Name	Data Type	Nullable	Description
TYPEMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the user-defined type belongs. The null value if not a module user-defined type.
TYPENAME	VARCHAR (128)		Unqualified name of the data type.
OWNER	VARCHAR (128)		Authorization ID of the owner of the type.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
SOURCESCHEMA	VARCHAR (128)	Y	For distinct types or array types, the schema name of the source data type. For user-defined structured types, the schema name of the built-in type of the reference representation type. Null for other data types.
SOURCEMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the source data type belongs. The null value if not a module source data type.
SOURCENAME	VARCHAR (128)	Y	For distinct types or array types, the unqualified name of the source data type. For user-defined structured types, the unqualified built-in type name of the reference representation type. Null for other data types.
METATYPE	CHAR (1)		• A = User-defined array type • C = User-defined cursor type • F = User-defined row type • L = User-defined associative array type • R = User-defined structured type • S = System predefined type • T = User-defined distinct type
TYPERULES	CHAR(1)		Indicates the type rules for the user-defined type. • S = Strong typing • W = Weak typing • Blank = Not applicable
TYPEID	SMALLINT		Identifier for the data type.
TYPEMODULEID	INTEGER	Y	Identifier for the module to which the user-defined type belongs. The null value if not a module user-defined type.
SOURCETYPEID	SMALLINT	Y	Identifier for the source type (the null value for built-in types). For user-defined structured types, this is the identifier of the reference representation type.

Table 186. SYSCAT.DATATYPES Catalog View (continued)

Column Name	Data Type	Nullable	Description
SOURCEMODULEID	INTEGER	Y	Identifier for the module to which the source data type belongs. The null value if not a module source data type.
PUBLISHED	CHAR (1)		Indicates whether the module user-defined type can be referenced outside its module. • N = The module user-defined type is not published • Y = The module user-defined type is published • Blank = Not applicable
LENGTH	INTEGER		Maximum length of the type. 0 for built-in parameterized types (for example, DECIMAL and VARCHAR). For user-defined structured types, this is the length of the reference representation type.
SCALE	SMALLINT		Scale for distinct types or reference representation types based on the built-in DECIMAL type; the number of digits of fractional seconds for distinct types based on the built-in TIMESTAMP type; 6 for the built-in TIMESTAMP type; 0 for all other types (including DECIMAL itself).
TYPESTRINGUNITS	VARCHAR (11)	Y	In a Unicode database, the string units that apply to a character string or graphic string data type. Otherwise, the null value.
STRINGUNITSLENGTH	INTEGER	Y	In a Unicode database, the declared number of string units for a character string or graphic string data type. Otherwise, the null value.
CODEPAGE	SMALLINT		Database code page for string types, distinct types based on string types, or reference representation types; 0 otherwise.
COLLATIONSCHEMA	VARCHAR (128)	Y	For string types, the schema name of the collation for the data type; the null value otherwise.
COLLATIONNAME	VARCHAR (128)	Y	For string types, the unqualified name of the collation for the data type; the null value otherwise.
ARRAY_LENGTH	INTEGER	Y	Maximum cardinality of the array. The null value if METATYPE is not 'A'.
ARRAYINDEXTYPESCHEMA	VARCHAR (128)	Y	Schema of the data type of the array index. The null value if METATYPE is not 'L'.
ARRAYINDEXTYPENAME	VARCHAR (128)	Y	Name of the data type of the array index. The null value if METATYPE is not 'L'.

Table 186. SYSCAT.DATATYPES Catalog View (continued)

Column Name	Data Type	Nullable	Description
ARRAYINDEXTYPEID	SMALLINT	Y	Identifier for the array index type. The null value if METATYPE is not 'L'.
ARRAYINDEXTYPELENGTH	INTEGER	Y	Maximum length of the array index data type. The null value if METATYPE is not 'L'.
ARRAYINDEXTYPE_ STRINGUNITS	VARCHAR (11)	Y	In a Unicode database, the string units that apply to a character string array index data type. Otherwise, the null value.
ARRAYINDEXTYPE_ STRINGUNITSLENGTH	INTEGER	Y	In a Unicode database, the declared number of string units for a character string array index data type. Otherwise, the null value.
CREATE_TIME	TIMESTAMP		Creation time of the data type.
VALID	CHAR (1)		• N = The data type is invalid • Y = The data type is valid
ATTRCOUNT	SMALLINT		Number of attributes in the data type.
INSTANTIABLE	CHAR (1)		• N = Type cannot be instantiated • Y = Type can be instantiated
WITH_FUNC_ACCESS	CHAR (1)		• N = Methods for this type cannot be invoked using function notation. • Y = All the methods for this type can be invoked using function notation.
FINAL	CHAR (1)		• N = The user-defined type can have subtypes. • Y = The user-defined type cannot have subtypes.
INLINE_LENGTH	INTEGER		Maximum length of a structured type that can be kept with a base table row; 0 otherwise.
NATURAL_ INLINE_LENGTH	INTEGER	Y	System-generated natural inline length of a structured type instance. The null value if this type is not a structured type.
JARSCHEMA	VARCHAR (128)	Y	Schema name of the JAR_ID that identifies the Jar file containing the Java class that implements the SQL type. The null value if the EXTERNAL NAME clause is not specified.
JAR_ID	VARCHAR (128)	Y	Identifier for the Jar file that contains the Java class that implements the SQL type. The null value if the EXTERNAL NAME clause is not specified.

Table 186. SYSCAT.DATATYPES Catalog View (continued)

Column Name	Data Type	Nullable	Description
CLASS	VARCHAR (384)	Y	Java class that implements the SQL type. The null value if the EXTERNAL NAME clause is not specified.
SQLJ_REPRESENTATION	CHAR (1)	Y	SQLJ "representation_spec" of the Java class that implements the SQL type. The null value if the EXTERNAL NAME ... LANGUAGE JAVA REPRESENTATION SPEC clause is not specified. • D = SQL data • S = Serializable
ALTER_TIME	TIMESTAMP		Time at which the data type was last altered.
DEFINER[1]	VARCHAR (128)		Authorization ID of the owner of the type.
NULLS	CHAR (1)		Nullability attribute for the type. • N = Type is not nullable • Y = Type is nullable
FUNC_PATH	CLOB (2K)	Y	SQL path in effect when the type was created. The null value if no data type check constraint exists.
CONSTRAINT_TEXT	CLOB (64K)	Y	Predicate text which constrains the values allowed for the data type. The null value if no data type check constraint exists.
LAST_REGEN_TIME	TIMESTAMP		Time at which the data type check constraint was last regenerated. The same value as CREATE_TIME if no data type check constraint exists.
ENVSTRINGUNITS	VARCHAR (11)		Default string units when the object was created.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.DBAUTH

Each row represents a user, group, or role that has been granted one or more database-level authorities.

Table 187. SYSCAT.DBAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of the authority.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user
GRANTEE	VARCHAR (128)		Holder of the authority.

Table 187. SYSCAT.DBAUTH Catalog View (continued)

Column Name	Data Type	Nullable	Description
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
BINDADDAUTH	CHAR (1)		Authority to create packages. • N = Not held • Y = Held
CONNECTAUTH	CHAR (1)		Authority to connect to the database. • N = Not held • Y = Held
CREATETABAUTH	CHAR (1)		Authority to create tables. • N = Not held • Y = Held
DBADMAUTH	CHAR (1)		DBADM authority. • N = Not held • Y = Held
EXTERNALROUTINEAUTH	CHAR (1)		Authority to create external routines. • N = Not held • Y = Held
IMPLSCHEMAAUTH	CHAR (1)		Authority to implicitly create schemas by creating objects in non-existent schemas. • N = Not held • Y = Held
LOADAUTH	CHAR (1)		Authority to use the Db2 load utility. • N = Not held • Y = Held
NOFENCEAUTH	CHAR (1)		Authority to create non-fenced user-defined functions. • N = Not held • Y = Held
QUIESCECONNECTAUTH	CHAR (1)		Authority to access the database when it is quiesced. • N = Not held • Y = Held
LIBRARYADMAUTH	CHAR (1)		Reserved for future use.

Table 187. SYSCAT.DBAUTH Catalog View (continued)

Column Name	Data Type	Nullable	Description
SECURITYADMAUTH	CHAR (1)		Authority to administer database security. • N = Not held • Y = Held
SQLADMAUTH	CHAR (1)		Authority to monitor and tune SQL statements. • N = Not held • Y = Held
WLMADMAUTH	CHAR (1)		Authority to manage WLM objects. • N = Not held • Y = Held
EXPLAINAUTH	CHAR (1)		Authority to explain SQL statements without requiring actual privileges on the objects in the statement. • N = Not held • Y = Held
DATAACCESSAUTH	CHAR (1)		Authority to access data. • N = Not held • Y = Held
ACCESSCTRLAUTH	CHAR (1)		Authority to grant and revoke database object privileges. • N = Not held • Y = Held
CREATESECUREAUTH	CHAR (1)		Authority to create secure objects. • N = Not held • Y = Held

SYSCAT.DBPARTITIONGROUPDEF

Each row represents a database partition that is contained in a database partition group.

Table 188. SYSCAT.DBPARTITIONGROUPDEF Catalog View

Column Name	Data Type	Nullable	Description
DBPGNAME	VARCHAR (128)		Name of the database partition group that contains the database partition.
DBPARTITIONNUM	SMALLINT		Partition number of a database partition that is contained in the database partition group. A valid partition number is between 0 and 999, inclusive.

Table 188. SYSCAT.DBPARTITIONGROUPDEF Catalog View (continued)

Column Name	Data Type	Nullable	Description
IN_USE	CHAR (1)		Status of the database partition. • A = The newly added database partition is not in the distribution map, but the containers for the table spaces in the database partition group have been created; the database partition is added to the distribution map when a redistribute database partition group operation has completed successfully. • D = The database partition will be dropped when a redistribute database partition group operation has completed successfully. • T = The newly added database partition is not in the distribution map, and it was added using the WITHOUT TABLESPACES clause; containers must be added to the table spaces in the database partition group. • Y = The database partition is in the distribution map.

SYSCAT.DBPARTITIONGROUPS

Each row represents a database partition group.

Table 189. SYSCAT.DBPARTITIONGROUPS Catalog View

Column Name	Data Type	Nullable	Description
DBPGNAME	VARCHAR (128)		Name of the database partition group.
OWNER	VARCHAR (128)		Authorization ID of the owner of the database partition group.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
PMAP_ID	SMALLINT		Identifier for the distribution map in the SYSCAT.PARTITIONMAPS catalog view.
REDISTRIBUTE_PMAP_ID	SMALLINT		Identifier for the distribution map currently being used for redistribution; -1 if redistribution is currently not in progress.
CREATE_TIME	TIMESTAMP		Creation time of the database partition group.
DEFINER[1]	VARCHAR (128)		Authorization ID of the owner of the database partition group.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.EVENTMONITORS

Each row represents an event monitor.

Table 190. SYSCAT.EVENTMONITORS Catalog View

Column Name	Data Type	Nullable	Description
EVMONNAME	VARCHAR (128)		Name of the event monitor.
OWNER	VARCHAR (128)		Authorization ID of the owner of the event monitor.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
TARGET_TYPE	CHAR (1)		Type of target to which event data is written. • F = File • P = Pipe • T = Table • U = Unformatted event table
TARGET	VARCHAR (762)		Name of the target to which file or pipe event monitor data is written. For files, it can be either an absolute path name or a relative path name (relative to the database path for the database; this can be seen using the LIST ACTIVE DATABASES command). For pipes, it can be an absolute path name.
MAXFILES	INTEGER	Y	Maximum number of event files that this event monitor permits in an event path. The null value if there is no maximum, or if TARGET_TYPE is not 'F' (file).
MAXFILESIZE	INTEGER	Y	Maximum size (in 4K pages) that each event file can attain before the event monitor creates a new file. The null value if there is no maximum, or if TARGET_TYPE is not 'F' (file).
BUFFERSIZE	INTEGER	Y	Size of the buffer (in 4K pages) that is used by event monitors with file targets; null value otherwise.
IO_MODE	CHAR (1)	Y	Mode of file input/output (I/O). • B = Blocked • N = Not blocked • Null value = TARGET_TYPE is not 'F' (file) or 'T' (table)

Table 190. SYSCAT.EVENTMONITORS Catalog View (continued)

Column Name	Data Type	Nullable	Description
WRITE_MODE	CHAR (1)	Y	Indicates how this event monitor handles existing event data when the monitor is activated. • A = Append • R = Replace • Null value = TARGET_TYPE is not 'F' (file)
AUTOSTART	CHAR (1)		Indicates whether this event monitor is to be activated automatically when the database starts. • N = No • Y = Yes
DBPARTITIONNUM[1]	SMALLINT		This column is deprecated and will be removed in a future release. Replaced by MEMBER.
MONSCOPE	CHAR (1)		Monitoring scope. • G = Global • L = Local • T = Each database partition on which the table space exists • Blank = WRITE TO TABLE event monitor
EVMON_ACTIVATES	INTEGER		Number of times the event monitor has been activated.
NODENUM[1]	SMALLINT		This column is deprecated and will be removed in a future release. Replaced by MEMBER.
DEFINER[2]	VARCHAR (128)		Authorization ID of the owner of the event monitor.
VERSIONNUMBER	INTEGER		Version, release, and modification level in which the event monitor was created or last upgraded.
MEMBER	SMALLINT		Number of the member where the event monitor runs and logs events.
REMARKS	VARCHAR (254)	Y	Reserved for future use.

Note:

1. The NODENUM column is included for backwards compatibility. See DBPARTITIONNUM.
2. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.EVENTS

Each row represents an event that is being monitored. An event monitor, in general, monitors multiple events.

Table 191. SYSCAT.EVENTS Catalog View

Column Name	Data Type	Nullable	Description
EVMONNAME	VARCHAR (128)		Name of the event monitor that is monitoring this event.
TYPE	VARCHAR (128)		Type of event being monitored. Possible values are: • ACTIVITIES • CHANGEHISTORY • CONNECTIONS • DATABASE • DEADLOCKS • DETAILDEADLOCKS • DLOCKWHIST • DLOCKWHISTAVAL • LOCKING • PKGCACHEBASE • PKGCACHEDETAILED • STATEMENTS • TABLES • TABLESPACES • THRESHOLDVIOLATIONS • TRANSACTIONS • STATISTICS • UOW
FILTER	CLOB (64K)	Y	Full text of the WHERE clause that applies to this event.

SYSCAT.EVENTTABLES

Each row represents the target table of an event monitor that writes to SQL tables.

Table 192. SYSCAT.EVENTTABLES Catalog View

Column Name	Data Type	Nullable	Description
EVMONNAME	VARCHAR (128)		Name of the event monitor.

Table 192. SYSCAT.EVENTTABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
LOGICAL_GROUP	VARCHAR (128)		Name of the logical data group. Possible values are: • ACTIVITYHISTORY • BUFFERPOOL • CHANGESUMMARY • CONN • CONNHEADER • CONTROL • DATAVAL • DB • DBDBMCFG • DDLSTMTEXEC • DEADLOCK • DLCONN • DLLOCK • EVMONSTART • LOCKING • PKGCACHEBASE • PKGCACHEDETAILED • REGVAR • SCMETRICS • SCSTATS • STMT • STMTHIST • STMTVALS • SUBSECTION • SUPERCLASSMETRICS • SUPERCLASSSTATS • TABLE • TABLESPACE • THRESHOLDVIOLATIONS • TXNCOMPLETION • UOW • UTILLOCATION • UTILPHASE • UTILSTART • UTILSTOP • WCSTATS • WLMETRICS • WLSTATS • XACT

Table 192. SYSCAT.EVENTTABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
TABSCHEMA	VARCHAR (128)		Schema name of the target table.
TABNAME	VARCHAR (128)		Unqualified name of the target table.
PCTDEACTIVATE	SMALLINT		A percent value that specifies how full a DMS table space must be before an event monitor automatically deactivates. Set to 100 for SMS table spaces.
TABOPTIONS	VARCHAR (32)		String indicating the logical data group options for the target table. Each character in the string represents an option. Possible values are: • E = EXCLUDES • I = INCLUDES • T = TRUNC • Blank = Not applicable

SYSCAT.EXTERNALTABLEOPTIONS

Each row represents a named external table.

Table 193. SYSCAT.EXTERNALTABLEOPTIONS Catalog View

Column Name	Data Type	Nullable	Description
TABLENAME	VARCHAR(128)	No	Name of the external table.
FILENAME	CLOB(4K)	No	Fully-qualified name of the file that contains the data for this external table.
FIELDDELIMITER	CHAR(1)	Yes	Character that indicates the end of a field.
RECORDDELIMITER	CHAR(4)	Yes	Character string that indicates the end of a record.
DECIMALDELIMITER	CHAR(1)	No	Character to represent the decimal delimiter.
DATEDELIMITER	CHAR(1)	No	Character to separate date components.
TIMEDELIMITER	CHAR(1)	No	Character to separate time components.
DATESTYLE	CHAR(12)	No	Format that determines how a date is represented.
TIMESTYLE	CHAR(6)	No	Time format. Possible values are '24HOUR' and '12HOUR'
BOOLEANSTYLE	CHAR(32)	No	Boolean style. Possible values are '1_0', 'TRUE_FALSE', and 'YES_NO'.
NULLVALUE	CHAR(8)	No	String that is used to indicate a null value. The default is 'NULL'.

Table 193. SYSCAT.EXTERNALTABLEOPTIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
QUOTEDVALUE	CHAR(12)	Yes	Type of quotation marks that are to be stripped away from data values that are enclosed by them. Possible values are 'YES' or 'SINGLE' (for single quotation marks), 'DOUBLE' (for double quotation marks), and 'NO' (if no quotation marks are to be stripped).
REQUIREQUOTES	CHAR(5)	Yes	Whether all data values are enclosed in quotation marks. Possible values are: 'TRUE' or 'FALSE'. If REQUIREQUOTES is set to 'TRUE', QUOTEDVALUE must be set to 'YES', 'SINGLE', or 'DOUBLE'.
RECORDLENGTH	INTEGER	Yes	Length of each record of a fixed-format file.
MAXERRORS	BIGINT	No	Maximum number of errors before an external table operation is rolled back.
MAXROWS	BIGINT	No	Maximum number of rows to load. If this value is exceeded, the load operation fails.
Y2BASE	SMALLINT	No	The hundreds component of a year that is specified as only 2 digits. For example, 19 if the 2-digit year 15 represents 1915; 20 if it represents 2015.
FORMAT	CHAR(8)	No	A character string that indicates the data format. Possible values are 'TEXT', 'INTERNAL', 'FIXED', 'BINARY', 'GENERIC', 'NZ_REPL', 'DB2Z_BRF' and 'DB2Z_RRF'.
ENCODING	CHAR(20)	Yes	Code set of the external data file.
REMOTESOURCE	CHAR(10)	Yes	Remote source type. Possible values are: 'ODBC', 'JDBC', 'LOCAL', 'OLEDB', or 'NZ_REPLSRV'.
SOCKETBUFFERSIZE	BIGINT	No	Chunk size, in bytes, at which data is read from the source file.
SKIPROWS	DECFLOAT	No	When reading a table, the number of rows from the top that are to be skipped.
ISFILLRECORD	CHAR(5)	Yes	Whether all fields must be specified. Possible values are: 'TRUE' or 'FALSE'.
ISESCAPE	CHAR(1)	Yes	A character in the range ASCII 32 to ASCII 127 that is interpreted as an escape character.
ISCRINSTRING	CHAR(5)	No	Whether a carriage return character is to be regarded as part of string. Possible values are: 'TRUE' or 'FALSE'.

Table 193. SYSCAT.EXTERNALTABLEOPTIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
ISTRUNCSTRING	CHAR(5)	Yes	Whether to truncate a string if it exceeds the size of the column of the external table into which it is to be loaded. Possible values are: 'TRUE' (a string that is too large to fit in a column is truncated) or 'FALSE' (a string that is too large terminates and rolls back the load operation).
ISCONTROLCHARACTERS	CHAR(5)	No	Whether ASCII characters 1 to 31 are to be allowed in a string. Possible values are: 'TRUE' or 'FALSE'.
ISIGNOREZERO	CHAR(5)	Yes	Whether all occurrences of ASCII character 0 in a string are to be discarded. Possible values are: 'TRUE' or 'FALSE'.
ISTIMEROUNDNANOS	CHAR(5)	Yes	Whether time values are to be rounded to the nearest microsecond. Possible values are: 'TRUE' or 'FALSE'.
ISCOMPRESS	CHAR(5)	Yes	Whether data that is being read from an external table is compressed, and data being written to an external table is to be compressed. Possible values are: 'TRUE' or 'FALSE'.
ISINCLUDEHEADER	CHAR(5)	No	Whether column names are to be included during an unload operation ('TRUE') or ignored ('FALSE').
ISINCLUDEZEROSECONDS	CHAR(5)	Yes	During an unload operation, whether values of 00 seconds are to be unloaded ('TRUE') or ignored ('FALSE').
LOGFILEPATH	CLOB(4K)	No	Name of the file in which to log external table operations.

SYSCAT.FULLHIERARCHIES

Each row represents the relationship between a subtable and a supertable, a subtype and a supertype, or a subview and a superview. All hierarchical relationships, including immediate ones, are included in this view.

Table 194. SYSCAT.FULLHIERARCHIES Catalog View

Column Name	Data Type	Nullable	Description
METATYPE	CHAR (1)		Relationship type. • R = Between structured types • U = Between typed tables • W = Between typed views
SUB_SCHEMA	VARCHAR (128)		Schema name of the subtype, subtable, or subview.
SUB_NAME	VARCHAR (128)		Unqualified name of the subtype, subtable, or subview.

Table 194. SYSCAT.FULLHIERARCHIES Catalog View (continued)

Column Name	Data Type	Nullable	Description
SUPER_SCHEMA	VARCHAR (128)	Y	Schema name of the supertype, supertable, or superview.
SUPER_NAME	VARCHAR (128)	Y	Unqualified name of the supertype, supertable, or superview.
ROOT_SCHEMA	VARCHAR (128)		Schema name of the table, view, or type that is at the root of the hierarchy.
ROOT_NAME	VARCHAR (128)		Unqualified name of the table, view, or type that is at the root of the hierarchy.

SYSCAT.FUNCMAPOPTIONS

Each row represents a function mapping option value.

Table 195. SYSCAT.FUNCMAPOPTIONS Catalog View

Column Name	Data Type	Nullable	Description
FUNCTION_MAPPING	VARCHAR (128)		Name of the function mapping.
OPTION	VARCHAR (128)		Name of the function mapping option.
SETTING	VARCHAR (2048)		Value of the function mapping option.

SYSCAT.FUNCMAPPARMOPTIONS

Each row represents a function mapping parameter option value.

Table 196. SYSCAT.FUNCMAPPARMOPTIONS Catalog View

Column Name	Data Type	Nullable	Description
FUNCTION_MAPPING	VARCHAR (128)		Name of the function mapping.
ORDINAL	SMALLINT		Position of the parameter.
LOCATION	CHAR (1)		Location of the parameter. • L = Local parameter • R = Remote parameter
OPTION	VARCHAR (128)		Name of the function mapping parameter option.
SETTING	VARCHAR (2048)		Value of the function mapping parameter option.

SYSCAT.FUNCMAPPINGS

Each row represents a function mapping.

Table 197. SYSCAT.FUNCMAPPINGS Catalog View

Column Name	Data Type	Nullable	Description
FUNCTION_MAPPING	VARCHAR (128)		Name of the function mapping (might be system-generated).

Table 197. SYSCAT.FUNCMAPPINGS Catalog View (continued)

Column Name	Data Type	Nullable	Description
FUNCSCHEMA	VARCHAR (128)	Y	Schema name of the function. If the null value, the function is assumed to be a built-in function.
FUNCNAME	VARCHAR (1024)	Y	Unqualified name of the user-defined or built-in function.
FUNCID	INTEGER	Y	Identifier for the function.
SPECIFICNAME	VARCHAR (128)	Y	Name of the routine instance (might be system-generated).
OWNER	VARCHAR (128)		Authorization ID of the owner of the mapping. 'SYSIBM' indicates that this is a built-in function.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
WRAPNAME	VARCHAR (128)	Y	Wrapper to which this mapping applies.
SERVERNAME	VARCHAR (128)	Y	Name of the data source.
SERVERTYPE	VARCHAR (30)	Y	Type of data source to which this mapping applies.
SERVERVERSION	VARCHAR (18)	Y	Version of the server type to which this mapping applies.
CREATE_TIME	TIMESTAMP		Time at which the mapping was created.
DEFINER[1]	VARCHAR (128)		Authorization ID of the owner of the mapping. 'SYSIBM' indicates that this is a built-in function.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.HIERARCHIES

Each row represents the relationship between a subtable and its immediate supertable, a subtype and its immediate supertype, or a subview and its immediate superview. Only immediate hierarchical relationships are included in this view.

Table 198. SYSCAT.HIERARCHIES Catalog View

Column Name	Data Type	Nullable	Description
METATYPE	CHAR (1)		Relationship type. • R = Between structured types • U = Between typed tables • W = Between typed views
SUB_SCHEMA	VARCHAR (128)		Schema name of the subtype, subtable, or subview.

Table 198. SYSCAT.HIERARCHIES Catalog View (continued)

Column Name	Data Type	Nullable	Description
SUB_NAME	VARCHAR (128)		Unqualified name of the subtype, subtable, or subview.
SUPER_SCHEMA	VARCHAR (128)		Schema name of the supertype, supertable, or superview.
SUPER_NAME	VARCHAR (128)		Unqualified name of the supertype, supertable, or superview.
ROOT_SCHEMA	VARCHAR (128)		Schema name of the table, view, or type that is at the root of the hierarchy.
ROOT_NAME	VARCHAR (128)		Unqualified name of the table, view, or type that is at the root of the hierarchy.

SYSCAT.HISTOGRAMTEMPLATEBINS

Each row represents a histogram template bin.

Table 199. SYSCAT.HISTOGRAMTEMPLATEBINS Catalog View

Column Name	Data Type	Nullable	Description
TEMPLATENAME	VARCHAR (128)	Y	Name of the histogram template.
TEMPLATEID	INTEGER		Identifier for the histogram template.
BINID	INTEGER		Identifier for the histogram template bin.
BINUPPERVALUE	BIGINT		The upper value for a single bin in the histogram template.

SYSCAT.HISTOGRAMTEMPLATES

Each row represents a histogram template.

Table 200. SYSCAT.HISTOGRAMTEMPLATES Catalog View

Column Name	Data Type	Nullable	Description
TEMPLATEID	INTEGER		Identifier for the histogram template.
TEMPLATENAME	VARCHAR (128)		Name of the histogram template.
CREATE_TIME	TIMESTAMP		Time at which the histogram template was created.
ALTER_TIME	TIMESTAMP		Time at which the histogram template was last altered.
NUMBINS	INTEGER		Number of bins in the histogram template, including the last bin that has an unbounded top value.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.HISTOGRAMTEMPLATEUSE

Each row represents a relationship between a workload management object that can use histogram templates and a histogram template.

Table 201. SYSCAT.HISTOGRAMTEMPLATEUSE Catalog View

Column Name	Data Type	Nullable	Description
TEMPLATENAME	VARCHAR (128)	Y	Name of the histogram template.
TEMPLATEID	INTEGER		Identifier for the histogram template.
HISTOGRAMTYPE	CHAR (1)		The type of information collected by histograms based on this template. • C = Activity estimated cost histogram • E = Activity execution time histogram • I = Activity interarrival time histogram • L = Activity life time histogram • Q = Activity queue time histogram • R = Request execution time histogram • U = Unit of work life time histogram
OBJECTTYPE	CHAR (1)		The type of WLM object. • b = Service class • k = Work action • w = Workload
OBJECTID	INTEGER		Identifier of the WLM object.
SERVICECLASSNAME	VARCHAR (128)	Y	Name of the service class.
PARENTSERVICECLASSNAME	VARCHAR (128)	Y	The name of the parent service class of the service subclass that uses the histogram template.
WORKACTIONNAME	VARCHAR (128)	Y	The name of the work action that uses the histogram template.
WORKACTIONSETNAME	VARCHAR (128)	Y	The name of the work action set containing the work action that uses the histogram template.
WORKLOADNAME	VARCHAR (128)	Y	The name of the workload that uses the histogram template.

SYSCAT.INDEXAUTH

Each row represents a user, group, or role that has been granted CONTROL privilege on an index.

Table 202. SYSCAT.INDEXAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of the privilege.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user

Table 202. SYSCAT.INDEXAUTH Catalog View (continued)

Column Name	Data Type	Nullable	Description
GRANTEE	VARCHAR (128)		Holder of the privilege.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
INDSCHEMA	VARCHAR (128)		Schema name of the index.
INDNAME	VARCHAR (128)		Unqualified name of the index.
CONTROLAUTH	CHAR (1)		CONTROL privilege. • N = Not held • Y = Held

SYSCAT.INDEXCOLUSE

Each row represents a column that participates in an index.

Table 203. SYSCAT.INDEXCOLUSE Catalog View

Column Name	Data Type	Nullable	Description
INDSCHEMA	VARCHAR (128)		Schema name of the index.
INDNAME	VARCHAR (128)		Unqualified name of the index.
COLNAME	VARCHAR (128)		Name of the column.
COLSEQ	SMALLINT		Numeric position of the column in the index (initial position is 1).
COLORDER	CHAR (1)		Order of the values in this index column. Possible values are: • A = Ascending • D = Descending • I = INCLUDE column (ordering ignored) • R = Random
COLLATIONSCHEMA	VARCHAR (128)	Y	For string types, the schema name of the collation for the column; the null value otherwise.
COLLATIONNAME	VARCHAR (128)	Y	For string types, the unqualified name of the collation for the column; the null value otherwise.

Table 203. SYSCAT.INDEXCOLUSE Catalog View (continued)

Column Name	Data Type	Nullable	Description
VIRTUAL	CHAR (1)	Y	• N = Column exists in the table on which this index is defined. • S = Virtual index column found in statistical view associated with the index. The expression for this part of the index key is stored in the TEXT column. • Y = Virtual index column that does not exist in the table on which this index is defined.
TEXT	CLOB (64K)	Y	The expression text for this part of the index key. The null value if this part of the index key is not based on an expression.

SYSCAT.INDEXDEP

Each row represents a dependency of an index on some other object. The index depends on an object of type BTYPE and name BNAME, so a change to the object affects the index.

Table 204. SYSCAT.INDEXDEP Catalog View

Column Name	Data Type	Nullable	Description
INDSCHEMA	VARCHAR (128)		Schema name of the index.
INDNAME	VARCHAR (128)		Unqualified name of the index.

Table 204. SYSCAT.INDEXDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
BTYPE	CHAR (1)		Type of object on which there is a dependency. Possible values are: • A = Table alias • B = Trigger • C = Column • F = Routine • G = Global temporary table • H = Hierachy table • I = Index • K = Package • L = Detached table • N = Nickname • O = Privilege dependency on all subtables or subviews in a table or view hierarchy • Q = Sequence • R = User-defined data type • S = Materialized query table • T = Table (not typed) • U = Typed table • V = View (not typed) • W = Typed view • X = Index extension • Z = XSR object • m = Module • q = Sequence alias • u = Module alias • v = Global variable • * = Anchored to the row of a base table
BSCHEMA	VARCHAR (128)		Schema name of the object on which there is a dependency.
BMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the object on which a dependency belongs. The null value if not a module object.
BNAME	VARCHAR (128)		Unqualified name of the object on which there is a dependency. For routines (BTYPE = 'F'), this is the specific name.
BMODULEID	INTEGER	Y	Identifier for the module of the object on which there is a dependency.
TABAUTH	SMALLINT	Y	If BTYPE = 'O', 'S', 'T', 'U', 'V', 'W', or 'v', encodes the privileges on the table or view that are required by the dependent index; the null value otherwise.

SYSCAT.INDEXES

Each row represents an index. Indexes on typed tables are represented by two rows: one for the "logical index" on the typed table, and one for the "H-index" on the hierarchy table.

Table 205. SYSCAT.INDEXES Catalog View

Column Name	Data Type	Nullable	Description
INDSCHEMA	VARCHAR (128)		Schema name of the index.
INDNAME	VARCHAR (128)		Unqualified name of the index.
OWNER	VARCHAR (128)		Authorization ID of the owner of the index.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
TABSCHEMA	VARCHAR (128)		Schema name of the table or nickname on which the index is defined.
TABNAME	VARCHAR (128)		Unqualified name of the table or nickname on which the index is defined.
COLNAMES	VARCHAR (640)		This column is no longer used and will be removed in the next release. Use SYSCAT.INDEXCOLUSE for this information.
UNIQUERULE	CHAR (1)		Unique rule. • D = Permits duplicates • U = Unique • P = Implements primary key
MADE_UNIQUE	CHAR (1)		• N = Index remains as it was created. • Y = Index was originally non-unique but was converted to a unique index to support a unique or primary key constraint. If the constraint is dropped, the index reverts to being non-unique.
COLCOUNT	SMALLINT		Number of columns in the key, plus the number of include columns, if any.
UNIQUE_COLCOUNT	SMALLINT		Number of columns required for a unique key. It is always <= COLCOUNT, and < COLCOUNT only if there are include columns; -1 if the index has no unique key (that is, it permits duplicates).

Table 205. SYSCAT.INDEXES Catalog View (continued)

Column Name	Data Type	Nullable	Description
INDEXTYPE[5]	CHAR (4)		Type of index. • BLOK = Block index • CLUS = Clustering index (controls the physical placement of newly inserted rows) • CPMA = Page map index for a column-organized table • DIM = Dimension block index • MDST = Modification state index • RCT = Key sequence index for a range-clustered table • REG = Regular index • TEXT = Text index • XPTH = XML path index • XRGN = XML region index • XVIL = Index over XML column (logical) • XVIP = Index over XML column (physical)
ENTRYTYPE	CHAR (1)		• H = This row represents an index on a hierarchy table • L = This row represents a logical index on a typed table • Blank = This row represents an index on an untyped table
PCTFREE	SMALLINT		Percentage of each index page to be reserved during the initial building of the index. This space is available for data insertions after the index has been built.
IID	SMALLINT		Identifier for the index.
NLEAF	BIGINT		Number of leaf pages; -1 if statistics are not collected.
NLEVELS	SMALLINT		Number of index levels; -1 if statistics are not collected.
FIRSTKEYCARD	BIGINT		Number of distinct first-key values; -1 if statistics are not collected.
FIRST2KEYCARD	BIGINT		Number of distinct keys using the first two columns of the index; -1 if statistics are not collected, or if not applicable.
FIRST3KEYCARD	BIGINT		Number of distinct keys using the first three columns of the index; -1 if statistics are not collected, or if not applicable.
FIRST4KEYCARD	BIGINT		Number of distinct keys using the first four columns of the index; -1 if statistics are not collected, or if not applicable.

Table 205. SYSCAT.INDEXES Catalog View (continued)

Column Name	Data Type	Nullable	Description
FULLKEYCARD	BIGINT		Number of distinct full-key values; -1 if statistics are not collected.
CLUSTERRATIO[3]	SMALLINT		Degree of data clustering with the index; -1 if statistics are not collected or if detailed index statistics are collected (in which case, CLUSTERFACTOR will be used instead).
CLUSTERFACTOR[3]	DOUBLE		Finer measurement of the degree of clustering; -1 if statistics are not collected or if the index is defined on a nickname.
SEQUENTIAL_PAGES	BIGINT		Number of leaf pages located on disk in index key order with few or no large gaps between them; -1 if statistics are not collected.
DENSITY	INTEGER		Ratio of SEQUENTIAL_PAGES to number of pages in the range of pages occupied by the index, expressed as a percent (integer between 0 and 100); -1 if statistics are not collected.
USER_DEFINED	SMALLINT		1 if this index was defined by a user and has not been dropped; 0 otherwise.
SYSTEM_REQUIRED	SMALLINT		• 1 if one or the other of the following conditions is met: – This index is required for a primary or unique key constraint, or this index is a dimension block index or composite block index for a multidimensional clustering (MDC) table or an insert time clustering (ITC) table. – This is the index on the object identifier (OID) column of a typed table. • 2 if both of the following conditions are met: – This index is required for a primary or unique key constraint, or this index is a dimension block index or composite block index for an MDC table or an ITC table. – This is the index on the OID column of a typed table. • 0 otherwise.
CREATE_TIME	TIMESTAMP		Time when the index was created.
STATS_TIME	TIMESTAMP	Y	Last time that any change was made to the recorded statistics for this index. The null value if no statistics are available.

Table 205. SYSCAT.INDEXES Catalog View (continued)

Column Name	Data Type	Nullable	Description
PAGE_FETCH_PAIRS[3]	VARCHAR (520)		A list of pairs of integers, represented in character form. Each pair represents the number of pages in a hypothetical buffer, and the number of page fetches required to scan the table with this index using that hypothetical buffer. Zero-length string if no data is available.
MINPCTUSED	SMALLINT		A non-zero integer value indicates that the index is enabled for online defragmentation, and represents the minimum percentage of used space on a page before a page merge can be attempted. A zero value indicates that no page merge is attempted.
REVERSE_SCANS	CHAR (1)		• N = Index does not support reverse scans • Y = Index supports reverse scans
INTERNAL_FORMAT	SMALLINT		Possible values are: • 1 = Index does not have backward pointers • 2 or greater = Index has backward pointers • 6 = Index is a composite block index
COMPRESSION	CHAR (1)		Specifies whether index compression is activated • N = Not activated • Y = Activated
IESCHEMA	VARCHAR (128)	Y	Schema name of the index extension. The null value for ordinary indexes.
IENAME	VARCHAR (128)	Y	Unqualified name of the index extension. The null value for ordinary indexes.
IEARGUMENTS	CLOB (64K)	Y	External information of the parameter specified when the index is created. The null value for ordinary indexes.
INDEX_OBJECTID	INTEGER		Identifier for the index object.
NUMRIDS	BIGINT		Total number of row identifiers (RIDs) or block identifiers (BIDs) in the index; -1 if not known.
NUMRIDS_DELETED	BIGINT		Total number of row identifiers (or block identifiers) in the index that are marked deleted, excluding those identifiers on leaf pages on which all the identifiers are marked deleted.

Table 205. SYSCAT.INDEXES Catalog View (continued)

Column Name	Data Type	Nullable	Description
NUM_EMPTY_LEAFS	BIGINT		Total number of index leaf pages that have all of their row identifiers (or block identifiers) marked deleted.
AVERAGE_RANDOM_FETCH_PAGES[1,2]	DOUBLE		Average number of random table pages between sequential page accesses when fetching using the index; -1 if not known.
AVERAGE_RANDOM_PAGES[2]	DOUBLE		Average number of random table pages between sequential page accesses; -1 if not known.
AVERAGE_SEQUENCE_GAP[2]	DOUBLE		Gap between index page sequences. Detected through a scan of index leaf pages, each gap represents the average number of index pages that must be randomly fetched between sequences of index pages; -1 if not known.
AVERAGE_SEQUENCE_FETCH_GAP[1,2]	DOUBLE		Gap between table page sequences when fetching using the index. Detected through a scan of index leaf pages, each gap represents the average number of table pages that must be randomly fetched between sequences of table pages; -1 if not known.
AVERAGE_SEQUENCE_PAGES[2]	DOUBLE		Average number of index pages that are accessible in sequence (that is, the number of index pages that the prefetchers would detect as being in sequence); -1 if not known.
AVERAGE_SEQUENCE_FETCH_PAGES[1,2]	DOUBLE		Average number of table pages that are accessible in sequence (that is, the number of table pages that the prefetchers would detect as being in sequence) when fetching using the index; -1 if not known.
TBSPACEID	INTEGER		Identifier for the index table space.
LEVEL2PCTFREE	SMALLINT		Percentage of each index level 2 page to be reserved during initial building of the index. This space is available for future inserts after the index has been built.
PAGESPLIT	CHAR (1)		Index page split behavior. • H = High • L = Low • S = Symmetric • Blank = Not applicable

Table 205. SYSCAT.INDEXES Catalog View (continued)

Column Name	Data Type	Nullable	Description
AVGPARTITION_ CLUSTERRATIO[3]	SMALLINT		Degree of data clustering within a single data partition. -1 if the table is not partitioned, if statistics are not collected, or if detailed statistics are collected (in which case AVGPARTITION_ CLUSTERFACTOR will be used instead).
AVGPARTITION_ CLUSTERFACTOR[3]	DOUBLE		Finer measurement of the degree of clustering within a single data partition. -1 if the table is not partitioned, if statistics are not collected, or if the index is defined on a nickname.
AVGPARTITION_PAGE_FETCH_ PAIRS[3]	VARCHAR (520)		A list of paired integers in character form. Each pair represents a potential buffer pool size and the corresponding page fetches required to access a single data partition from the table. Zero-length string if no data is available, or if the table is not partitioned.
PCTPAGESSAVED	SMALLINT		Approximate percentage of pages saved in the index as a result of index compression. -1 if statistics are not collected.
DATAPARTITION_ CLUSTERFACTOR	DOUBLE		A statistic measuring the "clustering" of the index keys with regard to data partitions. It is a number between 0 and 1, with 1 representing perfect clustering and 0 representing no clustering.
INDCARD	BIGINT		Cardinality of the index. This might be different from the cardinality of the table for indexes that do not have a one-to-one relationship between the table rows and the index entries.
AVGLEAFKEYSIZE	INTEGER		Average index key size for keys on leaf pages in the index.
AVGNLEAFKEYSIZE	INTEGER		Average index key size for keys on non-leaf pages in the index.
OS_PTR_SIZE	INTEGER		Platform word size with which the index was created. • 32 = 32-bit • 64 = 64-bit
COLLECTSTATISTCS	CHAR (1)		Specifies how statistics were collected at index creation time. • D = Collect detailed index statistics • S = Collect sampled detailed index statistics • Y = Collect basic index statistics • Blank = Do not collect index statistics

Table 205. SYSCAT.INDEXES Catalog View (continued)

Column Name	Data Type	Nullable	Description
DEFINER[4]	VARCHAR (128)		Authorization ID of the owner of the index.
LASTUSED	DATE		Date when the index was last used by any DML statement to perform a scan, or used to enforce referential integrity constraints. This column is not updated when the index is used on an HADR standby database, nor is it updated when rows are inserted into the table on which the index is defined. The default value is '0001-01-01'. This value is updated asynchronously not more than once within a 24 hour period and might not reflect usage within the last 15 minutes.
PERIODNAME	VARCHAR(128)	Y	Name of the period used to define this index.
PERIODPOLICY	CHAR (1)		If a period name was specified, the index uses this period policy. • N = Not applicable • O = Period overlaps not allowed
MADE_WITHOUTOVERLAPS	CHAR (1)		• N = Index remains as it was created. • Y = Index was converted to enforce WITHOUT OVERLAPS on the application period to support a primary or unique constraint. If the constraint is dropped, the index reverts to the original state.
NULLKEYS	CHAR (1)		• N = Keys that contain all null values are not indexed (not considering columns or expressions from the INCLUDE clause) • Y = Keys that contain all null values are indexed (not considering columns or expressions from the INCLUDE clause)
FUNC_PATH	CLOB (2K)	Y	SQL path in effect when the index was defined with an expression in the key. The null value if the key does not include any expressions.
VIEWSCHEMA	VARCHAR(128)	Y	Schema name of the statistical view associated with the index key, if the key includes at least one expression. The null value if there are no expressions in the key.
VIEWNAME	VARCHAR(128)	Y	Unqualified name of the statistical view associated with the index key, if the key includes at least one expression. The null value if there are no expressions in the key.
ENVSTRINGUNITS	VARCHAR (11)		Default string units when the object was created.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Table 205. SYSCAT.INDEXES Catalog View (continued)

Column Name	Data Type	Nullable	Description

Note:

1. When using DMS table spaces, this statistic cannot be computed.
2. Prefetch statistics are not gathered during a LOAD...STATISTICS USE PROFILE, or a CREATE INDEX...COLLECT STATISTICS operation, or when the database configuration parameter *seqdetect* is turned off.
3. AVGPARTITION_CLUSTERRATIO, AVGPARTITION_CLUSTERFACTOR, and AVGPARTITION_PAGE_FETCH_PAIRS measure the degree of clustering within a single data partition (local clustering). CLUSTERRATIO, CLUSTERFACTOR, and PAGE_FETCH_PAIRS measure the degree of clustering in the entire table (global clustering). Global clustering and local clustering values can diverge significantly if the table partitioning key is not a prefix of the index key, or when the table partitioning key and the index key are logically independent of each other.
4. The DEFINER column is included for backwards compatibility. See OWNER.
5. The XPTH, XRGN, and XVIP indexes are not recognized by any application programming interface that returns index metadata.

SYSCAT.INDEXEXPLOITRULES

Each row represents an index exploitation rule.

Table 206. SYSCAT.INDEXEXPLOITRULES Catalog View

Column Name	Data Type	Nullable	Description
FUNCID	INTEGER		Identifier for the function.
SPECID	SMALLINT		Number of the predicate specification.
IESCHEMA	VARCHAR (128)		Schema name of the index extension.
IENAME	VARCHAR (128)		Unqualified name of the index extension.
RULEID	SMALLINT		Identifier for the exploitation rule.
SEARCHMETHODID	SMALLINT		Identifier for the search method in the specific index extension.
SEARCHKEY	VARCHAR (640)		Key used to exploit the index.
SEARCHARGUMENT	VARCHAR (2700)		Search arguments used to exploit the index.
EXACT	CHAR (1)		• N = Index lookup is not exact in terms of predicate evaluation • Y = Index lookup is exact in terms of predicate evaluation

SYSCAT.INDEXEXTENSIONDEP

Each row represents a dependency of an index extension on some other object. The index extension depends on the object of type BTYPE of name BNAME, so a change to the object affects the index extension.

Table 207. SYSCAT.INDEXEXTENSIONDEP Catalog View

Column Name	Data Type	Nullable	Description
IESCHEMA	VARCHAR (128)		Schema name of the index extension.
IENAME	VARCHAR (128)		Unqualified name of the index extension.
BTYPE	CHAR (1)		Type of object on which there is a dependency. Possible values are: • A = Table alias • B = Trigger • C = Column • F = Routine • G = Global temporary table • H = Hierachy table • I = Index • K = Package • L = Detached table • N = Nickname • O = Privilege dependency on all subtables or subviews in a table or view hierarchy • Q = Sequence • R = User-defined data type • S = Materialized query table • T = Table (not typed) • U = Typed table • V = View (not typed) • W = Typed view • X = Index extension • Z = XSR object • m = Module • q = Sequence alias • u = Module alias • v = Global variable • * = Anchored to the row of a base table
BSCHEMA	VARCHAR (128)		Schema name of the object on which there is a dependency.
BMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the object on which a dependency belongs. The null value if not a module object.

Table 207. SYSCAT.INDEXEXTENSIONDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
BNAME	VARCHAR (128)		Unqualified name of the object on which there is a dependency. For routines (BTYPE = 'F'), this is the specific name.
BMODULEID	INTEGER	Y	Identifier for the module of the object on which there is a dependency.
TABAUTH	SMALLINT	Y	If BTYPE = 'O', 'S', 'T', 'U', 'V', 'W', or 'v', encodes the privileges on the table or view that are required by the dependent index extension; the null value otherwise.

SYSCAT.INDEXEXTENSIONMETHODS

Each row represents a search method. An index extension can contain more than one search method.

Table 208. SYSCAT.INDEXEXTENSIONMETHODS Catalog View

Column Name	Data Type	Nullable	Description
METHODNAME	VARCHAR (128)		Name of the search method.
METHODID	SMALLINT		Number of the method in the index extension.
IESCHEMA	VARCHAR (128)		Schema name of the index extension on which this method is defined.
IENAME	VARCHAR (128)		Unqualified name of the index extension on which this method is defined.
RANGEFUNCSCHEMA	VARCHAR (128)		Schema name of the range-through function.
RANGEFUNCNAME	VARCHAR (128)		Unqualified name of the range-through function.
RANGESPECIFICNAME	VARCHAR (128)		Function-specific name of the range-through function.
FILTERFUNCSCHEMA	VARCHAR (128)	Y	Schema name of the filter function.
FILTERFUNCNAME	VARCHAR (128)	Y	Unqualified name of the filter function.
FILTERSPECIFICNAME	VARCHAR (128)	Y	Function-specific name of the filter function.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.INDEXEXTENSIONPARMS

Each row represents an index extension instance parameter or source key column.

Table 209. SYSCAT.INDEXEXTENSIONPARMS Catalog View

Column Name	Data Type	Nullable	Description
IESCHEMA	VARCHAR (128)		Schema name of the index extension.
IENAME	VARCHAR (128)		Unqualified name of the index extension.

Table 209. SYSCAT.INDEXEXTENSIONPARMS Catalog View (continued)

Column Name	Data Type	Nullable	Description
ORDINAL	SMALLINT		Sequence number of the parameter or key column.
PARMNAME	VARCHAR (128)		Name of the parameter or key column.
TYPESCHEMA	VARCHAR (128)		Schema name of the data type of the parameter or key column.
TYPENAME	VARCHAR (128)		Unqualified name of the data type of the parameter or key column.
LENGTH	INTEGER		Data type length of the parameter or key column.
SCALE	SMALLINT		Data type scale of the parameter or key column; 0 if not applicable.
PARMTYPE	CHAR (1)		• K = Source key column • P = Index extension instance parameter
CODEPAGE	SMALLINT		Code page of the index extension instance parameter; 0 if not a string type.
COLLATIONSCHEMA	VARCHAR (128)	Y	For string types, the schema name of the collation for the parameter; the null value otherwise.
COLLATIONNAME	VARCHAR (128)	Y	For string types, the unqualified name of the collation for the parameter; the null value otherwise.

SYSCAT.INDEXEXTENSIONS

Each row represents an index extension.

Table 210. SYSCAT.INDEXEXTENSIONS Catalog View

Column Name	Data Type	Nullable	Description
IESCHEMA	VARCHAR (128)		Schema name of the index extension.
IENAME	VARCHAR (128)		Unqualified name of the index extension.
OWNER	VARCHAR (128)		Authorization ID of the owner of the index extension.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
CREATE_TIME	TIMESTAMP		Time at which the index extension was defined.
KEYGENFUNCSCHEMA	VARCHAR (128)		Schema name of the key generation function.
KEYGENFUNCNAME	VARCHAR (128)		Unqualified name of the key generation function.
KEYGENSPECIFICNAME	VARCHAR (128)		Name of the key generation function instance (might be system-generated).

Table 210. SYSCAT.INDEXEXTENSIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
TEXT	CLOB (2M)		Full text of the CREATE INDEX EXTENSION statement.
DEFINER[1]	VARCHAR (128)		Authorization ID of the owner of the index extension.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.INDEXOPTIONS

Each row represents an index-specific option value.

Table 211. SYSCAT.INDEXOPTIONS Catalog View

Column Name	Data Type	Nullable	Description
INDSCHEMA	VARCHAR (128)		Schema name of the index.
INDNAME	VARCHAR (128)		Unqualified name of the index.
OPTION	VARCHAR (128)		Name of the index option.
SETTING	VARCHAR (2048)		Value of the index option.

SYSCAT.INDEXPARTITIONS

Each row represents a partitioned index piece located on one data partition. Note that the index partition statistics represent one database partition if the table is created on multiple database partitions.

Table 212. SYSCAT.INDEXPARTITIONS Catalog View

Column Name	Data Type	Nullable	Description
INDSCHEMA	VARCHAR (128)		Schema name of the index.
INDNAME	VARCHAR (128)		Unqualified name of the index.
TABSCHEMA	VARCHAR (128)		Schema name of the table or nickname on which the index is defined.
TABNAME	VARCHAR (128)		Unqualified name of the table or nickname on which the index is defined.
IID	SMALLINT		Identifier for the index.
INDPARTITIONTBSPACEID	INTEGER		Identifier for the index partition table space.
INDPARTITIONOBJECTID	INTEGER		Identifier for the index partition object.
DATAPARTITIONID	INTEGER		This corresponds to the DATAPARTITIONID found in the SYSCAT.DATAPARTITIONS view.

