Contents

Tables

Chapter 1. Structured Query Language (SQL)

SQL is a standardized language for defining and manipulating data in a relational database.

In accordance with the relational model of data, the database is treated as a set of tables, relationships are represented by values in tables, and data is retrieved by specifying a result table that can be derived from one or more base tables.

SQL statements are executed by a database manager. One of the functions of the database manager is to transform the specification of a result table into a sequence of internal operations that optimize data retrieval. The transformation occurs in two phases: preparation and binding.

All executable SQL statements must be prepared before they can be executed. The result of preparation is the executable or operational form of the statement. The method of preparing an SQL statement and the persistence of its operational form distinguish static SQL from dynamic SQL.

How to read the syntax diagrams

This topic describes the structure of SQL syntax diagrams.

Read the syntax diagrams from left to right and top to bottom, following the path of the line.

The double right arrowhead and line symbol ►►— indicates the beginning of a syntax diagram.

The line and single right arrowhead symbol —► indicates that the syntax is continued on the next line.

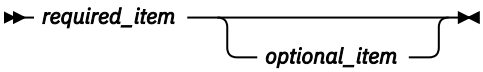
The right arrowhead and line symbol ►— indicates that the syntax is continued from the previous line.

The line, right arrowhead, and left arrowhead symbol —►◄ symbol indicates the end of a syntax diagram.

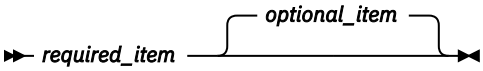
Syntax fragments start with the pipe and line symbol |— and end with the —| line and pipe symbol.

Required items appear on the horizontal line (the main path).

Optional items appear below the main path.

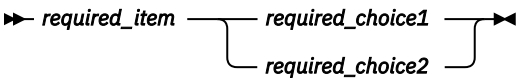


If an optional item appears above the main path, that item has no effect on execution, and is used only for readability.



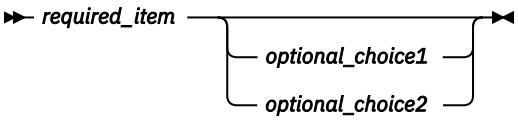
If you can choose from two or more items, they appear in a stack.

If you *must* choose one of the items, one item of the stack appears on the main path.

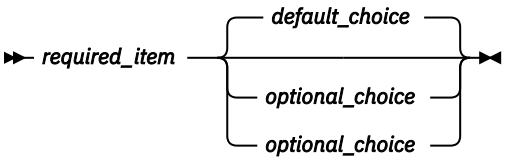


If choosing one of the items is optional, the entire stack appears below the main path.

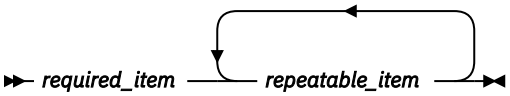
© Copyright IBM Corp. 2016, 2023



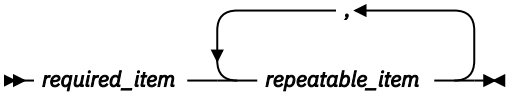
If one of the items is the default, it will appear above the main path, and the remaining choices will be shown below.



An arrow returning to the left, above the main line, indicates an item that can be repeated. In this case, repeated items must be separated by one or more blanks.



If the repeat arrow contains a comma, you must separate repeated items with a comma.



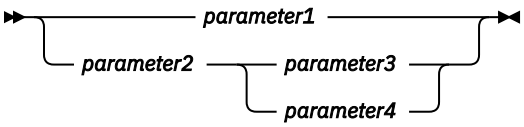
A repeat arrow above a stack indicates that you can make more than one choice from the stacked items or repeat a single choice.

Keywords appear in uppercase (for example, FROM). They must be spelled exactly as shown. Variables appear in lowercase (for example, `column-name`). They represent user-supplied names or values in the syntax.

If punctuation marks, parentheses, arithmetic operators, or other such symbols are shown, you must enter them as part of the syntax.

Sometimes a single variable represents a larger fragment of the syntax. For example, in the following diagram, the variable `parameter-block` represents the whole syntax fragment that is labeled **parameter-block**:

parameter-block



Adjacent segments occurring between "large bullets" (●) may be specified in any sequence.

The above diagram shows that item2 and item3 may be specified in either order. Both of the following are valid:

```
required_item item1 item2 item3 item4
required_item item1 item3 item2 item4
```

Conventions used for the SQL topics

Error conditions

An error condition is indicated within the text of the manual by listing the SQLSTATE associated with the error in parentheses.

For example:

```
A duplicate signature returns an SQL error (SQLSTATE 42723).
```

Highlighting conventions

This topic covers the conventions used in the SQL Reference.

- **Bold** indicates commands, keywords, and other items whose names are predefined by the system.
- *Italics* indicates one of the following items:
  - Names or values (variables) that must be supplied by the user
  - General emphasis
  - The introduction of a new term
  - A reference to another source of information

Conventions describing Unicode data

When a specific Unicode code point is referenced, it is expressed as U+*n* where *n* is four to six hexadecimal digits, using the digits 0-9 and uppercase letters A-F.

Leading zeros are omitted unless the code point would have fewer than four hexadecimal digits. The space character, for example, is expressed as U+0020. In most cases, the *n* value is the same as the UTF-16BE encoding.

Language elements

Characters

The basic symbols of keywords and operators in the SQL language are single-byte characters that are part of all IBM® character sets. Characters of the language are classified as letters, digits, or special characters.

A *letter* is any of the 26 uppercase (A through Z) or 26 lowercase (a through z) letters. Letters also include three code points reserved as alphabetic extenders for national languages (#, @, and $ in the United States). However these three code points should be avoided, especially for portable applications, because they represent different characters depending on the CCSID. Letters also include the alphabetics from the extended character sets. Extended character sets contain additional alphabetic characters; for example, those with diacritical marks (´ is an example of a diacritical mark). The available characters depend on the code page in use.

A *digit* is any of the characters 0 through 9.

A *special character* is any of the characters listed in the following table:

Table 1. Special characters

Character	Description	Character	Description
	space or blank	-	minus sign
"	quotation mark or double quote or double quotation mark	.	period

Table 1. Special characters (continued)

Character	Description	Character	Description
%	percent	/	slash
&	ampersand	:	colon
'	apostrophe or single quote or single quotation mark	;	semicolon
(	left parenthesis	<	less than
)	right parenthesis	=	equals
*	asterisk	>	greater than
+	plus sign	?	question mark
,	comma	_	underline or underscore
|	vertical bar[1]	^	caret
!	exclamation mark	[	left bracket
{	left brace	]	right bracket
}	right brace	\	reverse solidus or back slash[2]

[1] Using the vertical bar (|) character might inhibit code portability between IBM relational products. Use the CONCAT operator in place of the || operator.

[2] Some code pages do not have a code point for the reverse solidus (\) character. When entering Unicode string constants, the UESCAPE clause can be used to specify a Unicode escape character other than reverse solidus.

All multi-byte characters are treated as letters, except for the double-byte blank, which is a special character.

Tokens

Tokens are the basic syntactical units of SQL. A *token* is a sequence of one or more characters.

A token cannot contain blank characters, unless it is a string constant or a delimited identifier, which may contain blanks.

Tokens are classified as ordinary or delimiter:

- An *ordinary token* is a numeric constant, an ordinary identifier, a host identifier, or a keyword.

  Examples

  ```
  1       .1       +2       SELECT       E       3
  ```

- A *delimiter token* is a string constant, a delimited identifier, an operator symbol, or any of the special characters shown in the syntax diagrams. A question mark is also a delimiter token when it serves as a parameter marker.

  Examples

  ```
  ,       'string'       "fld1"       =       .
  ```

Spaces: A space is a sequence of one or more blank characters. Tokens other than string constants and delimited identifiers must not include a space. Any token may be followed by a space. Every ordinary token must be followed by a space or a delimiter token if allowed by the syntax.

Comments: SQL comments are either bracketed (introduced by /* and end with */) or simple (introduced by two consecutive hyphens and end with the end of line). Static SQL statements can include host language comments or SQL comments. Comments can be specified wherever a space can be specified, except within a delimiter token or between the keywords EXEC and SQL.

Case sensitivity: Any token may include lowercase letters, but a lowercase letter in an ordinary token is folded to uppercase, except for host variables in the C language, which has case-sensitive identifiers. Delimiter tokens are never folded to uppercase. Thus, the statement:

```
select * from EMPLOYEE where lastname = 'Smith';
```

is equivalent, after folding, to:

```
SELECT * FROM EMPLOYEE WHERE LASTNAME = 'Smith';
```

Multi-byte alphabetic letters are not folded to uppercase. Single-byte characters (a to z) *are* folded to uppercase.

For characters in Unicode:

- A character is folded to uppercase, if applicable, if the uppercase character in UTF-8 has the same length as the lowercase character in UTF-8. For example, the Turkish lowercase dotless 'i' is not folded, because in UTF-8, that character has the value X'C4B1', but the uppercase dotless 'I' has the value X'49'.
- The folding is done in a locale-insensitive manner. For example, the Turkish lowercase dotted 'i' is folded to the English uppercase (dotless) 'I'.
- Both halfwidth and fullwidth alphabetic letters are folded to uppercase. For example, the fullwidth lowercase 'a' (U+FF41) is folded to the fullwidth uppercase 'A' (U+FF21).

Identifiers

An *identifier* is a token that is used to form a name. An identifier in an SQL statement is either an SQL identifier or a host identifier.

- SQL identifiers

  There are two types of SQL identifiers: ordinary and delimited.

  – An ordinary identifier is an uppercase letter followed by zero or more characters, each of which is an uppercase letter, a digit, or the underscore character. Note that lowercase letters can be used when specifying an ordinary identifier, but they are converted to uppercase when processed. An ordinary identifier should not be a reserved word.

    The following example shows ordinary identifiers:

    ```
    WKLYSAL     WKLY_SAL
    ```

  – A delimited identifier is a sequence of one or more characters enclosed by double quotation marks. Leading blanks in the sequence are significant. Trailing blanks in the sequence are not significant, although they are stored with the identifier. Two consecutive quotation marks are used to represent one quotation mark within the delimited identifier. A delimited identifier can be used when the sequence of characters does not qualify as an ordinary identifier. In this way an identifier can include lowercase letters.

    The following example shows a series of delimited identifiers:

    ```
    "WKLY_SAL"     "WKLY SAL"     "UNION"     "wkly_sal"
    ```

  Character conversion of identifiers created on a double-byte code page, but used by an application or database on a multi-byte code page, may require special consideration: After conversion, such identifiers may exceed the length limit for an identifier.

- Host identifiers

A host identifier is a name declared in the host program. The rules for forming a host identifier are the rules of the host language. A host identifier should not be greater than 255 bytes in length and should not begin with SQL or DB2 (in uppercase or lowercase characters).

Naming conventions and implicit object name qualifications

The rules for forming a database object name depend on the type of the object designated by the name. A name may consist of a single SQL identifier or it may be qualified with one or more identifiers that more specifically identify the object. A period must separate each identifier.

The syntax diagrams use different terms for different types of names. The following list defines these terms.

alias-name
A schema-qualified name that designates an alias.

attribute-name
An identifier that designates an attribute of a structured data type.

array-type-name
A qualified or unqualified name that designates a user-defined array type. The unqualified form of array-type-name is an SQL identifier. An unqualified array type name in an SQL statement is implicitly qualified. The implicit qualifier is a schema name or a module name, which is determined by the context in which array-type-name appears. The qualified form is a schema-name followed by a period and an SQL identifier or a module-name (which can also be qualified by a schema-name) followed by a period and an SQL identifier. If the array type is defined in a module and used outside of the same module, it must be qualified by the module-name.

authorization-name
An identifier that designates a user, group, or role. For a user or a group:

- Valid characters are: 'A' through 'Z'; 'a' through 'z'; '0' through '9'; '#'; '@'; '$'; '_'; '!'; ' '(';')'; '{'; '}'; '-'; '.'; and '^'.
- The following characters must be delimited with quotation marks when entered through the command line processor: '!'; ' '(';')'; '{'; '}'; '-'; '.'; and '^'.
- The name must not begin with the characters 'SYS', 'IBM', or 'SQL'.
- The name must not be: 'ADMINS', 'GUESTS', 'LOCAL', 'PUBLIC', or 'USERS'.
- A delimited authorization ID must not contain lowercase letters.

bufferpool-name
An identifier that designates a buffer pool.

column-name
A qualified or unqualified name that designates a column of a table or view. The qualifier is a table name, a view name, a nickname, or a correlation name.

component-name
An identifier that designates a security label component.

condition-name
A qualified or unqualified name that designates a condition. An unqualified condition name in an SQL statement is implicitly qualified, depending on its context. If the condition is defined in a module and used outside of the same module, it must be qualified by the module-name.

constraint-name
An identifier that designates a referential constraint, primary key constraint, unique constraint, or a table check constraint.

correlation-name
An identifier that designates a result table.

cursor-name
An identifier that designates an SQL cursor. For host compatibility, a hyphen character may be used in the name.

cursor-type-name
A qualified or unqualified name that designates a user-defined cursor type. The unqualified form of cursor-type-name is an SQL identifier. An unqualified cursor-type-name in an SQL statement is implicitly qualified, depending on context. The implicit qualifier is a schema name or a module name, which is determined by the context in which cursor-type-name appears. The qualified form is a schema-name followed by a period and an SQL identifier or a module-name (which can also be qualified by a schema-name) followed by a period and an SQL identifier. If the cursor type is defined in a module and used outside of the same module, it must be qualified by the module-name.

cursor-variable-name
A qualified or unqualified name that designates a global variable, local variable or an SQL parameter of a cursor type. An unqualified cursor variable name in an SQL statement is implicitly qualified, depending on context.

data-source-name
An identifier that designates a data source. This identifier is the first part of a three-part remote object name.

db-partition-group-name
An identifier that designates a database partition group.

descriptor-name
A colon followed by a host identifier that designates an SQL descriptor area (SQLDA). For the description of a host identifier, see "References to host variables" on page 20. Note that a descriptor name never includes an indicator variable.

distinct-type-name
A qualified or unqualified name that designates a distinct type. The unqualified form of distinct-type-name is an SQL identifier. An unqualified distinct type name in an SQL statement is implicitly qualified. The implicit qualifier is a schema name or a module name, which is determined by the context in which distinct-type-name appears. The qualified form is a schema-name followed by a period and an SQL identifier or a module-name (which can also be qualified by a schema-name) followed by a period and an SQL identifier. If the distinct type is defined in a module and used outside of the same module, it must be qualified by the module-name.

event-monitor-name
An identifier that designates an event monitor.

function-mapping-name
An identifier that designates a function mapping.

function-name
A qualified or unqualified name that designates a function. The unqualified form of function-name is an SQL identifier. An unqualified function name in an SQL statement is implicitly qualified. The implicit qualifier is a schema name, which is determined by the context in which the function appears. The qualified form could be is a schema-name followed by a period and an SQL identifier or a module-name followed by a period and an SQL identifier. If the function is published in a module and used outside of the same module, it must be qualified by the module-name.

global-variable-name
A qualified or unqualified name that designates a global variable. The unqualified form of global-variable-name is an SQL identifier. An unqualified global variable name in an SQL statement is implicitly qualified. The implicit qualifier is a schema name or a module name, which is determined by the context in which global-variable-name appears. The qualified form is a schema-name followed by a period and an SQL identifier or a module-name (which can also be qualified by a schema-name) followed by a period and an SQL identifier. If the global variable is defined in a module and used outside of the same module, it must be qualified by the module-name.

group-name
An unqualified identifier that designates a transform group defined for a structured type.

host-variable
A sequence of tokens that designates a host variable. A host variable includes at least one host identifier, explained in "References to host variables" on page 20.

index-name
A schema-qualified name that designates an index or an index specification.

label
An identifier that designates a label in an SQL procedure.

method-name
An identifier that designates a method. The schema context for a method is determined by the schema of the subject type (or a supertype of the subject type) of the method.

module-name
A qualified or unqualified name that designates a module. An unqualified module-name in an SQL statement is implicitly qualified. The implicit qualifier is a schema name, which is determined by the context in which the module-name appears. The qualified form is a schema-name followed by a period and an SQL identifier.

nickname
A schema-qualified name that designates a federated server reference to a table or a view.

package-name
A qualified or unqualified name that designates a package.

parameter-name
An identifier that designates a parameter that can be referenced in a procedure, user-defined function, method, or index extension.

partition-name
An identifier that designates a data partition in a partitioned table.

period-name
An identifier that designates a period. SYSTEM_TIME and BUSINESS_TIME are the only supported period names.

procedure-name
A qualified or unqualified name that designates a procedure. The unqualified form of procedure-name is an SQL identifier. An unqualified procedure name in an SQL statement is implicitly qualified. The implicit qualifier is a schema name, which is determined by the context in which the procedure appears. The qualified form is a schema-name followed by a period and an SQL identifier or a module-name followed by a period and an SQL identifier. If the procedure is defined in a module and used outside of the same module, it must be qualified by the module-name.

remote-authorization-name
An identifier that designates a data source user. The rules for authorization names vary from data source to data source.

remote-function-name
A name that designates a function registered to a data source database.

remote-object-name
A three-part name that designates a data source table or view, and that identifies the data source in which the table or view resides. The parts of this name are data-source-name, remote-schema-name, and remote-table-name.

remote-schema-name
A name that designates the schema to which a data source table or view belongs. This name is the second part of a three-part remote object name.

remote-table-name
A name that designates a table or view at a data source. This name is the third part of a three-part remote object name.

remote-type-name
A data type supported by a data source database. Do not use the long form for built-in types (use CHAR instead of CHARACTER, for example).

role-name
An identifier that designates a role.

row-type-name
A qualified or unqualified name that designates a user-defined row type. The unqualified form of row-type-name is an SQL identifier. An unqualified row-type-name in an SQL statement is implicitly qualified. The implicit qualifier is a schema name or a module name, which is determined by the context in which the row-type-name appears. The qualified form is a schema-name followed by a period and an SQL identifier or a module-name (which can also be qualified by a schema-name) followed by a period and an SQL identifier. If the row type is defined in a module and used outside of the same module, it must be qualified by the module-name.

savepoint-name
An identifier that designates a savepoint.

schema-name
An identifier that provides a logical grouping for SQL objects. A schema name used as a qualifier for the name of an object may be implicitly determined:

- from the value of the CURRENT SCHEMA special register
- from the value of the QUALIFIER precompile/bind option
- on the basis of a resolution algorithm that uses the CURRENT PATH special register
- on the basis of the schema name for another object in the same SQL statement.

To avoid complications, it is recommended that the name SESSION not be used as a schema, except as the schema for declared global temporary tables (which *must* use the schema name SESSION).

security-label-name
A qualified or unqualified name that designates a security label. An unqualified security label name in an SQL statement is implicitly qualified by the applicable security-policy-name, when one applies. If no security-policy-name is implicitly applicable, the name must be qualified.

security-policy-name
An identifier that designates a security policy.

sequence-name
An identifier that designates a sequence.

server-name
An identifier that designates an application server. In a federated system, the server name also designates the local name of a data source.

specific-name
A qualified or unqualified name that designates a specific name. An unqualified specific name in an SQL statement is implicitly qualified, depending on context.

SQL-variable-name
The name of a local variable in an SQL procedure statement. SQL variable names can be used in other SQL statements where a host variable name is allowed. The name can be qualified by the label of the compound statement that declared the SQL variable.

statement-name
An identifier that designates a prepared SQL statement.

storagegroup-name
An identifier that designates a storage group.

supertype-name
A qualified or unqualified name that designates the supertype of a type. An unqualified supertype name in an SQL statement is implicitly qualified, depending on context.

table-name
A schema-qualified name that designates a table.

table-reference
A qualified or unqualified name that designates a table. An unqualified table reference in a common table expression is implicitly qualified by the default schema.

tablespace-name
An identifier that designates a table space.

trigger-name
A schema-qualified name that designates a trigger.

type-mapping-name
An identifier that designates a data type mapping.

type-name
A qualified or unqualified name that designates a type. An unqualified type name in an SQL statement is implicitly qualified, depending on context.

typed-table-name
A schema-qualified name that designates a typed table.

typed-view-name
A schema-qualified name that designates a typed view.

usage-list-name
A schema-qualified name that designates a usage list.

user-defined-type-name
A qualified or unqualified name that designates a user-defined data type. The unqualified form of user-defined-type-name is an SQL identifier. An unqualified user-defined-type-name in an SQL statement is implicitly qualified. The implicit qualifier is a schema name or a module name, which is determined by the context in which user-defined-type-name appears. The qualified form is a schema-name followed by a period and an SQL identifier or a module-name (which can also be qualified by a schema-name) followed by a period and an SQL identifier. If the user-defined data type is defined in a module and used outside of the same module, it must be qualified by the module-name.

view-name
A schema-qualified name that designates a view.

wrapper-name
An identifier that designates a wrapper.

XML-schema-name
A qualified or unqualified name that designates an XML schema.

xsrobject-name
A qualified or unqualified name that designates an object in the XML schema repository.

Aliases for database objects

An alias can be thought of as an alternative name for an SQL object. An SQL object, therefore, can be referred to in an SQL statement by its name or by an alias.

A public alias is an alias which can always be referenced without qualifying its name with a schema name. The implicit qualifier of a public alias is SYSPUBLIC, which can also be specified explicitly.

Aliases are also known as synonyms.

An alias can be used wherever the object it is based on can be used. An alias can be created even if the object does not exist (although it must exist by the time a statement referring to it is compiled). It can refer to another alias if no circular or repetitive references are made along the chain of aliases. An alias can only refer to a module, nickname, sequence, table, view, or another alias within the same database. An alias name cannot be used where a new object name is expected, such as in the CREATE TABLE or CREATE VIEW statements; for example, if the table alias name PERSONNEL has been created, subsequent statements such as CREATE TABLE PERSONNEL... will return an error.

The option of referring to an object by an alias is not explicitly shown in the syntax diagrams, or mentioned in the descriptions of SQL statements.

A new unqualified alias of a given object type, say for a sequence, cannot have the same fully-qualified name as an existing object of that object type. For example, a sequence alias named ORDERID cannot be defined in the KANDIL schema for the sequence named KANDIL.ORDERID.

The effect of using an alias in an SQL statement is similar to that of text substitution. The alias, which must be defined by the time that the SQL statement is compiled, is replaced at

statement compilation time by the qualified object name. For example, if PBIRD.SALES is an alias for DSPN014.DIST4_SALES_148, then at compilation time:

```
SELECT * FROM PBIRD.SALES
```

effectively becomes

```
SELECT * FROM DSPN014.DIST4_SALES_148
```

Authorization IDs and authorization names

An *authorization ID* is a character string that is obtained by the database manager when a connection is established between the database manager and either an application process or a program preparation process. It designates a set of privileges. It may also designate a user or a group of users, but this property is not controlled by the database manager.

Authorization IDs are used by the database manager to provide:

- Authorization checking of SQL statements
- A default value for the QUALIFIER precompile/bind option and the CURRENT SCHEMA special register. The authorization ID is also included in the default CURRENT PATH special register and the FUNCPATH precompile/bind option.

An authorization ID applies to every SQL statement. The authorization ID that applies to a static SQL statement is the authorization ID that is used during program binding. The authorization ID that applies to a dynamic SQL statement is based on the DYNAMICRULES option supplied at bind time, and on the current runtime environment for the package issuing the dynamic SQL statement:

- In a package that has bind behavior, the authorization ID used is the authorization ID of the package owner.
- In a package that has define behavior, the authorization ID used is the authorization ID of the corresponding routine's definer.
- In a package that has run behavior, the authorization ID used is the current authorization ID of the user executing the package.
- In a package that has invoke behavior, the authorization ID used is the authorization ID currently in effect when the routine is invoked. This is called the runtime authorization ID.

For more information, see “Dynamic SQL characteristics at run time” on page 12.

An *authorization name* specified in an SQL statement should not be confused with the authorization ID of the statement. An authorization name is an identifier that is used within various SQL statements. An authorization name is used in the CREATE SCHEMA statement to designate the owner of the schema. An authorization name is used in the GRANT and REVOKE statements to designate a target of the grant or revoke operation. Granting privileges to *X* means that *X* (or a member of the group or role *X*) will subsequently be the authorization ID of statements that require those privileges.

Examples

- Assume that SMITH is the user ID and the authorization ID that the database manager obtained when a connection was established with the application process. The following statement is executed interactively:

  ```
  GRANT SELECT ON TDEPT TO KEENE
  ```

  SMITH is the authorization ID of the statement. Therefore, in a dynamic SQL statement, the default value of the CURRENT SCHEMA special register is SMITH, and in static SQL, the default value of the QUALIFIER precompile/bind option is SMITH. The authority to execute the statement is checked against SMITH, and SMITH is the *table-name* implicit qualifier based on qualification rules described in “Naming conventions and implicit object name qualifications” on page 6.

KEENE is an authorization name specified in the statement. KEENE is given the SELECT privilege on SMITH.TDEPT.

- Assume that SMITH has administrative authority and is the authorization ID of the following dynamic SQL statements, with no SET SCHEMA statement issued during the session:

```
DROP TABLE TDEPT
```

Removes the SMITH.TDEPT table.

```
DROP TABLE SMITH.TDEPT
```

Removes the SMITH.TDEPT table.

```
DROP TABLE KEENE.TDEPT
```

Removes the KEENE.TDEPT table. Note that KEENE.TDEPT and SMITH.TDEPT are different tables.

```
CREATE SCHEMA PAYROLL AUTHORIZATION KEENE
```

KEENE is the authorization name specified in the statement that creates a schema called PAYROLL. KEENE is the owner of the schema PAYROLL and is given CREATEIN, ALTERIN, and DROPIN privileges, with the ability to grant them to others.

Dynamic SQL characteristics at run time

The BIND option DYNAMICRULES determines the authorization ID that is used for checking authorization when dynamic SQL statements are processed. In addition, the option also controls other dynamic SQL attributes, such as the implicit qualifier that is used for unqualified object references, and whether certain SQL statements can be invoked dynamically.

The set of values for the authorization ID and other dynamic SQL attributes is called the dynamic SQL statement behavior. The four possible behaviors are run, bind, define, and invoke. As the following table shows, the combination of the value of the DYNAMICRULES BIND option and the runtime environment determines which of the behaviors is used. DYNAMICRULES RUN, which implies run behavior, is the default.

Table 2. How DYNAMICRULES and the runtime environment determine dynamic SQL statement behavior

DYNAMICRULES value	**Behavior of dynamic SQL statements in a stand-alone program environment**	**Behavior of dynamic SQL statements in a routine environment**
BIND	Bind behavior	Bind behavior
RUN	Run behavior	Run behavior
DEFINEBIND	Bind behavior	Define behavior
DEFINERUN	Run behavior	Define behavior
INVOKEBIND	Bind behavior	Invoke behavior
INVOKERUN	Run behavior	Invoke behavior

Run behavior
The authorization ID of the user (the ID that initially connected to the database) that executes the package is used as the value for authorization checking of dynamic SQL statements. This authorization ID is also used as the initial value for implicit qualification of unqualified object references within dynamic SQL statements.

Bind behavior
At run time, all the rules that apply to static SQL for authorization and qualification are used. The authorization ID of the package owner is used as the value for authorization checking of dynamic

SQL statements. The package default qualifier is used for implicit qualification of unqualified object references within dynamic SQL statements.

Define behavior
Define behavior applies only if the dynamic SQL statement is in a package that is run within a routine context, and the package was bound with DYNAMICRULES DEFINEBIND or DYNAMICRULES DEFINERUN. The authorization ID of the routine definer (not the routine's package binder) is used as the value for authorization checking of dynamic SQL statements. This authorization ID is also used for implicit qualification of unqualified object references within dynamic SQL statements within that routine.

Invoke behavior
Invoke behavior applies only if the dynamic SQL statement is in a package that is run within a routine context, and the package was bound with DYNAMICRULES INVOKEBIND or DYNAMICRULES INVOKERUN. The statement authorization ID in effect when the routine is invoked is used as the value for authorization checking of dynamic SQL. This authorization ID is also used for implicit qualification of unqualified object references within dynamic SQL statements within that routine. This is summarized by the following table.

Invoking Environment	ID Used
any static SQL	implicit or explicit value of the OWNER of the package the SQL invoking the routine came from
used in definition of view or trigger	definer of the view or trigger
dynamic SQL from a bind behavior package	implicit or explicit value of the OWNER of the package the SQL invoking the routine came from
dynamic SQL from a run behavior package	ID used to make the initial connection to the database
dynamic SQL from a define behavior package	definer of the routine that uses the package that the SQL invoking the routine came from
dynamic SQL from an invoke behavior package	the current authorization ID invoking the routine

Restricted statements when run behavior does not apply
When bind, define, or invoke behavior is in effect, you cannot use the following dynamic SQL statements: GRANT, REVOKE, ALTER, CREATE, DROP, COMMENT, RENAME, SET INTEGRITY, SET EVENT MONITOR STATE; or queries that reference a nickname.

Considerations regarding the DYNAMICRULES option
The CURRENT SCHEMA special register cannot be used to qualify unqualified object references within dynamic SQL statements executed from bind, define or invoke behavior packages. This is true even after you issue the SET CURRENT SCHEMA statement to change the CURRENT SCHEMA special register; the register value is changed but not used.

In the event that multiple packages are referenced during a single connection, all dynamic SQL statements prepared by those packages will exhibit the behavior specified by the DYNAMICRULES option for that specific package and the environment in which they are used.

It is important to keep in mind that when a package exhibits bind behavior, the binder of the package should not have any authorities granted that the user of the package should not receive, because a dynamic statement will be using the authorization ID of the package owner. Similarly, when a package exhibits define behavior, the definer of the routine should not have any authorities granted that the user of the package should not receive.

Authorization IDs and statement preparation

If the VALIDATE BIND option is specified at bind time, the privileges required to manipulate tables and views must also exist at bind time. If these privileges or the referenced objects do not exist, and the SQLERROR NOPACKAGE option is in effect, the bind operation will be unsuccessful. If the SQLERROR

CONTINUE option is specified, the bind operation will be successful, and any statements in error will be flagged. Any attempt to execute such a statement will result in an error.

If a package is bound with the VALIDATE RUN option, all normal bind processing is completed, but the privileges required to use the tables and views that are referenced in the application need not exist yet. If a required privilege does not exist at bind time, an incremental bind operation is performed whenever the statement is first executed in an application, and all privileges required for the statement must exist. If a required privilege does not exist, execution of the statement is unsuccessful.

Authorization checking at run time is performed using the authorization ID of the package owner.

Column names

The meaning of a *column name* depends on its context. A column name can be used to:

- Declare the name of a column, as in a CREATE TABLE statement.
- Identify a column, as in a CREATE INDEX statement.
- Specify values of the column, as in the following contexts:
  - In an aggregate function, a column name specifies all values of the column in the group or intermediate result table to which the function is applied. For example, MAX(SALARY) applies the function MAX to all values of the column SALARY in a group.
  - In a GROUP BY or ORDER BY clause, a column name specifies all values in the intermediate result table to which the clause is applied. For example, ORDER BY DEPT orders an intermediate result table by the values of the column DEPT.
  - In an expression, a search condition, or a scalar function, a column name specifies a value for each row or group to which the construct is applied. For example, when the search condition CODE = 20 is applied to some row, the value specified by the column name CODE is the value of the column CODE in that row.
- Temporarily rename a column, as in the *correlation-clause* of a *table-reference* in a FROM clause.

Qualified column names

A qualifier for a column name may be a table, view, nickname, alias, or correlation name.

Whether a column name may be qualified depends on its context:

- Depending on the form of the COMMENT ON statement, a single column name may need to be qualified. Multiple column names must be unqualified.
- Where the column name specifies values of the column, it may be qualified at the user's option.
- In the assignment-clause of an UPDATE statement, it may be qualified at the user's option.
- In all other contexts, a column name must not be qualified.

Where a qualifier is optional, it can serve two purposes. They are described under “Column name qualifiers to avoid ambiguity” on page 16 and “Column name qualifiers in correlated references” on page 18.

Correlation names

A *correlation name* can be defined in the FROM clause of a query and in the first clause of an UPDATE or DELETE statement. For example, the clause FROM X.MYTABLE Z establishes Z as a correlation name for X.MYTABLE.

```
    FROM X.MYTABLE Z
```

With Z defined as a correlation name for X.MYTABLE, only Z can be used to qualify a reference to a column of that instance of X.MYTABLE in that SELECT statement.

A correlation name is associated with a table, view, nickname, alias, nested table expression, table function, or data change table reference only within the context in which it is defined. Hence, the same correlation name can be defined for different purposes in different statements, or in different clauses of the same statement.

As a qualifier, a correlation name can be used to avoid ambiguity or to establish a correlated reference. It can also be used merely as a shorter name for a table reference. In the example, Z might have been used merely to avoid having to enter X.MYTABLE more than once.

If a correlation name is specified for a table, view, nickname, or alias name, any qualified reference to a column of that instance of the table, view, nickname, or alias must use the correlation name, rather than the table, view, nickname, or alias name. For example, the reference to EMPLOYEE.PROJECT in the following example is incorrect, because a correlation name has been specified for EMPLOYEE:

Example

```
FROM EMPLOYEE E
  WHERE EMPLOYEE.PROJECT='ABC'      * incorrect*
```

The qualified reference to PROJECT should instead use the correlation name, "E", as shown in the following example:

```
FROM EMPLOYEE E
  WHERE E.PROJECT='ABC'
```

Names specified in a FROM clause are either *exposed* or *non-exposed*. A table, view, nickname, or alias name is said to be exposed in the FROM clause if a correlation name is not specified. A correlation name is always an exposed name. For example, in the following FROM clause, a correlation name is specified for EMPLOYEE but not for DEPARTMENT, so DEPARTMENT is an exposed name, and EMPLOYEE is not:

```
FROM EMPLOYEE E, DEPARTMENT
```

A table, view, nickname, or alias name that is exposed in a FROM clause may be the same as any other table name, view name or nickname exposed in that FROM clause or any correlation name in the FROM clause. This may result in ambiguous column name references which returns an error (SQLSTATE 42702).

The first two FROM clauses shown in the following list are correct, because each one contains no more than one reference to EMPLOYEE that is exposed:

1. Given the FROM clause:

   ```
   FROM EMPLOYEE E1, EMPLOYEE
   ```

   a qualified reference such as EMPLOYEE.PROJECT denotes a column of the second instance of EMPLOYEE in the FROM clause. A qualified reference to the first instance of EMPLOYEE must use the correlation name "E1" (E1.PROJECT).
2. Given the FROM clause:

   ```
   FROM EMPLOYEE, EMPLOYEE E2
   ```

   a qualified reference such as EMPLOYEE.PROJECT denotes a column of the first instance of EMPLOYEE in the FROM clause. A qualified reference to the second instance of EMPLOYEE must use the correlation name "E2" (E2.PROJECT).
3. Given the FROM clause:

   ```
   FROM EMPLOYEE, EMPLOYEE
   ```

   the two exposed table names included in this clause (EMPLOYEE and EMPLOYEE) are the same. This is allowed, but references to specific column names would be ambiguous (SQLSTATE 42702).
4. Given the following statement:

```
SELECT *
  FROM EMPLOYEE E1, EMPLOYEE E2             * incorrect *
  WHERE EMPLOYEE.PROJECT = 'ABC'
```

the qualified reference EMPLOYEE.PROJECT is incorrect, because both instances of EMPLOYEE in the FROM clause have correlation names. Instead, references to PROJECT must be qualified with either correlation name (E1.PROJECT or E2.PROJECT).

5. Given the FROM clause:

```
FROM EMPLOYEE, X.EMPLOYEE
```

a reference to a column in the second instance of EMPLOYEE must use X.EMPLOYEE (X.EMPLOYEE.PROJECT). If X is the CURRENT SCHEMA special register value in dynamic SQL or the QUALIFIER precompile/bind option in static SQL, then the columns cannot be referenced since any such reference would be ambiguous.

The use of a correlation name in the FROM clause also allows the option of specifying a list of column names to be associated with the columns of the result table. As with a correlation name, these listed column names become the *exposed* names of the columns that must be used for references to the columns throughout the query. If a column name list is specified, then the column names of the underlying table become *non-exposed*.

Given the FROM clause:

```
FROM DEPARTMENT D (NUM,NAME,MGR,ANUM,LOC)
```

a qualified reference such as D.NUM denotes the first column of the DEPARTMENT table that is defined in the table as DEPTNO. A reference to D.DEPTNO using this FROM clause is incorrect since the column name DEPTNO is a non-exposed column name.

Column name qualifiers to avoid ambiguity

In the context of a function, a GROUP BY clause, ORDER BY clause, an expression, or a search condition, a column name refers to values of a column in some table, view, nickname, nested table expression or table function. The tables, views, nicknames, nested table expressions and table functions that might contain the column are called the *object tables* of the context. Two or more object tables might contain columns with the same name; one reason for qualifying a column name is to designate the table from which the column comes. Qualifiers for column names are also useful in SQL procedures to distinguish column names from SQL variable names used in SQL statements.

A nested table expression or table function will consider *table-references* that precede it in the FROM clause as object tables. The *table-references* that follow are not considered as object tables.

Table designators

A qualifier that designates a specific object table is called a *table designator*. The clause that identifies the object tables also establishes the table designators for them. For example, the object tables of an expression in a SELECT clause are named in the FROM clause that follows it:

```
SELECT CORZ.COLA, OWNY.MYTABLE.COLA
  FROM OWNX.MYTABLE CORZ, OWNY.MYTABLE
```

Table designators in the FROM clause are established as follows:

- A name that follows a table, view, nickname, alias, nested table expression or table function is both a correlation name and a table designator. Thus, CORZ is a table designator. CORZ is used to qualify the first column name in the select list.
- An exposed table, view name, nickname or alias is a table designator. Thus, OWNY.MYTABLE is a table designator. OWNY.MYTABLE is used to qualify the second column name in the select list.

When qualifying a column with the exposed table name form of a table designator, either the qualified or unqualified form of the exposed table name can be used. If the qualified form is used, the qualifier must be the same as the default qualifier for the exposed table name.

For example, assume that the current schema is CORPDATA.

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT FROM EMPLOYEE
```

is valid because the EMPLOYEE table referenced in the FROM clause fully qualifies to CORPDATA.EMPLOYEE, which matches the qualifier for the WORKDEPT column.

```
SELECT EMPLOYEE.WORKDEPT, REGEMP.WORKDEPT
  FROM CORPDATA.EMPLOYEE, REGION.EMPLOYEE REGEMP
```

is also valid, because the first select list column references the unqualified exposed table designator CORPDATA.EMPLOYEE, which is in the FROM clause, and the second select list column references the correlation name REGEMP of the table object REGION.EMPLOYEE, which is also in the FROM clause.

Now assume that the current schema is REGION.

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT FROM EMPLOYEE
```

is not valid because the EMPLOYEE table referenced in the FROM clause fully qualifies to REGION.EMPLOYEE, and the qualifier for the WORKDEPT column represents the CORPDATA.EMPLOYEE table.

Each table designator should be unique within a particular FROM clause to avoid the possibility of ambiguous references to columns.

Avoiding undefined or ambiguous references

When a column name refers to values of a column, exactly one object table must include a column with that name. The following situations are considered errors:

- No object table contains a column with the specified name. The reference is undefined.
- The column name is qualified by a table designator, but the table designated does not include a column with the specified name. Again the reference is undefined.
- The name is unqualified, and more than one object table includes a column with that name. The reference is ambiguous.
- The column name is qualified by a table designator, but the table designated is not unique in the FROM clause and both occurrences of the designated table include the column. The reference is ambiguous.
- The column name is in a nested table expression which is not preceded by the TABLE keyword or in a table function or nested table expression that is the right operand of a right outer join or a full outer join and the column name does not refer to a column of a *table-reference* within the nested table expression's fullselect. The reference is undefined.

Avoid ambiguous references by qualifying a column name with a uniquely defined table designator. If the column is contained in several object tables with different names, the table names can be used as designators. Ambiguous references can also be avoided without the use of the table designator by giving unique names to the columns of one of the object tables using the column name list following the correlation name.

When qualifying a column with the exposed table name form of a table designator, either the qualified or unqualified form of the exposed table name may be used. However, the qualifier used and the table used must be the same after fully qualifying the table name, view name or nickname and the table designator.

1. If the authorization ID of the statement is CORPDATA:

   ```
   SELECT CORPDATA.EMPLOYEE.WORKDEPT
     FROM EMPLOYEE
   ```

   is a valid statement.

2. If the authorization ID of the statement is REGION:

```
SELECT CORPDATA.EMPLOYEE.WORKDEPT
  FROM EMPLOYEE                          * incorrect *
```

   is invalid, because EMPLOYEE represents the table REGION.EMPLOYEE, but the qualifier for WORKDEPT represents a different table, CORPDATA.EMPLOYEE.

Column name qualifiers in correlated references

A *fullselect* is a form of a query that may be used as a component of various SQL statements. A fullselect used within a search condition of any statement is called a *subquery*. A fullselect used to retrieve a single value as an expression within a statement is called a *scalar fullselect* or *scalar subquery*. A fullselect used in the FROM clause of a query is called a *nested table expression*. Subqueries in search conditions, scalar subqueries and nested table expressions are referred to as subqueries through the remainder of this topic.

A subquery may include subqueries of its own, and these may, in turn, include subqueries. Thus an SQL statement may contain a hierarchy of subqueries. Those elements of the hierarchy that contain subqueries are said to be at a higher level than the subqueries they contain.

Every element of the hierarchy contains one or more table designators. A subquery can reference not only the columns of the tables identified at its own level in the hierarchy, but also the columns of the tables identified previously in the hierarchy, back to the highest level of the hierarchy. A reference to a column of a table identified at a higher level is called a *correlated reference*.

For compatibility with existing standards for SQL, both qualified and unqualified column names are allowed as correlated references. However, it is good practice to qualify all column references used in subqueries; otherwise, identical column names may lead to unintended results. For example, if a table in a hierarchy is altered to contain the same column name as the correlated reference and the statement is prepared again, the reference will apply to the altered table.

When a column name in a subquery is qualified, each level of the hierarchy is searched, starting at the same subquery as the qualified column name appears and continuing to the higher levels of the hierarchy until a table designator that matches the qualifier is found. Once found, it is verified that the table contains the given column. If the table is found at a higher level than the level containing column name, then it is a correlated reference to the level where the table designator was found. A nested table expression must be preceded with the optional TABLE keyword in order to search the hierarchy above the fullselect of the nested table expression.

When the column name in a subquery is not qualified, the tables referenced at each level of the hierarchy are searched, starting at the same subquery where the column name appears and continuing to higher levels of the hierarchy, until a match for the column name is found. If the column is found in a table at a higher level than the level containing column name, then it is a correlated reference to the level where the table containing the column was found. If the column name is found in more than one table at a particular level, the reference is ambiguous and considered an error.

In either case, T, used in the following example, refers to the table designator that contains column C. A column name, T.C (where T represents either an implicit or an explicit qualifier), is a correlated reference if, and only if, these conditions are met:

- T.C is used in an expression of a subquery.
- T does not designate a table used in the from clause of the subquery.
- T designates a table used at a higher level of the hierarchy that contains the subquery.

Since the same table, view or nickname can be identified at many levels, unique correlation names are recommended as table designators. If T is used to designate a table at more than one level (T is the table name itself or is a duplicate correlation name), T.C refers to the level where T is used that most directly contains the subquery that includes T.C. If a correlation to a higher level is needed, a unique correlation name must be used.

The correlated reference T.C identifies a value of C in a row or group of T to which two search conditions are being applied: condition 1 in the subquery, and condition 2 at some higher level. If condition 2 is used in a WHERE clause, the subquery is evaluated for each row to which condition 2 is applied. If condition 2 is used in a HAVING clause, the subquery is evaluated for each group to which condition 2 is applied.

For example, in the following statement, the correlated reference X.WORKDEPT (in the last line) refers to the value of WORKDEPT in table EMPLOYEE at the level of the first FROM clause. (That clause establishes X as a correlation name for EMPLOYEE.) The statement lists employees who make less than the average salary for their department.

```
SELECT EMPNO, LASTNAME, WORKDEPT
  FROM EMPLOYEE X
  WHERE SALARY < (SELECT AVG(SALARY)
                    FROM EMPLOYEE
                    WHERE WORKDEPT = X.WORKDEPT)
```

The next example uses THIS as a correlation name. The statement deletes rows for departments that have no employees.

```
DELETE FROM DEPARTMENT THIS
   WHERE NOT EXISTS(SELECT *
                      FROM EMPLOYEE
                      WHERE WORKDEPT = THIS.DEPTNO)
```

References to variables

A *variable* in an SQL statement specifies a value that can be changed when the SQL statement is executed. There are several types of variables used in SQL statements:

host variable
Host variables are defined by statements of a host language. For more information about how to refer to host variables, see “References to host variables” on page 20.

transition variable
Transition variables are defined in a trigger and refer to either the old or new values of columns. For more information about how to refer to transition variables, see "CREATE TRIGGER statement" in the *SQL Reference Volume 2* .

SQL variable
SQL variables are defined by an SQL compound statement in an SQL function, SQL method, SQL procedure, trigger, or dynamic SQL statement. For more information about SQL variables, see "References to SQL parameters, SQL variables, and global variables" in the *SQL Reference Volume 2* .

global variable
Global variables are defined by the CREATE VARIABLE statement. For more information about global variables, see "CREATE VARIABLE" and "References to SQL parameters, SQL variables, and global variables" in the *SQL Reference Volume 2* .

module variable
Module variables are defined by the ALTER MODULE statement using the ADD VARIABLE or PUBLISH VARIABLE operation. For more information about module variables, see "ALTER MODULE" in the *SQL Reference Volume 2* .

SQL parameter
SQL parameters are defined by a CREATE FUNCTION, CREATE METHOD, or CREATE PROCEDURE statement. For more information about SQL parameters, see "References to SQL parameters, SQL variables, and global variables" in the *SQL Reference Volume 2* .

parameter marker
Parameter markers are specified in a dynamic SQL statement where host variables would be specified if the statement were a static SQL statement. An SQL descriptor or parameter binding is used to associate a value with a parameter marker during dynamic SQL statement processing. For more information about parameter markers, see "Parameter markers" in the *SQL Reference Volume 2* .

References to host variables

A *host variable* is either:

- A variable in a host language such as a C variable, a C++ variable, a COBOL data item, a FORTRAN variable, or a Java™ variable

or:

- A host language construct that was generated by an SQL precompiler from a variable declared using SQL extensions

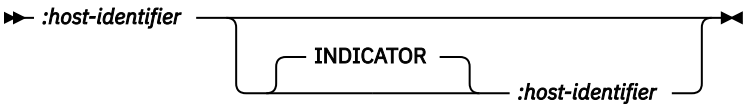
that is referenced in an SQL statement. Host variables are either directly defined by statements in the host language or are indirectly defined using SQL extensions.

A host variable in an SQL statement must identify a host variable described in the program according to the rules for declaring host variables.

All host variables used in an SQL statement must be declared in an SQL DECLARE section in all host languages except REXX. No variables may be declared outside an SQL DECLARE section with names identical to variables declared inside an SQL DECLARE section. An SQL DECLARE section begins with BEGIN DECLARE SECTION and ends with END DECLARE SECTION.

The meta-variable *host-variable*, as used in the syntax diagrams, shows a reference to a host variable. A host-variable as the target variable in a SET variable statement or in the INTO clause of a FETCH, SELECT INTO, or VALUES INTO statement, identifies a host variable to which a value from a column of a row or an expression is assigned. In all other contexts a host-variable specifies a value to be passed to the database manager from the application program.

The meta-variable *host-variable* in syntax diagrams can generally be expanded to:



Each *host-identifier* must be declared in the source program. The variable designated by the second host-identifier must have a data type of small integer.

The first host-identifier designates the *main variable*. Depending on the operation, it either provides a value to the database manager or is provided a value from the database manager. An input host variable provides a value in the runtime application code page. An output host variable is provided a value that, if necessary, is converted to the runtime application code page when the data is copied to the output application variable. A given host variable can serve as both an input and an output variable in the same program.

The second host-identifier designates its *indicator variable*. Indicator variables appear in two forms; normal indictor variables, and extended indicator variables.

The normal indicator variable has the following purposes:

- Specify a non-null value. A 0 (zero), or positive value of the indicator variable specifies that the associated, first, *host-identifier* provides the value of this host variable reference.
- Specify the null value. A negative value of the indicator variable specifies the null value.
- On output, indicate that a numeric conversion error (such as division by 0 or overflow) has occurred, if the **dft_sqlmathwarn** database configuration parameter is set to "yes" (or was set to "yes" during binding of a static SQL statement). A -2 value of the indicator variable indicates a null result because of either numeric truncation or friendly arithmetic warnings.
- On output, report the original length of a truncated string (if the source of the value is not a large object type).
- On output, report the seconds portion of a time if the time is truncated on assignment to a host variable.

Extended indicator variables are limited to the input of host variables. The extended indicator variable has the following purposes:

- Specify a non-null value. A 0 (zero), or positive value specifies that the associated, first, *host-identifier* provides the value of this host variable reference.
- Specify the null value. A -1, -2, -3, -4, or -6 value specifies the null value.
- Specify the default value. A -5 value specifies the target column for this host variable is to be set to its default value.
- Specify an unassigned value. A -7 value specifies the target column for this host variable is to be treated as if it had not been specified in the statement.

Extended indicator variables are only enabled if requested, and all indicator variables are otherwise normal indicator variables. In comparison to normal indicator variables, extended indicator variables have no additional restrictions for where the values for null and non-null can be used. There are no restrictions against using extended indicator variable values in indicator structures with host structures. Restrictions on where extended indicator variable values default and unassigned are allowed apply uniformly, no matter how they are represented in the host application. The default and unassigned extended indicator variable values may only appear in limited, specified uses. They may appear in expressions containing only a single host variable, or a host variable being explicitly cast (assigned to a column). Output indicator variable values are never extended indicator variables.

When extended indicator variables are enabled, there are no restrictions against use of 0 (zero), or positive indicator variable values. However, negative indicator variable values outside the range -1 through -7 must not be input (SQLSTATE 22010). When enabled, the default and unassigned extended indicator variable values must not appear in contexts in which they are not supported (SQLSTATE 22539).

When extended indicator variables are enabled, rules for data type validation in assignment and comparison are loosened for host variables whose extended indicator values are negative. Data type assignment and comparison validation rules will not be enforced for host variables having the values null, default, or unassigned.

For example, if :HV1:HV2 is used to specify an insert or update value, and if HV2 is negative, the value specified is the null value. If HV2 is not negative the value specified is the value of HV1.

Similarly, if :HV1:HV2 is specified in an INTO clause of a FETCH, SELECT INTO, or VALUES INTO statement, and if the value returned is null, HV1 is not changed, and HV2 is set to a negative value. If the database is configured with **dft_sqlmathwarn** yes (or was during binding of a static SQL statement), HV2 could be -2. If HV2 is -2, a value for HV1 could not be returned because of an error converting to the numeric type of HV1, or an error evaluating an arithmetic expression that is used to determine the value for HV1. If the value returned is not null, that value is assigned to HV1 and HV2 is set to zero (unless the assignment to HV1 requires string truncation of a non-LOB string; in which case HV2 is set to the original length of the string). If an assignment requires truncation of the seconds part of a time, HV2 is set to the number of seconds.

If the second host identifier is omitted, the host-variable does not have an indicator variable. The value specified by the host-variable reference :HV1 is always the value of HV1, and null values cannot be assigned to the variable. Thus, this form should not be used in an INTO clause unless the corresponding column cannot contain null values. If this form is used and the column contains nulls, the database manager will generate an error at run time.

An SQL statement that references host variables must be within the scope of the declaration of those host variables. For host variables referenced in the SELECT statement of a cursor, that rule applies to the OPEN statement rather than to the DECLARE CURSOR statement.

Example

Using the PROJECT table, set the host variable PNAME (VARCHAR(26)) to the project name (PROJNAME), the host variable STAFF (DECIMAL(5,2)) to the mean staffing level (PRSTAFF), and the host variable MAJPROJ (CHAR(6)) to the major project (MAJPROJ) for project (PROJNO) 'IF1000'. Columns PRSTAFF and MAJPROJ may contain null values, so provide indicator variables STAFF_IND (SMALLINT) and MAJPROJ_IND (SMALLINT).

```
SELECT PROJNAME, PRSTAFF, MAJPROJ
  INTO :PNAME, :STAFF :STAFF_IND, :MAJPROJ :MAJPROJ_IND
```

```
    FROM PROJECT
    WHERE PROJNO = 'IF1000'
```

MBCS Considerations: Whether multi-byte characters can be used in a host variable name depends on the host language.

Variables in dynamic SQL

In dynamic SQL statements, parameter markers are used instead of host variables. A parameter marker represents a position in a dynamic SQL statement where the application will provide a value; that is, where a host variable would be found if the statement string were a static SQL statement. The following example shows a static SQL statement using host variables:

```
INSERT INTO DEPARTMENT
  VALUES (:HV_DEPTNO, :HV_DEPTNAME, :HV_MGRNO, :HV_ADMRDEPT)
```

This example shows a dynamic SQL statement using unnamed parameter markers:

```
INSERT INTO DEPARTMENT VALUES (?, ?, ?, ?)
```

This example shows a dynamic SQL statement using named parameter markers:

```
INSERT INTO DEPARTMENT
  VALUES (:DEPTNO, :DEPTNAME, :MGRNO, :ADMRDEPT)
```

Named parameter markers can be used to improve the readability of dynamic statement. Although named parameter markers look like host variables, named parameter markers have no associated value and therefore a value must be provided for the parameter marker when the statement is executed. If the INSERT statement using named parameter markers has been prepared and given the prepared statement name of DYNSTMT, then values can be provided for the parameter markers using the following statement:

```
EXECUTE DYNSTMT
  USING :HV_DEPTNO, :HV_DEPTNAME :HV_MGRNO, :HV_ADMRDEPT
```

This same EXECUTE statement could be used if the INSERT statement using unnamed parameter markers had been prepared and given the prepared statement name of DYNSTMT.

References to LOB variables

Regular BLOB, CLOB, and DBCLOB variables, LOB locator variables (see “References to LOB locator variables” on page 22), and LOB file reference variables (see “References to LOB file reference variables” on page 23) can be defined in all host languages. Where LOBs are allowed, the term *host-variable* in a syntax diagram can refer to a regular host variable, a locator variable, or a file reference variable. Since these are not native data types, SQL extensions are used and the precompilers generate the host language constructs necessary to represent each variable. In the case of REXX, LOBs are mapped to strings.

It is sometimes possible to define a large enough variable to hold an entire large object value. If this is true and if there is no performance benefit to be gained by deferred transfer of data from the server, a locator is not needed. However, since host language or space restrictions will often dictate against storing an entire large object in temporary storage at one time or because of performance benefit, a large object may be referenced via a locator and portions of that object may be selected into or updated from host variables that contain only a portion of the large object at one time.

References to LOB locator variables

A *locator variable* is a host variable that contains the locator representing a LOB value on the application server.

A locator variable in an SQL statement must identify a locator variable described in the program according to the rules for declaring locator variables. This is always indirectly through an SQL statement.

The term locator variable, as used in the syntax diagrams, shows a reference to a locator variable. The meta-variable *locator-variable* can be expanded to include a *host-identifier* the same as that for *host-variable*.

As with all other host variables, a large object locator variable may have an associated indicator variable. Indicator variables for large object locator host variables behave in the same way as indicator variables for other data types. When a null value is returned from the database, the indicator variable is set and the locator host variable is unchanged. This means a locator can never point to a null value.

If a locator-variable that does not currently represent any value is referenced, an error is raised (SQLSTATE 0F001).

At transaction commit, or any transaction termination, all locators acquired by that transaction are released.

References to LOB file reference variables

BLOB, CLOB, and DBCLOB file reference variables are used for direct file input and output for LOBs, and can be defined in all host languages. Since these are not native data types, SQL extensions are used and the precompilers generate the host language constructs necessary to represent each variable. In the case of REXX, LOBs are mapped to strings.

A file reference variable represents (rather than contains) the file, just as a LOB locator represents, rather than contains, the LOB bytes. Database queries, updates and inserts may use file reference variables to store or to retrieve single column values.

A file reference variable has the following properties:

Data Type
BLOB, CLOB, or DBCLOB. This property is specified when the variable is declared.

Direction
This must be specified by the application program at run time (as part of the File Options value). The direction is one of:

- Input (used as a source of data on an EXECUTE statement, an OPEN statement, an UPDATE statement, an INSERT statement, or a DELETE statement).
- Output (used as the target of data on a FETCH statement or a SELECT INTO statement).

File name
This must be specified by the application program at run time. It is one of:

- The complete path name of the file (which is advised).
- A relative file name. If a relative file name is provided, it is appended to the current path of the client process.

Within an application, a file should only be referenced in one file reference variable.

File Name Length
This must be specified by the application program at run time. It is the length of the file name (in bytes).

File Options
An application must assign one of a number of options to a file reference variable before it makes use of that variable. Options are set by an INTEGER value in a field in the file reference variable structure. One of the following values must be specified for each file reference variable:

- Input (from client to server)

  SQL_FILE_READ
  This is a regular file that can be opened, read and closed. (The option is SQL-FILE-READ in COBOL, sql_file_read in FORTRAN, and READ in REXX.)

- Output (from server to client)

SQL_FILE_CREATE
Create a new file. If the file already exists, an error is returned. (The option is SQL-FILE-CREATE in COBOL, sql_file_create in FORTRAN, and CREATE in REXX.)

SQL_FILE_OVERWRITE (Overwrite)
If an existing file with the specified name exists, it is overwritten; otherwise a new file is created. (The option is SQL-FILE-OVERWRITE in COBOL, sql_file_overwrite in FORTRAN, and OVERWRITE in REXX.)

SQL_FILE_APPEND
If an existing file with the specified name exists, the output is appended to it; otherwise a new file is created. (The option is SQL-FILE-APPEND in COBOL, sql_file_append in FORTRAN, and APPEND in REXX.)

Data Length
This is unused on input. On output, the implementation sets the data length to the length of the new data written to the file. The length is in bytes.

As with all other host variables, a file reference variable may have an associated indicator variable.

Example of an output file reference variable (in C)

Given a declare section coded as:

```
EXEC SQL BEGIN DECLARE SECTION
   SQL TYPE IS CLOB_FILE  hv_text_file;
   char  hv_patent_title[64];
EXEC SQL END DECLARE SECTION
```

Following preprocessing this would be:

```
EXEC SQL BEGIN DECLARE SECTION
   /* SQL TYPE IS CLOB_FILE  hv_text_file; */
   struct {
       unsigned long  name_length; //  File Name Length
       unsigned long  data_length; //  Data Length
       unsigned long  file_options; // File Options
       char           name[255];   // File Name
   } hv_text_file;
   char  hv_patent_title[64];
EXEC SQL END DECLARE SECTION
```

Then, the following code can be used to select from a CLOB column in the database into a new file referenced by :hv_text_file.

```
strcpy(hv_text_file.name, "/u/gainer/papers/sigmod.94");
hv_text_file.name_length = strlen("/u/gainer/papers/sigmod.94");
hv_text_file.file_options = SQL_FILE_CREATE;

EXEC SQL SELECT content INTO :hv_text_file from papers
     WHERE TITLE = 'The Relational Theory behind Juggling';
```

Example of an input file reference variable (in C)

Given the same declare section as the previous one, the following code can be used to insert the data from a regular file referenced by :hv_text_file into a CLOB column.

```
strcpy(hv_text_file.name, "/u/gainer/patents/chips.13");
hv_text_file.name_length = strlen("/u/gainer/patents/chips.13");
hv_text_file.file_options = SQL_FILE_READ:
strcpy(:hv_patent_title, "A Method for Pipelining Chip Consumption");

EXEC SQL INSERT INTO patents( title, text )
         VALUES(:hv_patent_title, :hv_text_file);
```

References to structured type host variables

Structured type variables can be defined in all host languages except FORTRAN, REXX, and Java. Since these are not native data types, SQL extensions are used and the precompilers generate the host language constructs necessary to represent each variable.

As with all other host variables, a structured type variable may have an associated indicator variable. Indicator variables for structured type host variables behave in the same way as indicator variables for other data types. When a null value is returned from the database, the indicator variable is set and the structured type host variable is unchanged.

The actual host variable for a structured type is defined as a built-in data type. The built-in data type associated with the structured type must be assignable:

- from the result of the FROM SQL transform function for the structured type as defined by the specified TRANSFORM GROUP option of the precompile command; and
- to the parameter of the TO SQL transform function for the structured type as defined by the specified TRANSFORM GROUP option of the precompile command.

If using a parameter marker instead of a host variable, the appropriate parameter type characteristics must be specified in the SQLDA. This requires a "doubled" set of SQLVAR structures in the SQLDA, and the SQLDATATYPE_NAME field of the secondary SQLVAR must be filled with the schema and type name of the structured type. If the schema is omitted in the SQLDA structure, an error results (SQLSTATE 07002).

Example

Define the host variables *hv_poly* and *hv_point* (of type POLYGON, using built-in type BLOB(1048576)) in a C program.

```
EXEC SQL BEGIN DECLARE SECTION;
      static SQL
         TYPE IS POLYGON AS BLOB(1M)
         hv_poly, hv_point;
EXEC SQL END DECLARE SECTION;
```

SQL path

The SQL path is an ordered list of schema names. The database manager uses the SQL path to resolve the schema name for unqualified data type names (both built-in types and distinct types), global variable names, module names, function names, and procedure names that appear in any context other than as the main object of a CREATE, DROP, COMMENT, GRANT or REVOKE statement. For details, see "Qualification of unqualified object names".

For example, if the SQL path is SYSIBM. SYSFUN, SYSPROC, SYSIBMADM, SMITH, XGRAPHICS2 and an unqualified distinct type name MYTYPE was specified, the database manager looks for MYTYPE first in schema SYSIBM, then SYSFUN, then SYSPROC, then SYSIBMADM, then SMITH, and then XGRAPHICS2.

The SQL path used depends on the SQL statement:

- For static SQL statements (except for a CALL variable statement), the SQL path used is the SQL path specified when the containing package, procedure, function, trigger, or view was created.
- For dynamic SQL statements (and for a CALL variable statement), the SQL path is the value of the CURRENT PATH special register. CURRENT PATH can be set by the SET PATH statement.

If the SQL path is not explicitly specified, the SQL path is the system path followed by the authorization ID of the statement. .

Qualification of unqualified object names

Unqualified object names are implicitly qualified. The rules for qualifying a name differ depending on the type of object that the name identifies.

Unqualified alias, index, package, sequence, table, trigger, and view names

Unqualified alias, index, package, sequence, table, trigger, and view names are implicitly qualified by the default schema.

For static SQL statements, the default schema is the default schema specified when the containing function, package, procedure, or trigger was created.

For dynamic SQL statements, the default schema is the default schema specified for the application process. The default schema can be specified for the application process by using the SET SCHEMA statement. If the default schema is not explicitly specified, the default schema is the authorization ID of the statement.

Unqualified user-defined type, function, procedure, specific, global variable and module names

The qualification of data type (both built-in types and distinct types), global variable, module, function, procedure, and specific names depends on the SQL statement in which the unqualified name appears:

- If an unqualified name is the main object of a CREATE, ALTER, COMMENT, DROP, GRANT, or REVOKE statement, the name is implicitly qualified using the same rules as for qualifying unqualified table names (See “Unqualified alias, index, package, sequence, table, trigger, and view names” on page 26). The main object of an ADD, COMMENT, DROP, or PUBLISH operation of the ALTER MODULE statement must be specified without any qualifier.
- If the context of the reference is within a module, the database manager searches the module for the object, applying the appropriate resolution for the type of object to find a match. If no match is found, the search continues as specified in the next bullet.
- Otherwise, the implicit schema name is determined as follows:
  - For distinct type names, the database manager searches the SQL path and selects the first schema in the SQL path such that the data type exists in the schema.
  - For global variables, the database manager searches the SQL path and selects the first schema in the SQL path such that the global variable exists in the schema.
  - For procedure names, the database manager uses the SQL path in conjunction with procedure resolution.
  - For function names, the database manager uses the SQL path in conjunction with function resolution .
  - For specific names specified for sourced functions, see "CREATE FUNCTION (Sourced)".

New SYSIBM functions override unqualified user-defined functions with the same name

An existing user-defined function or a user-defined procedure might have the same name and signature as a new built-in function or SQL administrative routine. In such cases, an unqualified reference to those functions or routines in a dynamic SQL statement runs the built-in function or SQL administrative routine instead of the user-defined one.

The default SQL path contains the schemas SYSIBM, SYSFUN, SYSPROC, and SYSIBMADM before the schema name that is the value of the USER special register. These system schemas are also included in the SQL path when it is explicitly set with the SET PATH statement or the FUNCPATH bind option. During function resolution and procedure resolution, the built-in functions and SQL administrative routines in the SYSIBM, SYSFUN, SYSPROC, and SYSIBMADM schemas are encountered before user-defined functions and user-defined procedures.

This change does not affect static SQL in packages or SQL objects such as views, triggers, or SQL functions. In these cases, the user-defined function or procedure continues to run until an explicit bind of the package, or drop and create of the SQL object.

To run an unqualified user-defined routine instead of a new SYSIBM function with the same name, rename the user-defined routine or fully qualify the name before you run it. Alternatively, place in the SQL path

the schema in which the user-defined routine exists before the schema in which the built-in functions and SQL administrative routines exist. However, promoting the schema in the SQL path increases the resolution time for all built-in functions and SQL administrative routines because the system schemas are considered first.

Resolving qualified object names

Objects that are defined in a module that are available for use outside the module must be qualified by the module name. Since a module is a schema object that can also be implicitly qualified, the published module objects can be qualified using an unqualified module name or a schema-qualified module name. When an unqualified module name is used, the reference to the module object appears the same as a schema-qualified object that is not part of a module. Within a specific scope, such as a compound SQL statement, a two-part identifier could also be:

- a column name qualified by a table name
- a row field name qualified by a variable name
- a variable name qualified by a label
- a routine parameter name qualified by a routine name

These objects are resolved within their scope, before considering either schema objects or module object. The following process is used to resolve objects with two-part identifiers that could be a schema object or a module object.

- If the context of the reference is within a module and the qualifier matches the module name, the database manager searches the module for the object, applying the appropriate resolution for the type of object to find a match among published and unpublished module objects. If no match is found, the search continues as specified in the next bullets.
- Assume that the qualifier is a schema name and, if the schema exists, resolve the object in the schema.
- If the qualifier is not an existing schema or the object is not found in the schema that matches the qualifier and the qualifier did not match the context module name, search for the first module that matches the qualifier in the schemas on the SQL path. If authorized to the matching module, resolve to the object in that module, considering only published module objects.
- If the qualifier is not found as a module on the SQL path and the qualifier did not match the context module name, check for a module public synonym that matches the qualifier. If found, resolve the object in the module identified by the module public synonym, considering only published module objects.