Table 212. SYSCAT.INDEXPARTITIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
INDCARD	BIGINT		Cardinality of the index partition. This might be different from the cardinality of the corresponding data partition for partitioned indexes that do not have a one-to-one relationship between the data partition rows and the index entries.
NLEAF	BIGINT		Number of leaf pages in the index partition; -1 if statistics are not collected.
NUM_EMPTY_LEAFS	BIGINT		Total number of index leaf pages in the index partition that have all of their row identifiers (RIDs) or block identifiers (BIDs) marked deleted.
NUMRIDS	BIGINT		Total number of row identifiers (RIDs) or block identifiers (BIDs) in the index partition; -1 if not known.
NUMRIDS_DELETED	BIGINT		Total number of row identifiers (RIDs) or block identifiers (BIDs) in the index partition that are marked deleted, excluding those identifiers on leaf pages on which all the identifiers are marked deleted.
FULLKEYCARD	BIGINT		Number of distinct full-key values in the index partition; -1 if statistics are not collected.
NLEVELS	SMALLINT		Number of index levels in the index partition; -1 if statistics are not collected.
CLUSTERRATIO	SMALLINT		Degree of data clustering with the index partition; -1 in either of the following situations: • Statistics are not collected • Detailed index statistics are collected. In this situation, CLUSTERFACTOR will be used instead.
CLUSTERFACTOR	DOUBLE		Finer measurement of the degree of clustering; -1 if statistics are not collected.
FIRSTKEYCARD	BIGINT		Number of distinct first-key values; -1 if statistics are not collected.
FIRST2KEYCARD	BIGINT		Number of distinct keys using the first two columns of the index key; -1 if statistics are not collected, or if not applicable.
FIRST3KEYCARD	BIGINT		Number of distinct keys using the first three columns of the index key; -1 if statistics are not collected, or if not applicable.
FIRST4KEYCARD	BIGINT		Number of distinct keys using the first four columns of the index key; -1 if statistics are not collected, or if not applicable.

Table 212. SYSCAT.INDEXPARTITIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
AVGLEAFKEYSIZE	INTEGER		Average index key size for keys on leaf pages in the index partition; -1 if statistics are not collected.
AVGNLEAFKEYSIZE	INTEGER		Average index key size for keys on non-leaf pages in the index partition; -1 if statistics are not collected.
PCTFREE	SMALLINT		Percentage of each index page to be reserved during the initial building of the index partition. This space is available for data insertions after the index partition has been built.
PAGE_FETCH_PAIRS	VARCHAR (520)		A list of pairs of integers, represented in character form. Each pair represents the number of pages in a hypothetical buffer, and the number of page fetches required to scan the data partition with this index using that hypothetical buffer. Zero-length string if not data is available.
SEQUENTIAL_PAGES	BIGINT		Number of leaf pages located on disk in index key order with few or no large gaps between them; -1 if statistics are not collected.
DENSITY	INTEGER		Ratio of SEQUENTIAL_PAGES to number of pages in the range of pages occupied by the index partition, expressed as a percent (integer between 0 and 100); -1 if statistics are not collected.
AVERAGE_SEQUENCE_GAP	DOUBLE		Gap between index page sequences within the index partition. Detected through a scan of index leaf pages, each gap represents the average number of index pages that must be randomly fetched between sequences of index pages; -1 if not known.
AVERAGE_SEQUENCE_ FETCH_GAP	DOUBLE		Gap between table page sequences when fetching using the index partition. Detected through a scan of index leaf pages, each gap represents the average number of data partition pages that must be randomly fetched between sequences of data partition pages; -1 if not known.
AVERAGE_SEQUENCE_ PAGES	DOUBLE		Average number of index pages that are accessible in sequence (that is, the number of index pages that the prefetchers would detect as being in sequence); -1 if not known.

Table 212. SYSCAT.INDEXPARTITIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
AVERAGE_SEQUENCE_ FETCH_PAGES	DOUBLE		Average number of data partition pages that are accessible in sequence (that is, the number of data partition pages that the prefetchers would detect as being in sequence) when fetching using the index; -1 if not known.
AVERAGE_RANDOM_PAGES	DOUBLE		Average number of random data partition pages between sequential page accesses; -1 if not known.
AVERAGE_RANDOM_FETCH_ PAGES	DOUBLE		Average number of random data partition pages between sequential page accesses when fetching using the index partition; -1 if not known.
STATS_TIME	TIMESTAMP	Y	Last time that any change was made to the recorded statistics for this index partition. The null value if no statistics are available.
COMPRESSION	CHAR (1)		Specifies whether index compression is activated • N = Not activated • Y = Activated
PCTPAGESSAVED	SMALLINT		Approximate percentage of pages saved in the index as a result of index compression. -1 if statistics are not collected.

SYSCAT.INDEXXMLPATTERNS

Each row represents a pattern clause in an index over an XML column.

Table 213. SYSCAT.INDEXXMLPATTERNS Catalog View

Column Name	Data Type	Nullable	Description
INDSCHEMA	VARCHAR (128)		Schema name of the logical index.
INDNAME	VARCHAR (128)		Unqualified name of the logical index.
PINDNAME	VARCHAR (128)		Unqualified name of the physical index.
PINDID	SMALLINT		Identifier for the physical index.
TYPEMODEL	CHAR (1)		• Q = SQL DATA TYPE (Ignore invalid values) • R = SQL DATA TYPE (Reject invalid values)
DATATYPE	VARCHAR (128)		Name of the data type.
HASHED	CHAR (1)		Indicates whether or not the value is hashed. • N = Not hashed • Y = Hashed

Table 213. SYSCAT.INDEXXMLPATTERNS Catalog View (continued)

Column Name	Data Type	Nullable	Description
LENGTH	SMALLINT		Length if DATATYPE = 'VARCHAR' and HASHED = 'N'; precision if DATATYPE = 'DECIMAL'; 0 otherwise.
SCALE	SMALLINT		Scale if DATATYPE = 'DECIMAL'; 0 otherwise.
PATTERNID	SMALLINT		Identifier for the pattern.
PATTERN	CLOB (2M)	Y	Definition of the pattern.

Note:

1. When indexes over XML columns are created, logical indexes that use XML pattern information are created, resulting in the creation of physical B-tree indexes with key columns generated by the database manager to support the logical indexes. A physical index is created to support the data type that is specified in the xmltype-clause of the CREATE INDEX statement.

SYSCAT.INVALIDOBJECTS

Each row represents an invalid object.

Table 214. SYSCAT.INVALIDOBJECTS Catalog View

Column Name	Data Type	Nullable	Description
OBJECTSCHEMA	VARCHAR (128)		Schema name of the object being created or revalidated.
OBJECTMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the object being created or revalidated belongs. The null value if the object does not belong to a module.
OBJECTNAME	VARCHAR (128)		Unqualified name of the object being created or revalidated. For routines (OBJECTTYPE = 'F'), this is the specific name.
ROUTINENAME	VARCHAR (128)	Y	Unqualified name of the routine.
OBJECTTYPE	CHAR (1)		Type of the object being created or revalidated. Possible values are: • B = Trigger • F = Routine • R = User-defined data type • V = View • v = Global variable • y = Row permission • 2 = Column mask • 3 = Usage list
SQLCODE	INTEGER	Y	SQLCODE returned in CREATE with errors or revalidation. The null value if the object has never been revalidated.

Table 214. SYSCAT.INVALIDOBJECTS Catalog View (continued)

Column Name	Data Type	Nullable	Description
SQLSTATE	CHAR (5)	Y	SQLSTATE returned in CREATE with errors or revalidation. The null value if the object has never been revalidated.
ERRORMESSAGE	VARCHAR (4000)	Y	Short text for the message associated with SQLCODE. The null value if the object has never been revalidated.
LINENUMBER	INTEGER	Y	Line number where the error occurred in compiled objects. The null value if the object is not a compiled object.
INVALIDATE_TIME	TIMESTAMP		Time at which the object was last invalidated.
LAST_REGEN_TIME	TIMESTAMP	Y	Time at which the object was last revalidated. The null value if the object has never been revalidated.

SYSCAT.KEYCOLUSE

Each row represents a column that participates in a key defined by a unique, primary key, or foreign key constraint.

Table 215. SYSCAT.KEYCOLUSE Catalog View

Column Name	Data Type	Nullable	Description
CONSTNAME	VARCHAR (128)		Name of the constraint.
TABSCHEMA	VARCHAR (128)		Schema name of the table containing the column.
TABNAME	VARCHAR (128)		Unqualified name of the table containing the column.
COLNAME	VARCHAR (128)		Name of the column.
COLSEQ	SMALLINT		Numeric position of the column in the key for the constraint (initial position is 1). If a constraint uses an existing index, this value is the numeric position of the column in the index.

SYSCAT.MEMBERSUBSETATTRS

Each row represents a member subset attribute.

Table 216. SYSCAT.MEMBERSUBSETATTRS Catalog View

Column Name	Data Type	Nullable	Description
SUBSETID	INTEGER		Subset identifier.
ATTRID	SMALLINT		Attribute identifier. • 1 = DBALIAS
ATTRVALUE	VARCHAR(1000)	Y	Value of attribute.

SYSCAT.MEMBERSUBSETMEMBERS

Each row represents a member that is associated with a member subset.

Table 217. SYSCAT.MEMBERSUBSETMEMBERS Catalog View

Column Name	Data Type	Nullable	Description
SUBSETID	INTEGER		Subset identifier.
MEMBER	SMALLINT		Member ID as defined in db2nodes.cfg.
FAILOVER_PRIORITY	SMALLINT		Stores the failover priority value of the members.

SYSCAT.MEMBERSUBSETS

Each row represents a member subset.

Table 218. SYSCAT.MEMBERSUBSETS Catalog View

Column Name	Data Type	Nullable	Description
SUBSETNAME	VARCHAR(128)		Name of subset.
SUBSETID	INTEGER		Subset identifier.
CREATE_TIME	TIMESTAMP		Time at which subset was defined.
ALTER_TIME	TIMESTAMP		Time at which subset was last altered.
ENABLED	CHAR(1)		State of the member subset. • N = subset is currently disabled • Y = subset is currently enabled
MEMBERPRIORITYBASIS	CHAR(1)		Basis for member priorities: • E = Equal priorities • L = Member load
INCLUSIVESUBSET	CHAR(1)		Inclusiveness of member subset: • N = The member subset is not inclusive • Y = The member subset is inclusive
ALTERNATESERVER	CHAR(1)		Alternate server's inclusion in the member subsets server list: • N = The alternate server is not included in the member subsets server list • Y = The alternate server is included in the member subsets server list
CATALOGDATABASEALIAS	CHAR(1)		Database alias cataloged for member subset: • N = No database alias cataloged explicitly for this member subset • Y = Database alias cataloged explicitly for this member subset
REMARKS	VARCHAR(254)	Y	User provided comments, or the null value.

SYSCAT.MODULEAUTH

Each row represents a user, group, or role that has been granted a privilege on a module.

Table 219. SYSCAT.MODULEAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of a privilege
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user
GRANTEE	VARCHAR (128)		Holder of a privilege.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
MODULEID	INTEGER		Identifier for the module to which this privilege applies.
MODULESCHEMA	VARCHAR (128)		Schema name of the module to which this privilege applies.
MODULENAME	VARCHAR (128)		Unqualified name of the module to which this privilege applies.
EXECUTEAUTH	CHAR (1)		Privilege to execute objects in the identified module. • G = Held and grantable • N = Not held • Y = Held

SYSCAT.MODULEOBJECTS

Each row represents a function, procedure, global variable, condition, or user-defined type that belongs to a module.

Table 220. SYSCAT.MODULEOBJECTS Catalog View

Column Name	Data Type	Nullable	Description
OBJECTSCHEMA	VARCHAR (128)	N	Schema name of the module.
OBJECTMODULENAME	VARCHAR (128)	N	Unqualified name of the module to which the object belongs.
OBJECTNAME	VARCHAR (128)	N	Unqualified name of the object.
OBJECTTYPE	VARCHAR (9)	N	• CONDITION = The object is a condition • FUNCTION = The object is a function • PROCEDURE = The object is a procedure • TYPE = The object is a data type • VARIABLE = The object is a variable

Table 220. SYSCAT.MODULEOBJECTS Catalog View (continued)

Column Name	Data Type	Nullable	Description
PUBLISHED	CHAR (1)	N	Indicates whether the object can be referenced outside its module. • N = The object is not published • Y = The object is published
SPECIFICNAME	VARCHAR (128)	N	Routine specific name if OBJECTTYPE is 'FUNCTION', 'METHOD' or 'PROCEDURE'; the null value otherwise.
USERDEFINED	CHAR (1)	N	Indicates whether the object is generated by the system or defined by a user. • N = The object is system generated • Y = The object is defined by a user

SYSCAT.MODULES

Each row represents a module.

Table 221. SYSCAT.MODULES Catalog View

Column Name	Data Type	Nullable	Description
MODULESCHEMA	VARCHAR (128)		Schema name of the module.
MODULENAME	VARCHAR (128)		Unqualified name of the module.
MODULEID	INTEGER		Identifier for the module.
DIALECT	VARCHAR (10)		The source dialect of the SQL module. Possible values are: • DB2 SQL PL • PL/SQL • Blank = Not applicable for an alias
OWNER	VARCHAR (128)		Authorization ID of the owner of the module.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
MODULETYPE	CHAR (1)		Type of module. • A = Alias • M = Module • P = PL/SQL package
BASE_MODULESCHEMA	VARCHAR (128)	Y	If MODULETYPE is 'A', contains the schema name of the module or alias that is referenced by this alias; the null value otherwise.

Table 221. SYSCAT.MODULES Catalog View (continued)

Column Name	Data Type	Nullable	Description
BASE_MODULENAME	VARCHAR (128)	Y	If MODULETYPE is 'A', contains the unqualified name of the module or alias that is referenced by this alias; the null value otherwise.
CREATE_TIME	TIMESTAMP		Time at which the module was created.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.NAMEMAPPINGS

Each row represents the mapping between a "logical" object (typed table or view and its columns and indexes, including inherited columns) and the corresponding "implementation" object (hierarchy table or hierarchy view and its columns and indexes) that implements the logical object.

Table 222. SYSCAT.NAMEMAPPINGS Catalog View

Column Name	Data Type	Nullable	Description
TYPE	CHAR (1)		• C = Column • I = Index • U = Typed table
LOGICAL_SCHEMA	VARCHAR (128)		Schema name of the logical object.
LOGICAL_NAME	VARCHAR (128)		Unqualified name of the logical object.
LOGICAL_COLNAME	VARCHAR (128)	Y	Name of the logical column if TYPE = 'C'; null value otherwise.
IMPL_SCHEMA	VARCHAR (128)		Schema name of the implementation object that implements the logical object.
IMPL_NAME	VARCHAR (128)		Unqualified name of the implementation object that implements the logical object.
IMPL_COLNAME	VARCHAR (128)	Y	Name of the implementation column if TYPE = 'C'; null value otherwise.

SYSCAT.NICKNAMES

Each row represents a nickname.

Table 223. SYSCAT.NICKNAMES Catalog View

Column Name	Data Type	Nullable	Description
TABSCHEMA	VARCHAR (128)		Schema name of the nickname.
TABNAME	VARCHAR (128)		Unqualified name of the nickname.
OWNER	VARCHAR (128)		Authorization ID of the owner of the table, view, alias, or nickname.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user

Table 223. SYSCAT.NICKNAMES Catalog View (continued)

Column Name	Data Type	Nullable	Description
STATUS	CHAR (1)		Status of the object. • C = Set integrity pending • N = Normal • X = Inoperative
CREATE_TIME	TIMESTAMP		Time at which the object was created.
STATS_TIME	TIMESTAMP	Y	Time at which any change was last made to recorded statistics for this object. The null value if statistics are not collected.
COLCOUNT	SMALLINT		Number of columns, including inherited columns (if any).
TABLEID	SMALLINT		Internal logical object identifier.
TBSPACEID	SMALLINT		Internal logical identifier for the primary table space for this object.
CARD	BIGINT		Total number of rows in the table; -1 if statistics are not collected.
NPAGES	BIGINT		Total number of pages on which the rows of the nickname exist; -1 if statistics are not gathered.
FPAGES	BIGINT		Total number of pages; -1 if statistics are not gathered.
OVERFLOW	BIGINT		Total number of overflow records; -1 if statistics are not gathered.
PARENTS	SMALLINT	Y	Number of parent tables for this object; that is, the number of referential constraints in which this object is a dependent.
CHILDREN	SMALLINT	Y	Number of dependent tables for this object; that is, the number of referential constraints in which this object is a parent.
SELFREFS	SMALLINT	Y	Number of self-referencing referential constraints for this object; that is, the number of referential constraints in which this object is both a parent and a dependent.
KEYCOLUMNS	SMALLINT	Y	Number of columns in the primary key.
KEYINDEXID	SMALLINT	Y	Index identifier for the primary key index; 0 or the null value if there is no primary key.
KEYUNIQUE	SMALLINT		Number of unique key constraints (other than the primary key constraint) defined on this object.
CHECKCOUNT	SMALLINT		Number of check constraints defined on this object.

Table 223. SYSCAT.NICKNAMES Catalog View (continued)

Column Name	Data Type	Nullable	Description
DATACAPTURE	CHAR (1)		• L = Nickname participates in data replication, including replication of LONG VARCHAR and LONG VARGRAPHIC columns • N = Nickname does not participate in data replication • Y = Nickname participates in data replication
CONST_CHECKED	CHAR (32)		• Byte 1 represents foreign key constraint. • Byte 2 represents check constraint. • Byte 5 represents materialized query table. • Byte 6 represents generated column. • Byte 7 represents staging table. • Byte 8 represents data partitioning constraint. • Other bytes are reserved for future use. Possible values are: • F = In byte 5, the materialized query table cannot be refreshed incrementally. In byte 7, the content of the staging table is incomplete and cannot be used for incremental refresh of the associated materialized query table. • N = Not checked • U = Checked by user • W = Was in 'U' state when the table was placed in set integrity pending state • Y = Checked by system
PARTITION_MODE	CHAR (1)		Reserved for future use.
STATISTICS_PROFILE	CLOB (10M)	Y	RUNSTATS command used to register a statistical profile for the object.
ACCESS_MODE	CHAR (1)		Access restriction state of the object. These states only apply to objects that are in set integrity pending state or to objects that were processed by a SET INTEGRITY statement. Possible values are: • D = No data movement • F = Full access • N = No access • R = Read-only access

Table 223. SYSCAT.NICKNAMES Catalog View (continued)

Column Name	Data Type	Nullable	Description
CODEPAGE	SMALLINT		Code page of the object. This is the default code page used for all character columns, triggers, check constraints, and expression-generated columns.
REMOTE_TABLE	VARCHAR (128)	Y	Unqualified name of the specific data source object (such as a table or a view) for which the nickname was created.
REMOTE_SCHEMA	VARCHAR (128)	Y	Schema name of the specific data source object (such as a table or a view) for which the nickname was created.
SERVERNAME	VARCHAR (128)	Y	Name of the data source that contains the table or view for which the nickname was created.
REMOTE_TYPE	CHAR (1)	Y	Type of object at the data source. • A = Alias • N = Nickname • S = Materialized query table • T = Table (untyped) • V = View (untyped)
CACHINGALLOWED	VARCHAR (1)		• N = Caching is not allowed • Y = Caching is allowed
DEFINER[1]	VARCHAR (128)		Authorization ID of the owner of the table, view, alias, or nickname.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.PACKAGEAUTH

Each row represents a user, group, or role that has been granted one or more privileges on a package.

Table 224. SYSCAT.PACKAGEAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of the privilege.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user
GRANTEE	VARCHAR (128)		Holder of the privilege.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user

Table 224. SYSCAT.PACKAGEAUTH Catalog View (continued)

Column Name	Data Type	Nullable	Description
PKGSCHEMA	VARCHAR (128)		Schema name of the package.
PKGNAME	VARCHAR (128)		Unqualified name of the package.
CONTROLAUTH	CHAR (1)		CONTROL privilege. • N = Not held • Y = Held
BINDAUTH	CHAR (1)		Privilege to bind the package. • G = Held and grantable • N = Not held • Y = Held
EXECUTEAUTH	CHAR (1)		Privilege to execute the package. • G = Held and grantable • N = Not held • Y = Held

SYSCAT.PACKAGEDEP

Each row represents a dependency of a package on some other object. The package depends on the object of type BTYPE of name BNAME, so a change to the object affects the package.

Table 225. SYSCAT.PACKAGEDEP Catalog View

Column Name	Data Type	Nullable	Description
PKGSCHEMA	VARCHAR (128)		Schema name of the package.
PKGNAME	VARCHAR (128)		Unqualified name of the package.
BINDER	VARCHAR (128)		Binder of the package.
BINDERTYPE	CHAR (1)		• U = Binder is an individual user

Table 225. SYSCAT.PACKAGEDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
BTYPE	CHAR (1)		Type of object on which there is a dependency. Possible values are: • A = Table alias • B = Trigger • D = Server definition • F = Routine • G = Global temporary table • I = Index • M = Function mapping • N = Nickname • O = Privilege dependency on all subtables or subviews in a table or view hierarchy • P = Page size • Q = Sequence object • R = User-defined data type • S = Materialized query table • T = Table (untyped) • U = Typed table • V = View (untyped) • W = Typed view • Z = XSR object • m = Module • n = Database partition group • q = Sequence alias • u = Module alias • v = Global variable • 4 = Application-period temporal table • 5 = System-period temporal table
BSCHEMA	VARCHAR (128)		Schema name of an object on which the package depends.
BMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the object on which a dependency belongs. The null value if not a module object.
BNAME	VARCHAR (128)		Unqualified name of an object on which the package depends.
BMODULEID	INTEGER	Y	Identifier for the module of the object on which there is a dependency.
TABAUTH	SMALLINT	Y	If BTYPE is 'O', 'S', 'T', 'U', 'V', 'W', or 'v', encodes the privileges that are required by this package (SELECT, INSERT, UPDATE, or DELETE).

Table 225. SYSCAT.PACKAGEDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
VARAUTH	SMALLINT	Y	If BTYPE is 'v', encodes the privileges that are required by this package (READ or WRITE).
UNIQUE_ID	CHAR (8) FOR BIT DATA		Identifier for a specific package when multiple packages having the same name exist.
PKGVERSION	VARCHAR (64)	Y	Version identifier for the package.

Note:

1. If a function instance with dependencies is dropped, the package is put into an "inoperative" state, and it must be explicitly rebound. If any other object with dependencies is dropped, the package is put into an "invalid" state, and the system will attempt to rebind the package automatically when it is first referenced.

SYSCAT.PACKAGES

Each row represents a package that has been created by binding an application program.

Table 226. SYSCAT.PACKAGES Catalog View

Column Name	Data Type	Nullable	Description
PKGSCHEMA	VARCHAR (128)		Schema name of the package.
PKGNAME	VARCHAR (128)		Unqualified name of the package.
BOUNDBY	VARCHAR (128)		Authorization ID of the binder and owner of the package.
BOUNDBYTYPE	CHAR (1)		• U = The binder and owner is an individual user
OWNER	VARCHAR (128)		Authorization ID of the binder and owner of the package.
OWNERTYPE	CHAR (1)		• U = The binder and owner is an individual user
DEFAULT_SCHEMA	VARCHAR (128)		Default schema name used for unqualified names in static SQL statements.
VALID[1]	CHAR (1)		• N = Needs rebinding • V = Validate at run time • X = Package is inoperative because some function instance on which it depends has been dropped; explicit rebind is needed • Y = Valid
UNIQUE_ID	CHAR (8) FOR BIT DATA		Identifier for a specific package when multiple packages having the same name exist.
TOTAL_SECT	SMALLINT		Number of sections in the package.

Table 226. SYSCAT.PACKAGES Catalog View (continued)

Column Name	Data Type	Nullable	Description
FORMAT	CHAR (1)		Date and time format associated with the package. • 0 = Format associated with the territory code of the client • 1 = USA • 2 = EUR • 3 = ISO • 4 = JIS • 5 = LOCAL
ISOLATION	CHAR (2)	Y	Isolation level. • CS = Cursor Stability • RR = Repeatable Read • RS = Read Stability • UR = Uncommitted Read
CONCURRENTACCESSRESOLUTION	CHAR (1)	Y	The value of the CONCURRENTACCESSRESOLUTION bind option: • U = USE CURRENTLY COMMITTED • W = WAIT FOR OUTCOME • Blank = Not specified
BLOCKING	CHAR (1)	Y	Cursor blocking option. • B = Block all cursors • N = No blocking • U = Block unambiguous cursors
INSERT_BUF	CHAR (1)		Setting of the INSERT bind option (applies to partitioned database systems). • N = Inserts are not buffered • Y = Inserts are buffered at the coordinator member to minimize traffic among members
LANG_LEVEL	CHAR (1)	Y	Setting of the LANGLEVEL bind option. • 0 = SAA1 • 1 = MIA • 2 = SQL92E
FUNC_PATH	CLOB (2K)		SQL path in effect when the package was bound.
QUERYOPT	INTEGER		Optimization class under which this package was bound. Used for rebind operations.

Table 226. SYSCAT.PACKAGES Catalog View (continued)

Column Name	Data Type	Nullable	Description
EXPLAIN_LEVEL	CHAR (1)		Indicates whether Explain was requested using the EXPLAIN or EXPLSNAP bind option. • P = Package selection level • Blank = No Explain requested
EXPLAIN_MODE	CHAR (1)		Value of the EXPLAIN bind option. • A = ALL • N = No • R = REOPT • Y = Yes
EXPLAIN_SNAPSHOT	CHAR (1)		Value of the EXPLSNAP bind option. • A = ALL • N = No • R = REOPT • Y = Yes
SQLWARN	CHAR (1)		Indicates whether or not positive SQLCODEs resulting from dynamic SQL statements are returned to the application. • N = No, they are suppressed • Y = Yes
SQLMATHWARN	CHAR (1)		Value of the *dft_sqlmathwarn* database configuration parameter at bind time. Indicates whether arithmetic and retrieval conversion errors return warnings and null values (indicator -2), allowing query processing to continue whenever possible. • N = No, errors are returned • Y = Yes, warnings are returned
CREATE_TIME	TIMESTAMP		Time at which the package was first bound.
EXPLICIT_BIND_TIME	TIMESTAMP		Time at which this package was last changed by: • BIND • REBIND (explicit)

Table 226. SYSCAT.PACKAGES Catalog View (continued)

Column Name	Data Type	Nullable	Description
LAST_BIND_TIME	TIMESTAMP		Time at which the package was last changed by: • BIND • REBIND (explicit) • REBIND (implicit)
ALTER_TIME	TIMESTAMP		Time at which this package was last changed by: • BIND • REBIND (explicit) • REBIND (implicit) • ALTER PACKAGE
CODEPAGE	SMALLINT		Application code page at bind time; -1 if not known.
COLLATIONSCHEMA	VARCHAR (128)		Schema name of the collation for the package.
COLLATIONNAME	VARCHAR (128)		Unqualified name of the collation for the package.
COLLATIONSCHEMA_ORDERBY	VARCHAR (128)		Schema name of the collation for ORDER BY clauses in the package.
COLLATIONNAME_ORDERBY	VARCHAR (128)		Unqualified name of the collation for ORDER BY clauses in the package.
DEGREE	CHAR (5)		Degree of intrapartition parallelism that was specified when the package was bound. • 1 = No parallelism • 2-32767 = User-specified limit • ANY = Degree determined by the system (no limit specified)
MULTINODE_PLANS	CHAR (1)		• N = Package was not bound in a partitioned database environment • Y = Package was bound in a partitioned database environment

Table 226. SYSCAT.PACKAGES Catalog View (continued)

Column Name	Data Type	Nullable	Description
INTRA_PARALLEL	CHAR (1)		Use of intrapartition parallelism by static SQL statements within the package. • F = One or more static SQL statements in this package can use intrapartition parallelism; this parallelism has been disabled for use on a system that is not configured for intrapartition parallelism • N = No static SQL statement uses intrapartition parallelism • Y = One or more static SQL statements in the package use intrapartition parallelism
VALIDATE	CHAR (1)		Indicates whether validity checking can be deferred until run time. • B = All checking must be performed at bind time • R = Validation of tables, views, and privileges that do not exist at bind time is performed at run time

Table 226. SYSCAT.PACKAGES Catalog View (continued)

Column Name	Data Type	Nullable	Description
DYNAMICRULES	CHAR (1)		• B = BIND; dynamic SQL statements are executed with DYNAMICRULES BIND behavior • D = DEFINERBIND; when the package is run within a routine context, dynamic SQL statements in the package are executed with DEFINE behavior; when the package is not run within a routine context, dynamic SQL statements in the package are executed with BIND behavior • E = DEFINERRUN; when the package is run within a routine context, dynamic SQL statements in the package are executed with DEFINE behavior; when the package is not run within a routine context, dynamic SQL statements in the package are executed with RUN behavior • H = INVOKEBIND; when the package is run within a routine context, dynamic SQL statements in the package are executed with INVOKE behavior; when the package is not run within a routine context, dynamic SQL statements in the package are executed with BIND behavior • I = INVOKERUN; when the package is run within a routine context, dynamic SQL statements in the package are executed with INVOKE behavior; when the package is not run within a routine context, dynamic SQL statements in the package are executed with RUN behavior • R = RUN; dynamic SQL statements are executed with RUN behavior; this is the default
SQLERROR	CHAR (1)		SQLERROR option on the most recent subcommand that bound or rebound the package. • C = CONTINUE; creates a package, even if errors occur while binding SQL statements • N = NOPACKAGE; does not create a package or a bind file if an error occurs

Table 226. SYSCAT.PACKAGES Catalog View (continued)

Column Name	Data Type	Nullable	Description
REFRESHAGE	DECIMAL (20,6)		Timestamp duration indicating the maximum length of time between execution of a REFRESH TABLE statement for a materialized query table (MQT) and when that MQT is used in place of a base table.
FEDERATED	CHAR (1)		• N = FEDERATED bind or prep option is turned off • U = FEDERATED bind or prep option was not specified • Y = FEDERATED bind or prep option is turned on
TRANSFORMGROUP	VARCHAR (1024)	Y	Value of the TRANSFORM GROUP bind option; the null value if a transform group is not specified.
REOPTVAR	CHAR (1)		Indicates whether the access path is determined again at execution time using input variable values. • A = Access path is reoptimized for every OPEN or EXECUTE request • N = Access path is determined at bind time • O = Access path is reoptimized only at the first OPEN or EXECUTE request; it is subsequently cached
OS_PTR_SIZE	INTEGER		Word size for the platform on which the package was created. • 32 = Package is a 32-bit package • 64 = Package is a 64-bit package
PKGVERSION	VARCHAR (64)		Version identifier for the package.

Table 226. SYSCAT.PACKAGES Catalog View (continued)

Column Name	Data Type	Nullable	Description
STATICREADONLY	CHAR (1)		Indicates whether or not static cursors will be treated as READ ONLY. Possible values are: • I = Any static cursor that does not contain the FOR UPDATE clause is considered READ ONLY and INSENSITIVE • N = Static cursors take on the attributes that would normally be generated for the given statement text and the setting of the LANGLEVEL precompile option • Y = Any static cursor that does not contain the FOR UPDATE or the FOR READ ONLY clause is considered READ ONLY
FEDERATED_ASYNCHRONY	INTEGER		Indicates the limit on asynchrony (the number of ATQs in the plan) as a bind option when the package was bound. • 0 = No asynchrony • *n* = User-specified limit (32 767 maximum) • -1 = Degree of asynchrony determined by the system • -2 = Degree of asynchrony not specified For a non-federated system, the value is 0.
ANONBLOCK	CHAR (1)		• N = The package is not associated with an anonymous block • Y = The package is associated with an anonymous block
OPTPROFILESCHEMA	VARCHAR (128)	Y	Value of the optimization profile schema specified as part of the OPTPROFILE bind option.
OPTPROFILENAME	VARCHAR (128)	Y	Value of the optimization profile name specified as part of the OPTPROFILE bind option.
PKGID	BIGINT		Identifier for the package.
DBPARTITIONNUM	SMALLINT		Number of the database partition where the package was bound.
DEFINER[2]	VARCHAR (128)		Authorization ID of the binder and owner of the package.
PKG_CREATE_TIME[3]	TIMESTAMP		Time at which the package was first bound.

Table 226. SYSCAT.PACKAGES Catalog View (continued)

Column Name	Data Type	Nullable	Description
APREUSE	CHAR (1)		• N = The query compiler will not attempt to reuse access plans • Y = The access plans in this package should be reused, meaning that at rebind time the query compiler will attempt to choose plans like the ones currently in the package
EXTENDEDINDICATOR	CHAR (1)		• N = Extended indicator variable values are not recognized • Y = Extended indicator variable values are recognized
LASTUSED	DATE		Date when any statement in the package was last executed. This column is not updated for a package associated with an anonymous block. This column is not updated when a statement in the package is executed on an HADR standby database. The default value is '0001-01-01'. This value is updated asynchronously not more than once within a 24 hour period and might not reflect usage within the last 15 minutes.
BUSTIMESENSITIVE	CHAR (1)		• N = Statements that reference an application period temporal table (ATT) will not be affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register • Y = Statements that reference an ATT will be affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register
SYSTIMESENSITIVE	CHAR (1)		• N = Statements that reference a system period temporal table (STT) will not be affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register • Y = Statements that reference an STT will be affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register

Table 226. SYSCAT.PACKAGES Catalog View (continued)

Column Name	Data Type	Nullable	Description
KEEPDYNAMIC	CHAR (1)		Specifies whether dynamic SQL statements are kept after commit or rollback. • N = Inactive dynamic SQL statements need to be prepared again after commit or rollback • Y = Dynamic SQL statements are kept across transactions
STATICASDYNAMIC	CHAR (1)		• N = All static SQL statements in the package are compiled at bind time, using static SQL semantics • Y = All static SQL statements in the package are compiled at execution time, using dynamic SQL semantics
MEMBER	SMALLINT		Number of the member where the package was bound.
ENVSTRINGUNITS	VARCHAR (11)		Default string units when the object was created.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. If a function instance with dependencies is dropped, the package is put into an "inoperative" state, and it must be explicitly rebound. If any other object with dependencies is dropped, the package is put into an "invalid" state, and the system will attempt to rebind the package automatically when it is first referenced.
2. The DEFINER column is included for backwards compatibility. See OWNER.
3. The PKG_CREATE_TIME column is included for backwards compatibility. See CREATE_TIME.

SYSCAT.PARTITIONMAPS

Each row represents a distribution map that is used to distribute the rows of a table among the database partitions in a database partition group, based on hashing the table's distribution.

Table 227. SYSCAT.PARTITIONMAPS Catalog View

Column Name	Data Type	Nullable	Description
PMAP_ID	SMALLINT		Identifier for the distribution map.
PARTITIONMAP	BLOB (65536)		Distribution map, a vector of 32768 two-byte integers for a multiple partition database partition group. For a single partition database partition group, there is one entry denoting the partition number of the single partition.

SYSCAT.PASSTHRUAUTH

Each row represents a user, group, or role that has been granted pass-through authorization to query a data source.

Table 228. SYSCAT.PASSTHRUAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of the privilege.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user
GRANTEE	VARCHAR (128)		Holder of the privilege.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
SERVERNAME	VARCHAR (128)		Name of the data source to which authorization is being granted.

SYSCAT.PERIODS

Each row represents the definition of a period for use with a temporal table.

Table 229. SYSCAT.PERIODS Catalog View

Column Name	Data Type	Nullable	Description
PERIODNAME	VARCHAR (128)		Name of the period.
TABSCHEMA	VARCHAR (128)		Schema name of the table.
TABNAME	VARCHAR (128)		Unqualified name of the table.
BEGINCOLNAME	VARCHAR (128)		Period begin column name.
ENDCOLNAME	VARCHAR (128)		Period end column name.
PERIODTYPE	CHAR (1)		Type of period. • A = Application period • S = System period
HISTORYTABSCHEMA	VARCHAR (128)		Schema name of the history table.
HISTORYTABNAME	VARCHAR (128)		Unqualified name of the history table.

SYSCAT.PREDICATESPECS

Each row represents a predicate specification.

Table 230. SYSCAT.PREDICATESPECS Catalog View

Column Name	Data Type	Nullable	Description
FUNCSCHEMA	VARCHAR (128)		Schema name of the function.
FUNCNAME	VARCHAR (128)		Unqualified name of the function.
SPECIFICNAME	VARCHAR (128)		Name of the function instance.
FUNCID	INTEGER		Identifier for the function.

Table 230. SYSCAT.PREDICATESPECS Catalog View (continued)

Column Name	Data Type	Nullable	Description
SPECID	SMALLINT		Number of this predicate specification.
CONTEXTOP	CHAR (8)		Comparison operator, one of the built-in relational operators (=, <, >, >=, and so on).
CONTEXTEXP	CLOB (2M)		Constant, or an SQL expression.
FILTERTEXT	CLOB (32K)	Y	Text of the data filter expression.

SYSCAT.REFERENCES

Each row represents a referential integrity (foreign key) constraint.

Table 231. SYSCAT.REFERENCES Catalog View

Column Name	Data Type	Nullable	Description
CONSTNAME	VARCHAR (128)		Name of the constraint.
TABSCHEMA	VARCHAR (128)		Schema name of the dependent table.
TABNAME	VARCHAR (128)		Unqualified name of the dependent table.
OWNER	VARCHAR (128)		Authorization ID of the owner of the constraint.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
REFKEYNAME	VARCHAR (128)		Name of the parent key.
REFTABSCHEMA	VARCHAR (128)		Schema name of the parent table.
REFTABNAME	VARCHAR (128)		Unqualified name of the parent table.
COLCOUNT	SMALLINT		Number of columns in the foreign key.
DELETERULE	CHAR (1)		Delete rule. • A = NO ACTION • C = CASCADE • N = SET NULL • R = RESTRICT
UPDATERULE	CHAR (1)		Update rule. • A = NO ACTION • R = RESTRICT
CREATE_TIME	TIMESTAMP		Time at which the constraint was defined.
FK_COLNAMES	VARCHAR (640)		This column is no longer used and will be removed in a future release. Use SYSCAT.KEYCOLUSE for this information.
PK_COLNAMES	VARCHAR (640)		This column is no longer used and will be removed in a future release. Use SYSCAT.KEYCOLUSE for this information.

Table 231. SYSCAT.REFERENCES Catalog View (continued)

Column Name	Data Type	Nullable	Description
DEFINER[1]	VARCHAR (128)		Authorization ID of the owner of the constraint.

Note:

1. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.ROLEAUTH

Each row represents a role granted to a user, group, role, or PUBLIC.

Table 232. SYSCAT.ROLEAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Authorization ID that granted the role.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user
GRANTEE	VARCHAR (128)		Authorization ID to which the role was granted.
GRANTEETYPE	CHAR (1)		• G = The grantee is a group • R = The grantee is a role • U = The grantee is an individual user
ROLENAME	VARCHAR (128)		Name of the role.
ROLEID	INTEGER		Identifier for the role.
ADMIN	CHAR (1)		Privilege to grant or revoke the role to or from others, or to comment on the role. • N = Not held • Y = Held

SYSCAT.ROLES

Each row represents a role.

Table 233. SYSCAT.ROLES Catalog View

Column Name	Data Type	Nullable	Description
ROLENAME	VARCHAR (128)		Name of the role.
ROLEID	INTEGER		Identifier for the role.
CREATE_TIME	TIMESTAMP		Time when the role was created.
AUDITPOLICYID	INTEGER	Y	Identifier for the audit policy.
AUDITPOLICYNAME	VARCHAR (128)	Y	Name of the audit policy.
AUDITEXCEPTIONENABLED	CHAR (1)		Reserved for future use.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.ROUTINEAUTH

Each row represents a user, group, or role that has been granted EXECUTE privilege on either a particular routine (function, method, or procedure) in the database that is not defined in a module or all routines in a particular schema in the database that are not defined in a module.

Table 234. SYSCAT.ROUTINEAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of the privilege. "SYSIBM" if the privilege was granted by the system.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user
GRANTEE	VARCHAR (128)		Holder of the privilege.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
SCHEMA	VARCHAR (128)		Schema name of the routine.
SPECIFICNAME	VARCHAR (128)	Y	Specific name of the routine. If SPECIFICNAME is the null value and ROUTINETYPE is not "M", the privilege applies to all routines of the type specified in ROUTINETYPE in the schema specified in SCHEMA. If SPECIFICNAME is the null value and ROUTINETYPE is "M", the privilege applies to all methods for the subject type specified by TYPENAME in the schema specified by TYPESCHEMA. If SPECIFICNAME is the null value, ROUTINETYPE is "M", and both TYPENAME and TYPESCHEMA are null values, the privilege applies to all methods for all types in the schema.
TYPESCHEMA	VARCHAR (128)	Y	Schema name of the type for the method. The null value if ROUTINETYPE is not "M".
TYPENAME	VARCHAR (128)	Y	Unqualified name of the type for the method. The null value if ROUTINETYPE is not "M". If TYPENAME is the null value and ROUTINETYPE is "M", the privilege applies to all methods for any subject type if they are in the schema specified by SCHEMA.
ROUTINETYPE	CHAR (1)		Type of the routine. • F = Function • M = Method • P = Procedure

Table 234. SYSCAT.ROUTINEAUTH Catalog View (continued)

Column Name	Data Type	Nullable	Description
EXECUTEAUTH	CHAR (1)		Privilege to execute the routine. • G = Held and grantable • N = Not held • Y = Held
GRANT_TIME	TIMESTAMP		Time at which the privilege was granted.

SYSCAT.ROUTINEDEP

Each row represents a dependency of a routine on some other object. The routine depends on the object of type BTYPE of name BNAME, so a change to the object affects the routine.

Table 235. SYSCAT.ROUTINEDEP Catalog View

Column Name	Data Type	Nullable	Description
ROUTINESCHEMA	VARCHAR (128)		Schema name of the routine that has dependencies on another object.
ROUTINEMODULENAME	VARCHAR (128)	Y	Unqualified name of the module.
SPECIFICNAME	VARCHAR (128)		Specific name of the routine that has dependencies on another object.
ROUTINEMODULEID	INTEGER	Y	Identifier for the module of the object that has dependencies on another object.

Table 235. SYSCAT.ROUTINEDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
BTYPE	CHAR (1)		Type of object on which there is a dependency. Possible values are: • A = Table alias • B = Trigger • C = Column • F = Routine • G = Global temporary table • H = Hierachy table • I = Index • K = Package • L = Detached table • N = Nickname • O = Privilege dependency on all subtables or subviews in a table or view hierarchy • Q = Sequence • R = User-defined data type • S = Materialized query table • T = Table (not typed) • U = Typed table • V = View (not typed) • W = Typed view • X = Index extension • Z = XSR object • m = Module • q = Sequence alias • u = Module alias • v = Global variable • * = Anchored to the row of a base table
BSCHEMA	VARCHAR (128)		Schema name of the object on which there is a dependency.
BMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the object on which a dependency belongs. The null value if not a module object.
BNAME	VARCHAR (128)		Unqualified name of the object on which there is a dependency. For routines (BTYPE = 'F'), this is the specific name.
BMODULEID	INTEGER	Y	Identifier for the module of the object on which there is a dependency.
TABAUTH	SMALLINT	Y	If BTYPE = 'O', 'S', 'T', 'U', 'V', 'W', or 'v', encodes the privileges on the table or view that are required by the dependent routine; the null value otherwise.

Table 235. SYSCAT.ROUTINEDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
ROUTINENAME	VARCHAR (128)		This column is no longer used and will be removed in a future release. See SPECIFICNAME.

SYSCAT.ROUTINEOPTIONS

Each row represents a routine-specific option value.

Table 236. SYSCAT.ROUTINEOPTIONS Catalog View

Column Name	Data Type	Nullable	Description
ROUTINESCHEMA	VARCHAR (128)		Schema name of the routine if ROUTINEMODULEID is null; otherwise schema name of the module to which the routine belongs.
ROUTINEMODULENAME	VARCHAR (128)		Unqualified name of the module to which the routine belongs. The null value if not a module routine.
ROUTINENAME	VARCHAR (128)		Unqualified name of the routine.
SPECIFICNAME	VARCHAR (128)		Name of the routine instance (might be system-generated).
OPTION	VARCHAR (128)		Federated routine option name or routine environment variable name.
SETTING	VARCHAR (2048)		Federated routine option value or routine environment variable value.

SYSCAT.ROUTINEPARMOPTIONS

Each row represents a routine parameter-specific option value.

Table 237. SYSCAT.ROUTINEPARMOPTIONS Catalog View

Column Name	Data Type	Nullable	Description
ROUTINESCHEMA	VARCHAR (128)		Schema name of the routine if ROUTINEMODULEID is null; otherwise schema name of the module to which the routine belongs.
ROUTINENAME	VARCHAR (128)		Unqualified name of the routine.
SPECIFICNAME	VARCHAR (128)		Name of the routine instance (might be system-generated).
ORDINAL	SMALLINT		Position of the parameter within the routine signature.
OPTION	VARCHAR (128)		Name of the federated routine option.
SETTING	VARCHAR (2048)		Value of the federated routine option.

SYSCAT.ROUTINEPARMS

Each row represents a parameter, an aggregation state variable, or the result of a routine defined in SYSCAT.ROUTINES.

Table 238. SYSCAT.ROUTINEPARMS Catalog View

Column Name	Data Type	Nullable	Description
ROUTINESCHEMA	VARCHAR (128)	Y	Schema name of the routine if ROUTINEMODULEID is null; otherwise schema name of the module to which the routine belongs.
ROUTINEMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the routine belongs. The null value if not a module routine.
ROUTINENAME	VARCHAR (128)	Y	Unqualified name of the routine.
ROUTINEMODULEID	INTEGER	Y	Identifier for the module to which the routine belongs. The null value if not a module routine.
SPECIFICNAME	VARCHAR (128)	Y	Name of the routine instance (might be system-generated).
PARMNAME	VARCHAR (128)	Y	Name of the parameter, result column, or aggregation state variable; the null value if no name exists.
ROWTYPE	CHAR (1)	Y	• B = Both input and output parameter • C = Result after casting • O = Output parameter • P = Input parameter • R = Result before casting • S = Aggregation state variable
ORDINAL	SMALLINT	Y	If ROWTYPE = "B", "O", or "P", numerical position of the parameter within the routine signature, starting with 1; if ROWTYPE = "R" and the routine returns a table, numerical position of a named column in the result table, starting with 1; if ROWTYPE = "S", numerical position of an aggregation state variable within the routine definition, starting with 1; 0 otherwise.
TYPESCHEMA	VARCHAR (128)	Y	Schema name of the data type if TYPEMODULEID is null; otherwise schema name of the module to which the data type belongs.
TYPEMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the data type of the parameter or result belongs. The null value if not a module data type.
TYPENAME	VARCHAR (128)	Y	Unqualified name of the data type.

Table 238. SYSCAT.ROUTINEPARMS Catalog View (continued)

Column Name	Data Type	Nullable	Description
LOCATOR	CHAR (1)	Y	• N = Paramater or result is not passed in the form of a locator • Y = Paramater or result is passed in the form of a locator
LENGTH[1]	INTEGER	Y	Length of the data type; 0 for a user-defined data type; -1 if length attribute of data type is specified as ANY.
SCALE[1]	SMALLINT	Y	Scale if the data type is DECIMAL; the number of digits of fractional seconds if the data type is TIMESTAMP; 0 otherwise.
TYPESTRINGUNITS	VARCHAR (11)	Y	In a Unicode database, the string units that apply to a character string or graphic string data type. Otherwise, the null value.
STRINGUNITSLENGTH	INTEGER	Y	In a Unicode database, the declared number of string units for a character string or graphic string data type. Otherwise, the null value.
CODEPAGE	SMALLINT	Y	Code page associated with the data type; 0 denotes either not applicable, or a character data type declared with the FOR BIT DATA attribute.
COLLATIONSCHEMA	VARCHAR (128)	Y	For string types, the schema name of the collation for the parameter; the null value otherwise.
COLLATIONNAME	VARCHAR (128)	Y	For string types, the unqualified name of the collation for the parameter; the null value otherwise.
CAST_FUNCSCHEMA	VARCHAR (128)	Y	Schema name of the function used to cast an argument or a result. Applies to sourced and external functions; the null value otherwise.
CAST_FUNCSPECIFIC	VARCHAR (128)	Y	Unqualified name of the function used to cast an argument or a result. Applies to sourced and external functions; the null value otherwise.
TARGET_TYPESCHEMA	VARCHAR (128)	Y	Schema name of the target type if the type of the parameter or result is REFERENCE. Null value if the type of the parameter or result is not REFERENCE.
TARGET_TYPEMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the target type belongs if the type of the parameter or result is REFERENCE. The null value if the type of the parameter or result is not REFERENCE or if the target type is not a module data type.

Table 238. SYSCAT.ROUTINEPARMS Catalog View (continued)

Column Name	Data Type	Nullable	Description
TARGET_TYPENAME	VARCHAR (128)	Y	Unqualified name of the module to which the target type belongs if the type of the parameter or result is REFERENCE. The null value if the type of the parameter or result is not REFERENCE or if the target type is not a module data type.
SCOPE_TABSCHEMA	VARCHAR (128)	Y	Schema name of the scope (target table) if the parameter type is REFERENCE; null value otherwise.
SCOPE_TABNAME	VARCHAR (128)	Y	Unqualified name of the scope (target table) if the parameter type is REFERENCE; null value otherwise.
TRANSFORMGRPNAME	VARCHAR (128)	Y	Name of the transform group for a structured type parameter or result.
DEFAULT	CLOB (64K)	Y	Expression used to calculate the default value of the parameter. The null value if DEFAULT clause was not specified for the parameter.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note: LENGTH and SCALE are set to 0 for sourced functions (functions defined with a reference to another function), because they inherit the length and scale of parameters from their source.

SYSCAT.ROUTINES

Each row represents a user-defined routine (scalar function, table function, sourced function, aggregate interface function, method, or procedure).

Table 239. SYSCAT.ROUTINES Catalog View

Column Name	Data Type	Nullable	Description
ROUTINESCHEMA	VARCHAR (128)	Y	Schema name of the routine if ROUTINEMODULEID is null; otherwise schema name of the module to which the routine belongs.
ROUTINEMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the routine belongs. The null value if not a module routine.
ROUTINENAME	VARCHAR (128)	Y	Unqualified name of the routine.
ROUTINETYPE	CHAR (1)	Y	Type of routine. • F = Function • M = Method • P = Procedure
OWNER	VARCHAR (128)	Y	Authorization ID of the owner of the routine.

Table 239. SYSCAT.ROUTINES Catalog View (continued)

Column Name	Data Type	Nullable	Description
OWNERTYPE	CHAR (1)	Y	• S = The owner is the system • U = The owner is an individual user
SPECIFICNAME	VARCHAR (128)	Y	Name of the routine instance (might be system-generated).
ROUTINEID	INTEGER	Y	Identifier for the routine.
ROUTINEMODULEID	INTEGER	Y	Identifier for the module to which the routine belongs. The null value if not a module routine.
RETURN_TYPESCHEMA	VARCHAR (128)	Y	Schema name of the return type for a scalar function or method.
RETURN_TYPEMODULE	VARCHAR (128)	Y	The module name of the return type; the null value if the return type does not belong to any module.
RETURN_TYPENAME	VARCHAR (128)	Y	Unqualified name of the return type for a scalar function or method.
ORIGIN	CHAR (1)	Y	• A = User-defined aggregate interface function • B = Built-in • E = User-defined, external • M = Template function • F = Federated procedure • Q = SQL-bodied[1] • R = System-generated SQL-bodied routine • S = System-generated • T = System-generated transform function (not directly invokable) • U = User-defined, based on a source
FUNCTIONTYPE	CHAR (1)	Y	• C = Column or aggregate • R = Row • S = Scalar • T = Table • Blank = Procedure
PARM_COUNT	SMALLINT	Y	Number of routine parameters; -1 if parameters specified as VARARGS.
LANGUAGE	CHAR (8)	Y	Implementation language for the routine body (or for the source function body, if this function is sourced on another function). Possible values are "C", "CLR", "COBOL", "JAVA", "OLE", "OLEDB", "R", or "SQL". Blanks if ORIGIN is not "E", "Q", or "R".

Table 239. SYSCAT.ROUTINES Catalog View (continued)

Column Name	Data Type	Nullable	Description
DIALECT	VARCHAR (10)	Y	The source dialect of the SQL routine body: • Db2 SQL PL • PL/SQL • Blank = Not an SQL routine
SOURCESCHEMA	VARCHAR (128)	Y	If ORIGIN = "U" and the source function is a user-defined function, contains the schema name of the specific name of the source function. If ORIGIN = "U" and the source function is a built-in function, contains the value "SYSIBM". The null value if ORIGIN is not "U".
SOURCEMODULENAME	VARCHAR (128)	Y	Contains the module name of the specific name of the source function if ORIGIN = "U" and the source function is a user-defined function defined in a module; the null value otherwise.
SOURCESPECIFIC	VARCHAR (128)	Y	If ORIGIN = "U" and the source function is a user-defined function, contains the unqualified specific name of the source function. If ORIGIN = "U" and the source function is a built-in function, contains the value "N/A for built-in". The null value if ORIGIN is not "U".
PUBLISHED	CHAR (1)	Y	Indicates whether the module routine can be invoked outside its module. • N = The module routine is not published • Y = The module routine is published • Blank = Not applicable
DETERMINISTIC	CHAR (1)	Y	• N = Results are not deterministic (same parameters might give different results in different routine calls) • Y = Results are deterministic • Blank = ORIGIN is not "A", "E", "F", "Q", or "R"
EXTERNAL_ACTION	CHAR (1)	Y	• E = Function has external side-effects (therefore, the number of invocations is important) • N = No side-effects • Blank = ORIGIN is not "A", "E", "F", "Q", or "R"

Table 239. SYSCAT.ROUTINES Catalog View (continued)

Column Name	Data Type	Nullable	Description
NULLCALL	CHAR (1)	Y	• N = RETURNS NULL ON NULL INPUT (function result is implicitly the null value if one or more operands are null) • Y = CALLED ON NULL INPUT • Blank = ORIGIN is not "A", "E", "Q", or "R"
CAST_FUNCTION	CHAR (1)	Y	• N = Not a cast function • Y = Cast function • Blank = ROUTINETYPE is not "F"
ASSIGN_FUNCTION	CHAR (1)	Y	• N = Not an assignment function • Y = Implicit assignment function • Blank = ROUTINETYPE is not "F"
SCRATCHPAD	CHAR (1)	Y	• N = Routine has no scratchpad • Y = Routine has a scratchpad • Blank = ORIGIN is not "A" or "E", or ROUTINETYPE is "P"
SCRATCHPAD_LENGTH	SMALLINT	Y	Size (in bytes) of the scratchpad for the routine. • -1 = LANGUAGE is "OLEDB" and SCRATCHPAD is "Y" • 0 = SCRATCHPAD is not "Y"
FINALCALL	CHAR (1)	Y	• N = No final call is made • Y = Final call is made to this routine at the runtime end-of-statement • Blank = ORIGIN is not "A" or "E", or ROUTINETYPE is "P"
PARALLEL	CHAR (1)	Y	• N = Routine cannot be executed in parallel • Y = Routine can be executed in parallel • Blank = ORIGIN is not "A" or "E"

Table 239. SYSCAT.ROUTINES Catalog View (continued)

Column Name	Data Type	Nullable	Description
PARAMETER_STYLE	CHAR (8)	Y	Parameter style that was declared when the routine was created. Possible values are: • DB2DARI • DB2GENRL • DB2SQL • GENERAL • GNRLNULL • JAVA • NPSGENRC • SQL • Blanks if ORIGIN is not "E"
FENCED	CHAR (1)	Y	• N = Not fenced • Y = Fenced • Blank = ORIGIN is not "E"
SQL_DATA_ACCESS	CHAR (1)	Y	Indicates what type of SQL statements, if any, the database manager should assume is contained in the routine. • C = Contains SQL (simple expressions with no subqueries only) • M = Contains SQL statements that modify data • N = Does not contain SQL statements • R = Contains read-only SQL statements • Blank = ORIGIN is not "E", "F", "Q", or "R"
DBINFO	CHAR (1)	Y	Indicates whether a DBINFO parameter is passed to an external routine. • N = DBINFO is not passed • Y = DBINFO is passed • Blank = ORIGIN is not "E"
PROGRAMTYPE	CHAR (1)	Y	Indicates how the external routine is invoked. • M = Main • S = Subroutine • Blank = ORIGIN is "A" or "F"

Table 239. SYSCAT.ROUTINES Catalog View (continued)

Column Name	Data Type	Nullable	Description
COMMIT_ON_RETURN	CHAR (1)	Y	Indicates whether the transaction is committed on successful return from this procedure. • N = The unit of work is not committed • Y = The unit of work is committed • Blank = ROUTINETYPE is not "P"
AUTONOMOUS	CHAR (1)	Y	Indicates whether or not the routine executes autonomously. • N = Routine does not execute autonomously from invoking transaction • Y = Routine executes autonomously from invoking transaction • Blank = ROUTINETYPE is not "P"
RESULT_SETS	SMALLINT	Y	Estimated maximum number of result sets.
SPEC_REG	CHAR (1)	Y	Indicates the special registers values that are used when the routine is called. • I = Inherited special registers • Blank = PARAMETER_STYLE is "DB2DARI" or ORIGIN is not "E", "Q", or "R"
FEDERATED	CHAR (1)	Y	Indicates whether or not federated objects can be accessed from the routine. • Y = Federated objects can be accessed • Blank = ORIGIN is not "F"
THREADSAFE	CHAR (1)	Y	Indicates whether or not the routine can run in the same process as other routines. • N = Routine is not threadsafe • Y = Routine is threadsafe • Blank = ORIGIN is not "E"

Table 239. SYSCAT.ROUTINES Catalog View (continued)

Column Name	Data Type	Nullable	Description
VALID	CHAR (1)	Y	Applies to LANGUAGE = "SQL" and routines having parameters with default or ORIGIN = "A"; blank otherwise. • N = Routine needs rebinding • X = Routine is inoperative and must be recreated • Y = Routine is valid
MODULEROUTINEIMPLEMENTED	CHAR (1)	Y	• N = Module routine body is not implemented • Y = Module routine body is implemented • Blank = ROUTINEMODULENAME is null value
METHODIMPLEMENTED	CHAR (1)	Y	• N = Method body is not implemented • Y = Method body is implemented • Blank = ROUTINETYPE is not "M" or ROUTINEMODULENAME is not the null value
METHODEFFECT	CHAR (2)	Y	• CN = Constructor method • MU = Mutator method • OB = Observer method • Blanks = Not a system method
TYPE_PRESERVING	CHAR (1)	Y	• N = Return type is the declared return type of the method • Y = Return type is governed by a "type-preserving" parameter; all system-generated mutator methods are type-preserving • Blank = ROUTINETYPE is not "M"
WITH_FUNC_ACCESS	CHAR (1)	Y	• N = This method cannot be invoked by using functional notation • Y = This method can be invoked by using functional notation; that is, the "WITH FUNCTION ACCESS" attribute is specified • Blank = ROUTINETYPE is not "M"
OVERRIDDEN_METHODID	INTEGER	Y	Identifier for the overridden method when the OVERRIDING option is specified for a user-defined method. The null value if ROUTINETYPE is not "M".

Table 239. SYSCAT.ROUTINES Catalog View (continued)

Column Name	Data Type	Nullable	Description
SUBJECT_TYPESCHEMA	VARCHAR (128)	Y	Schema name of the subject type for the user-defined method. The null value if ROUTINETYPE is not "M".
SUBJECT_TYPENAME	VARCHAR (128)	Y	Unqualified name of the subject type for the user-defined method. The null value if ROUTINETYPE is not "M".
CLASS	VARCHAR (384)	Y	For LANGUAGE JAVA, CLR, or OLE, this is the class that implements this routine; null value otherwise.
JAR_ID	VARCHAR (128)	Y	For LANGUAGE JAVA, this is the JAR_ID of the installed jar file that implements this routine if a jar file was specified at routine creation time; null value otherwise. For LANGUAGE CLR, this is the assembly file that implements this routine.
JARSCHEMA	VARCHAR (128)	Y	For LANGUAGE JAVA when a JAR_ID is present, this is the schema name of the jar file that implements this routine; null value otherwise.
JAR_SIGNATURE	VARCHAR (2048)	Y	For LANGUAGE JAVA, this is the method signature of this routine's specified Java method. For LANGUAGE CLR, this is a reference field for this CLR routine. Null value otherwise.
CREATE_TIME	TIMESTAMP	Y	Time at which the routine was created.
ALTER_TIME	TIMESTAMP	Y	Time at which the routine was last altered.
FUNC_PATH	CLOB (2K)	Y	SQL path in effect when the routine was defined. The null value if LANGUAGE is not "SQL", ORIGIN is not "A", and no parameters have defaults.
QUALIFIER	VARCHAR (128)	Y	Value of the default schema at the time of object definition. Used to complete any unqualified references.
IOS_PER_INVOC	DOUBLE	Y	Estimated number of inputs/outputs (I/Os) per invocation; 0 is the default; -1 if not known.
INSTS_PER_INVOC	DOUBLE	Y	Estimated number of instructions per invocation; 450 is the default; -1 if not known.
IOS_PER_ARGBYTE	DOUBLE	Y	Estimated number of I/Os per input argument byte; 0 is the default; -1 if not known.

Table 239. SYSCAT.ROUTINES Catalog View (continued)

Column Name	Data Type	Nullable	Description
INSTS_PER_ARGBYTE	DOUBLE	Y	Estimated number of instructions per input argument byte; 0 is the default; -1 if not known.
PERCENT_ARGBYTES	SMALLINT	Y	Estimated average percent of input argument bytes that the routine will actually read; 100 is the default; -1 if not known.
INITIAL_IOS	DOUBLE	Y	Estimated number of I/Os performed the first time that the routine is invoked; 0 is the default; -1 if not known.
INITIAL_INSTS	DOUBLE	Y	Estimated number of instructions executed the first time the routine is invoked; 0 is the default; -1 if not known.
CARDINALITY	BIGINT	Y	Predicted cardinality of a table function; -1 if not known, or if the routine is not a table function.
SELECTIVITY[2]	DOUBLE	Y	For user-defined predicates; -1 if there are no user-defined predicates.
RESULT_COLS	SMALLINT	Y	For a table function (ROUTINETYPE = "F" and FUNCTIONTYPE = "T"), contains the number of columns in the result table; for a procedure (ROUTINETYPE = "P"), contains 0; contains 1 otherwise.
IMPLEMENTATION	VARCHAR (762)	Y	The value from the EXTERNAL NAME clause if ORIGIN="E" (an external routine); the name and signature of the source function if ORIGIN = "U" and the source function is built-in; the entry point in the library if LIB_ID is not null and LANGUAGE="SQL" (a compiled SQL routine); the null value otherwise.
LIB_ID	INTEGER	Y	Internal identifier for compiled SQL routines. Otherwise the null value.
TEXT_BODY_OFFSET	INTEGER	Y	If LANGUAGE = "SQL", the offset to the start of the compiled SQL routine body in the full text of the CREATE statement; -1 if LANGUAGE is not "SQL" or the SQL routine is not compiled.
TEXT	CLOB (2M)	Y	If LANGUAGE = "SQL" or ORIGIN = "A", the full text of the CREATE FUNCTION, CREATE METHOD, or CREATE PROCEDURE statement; null value otherwise.

Table 239. SYSCAT.ROUTINES Catalog View (continued)

Column Name	Data Type	Nullable	Description
NEWSAVEPOINTLEVEL	CHAR (1)	Y	Indicates whether the routine initiates a new savepoint level when it is invoked. • N = A new savepoint level is not initiated when the routine is invoked; the routine uses the existing savepoint level • Y = A new savepoint level is initiated when the routine is invoked • Blank = Not applicable
DEBUG_MODE[3]	VARCHAR (8)	Y	Indicates whether the routine can be debugged using the debugger that is integrated with the database. • DISALLOW = Routine is not debuggable • ALLOW = Routine is debuggable, and can participate in a client debug session with the integrated debugger • DISABLE = Routine is not debuggable, and this setting cannot be altered without dropping and recreating the routine • Blank = Routine type is not currently supported by the integrated debugger
TRACE_LEVEL	VARCHAR (1)	Y	Reserved for future use.
DIAGNOSTIC_LEVEL	VARCHAR (1)	Y	Reserved for future use.
CHECKOUT_USERID	VARCHAR (128)	Y	ID of the user who performed a checkout of the object; the null value if the object is not checked out.
PRECOMPILE_OPTIONS	VARCHAR (1024)	Y	The precompile and bind options that were in effect when the compiled SQL routine was created. The null value if LANGUAGE is not "SQL" or if the SQL routine is not compiled.
COMPILE_OPTIONS	VARCHAR (1024)	Y	The value of the SQL_CCFLAGS special register that was in effect when the compiled SQL routine was created and inquiry directives were present. An empty string if no inquiry directives were present in the compiled SQL routine. The null value if LANGUAGE is not "SQL" or if the SQL routine is not compiled.

Table 239. SYSCAT.ROUTINES Catalog View (continued)

Column Name	Data Type	Nullable	Description
EXECUTION_CONTROL	CHAR (1)	Y	Execution control mode of a common language runtime (CLR) routine. Possible values are: • N = Network • R = Fileread • S = Safe • U = Unsafe • W = Filewrite • Blank = LANGUAGE is not "CLR"
CODEPAGE	SMALLINT	Y	Routine code page, which specifies the default code page used for all character parameter types, result types, and local variables within the routine body.
COLLATIONSCHEMA	VARCHAR (128)	Y	Schema name of the collation for the routine.
COLLATIONNAME	VARCHAR (128)	Y	Unqualified name of the collation for the routine.
COLLATIONSCHEMA_ORDERBY	VARCHAR (128)	Y	Schema name of the collation for ORDER BY clauses in the routine.
COLLATIONNAME_ORDERBY	VARCHAR (128)	Y	Unqualified name of the collation for ORDER BY clauses in the routine.
ENCODING_SCHEME	CHAR (1)	Y	Encoding scheme of the routine, as specified in the PARAMETER CCSID clause. Possible values are: • A = ASCII • U = UNICODE • Blank = PARAMETER CCSID clause was not specified
LAST_REGEN_TIME	TIMESTAMP	Y	Time at which the SQL routine packed descriptor was last regenerated.
INHERITLOCKREQUEST	CHAR (1)	Y	• N = This function or method cannot be invoked in the context of an SQL statement that includes a lock-request-clause as part of a specified isolation-clause • Y = This function or method inherits the isolation level of the invoking statement; it also inherits the specified lock-request-clause • Blank = LANGUAGE is not "SQL" or ROUTINETYPE is "P"
DEFINER[4]	VARCHAR (128)	Y	Authorization ID of the owner of the routine.

Table 239. SYSCAT.ROUTINES Catalog View (continued)

Column Name	Data Type	Nullable	Description
SECURE	CHAR (1)	Y	Indicates whether the function is secure for row and column access control • N = Not secure • Y = Secure • Blank = ROUTINETYPE is not "F"
ENVSTRINGUNITS	VARCHAR (11)		Default string units when the object was created.
STAYRESIDENT	CHAR (1)		The STAYRESIDENT option of the routine, which determines whether the routine library is to be deleted from memory when the routine ends • N = The routine library is to be deleted from memory after the routine terminates • Blank = STAY RESIDENT NO clause not specified
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. During database upgrade, the SELECTIVITY column will be set to -1 in the packed descriptor and system catalogs for all user-defined routines. For a user-defined predicate, the selectivity in the system catalog will be -1. In this case, the selectivity value used by the optimizer is 0.01.
2. For Java routines, the DEBUG_MODE setting does not indicate whether the Java routine was actually compiled in debug mode, or whether a debug Jar was installed at the server.
3. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.ROUTINESFEDERATED

Each row represents a federated procedure.

Table 240. SYSCAT.ROUTINESFEDERATED Catalog View

Column Name	Data Type	Nullable	Description
ROUTINESCHEMA	VARCHAR (128)		Schema name of the routine if ROUTINEMODULEID is null; otherwise schema name of the module to which the routine belongs.
ROUTINENAME	VARCHAR (128)		Unqualified name of the routine.
ROUTINETYPE	CHAR (1)		Type of routine. • P = Procedure
OWNER	VARCHAR (128)		Authorization ID of the owner of the routine.

Table 240. SYSCAT.ROUTINESFEDERATED Catalog View (continued)

Column Name	Data Type	Nullable	Description
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
SPECIFICNAME	VARCHAR (128)		Name of the routine instance (might be system-generated).
ROUTINEID	INTEGER		Identifier for the routine.
PARM_COUNT	SMALLINT		Number of routine parameters; -1 if parameters specified as VARARGS.
DETERMINISTIC	CHAR (1)		• N = Results are not deterministic (same parameters might give different results in different routine calls) • Y = Results are deterministic
EXTERNAL_ACTION	CHAR (1)		• E = Routine has external side-effects (therefore, the number of invocations is important) • N = No side-effects
SQL_DATA_ACCESS	CHAR (1)		Indicates what type of SQL statements, if any, the database manager should assume is contained in the routine. • C = Contains SQL (simple expressions with no subqueries only) • M = Contains SQL statements that modify data • N = Does not contain SQL statements • R = Contains read-only SQL statements
COMMIT_ON_RETURN	CHAR (1)		Indicates whether the transaction is committed on successful return from this procedure. • N = The unit of work is not committed • Y = The unit of work is committed • Blank = ROUTINETYPE is not 'P'
RESULT_SETS	SMALLINT		Estimated maximum number of result sets.
CREATE_TIME	TIMESTAMP		Time at which the routine was created.
ALTER_TIME	TIMESTAMP		Time at which the routine was last altered.
QUALIFIER	VARCHAR (128)		Value of the default schema at the time of object definition. Used to complete any unqualified references.
RESULT_COLS	SMALLINT		For a procedure (ROUTINETYPE = 'P'), contains 0; contains 1 otherwise.

Table 240. SYSCAT.ROUTINESFEDERATED Catalog View (continued)

Column Name	Data Type	Nullable	Description
CODEPAGE	SMALLINT		Routine code page, which specifies the default code page used for all character parameter types, result types, and local variables within the routine body.
LAST_REGEN_TIME	TIMESTAMP		Time at which the SQL routine packed descriptor was last regenerated.
REMOTE_PROCEDURE	VARCHAR (128)	Y	Unqualified name of the source procedure for which the federated routine was created.
REMOTE_SCHEMA	VARCHAR (128)	Y	Schema name of the source procedure for which the federated routine was created.
SERVERNAME	VARCHAR (128)	Y	Name of the data source that contains the source procedure for which the federated routine was created.
REMOTE_PACKAGE	VARCHAR (128)	Y	Name of the package to which the source procedure belongs (applies only to wrappers for Oracle data sources).
REMOTE_PROCEDURE_ ALTER_TIME	VARCHAR (128)	Y	Reserved for future use.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.ROWFIELDS

Each row represents a field that is defined for a user-defined row data type.

Table 241. SYSCAT.ROWFIELDS Catalog View

Column Name	Data Type	Nullable	Description
TYPESCHEMA	VARCHAR (128)		Schema name of the row data type that includes the field.
TYPEMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the row data type belongs. The null value if not a module row data type.
TYPENAME	VARCHAR (128)		Unqualified name of the row data type that includes the field.
FIELDNAME	VARCHAR (128)		Field name.
FIELDTYPESCHEMA	VARCHAR (128)		Schema name of the data type of the field.
FIELDTYPEMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the data type of the field belongs. The null value if the field data type is not a module user-defined data type.
FIELDTYPENAME	VARCHAR (128)		Unqualified name of the data type of the field.
ORDINAL	SMALLINT		Position of the field in the definition of the row data type, starting with 0.

Table 241. SYSCAT.ROWFIELDS Catalog View (continued)

Column Name	Data Type	Nullable	Description
LENGTH	INTEGER		Length of the field data type. For decimal types, contains the precision.
SCALE	SMALLINT		For decimal types, contains the scale of the field data type; for timestamp types, contains the timestamp precision of the field data type; 0 otherwise.
TYPESTRINGUNITS	VARCHAR (11)	Y	In a Unicode database, the string units that apply to a character string or graphic string data type. Otherwise, the null value.
STRINGUNITSLENGTH	INTEGER	Y	In a Unicode database, the declared number of string units for a character string or graphic string data type. Otherwise, the null value.
CODEPAGE	SMALLINT		For string types, denotes the code page; 0 indicates FOR BIT DATA; 0 for non-string types.
COLLATIONSCHEMA	VARCHAR (128)	Y	For string types, the schema name of the collation for the field; the null value otherwise.
COLLATIONNAME	VARCHAR (128)	Y	For string types, the unqualified name of the collation for the field; the null value otherwise.
NULLS	CHAR (1)		Reserved for future use.
QUALIFIER	VARCHAR (128)	Y	Reserved for future use.
FUNC_PATH	CLOB (2K)	Y	Reserved for future use.
DEFAULT	CLOB (64K)	Y	Reserved for future use.
ENVSTRINGUNITS	VARCHAR (11)		Default string units when the object was created.

SYSCAT.SCHEMAAUTH

Each row represents a user, group, or role that has been granted one or more privileges on a schema.

Table 242. SYSCAT.SCHEMAAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of a privilege.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user
GRANTEE	VARCHAR (128)		Holder of a privilege.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user

Table 242. SYSCAT.SCHEMAAUTH Catalog View (continued)

Column Name	Data Type	Nullable	Description
SCHEMANAME	VARCHAR (128)		Name of the schema to which this privilege applies.
ALTERINAUTH	CHAR (1)		Privilege to alter or comment on objects in the named schema. • G = Held and grantable • N = Not held • Y = Held
CREATEINAUTH	CHAR (1)		Privilege to create objects in the named schema. • G = Held and grantable • N = Not held • Y = Held
DROPINAUTH	CHAR (1)		Privilege to drop objects from the named schema. • G = Held and grantable • N = Not held • Y = Held
SELECTINAUTH	CHAR (1)		Implicit SELECT privilege on all of the existing and future tables or views defined in the schema. • G = Held and grantable • N = Not held • Y = Held
INSERTINAUTH	CHAR (1)		Implicit INSERT privilege on all of the existing and future tables or updatable views defined in the schema. • G = Held and grantable • N = Not held • Y = Held
UPDATEINAUTH	CHAR (1)		Implicit UPDATE privilege on all of the existing and future tables or updatable views defined in the schema. • G = Held and grantable • N = Not held • Y = Held

Table 242. SYSCAT.SCHEMAAUTH Catalog View (continued)

Column Name	Data Type	Nullable	Description
DELETEINAUTH	CHAR (1)		Implicit DELETE privilege on all of the existing and future tables or updatable views defined in the schema. • G = Held and grantable • N = Not held • Y = Held
EXECUTEINAUTH	CHAR (1)		Implicit EXECUTE privilege on all of the existing and future routines, packages and module objects defined in the schema • G = Held and grantable • N = Not held • Y = Held
SCHEMAADMAUTH	CHAR (1)		SCHEMAADM authority. • N = Not held • Y = Held
ACCESSCTRLAUTH	CHAR (1)		Schema ACCESSCTRL authority to grant and revoke schema object privileges. • N = Not held • Y = Held
DATAACCESSAUTH	CHAR (1)		Schema DATAACCESS authority to access data. • N = Not held • Y = Held
LOADAUTH	CHAR (1)		Schema LOAD authority to use the load utility. • N = Not held • Y = Held

SYSCAT.SCHEMATA

Each row represents a schema.

Table 243. SYSCAT.SCHEMATA Catalog View

Column Name	Data Type	Nullable	Description
SCHEMANAME	VARCHAR (128)		Name of the schema.
OWNER	VARCHAR (128)		Authorization ID of the owner of the schema.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user

Table 243. SYSCAT.SCHEMATA Catalog View (continued)

Column Name	Data Type	Nullable	Description
DEFINER	VARCHAR (128)		Authorization ID of the definer of the schema or authorization ID of the owner of the schema if the ownership of the schema has been transferred.
DEFINERTYPE	CHAR (1)		• S = The definer is the system • U = The definer is an individual user
CREATE_TIME	TIMESTAMP		Time at which the schema was created.
AUDITPOLICYID	INTEGER	Y	Identifier for the audit policy.
AUDITPOLICYNAME	VARCHAR (128)		Name of the audit policy.
AUDITEXCEPTIONENABLED	CHAR (1)		Reserved for future use.
DATACAPTURE	CHAR (1)		Indicates the default data capture setting for new tables that are created within this schema. • N = New tables do not participate in data capture • Y = New tables participate in data capture, including replication of all columns
ROWMODIFICATIONTRACKING	VARCHAR (1)	N	Indicates tables in schema are enabled for logical backup • Y = Indicates the schema is enabled for row modification tracking • N = Indicates the schema is not enabled for row modification tracking
QUIESCED	VARCHAR (1)	N	Indicates the schema is locked by the in-progress LOGICAL_RESTORE operation • Y = Indicates the schema is locked by in-progress LOGICAL_RESTORE operation • N =Indicates the schema is not locked by in-progress LOGICAL_RESTORE operation
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.SCPREFTBSPACES

Each row represents a preferred system temporary table space for the service class.

Table 244. SYSCAT.SCPREFTBSPACES Catalog View

Column Name	Data Type	Nullable	Description
SERVICECLASSNAME	VARCHAR (128)		Name of the service class.
PARENTSERVICECLASSNAME	VARCHAR (128)		Service class name of the parent service superclass.

Table 244. SYSCAT.SCPREFTBSPACES Catalog View (continued)

Column Name	Data Type	Nullable	Description
TBSPACE	VARCHAR (128)		Name of the table space.
SERVICECLASSID	SMALLINT		Identifier for the service class.
PARENTSERVICECLASSID	SMALLINT		Identifier for the parent service class for the service class. 0 if the service class is a super service class.
TBSPACEID	INTEGER		Identifier for the table space.
DATATYPE	CHAR (1)		Type of data that can be stored in this table space. • A = All types of permanent data; regular table space • L = All types of permanent data; large table space • T = System temporary tables only • U = Created temporary tables or declared temporary tables only

SYSCAT.SECURITYLABELACCESS

Each row represents a security label that was granted to the database authorization ID.

Table 245. SYSCAT.SECURITYLABELACCESS Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of the security label.
GRANTEE	VARCHAR (128)		Holder of the security label.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
SECLABELID	INTEGER		Identifier for the security label. For the name of the security label, select the SECLABELNAME column for the corresponding SECLABELID value in the SYSCAT.SECURITYLABELS catalog view.
SECPOLICYID	INTEGER		Identifier for the security policy that is associated with the security label. For the name of the security policy, select the SECPOLICYNAME column for the corresponding SECPOLICYID value in the SYSCAT.SECURITYPOLICIES catalog view.
ACCESSTYPE	CHAR (1)		• B = Both read and write access • R = Read access • W = Write access
GRANT_TIME	TIMESTAMP		Time at which the security label was granted.

SYSCAT.SECURITYLABELCOMPONENTELEMENTS

Each row represents an element value for a security label component.

Table 246. SYSCAT.SECURITYLABELCOMPONENTELEMENTS Catalog View

Column Name	Data Type	Nullable	Description
COMPID	INTEGER		Identifier for the security label component.
ELEMENTVALUE	VARCHAR (32)		Element value for the security label component.
ELEMENTVALUEENCODING	CHAR (8) FOR BIT DATA		Encoded form of the element value.
PARENTELEMENTVALUE	VARCHAR (32)	Y	Name of the parent of an element for tree components; the null value for set and array components, and for the ROOT node of a tree component.

SYSCAT.SECURITYLABELCOMPONENTS

Each row represents a security label component.

Table 247. SYSCAT.SECURITYLABELCOMPONENTS Catalog View

Column Name	Data Type	Nullable	Description
COMPNAME	VARCHAR (128)		Name of the security label component.
COMPID	INTEGER		Identifier for the security label component.
COMPTYPE	CHAR (1)		Security label component type. • A = Array • S = Set • T = Tree
NUMELEMENTS	INTEGER		Number of elements in the security label component.
CREATE_TIME	TIMESTAMP		Time at which the security label component was created.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.SECURITYLABELS

Each row represents a security label.

Table 248. SYSCAT.SECURITYLABELS Catalog View

Column Name	Data Type	Nullable	Description
SECLABELNAME	VARCHAR (128)		Name of the security label.
SECLABELID	INTEGER		Identifier for the security label.
SECPOLICYID	INTEGER		Identifier for the security policy to which the security label belongs.
SECLABEL	SYSPROC. DB2SECURITYLABEL		Internal representation of the security label.

Table 248. SYSCAT.SECURITYLABELS Catalog View (continued)

Column Name	Data Type	Nullable	Description
CREATE_TIME	TIMESTAMP		Time at which the security label was created.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.SECURITYPOLICIES

Each row represents a security policy.

Table 249. SYSCAT.SECURITYPOLICIES Catalog View

Column Name	Data Type	Nullable	Description
SECPOLICYNAME	VARCHAR (128)		Name of the security policy.
SECPOLICYID	INTEGER		Identifier for the security policy.
NUMSECLABELCOMP	INTEGER		Number of security label components in the security policy.
RWSECLABELREL	CHAR (1)		Relationship between the security labels for read and write access granted to the same authorization ID. • S = The security label for write access granted to a user is a subset of the security label for read access granted to that same user
NOTAUTHWRITESECLABEL	CHAR (1)		Action to take when a user is not authorized to write the security label that is specified in the INSERT or UPDATE statement. • O = Override • R = Restrict
CREATE_TIME	TIMESTAMP		Time at which the security policy was created.
GROUPAUTHS	CHAR (1)		Indicates if authorizations of security labels and exemptions granted to an authorization ID that represents a group will be used or ignored. • I = Ignored • U = Used
ROLEAUTHS	CHAR (1)		Indicates if authorizations of security labels and exemptions granted to an authorization ID that represents a role will be used or ignored. • I = Ignored • U = Used
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.SECURITYPOLICYCOMPONENTRULES

Each row represents the read and write access rules for a security label component of the security policy.

Table 250. SYSCAT.SECURITYPOLICYCOMPONENTRULES Catalog View

Column Name	Data Type	Nullable	Description
SECPOLICYID	INTEGER		Identifier for the security policy.
COMPID	INTEGER		Identifier for the security label component of the security policy.
ORDINAL	INTEGER		Position of the security label component as it appears in the security policy, starting with 1.
READACCESSRULENAME	VARCHAR (128)		Name of the read access rule that is associated with the security label component.
READACCESSRULETEXT	VARCHAR (512)		Text of the read access rule that is associated with the security label component.
WRITEACCESSRULENAME	VARCHAR (128)		Name of the write access rule that is associated with the security label component.
WRITEACCESSRULETEXT	VARCHAR (512)		Text of the write access rule that is associated with the security label component.

SYSCAT.SECURITYPOLICYEXEMPTIONS

Each row represents a security policy exemption that was granted to a database authorization ID.

Table 251. SYSCAT.SECURITYPOLICYEXEMPTIONS Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of the exemption.
GRANTEE	VARCHAR (128)		Holder of the exemption.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
SECPOLICYID	INTEGER		Identifier for the security policy for which the exemption was granted. For the name of the security policy, select the SECPOLICYNAME column for the corresponding SECPOLICYID value in the SYSCAT.SECURITYPOLICIES catalog view.
ACCESSRULENAME	VARCHAR (128)		Name of the access rule for which the exemption was granted.
ACCESSTYPE	CHAR (1)		Type of access to which the rule applies. • R = Read access • W = Write access

Table 251. SYSCAT.SECURITYPOLICYEXEMPTIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
ORDINAL	INTEGER		Position of the security label component in the security policy to which the rule applies.
ACTIONALLOWED	CHAR (1)		If the rule is DB2LBACWRITEARRAY, then: • D = Write down • U = Write up Blank otherwise.
GRANT_TIME	TIMESTAMP		Time at which the exemption was granted.

SYSCAT.SEQUENCEAUTH

Each row represents a user, group, or role that has been granted one or more privileges on a sequence.

Table 252. SYSCAT.SEQUENCEAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of a privilege.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user
GRANTEE	VARCHAR (128)		Holder of a privilege.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
SEQSCHEMA	VARCHAR (128)		Schema name of the sequence.
SEQNAME	VARCHAR (128)		Unqualified name of the sequence.
ALTERAUTH	CHAR (1)		Privilege to alter the sequence. • G = Held and grantable • N = Not held • Y = Held
USAGEAUTH	CHAR (1)		Privilege to reference the sequence. • G = Held and grantable • N = Not held • Y = Held

SYSCAT.SEQUENCES

Each row represents a sequence or alias.

Table 253. SYSCAT.SEQUENCES Catalog View

Column Name	Data Type	Nullable	Description
SEQSCHEMA	VARCHAR (128)		Schema name of the sequence.

Table 253. SYSCAT.SEQUENCES Catalog View (continued)

Column Name	Data Type	Nullable	Description
SEQNAME	VARCHAR (128)		Unqualified name of the sequence.
DEFINER[1]	VARCHAR (128)		Authorization ID of the owner of the sequence.
DEFINERTYPE	CHAR (1)		• S = The definer is the system • U = The definer is an individual user
OWNER	VARCHAR (128)		Authorization ID of the owner of the sequence.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
SEQID	INTEGER		Identifier for the sequence or alias.
SEQTYPE	CHAR (1)		Type of sequence. • A = Alias • I = Identity sequence • S = Sequence
BASE_SEQSCHEMA	VARCHAR (128)	Y	If SEQTYPE is 'A', contains the schema name of the sequence or alias that is referenced by this alias; the null value otherwise.
BASE_SEQNAME	VARCHAR (128)	Y	If SEQTYPE is 'A', contains the unqualified name of the sequence or alias that is referenced by this alias; the null value otherwise.
INCREMENT	DECIMAL (31,0)	Y	Increment value. The null value if the sequence is an alias.
START	DECIMAL (31,0)	Y	Start value of the sequence. The null value if the sequence is an alias.
MAXVALUE	DECIMAL (31,0)	Y	Maximum value of the sequence. The null value if the sequence is an alias.
MINVALUE	DECIMAL (31,0)	Y	Minimum value of the sequence. The null value if the sequence is an alias.
NEXTCACHEFIRSTVALUE	DECIMAL (31,0)	Y	The first value available to be assigned in the next cache block. If no caching, the next value available to be assigned.
CYCLE	CHAR (1)		Indicates whether or not the sequence can continue to generate values after reaching its maximum or minimum value. • N = Sequence cannot cycle • Y = Sequence can cycle • Blank = Sequence is an alias.

Table 253. SYSCAT.SEQUENCES Catalog View (continued)

Column Name	Data Type	Nullable	Description
CACHE	INTEGER		Number of sequence values to pre-allocate in memory for faster access. 0 indicates that values of the sequence are not to be preallocated. In a partitioned database, this value applies to each database partition. -1 if the sequence is an alias.
ORDER	CHAR (1)		Indicates whether or not the sequence numbers must be generated in order of request. • N = Sequence numbers are not required to be generated in order of request • Y = Sequence numbers must be generated in order of request • Blank = Sequence is an alias.
DATATYPEID	INTEGER		For built-in types, the internal identifier of the built-in type. For distinct types, the internal identifier of the distinct type. 0 if the sequence is an alias.
SOURCETYPEID	INTEGER		For a built-in type or if the sequence is an alias, this has a value of 0. For a distinct type, this is the internal identifier of the built-in type that is the source type for the distinct type.
CREATE_TIME	TIMESTAMP		Time at which the sequence was created.
ALTER_TIME	TIMESTAMP		Time at which the sequence was last altered.
PRECISION	SMALLINT		Precision of the data type of the sequence. Possible values are: • 5 = SMALLINT • 10 = INTEGER • 19 = BIGINT For DECIMAL, it is the precision of the specified DECIMAL data type. 0 if the sequence is an alias.
ORIGIN	CHAR (1)		Origin of the sequence. • S = System-generated sequence • U = User-generated sequence
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.SERVEROPTIONS

Each row represents a server-specific option value.

Table 254. SYSCAT.SERVEROPTIONS Catalog View

Column Name	Data Type	Nullable	Description
WRAPNAME	VARCHAR (128)	Y	Name of the wrapper.
SERVERNAME	VARCHAR (128)	Y	Uppercase name of the server.
SERVERTYPE	VARCHAR (30)	Y	Type of server.
SERVERVERSION	VARCHAR (18)	Y	Server version.
CREATE_TIME	TIMESTAMP		Time at which the entry was created.
OPTION	VARCHAR (128)		Name of the server option.
SETTING	VARCHAR (2048)		Value of the server option.
SERVEROPTIONKEY	VARCHAR (18)		Uniquely identifies a row.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.SERVERS

Each row represents a data source.

Table 255. SYSCAT.SERVERS Catalog View

Column Name	Data Type	Nullable	Description
WRAPNAME	VARCHAR (128)		Name of the wrapper.
SERVERNAME	VARCHAR (128)		Uppercase name of the server.
SERVERTYPE	VARCHAR (30)	Y	Type of server.
SERVERVERSION	VARCHAR (18)	Y	Server version.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.SERVICECLASSES

Each row represents a service class.

Table 256. SYSCAT.SERVICECLASSES Catalog View

Column Name	Data Type	Nullable	Description
SERVICECLASSNAME	VARCHAR (128)		Name of the service class.
PARENTSERVICECLASSNAME	VARCHAR (128)	Y	Service class name of the parent service superclass.
SERVICECLASSID	SMALLINT		Identifier for the service class.
PARENTID	SMALLINT		Identifier for the parent service class for this service class. 0 if this service class is a super service class.
CREATE_TIME	TIMESTAMP		Time when the service class was created.
ALTER_TIME	TIMESTAMP		Time when the service class was last altered.

Table 256. SYSCAT.SERVICECLASSES Catalog View (continued)

Column Name	Data Type	Nullable	Description
ENABLED	CHAR (1)		State of the service class. • N = Disabled • Y = Enabled
AGENTPRIORITY	SMALLINT		This column is no longer used and will be removed in a future release.
PREFETCHPRIORITY	CHAR (1)		Prefetch priority of the agents in the service class. • H = High • L = Low • M = Medium • Blank = not set
MAXDEGREE	SMALLINT	Y	Possible values: • 1 - 32767 = Maximum degree of parallelism for the service class • -1 = MAXIMUM DEGREE NONE was specified for the service class • -2 = MAXIMUM DEGREE DEFAULT was specified for the service class
BUFFERPOOLPRIORITY	CHAR (1)		Bufferpool priority of the agents in the service class: • H = High • L = Low • M = Medium • Blank = Not set
INBOUNDCORRELATOR	VARCHAR (128)	Y	For future use.
OUTBOUNDCORRELATOR	VARCHAR (128)	Y	String used to associate the service class with an operating system workload manager service class.
COLLECTAGGACTDATA	CHAR (1)		Specifies what aggregate activity data should be captured for the service class by the applicable event monitor. • B = Collect base aggregate activity data • E = Collect extended aggregate activity data • N = None
COLLECTAGGREQDATA	CHAR (1)		Specifies what aggregate request data should be captured for the service class by the applicable event monitor. • B = Collect base aggregate request data • N = None

Table 256. SYSCAT.SERVICECLASSES Catalog View (continued)

Column Name	Data Type	Nullable	Description
COLLECTACTDATA	CHAR (1)		Specifies what activity data should be collected by the applicable event monitor. • D = Activity data with details • N = None • S = Activity data with details and section environment • V = Activity data with details and values • W = Activity data without details • X = Activity data with details, section environment, and values
COLLECTACTPARTITION	CHAR (1)		Specifies where activity data is collected. • C = Coordinator member of the activity • D = All members
COLLECTREQMETRICS	CHAR (1)		Specifies the monitoring level for requests submitted by a connection that is associated with the service superclass. • B = Collect base request metrics • E = Collect extended request metrics • N = None
CPUSHARES	INTEGER		The number of CPU shares allocated to this service class.
CPUSHARETYPE	CHAR (1)		Specifies the type of CPU shares. • S = Soft shares • H = Hard shares
CPULIMIT	SMALLINT		The maximum percentage of the CPU resource that can be allocated to the service class; -1 if there is no CPU limit.
SORTMEMORYPRIORITY	CHAR (1)		Reserved for future use.
SECTIONACTUALSOPTIONS	VARCHAR (32)		Specifies what section actuals are collected during the execution of a section. The first position in the string represents whether the collection of section actuals is enabled. • B = Enabled and collect basic operator cardinality counts and statistics for each object referenced by the section (DML statements only). • N = Not enabled. The second position is always 'N' and reserved for future use.

Table 256. SYSCAT.SERVICECLASSES Catalog View (continued)

Column Name	Data Type	Nullable	Description
COLLECTAGGUOWDATA	CHAR (1)		Specifies what aggregate unit of work data should be captured for the service class by the applicable event monitor. • B = Collect base aggregate unit of work data • N = None
RESOURCESHARES	INTEGER		The number of shares of resources this service class is entitled to when workload manager (WLM) adaptive admission control is enabled. This value is relative to other service classes in the same scope.
RESOURCESHARETYPE	CHAR (1)		Specifies the type of admission shares. • S = Soft shares • H = Hard shares
MINRESOURCESHAREPCT	SMALLINT		Specifies the percentage (0 - 100) of entitled resources reserved by workload manager (WLM) adaptive admission control. WLM adaptive admission control holds these resources in reserve for the service class when other service classes exceed their admission resource entitlement.
ADMISSIONQUEUEORDER	CHAR (1)		Specifies the order of the service class admission queue. • F = First in first out; queued requests are ordered based on the time in which they arrived. • L = Latency; queued requests are ordered based on their estimated execution time (latency) relative to the amount of time they have been queued. • Blank = Not applicable; this service class is a service superclass.
DEGREESCALEBACK	CHAR (1)		Specifies if query degree for queries running with DEGREE ANY can be scaled back at runtime when the system is under high CPU load. • D = Degree scaleback value is inherited from the superclass. This is the default for a service subclass. • Y = Degree scaleback is enabled. This is the default for a service superclass. • N = Degree scaleback is disabled.

Table 256. SYSCAT.SERVICECLASSES Catalog View (continued)

Column Name	Data Type	Nullable	Description
WORKLOADTYPE	SMALLINT	Y	Specifies the workload type for the service class. • NULL = Service class is a subclass • 1 = Custom • 2 = Mixed • 3 = Interactive • 4 = Batch
COLLECTHISTORY	CHAR (1)	Y	Specifies whether activity data with details is collected at the coordinator member. If COLLECT ACTIVITY DATA is independently modified, this value is NULL. • Y = Activity data with details is collected at coordinator member • N = Activity data is not collected
ACTSORTMEMLIMIT	INTEGER		The activity sort memory limit for queries executing in the service class. The default of 100 is shown if you do not specify a sort limit.
REMARKS	VARCHAR (254)	Y	User-provided comments, or NULL.

SYSCAT.STATEMENTS

Each row represents an SQL statement in a package.

Table 257. SYSCAT.STATEMENTS Catalog View

Column Name	Data Type	Nullable	Description
PKGSCHEMA	VARCHAR (128)		Schema name of the package.
PKGNAME	VARCHAR (128)		Unqualified name of the package.
STMTNO	INTEGER		Line number of the SQL statement in the source module of the application program.
SECTNO	SMALLINT		Number of the package section containing the SQL statement.
SEQNO	INTEGER		Always 1.
TEXT	CLOB (2M)		Text of the SQL statement.
UNIQUE_ID	CHAR (8) FOR BIT DATA		Identifier for a specific package when multiple packages having the same name exist.
VERSION	VARCHAR (64)	Y	Version identifier for the package.

SYSCAT.STOGROUPS

Each row represents a storage group object.

Table 258. SYSCAT.STOGROUPS Catalog View

Column Name	Data Type	Nullable	Description
SGNAME	VARCHAR (128)		Name of the storage group.
SGID	INTEGER		Identifier for the storage group.
OWNER	VARCHAR (128)		Authorization ID of the owner of the storage group.
CREATE_TIME	TIMESTAMP		Time at which the storage group was created.
DEFAULTSG	CHAR (1)		Indicates whether the storage group is the default storage group. • N = NO • Y = YES
OVERHEAD	DOUBLE		Controller overhead and disk seek and latency time, in milliseconds (average for the storage paths in this storage group); 0 indicates value is not defined (assigned only by upgrade processing).
DEVICEREADRATE	DOUBLE		Read transfer rate of the device, in megabytes per second (average for the storage paths in this storage group); 0 indicates value is not defined (assigned only by upgrade processing).
WRITEOVERHEAD	DOUBLE	Y	Reserved for future use.
DEVICEWRITERATE	DOUBLE	Y	Reserved for future use.
DATATAG	SMALLINT		Tag to identify data stored in this storage group. Valid user-specified range is 1 through 9; 0 indicates no data tag is specified.
CACHINGTIER	SMALLINT		Reserved for future use.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.STATEMENTTEXTS

Each row represents a user-provided SQL statement for statement thresholds.

Table 259. SYSCAT.STATEMENTTEXTS Catalog View

Column Name	Data Type	Nullable	Description
TEXTID	INTEGER		Identifier for the SQL statement.
TEXT	CLOB (2M)		Text of the SQL statement.

SYSCAT.SURROGATEAUTHIDS

Each row represents a user or a group that has been granted SETSESSIONUSER privilege on a user or PUBLIC.

Table 260. SYSCAT.SURROGATEAUTHIDS Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Authorization ID that granted TRUSTEDID the ability to act as a surrogate. When the TRUSTEDID represents a trusted context object, this field represents the authorization ID that created or altered the trusted context object.
TRUSTEDID	VARCHAR (128)		Identifier for the entity that is trusted to act as a surrogate.
TRUSTEDIDTYPE	CHAR (1)		• C = Trusted context • G = Group • U = User
SURROGATEAUTHID	VARCHAR (128)		Surrogate authorization ID that can be assumed by TRUSTEDID. 'PUBLIC' indicates that TRUSTEDID can assume any authorization ID.
SURROGATEAUTHIDTYPE	CHAR (1)		• G = Group • U = User
AUTHENTICATE	CHAR (1)		• N = No authentication is required • Y = Authentication token is required with the authorization ID to authenticate the user before the authorization ID can be assumed • Blank = TRUSTEDIDTYPE is not 'C'
CONTEXTROLE	VARCHAR (128)	Y	A specific role to be assigned to the assumed authorization ID, which supercedes the default role, if any, that is defined for the trusted context. Null value when TRUSTEDIDTYPE is not 'C'.
GRANT_TIME	TIMESTAMP		Time at which the grant was made .

SYSCAT.TABAUTH

Each row represents a user, group, or role that has been granted one or more privileges on a table, view or nickname.

Table 261. SYSCAT.TABAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of the privilege.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user

Table 261. SYSCAT.TABAUTH Catalog View (continued)

Column Name	Data Type	Nullable	Description
GRANTEE	VARCHAR (128)		Holder of the privilege.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
TABSCHEMA	VARCHAR (128)		Schema name of the table or view.
TABNAME	VARCHAR (128)		Unqualified name of the table or view.
CONTROLAUTH	CHAR (1)		CONTROL privilege. • N = Not held • Y = Held but not grantable
ALTERAUTH	CHAR (1)		Privilege to alter the table; allow a parent table to this table to drop its primary key or unique constraint; allow a table to become a materialized query table that references this table or view in the materialized query; or allow a table that references this table or view in its materialized query to no longer be a materialized query table. • G = Held and grantable • N = Not held • Y = Held
DELETEAUTH	CHAR (1)		Privilege to delete rows from a table or updatable view. • G = Held and grantable • N = Not held • Y = Held
INDEXAUTH	CHAR (1)		Privilege to create an index on a table. • G = Held and grantable • N = Not held • Y = Held
INSERTAUTH	CHAR (1)		Privilege to insert rows into a table or updatable view, or to run the import utility against a table or view. • G = Held and grantable • N = Not held • Y = Held

Table 261. SYSCAT.TABAUTH Catalog View (continued)

Column Name	Data Type	Nullable	Description
REFAUTH	CHAR (1)		Privilege to create and drop a foreign key referencing a table as the parent. • G = Held and grantable • N = Not held • Y = Held
SELECTAUTH	CHAR (1)		Privilege to retrieve rows from a table or view, create views on a table, or to run the export utility against a table or view. • G = Held and grantable • N = Not held • Y = Held
UPDATEAUTH	CHAR (1)		Privilege to run the UPDATE statement against a table or updatable view. • G = Held and grantable • N = Not held • Y = Held

SYSCAT.TABCONST

Each row represents a table constraint of type CHECK, UNIQUE, PRIMARY KEY, or FOREIGN KEY. For table hierarchies, each constraint is recorded only at the level of the hierarchy where the constraint was created.

Table 262. SYSCAT.TABCONST Catalog View

Column Name	Data Type	Nullable	Description
CONSTNAME	VARCHAR (128)		Name of the constraint.
TABSCHEMA	VARCHAR (128)		Schema name of the table to which this constraint applies.
TABNAME	VARCHAR (128)		Unqualified name of the table to which this constraint applies.
OWNER	VARCHAR (128)		Authorization ID of the owner of the constraint.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
TYPE	CHAR (1)		Indicates the constraint type. • F = Foreign key • I = Functional dependency • K = Check • P = Primary key • U = Unique

Table 262. SYSCAT.TABCONST Catalog View (continued)

Column Name	Data Type	Nullable	Description
ENFORCED	CHAR (1)		• N = Do not enforce constraint • Y = Enforce constraint
TRUSTED	CHAR (1)		If ENFORCED = 'N', specifies whether the data can be trusted to conform to the constraint. • N = Not trusted • Y = Trusted • Blank = Not applicable
CHECKEXISTINGDATA	CHAR (1)		• D = Defer checking any existing data • I = Immediately check existing data • N = Never check existing data
ENABLEQUERYOPT	CHAR (1)		• N = Query optimization is disabled • Y = Query optimization is enabled
DEFINER[1]	VARCHAR (128)		Authorization ID of the owner of the constraint.
PERIODNAME	VARCHAR (128)	Y	Name of the period used to define this constraint.
PERIODPOLICY	CHAR (1)		If a period name was specified, the constraint uses this period policy. • N = Not applicable • O = Period overlaps not allowed
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.TABDEP

Each row represents a dependency of a view or a materialized query table on some other object. The view or materialized query table depends on the object of type BTYPE of name BNAME, so a change to the object affects the view or materialized query table. Also encodes how privileges on views depend on privileges on underlying tables and views.

Table 263. SYSCAT.TABDEP Catalog View

Column Name	Data Type	Nullable	Description
TABSCHEMA	VARCHAR (128)		Schema name of the view or materialized query table.
TABNAME	VARCHAR (128)		Unqualified name of the view or materialized query table.

Table 263. SYSCAT.TABDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
DTYPE	CHAR (1)		Type of the depending object. • S = Materialized query table • T = Table (staging only) • V = View (untyped) • W = Typed view • 7 = Synopsis table
OWNER	VARCHAR (128)		Authorization ID of the creator of the view or materialized query table.
OWNERTYPE	CHAR (1)		• U = The owner is an individual user
BTYPE	CHAR (1)		Type of object on which there is a dependency. Possible values are: • A = Table alias • F = Routine • I = Index, if recording dependency on a base table • G = Global temporary table • N = Nickname • O = Privilege dependency on all subtables or subviews in a table or view hierarchy • R = User-defined structured type • S = Materialized query table • T = Table (untyped) • U = Typed table • V = View (untyped) • W = Typed view • Z = XSR object • m = Module • u = Module alias • v = Global variable
BSCHEMA	VARCHAR (128)		Schema name of the object on which the view or materialized query table depends.
BMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the object on which there is a dependency belongs. The null value if not a module object.
BNAME	VARCHAR (128)		Unqualified name of the object on which the view or materialized query table depends.
BMODULEID	INTEGER	Y	Identifier for the module of the object on which the view or materialized query table depends.