Reserved package names

A specific set of package names have been explicitly reserved for system use. To avoid collision with system use of these names it is recommended that these package names not be used by any application.

The set of package names that are reserved meet one of the following criteria:

- The package schema is a reserved schema
- The package schema is NULLID and the package name matches a reserved package name or contains a prefix that matches a reserved package name prefix.

The following package names are reserved within the NULLID schema:

- AGGDISC
- PRINTSG
- TUPLEWRT

The following package name prefixes are reserved within the NULLID schema:

- AOT
- ATS

- CADM
- CLI
- DB2
- POLY
- REVA
- SPIM
- SPUT
- SQL
- SYS
- TOOL

Data types

The smallest unit of data that can be manipulated in SQL is called a *value*. Values are interpreted according to the data type of their source.

Sources include:

- Constants
- Columns
- Functions
- Expressions
- Special registers
- Variables (such as host variables, SQL variables, global variables, parameter markers, module variable, and parameters of routines)
- Boolean values

All data types include the null value as a possible value. The null value is a special value that is distinct from all non-null values and thereby denotes the absence of a (non-null) value. Although all data types include the null value, a column defined as NOT NULL cannot contain null values.

A Unicode database also supports national character strings that are synonyms for graphic strings.

Built-in and user-defined data types

Data types that are pre-defined for use within the database management system are called *built-in data types*. Figure 1 on page 29 shows the supported built-in data types.

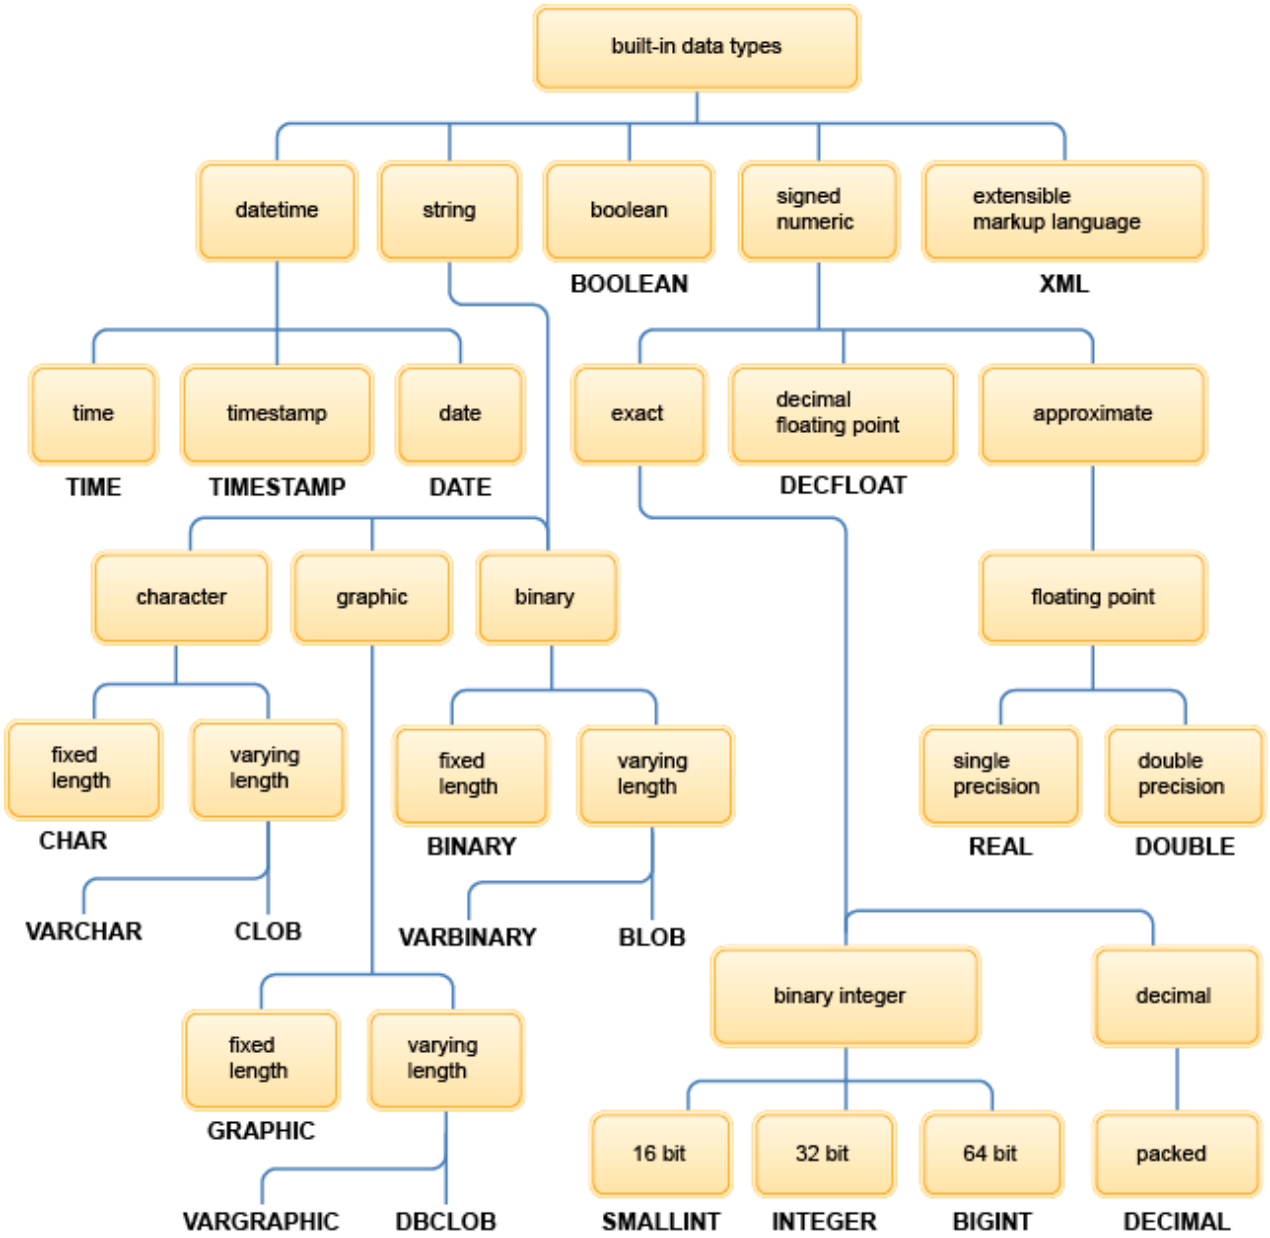


Figure 1. Built-in Data Types

Support for the following user-defined data types is also provided:

- Array
- Cursor
- Distinct
- Row
- Structured

Data type list

Numbers

The numeric data types are integer, decimal, floating-point, and decimal floating-point.

The numeric data types are categorized as follows:

- Exact numerics: integer and decimal

- Decimal floating-point
- Approximate numerics: floating-point

Integer includes small integer, large integer, and big integer. Integer numbers are exact representations of integers. Decimal numbers are exact representations of numbers with a fixed precision and scale. Integer and decimal numbers are considered exact numeric types.

Decimal floating-point numbers can have a precision of 16 or 34. Decimal floating-point supports both exact representations of real numbers and approximation of real numbers and so is not considered either an exact numeric type or an approximate numeric type.

Floating-point includes single precision and double precision. Floating-point numbers are approximations of real numbers and are considered approximate numeric types.

All numbers have a *sign*, a *precision*, and a *scale*. For all numbers except decimal floating-point, if a column value is zero, the sign is positive. Decimal floating-point numbers include negative and positive zeros. Decimal floating-point has distinct values for a number and the same number with various exponents (for example: 0.0, 0.00, 0.0E5, 1.0, 1.00, 1.0000). The precision is the total number of decimal digits, excluding the sign. The scale is the total number of decimal digits to the right of the decimal point. If there is no decimal point, the scale is zero.

See also the data type section in the description of "CREATE TABLE statement" in the *SQL Reference Volume 2*.

.

Small integer (SMALLINT)

A *small integer* is a two-byte integer with a precision of 5 digits. The range of small integers is -32 768 to 32 767.

Large integer (INTEGER)

A *large integer* is a four-byte integer with a precision of 10 digits. The range of large integers is -2 147 483 648 to +2 147 483 647.

Big integer (BIGINT)

A *big integer* is an eight-byte integer with a precision of 19 digits. The range of big integers is -9 223 372 036 854 775 808 to +9 223 372 036 854 775 807.

Decimal (DECIMAL or NUMERIC)

A *decimal* value is a packed decimal number with an implicit decimal point. The position of the decimal point is determined by the precision and the scale of the number. The scale, which is the number of digits in the fractional part of the number, cannot be negative or greater than the precision. The maximum precision is 31 digits.

All values in a decimal column have the same precision and scale. The range of a decimal variable or the numbers in a decimal column is -*n* to +*n*, where the absolute value of *n* is the largest number that can be represented with the applicable precision and scale. The maximum range is $-10^{31}+1$ to $10^{31}-1$.

Single-precision floating-point (REAL)

A *single-precision floating-point* number is a 32-bit approximation of a real number. The number can be zero or can range from -3.4028234663852886e+38 to -1.1754943508222875e-38, or from 1.1754943508222875e-38 to 3.4028234663852886e+38.

Double-precision floating-point (DOUBLE or FLOAT)

A *double-precision floating-point* number is a 64-bit approximation of a real number. The number can be zero or can range from -1.7976931348623158e+308 to -2.2250738585072014e-308, or from 2.2250738585072014e-308 to 1.7976931348623158e+308.

Decimal floating-point (DECFLOAT)

A *decimal floating-point* value is an IEEE 754r number with a decimal point. The position of the decimal point is stored in each decimal floating-point value. The maximum precision is 34 digits. The range of a decimal floating-point number is either 16 or 34 digits of precision, and an exponent range of 10^{-383} to 10^{+384} or 10^{-6143} to 10^{+6144}, respectively. The minimum exponent, E_{min}, for DECFLOAT values is -383 for DECFLOAT(16) and -6143 for DECFLOAT(34). The maximum exponent, E_{max}, for DECFLOAT values is 384 for DECFLOAT(16) and 6144 for DECFLOAT(34).

In addition to finite numbers, decimal floating-point numbers are able to represent one of the following named decimal floating-point special values:

- Infinity - a value that represents a number whose magnitude is infinitely large
- Quiet NaN - a value that represents undefined results and that does not cause an invalid number warning
- Signalling NaN - a value that represents undefined results and that causes an invalid number warning if used in any numeric operation

When a number has one of these special values, its coefficient and exponent are undefined. The sign of an infinity value is significant, because it is possible to have positive or negative infinity. The sign of a NaN value has no meaning for arithmetic operations.

Subnormal numbers and underflow

Nonzero numbers whose adjusted exponents are less than E_{min} are called subnormal numbers. These subnormal numbers are accepted as operands for all operations and can result from any operation.

For a subnormal result, the minimum values of the exponent become E_{min} - (precision-1), called E_{tiny}, where precision is the working precision. If necessary, the result is rounded to ensure that the exponent is no smaller than E_{tiny}. If the result becomes inexact during rounding, an underflow warning is returned. A subnormal result does not always return the underflow warning.

When a number underflows to zero during a calculation, its exponent will be E_{tiny}. The maximum value of the exponent is unaffected.

The maximum value of the exponent for subnormal numbers is the same as the minimum value of the exponent that can arise during operations that do not result in subnormal numbers. This occurs when the length of the coefficient in decimal digits is equal to the precision.

Character strings

A *character string* is a sequence of code units. The length of the string is the number of code units in the sequence. If the length is zero, the value is called the *empty string*, which should not be confused with the null value.

Fixed-length character string (CHAR)

All values in a fixed-length string column have the same length, which is determined by the length attribute of the column. The length attribute must be in the range 1 - 255, inclusive, unless the string unit is CODEUNITS32, which has a range of 1 - 63, inclusive.

Varying-length character strings

There are two types of varying-length character strings:

VARCHAR
A VARCHAR value can be up to 32,672 bytes long. If the string unit is CODEUNITS32, the length can be up to 8,168 string units.

CLOB
A character large object (CLOB) value can be up to 2 gigabytes minus 1 byte (2,147,483,647 bytes) long or, if the string unit is CODEUNITS32, up to 536,870,911 string units. A CLOB is used to store large SBCS or mixed (SBCS and MBCS) character-based data (such as documents written with a single character set) and, therefore, has an SBCS or mixed code page that is associated with it.

Special restrictions apply to expressions that result in a CLOB data type, and to structured type columns; such expressions and columns are not permitted in:

- A SELECT list that is preceded by the DISTINCT clause
- A GROUP BY clause
- An ORDER BY clause
- A subselect of a set operator other than UNION ALL
- A basic, quantified, BETWEEN, or IN predicate
- An aggregate function
- VARGRAPHIC, TRANSLATE, and datetime scalar functions
- The pattern operand in a LIKE predicate, or the search string operand in a POSSTR function
- The string representation of a datetime value.

The functions in the SYSFUN schema taking a VARCHAR as an argument will not accept VARCHARs greater than 4,000 bytes long as an argument. However, many of these functions also have an alternative signature accepting a CLOB(1M). For these functions, the user can explicitly cast the greater than 4,000 VARCHAR strings into CLOBs and then recast the result back into VARCHARs of the required length.

NUL-terminated character strings that are found in C are handled differently, depending on the standards level of the precompile option.

Each character string is further defined as one of:

Bit data
Data that is not associated with a code page.

Single-byte character set (SBCS) data
Data in which every character is represented by a single byte.

Mixed data
Data that might contain a mixture of characters from a single-byte character set and a multi-byte character set (MBCS).

Unicode data
Data that contains characters that are represented by one or more bytes. Each Unicode character string is encoded by using UTF-8. The CCSID for UTF-8 is 1208.

Note: The LONG VARCHAR data type continues to be supported but is deprecated, not recommended, and might be removed in a future release.

String units specification for character strings

The unit of length for the character string data type is OCTETS or CODEUNITS32. The unit of length defines the counting method that is used to determine the length of the data.

OCTETS
Indicates that the units for the length attribute are bytes. This unit of length applies to all non-Unicode character string data types. For a Unicode character string data type, OCTETS can be explicitly specified or determined based on an environment setting.

CODEUNITS32
Indicates that the units for the length attribute are Unicode UTF-32 code units which approximate counting in characters. This unit of length does not affect the underlying code page of the data type. The actual length of a data value is determined by counting the UTF-32 code units as if the data was converted to UTF-32. A string unit of CODEUNITS32 can be used only for a Unicode character string data type. CODEUNITS32 can be explicitly specified or determined based on an environment setting.

For a non-Unicode character string data type, the string unit is always OCTETS and cannot be changed. For a Unicode character string data type, the string units can be explicitly specified with the length attribute of a character string data type, or it can default based on an environment setting. If FOR BIT DATA is also specified for the character string data type, CODEUNITS32 cannot be specified and an environment setting of CODEUNITS32 does not apply.

The environment setting for string units is based on the value for the NLS_STRING_UNITS global variable, or the **string_units** database configuration parameter. The database configuration parameter can be set to either SYSTEM or CODEUNITS32. The global variable can also be set to either SYSTEM or CODEUNITS32, but also can be set to NULL. The NULL value indicates that the SQL session should use the **string_units** database configuration parameter setting. If the value for the environment setting is SYSTEM, then OCTETS is used as the default string units setting.

String units in built-in functions

The ability to specify string units for certain built-in string functions allows you to process string data in a more "character-based manner" than a "byte-based manner". The *string unit* determines the unit that is used for length or position when you execute the function. You can specify CODEUNITS16, CODEUNITS32, or OCTETS as the string unit for some string functions. When no string unit is specified, the default string unit is usually determined by the string units of the source string argument (refer to the description of the function that you are using for details). The string units argument can be specified for string functions that support the parameter in Unicode or non-Unicode databases.

CODEUNITS16
Specifies that Unicode UTF-16 is the unit for the operation. CODEUNITS16 is useful when an application is processing data in code units that are 2 bytes in width. Note some characters, which are known as *supplementary characters*, require two UTF-16 code units to be encoded. For example, the musical symbol G clef requires two UTF-16 code units (X'D834' and X'DD1E' in UTF-16BE).

CODEUNITS32
Specifies that Unicode UTF-32 is the unit for the operation. CODEUNITS32 is useful for applications that process data in a simple, fixed-length format, and that must return the same answer regardless of the storage format of the data (ASCII, UTF-8, or UTF-16).

Note: The storage on disk uses UTF-8 encoding.

OCTETS
Specifies that bytes are the units for the operation. OCTETS is often used when an application is interested in allocating buffer space or when operations need to use simple byte processing.

The calculated length of a string computed using OCTETS (bytes) might differ from that computed using CODEUNITS16 or CODEUNITS32. When you are using OCTETS, the length of the string is determined by simply counting the number of bytes in the string. When you are using CODEUNITS16 or CODEUNITS32, the length of the string is determined by counting the number of 16-bit or 32-bit code units necessary to represent the string in UTF-16 or UTF-32. A length that is determined using CODEUNITS16 and CODEUNITS32 is identical unless the data contains supplementary characters (see “Difference between CODEUNITS16 and CODEUNITS32” on page 34).

For example, assume that NAME, a VARCHAR(128) column that is encoded in Unicode UTF-8, contains the value 'Jürgen'. The following two queries, which count the length of the string in CODEUNITS16 or CODEUNITS32, return the same value (6).

```
SELECT CHARACTER_LENGTH(NAME,CODEUNITS16) FROM T1
  WHERE NAME = 'Jürgen'
```

```
SELECT CHARACTER_LENGTH(NAME,CODEUNITS32) FROM T1
  WHERE NAME = 'Jürgen'
```

The next query, which counts the length of the string in OCTETS, returns the value 7.

```
SELECT CHARACTER_LENGTH(NAME,OCTETS) FROM T1
  WHERE NAME = 'Jürgen'
```

These values represent the length of the string that is expressed in the specified string unit.

The following table shows the UTF-8, UTF-16BE (big-endian), and UTF-32BE (big-endian) representations of the name 'Jürgen':

```
Format    Representation of the name 'Jürgen'
--------  ------------------------------------
UTF-8      X'4AC3BC7267656E'
UTF-16BE     X'004A00FC007200670065006E'
UTF-32BE     X'0000004A000000FC00000072000000670000006500000006E'
```

The representation of the character 'ü' differs among the three string units:

- The UTF-8 representation of the character 'ü' is X'C3BC'.
- The UTF-16BE representation of the character 'ü' is X'00FC'.
- The UTF-32BE representation of the character 'ü' is X'000000FC'.

Specifying string units for a built-in function does not affect the data type, the string units, or the code page of the result of the function. If necessary, the data is converted to Unicode for evaluation when CODEUNITS16 or CODEUNITS32 is specified.

When OCTETS is specified for the LOCATE or POSITION function, and the code pages of the string arguments differ, the data is converted to the code page of the *source-string* argument. In this case, the result of the function is in the code page of the *source-string* argument. When OCTETS is specified for functions that take a single string argument, the data is evaluated in the code page of the string argument, and the result of the function is in the code page of the string argument.

Difference between CODEUNITS16 and CODEUNITS32

When CODEUNITS16 or CODEUNITS32 is specified, the result is the same except when the data contains Unicode supplementary characters. This is because a supplementary character is represented by two UTF-16 code units or one UTF-32 code unit. In UTF-8, a non-supplementary character is represented by 1 to 3 bytes, and a supplementary character is represented by 4 bytes. In UTF-16, a non-supplementary character is represented by one CODEUNITS16 code unit or 2 bytes, and a supplementary character is represented by two CODEUNITS16 code units or 4 bytes. In UTF-32, a character is represented by one CODEUNITS32 code unit or 4 bytes.

For example, the following table shows the hexadecimal values for the mathematical bold capital A and the Latin capital letter A. The mathematical bold capital A is a supplementary character that is represented by 4 bytes in UTF-8, UTF-16, and UTF-32.

Character	UTF-8 representation	UTF-16BE representation	UTF-32BE representation
Unicode value X'1D400' - 'A'; mathematical bold capital A	X'F09D9080'	X'D835DC00'	X'0001D400'
Unicode value X'0041' - 'A'; latin capital letter A	X'41'	X'0041'	X'00000041'

Assume that C1 is a VARCHAR(128) column, encoded in Unicode UTF-8, and that table T1 contains one row with the value of the mathematical bold capital A (X'F09D9080'). The following queries return different results:

```
Query                                              Returns
-----                                              -------
SELECT CHARACTER_LENGTH(C1,CODEUNITS16) FROM T1     2

SELECT CHARACTER_LENGTH(C1,CODEUNITS32) FROM T1     1

SELECT CHARACTER_LENGTH(C1,OCTETS) FROM T1          4
```

Graphic strings

A *graphic string* is a sequence of code units that represents double-byte character data.

The length of the string is the number of code units in the sequence. If the length is zero, the value is called the *empty string*. This value should not be confused with the null value.

Graphic strings are not supported in a database that is defined with a single-byte code page.

Graphic strings are not checked to ensure that their values contain only double-byte character code points. (The exception to this rule is an application that is precompiled with the WCHARTYPE CONVERT option. In this case, validation does occur.) Rather, the database manager assumes that double-byte character data is contained in graphic data fields. The database manager *does* check that a graphic string value is an even number of bytes long.

NUL-terminated graphic strings that are found in C are handled differently, depending on the standards level of the precompile option. This data type cannot be created in a table. It can be used only to insert data into and retrieve data from the database.

Fixed-length graphic strings (GRAPHIC)

All values in a fixed-length graphic string column have the same length, which is determined by the length attribute of the column. The length attribute must be 1 - 127, inclusive, unless the string unit is CODEUNITS32 which has a range of 1 - 63, inclusive.

Varying-length graphic strings

There are two types of varying-length graphic string:

- A VARGRAPHIC value can be up to 16 336 double-byte code units long. If the string unit is CODEUNITS32, the length can be up to 8 168 string units.
- A DBCLOB (double-byte character large object) value can be up to 1 073 741 823 double-byte code units long. If the string unit is CODEUNITS32, the length can be up to 536 870 911 string units. A DBCLOB is used to store large DBCS character-based data (such as documents written with a single character set) and, therefore, has a DBCS code page that is associated with it.

Special restrictions apply to an expression that results in a DBCLOB data type. These restrictions are the same as the restrictions specified in “Varying-length character strings” on page 31.

Note: The LONG VARGRAPHIC data type continues to be supported but is deprecated, not recommended, and might be removed in a future release.

String units specification for graphic strings

The unit of length for a graphic string data type is double bytes, CODEUNITS16, or CODEUNITS32. The unit of length defines the counting method that is used to determine the length of the data.

Double bytes
Indicates that the units for the length attribute are double bytes. This unit of length applies to all graphic string data types in a non-Unicode database. In a Unicode database, CODEUNITS16 is used.

CODEUNITS16
Indicates that the units for the length attribute are Unicode UTF-16 code units which are the same as counting in double bytes. This unit of length does not affect the underlying code page of the data type. A string unit of CODEUNITS16 can be used only with graphic string data types in a Unicode database. CODEUNITS16 can be explicitly specified or determined based on an environment setting.

CODEUNITS32
Indicates that the units for the length attribute are Unicode UTF-32 code units which approximate counting in characters. This unit of length does not affect the underlying code page of the data type. The actual length of a data value is determined by counting the UTF-32 code units as if the data was converted to UTF-32. A string unit of CODEUNITS32 can be used only in a Unicode database. CODEUNITS32 can be explicitly specified or determined based on an environment setting.

In a non-Unicode database, the string unit is always double bytes and cannot be changed. In a Unicode database, the string units can be explicitly specified with the length attribute of a graphic string data type, or it can default based on an environment setting.

The environment setting for string units is based on the value for the NLS_STRING_UNITS global variable, or the **string_units** database configuration parameter. The database configuration parameter can be set to either SYSTEM or CODEUNITS32. The global variable can also be set to either SYSTEM or CODEUNITS32, but also can be set to NULL. The NULL value indicates that the SQL session should use the **string_units** database configuration parameter setting. If the value for the environment setting is SYSTEM, then CODEUNITS16 is used as the default string units setting in a Unicode database and double bytes is used in a non-Unicode database.

National character strings

A national character string is a sequence of bytes that represents character data in UTF-8 or UTF-16 BE encoding.

National character strings are only allowed in a Unicode database.

The length of the string is the number of code units in the sequence. If the length is zero, the value is called the empty string. This value should not be confused with the null value.

National character strings are synonyms for Unicode character strings or graphic strings. Based on the value that is set for **nchar_mapping** database configuration parameter, national character strings are mapped as follows:

nchar_mapping is CHAR_CU32:

- NCHAR is a synonym for CHARACTER with string units CODEUNITS32
- NVARCHAR is a synonym for VARCHAR with string units CODEUNITS32
- NCLOB is a synonym for CLOB with string units CODEUNITS32

nchar_mapping is GRAPHIC_CU32:

- NCHAR is a synonym for GRAPHIC with string units CODEUNITS32
- NVARCHAR is a synonym for VARGRAPHIC with string units CODEUNITS32
- NCLOB is a synonym for DBCLOB with string units CODEUNITS32

nchar_mapping is GRAPHIC_CU16:

- NCHAR is a synonym for GRAPHIC with string units CODEUNITS16
- NVARCHAR is a synonym for VARGRAPHIC with string units CODEUNITS16
- NCLOB is a synonym for DBCLOB with string units CODEUNITS16

For details, refer to the topics "Character strings" and "Graphic strings".

Binary strings

A *binary string* is a sequence of bytes. Unlike character strings, which usually contain text data, binary strings are used to hold data such as pictures, voice, or mixed media.

Binary strings are not associated with a code page; their code page value is 0. The length of a binary string is the number of bytes it contains. Only character strings of the FOR BIT DATA subtype are compatible with binary strings.

The unit of length for the binary string data type is OCTETS and cannot be explicitly specified.

Fixed-length binary string

A fixed-length binary string has the data type BINARY. All values in a fixed-length string column have the same length, which is determined by the length attribute of the data type. The length attribute must be in the range 1 - 255, inclusive.

Varying-length binary strings

There are two types of varying-length binary string:

VARBINARY
A VARBINARY value can be up to 32,672 bytes long.

BLOB
A binary large object (BLOB) value can be up to 2 gigabytes minus 1 byte (2,147,483,647 bytes) long. A BLOB can hold structured data for exploitation by user-defined types and user-defined functions.

Special restrictions apply to an expression that results in a BLOB data type. These restrictions are the same as the restrictions described in "Varying-length character strings" on page 31.

Large objects (LOBs)

The term *large object* and the generic acronym LOB refer to the BLOB, CLOB, or DBCLOB data type. In a Unicode database, NCLOB can be used as a synonym for DBCLOB.

LOB values are subject to restrictions, as described in "Varying-length character strings" on page 31. These restrictions apply even if the length attribute of the LOB string is 254 bytes or less.

LOB values can be very large, and the transfer of these values from the database server to client application program host variables can be time consuming. Because application programs typically process LOB values one piece at a time, rather than as a whole, applications can reference a LOB value by using a large object locator.

A *large object locator*, or LOB locator, is a host variable whose value represents a single LOB value on the database server.

An application program can select a LOB value into a LOB locator. Then, using the LOB locator, the application program can request database operations on the LOB value (such as applying the scalar functions SUBSTR, CONCAT, VALUE, or LENGTH; performing an assignment; searching the LOB with LIKE or POSSTR; or applying user-defined functions against the LOB) by supplying the locator value as input. The resulting output (data assigned to a client host variable) would typically be a small subset of the input LOB value.

LOB locators can represent more than just base values; they can also represent the value associated with a LOB expression. For example, a LOB locator might represent the value associated with:

```
SUBSTR( <lob 1> CONCAT <lob 2> CONCAT <lob 3>, <start>, <length> )
```

When a null value is selected into a normal host variable, the indicator variable is set to -1, signifying that the value is null. In the case of LOB locators, however, the meaning of indicator variables is slightly different. Because a locator host variable can itself never be null, a negative indicator variable value indicates that the LOB value represented by the LOB locator is null. The null information is kept local to the client by virtue of the indicator variable value - the server does not track null values with valid locators.

It is important to understand that a LOB locator represents a value, not a row or a location in the database. Once a value is selected into a locator, there is no operation that one can perform on the original row or table that will affect the value which is referenced by the locator. The value associated with a locator is valid until the transaction ends, or until the locator is explicitly freed, whichever comes first. Locators do not force extra copies of the data to provide this function. Instead, the locator mechanism stores a description of the base LOB value. The materialization of the LOB value (or expression, as shown previously) is deferred until it is actually assigned to some location - either a user buffer in the form of a host variable, or another record in the database.

A LOB locator is only a mechanism used to refer to a LOB value during a transaction; it does not persist beyond the transaction in which it was created. It is not a database type; it is never stored in the database and, as a result, cannot participate in views or check constraints. However, because a LOB locator is a client representation of a LOB type, there are SQLTYPEs for LOB locators so that they can be described within an SQLDA structure used by FETCH, OPEN, or EXECUTE statements.

Datetime values

The datetime data types are DATE, TIME, and TIMESTAMP. Although datetime values can be used in certain arithmetic and string operations and are compatible with certain strings, they are not strings or numbers.

Date

A *date* is a three-part value (year, month, and day):

- The range of the month part is 1 - 12.
- The range of the day part is 1 - *x*, where *x* is 28, 29, 30, or 31, and depends on the month.
- The range of the year part is 0001 - 9999 for local tables.

The internal representation of a date is a string of 4 bytes. Each byte consists of 2 packed decimal digits. The first 2 bytes represent the year, the third byte the month, and the last byte the day.

The length of a DATE column, as described in the SQLDA, is 10 bytes, which is the appropriate length for a character string representation of the value.

Time

A *time* is a three-part value (hour, minute, and second) designating a time of day under a 24-hour clock:

- The range of the hour part is 0 - 24.
- The range of the minute and second parts is 0 - 59.

If the hour is 24, the minute and second specifications are 0.

Important: Using the value 24 when representing hours in a time value might result in errors or unexpected data. To avoid this issue, use 00 instead of 24.

The internal representation of a time is a string of 3 bytes. Each byte consists of 2 packed decimal digits. The first byte represents the hour, the second byte the minute, and the last byte the second.

The length of a TIME column, as described in the SQLDA, is 8 bytes, which is the appropriate length for a character string representation of the value.

Timestamp

A *timestamp* is a six or seven-part value (year, month, day, hour, minute, second, and optional fractions of a second) designating a date and time as defined in the previous sections, except that the time can also include an additional part designating a fraction of a second. The number of digits in the fractional seconds is specified using an attribute in the range from 0 to 12; the default is 6.

Important: Using the value 24 when representing hours in a timestamp value might result in errors or unexpected data. To avoid this issue, use 00 instead of 24.

The internal representation of a timestamp is a string of 7 - 13 bytes. Each byte consists of 2 packed decimal digits. The first 4 bytes represent the date, the next 3 bytes the time, and the last 0 - 6 bytes the fractions of a second.

The length of a TIMESTAMP column, as described in the SQLDA, is 19 - 32 bytes, which is the appropriate length for the character string representation of the value.

String representations of datetime values

Values whose data types are DATE, TIME, or TIMESTAMP are represented in an internal form that is transparent to the user. Date, time, and timestamp values can, however, also be represented by strings. This is useful because there are no constants or variables whose data types are DATE, TIME, or TIMESTAMP. Before it can be retrieved, a datetime value must be assigned to a string variable. The CHAR function or the GRAPHIC function (for Unicode databases only) can be used to change a datetime value to a string representation. The string representation is normally the default format of datetime values associated with the territory code of the application, unless overridden by specification of the DATETIME option when the program is precompiled or bound to the database.

No matter what its length, a large object string cannot be used as a string representation of a datetime value (SQLSTATE 42884).

When a valid string representation of a datetime value is used in an operation with an internal datetime value, the string representation is converted to the internal form of the date, time, or timestamp value before the operation is performed.

Date, time and timestamp strings must contain only characters and digits.

Date strings

Table 3. Formats for String Representations of Dates

Format Name	Abbreviation	Date Format	Example
International Standards Organization (with separators)	ISO	yyyy-mm-dd	'2018-10-27'
International Standards Organization (without separators)[1]	-	yyyymmdd	'20181027'
IBM USA standard	USA	mm/dd/yyyy	'10/27/2018'
IBM European standard	EUR	dd.mm.yyyy	'27.10.2018'
Japanese Industrial Standard Christian Era	JIS	yyyy-mm-dd	'2018-10-27'
Netezza®[1]	-	dd-mon-yy	'12-FEB-16'
Site-defined	LOC	Depends on the territory code of the application	-

[1] This format can be used for input values only, not for output values or constants.

Note:

- Trailing blanks can be included.
- Leading zeros can be omitted from the month and day portions.

Time strings

Table 4. Formats for String Representations of Times			
Format Name	**Abbreviation**	**Time Format**	**Example**
International Standards Organization	ISO	hh.mm or hh.mm.ss	'13.30.05'
IBM USA standard	USA	hh or hh:mm AM or PM	'1:30 PM'
IBM European standard	EUR	hh.mm or hh.mm.ss	'13.30.05'
Japanese Industrial Standard Christian Era	JIS	hh:mm or hh:mm:ss	'13:30:05'
Site-defined	LOC	Depends on the territory code of the application	-

Note:

- Trailing blanks can be included.
- A leading zero can be omitted from the hour.
- Seconds can be omitted, in which case an implicit specification of 0 seconds is assumed (for example, 13:30 is equivalent to 13:30:00).
- The International Standards Organization changed the time format so that it is identical to the Japanese Industrial Standard Christian Era format. Therefore, use the JIS format if an application requires the current International Standards Organization format.
- In the USA format:
  - Minutes can be omitted, in which case an implicit specification of 00 minutes is assumed (for example, 1 PM is equivalent to 1:00 PM).
  - The hour must not be greater than 12 and cannot be 0, except in the special case of 00:00 AM.
  - There is a single space before 'AM' or 'PM'.
  - 'AM' or 'PM' can be represented in lowercase or uppercase characters.
- The following table shows how the USA format corresponds to the JIS format:

USA format	**JIS format**
12:01 AM through 12:59 AM	00:01:00 through 00:59:00
01:00 AM through 11:59 AM	01:00:00 through 11:59:00
12:00 PM (noon) through 11:59 PM	12:00:00 through 23:59:00
12:00 AM (midnight)	24:00:00
00:00 AM (midnight)	00:00:00

Timestamp strings

Table 5. Formats for String Representations of Timestamps		
Format Name	**Timestamp Format**	**Example**
IBM SQL	yyyy-mm-dd-hh.mm.ss.nnnnnnnnnnnn	'2018-03-22-12.00.00.000000000005'

Table 5. Formats for String Representations of Timestamps (continued)		
Format Name	**Timestamp Format**	**Example**
ODBC[1]	yyyy-mm-dd hh:mm:ss.nnnnnnnnnnnn	'2018-03-22 08:30:58.000000000005'
Netezza	yyyymmdd hh:mm:ss AM or PM	'20180101 12:00:59 PM'
Netezza[1]	mm-dd-yyyy hh:mm:ss.nnnnnnnnnnnn	'05-18-2020 18:10:16.123456123456'
No delimiters	yyyymmddhhmmss	'20180322120000'
[1] The date and time portions of the timestamp are shown here as being separated by a blank. They can also be separated by a hyphen or the letter T. For example, '2018-03-22 08:30:58.7', '2018-03-22-08:30:58.7', and '2018-03-22T08:30:58.7' are all equivalent.		

Note:

- IBM SQL is the only supported output format
- Seconds can be specified to up to 12 decimal places.
- Trailing zeros can be truncated or entirely omitted from the fractional seconds.
- Leading zeros can be omitted from the month, day, and hour part of the timestamp.
- A character string can contain any number of trailing blanks.
- The separator character that follows the seconds element can be omitted if fractional seconds are not included.
- If a string representation of a timestamp is implicitly cast to a value with a TIMESTAMP data type, the precision of the result of the cast is determined by the precision of the TIMESTAMP operand in an expression or the precision of the TIMESTAMP target in an assignment:
  - Digits for fractional seconds that exceed the precision of the cast are truncated from the string. For example, if the string '2018-3-2-8.30.00297' is cast to TIMESTAMP(3), the result is 2018-03-02-08.30.00.002.
  - If the precision of the cast exceeds the precision of the string, the result is padded with zeros. For example, if the string '2018-3-2-8.30.07' is cast to TIMESTAMP(12), the result is 2018-03-02-08.30.00.070000000000.
- A string representation of a timestamp can be given a different timestamp precision by explicitly casting the value to a timestamp with a specified precision. If the string is a constant, an alternative is to precede the string constant with the TIMESTAMP keyword. For example, TIMESTAMP '2018-03-28 14:50:35.123' has the TIMESTAMP(3) data type.

Boolean values

A Boolean value represents a truth value; that is, TRUE or FALSE. A Boolean expression or predicate can result in a value of unknown, which is represented by the null value.

The following data types can be cast to the BOOLEAN data type:

- CHAR or VARCHAR can be cast to a BOOLEAN value:
  - Cast to TRUE: 't' , 'true' , 'y', 'yes' , 'on' ,'1'
  - Cast to FALSE: 'f', 'false', 'n', 'no', 'off', '0'

  A string can use any combination of uppercase and lowercase characters ('yes', 'YES', 'Yes', 'yES', and so on).
- decimal floating point or binary integer

– When a value of data type DECFLOAT, SMALLINT, INTEGER, or BIGINT is cast to a BOOLEAN value, the result is TRUE if the value is not zero, and FALSE if the value is zero.

Cursor values

A cursor value is used to represent a reference to an underlying cursor.

The CURSOR type is a built-in data type that can only be used as the data type of:

- A local variable in a compound SQL (compiled) statement
- A parameter of an SQL routine
- The returns type of an SQL function
- A global variable

A variable or parameter defined with the CURSOR type can only be used in compound SQL (compiled) statements.

A cursor variable is an SQL variable, SQL parameter, or global variable of a cursor type. A cursor variable is said to have an underlying cursor that corresponds to the cursor created for a SELECT statement and assigned to that variable. More than one cursor variable may share the same underlying cursor.

Cursor variables can be used the same way as conventional SQL cursors to iterate through a result set of a SELECT statement with OPEN, FETCH, and CLOSE statements.

XML values

An XML value represents well-formed XML in the form of an XML document, XML content, or a sequence of XML nodes.

An XML value that is stored in a table as a value of a column defined with the XML data type must be a well-formed XML document. XML values are processed in an internal representation that is not comparable to any string value. An XML value can be transformed into a serialized string value representing the XML document using the XMLSERIALIZE function. Similarly, a string value that represents an XML document can be transformed into an XML value using the XMLPARSE function. An XML value can be implicitly parsed or serialized when exchanged with application string and binary data types.

Special restrictions apply to expressions that result in an XML data type value; such expressions and columns are not permitted in (SQLSTATE 42818):

- A SELECT list preceded by the DISTINCT clause
- A GROUP BY clause
- An ORDER BY clause
- A subselect of a set operator other than UNION ALL
- A basic, quantified, BETWEEN, IN, or LIKE predicate
- An aggregate function with DISTINCT

Array values

An *array* is a structure that contains an ordered collection of data elements in which each element can be referenced by its index value in the collection.The *cardinality* of an array is the number of elements in the array. All elements in an array have the same data type.

An *ordinary array* has a defined upper bound on the number of elements, known as the maximum cardinality. Each element in the array is referenced by its ordinal position as the index value. If *N* is the number of elements in an ordinary array, the ordinal position associated with each element is an integer value greater than or equal to 1 and less than or equal to *N*.

An *associative array* has no specific upper bound on the number of elements. Each element is referenced by its associated index value. The data type of the index value can be an integer or a character string but is the same data type for the entire array.

The maximum cardinality of an ordinary array is not related to its physical representation, unlike the maximum cardinality of arrays in programming languages such as C. Instead, the maximum cardinality is used by the system at run time to ensure that subscripts are within bounds. The amount of memory required to represent an ordinary array value is not proportional to the maximum cardinality of its type.

The amount of memory required to represent an array value is usually proportional to its cardinality. When an array is being referenced, all of the values in the array are stored in main memory. Therefore, arrays that contain a large amount of data will consume large amounts of main memory.

The Array type is not supported for multi-row insert, update, or delete.

Anchored types

An anchored type defines a data type based on another SQL object such as a column, global variable, SQL variable, SQL parameter, or the row of a table or view.

A data type defined using an anchored type definition maintains a dependency on the object to which it is anchored. Any change in the data type of the anchor object will impact the anchored data type. If anchored to the row of a table or view, the anchored data type is ROW with the fields defined by the columns of the anchor table or anchor view.

User-defined types

A user-defined data type (UDT) is a data type that derived from an existing data type. You can use UDTs to extend the built-in types already available and create your own customized data types.

There are six user-defined types:

- Distinct type
- Structured type
- Reference type
- Array type
- Row type
- Cursor type

Each of these types is described in the following sections.

Distinct type

A *distinct type* is a user-defined data type that shares its internal representation with an existing built-in data type (its "source" type).

Distinct types include qualified identifiers. If the schema name is not used to qualify the distinct type name when used in other than the CREATE TYPE (Distinct), DROP, or COMMENT statements, the SQL path is searched in sequence for the first schema with a distinct type that matches.

Distinct types that are sourced on LOB types are subject to the same restrictions as their source type.

A distinct type is defined to use either strong typing or weak typing rules. Strong typing rules are the default.

Strongly typed distinct type

A strongly typed distinct type is considered to be a separate and incompatible type for most operations. For example, you want to define a picture type, a text type, and an audio type. Each of these types has different semantics, but each uses the built-in data type BLOB for their internal representation.

The following example illustrates the creation of a distinct type named AUDIO:

```
CREATE TYPE AUDIO  AS BLOB (1M)
```

Although AUDIO has the same representation as the built-in data type BLOB, it is considered to be a separate type; this consideration allows the creation of functions that are written specifically for

AUDIO, and assures that these functions are not applied to values of any other data type (for example pictures or text).

Strongly typed distinct types support strong typing by ensuring that only those functions and operators that are explicitly defined on the distinct type can be applied to its instances. For this reason, a strongly typed distinct type does not automatically acquire the functions and operators of its source type, because these functions and operators might not be meaningful. For example, a LENGTH function could be defined to support a parameter with the data type AUDIO that returns length of the object in seconds instead of bytes.

Weakly typed distinct type
A weakly typed distinct type is considered to be the same as its source type for all operations, except when the weakly typed distinct type applies constraints on values during assignments or casts. This consideration also applies to function resolution.

The following example illustrates the creation of a distinct type named POSITIVEINTEGER:

```
CREATE TYPE POSITIVEINTEGER AS INTEGER
      WITH WEAK TYPE RULES CHECK (VALUE>=0)
```

Weak typing means that except for accepting only positive integer values, POSITIVEINTEGER operates in the same way as its underlying data type of INTEGER.

A weakly typed distinct type can be used as an alternative method of referring to a built-in data type within application code. The ability to define constraints on the values that are associated with the distinct type provides a method for checking values during assignments and casts.

Using distinct types can provide benefits in the following categories:

Extensibility
By defining new data types, you increase the set of data types available to you to support your applications.

Flexibility
You can specify any semantics and behavior for your new data type by using user-defined functions (UDFs) to augment the diversity of the data types available in the system.

Consistent and inherited behavior
Strong typing guarantees that only functions defined on your distinct type can be applied to instances of the distinct type. Weak typing ensures that the distinct type behaves the same way as its underlying data type and so can use all the same functions and methods available to that underlying type.

Encapsulation
Using a weakly typed distinct type makes it possible to define data type constraints in one location for all usages within application code for that distinct type.

Performance
Distinct types are highly integrated into the database manager. Because distinct types are internally represented the same way as built-in data types, they share the same efficient code that is used to implement components such as built-in functions, comparison operators, and indexes for built-in data types.

Not all built-in data types can be used to define distinct types. The source data type cannot be XML, array, row, or cursor. For more information, see "CREATE TYPE (distinct) statement" in *SQL Reference Volume 1*.

Structured type

A *structured type* is a user-defined data type that has a structure that is defined in the database. It contains a sequence of named *attributes*, each of which has a data type. A structured type also includes a set of method specifications.

A structured type can be used as the type of a table, view, or column. When used as a type for a table or view, that table or view is known as a *typed table* or *typed view*. For typed tables and typed views, the names and data types of the attributes of the structured type become the names and data types of the columns of this typed table or typed view. Rows of the typed table or typed view can be thought of as a

representation of instances of the structured type. When used as a data type for a column, the column contains values of that structured type (or values of any of the subtypes for that type, as defined later in this section). Methods are used to retrieve or manipulate attributes of a structured column object.

A *supertype* is a structured type for which other structured types, called *subtypes*, are defined. A subtype inherits all the attributes and methods of its supertype and can have additional attributes and methods defined. The set of structured types that is related to a common supertype is called a type *hierarchy* and the type that does not have any supertype is called the *root type* of the type hierarchy.

The term subtype applies to a user-defined structured type and all user-defined structured types that are below it in the type hierarchy. Therefore, a subtype of a structured type T is T and all structured types below T in the hierarchy. A *proper subtype* of a structured type T is a structured type below T in the type hierarchy.

There are restrictions on having recursive type definitions in a type hierarchy. For this reason, it is necessary to develop a shorthand way of referring to the specific type of recursive definitions that are allowed. The following definitions are used:

- *Directly uses*: A type **A** is said to directly use another type **B**, if and only if one of the following statements is true:
  1. Type **A** has an attribute of type **B**.
  2. Type **B** is a subtype of **A**or a supertype of **A**.
- *Indirectly uses*: A type **A** is said to indirectly use a type **B**, if one of the following statements is true:
  1. Type **A** directly uses type **B**.
  2. Type **A** directly uses some type **C**and type **C** indirectly uses type **B**.

A type cannot be defined so that one of its attribute types directly or indirectly uses itself. If it is necessary to have such a configuration, consider using a reference as the attribute. For example, with structured type attributes, there cannot be an instance of "employee" with an attribute of "manager" when "manager" is of type "employee". There can, however, be an attribute of "manager" with a type of REF(employee).

A type cannot be dropped if certain other objects use the type, either directly or indirectly. For example, a type cannot be dropped if a table or view column makes direct or indirect use of the type.

Reference type

A *reference type* is a companion type to a structured type. Similar to a distinct type, a reference type is a scalar type that shares a common representation with one of the built-in data types. This same representation is shared for all types in the type hierarchy. The reference type representation is defined when the root type of a type hierarchy is created. When using a reference type, a structured type is specified as a parameter of the type. This parameter is called the *target type* of the reference.

The target of a reference is always a row in a typed table or a typed view. When a reference type is used, it can have a *scope* defined. The scope identifies a table (called the *target table*) or view (called the *target view*) that contains the target row of a reference value. The target table or view must have the same type as the target type of the reference type. An instance of a scoped reference type uniquely identifies a row in a typed table or typed view, called the *target row*.

Array type

A user-defined *array type* is a data type that is defined as an array with elements of another data type. Every ordinary array type has an index with the data type of INTEGER and has a defined maximum cardinality. Every associative array has an index with the data type of INTEGER or VARCHAR and does not have a defined maximum cardinality.

Row type

A *row type* is a data type that is defined as an ordered sequence of named fields, each with an associated data type, which effectively represents a row. A row type can be used as the data type for variables and parameters in SQL PL to provide simple manipulation of a row of data.

Cursor type

A user-defined *cursor type* is a user-defined data type defined with the keyword CURSOR and optionally with an associated row type. A user-defined cursor type with an associated row type is a *strongly typed cursor type*; otherwise, it is a *weakly typed cursor type*. A value of a user-defined cursor type represents a reference to an underlying cursor.

Promotion of data types

Data types can be classified into groups of related data types. Within such groups, a precedence order exists where one data type is considered to precede another data type. This precedence is used to allow the *promotion* of one data type to a data type later in the precedence ordering.

For example, the data type CHAR can be promoted to VARCHAR; INTEGER can be promoted to DOUBLE-PRECISION; but CLOB is NOT promotable to VARCHAR.

Promotion of data types is used when:

- Performing function resolution
- Casting user-defined types
- Assigning user-defined types to built-in data types

Table 6 on page 46 shows the precedence list (in order) for each data type and can be used to determine the data types to which a given data type can be promoted. The table shows that the best choice is always the same data type instead of choosing to promote to another data type.

Table 6. Data Type Precedence Table

Data Type	Data Type Precedence List (in best-to-worst order)
SMALLINT	SMALLINT, INTEGER, BIGINT, decimal, real, double, DECFLOAT
INTEGER	INTEGER, BIGINT, decimal, real, double, DECFLOAT
BIGINT	BIGINT, decimal, real, double, DECFLOAT
decimal	decimal, real, double, DECFLOAT
real	real, double, DECFLOAT
double	double, DECFLOAT
DECFLOAT	DECFLOAT
CHAR	CHAR, VARCHAR, CLOB
VARCHAR	VARCHAR, CLOB
CLOB	CLOB
GRAPHIC	GRAPHIC, VARGRAPHIC, DBCLOB
VARGRAPHIC	VARGRAPHIC, DBCLOB
DBCLOB	DBCLOB
BINARY	BINARY, VARBINARY, BLOB
VARBINARY	VARBINARY, BLOB

Table 6. Data Type Precedence Table (continued)

Data Type	Data Type Precedence List (in best-to-worst order)
BLOB	BLOB
DATE	DATE, TIMESTAMP
TIME	TIME
TIMESTAMP	TIMESTAMP
BOOLEAN	BOOLEAN
CURSOR	CURSOR
ARRAY	ARRAY
udt	udt (same name) or a supertype of udt
REF(T)	REF(S) (provided that S is a supertype of T)
ROW	ROW

Note:

1. The lowercase types in the preceding table are defined as follows:
   - decimal = DECIMAL(p,s) or NUMERIC(p,s)
   - real = REAL or FLOAT(*n*), where *n* is not greater than 24
   - double = DOUBLE, DOUBLE-PRECISION, FLOAT or FLOAT(*n*), where *n* is greater than 24
   - udt = a user-defined type (except for a weakly typed distinct type which uses the source type to determine data type precedence)

   Shorter and longer form synonyms of the listed data types are considered to be the same as the listed form.
2. For a Unicode database, the following data types are considered to be equivalent:
   - CHAR and GRAPHIC
   - VARCHAR and VARGRAPHIC
   - CLOB and DBCLOB

   When resolving a function within a Unicode database, if a user-defined function and a built-in function are both applicable for a given function invocation, then generally the built-in function will be invoked. The UDF will be invoked only if its schema precedes SYSIBM in the **CURRENT PATH** special register and if its argument data types match all the function invocation argument data types, regardless of Unicode data type equivalence.

Casting between data types

There are many occasions where a value with a given data type needs to be *cast* to a different data type or to the same data type with a different length, precision, or scale.

Data type promotion is one example where the promotion of one data type to another data type requires that the value be cast to the new data type. A data type that can be cast to another data type is *castable* from the source data type to the target data type.

The casting of one data type to another can occur implicitly or explicitly. The cast functions, CAST specification, or XMLCAST specification can be used to explicitly change a data type, depending on the data types involved. In addition, when a sourced user-defined function is created, the data types of the parameters of the source function must be castable to the data types of the function that is being created.

The supported casts between built-in data types are shown in Table 7 on page 49. The first column represents the data type of the cast operand (source data type), and the data types across the header

row represent the target data type of the cast operation. A 'Y' indicates that the CAST specification can be used for the combination of source and target data types. Cases in which only the XMLCAST specification can be used are noted.

If truncation occurs when any data type is cast to a character or graphic data type, a warning is returned if any non-blank characters are truncated. This truncation behavior is unlike the assignment to a character or graphic data type, when an error occurs if any non-blank characters are truncated.

In a Unicode database, character and graphic string source values can be cast to between different string units. Any truncation is applied according to the string units of the target data type.

The following casts involving strongly typed distinct types are supported (using the CAST specification unless noted otherwise):

- Cast from distinct type *DT* to its source data type *S*
- Cast from the source data type *S* of distinct type *DT* to distinct type *DT*
- Cast from distinct type *DT* to the same distinct type *DT*
- Cast from a data type *A* to distinct type *DT* where *A* is promotable to the source data type *S* of distinct type *DT*
- Cast from an INTEGER to distinct type *DT* with a source data type SMALLINT
- Cast from a DOUBLE to distinct type *DT* with a source data type REAL
- Cast from a DECFLOAT to distinct type DT with a source data type of DECFLOAT
- Cast from a VARBINARY to distinct type *DT* with a source data type BINARY
- Cast from a VARCHAR to distinct type *DT* with a source data type CHAR
- Cast from a VARGRAPHIC to distinct type *DT* with a source data type GRAPHIC
- For a Unicode database, cast from a VARCHAR or a VARGRAPHIC to distinct type *DT* with a source data type CHAR or GRAPHIC
- Cast from a distinct type *DT* with a source data type *S* to XML using the XMLCAST specification
- Cast from an XML to a distinct type *DT* with a source data type of any built-in data type, using the XMLCAST specification depending on the XML schema data type of the XML value

For casts involving a weakly typed distinct type as a target, the cast from data type must be castable to the source type of the weakly typed distinct type and the data type constraints must evaluate to true or unknown for the value. The only context in which an operand is implicitly cast to a weakly typed distinct type is when a source operand is assigned to a target with a data type that is a weakly typed distinct type.

FOR BIT DATA character types cannot be cast to CLOB.

For casts that involve an array type as a target, the data type of the elements of the source array value must be castable to the data type of the elements of the target array data (SQLSTATE 42846). If the target array type is an ordinary array, the source array value must be an ordinary array (SQLSTATE 42821) and the cardinality of the source array value must be less than or equal to the maximum cardinality of the target array data type (SQLSTATE 2202F). If the target array type is an associative array, the data type of the index for the source array value must be castable to data type of the index for the target array type. A user-defined array type value can be cast only to the same user-defined array type (SQLSTATE 42846).

A cursor type cannot be either the source data type or the target data type of a CAST specification, except to cast a parameter marker to a cursor type.

For casts that involve a row type as a target, the degree of the source row value expression and degree of the target row type must match and each field in the source row value expression must be castable to the corresponding target field. A user-defined row type value can only be cast to another user-defined row-type with the same name (SQLSTATE 42846).

It is not possible to cast a structured type value to something else. A structured type *ST* should not need to be cast to one of its supertypes, because all methods on the supertypes of *ST* are applicable to *ST*. If the required operation is only applicable to a subtype of *ST*, use the subtype-treatment expression to treat *ST* as one of its subtypes.

When a user-defined data type involved in a cast is not qualified by a schema name, the *SQL path* is used to find the first schema that includes the user-defined data type by that name.

The following casts involving reference types are supported:

- cast from reference type *RT* to its representation data type *S*
- cast from the representation data type *S* of reference type *RT* to reference type *RT*
- cast from reference type *RT* with target type *T* to a reference type *RS* with target type *S* where *S* is a supertype of *T*.
- cast from a data type *A* to reference type *RT*, where *A* is promotable to the representation data type *S* of reference type *RT*.

When the target type of a reference data type involved in a cast is not qualified by a schema name, the *SQL path* is used to find the first schema that includes the user-defined data type by that name.

Table 7. Supported Casts between Built-in Data Types

Source Data Type	**Target Data Type**																						
	SMALLINT	**INTEGER**	**BIGINT**	**DECIMAL**	**REAL**	**DOUBLE**	**DECFLOAT**	**CHAR**	**CHAR FBD 2**	**VARCHAR**	**VARCHAR FBD 2**	**CLOB**	**GRAPHIC**	**VARGRAPHIC**	**DBCLOB**	**BINARY**	**VARBINARY**	**BLOB**	**DATE**	**TIME**	**TIMESTAMP**	**XML**	**BOOLEAN**
SMALLINT	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	-	Y [1]	Y [1]	-	-	-	-	-	-	-	Y [3]	Y
INTEGER	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	-	Y [1]	Y [1]	-	-	-	-	-	-	-	Y [3]	Y
BIGINT	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	-	Y [1]	Y [1]	-	-	-	-	-	-	-	Y [3]	Y
DECIMAL	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	-	Y [1]	Y [1]	-	-	-	-	-	-	-	Y [3]	-

BLOB	-	-	-	-	-	-	-	-	Y	-	Y	-	-	-	-	Y	Y	Y	-	-	-	Y[4]	-
DATE	-	Y	Y	Y	-	-	-	Y	Y	Y	Y	-	Y[1]	Y[1]	-	-	-	-	Y	-	Y	Y[3]	-
TIME	-	Y	Y	Y	-	-	-	Y	Y	Y	Y	-	Y[1]	Y[1]	-	-	-	-	-	Y	-	Y[3]	-
TIMESTAMP	-	-	Y	Y	-	-	-	Y	Y	Y	Y	-	Y[1]	Y[1]	-	-	-	-	Y	Y	Y	Y[3]	-
XML	Y[5]	Y[5]	Y[5]	Y[5]	Y[5]	Y[5]	Y[5]	Y[5]	Y[5]	Y[5]	Y[5]	Y[5]	Y[5]	Y[5]	Y[5]	-	-	Y[5]	Y[5]	Y[5]	Y[5]	Y	-
BOOLEAN	Y	Y	Y	-	-	-	-	Y	-	Y	-	-	Y[1]	Y[1]	-	-	-	-	-	-	-	-	Y

Table 7. Supported Casts between Built-in Data Types (continued)

Source Data Type	Target Data Type																						
	SMALLINT	INTEGER	BIGINT	DECIMAL	REAL	DOUBLE	DECFLOAT	CHAR	CHAR FBD[2]	VARCHAR	VARCHAR FBD[2]	CLOB	GRAPHIC	VARGRAPHIC	DBCLOB	BINARY	VARBINARY	BLOB	DATE	TIME	TIMESTAMP	XML	BOOLEAN

Notes

- See the description preceding the table for information about supported casts involving user-defined types and reference types.
- It is not possible to cast a structured type value to anything else.
- The LONG VARCHAR and LONG VARGRAPHIC data types continue to be supported but are deprecated, not recommended, and might be removed in a future release.

[1] Cast is only supported for Unicode databases.

[2] FOR BIT DATA

[3] Cast can only be performed using XMLCAST.

[4] An XMLPARSE function is implicitly processed to convert a string to XML on assignment (INSERT or UPDATE) of a string to an XML column. The string must be a well-formed XML document for the assignment to succeed.

[5] Cast can only be performed using XMLCAST and depends on the underlying XML schema data type of the XML value. For details, see "XMLCAST".

[6] A cursor type cannot be either the source data type or the target data type of a CAST specification, except to cast a parameter marker to a cursor type.

Table 8 on page 51 shows where to find information about the rules that apply when casting to the identified target data types.

Table 8. Rules for Casting to a Data Type

Target Data Type	Rules
SMALLINT	“SMALLINT ” on page 502.
INTEGER	“INTEGER ” on page 379.
BIGINT	“BIGINT ” on page 290.
DECIMAL	“DECIMAL or DEC ” on page 331
NUMERIC	“DECIMAL or DEC ” on page 331
REAL	“REAL ” on page 455
DOUBLE	“DOUBLE_PRECISION or DOUBLE” on page 339
DECFLOAT	“DECFLOAT ” on page 327
CHAR	“CHAR ” on page 300

Table 8. Rules for Casting to a Data Type (continued)	
Target Data Type	**Rules**
VARCHAR	“VARCHAR ” on page 557
CLOB	“CLOB ” on page 308
GRAPHIC	“GRAPHIC ” on page 353
VARGRAPHIC	“VARGRAPHIC ” on page 573
DBCLOB	“DBCLOB ” on page 325
BINARY	“BINARY ” on page 292
VARBINARY	“VARBINARY ” on page 556
BLOB	“BLOB ” on page 295
DATE	“DATE ” on page 315
TIME	“TIME ” on page 525
TIMESTAMP	If the source type is a character string, see “TIMESTAMP ” on page 525, where one operand is specified. If the source data type is a DATE, the timestamp is composed of the specified date and a time of 00:00:00.
BOOLEAN	“BOOLEAN ” on page 295

Casting non-XML values to XML values

Table 9. Supported Casts from Non-XML Values to XML Values

Source Data Type	**Target Data Type**	
	XML	**Resulting XML Schema Type**
SMALLINT	Y	xs:short
INTEGER	Y	xs:int
BIGINT	Y	xs:long
DECIMAL or NUMERIC	Y	xs:decimal
REAL	Y	xs:float
DOUBLE	Y	xs:double
DECFLOAT	N	-
CHAR	Y	xs:string
VARCHAR	Y	xs:string
CLOB	Y	xs:string
GRAPHIC	Y	xs:string
VARGRAPHIC	Y	xs:string
DBCLOB	Y	xs:string
DATE	Y	xs:date
TIME	Y	xs:time

Table 9. Supported Casts from Non-XML Values to XML Values (continued)

Source Data Type	Target Data Type	
	XML	Resulting XML Schema Type
TIMESTAMP	Y	xs:dateTime[1]
BLOB	Y	xs:base64Binary
BOOLEAN	Y	xs:boolean
character type FOR BIT DATA	Y	xs:base64Binary
distinct type		use this chart with the source type of the distinct type

Notes

[1] The source data type TIMESTAMP supports timestamp precision of 0 to 12. The maximum fractional seconds precision of xs:dateTime is 6. If the timestamp precision of a TIMESTAMP source data type exceeds 6, the value is truncated when cast to xs:dateTime.

The LONG VARCHAR and LONG VARGRAPHIC data types continue to be supported but are deprecated, not recommended, and might be removed in a future release.

When character string values are cast to XML values, the resulting xs:string atomic value cannot contain illegal XML characters (SQLSTATE 0N002). If the input character string is not in Unicode, the input characters are converted to Unicode.

Casting to SQL binary types results in XQuery atomic values with the type xs:base64Binary.

Casting XML values to non-XML values

An XMLCAST from an XML value to a non-XML value can be described as two casts: an XQuery cast that converts the source XML value to an XQuery type corresponding to the SQL target type, followed by a cast from the corresponding XQuery type to the actual SQL type.

An XMLCAST is supported if the target type has a corresponding XQuery target type that is supported, and if there is a supported XQuery cast from the source value's type to the corresponding XQuery target type. The target type that is used in the XQuery cast is based on the corresponding XQuery target type and might contain some additional restrictions.

The following table lists the XQuery types that result from such conversion.

Table 10. Supported Casts from XML Values to Non-XML Values

Target Data Type	Source Data Type	
	XML	Corresponding XQuery Target Type
SMALLINT	Y	xs:short
INTEGER	Y	xs:int
BIGINT	Y	xs:long
DECIMAL or NUMERIC	Y	xs:decimal
REAL	Y	xs:float
DOUBLE	Y	xs:double
DECFLOAT	Y	no matching type[1]
CHAR	Y	xs:string

Table 10. Supported Casts from XML Values to Non-XML Values (continued)

Target Data Type	Source Data Type	
	XML	Corresponding XQuery Target Type
VARCHAR	Y	xs:string
CLOB	Y	xs:string
GRAPHIC	Y	xs:string
VARGRAPHIC	Y	xs:string
DBCLOB	Y	xs:string
DATE	Y	xs:date
TIME (without time zone)	Y	xs:time
TIMESTAMP (without time zone)	Y	xs:dateTime[2]
BLOB	Y	xs:base64Binary
BOOLEAN	Y	xs:boolean
CHAR FOR BIT DATA	N	not castable
VARCHAR FOR BIT DATA	Y	xs:base64Binary
distinct type		use this chart with the source type of the distinct type
row, reference, structured or abstract data type (ADT), other	N	not castable

Notes

[1] XML Schema 1.0 is supported, which does not provide a matching XML schema type for a DECFLOAT. Processing of the XQuery cast step of XMLCAST is handled as follows:

- If the source value is typed with an XML schema numeric type, use that numeric type.
- If the source value is typed with the XML schema type xs:boolean, use xs:double.
- Otherwise, use xs:string with additional checking for a valid numeric format.

[2] The maximum fractional seconds precision of xs:dateTime is 6. The source data type TIMESTAMP supports timestamp precision of 0 to 12. If the timestamp precision of a TIMESTAMP target data type is less than 6, the value is truncated when cast from xs:dateTime. If the timestamp precision of a TIMESTAMP target data type exceeds 6, the value is padded with zeros when cast from xs:dateTime.

In the following restriction cases, a derived by restriction XML schema data type is effectively used as the target data type for the XQuery cast.

- XML values that are to be converted to string types other than CHAR and VARCHAR must fit within the length limits of those data types without truncation of any characters or bytes. The name used for the derived XML schema type is the uppercase SQL type name followed by an underscore character and the maximum length of the string; for example, CLOB_1048576 if the XMLCAST target data type is CLOB(1M) .

  If an XML value is converted to a CHAR or VARCHAR type that is too small to contain all of the data, the data is truncated to fit the specified data type and no error is returned. If any non-blank characters are truncated, a warning (SQLSTATE 01004) is returned. If truncation of the value leads to the truncation of a multibyte character, the whole multibyte character is removed. Therefore, in some cases, truncation can produce a shorter string than expected. For example, the character, ñ, is represented in UTF-8 by 2 bytes, 'C3 B1'. When this character is cast as VARCHAR(1), the truncation of 'C3 B1' to 1 byte would

leave a partial character of 'C3'. This partial character, 'C3', is also removed, therefore the final result is an empty string.

- XML values that are to be converted to DECIMAL values must have no more than (*precision* - *scale*) digits before the decimal point; excess digits after the decimal point beyond the scale are truncated. The name used for the derived XML schema type is DECIMAL_*precision*_*scale*, where *precision* is the precision of the target SQL data type, and *scale* is the scale of the target SQL data type; for example, DECIMAL_9_2 if the XMLCAST target data type is DECIMAL(9,2).
- XML values that are to be converted to TIME values cannot contain a seconds component with nonzero digits after the decimal point. The name used for the derived XML schema type is TIME.

The derived XML schema type name only appears in a message if an XML value does not conform to one of these restrictions. This type name helps one to understand the error message, and does not correspond to any defined XQuery type. If the input value does not conform to the base type of the derived XML schema type (the corresponding XQuery target type), the error message might indicate that type instead. Because this derived XML schema type name format might change in the future, it should not be used as a programming interface.