Table 263. SYSCAT.TABDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
TABAUTH	SMALLINT	Y	If BTYPE is 'N', 'O', 'S', 'T', 'U', 'V', or 'W', encodes the privileges on the underlying table or view on which this view or materialized query table depends; the null value otherwise.
VARAUTH	SMALLINT	Y	If BTYPE is 'v', encodes the privileges on the underlying global variable on which this view or materialized query table depends; the null value otherwise.
DEFINER[1]	VARCHAR (128)		Authorization ID of the creator of the view or materialized query table.

Note:

1. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.TABDETACHEDDEP

Each row represents a detached dependency between a detached dependent table and a detached table.

Table 264. SYSCAT.TABDETACHEDDEP Catalog View

Column Name	Data Type	Nullable	Description
TABSCHEMA	VARCHAR (128)		Schema name of the detached table.
TABNAME	VARCHAR (128)		Unqualified name of the detached table.
DEPTABSCHEMA	VARCHAR (128)		Schema name of the detached dependent table.
DEPTABNAME	VARCHAR (128)		Unqualified name of the detached dependent table.

SYSCAT.TABLES

Each row represents a table, view, alias, or nickname. Each table or view hierarchy has one additional row that represents the hierarchy table or hierarchy view that implements the hierarchy. Catalog tables and views are included.

Table 265. SYSCAT.TABLES Catalog View

Column Name	Data Type	Nullable	Description
TABSCHEMA	VARCHAR (128)		Schema name of the object.
TABNAME	VARCHAR (128)		Unqualified name of the object.
OWNER	VARCHAR (128)		Authorization ID of the owner of the table, view, alias, or nickname.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user

Table 265. SYSCAT.TABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
TYPE	CHAR (1)		Type of object. • A = Alias • G = Created temporary table • H = Hierarchy table • L = Detached table • N = Nickname • S = Materialized query table • T = Table (untyped) • U = Typed table • V = View (untyped) • W = Typed view
STATUS	CHAR (1)		Status of the object. • C = Set integrity pending • N = Normal • X = Inoperative
BASE_TABSCHEMA	VARCHAR (128)	Y	If TYPE = 'A', contains the schema name of the table, view, alias, or nickname that is referenced by this alias; null value otherwise.
BASE_TABNAME	VARCHAR (128)	Y	If TYPE = 'A', contains the unqualified name of the table, view, alias, or nickname that is referenced by this alias; null value otherwise.
ROWTYPESCHEMA	VARCHAR (128)	Y	Schema name of the row type for this table, if applicable; null value otherwise.
ROWTYPENAME	VARCHAR (128)	Y	Unqualified name of the row type for this table, if applicable; null value otherwise.
CREATE_TIME	TIMESTAMP		Time at which the object was created.
ALTER_TIME	TIMESTAMP		Time at which the object was last altered.
INVALIDATE_TIME	TIMESTAMP		Time at which the object was last invalidated.
STATS_TIME	TIMESTAMP	Y	Time at which any change was last made to recorded statistics for this object. The null value if statistics are not collected.
COLCOUNT	SMALLINT		Number of columns, including inherited columns (if any).
TABLEID	SMALLINT		Internal logical object identifier.

Table 265. SYSCAT.TABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
TBSPACEID	SMALLINT		Internal logical identifier for the primary table space for this object.
CARD	BIGINT		Total number of rows in the table; -1 if statistics are not collected.
NPAGES	BIGINT		Total number of pages on which the rows of the table exist; -1 for a view or alias, or if statistics are not collected; -2 for a subtable or hierarchy table.
MPAGES	BIGINT		Total number of pages for table metadata. Non-zero only for a table that is organized by column. -1 for a view, an alias, or if statistics are not collected; -2 for subtables or hierarchy tables.
FPAGES	BIGINT		Total number of pages; -1 for a view or alias, or if statistics are not collected; -2 for a subtable or hierarchy table.
NPARTITIONS	BIGINT		Reserved for future use.
NFILES	BIGINT		Reserved for future use.
TABLESIZE	BIGINT		Reserved for future use.
OVERFLOW	BIGINT		Total number of overflow records in the table; -1 for a view or alias, or if statistics are not collected; -2 for a subtable or hierarchy table.
TBSPACE	VARCHAR (128)	Y	Name of the primary table space for the table. If no other table space is specified, all parts of the table are stored in this table space. The null value for aliases, views, and partitioned tables.
INDEX_TBSPACE	VARCHAR (128)	Y	Name of the table space that holds all indexes created on this table. The null value for aliases, views, and partitioned tables, or if the INDEX IN clause was omitted or specified with the same value as the IN clause of the CREATE TABLE statement.
LONG_TBSPACE	VARCHAR (128)	Y	Name of the table space that holds all long data (LONG or LOB column types) for this table. The null value for aliases, views, and partitioned tables, or if the LONG IN clause was omitted or specified with the same value as the IN clause of the CREATE TABLE statement.
PARENTS	SMALLINT	Y	Number of parent tables for this object; that is, the number of referential constraints in which this object is a dependent.

Table 265. SYSCAT.TABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
CHILDREN	SMALLINT	Y	Number of dependent tables for this object; that is, the number of referential constraints in which this object is a parent.
SELFREFS	SMALLINT	Y	Number of self-referencing referential constraints for this object; that is, the number of referential constraints in which this object is both a parent and a dependent.
KEYCOLUMNS	SMALLINT	Y	Number of columns in the primary key.
KEYINDEXID	SMALLINT	Y	Index identifier for the primary key index: 0 or the null value if there is no primary key.
KEYUNIQUE	SMALLINT		Number of unique key constraints (other than the primary key constraint) defined on this object.
CHECKCOUNT	SMALLINT		Number of check constraints that are defined on this object.
DATACAPTURE	CHAR (1)		• L = Table participates in data replication, including replication of LONG VARCHAR and LONG VARGRAPHIC columns • N = Table does not participate in data replication • Y = Table participates in data replication, excluding replication of LONG VARCHAR and LONG VARGRAPHIC columns

Table 265. SYSCAT.TABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
CONST_CHECKED	CHAR (32)		• Byte 1 represents foreign key constraint. • Byte 2 represents check constraint. • Byte 5 represents materialized query table. • Byte 6 represents generated column. • Byte 7 represents staging table. • Byte 8 represents data partitioning constraint. • Other bytes are reserved for future use. Possible values are: • F = In byte 5, the materialized query table cannot be refreshed incrementally. In byte 7, the content of the staging table is incomplete and cannot be used for incremental refresh of the associated materialized query table. • N = Not checked • U = Checked by user • W = Was in 'U' state when the table was placed in set integrity pending state • Y = Checked by system
PMAP_ID	SMALLINT	Y	Identifier for the distribution map that is currently in use by this table (the null value for aliases or views).
PARTITION_MODE	CHAR (1)		Indicates how data is distributed among database partitions in a partitioned database system. • H = Hashing • R = Replicated across database partitions • Blank = No database partitioning
LOG_ATTRIBUTE	CHAR (1)		• Always 0. This column is no longer used.
PCTFREE	SMALLINT		Percentage of each page to be reserved for future inserts.

Table 265. SYSCAT.TABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
APPEND_MODE	CHAR (1)		For row-organized tables, controls how rows are inserted into pages. • N = New rows are inserted into existing spaces, if available • Y = New rows are appended to the end of the data For column-organized tables, which are implicitly always in append mode, this field always has a value of 'N'.
REFRESH	CHAR (1)		Refresh mode. • D = Deferred • I = Immediate • O = Once • Blank = Not a materialized query table
REFRESH_TIME	TIMESTAMP	Y	For REFRESH = 'D' or 'O', time at which the data was last refreshed (REFRESH TABLE statement); null value otherwise.
LOCKSIZE	CHAR (1)		Indicates the preferred lock granularity for tables that are accessed by data manipulation language (DML) statements. Applies to tables only. Possible values are: • I = Block insert • R = Row • T = Table • Blank = Not applicable
VOLATILE	CHAR (1)		• C = Cardinality of the table is volatile • Blank = Not applicable
ROW_FORMAT	CHAR (1)		Not used.

Table 265. SYSCAT.TABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
PROPERTY	VARCHAR (32)		Properties for a table. A single blank indicates that the table has no properties. The following is position within string, value, and meaning: • 1, Y = User maintained materialized query table • 2, Y = Staging table • 3, Y = Propagate immediate • 11, Y = Nickname that will not be cached • 13, Y = Statistical view • 19, Y = Statistical view for an index with an expression-based key • 20, Y = Column-organized table • 21, Y = Synopsis table • 23, Y = Shadow table (materialized query table maintained by replication) • 25, Y = Random distribution table • 27, Y = External table
STATISTICS_PROFILE	CLOB (10M)	Y	RUNSTATS command used to register a statistical profile for the object.
COMPRESSION	CHAR (1)		• B = Both value and row compression are enabled • N = No compression is enabled; a row format that does not support compression is used • R = Row compression is enabled; a row format that supports compression might be used • V = Value compression is enabled; a row format that supports compression is used • Blank = Not applicable
ROWCOMPMODE	CHAR (1)		Row compression mode for the table. • A = ADAPTIVE • S = STATIC • Blank = Row compression is not enabled

Table 265. SYSCAT.TABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
ACCESS_MODE	CHAR (1)		Access restriction state of the object. These states apply to objects that are in set integrity pending state or to objects that were processed by a SET INTEGRITY statement only. Possible values are: • D = No data movement • F = Full access • N = No access • R = Read-only access
CLUSTERED	CHAR (1)	Y	• T = Table is clustered by insert time • Y = Table is clustered by dimensions (even if only by one dimension) • Null value = Table is not clustered by dimensions or insert time
ACTIVE_BLOCKS	BIGINT		Total number of active blocks in the table, or -1. Applies to multidimensional clustering (MDC) tables or insert time clustering (ITC) tables only.
DROPRULE	CHAR (1)		• N = No rule • R = Restrict rule applies on drop
MAXFREESPACESEARCH	SMALLINT		Reserved for future use.
AVGCOMPRESSEDROWSIZE	SMALLINT		Average length (in bytes) of compressed rows in this table; -1 if statistics are not collected.
AVGROWCOMPRESSIONRATIO	REAL		For compressed rows in the table, this is the average compression ratio by row, that is, the average uncompressed row length divided by the average compressed row length; -1 if statistics are not collected.
AVGROWSIZE	SMALLINT		Average length (in bytes) of both compressed and uncompressed rows in this table; -1 if statistics are not collected.
PCTROWSCOMPRESSED	REAL		Compressed rows as a percentage of the total number of rows in the table; -1 if statistics are not collected.

Table 265. SYSCAT.TABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
LOGINDEXBUILD	VARCHAR (3)	Y	Level of logging that is to be performed during create, re-create, or reorganize index operations on the table. • OFF = Index build operations on the table is logged minimally • ON = Index build operations on the table is logged completely • Null value = Value of the *logindexbuild* database configuration parameter is used to determine whether index build operations are to be logged completely
CODEPAGE	SMALLINT		Code page of the object. This is the default code page that is used for all character columns, triggers, check constraints, and expression-generated columns.
COLLATIONSCHEMA	VARCHAR (128)		Schema name of the collation for the table.
COLLATIONNAME	VARCHAR (128)		Unqualified name of the collation for the table.
COLLATIONSCHEMA_ORDERBY	VARCHAR (128)		Schema name of the collation for ORDER BY clauses in the table.
COLLATIONNAME_ORDERBY	VARCHAR (128)		Unqualified name of the collation for ORDER BY clauses in the table.
ENCODING_SCHEME	CHAR (1)		• A = CCSID ASCII was specified • U = CCSID UNICODE was specified • Blank = CCSID clause was not specified
PCTPAGESSAVED	SMALLINT	N	The approximate percentage of pages that are saved in a row-organized table as a result of row compression. For a column-organized table, the estimate is based on the number of data pages that are needed to store the table in uncompressed row organization.-1 if statistics are not collected.
LAST_REGEN_TIME	TIMESTAMP	Y	Time at which any views or check constraints on the table were last regenerated.
SECPOLICYID	INTEGER		Identifier for the security policy that protects the table; 0 for non-protected tables.

Table 265. SYSCAT.TABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
PROTECTIONGRANULARITY	CHAR (1)		• B = Both column- and row-level granularity • C = Column-level granularity • R = Row-level granularity • Blank = Non-protected table
AUDITPOLICYID	INTEGER	Y	Identifier for the audit policy.
AUDITPOLICYNAME	VARCHAR (128)	Y	Name of the audit policy.
AUDITEXCEPTIONENABLED	CHAR (1)		Reserved for future use.
DEFINER[1]	VARCHAR (128)		Authorization ID of the owner of the table, view, alias, or nickname.
ONCOMMIT	CHAR (1)		Specifies the action that is taken on the created temporary table when a COMMIT operation is performed. • D = Delete rows • P = Preserve rows • Blank = Table is not a created temporary table
LOGGED	CHAR (1)		Specifies whether the created temporary table is logged. • N = Not logged • Y = Logged • Blank = Table is not a created temporary table
ONROLLBACK	CHAR (1)		Specifies the action that is taken on the created temporary table when a ROLLBACK operation is performed. • D = Delete rows • P = Preserve rows • Blank = Table is not a created temporary table
LASTUSED	DATE		Date when the table was last used by any DML statement or the LOAD command. This column is not updated for an alias, created temporary table, nickname, or view. This column is not updated when the table is used on an HADR standby database. The default value is '0001-01-01'. This value is updated asynchronously not more than once within a 24 hour period and might not reflect usage within the last 15 minutes.

Table 265. SYSCAT.TABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
CONTROL	CHAR (1)		Access control that is enforced for the table • B = Both row and column • C = Column • R = Row • Blank = No access control
TEMPORALTYPE	CHAR (1)		Type of temporal table. • A = Application-period temporal table • B = Bitemporal table • N = Not a temporal table • S = System-period temporal table
TABLEORG	CHAR(1)		• C = Column-organized table • R = Row-organized table • N = Not a table
EXTENDED_ROW_SIZE	CHAR(1)		Indicates whether the row size of a table that is organized by row exceeds the maximum record length for the page size of the table space in which it is defined. • N = Row size does not exceed the maximum record length for the page size • Y = Row size exceeds the maximum record length for the page size • blank = Not applicable
PCTEXTENDEDROWS	REAL		Extended rows as a percentage of the total number of rows in the table; -1 if statistics are not collected.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.TABLESPACES

Each row represents a table space.

Table 266. SYSCAT.TABLESPACES Catalog View

Column Name	Data Type	Nullable	Description
TBSPACE	VARCHAR (128)		Name of the table space.
OWNER	VARCHAR (128)		Authorization ID of the owner of the table space.

Table 266. SYSCAT.TABLESPACES Catalog View (continued)

Column Name	Data Type	Nullable	Description
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
CREATE_TIME	TIMESTAMP		Time at which the table space was created.
TBSPACEID	INTEGER		Identifier for the table space.
TBSPACETYPE	CHAR (1)		Type of table space. • D = Database-managed space • S = System-managed space
DATATYPE	CHAR (1)		Type of data that can be stored in this table space. • A = All types of permanent data; regular table space • L = All types of permanent data; large table space • T = System temporary tables only • U = Created temporary tables or declared temporary tables only
EXTENTSIZE	INTEGER		Size of each extent, in pages of size PAGESIZE. This many pages are written to one container in the table space before switching to the next container.
PREFETCHSIZE	INTEGER		Number of pages of size PAGESIZE to be read when prefetching is performed; -1 when AUTOMATIC.
OVERHEAD	DOUBLE		Controller overhead and disk seek and latency time, in milliseconds (average for the containers in this table space); -1 when value is inherited from the storage group that the table space uses.
TRANSFERRATE	DOUBLE		Time to read one page of size PAGESIZE into the buffer (average for the containers in this table space); -1 when value is inherited from the storage group that the table space uses.
WRITEOVERHEAD	DOUBLE	Y	Reserved for future use.
WRITETRANSFERRATE	DOUBLE	Y	Reserved for future use.
PAGESIZE	INTEGER		Size (in bytes) of pages in this table space.
DBPGNAME	VARCHAR (128)		Name of the database partition group that is associated with this table space.
BUFFERPOOLID	INTEGER		Identifier for the buffer pool that is used by this table space (1 indicates the default buffer pool).

Table 266. SYSCAT.TABLESPACES Catalog View (continued)

Column Name	Data Type	Nullable	Description
DROP_RECOVERY	CHAR (1)		Indicates whether or not tables in this table space can be recovered after a drop table operation. • N = Tables are not recoverable • Y = Tables are recoverable
NGNAME[1]	VARCHAR (128)		Name of the database partition group that is associated with this table space.
DEFINER[2]	VARCHAR (128)		Authorization ID of the owner of the table space.
DATATAG	SMALLINT		A tag to identify data stored in this table space. Valid user-specified range is 1 through 9; 0 indicates no data tag specified; -1 indicates value is inherited from the storage group that the table space uses.
SGNAME	VARCHAR (128)	Y	Name of the storage group the table space is using; null value when the table space is not using automatic storage.
SGID	INTEGER		Identifier of the storage group the table space is using; -1 when the table space is not using automatic storage.
EFFECTIVEPREFETCHSIZE	INTEGER		Value of the effective prefetch size when PREFETCHSIZE is set to -1 (AUTOMATIC); otherwise same as PREFETCHSIZE.
CACHINGTIER	SMALLINT		Reserved for future use.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. The NGNAME column is included for backwards compatibility. See DBPGNAME.
2. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.TABOPTIONS

Each row represents an option that is associated with a remote table.

Table 267. SYSCAT.TABOPTIONS Catalog View

Column Name	Data Type	Nullable	Description
TABSCHEMA	VARCHAR (128)		Schema name of a table, view, alias, or nickname.
TABNAME	VARCHAR (128)		Unqualified name of a table, view, alias, or nickname.
OPTION	VARCHAR (128)		Name of the table option.
SETTING	CLOB (32K)		Value of the table option.

SYSCAT.TBSPACEAUTH

Each row represents a user, group, or role that has been granted the USE privilege on a particular table space in the database.

Table 268. SYSCAT.TBSPACEAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of the privilege.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user
GRANTEE	VARCHAR (128)		Holder of the privilege.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
TBSPACE	VARCHAR (128)		Name of the table space.
USEAUTH	CHAR (1)		Privilege to create tables within the table space. • G = Held and grantable • N = Not held • Y = Held

SYSCAT.THRESHOLDS

Each row represents a threshold.

Table 269. SYSCAT.THRESHOLDS Catalog View

Column Name	Data Type	Nullable	Description
THRESHOLDNAME	VARCHAR (128)		Name of the threshold.
THRESHOLDID	INTEGER		Identifier for the threshold.
ORIGIN	CHAR (1)		Origin of the threshold. • U = Threshold was created by a user • W = Threshold was created through a work action set
THRESHOLDCLASS	CHAR (1)		Classification of the threshold. • A = Aggregate threshold • C = Activity threshold

Table 269. SYSCAT.THRESHOLDS Catalog View (continued)

Column Name	Data Type	Nullable	Description
THRESHOLDPREDICATE	VARCHAR (15)		Type of the threshold. Possible values are: • AGGTEMPSPACE • CONCDBC • CONCWCN • CONCWOC • CONNIDLETIME • CPUTIME • CPUTIMEINSC • DATATAGINSC • DATATAGNOTINSC • DBCONN • ESTSQLCOST • ROWSREAD • ROWSREADINSC • ROWSRET • RUNTIME • RUNTIMEINALLSC • SCCONN • SORTSHRHEAPUTIL  **Attention:** This feature is available in Db2 Version 11.5 Mod Pack 2 and later versions. • TEMPSPACE • TOTALTIME • UOWTOTALTIME
THRESHOLDPREDICATEID	SMALLINT		Identifier for the threshold predicate.
DOMAIN	CHAR (2)		Domain of the threshold. • DB = Database • SB = Service subclass • SP = Service superclass • WA = Work action set • WD = Workload definition • SQ = SQL statement
DOMAINID	INTEGER		Identifier for the object with which the threshold is associated. This can be a service class, work action, workload unique ID, or SQL statement. If this is a database threshold, this value is 0.

Table 269. SYSCAT.THRESHOLDS Catalog View (continued)

Column Name	Data Type	Nullable	Description
ENFORCEMENT	CHAR (1)		Scope of enforcement for the threshold. • D = Database • P = Member • W = Workload occurrence
QUEUING	CHAR (1)		• N = The threshold is not queueing • Y = The threshold is queueing
MAXVALUE	BIGINT		Upper bound specified by the threshold. If THRESHOLDPREDICATE is 'DATATAGINSC' or 'DATATAGNOTINSC', this value encodes one or more data tags.
DATATAGLIST	VARCHAR (256)	Y	If THRESHOLDPREDICATE is 'DATATAGINSC' or 'DATATAGNOTINSC', this value represents one or more data tags as a comma separated list. Otherwise, the null value.
QUEUESIZE	INTEGER		If QUEUEING is 'Y', the size of the queue. -1 otherwise.
OVERFLOWPERCENT	SMALLINT		Reserved for future use.
COLLECTACTDATA	CHAR (1)		Specifies what activity data should be collected by the applicable event monitor. • D = Activity data with details • N = None • S = Activity data with details and section environment • V = Activity data with details and values • W = Activity data without details • X = Activity data with details, section environment, and values
COLLECTACTPARTITION	CHAR (1)		Specifies where activity data is collected. • C = Coordinator member of the activity • D = All members
EXECUTION	CHAR (1)		Indicates the execution action taken after a threshold has been exceeded. • C = Execution continues • F = Application is forced off the system • R = Execution is remapped to a different service subclass • S = Execution stops
REMAPSCID	SMALLINT		Target service subclass ID of the REMAP ACTIVITY action.

Table 269. SYSCAT.THRESHOLDS Catalog View (continued)

Column Name	Data Type	Nullable	Description
VIOLATIONRECORDLOGGED	CHAR (1)		Indicates whether a record is written to the event monitor upon threshold violation. • N = No • Y = Yes
CHECKINTERVAL	INTEGER		The interval, in seconds, in which the threshold condition is checked if THRESHOLDPREDICATE is: • 'CPUTIME' • 'CPUTIMEINSC' • 'ROWSREAD' • 'ROWSREADINSC' Otherwise, -1.
ENABLED	CHAR (1)		• N = This threshold is disabled. • Y = This threshold is enabled.
CREATE_TIME	TIMESTAMP		Time at which the threshold was created.
ALTER_TIME	TIMESTAMP		Time at which the threshold was last altered.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.TRANSFORMS

Each row represents the functions that handle transformations between a user-defined type and a base SQL type, or the reverse.

Table 270. SYSCAT.TRANSFORMS Catalog View

Column Name	Data Type	Nullable	Description
TYPEID	SMALLINT		Identifier for the data type.
TYPESCHEMA	VARCHAR (128)		Schema name of the data type if TYPEMODULEID is null; otherwise schema name of the module to which the data type belongs.
TYPENAME	VARCHAR (128)		Unqualified name of the data type.
GROUPNAME	VARCHAR (128)		Name of the transform group.
FUNCID	INTEGER		Identifier for the routine.
FUNCSCHEMA	VARCHAR (128)		Schema name of the routine if ROUTINEMODULEID is null; otherwise schema name of the module to which the routine belongs.
FUNCNAME	VARCHAR (128)		Unqualified name of the routine.
SPECIFICNAME	VARCHAR (128)		Name of the routine instance (might be system-generated).

Table 270. SYSCAT.TRANSFORMS Catalog View (continued)

Column Name	Data Type	Nullable	Description
TRANSFORMTYPE	VARCHAR (8)		• 'FROM SQL' = Transform function transforms a structured type from SQL • 'TO SQL' = Transform function transforms a structured type to SQL
FORMAT	CHAR (1)		Format produced by the FROM SQL transform. • S = Structured data type • U = User-defined
MAXLENGTH	INTEGER	Y	Maximum length (in bytes) of output from the FROM SQL transform; the null value for TO SQL transforms.
ORIGIN	CHAR (1)		Source of this group of transforms. • O = Original transform group • R = Redefined transform group
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.TRIGDEP

Each row represents a dependency of a trigger on some other object. The trigger depends on the object of type BTYPE of name BNAME, so a change to the object affects the trigger.

Table 271. SYSCAT.TRIGDEP Catalog View

Column Name	Data Type	Nullable	Description
TRIGSCHEMA	VARCHAR (128)		Schema name of the trigger.
TRIGNAME	VARCHAR (128)		Unqualified name of the trigger.

Table 271. SYSCAT.TRIGDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
BTYPE	CHAR (1)		Type of object on which there is a dependency. Possible values are: • A = Table alias • B = Trigger • C = Column • F = Routine • G = Global temporary table • H = Hierachy table • I = Index • K = Package • L = Detached table • N = Nickname • O = Privilege dependency on all subtables or subviews in a table or view hierarchy • Q = Sequence • R = User-defined data type • S = Materialized query table • T = Table (not typed) • U = Typed table • V = View (not typed) • W = Typed view • X = Index extension • Z = XSR object • m = Module • q = Sequence alias • u = Module alias • v = Global variable • * = Anchored to the row of a base table
BSCHEMA	VARCHAR (128)		Schema name of the object on which there is a dependency.
BMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the object on which a dependency belongs. The null value if not a module object.
BNAME	VARCHAR (128)		Unqualified name of the object on which there is a dependency. For routines (BTYPE = 'F'), this is the specific name.
BMODULEID	INTEGER	Y	Identifier for the module of the object on which there is a dependency.
TABAUTH	SMALLINT	Y	If BTYPE = 'O', 'S', 'T', 'U', 'V', 'W', or 'v', encodes the privileges on the table or view that are required by a dependent trigger; null value otherwise.

SYSCAT.TRIGGERS

Each row represents a trigger. For table hierarchies, each trigger is recorded only at the level of the hierarchy where the trigger was created.

Table 272. SYSCAT.TRIGGERS Catalog View

Column Name	Data Type	Nullable	Description
TRIGSCHEMA	VARCHAR (128)		Schema name of the trigger.
TRIGNAME	VARCHAR (128)		Unqualified name of the trigger.
OWNER	VARCHAR (128)		Authorization ID of the owner of the trigger.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
TABSCHEMA	VARCHAR (128)		Schema name of the table or view to which this trigger applies.
TABNAME	VARCHAR (128)		Unqualified name of the table or view to which this trigger applies.
TRIGTIME	CHAR (1)		Time at which triggered actions are applied to the base table, relative to the event that fired the trigger. • A = Trigger is applied after the event • B = Trigger is applied before the event • I = Trigger is applied instead of the event
TRIGEVENT	CHAR (1)		Event that fires the trigger. • D = Delete event • I = Insert event • M = Multiple events • U = Update event
EVENTUPDATE	CHAR (1)		Indicates whether an update event fires the trigger. • N = No • Y = Yes
EVENTDELETE	CHAR (1)		Indicates whether a delete event fires the trigger. • N = No • Y = Yes
EVENTINSERT	CHAR (1)		Indicates whether an insert event fires the trigger. • N = No • Y = Yes

Table 272. SYSCAT.TRIGGERS Catalog View (continued)

Column Name	Data Type	Nullable	Description
GRANULARITY	CHAR (1)		Trigger is executed once per: • R = Row • S = Statement
VALID	CHAR (1)		• N = Trigger is invalid • X = Trigger is inoperative and must be re-created • Y = Trigger is valid
CREATE_TIME	TIMESTAMP		Time at which the trigger was defined. Used in resolving functions and types.
QUALIFIER	VARCHAR (128)		Value of the default schema at the time of object definition. Used to complete any unqualified references.
FUNC_PATH	CLOB (2K)		SQL path in effect when the trigger was defined.
TEXT	CLOB (2M)		Full text of the CREATE TRIGGER statement, exactly as typed.
LAST_REGEN_TIME	TIMESTAMP		Time at which the packed descriptor for the trigger was last regenerated.
COLLATIONSCHEMA	VARCHAR (128)		Schema name of the collation for the trigger.
COLLATIONNAME	VARCHAR (128)		Unqualified name of the collation for the trigger.
COLLATIONSCHEMA_ORDERBY	VARCHAR (128)		Schema name of the collation for ORDER BY clauses in the trigger.
COLLATIONNAME_ORDERBY	VARCHAR (128)		Unqualified name of the collation for ORDER BY clauses in the trigger.
DEFINER[1]	VARCHAR (128)		Authorization ID of the owner of the trigger.
SECURE	CHAR (1)		Indicates whether the trigger is secure for row and column access control • N = Not secure • Y = Secure
ALTER_TIME	TIMESTAMP		Time at which the trigger was last altered.

Table 272. SYSCAT.TRIGGERS Catalog View (continued)

Column Name	Data Type	Nullable	Description
DEBUG_MODE	VARCHAR (8)		Indicates whether the trigger can be debugged using the Db2 debugger. • DISALLOW = Trigger is not debuggable • ALLOW = Trigger is debuggable, and can participate in a client debug session with the Db2 debugger • DISABLE = Trigger is not debuggable, and this setting cannot be altered without dropping and re-creating the trigger • Blank = Trigger type is not currently supported by the Db2 debugger
ENABLED	CHAR (1)		Reserved for future use.
LIB_ID	INTEGER	Y	Internal identifier for compiled SQL triggers. Otherwise, the null value.
PRECOMPILE_OPTIONS	VARCHAR(1024)	Y	The precompile and bind options that were in effect when the compiled trigger was created. The null value if the trigger is not compiled.
COMPILE_OPTIONS	VARCHAR(1024)	Y	The value of the SQL_CCFLAGS special register that was in effect when the compiled trigger was created and inquiry directives were present. An empty string if no inquiry directives were present in the compiled trigger. The null value if the trigger is not compiled.
ENVSTRINGUNITS	VARCHAR (11)		Default string units when the object was created.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. The DEFINER column is included for compatibility with earlier versions. See OWNER.

SYSCAT.TYPEMAPPINGS

Each row represents a data type mapping between a locally-defined data type and a data source data type. There are two mapping types (mapping directions):*forward type mapping*s map a data source data type to a locally-defined data type; *reverse type mapping*s map a locally-defined data type to a data source data type.

Table 273. SYSCAT.TYPEMAPPINGS Catalog View

Column Name	Data Type	Nullable	Description
TYPE_MAPPING	VARCHAR (18)		Name of the type mapping (might be system-generated).

Table 273. SYSCAT.TYPEMAPPINGS Catalog View (continued)

Column Name	Data Type	Nullable	Description
MAPPINGDIRECTION	CHAR (1)		Indicates whether this type mapping is a forward or a reverse type mapping. • F = Forward type mapping • R = Reverse type mapping
TYPESCHEMA	VARCHAR (128)	Y	Schema name of the local type in a data type mapping; the null value for built-in types.
TYPENAME	VARCHAR (128)		Unqualified name of the local type in a data type mapping.
TYPEID	SMALLINT		Identifier for the data type.
SOURCETYPEID	SMALLINT		Identifier for the source type.
OWNER	VARCHAR (128)		Authorization ID of the owner of the type mapping. 'SYSIBM' indicates a built-in type mapping.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
LENGTH	INTEGER	Y	Maximum length or precision of the local data type in this mapping. If the null value, the system determines the maximum length or precision. For character types, represents the maximum number of bytes.
SCALE	SMALLINT	Y	Maximum number of digits in the fractional part of a local decimal value or the maximum number of digits of fractional seconds of a local TIMESTAMP value in this mapping. If the null value, the system determines the maximum number.
LOWER_LEN	INTEGER	Y	Minimum length or precision of the local data type in this mapping. If the null value, the system determines the minimum length or precision. For character types, represents the minimum number of bytes.
UPPER_LEN	INTEGER	Y	Maximum length or precision of the local data type in this mapping. If the null value, the system determines the maximum length or precision. For character types, represents the maximum number of bytes.
LOWER_SCALE	SMALLINT	Y	Minimum number of digits in the fractional part of a local decimal value or the minimum number of digits of fractional seconds of a local TIMESTAMP value in this mapping. If the null value, the system determines the minimum number.

Table 273. SYSCAT.TYPEMAPPINGS Catalog View (continued)

Column Name	Data Type	Nullable	Description
UPPER_SCALE	SMALLINT	Y	Maximum number of digits in the fractional part of a local decimal value or the maximum number of digits of fractional seconds of a local TIMESTAMP value in this mapping. If the null value, the system determines the maximum number.
S_OPR_P	CHAR (2)	Y	Relationship between the scale and precision of a local decimal value in this mapping. Basic comparison operators (=, <, >, <=, >=, <>) can be used. A null value indicates that no specific relationship is required.
BIT_DATA	CHAR (1)	Y	Indicates whether or not this character type is for bit data. Possible values are: • N = This type is not for bit data • Y = This type is for bit data • Null value = This is not a character data type, or the system determines the bit data attribute
WRAPNAME	VARCHAR (128)	Y	Data access protocol (wrapper) to which this mapping applies.
SERVERNAME	VARCHAR (128)	Y	Uppercase name of the server.
SERVERTYPE	VARCHAR (30)	Y	Type of server.
SERVERVERSION	VARCHAR (18)	Y	Server version.
REMOTE_TYPESCHEMA	VARCHAR (128)	Y	Schema name of the data source data type.
REMOTE_TYPENAME	VARCHAR (128)		Unqualified name of the data source data type.
REMOTE_META_TYPE	CHAR (1)	Y	Indicates whether this remote type is a system built-in type or a distinct type. • S = System built-in type • T = Distinct type
REMOTE_LOWER_LEN	INTEGER	Y	Minimum length or precision of the remote data type in this mapping, or the null value. For character types, represents the minimum number of characters (not bytes). For binary types, represents the minimum number of bytes. A value of -1 indicates that the default length or precision is used, or that the remote type does not have a length or precision.

Table 273. SYSCAT.TYPEMAPPINGS Catalog View (continued)

Column Name	Data Type	Nullable	Description
REMOTE_UPPER_LEN	INTEGER	Y	Maximum length or precision of the remote data type in this mapping, or the null value. For character types, represents the maximum number of characters (not bytes). For binary types, represents the maximum number of bytes. A value of -1 indicates that the default length or precision is used, or that the remote type does not have a length or precision.
REMOTE_LOWER_SCALE	SMALLINT	Y	Minimum number of digits in the fractional part of a remote decimal value or the minimum number of digits of fractional seconds of a remote TIMESTAMP value in this mapping, or the null value.
REMOTE_UPPER_SCALE	SMALLINT	Y	Maximum number of digits in the fractional part of a remote decimal value or the maximum number of digits of fractional seconds of a remote TIMESTAMP value in this mapping, or the null value.
REMOTE_S_OPR_P	CHAR (2)	Y	Relationship between the scale and precision of a remote decimal value in this mapping. Basic comparison operators (=, <, >, <=, >=, <>) can be used. A null value indicates that no specific relationship is required.
REMOTE_BIT_DATA	CHAR (1)	Y	Indicates whether or not this remote character type is for bit data. Possible values are: • N = This type is not for bit data • Y = This type is for bit data • Null value = This is not a character data type, or the system determines the bit data attribute
USER_DEFINED	CHAR (1)		Indicates whether or not the mapping is user-defined. The value is always 'Y'; that is, the mapping is always user-defined.
CREATE_TIME	TIMESTAMP		Time at which this mapping was created.
DEFINER[1]	VARCHAR (128)		Authorization ID of the owner of the type mapping. 'SYSIBM' indicates a built-in type mapping.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

Note:

1. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.USAGELISTS

Each row represents a usage list for a table or index object.

Table 274. SYSCAT.USAGELISTS Catalog View

Column Name	Data Type	Nullable	Description
USAGELISTSCHEMA	VARCHAR (128)		Schema of the usage list.
USAGELISTNAME	VARCHAR (128)		Name of the usage list.
USAGELISTID	INTEGER		Identifier for the usage list.
OBJECTSCHEMA	VARCHAR (128)		Schema name of the object for which the usage list is defined.
OBJECTNAME	VARCHAR (128)		Unqualified name of the object for which the usage list is defined.
OBJECTTYPE	CHAR (1)		The type of the object for which this usage list is defined. • I = Index • T = Table
STATUS	CHAR (1)		The status of the usage list. • I = Invalid • V = Valid
MAXLISTSIZE	INTEGER		The maximum number of entries in the usage list.
WHENFULL	CHAR (1)		Action to be performed when the usage list is full. • D = Deactivate collection • W = Wrap
AUTOSTART	CHAR (1)		Indicates whether this usage list is to be activated automatically when the database starts. • N = Manual start • Y = Autostart
ACTIVEDURATION	INTEGER		Reserved for future use.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.USEROPTIONS

Each row represents a server-specific user option value.

Table 275. SYSCAT.USEROPTIONS Catalog View

Column Name	Data Type	Nullable	Description
AUTHID	VARCHAR (128)		Local authorization ID, in uppercase characters.
AUTHIDTYPE	CHAR (1)		• U = Grantee is an individual user

Table 275. SYSCAT.USEROPTIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
SERVERNAME	VARCHAR (128)		Name of the server on which the user is defined.
OPTION	VARCHAR (128)		Name of the user option.
SETTING	VARCHAR (2048)		Value of the user option.

SYSCAT.VARIABLEAUTH

Each row represents a user, group, or role that has been granted one or more privileges by a specific grantor on a global variable in the database that is not defined in a module.

Table 276. SYSCAT.VARIABLEAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of the privilege.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user
GRANTEE	VARCHAR (128)		Holder of the privilege.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
VARSCHEMA	VARCHAR (128)		Schema name of the global variable if VARMODULEID is null; otherwise schema name of the module to which the global variable belongs.
VARNAME	VARCHAR (128)		Unqualified name of the global variable.
VARID	INTEGER		Identifier for the global variable.
READAUTH	CHAR (1)		Privilege to read the global variable. • G = Held and grantable • N = Not held • Y = Held
WRITEAUTH	CHAR (1)		Privilege to write the global variable. • G = Held and grantable • N = Not held • Y = Held

SYSCAT.VARIABLEDEP

Each row represents a dependency of a global variable on some other object. The global variable depends on the object of type BTYPE of name BNAME, so a change to the object affects the global variable.

Table 277. SYSCAT.VARIABLEDEP Catalog View

Column Name	Data Type	Nullable	Description
VARSCHEMA	VARCHAR (128)		Schema name of the global variable that has dependencies on another object.
VARMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the global variable belongs. The null value if not a module variable.
VARNAME	VARCHAR (128)		Unqualified name of the global variable that has dependencies on another object.
VARMODULEID	INTEGER	Y	Identifier for the module of the object that has dependencies on another object.
BTYPE	CHAR (1)		Type of object on which there is a dependency. Possible values are: • A = Table alias • F = Routine • G = Global temporary table • H = Hierarchy table • I = Index • N = Nickname • O = Privilege dependency on all subtables or subviews in a table or view hierarchy • R = User-defined data type • S = Materialized query table • T = Table (not typed) • U = Typed table • V = View (not typed) • W = Typed view • m = Module • q = Sequence alias • u = Module alias • v = Global variable • * = Anchored to the row of a base table
BSCHEMA	VARCHAR (128)		Schema name of the object on which there is a dependency.
BMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the object on which a dependency belongs. The null value if not a module object.
BNAME	VARCHAR (128)		Unqualified name of the object on which there is a dependency. For routines (BTYPE = 'F'), this is the specific name.

Table 277. SYSCAT.VARIABLEDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
BMODULEID	INTEGER	Y	Identifier for the module of the object on which there is a dependency.
TABAUTH	SMALLINT	Y	If BTYPE = 'O', 'S', 'T', 'U', 'V', 'W', or 'v', encodes the privileges on the table or view that are required by the dependent global variable; the null value otherwise.

SYSCAT.VARIABLES

Each row represents a global variable.

Table 278. SYSCAT.VARIABLES Catalog View

Column Name	Data Type	Nullable	Description
VARSCHEMA	VARCHAR (128)		Schema name of the global variable if VARMODULEID is null; otherwise schema name of the module to which the global variable belongs.
VARMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the global variable belongs. The null value if not a module variable.
VARNAME	VARCHAR (128)		Unqualified name of the global variable.
VARMODULEID	INTEGER	Y	Identifier for the module to which the global variable belongs. The null value if not a module variable.
VARID	INTEGER		Identifier for the global variable.
OWNER	VARCHAR (128)		Authorization ID of the owner of the global variable.
OWNERTYPE	CHAR (1)		• U = The owner is an individual user
CREATE_TIME	TIMESTAMP		Time at which the global variable was created.
LAST_REGEN_TIME	TIMESTAMP		Time at which the default expression was last regenerated.
VALID	CHAR (1)		• N = The global variable is invalid • Y = The global variable is valid
PUBLISHED	CHAR (1)		Indicates whether the module variable can be referenced outside its module. • N = The module variable is not published • Y = The module variable is published • Blank = Not applicable

Table 278. SYSCAT.VARIABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
TYPESCHEMA	VARCHAR (128)		Schema name of the data type if TYPEMODULEID is null; otherwise schema name of the module to which the data type belongs.
TYPEMODULENAME	VARCHAR (128)		Unqualified name of the module to which the variable data type belongs. The null value if the variable data type does not belong to a module.
TYPENAME	VARCHAR (128)		Unqualified name of the data type.
TYPEMODULEID	INTEGER	Y	Identifier for the module to which the variable data type belongs. The null value if the variable data type does not belong to a module.
LENGTH	INTEGER		Maximum length of the global variable.
SCALE	SMALLINT		Scale if the global variable data type is DECIMAL or distinct type based on DECIMAL; the number of digits of fractional seconds if the global variable data type is TIMESTAMP or distinct type based on TIMESTAMP; 0 otherwise.
TYPESTRINGUNITS	VARCHAR (11)	Y	In a Unicode database, the string units that apply to a character string or graphic string data type. Otherwise, the null value.
STRINGUNITSLENGTH	INTEGER	Y	In a Unicode database, the declared number of string units for a character string or graphic string data type. Otherwise, the null value.
CODEPAGE	SMALLINT		Code page of the global variable.
COLLATIONSCHEMA	VARCHAR (128)		Schema name of the collation for the variable.
COLLATIONNAME	VARCHAR (128)		Unqualified name of the collation for the variable.
COLLATIONSCHEMA_ORDERBY	VARCHAR (128)		Schema name of the collation for ORDER BY clauses in the variable.
COLLATIONNAME_ORDERBY	VARCHAR (128)		Unqualified name of the collation for ORDER BY clauses in the variable.
SCOPE	CHAR (1)		Scope of the global variable. • D = Database • S = Session
DEFAULT	CLOB (64K)	Y	Expression used to calculate the initial value of the global variable when first referenced.

Table 278. SYSCAT.VARIABLES Catalog View (continued)

Column Name	Data Type	Nullable	Description
QUALIFIER	VARCHAR (128)	Y	Value of the default schema at the time the variable was defined.
FUNC_PATH	CLOB (2K)	Y	SQL path in effect when the variable was defined.
NULLS	CHAR (1)		Reserved for future use.
READONLY	CHAR (1)		• C = Read-only because the global variable is defined with a CONSTANT clause • N = Not read-only • S = Read-only because the global variable value is maintained by the database manager
ENVSTRINGUNITS	VARCHAR (11)		Default string units when the object was created.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.VIEWS

Each row represents a view or materialized query table.

Table 279. SYSCAT.VIEWS Catalog View

Column Name	Data Type	Nullable	Description
VIEWSCHEMA	VARCHAR (128)		Schema name of the view or materialized query table.
VIEWNAME	VARCHAR (128)		Unqualified name of the view or materialized query table.
OWNER	VARCHAR (128)		Authorization ID of the owner of the view or materialized query table.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
SEQNO	SMALLINT		Always 1.
VIEWCHECK	CHAR (1)		Type of view checking. • C = Cascaded check option • L = Local check option • N = No check option or is a materialized query table

Table 279. SYSCAT.VIEWS Catalog View (continued)

Column Name	Data Type	Nullable	Description
READONLY	CHAR (1)		• N = View can be updated by users with appropriate authorization or is a materialized query table • Y = View is read-only because of its definition
VALID	CHAR (1)		• N = View or materialized query table definition is invalid • X = View or materialized query table definition is inoperative and must be recreated • Y = View or materialized query table definition is valid
QUALIFIER	VARCHAR (128)		Value of the default schema at the time of object definition. Used to complete any unqualified references.
FUNC_PATH	CLOB (2K)		SQL path in effect when the view or materialized query table was defined.
TEXT	CLOB (2M)		Full text of the view or materialized query table CREATE statement, exactly as typed.
DEFINER[1]	VARCHAR (128)		Authorization ID of the owner of the view or materialized query table.
ENVSTRINGUNITS	VARCHAR (11)		Default string units when the object was created.

Note:

1. The DEFINER column is included for backwards compatibility. See OWNER.

SYSCAT.WORKACTIONS

Each row represents a work action that is defined for a work action set.

Table 280. SYSCAT.WORKACTIONS Catalog View

Column Name	Data Type	Nullable	Description
ACTIONNAME	VARCHAR (128)		Name of the work action.
ACTIONID	INTEGER		Identifier for the work action.
ACTIONSETNAME	VARCHAR (128)	Y	Name of the work action set.
ACTIONSETID	INTEGER		Identifier of the work action set to which this work action belongs. This column refers to the ACTIONSETID column in the SYSCAT.WORKACTIONSETS view.
WORKCLASSNAME	VARCHAR (128)	Y	Name of the work class.

Table 280. SYSCAT.WORKACTIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
WORKCLASSID	INTEGER		Identifier of the work class. This column refers to the WORKCLASSID column in the SYSCAT.WORKCLASSES view.
CREATE_TIME	TIMESTAMP		Time at which the work action was created.
ALTER_TIME	TIMESTAMP		Time at which the work action was last altered.
ENABLED	CHAR (1)		• N = This work action is disabled. • Y = This work action is enabled.

Table 280. SYSCAT.WORKACTIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
ACTIONTYPE	CHAR (1)		The type of action performed on each Db2 activity that matches the attributes in the work class within scope. • B = Collect basic aggregate activity data, specifiable only for work action sets that apply to service classes or workloads. • C = Allow any Db2 activity under the associated work class to execute and increment the work class counter. • D = Collect activity data with details at the coordinating member of the activity. • E = Collect extended aggregate activity data, specifiable only for work action sets that apply to service classes or workloads. • F = Collect activity data with details, section, and values at the coordinating member of the activity. • G = Collect activity details and section at the coordinating member of the activity and collect activity data at all members. • H = Collect activity details, section, and values at the coordinating member of the activity and collect activity data at all members. • M = Map to a service subclass, specifiable only for work action sets that apply to service classes. • P = Prevent the execution of any Db2 activity under the work class with which this work action is associated. • S = Collect activity data with details and section at the coordinating member of the activity. • T = The action represents a threshold, specifiable only for work action sets that are associated with a database or a workload. • U = Map all activities with a nesting level of zero and all activities nested under these activities to a service subclass, specifiable only for work action sets that apply to service classes. • V = Collect activity data with details and values at the coordinating member. • W = Collect activity data without details at the coordinating member. • X = Collect activity data with details at the coordinating member and collect activity data at all members. • Y = Collect activity data with details and values at the coordinating member and collect activity data at all members. • Z = Collect activity data without details at all members.

Table 280. SYSCAT.WORKACTIONS Catalog View (continued)

Column Name	Data Type	Nullable	Description
REFOBJECTID	INTEGER	Y	If ACTIONTYPE is 'M' (map) or 'N' (map nested), this value is set to the ID of the service subclass to which the Db2 activity is mapped. If ACTIONTYPE is 'T' (threshold), this value is set to the ID of the threshold to be used. For all other actions, this value is NULL.
REFOBJECTTYPE	VARCHAR (30)		If the ACTIONTYPE is 'M' or 'N', this value is set to 'SERVICE CLASS'; if the ACTIONTYPE is 'T', this value is 'THRESHOLD'; the null value otherwise.
SECTIONACTUALSOPTIONS	VARCHAR (32)		Specifies what section actuals are collected during the execution of a section. The first position in the string represents whether the collection of section actuals is enabled. • B = Enabled and collect basic operator cardinality counts and statistics for each object referenced by the section (DML statements only). • N = Not enabled. The second position is always 'N' and reserved for for future use.

SYSCAT.WORKACTIONSETS

Each row represents a work action set.

Table 281. SYSCAT.WORKACTIONSETS Catalog View

Column Name	Data Type	Nullable	Description
ACTIONSETNAME	VARCHAR (128)		Name of the work action set.
ACTIONSETID	INTEGER		Identifier for the work action set.
WORKCLASSSETNAME	VARCHAR (128)	Y	Name of the work class set.
WORKCLASSSETID	INTEGER		The identifier of the work class set that is to be mapped to the object specified by the OBJECTID. This column refers to WORKCLASSSETID in the SYSCAT.WORKCLASSSETS view.
CREATE_TIME	TIMESTAMP		Time at which the work action set was created.
ALTER_TIME	TIMESTAMP		Time at which the work action set was last altered.
ENABLED	CHAR (1)		• N = This work action set is disabled. • Y = This work action set is enabled.

Table 281. SYSCAT.WORKACTIONSETS Catalog View (continued)

Column Name	Data Type	Nullable	Description
OBJECTTYPE	CHAR (1)		• b = Service superclass • w = Workload • Blank = Database
OBJECTNAME	VARCHAR (128)	Y	Name of the service class or workload.
OBJECTID	INTEGER		The identifier of the object to which the work class set (specified by the WORKCLASSSETID) is mapped. If the OBJECTTYPE is 'b', the OBJECTID is the ID of the service superclass. If the OBJECTTYPE is 'w', the OBJECTID is the ID of the workload. If the OBJECTTYPE is blank, the OBJECTID is -1.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.WORKCLASSATTRIBUTES

Each row represents an attribute in the definition of a work class.

Table 282. SYSCAT.WORKCLASSATTRIBUTES Catalog View

Column Name	Data Type	Nullable	Description
WORKCLASSNAME	VARCHAR (128)		Name of the work class.
WORKCLASSSETNAME	VARCHAR (128)		Name of the work class set.
WORKCLASSID	INTEGER		Identifier for the work class.
WORKCLASSSETID	INTEGER		Identifier for the work class set.
TYPE	VARCHAR (30)		The type of work class attribute. Possible values are: • WORK TYPE • TIMERONCOST • CARDINALITY • DATA TAG • ROUTINE SCHEMA • RUNTIME

Table 282. SYSCAT.WORKCLASSATTRIBUTES Catalog View (continued)

Column Name	Data Type	Nullable	Description
VALUE1	DOUBLE	Y	The meaning of this value depends on the value in the TYPE column: **TYPE='WORK TYPE'** A number that indicates the type of database activity: • 1 = ALL • 2 = READ • 3 = WRITE • 4 = CALL • 5 = DML • 6 = DDL • 7 = LOAD **TYPE='TIMERONCOST'** The low value in the range. **TYPE='CARDINALITY'** The low value in the range. **TYPE='DATA TAG'** The tag that the estimated data tag list must contain. **TYPE='ROUTINE SCHEMA'** The null value.
VALUE2	DOUBLE	Y	The meaning of this value depends on the value in the TYPE column: **TYPE='WORK TYPE'** The null value. **TYPE='TIMERONCOST'** The high value in the range. The value -1 indicates that there is no upper bound. **TYPE='CARDINALITY'** The high value in the range. The value -1 indicates that there is no upper bound. **TYPE='DATA TAG'** The null value. **TYPE='ROUTINE SCHEMA'** The null value.
VALUE3	VARCHAR (128)	Y	The meaning of this value depends on the value in the TYPE column. If TYPE='ROUTINE SCHEMA', it specifies the schema name of the procedures that are called by the CALL statement. Otherwise, it is the null value.