Before an XML value is processed by the XQuery cast, any document node in the sequence is removed and each direct child of the removed document node becomes an item in the sequence. If the document node has multiple direct children nodes, the revised sequence will have more items than the original sequence. The XML value without any document nodes is then atomized using the XQuery fn:data function, with the resulting atomized sequence value used in the XQuery cast. If the atomized sequence value is an empty sequence, a null value is returned from the cast without any further processing. If there are multiple items in the atomized sequence value, an error is returned (SQLSTATE 10507).

If the target type of XMLCAST is the SQL data type DATE, TIME, or TIMESTAMP, the resulting XML value from the XQuery cast is also adjusted to UTC, and the time zone component of the value is removed.

When the corresponding XQuery target type value is converted to the SQL target type, binary XML data types, such as xs:base64Binary or xs:hexBinary, are converted from character form to actual binary data.

If an xs:double or xs:float value of INF, -INF, or NaN is cast (using XMLCAST) to an SQL data type DOUBLE or REAL value, an error is returned (SQLSTATE 22003). An xs:double or xs:float value of -0 is converted to +0.

The target type can be a user-defined distinct type if the source operand is not a user-defined distinct type. In this case, the source value is cast to the source type of the user-defined distinct type (that is, the target type) using the XMLCAST specification, and then this value is cast to the user-defined distinct type using the CAST specification.

In a non-Unicode database, casting from an XML value to a non-XML target type involves code page conversion from an internal UTF-8 format to the database code page. This conversion will result in the introduction of substitution characters if any code point in the XML value is not present in the database code page.

Assignments and comparisons

The basic operations of SQL are assignment and comparison.

Assignment operations are performed during the execution of INSERT, UPDATE, FETCH, SELECT INTO, VALUES INTO and SET transition-variable statements. Arguments of functions are also assigned when invoking a function. Comparison operations are performed during the execution of statements that include predicates and other language elements such as MAX, MIN, DISTINCT, GROUP BY, and ORDER BY.

One basic rule for both operations is that the data type of the operands involved must be compatible. The compatibility rule also applies to set operations.

Another basic rule for assignment operations is that a null value cannot be assigned to a column that cannot contain null values, nor to a host variable that does not have an associated indicator variable.

Following is a compatibility matrix showing the built-in data type compatibilities for assignment and comparison operations.

Table 11. Data type compatibility for assignments and comparisons

Operands	Binary Integer	Decimal Number	Floating-point	Decimal Floating-point	Character String	Graphic String	Binary String	Date	Time	Time-stamp	Boolean	UDT
Binary Integer	Yes	Yes	Yes	Yes	Yes	Yes [5]	No	No	No	No	Yes	2
Decimal Number	Yes	Yes	Yes	Yes	Yes	Yes [5]	No	No	No	No	No	2
Floating point	Yes	Yes	Yes	Yes	Yes	Yes [5]	No	No	No	No	No	2
Decimal Floating-point	Yes	Yes	Yes	Yes	Yes	Yes [5]	No	No	No	No	No	2
Character String	Yes	Yes	Yes	Yes	Yes	Yes [5,6]	Yes [3]	Yes	Yes	Yes	Yes	2
Graphic String	Yes [5]	Yes [5]	Yes [5]	Yes [5]	Yes [5,6]	Yes	No	Yes [5]	Yes [5]	Yes [5]	Yes	2
Binary String	No	No	No	No	Yes[3]	No	Yes	No	No	No	No	2
Date	No	No	No	No	Yes	Yes [5]	No	Yes	No	Yes	No	2
Time	No	No	No	No	Yes	Yes [5]	No	No	Yes	[1]	No	2
Time-stamp	No	No	No	No	Yes	Yes [5]	No	Yes	[1]	Yes	No	2
Boolean	Yes	No	No	No	Yes	Yes	No	No	No	No	Yes	2
UDT	2	2	2	2	2	2	2	2	2	2	2	Yes

[1] A TIMESTAMP value can be assigned to a TIME value; however, a TIME value cannot be assigned to a TIMESTAMP value and a TIMESTAMP value cannot be compared with a TIME value.

[2] For detailed user-defined type information see "User-defined type assignments" on page 62 and "User-defined type comparisons" on page 69.

[3] Character strings, except those with FOR BIT DATA, are not compatible with binary strings. FOR BIT DATA character strings and binary strings are considered compatible and any padding is performed based on the data type of the target. For example, when assigning a FOR BIT DATA column value to a fixed-length binary host variable, any necessary padding uses a pad byte of X'00'.

[4] For information about assignment and comparison of reference types, see "Reference type assignments" on page 65 and "Reference type comparisons" on page 71.

[5] Only supported for Unicode databases.

[6] Bit data and graphic strings are not compatible.

Numeric assignments

For numeric assignments, overflow is not allowed.

- When assigning to an exact numeric data type, overflow occurs if any digit of the whole part of the number would be eliminated. If necessary, the fractional part of a number is truncated.
- When assigning to an approximate numeric data type or decimal floating-point, overflow occurs if the most significant digit of the whole part of the number is eliminated. For floating-point and decimal floating-point numbers, the whole part of the number is the number that would result if the floating-point or decimal floating-point number were converted to a decimal number with unlimited precision. If necessary, rounding might cause the least significant digits of the number to be eliminated.

  For decimal floating-point numbers, truncation of the whole part of the number is allowed and results in infinity with a warning.

  For floating-point numbers, underflow is also not allowed. Underflow occurs for numbers between 1 and -1 if the most significant digit other than zero would be eliminated. For decimal floating-point, underflow is allowed and depending on the rounding mode, results in zero or the smallest positive number or the largest negative number that can be represented along with a warning.

  An overflow or underflow warning is returned instead of an error if an overflow or underflow occurs on assignment to a host variable with an indicator variable. In this case, the number is not assigned to the host variable and the indicator variable is set to negative 2.

For decimal floating-point numbers, the CURRENT DECFLOAT ROUNDING MODE special register indicates the rounding mode in effect.

Assignments to integer

When a decimal, floating-point, or decimal floating-point number is assigned to an integer column or variable, the fractional part of the number is eliminated. As a result, a number between 1 and -1 is reduced to 0.

Assignments to decimal

When an integer is assigned to a decimal column or variable, the number is first converted to a temporary decimal number and then, if necessary, to the precision and scale of the target. The precision and scale of the temporary decimal number is 5,0 for a small integer, 11,0 for a large integer, or 19,0 for a big integer.

When a decimal number is assigned to a decimal column or variable, the number is converted, if necessary, to the precision and the scale of the target. The necessary number of leading zeros is added, and in the fractional part of the decimal number the necessary number of trailing zeros is added, or the necessary number of trailing digits is eliminated.

When a floating-point number is assigned to a decimal column or variable, the number is first converted to a temporary decimal number of precision 31, and then, if necessary, truncated to the precision and scale of the target. In this conversion, the number is rounded (using floating-point arithmetic) to a precision of 31 decimal digits. As a result, a number between 1 and -1 that is less than the smallest positive number or greater than the largest negative number that can be represented in the decimal column or variable is reduced to 0. The scale is given the largest possible value that allows the whole part of the number to be represented without loss of significance.

When a decimal floating-point number is assigned to a decimal column or variable, the number is rounded to the precision and scale of the decimal column or variable. As a result, a number between 1 and -1 that is less than the smallest positive number or greater than the largest negative number that can be represented in the decimal column or variable is reduced to 0 or rounded to the smallest positive or largest negative value that can be represented in the decimal column or variable, depending on the rounding mode.

Assignments to floating-point

Floating-point numbers are approximations of real numbers. Hence, when an integer, decimal, floating-point, or decimal floating-point number is assigned to a floating-point column or variable, the result might not be identical to the original number. The number is rounded to the precision of the floating-point column or variable using floating-point arithmetic. A decimal floating-point value is first converted to a string representation, and is then converted to a floating-point number.

Assignments to decimal floating-point

When an integer number is assigned to a decimal floating-point column or variable, the number is first converted to a temporary decimal number and then to a decimal floating-point number. The precision and scale of the temporary decimal number is 5,0 for a small integer, 11,0 for a large integer, or 19,0 for a big integer. Rounding can occur when assigning a BIGINT to a DECFLOAT(16) column or variable.

When a decimal number is assigned to a decimal floating-point column or variable, the number is converted to the precision (16 or 34) of the target. Leading zeros are eliminated. Depending on the precision and scale of the decimal number and the precision of the target, the value might be rounded.

When a floating-point number is assigned to a decimal floating-point column or variable, the number is first converted to a temporary string representation of the floating-point number. The string representation of the number is then converted to decimal floating-point.

When a DECFLOAT(16) number is assigned to a DECFLOAT(34) column or variable, the resulting value is identical to the DECFLOAT(16) number.

When a DECFLOAT(34) number is assigned to a DECFLOAT(16) column or variable, the exponent of the source is converted to the corresponding exponent in the result format. The mantissa of the DECFLOAT(34) number is rounded to the precision of the target.

Assignments from strings to numeric

When a string is assigned to a numeric data type, it is converted to the target numeric data type using the rules for a CAST specification. For more information, see "CAST specification" in the *SQL Reference Volume 1*.

String assignments

There are two types of assignments:

- In *storage assignment*, a value is assigned and truncation of significant data is not desirable; for example, when assigning a value to a column
- In *retrieval assignment*, a value is assigned and truncation is allowed; for example, when retrieving data from the database

The rules for string assignment differ based on the assignment type and the type of string.

Binary string assignments

Storage assignment

The length of a string that is assigned to a binary string target must not be greater than the length attribute of the target. If the length of the string is greater than the length attribute of the target, the following actions might occur:

- The string is assigned with trailing hexadecimal zeros (X'00') truncated (except BLOB strings) to fit the length attribute of the target
- An error is returned (SQLSTATE 22001) in the following truncation scenarios:
  - Characters other than a hexadecimal zero (X'00) would be truncated from a binary string other than a BLOB string.
  - Any character (or byte) would be truncated from a BLOB string

When the string is assigned to a fixed-length binary target, and the length of the string is less than the length attribute of the target, the string is padded to the right with the necessary number of hexadecimal zeros.

Retrieval Assignment

The length of a string that is assigned to a target can be longer than the length attribute of the target. When a string is assigned to a target, and the length of the string is longer than the length attribute of the target, the string is truncated on the right by the necessary number of bytes. When this truncation occurs, a warning is returned (SQLSTATE 01004).

Furthermore, if the data is truncated when it is being assigned to a host variable, the value 'W' is assigned to the SQLWARN1 field of the SQLCA. Also, if an indicator variable is provided, and the source of the value is not a LOB, the indicator variable is set to the original length of the string.

If a string is assigned to a fixed-length target, and the length of the string is less than the length attribute of the target, the string is padded to the right with the necessary number of hexadecimal zeroes.

Character and graphic string assignments

Storage assignment

The basic rule is that the length of the string assigned to the target must not be greater than the length attribute of the target. If the length of the string is greater than the length attribute of the target, the following actions might occur:

- The string is assigned with trailing blanks truncated (from all string types except LOB strings) to fit the length attribute of the target
- An error is returned (SQLSTATE 22001) in the following truncation scenarios:
  - Non-blank characters would be truncated from strings other than a LOB string
  - Any character (or byte) would be truncated from a LOB string

In a Unicode database, length is defined as the number of code units in the string units of the target.

- If the target string units are OCTETS, the string assigned to the target must not have a greater byte length than the target.
- If the target string units are CODEUNITS16, the string assigned to the target must not have a greater number of Unicode UTF-16 code units than the length attribute of the target.
- If the target string units are CODEUNITS32, the string assigned to the target must not have a greater number of Unicode UTF-32 code units than the length attribute of the target.

If a string is assigned to a fixed-length target, and the length of the string is less than the length attribute of the target, the string is padded to the right with the necessary number of single-byte, double-byte, or UCS-2 blanks. The pad character is always a blank, even for columns defined with the FOR BIT DATA attribute. (UCS-2 defines several SPACE characters with different properties. For a Unicode database, the database manager always uses the ASCII SPACE at position x'0020' as UCS-2 blank. For an EUC database, the IDEOGRAPHIC SPACE at position x'3000' is used for padding GRAPHIC strings.)

Retrieval Assignment

The length of a string that is assigned to a target can be longer than the length attribute of the target. When a string is assigned to a target, and the length of the string is longer than the length attribute of the target, the string is truncated on the right by the necessary number of characters (or bytes). When this truncation occurs, a warning is returned (SQLSTATE 01004).

Furthermore, if the data is truncated when it is being assigned to a host variable, the value 'W' is assigned to the SQLWARN1 field of the SQLCA. Also, if an indicator variable is provided, and the source of the value is not a LOB, the indicator variable is set to the original length of the string.

Length is defined as the number of code units in the string units of the target.

- If the target string units are OCTETS and the source string has a greater byte length than the target, the string is truncated on the right by the necessary number of bytes.
- If the target string units are CODEUNITS16 and the source string has a greater number of Unicode UTF-16 code units than the length attribute of the target, the string is truncated on the right by the necessary number of Unicode UTF-16 code units.
- If the target string units are CODEUNITS32 and the source string has a greater number of Unicode UTF-32 code units than the length attribute of the target, the string is truncated on the right by the necessary number of Unicode UTF-32 code units.

If a character string is assigned to a fixed-length target, and the length of the string is less than the length attribute of the target, the string is padded to the right with the necessary number of single-byte, double-byte, or UCS-2 blanks. The pad character is always a blank, even for strings defined with the FOR BIT DATA attribute. (UCS-2 defines several SPACE characters with different properties. For a Unicode database, the database manager always uses the ASCII SPACE at position x'0020' as UCS-2 blank. For an EUC database, the IDEOGRAPHIC SPACE at position x'3000' is used for padding GRAPHIC strings.)

Retrieval assignment of C NUL-terminated host variables is handled based on options that are specified with the PREP or BIND command.

Conversion rules for string assignments

A character string or graphic string assigned to a column, variable, or parameter is first converted, if necessary, to the code page of the target. Character conversion is necessary only if all of the following are true:

- The code pages are different.
- The string is neither null nor empty.
- Neither string has a code page value of 0 (FOR BIT DATA).

For Unicode databases, character strings can be assigned to a graphic column, and graphic strings can be assigned to a character column.

MBCS considerations for character string assignments

There are several considerations when assigning character strings that could contain both single and multi-byte characters. These considerations apply to all character strings, including those defined as FOR BIT DATA.

- Blank padding is always done using the single-byte blank character (X'20').
- Blank truncation is always done based on the single-byte blank character (X'20'). The double-byte blank character is treated like any other character with respect to truncation.
- Assignment of a character string to a host variable might result in fragmentation of MBCS characters if the target host variable is not large enough to contain the entire source string. If an MBCS character is fragmented, each byte of the MBCS character fragment in the target is set to a single-byte blank character (X'20'), no further bytes are moved from the source, and SQLWARN1 is set to 'W' to indicate truncation. Note that the same MBCS character fragment handling applies even when the character string is defined as FOR BIT DATA.

DBCS considerations for graphic string assignments

Graphic string assignments are processed in a manner analogous to that for character strings. For non-Unicode databases, graphic string data types are compatible only with other graphic string data types, and never with numeric, character string, or datetime data types. For Unicode databases, graphic string data types are compatible with character string data types. However, graphic and character string data types cannot be used interchangeably in the SELECT INTO or the VALUES INTO statement.

If a graphic string value is assigned to a graphic string column, the length of the value must not be greater than the length of the column.

If a graphic string value (the 'source' string) is assigned to a fixed-length graphic string data type (the 'target', which can be a column, variable, or parameter), and the length of the source string is less than that of the target, the target will contain a copy of the source string which has been padded on the right with the necessary number of double-byte blank characters to create a value whose length equals that of the target.

If a graphic string value is assigned to a graphic string host variable and the length of the source string is greater than the length of the host variable, the host variable will contain a copy of the source string which has been truncated on the right by the necessary number of double-byte characters to create a value whose length equals that of the host variable. (Note that for this scenario, truncation need not be concerned with bisection of a double-byte character; if bisection were to occur, either the source value or target host variable would be an ill-defined graphic string data type.) The warning flag SQLWARN1 in the SQLCA will be set to 'W'. The indicator variable, if specified, will contain the original length (in double-byte characters) of the source string. In the case of DBCLOB, however, the indicator variable does not contain the original length.

Retrieval assignment of C NUL-terminated host variables (declared using wchar_t) is handled based on options specified with the PREP or BIND command.

Assignments from numeric to strings

When a number is assigned to a string data type, it is converted to the target string data type using the rules for a CAST specification. For more information, see "CAST specification" in the *SQL Reference Volume 1*.

If a nonblank character is truncated during the cast of a numeric value to a character or graphic data type, a warning is returned. This truncation behavior is unlike the assignment to a character or graphic data type that follows storage assignment rules, where if a nonblank character is truncated during assignment, an error is returned.

Datetime assignments

A TIME value can be assigned only to a TIME column or to a string variable or string column.

A DATE can be assigned to a DATE, TIMESTAMP or string data type. When a DATE value is assigned to a TIMESTAMP data type, the missing time information is assumed to be all zeros.

A TIMESTAMP value can be assigned to a DATE, TIME, TIMESTAMP or string data type. When a TIMESTAMP value is assigned to a DATE data type, the date portion is extracted and the time portion is truncated. When a TIMESTAMP value is assigned to a TIME data type, the date portion is ignored and the time portion is extracted, but with the fractional seconds truncated. When a TIMESTAMP value is assigned to a TIMESTAMP with lower precision, the excess fractional seconds are truncated. When a TIMESTAMP value is assigned to a TIMESTAMP with higher precision, missing digits are assumed to be zeros.

The assignment must not be to a CLOB, DBCLOB, or BLOB variable or column.

When a datetime value is assigned to a string variable or string column, conversion to a string representation is automatic. Leading zeros are not omitted from any part of the date, time, or timestamp. The required length of the target will vary, depending on the format of the string representation. If the length of the target is greater than required, and the target is a fixed-length string, it is padded on the right with blanks. If the length of the target is less than required, the result depends on the type of datetime value involved, and on the type of target.

When the target is not a host variable and has a character data type, truncation is not allowed. The length attribute of the column must be at least 10 for a date, 8 for a time, 19 for a TIMESTAMP(0), and 20+*p* for TIMESTAMP(*p*).

When the target is a string host variable, the following rules apply:

- **For a DATE:** If the length of the host variable is less than 10 characters, an error is returned.
- **For a TIME:** If the USA format is used, the length of the host variable must not be less than 8 characters; in other formats the length must not be less than 5 characters.

  If ISO or JIS formats are used, and if the length of the host variable is less than 8 characters, the seconds part of the time is omitted from the result and assigned to the indicator variable, if provided. The SQLWARN1 field of the SQLCA is set to indicate the omission.
- **For a TIMESTAMP:** If the length of the host variable is less than 19 characters, an error is returned. If the length is less than 32 characters, but greater than or equal to 19 characters, trailing digits of the fractional seconds part of the value are omitted. The SQLWARN1 field of the SQLCA is set to indicate the omission.

When a DATE is assigned to a TIMESTAMP, the time and fractional components of the timestamp are set to midnight and 0, respectively. When a TIMESTAMP is assigned to a DATE, the date portion is extracted and the time and fractional components are truncated.

When a TIMESTAMP is assigned to a TIME, the DATE portion is ignored and the fractional components are truncated.

XML assignments

The general rule for XML assignments is that only an XML value can be assigned to XML columns or to XML variables. There are exceptions to this rule, as follows.

- ***Processing of input XML host variables:*** This is a special case of the XML assignment rule, because the host variable is based on a string value. To make the assignment to XML within SQL, the string value is implicitly parsed into an XML value using the setting of the CURRENT IMPLICIT XMLPARSE OPTION

special register. This determines whether to preserve or to strip whitespace, unless the host variable is an argument of the XMLVALIDATE function, which always strips unnecessary whitespace.

- ***Assigning strings to input parameter markers of data type XML:*** If an input parameter marker has an implicit or explicit data type of XML, the value bound (assigned) to that parameter marker could be a character string variable, graphic string variable, or binary string variable. In this case, the string value is implicitly parsed into an XML value using the setting of the CURRENT IMPLICIT XMLPARSE OPTION special register to determine whether to preserve or to strip whitespace, unless the parameter marker is an argument of the XMLVALIDATE function, which always strips unnecessary whitespace.
- ***Assigning strings directly to XML columns in data change statements:*** If assigning directly to a column of type XML in a data change statement, the assigned expression can also be a character string or a binary string. In this case, the result of `XMLPARSE (DOCUMENT` *`expression`* `STRIP WHITESPACE)` is assigned to the target column. The supported string data types are defined by the supported arguments for the XMLPARSE function. Note that this XML assignment exception does not allow character or binary string values to be assigned to SQL variables or to SQL parameters of data type XML.
- ***Assigning XML to strings on retrieval:*** If retrieving XML values into host variables using a FETCH INTO statement or an EXECUTE INTO statement in embedded SQL, the data type of the host variable can be CLOB, DBCLOB, or BLOB. If using other application programming interfaces (such as CLI, JDBC, or .NET), XML values can be retrieved into the character, graphic, or binary string types that are supported by the application programming interface. In all of these cases, the XML value is implicitly serialized to a string encoded in UTF-8 and, for character or graphic string variables, converted into the client code page.

Character string or binary string values cannot be retrieved into XML host variables. Values in XML host variables cannot be assigned to columns, SQL variables, or SQL parameters of a character string data type or a binary string data type.

Assignment to XML parameters and variables in inlined SQL bodied UDFs and SQL procedures is done by reference. Passing parameters of data type XML to invoke an inlined SQL UDF or SQL procedure is also done by reference. When XML values are passed by reference, any input node trees are used directly. This direct usage preserves all properties, including document order, the original node identities, and all parent properties.

User-defined type assignments

Assignments involving user-defined type values generally allow assignment to the same user-defined type name with some additional rules for the different kinds of user-defined types. Additional information about specific user-defined types is in the sections that follow.

Strongly typed distinct type assignments

The rules that apply to the assignments of strongly typed distinct type values to host variables are different than the rules for all other assignments that involve strongly typed distinct type values

Assignments to host variables

The assignment of a strongly typed distinct type value to a host variable (or parameter marker) is based on the source data type of the distinct type. Therefore, the value of a strongly typed distinct type is assignable to a host variable (or parameter marker) only if the source data type of the distinct type is assignable to the variable

For example, the distinct type AGE is created by the following SQL statement:

```
CREATE TYPE AGE AS SMALLINT
```

When the statement is executed, the following cast functions are also generated:

```
AGE (SMALLINT) RETURNS AGE
AGE (INTEGER) RETURNS AGE
SMALLINT (AGE) RETURNS SMALLINT
```

Next, assume that column STU_AGE was defined in table STUDENTS with distinct type AGE. Now, consider this valid assignment of a student's age to host variable HV_AGE, which has an INTEGER data type:

```
SELECT STU_AGE INTO :HV_AGE FROM STUDENTS WHERE STU_NUMBER = 200
```

The strongly typed distinct type value is assignable to host variable HV_AGE because the source data type of the distinct type (SMALLINT) is assignable to the host variable (INTEGER). If strongly typed distinct type AGE had been sourced on a datetime data type such as DATE, the preceding assignment would be invalid because a datetime data type cannot be assigned to an integer type.

Assignments other than to host variables

A strongly typed distinct type can be either the source or target of an assignment. Assignment is based on whether the data type of the value to be assigned is castable to the data type of the target (see "Casting between data types" on page 47 for the casts supported when a distinct type is involved). A strongly typed distinct type value can be assigned to any target other than host a variable in the following cases:

- The target of the assignment has the same distinct type.
- The distinct type is castable to the data type of the target.

Any value can be assigned to a strongly typed distinct type when:

- The value to be assigned has the same distinct type as the target.
- The data type of the assigned value is castable to the target distinct type.

For example, the source data type for strongly typed distinct type AGE is SMALLINT:

```
CREATE TYPE AGE AS SMALLINT
```

Next, assume that the tables TABLE1 and TABLE2 are created with four identical column descriptions:

```
AGECOL AGE
SMINTCOL SMALLINT
INTCOL INTEGER
DECCOL DECIMAL(6,2)
```

Using the following SQL statement and substituting various values for X and Y to insert values into various columns of TABLE1 from TABLE2. The database manager uses assignment rules in this INSERT statement to determine if X can be assigned to Y. Table 12 on page 63 shows whether the assignments are valid.

```
INSERT INTO TABLE1(Y)
   SELECT X FROM TABLE2;
```

Table 12. Assessment of various assignments

TABLE2.X	TABLE1.Y	Valid	Reason
AGECOL	AGECOL	Yes	Source and target are the same distinct type
SMINTCOL	AGECOL	Yes	SMALLINT can be cast to AGE
INTCOL	AGECOL	Yes	INTEGER can be cast to AGE because the AGE source type is SMALLINT
DECCOL	AGECOL	No	DECIMAL cannot be cast to AGE
AGECOL	SMINTCOL	Yes	AGECOL can be cast to its source type of SMALLINT
AGECOL	INTCOL	No	AGE cannot be cast to INTEGER
AGECOL	DECCOL	No	AGE cannot be cast to DECIMAL

Weakly typed distinct type assignments

The value of a weakly typed distinct type can be assigned according to the assignment rules for the source type of the weakly typed distinct type. When the assignment target has a distinct type defined with data type constraints, the data type constraints are applied to the source value and must evaluate to true or unknown.

Structured type assignments

The value of a structured type can be assigned when the target of the assignment has the same structured type or one of its supertypes except in cases that involve host variables.

Assignment to and from host variables is based on the declared type of the host variable; that is, it follows the rule:

- A source value of a structured type is assignable to a target host variable if and only if the declared type of the host variable is the structured type or a supertype of the structured type.

If the target of the assignment is a column of a structured type, the source data type must be the target data type or a subtype of the target data type.

Array type assignments

The value for an element of an array must be assignable to the data type of the array elements. The assignment rules for that data type apply to the value assignment. The value specified for an index in the array must be assignable to the data type of the index for the array. The assignment rules for that data type apply to the value assignment. For an ordinary array, the index data type is INTEGER and for an associative array the data type is either INTEGER or VARCHAR(n), where n is any valid length attribute for the VARCHAR data type. If the index value for an assignment to an ordinary array is larger than the current cardinality of the array, then the cardinality of the array is increased to the new index value, provided the value does not exceed the maximum value for an INTEGER data type. An assignment of one new element to an associative array increases the cardinality by exactly 1 since the index values can be sparse.

The validity of an assignment to an SQL variable or parameter is determined according to the following rules:

- If the right side of the assignment is an SQL variable or parameter, an invocation of the TRIM_ARRAY function, an invocation of the ARRAY_DELETE function, or a CAST expression, then its type must be the same as the type of the SQL variable or parameter on the left side of the assignment.
- If the right side of the assignment is an array constructor or an invocation of the ARRAY_AGG function, then it is implicitly cast to the type of the SQL variable or parameter on the left side.

For example, assuming that the type of variable *V* is MYARRAY, the statement:

```
   SET V = ARRAY[1,2,3];
```

is equivalent to:

```
SET V = CAST(ARRAY[1,2,3] AS MYARRAY);
```

And the statement:

```
SELECT ARRAY_AGG(C1) INTO V FROM T
```

is equivalent to:

```
SELECT CAST(ARRAY_AGG(C1) AS MYARRAY) INTO V FROM T
```

The following are valid assignments that involve array type values:

- Array variable to another array variable with the same array type as the source variable.
- An expression of type array to an array variable, where the array element type in the source expression is assignable to the array element type in the target array variable.

Row type assignments

Assignments to fields within a row variable must conform to the same rules as if the field itself was a variable of the same data type as the field. A row variable can be assigned only to a row variable with the same user-defined row type. When using FETCH, SELECT, or VALUES INTO to assign values to a row variable, the source value types must be assignable to the target row fields. If the source or the target variable (or both) of an assignment is anchored to the row of a table or view, the number of fields must be the same and the field types of the source value must be assignable to the field types of the target value.

Cursor type assignments

Assignments to cursors depend on the type of cursor. The following values are assignable to a variable or parameter of built-in type CURSOR:

- A cursor value constructor
- A value of built-in type CURSOR
- A value of any user-defined cursor type

The following values are assignable to a variable or parameter of a weakly typed user-defined cursor type:

- A cursor value constructor
- A value of built-in type CURSOR
- A value of a user-defined cursor type with the same type name

The following values are assignable to a variable or parameter of strongly typed user-defined cursor type:

- A cursor value constructor
- A value of a user-defined cursor type with the same type name

Boolean type assignments

The following keywords represent values that are assignable to a variable, parameter, or return type of built-in type BOOLEAN:

- TRUE
- FALSE
- NULL

The result of the evaluation of a search condition can also be assigned. If the search condition evaluates to unknown, the value of NULL is assigned.

Reference type assignments

A reference type with a target type of *T* can be assigned to a reference type column that is also a reference type with target type of *S* where *S* is a supertype of *T*. If an assignment is made to a scoped reference column or variable, no check is performed to ensure that the actual value being assigned exists in the target table or view defined by the scope.

Assignment to host variables is done based on the representation type of the reference type. That is, it follows the rule:

- A value of a reference type on the right hand side of an assignment is assignable to a host variable on the left side if and only if the representation type of this reference type is assignable to this host variable.

If the target of the assignment is a column, and the right side of the assignment is a host variable, the host variable must be explicitly cast to the reference type of the target column.

Numeric comparisons

Numbers are compared algebraically; that is, with regard to sign. For example, -2 is less than +1.

If one number is an integer and the other is decimal, the comparison is made with a temporary copy of the integer, which has been converted to decimal.

When decimal numbers with different scales are compared, the comparison is made with a temporary copy of one of the numbers that has been extended with trailing zeros so that its fractional part has the same number of digits as the other number.

If one number is floating-point and the other is integer or decimal, the comparison is made with a temporary copy of the other number, which has been converted to double-precision floating-point.

Two floating-point numbers are equal only if the bit configurations of their normalized forms are identical.

If one number is decimal floating-point and the other number is integer, decimal, single precision floating-point, or double precision floating-point, the comparison is made with a temporary copy of the other number, which has been converted to decimal floating-point.

If one number is DECFLOAT(16) and the other number is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison is made.

The decimal floating-point data type supports both positive and negative zero. Positive and negative zero have different binary representations, but the = (equal) predicate will return true for comparisons of negative and positive zero.

The COMPARE_DECFLOAT and TOTALORDER scalar functions can be used to perform comparisons at a binary level if, for example, a comparison of 2.0 <> 2.00 is required.

The decimal floating-point data type supports the specification of negative and positive NaN (quiet and signalling), and negative and positive infinity. From an SQL perspective, INFINITY = INFINITY, NAN = NAN, SNAN = SNAN, and -0 = 0.

The comparison and ordering rules for special values are as follows:

- (+/-) INFINITY compares equal only to (+/-) INFINITY of the same sign.
- (+/-) NAN compares equal only to (+/-) NAN of the same sign.
- (+/-) SNAN compares equal only to (+/-) SNAN of the same sign.

The ordering among different special values is as follows:

- -NAN < -SNAN < -INFINITY < 0 < INFINITY < SNAN < NAN

When string and numeric data types are compared, the string is cast to DECFLOAT(34) using the rules for a CAST specification. For more information, see "CAST specification" in the *SQL Reference Volume 1*. The string must contain a valid string representation of a number.

String comparisons

Binary string comparisons

Binary string comparisons are always performed by comparing the binary values for the corresponding bytes of each string. Additionally, two binary strings are equal only if the actual length of the two strings is identical. The shorter string is considered less than the longer string when otherwise equal to the length of the shorter string. Binary strings cannot be compared with character strings unless the character string is cast to a binary string or the character string has a subtype of FOR BIT DATA. In this case, the FOR BIT DATA character string is treated as if it were a binary string.

BLOB strings that have an actual length less than 32673 bytes are supported as operands in basic predicates, IN, BETWEEN and the simple CASE expression. In comparisons that use the LIKE predicate, NULL predicate, and the POSSTR function, BLOB strings of any length continue to be supported.

Character and graphic string comparisons

Character strings are compared according to the collating sequence specified when the database was created with the following exceptions:

- Character strings with a FOR BIT DATA attribute are always compared according to their bit values.

- In a non-Unicode database, string comparisons that involve a Unicode string data type use the alternate collating sequence.

When comparing character strings of unequal lengths, the comparison is made using a logical copy of the shorter string, which is padded on the right with blanks sufficient to extend its length to that of the longer string. This logical extension is done for all character strings, including those tagged as FOR BIT DATA.

Character strings (except character strings tagged as FOR BIT DATA) are compared either according to the collating sequence specified when the database was created, or according to the alternate collating sequence. For example, the default collating sequence supplied by the database manager may give lowercase and uppercase versions of the same character the same weight. The database manager performs a two-pass comparison to ensure that only identical strings are considered equal to each other. In the first pass, strings are compared according to the database collating sequence. If the weights of the characters in the strings are equal, a second "tie-breaker" pass is performed to compare the strings on the basis of their actual code point values.

Two strings are equal if they are both empty or if all corresponding bytes are equal. If either operand is null, the result is unknown.

LOB strings that have an actual length less than 32673 bytes are now supported as operands in basic predicates, IN, BETWEEN and the simple CASE expression. In comparisons using the LIKE predicate, NULL predicate, and the POSSTR function, LOB strings of any length continue to be supported.

LOB strings are not supported in any other comparison operations such as MAX, MIN, DISTINCT, GROUP BY, and ORDER BY.

Portions of strings can be compared using the SUBSTR and VARCHAR scalar functions. For example, given the columns:

```
MY_SHORT_CLOB   CLOB(300)
MY_LONG_VAR     VARCHAR(8000)
```

then the following is valid:

```
WHERE VARCHAR(MY_SHORT_CLOB) > VARCHAR(SUBSTR(MY_LONG_VAR,1,300))
```

Examples:

For these examples, 'A', 'Á', 'a', and 'á', have the code point values X'41', X'C1', X'61', and X'E1' respectively.

Consider a collating sequence where the characters 'A', 'Á', 'a', 'á' have weights 136, 139, 135, and 138. Then the characters sort in the order of their weights as follows:

```
'a' < 'A' < 'á' < 'Á'
```

Now consider four DBCS characters D1, D2, D3, and D4 with code points 0xC141, 0xC161, 0xE141, and 0xE161, respectively. If these DBCS characters are in CHAR columns, they sort as a sequence of bytes according to the collation weights of those bytes. First bytes have weights of 138 and 139, therefore D3 and D4 come before D2 and D1; second bytes have weights of 135 and 136. Hence, the order is as follows:

```
D4 < D3 < D2 < D1
```

However, if the values being compared have the FOR BIT DATA attribute, or if these DBCS characters were stored in a GRAPHIC column, the collation weights are ignored, and characters are compared according to their code points as follows:

```
 'A' < 'a' < 'Á' < 'á'
```

The DBCS characters sort as sequence of bytes, in the order of code points as follows:

```
D1 < D2 < D3 < D4
```

Now consider a collating sequence where the characters 'A', 'Á', 'a', 'á' have (non-unique) weights 74, 75, 74, and 75. Considering collation weights alone (first pass), 'a' is equal to 'A', and 'á' is equal to 'Á'. The code points of the characters are used to break the tie (second pass) as follows:

```
'A' < 'a' < 'Á' < 'á'
```

DBCS characters in CHAR columns sort a sequence of bytes, according to their weights (first pass) and then according to their code points to break the tie (second pass). First bytes have equal weights, so the code points (0xC1 and 0xE1) break the tie. Therefore, characters D1 and D2 sort before characters D3 and D4. Then the second bytes are compared in similar way, and the final result is as follows:

```
D1 < D2 < D3 < D4
```

Once again, if the data in CHAR columns have the FOR BIT DATA attribute, or if the DBCS characters are stored in a GRAPHIC column, the collation weights are ignored, and characters are compared according to their code points:

```
D1 < D2 < D3 < D4
```

For this particular example, the result happens to be the same as when collation weights were used, but obviously this is not always the case.

Conversion rules for comparison

When two strings are compared, one of the strings is first converted, if necessary, to the encoding scheme, code page, and collating sequence of the other string.

Ordering of results

Results that require sorting are ordered based on the string comparison rules discussed in “String comparisons” on page 66. The comparison is performed at the database server. On returning results to the client application, code page conversion may be performed. This subsequent code page conversion does not affect the order of the server-determined result set.

MBCS considerations for string comparisons

Mixed SBCS/MBCS character strings are compared according to the collating sequence specified when the database was created. For databases created with default (SYSTEM) collation sequence, all single-byte ASCII characters are sorted in correct order, but double-byte characters are not necessarily in code point sequence. For databases created with IDENTITY sequence, all double-byte characters are correctly sorted in their code point order, but single-byte ASCII characters are sorted in their code point order as well. For databases created with COMPATIBILITY sequence, a compromise order is used that sorts properly for most double-byte characters, and is almost correct for ASCII.

Mixed character strings are compared byte-by-byte. This may result in unusual results for multi-byte characters that occur in mixed strings, because each byte is considered independently.

Example:

For this example, 'A', 'B', 'a', and 'b' double-byte characters have the code point values X'8260', X'8261', X'8281', and X'8282', respectively.

Consider a collating sequence where the code points X'8260', X'8261', X'8281', and X'8282' have weights 96, 65, 193, and 194. Then:

```
    'B' < 'A' < 'a' < 'b'
```

and

```
    'AB' < 'AA' < 'Aa' < 'Ab' < 'aB' < 'aA' < 'aa' < 'ab'
```

Graphic string comparisons are processed in a manner analogous to that for character strings.

Graphic string comparisons are valid between all graphic string data types except DBCLOB.

For graphic strings, the collating sequence of the database is not used. Instead, graphic strings are always compared based on the numeric (binary) values of their corresponding bytes.

Using the previous example, if the literals were graphic strings, then:

```
'A' < 'B' < 'a' < 'b'
```

and

```
'AA' < 'AB' < 'Aa' < 'Ab' < 'aA' < 'aB' < 'aa' < 'ab'
```

When comparing graphic strings of unequal lengths, the comparison is made using a logical copy of the shorter string which is padded on the right with double-byte blank characters sufficient to extend its length to that of the longer string.

Two graphic values are equal if they are both empty or if all corresponding graphics are equal. If either operand is null, the result is unknown. If two values are not equal, their relation is determined by a simple binary string comparison.

As indicated in this section, comparing strings on a byte by byte basis can produce unusual results; that is, a result that differs from what would be expected in a character by character comparison. The examples shown here assume the same MBCS code page, however, the situation can be further complicated when using different multi-byte code pages with the same national language. For example, consider the case of comparing a string from a Japanese DBCS code page and a Japanese EUC code page.

Datetime comparisons

A date, time, or timestamp value can be compared with another value of the same data type, a datetime constant of the same data type, or with a string representation of a value of that data type. A date value or a string representation of a date can also be compared with a TIMESTAMP, where the missing time information for the date value is assumed to be all zeros. All comparisons are chronological, which means the further a point in time is from January 1, 0001, the greater the value of that point in time. The time 24:00:00 is greater than the time 00:00:00.

Comparisons that involve time values and string representations of time values always include seconds. If the string representation omits seconds, zero seconds are implied.

Comparisons that involve timestamp values are evaluated according to the following rules:

- When comparing timestamp values with different precisions, the higher precision is used for the comparison and any missing digits for fractional seconds are assumed to be zero.
- When comparing a timestamp value with a string representation of a timestamp, the string representation is first converted to TIMESTAMP(12).
- Timestamp comparisons are chronological without regard to representations that might be considered equivalent. Thus, the following predicate is true:

```
TIMESTAMP('1990-02-23-00.00.00') > '1990-02-22-24.00.00'
```

User-defined type comparisons

Information about comparisons involving user-defined types is in the sections that follow.

Strongly typed distinct type comparisons

Values with a strongly typed distinct type only can be compared with values of exactly the same strongly typed distinct type.

For example, given the following YOUTH distinct type and CAMP_DB_ROSTER table:

```
CREATE TYPE YOUTH AS INTEGER

CREATE TABLE CAMP_DB_ROSTER
   ( NAME                VARCHAR(20),
     ATTENDEE_NUMBER     INTEGER NOT NULL,
     AGE                 YOUTH,
     HIGH_SCHOOL_LEVEL   YOUTH)
```

The following comparison is valid:

```
SELECT * FROM CAMP_DB_ROSTER
   WHERE AGE > HIGH_SCHOOL_LEVEL
```

The following comparison is not valid:

```
SELECT * FROM CAMP_DB_ROSTER
   WHERE AGE > ATTENDEE_NUMBER
```

However, AGE can be compared to ATTENDEE_NUMBER by using a function or CAST specification to cast between the distinct type and the source type. The following comparisons are all valid:

```
SELECT * FROM CAMP_DB_ROSTER
   WHERE INTEGER(AGE) > ATTENDEE_NUMBER

SELECT * FROM CAMP_DB_ROSTER
   WHERE CAST( AGE AS INTEGER) > ATTENDEE_NUMBER

SELECT * FROM CAMP_DB_ROSTER
   WHERE AGE > YOUTH(ATTENDEE_NUMBER)

SELECT * FROM CAMP_DB_ROSTER
   WHERE AGE > CAST(ATTENDEE_NUMBER AS YOUTH)
```

Weakly typed distinct type comparisons

Values with a weakly typed distinct type are compared according to the comparison rules for the source type of the distinct type. Data type constraints have no impact on the comparison. It is valid to compare different weakly typed distinct types if the underlying source types are comparable.

Structured type comparisons

Values with a user-defined structured type cannot be compared with any other value (the NULL predicate and the TYPE predicate can be used).

Array type comparisons

Comparisons of array type values are not supported. Elements of arrays can be compared based on the comparison rules for the data type of the elements.

Row type comparisons

A row variable cannot be compared to another row variable even if the row type name is the same. Individual fields within a row type can be compared to other values and the comparison rules for the data type of the field apply.

Cursor type comparisons

A cursor variable cannot be compared to another cursor variable even if the cursor type name is the same.

Boolean type comparisons

A Boolean value can be compared to another Boolean value or to a value that can be cast to a Boolean value. A value of TRUE is greater than a value of FALSE.

Reference type comparisons

Reference type values can be compared only if their target types have a common supertype. The appropriate comparison function will only be found if the schema name of the common supertype is included in the SQL path. The comparison is performed using the representation type of the reference types. The scope of the reference is not considered in the comparison.

XML comparisons in a non-Unicode database

When performed in a non-Unicode database, comparisons between XML data and character or graphic string values require a code page conversion of one of the two sets of data being compared. Character or graphic values used in an SQL or XQuery statement, either as a query predicate or as a host variable with a character or graphic string data type, are converted to the database code page before comparison. If any characters included in this data have code points that are not part of the database code page, substitution characters are added in their place, potentially causing unexpected results for the query.

For example, a client with a UTF-8 code page is used to connect to a database server created with the Greek encoding ISO8859-7. The expression $\Sigma_G\Sigma_M$ is sent as the predicate of an XQuery statement, where Σ_G represents the Greek sigma character in Unicode (U+03A3) and Σ_M represents the mathematical symbol sigma in Unicode (U+2211). This expression is first converted to the database code page, so that both "Σ" characters are converted to the equivalent code point for sigma in the Greek database code page, 0xD3. We may denote this code point as Σ_A. The newly converted expression $\Sigma_A\Sigma_A$ is then converted again to UTF-8 for comparison with the target XML data. Since the distinction between these two code points was lost as a result of the code page conversion required to pass the predicate expression into the database, the two initially distinct values Σ_G and Σ_M are passed to the XML parser as the expression $\Sigma_G\Sigma_G$. This expression then fails to match when compared to the value $\Sigma_G\Sigma_M$ in an XML document.

One way to avoid the unexpected query results that may be caused by code page conversion issues is to ensure that all characters used in a query expression have matching code points in the database code page. Characters that do not have matching code points can be included through the use of a Unicode character entity reference. A character entity reference will always bypass code page conversion. For example, using the character entity reference ࢣ in place of the Σ_M character ensures that the correct Unicode code point is used for the comparison, regardless of the database code page.

Rules for result data types

The data types of a result are determined by rules which are applied to the operands in an operation. This topic explains those rules.

These rules apply to:

- Corresponding columns in fullselects of set operations (UNION, INTERSECT and EXCEPT)
- Result expressions of a CASE expression and the DECODE and NVL2 scalar functions
- Arguments of the scalar function COALESCE (also NVL and VALUE)
- Arguments of the scalar functions GREATEST, LEAST, MAX, and MIN
- Expression values of the in list of an IN predicate
- Corresponding expressions of a multiple row VALUES clause
- Expression values for the elements in an array constructor
- Arguments of a BETWEEN predicate (except if the data types of all operands are numeric)
- Arguments for the aggregation group ranges in OLAP specifications

These rules are applied subject to other restrictions on long strings for the various operations.

The rules involving various data types follow. In some cases, a table is used to show the possible result data types. The LONG VARCHAR and LONG VARGRAPHIC data types continue to be supported but are deprecated and not recommended.

These tables identify the data type of the result, including the applicable length or precision and scale. The result type is determined by considering the operands. If there is more than one pair of operands,

start by considering the first pair. This gives a result type which is considered with the next operand to determine the next result type, and so on. The last intermediate result type and the last operand determine the result type for the operation. Processing of operations is done from left to right so that the intermediate result types are important when operations are repeated. For example, consider a situation involving:

```
CHAR(2) UNION CHAR(4) UNION VARCHAR(3)
```

The first pair results in a type of CHAR(4). The result values always have 4 bytes. The final result type is VARCHAR(4). Values in the result from the first UNION operation will always have a length of 4.

Character strings

A character string value is compatible with another character string value. Character strings include data types CHAR, VARCHAR, and CLOB.

If one operand is...	And the other operand is...	The data type of the result is...
CHAR(x)	CHAR(y)	CHAR(z) where z = max(x,y)
CHAR(x)	VARCHAR(y)	VARCHAR(z) where z = max(x,y)
VARCHAR(x)	CHAR(y) or VARCHAR(y)	VARCHAR(z) where z = max(x,y)
CLOB(x)	CHAR(y), VARCHAR(y), or CLOB(y)	CLOB(z) where z = max(x,y)

The code page of the result character string will be derived based on the rules for string conversions.

In a Unicode database, if either operand has string units CODEUNITS32 and the derived code page is not 0, the string units of the result character string is CODEUNITS32. If an operand is defined with CODEUNITS32, the other operand cannot be defined as FOR BIT DATA.Otherwise, the string units of the result character string is OCTETS. Special cases apply when the string units of one operand is CODEUNITS32 and the string units of the other operand is OCTETS with a length attribute that exceeds the data type maximum in CODEUNITS32.

If one operand is...	And the other operand is...	The data type of the result is...
CHAR(x OCTETS) with x>63	CHAR(y CODEUNITS32)	VARCHAR(z CODEUNITS32) where z = max(x,y)
VARCHAR(x OCTETS) with x>8168	CHAR(y CODEUNITS32) or VARCHAR(y CODEUNITS32)	Error
CLOB(x OCTETS) with x>536870911	CHAR(y CODEUNITS32), VARCHAR(y CODEUNITS32), or CLOB(y CODEUNITS32)	CLOB(536870911 CODEUNITS32)

Graphic strings

A graphic string value is compatible with another graphic string value. Graphic strings include data types GRAPHIC, VARGRAPHIC, and DBCLOB.

If one operand is...	And the other operand is...	The data type of the result is...
GRAPHIC(x)	GRAPHIC(y)	GRAPHIC(z) where z = max(x,y)
VARGRAPHIC(x)	GRAPHIC(y) OR VARGRAPHIC(y)	VARGRAPHIC(z) where z = max(x,y)
DBCLOB(x)	GRAPHIC(y), VARGRAPHIC(y), or DBCLOB(y)	DBCLOB(z) where z = max (x,y)

The code page of the result graphic string will be derived based on the rules for string conversions.

In a Unicode database, if either operand has string units CODEUNITS32 and the derived code page is not 0, the string units of the result character string is CODEUNITS32. If an operand is defined with CODEUNITS32, the other operand cannot be defined as FOR BIT DATA.Otherwise, the string units of the result character string is OCTETS. Special cases apply when the string units of one operand is CODEUNITS32 and the string units of the other operand is OCTETS with a length attribute that exceeds the data type maximum in CODEUNITS32. In a Unicode database, if either operand has string units CODEUNITS32, or CODEUNITS16, the string units of the result graphic string is CODEUNITS32. Special cases apply when the string units of one operand is CODEUNITS32 and the string units of the other operand is CODEUNITS16 with a length attribute that exceeds the data type maximum in CODEUNITS32.

If one operand is...	And the other operand is...	The data type of the result is...
GRAPHIC(x CODEUNITS16) with x>63	GRAPHIC(y CODEUNITS32)	VARGRAPHIC(z CODEUNITS32) where z = max(x,y)
VARGRAPHIC(x CODEUNITS16) with x>8168	GRAPHIC(y CODEUNITS32) or VARGRAPHIC(y CODEUNITS32)	Error
DBCLOB(x CODEUNITS16) with x>536870911	GRAPHIC(y CODEUNITS32), VARGRAPHIC(y CODEUNITS32) or DBCLOB(y CODEUNITS32)	DBCLOB(536870911 CODEUNITS32)

Character and graphic strings in a Unicode database

In a Unicode database, a character string value is compatible with a graphic string value.

If one operand is...	And the other operand is...	The data type of the result is...
GRAPHIC(x)	CHAR(y) or GRAPHIC(y)	GRAPHIC(z) where z = max(x,y)
VARGRAPHIC(x)	CHAR(y) or VARCHAR(y)	VARGRAPHIC(z) where z = max(x,y)
VARCHAR(x)	GRAPHIC(y) or VARGRAPHIC	VARGRAPHIC(z) where z = max(x,y)
DBCLOB(x)	CHAR(y) or VARCHAR(y) or CLOB(y)	DBCLOB(z) where z = max(x,y)
CLOB(x)	GRAPHIC(y) or VARGRAPHIC(y)	DBCLOB(z) where z = max(x,y)

The string units of the result graphic string will be CODEUNITS32 if either operand has string units CODEUNITS32, or CODEUNITS16. Special cases apply when the string units of one operand is CODEUNITS32 and the string units of the other operand is OCTETS or CODEUNITS16 with a length attribute that exceeds the data type maximum in CODEUNITS32.

If one operand is...	And the other operand is...	The data type of the result is...
CHAR(x OCTETS) with x>63	GRAPHIC(y CODEUNITS32)	VARGRAPHIC(z CODEUNITS32) where z = max(x,y)
GRAPHIC(x CODEUNITS16) with x>63	CHAR(y CODEUNITS32)	VARGRAPHIC(z CODEUNITS32) where z = max(x,y)
VARCHAR(x OCTETS) with x>8168	GRAPHIC(y CODEUNITS32) or VARGRAPHIC(y CODEUNITS32)	Error

If one operand is...	And the other operand is...	The data type of the result is...
VARGRAPHIC(x CODEUNITS16) with x>8168	CHAR(y CODEUNITS32) or VARCHAR(y CODEUNITS32)	Error
CLOB(x OCTETS) with x>536870911	GRAPHIC(y CODEUNITS32), VARGRAPHIC(y CODEUNITS32), or DBCLOB(y CODEUNITS32)	DBCLOB(536870911 CODEUNITS32)
DBCLOB(x CODEUNITS16) with x>536870911	CHAR(y CODEUNITS32), VARCHAR(y CODEUNITS32), or CLOB(y CODEUNITS32)	DBCLOB(536 870 911 CODEUNITS32)

Binary strings

Binary strings are compatible with other binary strings and FOR BIT DATA character strings. Binary strings include BINARY, VARBINARY and BLOB.

Table 13. Operands and the resulting data type

If one operand is...	And the other operand is...	The data type of the result is...
BINARY(x)	BINARY(y) or CHAR(y) FOR BIT DATA	BINARY(z) where z=max(x,y)
VARBINARY(x)	BINARY(y), VARBINARY(y), CHAR(y) FOR BIT DATA, or VARCHAR(y) FOR BIT DATA	VARBINARY(z) where z=max(x,y)
VARCHAR(x) FOR BIT DATA	BINARY(y) or VARBINARY(y)	VARBINARY(z) where z=max(x,y)
BLOB(x)	BINARY(y), VARBINARY(y), BLOB(y), CHAR(y) FOR BIT DATA, or VARCHAR(y) FOR BIT DATA	BLOB(z) where z=max(x,y)

Numeric

Numeric types are compatible with other numeric data types, character-string data types (except CLOB), and in a Unicode database, graphic-string data types (except DBCLOB). Numeric types include SMALLINT, INTEGER, BIGINT, DECIMAL, REAL, DOUBLE, and DECFLOAT.

Table 14. Operands and the resulting data type

If one operand is...	And the other operand is...	The data type of the result is...
SMALLINT	SMALLINT	SMALLINT
SMALLINT	String	DECFLOAT(34)
INTEGER	SMALLINT or INTEGER	INTEGER
INTEGER	String	DECFLOAT(34)
BIGINT	SMALLINT, INTEGER, or BIGINT	BIGINT
BIGINT	String	DECFLOAT(34)
DECIMAL(w,x)	SMALLINT	DECIMAL(p,x) where p = x+max(w-x,5)[1]

Table 14. Operands and the resulting data type (continued)

If one operand is...	And the other operand is...	The data type of the result is...
DECIMAL(w,x)	INTEGER	DECIMAL(p,x) where p = x+max(w-x,11)[1]
DECIMAL(w,x)	BIGINT	DECIMAL(p,x) where p = x+max(w-x,19)[1]
DECIMAL(w,x)	DECIMAL(y,z)	DECIMAL(p,s) where p = max(x,z)+max(w-x,y-z)[1] s = max(x,z)
DECIMAL(w,x)	String	DECFLOAT(34)
REAL	REAL	REAL
REAL	SMALLINT, INTEGER, BIGINT, or DECIMAL	DOUBLE
REAL	String	DECFLOAT(34)
DOUBLE	SMALLINT, INTEGER, BIGINT, DECIMAL, REAL, or DOUBLE	DOUBLE
DOUBLE	String	DECFLOAT(34)
DECFLOAT(n)	SMALLINT, INTEGER, DECIMAL (<=16,s), REAL, or DOUBLE	DECFLOAT(n)
DECFLOAT(n)	BIGINT or DECIMAL (>16,s)	DECFLOAT(34)
DECFLOAT(n)	DECFLOAT(m)	DECFLOAT(MAX(n,m))
DECFLOAT(n)	String	DECFLOAT(34)

[1] Precision cannot exceed 31.

Datetime

Datetime data types are compatible with other operands of the same data type or any CHAR or VARCHAR expression that contains a valid string representation of the same data type. In addition, DATE is compatible with TIMESTAMP and the other operand of a TIMESTAMP can be the string representation of a timestamp or a date. In a Unicode database, character and graphic strings are compatible which implies that GRAPHIC or VARGRAPHIC string representations of datetime values are compatible with other datetime operands.

Table 15. Result data types with datetime operands

If one operand is...	And the other operand is...	The data type of the result is...
DATE	DATE, CHAR(*y*), or VARCHAR(*y*)	DATE
TIME	TIME, CHAR(*y*), or VARCHAR(*y*)	TIME
TIMESTAMP(*x*)	TIMESTAMP(*y*)	TIMESTAMP(*max(x,y)*)
TIMESTAMP(*x*)	DATE, CHAR(*y*), or VARCHAR(*y*)	TIMESTAMP(*x*)

XML

An XML value is compatible with another XML value. The data type of the result is XML.

Boolean

A Boolean value is compatible with the following values or types:

- Another Boolean value.
- Binary integer data types, such as SMALLINT, INTEGER, and BIGINT.
- Character-string data types, except for CLOB.
- Graphic-string data types, except for DBCLOB, in a Unicode database.

The data type of the result is BOOLEAN.

A Boolean value is compatible with another Boolean value. The data type of the result is BOOLEAN.

User-defined types

Distinct types
A strongly typed distinct type value is compatible only with another value of the same distinct type. The data type of the result is the distinct type.

If both operands have the same weakly typed distinct type, the result is the distinct type. Otherwise, if any operand is a weakly typed distinct type then the data type of the operand is considered to be the source data type and the result data type is determined based on the combination of built-in data type operands.

Array data types
A user-defined array data type value is compatible only with another value of the same user-defined array data type. The data type of the result is the user-defined array data type.

Cursor data types
A CURSOR value is compatible with another CURSOR value. The result data type is CURSOR. A user-defined cursor data type value is compatible only with another value of the same user-defined cursor data type. The data type of the result is the user-defined cursor data type.

Row data types
A user-defined row data type value is compatible only with another value of the same user-defined row data type. The data type of the result is the user-defined row data type.

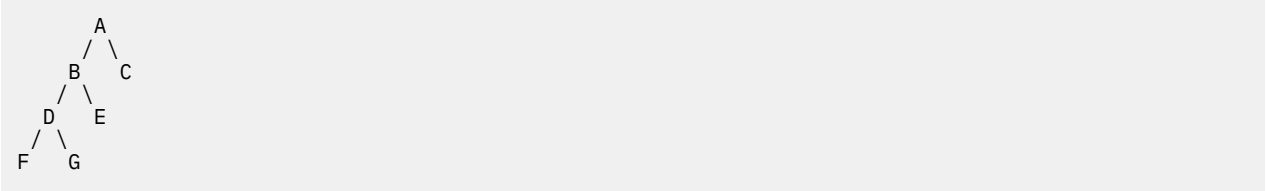
Reference types

A reference type value is compatible with another value of the same reference type provided that their target types have a common supertype. The data type of the result is a reference type having the common supertype as the target type. If all operands have the identical scope table, the result has that scope table. Otherwise the result is unscoped.

Structured types

A structured type value is compatible with another value of the same structured type provided that they have a common supertype. The static data type of the resulting structured type column is the structured type that is the least common supertype of either column.

For example, consider the following structured type hierarchy,



Structured types of the static type E and F are compatible with the resulting static type of B, which is the least common super type of E and F.

Nullable attribute of result

With the exception of INTERSECT and EXCEPT, the result allows nulls unless both operands do not allow nulls.

- For INTERSECT, if either operand does not allow nulls the result does not allow nulls (the intersection would never be null).
- For EXCEPT, if the first operand does not allow nulls the result does not allow nulls (the result can only be values from the first operand).

Rules for string conversions

The code page used to perform an operation is determined by rules which are applied to the operands in that operation. This topic explains those rules.

These rules apply to:

- Corresponding string columns in fullselects with set operations (UNION, INTERSECT and EXCEPT)
- Operands of concatenation
- Operands of predicates (with the exception of LIKE)
- Result expressions of a CASE expression and the DECODE scalar function
- Arguments of the scalar function COALESCE (also NVL and VALUE)
- Arguments of the scalar functions GREATEST, LEAST, MAX, and MIN
- The *source-string* and *insert-string* arguments of the scalar function OVERLAY (and INSERT)
- Expression values of the in list of an IN predicate
- Corresponding expressions of a multiple row VALUES clause.

In each case, the code page of the result is determined at bind time, and the execution of the operation may involve conversion of strings to the code page identified by that code page. A character that has no valid conversion is mapped to the substitution character for the character set and SQLWARN10 is set to 'W' in the SQLCA.

The code page of the result is determined by the code pages of the operands. The code pages of the first two operands determine an intermediate result code page, this code page and the code page of the next operand determine a new intermediate result code page (if applicable), and so on. The last intermediate result code page and the code page of the last operand determine the code page of the result string or column. For each pair of code pages, the result is determined by the sequential application of the following rules:

- If the code pages are equal, the result is that code page.
- If either code page is BIT DATA (code page 0), the result code page is BIT DATA.
- If both code pages are Unicode, and if one code page denotes data in an encoding scheme that is different from the other code page, the result is UTF-16 BE over UTF-8 (that is, the graphic data type over the character data type).
- If one code page is Unicode and the other is neither Unicode nor BIT DATA, the result is Unicode with the same encoding as the Unicode operand (either UTF-16 BE or UTF-8).
- For operands that are host variables (whose code page is not BIT DATA), the result code page is the database code page. Input data from such host variables is converted from the application code page to the database code page before being used.

In a non-Unicode database, if the result code page is Unicode, then the result collation is the alternate collating sequence as defined by the **ALT_COLLATE** database configuration parameter.

Conversions to the code page of the result are performed, if necessary, for:

- An operand of the concatenation operator
- The selected argument of the COALESCE (also NVL and VALUE) scalar function
- The selected argument of the scalar functions GREATEST, LEAST, MAX, and MIN

- The *source-string* and *insert-string* arguments of the scalar function OVERLAY (and INSERT)
- The selected result expression of the CASE expression and the DECODE scalar function
- The expressions of the in list of the IN predicate
- The corresponding expressions of a multiple row VALUES clause
- The corresponding columns involved in set operations.

Character conversion is necessary if all of the following are true:

- The code pages are different
- Neither string is BIT DATA
- The string is neither null nor empty

Examples

Example 1: Given the following in a database created with code page 850:

Expression	Type	Code Page
COL_1	column	850
HV_2	host variable	437

When evaluating the predicate:

```
COL_1 CONCAT :HV_2
```

the result code page of the two operands is 850, because the host variable data will be converted to the database code page before being used.

Example 2: Using information from the previous example when evaluating the predicate:

```
COALESCE(COL_1, :HV_2:NULLIND,)
```

the result code page is 850; therefore, the result code page for the COALESCE scalar function will be code page 850.

String comparisons in a Unicode database

Pattern matching is one area where the behavior of existing MBCS databases is slightly different from the behavior of a Unicode database.

For MBCS databases in Db2®, the current behavior is as follows: If the match-expression contains MBCS data, the pattern can include both SBCS and non-SBCS characters. The special characters in the pattern are interpreted as follows:

- An SBCS halfwidth underscore refers to one SBCS character.
- A non-SBCS fullwidth underscore refers to one non-SBCS character.
- A percent (either SBCS halfwidth or non-SBCS fullwidth) refers to zero or more SBCS or non-SBCS characters.

In a Unicode database, there is really no distinction between "single-byte" and "non-single-byte" characters. Although the UTF-8 format is a "mixed-byte" encoding of Unicode characters, there is no real distinction between SBCS and non-SBCS characters in UTF-8. Every character is a Unicode character, regardless of the number of bytes in UTF-8 format. In a Unicode graphic string, every non-supplementary character, including the halfwidth underscore (U+005F) and halfwidth percent (U+0025), is two bytes in width. For Unicode databases, the special characters in the pattern are interpreted as follows:

- For character strings, a halfwidth underscore (X'5F') or a fullwidth underscore (X'EFBCBF') refers to one Unicode character. A halfwidth percent (X'25') or a fullwidth percent (X'EFBC85') refers to zero or more Unicode characters.

- For graphic strings, a halfwidth underscore (U+005F) or a fullwidth underscore (U+FF3F) refers to one Unicode character. A halfwidth percent (U+0025) or a fullwidth percent (U+FF05) refers to zero or more Unicode characters.

Note: Two underscores are needed to match a Unicode supplementary graphic character because such a character is represented by two UCS-2 characters in a graphic string. Only one underscore is needed to match a Unicode supplementary character in a character string.

For the optional "escape expression", which specifies a character to be used to modify the special meaning of the underscore and percent sign characters, the expression can be specified by any one of:

- A constant
- A special register
- A host variable
- A scalar function whose operands are any of the previously mentioned operands
- An expression concatenating any of the previously mentioned operands or functions

with the restrictions that:

- No element in the expression can be of type CLOB or DBCLOB. In addition, it cannot be a BLOB file reference variable.
- For character strings, the result of the expression must be one character or a FOR BIT DATA string containing exactly one (1) byte (SQLSTATE 22019). For graphic strings, the result of the expression must be one character (SQLSTATE 22019).

Resolving the anchor object for an anchored type

The anchor object of an anchored type that does not specify ROW is specified with a name that could represent an SQL variable, an SQL parameter, a global variable, a module variable, a column of a table, or a column of a view.

The way the anchor object is resolved depends on the number of identifiers in the anchor object name and the context of the statement using the ANCHOR clause.

- If the anchor object name is specified with 1 identifier, the name could represent an SQL variable, an SQL parameter, a module variable, or a global variable.
- If the anchor object name is specified with 2 identifiers, the name could represent a label-qualified SQL variable, a routine-qualified SQL parameter, a schema-qualified global variable, a module variable, the column of a table, or the column of a view.
- If the anchor object name is specified with 3 identifiers, the name represents a column of a schema-qualified table, a column of a schema-qualified view, a global variable qualified by the current server name and a schema, or a schema-qualified module variable.

An SQL variable is a candidate for an anchor object name only if the ANCHOR clause is used in an SQL variable declaration within a compound statement. An SQL parameter is a candidate for an anchor object name only if the ANCHOR clause is used in an SQL variable declaration within a compound statement used in an SQL routine body.

Resolving the anchor object name that has 1 identifier is done using the following steps:

1. If the ANCHOR clause is in an SQL variable declaration of a compound statement, search for a matching SQL variable name starting from the innermost nested compound to the outermost compound.
2. If the ANCHOR clause is in an SQL variable declaration of a compound statement within a routine body, search for a matching SQL parameter name for the routine.
3. If the ANCHOR clause is used in defining a module object, then search for a matching module variable name within the module.
4. If not yet found, then search for a table or view using the first identifier as the schema name and the second identifier as the table or view name.

5. If not yet found, then search for a global variable with a matching global variable name on the SQL path.

Resolving the anchor object name that has 2 identifiers is done using the following steps:

1. If the ANCHOR clause is in an SQL variable declaration of a compound statement, search for a matching qualified SQL variable name starting from the innermost nested compound to the outermost compound.
2. If the ANCHOR clause is in an SQL variable declaration of a compound statement within a routine body, search for a matching SQL parameter name for the routine if the first identifier of the anchor object name matches the name of the routine.
3. If the ANCHOR clause is used in defining a module object and if the first identifier matches the module name of that module, then search for a module variable name within the module that matches the second identifier.
4. If not yet found, then search for a table or view column in the current schema using the first identifier as a table or view name and the second identifier as a column name.
5. If not yet found, then search for a global variable using the first identifier as a schema name and the second identifier as a global variable name.
6. If not found and a module was not searched in step 3, then search for a module on the SQL path with a name that matches the first identifier. If found, then use the second identifier to search for a matching published module variable name in the module.
7. If a module is not found using the SQL path in step 6, check for a module public alias that matches the name of the first identifier. If found, then use the second identifier to search for a matching published module variable name in the module identified by the module public alias.

Resolving the anchor object name that has 3 identifiers is done using the following steps:

1. If the ANCHOR clause is used in defining a module object and if the first 2 identifiers match the schema name and the module name of that module, then search for a module variable with a name that matches the last identifier.
2. If not found in the previous step or the step is not applicable, then search for a table or view column using the first identifier as a schema name, the second identifier as a table or view name and the third identifier as a column name.
3. If not found in the previous step and the first identifier is the same as the current server name, then search for a global variable using the second identifier as a schema name, and the third identifier as a global variable name.
4. If not found and a module was not searched in step 1, then search for a published module variable using the first identifier as a schema name, the second identifier as a module name and, if such a module exists, use the third identifier to search for a matching published module variable name in the module.