SYSCAT.WORKCLASSES

Each row represents a work class defined for a work class set.

Table 283. SYSCAT.WORKCLASSES Catalog View

Column Name	Data Type	Nullable	Description
WORKCLASSNAME	VARCHAR (128)		Name of the work class.
WORKCLASSSETNAME	VARCHAR (128)	Y	Name of the work class set.
WORKCLASSID	INTEGER		Identifier for the work class.
WORKCLASSSETID	INTEGER		Identifier for the work class set to which this work class belongs. This column refers to the WORKCLASSSETID column in the SYSCAT.WORKCLASSSETS view.
CREATE_TIME	TIMESTAMP		Time at which the work class was created.
ALTER_TIME	TIMESTAMP		Time at which the work class was last altered.
EVALUATIONORDER	SMALLINT		Uniquely identifies the evaluation order used for choosing a work class within a work class set.

SYSCAT.WORKCLASSSETS

Each row represents a work class set.

Table 284. SYSCAT.WORKCLASSSETS Catalog View

Column Name	Data Type	Nullable	Description
WORKCLASSSETNAME	VARCHAR (128)		Name of the work class set.
WORKCLASSSETID	INTEGER		Identifier for the work class set.
CREATE_TIME	TIMESTAMP		Time at which the work class set was created.
ALTER_TIME	TIMESTAMP		Time at which the work class set was last altered.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.WORKLOADAUTH

Each row represents a user, group, or role that has been granted USAGE privilege on a workload.

Table 285. SYSCAT.WORKLOADAUTH Catalog View

Column Name	Data Type	Nullable	Description
WORKLOADID	INTEGER		Identifier for the workload.
WORKLOADNAME	VARCHAR (128)		Name of the workload.
GRANTOR	VARCHAR (128)		Grantor of the privilege.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantee is an individual user
GRANTEE	VARCHAR (128)		Holder of the privilege.

Table 285. SYSCAT.WORKLOADAUTH Catalog View (continued)

Column Name	Data Type	Nullable	Description
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
USAGEAUTH	CHAR (1)		Indicates whether grantee holds USAGE privilege on the workload. • N = Not held • Y = Held

SYSCAT.WORKLOADCONNATTR

Each row represents a connection attribute in the definition of a workload.

Table 286. SYSCAT.WORKLOADCONNATTR Catalog View

Column Name	Data Type	Nullable	Description
WORKLOADID	INTEGER		Identifier for the workload.
WORKLOADNAME	VARCHAR (128)		Name of the workload.
CONNATTRTYPE	VARCHAR (30)		Type of the connection attribute. • 1 = APPLNAME • 2 = SYSTEM_USER • 3 = SESSION_USER • 4 = SESSION_USER GROUP • 5 = SESSION_USER ROLE • 6 = CURRENT CLIENT_USERID • 7 = CURRENT CLIENT_APPLNAME • 8 = CURRENT CLIENT_WRKSTNNAME • 9 = CURRENT CLIENT_ACCTNG • 10 = ADDRESS
CONNATTRVALUE	VARCHAR (1000)		Value of the connection attribute.

SYSCAT.WORKLOADS

Each row represents a workload.

Table 287. SYSCAT.WORKLOADS Catalog View

Column Name	Data Type	Nullable	Description
WORKLOADID	INTEGER		Identifier for the workload.
WORKLOADNAME	VARCHAR (128)		Name of the workload.
EVALUATIONORDER	SMALLINT		Evaluation order used for choosing a workload.
CREATE_TIME	TIMESTAMP		Time at which the workload was created.

Table 287. SYSCAT.WORKLOADS Catalog View (continued)

Column Name	Data Type	Nullable	Description
ALTER_TIME	TIMESTAMP		Time at which the workload was last altered.
ENABLED	CHAR (1)		• N = This workload is disabled. • Y = This workload is enabled.
ALLOWACCESS	CHAR (1)		• N = A UOW associated with this workload will be rejected. • Y = A unit of work (UOW) associated with this workload can access the database.
MAXDEGREE	SMALLINT		Maximum degree of parallelism for the workload. The valid values are: 1 to 32767, and -1. If MAXIMUM DEGREE is DEFAULT, the value is -1.
SERVICECLASSNAME	VARCHAR (128)		Name of the service subclass to which a unit of work (associated with this workload) is assigned.
PARENTSERVICECLASSNAME	VARCHAR (128)	Y	Name of the service superclass to which a unit of work (associated with this workload) is assigned.
COLLECTAGGACTDATA	CHAR (1)		Specifies what aggregate activity data should be captured for the workload by the applicable event monitor. • B = Collect base aggregate activity data • E = Collect extended aggregate activity data • N = None
COLLECTACTDATA	CHAR (1)		Specifies what activity data should be collected by the applicable event monitor. • D = Activity data with details • N = None • S = Activity data with details and section environment • V = Activity data with details and values. Applies when the COLLECT column is set to 'C' • W = Activity data without details • X = Activity data with details, section environment, and values
COLLECTACTPARTITION	CHAR (1)		Specifies where activity data is collected. • C = Coordinator member of the activity • D = All members

Table 287. SYSCAT.WORKLOADS Catalog View (continued)

Column Name	Data Type	Nullable	Description
COLLECTDEADLOCK	CHAR (1)		Specifies that deadlock events should be collect by the applicable event monitor. • H = Collect deadlock data with past activities only • V = Collect deadlock data with past activities and values • W = Collect deadlock data without past activities and values
COLLECTLOCKTIMEOUT	CHAR (1)		Specifies that lock timeout events should be collect by the applicable event monitor. • H = Collect lock timeout data with past activities only • N = Do not not collect lock timeout data • V = Collect lock timeout data with past activities and values • W = Collect lock timeout data without past activities and values
COLLECTLOCKWAIT	CHAR (1)		Specifies that lock wait events should be collect by the applicable event monitor. • H = Collect lock wait data with past activities only • N = Do not not collect lock wait data • V = Collect lock wait data with past activities and values • W = Collect lock wait data without past activities and values
LOCKWAITVALUE	INTEGER		Specifies the time in milliseconds a lock should wait before a lock event is collected by the applicable event monitor; 0 when COLLECTLOCKWAIT = 'N'
COLLECTACTMETRICS	CHAR (1)		Specifies the monitoring level for activities submitted by an occurrence of the workload. • B = Collect base activity metrics • E = Collect extended activity metrics • N = None

Table 287. SYSCAT.WORKLOADS Catalog View (continued)

Column Name	Data Type	Nullable	Description
COLLECTUOWDATAOPTIONS	VARCHAR (32)		Specifies what unit of work data is collected by the applicable event monitor. The first position in the string represents whether the collection of unit of work data is enabled. • B = Enabled and collect base unit of work data • N = Not enabled Starting from second position, each position in the string represents a specific extended option: • 2 = Package Reference List • 3 = Executable ID list Each position representing an extended option is then set to one of the following values: • Y = Extended option is included • N = Extended option is not included
COLLECTUOWDATA	CHAR (1)		Specifies what unit of work data should be collected by the applicable event monitor. • B = Collect base unit of work data • N = None • P = Collect base unit of work data and the package list This column is deprecated. Information for the column is available from COLLECTUOWDATAOPTIONS.
EXTERNALNAME	VARCHAR (128)	Y	Reserved for future use.
SECTIONACTUALSOPTIONS	VARCHAR (32)		Specifies what section actuals are collected during the execution of a section. The first position in the string represents the whether the collection of section actuals is enabled. • B = Enabled and collect basic operator cardinality counts and statistics for each object referenced by the section (DML statements only). • N = Not enabled. The second position is always 'N' and reserved for for future use.

Table 287. SYSCAT.WORKLOADS Catalog View (continued)

Column Name	Data Type	Nullable	Description
COLLECTAGGUOWDATA	CHAR (1)		Specifies what aggregate unit of work data should be captured for the workload by the applicable event monitor. • B = Collect base aggregate unit of work data • N = None
PRIORITY **Attention:** This property is available to users of Db2 v11.5.5 and later versions.	CHAR(8)	N	Specifies the WLM priority for the workload. The priority can be set to one of the following values: • CRITICAL • HIGH • MEDIUM • LOW
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.WRAPOPTIONS

Each row represents a wrapper-specific option.

Table 288. SYSCAT.WRAPOPTIONS Catalog View

Column Name	Data Type	Nullable	Description
WRAPNAME	VARCHAR (128)		Name of the wrapper.
OPTION	VARCHAR (128)		Name of the wrapper option.
SETTING	VARCHAR (2048)		Value of the wrapper option.

SYSCAT.WRAPPERS

Each row represents a registered wrapper.

Table 289. SYSCAT.WRAPPERS Catalog View

Column Name	Data Type	Nullable	Description
WRAPNAME	VARCHAR (128)		Name of the wrapper.
WRAPTYPE	CHAR (1)		Type of wrapper. • N = Non-relational • R = Relational
WRAPVERSION	INTEGER		Version of the wrapper.
LIBRARY	VARCHAR (255)		Name of the file that contains the code used to communicate with the data sources that are associated with this wrapper.
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSCAT.XDBMAPGRAPHS

Each row represents a schema graph for an XDB map (XSR object).

Table 290. SYSCAT.XDBMAPGRAPHS Catalog View

Column Name	Data Type	Nullable	Description
OBJECTID	BIGINT		Unique generated identifier for an XSR object.
OBJECTSCHEMA	VARCHAR (128)		Schema name of the XSR object.
OBJECTNAME	VARCHAR (128)		Unqualified name of the XSR object.
SCHEMAGRAPHID	INTEGER		Schema graph identifier, which is unique within an XDB map identifier.
NAMESPACE	VARCHAR (1001)	Y	String identifier for the namespace URI of the root element.
ROOTELEMENT	VARCHAR (1001)	Y	String identifier for the element name of the root element.

SYSCAT.XDBMAPSHREDTREES

Each row represents one shred tree for a given schema graph identifier.

Table 291. SYSCAT.XDBMAPSHREDTREES Catalog View

Column Name	Data Type	Nullable	Description
OBJECTID	BIGINT		Unique generated identifier for an XSR object.
OBJECTSCHEMA	VARCHAR (128)		Schema name of the XSR object.
OBJECTNAME	VARCHAR (128)		Unqualified name of the XSR object.
SCHEMAGRAPHID	INTEGER		Schema graph identifier, which is unique within an XDB map identifier.
SHREDTREEID	INTEGER		Shred tree identifier, which is unique within an XDB map identifier.
MAPPINGDESCRIPTION	CLOB (1M)	Y	Diagnostic mapping information.

SYSCAT.XMLSTRINGS

Each row represents a single string and its unique string ID, used to condense structural XML data. The string is provided in both UTF-8 encoding and database code page encoding.

Table 292. SYSCAT.XMLSTRINGS Catalog View

Column Name	Data Type	Nullable	Description
STRINGID	INTEGER		Unique string ID.
STRING	VARCHAR (1001)		The string represented in the database code page.
STRING_UTF8	VARCHAR (1001)		The string in UTF-8 encoding (as stored in the catalog table).

SYSCAT.XSROBJECTAUTH

Each row represents a user, group, or role that has been granted the USAGE privilege on a particular XSR object.

Table 293. SYSCAT.XSROBJECTAUTH Catalog View

Column Name	Data Type	Nullable	Description
GRANTOR	VARCHAR (128)		Grantor of the privilege.
GRANTORTYPE	CHAR (1)		• S = Grantor is the system • U = Grantor is an individual user
GRANTEE	VARCHAR (128)		Holder of the privilege.
GRANTEETYPE	CHAR (1)		• G = Grantee is a group • R = Grantee is a role • U = Grantee is an individual user
OBJECTID	BIGINT		Identifier for the XSR object.
USAGEAUTH	CHAR (1)		Privilege to use the XSR object and its components. • N = Not held • Y = Held

SYSCAT.XSROBJECTCOMPONENTS

Each row represents an XSR object component.

Table 294. SYSCAT.XSROBJECTCOMPONENTS Catalog View

Column Name	Data Type	Nullable	Description
OBJECTID	BIGINT		Unique generated identifier for an XSR object.
OBJECTSCHEMA	VARCHAR (128)		Schema name of the XSR object.
OBJECTNAME	VARCHAR (128)		Unqualified name of the XSR object.
COMPONENTID	BIGINT		Unique generated identifier for an XSR object component.
TARGETNAMESPACE	VARCHAR (1001)	Y	String identifier for the target namespace.
SCHEMALOCATION	VARCHAR (1001)	Y	String identifier for the schema location.
COMPONENT	BLOB (30M)		External representation of the component.
CREATE_TIME	TIMESTAMP		Time at which the XSR object component was registered.
STATUS	CHAR (1)		Registration status. • C = Complete • I = Incomplete

SYSCAT.XSROBJECTDEP

Each row represents a dependency of an XSR object on some other object. The XSR object depends on the object of type BTYPE of name BNAME, so a change to the object affects the XSR object.

Table 295. SYSCAT.XSROBJECTDEP Catalog View

Column Name	Data Type	Nullable	Description
OBJECTID	BIGINT		Unique generated identifier for an XSR object.
OBJECTSCHEMA	VARCHAR (128)		Schema name of the XSR object.
OBJECTNAME	VARCHAR (128)		Unqualified name of the XSR object.
BTYPE	CHAR (1)		Type of object on which there is a dependency. Possible values are: • A = Table alias • B = Trigger • C = Column • F = Routine • G = Global temporary table • H = Hierachy table • I = Index • K = Package • L = Detached table • N = Nickname • O = Privilege dependency on all subtables or subviews in a table or view hierarchy • Q = Sequence • R = User-defined data type • S = Materialized query table • T = Table (not typed) • U = Typed table • V = View (not typed) • W = Typed view • X = Index extension • Z = XSR object • m = Module • q = Sequence alias • u = Module alias • v = Global variable • * = Anchored to the row of a base table
BSCHEMA	VARCHAR (128)		Schema name of the object on which there is a dependency.
BMODULENAME	VARCHAR (128)	Y	Unqualified name of the module to which the object on which a dependency belongs. The null value if not a module object.

Table 295. SYSCAT.XSROBJECTDEP Catalog View (continued)

Column Name	Data Type	Nullable	Description
BNAME	VARCHAR (128)		Unqualified name of the object on which there is a dependency. For routines (BTYPE = 'F'), this is the specific name.
BMODULEID	INTEGER	Y	Identifier for the module of the object on which there is a dependency.
TABAUTH	SMALLINT	Y	If BTYPE = 'O', 'S', 'T', 'U', 'V', 'W', or 'v', encodes the privileges on the table or view that are required by a dependent trigger; null value otherwise.

SYSCAT.XSROBJECTDETAILS

Each row represents an XML schema repository object.

Table 296. SYSCAT.XSROBJECTDETAILS Catalog View

Column Name	Data Type	Nullable	Description
OBJECTID	BIGINT		Unique generated identifier for an XML schema object.
OBJECTSCHEMA	VARCHAR (128)		Schema name of the XML schema object.
OBJECTNAME	VARCHAR (128)		Unqualified name of the XML schema object.
GRAMMAR	BLOB (127M)	Y	Binary representation of the grammar for the XML schema object.
PROPERTIES	BLOB (4190000)	Y	Properties document for the XML schema object.

SYSCAT.XSROBJECTHIERARCHIES

Each row represents the hierarchical relationship between an XSR object and its components.

Table 297. SYSCAT.XSROBJECTHIERARCHIES Catalog View

Column Name	Data Type	Nullable	Description
OBJECTID	BIGINT		Identifier for an XSR object.
COMPONENTID	BIGINT		Identifier for an XSR component.
HTYPE	CHAR (1)		Hierarchy type. • D = Document • N = Top-level namespace • P = Primary document
TARGETNAMESPACE	VARCHAR (1001)	Y	String identifier for the component's target namespace.
SCHEMALOCATION	VARCHAR (1001)	Y	String identifier for the component's schema location.

SYSCAT.XSROBJECTS

Each row represents an XML schema repository object.

Table 298. SYSCAT.XSROBJECTS Catalog View

Column Name	Data Type	Nullable	Description
OBJECTID	BIGINT		Unique generated identifier for an XSR object.
OBJECTSCHEMA	VARCHAR (128)		Schema name of the XSR object.
OBJECTNAME	VARCHAR (128)		Unqualified name of the XSR object.
TARGETNAMESPACE	VARCHAR (1001)	Y	String identifier for the target namespace, or public identifier.
SCHEMALOCATION	VARCHAR (1001)	Y	String identifier for the schema location, or system identifier.
OBJECTINFO	XML	Y	Metadata document.
OBJECTTYPE	CHAR (1)		XSR object type. • D = DTD • E = External entity • S = XML schema
OWNER	VARCHAR (128)		Authorization ID of the owner of the XSR object.
OWNERTYPE	CHAR (1)		• S = The owner is the system • U = The owner is an individual user
CREATE_TIME	TIMESTAMP		Time at which the object was registered.
ALTER_TIME	TIMESTAMP		Time at which the object was last updated (replaced).
STATUS	CHAR (1)		Registration status. • C = Complete • I = Incomplete • R = Replace • T = Temporary
DECOMPOSITION	CHAR (1)		Indicates whether or not decomposition (shredding) is enabled on this XSR object. • N = Not enabled • X = Inoperative • Y = Enabled
REMARKS	VARCHAR (254)	Y	User-provided comments, or the null value.

SYSIBM.SYSDUMMY1

Contains one row. This view is available for applications that require compatibility with Db2 for z/OS.

Table 299. SYSIBM.SYSDUMMY1 Catalog View

Column Name	Data Type	Nullable	Description
IBMREQD	CHAR (1)		'Y'

SYSSTAT.COLDIST

Each row represents the *n*th most frequent value of some column, or the *n*th quantile (cumulative distribution) value of the column. Applies to columns of real tables only (not views). No statistics are recorded for inherited columns of typed tables.

Table 300. SYSSTAT.COLDIST Catalog View

Column Name	Data Type	Nullable	Updat-able	Description
TABSCHEMA	VARCHAR (128)			Schema name of the table to which the statistics apply.
TABNAME	VARCHAR (128)			Unqualified name of the table to which the statistics apply.
COLNAME	VARCHAR (128)			Name of the column to which the statistics apply.
TYPE	CHAR (1)			• F = Frequency value • Q = Quantile value
SEQNO	SMALLINT			If TYPE = "F", *n* in this column identifies the *n*th most frequent value. If TYPE = "Q", *n* in this column identifies the *n*th quantile value.
COLVALUE[1]	VARCHAR (254)	Y	Y	Data value as a character literal or a null value.
VALCOUNT	BIGINT		Y	If TYPE = "F", VALCOUNT is the number of occurrences of COLVALUE in the column. If TYPE = "Q", VALCOUNT is the number of rows whose value is less than or equal to COLVALUE.
DISTCOUNT[2]	BIGINT	Y	Y	If TYPE = "Q", this column records the number of distinct values that are less than or equal to COLVALUE (the null value if unavailable).

Note:

1. In the catalog view, the value of COLVALUE is always shown in the database code page and can contain substitution characters. However, the statistics are gathered internally in the code page of the column's table, and will therefore use actual column values when applied during query optimization.
2. DISTCOUNT is collected only for columns that are the first key column in an index.

SYSSTAT.COLGROUPDIST

Each row represents the value of the column in a column group that makes up the *n*th most frequent value of the column group or the *n*th quantile value of the column group.

Table 301. SYSSTAT.COLGROUPDIST Catalog View

Column Name	Data Type	Nullable	Updatable	Description
COLGROUPID	INTEGER			Identifier for the column group.
TYPE	CHAR (1)			• F = Frequency value • Q = Quantile value
ORDINAL	SMALLINT			Ordinal number of the column in the column group.
SEQNO	SMALLINT			If TYPE = 'F', *n* in this column identifies the *n*th most frequent value. If TYPE = 'Q', *n* in this column identifies the *n*th quantile value.
COLVALUE	VARCHAR (254)		Y	Data value as a character literal or a null value.

SYSSTAT.COLGROUPDISTCOUNTS

Each row represents the distribution statistics that apply to the *n*th most frequent value of a column group or the *n*th quantile of a column group.

Table 302. SYSSTAT.COLGROUPDISTCOUNTS Catalog View

Column Name	Data Type	Nullable	Updatable	Description
COLGROUPID	INTEGER			Identifier for the column group.
TYPE	CHAR (1)			• F = Frequency value • Q = Quantile value
SEQNO	SMALLINT			Sequence number *n* representing the *n*th TYPE value.
VALCOUNT	BIGINT		Y	If TYPE = 'F', VALCOUNT is the number of occurrences of COLVALUE for the column group with this SEQNO. If TYPE = 'Q', VALCOUNT is the number of rows whose value is less than or equal to COLVALUE for the column group with this SEQNO.
DISTCOUNT	BIGINT		Y	If TYPE = 'Q', this column records the number of distinct values that are less than or equal to COLVALUE for the column group with this SEQNO (the null value if unavailable).

SYSSTAT.COLGROUPS

Each row represents a column group and statistics that apply to the entire column group.

Table 303. SYSSTAT.COLGROUPS Catalog View

Column Name	Data Type	Nullable	Updat-able	Description
COLGROUPSCHEMA	VARCHAR (128)			Schema name of the column group.
COLGROUPNAME	VARCHAR (128)			Unqualified name of the column group.
COLGROUPID	INTEGER			Identifier for the column group.
COLGROUPCARD	BIGINT		Y	Cardinality of the column group.
NUMFREQ_VALUES	SMALLINT			Number of frequent values collected for the column group.
NUMQUANTILES	SMALLINT			Number of quantiles collected for the column group.

SYSSTAT.COLUMNS

Each row represents a column defined for a table, view, or nickname.

Table 304. SYSSTAT.COLUMNS Catalog View

Column Name	Data Type	Nullable	Updat-able	Description
TABSCHEMA	VARCHAR (128)			Schema name of the table, view, or nickname that contains the column.
TABNAME	VARCHAR (128)			Unqualified name of the table, view, or nickname that contains the column.
COLNAME	VARCHAR (128)			Name of the column.
COLCARD	BIGINT		Y	Number of distinct values in the column; -1 if statistics are not collected; -2 for inherited columns and columns of hierarchy tables.
HIGH2KEY[1]	VARCHAR (254)	Y	Y	Second-highest data value. Representation of numeric data changed to character literals. Empty if statistics are not collected. Empty for inherited columns and columns of hierarchy tables.
LOW2KEY[1]	VARCHAR (254)	Y	Y	Second-lowest data value. Representation of numeric data changed to character literals. Empty if statistics are not collected. Empty for inherited columns and columns of hierarchy tables.

Table 304. SYSSTAT.COLUMNS Catalog View (continued)

Column Name	Data Type	Nullable	Updat-able	Description
AVGCOLLEN	INTEGER		Y	Average space in bytes when the column is stored in database memory or a temporary table. For LOB data types that are not inlined, LONG data types, and XML documents, the value used to calculate the average column length is the length of the data descriptor. An extra byte is required if the column is nullable; -1 if statistics have not been collected; -2 for inherited columns and columns of hierarchy tables. Note: The average space required to store the column on disk may be different than the value represented by this statistic.
NUMNULLS	BIGINT		Y	Number of null values in the column; -1 if statistics are not collected.
PCTINLINED	SMALLINT			Percentage of inlined data for columns with VARCHAR, VARGRAPHIC, LOB, or XML data types. -1 if statistics have not been collected or the column data type does not support storing data outside the row. Also -1 for VARCHAR and VARGRAPHIC column if the table is organized by column or the table is organized by row and the row size of the table does not exceed the maximum record length for the page size of the table space.
SUB_COUNT	SMALLINT		Y	Average number of sub-elements in the column. Applicable to character string columns only.
SUB_DELIM_LENGTH	SMALLINT		Y	Average length of the delimiters that separate each sub-element in the column. Applicable to character string columns only.
AVGCOLLENCHAR	INTEGER		Y	Average number of characters (based on the collation in effect for the column) required for the column; -1 if the data type of the column is long, LOB, or XML or if statistics have not been collected; -2 for inherited columns and columns of hierarchy tables.

Table 304. SYSSTAT.COLUMNS Catalog View (continued)

Column Name	Data Type	Nullable	Updat-able	Description
PCTENCODED	SMALLINT		Y	Percentage of values that are encoded as a result of compression for a column in a column-organized table; -1 if the table is not organized by column or if statistics are not collected; -2 for inherited columns and columns of hierarchy tables.
PAGEVARIANCERATIO	DOUBLE		Y	Reserved for future use.
AVGENCODEDCOLLEN	DOUBLE		Y	Average space in bytes when the column is stored in database memory, taking into account that some of the column values might be compressed; -1 if the table is not organized by column or if statistics are not collected; -2 for inherited columns and columns of hierarchy tables.

Note:

1. In the catalog view, the values of HIGH2KEY and LOW2KEY are always shown in the database code page and can contain substitution characters. However, the statistics are gathered internally in the code page of the column's table, and will therefore use actual column values when applied during query optimization.

SYSSTAT.INDEXES

Each row represents an index. Indexes on typed tables are represented by two rows: one for the "logical index" on the typed table, and one for the "H-index" on the hierarchy table.

Table 305. SYSSTAT.INDEXES Catalog View

Column Name	Data Type	Nullable	Updat-able	Description
INDSCHEMA	VARCHAR (128)			Schema name of the index.
INDNAME	VARCHAR (128)			Unqualified name of the index.
TABSCHEMA	VARCHAR (128)			Schema name of the table or nickname on which the index is defined.
TABNAME	VARCHAR (128)			Unqualified name of the table or nickname on which the index is defined.
COLNAMES	VARCHAR (640)			This column is no longer used and will be removed in the next release. Use SYSCAT.INDEXCOLUSE for this information.
NLEAF	BIGINT		Y	Number of leaf pages; -1 if statistics are not collected.
NLEVELS	SMALLINT		Y	Number of index levels; -1 if statistics are not collected.

Table 305. SYSSTAT.INDEXES Catalog View (continued)

Column Name	Data Type	Nullable	Updat-able	Description
FIRSTKEYCARD	BIGINT		Y	Number of distinct first-key values; -1 if statistics are not collected.
FIRST2KEYCARD	BIGINT		Y	Number of distinct keys using the first two columns of the index; -1 if statistics are not collected, or if not applicable.
FIRST3KEYCARD	BIGINT		Y	Number of distinct keys using the first three columns of the index; -1 if statistics are not collected, or if not applicable.
FIRST4KEYCARD	BIGINT		Y	Number of distinct keys using the first four columns of the index; -1 if statistics are not collected, or if not applicable.
FULLKEYCARD	BIGINT		Y	Number of distinct full-key values; -1 if statistics are not collected.
CLUSTERRATIO[4]	SMALLINT		Y	Degree of data clustering with the index; -1 if statistics are not collected or if detailed index statistics are collected (in which case, CLUSTERFACTOR will be used instead).
CLUSTERFACTOR[4]	DOUBLE		Y	Finer measurement of the degree of clustering; -1 if statistics are not collected or if the index is defined on a nickname.
SEQUENTIAL_PAGES	BIGINT		Y	Number of leaf pages located on disk in index key order with few or no large gaps between them; -1 if statistics are not collected.
DENSITY	INTEGER		Y	Ratio of SEQUENTIAL_PAGES to number of prefetched pages. Expressed as a percentage; -1 if statistics are not collected.
PAGE_FETCH_PAIRS[4]	VARCHAR (520)		Y	A list of pairs of integers, represented in character form. Each pair represents the number of pages in a hypothetical buffer, and the number of page fetches required to scan the table with this index using that hypothetical buffer. Zero-length string if no data is available.
NUMRIDS[4]	BIGINT		Y	Total number of row identifiers (RIDs) or block identifiers (BIDs) in the index; -1 if not known.

Table 305. SYSSTAT.INDEXES Catalog View (continued)

Column Name	Data Type	Nullable	Updat-able	Description
NUMRIDS_DELETED[4]	BIGINT		Y	Total number of row identifiers (or block identifiers) in the index that are marked deleted, excluding those identifiers on leaf pages on which all the identifiers are marked deleted.
NUM_EMPTY_LEAFS	BIGINT		Y	Total number of index leaf pages that have all of their row identifiers (or block identifiers) marked deleted.
AVERAGE_RANDOM_ FETCH_PAGES[1,2,4]	DOUBLE		Y	Average number of random table pages between sequential page accesses when fetching using the index; -1 if not known.
AVERAGE_RANDOM_ PAGES[2]	DOUBLE		Y	Average number of random table pages between sequential page accesses; -1 if not known.
AVERAGE_SEQUENCE_ GAP[2]	DOUBLE		Y	Gap between index page sequences. Detected through a scan of index leaf pages, each gap represents the average number of index pages that must be randomly fetched between sequences of index pages; -1 if not known.
AVERAGE_SEQUENCE_ FETCH_GAP[1,2,4]	DOUBLE		Y	Gap between table page sequences when fetching using the index. Detected through a scan of index leaf pages, each gap represents the average number of table pages that must be randomly fetched between sequences of table pages; -1 if not known.
AVERAGE_SEQUENCE_ PAGES[2]	DOUBLE		Y	Average number of index pages that are accessible in sequence (that is, the number of index pages that the prefetchers would detect as being in sequence); -1 if not known.
AVERAGE_SEQUENCE_ FETCH_PAGES[1,2,4]	DOUBLE		Y	Average number of table pages that are accessible in sequence (that is, the number of table pages that the prefetchers would detect as being in sequence) when fetching using the index; -1 if not known.
AVGPARTITION_ CLUSTERRATIO[3,4]	SMALLINT		Y	Degree of data clustering within a single data partition. -1 if the table is not partitioned, if statistics are not collected, or if detailed statistics are collected (in which case AVGPARTITION_ CLUSTERFACTOR will be used instead).

Table 305. SYSSTAT.INDEXES Catalog View (continued)

Column Name	Data Type	Nullable	Updat-able	Description
AVGPARTITION_ CLUSTERFACTOR[3,4]	DOUBLE		Y	Finer measurement of the degree of clustering within a single data partition. -1 if the table is not partitioned, if statistics are not collected, or if the index is defined on a nickname.
AVGPARTITION_PAGE_ FETCH_PAIRS[3,4]	VARCHAR (520)		Y	A list of paired integers in character form. Each pair represents a potential buffer pool size and the corresponding page fetches required to access a single data partition from the table. Zero-length string if no data is available, or if the table is not partitioned.
DATAPARTITION_ CLUSTERFACTOR	DOUBLE		Y	A statistic measuring the "clustering" of the index keys with regard to data partitions. It is a number between 0 and 1, with 1 representing perfect clustering and 0 representing no clustering.
INDCARD	BIGINT		Y	Cardinality of the index. This might be different from the cardinality of the table for indexes that do not have a one-to-one relationship between the table rows and the index entries.
PCTPAGESSAVED	SMALLINT			Approximate percentage of pages saved in the index as a result of index compression. -1 if statistics are not collected.
AVGLEAFKEYSIZE	INTEGER		Y	Average index key size for keys on leaf pages in the index.
AVGNLEAFKEYSIZE	INTEGER		Y	Average index key size for keys on non-leaf pages in the index.

Table 305. SYSSTAT.INDEXES Catalog View (continued)

Column Name	Data Type	Nullable	Updat-able	Description

Note:

1. When using DMS table spaces, this statistic cannot be computed.
2. Prefetch statistics are not gathered during a LOAD...STATISTICS USE PROFILE, or a CREATE INDEX...COLLECT STATISTICS operation, or when the database configuration parameter *seqdetect* is turned off.
3. AVGPARTITION_CLUSTERRATIO, AVGPARTITION_CLUSTERFACTOR, and AVGPARTITION_PAGE_FETCH_PAIRS measure the degree of clustering within a single data partition (local clustering). CLUSTERRATIO, CLUSTERFACTOR, and PAGE_FETCH_PAIRS measure the degree of clustering in the entire table (global clustering). Global clustering and local clustering values can diverge significantly if the table partitioning key is not a prefix of the index key, or when the table partitioning key and the index key are logically independent of each other.
4. This statistic cannot be updated if the index type is 'XPTH' (an XML path index).
5. Because logical indexes on an XML column do not have statistics, the SYSSTAT.INDEXES catalog view excludes rows whose index type is 'XVIL'.
6. There is a limitation for small and medium indexes. The density column will have values, which are not counted as described above. This behavior will not impact optimizer costing.

SYSSTAT.ROUTINES

Each row represents a user-defined routine (scalar function, table function, sourced function, method, or procedure). Does not include built-in functions.

Table 306. SYSSTAT.ROUTINES Catalog View

Column Name	Data Type	Nullable	Updat-able	Description
ROUTINESCHEMA	VARCHAR (128)			Schema name of the routine if ROUTINEMODULENAME is null; otherwise schema name of the module to which the routine belongs.
ROUTINEMODULENAME	VARCHAR (128)			Unqualified name of the module to which the routine belongs. The null value if not a module routine.
ROUTINENAME	VARCHAR (128)			Unqualified name of the routine.
ROUTINETYPE	CHAR (1)			Type of routine. • F = Function • M = Method • P = Procedure
SPECIFICNAME	VARCHAR (128)			Name of the routine instance (might be system-generated).
IOS_PER_INVOC	DOUBLE		Y	Estimated number of inputs/outputs (I/Os) per invocation; 0 is the default; -1 if not known.

Table 306. SYSSTAT.ROUTINES Catalog View (continued)

Column Name	Data Type	Nullable	Updat-able	Description
INSTS_PER_INVOC	DOUBLE		Y	Estimated number of instructions per invocation; 450 is the default; -1 if not known.
IOS_PER_ARGBYTE	DOUBLE		Y	Estimated number of I/Os per input argument byte; 0 is the default; -1 if not known.
INSTS_PER_ARGBYTE	DOUBLE		Y	Estimated number of instructions per input argument byte; 0 is the default; -1 if not known.
PERCENT_ARGBYTES	SMALLINT		Y	Estimated average percent of input argument bytes that the routine will actually read; 100 is the default; -1 if not known.
INITIAL_IOS	DOUBLE		Y	Estimated number of I/Os performed the first time that the routine is invoked; 0 is the default; -1 if not known.
INITIAL_INSTS	DOUBLE		Y	Estimated number of instructions executed the first time the routine is invoked; 0 is the default; -1 if not known.
CARDINALITY	BIGINT		Y	Predicted cardinality of a table function; -1 if not known, or if the routine is not a table function.
SELECTIVITY	DOUBLE		Y	For user-defined predicates; -1 if there are no user-defined predicates.

SYSSTAT.TABLES

Each row represents a table, view, alias, or nickname. Each table or view hierarchy has one additional row representing the hierarchy table or hierarchy view that implements the hierarchy. Catalog tables and views are included.

Table 307. SYSSTAT.TABLES Catalog View

Column Name	Data Type	Nullabl e	Updat-able	Description
TABSCHEMA	VARCHAR (128)			Schema name of the object.
TABNAME	VARCHAR (128)			Unqualified name of the object.
CARD	BIGINT		Y	Total number of rows in the table; -1 if statistics are not collected.
NPAGES	BIGINT		Y	Total number of pages on which the rows of the table exist; -1 for a view or alias, or if statistics are not collected; -2 for a subtable or hierarchy table.

Table 307. SYSSTAT.TABLES Catalog View (continued)

Column Name	Data Type	Nullable	Updatable	Description
MPAGES	BIGINT		Y	Total number of pages for table metadata. Non-zero only for a table that is organized by column; -1 for a view, an alias, or if statistics are not collected; -2 for subtables or hierarchy tables.
FPAGES	BIGINT		Y	Total number of pages; -1 for a view or alias, or if statistics are not collected; -2 for a subtable or hierarchy table.
NPARTITIONS	BIGINT			Reserved for future use.
NFILES	BIGINT			Reserved for future use.
TABLESIZE	BIGINT			Reserved for future use.
OVERFLOW	BIGINT		Y	Total number of overflow records in the table; -1 for a view or alias, or if statistics are not collected; -2 for a subtable or hierarchy table.
CLUSTERED	CHAR (1)	Y		• T = Table is clustered by insert time • Y = Table is clustered by dimensions (even if only by one dimension) • Null value = Table is not clustered by dimensions or insert time
ACTIVE_BLOCKS	BIGINT		Y	Total number of active blocks in the table, or -1. Applies to multidimensional clustering (MDC) tables or insert time clustering (ITC) tables only.
AVGCOMPRESSEDROWSIZE	SMALLINT		Y	Average length (in bytes) of compressed rows in this table; -1 if statistics are not collected.
AVGROWCOMPRESSIONRATIO	REAL		Y	For compressed rows in the table, this is the average compression ratio by row; that is, the average uncompressed row length divided by the average compressed row length; -1 if statistics are not collected.
AVGROWSIZE	SMALLINT			Average length (in bytes) of both compressed and uncompressed rows in this table; -1 if statistics are not collected.

Table 307. SYSSTAT.TABLES Catalog View (continued)

Column Name	Data Type	Nullable	Updatable	Description
PCTROWSCOMPRESSED	REAL		Y	Compressed rows as a percentage of the total number of rows in the table; -1 if statistics are not collected.
PCTPAGESSAVED	SMALLINT		N	Approximate percentage of pages saved in a row-organized table as a result of row compression. For a column-organized table, the estimate is based on the number of data pages needed to store the table in uncompressed row organization.-1 if statistics are not collected.
PCTEXTENDEDROWS	REAL			Extended rows as a percentage of the total number of rows in the table; -1 if statistics are not collected.

SQL and XML limits

The tables in this topic describe SQL and XML limits. Adhering to the most restrictive case can help you to design application programs that are easily portable.

Table 308 on page 2125 lists limits in bytes. These limits are enforced after conversion from the application code page to the database code page when creating identifiers. The limits are also enforced after conversion from the database code page to the application code page when retrieving identifiers from the database. If during either of these processes the identifier length limit is exceeded, truncation occurs, or an error is returned.

Character limits vary depending on the code page of the database and the code page of the application. For example, because the width of a UTF-8 character can range 1 - 4 bytes, the character limit for an identifier in a Unicode table whose limit is 128 bytes must range 32 - 128 characters, depending on which characters are used. If an attempt is made to create an identifier whose name is longer than the limit for this table after conversion to the database code page, an error is returned.

Applications that store identifier names must be able to handle the potentially increased size of identifiers after code page conversion occurs. When identifiers are retrieved from the catalog, they are converted to the application code page. Conversion from the database code page to the application code page can result in an identifier becoming longer than the byte limit for the table. If a host variable that is declared by the application cannot store the entire identifier after code page conversion, it is truncated. If that is unacceptable, the host variable can be increased in size to be able to accept the entire identifier name.

The same rules apply to Db2 utilities retrieving data and converting it to a user-specified code page. If a Db2 utility, such as export, is retrieving the data and forcing conversion to a user-specified code page (by using the export CODEPAGE modifier or the **DB2CODEPAGE** registry variable), and the identifier expands beyond the limit that is documented in this table because of code page conversion, an error might be returned or the identifier might be truncated.

Table 308. Identifier Length Limits

Description	Maximum in Bytes
Alias name	128
Attribute name	128

Table 308. Identifier Length Limits (continued)

Description	Maximum in Bytes
Audit policy name	128
Authorization name (can be single-byte characters only)	128
Buffer pool name	18
Column name[2]	128
Constraint name	128
Correlation name	128
Cursor name	128
Data partition name	128
Data source column name	255
Data source index name	128
Data source name	128
Data source table name (*remote-table-name*)	128
Database partition group name	128
Database partition name	128
Event monitor name	128
External program name	128
Function mapping name	128
Group name	128
Host identifier[1]	255
Identifier for a data source user (*remote-authorization-name*)	128
Identifier in an SQL procedure (condition name, for loop identifier, label, result set locator, statement name, variable name)	128
Index name	128
Index extension name	18
Index specification name	128
Label name	128
Namespace uniform resource identifier (URI)	1000
Nickname	128
Package name	128
Package version ID	64
Parameter name	128
Password to access a data source	32
Procedure name	128
Role name	128
Savepoint name	128

Table 308. Identifier Length Limits (continued)

Description	Maximum in Bytes
Schema name[2,3]	128
Security label component name	128
Security label name	128
Security policy name	128
Sequence name	128
Server (database alias) name	8
Specific name	128
SQL condition name	128
SQL variable name	128
Statement name	128
Storage Group	128
Table name	128
Table space name	18
Transform group name	18
Trigger name	128
Trusted context name	128
Type mapping name	18
User-defined function name	128
User-defined method name	128
User-defined type name[2]	128
View name	128
Wrapper name	128
XML element name, attribute name, or prefix name	1000
XML schema location uniform resource identifier (URI)	1000

Note:

1. Individual host language compilers might have a more restrictive limit on variable names.
2. The SQLDA structure is limited to storing 30-byte column names, 18-byte user-defined type names, and 8-byte schema names for user-defined types. Because the SQLDA is used in the DESCRIBE statement, embedded SQL applications that use the DESCRIBE statement to retrieve column or user-defined type name information must conform to these limits.
3. Schema names that are shorter than 8-bytes are padded with blanks and stored in the catalog as 8-byte names.

Table 309. Numeric Limits

Description	Limit
Smallest SMALLINT value	-32,768

Table 309. Numeric Limits (continued)

Description	Limit
Largest SMALLINT value	+32,767
Smallest INTEGER value	-2,147,483,648
Largest INTEGER value	+2,147,483,647
Smallest BIGINT value	-9,223,372,036,854,775,808
Largest BIGINT value	+9,223,372,036,854,775,807
Largest decimal precision	31
Maximum exponent (E_{max}) for REAL values	38
Smallest REAL value	-3.402E+38
Largest REAL value	+3.402E+38
Minimum exponent (E_{min}) for REAL values	-37
Smallest positive REAL value	+1.175E-37
Largest negative REAL value	-1.175E-37
Maximum exponent (E_{max}) for DOUBLE values	308
Smallest DOUBLE value	-1.79769E+308
Largest DOUBLE value	+1.79769E+308
Minimum exponent (E_{min}) for DOUBLE values	-307
Smallest positive DOUBLE value	+2.225E-307
Largest negative DOUBLE value	-2.225E-307
Maximum exponent (E_{max}) for DECFLOAT(16) values	384
Smallest DECFLOAT(16) value[1]	-9.999999999999999E+384
Largest DECFLOAT(16) value	9.999999999999999E+384
Minimum exponent (E_{min}) for DECFLOAT(16) values	-383
Smallest positive DECFLOAT(16) value	1.000000000000000E-383
Largest negative DECFLOAT(16) value	-1.000000000000000E-383
Maximum exponent (E_{max}) for DECFLOAT(34) values	6144
Smallest DECFLOAT(34) value[1]	-9.999999999999999999999999999999999E+6144
Largest DECFLOAT(34) value	9.999999999999999999999999999999999E+6144
Minimum exponent (E_{min}) for DECFLOAT(34) values	-6143

Table 309. Numeric Limits (continued)

Description	Limit
Smallest positive DECFLOAT(34) value	1.000000000000000000000000000000000E-6143
Largest negative DECFLOAT(34) value	-1.000000000000000000000000000000000E-6143

Note:

1. These are the limits of normal decimal floating-point numbers. Valid decimal floating-point values include the special values NAN, -NAN, SNAN, -SNAN, INFINITY, and -INFINITY. In addition, valid values include subnormal numbers.

   Subnormal numbers are nonzero numbers whose adjusted exponents are less than E_{min}. For a subnormal number, the minimum value of the exponent is E_{min} - (*precision*-1), called E_{tiny}, where *precision* is the working precision (16 or 34). That is, subnormal numbers extend the range of numbers close to zero by 15 or 33 orders of magnitude for DECFLOAT(16) or DECFLOAT(34), respectively. Subnormal numbers are different from normal numbers because the maximum number of digits for a subnormal number is less than the working precision (16 or 34). Decimal floating-point cannot represent the subnormal numbers with the same accuracy as it can represent normal numbers. The smallest positive subnormal number for DECFLOAT(34) is $1x10^{-6176}$, which contains only one digit, whereas the smallest positive normal number for DECFLOAT(34) is $1.000000000000000000000000000000000x10^{-6143}$, which contains 34 digits. The smallest positive subnormal number for DECFLOAT(16) is $1x10^{-398}$.

Table 310. String Limits

Description	Limit
Maximum length of CHAR (in bytes or OCTETS)	255
Maximum length of CHAR (in CODEUNITS32)	63
Maximum length of VARCHAR (in bytes or OCTETS)[2]	32,672
Maximum length of VARCHAR (in CODEUNITS32)[2]	8168
Maximum length of LONG VARCHAR (in bytes)[1]	32,700
Maximum length of CLOB (in bytes or OCTETS)	2,147,483,647
Maximum length of CLOB (in CODEUNITS32)	536,870,911
Maximum length of serialized XML (in bytes)	2,147,483,647
Maximum length of GRAPHIC (in double-byte characters or CODEUNITS16)	127
Maximum length of GRAPHIC (in CODEUNITS32)	63
Maximum length of VARGRAPHIC (in double-byte characters or CODEUNITS16)[2]	16,336
Maximum length of VARGRAPHIC (in CODEUNITS32)	8168
Maximum length of LONG VARGRAPHIC (in double-byte characters)[1]	16,350
Maximum length of DBCLOB (in double-byte characters or CODEUNITS16)	1,073,741,823
Maximum length of DBCLOB (in CODEUNITS32)	536,870,911
Maximum length of BINARY (in bytes)	255

Table 310. String Limits (continued)

Description	Limit
Maximum length of VARBINARY (in bytes)[2]	32,672
Maximum length of BLOB (in bytes)	2,147,483,647
Maximum length of character constant	32,672
Maximum length of graphic constant	16,336
Maximum length of concatenated character string	2,147,483,647
Maximum length of concatenated graphic string	1,073,741,823
Maximum length of concatenated binary string	2,147,483,647
Maximum number of hexadecimal constant digits	32,672
Largest instance of a structured type column object at run time (in gigabytes)	1
Maximum size of a catalog comment (in bytes)	254

Note:

1. The LONG VARCHAR and LONG VARGRAPHIC data types are deprecated and might be removed in a future release.
2. For page size-specific string limits for column-organized tables, see Table 311 on page 2130.

Table 311. Page Size-specific String Limits for Column-organized Tables

Description	4K page size limit	8K page size limit	16K page size limit	32K page size limit
Maximum length of VARCHAR (in bytes)	3920	8016	16,208	32,592
Maximum length of VARCHAR (in CODEUNITS32)	980	2004	4052	8148
Maximum length of VARGRAPHIC (in bytes)	1960	4008	8104	16,296
Maximum length of VARBINARY (in bytes)	3920	8016	16,208	32,592

Note: A column-organized table has an overhead of 176 bytes per page.

Table 312. Page Size-specific String Limits for Column-organized Tables. These limits are only applicable when you increase the column length by using ALTER TABLE

Description	4K page size limit	8K page size limit	16K page size limit	32K page size limit
Maximum length of VARCHAR (in bytes)	3888	7984	16,176	32,560
Maximum length of VARGRAPHIC (in bytes)	1944	3992	8088	16,280

Table 313. XML Limits

Description	Limit
Maximum depth of an XML document (in levels)	125
Maximum size of an XML schema document (in bytes)	31,457,280

Table 314. Datetime Limits

Description	Limit
Smallest DATE value	0001-01-01
Largest DATE value	9999-12-31
Smallest TIME value	00:00:00
Largest TIME value	24:00:00
Smallest TIMESTAMP value	0001-01-01-00.00.00.000000000000
Largest TIMESTAMP value	9999-12-31-24.00.00.000000000000
Smallest timestamp precision	0
Largest timestamp precision	12

Table 315. Database Manager Limits

Category	Description	Limit
Applications	Maximum number of host variable declarations in a precompiled program[3]	Storage. This number can go down with future versions. It is recommended to stay under 10000.
	Maximum length of a host variable value (in bytes)	2,147,483,647
	Maximum number of declared cursors in a program	storage
	Maximum number of rows that are changed in a unit of work	storage
	Maximum number of cursors that are opened at one time	storage
	Maximum number of connections per process within a database client	512
	Maximum number of simultaneously opened LOB locators in a transaction	4,194,304
	Maximum size of an SQLDA (in bytes)	storage
	Maximum number of prepared statements	storage

Table 315. Database Manager Limits (continued)

Category	Description	Limit
Buffer Pools	Maximum NPAGES in a buffer pool for 32-bit releases	1,048,576
	Maximum NPAGES in a buffer pool for 64-bit releases	2,147,483,647
	Maximum total size of all buffer pool slots (4K)	2,147,483,646
Concurrency	Maximum number of concurrent users of a server[4]	64,000
	Maximum number of concurrent users per instance	64,000
	Maximum number of concurrent applications per database	60,000
	Maximum number of databases per instance concurrently in use	256
Constraints	Maximum number of constraints on a table	storage
	Maximum number of columns in a UNIQUE constraint (supported through a UNIQUE index)	64
	Maximum combined length of columns in a UNIQUE constraint (supported through a UNIQUE index, in bytes)[8]	8192
	Maximum number of referencing columns in a foreign key	64
	Maximum combined length of referencing columns in a foreign key (in bytes)[8]	8192
	Maximum length of a check constraint specification (in bytes)	65,535
Databases	Maximum database partition number	999
	Maximum members in a Db2 pureScale environment	128

Table 315. Database Manager Limits (continued)

Category	Description	Limit
Indexes	Maximum number of indexes on a table	32,767 or storage
	Maximum number of columns in an index key	64
	Maximum length of an index key, including all overhead[6 8]	*indexpagesize*/4
	Maximum length of a variable index key part (in bytes)[7]	1022 or storage
	Maximum size of an index per database partition in an SMS table space (in terabytes)[6]	64
	Maximum size of an index per database partition in a regular DMS table space (in gigabytes)[6]	512
	Maximum size of an index per database partition in a large DMS table space (in terabytes)[6]	64
	Maximum length of a variable index key part for an index over XML data (in bytes)[7]	*pagesize*/4 - 207
Log records	Maximum Log Sequence Number	0xFFFF FFFF FFFF FFFF
Monitoring	Maximum number of simultaneously active event monitors	128
	In a partitioned database environment, maximum number of simultaneously active GLOBAL event monitors	32
Routines	Maximum number of parameters in a procedure with LANGUAGE SQL	32,767
	Maximum number of parameters in an external procedure with PROGRAM TYPE MAIN	32,767
	Maximum number of parameters in an external procedure with PROGRAM TYPE SUB	90
	Maximum number of parameters in a cursor value constructor	32,767
	Maximum number of parameters in a user-defined function	90
	Maximum number of nested levels for routines	64
	Maximum number of schemas in the SQL path	64
	Maximum length of the SQL path (in bytes)	2048
Security	Maximum number of elements in a security label component of type set or tree	64
	Maximum number of elements in a security label component of type array	65,535
	Maximum number of security label components in a security policy	16

Table 315. Database Manager Limits (continued)		
Category	**Description**	**Limit**
SQL	Maximum total length of an SQL statement (in bytes)	2,097,152
	Maximum number of tables that are referenced in an SQL statement or a view	storage
	Maximum number of host variable references in a dynamic SQL statement	32,767
	Maximum number of constants in a statement	storage
	Maximum number of elements in a select list[6]	2048
	Maximum number of predicates in a WHERE or HAVING clause	storage
	Maximum number of columns in a GROUP BY clause[6]	2048
	Maximum total length of columns in a GROUP BY clause (in bytes)[6]	32,677
	Maximum number of columns in an ORDER BY clause[6]	2048
	Maximum total length of columns in an ORDER BY clause (in bytes)[6]	32,677
	Maximum level of subquery nesting	storage
	Maximum number of subqueries in a single statement	storage
	Maximum number of values in an insert operation[6]	2048
Storage Groups	Maximum number of storage groups in a database	256
	Maximum number of storage paths in a storage group	128
	Maximum length of a storage path (in bytes)	175

Table 315. Database Manager Limits (continued)

Category	Description	Limit
Tables and Views	Maximum number of columns in a table [6] [10]	2048
	Maximum number of columns in a view[1]	5000
	Maximum number of columns in a data source table or view that is referenced by a nickname	5000
	Maximum number of columns in a distribution key[5]	500
	Maximum length of a row, including all overhead[2] [6] [9]	32,677
	Maximum number of rows in a non-partitioned table, per database partition	128×10^{10}
	Maximum number of rows in a data partition, per database partition	128×10^{10}
	Maximum size of a table per database partition in a regular table space (in gigabytes)[3] [6]	512
	Maximum size of a table per database partition in a large DMS table space (in terabytes)[6]	64
	Maximum number of data partitions for a single table	32,767
	Maximum number of table partitioning columns	16
	Maximum number of fields in a user-defined row data type	1012
Table Spaces	Maximum size of a LOB object per table or per table partition (in terabytes)	4
	Maximum size of an LF object per table or per table partition (in terabytes)	2
	Maximum number of table spaces in a database	32,768
	Maximum number of tables in an SMS table space	65,532
	Maximum size of a regular DMS table space (in gigabytes) [3] [6]	512
	Maximum size of a large DMS table space (in terabytes) [3] [6]	64
	Maximum size of a temporary DMS table space (in terabytes) [3] [6]	64
	Maximum number of table objects in a DMS table space	See Table 316 on page 2136
Triggers	Maximum runtime depth of cascading triggers	16
User-defined Types	Maximum number of attributes in a structured type	4082

Table 315. Database Manager Limits (continued)

Category	Description	Limit
Workload Manager	Maximum number of user-defined service superclasses per database	64
	Maximum number of user-defined service subclasses per service superclass	61
Open Files	Maximum number of files opened by a single Db2 instance. This includes, but not limited to, table space container files and transaction log files for all databases in the instance. In addition, the operating system might impose a lower limit.	65534

Note:

1. This maximum can be achieved by using a join in the CREATE VIEW statement. Selecting from such a view is subject to the limit of most elements in a select list.
2. The actual data for BLOB, CLOB, LONG VARCHAR, DBCLOB, and LONG VARGRAPHIC columns are not included in this count. However, information about the location of that data does take up some space in the row.
3. The numbers that are shown are architectural limits and approximations. The practical limits might be less.
4. The actual value is controlled by the **max_connections** and **max_coordagents** database manager configuration parameters.
5. This is an architectural limit. The limit on the most columns in an index key should be used as the practical limit.
6. For page size-specific values, see Table 316 on page 2136.
7. This is limited only by the longest index key, including all overhead (in bytes). As the number of index key parts increases, the maximum length of each key part decreases.
8. The maximum can be less, depending on index options.
9. If the **extended_row_sz** database configuration parameter is set to ENABLE and there are VARCHAR, VARBINARY, or VARGRAPHIC columns in the table, the maximum row size is 1,048,319 bytes, which includes all overhead.
10. Must account for columns that are generated internally by the database manager. The RANDOM_DISTRIBUTION_KEY is an example: it is created for random distribution tables that use the random by generation method.