Resolving the anchor object for an anchored row type

The anchor object of an anchored type that includes the ROW keyword is specified with a name that could represent a variety of objects, depending on the context and the number of identifiers in the name and the context of the ANCHOR clause.

The objects include the following:

- An SQL variable
- An SQL parameter
- A global variable
- A module variable
- A table
- A view

The way the anchor object is resolved depends on the number of identifiers in the anchor object name and the context of the statement using the ANCHOR clause.

- If the anchor object name is specified with 1 identifier, the name could represent an SQL variable, an SQL parameter, a module variable, a global variable, a table, or a view.
- If the anchor object name is specified with 2 identifiers, the name could represent a label-qualified SQL variable, a routine-qualified SQL parameter, a schema-qualified global variable, a module variable, a schema-qualified table, or a schema-qualified view.
- If the anchor object name is specified with 3 identifiers, the name could represent a global variable qualified by the current server name and a schema, a table qualified by the current server name and a schema, a view qualified by the current server name and a schema, or a schema-qualified module variable.

An SQL variable is a candidate for an anchor object name only if the ANCHOR clause is used in an SQL variable declaration within a compound statement. An SQL parameter is a candidate for an anchor object name only if the ANCHOR clause is used in an SQL variable declaration within a compound statement used in an SQL routine body. Resolving the anchor object name that has 1 identifier is done using the following steps:

1. If the ANCHOR clause is in an SQL variable declaration of a compound statement, search for a matching SQL variable name starting from the innermost nested compound to the outermost compound.
2. If the ANCHOR clause is in an SQL variable declaration of a compound statement within a routine body, search for a matching SQL parameter name for the routine.
3. If the ANCHOR clause is used in defining a module object, then search for a matching module variable name within the module.
4. If not yet found, then search for a table or view with a matching name in the current schema.
5. If not yet found, then search for a schema global variable with a matching global variable name on the SQL path.

Resolving the anchor object name that has 2 identifiers is done using the following steps:

1. If the ANCHOR clause is in an SQL variable declaration of a compound statement, search for a matching qualified SQL variable name starting from the innermost nested compound to the outermost compound.
2. If the ANCHOR clause is in an SQL variable declaration of a compound statement within a routine body, search for a matching SQL parameter name for the routine if the first identifier of the anchor object name matches the name of the routine.
3. If the ANCHOR clause is used in defining a module object and if the first identifier matches the module name of that module, then search for a module variable name within the module that matches the second identifier.
4. If not yet found, then search for a table or view using the first identifier as the schema name and the second identifier as the table or view name.
5. If not yet found, then search for a global variable using the first identifier as a schema name and the second identifier as a global variable name.
6. If not found and a module was not searched in step 3, then search for a module on the SQL path with a name that matches the first identifier. If found, then use the second identifier to search for a matching published module variable name in the module.
7. If a module is not found using the SQL path in step 6, check for a module public alias that matches the name of the first identifier. If found, then use the second identifier to search for a matching published module variable name in the module identified by the module public alias.

Resolving the anchor object name that has 3 identifiers is done using the following steps:

1. If the ANCHOR clause is used in defining a module object and if the first 2 identifiers match the schema name and the module name of that module, then search for a module variable with a name that matches the last identifier.

2. If not found and the first identifier is the same as the current server name, then search for a table or view using the second identifier as the schema name and the third identifier as the table or view name.
3. If not found and the first identifier is the same as the current server name, then search for a global variable using the second identifier as the schema name and the third identifier as the global variable name.
4. If not found and a module was not searched in step 1, then search for a published module variable using the first identifier as a schema name, the second identifier as a module name and, if such a module exists, use the third identifier to search for a matching published variable name in the module.

Database partition-compatible data types

Database partition compatibility is defined between the base data types of corresponding columns of distribution keys. Database partition-compatible data types have the property that two variables, one of each type, with the same value, are mapped to the same distribution map index by the same database partitioning function.

Table 16 on page 83 shows the compatibility of data types in database partitions.

Database partition compatibility has the following characteristics:

- Internal formats are used for DATE, TIME, and TIMESTAMP. They are not compatible with each other, and none are compatible with character or graphic data types.
- Partition compatibility is not affected by the nullability of a column.
- Partition compatibility is affected by collation. Locale-sensitive UCA-based collations require an exact match in collation, except that the strength (S) attribute of the collation is ignored. All other collations are considered equivalent for the purposes of determining partition compatibility.
- Character columns defined with FOR BIT DATA are only compatible with character columns without FOR BIT DATA when a collation other than a locale-sensitive UCA-based collation is used.
- Null values of compatible data types are treated identically. Different results might be produced for null values of non-compatible data types.
- Base data type of the UDT is used to analyze database partition compatibility.
- Timestamps of the same value in the distribution key are treated identically, even if their timestamp precisions differ.
- Decimals of the same value in the distribution key are treated identically, even if their scale and precision differ.
- Trailing blanks in character strings (CHAR, VARCHAR, GRAPHIC or VARGRAPHIC) are ignored by the system-provided hashing function.
- When a locale-sensitive UCA-based collation is used, CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are compatible data types. When other collations are used, CHAR and VARCHAR are compatible types and GRAPHIC and VARGRAPHIC are compatible types, but CHAR and VARCHAR are not compatible types with GRAPHIC and VARGRAPHIC. CHAR or VARCHAR of different lengths are compatible data types.
- DECFLOAT values that are equal are treated identically even if their precision differs. DECFLOAT values that are numerically equal are treated identically even if they have a different number of significant digits.
- Data types that are not supported as part of a distribution key are not applicable for database partition compatibility. Examples of such data types are:
  - BLOB
  - CLOB
  - DBCLOB
  - XML
  - A distinct type based on BLOB, CLOB, DBCLOB, or XML
  - A structured type

Table 16. Database Partition Compatibilities

Operands	Binary Integer	Decimal Number	Floating-point	Decimal Floating-point	Character String	Graphic String	Binary String	Date	Time	Time-stamp	Distinct Type	Boolean
Binary Integer	Yes	No	No	No	No	No	No	No	No	No	1	No
Decimal Number	No	Yes	No	No	No	No	No	No	No	No	1	No
Floating-point	No	No	Yes	No	No	No	No	No	No	No	1	No
Decimal Floating-point	No	No	No	Yes	No	No	No	No	No	No	1	No
Character String	No	No	No	No	Yes[2]	2, 3	No	No	No	No	1	No
Graphic String	No	No	No	No	2, 3	Yes[2]	No	No	No	No	1	No
Binary String							Yes					No
Date	No	No	No	No	No	No	No	Yes	No	No	1	No
Time	No	No	No	No	No	No	No	No	Yes	No	1	No
Timestamp	No	No	No	No	No	No	No	No	No	Yes	1	No
Distinct Type	1	1	1	1	1	1	1	1	1	1	1	1
Boolean	No	No	No	No	No	No	No	No	No	No	1	Yes

Note:

1
A distinct type value is database partition compatible with the source data type of the distinct type or with any other distinct type with the same source data type. The source data type of the distinct type must be a data type that is supported as part of a distribution key. A user-defined distinct type (UDT) value is database partition compatible with the source type of the UDT or any other UDT with a database partition compatible source type. A distinct type cannot be based on BLOB, CLOB, DBCLOB, or XML.

2
Character and graphic string types are compatible when they have compatible collations.

3
Character and graphic string types are compatible when a locale-sensitive UCA-based collation is in effect. Otherwise, they are not compatible types.

Constants

A *constant* (sometimes called a *literal*) specifies a value. Constants are classified as string constants or numeric constants. Numeric constants are further classified as integer, floating-point, or decimal.

All constants have the NOT NULL attribute.

A negative zero value in a numeric constant (-0) is the same value as a zero without the sign (0).

User-defined types have strong typing, except for weakly typed distinct types.. This means that a strongly typed user-defined type is only compatible with its own type. A constant, however, has a built-in type. Therefore, an operation involving a strongly typed user-defined type and a constant is only possible if the user-defined type has been cast to the constant's built-in type, or if the constant has been cast to the user-defined type. For example, using the table and distinct type in “User-defined type comparisons” on page 69, the following comparisons with the constant 14 are valid:

```
SELECT * FROM CAMP_DB_ROSTER
  WHERE AGE > CAST(14 AS YOUTH)
```

```
SELECT * FROM CAMP_DB_ROSTER
  WHERE CAST(AGE AS INTEGER) > 14
```

The following comparison is not valid:

```
SELECT * FROM CAMP_DB_ROSTER
  WHERE AGE > 14
```

Integer constants

An *integer constant* specifies an integer as a signed or unsigned number with a maximum of 19 digits that does not include a decimal point. The data type of an integer constant is large integer if its value is within the range of a large integer. The data type of an integer constant is big integer if its value is outside the range of large integer but within the range of a big integer. A constant that is defined outside the range of big integer values is considered a decimal constant.

Note that the smallest literal representation of a large integer constant is -2,147,483,647 and not -2,147,483,648, which is the limit for integer values. Similarly, the smallest literal representation of a big integer constant is -9,223,372,036,854,775,807 and not -9,223,372,036,854,775,808, which is the limit for big integer values.

Examples:

```
64     -15     +100     32767     720176      12345678901
```

In syntax diagrams, the term "integer" is used for a large integer constant that must not include a sign.

Floating-point constants

A *floating-point constant* specifies a floating-point number as two numbers separated by an E. The first number may include a sign and a decimal point; the second number may include a sign but not a decimal point. The data type of a floating-point constant is double-precision. The value of the constant is the product of the first number and the power of 10 specified by the second number; it must be within the range of floating-point numbers. The number of bytes in the constant must not exceed 30.

Examples:

```
15E1     2.E5     2.2E-1     +5.E+2
```

Decimal constants

A *decimal constant* is a signed or unsigned number that consists of no more than 31 digits and either includes a decimal point or is not within the range of binary integers. It must be within the range of decimal numbers. The precision is the total number of digits (including leading and trailing zeros); the scale is the number of digits to the right of the decimal point (including trailing zeros).

Examples:

```
25.5     1000.     -15.     +37589.3333333333
```

Decimal floating-point constants

There are no decimal floating-point constants except for the decimal floating-point special values, which are interpreted as DECFLOAT(34).

These special values are: INFINITY, NAN, and SNAN. INFINITY represents infinity, a number whose magnitude is infinitely large. INFINITY can be preceded by an optional sign. INF can be specified in place of INFINITY. NAN represents Not a Number (NaN) and is sometimes called quiet NaN. It is a value that represents undefined results which does not cause a warning or exception. SNAN represents signaling NaN (sNaN). It is a value that represents undefined results which will cause a warning or exception if used in any operation that is defined in any numeric operation. Both NAN and SNAN can be preceded by an

optional sign, but the sign is not significant for arithmetic operations.. SNAN can be used in non-numeric operations without causing a warning or exception, for example in the VALUES list of an INSERT or as a constant compared in a predicate.

```
SNAN   -INFINITY
```

When one of the special values (INFINITY, INF, NAN, or SNAN) is used in a context where it could be interpreted as an identifier, such as a column name, cast a string representation of the special value to decimal floating-point. Examples:

```
CAST ('snan' AS DECFLOAT)
CAST ('INF' AS DECFLOAT)
CAST ('Nan' AS DECFLOAT)
```

All non-special values are interpreted as integer, floating-point or decimal constants, in accordance with the rules specified previously. To obtain a numeric decimal floating-point value, use the DECFLOAT cast function with a character string constant. It is not recommended to use floating-point constants as arguments to the DECFLOAT function, because floating-point is not exact and the resulting decimal floating-point value might be different than the decimal digit characters that make up the argument. Instead, use character constants as arguments to the DECFLOAT function.

For example, DECFLOAT('6.0221415E23', 34) returns the decimal floating-point value 6.0221415E+23, but DECFLOAT(6.0221415E23, 34) returns the decimal floating-point value 6.0221415000000003E+23.

Character string constants

A *character string constant* specifies a varying-length character string of type VARCHAR. The constant value string units are determined by the environment default string units. There are three forms of a character string constant:

- A sequence of characters that starts and ends with a string delimiter, which is an apostrophe ('). The number of bytes between the string delimiters cannot be greater than 32672. When the environment string unit is CODEUNITS32, the number of code units cannot be greater than 8168. Two consecutive string delimiters are used to represent one string delimiter within the character string. Two consecutive string delimiters that are not contained within a string represent the empty string.
- X followed by a sequence of characters that starts and ends with a string delimiter. This form of a character string constant is also called a *hexadecimal constant*. The characters between the string delimiters must be an even number of hexadecimal digits. Blanks between the string delimiters are ignored. The number of hexadecimal digits must not exceed 32672. When the environment string unit is CODEUNITS32, the number of code units that the hexadecimal constant represents cannot be greater than 8168. Two consecutive string delimiters are used to represent one string delimiter within the character string. A hexadecimal digit is a digit 0 through 9 or any of the letters A through F (uppercase or lowercase). Under the conventions of hexadecimal notation, each pair of hexadecimal digits represents a byte. The constant is interpreted in the section code page. This form of a character string constant allows you to specify characters that do not have a keyboard representation.
- U& followed by a sequence of characters that starts and ends with a string delimiter and that is optionally followed by the UESCAPE clause. This form of a character string constant is also called a *Unicode string constant*. The number of bytes between the string delimiters cannot be greater than 32672. When the environment string unit is CODEUNITS32, the number of code units that the Unicode string constant represents cannot be greater than 8168. The Unicode string constant is converted from UTF-8 to the section code page during statement compilation. Two consecutive string delimiters are used to represent one string delimiter within the character string. Two consecutive Unicode escape characters are used to represent one Unicode escape character within the character string, but these characters count as one character when calculating the lengths of character constants. Two consecutive string delimiters that are not contained within a string represent the empty string. Because a character in UTF-8 can range from 1 to 4 bytes, a Unicode string constant of the maximum length might actually represent fewer than 32672 characters.

  A character can be expressed by either its typographical character (*glyph*) or its Unicode code point. The code point of a Unicode character ranges from X'000000' to X'10FFFF'. To express a Unicode

character through its code point, use the Unicode escape character followed by 4 hexadecimal digits, or the Unicode escape character followed by a plus sign (+) and 6 hexadecimal digits. The default Unicode escape character is the reverse solidus (\), but a different character can be specified with the UESCAPE clause. The UESCAPE clause is specified as the UESCAPE keyword followed by a single character between string delimiters. The Unicode escape character cannot be a plus sign (+), a double quotation mark ("), a single quotation mark ('), a blank, or any of the characters 0 through 9 or A through F, in either uppercase or lowercase (SQLSTATE 42604). An example of the two ways in which the Latin capital letter A can be specified as a Unicode code point is \0041 and \+000041.

The constant value is always converted to the database code page when it is bound to the database. It is considered to be in the database code page. Therefore, if used in an expression that combines a constant with a FOR BIT DATA column, and whose result is FOR BIT DATA, the constant value will not be converted from its database code page representation when used.

Examples:

```
'12/14/1985'    '32'    'DON''T CHANGE'    ''
X'FFFF'    X'46 72 61 6E 6B'
U&'\0141ód\017A is a city in Poland'   U&'c:\\temp'   U&'@+01D11E' UESCAPE '@'
```

The rightmost string on the second line in the example represents the VARCHAR pattern of the ASCII string "Frank". The last line corresponds to: "Łódź is a city in Poland", c:\temp, and a single character representing the musical symbol G clef.

Graphic string constants

A *graphic string constant* specifies a varying-length graphic string of type VARGRAPHIC.

Non-Unicode databases

In a non-Unicode database, a graphic string constant consists of a sequence of double-byte characters that starts and ends with a single-byte apostrophe ('), and that is preceded by a single-byte G or N. The characters between the apostrophes must represent an even number of bytes, and the length of the graphic string must not exceed 16336 double bytes. The apostrophe must not appear as part of an MBCS character to be considered a delimiter. For example:

```
G'double-byte character string'
N'double-byte character string'
```

Unicode databases

In a Unicode database, a graphic string constant consists of a sequence of characters that starts and ends with an apostrophe ('), and that is preceded by a G or N character. The constant value string units are determined by the environment default string units. The characters between the apostrophes are converted to code page 1200 and the length of the graphic string must not exceed 16336 double bytes. When the environment string unit is CODEUNITS32, the number of code units must not exceed 8168.

In a Unicode or DBCS database, a hexadecimal graphic string constant that specifies a varying-length graphic string is also supported. The format of a hexadecimal graphic string constant is: GX followed by a sequence of characters that starts and ends with an apostrophe. The characters between the apostrophes must be an even multiple of four hexadecimal digits. The number of hexadecimal digits must not exceed 32 672. When the environment string unit is CODEUNITS32, the number of code units that the hexadecimal graphic string constant represents must not exceed 8 168; otherwise, an error is returned (SQLSTATE 54002). If a hexadecimal graphic string constant is improperly formed, an error is returned (SQLSTATE 42606). Each group of four digits represents a single graphic character in the section DBCS code page. In a Unicode database, this would be a single UTF-16 BE graphic character.

Examples:

```
GX'FFFF'
```

represents the bit pattern '1111111111111111' in a Unicode database.

```
GX'005200690063006B'
```

represents the VARGRAPHIC pattern of the ASCII string "Rick" in a Unicode database.

Binary string constants

A binary string constant specifies a varying-length binary string of type VARBINARY.

A binary string constant is formed by specifying a BX followed by a sequence of characters that starts and ends with a string delimiter. The characters between the string delimiters must be an even number of hexadecimal digits. The number of hexadecimal digits must not exceed 32672.

A hexadecimal digit is a digit 0 - 9 or any of the letters A through F (uppercase or lowercase).
Under the conventions of hexadecimal notation, each pair of hexadecimal digits represents 1 byte. This representation is similar to the representation of the character-constant that uses the X'' form. However, binary string constant and character-string constant are not compatible and the X'' form cannot be used to specify a binary string constant, just as the BX'' form cannot be used to specify a character-string constant.

Examples of binary string constants:

```
BX'0000'
BX'C141C242'
BX'FF00FF01FF'
```

Datetime constants

A *datetime constant* specifies a date, time, or timestamp.

Typically, character-string constants are used to represent constant datetime values in assignments and comparisons. However, the associated data type name can be used preceding specific formats of the character-string constant to specifically denote the constant as a datetime constant instead of a character-string constant. The format for the three datetime constants are:

DATE '*yyyy-mm-dd*'
The data type of the value is DATE.

TIME '*hh:mm:ss*'
or
TIME '*hh:mm*'
The data type of the value is TIME.

TIMESTAMP '*yyyy-mm-dd hh:mm:ss.nnnnnnnnnnn*'
or
TIMESTAMP '*yyyy-mm-dd-hh.mm.ss.nnnnnnnnnnn*'
where the number of digits of fractional seconds can vary from 0 to 12 and the period character can be omitted if there are no fractional seconds. The data type of the value is TIMESTAMP(*p*), where *p* is the number of digits of fractional seconds.

Leading zeros can be omitted from the month, day, and hour part of the character-string constant portion, where applicable, in each of these datetime constants. Leading zero characters must be included for minutes and seconds elements of TIME or TIMESTAMP constants. Trailing blanks can be included and are ignored.

UTF-16 BE graphic string constants

A hexadecimal UTF-16 BE graphic string that specifies a varying-length UTF-16 BE graphic string constant is supported. The format of a hexadecimal UTF-16 BE graphic string constant is: UX followed by a sequence of characters that starts and ends with an apostrophe. The characters between the apostrophes must be an even multiple of four hexadecimal digits. The number of hexadecimal digits must not exceed 16336; otherwise, an error is returned (SQLSTATE 54002). If a hexadecimal UTF-16 BE graphic string constant is improperly formed, an error is returned (SQLSTATE 42606). Each group of four digits represents a single UTF-16 BE graphic character.

Example:

```
UX'0042006F006200620079'
```

represents the VARGRAPHIC pattern of the ASCII string "Bobby".

Boolean constants

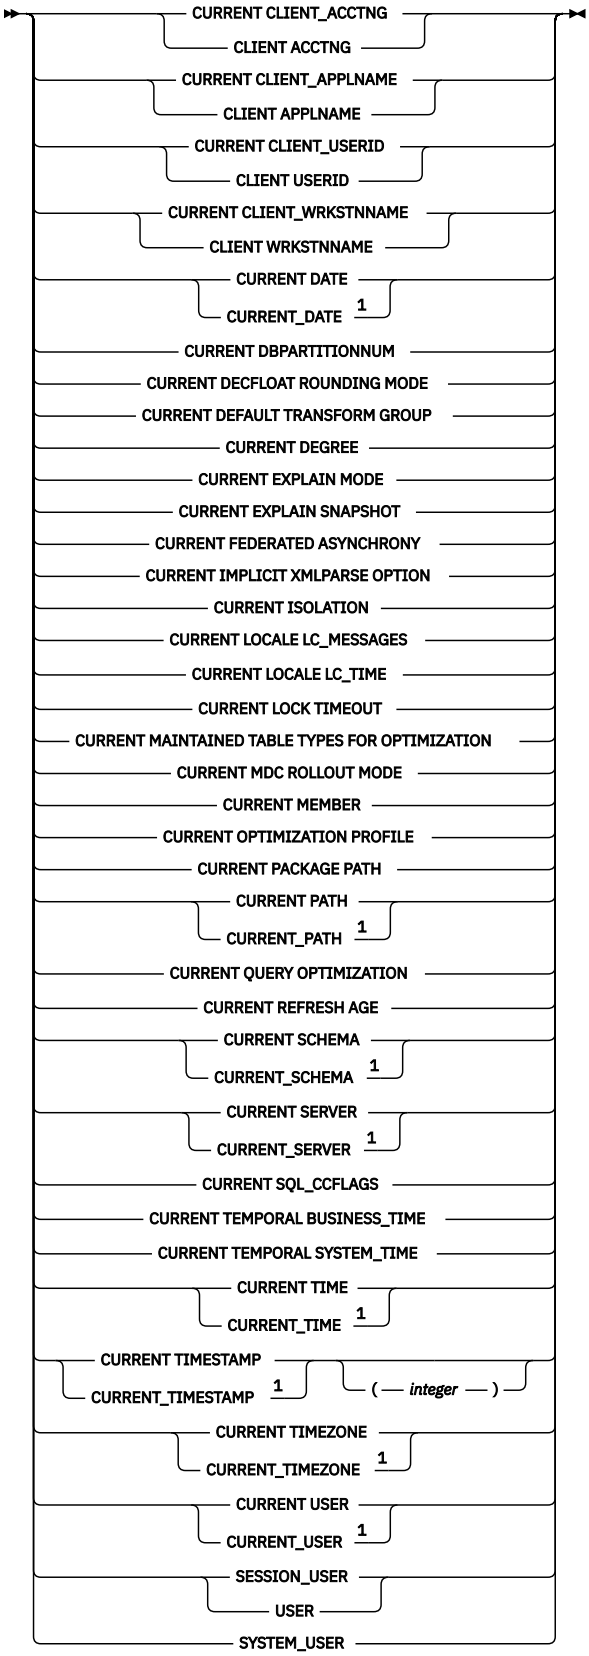
A Boolean constant specifies the keyword TRUE or FALSE, which represents the corresponding truth value. An unknown truth value can be specified using CAST(NULL AS BOOLEAN).

Special registers

A *special register* is a storage area that is defined for an application process by the database manager. It is used to store information that can be referenced in SQL statements.

A reference to a special register is a reference to a value provided by the current server. If the value is a string, its CCSID is a default CCSID of the current server.

The special registers can be referenced as follows:



Notes:

[1] The SQL2008 Core standard uses the form with the underscore.

Some special registers can be updated using the SET statement. The following table shows which of the special registers can be updated as well as indicating which special register can be the null value.

Table 17. Updatable and nullable special registers

Special Register	Updatable	Nullable
CURRENT CLIENT_ACCTNG	No	No
CURRENT CLIENT_APPLNAME	No	No
CURRENT CLIENT_USERID	No	No
CURRENT CLIENT_WRKSTNNAME	No	No
CURRENT DATE	No	No
CURRENT DBPARTITIONNUM	No	No
CURRENT DECFLOAT ROUNDING MODE	No	No
CURRENT DEFAULT TRANSFORM GROUP	Yes	No
CURRENT DEGREE	Yes	No
CURRENT EXPLAIN MODE	Yes	No
CURRENT EXPLAIN SNAPSHOT	Yes	No
CURRENT FEDERATED ASYNCHRONY	Yes	No
CURRENT IMPLICIT XMLPARSE OPTION	Yes	No
CURRENT ISOLATION	Yes	No
“CURRENT LOCALE LC_MESSAGES ” on page 98	Yes	No
CURRENT LOCALE LC_TIME	Yes	No
CURRENT LOCK TIMEOUT	Yes	Yes
CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION	Yes	No
CURRENT MDC ROLLOUT MODE	Yes	No
CURRENT MEMBER	No	No
CURRENT OPTIMIZATION PROFILE	Yes	Yes
CURRENT PACKAGE PATH	Yes	No
CURRENT PATH	Yes	No
CURRENT QUERY OPTIMIZATION	Yes	No
CURRENT REFRESH AGE	Yes	No
CURRENT SCHEMA	Yes	No
CURRENT SERVER	No	No
CURRENT SQL_CCFLAGS	Yes	No
CURRENT TEMPORAL BUSINESS_TIME	Yes	Yes
CURRENT TEMPORAL SYSTEM_TIME	Yes	Yes
CURRENT TIME	No	No
CURRENT TIMESTAMP	No	No
CURRENT TIMEZONE	No	No
CURRENT USER	No	No

Table 17. Updatable and nullable special registers (continued)

Special Register	Updatable	Nullable
SESSION_USER	Yes	No
SYSTEM_USER	No	No
USER	Yes	No

When a special register is referenced in a routine, the value of the special register in the routine depends on whether the special register is updatable or not. For non-updatable special registers, the value is set to the default value for the special register. For updatable special registers, the initial value is inherited from the invoker of the routine and can be changed with a subsequent SET statement inside the routine.

CURRENT CLIENT_ACCTNG

The CURRENT CLIENT_ACCTNG (or CLIENT ACCTNG) special register contains the value of the accounting string from the client information specified for this connection.

The data type of the register is VARCHAR(255). The default value of this register is an empty string.

The value of the accounting string can be changed by using the Set Client Information (sqleseti) API or the wlm_set_client_info procedure.

Note that the value provided via the sqleseti API is in the application code page, and the special register value is stored in the database code page. Depending on the data values used when setting the client information, truncation of the data value stored in the special register may occur during code page conversion.

Example: Get the current value of the accounting string for this connection.

```
VALUES (CURRENT CLIENT_ACCTNG)
  INTO :ACCT_STRING
```

CURRENT CLIENT_APPLNAME

The CURRENT CLIENT_APPLNAME (or CLIENT APPLNAME) special register contains the value of the application name from the client information specified for this connection.

The data type of the register is VARCHAR(255). The default value of this register is an empty string.

The value of the application name can be changed by using the `sqleseti` API or the **`wlm_set_client_info`** procedure.

Note that the value provided via the `sqleseti` API is in the application code page, and the special register value is stored in the database code page. Depending on the data values used when setting the client information, truncation of the data value stored in the special register may occur during code page conversion.

A client sends the default client information register values to the Db2 for z/OS® server when they are not explicitly set by the user. The default **`CURRENT CLIENT_APPLNAME`** special register value is the current process name. The `sqleqryi` API can return the default value only when the **`enableDefaultClientInfo`** keyword is set to `True` in the IBM data server driver configuration file.

Example: Select which departments are allowed to use the application being used in this connection.

```
SELECT DEPT
  FROM DEPT_APPL_MAP
  WHERE APPL_NAME = CURRENT CLIENT_APPLNAME
```

CURRENT CLIENT_USERID

The CURRENT CLIENT_USERID (or CLIENT USERID) special register contains the value of the client user ID from the client information specified for this connection.

The data type of the register is VARCHAR(255). The default value of this register is an empty string.

The value of the client user ID can be changed by using the `sqleseti` API or the **wlm_set_client_info** procedure.

Note that the value provided via the `sqleseti` API is in the application code page, and the special register value is stored in the database code page. Depending on the data values used when setting the client information, truncation of the data value stored in the special register may occur during code page conversion.

A client sends the default client information register values to the Db2 for z/OS server when they are not explicitly set by the user. The default **CURRENT CLIENT_USERID** special register value is the user ID that is specified for a connection. The `sqleqryi` API can return the default value only when the **enableDefaultClientInfo** keyword is set to `True` in the IBM data server driver configuration file.

Example: Find out in which department the current client user ID works.

```
SELECT DEPT
  FROM DEPT_USERID_MAP
  WHERE USER_ID = CURRENT CLIENT_USERID
```

CURRENT CLIENT_WRKSTNNAME

The CURRENT CLIENT_WRKSTNNAME (or CLIENT WRKSTNNAME) special register contains the value of the workstation name from the client information specified for this connection.

The data type of the register is VARCHAR(255). The default value of this register is an empty string.

The value of the workstation name can be changed by using the `sqleseti` API or the **wlm_set_client_info** procedure.

Note that the value provided via the `sqleseti` API is in the application code page, and the special register value is stored in the database code page. Depending on the data values used when setting the client information, truncation of the data value stored in the special register may occur during code page conversion.

A client sends the default client information register values to the Db2 for z/OS server when they are not explicitly set by the user. The default **CURRENT CLIENT_WRKSTNNAME** special register value is the host name of the client. The `sqleqryi` API can return the default value only when the **enableDefaultClientInfo** keyword is set to `True` in the IBM data server driver configuration file.

Example: Get the workstation name being used for this connection.

```
VALUES (CURRENT CLIENT_WRKSTNNAME)
  INTO :WS_NAME
```

CURRENT DATE

The CURRENT DATE (or CURRENT_DATE) special register specifies a date that is based on a reading of the time-of-day clock when the SQL statement is executed at the application server.

If this special register is used more than once within a single SQL statement, or used with CURRENT TIME or CURRENT TIMESTAMP within a single statement, all values are based on a single clock reading.

When used in an SQL statement inside a routine, CURRENT DATE is not inherited from the invoking statement.

In a federated system, CURRENT DATE can be used in a query intended for data sources. When the query is processed, the date returned will be obtained from the CURRENT DATE register at the federated server, not from the data sources.

Examples

1. Run the following command from the Db2 CLP to obtain the current date.

```
db2 values CURRENT DATE
```

2. Using the PROJECT table, set the project end date (PRENDATE) of the MA2111 project (PROJNO) to the current date.

```
UPDATE PROJECT
  SET PRENDATE = CURRENT DATE
  WHERE PROJNO = 'MA2111'
```

CURRENT DBPARTITIONNUM

The CURRENT DBPARTITIONNUM special register specifies an INTEGER value that identifies the coordinator database partition number for the statement.

For statements issued from an application, the coordinator is the database partition number to which the application connects.

For statements issued from a routine, the coordinator is the database partition number from which the routine is invoked.

When used in an SQL statement inside a routine, CURRENT DBPARTITIONNUM is never inherited from the invoking statement.

CURRENT DBPARTITIONNUM returns 0 if the database instance is not defined to support database partitioning. For a partitioned database, the db2nodes.cfg file exists and contains database partition and database partition number definitions.

In a database partitioning environment, the CURRENT DBPARTITIONNUM special register can be changed through the CONNECT statement, but only under certain conditions.

Examples

Example 1: Set the host variable APPL_DBPNUM (integer) to the number of the database partition to which the application is connected.

```
VALUES CURRENT DBPARTITIONNUM
  INTO :APPL_DBPNUM
```

Example 2: The following command is issued on member 0 and on a 4 member system in a partitioned database environment. This query will retrieve the currently connected database partition number.

```
VALUES CURRENT DBPARTITIONNUM

1
-----------
          0
```

CURRENT DECFLOAT ROUNDING MODE

The CURRENT DECFLOAT ROUNDING MODE special register specifies the rounding mode that is used for DECFLOAT values.

The data type is VARCHAR(128). The following rounding modes are supported:

- ROUND_CEILING rounds the value toward positive infinity. If all of the discarded digits are zero or if the sign is negative, the result is unchanged (except for the removal of the discarded digits). Otherwise, the result coefficient is incremented by 1.
- ROUND_DOWN rounds the value toward 0 (truncation). The discarded digits are ignored.

- ROUND_FLOOR rounds the value toward negative infinity. If all of the discarded digits are zero or if the sign is positive, the result is unchanged (except for the removal of the discarded digits). Otherwise, the sign is negative and the result coefficient is incremented by 1.
- ROUND_HALF_EVEN rounds the value to the nearest value. If the values are equidistant, rounds the value so that the final digit is even. If the discarded digits represent more than half of the value of a number in the next left position, the result coefficient is incremented by 1. If they represent less than half, the result coefficient is not adjusted (that is, the discarded digits are ignored). Otherwise, the result coefficient is unaltered if its rightmost digit is even, or incremented by 1 if its rightmost digit is odd (to make an even digit).
- ROUND_HALF_UP rounds the value to the nearest value. If the values are equidistant, rounds the value up. If the discarded digits represent half or more than half of the value of a number in the next left position, the result coefficient is incremented by 1. Otherwise, the discarded digits are ignored.

The value of the DECFLOAT rounding mode on a client can be confirmed to match that of the server by invoking the SET CURRENT DECFLOAT ROUNDING MODE statement. However, this statement cannot be used to change the rounding mode of the server. The initial value of CURRENT DECFLOAT ROUNDING MODE is determined by the **decflt_rounding** database configuration parameter and can only be changed by changing the value of this database configuration parameter.

CURRENT DEFAULT TRANSFORM GROUP

The CURRENT DEFAULT TRANSFORM GROUP special register specifies a VARCHAR(18) value that identifies the name of the transform group used by dynamic SQL statements for exchanging user-defined structured type values with host programs.

This special register does not specify the transform groups used in static SQL statements, or in the exchange of parameters and results with external functions or methods.

Its value can be set by the SET CURRENT DEFAULT TRANSFORM GROUP statement. If no value is set, the initial value of the special register is the empty string (a VARCHAR with a length of zero).

In a dynamic SQL statement (that is, one which interacts with host variables), the name of the transform group used for exchanging values is the same as the value of this special register, unless this register contains the empty string. If the register contains the empty string (no value was set by using the SET CURRENT DEFAULT TRANSFORM GROUP statement), the DB2_PROGRAM transform group is used for the transform. If the DB2_PROGRAM transform group is not defined for the structured type subject, an error is raised at run time (SQLSTATE 42741).

Examples

- Set the default transform group to MYSTRUCT1. The TO SQL and FROM SQL functions defined in the MYSTRUCT1 transform are used to exchange user-defined structured type variables with the host program.

```
SET CURRENT DEFAULT TRANSFORM GROUP = MYSTRUCT1
```

- Retrieve the name of the default transform group assigned to this special register.

```
VALUES (CURRENT DEFAULT TRANSFORM GROUP)
```

CURRENT DEGREE

The CURRENT DEGREE special register specifies the degree of intrapartition parallelism for the execution of dynamic SQL statements. (For static SQL, the DEGREE bind option provides the same control.)

The data type of the register is CHAR(5). Valid values are ANY or the string representation of an integer between 1 and 32 767, inclusive.

If the value of CURRENT DEGREE represented as an integer is 1 when an SQL statement is dynamically prepared, the execution of that statement will not use intrapartition parallelism.

If the value of CURRENT DEGREE represented as an integer is greater than 1 and less than or equal to 32 767 when an SQL statement is dynamically prepared, the execution of that statement can involve intrapartition parallelism with the specified degree.

If the value of CURRENT DEGREE is ANY when an SQL statement is dynamically prepared, the execution of that statement can involve intrapartition parallelism using a degree determined by the database manager.

The actual runtime degree of parallelism will be the lower of:

- The value of the maximum query degree (**max_querydegree**) configuration parameter
- The application runtime degree
- The SQL statement compilation degree
- MAXIMUM DEGREE service class option
- MAXIMUM DEGREE workload option

If the **intra_parallel** database manager configuration parameter is set to NO, the value of the CURRENT DEGREE special register will be ignored for the purpose of optimization, and the statement will not use intrapartition parallelism.

If DB2_WORKLOAD=ANALYTICS and MAXIMUM DEGREE for the workload is DEFAULT, the value of the **intra_parallel** setting for the workload is overridden to ON.

The value can be changed by invoking the SET CURRENT DEGREE statement.

The initial value of CURRENT DEGREE is determined by the **dft_degree** database configuration parameter.

The value in the CURRENT DEGREE special register and the **intra_parallel** setting can be overridden in a workload by setting the MAXIMUM DEGREE workload attribute.

CURRENT EXPLAIN MODE

The CURRENT EXPLAIN MODE special register holds a VARCHAR(254) value which controls the behavior of the Explain facility with respect to eligible dynamic SQL statements.

The CURRENT EXPLAIN MODE special register holds a VARCHAR(254) value which controls the behavior of the Explain facility with respect to eligible dynamic SQL statements. This facility generates and inserts Explain information into the Explain tables. This information does not include the Explain snapshot. Possible values are YES, EXPLAIN, NO, REOPT, RECOMMEND INDEXES, and EVALUATE INDEXES. (For static SQL, the **EXPLAIN** bind option provides the same control. In the case of the **PREP** and **BIND** commands, the **EXPLAIN** option values are: YES, NO, and ALL).

YES
Enables the Explain facility and causes Explain information for a dynamic SQL statement to be captured when the statement is compiled.

EXPLAIN
Enables the facility, but dynamic statements are not executed.

NO
Disables the Explain facility.

REOPT
Enables the Explain facility and causes Explain information for a dynamic (or incremental-bind) SQL statement to be captured only when the statement is reoptimized using real values for the input variables (host variables, special registers, global variables, or parameter markers).

RECOMMEND INDEXES
Recommends a set of indexes for each dynamic query. Populates the ADVISE_INDEX table with the set of indexes.

EVALUATE INDEXES
Enables the SQL compiler to evaluate virtual recommended indexes for dynamic queries. Queries executed in this explain mode will be compiled and optimized using fabricated statistics based on

the virtual indexes. The statements are not executed. The indexes to be evaluated are read from the ADVISE_INDEX table if the USE_INDEX column contains "Y". Existing non-unique indexes can also be ignored by setting the USE_INDEX column to "I" and the EXISTS column to "Y". If a combination of USE_INDEX="I" and EXISTS="N" is given then index evaluation for the query will continue normally but the index in question will not be ignored.

The initial value is NO. The value can be changed by invoking the SET CURRENT EXPLAIN MODE statement.

The CURRENT EXPLAIN MODE and CURRENT EXPLAIN SNAPSHOT special register values interact when the Explain facility is invoked. The CURRENT EXPLAIN MODE special register also interacts with the EXPLAIN bind option. RECOMMEND INDEXES and EVALUATE INDEXES can only be set for the CURRENT EXPLAIN MODE register, and must be set using the SET CURRENT EXPLAIN MODE statement.

Example: Set the host variable EXPL_MODE (VARCHAR(254)) to the value currently in the CURRENT EXPLAIN MODE special register.

```
VALUES CURRENT EXPLAIN MODE
  INTO :EXPL_MODE
```

CURRENT EXPLAIN SNAPSHOT

The CURRENT EXPLAIN SNAPSHOT special register holds a CHAR(8) value that controls the behavior of the Explain snapshot facility. This facility generates compressed information, including access plan information, operator costs, and bind-time statistics.

Only the following statements consider the value of this register: CALL, Compound SQL (Dynamic), DELETE, INSERT, MERGE, REFRESH, SELECT, SELECT INTO, SET INTEGRITY, UPDATE, VALUES, or VALUES INTO. Possible values are YES, EXPLAIN, NO, and REOPT. (For static SQL, the EXPLSNAP bind option provides the same control. In the case of the PREP and BIND commands, the EXPLSNAP option values are: YES, NO, and ALL.)

YES
Enables the Explain snapshot facility and takes a snapshot of the internal representation of a dynamic SQL statement as the statement is compiled.

EXPLAIN
Enables the Explain snapshot facility, but dynamic statements are not executed.

NO
Disables the Explain snapshot facility.

REOPT
Enables the Explain facility and causes Explain information for a dynamic (or incremental-bind) SQL statement to be captured only when the statement is reoptimized using real values for the input variables (host variables, special registers, global variables, or parameter markers).

The initial value is NO. The value can be changed by invoking the SET CURRENT EXPLAIN SNAPSHOT statement.

The CURRENT EXPLAIN SNAPSHOT and CURRENT EXPLAIN MODE special register values interact when the Explain facility is invoked. The CURRENT EXPLAIN SNAPSHOT special register also interacts with the EXPLSNAP bind option.

Example: Set the host variable EXPL_SNAP (char(8)) to the value currently in the CURRENT EXPLAIN SNAPSHOT special register.

```
VALUES CURRENT EXPLAIN SNAPSHOT
  INTO :EXPL_SNAP
```

CURRENT FEDERATED ASYNCHRONY

The CURRENT FEDERATED ASYNCHRONY special register specifies the degree of asynchrony for the execution of dynamic SQL statements. The FEDERATED_ASYNCHRONY bind option provides the same control for static SQL.

The data type of the register is INTEGER. Valid values are ANY (representing -1) or an integer between 0 and 32 767, inclusive. If, when an SQL statement is dynamically prepared, the value of CURRENT FEDERATED ASYNCHRONY is:

- 0, the execution of that statement will not use asynchrony
- Greater than 0 and less than or equal to 32 767, the execution of that statement can involve asynchrony using the specified degree
- ANY (representing -1), the execution of that statement can involve asynchrony using a degree that is determined by the database manager

The value of the CURRENT FEDERATED ASYNCHRONY special register can be changed by invoking the SET CURRENT FEDERATED ASYNCHRONY statement.

The initial value of the CURRENT FEDERATED ASYNCHRONY special register is determined by the **federated_async** database manager configuration parameter if the dynamic statement is issued through the command line processor (CLP). The initial value is determined by the FEDERATED_ASYNCHRONY bind option if the dynamic statement is part of an application that is being bound.

Example: Set the host variable FEDASYNC (INTEGER) to the value of the CURRENT FEDERATED ASYNCHRONY special register.

```
VALUES CURRENT FEDERATED ASYNCHRONY INTO :FEDASYNC
```

CURRENT IMPLICIT XMLPARSE OPTION

The CURRENT IMPLICIT XMLPARSE OPTION special register specifies the whitespace handling options that are to be used when serialized XML data is implicitly parsed by the database server, without validation.

An implicit non-validating parse operation occurs when an SQL statement is processing an XML host variable or an implicitly or explicitly typed XML parameter marker that is not an argument of the XMLVALIDATE function. The data type of the register is VARCHAR(19).

The value of the CURRENT IMPLICIT XMLPARSE OPTION special register can be changed by invoking the SET CURRENT IMPLICIT XMLPARSE OPTION statement. Its initial value is 'STRIP WHITESPACE'.

Examples

- Retrieve the value of the CURRENT IMPLICIT XMLPARSE OPTION special register into a host variable named CURXMLPARSEOPT:

  ```
  EXEC SQL VALUES (CURRENT IMPLICIT XMLPARSE OPTION) INTO :CURXMLPARSEOPT;
  ```

- Set the CURRENT IMPLICIT XMLPARSE OPTION special register to 'PRESERVE WHITESPACE'.

  ```
  SET CURRENT IMPLICIT XMLPARSE OPTION = 'PRESERVE WHITESPACE'
  ```

  Whitespace is then preserved when the following SQL statement executes:

  ```
  INSERT INTO T1 (XMLCOL1) VALUES (?)
  ```

CURRENT ISOLATION

The CURRENT ISOLATION special register holds a CHAR(2) value that identifies the isolation level (in relation to other concurrent sessions) for any dynamic SQL statements issued within the current session.

The possible values are:

(blanks)
Not set; use the isolation attribute of the package.

UR
Uncommitted Read

CS
Cursor Stability

RR
Repeatable Read

RS
Read Stability

The value of the CURRENT ISOLATION special register can be changed by the SET CURRENT ISOLATION statement.

Until a SET CURRENT ISOLATION statement is issued within a session, or after RESET has been specified for SET CURRENT ISOLATION, the CURRENT ISOLATION special register is set to blanks and is not applied to dynamic SQL statements; the isolation level used is taken from the isolation attribute of the package which issued the dynamic SQL statement. Once a SET CURRENT ISOLATION statement has been issued, the CURRENT ISOLATION special register provides the isolation level for any subsequent dynamic SQL statement compiled within the session, regardless of the settings for the package issuing the statement. This will remain in effect until the session ends or until a SET CURRENT ISOLATION statement is issued with the RESET option.

Example: Set the host variable ISOLATION_MODE (CHAR(2)) to the value currently stored in the CURRENT ISOLATION special register.

```
VALUES CURRENT ISOLATION
  INTO :ISOLATION_MODE
```

CURRENT LOCALE LC_MESSAGES

The CURRENT LOCALE LC_MESSAGES special register identifies the locale that is used by EVMON_UPGRADE_TABLES as well as monitoring routines in the **monreport** module.

EVMON_UPGRADE_TABLES and the monitoring routines use the value of CURRENT LOCALE LC_MESSAGES to determine in which language the result set text output should be returned. User-defined routines that are coded to return messages could also use the value of CURRENT LOCALE LC_MESSAGES to determine what language to use for message text.

The data type is VARCHAR(128).

The initial value of CURRENT LOCALE LC_MESSAGES is "en_US" for English (United States). The value can be changed by invoking the SET CURRENT LOCALE LC_MESSAGES statement.

CURRENT LOCALE LC_TIME

The CURRENT LOCALE LC_TIME special register identifies the locale that is used for SQL statements that involve the datetime related built-in functions.

These functions include DAYNAME, MONTHNAME, NEXT_DAY, ROUND, ROUND_TIMESTAMP, TIMESTAMP_FORMAT, TRUNCATE, TRUNC_TIMESTAMP and VARCHAR_FORMAT. These functions use the value of CURRENT LOCALE LC_TIME if the *locale-name* argument is not explicitly specified.

The data type is VARCHAR(128).

The initial value of CURRENT LOCALE LC_TIME is "en_US" for English (United States). The value can be changed by invoking the SET CURRENT LOCALE LC_TIME statement.

CURRENT LOCK TIMEOUT

The CURRENT LOCK TIMEOUT special register specifies the number of seconds to wait for a lock before returning an error indicating that a lock cannot be obtained. This special register impacts row, table, alter table, online backup, keyvalue, MDC block, reorg, XML path, extent movement, plan, variation, catalog, insert range, dictionary and table serialize locks.

The data type of the register is INTEGER.

Valid values for the CURRENT LOCK TIMEOUT special register are integers between -1 and 32767, inclusive. This special register can also be set to the null value. A value of -1 specifies that timeouts are not to take place, and that the application is to wait until the lock is released or a deadlock is detected. A value of 0 specifies that the application is not to wait for a lock; if a lock cannot be obtained, an error is to be returned immediately.

The value of the CURRENT LOCK TIMEOUT special register can be changed by invoking the SET CURRENT LOCK TIMEOUT statement. The initial value is null; in this case, the current value of the **locktimeout** database configuration parameter is used when waiting for a lock, and this value is returned for the special register.

CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION

The CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register specifies a VARCHAR(254) value that identifies the types of tables that can be considered when optimizing the processing of dynamic SQL queries. Materialized query tables are never considered by static embedded SQL queries.

The initial value of CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION is set to the value of the **dft_mttb_types** database configuration parameter. The default value of **dft_mttb_types** parameter is SYSTEM.

CURRENT MDC ROLLOUT MODE

The CURRENT MDC ROLLOUT MODE special register specifies the behavior on multidimensional clustering (MDC) tables of DELETE statements that qualify for rollout processing.

The default value of this register is determined by the DB2_MDC_ROLLOUT registry variable. The value can be changed by invoking the SET CURRENT MDC ROLLOUT MODE statement. When the CURRENT MDC ROLLOUT MODE special register is set to a particular value, the execution behavior of subsequent DELETE statements that qualify for rollout is impacted. The DELETE statement does not need to be recompiled for the behavior to change.

CURRENT MEMBER

The CURRENT MEMBER special register specifies an INTEGER value that identifies the coordinator member for the statement.

For statements issued from an application, the coordinator is the member to which the application connects. For statements issued from a routine, the coordinator is the member from which the routine is invoked.

When used in an SQL statement inside a routine, CURRENT MEMBER is never inherited from the invoking statement.

CURRENT MEMBER returns 0 if the database instance is not defined to support database partitioning or the IBM Db2 pureScale® Feature. The database instance is not defined for such support if there is no db2nodes.cfg file. For a partitioned database or a Db2 pureScale environment, the db2nodes.cfg file exists and contains database partition and member definitions.

CURRENT MEMBER can be changed through the CONNECT statement, but only under certain conditions.

For compatibility with previous versions of Db2 and with other database products, NODE can be specified in place of MEMBER.

Examples

Example 1: Set the host variable APPL_NODE (integer) to the number of the member to which the application is connected.

```
VALUES CURRENT MEMBER
  INTO :APPL_NODE
```

Example 2: The following command is issued on member 0 and on a 4 member system in a partitioned database environment. This query will retrieve the currently connected database member number.

```
VALUES CURRENT MEMBER

1
-----------
          0
```

CURRENT OPTIMIZATION PROFILE

The CURRENT OPTIMIZATION PROFILE special register specifies the qualified name of the optimization profile to be used by DML statements that are dynamically prepared for optimization.

The initial value is the null value. The value can be changed by invoking the SET CURRENT OPTIMIZATION PROFILE statement. An optimization profile that is not qualified with a schema name will be implicitly qualified with the value of the CURRENT DEFAULT SCHEMA special register.

Example 1: Set the optimization profile to 'JON.SALES'.

```
SET CURRENT OPTIMIZATION PROFILE = JON.SALES
```

Example 2: Get the current value of the optimization profile name for this connection.

```
VALUES (CURRENT OPTIMIZATION PROFILE) INTO :PROFILE
```

CURRENT PACKAGE PATH

The CURRENT PACKAGE PATH special register specifies a VARCHAR(4096) value that identifies the path to be used when resolving references to packages that are needed when executing SQL statements.

The value can be an empty or a blank string, or a list of one or more schema names that are delimited with double quotation marks and separated by commas. Any double quotation marks appearing as part of the string will need to be represented as two double quotation marks, as is common practice with delimited identifiers. The delimiters and commas contribute to the length of the special register.

This special register applies to both static and dynamic statements.

The initial value of CURRENT PACKAGE PATH in a user-defined function, method, or procedure is inherited from the invoking application. In other contexts, the initial value of CURRENT PACKAGE PATH is an empty string. The value is a list of schemas only if the application process has explicitly specified a list of schemas by means of the SET CURRENT PACKAGE PATH statement.

Examples

- An application will be using multiple SQLJ packages (in schemas SQLJ1 and SQLJ2) and a JDBC package (in schema DB2JAVA). Set the CURRENT PACKAGE PATH special register to check SQLJ1, SQLJ2, and DB2JAVA, in that order.

  ```
  SET CURRENT PACKAGE PATH = "SQLJ1", "SQLJ2", "DB2JAVA"
  ```

- Set the host variable HVPKLIST to the value currently stored in the CURRENT PACKAGE PATH special register.

```
VALUES CURRENT PACKAGE PATH INTO :HVPKLIST
```

CURRENT PATH

The CURRENT PATH (or CURRENT_PATH) special register specifies a VARCHAR(2048) value that identifies the SQL path used when resolving unqualified function names, procedure names, data type names, global variable names, and module object names in dynamically prepared SQL statements. CURRENT FUNCTION PATH is a synonym for CURRENT PATH.

The initial value is the default value specified in a following paragraph. For static SQL, the FUNCPATH bind option provides an SQL path that is used for function and data type resolution.

The CURRENT PATH special register contains a list of one or more schema names that are enclosed by double quotation marks and separated by commas. For example, an SQL path specifying that the database manager is to look first in the FERMAT schema, then in the XGRAPHIC schema, and finally in the SYSIBM schema, is returned in the CURRENT PATH special register as:

```
"FERMAT","XGRAPHIC","SYSIBM"
```

The default value is "SYSIBM","SYSFUN","SYSPROC","SYSIBMADM",*X*, where *X* is the value of the USER special register, delimited by double quotation marks. The value can be changed by invoking the SET CURRENT PATH statement. The schema SYSIBM does not need to be specified. If it is not included in the SQL path, it is implicitly assumed to be the first schema. SYSIBM does not take up any of the 2048 bytes if it is implicitly assumed.

A data type that is not qualified with a schema name will be implicitly qualified with the first schema in the SQL path that contains a data type with the same unqualified name. There are exceptions to this rule, as outlined in the descriptions of the following statements: CREATE TYPE (Distinct), CREATE FUNCTION, COMMENT, and DROP.

Example: Using the SYSCAT.ROUTINES catalog view, find all user-defined routines that can be invoked without qualifying the routine name, because the CURRENT PATH special register contains the schema name.

```
SELECT ROUTINENAME, ROUTINESCHEMA FROM SYSCAT.ROUTINES
  WHERE POSITION (ROUTINESCHEMA, CURRENT PATH, CODEUNITS16) <> 0
```

CURRENT QUERY OPTIMIZATION

The CURRENT QUERY OPTIMIZATION special register specifies an INTEGER value that controls the class of query optimization performed by the database manager when binding dynamic SQL statements.

The QUERYOPT bind option controls the class of query optimization for static SQL statements. The possible values range from 0 to 9. For example, if the query optimization class is set to 0 (minimal optimization), then the value in the special register is 0. The default value is determined by the **dft_queryopt** database configuration parameter. The value can be changed by invoking the SET CURRENT QUERY OPTIMIZATION statement.

Example: Using the SYSCAT.PACKAGES catalog view, find all plans that were bound with the same setting as the current value of the CURRENT QUERY OPTIMIZATION special register.

```
SELECT PKGNAME, PKGSCHEMA FROM SYSCAT.PACKAGES
  WHERE QUERYOPT = CURRENT QUERY OPTIMIZATION
```

CURRENT REFRESH AGE

The CURRENT REFRESH AGE special register specifies a time stamp duration value with a data type of DECIMAL(20,6).

The value of the CURRENT REFRESH AGE special register must be 0 - 99999999999999. The default value is determined by the **dft_refresh_age** database configuration parameter. You can change the value by issuing the SET CURRENT REFRESH AGE statement.

The value represents the maximum duration since a particular time-stamped event occurred to a cached data object. The cached data object can be used during this period to help optimize the processing of a query. An example of a time-stamped event is processing a REFRESH TABLE statement on a system-maintained REFRESH DEFERRED materialized query table.

For example, if the CURRENT REFRESH AGE special register has a value of 99999999999999 and the query optimization class is 2 or is greater than or equal to 5, the types of refresh deferred materialized query tables that you specify for the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register are considered during optimization of the processing of a dynamic SQL query.

CURRENT SCHEMA

The CURRENT SCHEMA (or CURRENT_SCHEMA) special register specifies a VARCHAR(128) value that identifies the schema name used to qualify database object references, where applicable, in dynamically prepared SQL statements.

For compatibility with Db2 for z/OS, CURRENT SQLID (or CURRENT_SQLID) can be specified in place of CURRENT SCHEMA.

The initial value of CURRENT SCHEMA is the authorization ID of the current session user. The value can be changed by invoking the SET SCHEMA statement.

The setting of CURRENT SCHEMA does not affect the Explain facility's selection of explain tables.

The QUALIFIER bind option controls the schema name used to qualify database object references, where applicable, for static SQL statements.

Example: Set the schema for object qualification to 'D123'.

```
SET CURRENT SCHEMA =  'D123'
```

CURRENT SERVER

The CURRENT SERVER (or CURRENT_SERVER) special register specifies a VARCHAR(18) value that identifies the current database server (sometimes referred to as the application server). The register contains the actual name of the database, not an alias.

CURRENT SERVER can be changed through the CONNECT statement, but only under certain conditions.

When used in an SQL statement inside a routine, CURRENT SERVER is not inherited from the invoking statement.

Example: Set the host variable APPL_SERVE (VARCHAR(18)) to the name of the database server to which the application is connected.

```
VALUES CURRENT SERVER INTO :APPL_SERVE
```

CURRENT SQL_CCFLAGS

The CURRENT SQL_CCFLAGS special register specifies the conditional compilation named constants that are defined for use during compilation of SQL statements.

The data type of the special register is VARCHAR(1024).

The CURRENT SQL_CCFLAGS special register contains a list of name and value pairs separated by a comma and a blank. The name is separated from the value in a pair using the colon character. The values in the list are a BOOLEAN constant, an INTEGER constant, or the keyword NULL. The names can be specified using any combination of uppercase or lowercase characters which are folded to all uppercase characters. For example, conditional compilation values defined for debug and tracing could appear in the special register as the string value:

```
    CC_DEBUG:TRUE, CC_TRACE_LEVEL:2
```

The initial value of the special register is the value of the **sql_ccflags** database configuration parameter when the special register is first used. The first use can occur as a result of processing a statement with an inquiry directive or as a direct reference to the special register. If the value assigned to the **sql_ccflags** database configuration parameter is not valid, an error is returned on the first use (SQLSTATE 42815 or 428HV).

The value of the special register can be changed by executing the SET CURRENT SQL_CCFLAGS statement.

CURRENT TEMPORAL BUSINESS_TIME

The CURRENT TEMPORAL BUSINESS_TIME special register specifies a TIMESTAMP(12) value that is used in the default BUSINESS_TIME period specification for references to application-period temporal tables.

When an application-period temporal table is referenced and the value in effect for the CURRENT TEMPORAL BUSINESS_TIME special register is represented by *CTBT*, which is the non-null value, the following period specification is implicit:

```
FOR BUSINESS_TIME AS OF CTBT
```

When an application-period temporal table is the target of an UPDATE or DELETE statement and the value in effect for the CURRENT TEMPORAL BUSINESS_TIME special register is not the null value, the following additional predicate is implicit:

```
bt_begin <= CURRENT TEMPORAL BUSINESS_TIME
    AND bt_end > CURRENT TEMPORAL BUSINESS_TIME
```

where `bt_begin` and `bt_end` are the begin and end columns of the BUSINESS_TIME period of the target table of the UPDATE statement.

The initial value of the special register in a user-defined function or procedure is inherited from the invoking application. In other contexts the initial value of the special register is the null value.

The value of this special register can be changed by executing the SET CURRENT TEMPORAL BUSINESS_TIME statement.

The setting of the CURRENT TEMPORAL BUSINESS_TIME special register impacts the following compiled SQL objects when the associated package is bound with the BUSTIMESENSITIVE bind option set to YES:

- SQL procedures
- Compiled functions
- Compiled triggers
- Compound SQL (compiled) statements
- External UDFs

The setting for the BUSTIMESENSITIVE bind option determines whether references to application-period temporal tables and bitemporal tables in both static SQL statements and dynamic SQL statements in a package are affected by the value of the CURRENT TEMPORAL BUSINESS_TIME special register. The bind option can be set to YES or NO.

For the following examples, assume the table IN_TRAY is an application-period temporal table.

Example 1: Based on the state of the messages in IN_TRAY as of the date specified by the CURRENT TEMPORAL BUSINESS_TIME special register, list the user IDs and subject lines.

```
SELECT SOURCE, SUBJECT FROM IN_TRAY
```

Assuming that the CURRENT TEMPORAL BUSINESS_TIME special register was previously set to the value CURRENT TIMESTAMP-4 DAYS and is currently set to the null value, the following statement returns the same result.

```
SELECT SOURCE, SUBJECT
    FROM IN_TRAY
    FOR BUSINESS_TIME AS OF CURRENT TIMESTAMP-4 DAYS
```

Example 2: List the user ID and subject line for the messages in IN_TRAY sent before the date specified by the CURRENT TEMPORAL BUSINESS_TIME special register.

```
SELECT SOURCE, SUBJECT
    FROM IN_TRAY
    WHERE DATE(RECEIVED) < DATE(CURRENT TEMPORAL BUSINESS_TIME)
```

Assuming that the CURRENT TEMPORAL BUSINESS_TIME special register was previously set to '2011-01-01-00.00.00' and is currently set to the null value, the following statement returns the same result.

```
SELECT SOURCE, SUBJECT
   FROM IN_TRAY
   FOR BUSINESS_TIME AS OF '2011-01-01-00.00.00'
   WHERE DATE(RECEIVED) < DATE('2011-01-01-00.00.00')
```

CURRENT TEMPORAL SYSTEM_TIME

The CURRENT TEMPORAL SYSTEM_TIME special register specifies a TIMESTAMP(12) value that is used in the default SYSTEM_TIME period specification for references to system-period temporal tables.

When a system-period temporal table is referenced and the value in effect for the CURRENT TEMPORAL SYSTEM_TIME special register is represented by *CTST*, which is the non-null value, , the following period specification is implicit:

```
FOR SYSTEM_TIME AS OF CTST
```

The initial value of the special register in a user-defined function or procedure is inherited from the invoking application. In other contexts the initial value of the special register is the null value.

The value of this special register can be changed by executing the SET CURRENT TEMPORAL SYSTEM_TIME statement.

The setting of the CURRENT TEMPORAL SYSTEM_TIME special register impacts the following compiled SQL objects when they have been bound with the SYSTIMESENSITIVE bind option set to YES:

- SQL procedures
- Compiled functions
- Compiled triggers
- Compound SQL (compiled) statements
- External UDFs)

The setting for the SYSTIMESENSITIVE bind option determines whether references to system-period temporal tables in both static SQL statements and dynamic SQL statements in a package are affected by the value of the CURRENT TEMPORAL SYSTEM_TIME special register. The bind option can be set to YES or NO.

For the following examples, assume the table IN_TRAY is a system-period temporal table.

Example 1: Based on the state of the messages in IN_TRAY as of the date specified by the CURRENT TEMPORAL SYSTEM_TIME special register, list the user IDs and subject lines.

```
SELECT SOURCE, SUBJECT
    FROM IN_TRAY
```

Assuming that the CURRENT TEMPORAL SYSTEM_TIME special register was previously set to the value CURRENT TIMESTAMP-7 DAYS and is currently set to the null value, the following statement returns the same result.

```
SELECT SOURCE, SUBJECT
    FROM IN_TRAY
    FOR SYSTEM_TIME AS OF CURRENT TEMPORAL SYSTEM_TIME
```

Example 2: List the user ID and subject line for the messages in IN_TRAY sent before the value specified by the CURRENT TEMPORAL SYSTEM_TIME special register.

```
SELECT SOURCE, SUBJECT
    FROM IN_TRAY
    WHERE RECEIVED < CURRENT TEMPORAL SYSTEM_TIME
```

Assuming that the CURRENT TEMPORAL SYSTEM_TIME special register was previously set to '2011-01-01-00.00.00' and is currently set to the null value, the following statement returns the same result.

```
SELECT SOURCE, SUBJECT
    FROM IN_TRAY
    FOR SYSTEM_TIME AS OF '2011-01-01-00.00.00'
    WHERE DATE(RECEIVED) < DATE('2011-01-01-00.00.00')
```

CURRENT TIME

The CURRENT TIME (or CURRENT_TIME) special register specifies a time that is based on a reading of the time-of-day clock when the SQL statement is executed at the application server.

If this special register is used more than once within a single SQL statement, or used with CURRENT DATE or CURRENT TIMESTAMP within a single statement, all values are based on a single clock reading.

When used in an SQL statement inside a routine, CURRENT TIME is not inherited from the invoking statement.

In a federated system, CURRENT TIME can be used in a query intended for data sources. When the query is processed, the time returned will be obtained from the CURRENT TIME register at the federated server, not from the data sources.

Examples

1. Run the following command from the Db2 CLP to obtain the current time.

   ```
   db2 values CURRENT TIME
   ```

2. Using the CL_SCHED table, select all the classes (CLASS_CODE) that start (STARTING) later today. Today's classes have a value of 3 in the DAY column.

   ```
   SELECT CLASS_CODE FROM CL_SCHED
     WHERE STARTING > CURRENT TIME AND DAY = 3
   ```

CURRENT TIMESTAMP

The CURRENT TIMESTAMP (or CURRENT_TIMESTAMP) special register specifies a timestamp that is based on a reading of the time-of-day clock when the SQL statement is executed at the application server.

If this special register is used more than once within a single SQL statement, or used with CURRENT DATE or CURRENT TIME within a single statement, all values are based on a single clock reading. It is possible

for separate CURRENT TIMESTAMP special register requests to return the same value; if unique values are required, consider using the GENERATE_UNIQUE function, a sequence, or an identity column.

If a timestamp with a specific precision is desired, the special register can be referenced as CURRENT TIMESTAMP(*integer*), where *integer* can range from 0 to 12. The default precision is 6. The precision of the clock reading varies by platform and the resulting value is padded with zeros where the precision of the retrieved clock reading is less than the precision of the request.

For example:

- CURRENT TIMESTAMP()
  - Output in Windows: 2015-03-23-09.41.24.684000
  - Output in Linux: 2015-03-23-09.41.24.684842
  - Output in UNIX: 2015-03-23-09.41.24.684842
- CURRENT TIMESTAMP(12)
  - Output in Windows: 2015-03-23-09.41.24.684000000000
  - Output in Linux: 2015-03-23-09.41.24.684842000000
  - Output in UNIX: 2015-03-23-09.41.24.684842000000
- CURRENT TIMESTAMP(6)
  - Output in Windows: 2015-03-23-09.41.24.684000
  - Output in Linux: 2015-03-23-09.41.24.684842
  - Output in UNIX: 2015-03-23-09.41.24.684842
- CURRENT TIMESTAMP(3)
  - Output in Windows: 2015-03-23-09.41.24.684
  - Output in Linux: 2015-03-23-09.41.24.684
  - Output in UNIX: 2015-03-23-09.41.24.684

When used in an SQL statement inside a routine, CURRENT TIMESTAMP is not inherited from the invoking statement.

In a federated system, CURRENT TIMESTAMP can be used in a query intended for data sources. When the query is processed, the timestamp returned will be obtained from the CURRENT TIMESTAMP register at the federated server, not from the data sources.

On a Db2 pureScale instance, with transaction workload balancing enabled, the CURRENT TIMESTAMP special register does not necessarily return increasing values across transactions if those transactions are executed on different members.

SYSDATE can also be specified as a synonym for CURRENT TIMESTAMP(0).

LOCALTIMESTAMP can also be specified as a synonym for CURRENT TIMESTAMP.

LOCALTIMESTAMP(*integer*) can also be specified as a synonym for CURRENT TIMESTAMP(*integer*).