Table 316. Database Manager Page Size-specific Limits

Description	4K page size limit	8K page size limit	16K page size limit	32K page size limit
Maximum number of table objects in a DMS table space[1]	51,971[2] 53,212[3]	53,299	53,747	54,264
Maximum number of columns in a row-organized table	500	1012	1012	2048
Maximum number of columns in a column-organized table	2048	2048	2048	2048
Maximum length of a row in a row-organized table, including all overhead	4005	8101	16,293	32,677

Table 316. Database Manager Page Size-specific Limits (continued)

Description	4K page size limit	8K page size limit	16K page size limit	32K page size limit
Maximum length of a row in a column-organized table, including all overhead	1,048,319	1,048,319	1,048,319	1,048,319
Maximum size of a table per database partition in a regular table space (in gigabytes)	64	128	256	512
Maximum size of a table per database partition in a large DMS table space (in terabytes)	8	16	32	64
Maximum length of an index key, including all overhead (in bytes)	1024	2048	4096	8192
Maximum size of an index per database partition in an SMS table space (in terabytes)	8	16	32	64
Maximum size of an index per database partition in a regular DMS table space (in gigabytes)	64	128	256	512
Maximum size of an index per database partition in a large DMS table space (in terabytes)	8	16	32	64
Maximum size of a regular DMS table space per database partition (in gigabytes)	64	128	256	512
Maximum size of a large DMS table space (in terabytes)	8	16	32	64
Maximum size of a temporary DMS table space (in terabytes)	8	16	32	64
Maximum number of elements in a select list	500[4]	1012[5]	1012[5]	2048
Maximum number of columns in a GROUP BY clause	500	1012[5]	1012[5]	2048
Maximum total length of columns in a GROUP BY clause (in bytes)	4005	8101	16,293	32,677
Maximum number of columns in an ORDER BY clause	500	1012[5]	1012[5]	2048
Maximum total length of columns in an ORDER BY clause (in bytes)	4005	8101	16,293	32,677
Maximum number of values in an insert operation	500	1012[5]	1012[5]	2048
Maximum number of SET clauses in a single update operation	500	1012[5]	1012[5]	2048
Maximum records per page for a regular table space	251	253	254	253

Table 316. Database Manager Page Size-specific Limits (continued)

Description	4K page size limit	8K page size limit	16K page size limit	32K page size limit
Maximum records per page for a large table space	287	580	1165	2335

Note:

1. Table objects include table data, indexes, LONG VARCHAR columns, LONG VARGRAPHIC columns, and LOB columns. Table objects that are in the same table space as the table data do not count extra toward the limit. However, each table object that is in a different table space than the table data does contribute one toward the limit for each table object type per table in the table space in which the table object resides.
2. When extent size is two pages.
3. When extent size is any size other than two pages.
4. In cases where the only system temporary table space is 4KB and the data overflows to the sort buffer, an error is generated. If the result set can fit into memory, there is no error.
5. May be up to 2048 for columnar tables.

Reserved schema names and reserved words

There are restrictions on the use of certain names that are required by the database manager.

In some cases, names are reserved, and cannot be used by application programs. In other cases, certain names are not recommended for use by application programs, although their use is not prevented by the database manager.

The reserved schema names are:

- SYSCAT
- SYSFUN
- SYSIBM
- SYSIBMADM
- SYSPROC
- SYSPUBLIC
- SYSSTAT

It is strongly recommended that schema names never begin with the 'SYS' prefix, because 'SYS', by convention, is used to indicate an area that is reserved by the system. No aliases, global variables, triggers, user-defined functions, or user-defined types can be placed into a schema whose name starts with 'SYS' (SQLSTATE 42939).

The DB2QP schema and the SYSTOOLS schema are set aside for utilities used by the database. It is recommended that users not explicitly define objects in these schemas, although their use is not prevented by the database manager.

It is recommended that schema names never begin with the 'Q' prefix, because on other Db2 database managers 'Q', by convention, is used to indicate an area reserved by the system.

It is also recommended that SESSION not be used as a schema name. Because declared temporary tables must be qualified by SESSION, it is possible to have an application declare a temporary table with a name that is identical to that of a persistent table, complicating the application logic. To avoid this possibility, do not use the schema SESSION except when dealing with declared temporary tables.

Keywords can be used as ordinary identifiers, except in a context where they could also be interpreted as SQL keywords. In such cases, the word must be specified as a delimited identifier. For example, COUNT cannot be used as a column name in a SELECT statement, unless it is delimited.

ISO/ANSI SQL2003 and other IBM database products include reserved words that are not enforced by Db2; however, it is recommended that these words not be used as ordinary identifiers, because it reduces portability.

For portability across the IBM database products, the following words should be considered reserved words:

```
ACTIVATE                DOUBLE                LOCALE
RESULT                            WLM
ADD                     DROP                  LOCALTIME
RESULT_SET_LOCATOR                WRITE
AFTER                   DSSIZE                LOCALTIMESTAMP
RETURN                            XMLELEMENT
ALIAS                   DYNAMIC               LOCATOR
RETURNS                           XMLEXISTS
ALL                     EACH                  LOCATORS
REVOKE                            XMLNAMESPACES
ALLOCATE                EDITPROC              LOCK
RIGHT                             YEAR
ALLOW                   ELSE                  LOCKMAX
ROLE                              YEARS
ALTER                   ELSEIF                LOCKSIZE              ROLLBACK

[1] As of Db2 Version 11.1.0.0, **FIRST** is a SQL keyword in some expression contexts, for example, within an OLAP specification. This means **FIRST**, when used as an identifier, must be delimited when used within these contexts.

[2] As of Db2 Version 11.1.1.1, **NOT** is a valid operator in certain contexts, for example, within a select-list. This means **NOT**, when used as an identifier, must be delimited when used within these contexts.

```

Communications areas, descriptor areas, and exception tables

SQLCA (SQL communications area)

An SQLCA is a collection of variables that is updated at the end of the execution of every SQL statement.

A program that contains executable SQL statements and is precompiled with option LANGLEVEL SAA1 (the default) or MIA must provide exactly one SQLCA, though more than one SQLCA is possible by having one SQLCA per thread in a multi-threaded application.

When a program is precompiled with option LANGLEVEL SQL92E, an SQLCODE or SQLSTATE variable may be declared in the SQL declare section or an SQLCODE variable can be declared somewhere in the program.

An SQLCA should not be provided when using LANGLEVEL SQL92E. The SQL INCLUDE statement can be used to provide the declaration of the SQLCA in all languages but REXX. The SQLCA is automatically provided in REXX.

To display the SQLCA after each command executed through the command line processor, issue the command db2 -a. The SQLCA is then provided as part of the output for subsequent commands. The SQLCA is also dumped in the **db2diag** log file.

SQLCA field descriptions

Table 317. Fields of the SQLCA. The field names shown are those present in an SQLCA that is obtained via an INCLUDE statement.

Name	Data Type	Field Values
sqlcaid	CHAR(8)	An "eye catcher" for storage dumps containing "SQLCA". The sixth byte is "L" if line number information is returned from parsing an SQL routine, SQL trigger, or dynamic compound SQL statement. The sixth byte is "M" if the line number and object ID information is returned from executing a compiled SQL routine, compiled SQL trigger, or dynamic compound SQL (compiled) statement.
sqlcabc	INTEGER	Contains the length of the SQLCA, 136.

Table 317. Fields of the SQLCA. The field names shown are those present in an SQLCA that is obtained via an INCLUDE statement. *(continued)*

Name	Data Type	Field Values
sqlcode	INTEGER	Contains the SQL return code: **0** Successful execution (although one or more SQLWARN indicators may be set). **positive** Successful execution, but with a warning condition. **negative** Error condition.
sqlerrml	SMALLINT	Length indicator for *sqlerrmc*, in the range 0 through 70. 0 means that the value of *sqlerrmc* is not relevant.
sqlerrmc	VARCHAR (70)	Contains one or more tokens, separated by X'FF', which are substituted for variables in the descriptions of error conditions. This field is also used when a successful connection is completed. When a NOT ATOMIC compound SQL statement is issued, it can contain information about seven or fewer errors. The last token might be followed by X'FF'. The *sqlerrml* value will include any trailing X'FF'.
sqlerrp	CHAR(8)	Starting with V11.1, the format of the SQLERRP field is changed to **SQL*vvrrmm***, where: • ***vv*** represents the version number • ***rr*** represents the release number • ***m*** represents the modification value The following examples illustrate the relationship between the product signature and the new token in the SQLERRP field. All subsequent fix packs for a given Mod Pack return the same SQLERRP value. **Product signature** / **SQLERRP token** Db2 10.5.0.7 — SQL10057 Db2 11.0.0.0 — SQL11010 Db2 11.1.1.1 — SQL11011 Db2 11.1.2.0 — SQL11012
sqlerrd	ARRAY	Six INTEGER variables that provide diagnostic information. These values are generally empty if there are no errors, except for sqlerrd(6) from a partitioned database.
sqlerrd(1)	INTEGER	If connection is invoked and successful, contains the maximum expected difference in length of mixed character data (CHAR data types) when converted to the database code page from the application code page. A value of 0 or 1 indicates no expansion; a value greater than 1 indicates a possible expansion in length; a negative value indicates a possible contraction. On successful return from an SQL procedure, contains the return status value from the SQL procedure.

Table 317. Fields of the SQLCA. The field names shown are those present in an SQLCA that is obtained via an INCLUDE statement. *(continued)*

Name	Data Type	Field Values
sqlerrd(2)	INTEGER	If connection is invoked and successful, contains the maximum expected difference in length of mixed character data (CHAR data types) when converted to the application code page from the database code page. A value of 0 or 1 indicates no expansion; a value greater than 1 indicates a possible expansion in length; a negative value indicates a possible contraction. If the SQLCA results from a NOT ATOMIC compound SQL statement that encountered one or more errors, the value is set to the number of statements that failed.
sqlerrd(3)	INTEGER	If PREPARE is invoked and successful, contains an estimate of the number of rows that will be returned. After INSERT, UPDATE, DELETE, or MERGE, contains the actual number of rows that qualified for the operation. For a TRUNCATE statement, the value will be -1. If compound SQL is invoked, contains an accumulation of all sub-statement rows. If CONNECT is invoked, contains 1 if the database can be updated, or 2 if the database is read only. If the OPEN statement is invoked, and the cursor contains SQL data change statements, this field contains the sum of the number of rows that qualified for the embedded insert, update, delete, or merge operations. If an error is encountered during the compilation of an SQL routine, trigger, or dynamic compound SQL (inlined or compiled) statement, sqlerrd(3) contains the line number where the error was encountered. The sixth byte of sqlcaid must be "L" for this entry to be a valid line number. If an error is encountered during the execution of a compiled SQL routine, trigger, or dynamic SQL (compiled) statement, sqlerrd(3) contains the line number where the error was raised. The sixth byte of sqlcaid must be "M" for this to be a valid line number.
sqlerrd(4)	INTEGER	If PREPARE is invoked and successful , contains a relative cost estimate of the resources required to process the statement. If compound SQL is invoked, contains a count of the number of successful sub-statements. If CONNECT is invoked, contains 0 for a one-phase commit from a client which is not at the latest level; 1 for a one-phase commit; 2 for a one-phase, read-only commit; and 3 for a two-phase commit. If an error is encountered during the execution of a compiled SQL routine or trigger, sqlerrd(4) contains an integer number that uniquely identifies the routine or trigger within which the error was raised. The sixth byte of sqlcaid must be "M" for this entry to be a valid line number

Table 317. Fields of the SQLCA. The field names shown are those present in an SQLCA that is obtained via an INCLUDE statement. *(continued)*

Name	Data Type	Field Values
sqlerrd(5)	INTEGER	Contains the total number of rows deleted, inserted, or updated as a result of both: • The enforcement of constraints after a successful delete operation • The processing of triggered SQL statements from activated inlined triggers If compound SQL is invoked, contains an accumulation of the number of such rows for all sub-statements. In some cases, when an error is encountered, this field contains a negative value that is an internal error pointer. If CONNECT is invoked, contains an authentication type value: • 0 for server authentication • 1 for client authentication • 2 for authentication using Db2 Connect • 4 for SERVER_ENCRYPT authentication • 5 for authentication using Db2 Connect with encryption; • 7 for KERBEROS authentication • 9 for GSSPLUGIN authentication • 11 for DATA_ENCRYPT authentication • 255 for unspecified authentication. **Important:** The DATA_ENCRYPT authentication type is deprecated and might be removed in a future release. To encrypt data in-transit between clients and Db2 databases, we recommend that you use the Db2 database system support of Transport Layer Security (TLS). For more information, see Encryption of data in transit
sqlerrd(6)	INTEGER	For a partitioned database, contains the partition number of the database partition that encountered the error or warning. If no errors or warnings were encountered, this field contains the partition number of the coordinator partition. The number in this field is the same as that specified for the database partition in the db2nodes.cfg file.
sqlwarn	Array	A set of warning indicators, each containing a blank or W. If compound SQL is invoked, contains an accumulation of the warning indicators set for all sub-statements.
sqlwarn0	CHAR(1)	Blank if all other indicators are blank; contains "W" if at least one other indicator is not blank.
sqlwarn1	CHAR(1)	Contains "W" if the value of a string column was truncated when assigned to a host variable. Contains "N" if the null terminator was truncated. Contains "A" if the CONNECT or ATTACH is successful, and the authorization name for the connection is longer than 8 bytes. Contains "P" if the PREPARE statement relative cost estimate stored in sqlerrd(4) exceeded the value that could be stored in an INTEGER or was less than 1, and either the CURRENT EXPLAIN MODE or the CURRENT EXPLAIN SNAPSHOT special register is set to a value other than NO.

Table 317. Fields of the SQLCA. The field names shown are those present in an SQLCA that is obtained via an INCLUDE statement. *(continued)*

Name	Data Type	Field Values
sqlwarn2	CHAR(1)	Contains "W" if null values were eliminated from the argument of an aggregate function. [a] If CONNECT is invoked and successful, contains "D" if the database is in quiesce state, or "I" if the instance is in quiesce state.
sqlwarn3	CHAR(1)	Contains "W" if the number of columns is not equal to the number of host variables. Contains "Z" if the number of result set locators specified on the ASSOCIATE LOCATORS statement is less than the number of result sets returned by a procedure.
sqlwarn4	CHAR(1)	Contains "W" if a prepared UPDATE or DELETE statement does not include a WHERE clause.
sqlwarn5	CHAR(1)	Contains "E" if an error was tolerated during SQL statement execution.
sqlwarn6	CHAR(1)	Contains "W" if the result of a date calculation was adjusted to avoid an impossible date.
sqlwarn7	CHAR(1)	If CONNECT is invoked and successful, contains a "B" if the server is **BigSQL**, or "D" if the server is **Db2 Warehouse on Cloud**.
sqlwarn8	CHAR(1)	Contains "W" if a character that could not be converted was replaced with a substitution character. Contains "Y" if there was an unsuccessful attempt to establish a trusted connection.
sqlwarn9	CHAR(1)	Contains "W" if arithmetic expressions with errors were ignored during aggregate function processing.
sqlwarn10	CHAR(1)	Contains "W" if there was a conversion error when converting a character data value in one of the fields in the SQLCA.
sqlstate	CHAR(5)	A return code that indicates the outcome of the most recently executed SQL statement.

[a] Some functions may not set SQLWARN2 to W, even though null values were eliminated, because the result was not dependent on the elimination of null values.

Error reporting

The order of error reporting is:

1. Severe error conditions are always reported. When a severe error is reported, there are no additions to the SQLCA.
2. If no severe error occurs, a deadlock error takes precedence over other errors.
3. For all other errors, the SQLCA for the first negative SQL code is returned.
4. If no negative SQL codes are detected, the SQLCA for the first warning (that is, positive SQL code) is returned.

   In a partitioned database system, the exception to this rule occurs if a data manipulation operation is invoked against a table that is empty on one database partition, but has data on other database partitions. SQLCODE +100 is only returned to the application if agents from all database partitions return SQL0100W, either because the table is empty on all database partitions, or there are no more rows that satisfy the WHERE clause in an UPDATE statement.

SQLCA usage in partitioned database systems

In partitioned database systems, one SQL statement may be executed by a number of agents on different database partitions, and each agent may return a different SQLCA for different errors or warnings. The coordinator agent also has its own SQLCA.

To provide a consistent view for applications, all SQLCA values are merged into one structure, and SQLCA fields indicate global counts, such that:

- For all errors and warnings, the *sqlwarn* field contains the warning flags received from all agents.
- Values in the *sqlerrd* fields indicating row counts are accumulations from all agents.

Note: SQLSTATE 09000 might not be returned every time an error occurs during the processing of a triggered SQL statement.

SQLDA (SQL descriptor area)

An SQLDA is a collection of variables that is required for execution of the SQL DESCRIBE statement.

The SQLDA variables are options that can be used by the PREPARE, OPEN, FETCH, and EXECUTE statements. An SQLDA communicates with dynamic SQL; it can be used in a DESCRIBE statement, modified with the addresses of host variables, and then reused in a FETCH or EXECUTE statement.

SQLDAs are supported for all languages, but predefined declarations are provided only for C, REXX, FORTRAN, and COBOL.

The meaning of the information in an SQLDA depends on its use. In PREPARE and DESCRIBE, an SQLDA provides information to an application program about a prepared statement. In OPEN, EXECUTE, and FETCH, an SQLDA describes host variables.

In DESCRIBE and PREPARE, if any one of the columns being described is either a LOB type (LOB locators and file reference variables do not require doubled SQLDAs), reference type, or a user-defined type, the number of SQLVAR entries for the entire SQLDA will be doubled. For example:

- When describing a table with 3 VARCHAR columns and 1 INTEGER column, there will be 4 SQLVAR entries
- When describing a table with 2 VARCHAR columns, 1 CLOB column, and 1 integer column, there will be 8 SQLVAR entries

In EXECUTE, FETCH, and OPEN, if any one of the variables being described is a LOB type (LOB locators and file reference variables do not require doubled SQLDAs) or a structured type, the number of SQLVAR entries for the entire SQLDA must be doubled. (Distinct types and reference types are not relevant in these cases, because the additional information in the double entries is not required by the database. Array, cursor and row types are not supported as SQLDA variables in EXECUTE, FETCH and OPEN statements.)

SQLDA field descriptions

An SQLDA consists of four variables followed by an arbitrary number of occurrences of a sequence of variables collectively named SQLVAR. In OPEN, FETCH, and EXECUTE, each occurrence of SQLVAR describes a host variable. In DESCRIBE and PREPARE, each occurrence of SQLVAR describes a column of a result table or a parameter marker. There are two types of SQLVAR entries:

- **Base SQLVARs:** These entries are always present. They contain the base information about the column, parameter marker, or host variable such as data type code, length attribute, column name, host variable address, and indicator variable address.
- **Secondary SQLVARs:** These entries are only present if the number of SQLVAR entries is doubled as per the rules outlined previously. For user-defined types (excluding reference types), they contain the user-defined type name. For reference types, they contain the target type of the reference. For LOBs, they contain the length attribute of the host variable and a pointer to the buffer that contains the actual length. (The distinct type and LOB information does not overlap, so distinct types can be based on LOBs

without forcing the number of SQLVAR entries on a DESCRIBE to be tripled.) If locators or file reference variables are used to represent LOBs, these entries are not necessary.

In SQLDAs that contain both types of entries, the base SQLVARs are in a block before the block of secondary SQLVARs. In each, the number of entries is equal to the value in SQLD (even though many of the secondary SQLVAR entries may be unused).

The circumstances under which the SQLVAR entries are set by DESCRIBE is detailed in "Effect of DESCRIBE on the SQLDA" on page 2151.

Fields in the SQLDA header

Table 318. Fields in the SQLDA Header

C Name	SQL Data Type	Usage in DESCRIBE and PREPARE (set by the database manager except for SQLN)	Usage in FETCH, OPEN, and EXECUTE (set by the application before executing the statement)
sqldaid	CHAR(8)	The seventh byte of this field is a flag byte named SQLDOUBLED. The database manager sets SQLDOUBLED to the character "2" if two SQLVAR entries have been created for each column; otherwise it is set to a blank (X'20' in ASCII, X'40' in EBCDIC). See "Effect of DESCRIBE on the SQLDA" on page 2151 for details on when SQLDOUBLED is set.	The seventh byte of this field is used when the number of SQLVARs is doubled. It is named SQLDOUBLED. If any of the host variables being described is a structured type, BLOB, CLOB, or DBCLOB, the seventh byte must be set to the character "2"; otherwise it can be set to any character but the use of a blank is recommended.
sqldabc	INTEGER	For 32 bit, the length of the SQLDA, equal to SQLN*44+16. For 64 bit, the length of the SQLDA, equal to SQLN*56+16	For 32 bit, the length of the SQLDA, >= to SQLN*44+16. For 64 bit, the length of the SQLDA, >= to SQLN*56+16.
sqln	SMALLINT	Unchanged by the database manager. Must be set to a value greater than or equal to zero before the DESCRIBE statement is executed. Indicates the total number of occurrences of SQLVAR.	Total number of occurrences of SQLVAR provided in the SQLDA. SQLN must be set to a value greater than or equal to zero.
sqld	SMALLINT	Set by the database manager to the number of columns in the result table or to the number of parameter markers.	The number of host variables described by occurrences of SQLVAR.

Fields in an occurrence of a base SQLVAR

Table 319. Fields in a Base SQLVAR

Name	Data Type	Usage in DESCRIBE and PREPARE	Usage in FETCH, OPEN, and EXECUTE
sqltype	SMALLINT	Indicates the data type of the column or parameter marker, and whether it can contain nulls. (Parameter markers are always considered nullable.) Table 321 on page 2152 lists the allowable values and their meanings. Note that for a distinct, array, cursor, row, or reference type, the data type of the base type is placed into this field. For a structured type, the data type of the result of the FROM SQL transform function of the transform group (based on the CURRENT DEFAULT TRANSFORM GROUP special register) for the type is placed into this field. There is no indication in the base SQLVAR that it is part of the description of a user-defined type or reference type.	Same for host variable. Host variables for datetime values must be character string variables. For FETCH, a datetime type code means a fixed-length character string. If sqltype is an even number value, the sqlind field is ignored.
sqllen	SMALLINT	The length attribute of the column or parameter marker. For datetime columns and parameter markers, the length of the string representation of the values. See Table 321 on page 2152. Note that the value is set to 0 for large object strings (even for those whose length attribute is small enough to fit into a two byte integer).	The length attribute of the host variable. See Table 321 on page 2152. Note that the value is ignored by the database manager for CLOB, DBCLOB, and BLOB columns. The len.sqllonglen field in the Secondary SQLVAR is used instead.
sqldata	pointer	For string SQLVARS, sqldata contains the code page. For character-string SQLVARs where the column is defined with the FOR BIT DATA attribute, sqldata contains 0. For other character-string SQLVARS, sqldata contains either the SBCS code page for SBCS data, or the SBCS code page associated with the composite MBCS code page for MBCS data. For Japanese EUC, Traditional Chinese EUC, and Unicode UTF-8 character-string SQLVARS, sqldata contains 954, 964, and 1208 respectively. For all other column types, sqldata is undefined.	Contains the address of the host variable (where the fetched data will be stored).

Table 319. Fields in a Base SQLVAR (continued)

Name	Data Type	Usage in DESCRIBE and PREPARE	Usage in FETCH, OPEN, and EXECUTE
sqlind	pointer	For character-string SQLVARS, sqlind contains 0, except for MBCS data, when sqlind contains the DBCS code page associated with the composite MBCS code page. For all other types, sqlind is undefined.	Contains the address of an associated indicator variable, if there is one; otherwise, not used. If sqltype is an even number value, the sqlind field is ignored.
sqlname	VARCHAR (30)	Contains the unqualified name of the column or parameter marker. For columns and parameter markers that have a system-generated name, the thirtieth byte is set to X'FF'. For column names specified by the AS clause, this byte is X'00'.	When connecting to a host database, sqlname can be set to indicate a FOR BIT DATA string as follows: • The sixth byte of the SQLDAID in the SQLDA header is set to "+" • The length of sqlname is 8 • The first two bytes of sqlname are X'0000' • The third and fourth bytes of sqlname are X'0000' • The remaining four bytes of sqlname are reserved and should be set to X'00000000' When working with XML data, sqlname can be set to indicate an XML subtype as follows: • The length of sqlname is 8 • The first two bytes of sqlname are X'0000' • The third and fourth bytes of sqlname are X'0000' • The fifth byte of sqlname is X'01' • The remaining three bytes of sqlname are reserved and should be set to X'000000'

Fields in an occurrence of a secondary SQLVAR

Table 320. Fields in a Secondary SQLVAR

Name	Data Type	Usage in DESCRIBE and PREPARE	Usage in FETCH, OPEN, and EXECUTE
len.sqllonglen	INTEGER	The length attribute of a BLOB, CLOB, or DBCLOB column or parameter marker.	The length attribute of a BLOB, CLOB, or DBCLOB host variable. The database manager ignores the SQLLEN field in the Base SQLVAR for the data types. The length attribute stores the number of bytes for a BLOB or CLOB, and the number of double-byte characters for a DBCLOB.

Table 320. Fields in a Secondary SQLVAR (continued)

Name	Data Type	Usage in DESCRIBE and PREPARE	Usage in FETCH, OPEN, and EXECUTE
reserve2	CHAR(3) for 32 bit, and CHAR(11) for 64 bit.	Not used.	Not used.
sqlflag4	CHAR(1)	The value is X'01' if the SQLVAR represents a reference type with a target type named in sqldatatype_name. The value is X'12' if the SQLVAR represents a structured type, with the user-defined type name in sqldatatype_name. Otherwise, the value is X'00'.	Set to X'01' if the SQLVAR represents a reference type with a target type named in sqldatatype_name. Set to X'12' if the SQLVAR represents a structured type, with the user-defined type name in sqldatatype_name. Otherwise, the value is X'00'.
sqldatalen	pointer	Not used.	Used for BLOB, CLOB, and DBCLOB host variables only. If this field is the null value, then the actual length (in double-byte characters) should be stored in the 4 bytes immediately before the start of the data and SQLDATA should point to the first byte of the field length. If this field is not the null value, it contains a pointer to a 4 byte long buffer that contains the actual length *in bytes* (even for DBCLOB) of the data in the buffer pointed to from the SQLDATA field in the matching base SQLVAR. Note that, whether or not this field is used, the len.sqllonglen field must be set.
sqldatatype_name	VARCHAR(27)	For a user-defined type, the database manager sets this to the fully qualified user-defined type name.[1] For a reference type, the database manager sets this to the fully qualified type name of the target type of the reference.	For structured types, set to the fully qualified user-defined type name in the format indicated in the table note.[1]
reserved	CHAR(3)	Not used.	Not used.

Table 320. Fields in a Secondary SQLVAR (continued)

Name	Data Type	Usage in DESCRIBE and PREPARE	Usage in FETCH, OPEN, and EXECUTE

[1] The first 8 bytes contain the schema name of the type (extended to the right with spaces, if necessary). Byte 9 contains a dot (.). Bytes 10 to 27 contain the low order portion of the type name, which is *not* extended to the right with spaces.

Note that, although the prime purpose of this field is for the name of user-defined types, the field is also set for IBM predefined data types. In this case, the schema name is SYSIBM, and the low order portion of the name is the name stored in the TYPENAME column of the DATATYPES catalog view. For example:

```
type name        length   sqldatatype_name
---------        ------   ----------------
A.B              10       A       .B
INTEGER          16       SYSIBM  .INTEGER
"Frank's".SMINT  13       Frank's .SMINT
MY."type  "      15       MY      .type
```

Effect of DESCRIBE on the SQLDA

For a DESCRIBE OUTPUT or PREPARE OUTPUT INTO statement, the database manager always sets SQLD to the number of columns in the result set, or the number of output parameter markers. For a DESCRIBE INPUT or PREPARE INPUT INTO statement, the database manager always sets SQLD to the number of input parameter markers in the statement. Note that a parameter marker that corresponds to an INOUT parameter in a CALL statement is described in both the input and output descriptors.

The SQLVARs in the SQLDA are set in the following cases:

- SQLN >= SQLD and no entry is either a LOB, user-defined type or reference type

  The first SQLD SQLVAR entries are set and SQLDOUBLED is set to blank.
- SQLN >= 2*SQLD and at least one entry is a LOB, user-defined type or reference type

  Two times SQLD SQLVAR entries are set, and SQLDOUBLED is set to "2".
- SQLD <= SQLN < 2*SQLD and at least one entry is a distinct, array, cursor, row, or reference type, but there are no LOB entries or structured type entries

  The first SQLD SQLVAR entries are set and SQLDOUBLED is set to blank. If the SQLWARN bind option is YES, a warning SQLCODE +237 (SQLSTATE 01594) is issued.

The SQLVARs in the SQLDA are NOT set (requiring allocation of additional space and another DESCRIBE) in the following cases:

- SQLN < SQLD and no entry is either a LOB, user-defined type or reference type

  No SQLVAR entries are set and SQLDOUBLED is set to blank. If the SQLWARN bind option is YES, a warning SQLCODE +236 (SQLSTATE 01005) is issued.

  Allocate SQLD SQLVARs for a successful DESCRIBE.
- SQLN < SQLD and at least one entry is a distinct, array, cursor, row, or reference type, but there are no LOB entries or structured type entries

  No SQLVAR entries are set and SQLDOUBLED is set to blank. If the SQLWARN bind option is YES, a warning SQLCODE +239 (SQLSTATE 01005) is issued.

  Allocate 2*SQLD SQLVARs for a successful DESCRIBE including the names of the distinct, array, cursor, and row types and target types of reference types.
- SQLN < 2*SQLD and at least one entry is a LOB or a structured type

  No SQLVAR entries are set and SQLDOUBLED is set to blank. A warning SQLCODE +238 (SQLSTATE 01005) is issued (regardless of the setting of the SQLWARN bind option).

  Allocate 2*SQLD SQLVARs for a successful DESCRIBE.

References in the previous lists to LOB entries include distinct type entries whose source type is a LOB type.

The SQLWARN option of the BIND or PREP command is used to control whether the DESCRIBE (or PREPARE INTO) will return the warning SQLCODEs +236, +237, +239. It is recommended that your application code always consider that these SQLCODEs could be returned. The warning SQLCODE +238 is always returned when there are LOB or structured type entries in the select list and there are insufficient SQLVARs in the SQLDA. This is the only way the application can know that the number of SQLVARs must be doubled because of a LOB or structured type entry in the result set.

If a structured type entry is being described, but no FROM SQL transform is defined (either because no TRANSFORM GROUP was specified using the CURRENT DEFAULT TRANSFORM GROUP special register (SQLSTATE 42741) or because the name group does not have a FROM SQL transform function defined (SQLSTATE 42744)), the DESCRIBE will return an error. This error is the same error returned for a DESCRIBE of a table with a structured type entry.

If the database manager returns identifiers that are longer than those that can be stored in the SQLDA, the identifier is truncated and a warning is returned (SQLSTATE 01665); however, when the name of a structured type is truncated, an error is returned (SQLSTATE 42622). For details on identifier length limitations, see "SQL and XQuery limits" .

SQLTYPE and SQLLEN

Table 321 on page 2152 shows the values that may appear in the SQLTYPE and SQLLEN fields of the SQLDA. In DESCRIBE and PREPARE INTO, an even value of SQLTYPE means that the column does not allow nulls, and an odd value means the column does allow nulls. In FETCH, OPEN, and EXECUTE, an even value of SQLTYPE means that no indicator variable is provided, and an odd value means that SQLIND contains the address of an indicator variable.

Table 321. SQLTYPE and SQLLEN values for DESCRIBE, FETCH, OPEN, and EXECUTE

SQLTYPE	Column data type for DESCRIBE and PREPARE INTO	SQLLEN for DESCRIBE and PREPARE INTO	Host variable data type for FETCH, OPEN, and EXECUTE	SQLLEN for FETCH, OPEN, and EXECUTE
384/385	date	10	fixed-length character string representation of a date	length attribute of the host variable
388/389	time	8	fixed-length character string representation of a time	length attribute of the host variable
392/393	timestamp	19 for TIMESTAMP(0) otherwise 20+*p* for TIMESTAMP(*p*)	fixed-length character string representation of a timestamp	length attribute of the host variable
400/401	N/A	N/A	NULL-terminated graphic string	length attribute of the host variable
404/405	BLOB	0 *	BLOB	Not used. *
408/409	CLOB	0 *	CLOB	Not used. *
412/413	DBCLOB	0 *	DBCLOB	Not used. *
448/449	varying-length character string	length attribute of the column	varying-length character string	length attribute of the host variable

Table 321. SQLTYPE and SQLLEN values for DESCRIBE, FETCH, OPEN, and EXECUTE (continued)

SQLTYPE	Column data type for DESCRIBE and PREPARE INTO	SQLLEN for DESCRIBE and PREPARE INTO	Host variable data type for FETCH, OPEN, and EXECUTE	SQLLEN for FETCH, OPEN, and EXECUTE
452/453	fixed-length character string	length attribute of the column	fixed-length character string	length attribute of the host variable
456/457	long varying-length character string	length attribute of the column	long varying-length character string	length attribute of the host variable
460/461	not applicable	not applicable	NULL-terminated character string	length attribute of the host variable
464/465	varying-length graphic string	length attribute of the column	varying-length graphic string	length attribute of the host variable
468/469	fixed-length graphic string	length attribute of the column	fixed-length graphic string	length attribute of the host variable
472/473	long varying-length graphic string	length attribute of the column	long graphic string	length attribute of the host variable
480/481	floating-point	8 for double precision, 4 for single precision	floating-point	8 for double precision, 4 for single precision
484/485	packed decimal	precision in byte 1; scale in byte 2	packed decimal	precision in byte 1; scale in byte 2
492/493	big integer	8	big integer	8
496/497	large integer	4	large integer	4
500/501	small integer	2	small integer	2
908/909	varying-length binary string	length attribute of the column	varying-length binary string	length attribute of the host variable
912/913	fixed-length binary string	length attribute of the column	fixed-length binary string	length attribute of the host variable
916/917	not applicable	not applicable	BLOB file reference variable	267
920/921	not applicable	not applicable	CLOB file reference variable	267
924/925	not applicable	not applicable	DBCLOB file reference variable.	267
960/961	not applicable	not applicable	BLOB locator	4
964/965	not applicable	not applicable	CLOB locator	4
968/969	not applicable	not applicable	DBCLOB locator	4
988/989	XML	0	not applicable; use an XML AS <string or binary LOB type> host variable instead	not used

Table 321. SQLTYPE and SQLLEN values for DESCRIBE, FETCH, OPEN, and EXECUTE (continued)

SQLTYPE	Column data type for DESCRIBE and PREPARE INTO	SQLLEN for DESCRIBE and PREPARE INTO	Host variable data type for FETCH, OPEN, and EXECUTE	SQLLEN for FETCH, OPEN, and EXECUTE
996	decimal floating-point	8 for DECFLOAT(16), 16 for DECFLOAT(34)	decimal floating-point	8 for DECFLOAT(16), 16 for DECFLOAT(34)
2440/2441	row	not applicable	row	not used
2440/2441	cursor	not applicable	row	not used

Note:

- The len.sqllonglen field in the secondary SQLVAR contains the length attribute of the column.
- The SQLTYPE has changed from previous versions for portability reasons. The values from the previous version (see previous version SQL Reference) continue to be supported.

Unrecognized and unsupported SQLTYPEs

The values that appear in the SQLTYPE field of the SQLDA are dependent on the level of data type support available at the sender as well as at the receiver of the data. This is particularly important as new data types are added to the product.

New data types may or may not be supported by the sender or receiver of the data and may or may not even be recognized by the sender or receiver of the data. Depending on the situation, the new data type may be returned, or a compatible data type agreed upon by both the sender and receiver of the data may be returned or an error may result.

When the sender and receiver agree to use a compatible data type, the following table indicates the mapping that will take place. This mapping will take place when at least one of the sender or the receiver does not support the data type provided. The unsupported data type can be provided by either the application or the database manager.

Data Type	Compatible Data Type
BIGINT	DECIMAL(19, 0)
ROWID	VARCHAR(40) FOR BIT DATA

Note that no indication is given in the SQLDA that the data type is substituted.

Packed decimal numbers

Packed decimal numbers are stored in a variation of Binary Coded Decimal (BCD) notation. In BCD, each nybble (four bits) represents one decimal digit. For example, 0001 0111 1001 represents 179. Therefore, read a packed decimal value nybble by nybble. Store the value in bytes and then read those bytes in hexadecimal representation to return to decimal. For example, 0001 0111 1001 becomes 00000001 01111001 in binary representation. By reading this number as hexadecimal, it becomes 0179.

The decimal point is determined by the scale. In the case of a DEC(12,5) column, for example, the rightmost 5 digits are to the right of the decimal point.

Sign is indicated by a nybble to the right of the nybbles representing the digits. A positive or negative sign is indicated as follows:

Table 322. Values for Sign Indicator of a Packed Decimal Number

Sign	Binary representation	Decimal representation	Hexadecimal representation
Positive (+)	1100	12	C
Negative (-)	1101	13	D

In summary:

- To store any value, allocate *p*/2+1 bytes, where *p* is precision.
- Assign the nybbles from left to right to represent the value. If a number has an even precision, a leading zero nybble is added. This assignment includes leading (insignificant) and trailing (significant) zero digits.
- The sign nybble will be the second nybble of the last byte.

For example:

Column	Value	Nybbles in Hexadecimal Grouped by Bytes
DEC(8,3)	6574.23	00 65 74 23 0C
DEC(6,2)	-334.02	00 33 40 2D
DEC(7,5)	5.2323	05 23 23 0C
DEC(5,2)	-23.5	02 35 0D

SQLLEN field for decimal

The SQLLEN field contains the precision (first byte) and scale (second byte) of the decimal column. If writing a portable application, the precision and scale bytes should be set individually, versus setting them together as a short integer. This will avoid integer byte reversal problems.

For example, in C:

```
((char *)&(sqlda->sqlvar[i].sqllen))[0] = precision;
((char *)&(sqlda->sqlvar[i].sqllen))[1] = scale;
```

Exception tables

Exception tables are user-created tables that mimic the definition of the tables that are specified to be checked using the SET INTEGRITY statement with the IMMEDIATE CHECKED option. They are used to store copies of the rows that violate constraints in the tables being checked.

The exception tables that are used by the load utility are identical to the ones described here, and can therefore be reused during checking with the SET INTEGRITY statement.

Rules for creating an exception table

The rules for creating an exception table are as follows:

- If the table is protected by a security policy, the exception table must be protected by the same security policy.
- The first "n" columns of the exception table are the same as the columns of the table being checked. All column attributes, including name, data type, and length should be identical. For protected columns, the security label protecting the column must be the same in both tables.
- All of the columns of the exception table must be free of constraints and triggers. Constraints include referential integrity and check constraints, as well as unique index constraints that could cause errors on insert.

- The "(n+1)" column of the exception table is an optional TIMESTAMP column. This serves to identify successive invocations of checking by the SET INTEGRITY statement on the same table, if the rows within the exception table have not been deleted before issuing the SET INTEGRITY statement to check the data. The timestamp precision can be any value from 0 to 12 and the value assigned will be the result of CURRENT TIMESTAMP special register
- The "(n+2)" column should be of type CLOB(32K) or larger. This column is optional but recommended, and will be used to give the names of the constraints that the data within the row violates. If this column is not provided (as could be warranted if, for example, the original table had the maximum number of columns allowed), then only the row where the constraint violation was detected is copied.
- The exception table should be created with both "(n+1)" and "(n+2)" columns.
- There is no enforcement of any particular name for the previously listed additional columns. However, the type specification must be exactly followed.
- No additional columns are allowed.
- If the original table has generated columns (including the IDENTITY property), the corresponding columns in the exception table should not specify the generated property.
- Users invoking the SET INTEGRITY statement to check data must hold the INSERT privilege on the exception tables.
- The exception table cannot be a data partitioned table, a range clustered table, or a detached table.
- The exception table cannot be a materialized query table or a staging table.
- The exception table cannot have any dependent refresh immediate materialized query tables or any dependent propagate immediate staging tables.

The information in the "message" column has the following structure:

Table 323. Exception Table Message Column Structure

Field number	Contents	Size	Comments
1	Number of constraint violations	5 bytes	Right justified padded with "0"
2	Type of first constraint violation	1 byte	• "D" - Delete Cascade violation • "F" - Foreign Key violation • "G" - Generated Column violation • "I" - Unique Index violation[a] • "K" - Check Constraint violation • "L" - LBAC Write rules violation • "P" - Data Partitioning violation • "S" - Invalid Row Security Label • "X" - Index defined on XML column violation[d]
3	Length of constraint/column[b] /index ID[c]	5 bytes	Right justified padded with "0"
4	Constraint name/Column name[b]/index ID[c]	length from the previous field	
5	Separator	3 bytes	<space><colon><space>

Table 323. Exception Table Message Column Structure (continued)

Field number	Contents	Size	Comments
6	Type of next constraint violation	1 byte	• "D" - Delete Cascade violation • "F" - Foreign Key violation • "G" - Generated Column violation • "I" - Unique Index violation • "K" - Check Constraint violation • "L" - LBAC Write rules violation • "P" - Data Partitioning violation • "S" - Invalid Row Security Label • "X" - Index defined on XML column violation[d]
7	Length of constraint/column/index ID	5 bytes	Right justified padded with "0"
8	Constraint name/Column name/Index ID	length from the previous field	
.....	.....	.....	Repeat Field 5 through 8 for each violation

- [a] Unique index violations will not occur during checking using the SET INTEGRITY statement, unless it is after an attach operation. This will be reported, however, when running LOAD if the FOR EXCEPTION option is chosen. However, LOAD will not report check constraint, generated column, foreign key, delete cascade, or data partitioning violations in the exception tables.
- [b] To retrieve the expression of a generated column from the catalog views, use a select statement. For example, if field 4 is MYSCHEMA.MYTABLE.GEN_1, then SELECT SUBSTR(TEXT, 1, 50) FROM SYSCAT.COLUMNS WHERE TABSCHEMA='MYSCHEMA' AND TABNAME='MYNAME' AND COLNAME='GEN_1'; will return the first fifty bytes of the expression, in the form "AS (<expression>)"
- [c] To retrieve an index ID from the catalog views, use a select statement. For example, if field 4 is 1234, then SELECT INDSCHEMA, INDNAME FROM SYSCAT.INDEXES WHERE IID=1234.
- [d] For Index defined on XML column violations, the constraint name, column name, or index ID field identifies the XML column that had an integrity violation in one of its indexes. It does not identify the index that had the integrity violation. It identifies only the name of the XML column on which the index violation occurs. For example, the value "X00006XTCOLZ" in the message column indicates an index violation occurred in one of the indexes on the XTCOL2 column.

Handling rows in an exception table

The information in exception tables can be processed in various ways. Data can be corrected and rows re-inserted into the original tables.

If there are no INSERT triggers on the original table, transfer the corrected rows by issuing an INSERT statement with a subquery on the exception table.

If there are INSERT triggers, and you want to complete the load operation with the corrected rows from exception tables without firing the triggers:

- Design the INSERT triggers to be fired depending on the value in a column that has been defined explicitly for the purpose.
- Unload data from the exception tables and append it using the load utility. In this case, if you want to recheck the data, note that constraints checking is not confined to the appended rows.
- Save the trigger definition text from the relevant system catalog view. Then drop the INSERT trigger and use INSERT to transfer the corrected rows from the exception tables. Finally, re-create the trigger using the saved trigger definition.

No explicit provision is made to prevent the firing of triggers when inserting rows from exception tables.

Only one violation per row is reported for unique index violations.

If values with LONG VARCHAR, LONG VARGRAPHIC, or LOB data types are in the table, the values are not inserted into the exception table in the case of unique index violations.

Querying exception tables

The message column structure in an exception table is a concatenated list of constraint names, lengths, and delimiters, as described earlier. This information can be queried.

For example, to retrieve a list of all violations, repeating each row with only the constraint name, assume that the original table T1 had two columns, C1 and C2. Assume also, that the corresponding exception table, E1, has columns C1 and C2, corresponding to those in T1, as well as a message column, MSGCOL. The following query uses recursion to list one constraint name per row (repeating rows that have more than one violation):

```
WITH IV  (C1, C2, MSGCOL, CONSTNAME, I, J) AS
 (SELECT C1, C2, MSGCOL,
     CHAR(SUBSTR(MSGCOL, 12,
                 INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,7,5)),5,0)))),
     1,
     15+INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,7,5)),5,0))
    FROM E1
  UNION ALL
  SELECT C1, C2, MSGCOL,
      CHAR(SUBSTR(MSGCOL, J+6,
                  INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,J+1,5)),5,0)))),
      I+1,
      J+9+INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,J+1,5)),5,0))
    FROM IV
    WHERE I < INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,1,5)),5,0))
 ) SELECT C1, C2, CONSTNAME FROM IV;
```

To list all of the rows that violated a particular constraint, the previous query could be extended as follows:

```
WITH IV  (C1, C2, MSGCOL, CONSTNAME, I, J) AS
 (SELECT C1, C2, MSGCOL,
      CHAR(SUBSTR(MSGCOL, 12,
                  INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,7,5)),5,0)))),
      1,
      15+INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,7,5)),5,0))
    FROM E1
  UNION ALL
  SELECT C1, C2, MSGCOL,
      CHAR(SUBSTR(MSGCOL, J+6,
                 INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,J+1,5)),5,0)))),
      I+1,
      J+9+INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,J+1,5)),5,0))
    FROM IV
    WHERE I < INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,1,5)),5,0))
 ) SELECT C1, C2, CONSTNAME FROM IV WHERE CONSTNAME = 'constraintname';
```

The following query could be used to obtain all of the check constraint violations:

```
WITH IV  (C1, C2, MSGCOL, CONSTNAME, CONSTTYPE, I, J) AS
  (SELECT C1, C2, MSGCOL,
       CHAR(SUBSTR(MSGCOL, 12,
                   INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,7,5)),5,0)))),
       CHAR(SUBSTR(MSGCOL, 6, 1)),
       1,
       15+INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,7,5)),5,0))
     FROM E1
   UNION ALL
   SELECT C1, C2, MSGCOL,
       CHAR(SUBSTR(MSGCOL, J+6,
                  INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,J+1,5)),5,0)))),
       CHAR(SUBSTR(MSGCOL, J, 1)),
       I+1,
       J+9+INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,J+1,5)),5,0))
     FROM IV
     WHERE I < INTEGER(DECIMAL(VARCHAR(SUBSTR(MSGCOL,1,5)),5,0))
 ) SELECT C1, C2, CONSTNAME FROM IV WHERE CONSTTYPE = 'K';
```

Regular expression control characters

Control characters are metacharacters, operators, and replacement text characters that can be used in regular expressions.

Only half-width characters are recognized. Any full-width characters that correspond to the characters in the following tables are not recognized.