Example: Insert a row into the IN_TRAY table. The value of the RECEIVED column should be a timestamp that indicates when the row was inserted. The values for the other three columns come from the host variables SRC (char(8)), SUB (char(64)), and TXT (VARCHAR(200)).

```
INSERT INTO IN_TRAY
  VALUES (CURRENT TIMESTAMP, :SRC, :SUB, :TXT)
```

CURRENT TIMEZONE

The CURRENT TIMEZONE (or CURRENT_TIMEZONE) special register specifies the difference between UTC (Coordinated Universal Time, formerly known as GMT) and local time at the application server.

The difference is represented by a time duration (a decimal number in which the first two digits are the number of hours, the next two digits are the number of minutes, and the last two digits are the number of seconds). The number of hours is between -24 and 24 exclusive. Subtracting CURRENT TIMEZONE from a local time converts that local time to UTC. The time is calculated from the operating system time at the moment the SQL statement is executed. (The CURRENT TIMEZONE value is determined from C runtime functions.)

The CURRENT TIMEZONE special register can be used wherever an expression of the DECIMAL(6,0) data type is used; for example, in time and timestamp arithmetic.

When used in an SQL statement inside a routine, CURRENT TIMEZONE is not inherited from the invoking statement.

Example: Insert a record into the IN_TRAY table, using a UTC timestamp for the RECEIVED column.

```
INSERT INTO IN_TRAY VALUES (
  CURRENT TIMESTAMP - CURRENT TIMEZONE,
  :source,
  :subject,
  :notetext )
```

CURRENT USER

The CURRENT USER (or CURRENT_USER) special register specifies the authorization ID that is used for statement authorization for the statement in which it was referenced.

For dynamic SQL statements, the value depends on the dynamic SQL statement behavior in effect for the package issuing the dynamic SQL statement in which this special register is referenced. See "Effect of DYNAMICRULES bind option on dynamic SQL" for details. The data type of the register is VARCHAR(128). If the length of the authorization ID is less than 8 bytes, the special register value is padded with trailing blanks such that the length is 8 bytes.

Example: Select table names whose schema matches the value of the CURRENT USER special register.

```
SELECT TABNAME FROM SYSCAT.TABLES
  WHERE TABSCHEMA = CURRENT USER AND TYPE = 'T'
```

If this statement is executed as a static SQL statement, it returns the tables whose schema name matches the binder of the package that includes the statement. If this statement is executed as a dynamic SQL statement using dynamic SQL statement run behavior, it returns the tables whose schema name matches the current value of the SESSION_USER special register.

SESSION_USER

The SESSION_USER special register specifies the current runtime authorization ID that is being used for the current session.

The data type of the register is VARCHAR(128). If the length of the authorization ID is less than 8 bytes, the special register value is padded with trailing blanks such that the length is 8 bytes.

The initial value of SESSION_USER for a new connection is the same as the value of the SYSTEM_USER special register. Its value can be changed by invoking the SET SESSION AUTHORIZATION statement.

SESSION_USER is a synonym for the USER special register.

Example: Determine what routines can be executed by current runtime authorization ID if it were to issue invocations through dynamic SQL.

```
SELECT SCHEMA, SPECIFICNAME FROM SYSCAT.ROUTINEAUTH
  WHERE GRANTEE = SESSION_USER
  AND EXECUTEAUTH IN ('Y', 'G')
```

SYSTEM_USER

The SYSTEM_USER special register specifies the authorization ID of the user that connected to the database.

The value of this register can only be changed by connecting as a user with a different authorization ID. The data type of the register is VARCHAR(128). If the length of the authorization ID is less than 8 bytes, the special register value is padded with trailing blanks such that the length is 8 bytes.

See "Example" in the description of the SET SESSION AUTHORIZATION statement.

USER

The USER special register specifies the runtime authorization ID that is used for the current session.

The data type of the register is VARCHAR(128). If the length of the authorization ID is less than 8 bytes, the special register value is padded with trailing blanks such that the length is 8 bytes.

USER is a synonym for the SESSION_USER special register. SESSION_USER is the preferred spelling.

Example: Select all notes from the IN_TRAY table that were placed there by the user.

```
SELECT * FROM IN_TRAY
  WHERE SOURCE = USER
```

Global variables

A global variable is a named memory variable that is retrieved or modified through SQL statements.

Global variables enable applications to share relational data among SQL statements, without the need for additional application logic to support this data transfer.

A global variable is defined within a schema. A global variable defined in a module within a schema is referred to as a *module global variable*. All other global variables are referred to as *schema global variables*.

The definitions for global variables are recorded in the system catalogs.

Types of global variables

There are three different ways to classify global variables: by the ownership of the variable, by the scope of the value, and by the method used to maintain the value.

Ownership of the variable

A global variable can be classified based on whether the variable is owned by the database manager, or if the variable is user-defined:

- The database manager creates *built-in global variables*. Built-in global variables are registered to the database manager in the system catalog. Built-in global variables belong to the following schema:
  - SYSIBM
  - SYSIBMADM

  Some built-in *module global variables* are located inside modules within the SYSIBMADM schema.
- A user creates a *user-defined global variable* by using an SQL DDL statement. User-defined global variables are registered to the database manager in the system catalog. A *user-defined schema global variable* is created by using the CREATE VARIABLE SQL statement. A *user-defined module global variable* is created using the ADD VARIABLE or PUBLISH VARIABLE option of the ALTER MODULE SQL statement.

Scope of the value

A global variable can be classified as either session or database based on the scope of the value:

- The value of a *session global variable* is uniquely associated with each session that uses this particular global variable. Session global variables are either built-in global variables or user-defined global variables.
- The value of a *database global variable* is a single value that remains the same for all sessions that use this particular global variable. Database global variables are always built-in global variables.

Method by which the value is maintained

A global variable can be classified based on how the variable is maintained:

- A *constant global variable* has a fixed value that is instantiated based on evaluation of the CONSTANT clause when the global variable is first referenced in the session or the database, depending on the scope of the global variable. This type of global variable is created by using the CONSTANT clause in the CREATE VARIABLE statement. A value cannot be assigned to the global variable using an SQL statement. Constant global variables are read-only global variables.
- A *maintained-by-system global variable* has a value that is set by the database manager. A value cannot be assigned using an SQL statement. Only built-in global variables can be defined as maintained-by-system global variables, and most built-in global variables are defined as maintained-by-system global variables. Maintained-by-system global variables are read-only global variables.
- A *maintained-by-user global variable* can be assigned a value using an SQL statement; however, this assignment requires WRITE privilege on the global variable. This type of global variable is the default for user-defined global variables that are defined without using a CONSTANT clause. Built-in global variables can also be defined so values can be assigned using an SQL statement.

Authorization required for global variables

To access a global variable, the authorization ID requires certain privileges or DATAACCESS authority.

Schema global variables

To retrieve the value of a schema global variable, the authorization ID of the statement must have one of these authorizations:

- READ privilege on the schema global variable
- DATAACCESS authority

To specify a schema global variable as the target of a value assignment, the authorization ID of the statement must have one of these authorizations:

- WRITE privilege on the schema global variable
- DATAACCESS authority

Module global variables

If a module global variable is published and is then referenced from outside the module that defined it, the authorization ID of the statement must have one of these authorizations:

- EXECUTE privilege on the module in which the global variable is defined
- DATAACCESS authority

References to module global variables from objects that are defined within the same module as the global variable do not require any authorizations to be held by the authorization ID of the statement.

Resolution of global variable references

Global variable reference resolution depends on whether a global variable name is qualified and where the global variable is referenced.

The order of resolving a global variable reference in relation to the names for a column, SQL variable, SQL parameter, or row variable field is described in "References to SQL parameters, SQL variables, and global variables" in SQL Reference Volume 2.

The implicit qualification of an unqualified global variable name that is used as the main object of a CREATE, ALTER, COMMENT, DROP, GRANT, or REVOKE statement is described in “Unqualified user-defined type, function, procedure, specific, global variable and module names” on page 26.

A best practice is to fully qualify the name of the global variable when referencing the global variable in an SQL statement. This prevents a subsequent change in the SQL path from having an impact on the resolution of the global variable.

The resolution of a global variable reference by the database manager in all other contexts depends on whether the global variable name is qualified.

Qualified names

To resolve the name of a qualified global variable, the reference is evaluated according to the following process:

1. If the global variable reference is made from within a module and the qualifier matches the name of the module, the module is searched for a matching module global variable. The following rules are applied:
   - If the qualifier is a single identifier, the schema name of the module is ignored when the qualifier is compared to the module name.
   - If the qualifier is a two-part identifier, it is compared to the schema-qualified module name.

   If the name of a module global variable matches the unqualified global variable name in the reference, resolution is complete. If the qualifier does not match the name of the module or there is no matching module global variable, resolution continues with the next step.
2. The qualifier is now considered to be a schema name. That specified schema is searched for a matching schema global variable.
   - If a schema global variable name matches the unqualified global variable name in the reference, resolution is complete.
   - If the schema does not exist, then an error is returned.
   - If there are no matching schema global variables in the schema, and the qualifier matched the name of the module in the first step, then an error is returned.
   - Otherwise, resolution continues with the next step.
3. The qualifier is now considered to be a module name. The following rules are applied:
   - If the module name is qualified with a schema name, the module is searched for a matching published module global variable.
   - If the module name is not qualified with a schema name, the schema for the module is the first schema in the SQL path that has a matching module name. If the name of a module matches the schema name that is found in the SQL path, that module is searched for a matching published module global variable.
   - If the module is not found through the SQL path, the existence of a module public alias that matches the name of the global variable qualifier is considered. If a module public alias is found, the module that is associated with the module public alias is searched for a matching published module global variable.

If the name of a published module global variable matches the unqualified global variable name in the global variable reference, resolution is complete. If a matching module is not found or there is no matching module global variable in the matching module, an error is returned.

Unqualified names

To resolve the name of an unqualified global variable, the reference is evaluated according to the following process:

1. If an unqualified global variable reference is made from within a module, the module is searched for a matching module global variable. If a module global variable name matches the global variable name in the reference, resolution is complete. If there is no matching module global variable, resolution continues with the next step.
2. The schemas in the SQL path are searched in order from left to right for a matching schema global variable. If a schema global variable name matches the global variable name in the reference, resolution is complete. If no matching global variable is found after completing this step, an error is returned.

Using global variables

Using global variables requires an understanding of the usage restrictions, the rules for assignment to global variables, and the rules for retrieving global variable values.

Usage restrictions

Global variables can be referenced from within any SQL expression, unless the context of the expression requires that the expression be deterministic. The following situations are examples of contexts that require deterministic expressions and therefore preclude the use of global variables:

- In a table check constraint or data type check constraint
- In the definition of a generated expression column
- In a refresh-immediate materialized query table (MQT)

If the data type of the global variable is a cursor type, then the underlying cursor of the global cursor variable can be referenced anywhere that a *cursor-variable-name* can be specified.

If the data type of the global variable is a row type, a field of the global row variable can be referenced anywhere that a global variable with the same type as the field can be referenced. The global variable name that qualifies the field name is resolved in the same way as any other global variable name.

Assignment

The value of a global variable can be changed if both of the following conditions are true:

- The global variable is not a read-only variable.
- The authorization ID of the statement is authorized to write to the global variable.

A value can be assigned to a global variable using any of the following SQL statements:

- A SET variable statement with a global variable as the target variable
- An EXECUTE, FETCH, SELECT INTO, or VALUE INTO statement with a global variable as an assignment target in the INTO clause
- A CALL statement with a global variable as an argument for an OUT or INOUT parameter of the procedure
- A function invocation with a global variable as an argument for an OUT or INOUT parameter of the function (this is supported only for the source expression of a SET variable statement).

Retrieval

The value of a global variable is obtained by referencing the variable from within the SQL context where the value is needed.

The following table shows when the value of a global variable is read, for the indicated reference of that global variable.

Table 18. When the value of a global variable is read, based on the reference context

Context of the global variable reference	**The reference uses the value of the global variable at the beginning of:**
An SQL statement in a compound SQL (inlined) statement	The compound SQL (inlined) statement
An SQL statement in a compound SQL (compiled) statement	The SQL statement within the compound SQL (compiled) statement
An SQL statement, possibly with a function invocation or a trigger activation[1]	The SQL statement
An SQL statement in an invoked inlined SQL function	The SQL statement invoking the inlined SQL function
An SQL statement in an activated inlined trigger	The SQL statement activating the inlined trigger
An SQL statement in an invoked inlined SQL method	The SQL statement invoking the inlined SQL method
An SQL statement in an invoked compiled SQL function	The SQL statement in the compiled SQL function
An SQL statement in an activated compiled trigger	The SQL statement in the compiled trigger
An SQL statement in an invoked external routine	The SQL statement in the external routine

Note: [1] In this table, the SQL statement that might call a function or activate a trigger does not include the compound SQL (inlined) statement or the compound SQL (compiled) statement.

Functions

A *function* is an operation denoted by a function name followed by one or more operands that are enclosed in parentheses.

A function represents a relationship between a set of input values and a set of result values. The input values to a function are called *arguments*. For example, the TIMESTAMP function can be passed arguments of type DATE and TIME, and the result is a TIMESTAMP.

There are several ways to classify functions.

One way is to classify functions as ether built-in or user-defined.

- *Built-in functions* are functions provided with the database manager. Built-in functions include aggregate functions (for example, AVG), operator functions (for example, +), casting functions (for example, DECIMAL), scalar functions (for example, CEILING), and table functions (for example, BASE_TABLE). Built-in functions are generally defined in schemas that begin with 'SYS' (for example, SYSIBM, SYSFUN, and SYSIBMADM) although some are also defined in schemas that begin with 'DB2' (for example DB2MQ).
- *User-defined functions* are functions that are created using an SQL data definition statement and registered to the database manager in the catalog. *User-defined schema functions* are created using the CREATE FUNCTION statement.*User-defined module functions* are created using the ALTER MODULE ADD FUNCTION or ALTER MODULE PUBLISH FUNCTION statements. A set of *user-defined module functions* is provided with the database manager in a set of modules in a schema called SYSIBMADM. A

user-defined function resides in the schema in which it was created or in the module where it was added or published.

User-defined functions extend the capabilities of the database system by adding function definitions (provided by users or third party vendors) that can be applied in the database engine itself. Extending database functions lets the database exploit the same functions in the engine that an application uses, providing more synergy between application and database.

Another way to classify a user-defined function is as an external function, an SQL function, a sourced function, or an interface function:

- An *external function* is defined to the database with a reference to an object code library, and a function within that library that will be executed when the function is invoked. External functions cannot be aggregate functions.
- An *SQL function* is defined to the database using only SQL statements, including at least one RETURN statement. It can return a scalar value, a row, or a table. SQL functions cannot be aggregate functions.
- A *sourced function* is defined to the database with a reference to another built-in or user-defined function that is already known to the database. Sourced functions can be scalar functions or aggregate functions. They are useful for supporting existing functions with user-defined types.
- An *interface function* is defined to the database with reference to several user-defined routines that are already known to the database. Interface functions can be aggregate functions only.

Another way to classify functions is as scalar, aggregate, row, or table function, depending on the input data values and result values. A *scalar function* is a function that returns a single-valued answer each time it is called. For example, the built-in function SUBSTR() is a scalar function. Scalar UDFs can be either external or sourced.

An *aggregate function* is one which conceptually is passed a set of like values (a column) and returns a single-valued answer. An example of an aggregate function is the built-in function AVG(). A column UDF, which is sourced upon one of the built-in aggregate functions, can be defined. This is useful for distinct types. For example, if there is a distinct type SHOESIZE defined with base type INTEGER, a UDF AVG(SHOESIZE), which is sourced on the built-in function AVG(INTEGER), could be defined, and it would be an aggregate function. An aggregate interface function, which is sourced on multiple user-defined routines, can be defined.

A *row function* is a function that returns one row of values. It can be used in a context where a row expression is supported. It can also be used as a transform function, mapping attribute values of a structured type into values in a row. A row function must be defined as an SQL function.

A *table function* is a function that returns a table to the SQL statement which references it. It may only be referenced in the FROM clause of a SELECT statement. Such a function can be used to apply SQL language processing power to data that does not reside in the database, or to convert such data into a table in the database. A table function can read a file, get data from the Web, or access a Lotus Notes® database and return a result table. This information can be joined with other tables in the database. A table function can be defined as an external function or as an SQL function. (A table function cannot be a sourced function.)

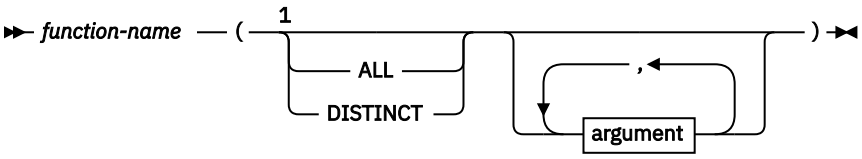
Function signatures

A schema function is identified by its schema name, a function name, the number of parameters, and the data types of its parameters. A module function is identified by its schema name, module name, a function name, the number of parameters, and the data types of its parameters. This identification of a schema function or a module function is called a *function signature*, which must be unique within the database; for example, TEST.RISK(INTEGER). There can be more than one function with the same name in a schema or a module, provided that the number of parameters or the data types of the parameters are different. A function name for which there are multiple function instances with the same number of parameters is called an *overloaded* function. A function name can be overloaded within a schema, in which case there is more than one function by that name with the same number of parameters in the schema. Similarly, a function name can be overloaded within a module, in which case there is more than one function by that name with the same number of parameters in the module. These functions must have different parameter data types. Functions can also be overloaded across the schemas of an SQL

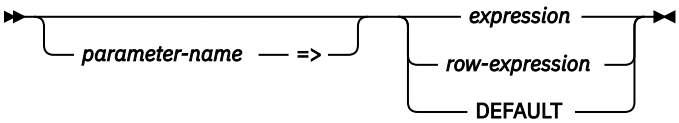
path, in which case there is more than one function by that name with the same number of parameters in different schemas of the SQL path. These functions do not necessarily have different parameter data types.

Function invocation

Each reference to a function conforms to the following syntax:



argument



Notes:

[1] The ALL or DISTINCT keyword can be specified for certain built-in aggregate functions or a user-defined function that is sourced on certain built-in aggregate functions. The ALL keyword can be specified for an aggregate interface function.

In the syntax shown previously, *expression* and *row-expression* cannot include an aggregate function. See "Expressions" for other rules for *expression*.

A function is invoked by referring (in an allowable context) to its qualified or unqualified function name followed by the list of arguments enclosed in parentheses. The possible qualifiers for a function name are:

- A schema name
- An unqualified module name
- A schema-qualified module name

The qualifier used when invoking a function determines the scope used to search for a matching function.

- If a schema-qualified module name is used as the qualifier, the scope is the specified module.
- If a single identifier is used as the qualifier, the scope includes:
  - The schema that matches the qualifier
  - One of the following modules:
    - The invoking module, if the invoking module name matches the qualifier
    - The first module in a schema in the SQL path that matches the qualifier
- If no qualifier is used, the scope includes the schemas in the SQL path and, if the function is invoked from within a module object, the same module from which the function is invoked.

For static SQL statements, the SQL path is specified using the **FUNCPATH** bind option. For dynamic SQL statements, the SQL path is the value of the CURRENT PATH special register.

When any function is invoked, the database manager must determine which function to execute. This process is called *function resolution* and applies to both built-in and user-defined functions. It is recommended that function invocations intending to invoke a user-defined function be fully qualified. This improves performance of function resolution and prevents unexpected function resolution results as new functions are added or privileges granted.

An *argument* is a value passed to a function upon invocation or the specification of DEFAULT. When a function is invoked in SQL, it is passed a list of zero or more arguments. They are positional in that the semantics of an argument are determined by its position in the argument list. A *parameter* is a formal definition of an input to a function or an output from a function. When a function is defined to

the database, either internally (a built-in function) or by a user (a user-defined function), its parameters (zero or more) are specified, and the order of their definitions defines their positions and their semantics. Therefore, every parameter is a particular positional input to a function or an output from a function. On invocation, an argument is assigned to a parameter using either the positional syntax or the named syntax. If using the positional syntax, an argument corresponds to a particular parameter according to its position in the list of arguments. If using the named syntax, an argument corresponds to a particular parameter by the name of the parameter. When an argument is assigned to a parameter using the named syntax, then all the arguments that follow it must also be assigned using the named syntax (SQLSTATE 4274K). The name of a named argument can appear only once in a function invocation (SQLSTATE 4274K). In cases where the data types of the arguments of the function invocation are not a match to the data types of the parameters of the selected function, the arguments are converted to the data type of the parameter at execution time using the same rules as assignment to columns. This includes the case where precision, scale, or length differs between the argument and the parameter. In cases where the arguments of the function invocation are the specification of DEFAULT, the actual value used for the argument is the value specified as the default for the corresponding parameter in the function definition. If no default value was defined for the parameter, the null value is used. If an untyped expression (a parameter marker, a NULL keyword, or a DEFAULT keyword) is used as the argument, the data type associated with the argument is determined by the parameter data type of the parameter of the selected function.

Access to schema functions is controlled through the EXECUTE privilege on the schema functions. If the authorization ID of the statement invoking the function does not have EXECUTE privilege, the schema function will not be considered by the function resolution algorithm, even if it is a better match. Built-in functions in the SYSIBM and SYSFUN schemas have the EXECUTE privilege implicitly granted to PUBLIC.

Access to module functions is controlled through EXECUTE privilege on the module for all functions within the module. The authorization ID of the statement invoking the function might not have EXECUTE privilege on a module. In such cases, module functions within that module, unlike schema functions, are still considered by the function resolution algorithm even though they cannot be executed.

When the user-defined function is invoked, the value of each of its arguments is assigned, using storage assignment, to the corresponding parameter of the function. Control is passed to external functions according to the calling conventions of the host language. When execution of a user-defined scalar function or a user-defined aggregate function is complete, the result of the function is assigned, using storage assignment, to the result data type. For details on the assignment rules, see "Assignments and comparisons".

Table functions can be referenced only in the FROM clause of a subselect. For more information on referencing a table function, see “table-reference” on page 644.

Function resolution

After a function is invoked, the database manager must determine which function to execute. This process is called function resolution and applies for both built-in and user-defined functions.

The database manager first determines the set of candidate functions based on the following information:

- The qualification of the name of the invoked function
- The context that invokes the function
- The unqualified name of the invoked function
- The number of arguments specified
- Any argument names that are specified
- The authorization of schema functions.

See “Determining the set of candidate functions” on page 116 for details.

The database manager then determines the best fit from the set of candidate functions based on the data types of the arguments of the invoked function as compared with the data types of the parameters of the functions in the set of candidate functions. The SQL path and number of parameters is also considered. See “Determining the best fit” on page 117 for details.

Once a function is selected, it is still possible for an error to be returned for one of the following reasons:

- If a module function is selected and either the function is invoked from outside a module or the function is invoked from within a module object and the qualifier does not match the context module name, the authorization ID of the statement that invoked the function must have EXECUTE privilege on the module that contains the selected function (SQLSTATE 42501).
- If a function is selected, its successful use depends on it being invoked in a context in which the returned result is allowed. For example, if the function returns a table where a table is not allowed, an error is returned (SQLSTATE 42887).
- If a cast function is selected, either built-in or user-defined, and any argument would need to be implicitly cast (not promoted) to the data type of the parameter, an error is returned (SQLSTATE 42884).
- If a function invocation involves an argument with an unnamed row type, an error is returned (SQLSTATE 42884) if either of the following conditions occur:
  - The number of fields of the argument does not match the number of fields of the parameter.
  - The data types of the fields of the argument are not assignable to the corresponding data type of the fields of the parameter.

Determining the set of candidate functions

- Let *A* be the number of arguments in a function invocation.
- Let *P* be the number of parameters in a function signature.
- Let *N* be the number of parameters in a function signature without a defined default.

Candidate functions for resolution of a function invocation are selected based on the following criteria:

- Each candidate function has a matching name and applicable number of parameters. An applicable number of parameters satisfies the condition $N \leq A \leq P$.
- Each candidate function has parameters such that for each named argument in the function invocation there exists a parameter with a matching name that does not already correspond to a positional (unnamed) argument.
- Each parameter of a candidate function that does not have a corresponding argument in the function invocation, specified by either position or name, is defined with a default.
- Each candidate function from a set of one or more schemas has the EXECUTE privilege associated with the authorization ID of the statement invoking the function.
- Each candidate function from a module other than the context module is a published module function.

The functions selected for the set of candidate functions are from one or more of the following search spaces.

1. The *context module*, that is, the module which contains the module object that invoked the function
2. A set of one or more schemas
3. A module other than the context module

The specific search spaces considered are affected by the qualification of the name of the invoked function.

- *Qualified function invocation*: When a function is invoked with a function name and a qualifier, the database manager uses the qualifier and, in some cases, the context of the invoked function to determine the set of candidate functions.
  1. If a function is invoked from within a module object using a function name with a qualifier, the database manager considers if the qualifier matches the context module name. If the qualifier is a single identifier, then the schema name of the module is ignored when determining a match. If the qualifier is a two-part identifier, then it is compared to the schema-qualified module name when determining a match. If the qualifier matches the context module name, the database manager searches the context module for candidate functions.

If one or more candidate functions are found in the context module, then this set of candidate functions is processed for best fit without consideration of possible candidate functions in any other search space (see "Determining the best fit"). Otherwise, continue to the next search space.

2. If the qualifier is a single identifier, the database manager considers the qualifier as a schema name and searches that schema for candidate functions.

   If one or more candidate functions are found in the schema, then this set of candidate functions is processed for best fit without consideration of possible candidate functions in any other search space (see "Determining the best fit"). Otherwise, continue to the next search space, if applicable.

3. If the function is invoked from outside a module or the qualifier does not match the context module name when it is invoked from within a module object, the database manager considers the qualifier as a module name. Without considering EXECUTE privilege on modules, the database manager then selects the first module that matches based on the following criteria:
   - If the module name is qualified with a schema name, select the module with that schema name and module name.
   - If the module name is not qualified with a schema name, select the module with that module name that is found in the schema earliest in the SQL path.
   - If the module is not found using the SQL path, select the module public alias with that module name.

   If a matching module is not found, then there are no candidate functions. If a matching module is found, the database manager searches the selected module for candidate functions.

   If one or more candidate functions are found in the selected modules, then this set of candidate functions is processed for best fit (see "Determining the best fit").

- *Unqualified function invocation*: When a function is invoked without a qualifier, the database manager considers the context of the invoked function to determine the sets of candidate functions.

  1. If a function is invoked with an unqualified function name from within a module object, the database manager searches the context module for candidate functions.

     If one or more candidate functions are found in the context module, then these candidate functions are included with any candidate functions from the schemas in the SQL path (see next item).

  2. If a function is invoked with an unqualified function name, either from within a module object or from outside a module, the database manager searches the list of schemas in the SQL path to resolve the function instance to execute. For each schema in the SQL path (see "SQL path"), the database manager searches the schema for candidate functions.

     If one or more candidate functions are found in the schemas in the SQL path, then these candidate functions are included with any candidate functions from the context module (see previous item). This set of candidate functions is processed for best fit (see "Determining the best fit").

If the database manager does not find any candidate functions, an error is returned (SQLSTATE 42884).

Determining the best fit

The set of candidate functions may contain one function or more than one function with the same name. In either case, the data types of the parameters, the position of the schema in the SQL path, and the total number of parameters of each function in the set of candidate functions are used to determine if the function meets the best fit requirements.

If the set of candidate functions contains more than one function and named arguments are used in the function invocation, the ordinal position of the parameter corresponding to a named argument must be the same for all candidate functions (SQLSTATE 4274K).

The term *set of parameters* is used to refer to all of the parameters at the same position in the parameter lists (where such a parameter exists) for the set of candidate functions. The corresponding argument of a parameter is determined based on how the arguments are specified in the function invocation. For positional arguments, the corresponding argument to a parameter is the argument in the same position in the function invocation as the position of the parameter in the parameter list of the candidate function.

For named arguments, the corresponding argument to a parameter is the argument with the same name as the parameter. In this case, the order of the arguments in the function invocation is not considered while determining the best fit. If the number of parameters in a candidate function is greater than the number of arguments in the function invocation, each parameter that does not have a corresponding argument is processed as if it does have a corresponding argument that has the DEFAULT keyword as the value.

The following steps are used to determine the function that is the best fit:

Step 1: Considering arguments that are typed expressions

The database manager determines the function, or set of functions, that meet the best fit requirements for the invocation by comparing the data type of each parameter with the data type of the corresponding argument.

When determining whether the data type of a parameter is the same as the data type of its corresponding argument:

- Synonyms of data types match. For example, FLOAT and DOUBLE are considered to be the same.
- Attributes of a data type such as length, precision, scale, and code page are ignored. Therefore, CHAR(8) and CHAR(35) are considered to be the same, as are DECIMAL(11,2), and DECIMAL(4,3).

A subset of the candidate functions is obtained by considering only those functions for which the data type of each argument of the function invocation that is not an untyped expression matches or is promotable to the data type of the corresponding parameter of the function instance. If the argument of the function invocation is an untyped expression, the data type of the corresponding parameter can be any data type. The precedence list for the promotion of data types in "Promotion of data types" on page 46 shows the data types that fit (considering promotion) for each data type in best-to-worst order. If this subset is not empty, then the best fit is determined using the Promotable process on this subset of candidate functions. If this subset is empty, then the best fit is determined using the Castable process on the original set of candidate functions.

Promotable process

This process determines the best fit only considering whether arguments in the function invocation match or can be promoted to the data type of the corresponding parameter of the function definition. For the subset of candidate functions, the parameter lists are processed from left to right, processing the set of parameters in the first position from the subset of candidate functions before moving on to the set of parameters in the second position, and so on. The following steps are used to eliminate candidate functions from the subset of candidate functions (only considering promotion):

1. If one candidate function has a parameter where the data type of the corresponding argument fits (only considering promotion) the data type of the parameter better than other candidate functions, those candidate functions that do not fit the function invocation equally well are eliminated. The precedence list for the promotion of data types in "Promotion of data types" on page 46 shows the data types that fit (considering promotion) for each data type in best-to-worst order.
2. If the data type of the corresponding argument is an untyped expression, no candidate functions are eliminated.
3. These steps are repeated for the next set of parameters from the remaining candidate functions until there are no more sets of parameters.

Castable process

This process determines the best fit first considering, for each parameter, if the data type of the corresponding argument in the function invocation matches or can be promoted to the data type of the parameter of the function definition. Then, for each set of parameters where no corresponding argument has a data type that was promotable, the database manager considers, for each parameter, if the data type of the corresponding argument can be implicitly cast for function resolution to the data type of the parameter.

For the set of candidate functions, the parameters in the parameter lists are processed from left to right, processing the set of parameters in the first position from all the candidate functions before

moving on to the set of parameters in the second position, and so on. The following steps are used to eliminate candidate functions from the set of candidate functions (only considering promotion):

1. If one candidate function has a parameter where the data type of the corresponding argument fits (only considering promotion) the data type of the parameter better than other candidate functions, those candidate functions that do not fit the function invocation equally well are eliminated. The precedence list for the promotion of data types in "Promotion of data types" on page 46 shows the data types that fit (considering promotion) for each data type in best-to-worst order.
2. If the data type for the corresponding argument is not promotable (which includes the case when the corresponding argument is an untyped expression) to the data type of the parameter of any candidate function, no candidate functions are eliminated.
3. These steps are repeated for the next set of parameters from the remaining candidate functions until there are no more sets of parameters.

If at least one set of parameters has no corresponding argument that fit (only considering promotion) and the corresponding argument for the set of parameters has a data type, the database manager compares each such set of parameters from left to right. The following steps are used to eliminate candidate functions from the set of candidate functions (considering implicit casting).

1. If all the data types of the set of parameters for all remaining candidate functions do not belong to the same data type precedence list, as specified in "Promotion of data types" on page 46, an error is returned (SQLSTATE 428F5).
2. If the data type of the corresponding arguments cannot be implicitly cast to the data type of the parameters, as specified in Implicit casting for function resolution, an error is returned (SQLSTATE 42884).
3. If one candidate function has a parameter where the data type of the corresponding argument fits (considering implicit casting) the data type of the parameter better than other candidate functions, those candidate functions that do not fit the function invocation equally well are eliminated. The data type list in Implicit casting for function resolution shows the data type that fits (considering implicit casting) better.
4. These steps are repeated for the next set of parameters which has no corresponding argument that fit (only considering promotion) and the corresponding argument for the set of parameters has a data type until there are no more such sets of parameters or an error occurs.

Step 2: Considering SQL path

If more than one candidate function remains and a context module exists that still includes candidate functions, the database manager selects those functions. If there is no context module or no candidate functions remain in the context module, the database manager selects those candidate functions whose schema is earliest in the SQL path.

Step 3: Considering number of arguments in the function invocation

If more than one candidate function remains and if one candidate function has a number of parameters that is less than or equal to the number of parameters of the other candidate functions, those candidate functions that have a greater number of parameters are eliminated.

Step 4: Considering arguments that are untyped expressions

If more than one candidate function remains and at least one set of parameters has a corresponding argument that is an untyped expression, the database manager compares each such set of parameters from left to right. The following steps are used to eliminate candidate functions from the set of candidate functions:

1. If all the data types of the set of parameters for all remaining candidate functions do not belong to the same data type precedence list, as specified in "Promotion of data types" on page 46, an error is returned (SQLSTATE 428F5).
2. If the data type of the parameter of one candidate function is further left in the data type ordering for implicit casting than other candidate functions, those candidate functions where the data type

of the parameter is further right in the data type ordering are eliminated. The data type list in "Implicit casting for function resolution" shows the data type ordering for implicit casting.

If there are still multiple candidate functions, an error is returned (SQLSTATE 428F5).

Implicit casting for function resolution

Implicit casting for function resolution is not supported for arguments with a user-defined type, reference type, or XML data type. It is also not supported for built-in or user-defined cast functions. It is supported for the following cases:

- A value of one data type can be cast to any other data type that is in the same data type precedence list, as specified in “Promotion of data types” on page 46.
- A numeric or datetime data type can be cast to:
  - In a Unicode database, a character data type other than CLOB or a graphic data type other than DBCLOB.
  - In a non-Unicode database, a character data type other than CLOB.
- A character data type other than CLOB can be cast to a numeric or datetime data type.
- In a Unicode database, a graphic data type other than DBCLOB can be cast to a numeric or datetime data type.
- A character FOR BIT DATA can be cast to a binary string data type.
- A binary string data type can be cast to a character FOR BIT DATA.
- A TIMESTAMP data type can be cast to a TIME data type.
- A BOOLEAN data type can be cast to a binary integer data type, a character data type other than CLOB, or a graphic data type other than DBCLOB.
- A binary integer data type, a character data type other than CLOB, or a graphic data type other than DBCLOB can be cast to BOOLEAN.
- An untyped argument can be cast to any data type.

Similar to the data type precedence list for promotion, for implicit casting there is an order to the data types that are in the group of related data types. This order is used when performing function resolution that considers implicit casting. Table 19 on page 120 shows the data type ordering for implicit casting for function resolution. The data types are listed in best-to-worst order (note that this is different than the ordering in the data type precedence list for promotion). In a Unicode database, when function resolution selects a built-in function from the SYSIBM schema and implicit casting is necessary for some argument, if the built-in function supports both character input and graphic input for the parameter, the argument is implicitly cast to character.

Table 19. Data type ordering for implicit casting for function resolution

Data type group	**Data type list for implicit casting for function resolution (in best-to-worst order)**
Numeric data types	DECFLOAT, double, real, decimal, BIGINT, INTEGER, SMALLINT
Character and graphic string data types	VARCHAR or VARGRAPHIC, CHAR or GRAPHIC, CLOB or DBCLOB
Binary string data types	VARBINARY, BINARY, BLOB
Datetime data types	TIMESTAMP, DATE

Notes:

1. The lowercase types in the previous table are defined as follows:
   - decimal = DECIMAL (*p*,*s*) or NUMERIC(*p*,*s*)
   - real = REAL or FLOAT(*n*) where *n* is not greater than 24

- double = DOUBLE, DOUBLE-PRECISION, FLOAT or FLOAT(*n*), where *n* is greater than 24

Shorter and longer form synonyms of the listed data types are considered to be the same as the listed form.

2. For a Unicode database only, the following are considered to be equivalent data types:
   - CHAR or GRAPHIC
   - VARCHAR and VARGRAPHIC
   - CLOB and DBCLOB

Table 20. Derived length of an argument when invoking a built-in scalar function from the SYSIBM schema in cases where implicit casting is needed

Source Data Type	Target Type and Length											
	Char	**Graphic**	**Varchar**	**Vargraphic**	**Clob**	**DBclob**	**Binary**	**Varbinary**	**Blob**	**Timestamp**	**Decfloat**	**Boolean**
UNTYPED	127	127	254	254	32767	32767	-	-	32767	12	34	5
SMALLINT	6	6	6	6	-	-	-	-	-	-	-	5
INTEGER	11	11	11	11	-	-	-	-	-	-	-	5
BIGINT	20	20	20	20	-	-	-	-	-	-	-	5
DECIMAL(*p*,*s*)	2+*p*	2+*p*	2+*p*	2+*p*	-	-	-	-	-	-	-	-
REAL	24	24	24	24	-	-	-	-	-	-	-	-
DOUBLE	24	24	24	24	-	-	-	-	-	-	-	-
DECFLOAT	42	42	42	42	-	-	-	-	-	-	-	-
CHAR(*n*)	-	-	-	-	-	-	*n*	*n*	*n*	12	34	-

DATE	10	10	10	10	-	-	-	-	-	-	-	-
TIMESTAMP(*p*)	if *p*=0 then 19 else *p*+20	if *p*=0 then 19 else *p*+20	if *p*=0 then 19 else *p*+20	if *p*=0 then 19 else *p*+20	-	-	-	-	-	-	-	-
BOOLEAN	5	5	5	5	-	-	-	-	-	-	-	-

Note
This table shows character string and graphic string data types in string units associated with a Unicode database environment where the string units default is SYSTEM. If the Unicode database environment has the string units set to CODEUNITS32, then any character string or graphic string length attributes that represent the data type maximum length should be considered to represent the data type maximum in CODEUNITS32. All character string or graphic string data types have the default string units of the database environment.

SQL path considerations for built-in functions

Function resolution applies to all functions, including schema functions and modules functions that are built-in or user-defined. If a function is invoked without its schema name, the SQL path is used to resolve the function invocation to a specific function.

The built-in functions in the SYSIBM schema are always considered during function resolution, even when SYSIBM is not explicitly included in the SQL path. Omission of SYSIBM from the path results in the assumption (for function and data type resolution) that SYSIBM is the first schema on the path.

For example, if a user's SQL path is defined as:

```
"SHAREFUN","SYSIBM","SYSFUN"
```

and there is a LENGTH function defined in schema SHAREFUN with the same number and types of arguments as SYSIBM.LENGTH, then an unqualified reference to LENGTH in this user's SQL statement will result in selecting SHAREFUN.LENGTH. However, if the user's SQL path is defined as:

```
"SHAREFUN","SYSFUN"
```

and the same SHAREFUN.LENGTH function exists, then an unqualified reference to LENGTH in this user's SQL statement will result in selecting SYSIBM.LENGTH, because SYSIBM implicitly appears first in the path.

To minimize potential problems in this area:

- Never use the names of built-in functions for user-defined functions.
- If, for some reason, it is necessary to create a user-defined function with the same name as a built-in function, be sure to qualify any references to it.

Note: Some invocations of built-in functions do not support SYSIBM as an explicit qualifier and resolve directly to the built-in function without considering the SQL path. Specific cases are covered in the description of the built-in function.

Examples of function resolution

The following are examples of function resolution. (Note that not all required keywords are shown.)

- This is an example illustrating the SQL path considerations in function resolution. For this example, there are eight ACT functions, in three different schemas, registered as:

```
CREATE FUNCTION AUGUSTUS.ACT (CHAR(5), INT, DOUBLE) SPECIFIC ACT_1 ...
CREATE FUNCTION AUGUSTUS.ACT (INT, INT, DOUBLE) SPECIFIC ACT_2 ...
CREATE FUNCTION AUGUSTUS.ACT (INT, INT, DOUBLE, INT) SPECIFIC ACT_3 ...
CREATE FUNCTION JULIUS.ACT (INT, DOUBLE, DOUBLE) SPECIFIC ACT_4 ...
CREATE FUNCTION JULIUS.ACT (INT, INT, DOUBLE) SPECIFIC ACT_5 ...
CREATE FUNCTION JULIUS.ACT (SMALLINT, INT, DOUBLE) SPECIFIC ACT_6 ...
CREATE FUNCTION JULIUS.ACT (INT, INT, DECFLOAT) SPECIFIC ACT_7 ...
CREATE FUNCTION NERO.ACT (INT, INT, DEC(7,2)) SPECIFIC ACT_8 ...
```

  The function reference is as follows (where I1 and I2 are INTEGER columns, and D is a DECIMAL column):

```
SELECT ... ACT(I1, I2, D) ...
```

  Assume that the application making this reference has an SQL path established as:

```
"JULIUS","AUGUSTUS","CAESAR"
```

  Following through the algorithm...

  – The function with specific name ACT_8 is eliminated as a candidate, because the schema NERO is not included in the SQL path.
  – The function with specific name ACT_3 is eliminated as a candidate, because it has the wrong number of parameters. ACT_1 and ACT_6 are eliminated because, in both cases, the first argument cannot be promoted to the data type of the first parameter.
  – Because there is more than one candidate remaining, the arguments are considered in order.
  – For the first argument, the remaining functions, ACT_2, ACT_4, ACT_5, and ACT_7 are an exact match with the argument type. No functions can be eliminated from consideration; therefore the next argument must be examined.
  – For this second argument, ACT_2, ACT_5, and ACT_7 are exact matches, but ACT_4 is not, so it is eliminated from consideration. The next argument is examined to determine some differentiation among ACT_2, ACT_5, and ACT_7.

- For the third and last argument, neither ACT_2, ACT_5, nor ACT_7 match the argument type exactly. Although ACT_2 and ACT_5 are equally good, ACT_7 is not as good as the other two because the type DOUBLE is closer to DECIMAL than is DECFLOAT. ACT_7 is eliminated..
- There are two functions remaining, ACT_2 and ACT_5, with identical parameter signatures. The final tie-breaker is to see which function's schema comes first in the SQL path, and on this basis, ACT_5 is the function chosen.

- This is an example of a situation where function resolution will result in an error (SQLSTATE 428F5) since more than one candidate function fits the invocation equally well, but the corresponding parameters for one of the arguments do not belong to the same type precedence list.

  For this example, there are only three function in a single schema defined as follows:

  ```
  CREATE FUNCTION CAESAR.ACT (INT, VARCHAR(5), VARCHAR(5))SPECIFIC ACT_1 ...
  CREATE FUNCTION CAESAR.ACT (INT, INT, DATE)     SPECIFIC ACT_2 ...
  CREATE FUNCTION CAESAR.ACT (INT, INT, DOUBLE)   SPECIFIC ACT_3 ...
  ```

  The function reference is as follows (where I1 and I2 are INTEGER columns, and VC is a VARCHAR column):

  ```
  SELECT ... ACT(I1, I2, VC) ...
  ```

  Assume that the application making this reference has an SQL path established as:

  ```
  "CAESAR"
  ```

  Following through the algorithm ...

  - Each of the candidate functions is evaluated to determine if the data type of each input argument of the function invocation matches or is promotable to the data type of the corresponding parameter of the function instance:
    - For the first argument, all the candidate functions have an exact match with the parameter type.
    - For the second argument, ACT_1 is eliminated because INTEGER is not promotable to VARCHAR.
    - For the third argument, both ACT_2 and ACT_3 are eliminated since VARCHAR is not promotable to DATE or DOUBLE, so no candidate functions remain.
  - Since the subset of candidate functions is empty, the candidate functions are considered using the castable process:
    - For the first argument, all the candidate functions have an exact match with the parameter type.
    - For the second argument, ACT_1 is eliminated since INTEGER is not promotable to VARCHAR. ACT_2 and ACT_3 are better candidates.
    - For the third argument, the data type of the corresponding parameters of ACT_2 and ACT_3 do not belong to the same data type precedence list, so an error is returned (SQLSTATE 428F5).

- This example illustrates a situation where function resolution will succeed using the castable process. For this example, there are only three function in a single schema defined as follows:

  ```
  CREATE FUNCTION CAESAR.ACT (INT, VARCHAR(5), VARCHAR(5))SPECIFIC ACT_1 ...
  CREATE FUNCTION CAESAR.ACT (INT, INT, DECFLOAT)     SPECIFIC ACT_2 ...
  CREATE FUNCTION CAESAR.ACT (INT, INT, DOUBLE)   SPECIFIC ACT_3 ...
  ```

  The function reference is as follows (where I1 and I2 are INTEGER columns, and VC is a VARCHAR column):

  ```
  SELECT ... ACT(I1, I2, VC) ...
  ```

  Assume that the application making this reference has an SQL path established as:

  ```
  "CAESAR"
  ```

  Following through the algorithm ...

– Each of the candidate functions is evaluated to determine if the data type of each input argument of the function invocation matches or is promotable to the data type of the corresponding parameter of the function instance:
  - For the first argument, all the candidate functions have an exact match with the parameter type.
  - For the second argument, ACT_1 is eliminated because INTEGER is not promotable to VARCHAR.
  - For the third argument, both ACT_2 and ACT_3 are eliminated since VARCHAR is not promotable to DECFLOAT or DOUBLE, so no candidate functions remain.
– Since the subset of candidate functions is empty, the candidate functions are considered using the castable process:
  - For the first argument, all the candidate functions have an exact match with the parameter type.
  - For the second argument, ACT_1 is eliminated since INTEGER is not promotable to VARCHAR. ACT_2 and ACT_3 are better candidates.
  - For the third argument, both DECFLOAT and DOUBLE are in the same data type precedence list and VARCHAR can be implicitly cast to both DECFLOAT and DOUBLE. Since DECFLOAT is a better fit for the purpose of implicit casting, ACT_2 is the best fit

- This example illustrates that during function resolution using the castable process that promotion of later arguments takes precedence over implicit casting. For this example, there are only three function in a single schema defined as follows:

```
CREATE FUNCTION CAESAR.ACT (INT, INT, VARCHAR(5))SPECIFIC ACT_1 ...
CREATE FUNCTION CAESAR.ACT (INT, INT, DECFLOAT) SPECIFIC ACT_2 ...
CREATE FUNCTION CAESAR.ACT (INT, INT, DOUBLE)  SPECIFIC ACT_3 ...
```

  The function reference is as follows (where I1 is an INTEGER column, and VC1 is a VARCHAR column and C1 is a CHAR column):

```
SELECT ... ACT(I1, VC1, C1) ...
```

  Assume that the application making this reference has an SQL path established as:

```
"CAESAR"
```

  Following through the algorithm:

  – Each of the candidate functions is evaluated to determine if the data type of each input argument of the function invocation matches or is promotable to the data type of the corresponding parameter of the function instance:
    - For the first argument, all the candidate functions have an exact match with the parameter type.
    - For the second argument, all candidate functions are eliminated since VARCHAR is not promotable to INTEGER, so no candidate functions remain.
  – Since the subset of candidate functions is empty, the candidate functions are considered using the castable process
    - For the first argument, all the candidate functions have an exact match with the parameter type.
    - For the second argument, none of the candidate functions have a parameter to which the corresponding argument can be promoted, so no candidate functions are eliminated.
    - Since the third argument can be promoted to the parameter of ACT_1, but not to the parameters of ACT_2 or ACT_3, ACT_1 is the best fit.

Methods

A database method of a structured type is a relationship between a set of input data values and a set of result values, where the first input value (or *subject argument*) has the same type, or is a subtype of the subject type (also called *subject parameter*), of the method.

For example, a method called CITY, of type ADDRESS, can be passed input data values of type VARCHAR, and the result is an ADDRESS (or a subtype of ADDRESS).

Methods are defined implicitly or explicitly, as part of the definition of a user-defined structured type.

Implicitly defined methods are created for every structured type. *Observer methods* are defined for each attribute of the structured type. Observer methods allow applications to get the value of an attribute for an instance of the type. *Mutator methods* are also defined for each attribute, allowing applications to mutate the type instance by changing the value for an attribute of a type instance. The CITY method described previously is an example of a mutator method for the type ADDRESS.

Explicitly defined methods, or *user-defined methods*, are methods that are registered to a database in SYSCAT.ROUTINES, by using a combination of CREATE TYPE (or ALTER TYPE ADD METHOD) and CREATE METHOD statements. All methods defined for a structured type are defined in the same schema as the type.

User-defined methods for structured types extend the function of the database system by adding method definitions (provided by users or third party vendors) that can be applied to structured type instances in the database engine. Defining database methods lets the database exploit the same methods in the engine that an application uses, providing more synergy between application and database.

External and SQL user-defined methods

A user-defined method can be either external or based on an SQL expression. An external method is defined to the database with a reference to an object code library and a function within that library that will be executed when the method is invoked. A method based on an SQL expression returns the result of the SQL expression when the method is invoked. Such methods do not require any object code library, because they are written completely in SQL.

A user-defined method can return a single-valued answer each time it is called. This value can be a structured type. A method can be defined as *type preserving* (using SELF AS RESULT), to allow the dynamic type of the subject argument to be returned as the returned type of the method. All implicitly defined mutator methods are type preserving.

Method signatures

A method is identified by its subject type, a method name, the number of parameters, and the data types of its parameters. This is called a *method signature*, and it must be unique within the database.

There can be more than one method with the same name for a structured type, provided that:

- The number of parameters or the data types of the parameters are different, or
- The methods are part of the same method hierarchy (that is, the methods are in an overriding relationship or override the same original method), or
- The same function signature (using the subject type or any of its subtypes or supertypes as the first parameter) does not exist.

A method name that has multiple method instances is called an *overloaded method*. A method name can be overloaded within a type, in which case there is more than one method by that name for the type (all of which have different parameter types). A method name can also be overloaded in the subject type hierarchy, in which case there is more than one method by that name in the type hierarchy. These methods must have different parameter types.

A method can be invoked by referring (in an allowable context) to the method name, preceded by both a reference to a structured type instance (the subject argument), and the double dot operator. A list of arguments enclosed in parentheses must follow. Which method is actually invoked depends on the static

type of the subject type, using the method resolution process described in the following section. Methods defined WITH FUNCTION ACCESS can also be invoked using function invocation, in which case the regular rules for function resolution apply.

If function resolution results in a method defined WITH FUNCTION ACCESS, all subsequent steps of method invocation are processed.

Access to methods is controlled through the EXECUTE privilege. GRANT and REVOKE statements are used to specify who can or cannot execute a specific method or a set of methods. The EXECUTE privilege (or DATAACCESS authority) is needed to invoke a method. The definer of the method automatically receives the EXECUTE privilege. The definer of an external method or an SQL method having the WITH GRANT option on all underlying objects also receives the WITH GRANT option with the EXECUTE privilege on the method. The definer (or authorization ID with the ACCESSCTRL or SECADM authority) must then grant it to the user who wants to invoke the method from any SQL statement, or reference the method in any DDL statement (such as CREATE VIEW, CREATE TRIGGER, or when defining a constraint). If the EXECUTE privilege is not granted to a user, the method will not be considered by the method resolution algorithm, even if it is a better match.

Method resolution

After method invocation, the database manager must decide which of the possible methods with the same name is the "best fit". Functions (built-in or user-defined) are not considered during method resolution.

An *argument* is a value passed to a method upon invocation. When a method is invoked in SQL, it is passed the subject argument (of some structured type) and a list of zero or more arguments. They are positional in that the semantics of an argument are determined by its position in the argument list. A *parameter* is a formal definition of an input to a method. When a method is defined to the database, either implicitly (system-generated for a type) or by a user (a user-defined method), its parameters are specified (with the subject parameter as the first parameter), and the order of their definitions defines their positions and their semantics. Therefore, every parameter is a particular positional input to a method. On invocation, an argument corresponds to a particular parameter by virtue of its position in the list of arguments.

The database manager uses the name of the method given in the invocation, EXECUTE privilege on the method, the number and data types of the arguments, all the methods with the same name for the subject argument's static type (and it's supertypes), and the data types of their corresponding parameters as the basis for deciding whether or not to select a method. The following are the possible outcomes of the decision process:

- A particular method is deemed to be the best fit. For example, given the methods named RISK for the type SITE with signatures defined as:

  ```
  PROXIMITY(INTEGER) FOR SITE
  PROXIMITY(DOUBLE) FOR SITE
  ```

  the following method invocation (where ST is a SITE column, DB is a DOUBLE column):

  ```
  SELECT ST..PROXIMITY(DB) ...
  ```

  then, the second PROXIMITY will be chosen.

  The following method invocation (where SI is a SMALLINT column):

  ```
  SELECT ST..PROXIMITY(SI) ...
  ```

  would choose the first PROXIMITY, because SMALLINT can be promoted to INTEGER and is a better match than DOUBLE, which is further down the precedence list.

  When considering arguments that are structured types, the precedence list includes the supertypes of the static type of the argument. The best fit is the function defined with the supertype parameter that is closest in the structured type hierarchy to the static type of the function argument.

- No method is deemed to be an acceptable fit. For example, given the same two functions in the previous case and the following function reference (where C is a CHAR(5) column):

```
SELECT ST..PROXIMITY(C) ...
```

  the argument is inconsistent with the parameter of both PROXIMITY functions.
- A particular method is selected based on the methods in the type hierarchy and the number and data types of the arguments passed on invocation. For example, given methods named RISK for the types SITE and DRILLSITE (a subtype of SITE) with signatures defined as:

```
RISK(INTEGER) FOR DRILLSITE
RISK(DOUBLE) FOR SITE
```

  and the following method invocation (where DRST is a DRILLSITE column, DB is a DOUBLE column):

```
SELECT DRST..RISK(DB) ...
```

  the second RISK will be chosen, because DRILLSITE can be promoted to SITE.

  The following method reference (where SI is a SMALLINT column):

```
SELECT DRST..RISK(SI) ...
```

  would choose the first RISK, because SMALLINT can be promoted to INTEGER, which is closer on the precedence list than DOUBLE, and DRILLSITE is a better match than SITE, which is a supertype.

  Methods within the same type hierarchy cannot have the same signatures, considering parameters other than the subject parameter.

Determining the best fit

A comparison of the data types of the arguments with the defined data types of the parameters of the methods under consideration forms the basis for the decision of which method in a group of like-named methods is the "best fit". Note that the data types of the results of the methods under consideration do not enter into this determination.

For method resolution, whether the data type of the input arguments can be promoted to the data type of the corresponding parameter is considered when determining the best fit. Unlike function resolution, whether the input arguments can be implicitly cast to the data type of the corresponding parameter is not considered when determining the best fit. Modules are not considered during method resolution because methods cannot be defined in modules.

Method resolution is performed using the following steps:

1. First, find all methods from the catalog (SYSCAT.ROUTINES) such that all of the following are true:
   - The method name matches the invocation name, and the subject parameter is the same type or is a supertype of the static type of the subject argument.
   - The invoker has the EXECUTE privilege on the method.
   - The number of defined parameters matches the invocation.
   - Each invocation argument matches the method's corresponding defined parameter in data type, or is "promotable" to it.
2. Next, consider each argument of the method invocation, from left to right. The leftmost argument (and thus the first argument) is the implicit SELF parameter. For example, a method defined for type ADDRESS_T has an implicit first parameter of type ADDRESS_T. For each argument, eliminate all functions that are not the best match for that argument. The best match for a given argument is the first data type appearing in the precedence list corresponding to the argument data type for which there exists a function with a parameter of that data type. Length, precision, scale, and the FOR BIT DATA attribute are not considered in this comparison. For example, a DECIMAL(9,1) argument is considered an exact match for a DECIMAL(6,5) parameter, a DECFLOAT(34) argument is considered

an exact match for a DECFLOAT(16) parameter, and a VARCHAR(19) argument is an exact match for a VARCHAR(6) parameter.

The best match for a user-defined structured-type argument is itself; the next best match is its immediate supertype, and so on for each supertype of the argument. Note that only the static type (declared type) of the structured-type argument is considered, not the dynamic type (most specific type).

3. At most, one candidate method remains after Step 2. This is the method that is chosen.
4. If there are no candidate methods remaining after step 2, an error is returned (SQLSTATE 42884).

Example of method resolution

Following is an example of successful method resolution.

There are seven FOO methods for three structured types defined in a hierarchy of GOVERNOR as a subtype of EMPEROR as a subtype of HEADOFSTATE, registered with the following signatures:

```
CREATE METHOD FOO (CHAR(5), INT, DOUBLE)  FOR HEADOFSTATE SPECIFIC FOO_1 ...
CREATE METHOD FOO (INT, INT, DOUBLE)      FOR HEADOFSTATE SPECIFIC FOO_2 ...
CREATE METHOD FOO (INT, INT, DOUBLE, INT) FOR HEADOFSTATE SPECIFIC FOO_3 ...
CREATE METHOD FOO (INT, DOUBLE, DOUBLE)   FOR EMPEROR     SPECIFIC FOO_4 ...
CREATE METHOD FOO (INT, INT, DOUBLE)      FOR EMPEROR     SPECIFIC FOO_5 ...
CREATE METHOD FOO (SMALLINT, INT, DOUBLE) FOR EMPEROR     SPECIFIC FOO_6 ...
CREATE METHOD FOO (INT, INT, DEC(7,2))    FOR GOVERNOR    SPECIFIC FOO_7 ...
```

The method reference is as follows (where I1 and I2 are INTEGER columns, D is a DECIMAL column and E is an EMPEROR column):

```
SELECT E..FOO(I1, I2, D) ...
```

Following through the algorithm...

- FOO_7 is eliminated as a candidate, because the type GOVERNOR is a subtype (not a supertype) of EMPEROR.
- FOO_3 is eliminated as a candidate, because it has the wrong number of parameters.
- FOO_1 and FOO_6 are eliminated because, in both cases, the first argument (not the subject argument) cannot be promoted to the data type of the first parameter. Because there is more than one candidate remaining, the arguments are considered in order.
- For the subject argument, FOO_2 is a supertype, while FOO_4 and FOO_5 match the subject argument.
- For the first argument, the remaining methods, FOO_4 and FOO_5, are an exact match with the argument type. No methods can be eliminated from consideration; therefore the next argument must be examined.
- For this second argument, FOO_5 is an exact match, but FOO_4 is not, so it is eliminated from consideration. This leaves FOO_5 as the method chosen.

Method invocation

Once the method is selected, there are still possible reasons why the use of the method may not be permitted.

Each method is defined to return a result with a specific data type. If this result data type is not compatible with the context in which the method is invoked, an error will occur. For example, assume that the following methods named STEP are defined, each with a different data type as the result:

```
STEP(SMALLINT) FOR TYPEA RETURNS CHAR(5)
STEP(DOUBLE) FOR TYPEA RETURNS INTEGER
```

and the following method reference (where S is a SMALLINT column and TA is a column of TYPEA):

```
SELECT 3 + TA..STEP(S) ...
```

then, because there is an exact match on argument type, the first STEP is chosen. An error occurs on the statement, because the result type is CHAR(5) instead of a numeric type, as required for an argument of the addition operator.

Starting from the method that has been chosen, the algorithm described in "Dynamic dispatch of methods" is used to build the set of dispatchable methods at compile time. Exactly which method is invoked is described in "Dynamic dispatch of methods".

Note that when the selected method is a type preserving method:

- the static result type following function resolution is the same as the static type of the subject argument of the method invocation
- the dynamic result type when the method is invoked is the same as the dynamic type of the subject argument of the method invocation.

This may be a subtype of the result type specified in the type preserving method definition, which in turn may be a supertype of the dynamic type that is actually returned when the method is processed.

In cases where the arguments of the method invocation were not an exact match to the data types of the parameters of the selected method, the arguments are converted to the data type of the parameter at execution using the same rules as assignment to columns. This includes the case where precision, scale, or length differs between the argument and the parameter, but excludes the case where the dynamic type of the argument is a subtype of the parameter's static type.

Dynamic dispatch of methods

Methods provide the functionality and encapsulate the data of a type. A method is defined for a type and can always be associated with this type. One of the method's parameters is the implicit SELF parameter. The SELF parameter is of the type for which the method has been declared. The argument that is passed as the SELF argument when the method is invoked in a DML statement is called *subject*.

When a method is chosen using method resolution (see “Method resolution” on page 126), or a method has been specified in a DDL statement, this method is known as the "most specific applicable authorized method". If the subject is of a structured type, that method could have one or more overriding methods. A determination is then made to select which method to invoke, based on the dynamic type (most specific type) of the subject at run time. This determination is called "determining the most specific dispatchable method". That process is described here.

1. Find the original method in the method hierarchy that the most specific applicable authorized method is part of. This is called the *root method*.
2. Create the set of dispatchable methods, which includes the following:
   - The most specific applicable authorized method.
   - Any method that overrides the most specific applicable authorized method, and which is defined for a type that is a subtype of the subject of this invocation.
3. Determine the most specific dispatchable method, as follows:
   a. Start with an arbitrary method that is an element of the set of dispatchable methods and that is a method of the dynamic type of the subject, or of one of its supertypes. This is the initial most specific dispatchable method.
   b. Iterate through the elements of the set of dispatchable methods. For each method: If the method is defined for one of the proper subtypes of the type for which the most specific dispatchable method is defined, and if it is defined for one of the supertypes of the most specific type of the subject, then repeat step 2 with this method as the most specific dispatchable method; otherwise, continue iterating.
4. Invoke the most specific dispatchable method.

Example:

Given are three types, "Person", "Employee", and "Manager". There is an original method "income", defined for "Person", which computes a person's income. A person is by default unemployed (a child, a

retiree, and so on). Therefore, "income" for type "Person" always returns zero. For type "Employee" and for type "Manager", different algorithms have to be applied to calculate the income. Hence, the method "income" for type "Person" is overridden in "Employee" and "Manager".

Create and populate a table as follows:

```
CREATE TABLE aTable (id integer, personColumn Person);
  INSERT INTO aTable VALUES (0, Person()), (1, Employee()), (2, Manager());
```

List all persons who have a minimum income of $40000:

```
SELECT id, person, name
  FROM aTable
  WHERE person..income() >= 40000;
```

The method "income" for type "Person" is chosen, using method resolution, to be the most specific applicable authorized method.

1. The root method is "income" for "Person" itself.
2. The second step of the previous algorithm is carried out to construct the set of dispatchable methods:
   - The method "income" for type "Person" is included, because it is the most specific applicable authorized method.
   - The method "income" for type "Employee", and "income" for "Manager" is included, because both methods override the root method, and both "Employee" and "Manager" are subtypes of "Person".

   Therefore, the set of dispatchable methods is: {"income" for "Person", "income" for "Employee", "income" for "Manager"}.
3. Determine the most specific dispatchable method:
   - For a subject whose most specific type is "Person":
     a. Let the initial most specific dispatchable method be "income" for type "Person".
     b. Because there is no other method in the set of dispatchable methods that is defined for a proper subtype of "Person" and for a supertype of the most specific type of the subject, "income" for type "Person" is the most specific dispatchable method.
   - For a subject whose most specific type is "Employee":
     a. Let the initial most specific dispatchable method be "income" for type "Person".
     b. Iterate through the set of dispatchable methods. Because method "income" for type "Employee" is defined for a proper subtype of "Person" and for a supertype of the most specific type of the subject (Note: A type is its own super- and subtype.), method "income" for type "Employee" is a better match for the most specific dispatchable method. Repeat this step with method "income" for type "Employee" as the most specific dispatchable method.
     c. Because there is no other method in the set of dispatchable methods that is defined for a proper subtype of "Employee" and for a supertype of the most specific type of the subject, method "income" for type "Employee" is the most specific dispatchable method.
   - For a subject whose most specific type is "Manager":
     a. Let the initial most specific dispatchable method be "income" for type "Person".
     b. Iterate through the set of dispatchable methods. Because method "income" for type "Manager" is defined for a proper subtype of "Person" and for a supertype of the most specific type of the subject (Note: A type is its own super- and subtype.), method "income" for type "Manager" is a better match for the most specific dispatchable method. Repeat this step with method "income" for type "Manager" as the most specific dispatchable method.
     c. Because there is no other method in the set of dispatchable methods that is defined for a proper subtype of "Manager" and for a supertype of the most specific type of the subject, method "income" for type "Manager" is the most specific dispatchable method.
4. Invoke the most specific dispatchable method.

Conservative binding semantics

Object resolution takes place when defining an SQL object or processing a package bind operation.

The database manager chooses which particular defined SQL object to use for an SQL object referenced in a DDL statement or coded in an application.

At a later time, the database manager might resolve to a different SQL object, even though the original SQL object did not change in any way. This resolution to a different SQL object happens as a result of defining another SQL object (or adding a privilege to an existing function) that the object resolution algorithm defines as resolved ahead of the SQL object originally chosen. Examples of SQL objects and situations to which this resolution to a different SQL object applies include the following situations:

- Routines - a new routine could be defined that is a better fit or that is an equally good fit but earlier in the SQL path; or a privilege could be granted to an existing routine that is a better fit or that is an equally good fit but earlier in the SQL path
- User-defined data types - a new user-defined data type could be defined with the same name and in a schema that is earlier in the SQL path
- Global variables - a new global variable could be defined with the same name and in a schema that is earlier in the SQL path
- Tables or views that resolve using a public alias - an actual table, view, or private alias could be defined with the same name in the current schema
- Sequences that resolve using a public sequence alias - an actual sequence or private sequence alias could be defined with the same name in the current schema
- Modules that resolve to a public module alias - an actual module or private module alias could be defined with the same name in a schema that is in the SQL path

There are instances where the database manager must be able to repeat the resolution of SQL objects as originally resolved when the statement was processed. This is true when the following static objects are used:

- Static DML statements in packages
- Views
- Triggers
- Check constraints
- SQL routines
- Global variables with a user-defined type or default expression
- Routines with a user-defined parameter type or default expression

For static DML statements in packages, SQL object references are resolved during a bind operation. SQL object references in views, triggers, SQL routines, and check constraints are resolved when the SQL object is defined or revalidated. When an existing static object is used, *conservative binding semantics* are applied unless the object has been marked invalid or inoperative by a change in the database schema.

Conservative binding semantics ensure that SQL object references will be resolved using the same SQL path, default schema, and set of routines that were used when it was previously resolved. It also ensures that the timestamp of the definition of the SQL objects considered during conservative binding resolution is not later than the timestamp when the statement was last bound or validated using *non-conservative binding* semantics. Non-conservative binding semantics use the same SQL path and default schema as the original generation of the package or statement, but does not consider the timestamp of the definition of the SQL objects and does not consider any previously resolved set of routines.

Some changes to the database schema, such as dropping objects, altering objects, or revoking privileges, can impact an SQL object so that the database manager can no longer resolve all dependent SQL objects of an existing SQL object using conservative binding semantics.

- When this happens for a static statement in an SQL package, the package is marked inoperative. The next use of a statement in this package will cause an implicit rebind of the package using non-

conservative binding semantics in order to be able to resolve to SQL objects considering the latest changes in the database schema that caused that package to become inoperative.

- When this happens for a view, trigger, check constraint, or SQL routine, the SQL object is marked invalid. The next use of the object causes an implicit revalidation of the SQL object using non-conservative binding semantics.

Consider a database with two functions that have the signatures SCHEMA1.BAR(INTEGER) and SCHEMA2.BAR(DOUBLE). Assume the SQL path contains both schemas SCHEMA1 and SCHEMA2 (although their order within the SQL path does not matter). USER1 has been granted the EXECUTE privilege on the function SCHEMA2.BAR(DOUBLE). Suppose USER1 creates a view that invokes BAR(INT_VAL), where INT_VAL is a column or global variable defined with the INTEGER data type. This function reference in the view resolves to the function SCHEMA2.BAR(DOUBLE) because USER1 does not have the EXECUTE privilege on SCHEMA1.BAR(INTEGER). If USER1 is granted the EXECUTE privilege on SCHEMA1.BAR(INTEGER) after the view has been created, the view will continue to use SCHEMA2.BAR(DOUBLE) unless a database schema change causes the view to be marked invalid. The view is marked invalid if a required privilege is revoked or an object it depends on gets dropped or altered.

For static DML in packages, packages can rebind implicitly, or by explicitly issuing the REBIND command (or corresponding API), or the BIND command (or corresponding API). The implicit rebind is performed with conservative binding semantics if the package is marked invalid, but uses non-conservative binding semantics when the package is marked inoperative. A package is marked invalid only if an index on which it depends is dropped or altered. The REBIND command provides the option to resolve with conservative binding semantics (RESOLVE CONSERVATIVE) or to resolve by considering new routines, data types, or global variables (RESOLVE ANY, which is the default option). The RESOLVE CONSERVATIVE option can be used only if the package has not been marked inoperative by the database manager (SQLSTATE 51028).

The description of conservative binding semantics in this topic has assumed that the database configuration parameter **auto_reval** has a setting other than DISABLED. The default setting for **auto_reval** for new databases is DEFERRED. The default setting for **auto_reval** for databases upgraded to Version 9.7 is DISABLED. If **auto_reval** is set to DISABLED, then conservative binding semantics, invalidation, and revalidation behavior are the same as in releases previous to Version 9.7. Under a **auto_reval** setting of DISABLED, conservative binding semantics only considers the timestamp of the definition of the SQL objects for functions, methods, user-defined types, and global variables. For invalidation and revalidation behavior, this means, in the case of the DROP, REVOKE, and ALTER statements, that either the semantics are more restrictive or the impact on dependent objects is to cascade and drop the object. In the case of packages, most database schema changes result in marking the package invalid and using conservative binding semantics during implicit rebind. However, when the schema is changed by dropping a dependent function and **auto_reval** is set to DISABLED, the package dependent on the function is marked inoperative and there is no implicit rebind of the inoperative package.

Expressions

An expression specifies a value. It can be a simple value, consisting of only a constant or a column name, or it can be more complex. If you repeatedly use similar complex expressions, consider using an SQL function to encapsulate a common expression.

Authorization

The use of some of the expressions, such as a scalar-subselect, sequence-reference, or function-invocation, might require special authorization. For these expressions, the privileges held by the authorization ID of the statement must include the following authorizations:

scalar-subselect
For information about authorization considerations, see "SQL Queries".

sequence-reference
The authorization to reference the sequence. For information about authorization considerations, see "Sequence authorization".

function-invocation
The authorization to execute a user-defined function. For information about authorization considerations, see the "Function invocation" section in "Functions".

variable
If the variable is a global variable, the authorization to reference the global variable is required. For information, see "Global variables".

In a Unicode database, an expression that accepts a character or graphic string will accept any string types for which conversion is supported.

[20] The || operator can be used as a synonym for CONCAT.

Expressions without operators

If no operators are used, the result of the expression is the specified value. For example:

```
SALARY:SALARY'SALARY'MAX(SALARY)
```

Expressions with the concatenation operator

The concatenation operator (CONCAT or ||) combines two operands to form a *string expression*.

The first operand is an expression that returns a value of any string data type, any numeric data type, or any datetime data type. The second operand is also an expression that returns a value of any string data type, any numeric data type, or any datetime data type. However, some data types are not supported in combination with the data type of the first operand, as described in the remainder of this section.

Each operand can be of any of the following types:

- String (except binary string)

- Numeric (this is implicitly cast to VARCHAR)
- Datetime (this is implicitly cast to VARCHAR)
- Boolean (this is implicitly cast to VARCHAR)

However, a binary string can be concatenated only with another binary string or with a character string that is defined as FOR BIT DATA.

Concatenation involving both character string operands and graphic string operands is supported only in a Unicode database. Character operands are first converted to the graphic data type before the concatenation. Character strings defined as FOR BIT DATA cannot be cast to the graphic data type.

If either operand can be null, the result can be null, and if either is null, the result is the null value. Otherwise, the result consists of the first operand string followed by the second. Note that no check is made for improperly formed mixed data when doing concatenation.

The length of the result is the sum of the lengths of the operands. In a Unicode database, the string unit of the result is the maximum string unit of the operands, as described in "Rules for result data types".

The data type and length attribute of the result is determined from that of the operands as shown in the following table unless an operand is defined with CODEUNITS32:

Table 21. Data Type and Length of Concatenated Operands without CODEUNITS32

Operands	**Combined Length Attributes**[1]	**Result**
CHAR(A) CHAR(B)	<256	CHAR(A+B)
CHAR(A) CHAR(B)	>255	VARCHAR(A+B)
CHAR(A) VARCHAR(B)	<4001	VARCHAR(A+B)

BLOB(A) VARBINARY(B)	-	BLOB(MIN(A+B, 2147483647))
BLOB(A) VARCHAR(B) FOR BIT DATA	-	BLOB(MIN(A+B, 2147483647))
BLOB(A) BLOB(B)	-	BLOB(MIN(A+B, 2147483647))
Notes [1] The numbers specified for the Combined Length Attributes are listed in OCTETS for character strings and CODEUNITS16 for graphic strings. Refer to the next table if an operand is defined with CODEUNITS32.		

If an operand is defined with CODEUNITS32, the other operand cannot be defined as FOR BIT DATA. Otherwise, when an operand is defined with CODEUNITS32, the data type and length attribute of the result is determined from that of the operands as shown in the following table:

Table 22. Data Type and Length of Concatenated Operands with CODEUNITS32		
Operands	**Combined Length Attributes**	**Result**
CHAR(A) CHAR(B)	<64	CHAR(A+B)
CHAR(A) CHAR(B)	>63	VARCHAR(A+B)
CHAR(A) VARCHAR(B)	-	VARCHAR(MIN(A+B, 8168))

Table 22. Data Type and Length of Concatenated Operands with CODEUNITS32 (continued)		
Operands	**Combined Length Attributes**	**Result**
VARCHAR(A) VARCHAR(B)	-	VARCHAR(MIN(A+B, 8168))
CLOB(A) CHAR(B)	-	CLOB(MIN(A+B, 536870911))
CLOB(A) VARCHAR(B	-	CLOB(MIN(A+B, 536870911))
CLOB(A) CLOB(B)	-	CLOB(MIN(A+B, 536870911))
GRAPHIC(A) GRAPHIC(B)	<64	GRAPHIC(A+B)
GRAPHIC(A) GRAPHIC(B)	>63	VARGRAPHIC(A+B)
GRAPHIC(A) VARGRAPHIC(B)	-	VARGRAPHIC(MIN(A+B, 8168))
VARGRAPHIC(A) VARGRAPHIC(B)	-	VARGRAPHIC(MIN(A+B, 8168))
DBCLOB(A) CHAR(B)	-	DBCLOB(MIN(A+B, 536870911))
DBCLOB(A) VARCHAR(B)	-	DBCLOB(MIN(A+B, 536870911))
DBCLOB(A) DBCLOB(B)	-	DBCLOB(MIN(A+B, 536870911))

For compatibility with previous versions or other database products, there is no automatic escalation of results involving LONG VARCHAR or LONG VARGRAPHIC data types to LOB data types. For example, concatenation of a CHAR(200) value and a completely full LONG VARCHAR value would result in an error rather than in a promotion to a CLOB data type.

The code page of the result is considered a derived code page and is determined by the code page of its operands.

One operand may be a parameter marker. If a parameter marker is used, then the data type and length attributes of that operand are considered to be the same as those for the non-parameter marker operand. The order of operations must be considered to determine these attributes in cases with nested concatenation.

Example 1: If FIRSTNME is Pierre and LASTNAME is Fermat, then the following:

```
    FIRSTNME CONCAT ' ' CONCAT LASTNAME
```

returns the value `Pierre Fermat`.

Example 2: Given:

- The column `COLA` is defined as VARCHAR(5) and the value `'AA'` was inserted into it.
- The character host variable `:host_var` is defined with length 5 and value `'BB  '`.
- The column `COLC` defined as CHAR(5) and the value `'CC'` was inserted into it.
- The column `COLD` defined as CHAR(5) and the value `'DDDDD'` was inserted into it.

The value of `COLA` **`CONCAT`** `:host_var` **`CONCAT`** `COLC` **`CONCAT`** `COLD` is `'AABB  CC  DDDDD'`

The data type of the result is VARCHAR and its length attribute is 2+5+5+5=17. The result code page is the section code page. For more information about section code pages, see "Derivation of code page values".

Example 3: Given:

- `COLA` defined as CHAR(10)
- `COLB` defined as VARCHAR(5)

The parameter marker in the expression:

```
COLA CONCAT COLB CONCAT ?
```

is considered VARCHAR(15), because COLA CONCAT COLB is evaluated first, giving a result that is the first operand of the second CONCAT operation.

User-defined types and the concatenation operator

A weakly typed distinct type is the only user-defined type that can be used with the concatenation operator. The source type of the weakly typed distinct type is used as the data type of the operand when processing the concatenation operator.

A strongly typed user-defined type cannot be used with the concatenation operator, even if it is a strongly typed distinct type with a source data type that is a string type. To concatenate, create a function with the CONCAT operator as its source. For example, if there were distinct types TITLE and TITLE_DESCRIPTION, both of which had VARCHAR(25) data types, the following user-defined function, ATTACH, can be used to concatenate them.

```
CREATE FUNCTION ATTACH (TITLE, TITLE_DESCRIPTION)
  RETURNS VARCHAR(50) SOURCE CONCAT (VARCHAR(), VARCHAR())
```

Alternately, the concatenation operator can be overloaded using a user-defined function to add the new data types.

```
CREATE FUNCTION CONCAT (TITLE, TITLE_DESCRIPTION)
  RETURNS VARCHAR(50) SOURCE CONCAT (VARCHAR(), VARCHAR())
```

Expressions with arithmetic operators

If an expression uses arithmetic operators, the result of the expression is a value derived from the application of the operators to the values of the operands. These operators can be specified using either infix or prefix notation. For example, the statements a+b and "+"(a,b) are equivalent.

If any operand in an arithmetic expression can be null, or if the database is configured with **dft_sqlmathwarn** set to *yes*, the result can be null. If any operand in an arithmetic expression has the null value, the result of the expression is the null value.

Arithmetic operators can be applied to signed numeric types and datetime types (see "Datetime arithmetic in SQL" on page 147). For example, USER+2 is invalid. When any operand of an arithmetic operation is a weakly typed distinct type, the operation is performed assuming that the data type of the operand is the source type of the weakly typed distinct type. Sourced functions can be defined for arithmetic operations on strongly typed distinct types with a source type that is a signed numeric type.

The unary plus (+) prefix operator does not change its operand. The unary minus (-) prefix operator reverses the sign of:

- A nonzero non-decimal floating-point operand
- A decimal floating-point operand, including 0, -0, quiet NaNs, signalling NaNs, +infinity, and -infinity

If the data type of a value x is small integer, the data type of -x is large integer. The first character of the token following a prefix operator cannot be a plus (+) or minus (-) symbol.

Table 23. Binary Arithmetic Operators

Arithmetic Operator	Name	Description
+	Addition	The result is the sum of the first and second arguments.
-	Subtraction	The result is the first argument minus the second argument.
*	Multiplication	The result is the first argument multiplied by the second argument.

Table 23. Binary Arithmetic Operators (continued)		
Arithmetic Operator	**Name**	**Description**
/	Division	The result is the first argument divided by the second argument. The value of the second operand may not be zero, unless the calculation is performed using decimal floating-point arithmetic.
%	Modulo	The result is the remainder of the first argument divided by the second argument.
**	Exponential	The result is the first argument raised to the power of the second argument. The data type of the result is: • INTEGER if both arguments are of type INTEGER or SMALLINT • BIGINT if one argument is of type BIGINT and the other argument is of type BIGINT, INTEGER, or SMALLINT • DECFLOAT(34) if either or both arguments are of type DECFLOAT, unless one of the following statements is true, in which case the result is of type NAN and an invalid operation condition is issued: – Both arguments are zero. – The second argument has a nonzero fractional part. – The second argument has more than 9 digits. – The second argument is INFINITY. • DOUBLE otherwise

Before an arithmetic operation is performed, an operand that is a non-LOB string is converted to DECFLOAT(34) using the rules for CAST specification. For more information, see "Casting between data types" on page 47. Arithmetic operations involving graphic string operands can be performed only for Unicode databases.

Arithmetic errors

If an arithmetic error such as divide-by-zero or a numeric overflow occurs during the processing of an non-decimal floating-point expression, an error is returned (SQLSTATE 22003 or 22012). For decimal floating-point expressions, a warning is returned (SQLSTATEs 0168C, 0168D, 0168E, or 0168F, depending on the nature of the arithmetic condition).

A database can be configured (using **dft_sqlmathwarn** set to YES) so that arithmetic errors return a null value for the non-decimal floating-point expression, the query returns a warning (SQLSTATE 01519 or 01564), and proceeds with processing the SQL statement.

For decimal floating-point expressions, the setting of **dft_sqlmathwarn** has no effect; arithmetic conditions return an appropriate value (possibly a decimal floating-point special value), the query returns a warning (SQLSTATEs 0168C, 0168D, 0168E, or 0168F), and proceeds with processing of the SQL statement. Special values returned include plus and minus infinity and not a number. Arithmetic expressions involving one or more decimal floating-point numbers never evaluate to a null value unless one or more of the arguments to the expression are null.

When arithmetic errors are treated as nulls, there are implications on the results of SQL statements. The following are some examples of these implications.

- An arithmetic error that occurs in the expression that is the argument of an aggregate function causes the row to be ignored in the determining the result of the aggregate function. If the arithmetic error was an overflow, this may significantly impact the result values.

- An arithmetic error that occurs in the expression of a predicate in a WHERE clause can cause rows to not be included in the result.
- An arithmetic error that occurs in the expression of a predicate in a check constraint results in the update or insert proceeding since the constraint is not false.

If these types of impacts are not acceptable, additional steps should be taken to handle the arithmetic error to produce acceptable results. Examples:

- Add a case expression to check for divide-by-zero and set the required value for such a situation
- Add additional predicates to handle nulls (like a check constraint on not nullable columns could become:

  ```
  check (c1*c2 is not null and c1*c2>5000)
  ```

  to cause the constraint to be violated on an overflow).

Two integer operands

If both operands of an arithmetic operator are integers, the operation is performed in binary and the result is a *large integer* unless either (or both) operand is a big integer, in which case the result is a big integer. Any remainder of division is lost. The result of an integer arithmetic operation (including negation by means of a unary minus operator) must be within the range of the result type.

Integer and decimal operands

If one operand is an integer and the other is a decimal, the operation is performed in decimal using a temporary copy of the integer that has been converted to a decimal number with precision *p* and scale 0; *p* is 19 for a big integer, 11 for a large integer, and 5 for a small integer.

Two decimal operands

If both operands are decimal, the operation is performed in decimal. The result of any decimal arithmetic operation is a decimal number with a precision and scale that are dependent on the operation and the precision and scale of the operands. If the operation is addition or subtraction and the operands do not have the same scale, the operation is performed with a temporary copy of one of the operands. The copy of the shorter operand is extended with trailing zeros so that its fractional part has the same number of digits as the longer operand.

The result of a decimal operation cannot have a precision greater than 31. The result of decimal addition, subtraction, and multiplication is derived from a temporary result which can have a precision greater than 31. If the precision of the temporary result is not greater than 31, the final result is the same as the temporary result.

Decimal arithmetic in SQL

Use the formulas shown here to calculate the precision and scale of the result of decimal operations in SQL. The formulas use the following symbols:

p
Precision of the first operand.

s
Scale of the first operand.

p'
Precision of the second operand.

s'
Scale of the second operand.

Addition and subtraction
The scale of the result is `MAX(s,s')`. If DEC15 mode is in effect and p<15 and p'<15, the precision is `MIN(15,MAX(p-s,p'-s')+MAX(s,s')+1)`. Otherwise, the precision is `MIN(31,MAX(p-s,p'-s')+MAX(s,s')+1)`.

Multiplication
If DEC15 mode is in effect and p<15 and p'<15, the precision is `MIN(15,p+p')` and the scale is `MIN(15,s+s')`. Otherwise the precision is `MIN(31,p+p')` and the scale is `MIN(31,s+s')`.

Division
The following table shows the result precision and scale based on various factors.

Table 24. Precision and scale of the result of a decimal division

DECIMAL arithmetic mode[1]	p	p'	Result precision	Result scale
default	n/a	n/a	31	`31-p+s-s'`
DEC15	<=15	<=15	15	`15-(p-s+s')`
DEC15	>15	<=15	31	*N*`-(p-s+s')`, where: • *N* is `30-p' if p'` is odd • *N* is `29-p' if p'` is even
DEC31	n/a	<=15	31	*N*`-(p-s+s')`, where: • *N* is `30-p' if p'` is odd • *N* is `29-p' if p'` is even
DEC15 or DEC31	n/a	>15	31	`15-(p-s+MAX(0,s'-(p'-15)))`

Note:

1. These modes are determined by the **dec_arithmetic** configuration parameter.

If a minimum DECIMAL division scale *S* is in effect, then the scale is the minimum of *S* and the scale derived from Table 24 on page 141. Otherwise, a negative scale results in an error (SQLSTATE 42911).

Exponential
The result type is DOUBLE.

Floating-point operands

If either operand of an arithmetic operator is floating-point, but not decimal floating-point, the operation is performed in floating-point. The operands are first converted to double-precision floating-point numbers, if necessary. Thus, if any element of an expression is a floating-point number, the result of the expression is a double-precision floating-point number.

An operation involving a floating-point number and an integer is performed with a temporary copy of the integer which has been converted to double-precision floating-point. An operation involving a floating-point number and a decimal number is performed with a temporary copy of the decimal number which has been converted to double-precision floating-point. The result of a floating-point operation must be within the range of floating-point numbers.

The order in which floating-point operands (or arguments to functions) are processed can slightly affect results because floating-point operands are approximate representations of real numbers. Since the order in which operands are processed may be implicitly modified by the optimizer (for example, the optimizer may decide what degree of parallelism to use and what access plan to use), an application that uses floating-point operands should not depend on the results being precisely the same each time an SQL statement is executed.

Decimal floating-point operands

If either operand of an arithmetic operator is decimal floating-point, the operation is performed in decimal floating-point.

Integer and decimal floating-point operands
If one operand is a small integer or large integer and the other is a DECFLOAT(*n*) number, the operation is performed in DECFLOAT(*n*) using a temporary copy of the integer that has been converted to a DECFLOAT(*n*) number. If one operand is a big integer, and the other is a decimal floating-point number, a temporary copy of the big integer is converted to a DECFLOAT(34) number. The rules for two-decimal floating-point operands then apply.

Decimal and decimal floating-point operands
If one operand is a decimal and the other is a decimal floating-point number, the operation is performed in decimal floating-point using a temporary copy of the decimal number that has been converted to a decimal floating-point number based on the precision of the decimal number. If the decimal number has a precision less than 17, the decimal number is converted to a DECFLOAT(16) number; otherwise, the decimal number is converted to a DECFLOAT(34) number. The rules for two-decimal floating-point operands then apply.

Floating-point and decimal floating-point operands
If one operand is a floating-point number (REAL or DOUBLE) and the other is a DECFLOAT(*n*) number, the operation is performed in decimal floating-point using a temporary copy of the floating-point number that has been converted to a DECFLOAT(*n*) number.

Two decimal floating-point operands
If both operands are DECFLOAT(*n*), the operation is performed in DECFLOAT(*n*). If one operand is DECFLOAT(16) and the other is DECFLOAT(34), the operation is performed in DECFLOAT(34).

General arithmetic operation rules for decimal floating-point

The following general rules apply to all arithmetic operations on the decimal floating-point data type:

- Every operation on finite numbers is carried out as though an exact mathematical result is computed, using integer arithmetic on the coefficient, where possible.

  If the coefficient of the theoretical exact result has no more than the number of digits that reflect its precision (16 or 34), it is used for the result without change (unless there is an underflow or overflow condition). If the coefficient has more than the number of digits that reflect its precision, it is rounded to exactly the number of digits that reflect its precision (16 or 34), and the exponent is increased by the number of digits that are removed.

  The CURRENT DECFLOAT ROUNDING MODE special register determines the rounding mode.

  If the value of the adjusted exponent of the result is less than E_{min}, the calculated coefficient and exponent form the result, unless the value of the exponent is less than E_{tiny}, in which case the exponent is set to E_{tiny}, the coefficient is rounded (possibly to zero) to match the adjustment of the exponent, and the sign remains unchanged. If this rounding gives an inexact result, an underflow exception condition is returned.

  If the value of the adjusted exponent of the result is larger than E_{max}, an overflow exception condition is returned. In this case, the result is defined as an overflow exception condition and might be infinite. It has the same sign as the theoretical result.
- Arithmetic that uses the special value infinity follows the usual rules, where negative infinity is less than every finite number and positive infinity is greater than every finite number. Under these rules, an infinite result is always exact. Certain uses of infinity return an invalid operation condition. The following list shows the operations that can cause an invalid operation condition. The result of such an operation is a NaN when one of the operands is infinity but the other operand is not a NaN (quiet or signalling).
  - Add +infinity to -infinity during an addition or subtraction operation
  - Multiply 0 by +infinity or -infinity
  - Divide either +infinity or -infinity by either +infinity or -infinity

– Either argument of the QUANTIZE function is +infinity or -infinity
– The second argument of the POWER function is +infinity or -infinity
– A signaling NaN is an operand of an arithmetic operation

The following rules apply to arithmetic operations and the NaN value:

– The result of any arithmetic operation that has a NaN (quiet or signalling) operand is NaN. The sign of the result is copied from the first operand that is a signalling NaN; if neither operand is signalling, the sign is copied from the first operand that is a NaN. Whenever a result is a NaN, the sign of the result depends only on the copied operand.
– The sign of the result of a multiplication or division operation is negative only if the operands have different signs and neither is a NaN.
– The sign of the result of an addition or subtraction operation is negative only if the result is less than zero and neither operand is a NaN, except for the following cases, in which the result is -0:
  - A result is rounded to 0, and the value, before rounding, had a negative sign
  - 0 is subtracted from -0
  - Operands with opposite signs are added, or operands with the same sign are subtracted; the result has a coefficient of 0, and the rounding mode is ROUND_FLOOR
  - Operands are multiplied or divided, the result has a coefficient of 0, and the signs of the operands are different
  - The first argument of the POWER function is -0, and the second argument is a positive odd number
  - The argument of the CEIL, FLOOR, or SQRT function is -0
  - The first argument of the ROUND or TRUNCATE function is -0

The following examples show special decimal floating-point values as operands:

```
INFINITY + 1          = INFINITY
INFINITY + INFINITY   = INFINITY
INFINITY + -INFINITY  = NAN         -- warning
NAN + 1               = NAN
NAN + INFINITY        = NAN
1 - INFINITY          = -INFINITY
INFINITY - INFINITY   = NAN         -- warning
-INFINITY - -INFINITY = NAN         -- warning
-0.0 - 0.0E1          = -0.0
-1.0 * 0.0E1          = -0.0
1.0E1 / 0             = INFINITY    -- warning
-1.0E5 / 0.0          = -INFINITY   -- warning
1.0E5 / -0            = -INFINITY   -- warning
INFINITY / -INFINITY  = NAN         -- warning
INFINITY / 0          = INFINITY
-INFINITY / 0         = -INFINITY
-INFINITY / -0        = INFINITY
```

User-defined types as operands of arithmetic operators

Weakly typed distinct type operands can be used with arithmetic operators, provided that source type of the weakly typed distinct type is supported by the arithmetic operator. There is no need to create additional user-defined functions to support arithmetic operations for weakly typed distinct type operands.

A strongly typed user-defined type cannot be used with arithmetic operators, even if its source data type is numeric. To perform an arithmetic operation, create a function with the arithmetic operator as its source. For example, if there were strongly typed distinct types INCOME and EXPENSES, both of which had DECIMAL(8,2) data types, then the following user-defined function, REVENUE, could be used to subtract one from the other.

```
CREATE FUNCTION REVENUE (INCOME, EXPENSES)
  RETURNS DECIMAL(8,2) SOURCE "-" (DECIMAL, DECIMAL)
```

Alternately, the minus (-) operator could be overloaded using a user-defined function to subtract the new data types.

```
CREATE FUNCTION "-" (INCOME, EXPENSES)
  RETURNS DECIMAL(8,2) SOURCE "-" (DECIMAL, DECIMAL)
```

Expressions with bitwise operators

The bitwise operators BITAND (&), BITOR (|), BITXOR (^), and BITNOT (~) correspond to the similarly named scalar functions described in "BITAND, BITANDNOT, BITOR, BITXOR, and BITNOT " on page 293.

If any operand in a bitwise expression can be null, the result can be null. If any operand in a bitwise expression has the null value, the result of the expression is the null value.

The unary bitwise BITNOT (~) prefix operator reverses each bit of the operand to which it applies. If the data type of a value x is DECIMAL, REAL, DOUBLE, or DECFLOAT(16), the data type of ~x is DECFLOAT(34); otherwise, the data type is the same as that of x.

Table 25. Binary Bitwise Operators

Bitwise Operator	Name	Description
&	BITAND	The result is a bit pattern in which each bit is the result of a logical AND operation performed on the corresponding bits of the input arguments.
|	BITOR	The result is a bit pattern in which each bit is the result of a logical OR operation performed on the corresponding bits of the input arguments.
^	BITXOR	The result is a bit pattern in which each bit is the result of a logical XOR (exclusive OR) operation performed on the corresponding bits of the input arguments.

If the data type of either operand in a bitwise BITAND (&), BITOR (|), or BITXOR (^) expression is DECFLOAT, the data type of the result is DECFLOAT(34). Otherwise, the data type of the result is that of the operand whose data type is ranked highest in the order of data type precedence (see Table 6 on page 46).

Before a bitwise operation is performed, an operand that is a non-LOB string is converted to DECFLOAT(34) using the rules for CAST specification. For more information, see "Casting between data types" on page 47. Bitwise operations involving graphic string operands can be performed only for Unicode databases.

Precedence of operations

Expressions within parentheses and dereference operations are evaluated first and from left to right. (Parentheses are also used in fullselects, search conditions, and functions. However, they should not be used to arbitrarily group sections within SQL statements.) When the order of evaluation is not specified by parentheses, operators are evaluated in the following order:

1. Unary BITNOT (~)
2. Unary positive (+) or unary negative (-) prefix
3. Exponential (**)
4. Multiplication (*), division (/), modulo (%), or concatenation (CONCAT or ||)
5. Addition (+) or subtraction (-)
6. BITAND (&), BITOR (|), or BITXOR (^).
7. Predicates.
8. Logical NOT.

9. Logical AND.
10. Logical OR.

Operators at the same precedence level are evaluated from left to right.

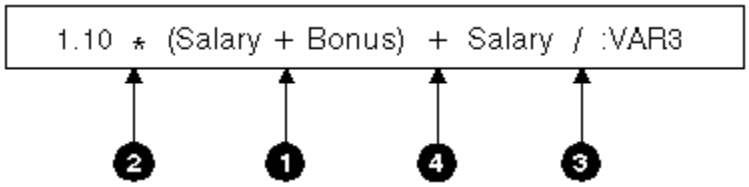

Figure 2. Example illustrating the precedence of operations

Scalar fullselect

Scalar fullselect

A *scalar fullselect* is a fullselect, enclosed in parentheses, that returns a single row consisting of a single column value. If the fullselect does not return a row, the result of the expression is the null value. If the select list element is an expression that is simply a column name or a dereference operation, the result column name is based on the name of the column. The authorization required for a scalar fullselect is the same as that required for an SQL query.

Compatability features

When the SQL_COMPAT global variable is set to 'NPS':

- The symbol ^ is interpreted as the exponential operator (equivalent to **) and not as the BITXOR operator. The symbol ** is also interpreted as the exponential operator.
- The symbol # is interpreted as the BITXOR operator.

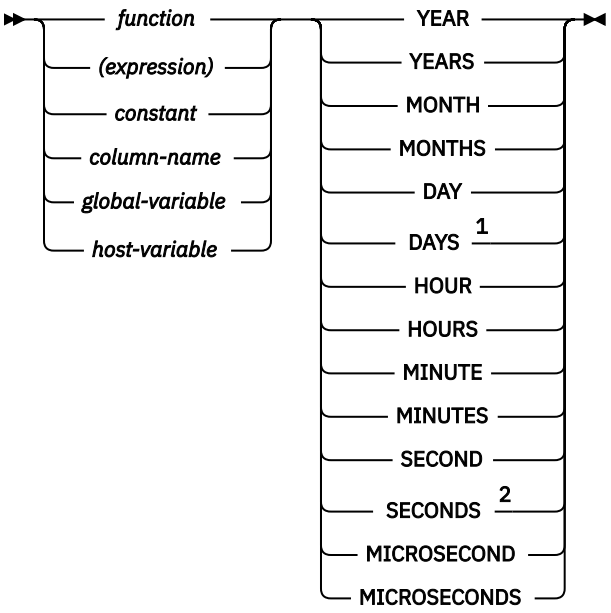
Datetime operations and durations

Datetime values can be incremented, decremented, and subtracted. These operations can involve decimal numbers called durations.

Durations

A *duration* is a number representing an interval of time.

labeled-duration



Notes:

[1] DAYS is the default for non-decimal numeric arithmetic involving dates and timestamps.

[2] SECONDS is the default for non-decimal numeric arithmetic involving time.

A duration can be of one of the following types:

labeled duration
A specific unit of time as expressed by a number (which can be the result of an expression) followed by one of the seven duration keywords: YEARS, MONTHS, DAYS, HOURS, MINUTES, SECONDS, or MICROSECONDS. (The singular form of these keywords is also acceptable: YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, and MICROSECOND.) The number specified is converted as if it were assigned to a DECIMAL(15,0) number, except for SECONDS which uses DECIMAL(27,12) to allow 0 to 12 digits of fractional seconds to be included. A labeled duration can only be used as an operand of an arithmetic operator in which the other operand is a value of data type DATE, TIME, or TIMESTAMP. Thus, the expression HIREDATE + 2 MONTHS + 14 DAYS is valid, whereas the expression HIREDATE + (2 MONTHS + 14 DAYS) is not. In both of these expressions, the labeled durations are 2 MONTHS and 14 DAYS.

date duration
A number of years, months, and days, expressed as a DECIMAL(8,0) number. To be properly interpreted, the number must have the format *yyyymmdd.*, where *yyyy* represents the number of years, *mm* the number of months, and *dd* the number of days. (The period in the format indicates a DECIMAL data type.) The result of subtracting one date value from another, as in the expression HIREDATE - BRTHDATE, is a date duration.

time duration
A number of hours, minutes, and seconds, expressed as a DECIMAL(6,0) number. To be properly interpreted, the number must have the format *hhmmss.*, where *hh* represents the number of hours, *mm* the number of minutes, and *ss* the number of seconds. (The period in the format indicates a DECIMAL data type.) The result of subtracting one time value from another is a time duration.

timestamp duration
A number of years, months, days, hours, minutes, seconds, and fractional seconds, expressed as a DECIMAL(14+*s*,*s*) number, where *s* is the number of digits of fractional seconds ranging from 0 to 12. To be properly interpreted, the number must have the format *yyyymmddhhmmss.nnnnnnnnnnnn*, where *yyyy*, *mm*, *dd*, *hh*, *mm*, *ss*, and *nnnnnnnnnnnn* represent, respectively, the number of years, months, days, hours, minutes, seconds, and fractional seconds. The result of subtracting one timestamp value from another is a timestamp duration, with scale that matches the maximum timestamp precision of the timestamp operands.

Datetime arithmetic in SQL

The only arithmetic operations that can be performed on datetime values are addition and subtraction. If a datetime value is the operand of addition, the other operand must be a duration. The specific rules governing the use of the addition operator with datetime values follow.

- If one operand is a date, the other operand must be a date duration or labeled duration of YEARS, MONTHS, or DAYS.
- If one operand is a time, the other operand must be a time duration or a labeled duration of HOURS, MINUTES, or SECONDS.
- If one operand is a timestamp, the other operand must be a duration. Any type of duration is valid.
- Neither operand of the addition operator can be a parameter marker.

The rules for the use of the subtraction operator on datetime values are not the same as those for addition because a datetime value cannot be subtracted from a duration, and because the operation of subtracting two datetime values is not the same as the operation of subtracting a duration from a datetime value. The specific rules governing the use of the subtraction operator with datetime values follow.

- If the first operand is a timestamp, the second operand must be a date, a timestamp, a string representation of a date, a string representation of a timestamp, or a duration. If the second operand is a string representation of a timestamp, it is implicitly converted to a timestamp with the same precision of the first operand.
- If the second operand is a timestamp, the first operand must be a date, a timestamp, a string representation of a date, or a string representation of a timestamp. If the first operand is a string representation of a timestamp, it is implicitly converted to a timestamp with the same precision of the second operand.
- If the first operand is a date, the second operand must be a date, a date duration, a string representation of a date, or a labeled duration of YEARS, MONTHS, or DAYS.
- If the second operand is a date, the first operand must be a date, or a string representation of a date.
- If the first operand is a time, the second operand must be a time, a time duration, a string representation of a time, or a labeled duration of HOURS, MINUTES, or SECONDS.
- If the second operand is a time, the first operand must be a time, or string representation of a time.
- Neither operand of the subtraction operator can be a parameter marker.

Date arithmetic

Dates can be subtracted, incremented, or decremented.

- The result of subtracting one date (DATE2) from another (DATE1) is a date duration that specifies the number of years, months, and days between the two dates. The data type of the result is DECIMAL(8,0). If DATE1 is greater than or equal to DATE2, DATE2 is subtracted from DATE1. If DATE1 is less than DATE2, however, DATE1 is subtracted from DATE2, and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation result = DATE1 - DATE2.

```
If DAY(DATE2) <= DAY(DATE1)
then DAY(RESULT) = DAY(DATE1) - DAY(DATE2).
```

```
If DAY(DATE2) > DAY(DATE1)
then DAY(RESULT) = N + DAY(DATE1) - DAY(DATE2)
where N = the last day of MONTH(DATE2).
MONTH(DATE2) is then incremented by 1.
```

```
If MONTH(DATE2) <= MONTH(DATE1)
then MONTH(RESULT) = MONTH(DATE1) - MONTH(DATE2).
```

```
If MONTH(DATE2) > MONTH(DATE1)
then MONTH(RESULT) = 12 + MONTH(DATE1) - MONTH(DATE2).
YEAR(DATE2) is then incremented by 1.
```

```
YEAR(RESULT) = YEAR(DATE1) - YEAR(DATE2).
```

For example, the result of DATE('3/15/2000') - '12/31/1999' is 00000215. (or, a duration of 0 years, 2 months, and 15 days).

- The result of adding a duration to a date, or of subtracting a duration from a date, is itself a date. (For the purposes of this operation, a month denotes the equivalent of a calendar page. Adding months to a date, then, is like turning the pages of a calendar, starting with the page on which the date appears.) The result must fall between the dates January 1, 0001 and December 31, 9999 inclusive.

  If a duration of years is added or subtracted, only the year portion of the date is affected. The month is unchanged, as is the day unless the result would be February 29 of a non-leap-year. In this case, the day is changed to 28, and a warning indicator in the SQLCA is set to indicate the adjustment.

  Similarly, if a duration of months is added or subtracted, only months and, if necessary, years are affected. The day portion of the date is unchanged unless the result would be invalid (September 31, for example). In this case, the day is set to the last day of the month, and a warning indicator in the SQLCA is set to indicate the adjustment.

  Adding or subtracting a duration of days will, of course, affect the day portion of the date, and potentially the month and year.

  Date durations, whether positive or negative, may also be added to and subtracted from dates. As with labeled durations, the result is a valid date, and a warning indicator is set in the SQLCA whenever an end-of-month adjustment is necessary.

  When a positive date duration is added to a date, or a negative date duration is subtracted from a date, the date is incremented by the specified number of years, months, and days, in that order. Thus, DATE1 + X, where X is a positive DECIMAL(8,0) number, is equivalent to the expression:

```
DATE1 + YEAR(X) YEARS + MONTH(X) MONTHS + DAY(X) DAYS.
```

  When a positive date duration is subtracted from a date, or a negative date duration is added to a date, the date is decremented by the specified number of days, months, and years, in that order. Thus, DATE1 - X, where X is a positive DECIMAL(8,0) number, is equivalent to the expression:

```
DATE1 - DAY(X) DAYS - MONTH(X) MONTHS - YEAR(X) YEARS.
```

  When adding durations to dates, adding one month to a given date gives the same date one month later unless that date does not exist in the later month. In that case, the date is set to that of the last day of the later month. For example, January 28 plus one month gives February 28; and one month added to January 29, 30, or 31 results in either February 28 or, for a leap year, February 29.

  Note: If one or more months is added to a given date and then the same number of months is subtracted from the result, the final date is not necessarily the same as the original date.

Time arithmetic

Times can be subtracted, incremented, or decremented.

- The result of subtracting one time (TIME2) from another (TIME1) is a time duration that specifies the number of hours, minutes, and seconds between the two times. The data type of the result is DECIMAL(6,0).

  If TIME1 is greater than or equal to TIME2, TIME2 is subtracted from TIME1.

  If TIME1 is less than TIME2, however, TIME1 is subtracted from TIME2, and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation result = TIME1 - TIME2.

```
If SECOND(TIME2) <= SECOND(TIME1)
then SECOND(RESULT) = SECOND(TIME1) - SECOND(TIME2).
```

```
If SECOND(TIME2) > SECOND(TIME1)
then SECOND(RESULT) = 60 + SECOND(TIME1) - SECOND(TIME2).
MINUTE(TIME2) is then incremented by 1.
```

```
If MINUTE(TIME2) <= MINUTE(TIME1)
then MINUTE(RESULT) = MINUTE(TIME1) - MINUTE(TIME2).
```

```
If MINUTE(TIME1) > MINUTE(TIME1)
then MINUTE(RESULT) = 60 + MINUTE(TIME1) - MINUTE(TIME2).
HOUR(TIME2) is then incremented by 1.
```

```
HOUR(RESULT) = HOUR(TIME1) - HOUR(TIME2).
```

For example, the result of TIME('11:02:26') - '00:32:56' is 102930. (a duration of 10 hours, 29 minutes, and 30 seconds).

- The result of adding a duration to a time, or of subtracting a duration from a time, is itself a time. Any overflow or underflow of hours is discarded, thereby ensuring that the result is always a time. If a duration of hours is added or subtracted, only the hours portion of the time is affected. The minutes and seconds are unchanged.

  Similarly, if a duration of minutes is added or subtracted, only minutes and, if necessary, hours are affected. The seconds portion of the time is unchanged.

  Adding or subtracting a duration of seconds will, of course, affect the seconds portion of the time, and potentially the minutes and hours.

  Time durations, whether positive or negative, also can be added to and subtracted from times. The result is a time that has been incremented or decremented by the specified number of hours, minutes, and seconds, in that order. TIME1 + X, where "X" is a DECIMAL(6,0) number, is equivalent to the expression:

  ```
  TIME1 + HOUR(X) HOURS + MINUTE(X) MINUTES + SECOND(X) SECONDS
  ```

  When subtracting a labeled duration of SECOND or SECONDS with a value that includes fractions of a second, the subtraction is performed as if the time value has up to 12 fractional second digits but the result is returned with the fractional seconds truncated.

  Note: Although the time '24:00:00' is accepted as a valid time, it is never returned as the result of time addition or subtraction, even if the duration operand is zero (for example, time('24:00:00')±0 seconds = '00:00:00').

Timestamp arithmetic

Timestamps can be subtracted, incremented, or decremented.

- The result of subtracting one timestamp (TS2) from another (TS1) is a timestamp duration that specifies the number of years, months, days, hours, minutes, seconds, and fractional seconds between the two timestamps. The data type of the result is DECIMAL(14+*s*,*s*), where *s* is the maximum timestamp precision of TS1 and TS2.

  If TS1 is greater than or equal to TS2, TS2 is subtracted from TS1. If TS1 is less than TS2, however, TS1 is subtracted from TS2 and the sign of the result is made negative. The following procedural description clarifies the steps involved in the operation result = TS1 - TS2:

  ```
  If SECOND(TS2,s) <= SECOND(TS1,s)
  then SECOND(RESULT,s) = SECOND(TS1,s) -
  SECOND(TS2,s).
  ```

  ```
  If SECOND(TS2,s) > SECOND(TS1,s)
  then SECOND(RESULT,s) = 60 +
  SECOND(TS1,s) - SECOND(TS2,s).
  MINUTE(TS2) is then incremented by 1.
  ```

The minutes part of the timestamps are subtracted as specified in the rules for subtracting times.

```
If HOUR(TS2) <= HOUR(TS1)
then HOUR(RESULT) = HOUR(TS1) - HOUR(TS2).
```

```
If HOUR(TS2) > HOUR(TS1)
then HOUR(RESULT) = 24 + HOUR(TS1) - HOUR(TS2)
and DAY(TS2) is incremented by 1.
```

The date part of the timestamps is subtracted as specified in the rules for subtracting dates.

- The result of subtracting a date (D1) from a timestamp (TS1) is the same as subtracting TIMESTAMP(D1) from TS1. Similarly, the result of subtracting one timestamp (TS1) from a date (D2) is the same as subtracting TS1 from TIMESTAMP(D2).
- The result of adding a duration to a timestamp, or of subtracting a duration from a timestamp is itself a timestamp.The precision of the result timestamp matches the precision of the timestamp operand. The date arithmetic portion is performed as previously defined, except that an overflow or underflow of hours is carried into the date part of the result, which must be within the range of valid dates. The time arithmetic portion is similar to time arithmetic except that it also considers the fractional seconds included in the duration. Thus, subtracting a duration, *X*, from a timestamp, TIMESTAMP1, where *X* is a DECIMAL(14+s,s) number, is equivalent to the expression:

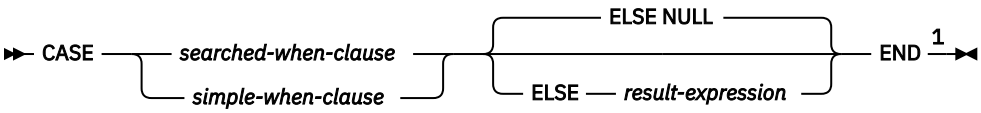
```
TIMESTAMP1 - YEAR(X)  YEARS - MONTH(X)  MONTHS - DAY(X)  DAYS
           - HOUR(X)  HOURS - MINUTE(X)  MINUTES - SECOND(X, s)  SECONDS
```

When subtracting a duration with non-zero scale or a labeled duration of SECOND or SECONDS with a value that includes fractions of a second, the subtraction is performed as if the timestamp value has up to 12 fractional second digits. The resulting value is assigned to a timestamp value with the timestamp precision of the timestamp operand which could result in truncation of fractional second digits.

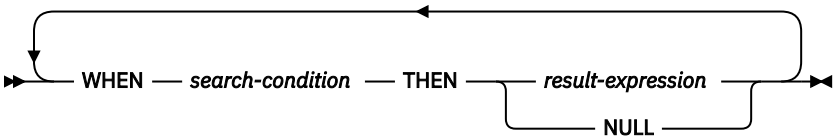
CASE expression

CASE expressions allow an expression to be selected based on the evaluation of one or more conditions.

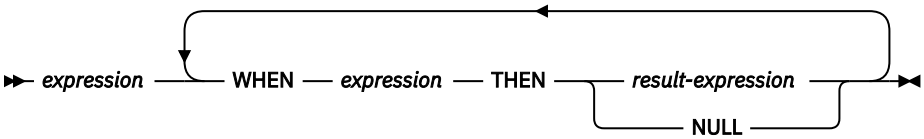
case-expression



searched-when-clause



simple-when-clause



Notes:

[1] If the result type of *result-expression* is a row type, then the syntax represents a *row-case-expression* and can only be used where a *row-expression* is allowed.

In general, the value of the *case-expression* is the value of the *result-expression* following the first (leftmost) case that evaluates to true. If no case evaluates to true and the ELSE keyword is present then the result is the value of the *result-expression* or NULL. If no case evaluates to true and the ELSE keyword

is not present then the result is NULL. Note that when a case evaluates to unknown (because of NULLs), the case is not true and hence is treated the same way as a case that evaluates to false.

If the CASE expression is in a VALUES clause, an IN predicate, a GROUP BY clause, or an ORDER BY clause, the *search-condition* in a *searched-when-clause* cannot be a quantified predicate, IN predicate using a fullselect, or an EXISTS predicate (SQLSTATE 42625).

When using the *simple-when-clause*, the value of the *expression* before the first *WHEN* keyword is tested for equality with the value of the *expression* following the WHEN keyword. The data type of the *expression* before the first *WHEN* keyword must therefore be comparable to the data types of each *expression* following the WHEN keyword(s). The *expression* before the first *WHEN* keyword in a *simple-when-clause* cannot include a function that is not deterministic or has an external action (SQLSTATE 42845).

A *result-expression* is an *expression* following the THEN or ELSE keywords. There must be at least one *result-expression* in the CASE expression (NULL cannot be specified for every case) (SQLSTATE 42625). All result expressions must have compatible data types (SQLSTATE 42804).

Examples

- If the first character of a department number is a division in the organization, then a CASE expression can be used to list the full name of the division to which each employee belongs:

```
SELECT EMPNO, LASTNAME,
  CASE SUBSTR(WORKDEPT,1,1)
    WHEN 'A' THEN 'Administration'
    WHEN 'B' THEN 'Human Resources'
    WHEN 'C' THEN 'Accounting'
    WHEN 'D' THEN 'Design'
    WHEN 'E' THEN 'Operations'
  END
  FROM EMPLOYEE;
```

- The number of years of education are used in the EMPLOYEE table to give the education level. A CASE expression can be used to group these and to show the level of education.

```
SELECT EMPNO, FIRSTNME, MIDINIT, LASTNAME,
  CASE
    WHEN EDLEVEL < 15 THEN 'SECONDARY'
    WHEN EDLEVEL < 19 THEN 'COLLEGE'
    ELSE 'POST GRADUATE'
  END
  FROM EMPLOYEE
```

- Another interesting example of CASE statement usage is in protecting from division by 0 errors. For example, the following code finds the employees who earn more than 25% of their income from commission, but who are not fully paid on commission:

```
SELECT EMPNO, WORKDEPT, SALARY+COMM FROM EMPLOYEE
WHERE (CASE WHEN SALARY=0 THEN NULL
  ELSE COMM/SALARY
  END) > 0.25;
```

- The following CASE expressions are the same:

```
SELECT LASTNAME,
  CASE
  WHEN LASTNAME = 'Haas' THEN 'President'
  ...

SELECT LASTNAME,
  CASE LASTNAME
  WHEN 'Haas' THEN 'President'
  ...
```

There are two scalar functions, NULLIF and COALESCE, that are specialized to handle a subset of the functionality provided by CASE. Table 26 on page 152 shows the equivalent expressions using CASE or these functions.

Table 26. Equivalent CASE Expressions

Expression	Equivalent Expression

`CASE`
`  WHEN e1=e2 THEN NULL`
`  ELSE e1`
`END`
	NULLIF(e1,e2)

`CASE`
`  WHEN e1 IS NOT NULL THEN e1`
`  ELSE e2`
`END`
	COALESCE(e1,e2)

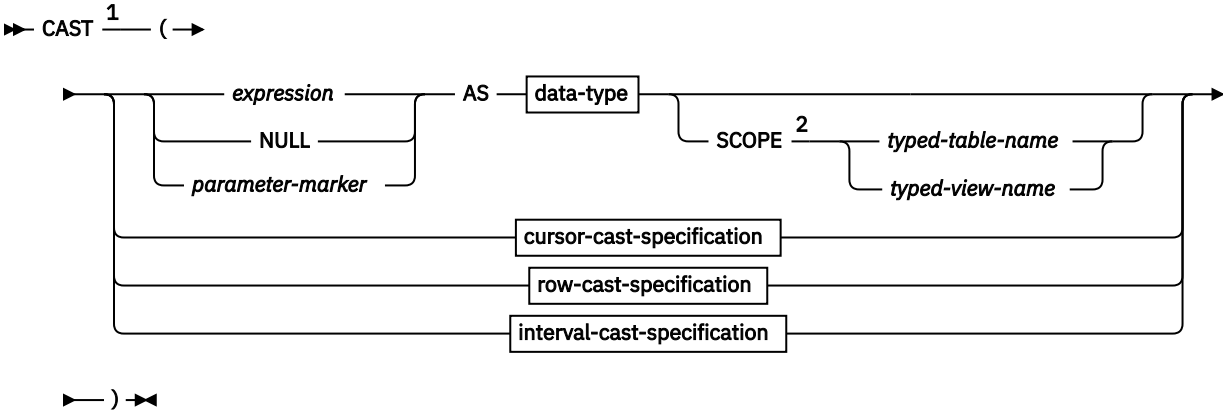
`CASE`
`  WHEN e1 IS NOT NULL THEN e1`
`  ELSE COALESCE(e2,...,eN)`
`END`
	COALESCE(e1,e2,...,eN)

`CASE`
`  WHEN c1=var1 OR (c1 IS NULL AND var1 IS NULL)`
`  THEN 'a'`
`  WHEN c1=var2 OR (c1 IS NULL AND var2 IS NULL)`
`  THEN 'b'`
`  ELSE NULL`
`END`
	DECODE(c1,var1, 'a', var2, 'b')

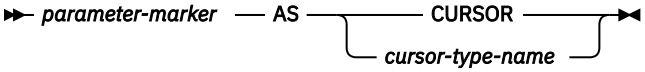
CAST specification

The CAST specification returns the cast operand (the first operand) cast to the type specified by the *data-type*. If the cast is not supported, an error is returned (SQLSTATE 42846).

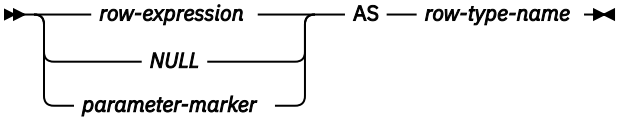
cast-specification



cursor-cast-specification

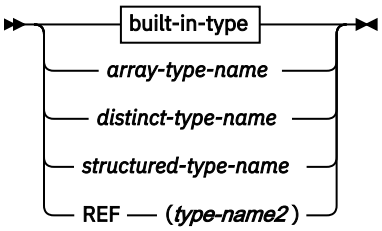


row-cast-specification

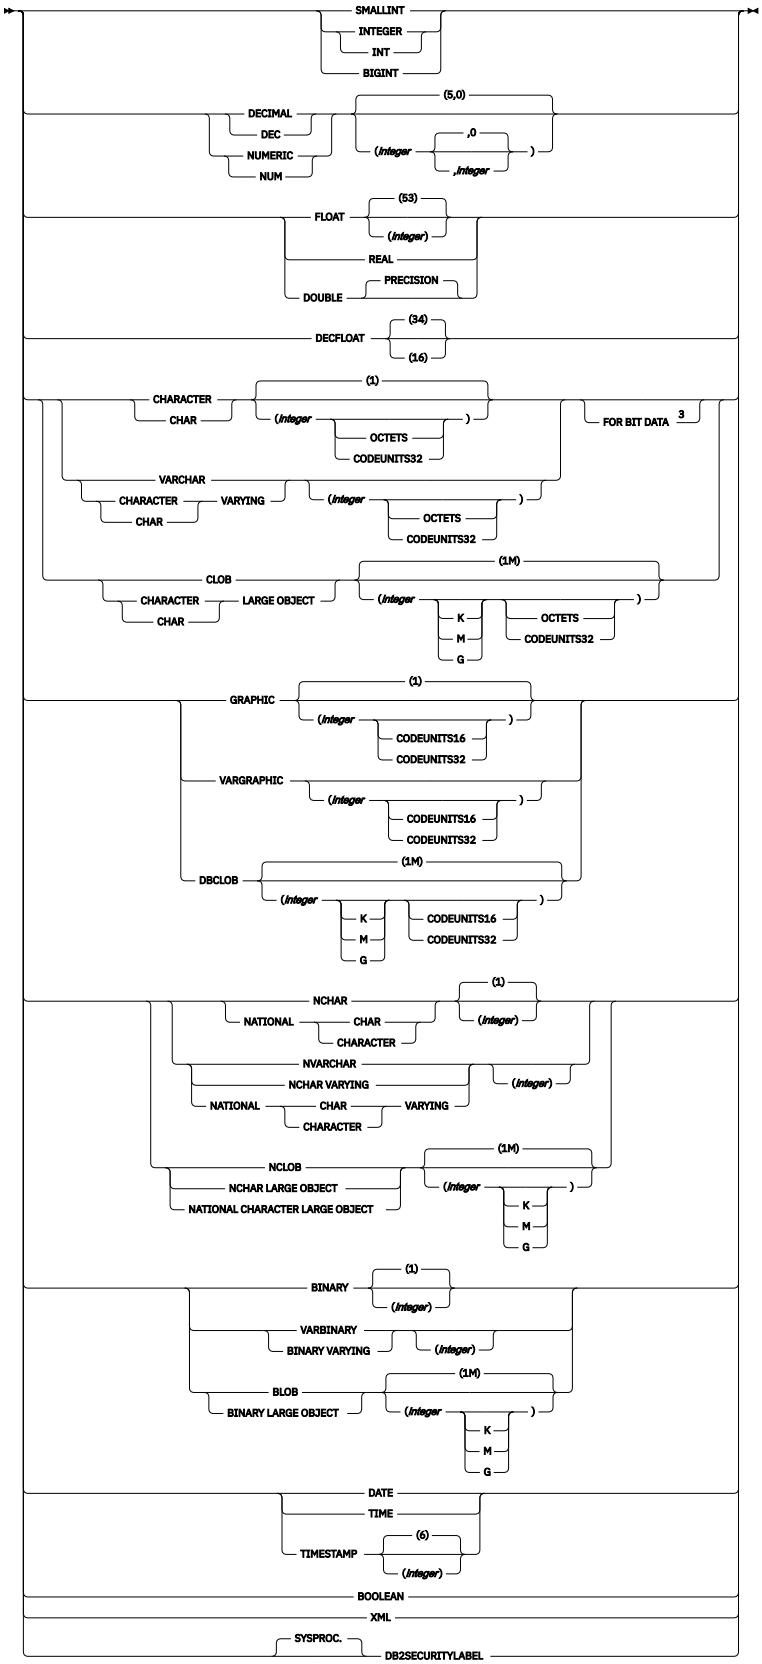


interval-cast-specification

data-type



built-in-type



Notes:

[1] For compatibility purposes, you can use `::` as the type cast operator. For example, the statements `C1::INTEGER` and `cast(C1 as INTEGER)` are equivalent.

[2] The SCOPE clause only applies to the REF data type.

[3] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

expression
If the cast operand is an expression (other than parameter marker or NULL), the result is the argument value converted to the specified target *data-type*.

When casting character strings (other than CLOBs) to a character string with a different length, a warning (SQLSTATE 01004) is returned if truncation of other than trailing blanks occurs. When casting graphic character strings (other than DBCLOBs) to a graphic character string with a different length, a warning (SQLSTATE 01004) is returned if truncation of other than trailing blanks occurs. For BLOB, CLOB and DBCLOB cast operands, the warning is issued if any characters are truncated.

When casting an array, the target data type must be a user-defined array data type (SQLSTATE 42821). The data type of the elements of the array must be the same as the data type of the elements of the target array data type (SQLSTATE 42846). The cardinality of the array must be less than or equal to the maximum cardinality of the target array data type (SQLSTATE 2202F).

NULL
If the cast operand is the keyword NULL, the result is a null value that has the specified *data-type*.

parameter-marker
A parameter marker is normally considered an expression, but is documented separately in this case because it has a special meaning. If the cast operand is a *parameter-marker*, the specified *data-type* is considered a promise that the replacement will be assignable to the specified data type (using store assignment for strings). Such a parameter marker is considered a *typed parameter marker*. Typed parameter markers will be treated like any other typed value for the purpose of function resolution, DESCRIBE of a select list or for column assignment.

cursor-cast-specification
A cast specification used to indicate that a parameter marker is expected to be a cursor type. It can be used wherever an expression is supported in contexts that allow cursor types.

parameter-marker
The cast operand is a parameter marker and is considered a promise that the replacement will be assignable to the specified cursor type.

CURSOR
Specifies the built-in data type CURSOR.

cursor-type-name
Specifies the name of a user-defined cursor type.

row-cast-specification
A cast specification where the input is a row value and the result is a user-defined row type. A *row-cast-specification* is valid only where a *row-expression* is allowed.

row-expression
The data type of *row-expression* must be a variable of row type that is anchored to the definition of a table or view. The data type of *row-expression* must not be a user-defined row type (SQLSTATE 42846).

NULL
Specifies that the cast operand is the null value. The result is a row with the null value for every field of the specified data type.

parameter-marker
The cast operand is a parameter marker and is considered a promise that the replacement will be assignable to the specified *row-type-name*.

row-type-name
Specifies the name of a user-defined row type. The *row-expression* must be castable to *row-type-name* (SQLSTATE 42846).

interval-cast-specification
A cast specification where the input is a character string representation of an interval and the result is a decimal duration. The following statements are equivalent:

```
CAST (string-constant as INTERVAL)
INTERVAL string-constant
```

For more information about possible string-constant values, see “INTERVAL ” on page 376.

data-type
The name of an existing data type. If the type name is not qualified, the SQL path is used to perform data type resolution. A data type that has associated attributes, such as length or precision and scale, should include these attributes when specifying *data-type*.

- CHAR defaults to a length of 1
- BINARY defaults to a length of 1
- DECIMAL defaults to a precision of 5 and a scale of 0
- DECFLOAT defaults to a precision of 34 if not specified

The FOR SBCS DATA clause or the FOR MIXED DATA clause (only one is supported depending on whether or not the database supports the graphic data type) can be used to cast a FOR BIT DATA string to the database code page. Restrictions on the supported data types are based on the specified cast operand.

- For a cast operand that is an *expression*, the supported target data types depend on the data type of the cast operand (source data type). If the length attribute is not specified for a VARCHAR, VARGRAPHIC, NVARCHAR, or VARBINARY data type, the length attribute is determined based on the data type of the first argument using the rules of the corresponding built-in cast function when specified with no length argument.
- For a cast operand that is the keyword NULL, any existing data type can be used. If the length attribute is not specified for a VARCHAR, VARGRAPHIC, NVARCHAR, or VARBINARY data type, a length attribute of 1 is used.
- For a cast operand that is a parameter marker, the target data type can be any existing data type. If the data type is a user-defined distinct type, the application using the parameter marker will use the source data type of the user-defined distinct type. If the data type is a user-defined structured type, the application using the parameter marker will use the input parameter type of the TO SQL transform function for the user-defined structured type. If the length attribute is not specified for a VARCHAR, VARGRAPHIC, NVARCHAR, or VARBINARY data type, a length attribute of 254 is used.

If the data type is a distinct type defined with data type constraints, the data type constraints are applied and the constraints must evaluate to true or unknown otherwise an error is returned (SQLSTATE 23528).

built-in-type
See "CREATE TABLE" for the description of built-in data types.

SCOPE
When the data type is a reference type, a scope may be defined that identifies the target table or target view of the reference.

typed-table-name
The name of a typed table. The table must already exist (SQLSTATE 42704). The cast must be to *data-type* REF(*S*), where *S* is the type of *typed-table-name* (SQLSTATE 428DM).

typed-view-name
The name of a typed view. The view must exist or have the same name as the view being created that includes the cast as part of the view definition (SQLSTATE 42704). The cast must be to *data-type* REF(*S*), where *S* is the type of *typed-view-name* (SQLSTATE 428DM).

When numeric data is cast to character data, the result data type is a fixed-length character string. When character data is cast to numeric data, the result data type depends on the type of number specified. For example, if cast to integer, it becomes a large integer.

Examples

- An application is only interested in the integer portion of the SALARY (defined as decimal(9,2)) from the EMPLOYEE table. The following query, including the employee number and the integer value of SALARY, could be prepared.

```
SELECT EMPNO, CAST(SALARY AS INTEGER) FROM EMPLOYEE
```

- Assume the existence of a distinct type called T_AGE that is defined on SMALLINT and used to create column AGE in PERSONNEL table. Also assume the existence of a distinct type called R_YEAR that is defined on INTEGER and used to create column RETIRE_YEAR in PERSONNEL table. The following update statement could be prepared.

```
UPDATE PERSONNEL SET RETIRE_YEAR =?
  WHERE AGE = CAST( ? AS T_AGE)
```

  The first parameter is an untyped parameter marker that would have a data type of R_YEAR, although the application will use an integer for this parameter marker. This does not require the explicit CAST specification because it is an assignment.

  The second parameter marker is a typed parameter marker that is cast as a distinct type T_AGE. This satisfies the requirement that the comparison must be performed with compatible data types. The application will use the source data type (which is SMALLINT) for processing this parameter marker.

  Successful processing of this statement assumes that the SQL path includes the schema name of the schema (or schemas) where the two distinct types are defined.

- An application supplies a value that is a series of bits, for example an audio stream, and it should not undergo code page conversion before being used in an SQL statement. The application could use the following CAST:

```
CAST( ? AS VARCHAR(10000) FOR BIT DATA)
```

- Assume that an array type and a table have been created as follows:

```
CREATE TYPE PHONELIST AS DECIMAL(10, 0) ARRAY[5]

CREATE TABLE EMP_PHONES
  (ID          INTEGER,
   PHONENUMBER DECIMAL(10,0) )
```

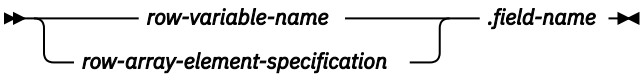
  The following procedure returns an array with the phone numbers for the employee with ID 1775. If there are more than five phone numbers for this employee, an error is returned (SQLSTATE 2202F).

```
CREATE PROCEDURE GET_PHONES(OUT EPHONES PHONELIST)
BEGIN
  SELECT CAST(ARRAY_AGG(PHONENUMBER) AS PHONELIST)
  INTO EPHONES
  FROM EMP_PHONES
  WHERE ID = 1775;
END
```

Field reference

A field of a row type is referenced by using the field name qualified by a variable that returns a row type which includes a field with that field name, or an array element specification that returns a row type which includes a field with that field name.

field-reference



row-variable-name
The name of a variable with a data type that is a row type.

row-array-element-specification
An *array-element-specification* where the data type of the array element is a row type.

field-name
The name of a field within the row type.

Examples

1. To reference a field of a simple row type:

```
CREATE OR REPLACE  TYPE REC_TYPE AS ROW
(
   ID INTEGER,
   NAME VARCHAR(10)
)@

BEGIN
     DECLARE NAME VARCHAR(10);
     DECLARE TMPREC REC_TYPE;
     SET NAME = TMPREC.NAME;
END @
```

2. To reference a field of a nested row type, you must assign the inner row to a temporary variable before a field of this inner row can be referenced:

```
CREATE OR REPLACE TYPE INNER_REC_TYPE AS ROW
(
  ID INTEGER,
  NAME VARCHAR(10)
)@
CREATE OR REPLACE  TYPE REC_TYPE AS ROW
(
  INNER_REC INNER_REC_TYPE
)@
CREATE OR REPLACE TYPE ARRAY_TYPE AS REC_TYPE ARRAY[INTEGER]@

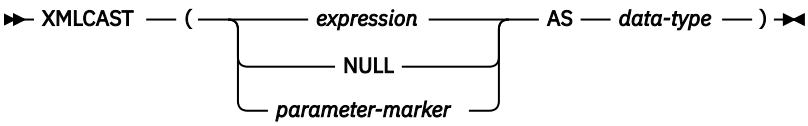
BEGIN
  DECLARE TMPRECORD INNER_REC_TYPE;
  DECLARE TMPARRAY ARRAY_TYPE;
  DECLARE NAME VARCHAR(10);

  SET TMPRECORD = TMPARRAY[1].INNER_REC;
  SET NAME = TMPRECORD.NAME;
  END @
```

XMLCAST specification

The XMLCAST specification returns the cast operand (the first operand) cast to the type specified by the data type. XMLCAST supports casts involving XML values, including conversions between non-XML data types and the XML data type. If the cast is not supported, an error is returned (SQLSTATE 22003).

xmlcast-specification



expression
If the cast operand is an expression (other than a parameter marker or NULL), the result is the argument value converted to the specified target data type. The expression or the target data type must be the XML data type (SQLSTATE 42846).

NULL
If the cast operand is the keyword NULL, the target data type must be the XML data type (SQLSTATE 42846). The result is a null XML value.

parameter-marker
If the cast operand is a parameter marker, the target data type must be XML (SQLSTATE 42846). A parameter marker is normally considered to be an expression, but is documented separately in this

case because it has special meaning. If the cast operand is a parameter marker, the specified data type is considered to be a promise that the replacement will be assignable to the specified (XML) data type (using store assignment). Such a parameter marker is considered to be a typed parameter marker, which is treated like any other typed value for the purpose of function resolution, a describe operation on a select list, or column assignment.

data-type
The name of an existing SQL data type. If the name is not qualified, the SQL path is used to perform data type resolution. If a data type has associated attributes, such as length or precision and scale, these attributes should be included when specifying a value for *data-type*. CHAR defaults to a length of 1, and DECIMAL defaults to a precision of 5 and a scale of 0 if not specified. Restrictions on the supported data types are based on the specified cast operand.

- For a cast operand that is an expression, the supported target data types depend on the data type of the cast operand (source data type).
- For a cast operand that is the keyword NULL, the target data type must be XML.
- For a cast operand that is a parameter marker, the target data type must be XML.