Table 324. Regular expression metacharacters

Character	Allowed outside of sets	Allowed inside of sets	Description
\a	Yes	Yes	Match a BELL, \u0007
\A	Yes		Match at the beginning of the input. Differs from ^ in that \A does not match after a new line within the input.
\b	Yes		Match if the current position is a word boundary. Boundaries occur at the transitions between word (\w) and non-word (\W) characters, with combining marks ignored.
\B	Yes		Match if the current position is not a word boundary.
\cX	Yes	Yes	Match a control-X character.
\d	Yes	Yes	Match any character with the Unicode General Category of Nd (Number, Decimal Digit.)
\D	Yes	Yes	Match any character that is not a decimal digit.
\e	Yes	Yes	Match an ESCAPE, \u001B
\E	Yes	Yes	Terminates a \Q ... \E quoted sequence.
\f	Yes	Yes	Match a FORM FEED, \u000C.
\G	Yes		Match if the current position is at the end of the previous match.
\n	Yes	Yes	Match a LINE FEED, \u000A
\N{UNICODE CHARACTER NAME}	Yes	Yes	Match the named character.
\p{UNICODE PROPERTY NAME}	Yes	Yes	Match any character with the specified Unicode Property.
\P{UNICODE PROPERTY NAME}	Yes	Yes	Match any character not having the specified Unicode Property.
\Q	Yes	Yes	Places quotation marks around all following characters until \E
\r	Yes	Yes	Match a CARRIAGE RETURN, \u000D
\s	Yes	Yes	Match a white space character. White space is defined as [\t\n\f\r\p{Z}]
\S	Yes	Yes	Match a non-white space character.
\t	Yes	Yes	Match a HORIZONTAL TABULATION, \u0009
\uhhhh	Yes	Yes	Match the character with the hex value hhhh

Table 324. Regular expression metacharacters (continued)

Character	Allowed outside of sets	Allowed inside of sets	Description
\Uhhhhhhhh	Yes	Yes	Match the character with the hex value hhhhhhhh. Exactly 8 hex digits must be provided, even though the largest Unicode code point is \U0010ffff

\w	Yes	Yes	Match a word character. Word characters are as follows:
			`[\p{Alphabetic}`
			`\p{Mark}`
			`\p{Decimal_Number}`
			`\p{Connector_Punctuation}`
			`\u200c`
			`\u200d]`

\W	Yes	Yes	Match a non-word character.
\x{hhhh}	Yes	Yes	Match the character with hex value hhhh. From one to 6 hex digits can be supplied.
\xhh	Yes	Yes	Match the character with two-digit hex value hh
\X	Yes		Match a Grapheme Cluster.
\Z	Yes		Match if the current position is at the end of input, but before the final line terminator, if one exists.
\z	Yes		Match if the current position is at the end of input.
\n	Yes		Back Reference. Match whatever the nth capturing group matched. n must be a number > 1 and < total number of capture groups in the pattern.
\0ooo	Yes	Yes	Match an Octal character. 'ooo' is from one to three octal digits. 0377 is the largest allowed Octal character. The leading zero is required; it distinguishes Octal constants from back references.
[pattern]	Yes	Yes	Match any one character from the set.
.	Yes		Match any character.
^	Yes		Match at the beginning of a line.
$	Yes		Match at the end of a line.
\	Yes		Places quotation marks around the character that follows. Characters that must have surrounding quotation marks to be treated as literals are * ? + [( ) { } ^ $ | \ . /
\		Yes	Places quotation marks around the character that follows. Characters that must be quoted to be treated as literals are [ ] \ Characters that might need to be quoted, depending on the context are - &

Table 325. Regular expression operators

Operator	Description
|	Alternation. A | B matches either A or B

Table 325. Regular expression operators (continued)

Operator	Description
*	Match 0 or more times. Match as many times as possible.
+	Match 1 or more times. Match as many times as possible.
?	Match zero or one time. Prefer one.
{n}	Match exactly n times.
{n,}	Match at least n times. Match as many times as possible.
{n,m}	Match between n and m times. Match as many times as possible, but not more than m.
*?	Match 0 or more times. Match as few times as possible.
+?	Match 1 or more times. Match as few times as possible.
??	Match zero or one time. Prefer zero.
{n}?	Match exactly n times.
{n,}?	Match at least n times, but no more than required for an overall pattern match.
{n,m}?	Match between n and m times. Match as few times as possible, but not less than n
*+	Match 0 or more times. Match as many times as possible when first encountered, do not retry with fewer even if overall match fails (Possessive Match)
++	Match 1 or more times. Possessive match.
?+	Match zero or 1 time. Possessive match.
{n}+	Match exactly n times.
{n,}+	Match at least n times. Possessive Match.
{n,m}+	Match between n and m times. Possessive Match.
(...)	Capturing parentheses. Range of input that matched the parenthesized subexpression is available after the match.
(?: ...)	Non-capturing parentheses. Groups the included pattern, but does not provide capturing of matching text. More efficient than capturing parentheses.
(?> ...)	Atomic-match parentheses. First match of the parenthesized subexpression is the only one tried. If it does not lead to an overall pattern match, back up the search for a match to a position before the "(?>"
(?# ...)	Free-format comment (?# comment)
(?= ...)	Look-ahead assertion. True if the parenthesized pattern matches at the current input position, but does not advance the input position.
(?! ...)	Negative look-ahead assertion. True if the parenthesized pattern does not match at the current input position. Does not advance the input position.
(?<= ...)	Look-behind assertion. True if the parenthesized pattern matches text that precedes the current input position. The last character of the match is the input character just before the current position. Does not alter the input position. The length of possible strings that is matched by the look-behind pattern must not be unbounded (no * or + operators.)

Table 325. Regular expression operators (continued)	
Operator	**Description**
`(?<!...)`	Negative Look-behind assertion. True if the parenthesized pattern does not match text that precedes preceding the current input position. The last character of the match is the input character just before the current position. Does not alter the input position. The length of possible strings that is matched by the look-behind pattern must not be unbounded (no * or + operators.)
`(?ismwx-ismwx: ... )`	Flag settings. Evaluate the parenthesized expression with the specified flags enabled or disabled.
`(?ismx-ismx)`	Flag settings. Change the flag settings. Changes apply to the portion of the pattern that follows the setting. For example, `(?i)` changes to a not case-sensitive match.

Table 326. Set expressions (character classes)	
Example expression	**Description**
`[abc]`	Match any of the characters a, b, or c
`[^abc]`	Negation - match any character except a, b, or c
`[A-M]`	Range - match any character from A to M. The characters to include are determined by Unicode code point order.
`[\u0000-\U0010ffff]`	Range - match all characters.

`[\p{Letter}]`
`[\p{General_Category=Letter}]`
`[\p{L}]`
	Characters with Unicode Category = `Letter`. All forms that are shown are equivalent.

`[\P{Letter}]`	Negated property. (Uppercase \P) Match everything except Letters.
`[\p{numeric_value=9}]`	Match all numbers with a numeric value of 9. Any Unicode Property might be used in set expressions.
`[\p{Letter}&&\p{script=cyrillic}]`	Logical AND or intersection. Match the set of all Cyrillic letters.
`[\p{Letter}--\p{script=latin}]`	Subtraction. Match all non-Latin letters.
`[[a-z][A-Z][0-9]] [a-zA-Z0-9]]`	Implicit Logical OR or Union of Sets. The examples match ASCII letters and digits. The two forms are equivalent.
`[:script=Greek:]`	Alternate POSIX-like syntax for properties. Equivalent to `\p{script=Greek}`

Explain tables

The Explain tables capture access plans when the Explain facility is activated.

The Explain tables must be created before Explain can be invoked. You can create them using one of the following methods:

- Call the SYSPROC.SYSINSTALLOBJECTS procedure:

```
CONNECT TO database-name
CALL SYSPROC.SYSINSTALLOBJECTS('EXPLAIN', 'C',
        CAST (NULL AS VARCHAR(128)), CAST (NULL AS VARCHAR(128)))
```

This call creates the explain tables under the SYSTOOLS schema. To create them under a different schema, specify a schema name as the last parameter in the call.

- Run the EXPLAIN.DDL command file:

```
CONNECT TO database-name
db2 -tf EXPLAIN.DDL
```

This command file creates explain tables under the current schema. The location of this command file depends on the operating system, as illustrated in the following table:

Operating system	Location of the EXPLAIN command file
Linux AIX	Located in the INSTHOME/sqllib/misc directory. INSTHOME is the instance home directory.
Windows	Located at the DB2PATH\misc directory on Windows operating systems. DB2PATH is the location where you install your Db2 copy

Calling the SYSPROC.SYSINSTALLOBJECTS procedure is preferred over using the EXPLAIN.DDL file since it can automatically adapt to different database configurations. For example, if **BLOCKNONLOGGED** parameter is set to yes, then some statements in EXPLAIN.DDL fail because **NOT LOGGED** clause is used for LOB columns. However, if **BLOCKNONLOGGED** parameter is set to yes then the SYSPROC.SYSINSTALLOBJECTS procedure automatically avoids the use of **NOT LOGGED** clause.

Db2 modification packs can occasionally contain changes to the format of one or more of the Explain tables. When such changes occur, existing Explain tables will need to be re-created, as discussed above, or be updated using either the **db2exmig** tool or the SYSINSTALLOBJECTS procedure (using the M action). Failure to update existing Explain tables can result in one of the following errors occurring during use of the Explain facility or one of its related tools: SQL0206N, SQL0220N, SQL1184N.

Note: The format of the Explain tables has been changed in version 11.5.5.

The Explain facility uses the following IDs as the schema when qualifying Explain tables that it is populating:

- The session authorization ID for dynamic SQL
- The statement authorization ID for static SQL
- The SYSTOOLS schema if explain tables do not exist with the authorization ID schema

The schema can be associated with a set of Explain tables, or aliases that point to a set of Explain tables under a different schema. If no Explain tables are found under the schema, the Explain facility checks for Explain tables under the SYSTOOLS schema and attempts to use those tables.

The population of the Explain tables by the Explain facility will not activate triggers or referential or check constraints. For example, if an insert trigger were defined on the EXPLAIN_INSTANCE table, and an eligible statement were explained, the trigger would not be activated.

To improve the performance of the Explain facility in a partitioned database system, it is recommended that the Explain tables be created in a single partition database partition group, preferably on the same database partition to which you will be connected when compiling the query.

ADVISE_INDEX table

The ADVISE_INDEX table represents the recommended indexes.

Table 327. ADVISE_INDEX Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable ?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	No	Authorization ID of initiator of this Explain request.

Table 327. ADVISE_INDEX Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable ?	Key?	Description
EXPLAIN_TIME	TIMESTAMP	No	No	Time of initiation for Explain request.
SOURCE_NAME	VARCHAR(128)	No	No	Name of the package running when the dynamic statement was explained or name of the source file when static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	No	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	No	Version of the source of the Explain request.
EXPLAIN_LEVEL	CHAR(1)	No	No	Level of Explain information for which this row is relevant.
STMTNO	INTEGER	No	No	Statement number within package to which this explain information is related.
SECTNO	INTEGER	No	No	Section number within package to which this explain information is related.
QUERYNO	INTEGER	No	No	Numeric identifier for explained SQL statement. For dynamic SQL statements (excluding the EXPLAIN SQL statement) issued through CLP or CLI, the default value is a sequentially incremented value. Otherwise, the default value is the value of STMTNO for static SQL statements and 1 for dynamic SQL statements.
QUERYTAG	CHAR(20)	No	No	Identifier tag for each explained SQL statement. For dynamic SQL statements issued through CLP (excluding the EXPLAIN SQL statement), the default value is "CLP". For dynamic SQL statements issued through CLI (excluding the EXPLAIN SQL statement), the default value is "CLI". Otherwise, the default value used is blanks.
NAME	VARCHAR(128)	No	No	Name of the index.
CREATOR	VARCHAR(128)	No	No	Qualifier of the index name.
TBNAME	VARCHAR(128)	No	No	Name of the table or nickname on which the index is defined.
TBCREATOR	VARCHAR(128)	No	No	Qualifier of the table name.
COLNAMES	CLOB(2M)	No	No	List of column names.
UNIQUERULE	CHAR(1)	No	No	Unique rule: • D = Duplicates allowed • P = Primary index • U = Unique entries only allowed
COLCOUNT	SMALLINT	No	No	Number of columns in the key plus the number of include columns if any.
IID	SMALLINT	No	No	Internal index ID.

Table 327. ADVISE_INDEX Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
NLEAF	BIGINT	No	No	Number of leaf pages; -1 if statistics are not gathered.
NLEVELS	SMALLINT	No	No	Number of index levels; -1 if statistics are not gathered.
FIRSTKEYCARD	BIGINT	No	No	Number of distinct first key values; -1 if statistics are not gathered.
FULLKEYCARD	BIGINT	No	No	Number of distinct full key values; -1 if statistics are not gathered.
CLUSTERRATIO	SMALLINT	No	No	Degree of data clustering with the index; -1 if statistics are not gathered or if detailed index statistics are gathered (in which case, CLUSTERFACTOR will be used instead).
AVGPARTITION_ CLUSTERRATIO	SMALLINT	No	No	Degree of data clustering within a single data partition. -1 if the table is not table partitioned, if statistics are not gathered, or if detailed statistics are gathered (in which case AVGPARTITION_CLUSTERFACTOR will be used instead).
AVGPARTITION_ CLUSTERFACTOR	DOUBLE	No	No	Finer measurement of the degree of clustering within a single data partition. -1 if the table is not table partitioned, if statistics are not gathered, or if the index is defined on a nickname.
AVGPARTITION_PAGE_ FETCH_PAIRS	VARCHAR(520)	No	No	A list of paired integers in character form. Each pair represents a potential buffer pool size and the corresponding page fetches required to access a single data partition from the table. Zero-length string if no data is available, or if the table is not table partitioned.
DATAPARTITION_ CLUSTERFACTOR	DOUBLE	No	No	A statistic measuring the "clustering" of the index keys with regard to data partitions. This field holds a number between zero and one, with one representing perfect clustering and zero representing no clustering.
CLUSTERFACTOR	DOUBLE	No	No	Finer measurement of degree of clustering, or -1 if detailed index statistics have not been gathered or if the index is defined on a nickname.
USERDEFINED	SMALLINT	No	No	Defined by the user.

Table 327. ADVISE_INDEX Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
SYSTEM_REQUIRED	SMALLINT	No	No	• 1 if one or the other of the following conditions is met: – This index is required for a primary or unique key constraint, or this index is a dimension block index or composite block index for a multi-dimensional clustering (MDC) table. – This is an index on the (OID) column of a typed table. • 2 if both of the following conditions are met: – This index is required for a primary or unique key constraint, or this index is a dimension block index or composite block index for an MDC table. – This is an index on the (OID) column of a typed table. • 0 otherwise.
CREATE_TIME	TIMESTAMP	No	No	Time when the index was created.
STATS_TIME	TIMESTAMP	Yes	No	Last time when any change was made to recorded statistics for this index. Null if no statistics available.
PAGE_FETCH_PAIRS	VARCHAR(520)	No	No	A list of pairs of integers, represented in character form. Each pair represents the number of pages in a hypothetical buffer, and the number of page fetches required to scan the table with this index using that hypothetical buffer. (Zero-length string if no data available.)
REMARKS	VARCHAR(254)	Yes	No	User-supplied comment, or null.
DEFINER	VARCHAR(128)	No	No	User who created the index.
CONVERTED	CHAR(1)	No	No	Reserved for future use.
SEQUENTIAL_PAGES	BIGINT	No	No	Number of leaf pages located on disk in index key order with few or no large gaps between them. (-1 if no statistics are available.)
DENSITY	INTEGER	No	No	Ratio of SEQUENTIAL_PAGES to number of pages in the range of pages occupied by the index, expressed as a percent (integer between 0 and 100, -1 if no statistics are available.)
FIRST2KEYCARD	BIGINT	No	No	Number of distinct keys using the first two columns of the index (-1 if no statistics or inapplicable)
FIRST3KEYCARD	BIGINT	No	No	Number of distinct keys using the first three columns of the index (-1 if no statistics or inapplicable)

Table 327. ADVISE_INDEX Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable ?	Key?	Description
FIRST4KEYCARD	BIGINT	No	No	Number of distinct keys using the first four columns of the index (-1 if no statistics or inapplicable)
PCTFREE	SMALLINT	No	No	Percentage of each index leaf page to be reserved during initial building of the index. This space is available for future inserts after the index is built.
UNIQUE_COLCOUNT	SMALLINT	No	No	The number of columns required for a unique key. Always <=COLCOUNT. < COLCOUNT only if there a include columns. -1 if index has no unique key (permits duplicates)
MINPCTUSED	SMALLINT	No	No	If not zero, then online index defragmentation is enabled, and the value is the threshold of minimum used space before merging pages.
REVERSE_SCANS	CHAR(1)	No	No	• Y = Index supports reverse scans • N = Index does not support reverse scans
USE_INDEX	CHAR(1)	Yes	No	• Y = index recommended or evaluated • N = index not to be recommended • R = an existing clustering RID index was recommended (by the Design Advisor) to be unclustered; this is the case when a new clustering RID index is recommended for the table • I = Ignore an existing non-unique index. The EXISTS column should be "Y" in this case or the index will not be ignored.
CREATION_TEXT	CLOB(2M)	No	No	The SQL statement used to create the index.
PACKED_DESC	BLOB(1M)	Yes	No	Internal description of the table.
RUN_ID	TIMESTAMP	Yes	FK	A value corresponding to the START_TIME of a row in the ADVISE_INSTANCE table, linking it to the same Design Advisor run.
INDEXTYPE	VARCHAR(4)	No	No	Type of index. • CLUS = Clustering • REG = Regular • DIM = Dimension block index • BLOK = Block index
EXISTS	CHAR(1)	No	No	Set to "Y" if the index exists in the database catalog or "N" if the index does not currently exist in the catalog.
RIDTOBLOCK	CHAR(1)	No	No	Set to "Y" if the RID index was used to make a block index in the Design Advisor.

Table 327. ADVISE_INDEX Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
NULLKEYS	CHAR(1)	No	No	Specifies whether null keys are indexed. • N = Keys that contain all null values are not indexed (not considering columns or expressions from the INCLUDE clause) • Y = Keys that contain all null values are indexed (not considering columns or expressions from the INCLUDE clause)

ADVISE_INSTANCE table

The ADVISE_INSTANCE table contains information about db2advis execution, including start time.

Contains one row for each execution of db2advis. Other ADVISE tables have a foreign key (RUN_ID) that links to the START_TIME column of the ADVISE_INSTANCE table for rows created during the same Design Advisor run.

Table 328. ADVISE_INSTANCE Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable?	Key?	Description
START_TIME	TIMESTAMP	No	PK	Time at which db2advis execution begins.
END_TIME	TIMESTAMP	No	No	Time at which db2advis execution ends.
MODE	VARCHAR(4)	No	No	The value that was specified with the -m option on the Design Advisor; for example, 'MC' to specify MQT and MDC.
WKLD_COMPRESSION	CHAR(4)	No	No	The workload compression under which the Design Advisor was run.
STATUS	CHAR(9)	No	No	The status of a Design Advisor run. Status can be 'STARTED', 'COMPLETED' (if successful), or an error number that is prefixed by 'EI' for internal errors or 'EX' for external errors, in which case the error number represents the SQLCODE.

ADVISE_MQT table

The ADVISE_MQT table contains information about materialized query tables (MQT) recommended by the Design Advisor.

Table 329. ADVISE_MQT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	No	Authorization ID of initiator of this Explain request.
EXPLAIN_TIME	TIMESTAMP	No	No	Time of initiation for Explain request.

Table 329. ADVISE_MQT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable ?	Key?	Description
SOURCE_NAME	VARCHAR(128)	No	No	Name of the package running when the dynamic statement was explained or name of the source file when the static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	No	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	No	Version of the source of the Explain request.
EXPLAIN_LEVEL	CHAR(1)	No	No	Level of Explain information for which this row is relevant.
STMTNO	INTEGER	No	No	Statement number within package to which this Explain information is related.
SECTNO	INTEGER	No	No	Statement number within package to which this Explain information is related.
NAME	VARCHAR(128)	No	No	MQT name.
CREATOR	VARCHAR(128)	No	No	MQT creator name.
IID	SMALLINT	No	No	Internal identifier.
CREATE_TIME	TIMESTAMP	No	No	Time at which the MQT was created.
STATS_TIME	TIMESTAMP	Yes	No	Time at which statistics were taken.
NUMROWS	DOUBLE	No	No	The number of estimated rows in the MQT.
NUMCOLS	SMALLINT	No	No	Number of columns defined in the MQT.
ROWSIZE	DOUBLE	No	No	Average length (in bytes) of a row in the MQT.
BENEFIT	FLOAT	No	No	Reserved for future use.
USE_MQT	CHAR(1)	Yes	No	Set to 'Y' when the MQT is recommended.
MQT_SOURCE	CHAR(1)	Yes	No	Indicates where the MQT candidate was generated. Set to 'I' if the MQT candidate is a refresh-immediate MQT, or 'D' if it can only be created as a full refresh-deferred MQT.
QUERY_TEXT	CLOB(2M)	No	No	Contains the query that defines the MQT.
CREATION_TEXT	CLOB(2M)	No	No	Contains the CREATE TABLE DDL for the MQT.
SAMPLE_TEXT	CLOB(2M)	No	No	Contains the sampling query that is used to get detailed statistics for the MQT. Only used when detailed statistics are required for the Design Advisor. The resulting sampled statistics will be shown in this table. If null, then no sampling query was created for this MQT.
COLSTATS	CLOB(2M)	No	No	Contains the column statistics for the MQT (if not null). These statistics are in XML format and include the column name, column cardinality and, optionally, the HIGH2KEY and LOW2KEY values.
EXTRA_INFO	BLOB(2M)	No	No	Reserved for miscellaneous output.

Table 329. ADVISE_MQT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
TBSPACE	VARCHAR(128)	No	No	The table space that is recommended for the MQT.
RUN_ID	TIMESTAMP	Yes	FK	A value corresponding to the START_TIME of a row in the ADVISE_INSTANCE table, linking it to the same Design Advisor run.
REFRESH_TYPE	CHAR(1)	No	No	Set to 'I' for immediate or 'D' for deferred.
EXISTS	CHAR(1)	No	No	Set to 'Y' if the MQT exists in the database catalog.

ADVISE_PARTITION table

The ADVISE_PARTITION table contains information about database partitions recommended by the Design Advisor, and can only be populated in a partitioned database environment.

Table 330. ADVISE_PARTITION Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	No	Authorization ID of initiator of this Explain request.
EXPLAIN_TIME	TIMESTAMP	No	No	Time of initiation for Explain request.
SOURCE_NAME	VARCHAR(128)	No	No	Name of the package running when the dynamic statement was explained or name of the source file when the static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	No	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	No	Version of the source of the Explain request.
EXPLAIN_LEVEL	CHAR(1)	No	No	Level of Explain information for which this row is relevant.
STMTNO	INTEGER	No	No	Statement number within package to which this Explain information is related.
SECTNO	INTEGER	No	No	Statement number within package to which this Explain information is related.
QUERYNO	INTEGER	No	No	Numeric identifier for explained SQL statement. For dynamic SQL statements (excluding the EXPLAIN SQL statement) issued through CLP or CLI, the default value is a sequentially incremented value. Otherwise, the default value is the value of STMTNO for static SQL statements and 1 for dynamic SQL statements.

Table 330. ADVISE_PARTITION Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable ?	Key?	Description
QUERYTAG	CHAR(20)	No	No	Identifier tag for each explained SQL statement. For dynamic SQL statements issued through CLP (excluding the EXPLAIN SQL statement), the default value is 'CLP'. For dynamic SQL statements issued through CLI (excluding the EXPLAIN SQL statement), the default value is 'CLI'. Otherwise, the default value used is blanks.
TBNAME	VARCHAR(128)	Yes	No	Specifies the table name.
TBCREATOR	VARCHAR(128)	Yes	No	Specifies the table creator name.
PMID	SMALLINT	Yes	No	Specifies the distribution map ID.
TBSPACE	VARCHAR(128)	Yes	No	Specifies the table space in which the table resides.
COLNAMES	CLOB(2M)	Yes	No	Specifies database partition column names, separated by commas.
COLCOUNT	SMALLINT	Yes	No	Specifies the number of database partitioning columns.
REPLICATE	CHAR(1)	Yes	No	Specifies whether or not the database partition is replicated.
COST	DOUBLE	Yes	No	Specifies the cost of using the database partition.
USEIT	CHAR(1)	Yes	No	Specifies whether or not the database partition is used in EVALUATE PARTITION mode. A database partition is used if USEIT is set to 'Y' or 'y'.
RUN_ID	TIMESTAMP	Yes	FK	A value corresponding to the START_TIME of a row in the ADVISE_INSTANCE table, linking it to the same Design Advisor run.

ADVISE_TABLE table

The ADVISE_TABLE table stores the data definition language (DDL) for table creation, using the final Design Advisor recommendations for materialized query tables (MQTs), multidimensional clustered tables (MDCs), and database partitioning.

Table 331. ADVISE_TABLE Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable ?	Key?	Description
RUN_ID	TIMESTAMP	Yes	FK	A value corresponding to the START_TIME of a row in the ADVISE_INSTANCE table, linking it to the same Design Advisor run.
TABLE_NAME	VARCHAR(128)	No	No	Name of the table.
TABLE_SCHEMA	VARCHAR(128)	No	No	Name of the table creator.
TABLESPACE	VARCHAR(128)	No	No	The table space in which the table is to be created.

Table 331. ADVISE_TABLE Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable ?	Key?	Description
SELECTION_FLAG	VARCHAR(4)	No	No	Indicates the recommendation type. Valid values are 'M' for MQT, 'P' for database partitioning, and 'C' for MDC. This field can include any subset of these values. For example, 'MC' indicates that the table is recommended as an MQT and an MDC table.
TABLE_EXISTS	CHAR(1)	No	No	Set to 'Y' if the table exists in the database catalog.
USE_TABLE	CHAR(1)	No	No	Set to 'Y' if the table has recommendations from the Design Advisor.
GEN_COLUMNS	CLOB(2M)	No	No	Contains a generated columns string if this row includes an MDC recommendation that requires generated columns in the create table DDL.
ORGANIZE_BY	CLOB(2M)	No	No	For MDC recommendations, contains the ORGANIZE BY clause of the create table DDL.
CREATION_TEXT	CLOB(2M)	No	No	Contains the create table DDL.
ALTER_COMMAND	CLOB(2M)	No	No	Contains an ALTER TABLE statement for the table.

ADVISE_WORKLOAD table

The ADVISE_WORKLOAD table represents the statement that makes up the workload.

Table 332. ADVISE_WORKLOAD Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable ?	Key?	Description
WORKLOAD_NAME	CHAR(128)	No	No	Name of the collection of SQL statements (workload) to which this statement belongs.
STATEMENT_NO	INTEGER	No	No	Statement number within the workload to which this explain information is related.
STATEMENT_TEXT	CLOB(1M)	No	No	Content of the SQL statement.
STATEMENT_TAG	VARCHAR(256)	No	No	Identifier tag for each explained SQL statement.
FREQUENCY	INTEGER	No	No	The number of times this statement appears within the workload.
IMPORTANCE	DOUBLE	No	No	Importance of the statement.
WEIGHT	DOUBLE	No	No	Priority of the statement.
COST_BEFORE	DOUBLE	Yes	No	The cost of the query (in timerons) if the recommendations are not created.

Table 332. ADVISE_WORKLOAD Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
COST_AFTER	DOUBLE	Yes	No	The cost of the query (in timerons) if the recommendations are created. COST_AFTER reflects all recommendations except those that pertain to clustered indexes and multidimensional clustering (MDC).
COMPILABLE	CHAR(17)	Yes	No	Indicates any query compile errors that occurred while trying to prepare the statement. If this column is NULL or does not start with SQLCA, the SQL query could be compiled by db2advis. If a compile error is found by db2advis or the Design Advisor, the COMPILABLE column value consists of an 8 byte long SQLCA.sqlcaid field, followed by a colon (:) and an 8 byte long SQLCA.sqlstate field, which is the return code for the SQL statement.

EXPLAIN_ACTUALS table

The EXPLAIN_ACTUALS table contains Explain section actuals information.

Table 333. EXPLAIN_ACTUALS Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	FK	Authorization ID of initiator of this Explain request.
EXPLAIN_TIME	TIMESTAMP	No	FK	Time of initiation for Explain request.
SOURCE_NAME	VARCHAR(128)	No	FK	Name of the package running when the dynamic statement was explained or name of the source file when static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	FK	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	FK	Version of the source of the Explain request.
EXPLAIN_LEVEL	CHAR(1)	No	FK	Level of Explain information for which this row is relevant.
STMTNO	INTEGER	No	FK	Statement number within package to which this Explain information is related.
SECTNO	INTEGER	No	FK	Section number within package to which this Explain information is related.
OPERATOR_ID	INTEGER	No	FK	Unique ID for this operator within this query.
DBPARTITIONNUM	INTEGER	No	No	The partition number of the database partition where the operator has run.
PREDICATE_ID	INTEGER	Yes	No	ID of the predicate applied on this operator. NULL if the actuals are operator actuals.
HOW_APPLIED	CHAR(10)	Yes	No	How predicate is used by this operator. NULL if PREDICATE_ID is NULL.
ACTUAL_TYPE	VARCHAR(12)	No	No	The type of the actual.
ACTUAL_VALUE	DOUBLE	Yes	No	The value of the actual. NULL if actual is not available for this operator.

EXPLAIN_ARGUMENT table

The EXPLAIN_ARGUMENT table represents the unique characteristics for each individual operator, if there are any.

Table 334. EXPLAIN_ARGUMENT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	FK	Authorization ID of initiator of this Explain request.
EXPLAIN_TIME	TIMESTAMP	No	FK	Time of initiation for Explain request.
SOURCE_NAME	VARCHAR(128)	No	FK	Name of the package running when the dynamic statement was explained or name of the source file when static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	FK	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	FK	Version of the source of the Explain request.
EXPLAIN_LEVEL	CHAR(1)	No	FK	Level of Explain information for which this row is relevant.
STMTNO	INTEGER	No	FK	Statement number within package to which this Explain information is related.
SECTNO	INTEGER	No	FK	Section number within package to which this Explain information is related.
OPERATOR_ID	INTEGER	No	No	Unique ID for this operator within this query.
ARGUMENT_TYPE	CHAR(8)	No	No	The type of argument for this operator.
ARGUMENT_VALUE	VARCHAR(1024)	Yes	No	The value of the argument for this operator. NULL if the value is in LONG_ARGUMENT_VALUE.
LONG_ARGUMENT_ VALUE	CLOB(2M)	Yes	No	The value of the argument for this operator, when the text will not fit in ARGUMENT_VALUE. NULL if the value is in ARGUMENT_VALUE.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
AGGMODE	COMPLETE PARTIAL HASHED PARTIAL HASHED COMPLETE INTERMEDIATE FINAL COMPLETE UNIQUE PARTIAL UNIQUE INTERMEDIATE UNIQUE FINAL UNIQUE	Indicates how the operator aggregates values; for example, whether the aggregation is complete or partial aggregation. HASHED COMPLETE identifies a column-organized data grouping.
APREUSE	TRUE	Indicates if access plan reuse bind option is in effect for this statement.
BACKJOIN	TRUE FALSE	Indicates whether the ZZJOIN operator is used as a backjoin in the all-probe list-prefetch plan.
BITFLTR	INTEGER FALSE	Size of a hash join bit filter. A hash join bit filter can sometimes also be used by a table queue.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
BLDLEVEL	Database build identifier.	Internal identification string for source code version. Db2 vVV.RR.MM.FF : nYYMMDDHHMM, for example Db2 v11.1.1.1: n1610171423
BLKLOCK	EXCLUSIVE INTENT EXCLUSIVE INTENT SHARE NONE SHARE UPDATE	Block level lock intent.
BUFFSCAN **Attention:** This column is available in the container-only release of Db2 Version 11.5 Mod Pack 1 and later versions.	FALSE TRUE	Buffered scan.
BUFFSORT	TRUE	Indicates whether SORT is used as a buffering operation.
BUSTSENS	YES NO	Indicates whether the BUSTIMESENSITIVE bind option is in effect for this statement.
BY DPART	TRUE FALSE	Indicates whether ZZJN is performed across the dimensions of a data partitioned table.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description

CONCACCR	Each row of this type will contain:
	• Level of the setting for this statement:
	BIND
	`Application BIND with CONCURRENT ACCESS RESOLUTION option`
	PREP
	`Statement prepared with CONCURRENT ACCESS RESOLUTION attributes`
	• The concurrent access resolution in effect:
	USE CURRENTLY COMMITTED
	`Concurrent access resolution of application bind or statement prepare is USE CURRENTLY COMMITTED`
	WAIT FOR OUTCOME
	`Concurrent access resolution of application bind or statement prepare is WAIT FOR OUTCOME`
		Indicates the concurrent access resolution used to generate the access plan for this statement.

CSERQY	TRUE FALSE	Remote query is a common subexpression.
CSETEMP	TRUE FALSE	Temporary Table over Common Subexpression Flag.
CUR_COMM	TRUE	Access currently committed rows when the value for the database configuration parameter **cur_commit** is not DISABLE. This access plan is enabled for applicable statements by using either: • CONCURRENT ACCESS RESOLUTION with the USE CURRENTLY COMMITTED option on bind or prepare • The database configuration parameter **cur_commit** with a value of ON

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
DEGREE	INTEGER	If the RETURN operator represents the return from column-organized data processing of the insertion, update, or deletion of rows, the DEGREE of the RETURN operator represents the maximum degree of all the subsections involved in the statement. The degree of parallelism for specific subsections is indicated by the DEGREE argument on plan operators below the RETURN operator. If the insert/update/delete statements is modifying a column-organized target table, the DEGREE of INSERT/UPDATE/DELETE operator is the number of parallel subagents that are used for the INSERT/UPDATE/DELETE operators.
DIRECT	TRUE	Direct fetch indicator.
DPESTFLG	TRUE FALSE	Indicates whether or not the DPNUMPRT value is based on an estimate. Possible values are "TRUE" (DPNUMPRT represents the estimated number of accessed data partitions) or "FALSE" (DPNUMPRT represents the actual number of accessed data partitions).
DPFXMLMV	REFERENCE COMBINATION	Indicates whether XML column data is moved between DPF partitions.
DPLSTPRT	NONE CHARACTER	Represents accessed data partitions. It is a comma-delimited list (for example: 1,3,5) or a hyphenated list (for example: 1-5) of accessed data partitions. A value of "NONE" means that no data partition remains after specified predicates have been applied.
DPNUMPRT	INTEGER	Represents the actual or estimated number of data partitions accessed.
DSTSEVER	Server name	Destination (ship from) server.
DUPLWARN	TRUE FALSE	Duplicates Warning flag.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
EARLYOUT	LEFT LEFT (REMOVE INNER DUPLICATES) RIGHT GROUPBY NONE	Early out indicator. LEFT indicates that each row from the outer table only needs to be joined with at most one row from the inner table. LEFT (REMOVE INNER DUPLICATES) indicates that an attempt to remove some duplicate rows from the inner table has taken place. RIGHT indicates that each row from the inner table only needs to be joined with at most one row from the outer table. NONE indicates no early out processing. GROUPBY indicates that early out processing is allowed because of a group by operation.
ENVVAR	Each row of this type will contain: • Environment variable name • Environment variable value	Environment variable affecting the optimizer
ERRTOL	Each row of this type will contain an SQLSTATE and SQLCODE pair.	A list of errors to be tolerated.
EXTROWS	Y N The argument does not show in the explain tables and formatted output when the value is "N".	Indicates that the maximum row size of the system temporary table might be too large to fit in a 32K page. Some rows might need to be represented as a large object (LOB).
EVALUNCO	TRUE	Evaluate uncommitted data using lock deferral. This is enabled with the **DB2_EVALUNCOMMITTED** registry variable.
EXECUTID	An opaque binary token formatted as an hexadecimal string representing the executable ID.	Indicates the executable ID of the section being explained.
FETCHMAX	IGNORE INTEGER	Override value for MAXPAGES argument on FETCH operator.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description

FILTER	Each row of this type contains the following items:
	• Filter type identifier (BIT or RANGE)
	• Target operator identifier
	• Size, in bytes, for bit filters; blank for range filters
	Each item in the preceding list is separated by a colon and a space.
		Indicates that a hash join bit filter or a hash join range filter is built at the current operator and provides details for that filter. The use of a filter allows the elimination of rows as early as possible during query execution.
		A hash join bit filter is a space efficient data structure that is used to test whether an element is a member of a set. The following is an example of a hash join bit filter argument value:
		`BIT: 13: 8192`
		A range filter consists of a minimum and a maximum value that defines the valid range for a column value. The following is an example of a hash join range filter argument value:
		`RANGE: 13`

FLTRAPPL	TQ PUSHDOWN	Indicates the bit filter application method used by the optimizer. A value of "TQ PUSHDOWN" indicates that the bit filter operation has been pushed down. This argument will not be included at all when the optimizer does not use a pushdown with the hash join.
GREEDY	TRUE	Indicates whether the optimizer used a greedy algorithm to plan access.
GLOBLOCK	EXCLUSIVE INTENT EXCLUSIVE INTENT NONE INTENT SHARE NO LOCK OBTAINED SHARE SHARE INTENT EXCLUSIVE SUPER EXCLUSIVE UPDATE	Represents global lock intent information for a partitioned table object.
GROUPBYC	TRUE FALSE	Whether Group By columns were provided. This argument can be associated with a GRPBY operator or with a TEMP operator when it is part of a query with multiple distinct aggregations.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
GROUPBYN	Integer	Number of comparison columns. This number may be less than the number of columns present in the GROUP BY clause of the SQL statement if predicates eliminated the need to compare some columns. This argument can be associated with a GRPBY operator or with a TEMP operator when it is part of a query with multiple distinct aggregations.
GROUPBYR	Each row of this type will contain: • Ordinal value of column in group by clause (followed by a colon and a space) • Name of column	Group By requirement. This argument can be associated with a GRPBY operator or with a TEMP operator when it is part of a query with multiple distinct aggregations.
GROUPS	Integer	Number of times the operator will repeat.
HASHCODE	24 32	Size (in bits) of hash join hash code used for hash joins. A hash join hash code can sometimes also be used by a table queue.
HASHTBSZ	INTEGER	The number of expected entries in the hash table of a hash join.
IDXMSTLY	TRUE	Indicates whether the FETCH is performed over block identifiers returned from a multi dimensional clustered index.
IDXOVTMP	TRUE FALSE	Indicates whether the scan builds an index or a fast integer sort structure for random access of the temporary tables. If value is "TRUE", the scan builds an index over the temporary tables for random access of the temporary tables. If value is "FALSE", the scan builds a fast integer sort structure for random access of the temporary tables.
INNERCOL	Each row of this type will contain: • Ordinal value of column in order (followed by a colon and a space) • Name of column • Order value **(A)** Ascending **(D)** Descending	Inner order columns.
INPUTXID	A context node identifier	INPUTXID identifies the input context node used by the XSCAN operator.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
ISCANMAX	IGNORE INTEGER	Override value for MAXPAGES argument on ISCAN operator.
JN INPUT	INNER OUTER	Indicates if operator is the operator feeding the inner or outer of a join.
JUMPSCAN	TRUE FALSE	Indicates that the index scan is a jump scan.
LCKAVOID	TRUE	Lock avoidance: row access will avoid locking committed data.
LISTENER	TRUE FALSE	Listener Table Queue indicator.
MAX CARD	INTEGER	The maximum possible output cardinality for an operator. The value represents the sum across all database partitions on which the operator is executing in a partitioned database environment.
MAXPAGES	ALL NONE INTEGER	Maximum pages expected for Prefetch.
MAXRIDS	NONE INTEGER	Maximum Row Identifiers to be included in each list prefetch request.
MXPPSCAN	TRUE FALSE	Provides additional information about how MAXPAGES is calculated in the case of a jump scan. A jump scan can be conceptualized as multiple contiguous scans separated by jumps. If the value is "TRUE", then MAXPAGES is the number of pages that are expected to be accessed by each contiguous scan individually. If the value is "FALSE", then MAXPAGES is the number of pages that are expected to be accessed by all the contiguous scans in total.
NUMROWS	INTEGER	Number of rows expected to be sorted.
ONEFETCH	TRUE FALSE	Indicates the GROUP BY conditions are satisfied by the first row produced by the input stream.
OPROFERR	TRUE FALSE	Indicates that one or more errors occurred while parsing or applying the optimization profile. For details, see explain diagnostic messages.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
OUTERCOL	Each row of this type will contain: • Ordinal value of column in order (followed by a colon and a space) • Name of column • Order value **(A)** Ascending **(D)** Descending	Outer order columns.
OUTERJN	LEFT RIGHT FULL LEFT (ANTI) RIGHT (ANTI)	Outer join indicator.
OVERHEAD	DOUBLE	Optimizer used OVERHEAD value.
PARTCOLS	Name of Column	Partitioning columns for operator.
PBLKLOCK	EXCLUSIVE INTENT EXCLUSIVE INTENT NONE INTENT SHARE REUSE SHARE SHARE INTENT EXCLUSIVE SUPER EXCLUSIVE UPDATE	Positioning scan table lock intent.
PGLOLOCK	EXCLUSIVE INTENT EXCLUSIVE INTENT NONE INTENT SHARE REUSE SHARE SHARE INTENT EXCLUSIVE SUPER EXCLUSIVE UPDATE	Positioning scan global table lock intent.
PLANID	Hexadecimal string representing a BIGINT value	Identifier uniquely representing a query plan configuration for a given statement. The layout of the operators, accessed objects and relevant operator arguments and other plan properties affecting performance are represented by this value.
PREFETCH	DYNAMIC LIST LIST NONE READAHEAD SEQUENTIAL SEQUENTIAL, READAHEAD	Type of prefetch eligible.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
PFTCHSZ	INTEGER	Optimizer used PREFETCHSIZE value.
PROWLOCK	EXCLUSIVE NONE REUSE SHARE SHORT (INSTANT) SHARE UPDATE	Positioning scan row lock intent.
PTABLOCK	EXCLUSIVE INTENT EXCLUSIVE INTENT NONE INTENT SHARE REUSE SHARE SHARE INTENT EXCLUSIVE SUPER EXCLUSIVE UPDATE	Positioning scan table lock intent.
RAND ACC	TRUE	Indicates that the regular TEMP table allows random access. Random access is required for the ZZJN operator.
REOPT	ALWAYS ONCE	The statement is optimized using bind-in values for parameter markers, host variables, and special registers.
RMTQTXT	Query text	Remote Query Text
RNG_PROD	Function name	Range producing function for extended index access.
ROWLOCK	EXCLUSIVE NONE REUSE SHARE SHORT (INSTANT) SHARE UPDATE	Row Lock Intent.
ROWWIDTH	INTEGER	Width of row to be sorted.
RSUFFIX	Query text	Remote SQL suffix.
SCANDIR	FORWARD REVERSE	Scan Direction.
SCANGRAN	INTEGER	Intrapartition parallelism, granularity of the intrapartition parallel scan, expressed in SCANUNITs.
SCANTYPE	LOCAL PARALLEL	Intrapartition parallelism, index scan, table scan, or column-organized data scan.
SCANUNIT	ROW PAGE	Intrapartition parallelism, scan granularity unit.
SEMEVID	Hexadecimal string representing a BIGINT value	Identifier for semantic environment at the time the statement was compiled. SEMEVID corresponds to monitoring element SEMANTIC_ENV_ID.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
SEMIJOIN	TRUE FALSE	This argument on the HSJOIN operator indicates whether column-organized processing should deploy the semi-join optimization technique to reduce the size of the hash table that is created for large hash join inner tables.
SHARED	TRUE	Intrapartition parallelism, shared TEMP indicator.
SHRCSE	TRUE	Temporary table over common subexpression shared between subsections.
SKIP_INS	TRUE	Skip inserted. Row access will skip uncommitted inserted rows. This behavior is enabled with the **DB2_SKIPINSERTED** registry variable or when currently committed semantics are in effect.
SKIPDKEY	TRUE	Skip deleted keys. Row access will skip uncommitted deleted keys. This behavior is enabled with the **DB2_SKIPDELETED** registry variable.
SKIPDROW	TRUE	Skip deleted rows. Row access will skip uncommitted deleted rows. This behavior is enabled with the **DB2_SKIPDELETED** registry variable.
SKIPLOCK	TRUE	The concurrent access resolution "skip locked data" is in effect.
SLOWMAT	TRUE FALSE	Slow Materialization flag.
SNGLPROD	TRUE FALSE	Intrapartition parallelism sort or temp produced by a single agent.
SORTKEY	Each row of this type will contain: • Ordinal value of column in key (followed by a colon and a space) • Name of column • Order value **(A)** Ascending **(D)** Descending **(R)** Random	Sort key columns.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
SORTTYPE	GLOBAL MERGE PARTITIONED ROUND ROBIN REPLICATED SHARED	Intrapartition parallelism, sort type.
SRCSEVER	Server name	Source (ship to) server.
SPEED	SLOW FAST	"SLOW" indicates that the scan is expected to progress slowly over the table. For example, if the scan is the outer of a nested loop join). "FAST" indicates that the scan is expected to progress with higher speed. This information is used to group scans together for efficient sharing of bufferpool records.
SPILLED	INTEGER	Estimated number of pages in SORT spill.
SQLCA	Warning information	Warnings and reason codes issued during Explain operation.
STARJOIN	YES	The IXAND operator is part of a star join
STMTHEAP	INTEGER	Size of statement heap at start of statement compile.
STMTID	Hexadecimal string representing a BIGINT value	Identifier uniquely representing a normalized form of the SQL statement. The statement normalization follows the optimization profile's inexact matching rules.
STREAM	TRUE FALSE	Remote source is streaming.
SYSTSENS	YES NO	Indicates that the SYSTIMESENSITIVE bind option is in effect
TABLOCK	EXCLUSIVE INTENT EXCLUSIVE INTENT NONE INTENT SHARE REUSE SHARE SHARE INTENT EXCLUSIVE SUPER EXCLUSIVE UPDATE	Table Lock Intent.
TBISOLVL	UNCOMMITED READ READ STABILITY CURSOR STABILITY REPEATABLE READ	Indicates the isolation level used by the operator to access the specific table
TEMPSIZE	INTEGER	Temporary table page size.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
THROTTLE	TRUE FALSE	Throttling improves the performance of other scans that would otherwise lag behind and be forced to reread the same pages. "TRUE" if the scan can be throttled. "FALSE" if the scan must not be throttled.
TMPCMPRS	YES ELIGIBLE	The value YES indicates that compression is applied. The value ELIGIBLE indicates that compression may be applied if the table becomes large enough. The absence of TMPCMPRS indicates that the temporary table is not compressed.
TQDEGREE	INTEGER	Intrapartition parallelism, number of subagents accessing Table Queue. If the TQ operator represents the transition between column-organized data processing and row-organized data processing, the TQDEGREE argument indicates the number of column-organized processing subagents that are used to process the query in parallel.
TQMERGE	TRUE FALSE	Merging (sorted) Table Queue indicator.
TQNUMBER	INTEGER	Table queue identification number.
TQREAD	READ AHEAD STEPPING SUBQUERY STEPPING	Table Queue reading property.
TQSECNFM	INTEGER	Subsection number at the sending end of the table queue.
TQSECNTO	INTEGER	Subsection number at the receiving end of the table queue.
TQSEND	BROADCAST DIRECTED SCATTER SUBQUERY DIRECTED	Table Queue send property.
TQ TYPE	LOCAL	Intrapartition parallelism, Table Queue.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
TQORIGIN	ASYNCHRONY XTQ COLUMN-ORGANIZED DATA ROW-ORGANIZED DATA	The reason that Table Queue was introduced into the access plan. `COLUMN-ORGANIZED DATA` indicates that the TQ operator is being used to transfer data from column-organized processing to row-organized processing. `ROW-ORGANIZED DATA` indicates that the TQ operator is being used to transfer data from row-organized processing to column-organized processing. `COLUMN-ORGANIZED DATA` or `ROW-ORGANIZED DATA` values result in the TQ operator being displayed as `CTQ` in the access plan.
TRUNCTQ	INPUT OUTPUT INPUT AND OUTPUT	Truncated Table Queue indicator. INPUT indicates that truncation occurs on input to the Table Queue. OUPUT indicates that truncation occurs on output from the Table Queue. INPUT and OUTPUT indicates that truncation occurs on both input to the Table Queue and on output from the Table Queue.
TRUNCSRT	TRUE	Truncated sort (limits number of rows produced).
TUPBLKSZ	INTEGER	Component of the total sort heap required to perform a hash join that determines the number of bytes that a tuple will be stored in. This can be used by service to diagnose memory, temporary table and to some degree sort heap usage.
UNIQUE	TRUE FALSE HASHED PARTIAL HASHED COMPLETE	This operator eliminates rows having duplicate values for a set of columns. HASHED PARTIAL indicates that a partial early distinct operation was performed to efficiently remove many, if not all, duplicates. This reduces the amount of data that must be processed later in the query evaluation. HASHED COMPLETE indicates that hashing is used to eliminate duplicates during column-organized data processing.
UNIQKEY	Each row of this type will contain: • Ordinal value of column in key (followed by a colon and a space) • Name of Column	Unique key columns.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
UR_EXTRA	TRUE	Uncommitted read isolation, but with extra processing to ensure correct isolation. This access has extra table level locking; the same table level locking as cursor stability. Also, when the statement is executing, the isolation level might upgrade to cursor stability, for example, if an online load is running concurrently. Another part of the statement execution plan will ensure the isolation level is correct, such as a FETCH operator at a higher isolation level.
USAGE	SCALAR_SUBQUERY	Indicates how the NLJOIN operator is being used. SCALAR_SUBQUERY indicates that the NLJOIN operator is being used to apply a scalar subquery predicate. Hash join is the only join method used for column-organized tables. However, the optimizer uses the NLJOIN operator to model the application of scalar subqueries during column-organized data processing. One of the input legs to the NLJOIN operator is the single value that is computed by the scalar subquery. The other input to the operator is the data stream whose predicate references the scalar value.
VISIBLE	TRUE FALSE	Whether shared scans are visible to other shared scans. A shared scan that is visible can influence the behavior of other scans. Examples of affected behavior include start location and throttling.
VOLATILE	TRUE	Volatile table
WRAPPING	TRUE FALSE	Whether a shared scan is allowed to start at any record in the table and wrap once it reaches the last record. Wrapping allows bufferpool records to be shared with other ongoing scans.
XFERRATE	DOUBLE	Optimizer used TRANSFERRATE value.
XDFOUT	DECIMAL	XDFOUT indicates the expected number of documents to be returned by the XISCAN operator for each context node.
XLOGID	An identifier consisting of an SQL schema name and the name of an index over XML data	XLOGID identifies the index over XML data chosen by the optimizer for the XISCAN operator.

Table 335. ARGUMENT_TYPE and ARGUMENT_VALUE column values (continued)

ARGUMENT_TYPE Value	Possible ARGUMENT_VALUE Values	Description
XPATH	An XPATH expression and result set in an internal format	This argument indicates the evaluation of an XPATH expression by the XSCAN operator.
XPHYID	An identifier consisting of an SQL schema name and the name of a physical index over XML data	XPHYID identifies the physical index that is associated with an index over XML data used by the XISCAN operator.

EXPLAIN_DIAGNOSTIC table

The EXPLAIN_DIAGNOSTIC table contains an entry for each diagnostic message produced for a particular instance of an explained statement in the EXPLAIN_STATEMENT table.

The EXPLAIN_GET_MSGS table function queries the EXPLAIN_DIAGNOSTIC and EXPLAIN_DIAGNOSTIC_DATA Explain tables and returns formatted messages.

Table 336. EXPLAIN_DIAGNOSTIC Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	PK, FK	Authorization ID of initiator of this Explain request.
EXPLAIN_TIME	TIMESTAMP	No	PK, FK	Time of initiation for Explain request.
SOURCE_NAME	VARCHAR(128)	No	PK, FK	Name of the package running when the dynamic statement was explained or name of the source file when the static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	PK, FK	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	PK, FK	Version of the source of the Explain request.
EXPLAIN_LEVEL	CHAR(1)	No	PK, FK	Level of Explain information for which this row is relevant. Valid values are: **O** Original text (as entered by user) **P** PLAN SELECTION
STMTNO	INTEGER	No	PK, FK	Statement number within package to which this Explain information is related. Set to 1 for dynamic Explain SQL statements. For static SQL statements, this value is the same as the value used for the SYSCAT.STATEMENTS catalog view.

Table 336. EXPLAIN_DIAGNOSTIC Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
SECTNO	INTEGER	No	PK, FK	Section number within package that contains this SQL statement. For dynamic Explain SQL statements, this is the section number used to hold the section for this statement at run time. For static SQL statements, this value is the same as the value used for the SYSCAT.STATEMENTS catalog view.
DIAGNOSTIC_ID	INTEGER	No	PK	ID of the diagnostic for a particular instance of a statement in the EXPLAIN_STATEMENT table.
CODE	INTEGER	No	No	A unique number assigned to each diagnostic message. The number can be used by a message API to retrieve the full text of the diagnostic message.

EXPLAIN_DIAGNOSTIC_DATA table

The EXPLAIN_DIAGNOSTIC_DATA table contains message tokens for specific diagnostic messages that are recorded in the EXPLAIN_DIAGNOSTIC table. The message tokens provide additional information that is specific to the execution of the SQL statement that generated the message.

The EXPLAIN_GET_MSGS table function queries the EXPLAIN_DIAGNOSTIC and EXPLAIN_DIAGNOSTIC_DATA Explain tables, and returns formatted messages.