Note: Support in non-Unicode databases: When XMLCAST is used to convert an XML value to an SQL data type, code page conversion is performed. The encoding of the cast expression is converted from UTF-8 to the database code page. Characters in the original expression that are not present in the database code page are replaced by substitution characters as a result of this conversion.

Examples

- Create a null XML value.

```
XMLCAST(NULL AS XML)
```

- Convert a value extracted from an XMLQUERY expression into an INTEGER:

```
XMLCAST(XMLQUERY('$m/PRODUCT/QUANTITY'
  PASSING xmlcol AS "m") AS INTEGER)
```

- Convert a value extracted from an XMLQUERY expression into a varying-length character string:

```
XMLCAST(XMLQUERY('$m/PRODUCT/ADD-TIMESTAMP'
  PASSING xmlcol AS "m") AS VARCHAR(30))
```

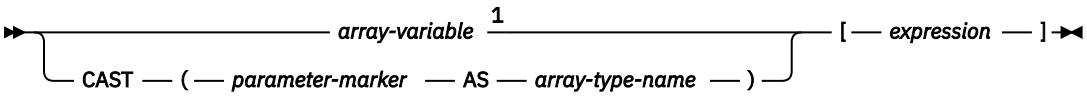
- Convert a value extracted from an SQL scalar subquery into an XML value.

```
XMLCAST((SELECT quantity FROM product AS p
  WHERE p.id = 1077) AS XML)
```

ARRAY element specification

The ARRAY element specification returns the element from an array specified by *expression*. If any argument to *expression* is null, the null value is returned.

array-element-specification



Notes:

[1] If the data type of the elements in the array is a row type, then the syntax represents an array-element-specification with a row data type and can only be used where a *row-expression* is allowed.

array-variable
An SQL variable, SQL parameter, or global variable of an array type.

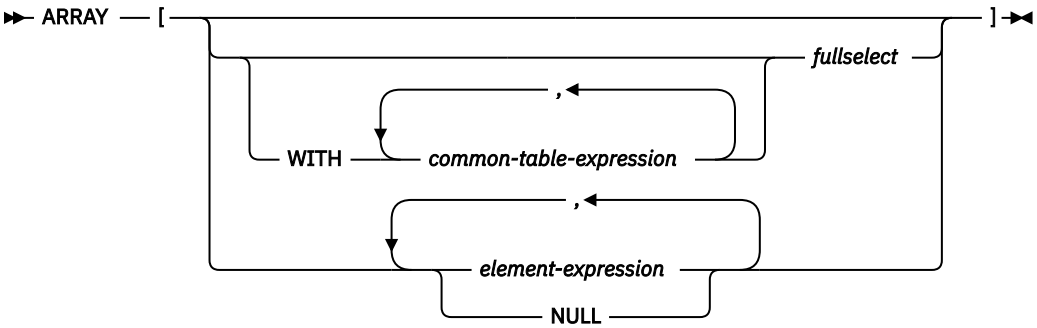
CAST (*parameter-marker* AS *array-type-name*)
A parameter marker is normally considered to be an expression, but in this case it must explicitly be cast to a user-defined array data type.

[*expression*]
Specifies the array index of the element that is to be extracted from the array. The array index of an ordinary array must be assignable to INTEGER (SQLSTATE 428H1). The value must be between 1 and the cardinality of the array (SQLSTATE 2202E). The array index of an associative array must be assignable to the index data type (SQLSTATE 428H1).

Array constructor

An array constructor is a language element that can be used to define and construct an array data type value within a valid context.

Syntax



Authorization

No specific authorizations are required to reference an array constructor within an SQL statement, however for the statement execution to be successful all other authorization requirements for the statement must be satisfied.

Description

WITH *common-table-expression*
Defines a common table expression for use with the following fullselect.

fullselect
A fullselect that returns a single column. The values that are returned by the fullselect for each row are the elements of the array. The cardinality of the array is equal to the number of rows that are returned by the fullselect. If the fullselect includes an *order-by-clause*, the order determines the order in which row values are assigned to elements of the array. If no *order-by-clause* is specified, the order in which row values are assigned to elements of the array is not deterministic.

element-expression
An expression that defines the value of an element in the array. The cardinality of the array is equal to the number of element expressions. The first *element-expression* is assigned to the array element with array index 1. The second *element-expression* is assigned to the array element with array index 2 and so on. Every *element-expression* must have a compatible data type with every other *element-expression* and the base type of the array is determined using the "Rules for result data types" topic.

NULL
Specifies the null value.

If no value is specified within the brackets, the result is an empty array.

Rules

- The base type of the *array-constructor*, as derived from the *element-expression*s or the *fullselect*, must be assignable to the base type of the target array (SQLSTATE 42821).
- The number of elements in the *array-constructor* must not exceed the maximum cardinality of the target array variable (SQLSTATE 2202F).

Notes

- An array constructor can be used to define only an ordinary array with elements that are not a row type. An array constructor cannot be used to define an associative array or an ordinary array with elements that are a row type. Such arrays can only be constructed by assigning the individual elements.

Examples

Example 1: Set the array variable RECENT_CALLS of array type PHONENUMBERS to an array of fixed numbers.

```
SET RECENT_CALLS = ARRAY[9055553907, 4165554213, 4085553678]
```

Example 2: Set the array variable DEPT_PHONES of array type PHONENUMBERS to an array of phone numbers retrieved from the DEPARTMENT_INFO table.

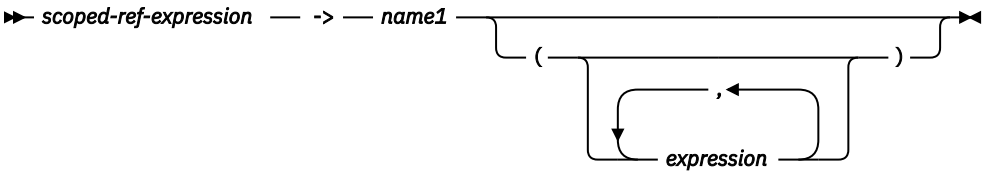
```
SET DEPT_PHONES = ARRAY[SELECT DECIMAL(AREA_CODE CONCAT '555' CONCAT EXTENSION,16)
                                  FROM DEPARTMENT_INFO
                                  WHERE DEPTID = 624]
```

Dereference operation

The scope of the scoped reference expression is a table or view called the *target* table or view.

The scoped reference expression identifies a *target row*. The *target row* is the row in the target table or view (or in one of its subtables or subviews) whose object identifier (OID) column value matches the reference expression. The dereference operation can be used to access a column of the target row, or to invoke a method, using the target row as the subject of the method. The result of a dereference operation can always be null. The dereference operation takes precedence over all other operators.

dereference-operation



scoped-ref-expression
An expression that is a reference type that has a scope (SQLSTATE 428DT). If the expression is a host variable, parameter marker or other unscoped reference type value, a CAST specification with a SCOPE clause is required to give the reference a scope.

name1
Specifies an unqualified identifier.

If no parentheses follow *name1*, and *name1* matches the name of an attribute of the target type, then the value of the dereference operation is the value of the named column in the target row. In this case, the data type of the column (made nullable) determines the result type of the dereference operation. If no target row exists whose object identifier matches the reference expression, then the result of the dereference operation is null. If the dereference operation is used in a select list and is not included as part of an expression, *name1* becomes the result column name.

If parentheses follow *name1*, or if *name1* does not match the name of an attribute of the target type, then the dereference operation is treated as a method invocation. The name of the invoked method is *name1*. The subject of the method is the target row, considered as an instance of its structured type. If no target row exists whose object identifier matches the reference expression, the subject of the method is a null value of the target type. The expressions inside parentheses, if any, provide the remaining parameters of the method invocation. The normal process is used for resolution of the method invocation. The result type of the selected method (made nullable) determines the result type of the dereference operation.

The authorization ID of the statement that uses a dereference operation must have SELECT privilege on the target table of the *scoped-ref-expression* (SQLSTATE 42501).

A dereference operation can never modify values in the database. If a dereference operation is used to invoke a mutator method, the mutator method modifies a copy of the target row and returns the copy, leaving the database unchanged.

Examples

- Assume the existence of an EMPLOYEE table that contains a column called DEPTREF which is a reference type scoped to a typed table based on a type that includes the attribute DEPTNAME. The values of DEPTREF in the table EMPLOYEE should correspond to the OID column values in the target table of DEPTREF column.

```
SELECT EMPNO, DEPTREF->DEPTNAME
  FROM EMPLOYEE
```

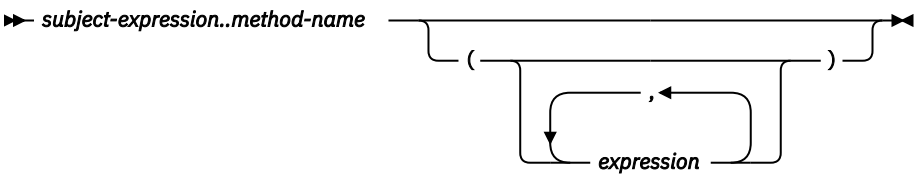
- Using the same tables as in the previous example, use a dereference operation to invoke a method named BUDGET, with the target row as subject parameter, and '1997' as an additional parameter.

```
SELECT EMPNO, DEPTREF->BUDGET('1997') AS DEPTBUDGET97
  FROM EMPLOYEE
```

Method invocation

Both system-generated observer and mutator methods, as well as user-defined methods are invoked using the double-dot operator.

method-invocation



subject-expression
An expression with a static result type that is a user-defined structured type.

method-name
The unqualified name of a method. The static type of *subject-expression* or one of its supertypes must include a method with the specified name.

(*expression*,...)
The arguments of *method-name* are specified within parentheses. Empty parentheses can be used to indicate that there are no arguments. The *method-name* and the data types of the specified argument expressions are used to resolve to the specific method, based on the static type of *subject-expression*.

The double-dot operator used for method invocation is a high precedence left to right infix operator. For example, the following two expressions are equivalent:

```
a..b..c + x..y..z
```

and

```
((a..b)..c) + ((x..y)..z)
```

If a method has no parameters other than its subject, it can be invoked with or without parentheses. For example, the following two expressions are equivalent:

```
point1..x
point1..x()
```

Null subjects in method calls are handled as follows:

- If a system-generated mutator method is invoked with a null subject, an error results (SQLSTATE 2202D)
- If any method other than a system-generated mutator is invoked with a null subject, the method is not executed, and its result is null. This rule includes user-defined methods with SELF AS RESULT.

When a database object (a package, view, or trigger, for example) is created, the best fit method that exists for each of its method invocations is found.

Note: Methods of types defined WITH FUNCTION ACCESS can also be invoked using the regular function notation. Function resolution considers all functions, as well as methods with function access as candidate functions. However, functions cannot be invoked using method invocation. Method resolution considers all methods and does not consider functions as candidate methods. Failure to resolve to an appropriate function or method results in an error (SQLSTATE 42884).

Example

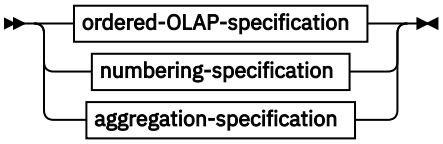
- Use the double-dot operator to invoke a method called AREA. Assume the existence of a table called RINGS, with a column CIRCLE_COL of structured type CIRCLE. Also, assume that the method AREA has been defined previously for the CIRCLE type as AREA() RETURNS DOUBLE.

```
SELECT CIRCLE_COL..AREA() FROM RINGS
```

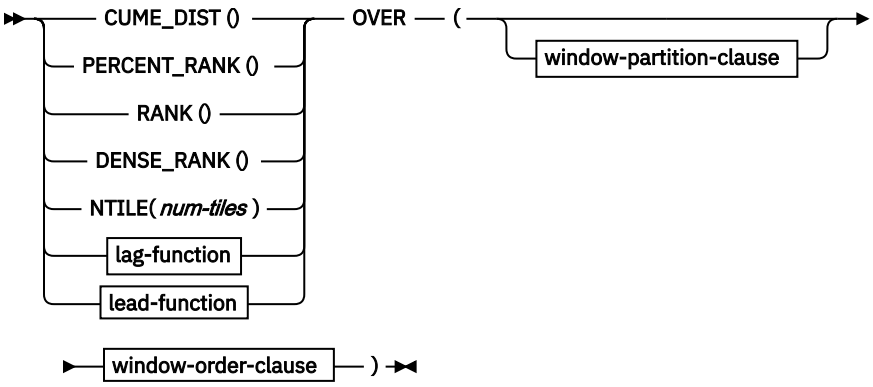
OLAP specification

On-Line Analytical Processing (OLAP) functions provide the ability to return ranking, row numbering and existing aggregate function information as a scalar value in a query result.

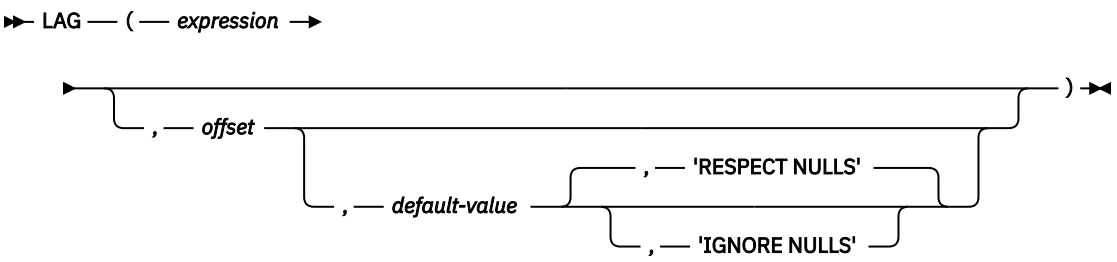
OLAP-specification



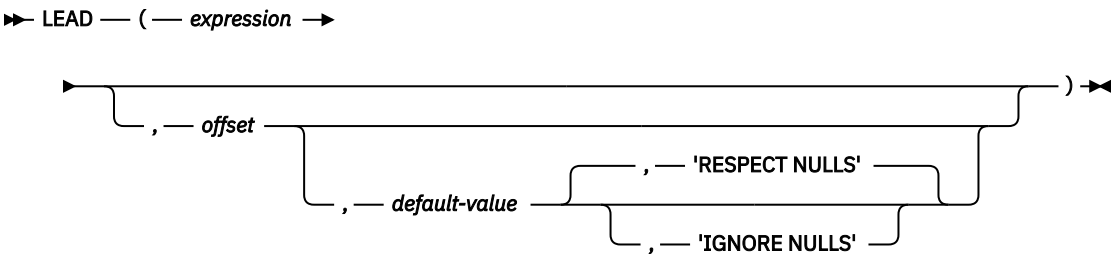
ordered-OLAP-specification



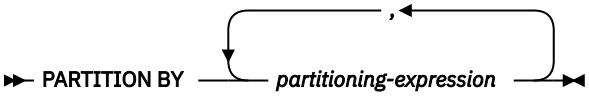
lag-function



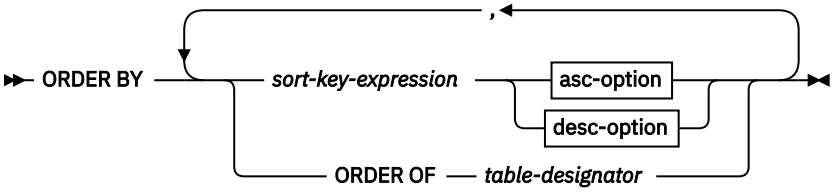
lead-function



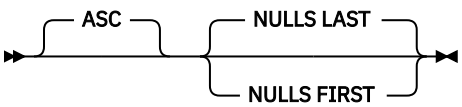
window-partition-clause



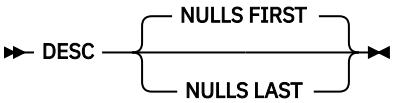
window-order-clause



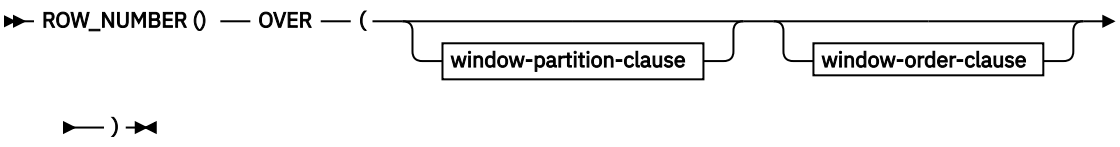
asc-option



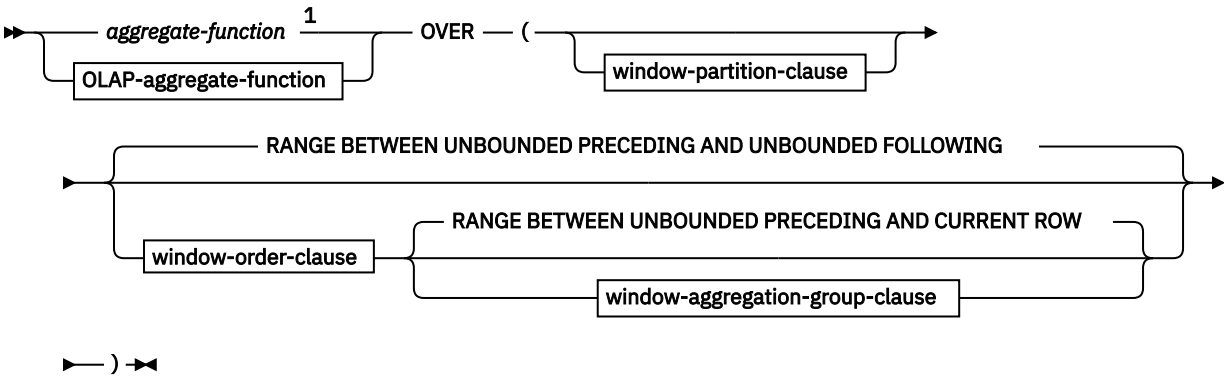
desc-option



numbering-specification



aggregation-specification



OLAP-aggregate-function

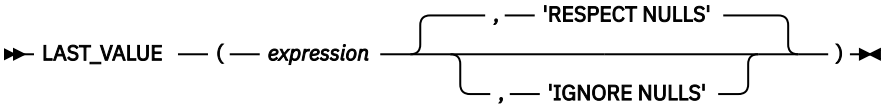
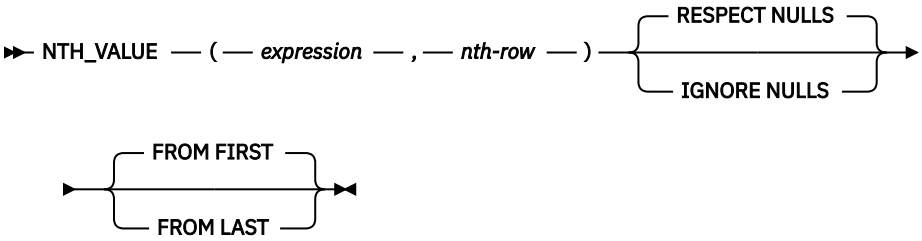
last-value-function

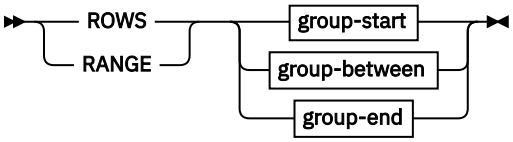


nth-value-function

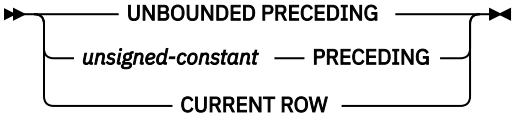


ratio-to-report-function

window-aggregation-group-clause

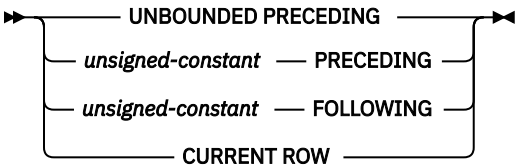


group-start

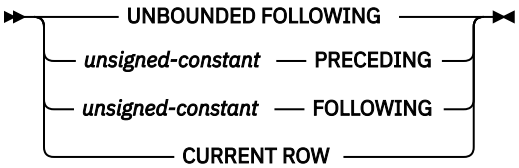


group-between

group-bound1



group-bound2



group-end

Notes:

[1] ARRAY_AGG, CUME_DIST, and PERCENT_RANK are not supported as an aggregate function in *aggregation-specification* (SQLSTATE 42887).

An OLAP function can be included in expressions in a select-list or the ORDER BY clause of a select-statement (SQLSTATE 42903). An OLAP function cannot be used within an argument to an XMLQUERY or XMLEXISTS expression (SQLSTATE 42903). An OLAP function cannot be used as an argument of an aggregate function (SQLSTATE 42607). The query result to which the OLAP function is applied is the result table of the innermost subselect that includes the OLAP function.

When specifying an OLAP function, a window is specified that defines the rows over which the function is applied, and in what order. When used with an aggregate function, the applicable rows can be further refined, relative to the current row, as either a range or a number of rows preceding and following the current row. For example, within a partition by month, an average can be calculated over the previous three month period.

The **CUME_DIST** function is a distribution function that returns a cumulative distribution of a row within an OLAP window, expressed as a value between 0.0 - 1.0. The result is computed as follows:

The number of rows preceding or peer with the current row in the OLAP window, divided by the number of rows in the OLAP window.

The data type of the result is DECFLOAT(34). The result cannot be NULL.

The **PERCENT_RANK** function is a distribution function that returns a relative percentile rank of a row within an OLAP window, expressed as a value between 0.0 - 1.0. When the number of rows in the OLAP window is greater than 1, the result is computed as follows:

The RANK of the current row in the OLAP window minus 1 divided by the number of rows in the OLAP window minus 1.

Otherwise, the result is 0.0.

The data type of the result is DECFLOAT(34). The result cannot be NULL.

The ranking function computes the ordinal rank of a row within the window. Rows that are not distinct with respect to the ordering within their window are assigned the same rank. The results of ranking may be defined with or without gaps in the numbers resulting from duplicate values.

If **RANK** is specified, the rank of a row is defined as 1 plus the number of rows that strictly precede the row. Thus, if two or more rows are not distinct with respect to the ordering, then there will be one or more gaps in the sequential rank numbering.

If **DENSE_RANK (or DENSERANK)** is specified, the rank of a row is defined as 1 plus the number of preceding rows that are distinct with respect to the ordering. Therefore, there will be no gaps in the sequential rank numbering.

The **ROW_NUMBER (or ROWNUMBER)** function computes the sequential row number of the row within the window defined by the ordering, starting with 1 for the first row. If the ORDER BY clause is not specified in the window, the row numbers are assigned to the rows in arbitrary order, as returned by the subselect (not according to any ORDER BY clause in the select-statement).

If the fetch-clause is used along with the ROW_NUMBER function, the row numbers might not be displayed in order. The fetch-clause is applied after the result set (including any ROW_NUMBER assignments) is generated; therefore, if the row number order is not the same as the order of the result set, some assigned numbers might be missing from the sequence.

The data type of the result of RANK, DENSE_RANK or ROW_NUMBER is BIGINT. The result cannot be null.

The **NTILE** function returns the quantile rank of a row.

num-tiles
An expression that specifies the number of quantiles. The expression must return a value that is a built-in numeric data type, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the expression is not a SMALLINT, INTEGER, or BIGINT, it is cast to BIGINT before the function is evaluated. The value must be greater than 0 (SQLSTATE 22014). The expression must be a constant, a variable, or a cast of a constant or variable (SQLSTATE 42601).

The data type of the result of NTILE is the same data type as the data type of *num-tiles* after any implicit casting. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

The NTILE function computes the quantile rank of a row by dividing the ordered rows within the OLAP window into *num-tiles* quantiles and returns a value between 1 and MIN(*n*, *num-tiles*), where *n* is the number of rows within the OLAP window. If *n* is evenly divisible by *num-tiles*, the rows in the OLAP window are grouped into *num-tiles* quantiles, each containing (*n* / *num-tiles*) rows. Otherwise, each of the quantiles 1 through MOD(*n*, *num-tiles*) is assigned (*n* / *num-tiles* + 1) rows while each of the quantiles (MOD(*n*, *num-tiles*) + 1) through *num-tiles* is assigned (*n* / *num-tiles*) rows. The result is the quantile rank which is associated with the current row.

Equivalent sort keys are not considered when rows are divided into quantiles. Rows with equivalent sort keys can be assigned to different quantiles based on the non-deterministic order of these sort keys. Therefore, NTILE is a non-deterministic function.

The **LAG** function returns the expression value for the row at *offset* rows before the current row. The *offset* must be a positive integer constant (SQLSTATE 42815). An *offset* value of 0 means the current row. If a window-partition-clause is specified, *offset* means *offset* rows before the current row and within the current partition. If *offset* is not specified, the value 1 is used. If *default-value* (which can be an expression) is specified, it will be returned if the offset goes beyond the scope of the current partition. Otherwise, the null value is returned. If 'IGNORE NULLS' is specified, all rows where the expression value for the row is the null value are not considered in the calculation. If 'IGNORE NULLS' is specified and all rows are null, *default-value* (or the null value if *default-value* was not specified) is returned.

The **LEAD** function returns the expression value for the row at *offset* rows after the current row. The *offset* must be a positive integer constant (SQLSTATE 42815). An *offset* value of 0 means the current row. If a window-partition-clause is specified, *offset* means *offset* rows after the current row and within the current partition. If *offset* is not specified, the value 1 is used. If *default-value* (which can be an expression) is specified, it will be returned if the offset goes beyond the scope of the current partition. Otherwise, the null value is returned. If 'IGNORE NULLS' is specified, all rows where the expression value for the row is the null value are not considered in the calculation. If 'IGNORE NULLS' is specified and all rows are null, *default-value* (or the null value if *default-value* was not specified) is returned.

The **FIRST_VALUE** function returns the expression value for the first row in an OLAP window. If 'IGNORE NULLS' is specified, all rows where the expression value for the row is the null value are not considered in the calculation. If 'IGNORE NULLS' is specified and all values in the OLAP window are null, FIRST_VALUE returns the null value.

The **LAST_VALUE** function returns the expression value for the last row in an OLAP window. If 'IGNORE NULLS' is specified, all rows where the expression value for the row is the null value are not considered in the calculation. If 'IGNORE NULLS' is specified and all values in the OLAP window are null, LAST_VALUE returns the null value.

The data type of the result of FIRST_VALUE, LAG, LAST_VALUE, and LEAD is the data type of the expression. The result can be null.

The NTH_VALUE function returns the expression value for the *nth-row* row in an OLAP window.

expression
An expression that specifies the current row in an OLAP window. The expression must return a value that is a built-in data type.(SQLSTATE 42884).

nth-row
An expression that specifies which row of the OLAP window to return. The expression must return a value that is a built-in numeric data type, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported using implicit casting. If the expression is not a SMALLINT, INTEGER, or BIGINT, it is cast to BIGINT before the function is evaluated. The value must be greater than 0 (SQLSTATE 22016). The expression must be a constant, a variable, or a cast of a constant or variable (SQLSTATE 428I9).

FROM FIRST or FROM LAST
Specifies how *nth-row* is applied. If FROM FIRST is specified, *nth-row* is treated as counting forward from the first row in the OLAP window. If FROM LAST is specified, *nth-row* is treated as counting backward from the last row in the OLAP window.

RESPECT NULLS or IGNORE NULLS
Specifies how NULL values in the OLAP window are handled. If RESPECT NULLS is specified, all rows where the expression value for the row is the null value are considered in the calculation. If IGNORE NULLS is specified, all rows where the expression value for the row is the null value are not considered in the calculation.

The data type of the result of NTH_VALUE is the same as the data type of *expression*.

The result can be null. If *nth-row* is null, the result is the null value. If the number of rows in the OLAP window (including null values if RESPECT NULLS is specified or excluding null values if IGNORE NULLS is specified) is less than the value of *nth-row*, the result is the null value.

The NTH_VALUE function is a non-deterministic function because the window-order-clause is not required and when window-order-clause is specified, rows with equivalent sort keys have a non-deterministic order.

The RATIO_TO_REPORT function returns the ratio of an argument to the sum of the arguments in an OLAP partition. For example, the following functions are equivalent:

```
RATIO_TO_REPORT(expression) OVER (...)
CAST(expression AS DECFLOAT(34)) / SUM(expression) OVER(...)
```

The division is always performed using DECFLOAT(34). The result data type is DECFLOAT(34). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

PARTITION BY (*partitioning-expression*,...)
Defines the partition within which the function is applied. A *partitioning-expression* is an expression that is used in defining the partitioning of the result set. Each *column-name* that is referenced in a *partitioning-expression* must unambiguously reference a column of the result table of the subselect that contains the OLAP specification (SQLSTATE 42702 or 42703). A *partitioning-expression* cannot include a scalar fullselect or an XMLQUERY or XMLEXISTS expression (SQLSTATE 42822), or any function or query that is not deterministic or that has an external action (SQLSTATE 42845).

window-order-clause

ORDER BY (*sort-key-expression*,...)
Defines the ordering of rows within a partition that determines the value of the OLAP function or the meaning of the ROW values in the window-aggregation-group-clause (it does not define the ordering of the query result set).

sort-key-expression
An expression used in defining the ordering of the rows within a window partition. Each column name referenced in a *sort-key-expression* must unambiguously reference a column of the result set of the subselect, including the OLAP function (SQLSTATE 42702 or 42703). A *sort-key-expression* cannot include a scalar fullselect or an XMLQUERY or XMLEXISTS expression (SQLSTATE 42822), or any function or query that is not deterministic or that has an external action (SQLSTATE 42845). This clause is required for the RANK and DENSE_RANK functions (SQLSTATE 42601).

ASC
Uses the values of the sort-key-expression in ascending order.

DESC
Uses the values of the sort-key-expression in descending order.

NULLS FIRST
The window ordering considers null values *before* all non-null values in the sort order.

NULLS LAST
The window ordering considers null values *after* all non-null values in the sort order.

ORDER OF *table-designator*
Specifies that the same ordering used in *table-designator* should be applied to the result table of the subselect. There must be a table reference matching *table-designator* in the FROM clause of the subselect that specifies this clause (SQLSTATE 42703). The ordering that is applied is the same as if the columns of the ORDER BY clause in the nested subselect (or fullselect) were included in the outer subselect (or fullselect), and these columns were specified in place of the ORDER OF clause.

window-aggregation-group-clause
The aggregation group of a row R is a set of rows defined in relation to R (in the ordering of the rows of R's partition). This clause specifies the aggregation group. If this clause is not specified and a window-order-clause is also not specified, the aggregation group consists of all the rows of the window partition. This default can be specified explicitly using RANGE (as shown) or ROWS.

If window-order-clause is specified, the default behavior is different when window-aggregation-group-clause is not specified. The window aggregation group consists of all rows of the partition of R that precede R and that are peers of R in the window ordering of the window partition defined by the window-order-clause.

ROWS
Indicates the aggregation group is defined by counting rows.

RANGE
Indicates the aggregation group is defined by an offset from a sort key.

group-start
Specifies the starting point for the aggregation group. The aggregation group end is the current row. Specification of the group-start clause is equivalent to a group-between clause of the form "BETWEEN group-start AND CURRENT ROW".

group-between
Specifies the aggregation group start and end based on either ROWS or RANGE.

group-end
Specifies the ending point for the aggregation group. The aggregation group start is the current row. Specification of the group-end clause is equivalent to a group-between clause of the form "BETWEEN CURRENT ROW AND group-end".

UNBOUNDED PRECEDING
Includes the entire partition preceding the current row. This can be specified with either ROWS or RANGE. Also, this can be specified with multiple sort-key-expressions in the window-order-clause.

UNBOUNDED FOLLOWING
Includes the entire partition following the current row. This can be specified with either ROWS or RANGE. Also, this can be specified with multiple sort-key-expressions in the window-order-clause.

CURRENT ROW
Specifies the start or end of the aggregation group based on the current row. If ROWS is specified, the current row is the aggregation group boundary. If RANGE is specified, the aggregation group boundary includes the set of rows with the same values for the *sort-key-expressions* as the current row. This clause cannot be specified in *group-bound2* if *group-bound1* specifies *value* FOLLOWING.

***unsigned-constant* PRECEDING**
Specifies either the range or number of rows preceding the current row. If ROWS is specified, then *unsigned-constant* must be zero or a positive integer indicating a number of rows. If RANGE is specified, then the data type of *unsigned-constant* must be comparable to the type of the *sort-key-expression* of the *window-order-clause*. There can only be one *sort-key-expression*, and the data type of the *sort-key-expression* must allow subtraction. This clause cannot be specified in *group-bound2* if *group-bound1* is CURRENT ROW or *unsigned-constant* FOLLOWING.

***unsigned-constant* FOLLOWING**
Specifies either the range or number of rows following the current row. If ROWS is specified, then *unsigned-constant* must be zero or a positive integer indicating a number of rows. If RANGE is specified, then the data type of *unsigned-constant* must be comparable to the type of the *sort-key-expression* of the *window-order-clause*. There can only be one *sort-key-expression*, and the data type of the *sort-key-expression* must allow addition.

Examples

1. Display the ranking of employees, in order by surname, according to their total salary (based on salary plus bonus) that have a total salary more than $30,000.

```
SELECT EMPNO, LASTNAME, FIRSTNME, SALARY+BONUS AS TOTAL_SALARY,
    RANK() OVER (ORDER BY SALARY+BONUS DESC) AS RANK_SALARY
  FROM EMPLOYEE WHERE SALARY+BONUS > 30000
  ORDER BY LASTNAME
```

Note that if the result is to be ordered by the ranking, then replace ORDER BY LASTNAME with:

```
ORDER BY RANK_SALARY
```

or

```
ORDER BY RANK() OVER (ORDER BY SALARY+BONUS DESC)
```

2. Rank the departments according to their average total salary.

```
SELECT WORKDEPT, AVG(SALARY+BONUS) AS AVG_TOTAL_SALARY,
    RANK() OVER (ORDER BY AVG(SALARY+BONUS) DESC) AS RANK_AVG_SAL
  FROM EMPLOYEE
  GROUP BY WORKDEPT
  ORDER BY RANK_AVG_SAL
```

3. Rank the employees within a department according to their education level. Having multiple employees with the same rank in the department should not increase the next ranking value.

```
SELECT WORKDEPT, EMPNO, LASTNAME, FIRSTNME, EDLEVEL,
    DENSE_RANK() OVER
      (PARTITION BY WORKDEPT ORDER BY EDLEVEL DESC) AS RANK_EDLEVEL
```

```
  FROM EMPLOYEE
  ORDER BY WORKDEPT, LASTNAME
```

4. Provide row numbers in the result of a query.

```
SELECT ROW_NUMBER() OVER (ORDER BY WORKDEPT, LASTNAME) AS NUMBER,
    LASTNAME, SALARY
  FROM EMPLOYEE
  ORDER BY WORKDEPT, LASTNAME
```

5. List the top five wage earners.

```
SELECT EMPNO, LASTNAME, FIRSTNME, TOTAL_SALARY, RANK_SALARY
  FROM (SELECT EMPNO, LASTNAME, FIRSTNME, SALARY+BONUS AS TOTAL_SALARY,
    RANK() OVER (ORDER BY SALARY+BONUS DESC) AS RANK_SALARY
    FROM EMPLOYEE) AS RANKED_EMPLOYEE
  WHERE RANK_SALARY < 6
  ORDER BY RANK_SALARY
```

Note that a nested table expression was used to first compute the result, including the rankings, before the rank could be used in the WHERE clause. A common table expression could also have been used.

6. For each department, list employee salaries and show how much less each person makes compared to the employee in that department with the next highest salary.

```
SELECT EMPNO, WORKDEPT, LASTNAME, FIRSTNME, JOB, SALARY,
    LEAD(SALARY, 1) OVER (PARTITION BY WORKDEPT
      ORDER BY SALARY) - SALARY AS DELTA_SALARY
  FROM EMPLOYEE
  ORDER BY WORKDEPT, SALARY
```

7. Calculate an employee's salary relative to the salary of the employee who was first hired for the same type of job.

```
SELECT JOB, HIREDATE, EMPNO, LASTNAME, FIRSTNME, SALARY,
    FIRST_VALUE(SALARY) OVER (PARTITION BY JOB
      ORDER BY HIREDATE) AS FIRST_SALARY,
    SALARY - FIRST_VALUE(SALARY) OVER (PARTITION BY JOB
      ORDER BY HIREDATE) AS DELTA_SALARY
  FROM EMPLOYEE
  ORDER BY JOB, HIREDATE
```

8. Calculate the average close price for stock XYZ during the month of January, 2006. If a stock doesn't trade on a given day, its close price in the DAILYSTOCKDATA table is the null value. Instead of returning the null value for days that a stock doesn't trade, use the COALESCE function and LAG function to return the close price for the most recent day the stock was traded. Limit the search for a previous not-null close value to one month before January 1st, 2006.

```
WITH V1(SYMBOL, TRADINGDATE, CLOSEPRICE) AS
(
SELECT SYMBOL, TRADINGDATE,
  COALESCE(CLOSEPRICE,
    LAG(CLOSEPRICE,
      1,
      CAST(NULL AS DECIMAL(8,2)),
      'IGNORE NULLS')
    OVER (PARTITION BY SYMBOL
    ORDER BY TRADINGDATE)
)
FROM DAILYSTOCKDATA
WHERE SYMBOL = 'XYZ' AND
  TRADINGDATE BETWEEN '2005-12-01' AND '2006-01-31'
)
SELECT SYMBOL, AVG(CLOSEPRICE) AS AVG
  FROM V1
  WHERE TRADINGDATE BETWEEN '2006-01-01' AND '2006-01-31'
  GROUP BY SYMBOL
```

9. Calculate the 30-day moving average for stocks ABC and XYZ during the year 2005.

```
WITH V1(SYMBOL, TRADINGDATE, MOVINGAVG30DAY) AS
(
```

```
SELECT SYMBOL, TRADINGDATE,
  AVG(CLOSEPRICE) OVER (PARTITION BY SYMBOL
    ORDER BY TRADINGDATE
  ROWS BETWEEN 29 PRECEDING AND CURRENT ROW)
FROM DAILYSTOCKDATA
WHERE SYMBOL IN ('ABC', 'XYZ')
  AND TRADINGDATE BETWEEN DATE('2005-01-01') - 2 MONTHS
    AND '2005-12-31'
)
SELECT SYMBOL, TRADINGDATE, MOVINGAVG30DAY
  FROM V1
  WHERE TRADINGDATE BETWEEN '2005-01-01' AND '2005-12-31'
  ORDER BY SYMBOL, TRADINGDATE
```

10. Use an expression to define the cursor position and query a sliding window of 50 rows before that position.

```
SELECT DATE, FIRST_VALUE(CLOSEPRICE + 100) OVER
    (PARTITION BY SYMBOL
    ORDER BY DATE
    ROWS BETWEEN 50 PRECEDING AND 1 PRECEDING) AS FV
  FROM DAILYSTOCKDATA
  ORDER BY DATE
```

11. For each employee, calculate the average salary for the set of employees that includes those employees in the same department who have an education level 1 lower and 1 higher than the employee.

```
SELECT WORKDEPT, EDLEVEL, SALARY, AVG(SALARY)
      OVER (PARTITION BY WORKDEPT
      ORDER BY EDLEVEL
      RANGE BETWEEN 1 PRECEDING AND 1 FOLLOWING)
   FROM EMPLOYEE
   ORDER BY WORKDEPT, EDLEVEL
```

12. Calculate which quartile (4-quantiles) each employee's salary is in.

```
SELECT EMPNO, SALARY, NTILE(4) OVER
      (ORDER BY SALARY) AS QUARTILE
   FROM EMPLOYEE
   ORDER BY SALARY
```

The result set is:

```
EMPNO  SALARY      QUARTILE
------ ----------- -----------
200340    31840.00           1
000290    35340.00           1
200330    35370.00           1

000020    94250.00           4
000070    96170.00           4
000030    98250.00           4
000010   152750.00           4

  42 record(s) selected.
```

13. The query in the following example divides the rows into 3 buckets, grouping them by maximum salary. The maximum salary is included to show what values go into each bucket:

```
   SELECT NTILE(3) OVER (ORDER BY MAX_SALARY) AS Bucket,
MAX_SALARY FROM GOSALESDW.EMP_POSITION_DIM;
```

A portion of the output from the query is in the following table:

Table 27. Example output

BUCKET	MAX_SALARY
1	0.00
...	...
1	35000.00
2	5000.00
...	...
2	12000.00
3	13000.00
...	...
3	301500.00

14. Find the cumulative distribution and the relative percentile rank of each employee's salary within their department.

```
   SELECT EMPNO, WORKDEPT, SALARY,
      CAST(CUME_DIST() OVER (PARTITION BY WORKDEPT ORDER BY SALARY) AS DECIMAL(4,3))
         AS CUME_DIST,
      CAST(PERCENT_RANK() OVER (PARTITION BY WORKDEPT ORDER BY SALARY)
         AS DECIMAL(4,3))
         AS PERCENT_RANK FROM EMP
      ORDER BY WORKDEPT, SALARY
```

The result set is:

```
EMPNO  WORKDEPT SALARY      CUME_DIST PERCENT_RANK
------ -------- ----------- --------- ------------
200120 A00         39250.00     0.200        0.000

```

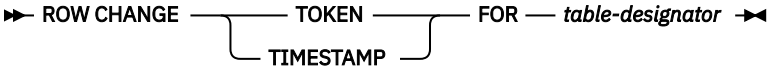
ROW CHANGE expression

A ROW CHANGE expression returns a token or a timestamp that represents the last change to a row.

row-change-expression



TOKEN
Specifies that a BIGINT value representing a relative point in the modification sequence of a row is to be returned. If the row has not been changed, the result is a token that represents when the initial value was inserted. The result can be null. ROW CHANGE TOKEN is not deterministic.

TIMESTAMP
Specifies that a TIMESTAMP value representing the last time that a row was changed is to be returned. If the row has not been changed, the result is the time that the initial value was inserted. The result can be null. ROW CHANGE TIMESTAMP is not deterministic.

FOR *table-designator*
Identifies the table in which the expression is referenced. The *table-designator* must uniquely identify a base table, view, or nested table expression (SQLSTATE 42867). If *table-designator* identifies a view or a nested table expression, the ROW CHANGE expression returns the TOKEN or TIMESTAMP of the base table of the view or nested table expression. The view or nested table expression must contain only one base table in its outer subselect (SQLSTATE 42867). If the *table-designator* is a view or nested table expression, it must be deletable (SQLSTATE 42703). For information about deletable views, see the "Notes" section of "CREATE VIEW". The table designator of a ROW CHANGE TIMESTAMP expression must resolve to a base table that contains a row change timestamp column (SQLSTATE 55068).

Notes

- ROW CHANGE TOKEN and ROW CHANGE TIMESTAMP are not valid expressions for a column-organized table (SQLSTATE 42703).

Examples

- Return a timestamp value that corresponds to the most recent change to each row from the EMPLOYEE table for employees in department 20. Assume that the EMPLOYEE table has been altered to contain a column defined with the ROW CHANGE TIMESTAMP clause.

```
SELECT ROW CHANGE TIMESTAMP FOR EMPLOYEE
  FROM EMPLOYEE WHERE DEPTNO = 20
```

- Return a BIGINT value that represents a relative point in the modification sequence of the row corresponding to employee number 3500. Also return the RID_BIT scalar function value that is to be used in an optimistic locking DELETE scenario. Specify the WITH UR option to get the latest ROW CHANGE TOKEN value.

```
SELECT ROW CHANGE TOKEN FOR EMPLOYEE, RID_BIT (EMPLOYEE)
  FROM EMPLOYEE WHERE EMPNO = '3500' WITH UR
```

The preceding statement succeeds whether or not there is a row change timestamp column in the EMPLOYEE table. The following searched DELETE statement deletes the row specified by the

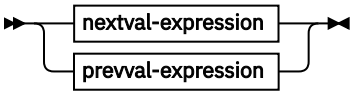
ROW CHANGE TOKEN and RID_BIT values from the preceding SELECT statement, assuming the two parameter marker values are set to the values obtained from the preceding statement.

```
DELETE FROM EMPLOYEE E
  WHERE RID_BIT (E) = ? AND ROW CHANGE TOKEN FOR E = ?
```

Sequence reference

A sequence reference is an expression which references a sequence defined at the application server.

sequence-reference



nextval-expression

prevval-expression

NEXT VALUE FOR *sequence-name*
A NEXT VALUE expression generates and returns the next value for the sequence specified by *sequence-name*.

PREVIOUS VALUE FOR *sequence-name*
A PREVIOUS VALUE expression returns the most recently generated value for the specified sequence for a previous statement within the current application process. This value can be referenced repeatedly by using PREVIOUS VALUE expressions that specify the name of the sequence. There may be multiple instances of PREVIOUS VALUE expressions specifying the same sequence name within a single statement; they all return the same value. In a partitioned database environment, a PREVIOUS VALUE expression may not return the most recently generated value.

A PREVIOUS VALUE expression can only be used if a NEXT VALUE expression specifying the same sequence name has already been referenced in the current application process, in either the current or a previous transaction (SQLSTATE 51035).

Notes

- ***Authorization:*** If a sequence-reference is used in a statement, the privileges held by the authorization ID of the statement must include at least one of the following privileges:
  - The USAGE privilege on the sequence
  - DATAACCESS authority
- A new value is generated for a sequence when a NEXT VALUE expression specifies the name of that sequence. However, if there are multiple instances of a NEXT VALUE expression specifying the same sequence name within a query, the counter for the sequence is incremented only once for each row of the result, and all instances of NEXT VALUE return the same value for a row of the result.
- The same sequence number can be used as a unique key value in two separate tables by referencing the sequence number with a NEXT VALUE expression for the first row (this generates the sequence value), and a PREVIOUS VALUE expression for the other rows (the instance of PREVIOUS VALUE refers to the sequence value most recently generated in the current session), as shown in the following example:

```
INSERT INTO order(orderno, cutno)
  VALUES (NEXT VALUE FOR order_seq, 123456);

INSERT INTO line_item (orderno, partno, quantity)
  VALUES (PREVIOUS VALUE FOR order_seq, 987654, 1);
```

- NEXT VALUE and PREVIOUS VALUE expressions can be specified in the following places:

  - select-statement or SELECT INTO statement (within the select-clause, provided that the statement does not contain a DISTINCT keyword, a GROUP BY clause, an ORDER BY clause, a UNION keyword, an INTERSECT keyword, or EXCEPT keyword)
  - INSERT statement (within a VALUES clause)
  - INSERT statement (within the select-clause of the fullselect)
  - UPDATE statement (within the SET clause (either a searched or a positioned UPDATE statement), except that NEXT VALUE cannot be specified in the select-clause of the fullselect of an expression in the SET clause)
  - SET Variable statement (except within the select-clause of the fullselect of an expression; a NEXT VALUE expression can be specified in a trigger, but a PREVIOUS VALUE expression cannot)
  - VALUES INTO statement (within the select-clause of the fullselect of an expression)
  - CREATE PROCEDURE statement (within the routine-body of an SQL procedure)
  - CREATE TRIGGER statement within the triggered-action (a NEXT VALUE expression may be specified, but a PREVIOUS VALUE expression cannot)
- NEXT VALUE and PREVIOUS VALUE expressions cannot be specified (SQLSTATE 428F9) in the following places:
  - Join condition of a full outer join
  - DEFAULT value for a column in a CREATE TABLE or ALTER TABLE statement
  - Generated column definition in a CREATE TABLE or ALTER TABLE statement
  - Summary table definition in a CREATE TABLE or ALTER TABLE statement
  - Condition of a CHECK constraint
  - CREATE TRIGGER statement (a NEXT VALUE expression may be specified, but a PREVIOUS VALUE expression cannot)
  - CREATE VIEW statement
  - CREATE METHOD statement
  - CREATE FUNCTION statement
  - An argument list of an XMLQUERY, XMLEXISTS, or XMLTABLE expression
- In addition, a NEXT VALUE expression cannot be specified (SQLSTATE 428F9) in the following places:
  - CASE expression
  - Parameter list of an aggregate function
  - Subquery in a context other than those explicitly allowed, as described previously
  - SELECT statement for which the outer SELECT contains a DISTINCT operator
  - Join condition of a join
  - SELECT statement for which the outer SELECT contains a GROUP BY clause
  - SELECT statement for which the outer SELECT is combined with another SELECT statement using the UNION, INTERSECT, or EXCEPT set operator
  - Nested table expression
  - Parameter list of a table function
  - WHERE clause of the outer-most SELECT statement, or a DELETE or UPDATE statement
  - ORDER BY clause of the outer-most SELECT statement
  - select-clause of the fullselect of an expression, in the SET clause of an UPDATE statement
  - IF, WHILE, DO ... UNTIL, or CASE statement in an SQL routine
- When a value is generated for a sequence, that value is consumed, and the next time that a value is requested, a new value will be generated. This is true even when the statement containing the NEXT VALUE expression fails or is rolled back.

If an INSERT statement includes a NEXT VALUE expression in the VALUES list for the column, and if an error occurs at some point during the execution of the INSERT (it could be a problem in generating the next sequence value, or a problem with the value for another column), then an insertion failure occurs (SQLSTATE 23505), and the value generated for the sequence is considered to be consumed. In some cases, reissuing the same INSERT statement might lead to success.

For example, consider an error that is the result of the existence of a unique index for the column for which NEXT VALUE was used and the sequence value generated already exists in the index. It is possible that the next value generated for the sequence is a value that does not exist in the index and so the subsequent INSERT would succeed.

- ***Scope of PREVIOUS VALUE:*** The value of PREVIOUS VALUE persists until the next value is generated for the sequence in the current session, the sequence is dropped or altered, or the application session ends. The value is unaffected by COMMIT or ROLLBACK statements. The value of PREVIOUS VALUE cannot be directly set and is a result of executing the NEXT VALUE expression for the sequence.

  A technique commonly used, especially for performance, is for an application or product to manage a set of connections and route transactions to an arbitrary connection. In these situations, the availability of the PREVIOUS VALUE for a sequence should be relied on only until the end of the transaction. Examples of where this type of situation can occur include applications that use XA protocols, use connection pooling, use the connection concentrator, and use HADR to achieve failover.
- If in generating a value for a sequence, the maximum value for the sequence is exceeded (or the minimum value for a descending sequence) and cycles are not permitted, then an error occurs (SQLSTATE 23522). In this case, the user could ALTER the sequence to extend the range of acceptable values, or enable cycles for the sequence, or DROP and CREATE a new sequence with a different data type that has a larger range of values.

  For example, a sequence may have been defined with a data type of SMALLINT, and eventually the sequence runs out of assignable values. DROP and re-create the sequence with the new definition to redefine the sequence as INTEGER.
- A reference to a NEXT VALUE expression in the select statement of a cursor refers to a value that is generated for a row of the result table. A sequence value is generated for a NEXT VALUE expression for each row that is fetched from the database. If blocking is done at the client, the values may have been generated at the server before the processing of the FETCH statement. This can occur when there is blocking of the rows of the result table. If the client application does not explicitly FETCH all the rows that the database has materialized, then the application will not see the results of all the generated sequence values (for the materialized rows that were not returned).
- A reference to a PREVIOUS VALUE expression in the select statement of a cursor refers to a value that was generated for the specified sequence before the opening of the cursor. However, closing the cursor can affect the values returned by PREVIOUS VALUE for the specified sequence in subsequent statements, or even for the same statement in the event that the cursor is reopened. This would be the case when the select statement of the cursor included a reference to NEXT VALUE for the same sequence name.
- ***Syntax alternatives***: The following are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - NEXTVAL and PREVVAL can be specified in place of NEXT VALUE and PREVIOUS VALUE
  - *sequence-name*.NEXTVAL can be specified in place of NEXT VALUE FOR *sequence-name*
  - *sequence-name*.CURRVAL can be specified in place of PREVIOUS VALUE FOR *sequence-name*

Examples

Assume that there is a table called "order", and that a sequence called "order_seq" is created as follows:

```
CREATE SEQUENCE order_seq
  START WITH 1
  INCREMENT BY 1
  NO MAXVALUE
  NO CYCLE
  CACHE 24
```

Following are some examples of how to generate an "order_seq" sequence number with a NEXT VALUE expression:

```
INSERT INTO order(orderno, custno)
  VALUES (NEXT VALUE FOR order_seq, 123456);
```

or

```
UPDATE order
  SET orderno = NEXT VALUE FOR order_seq
  WHERE custno = 123456;
```

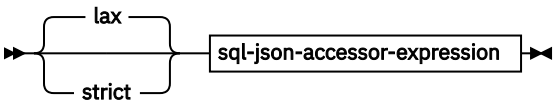
or

```
VALUES NEXT VALUE FOR order_seq INTO :hv_seq;
```

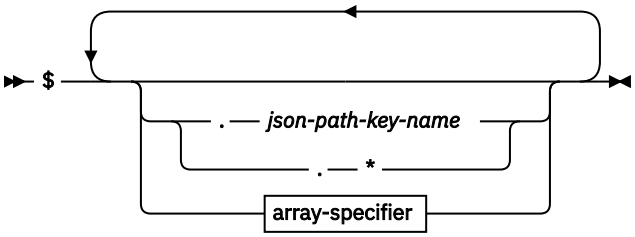
sql-json-path-expression

An SQL/JSON path expression defines access to the elements of a JSON document.

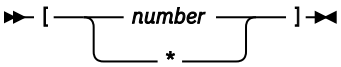
sql-json-path-expression



sql-json-accessor-expression



array-specifier



lax or strict

Specifies the JSON path mode.

lax

Specifies that certain structural errors are tolerated when the current JSON document is navigated, including the following structural errors:

- Automatic unnesting of arrays.
- Automatic wrapping of scalar values to be a single element array, if referenced as an array.
- Specifying nonexistent items, including array index values that are out of range.

If an item does not exist, the SQL/JSON path expression returns an empty string, which is handled according to the options specified in a function's ON EMPTY clause.

strict

Specifies that an error is reported when the specified path expression cannot be used to navigate the current JSON document. The error is handled according to the current ON ERROR clause.

sql-json-accessor-expression

$

Specifies the start of the context item to which the rest of the SQL/JSON path expression is applied.

json-path-key-name
Specifies the key name of a key:value pair in the JSON document.

*****
Specifies that the values for all the keys are returned as an SQL/JSON sequence.

array-specifier
Specifies the index values to apply to an array. The first element of the array has an index of 0. If specified index is out of range, then it is considered an error.

number
An unsigned integer constant that represents an array element. The first element of the array has an index of 0.

*****
Indicates that all array elements are selected.

Special semantics are associated with some characters, when used as part of a SQL/JSON path expression:

.
Used for going to the next level within JSON document.

*****
Used for matching all the keys at the current level.

[and]
Used for specifying an index of an array.

To allow these characters to be used within *json-path-key-name*, use an escape backslash character (\) before these characters to indicate that these characters are part of the key name.

Examples

1. This example is based on the following JSON document:

```
{ "isbn": "123-456-222", "author": [ { "name":"Jones"},{"name":"Smith"}]}
```

The following table shows the results of using various SQL/JSON path expressions to access items in the JSON document:

Path	Number of matches	Matches
$.isbn	1	"123-456-222"
$.author[0].name	1	"Jones"
$.author[1].name	1	"Smith"

2. This example is based on the following JSON document:

```
{
  "person"   : {"firstname":"Fred", "lastname":"Gauss"},
  "where"    : "General Products",
  "friends"  : [ { "name": "Lili","rank": 5 }, {"name": "Hank", "rank": 7} ],
  "work.area": "Finance"
}
```

The following table shows the results of using various SQL/JSON path expressions to access items in the JSON document:

Path	Number of matches	Matches
$.person.lastname	1	"Gauss"
$.friends	1	[{ "name": "Lili", "rank": 5 }, { "name": "Hank", "rank": 7}]

Path	Number of matches	Matches
$.*.firstname	1	"Fred"
$.person.*	2	"Fred" and "Gauss"
$.friends[*]	2	{ "name": "Lili", "rank": 5 } and { "name": "Hank", "rank": 7}
$.friends[*].rank	2	5 and 7
$.work.area	0	
$.work\.area	1	"Finance"

3. This example is based on the following JSON document:

```
{ "a":[{"b1":10}, {"b2":11}], "c":"hi" }
```

The following table shows the results of using various SQL/JSON path expressions to access items in the JSON document:

Path	Matches	Remark
lax $.a.b1	10	Automatic unnesting of array element at `'a'`. Treated as `'a[*]'`.
strict $.a.b1	Error	No automatic unnesting of array.
lax $.c[0]	"hi"	Automatic wrapping of scalar value into single element array.
strict $.c[0]	Error	No automatic wrapping of scalar value into single element array.

4. This example illustrates the difference between JSON_VALUE and JSON_QUERY behavior. This example is based on the following JSON document:

```
{ "a": [1,2], "b": { "c1":1, "c2":2 } }
```

This example is based on the following path results:

Path expression	Number of values returned	Values returned
$.a	Single	[1,2]
$.b.*	Multiple	1 2

The following table shows the results of using various SQL/JSON path expressions to access items in the JSON document:

Operator	$.a	$.b.*	Remark
JSON_VALUE	Error	Error	Error for accessing array type and multiple matches.
JSON_QUERY WITHOUT ARRAY WRAPPER	[1,2]	Error	Error for multiple values with no array wrapper.
JSON_QUERY WITH UNCONDITIONAL ARRAY WRAPPER	[[1,2]]	[1,2]	You must use an array wrapper, even if the type is array.

Operator	$.a	$.b.*	Remark
JSON_QUERY WITH CONDITIONAL ARRAY WRAPPER	[1,2]	[1,2]	An array wrapper is not necessary, if the type is array.

Subtype treatment

The *subtype-treatment* is used to cast a structured type expression into one of its subtypes.

subtype-treatment

The static type of *expression* must be a user-defined structured type, and that type must be the same type as, or a supertype of, *data-type*. If the type name in *data-type* is unqualified, the SQL path is used to resolve the type reference. The static type of the result of subtype-treatment is *data-type*, and the value of the subtype-treatment is the value of the expression. At run time, if the dynamic type of the expression is not *data-type* or a subtype of *data-type*, an error is returned (SQLSTATE 0D000).

Example

- If an application knows that all column object instances in a column CIRCLE_COL have the dynamic type COLOREDCIRCLE, use the following query to invoke the method RGB on such objects. Assume the existence of a table called RINGS, with a column CIRCLE_COL of structured type CIRCLE. Also, assume that COLOREDCIRCLE is a subtype of CIRCLE and that the method RGB has been defined previously for COLOREDCIRCLE as `RGB() RETURNS DOUBLE`.

  ```
  SELECT TREAT (CIRCLE_COL AS COLOREDCIRCLE)..RGB()
    FROM RINGS
  ```

  At run time, if there are instances of dynamic type CIRCLE, an error is raised (SQLSTATE 0D000). This error can be avoided by using the TYPE predicate in a CASE expression, as follows:

  ```
  SELECT (CASE
    WHEN CIRCLE_COL IS OF (COLOREDCIRCLE)
      THEN TREAT (CIRCLE_COL AS COLOREDCIRCLE)..RGB()
      ELSE NULL
    END)
    FROM RINGS
  ```

Determining data types of untyped expressions

An untyped expression refers to the usage of a parameter marker which is specified without a target data type associated with it, a null value which is specified without a target data type associated with it, or a DEFAULT keyword.

Untyped expressions can be used in SQL statements as long as one of the following conditions is true:

- A PREPARE statement is being executed by a CLI or JDBC application to compile the SQL statement; the client interface is using deferred prepare; and the registry variable, DB2_DEFERRED_PREPARE_SEMANTICS is set to YES. In this case, any untyped parameter marker derives its data type based on the input descriptor associated with the subsequent OPEN or EXECUTE statement. The length attribute is set to the maximum of the length according to the UNTYPED row, as described in the Table 20 on page 121 in "Functions" and the length as determined from the following tables. For data types not listed as a target type in Table 20 on page 121 in "Functions", the length from the input descriptor associated with the subsequent OPEN or EXECUTE statement will be used. The data types and lengths may be modified depending on the usage of the untyped parameter marker in the SQL statement.
- The data type can be determined based on the context in the SQL statement. These locations and the resulting data types are shown in the following table. The locations are grouped into expressions, predicates, built-in functions, and user-defined routines to assist in determining the applicability of an untyped expression. If the data type cannot be determined based on the context, an error is issued.

For some cases not listed, untyped expressions in a select list will be resolved to a data type determined based on the usage in the SQL statement.

The code page of the untyped expression is determined by the context. Where there is no context, the code page is the same as if the untyped expression was cast to a VARCHAR data type.

The tables that follow show character string and graphic string data types in string units associated with a database environment where the string units default is SYSTEM. If the Unicode database environment has the string units set to CODEUNITS32, then any character string or graphic string length attributes that represent the data type maximum length should be considered to represent the data type maximum in CODEUNITS32. All character string or graphic string data types have the default string units of the database environment.

Table 28. Untyped Expression Usage in Expressions (Including Select List, CASE, and VALUES)

Untyped Expression Location	**Data Type**
Alone in a select list	If the untyped expression is unnamed or is named but not subsequently referenced in the SQL statement, then an error is returned, unless the untyped expression is the null value. In such cases, the data type is VARCHAR(1). If the untyped expression is named and subsequently referenced in the SQL statement, then the data type may be determined from the subsequent usage. For more information, refer to the "Determining data type from usage" note that follows this table.
Both operands of a single arithmetic operator, after considering operator precedence and order of operation rules Includes cases such as: `(? + ?) + 10`	DECFLOAT(34)
One operand of a single operator in an arithmetic expression (not a datetime expression) Includes cases such as: `? + (? * 10)`	The data type of the other operand
Labelled duration within a datetime expression (note that the portion of a labelled duration that indicates the type of units cannot be a parameter marker)	DECIMAL(15,0)
Any other operand of a datetime expression (for example, 'timecol + ?' or '? - datecol')	Error
Both operands of a CONCAT operator	VARCHAR(254)
One operand of a CONCAT operator when the other operand is a non-CLOB character data type	If one operand is either CHAR(*n*) or VARCHAR(*n*), where *n* is less than 128, the other is VARCHAR(254 - *n*); in all other cases, the data type is VARCHAR(254)

Table 28. Untyped Expression Usage in Expressions (Including Select List, CASE, and VALUES) (continued)

Untyped Expression Location	Data Type
One operand of a CONCAT operator when the other operand is a non-BLOB binary data type	If one operand is either BINARY(*n*) or VARBINARY(*n*), where *n* is less than 128, the other is VARBINARY(254 - *n*); in all other cases, the data type is VARBINARY(254)
One operand of a CONCAT operator, when the other operand is a non-DBCLOB graphic data type	If one operand is either GRAPHIC(*n*) or VARGRAPHIC(*n*), where *n* is less than 64, the other is VARGRAPHIC(127 - *n*); in all other cases, the data type is VARGRAPHIC(127)
One operand of a CONCAT operator, when the other operand is a large object string	Same as that of the other operand
The expression following the CASE keyword in a simple CASE expression	Result of applying the "Rules for the result data types" to the expressions following the WHEN keyword that are other than untyped expressions
At least one of the result-expressions in a CASE expression (both simple and searched), with the rest of the result-expressions being untyped expressions	Error
Any or all expressions following the WHEN keyword in a simple CASE expression	Result of applying the "Rules for result data types" to the expression following CASE and the expressions following WHEN keyword that are other than an untyped expression
A result-expression in a CASE expression (both simple and searched), when at least one result-expression is not an untyped expression	Result of applying the "Rules for result data types" to all result-expressions that are other than an untyped expression
Alone as a column-expression in a single-row VALUES clause that is not within an INSERT statement and not within the VALUES clause of in insert operation of a MERGE statement	Error if the untyped expression is unnamed or is named but not subsequently referenced in the SQL statement. If the untyped expression is named and subsequently referenced in the SQL statement, then the data type may be determined from the subsequent usage. For more information, refer to the "Determining data type from usage" note that follows this table.
Alone as a column-expression in a multi-row VALUES clause that is not within an INSERT statement, and for which the column-expressions in the same position in all other row-expressions are untyped expressions	Error if the untyped expression is unnamed or is named but not subsequently referenced in the SQL statement. If the untyped expression is named and subsequently referenced in the SQL statement, then the data type may be determined from the subsequent usage. For more information, refer to the "Determining data type from usage" note that follows this table.
Alone as a column-expression in a multi-row VALUES clause that is not within an INSERT statement, and for which the expression in the same position of at least one other row-expression is not an untyped expression	Result of applying the "Rules for result data types" on all operands that are other than untyped expressions

Table 28. Untyped Expression Usage in Expressions (Including Select List, CASE, and VALUES) (continued)

Untyped Expression Location	Data Type
Alone as a column-expression in a single-row VALUES clause within an INSERT statement	The data type of the column. If the column is defined as a user-defined distinct type, it is the source data type of the user-defined distinct type. If the column is defined as a user-defined structured type, it is the structured type, also indicating the return type of the transform function.
Alone as a column-expression in a multi-row VALUES clause within an INSERT statement	The data type of the column. If the column is defined as a user-defined distinct type, it is the source data type of the user-defined distinct type. If the column is defined as a user-defined structured type, it is the structured type, also indicating the return type of the transform function.
Alone as a column-expression in a values-clause of the source table for a MERGE statement	Error if the untyped expression is unnamed or is named but not subsequently referenced in the SQL statement. If the untyped expression is named and subsequently referenced in the SQL statement, then the data type may be determined from the subsequent usage. For more information, refer to the "Determining data type from usage" note that follows this table.
Alone as a column-expression in the VALUES clause of an insert operation of a MERGE statement	The data type of the column. If the column is defined as a user-defined distinct type, it is the source data type of the user-defined distinct type. If the column is defined as a user-defined structured type, it is the structured type, also indicating the return type of the transform function.
Alone as a column-expression on the right side of assignment-clause for an update operation of a MERGE statement	The data type of the column. If the column is defined as a user-defined distinct type, it is the source data type of the user-defined distinct type. If the column is defined as a user-defined structured type, it is the structured type, also indicating the return type of the transform function.
Alone as a column-expression on the right side of a SET clause in an UPDATE statement	The data type of the column. If the column is defined as a user-defined distinct type, it is the source data type of the user-defined distinct type. If the column is defined as a user-defined structured type, it is the structured type, also indicating the return type of the transform function.
As a value on the right side of a SET special register statement	The data type of the special register
Argument of the TABLESAMPLE clause of the tablesample-clause of a table-reference	DOUBLE
Argument of the REPEATABLE subclause of the tablesample-clause of a table-reference	INTEGER
Alone as fetch-row-count in a fetch-clause	BIGINT
Alone as offset-row-count in an OFFSET clause	BIGINT
As a value in a FREE LOCATOR statement	Locator

Table 28. Untyped Expression Usage in Expressions (Including Select List, CASE, and VALUES) (continued)

Untyped Expression Location	Data Type
As a value for the password in a SET ENCRYPTION PASSWORD statement	VARCHAR(128)

Note:

Determining data type from usage

The following is an example of how the data type for an untyped expression can be determined from subsequent usage:

If the named untyped expression is subsequently referenced in a comparison operator, it will then have the data type of the other operand. If there are multiple references of the named untyped expression in the SQL statement, the data type, length, precision, scale, and code page that is independently determined for each of those references must be identical or an error is returned.