Table 337. EXPLAIN_DIAGNOSTIC_DATA Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	FK	Authorization ID of initiator of this Explain request.
EXPLAIN_TIME	TIMESTAMP	No	FK	Time of initiation for Explain request.
SOURCE_NAME	VARCHAR(128)	No	FK	Name of the package running when the dynamic statement was explained or name of the source file when the static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	FK	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	FK	Version of the source of the Explain request.
EXPLAIN_LEVEL	CHAR(1)	No	FK	Level of Explain information for which this row is relevant. Valid values are: **O** Original text (as entered by user) **P** PLAN SELECTION

Table 337. EXPLAIN_DIAGNOSTIC_DATA Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
STMTNO	INTEGER	No	FK	Statement number within package to which this Explain information is related. Set to 1 for dynamic Explain SQL statements. For static SQL statements, this value is the same as the value used for the SYSCAT.STATEMENTS catalog view.
SECTNO	INTEGER	No	FK	Section number within package that contains this SQL statement. For dynamic Explain SQL statements, this is the section number used to hold the section for this statement at run time. For static SQL statements, this value is the same as the value used for the SYSCAT.STATEMENTS catalog view.
DIAGNOSTIC_ID	INTEGER	No	PK	ID of the diagnostic for a particular instance of a statement in the EXPLAIN_STATEMENT table.
ORDINAL	INTEGER	No	No	Position of token in the full message text.
TOKEN	VARCHAR(1000)	Yes	No	Message token to be inserted into the full message text; might be truncated.
TOKEN_LONG	BLOB(3M)	Yes	No	More detailed information, if available.

EXPLAIN_INSTANCE table

The EXPLAIN_INSTANCE table is the main control table for all Explain information. Each row of data in the Explain tables is explicitly linked to one unique row in this table.

The EXPLAIN_INSTANCE table gives basic information about the source of the SQL statements being explained as well as information about the environment in which the explanation took place.

Table 338. EXPLAIN_INSTANCE Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	PK	Authorization ID of initiator of this Explain request.
EXPLAIN_TIME	TIMESTAMP	No	PK	Time of initiation for Explain request.
SOURCE_NAME	VARCHAR(128)	No	PK	Name of the package running when the dynamic statement was explained or name of the source file when the static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	PK	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	PK	Version of the source of the Explain request.

Table 338. EXPLAIN_INSTANCE Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
EXPLAIN_OPTION	CHAR(1)	No	No	Indicates what Explain Information was requested for this request. Possible values are: **P** PLAN SELECTION **S** Section Explain
SNAPSHOT_TAKEN	CHAR(1)	No	No	Indicates whether an Explain Snapshot was taken for this request. Possible values are: **Y** Yes, an Explain Snapshot(s) was taken and stored in the EXPLAIN_STATEMENT table. Regular Explain information was also captured. **N** No Explain Snapshot was taken. Regular Explain information was captured. **O** Only an Explain Snapshot was taken. Regular Explain information was not captured.
DB2_VERSION	CHAR(7)	No	No	Release number for the Db2 product that processed this explain request. Format is: VV.RR.M., where: **vv** Version number **rr** Release number **m** Modification pack To see the complete product signature information for an EXPLAIN instance, review BLDLEVEL argument row recorded in the "EXPLAIN_ARGUMENT table" on page 2174.
SQL_TYPE	CHAR(1)	No	No	Indicates whether the Explain Instance was for static or dynamic SQL. Possible values are: **S** Static SQL **D** Dynamic SQL

Table 338. EXPLAIN_INSTANCE Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
QUERYOPT	INTEGER	No	No	Indicates the query optimization class used by the SQL Compiler at the time of the Explain invocation. The value indicates what level of query optimization was performed by the SQL Compiler for the SQL statements being explained.
BLOCK	CHAR(1)	No	No	Indicates what type of cursor blocking was used when compiling the SQL statements. Possible values are: **N** No Blocking **U** Block Unambiguous Cursors **B** Block All Cursors
ISOLATION	CHAR(2)	No	No	Indicates what type of isolation was used when compiling the SQL statements. Possible values are: **RR** Repeatable Read **RS** Read Stability **CS** Cursor Stability **UR** Uncommitted Read
BUFFPAGE	INTEGER	No	No	Contains the value of the **buffpage** database configuration setting at the time of the Explain invocation. **Important:** The **buffpage** database configuration is deprecated and might be remove in a future release.
AVG_APPLS	INTEGER	No	No	Contains the value of the **avg_appls** configuration parameter at the time of the Explain invocation.
SORTHEAP	INTEGER	No	No	Contains the value of the **sortheap** database configuration parameter at the time of the Explain invocation.
LOCKLIST	INTEGER	No	No	Contains the value of the **locklist** database configuration parameter at the time of the Explain invocation.

Table 338. EXPLAIN_INSTANCE Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable ?	Key?	Description
MAXLOCKS	SMALLINT	No	No	Contains the value of the **maxlocks** database configuration parameter at the time of the Explain invocation.
LOCKS_AVAIL	INTEGER	No	No	Contains the number of locks assumed to be available by the optimizer for each user. (Derived from **locklist** and **maxlocks**.)
CPU_SPEED	DOUBLE	No	No	Contains the value of the **cpuspeed** database manager configuration parameter at the time of the Explain invocation.
REMARKS	VARCHAR(254)	Yes	No	User-provided comment.
DBHEAP	INTEGER	No	No	Contains the value of the **dbheap** database configuration parameter at the time of Explain invocation.
COMM_SPEED	DOUBLE	No	No	Contains the value of the **comm_bandwidth** database configuration parameter at the time of Explain invocation.
PARALLELISM	CHAR(2)	No	No	Possible values are: • N = No parallelism • P = Intrapartition parallelism • IP = Interpartition parallelism • BP = Intrapartition parallelism and interpartition parallelism
DATAJOINER	CHAR(1)	No	No	Possible values are: • N = Non-federated systems plan • Y = Federated systems plan
EXECUTABLE_ID	VARCHAR(32) FOR BIT DATA	Yes	No	A binary token generated on the data server that uniquely identifies the SQL statement section that was executed.
EXECUTION_TIME	TIMESTAMP	Yes	No	Time the section started execution.

EXPLAIN_OBJECT table

The EXPLAIN_OBJECT table identifies those data objects required by the access plan generated to satisfy the SQL statement.

Table 339. EXPLAIN_OBJECT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable ?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	FK	Authorization ID of initiator of this Explain request.
EXPLAIN_TIME	TIMESTAMP	No	FK	Time of initiation for Explain request.

Table 339. EXPLAIN_OBJECT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable ?	Key?	Description
SOURCE_NAME	VARCHAR(128)	No	FK	Name of the package running when the dynamic statement was explained or name of the source file when the static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	FK	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	FK	Version of the source of the Explain request.
EXPLAIN_LEVEL	CHAR(1)	No	FK	Level of Explain information for which this row is relevant.
STMTNO	INTEGER	No	FK	Statement number within package to which this explain information is related.
SECTNO	INTEGER	No	FK	Section number within package to which this explain information is related.
OBJECT_SCHEMA	VARCHAR(128)	No	No	Schema to which this object belongs.
OBJECT_NAME	VARCHAR(128)	No	No	Name of the object.
OBJECT_TYPE	CHAR(2)	No	No	Descriptive label for the type of object.
CREATE_TIME	TIMESTAMP	Yes	No	Time of Object's creation; null if a table function.
STATISTICS_TIME	TIMESTAMP	Yes	No	Last time of update to statistics for this object; null if statistics do not exist for this object.
COLUMN_COUNT	SMALLINT	No	No	Number of columns in this object.
ROW_COUNT	INTEGER	No	No	Estimated number of rows in this object.
WIDTH	INTEGER	No	No	The average width of the object in bytes. Set to -1 for an index.
PAGES	BIGINT	No	No	Estimated number of pages that the object occupies in the buffer pool. Set to -1 for a table function.
DISTINCT	CHAR(1)	No	No	Indicates whether the rows in the object are distinct (that is, whether there are duplicates). Possible values are: **Y** Yes **N** No
TABLESPACE_NAME	VARCHAR(128)	Yes	No	Name of the table space in which this object is stored; set to null if no table space is involved.

Table 339. EXPLAIN_OBJECT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable ?	Key?	Description
OVERHEAD	DOUBLE	No	No	Total estimated overhead, in milliseconds, for a single random I/O to the specified table space. Includes controller overhead, disk seek, and latency times. Set to -1 if: • no table space is involved • a partitioned object is involved and the respective table spaces for the partitions have different values • a partitioned object is involved and the EXPLAIN_OBJECT table is populated using section explain
TRANSFER_RATE	DOUBLE	No	No	Estimated time to read a data page, in milliseconds, from the specified table space. Set to -1 if: • no table space is involved • a partitioned object is involved and the respective table spaces for the partitions have different values • a partitioned object is involved and the EXPLAIN_OBJECT table is populated using section explain
PREFETCHSIZE	INTEGER	No	No	Number of data pages to be read when prefetch is performed. Set to -1 if: • no table space is involved • a partitioned object is involved and the respective table spaces for the partitions have different values • a partitioned object is involved and the EXPLAIN_OBJECT table is populated using section explain
EXTENTSIZE	INTEGER	No	No	Size of extent, in data pages. This many pages are written to one container in the table space before switching to the next container. Set to -1 for a table function.
CLUSTER	DOUBLE	No	No	Degree of data clustering with the index. If >= 1, this is the CLUSTERRATIO. If >= 0 and < 1, this is the CLUSTERFACTOR. Set to -1 for a table, table function, or if this statistic is not available.
NLEAF	BIGINT	No	No	Number of leaf pages this index object's values occupy. Set to -1 for a table, table function, or if this statistic is not available.
NLEVELS	INTEGER	No	No	Number of index levels in this index object's tree. Set to -1 for a table, table function, or if this statistic is not available.

Table 339. EXPLAIN_OBJECT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable ?	Key?	Description
FULLKEYCARD	BIGINT	No	No	Number of distinct full key values contained in this index object. Set to -1 for a table, table function, or if this statistic is not available.
OVERFLOW	BIGINT	No	No	Total number of overflow records in the table. Set to -1 for an index, table function, or if this statistic is not available.
FIRSTKEYCARD	BIGINT	No	No	Number of distinct first key values. Set to -1 for a table, table function, or if this statistic is not available.
FIRST2KEYCARD	BIGINT	No	No	Number of distinct first key values using the first 2 columns of the index. Set to -1 for a table, table function, or if this statistic is not available.
FIRST3KEYCARD	BIGINT	No	No	Number of distinct first key values using the first 3 columns of the index. Set to -1 for a table, table function, or if this statistic is not available.
FIRST4KEYCARD	BIGINT	No	No	Number of distinct first key values using the first 4 columns of the index. Set to -1 for a table, table function, or if this statistic is not available.
SEQUENTIAL_PAGES	BIGINT	No	No	Number of leaf pages located on disk in index key order with few or no large gaps between them. Set to -1 for a table, table function, or if this statistic is not available.
DENSITY	INTEGER	No	No	Ratio of SEQUENTIAL_PAGES to number of pages in the range of pages occupied by the index, expressed as a percentage (integer between 0 and 100). Set to -1 for a table, table function, or if this statistic is not available.
STATS_SRC	CHAR(1)	No	No	Indicates the source for the statistics. Set to 1 if from single node.
AVERAGE_SEQUENCE_GAP	DOUBLE	No	No	Gap between sequences.
AVERAGE_SEQUENCE_FETCH_GAP	DOUBLE	No	No	Gap between sequences when fetching using the index.
AVERAGE_SEQUENCE_PAGES	DOUBLE	No	No	Average number of index pages accessible in sequence.
AVERAGE_SEQUENCE_FETCH_PAGES	DOUBLE	No	No	Average number of table pages accessible in sequence when fetching using the index.
AVERAGE_RANDOM_PAGES	DOUBLE	No	No	Average number of random index pages between sequential page accesses.
AVERAGE_RANDOM_FETCH_PAGES	DOUBLE	No	No	Average number of random table pages between sequential page accesses when fetching using the index.
NUMRIDS	BIGINT	No	No	Total number of row identifiers in the index.

Table 339. EXPLAIN_OBJECT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
NUMRIDS_DELETED	BIGINT	No	No	Total number of psuedo-deleted row identifiers in the index.
NUM_EMPTY_LEAFS	BIGINT	No	No	Total number of empty leaf pages in the index.
ACTIVE_BLOCKS	BIGINT	No	No	Total number of active multidimensional clustering (MDC) blocks in the table.
NUM_DATA_PART	INTEGER	No	No	Number of data partitions for a partitioned table. Set to 1 if the table is not partitioned.
NULLKEYS	CHAR(1)	Yes	No	Specifies whether null keys are indexed. • N = Keys that contain all null values are not indexed (not considering columns or expressions from the INCLUDE clause) • Y = Keys that contain all null values are indexed (not considering columns or expressions from the INCLUDE clause) A null value indicates that this object is not an index.
OBJECT_TENANTID	INTEGER	No	No	ID for tenant where object is defined.

Table 340. Possible OBJECT_TYPE Values

Value	Description
IX	Index
NK	Nickname
RX	RCT index
DP	Data partitioned table
TA	Table
TF	Table function
+A	Compiler-referenced alias
+C	Compiler-referenced constraint
+F	Compiler-referenced function
+G	Compiler-referenced trigger
+N	Compiler-referenced nickname
+T	Compiler-referenced table
+V	Compiler-referenced view
XI	Logical XML index
PI	Physical XML index
LI	Partitioned index

Table 340. Possible OBJECT_TYPE Values (continued)

Value	Description
LX	Partitioned logical XML index
LP	Partitioned physical XML index
CO	Column-organized table

EXPLAIN_OPERATOR table

The EXPLAIN_OPERATOR table contains all the operators needed to satisfy the query statement by the query compiler.

Table 341. EXPLAIN_OPERATOR Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable ?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	PK	Authorization ID of initiator of this Explain request.
EXPLAIN_TIME	TIMESTAMP	No	PK	Time of initiation for Explain request.
SOURCE_NAME	VARCHAR(128)	No	PK	Name of the package running when the dynamic statement was explained or name of the source file when the static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	PK	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	PK	Version of the source of the Explain request.
EXPLAIN_LEVEL	CHAR(1)	No	PK	Level of Explain information for which this row is relevant.
STMTNO	INTEGER	No	PK	Statement number within package to which this explain information is related.
SECTNO	INTEGER	No	PK	Section number within package to which this explain information is related.
OPERATOR_ID	INTEGER	No	PK	Unique ID for this operator within this query.
OPERATOR_TYPE	CHAR(6)	No	No	Descriptive label for the type of operator.
TOTAL_COST	DOUBLE	No	No	Estimated cumulative total cost (in timerons) of executing the chosen access plan up to and including this operator.
IO_COST	DOUBLE	No	No	Estimated cumulative I/O cost (in data page I/Os) of executing the chosen access plan up to and including this operator.
CPU_COST	DOUBLE	No	No	Estimated cumulative CPU cost (in instructions) of executing the chosen access plan up to and including this operator.
FIRST_ROW_COST	DOUBLE	No	No	Estimated cumulative cost (in timerons) of fetching the first row for the access plan up to and including this operator. This value includes any initial overhead required.

Table 341. EXPLAIN_OPERATOR Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
RE_TOTAL_COST	DOUBLE	No	No	Estimated cumulative cost (in timerons) of fetching the next row for the chosen access plan up to and including this operator.
RE_IO_COST	DOUBLE	No	No	Estimated cumulative I/O cost (in data page I/Os) of fetching the next row for the chosen access plan up to and including this operator.
RE_CPU_COST	DOUBLE	No	No	Estimated cumulative CPU cost (in instructions) of fetching the next row for the chosen access plan up to and including this operator.
COMM_COST	DOUBLE	No	No	Estimated cumulative communication cost (in TCP/IP frames) of network traffic flowing across a single network adapter when executing the chosen access plan up to and including this operator. (See notes 1 and 2.)
FIRST_COMM_COST	DOUBLE	No	No	Estimated cumulative communications cost (in TCP/IP frames) of network traffic flowing across a single network adapter when fetching the first row for the chosen access plan up to and including this operator. This value includes any initial overhead required. (See notes 1 and 2.)
BUFFERS	DOUBLE	No	No	Estimated buffer requirements for this operator and its inputs.
REMOTE_TOTAL_COST	DOUBLE	No	No	Estimated cumulative total cost (in timerons) of performing operation(s) on remote database(s).
REMOTE_COMM_COST	DOUBLE	No	No	Estimated cumulative communication cost of executing the chosen remote access plan up to and including this operator.

Note:

1. If there is more than one network adapter involved, the cumulative communication cost for the adapter with the highest value is returned.
2. This value only includes the costs of network traffic between physical machines. It does not include the virtual communication costs between node partitions on the same physical machine in a partitioned database environment.

Table 342. OPERATOR_TYPE values

Value	Description
CMPEXP	Represent the projection of columns and expression from a subselect in the optimized version of an SQL statement
DELETE	Delete
EISCAN	Extended Index Scan
FETCH	Fetch
FILTER	Filter rows

Table 342. OPERATOR_TYPE values (continued)

Value	Description
GENROW	Generate Row
GRPBY	Group By
HSJOIN	Hash Join
INSERT	Insert
IXAND	Dynamic Bitmap Index ANDing
IXSCAN	Relational index scan
MSJOIN	Merge Scan Join
NLJOIN	Nested loop Join
REBAL	Rebalance rows between SMP subagents
RETURN	Result
RIDSCN	Row Identifier (RID) Scan
RPD	Remote PushDown
SHIP	Ship query to remote system
SORT	Sort
TBFUNC	In-stream table function operator
TBSCAN	Table Scan
TEMP	Temporary Table Construction
TQ	Table Queue
UNION	Union
UNIQUE	Duplicate Elimination
UPDATE	Update
XISCAN	Index scan over XML data
XSCAN	XML document navigation scan
XANDOR	Index ANDing and ORing over XML data
ZZJOIN	Zigzag join

EXPLAIN_PREDICATE table

The EXPLAIN_PREDICATE table identifies which predicates are applied by a specific operator.

Table 343. EXPLAIN_PREDICATE Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable ?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	FK	Authorization ID of initiator of this Explain request.
EXPLAIN_TIME	TIMESTAMP	No	FK	Time of initiation for Explain request.

Table 343. EXPLAIN_PREDICATE Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
SOURCE_NAME	VARCHAR(128)	No	FK	Name of the package running when the dynamic statement was explained or name of the source file when the static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	FK	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	FK	Version of the source of the Explain request.
EXPLAIN_LEVEL	CHAR(1)	No	FK	Level of Explain information for which this row is relevant.
STMTNO	INTEGER	No	FK	Statement number within package to which this explain information is related.
SECTNO	INTEGER	No	FK	Section number within package to which this explain information is related.
OPERATOR_ID	INTEGER	No	No	Unique ID for this operator within this query.
PREDICATE_ID	INTEGER	No	No	Unique ID for this predicate for the specified operator. A value of "-1" is shown for operator predicates constructed by the Explain tool which are not optimizer objects and do not exist in the optimizer plan.
HOW_APPLIED	CHAR(10)	No	No	How predicate is being used by the specified operator.
WHEN_EVALUATED	CHAR(3)	No	No	Indicates when the subquery used in this predicate is evaluated. Possible values are: **blank** This predicate does not contain a subquery. **EAA** The subquery used in this predicate is evaluated at application (EAA). That is, it is re-evaluated for every row processed by the specified operator, as the predicate is being applied. **EAO** The subquery used in this predicate is evaluated at open (EAO). That is, it is re-evaluated only once for the specified operator, and its results are re-used in the application of the predicate for each row. **MUL** There is more than one type of subquery in this predicate.
RELOP_TYPE	CHAR(2)	No	No	The type of relational operator used in this predicate.

Table 343. EXPLAIN_PREDICATE Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
SUBQUERY	CHAR(1)	No	No	Whether or not a data stream from a subquery is required for this predicate. There may be multiple subquery streams required. Possible values are: **N** No subquery stream is required **Y** One or more subquery streams is required
FILTER_FACTOR	DOUBLE	No	No	The estimated fraction of rows that will be qualified by this predicate. A value of "-1" is shown when FILTER_FACTOR is not applicable. FILTER_FACTOR is not applicable for operator predicates constructed by the Explain tool which are not optimizer objects and do not exist in the optimizer plan.
PREDICATE_TEXT	CLOB(2M)	Yes	No	The text of the predicate as recreated from the internal representation of the SQL or XQuery statement. If the value of a host variable, special register, or parameter marker is used during compilation of the statement, this value will appear at the end of the predicate text enclosed in a comment. The value will be stored in the EXPLAIN_PREDICATE table only if the statement is executed by a user who has DBADM authority, or if the DB2_VIEW_REOPT_VALUES registry variable is set to YES; otherwise, an empty comment will appear at the end of the predicate text. Null if not available.
RANGE_NUM	INTEGER	Yes	No	Range of data partition elimination predicates, which enables the grouping of predicates that are used for data partition elimination by range. Null value for all other predicate types.
INDEX_COLSEQ	INTEGER	No	No	Indicates the index column that the predicate belongs to if it is part of a key predicate. A key predicate always belongs to one index key part. A value of "-1" is shown for predicates that are not part of a key predicate.

Table 344. Possible HOW_APPLIED Values

Value	Description
BIT_FLTR	Predicate is applied as a bit filter

Table 344. Possible HOW_APPLIED Values (continued)

Value	Description
BSARG	Evaluated as a sargable predicate once for every block
DPSTART	Start key predicate used in data partition elimination
DPSTOP	Stop key predicate used in data partition elimination
ESARG	Evaluated as a sargable predicate by external reader.
JOIN	Used to join tables
RANGE_FLTR	Predicate is applied as a range filter
RESID	Evaluated as a residual predicate
SARG	Evaluated as a sargable predicate for index or data page
GAP_START	Used as a start condition on an index gap
GAP_STOP	Used as a stop condition on an index gap
START	Used as a start condition
STOP	Used as a stop condition
FEEDBACK	Zigzag join feedback predicate

Table 345. Possible RELOP_TYPE Values

Value	Description
blanks	Not Applicable
EQ	Equals
GE	Greater Than or Equal
GT	Greater Than
IN	In list
IC	In list, sorted during query optimization
IR	In list, sorted at runtime
LE	Less Than or Equal
LK	Like
LT	Less Than
NE	Not Equal
NL	Is Null
NN	Is Not Null
RE	REGEXP_LIKE

EXPLAIN_STATEMENT table

The EXPLAIN_STATEMENT table contains the text of the SQL statement as it exists for the different levels of Explain information.

The original SQL statement as entered by the user is stored in this table along with the version used (by the optimizer) to choose an access plan to satisfy the SQL statement. The latter version may bear

little resemblance to the original as it may have been rewritten or enhanced with additional predicates as determined by the SQL Compiler. In addition, if statement concentrator is enabled and the statement was changed as a result of statement concentrator, the effective SQL statement will also be stored in this table. This statement will resemble the original statement except that the literal values will be replaced with system generated named parameter markers. The plan information will be based on the effective statement in this case.

Table 346. EXPLAIN_STATEMENT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	PK, FK	Authorization ID of initiator of this Explain request.
EXPLAIN_TIME	TIMESTAMP	No	PK, FK	Time of initiation for Explain request.
SOURCE_NAME	VARCHAR(128)	No	PK, FK	Name of the package running when the dynamic statement was explained or name of the source file when the static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	PK, FK	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	PK, FK	Version of the source of the Explain request.
EXPLAIN_LEVEL	CHAR(1)	No	PK	Level of Explain information for which this row is relevant. Valid values are: **E** Effective SQL text **F** Statement with row and column access control applied, before optimization **O** Original Text (as entered by user) **P** PLAN SELECTION **S** Section Explain
STMTNO	INTEGER	No	PK	Statement number within package to which this explain information is related. Set to 1 for dynamic Explain SQL statements. For static SQL statements, this value is the same as the value used for the SYSCAT.STATEMENTS catalog view.
SECTNO	INTEGER	No	PK	Section number within package that contains this SQL statement. For dynamic Explain SQL statements, this is the section number used to hold the section for this statement at runtime. For static SQL statements, this value is the same as the value used for the SYSCAT.STATEMENTS catalog view.

Table 346. EXPLAIN_STATEMENT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
QUERYNO	INTEGER	No	No	Numeric identifier for explained SQL statement. For dynamic SQL statements (excluding the EXPLAIN SQL statement) issued through CLP or CLI, the default value is a sequentially incremented value. Otherwise, the default value is the value of STMTNO for static SQL statements and 1 for dynamic SQL statements.
QUERYTAG	CHAR(20)	No	No	Identifier tag for each explained SQL statement. For dynamic SQL statements issued through CLP (excluding the EXPLAIN SQL statement), the default value is "CLP". For dynamic SQL statements issued through CLI (excluding the EXPLAIN SQL statement), the default value is "CLI". Otherwise, the default value used is blanks.
STATEMENT_TYPE	CHAR(2)	No	No	Descriptive label for type of query being explained. Possible values are: **CL** Call **CP** Compound SQL (Dynamic) **D** Delete **DC** Delete where current of cursor **I** Insert **M** Merge **S** Select **SI** Set Integrity or Refresh Table **U** Update **UC** Update where current of cursor

Table 346. EXPLAIN_STATEMENT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
UPDATABLE	CHAR(1)	No	No	Indicates if this statement is considered updatable. This is particularly relevant to SELECT statements which may be determined to be potentially updatable. Possible values are: **' '** Not applicable (blank) **N** No **Y** Yes
DELETABLE	CHAR(1)	No	No	Indicates if this statement is considered deletable. This is particularly relevant to SELECT statements which may be determined to be potentially deletable. Possible values are: **' '** Not applicable (blank) **N** No **Y** Yes
TOTAL_COST	DOUBLE	No	No	Estimated total cost (in timerons) of executing the chosen access plan for this statement; set to 0 (zero) if EXPLAIN_LEVEL is 0 or E (original or effective text) since no access plan has been chosen at this time.
STATEMENT_TEXT	CLOB(2M)	No	No	Text or portion of the text of the SQL statement being explained. The text shown for the Plan Selection or Section Explain levels of Explain has been reconstructed from the internal representation and is SQL-like in nature; that is, the reconstructed statement is not guaranteed to follow correct SQL syntax.
SNAPSHOT	BLOB(10M)	Yes	No	Snapshot of internal representation for this SQL statement at the Explain_Level shown. Column is set to NULL if EXPLAIN_LEVEL is not P (Plan Selection) since no access plan has been chosen at the time that this specific version of the statement is captured.

Table 346. EXPLAIN_STATEMENT Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
QUERY_DEGREE	INTEGER	No	No	Indicates the degree of intrapartition parallelism at the time of Explain invocation. For the original statement, this contains the directed degree of intrapartition parallelism. Otherwise, this contains the degree of intrapartition parallelism generated for the plan to use.

EXPLAIN_STREAM table

The EXPLAIN_STREAM table represents the input and output data streams between individual operators and data objects. The data objects themselves are represented in the EXPLAIN_OBJECT table. The operators involved in a data stream are to be found in the EXPLAIN_OPERATOR table.

Table 347. EXPLAIN_STREAM Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key.

Column Name	Data Type	Nullable?	Key?	Description
EXPLAIN_REQUESTER	VARCHAR(128)	No	FK	Authorization ID of initiator of this Explain request.
EXPLAIN_TIME	TIMESTAMP	No	FK	Time of initiation for Explain request.
SOURCE_NAME	VARCHAR(128)	No	FK	Name of the package running when the dynamic statement was explained or name of the source file when the static SQL was explained.
SOURCE_SCHEMA	VARCHAR(128)	No	FK	Schema, or qualifier, of source of Explain request.
SOURCE_VERSION	VARCHAR(64)	No	FK	Version of the source of the Explain request.
EXPLAIN_LEVEL	CHAR(1)	No	FK	Level of Explain information for which this row is relevant.
STMTNO	INTEGER	No	FK	Statement number within package to which this explain information is related.
SECTNO	INTEGER	No	FK	Section number within package to which this explain information is related.
STREAM_ID	INTEGER	No	No	Unique ID for this data stream within the specified operator.
SOURCE_TYPE	CHAR(1)	No	No	Indicates the source of this data stream: **O** Operator **D** Data Object
SOURCE_ID	SMALLINT	No	No	Unique ID for the operator within this query that is the source of this data stream. Set to -1 if SOURCE_TYPE is 'D'.

Table 347. EXPLAIN_STREAM Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable ?	Key?	Description
TARGET_TYPE	CHAR(1)	No	No	Indicates the target of this data stream: **O** Operator **D** Data Object
TARGET_ID	SMALLINT	No	No	Unique ID for the operator within this query that is the target of this data stream. Set to -1 if TARGET_TYPE is 'D'.
OBJECT_SCHEMA	VARCHAR(128)	Yes	No	Schema to which the affected data object belongs. Set to null if both SOURCE_TYPE and TARGET_TYPE are 'O'.
OBJECT_NAME	VARCHAR(128)	Yes	No	Name of the object that is the subject of data stream. Set to null if both SOURCE_TYPE and TARGET_TYPE are 'O'.
STREAM_COUNT	DOUBLE	No	No	Estimated cardinality of data stream.
COLUMN_COUNT	SMALLINT	No	No	Number of columns in data stream.
PREDICATE_ID	INTEGER	No	No	If this stream is part of a subquery for a predicate, the predicate ID will be reflected here, otherwise the column is set to -1.
COLUMN_NAMES	CLOB(2M)	Yes	No	This column contains the names and ordering information of the columns involved in this stream. These names will be in the format of: `NAME1(A) + NAME2(D) + NAME3(E) + NAME4` Where *(A)* indicates a column in ascending order, *(D)* indicates a column in descending order, and no ordering information indicates that either the column is not ordered or ordering is not relevant. *(E)* indicates a column in a column-organized table which is encoded as a result of compression, and can occur with or without ordering information.
PMID	SMALLINT	No	No	Distribution map ID.

Table 347. EXPLAIN_STREAM Table. PK means that the column is part of a primary key; FK means that the column is part of a foreign key. *(continued)*

Column Name	Data Type	Nullable?	Key?	Description
SINGLE_NODE	CHAR(5)	Yes	No	Indicates whether this data stream is on a single or on multiple database partitions: **MULT** On multiple database partitions **COOR** On coordinator node **HASH** Directed using hashing **RID** Directed using the row ID **FUNC** Directed using a function (HASHEDVALUE() or DBPARTITIONNUM()) **CORR** Directed using a correlation value **Numeric** Directed to predetermined single node
PARTITION_COLUMNS	CLOB(2M)	Yes	No	List of the columns on which this data stream is distributed.
SEQUENCE_SIZES	CLOB(2M)	Yes	No	Lists the expected sequence size for XML columns, or shows "NA" (not applicable) for any non-XML columns in the data stream. Set to null if there is not at least one XML column in the data stream.
OBJECT_TENANTID	INTEGER	Yes	No	ID for tenant where object is defined.

OBJECT_METRICS table

The OBJECT_METRICS table contains runtime statistics collected for each object referenced in a specific execution of a section (identified by executable ID) at a specific time (identified by execution time).

If object statistics are collected on multiple database members, there will be a row per database member for each object. If it is a partitioned object, then there will be one row per data partition.

The OBJECT_METRICS table is populated only if section actuals were captured by the activity event monitor.

Table 348. OBJECT_METRICS table

Column Name	Data Type	Nullable?	Key?	Description
EXECUTABLE_ID	VARCHAR(32) FOR BIT DATA	No	PK	A binary token generated on the data server that uniquely identifies the SQL statement section that was executed.
EXECUTION_TIME	TIMESTAMP	No	PK	Time the section started execution.
OBJECT_SCHEMA	VARCHAR(128)	No	PK	Schema to which this object belongs.

Table 348. OBJECT_METRICS table (continued)

Column Name	Data Type	Nullable ?	Key?	Description
OBJECT_NAME	VARCHAR(128)	No	PK	Name of the object.
OBJECT_TYPE	CHAR(2)	No	PK	Descriptive label for the type of object. Possible values: **IX** Index **DP** Data partitioned table **TA** Table **PI** Physical XML Index **LI** Partitioned index **LP** Partitioned physical XML index
OBJECT_TENANTID	INTEGER	No	PK	ID for tenant where object is defined.
MEMBER	SMALLINT	No	PK	The database member where the object statistics is collected.
DATA_PARTITION_ID	INTEGER	No	PK	The identifier of the data partition for which information is returned . This element is applicable only to partitioned tables or indexes.
ROWS_READ	BIGINT	Yes	No	The total number of rows read.
ROWS_INSERTED	BIGINT	Yes	No	The total number of row insertions attempted.
ROWS_UPDATED	BIGINT	Yes	No	The total number of row updates attempted.
ROWS_DELETED	BIGINT	Yes	No	The total number of row deletions attempted.
OVERFLOW_CREATES	BIGINT	Yes	No	The number of overflowed rows created on this table object.
OVERFLOW_ACCESSES	BIGINT	Yes	No	The number of accesses (reads and writes) to overflowed rows of this table object.
LOCK_WAIT_TIME	BIGINT	Yes	No	The total elapsed time spent waiting for local locks. The value is given in milliseconds.
LOCK_WAIT_TIME_ GLOBAL	BIGINT	Yes	No	The total elapsed time spent waiting for global locks. The value is given in milliseconds.
LOCK_WAITS	BIGINT	Yes	No	The total number of times that the section waited on locks.
LOCK_WAITS_ GLOBAL	BIGINT	Yes	No	The total number of times that the section waited on global locks.
LOCK_ESCALS	BIGINT	Yes	No	The total number of times that local locks have been escalated.
LOCK_ESCALS_ GLOBAL	BIGINT	Yes	No	The total number of times that global locks have been escalated.

Table 348. OBJECT_METRICS table (continued)

Column Name	Data Type	Nullable?	Key?	Description
DIRECT_WRITES	BIGINT	Yes	No	The total number of write operations that do not use a buffer pool.
DIRECT_WRITE_REQS	BIGINT	Yes	No	The total number of requests to perform a direct write of one or more sectors of data.
DIRECT_READS	BIGINT	Yes	No	The total number of read operations that do not use a buffer pool.
DIRECT_READ_REQS	BIGINT	Yes	No	The total number of requests to perform a direct read of one or more sectors of data.
OBJECT_DATA_L_READS	BIGINT	Yes	No	Indicates the number of data pages which have been requested for the table (logical).
OBJECT_DATA_P_READS	BIGINT	Yes	No	Indicates the number of data pages read in for the table (physical).
OBJECT_DATA_GBP_L_READS	BIGINT	Yes	No	The number of times a Group Buffer Pool (GBP) dependent data page was attempted to be read for the table from the group buffer pool because the page was either invalid or not present in the Local Buffer Pool (LBP).
OBJECT_DATA_GBP_P_READS	BIGINT	Yes	No	The number of times a Group Buffer Pool (GBP) dependent data page was read for the table into the local buffer pool from disk because it was not found in the group buffer pool.
OBJECT_DATA_GBP_INVALID_PAGES	BIGINT	Yes	No	The number of times a data page for XML Storage (XDAs) was attempted to be read for the table from the group buffer pool because the page was invalid in the local buffer pool.
OBJECT_DATA_LBP_PAGES_FOUND	BIGINT	Yes	No	The number of times a data page for the table was present in the local buffer pool.
OBJECT_DATA_GBP_INDEP_PAGES_FOUND_IN_LBP	BIGINT	Yes	No	The number of group buffer pool (GBP) independent data pages found in the local buffer pool (LBP) by the agent.
OBJECT_XDA_L_READS	BIGINT	Yes	No	Indicates the number of data pages for XML Storage (XDAs) which have been requested for the table (logical).
OBJECT_XDA_P_READS	BIGINT	Yes	No	Indicates the number of data pages for XML storage (XDAs) read in for the table (physical).
OBJECT_XDA_GBP_L_READS	BIGINT	Yes	No	The number of times a Group Buffer Pool (GBP) dependent data page for XML Storage (XDAs) was attempted to be read for the table from the group buffer pool because the page was either invalid or not present in the Local Buffer Pool (LBP).
OBJECT_XDA_GBP_P_READS	BIGINT	Yes	No	The number of times a Group Buffer Pool (GBP) dependent data page for XML Storage (XDAs) was read for the table into the local buffer pool from disk because it was not found in the GBP.

Table 348. OBJECT_METRICS table (continued)

Column Name	Data Type	Nullable ?	Key?	Description
OBJECT_XDA_ GBP_INVALID_PAGES	BIGINT	Yes	No	The number of times a data page was attempted to be read for the table from the group buffer pool because the page was invalid in the local buffer pool.
OBJECT_XDA_ LBP_PAGES_FOUND	BIGINT	Yes	No	The number of times a XML Storage (XDAs) data page for the table was present in the local buffer pool.
OBJECT_XDA_ GBP_INDEP_PAGES_ FOUND_IN_LBP	BIGINT	Yes	No	The number of group buffer pool (GBP) independent XML storage object (XDA) data pages found in the local buffer pool (LBP) by the agent.
OBJECT_INDEX_ L_READS	BIGINT	Yes	No	Indicates the number of index pages which have been requested for the index (logical).
OBJECT_INDEX_ P_READS	BIGINT	Yes	No	Indicates the number of index pages read in for the index (physical).
OBJECT_INDEX_ GBP_L_READS	BIGINT	Yes	No	The number of times a Group Buffer Pool (GBP) dependent index page was attempted to be read for the index from the group buffer pool because the page was either invalid or not present in the Local Buffer Pool (LBP).
OBJECT_INDEX_ GBP_P_READS	BIGINT	Yes	No	The number of times a Group Buffer Pool (GBP) dependent index page was read for the index into the local buffer pool from disk because it was not found in the GBP.
OBJECT_INDEX_ GBP_INVALID_PAGES	BIGINT	Yes	No	The number of times an index page was attempted to be read for the index from the group buffer pool because the page was invalid in the local buffer pool.
OBJECT_INDEX_ LBP_PAGES_FOUND	BIGINT	Yes	No	The number of times an index page for the index was present in the local buffer pool.
OBJECT_INDEX_ GBP_INDEP_PAGES_ FOUND_IN_LBP	BIGINT	Yes	No	The number of group buffer pool (GBP) independent index pages found in the local buffer pool (LBP) by the agent.
OBJECT_COL_L_READS	BIGINT	Yes	No	The number of column-organized pages that are logically read from the buffer pool for a table.
OBJECT_COL_P_READS	BIGINT	Yes	No	The number of column-organized pages that are physically read for a table.
OBJECT_COL_GBP_ L_READS	BIGINT	Yes	No	The number of times that a group buffer pool (GBP) dependent column-organized page is requested from the GBP for a table. The page is requested because a valid version of the page does not exist in the local buffer pool (LBP).

Table 348. OBJECT_METRICS table (continued)

Column Name	Data Type	Nullable?	Key?	Description
OBJECT_COL_GBP_P_READS	BIGINT	Yes	No	The number of times that a group buffer pool (GBP) dependent column-organized page is read into the local buffer pool (LBP) from disk for a table. The page is read from disk into the LBP because the page is not in the GBP.
OBJECT_COL_GBP_INVALID_PAGES	BIGINT	Yes	No	The number of times that a column-organized page is requested from the group buffer pool (GBP) for a table. The page is requested because the version of the page in the local buffer pool (LBP) is invalid. Outside of a Db2 pureScale environment, this value is null.
OBJECT_COL_LBP_PAGES_FOUND	BIGINT	Yes	No	The number of times that a column-organized page for a table is present in the local buffer pool (LBP).
OBJECT_COL_GBP_INDEP_PAGES_FOUND_IN_LBP	BIGINT	Yes	No	The number of group buffer pool (GBP) independent column-organized pages found in a local buffer pool (LBP) by an agent.
OBJECT_DATA_CACHING_TIER_L_READS	BIGINT	Yes	No	Reserved for future use.
OBJECT_DATA_CACHING_TIER_PAGES_FOUND	BIGINT	Yes	No	Reserved for future use.
OBJECT_DATA_CACHING_TIER_GBP_INVALID_PAGES	BIGINT	Yes	No	Reserved for future use.
OBJECT_DATA_CACHING_TIER_GBP_INDEP_PAGES_FOUND	BIGINT	Yes	No	Reserved for future use.
OBJECT_XDA_CACHING_TIER_L_READS	BIGINT	Yes	No	Reserved for future use.
OBJECT_XDA_CACHING_TIER_PAGES_FOUND	BIGINT	Yes	No	Reserved for future use.
OBJECT_XDA_CACHING_TIER_GBP_INVALID_PAGES	BIGINT	Yes	No	Reserved for future use.
OBJECT_XDA_CACHING_TIER_GBP_INDEP_PAGES_FOUND	BIGINT	Yes	No	Reserved for future use.
OBJECT_INDEX_CACHING_TIER_L_READS	BIGINT	Yes	No	Reserved for future use.

Table 348. OBJECT_METRICS table (continued)

Column Name	Data Type	Nullable ?	Key?	Description
OBJECT_INDEX_ CACHING_TIER_ PAGES_FOUND	BIGINT	Yes	No	Reserved for future use.
OBJECT_INDEX_ CACHING_TIER_ GBP_INVALID_PAGES	BIGINT	Yes	No	Reserved for future use.
OBJECT_INDEX_ CACHING_TIER_ GBP_INDEP_ PAGES_FOUND	BIGINT	Yes	No	Reserved for future use.
OBJECT_COL_ CACHING_TIER_ L_READS	BIGINT	Yes	No	Reserved for future use.
OBJECT_COL_ CACHING_TIER_ PAGES_FOUND	BIGINT	Yes	No	Reserved for future use.
OBJECT_COL_ CACHING_TIER_ GBP_INVALID_PAGES	BIGINT	Yes	No	Reserved for future use.
OBJECT_COL_ CACHING_TIER_ GBP_INDEP_ PAGES_FOUND	BIGINT	Yes	No	Reserved for future use.
EXT_TABLE_RECV_ WAIT_TIME	BIGINT	Yes	No	Total time the agent spent waiting for the external table readers to read and process data from external tables. The value is given in milliseconds.
EXT_TABLE_ RECVS_TOTAL	BIGINT	Yes	No	Total number of buffers that were received by the agent from the external table readers.
EXT_TABLE_ RECV_VOLUME	BIGINT	Yes	No	Total volume that were received by the agent from the external table readers. The value is given in bytes.
EXT_TABLE_ READ_VOLUME	BIGINT	Yes	No	Total volume that was read by the external table reader from physical devices, such as disks. The value is given in bytes.
EXT_TABLE_SEND_ WAIT_TIME	BIGINT	Yes	No	Total time the agent spent waiting for the sent data to be processed and written by the external table writers. The value is given in milliseconds.
EXT_TABLE_ SENDS_TOTAL	BIGINT	Yes	No	Total number of buffers that were sent to the external table writers.
EXT_TABLE_ SEND_VOLUME	BIGINT	Yes	No	Total volume that was sent by the agent to the external table writers. The value is given in bytes.
EXT_TABLE_ WRITE_VOLUME	BIGINT	Yes	No	Total volume that was written by the external writers to physical devices, such as disks. The value is given in bytes.

Explain register values

The tables in this topic describe the interaction of the CURRENT EXPLAIN MODE and CURRENT EXPLAIN SNAPSHOT special register values, both with each other and with the PREP and BIND commands.

With dynamic SQL, the CURRENT EXPLAIN MODE and CURRENT EXPLAIN SNAPSHOT special register values interact as follows.

Table 349. Interaction of Explain Special Register Values (Dynamic SQL)

EXPLAIN SNAPSHOT values	EXPLAIN MODE values					
	NO	**YES**	**EXPLAIN**	**REOPT**	**RECOMMEND INDEXES**	**EVALUATE INDEXES**
NO	• Results of query returned.	• Explain tables populated. • Results of query returned.	• Explain tables populated. • Results of query not returned (dynamic statements not executed).	• Explain tables populated when a statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain tables populated. • Results of query not returned (dynamic statements not executed). • Indexes recommended.	• Explain tables populated. • Results of query not returned (dynamic statements not executed). • Indexes evaluated.
YES	• Explain Snapshot taken. • Results of query returned.	• Explain tables populated. • Explain Snapshot taken. • Results of query returned.	• Explain tables populated. • Explain Snapshot taken. • Results of query not returned (dynamic statements not executed).	• Explain tables populated when a statement qualifies for reoptimization at execution time. • Explain Snapshot taken. • Results of query returned.	• Explain tables populated. • Explain Snapshot taken. • Results of query not returned (dynamic statements not executed). • Indexes recommended.	• Explain tables populated. • Explain Snapshot taken. • Results of query not returned (dynamic statements not executed). • Indexes evaluated.
EXPLAIN	• Explain Snapshot taken. • Results of query not returned (dynamic statements not executed).	• Explain tables populated. • Explain Snapshot taken. • Results of query not returned (dynamic statements not executed).	• Explain tables populated. • Explain Snapshot taken. • Results of query not returned (dynamic statements not executed).	• Explain tables populated when a statement qualifies for reoptimization at execution time. • Explain Snapshot taken when a statement qualifies for reoptimization at execution time. • Results of query not returned (dynamic or incremental-bind statements not executed).	• Explain tables populated. • Explain Snapshot taken. • Results of query not returned (dynamic statements not executed). • Indexes recommended.	• Explain tables populated. • Explain Snapshot taken. • Results of query not returned (dynamic statements not executed). • Indexes evaluated.

Table 349. Interaction of Explain Special Register Values (Dynamic SQL) (continued)

EXPLAIN SNAPSHOT values	EXPLAIN MODE values					
	NO	YES	EXPLAIN	REOPT	RECOMMEND INDEXES	EVALUATE INDEXES
REOPT	• Explain Snapshot taken when a statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain tables populated. • Explain Snapshot taken when a statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain tables populated. • Explain Snapshot taken when a statement qualifies for reoptimization at execution time. • Results of query not returned (dynamic or incremental-bind statements not executed).	• Explain tables populated when a statement qualifies for reoptimization at execution time. • Explain Snapshot taken when a statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain tables populated. • Explain Snapshot taken when a statement qualifies for reoptimization at execution time. • Results of query not returned (dynamic or incremental-bind statements not executed). • Indexes recommended.	• Explain tables populated. • Explain Snapshot taken when a statement qualifies for reoptimization at execution time. • Results of query not returned (dynamic or incremental-bind statements not executed). • Indexes evaluated.

The CURRENT EXPLAIN MODE special register interacts with the EXPLAIN bind option in the following way for dynamic SQL.

Table 350. Interaction of EXPLAIN Bind Option and CURRENT EXPLAIN MODE

EXPLAIN MODE values	EXPLAIN Bind option values			
	NO	YES	REOPT	ALL
NO	• Results of query returned.	• Explain tables populated for static SQL. • Results of query returned.	• Explain tables populated for static SQL when statement qualifies for reoptimization at execution time. • Explain tables populated for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain tables populated for static SQL. • Explain tables populated for dynamic SQL. • Results of query returned.

Table 350. Interaction of EXPLAIN Bind Option and CURRENT EXPLAIN MODE (continued)

EXPLAIN MODE values	EXPLAIN Bind option values			
	NO	**YES**	**REOPT**	**ALL**
YES	• Explain tables populated for dynamic SQL. • Results of query returned.	• Explain tables populated for static SQL. • Explain tables populated for dynamic SQL. • Results of query returned.	• Explain tables populated for static SQL when statement qualifies for reoptimization at execution time. • Explain tables populated for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain tables populated for static SQL. • Explain tables populated for dynamic SQL. • Results of query returned.
EXPLAIN	• Explain tables populated for dynamic SQL. • Results of query not returned (dynamic statements not executed).	• Explain tables populated for static SQL. • Explain tables populated for dynamic SQL. • Results of query not returned (dynamic statements not executed).	• Explain tables populated for static SQL when statement qualifies for reoptimization at execution time. • Explain tables populated for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query not returned (dynamic statements not executed).	• Explain tables populated for static SQL. • Explain tables populated for dynamic SQL. • Results of query not returned (dynamic statements not executed).

Table 350. Interaction of EXPLAIN Bind Option and CURRENT EXPLAIN MODE (continued)

EXPLAIN MODE values	EXPLAIN Bind option values			
	NO	**YES**	**REOPT**	**ALL**
REOPT	• Explain tables populated for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain tables populated for static SQL when statement qualifies for reoptimization at execution time. • Explain tables populated for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain tables populated for static SQL when statement qualifies for reoptimization at execution time. • Explain tables populated for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain tables populated for static SQL when statement qualifies for reoptimization at execution time. • Explain tables populated for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query returned.
RECOMMEND INDEXES	• Explain tables populated for dynamic SQL. • Results of query not returned (dynamic statements not executed). • Recommend indexes.	• Explain tables populated for static SQL. • Explain tables populated for dynamic SQL. • Results of query not returned (dynamic statements not executed). • Recommend indexes.	• Explain tables populated for static SQL when statement qualifies for reoptimization at execution time. • Explain tables populated for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query not returned (dynamic statements not executed). • Recommend indexes.	• Explain tables populated for static SQL. • Explain tables populated for dynamic SQL. • Results of query not returned (dynamic statements not executed). • Recommend indexes.

Table 350. Interaction of EXPLAIN Bind Option and CURRENT EXPLAIN MODE (continued)

EXPLAIN MODE values	EXPLAIN Bind option values			
	NO	YES	REOPT	ALL
EVALUATE INDEXES	• Explain tables populated for dynamic SQL. • Results of query not returned (dynamic statements not executed). • Evaluate indexes.	• Explain tables populated for static SQL. • Explain tables populated for dynamic SQL. • Results of query not returned (dynamic statements not executed). • Evaluate indexes.	• Explain tables populated for static SQL when statement qualifies for reoptimization at execution time. • Explain tables populated for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query not returned (dynamic statements not executed). • Evaluate indexes.	• Explain tables populated for static SQL. • Explain tables populated for dynamic SQL. • Results of query not returned (dynamic statements not executed). • Evaluate indexes.

The CURRENT EXPLAIN SNAPSHOT special register interacts with the EXPLSNAP bind option in the following way for dynamic SQL.

Table 351. Interaction of EXPLSNAP bind Option and CURRENT EXPLAIN SNAPSHOT

EXPLAIN SNAPSHOT values	EXPLSNAP Bind option values			
	NO	YES	REOPT	ALL
NO	• Results of query returned.	• Explain Snapshot taken for static SQL. • Results of query returned.	• Explain Snapshot taken for static SQL when statement qualifies for reoptimization at execution time. • Explain Snapshot taken for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain Snapshot taken for static SQL. • Explain Snapshot taken for dynamic SQL. • Results of query returned.

Table 351. Interaction of EXPLSNAP bind Option and CURRENT EXPLAIN SNAPSHOT (continued)

EXPLAIN SNAPSHOT values	EXPLSNAP Bind option values			
	NO	**YES**	**REOPT**	**ALL**
YES	• Explain Snapshot taken for dynamic SQL. • Results of query returned.	• Explain Snapshot taken for static SQL. • Explain Snapshot taken for dynamic SQL. • Results of query returned.	• Explain Snapshot taken for static SQL when statement qualifies for reoptimization at execution time. • Explain Snapshot taken for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain Snapshot taken for static SQL. • Explain Snapshot taken for dynamic SQL. • Results of query returned.
EXPLAIN	• Explain Snapshot taken for dynamic SQL. • Results of query not returned (dynamic statements not executed).	• Explain Snapshot taken for static SQL. • Explain Snapshot taken for dynamic SQL. • Results of query not returned (dynamic statements not executed).	• Explain Snapshot taken for static SQL when statement qualifies for reoptimization at execution time. • Explain Snapshot taken for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query not returned (dynamic statements not executed).	• Explain Snapshot taken for static SQL. • Explain Snapshot taken for dynamic SQL. • Results of query not returned (dynamic statements not executed).

Table 351. Interaction of EXPLSNAP bind Option and CURRENT EXPLAIN SNAPSHOT (continued)

EXPLAIN SNAPSHOT values	EXPLSNAP Bind option values			
	NO	**YES**	**REOPT**	**ALL**
REOPT	• Explain Snapshot taken for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain Snapshot taken for static SQL when statement qualifies for reoptimization at execution time. • Explain Snapshot taken for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain Snapshot taken for static SQL when statement qualifies for reoptimization at execution time. • Explain Snapshot taken for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query returned.	• Explain Snapshot taken for static SQL when statement qualifies for reoptimization at execution time. • Explain Snapshot taken for dynamic SQL when statement qualifies for reoptimization at execution time. • Results of query returned.