Table 29. Untyped Expression Usage in Predicates

Untyped Expression Location	Data Type
Both operands of a comparison operator	VARCHAR(254)
One operand of a comparison operator, when the other operand is other than an untyped expression	The data type of the other operand
All operands of a BETWEEN predicate	VARCHAR(254)
Two operands of a BETWEEEN predicate	Same as that of the only typed expression
Only one operand of a BETWEEN predicate	Result of applying the "Rules for result data types" on all operands that are other than untyped expressions
All operands of an IN predicate, for example, ? IN (?,?,?)	VARCHAR(254)
The first operand of an IN predicate, when the right side is a fullselect, for example, IN (fullselect)	Data type of the selected column
The first operand of an IN predicate, when the right side is not a subselect;, for example, ? IN (?,A,B), or ? IN (A,?,B,?)	Result of applying the "Rules for result data types" on all operands of the IN list (operands to the right of the IN keyword) that are other than untyped expressions
Any or all operands of the IN list of the IN predicate, for example, A IN (?,B, ?)	Result of applying the "Rules for result data types" on all operands of the IN predicate (operands to the left and right of the IN keyword) that are other than untyped expressions
Both the operand in a row-value-expression of an IN predicate, and the corresponding result column of the fullselect, for example, (c1, ?) IN (SELECT c1, ? FROM ...)	VARCHAR(254)
Any operands in a row-value-expression of an IN predicate, for example, (c1,?) IN fullselect	Data type of the corresponding result column of the fullselect
Any select list items in a subquery if a row-value-expression is specified in an IN predicate, for example, (c1,c2) IN (SELECT?, c1, FROM ...)	Data type of the corresponding operand in the row-value-expression

Table 29. Untyped Expression Usage in Predicates (continued)

Untyped Expression Location	Data Type
All three operands of the LIKE predicate	Match expression (operand 1) and pattern expression (operand 2) are VARCHAR(32672); escape expression (operand 3) is VARCHAR(2)
The match expression of the LIKE predicate when either the pattern expression or the escape expression is other than an untyped expression	VARCHAR(32672), VARBINARY(32672), or VARGRAPHIC(16336), depending on the data type of the first operand that is not an untyped expression
The pattern expression of the LIKE predicate when either the match expression or the escape expression is other than an untyped expression	VARCHAR(32672), VARBINARY(32672), or VARGRAPHIC(16336), depending on the data type of the first operand that is not an untyped expression.
The escape expression of the LIKE predicate when either the match expression or the pattern expression is other than an untyped expression	VARCHAR(2), VARBINARY(1), or VARGRAPHIC(1), depending on the data type of the first operand that is not an untyped expression.
Operand of the NULL predicate	VARCHAR(254)

Table 30. Untyped Expression Usage in Built-in Functions

Untyped Parameter Marker Location	Data Type
Array index of an ARRAY	BIGINT
All arguments of COALESCE, when all arguments are untyped parameter markers	Error
Any argument of COALESCE, when at least one argument is not an untyped parameter marker	Result of applying the "Rules for result data types" on all arguments that are other than untyped parameter markers
First argument of DAYNAME	TIMESTAMP(12)
The argument of DIGITS	DECIMAL(31,6)
First argument of FROM_UTC_TIMESTAMP	TIMESTAMP(6)
All arguments of MAX, MIN, or NULLIF, when all arguments are untyped parameter markers	Error
Any argument of MAX, MIN, or NULLIF, when at least one argument is not an untyped parameter marker	Result of applying the "Rules for result data types" on all arguments that are other than untyped parameter markers
First argument of MONTHNAME	TIMESTAMP(12)
POSSTR (both arguments)	Both arguments are VARCHAR(32672)
POSSTR (one argument, when the other argument is a character data type)	VARCHAR(32672)
POSSTR (one argument, when the other argument is a graphic data type)	VARGRAPHIC(16336)
POSSTR (the search-string argument, when the other argument is a binary data type)	VARBINARY(32672)

Table 30. Untyped Expression Usage in Built-in Functions (continued)

Untyped Parameter Marker Location	Data Type
First and second arguments of REGEXP_LIKE, REGEXP_INSTR, REGEXP_SUBSTR, REGEXP_COUNT	VARCHAR(32672)
First argument of REGEXP_LIKE, REGEXP_INSTR, REGEXP_SUBSTR, or REGEXP_COUNT when second argument is not an untyped expression	VARGRAPHIC(16336) if second argument is a graphic data type; VARCHAR(32672) otherwise
Second argument of REGEXP_LIKE, REGEXP_INSTR, REGEXP_SUBSTR, or REGEXP_COUNT when first argument is not an untyped expression	VARGRAPHIC(16336) if first argument is a graphic data type in a Unicode database; VARCHAR(32672) otherwise
First three arguments of REGEXP_REPLACE	VARCHAR(32672)
First argument of REGEXP_REPLACE when second or third argument is not an untyped expression	VARGRAPHIC(16336) if third argument is a graphic data type or third argument is an untyped expression and second argument is a graphic data type; VARCHAR(32672) otherwise
Second argument of REGEXP_REPLACE when first or third argument is not an untyped expression	VARGRAPHIC(16336) if first argument is a graphic data type in a Unicode database; VARCHAR(32672) otherwise
Third argument of REGEXP_REPLACE when first or second argument is not an untyped expression	VARGRAPHIC(16336) if first argument is a graphic data type or first argument is an untyped expression and second argument is a graphic data type; VARCHAR(32672) otherwise
First argument of SUBSTR	VARCHAR(32672)
Second and third argument of SUBSTR	INTEGER
First argument of SUBSTRB	VARCHAR(32672)
First argument of SUBSTR2	VARGRAPHIC(16336) if database supports graphic types; otherwise VARCHAR(32672)
First argument of SUBSTR4	VARCHAR(32672)
Second argument of TIMESTAMP	TIME
First argument of TIMESTAMP_FORMAT	VARCHAR(254)
First argument of TIMEZONE	TIMESTAMP(6)
First argument of TO_UTC_TIMESTAMP	TIMESTAMP(6)
Second and third arguments of TRANSLATE	VARCHAR(32672) if the first argument is a character type; VARGRAPHIC(16336) if the first argument is a graphic type
Fourth argument of TRANSLATE	VARCHAR(1) if the first argument is a character type; VARGRAPHIC(1) if the first argument is a graphic type
Second argument of TRIM_ARRAY	BIGINT
Unary minus	DECFLOAT(34)
Unary plus	DECFLOAT(34)

Table 30. Untyped Expression Usage in Built-in Functions (continued)

Untyped Parameter Marker Location	Data Type
All arguments of VALUE, when all arguments are untyped parameter markers	Error
Any argument of VALUE, when at least one argument is not an untyped parameter marker	Result of applying the "Rules for result data types" on all arguments that are other than untyped parameter markers
First argument of VARCHAR_FORMAT	TIMESTAMP(12)
First argument of XMLCOMMENT	VARCHAR(32672)
All arguments of XMLCONCAT	XML
First argument of XMLDOCUMENT	XML
Arguments of XMLELEMENT or XMLEXISTS	Error
Second argument of XMLPI	VARCHAR(32672)
Arguments of XMLQUERY	Error
First argument of XMLSERIALIZE	XML
Arguments of XMLTABLE	Error
First argument of XMLTEXT	VARCHAR(32672)
First argument of XMLVALIDATE	XML
First argument of XMLXSROBJECTID	XML
Arguments of an aggregate function	Error
All other arguments of all other scalar functions	The data type of the parameter of the function definition as determined by function resolution. The length of the argument is derived based on Table 20 on page 121 in Function Resolution section.

Table 31. Untyped Expression Usage in User-defined Routines

Untyped Parameter Marker Location	Data Type
Argument of a function	The data type and length of the parameter, as defined when the function was created.
Argument of a method	Error
Argument of a procedure	The data type of the parameter, as defined when the procedure was created

Row expression

A row expression specifies a row of data that could have a specific user-defined row type or the built-in data type ROW.

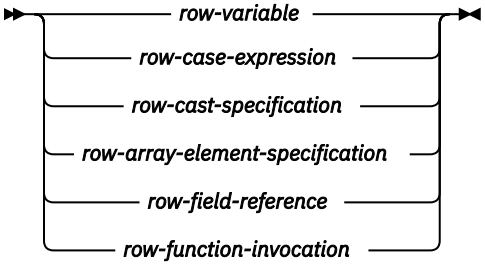
Authorization

The use of some of the row expressions may require having the appropriate authorization. For these row expressions, the privileges held by the authorization ID of the statement must include the following authorization:

- *row-variable.* For information about authorization considerations when *row-variable* is a global variable, see "Global variables".
- *row-function-invocation.* The authorization to execute the function. For information about authorization considerations, see "Function invocation" in the "Functions" topic
- *expression*. Authorizations might be required for the use of certain expressions referenced in a *row-expression*. For information about authorization considerations, see "Expressions".

Syntax

row-expression



Description

row-variable
A variable that is defined with row type.

row-case-expression
A case-expression that returns a row type.

row-cast-specification
A CAST that returns a row type.

row-array-element-specification
An array-element-specification of an array with row type elements.

row-field-reference
A field-reference of a row where the field is also a row type

row-function-invocation
A *function-invocation* of a user-defined function that has a return type that is a row type. The function could return a user-defined row type or the data type ROW with defined field names and field types.

Notes

- Row expressions can be used to generate a row within SQL PL contexts.

Predicates

A *predicate* specifies a condition that is true, false, or unknown about a given value, row, or group.

The following rules apply to all types of predicates:

- All values specified in a predicate must be compatible.
- An expression used in a basic, quantified, IN, or BETWEEN predicate must not result in a character string with a length attribute greater than 4000, a graphic string with a length attribute greater than 2000, or a LOB string of any size.
- The value of a host variable can be null (that is, the variable may have a negative indicator variable).
- The code page conversion of operands of predicates involving two or more operands, with the exception of LIKE, is done according to the rules for string conversions.
- Use of a structured type value is limited to the NULL predicate and the TYPE predicate.

- In a Unicode database, all predicates that accept a character or graphic string will accept any string type for which conversion is supported.

A fullselect is a form of the SELECT statement that, when used in a predicate, is also called a *subquery*.

Row-value-expression

The operand of several predicates (basic, quantified, and IN) can be expressed as a row value expression:

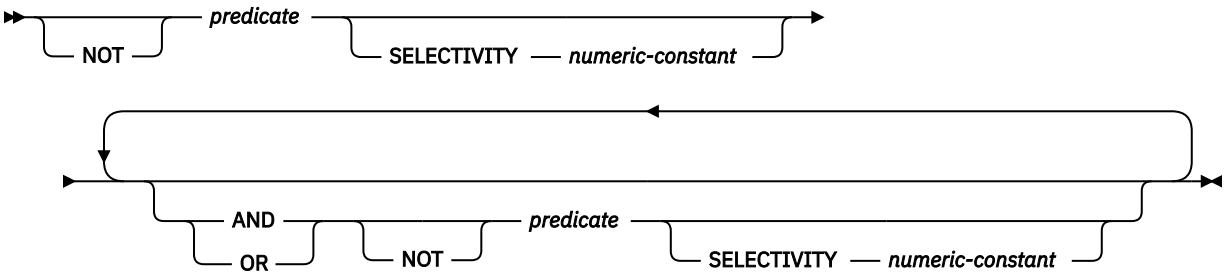
row-value-expression

A row value expression returns a single row that consists of one or more fields. The field values can be specified as a list of expressions. The number of fields that are returned by the row value expression is equal to the number of expressions that are specified in the list.

Search conditions

A *search condition* specifies a condition that is "true," "false," or "unknown" about a given value, row, or group. A search condition can also be a Boolean column, value, or literal.

search-condition



The result of a search condition is derived by application of the specified *logical operators* (AND, OR, NOT) to the result of each specified predicate. If logical operators are not specified, the result of the search condition is the result of the specified predicate.

AND and OR are defined in Table 32 on page 191, in which P and Q are any predicates:

Table 32. Truth Tables for AND and OR

P	Q	P AND Q	P OR Q
True	True	True	True
True	False	False	True
True	Unknown	Unknown	True
False	True	False	True
False	False	False	False
False	Unknown	False	Unknown
Unknown	True	Unknown	True
Unknown	False	False	Unknown
Unknown	Unknown	Unknown	Unknown

NOT(true) is false, NOT(false) is true, and NOT(unknown) is unknown.

Search conditions within parentheses are evaluated first. If the order of evaluation is not specified by parentheses, NOT is applied before AND, and AND is applied before OR. The order in which operators at the same precedence level are evaluated is undefined to allow for optimization of search conditions.

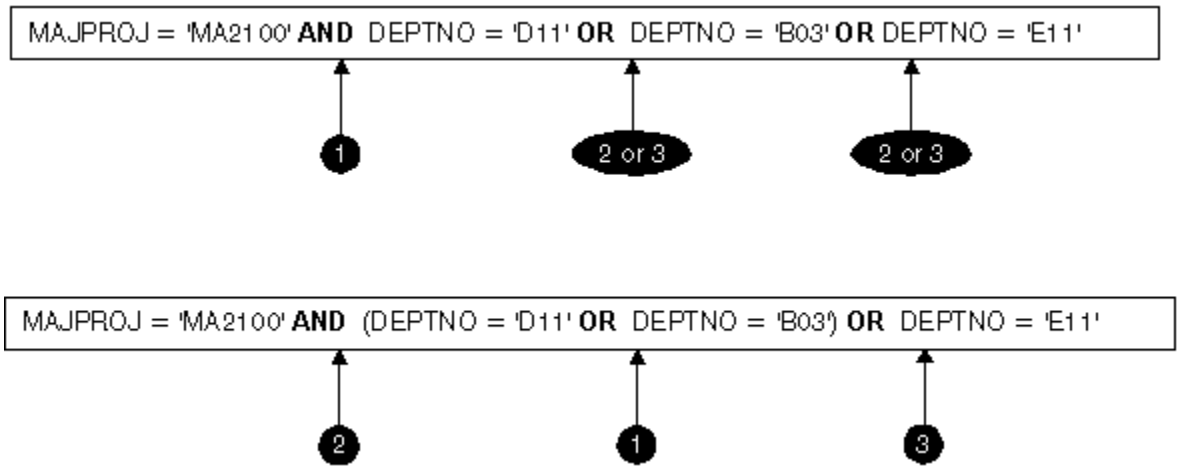


Figure 3. Search Conditions Evaluation Order

SELECTIVITY *numeric-constant*

The SELECTIVITY clause is used to indicate what the expected selectivity percentage is for the predicate. SELECTIVITY can be specified for the following predicates:

- A user-defined predicate, regardless of the *DB2_SELECTIVITY* query compiler registry variable setting
- A basic predicate in which at least one expression contains host variables or parameter markers. Specifying SELECTIVITY for this type of predicate applies only when the *DB2_SELECTIVITY* query compiler registry variable is set to YES.
- Any predicate when the DB2_SELECTIVITY query compiler registry variable is set to ALL.

A user-defined predicate is a predicate that consists of a user-defined function invocation, in the context of a predicate specification that matches the predicate specification on the PREDICATES clause of CREATE FUNCTION. For example, if the function `myfunction` is defined with PREDICATES WHEN=1..., then the following use of SELECTIVITY is valid:

```
SELECT *
  FROM STORES
  WHERE myfunction(parm,parm) = 1 SELECTIVITY 0.004
```

The selectivity value must be a numeric literal value in the inclusive range from 0 to 1 (SQLSTATE 42615). If SELECTIVITY is not specified, the default value is 0.01 (that is, the user-defined predicate is expected to filter out all but one percent of all the rows in the table). The SELECTIVITY default can be changed for any given function by updating its SELECTIVITY column in the SYSSTAT.ROUTINES view. An error will be returned if the SELECTIVITY clause is specified for a non user-defined predicate (SQLSTATE 428E5).

A user-defined function (UDF) can be applied as a user-defined predicate and, hence, is potentially applicable for index exploitation if:

- The predicate specification is present in the CREATE FUNCTION statement
- The UDF is invoked in a WHERE clause being compared (syntactically) in the same way as specified in the predicate specification
- There is no negation (NOT operator)

Examples

In the following query, the `within` UDF specification in the WHERE clause satisfies all three conditions and is considered a user-defined predicate.

```
SELECT *
  FROM customers
  WHERE within(location, :sanJose) = 1 SELECTIVITY  0.2
```

However, the presence of `within` in the following query is not index-exploitable due to negation and is not considered a user-defined predicate.

```
SELECT *
  FROM customers
  WHERE NOT(within(location, :sanJose) = 1) SELECTIVITY  0.3
```

In the next example, consider identifying customers and stores that are within a certain distance of each other. The distance from one store to another is computed by the radius of the city in which the customers live.

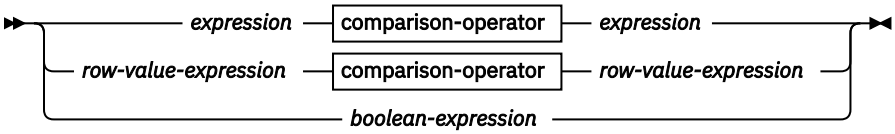
```
SELECT *
  FROM customers, stores
  WHERE distance(customers.loc, stores.loc) <
    CityRadius(stores.loc) SELECTIVITY 0.02
```

In the preceding query, the predicate in the WHERE clause is considered a user-defined predicate. The result produced by CityRadius is used as a search argument to the range producer function.

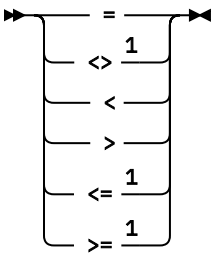
However, since the result produced by CityRadius is used as a range producer function, the user-defined predicate shown previously will not be able to make use of the index extension defined on the stores.loc column. Therefore, the UDF will make use of only the index defined on the customers.loc column.

Basic predicate

A *basic predicate* compares two values or compares a set of values with another set of values.



comparison-operator



Notes:

[1] See "Alternative forms" on page 195.

The six comparison operators can effectively be expressed based on just two of the comparison operators. If the predicate operands are *x* and *y*, then the other four comparison operators can be expressed using the following alternative predicates.

Table 33. Predicates and alternative predicates

Predicate	Alternative predicate
x <> *y*	NOT (*x* = *y*)

Table 33. Predicates and alternative predicates (continued)	
Predicate	**Alternative predicate**
x > *y*	*y* < *x*
x <= *y*	*x* < *y* OR *x* = *y*
x >= *y*	*y* < *x* OR *x* = *y*

When the predicate operands are specified as an *expression*, the data types of the expressions must be comparable. If the value of either operand is null, the result of the predicate is unknown. Otherwise the result is either true or false.

Table 34. Predicate evaluation with scalar operands		
Predicate (with operand values *x* and *y*)	**Boolean value**	**If and Only If...**
x = *y*	is True	*x* is equal to *y*
x < *y*	is True	*x* is less than *y*
x = *y*	is False	*x* is not equal to *y*
x < *y*	is False	*x* = *y* is True or *y* < *x* is True

When the predicate operands are specified as a *row-value-expression*, they must have the same number of fields and the data types of the corresponding fields of the operands must be comparable. The result of the comparison is based on comparisons of the corresponding fields in the *row-value-expression* operands.

Table 35. Predicate evaluation with row operands		
Predicate (with operand values *Rx* and *Ry* that have fields *Rxi* and *Ryi* where 0 < *i* < *number of fields*)	**Boolean value**	**If and Only If...**
Rx = *Ry*	is True	All pairs of corresponding value expressions are equal (*Rxi* = *Ryi* is True for all values of *i*).
Rx < *Ry*	is True	The first *N* pairs of corresponding value expressions are equal and the next pair has the left value expression less than the right value expression for some value of *N* (*Rxi* = *Ryi* is True for all values of *i* < *n* and *Rxn* < *Ryn* is True for some value of *n*).
Rx = *Ry*	is False	At least one pair of corresponding value expressions are not equal (NOT (*Rxi* = *Ryi*) is True for some value of *i*).

Table 35. Predicate evaluation with row operands (continued)		
Predicate (with operand values *Rx* and *Ry* that have fields *Rxi* and *Ryi* where 0 < *i* < *number of fields*)	**Boolean value**	**If and Only If...**
Rx < *Ry*	is False	All pairs of corresponding value expressions are equal (*Rx* = *Ry* is True) or the first *N* pairs of corresponding value expressions are equal and the next pair has the right value expression less than the left value expression for some value of *N* (*Rxi* = *Ryi* is True for all values of *i* < *n* and *Ryn* < *Rxn* is True for some value of *n*).
Rx comparison operator Ry	is Unknown	The comparison is neither True nor False.

Boolean values

You can use a basic predicate to compare a Boolean value with another Boolean value or with a value of a data type that can be cast to a Boolean value. A value of TRUE is greater than a value of FALSE. For example:

- `TRUE = 'on'` is TRUE
- `DECFLOAT(4.3) = TRUE` is TRUE
- `'0' <= FALSE` is TRUE
- `'yes' <= FALSE` is FALSE

Alternative forms

For the comparison operators <>, <=, and >=, alternative forms are also supported. (The forms ¬=, ¬<, and ¬> are supported only in code pages 437, 819, and 850.) Support for these alternative forms is intended only to accommodate existing SQL statements; these forms are not recommended for new SQL statements.

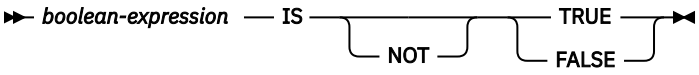
Comparison Operator	Alternative Forms
<>	^= != ¬=
<=	^> !> ¬>
>=	^< !< ¬<

Examples:

```
  EMPNO='528671'
  SALARY < 20000
  PRSTAFF <> :VAR1
  SALARY > (SELECT AVG(SALARY) FROM EMPLOYEE)
(YEARVAL, MONTHVAL) >= (2009, 10)
```

Boolean predicate

A *Boolean predicate* returns the truth value of a Boolean expression.



boolean-expression
An expression that returns the Boolean value (or representation of a Boolean value) that is to be evaluated by the function. The data type of the returned value must be of one of the following data types (SQLSTATE 42884):

- BOOLEAN
- SMALLINT, INTEGER, BIGINT (binary integer)
- DECFLOAT (floating decimal)
- CHAR or VARCHAR (string)
- GRAPHIC or VARGRAPHIC (graphic; applies only to a Unicode database)

Non-Boolean values are implicitly cast to Boolean values as described in "Boolean values" on page 41.

If the returned value is a string, it must be a valid representation of a Boolean value as described in "Boolean values" on page 41 (SQLSTATE 22018).

Null values are treated differently by different predicates:

- The IS TRUE predicate returns:
  - TRUE when the truth value of the value returned by input expression is TRUE
  - FALSE when the truth value is FALSE or NULL
- The IS FALSE predicate returns:
  - TRUE when the truth value of the value returned by input expression is FALSE
  - FALSE when the truth value is TRUE or NULL
- The IS NOT TRUE predicate returns:
  - TRUE when the truth value of the value returned by input expression is FALSE or NULL
  - FALSE when the truth value is TRUE
- The IS NOT FALSE predicate returns
  - TRUE when the truth value of the value returned by input expression is TRUE or NULL
  - FALSE when the truth value is FALSE

Alternative syntax: The keyword ON can be used instead of TRUE; OFF can be used instead of FALSE.

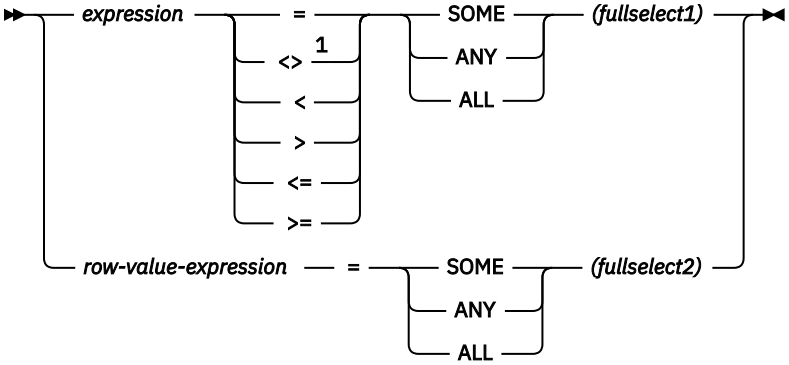
Example

The following statement returns those values from COLA that are not equal to the corresponding value in COLX.

```
SELECT COLA FROM TBLAB WHERE COLA = COLX IS NOT TRUE
```

Quantified predicate

A *quantified predicate* compares a value or values with a collection of values.



Notes:

[1] The following forms of the comparison operators are also supported in basic and quantified predicates: ^=, ^<, ^>, !=, !<, and !>. In code pages 437, 819, and 850, the forms ¬=, ¬<, and ¬> are supported. All of these product-specific forms of the comparison operators are intended only to support existing SQL statements that use these operators, and are not recommended for use when writing new SQL statements.

The fullselect must identify a number of columns that is the same as the number of expressions specified to the left of the predicate operator (SQLSTATE 428C4). The fullselect may return any number of rows.

When ALL is specified:

- The result of the predicate is true if the fullselect returns no values or if the specified relationship is true for every value returned by the fullselect.
- The result is false if the specified relationship is false for at least one value returned by the fullselect.
- The result is unknown if the specified relationship is not false for any values returned by the fullselect and at least one comparison is unknown because of the null value.

When SOME or ANY is specified:

- The result of the predicate is true if the specified relationship is true for each value of at least one row returned by the fullselect.
- The result is false if the fullselect returns no rows or if the specified relationship is false for at least one value of every row returned by the fullselect.
- The result is unknown if the specified relationship is not true for any of the rows and at least one comparison is unknown because of a null value.

Examples: Use the following tables when referring to the following examples.

TBL***AB***:

COL***A***	COL***B***
1	12
2	12
3	13
4	14
-	-

TBL***XY***:

COL***X***	COL***Y***
2	22
3	23

Figure 4. Tables for quantified predicate examples

Example 1

```
SELECT COLA FROM TBLAB
   WHERE COLA = ANY(SELECT COLX FROM TBLXY)
```

Results in 2,3. The subselect returns (2,3). COLA in rows 2 and 3 equals at least one of these values.

Example 2

```
SELECT COLA FROM TBLAB
   WHERE COLA > ANY(SELECT COLX FROM TBLXY)
```

Results in 3,4. The subselect returns (2,3). COLA in rows 3 and 4 is greater than at least one of these values.

Example 3

```
SELECT COLA FROM TBLAB
   WHERE COLA > ALL(SELECT COLX FROM TBLXY)
```

Results in 4. The subselect returns (2,3). COLA in row 4 is the only one that is greater than both these values.

Example 4

```
SELECT COLA FROM TBLAB
   WHERE COLA > ALL(SELECT COLX FROM TBLXY
                    WHERE COLX<0)
```

Results in 1,2,3,4, null. The subselect returns no values. Thus, the predicate is true for all rows in TBLAB.

Example 5

```
SELECT * FROM TBLAB
   WHERE (COLA,COLB+10) = SOME (SELECT COLX, COLY FROM TBLXY)
```

The subselect returns all entries from TBLXY. The predicate is true for the subselect, hence the result is as follows:

```
COLA        COLB
----------- -----------
          2          12
          3          13
```

Example 6

```
SELECT * FROM TBLAB
   WHERE (COLA,COLB) = ANY (SELECT COLX,COLY-10 FROM TBLXY)
```

The subselect returns COLX and COLY-10 from TBLXY. The predicate is true for the subselect, hence the result is as follows:

```
COLA        COLB
----------- -----------
          2          12
          3          13
```

ARRAY_EXISTS

The ARRAY_EXISTS predicate tests for the existence of an array index in an array.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification of a parameter marker to an array type.

array-index
The data type of *array-index* must be assignable to the data type of the array index of the array. If *array-expression* is an ordinary array, then *array-index* must be assignable to INTEGER (SQLSTATE 428H1).

The result is true if *array-expression* includes an array index that is equal to *array-index*cast to the data type of the array index of *array-expression*; otherwise the result is false.

The result cannot be unknown; if either argument is null, the result is false.

Example

1. Assume that array variableRECENT_CALLS is defined as an ordinary array of array type PHONENUMBERS. The following IF statement tests if the recent calls list has reached the 40th saved call yet. If it has, the local Boolean variable EIGHTY_PERCENT is set to true:

```
IF (ARRAY_EXISTS(RECENT_CALLS, 40)) THEN
  SET EIGHTY_PERCENT = TRUE;
END IF
```

BETWEEN predicate

The BETWEEN predicate compares a value with a range of values.

If the data types of the operands are not the same, all values are converted to the data type that would result by applying the "Rules for result data types", except if the data types of all the operands are numeric, in which case no values are converted.

The BETWEEN predicate:

```
value1 BETWEEN value2 AND value3
```

is equivalent to the search condition:

```
value1 >= value2 AND value1 <= value3
```

The BETWEEN predicate:

```
value1 NOT BETWEEN value2 AND value3
```

is equivalent to the search condition:

```
NOT(value1 BETWEEN value2 AND value3); that is,
value1 < value2 OR value1 > value3.
```

The first operand (expression) cannot include a function that is not deterministic or has an external action (SQLSTATE 42845).

Examples

Example 1

```
EMPLOYEE.SALARY BETWEEN 20000 AND 40000
```

Results in all salaries between $20,000.00 and $40,000.00.

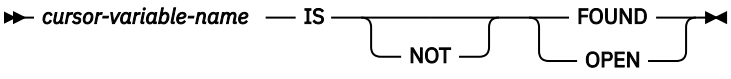
Example 2

```
SALARY NOT BETWEEN 20000 + :HV1 AND 40000
```

Assuming :HV1 is 5000, results in all salaries below $25,000.00 and above $40,000.00.

Cursor predicates

Cursor predicates are SQL keywords that can be used to determine the state of a cursor defined within the current scope. They provide a means for easily referencing whether a cursor is open, closed or if there are rows associated with the cursor.



cursor-variable-name
The name of a SQL variable or SQL parameter of a cursor type.

IS
Specifies that a cursor predicate property is to be tested.

NOT
Specifies that the opposite value of testing the cursor predicate property is to be returned.

FOUND
Specifies to check if the cursor contains rows after the execution of a FETCH statement. If the last FETCH statement executed was successful, and if the IS FOUND predicate syntax is used, the returned value is TRUE. If the last FETCH statement executed resulted in a condition where rows were not found, the result is false. The result is unknown when:

- the value of cursor-variable-name is null
- the underlying cursor of cursor-variable-name is not open
- the predicate is evaluated before the first FETCH action was performed on the underlying cursor
- the last FETCH action returned an error

The IS FOUND predicate can be useful within a portion of SQL PL logic that loops and performs a fetch with each iteration. The predicate can be used to determine if rows remain to be fetched. It provides an efficient alternative to using a condition handler that checks for the error condition that is raised when no more rows remain to be fetched.

When the NOT keyword is specified, so that the syntax is IS NOT FOUND, the result value is the opposite.

OPEN
Specifies to check if the cursor is in an open state. If the cursor is in open and if the IS OPEN predicate syntax is used, the returned value is TRUE. This can be a useful predicate in cases where cursors are passed as parameters to functions and procedures. Before attempting to open the cursor, this predicate can be used to determine if the cursor is already open.

When the NOT keyword is specified, so that the syntax is IS NOT OPEN, the result value is the opposite.

Notes

- A cursor predicate can only be used in statements within a compound SQL (compiled) statement (SQLSTATE 42818).

Example

The following script defines an SQL procedure that contains references to these predicates as well as the prerequisite objects required to successfully compile and call the procedure:

```
CREATE TABLE T1 (c1 INT, c2 INT, c3 INT)@

INSERT INTO T1 VALUES (1,1,1),(2,2,2),(3,3,3) @

CREATE TYPE myRowType AS ROW(c1 INT, c2 INT, c3 INT)@

CREATE TYPE myCursorType AS myRowType CURSOR@

CREATE PROCEDURE p(OUT count INT)
LANGUAGE SQL
BEGIN
  DECLARE C1 CURSOR;
  DECLARE lvarInt INT;

  SET count = -1;
  SET c1 = CURSOR FOR SELECT c1 FROM t1;

  IF (c1 IS NOT OPEN) THEN
     OPEN c1;
  ELSE
     set count = -2;
  END IF;

  SET count = 0;
  IF (c1 IS OPEN) THEN

    FETCH c1 INTO lvarInt;

    WHILE (c1 IS FOUND) DO
      SET count = count + 1;
      FETCH c1 INTO lvarInt;
    END WHILE;
  ELSE
     SET COUNT = 0;
  END IF;

END@

CALL p()@
```

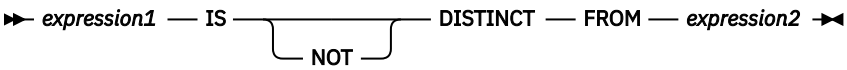
DISTINCT predicate

The DISTINCT predicate compares two expressions and evaluates to TRUE if their values are not identical.

The result of a DISTINCT predicate depends on whether either or both of its input expressions are null:

Input expressions	IS DISTINCT FROM	IS NOT DISTINCT FROM
Both inputs are non-null.	Evaluates to TRUE if the inputs are not identical and FALSE if they are. Equivalent to the <> operator.	Evaluates to FALSE if the inputs are not identical and TRUE if they are. Equivalent to the = operator.
One input is null.	Evaluates to TRUE.	Evaluates to FALSE.
Both inputs are null.	Evaluates to FALSE.	Evaluates to TRUE.

The result of a DISTINCT predicate cannot be null.



expression1* and *expression2
The expressions that are to be compared.

Examples

Assume that HV is a host variable and T1 is a table with one column (C1) and three rows:

```
C1
----
1
2
NULL
```

- If HV=2, the statement

  ```
  SELECT * FROM T1 WHERE C1 IS DISTINCT FROM :HV;
  ```

  returns rows 1 and 3.

  If HV=2, the statement

  ```
  SELECT * FROM T1 WHERE C1 IS NOT DISTINCT FROM :HV;
  ```

  returns row 2.
- If HV=NULL, the statement

  ```
  SELECT * FROM T1 WHERE C1 IS DISTINCT FROM :HV;
  ```

  returns rows 1 and 2.

  If HV=NULL, the statement

  ```
  SELECT * FROM T1 WHERE C1 IS NOT DISTINCT FROM :HV;
  ```

  returns row 3.

EXISTS predicate

The EXISTS predicate tests for the existence of certain rows.

The fullselect may specify any number of columns, and

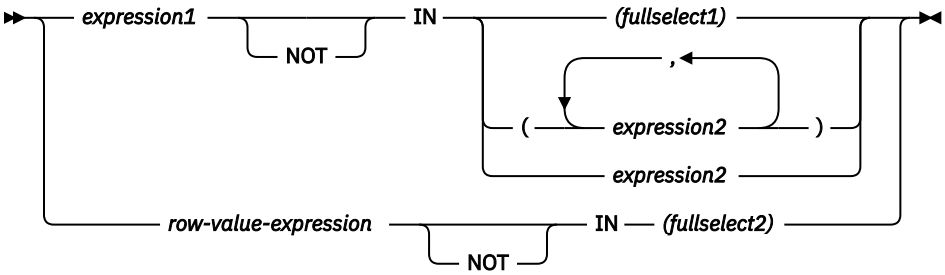
- The result is true only if the number of rows specified by the fullselect is not zero.
- The result is false only if the number of rows specified is zero
- The result cannot be unknown.

Example

```
   EXISTS (SELECT * FROM TEMPL WHERE SALARY < 10000)
```

IN predicate

The IN predicate compares a value or values with a collection of values.



The fullselect must identify a number of columns that is the same as the number of expressions specified to the left of the IN keyword (SQLSTATE 428C4). The fullselect may return any number of rows.

- An IN predicate of the form:

  ```
  expression IN expression
  ```

  is equivalent to a basic predicate of the form:

  ```
  expression = expression
  ```

- An IN predicate of the form:

  ```
  expression IN (fullselect)
  ```

  is equivalent to a quantified predicate of the form:

  ```
  expression = ANY (fullselect)
  ```

- An IN predicate of the form:

  ```
  expression NOT IN (fullselect)
  ```

  is equivalent to a quantified predicate of the form:

  ```
  expression <> ALL (fullselect)
  ```

- An IN predicate of the form:

  ```
  expression IN (expressiona, expressionb, ..., expressionk)
  ```

  is equivalent to:

  ```
  expression = ANY (fullselect)
  ```

  where fullselect in the values-clause form is:

  ```
  VALUES (expressiona), (expressionb), ..., (expressionk)
  ```

- An IN predicate of the form:

  ```
  (expressiona, expressionb,..., expressionk) IN (fullselect)
  ```

  is equivalent to a quantified predicate of the form:

  ```
  (expressiona, expressionb,..., expressionk) = ANY (fullselect)
  ```

  Note that the operand on the left side of this form of these predicates is referred to as a *row-value-expression*.

The values for *expression1* and *expression2* or the column of *fullselect1* in the IN predicate must be compatible. Each field of the *row-value-expression* and its corresponding column of *fullselect2* in the IN predicate must be compatible. The rules for result data types can be used to determine the attributes of the result used in the comparison.

The values for the expressions in the IN predicate (including corresponding columns of a fullselect) can have different code pages. If a conversion is necessary, the code page is determined by applying rules for string conversions to the IN list first, and then to the predicate, using the derived code page for the IN list as the second operand.

Examples

Example 1: The following condition evaluates to true if the value in the row under evaluation in the DEPTNO column contains D01, B01, or C01:

```
DEPTNO IN ('D01', 'B01', 'C01')
```

Example 2: The following condition evaluates to true only if the EMPNO (employee number) on the left side matches the EMPNO of an employee in department E11:

```
EMPNO IN (SELECT EMPNO FROM EMPLOYEE WHERE WORKDEPT = 'E11')
```

Example 3: Given the following information, this example evaluates to true if the specific value in the row of the COL_1 column matches any of the values in the list:

Table 36. IN Predicate example

Expressions	Type	Code Page
COL_1	column	850
HV_2	host variable	437
HV_3	host variable	437
CON_1	constant	850

When evaluating the predicate:

```
COL_1 IN (:HV_2, :HV_3, CON_4)
```

the two host variables will be converted to code page 850, based on the rules for string conversions.

Example 4: The following condition evaluates to true if the specified year in EMENDATE (the date an employee activity on a project ended) matches any of the values specified in the list (the current year or the two previous years):

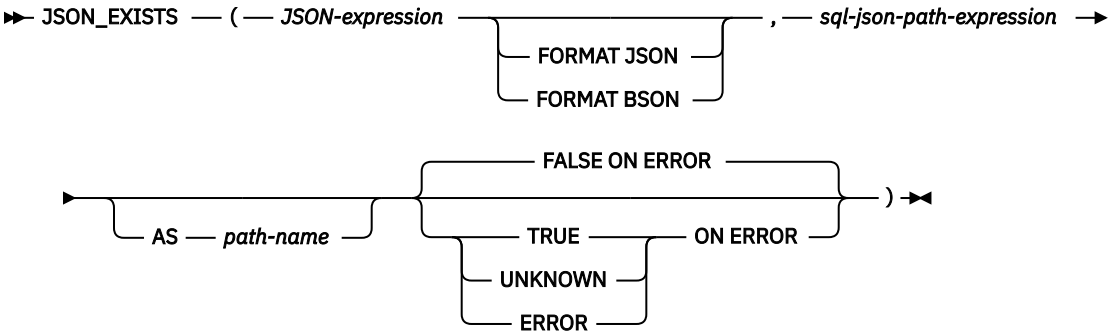
```
YEAR(EMENDATE) IN (YEAR(CURRENT DATE),
                   YEAR(CURRENT DATE - 1 YEAR),
                   YEAR(CURRENT DATE - 2 YEARS))
```

Example 5: The following condition evaluates to true if both ID and DEPT on the left side match MANAGER and DEPTNUMB respectively for any row of the ORG table.

```
(ID, DEPT) IN (SELECT MANAGER, DEPTNUMB FROM ORG)
```

JSON_EXISTS predicate

The JSON_EXISTS predicate determines whether JSON data contains a JSON value that can be located by using the specified *sql-json-path-expression*.



The result of the JSON_EXISTS predicate is true if at least one value can be located in *JSON-expression* by using *sql-json-path-expression*.

If *sql-json-path-expression* uses strict mode and an error occurs, the result of the predicate is determined by the ON ERROR clause.

The result of the JSON_EXISTS predicate is UNKNOWN if *JSON-expression* is the null value.

JSON-expression
An expression that returns a value that is a built-in string data type, except the following data types (SQLSTATE 42815):

- GRAPHIC
- VARGRAPHIC
- DBCLOB
- BINARY
- CHAR FOR BIT DATA
- VARCHAR FOR BIT DATA
- A user-defined type that is sourced on any of the previously listed data types

If a character value is returned, it must contain correctly formatted JSON data (SQLSTATE 22032). If a binary data type is returned, it is interpreted according to the explicit or implicit FORMAT clause.

FORMAT JSON
JSON-expression is formatted as JSON data.

If *JSON-expression* is a character string data type, it is treated as JSON data.

If *JSON-expression* is a binary string data type, it is interpreted as UTF-8 data.

FORMAT BSON
Specifies that *JSON-expression* is formatted as the BSON representation of JSON data (SQLSTATE 22032). *JSON-expression* must be a binary string data type (SQLSTATE 42815).

sql-json-path-expression
An expression that returns a value that is a built-in character string data type. The string is interpreted as an SQL/JSON path expression and is used to locate a JSON value within the JSON data that is specified by *JSON-expression*. For more information about the SQL/JSON path expression, see “sql-json-path-expression” on page 179.

AS *path-name*
Specifies a name to be used to identify *sql-json-path-expression*.

ON ERROR
Specifies the behavior when an error is encountered by JSON_EXISTS.

FALSE ON ERROR
The result is false if an error is encountered. This clause is the default.

TRUE ON ERROR
The result is true if an error is encountered.

UNKNOWN ON ERROR
The result is unknown if an error is encountered.

ERROR ON ERROR
An error is returned if an error is encountered.

Notes

- If parameter markers are not explicitly cast to a supported data type, an error is returned (SQLSTATE 42815)

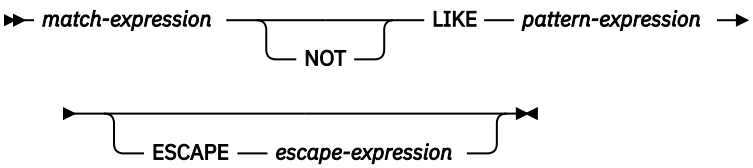
Example

1. Return rows for employees who do not have an emergency contact in their JSON_DATA column. COALESCE causes null values to be treated as an empty string. The FALSE ON ERROR clause is used so all rows that do not contain an emergency value are returned.

```
SELECT empno, lastname FROM employee
  WHERE NOT JSON_EXISTS(COALESCE(JSON_DATA, ''), 'strict $.emergency' FALSE ON ERROR);
```

LIKE predicate

The LIKE predicate searches for strings that have a certain pattern. The pattern is specified by a string in which the underscore and the percent sign may have special meanings. Trailing blanks in a pattern are part of the pattern.



If the value of any of the arguments is null, the result of the LIKE predicate is unknown.

The values for *match-expression*, *pattern-expression*, and *escape-expression* are compatible string expressions. There are slight differences in the types of string expressions supported for each of the arguments. The valid types of expressions are listed under the description of each argument.

None of the expressions can yield a distinct type. However, it can be a function that casts a distinct type to its source type.

match-expression
An expression that specifies the string that is to be examined to see if it conforms to a certain pattern of characters.

LIKE *pattern-expression*
An expression that specifies the string that is to be matched.

The expression can be specified in the same way as *match-expression* with the following restrictions:

- No element in the expression can be of type CLOB or DBCLOB. In addition it cannot be a BLOB file reference variable.
- The actual length of *pattern-expression* cannot be more than 32 672 bytes.

A **simple description** of the use of the LIKE predicate is that the pattern is used to specify the conformance criteria for values in the *match-expression*, where:

- The underscore character (_) represents any single character.

- The percent sign (%) represents a string of zero or more characters.
- Any other character represents itself.

If the *pattern-expression* needs to include either the underscore or the percent character, the *escape-expression* is used to specify a character to precede either the underscore or the percent character in the pattern.

A **rigorous description** of the use of the LIKE predicate follows. Note that this description ignores the use of the *escape-expression*; its use is covered later.

- Let *m* denote the value of *match-expression* and let *p* denote the value of *pattern-expression*. The string *p* is interpreted as a sequence of the minimum number of substring specifiers so each character of *p* is part of exactly one substring specifier. A substring specifier is an underscore, a percent sign, or any non-empty sequence of characters other than an underscore or a percent sign.

  The result of the predicate is unknown if *m* or *p* is the null value. Otherwise, the result is either true or false. The result is true if *m* and *p* are both empty strings or there exists a partitioning of *m* into substrings such that:

  – A substring of *m* is a sequence of zero or more contiguous characters and each character of *m* is part of exactly one substring.
  – If the *n*th substring specifier is an underscore, the *n*th substring of *m* is any single character.
  – If the *n*th substring specifier is a percent sign, the *n*th substring of *m* is any sequence of zero or more characters.
  – If the *n*th substring specifier is neither an underscore nor a percent sign, the *n*th substring of *m* is equal to that substring specifier and has the same length as that substring specifier.
  – The number of substrings of *m* is the same as the number of substring specifiers.

  Thus, if *p* is an empty string and *m* is not an empty string, the result is false. Similarly, it follows that if *m* is an empty string and *p* is not an empty string (except for a string containing only percent signs), the result is false.

  The predicate *m* NOT LIKE *p* is equivalent to the search condition NOT (*m* LIKE *p*).

When the *escape-expression* is specified, the *pattern-expression* must not contain the escape character identified by the *escape-expression*, except when immediately followed by the escape character, the underscore character, or the percent sign character (SQLSTATE 22025).

If the *match-expression* is a character string in an MBCS database, it can contain mixed data. In this case, the pattern can include both SBCS and non-SBCS characters. For non-Unicode databases, the special characters in the pattern are interpreted as follows:

- An SBCS halfwidth underscore refers to one SBCS character.
- A non-SBCS fullwidth underscore refers to one non-SBCS character.
- An SBCS halfwidth or non-SBCS fullwidth percent sign refers to zero or more SBCS or non-SBCS characters.

In a Unicode database, there is really no distinction between "single-byte" and "non-single-byte" characters. Although the UTF-8 format is a "mixed-byte" encoding of Unicode characters, there is no real distinction between SBCS and non-SBCS characters in UTF-8. Every character is a Unicode character, regardless of the number of bytes in UTF-8 format.

In a Unicode graphic column, every non-supplementary character, including the halfwidth underscore character (U&'\005F') and the halfwidth percent sign character (U&'\0025'), is two bytes in width. In a Unicode database, special characters in a pattern are interpreted as follows:

- For character strings, a halfwidth underscore character (X'5F') or a fullwidth underscore character (X'EFBCBF') refers to one Unicode character, and a halfwidth percent sign character (X'25') or a fullwidth percent sign character (X'EFBC85') refers to zero or more Unicode characters.
- For graphic strings, a halfwidth underscore character (U&'\005F') or a fullwidth underscore character (U&'\FF3F') refers to one Unicode character, and a halfwidth percent sign character

(U&'\0025') or a fullwidth percent sign character (U&'\FF05') refers to zero or more Unicode characters.

- To be recognized as special characters when a locale-sensitive UCA-based collation is in effect, the underscore character and the percent sign character must not be followed by non-spacing combining marks (diacritics). For example, the pattern U&'%\0300' (percent sign character followed by non-spacing combining grave accent) will be interpreted as a search for % and not as a search for zero or more Unicode characters followed by a letter with a grave accent.

A Unicode supplementary character is stored as two graphic code points in a Unicode graphic column. To match a Unicode supplementary character in a Unicode graphic column, use one underscore if the database uses locale-sensitive UCA-based collation, and two underscores otherwise. To match a Unicode supplementary character in a Unicode character column, use one underscore for all collations. To match a base character with one or more trailing non-spacing combining characters, use one underscore if the database uses locale-sensitive UCA-based collation. Otherwise, use as many underscore characters as the number of non-spacing combining characters plus the base character.

escape-expression

This optional argument is an expression that specifies a character to be used to modify the special meaning of the underscore (_) and percent (%) characters in the *pattern-expression*. This allows the LIKE predicate to be used to match values that contain the actual percent and underscore characters.

The expression can be specified by any one of:

- A constant
- A special register
- A global variable
- A host variable
- A scalar function with any of the previously mentioned operands
- An expression concatenating any of the previously listed items

with the restrictions that:

- No element in the expression can be of type CLOB or DBCLOB. In addition, it cannot be a BLOB file reference variable.
- For character columns, the result of the expression must be one character, or a binary string containing exactly one byte (SQLSTATE 22019).
- For graphic columns, the result of the expression must be one character (SQLSTATE 22019).
- The result of the expression must not be a non-spacing combining character sequence (for example, U&'\0301', Combining Acute Accent).

When escape characters are present in the pattern string, an underscore, percent sign, or escape character can represent a literal occurrence of itself. This is true if the character in question is preceded by an odd number of successive escape characters. It is not true otherwise.

In a pattern, a sequence of successive escape characters is treated as follows:

- Let S be such a sequence, and suppose that S is not part of a larger sequence of successive escape characters. Suppose also that S contains a total of n characters. Then the rules governing S depend on the value of n:
  - If n is odd, S must be followed by an underscore or percent sign (SQLSTATE 22025). S and the character that follows it represent (n-1)/2 literal occurrences of the escape character followed by a literal occurrence of the underscore or percent sign.
  - If n is even, S represents n/2 literal occurrences of the escape character. Unlike the case where n is odd, S could end the pattern. If it does not end the pattern, it can be followed by any character (except, of course, an escape character, which would violate the assumption that S is not part of a larger sequence of successive escape characters). If S is followed by an underscore or percent sign, that character has its special meaning.

Following is an illustration of the effect of successive occurrences of the escape character which, in this case, is the back slash (\).

Pattern string
Actual Pattern

\%
A percent sign

\\%
A back slash followed by zero or more arbitrary characters

\\\%
A back slash followed by a percent sign

The code page used in the comparison is based on the code page of the *match-expression* value.

- The *match-expression* value is never converted.
- If the code page of *pattern-expression* is different from the code page of *match-expression*, the value of *pattern-expression* is converted to the code page of *match-expression*, unless either operand is defined as FOR BIT DATA or is a binary type (in which case there is no conversion).
- If the code page of *escape-expression* is different from the code page of *match-expression*, the value of *escape-expression* is converted to the code page of *match-expression*, unless either operand is defined as FOR BIT DATA or is a binary type (in which case there is no conversion).

Notes

- The number of trailing blanks is significant in both the *match-expression* and the *pattern-expression*. If the strings are not the same length, the shorter string is not padded with blank spaces. For example, the expression `'PADDED ' LIKE 'PADDED'` would not result in a match.
- If the pattern specified in a LIKE predicate is a parameter marker, and a fixed-length character host variable is used to replace the parameter marker, the value specified for the host variable must have the correct length. If the correct length is not specified, the select operation will not return the intended results.

  For example, if the host variable is defined as CHAR(10), and the value WYSE% is assigned to that host variable, the host variable is padded with blanks on assignment. The pattern used is:

  ```
  'WYSE%     '
  ```

  The database manager searches for all values that start with WYSE and that end with five blank spaces. If you want to search only for values that start with "WYSE", assign a value of `WSYE%%%%%` to the host variable.
- The pattern is matched using the collation of the database, unless either operand is defined as FOR BIT DATA, in which case the pattern is matched using a binary comparison.

Examples

- Search for the string "SYSTEMS" appearing anywhere within the PROJNAME column in the PROJECT table.

  ```
  SELECT PROJNAME FROM PROJECT
    WHERE PROJECT.PROJNAME LIKE '%SYSTEMS%'
  ```

- Search for a string with a first character of "J" that is exactly two characters long in the FIRSTNME column of the EMPLOYEE table.

  ```
  SELECT FIRSTNME FROM EMPLOYEE
    WHERE EMPLOYEE.FIRSTNME LIKE 'J_'
  ```

- Search for a string of any length, with a first character of "J", in the FIRSTNME column of the EMPLOYEE table.

```
SELECT FIRSTNME FROM EMPLOYEE
  WHERE EMPLOYEE.FIRSTNME LIKE 'J%'
```

- In the CORP_SERVERS table, search for a string in the LA_SERVERS column that matches the value in the CURRENT SERVER special register.

```
SELECT LA_SERVERS FROM CORP_SERVERS
  WHERE CORP_SERVERS.LA_SERVERS LIKE CURRENT SERVER
```

- Retrieve all strings that begin with the character sequence "_\" in column A of table T.

```
SELECT A FROM T
  WHERE T.A LIKE '\_\\%' ESCAPE '\'
```

- Use a binary string constant to specify a one-byte escape character that is compatible with the match and pattern data types (both BLOBs).

```
SELECT COLBLOB FROM TABLET
  WHERE COLBLOB LIKE :pattern_var ESCAPE BX'0E'
```

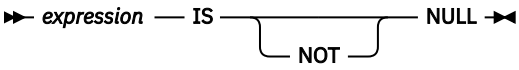
- In a Unicode database defined with the case insensitive collation CLDR181_LEN_S1, find all names that start with "Bill".

```
SELECT NAME FROM CUSTDATA WHERE NAME LIKE 'Bill%'
```

  This query returns the names "Bill Smith", "billy simon", and "BILL JONES".

NULL predicate

The NULL predicate tests for null values.



The result of a NULL predicate cannot be unknown. If the value of the expression is null, the result is true. If the value is not null, the result is false. If NOT is specified, the result is reversed.

A row type value cannot be used as the operand in a NULL predicate, except as the qualifier of a field name. If *expression* is a row type, an error is returned (SQLSTATE 428H2).

For compatibility with other SQL dialects, you can use ISNULL as a synonym for IS NULL and NOTNULL as a synonym for IS NOT NULL.

Examples

```
PHONENO IS NULL

SALARY IS NOT NULL
```

OVERLAPS predicate

The OVERLAPS predicate determines whether two chronological periods overlap. A chronological period is specified by a pair of date-time expressions (the first expression specifies the start of a period; the second specifies its end).

Each of the date-time expressions (*start1*, *end1*, *start2*, and *end2*) must return a value that is a DATE, TIME, or TIMESTAMP:

- If *start1* returns a DATE or TIMESTAMP value, the other expressions must all return either a DATE or TIMESTAMP value; otherwise, error SQL0401N is returned. The default time associated with a returned DATE value is 00:00.
- If *start1* returns a TIME value, the other expressions must all return a TIME value; otherwise, error SQL0401N is returned.

The begin and end values are not included in the periods. For example, the periods **2016-10-19 to 2016-10-20** and **2016-10-20 to 2016-10-21** do not overlap.

If none of the expressions return a null value, the OVERLAPS predicate returns **true** if the time periods overlap and **false** if they do not. If one or more of the date-time expressions returns a null value, that influences the result:

- If one of the expressions returns a null value, the result is true if the other value for that period falls within the other period; otherwise, the result is NULL.
- If two or more of the expressions return a null value, the result is NULL.

Examples

The following statement returns rows because the OVERLAPS predicate is true (the period 17-21 March 2016 overlaps the period 20-22 March 2016):

```
SELECT * from T1 where (cast('2016-03-17' as DATE),
      cast('2016-03-21' as DATE)) OVERLAPS
      (cast('2016-03-20' as DATE), cast('2016-03-22' as DATE));
```

The following statement does not return rows because the OVERLAPS predicate is false (the begin and end values are not included in the periods, so the period 19-20 October 2016 does not overlap the period 20-21 October 2016):

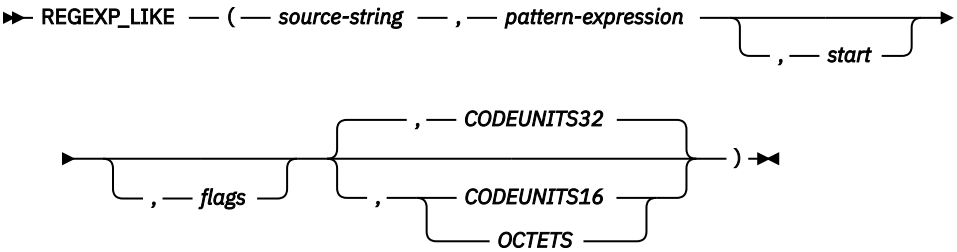
```
SELECT * from T1 where (cast('2016-10-19' as DATE),
      cast('2016-10-20' as DATE)) OVERLAPS
      (cast('2016-10-20' as DATE), cast('2016-10-21' as DATE));
```

The following statement returns rows because the OVERLAPS predicate is true (the date 22 March 2016 is within the period 20-23 March 2016):

```
SELECT * from T1 where (cast('2016-10-22' as DATE),NULL) OVERLAPS
      (cast('2016-10-20' as DATE), cast('2016-10-23' as DATE));
```

REGEXP_LIKE predicate

The REGEXP_LIKE predicate searches for a regular expression pattern in a string.



If the *pattern-expression* is found, the result is true. If the pattern-expression is not found, the result is false. If the value of any of the arguments is null, the result of the REGEXP_LIKE predicate is unknown.

source-string
An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815).

pattern-expression
An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. The length of a CLOB or DBCLOB expression must not be greater than the maximum length of a VARCHAR or VARGRAPHIC data type. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815).

start
An expression that specifies the position within *source-string* at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd (SQLSTATE 428GC). The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

flags
An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute (SQLSTATE 42815). The string can include one or more valid flag values and the combination of flag values must be valid (SQLSTATE 2201T). An empty string is the same as the value 'c'. The default flag value is 'c'.

Table 37. Supported flag values

Flag value	Description
c	Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.
i	Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.
m	Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, "^" and "$" also matches at the start and end of each line within the input string.
n	Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator, and matches a single "." in a pattern.
s	Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.
x	Specifies that white space characters in a pattern are ignored, unless escaped.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of the start value:

- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string unit of the source string is CODEUNITS32, an error is returned (SQLSTATE 428GC).

For more information, see "String units in built-in functions" in “Character strings” on page 31.

Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- **Considerations for non-Unicode databases**:
  - A regular expression pattern supports only half-width control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.

Examples

1. Select the employee number where the last name is spelled LUCCHESSI, LUCHESSI, or LUCHESI from the EMPLOYEE table without considering upper or lower case letters.

   ```
   SELECT EMPNO FROM EMPLOYEE
      WHERE REGEXP_LIKE(LASTNAME,'luc+?hes+?i','i')
   ```

   The result is 1 row with EMPNO value '000110'.
2. Select any invalid product identifier values from the PRODUCT table. The expected format is 'nnn-nnn-nn' where 'n' is a digit 0 - 9.

   ```
   SELECT PID FROM PRODUCT
      WHERE NOT REGEXP_LIKE(pid,'[0-9]{3}-[0-9]{3}-[0-9]{2}')
   ```

   The result is 0 rows because all the product identifiers match the pattern.

Trigger event predicates

A trigger event predicate is used in a triggered action to test the event that activated the trigger. It is only valid in the triggered action of a compiled trigger definition (SQLSTATE 42601).

DELETING
True if the trigger was activated by a delete operation. False otherwise.

INSERTING
True if the trigger was activated by an insert operation. False otherwise.

UPDATING
True if the trigger was activated by an update operation. False otherwise.

Notes

- Trigger event predicates can be used anywhere in the triggered action of a CREATE TRIGGER statement that uses a compound SQL (compiled) statement as the *SQL-procedure-statement*. In other contexts the keywords will not be recognized and will attempt to resolve as column or variable names.

Example

The following trigger increments the number of employees each time a new person is hired (that is, each time a new row is inserted into the EMPLOYEE table); decrements the number of employees each time an employee leaves the company; and raises an error when an update occurs that would result in a salary increase greater than ten percent of the current salary, by using trigger event predicates in its conditions:

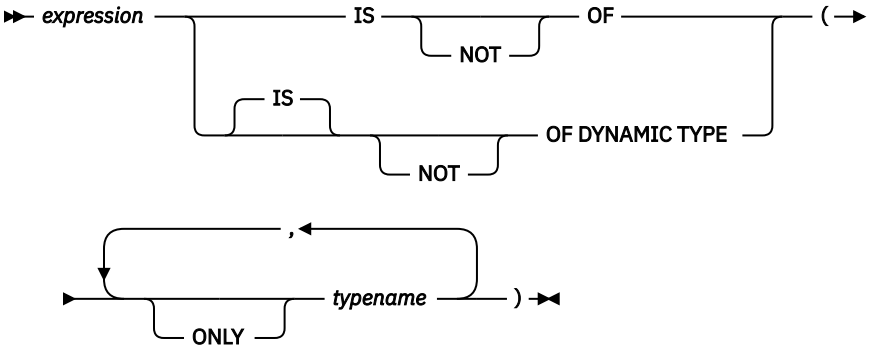
```
CREATE TRIGGER HIRED
  AFTER INSERT OR DELETE OR UPDATE OF SALARY ON EMPLOYEE
  REFERENCING NEW AS N OLD AS O FOR EACH ROW
    BEGIN
      IF INSERTING
      THEN UPDATE COMPANY_STATS SET NBEMP = NBEMP + 1;
      END IF;

      IF DELETING
      THEN UPDATE COMPANY_STATS SET NBEMP = NBEMP - 1;
      END IF;

      IF (UPDATING AND (N.SALARY > 1.1 * O.SALARY))
      THEN SIGNAL SQLSTATE '75000' SET MESSAGE_TEXT = 'Salary increase>10%'
      END IF;
    END;
```

TYPE predicate

A *TYPE predicate* compares the type of an expression with one or more user-defined structured types.



The dynamic type of an expression involving the dereferencing of a reference type is the actual type of the referenced row from the target typed table or view. This might differ from the target type of an expression involving the reference, which is called the static type of the expression.

If the value of *expression* is null, the result of the predicate is unknown. The result of the predicate is true if the dynamic type of the *expression* is a subtype of one of the structured types specified by *typename*, otherwise the result is false. If ONLY precedes any *typename* the proper subtypes of that type are not considered.

If *typename* is not qualified, it is resolved using the SQL path. Each *typename* must identify a user-defined type that is in the type hierarchy of the static type of *expression* (SQLSTATE 428DU).

The DEREF function should be used whenever the TYPE predicate has an expression involving a reference type value. The static type for this form of *expression* is the target type of the reference.

The syntax IS OF and OF DYNAMIC TYPE are equivalent alternatives for the TYPE predicate. Similarly, IS NOT OF and NOT OF DYNAMIC TYPE are equivalent alternatives.

Examples

A table hierarchy exists with root table EMPLOYEE of type EMP and subtable MANAGER of type MGR. Another table, ACTIVITIES, includes a column called WHO_RESPONSIBLE that is defined as REF(EMP) SCOPE EMPLOYEE. The following example shows a type predicate that evaluates to true when a row corresponding to WHO_RESPONSIBLE is a manager:

```
DEREF (WHO_RESPONSIBLE) IS OF (MGR)
```

If a table contains a column EMPLOYEE of type EMP, EMPLOYEE may contain values of type EMP as well as values of its subtypes like MGR. The following predicate

```
EMPL IS OF (MGR)
```

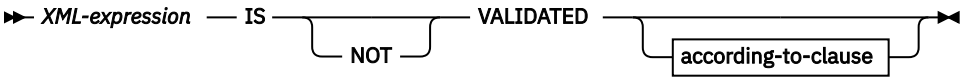
returns true when EMPL is not null and is actually a manager.

VALIDATED predicate

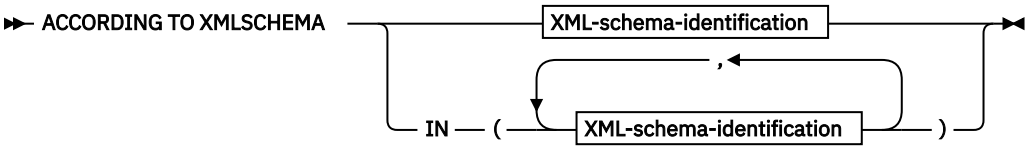
The VALIDATED predicate tests whether or not the value specified by *XML-expression* has been validated using the XMLVALIDATE function.

If the value specified is null, the result of the validation constraint is unknown; otherwise, the result of the validation constraint is either true or false. The value you specify must be of type XML.

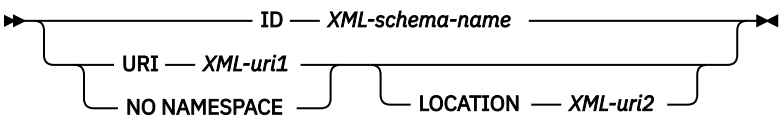
If the ACCORDING TO XMLSCHEMA clause is not specified, then XML schemas used for validation do not impact the result of the validation constraint.



according-to-clause



XML-schema-identification



Description

XML-expression

Specifies the XML value tested, where *XML-expression* can consist of an XML document, XML content, a sequence of XML nodes, an XML *column-name*, or an XML *correlation-name*.

If an XML *column-name* is specified, the predicate evaluates whether or not XML documents associated with the specified column name have been validated.

See "CREATE TRIGGER" for information about specifying correlation names of type XML as part of triggers.

IS VALIDATED or IS NOT VALIDATED

Specifies the required validation state for the *XML-expression* operand.

For a constraint that specifies IS VALIDATED to evaluate as true, the operand must have been validated. If an optional ACCORDING TO XMLSCHEMA clause includes one or several XML schemas, the operand must have been validated using one of the identified XML schemas.

For a constraint that specifies IS NOT VALIDATED to evaluate as false, the operand must be in an validated state. If an optional ACCORDING TO XMLSCHEMA clause includes one or several XML schemas, the operand must have been validated using one of the identified XML schemas.

according-to-clause

Specifies one or several XML schemas against which the operand must or must not have been validated. Only XML schemas previously registered with the XML schema repository may be specified.

ACCORDING TO XMLSCHEMA

ID *XML-schema-name*

Specifies an SQL identifier for the XML schema. The name, including the implicit or explicit SQL schema qualifier, must uniquely identify an existing XML schema in the XML schema repository at the current server. If no XML schema by this name exists in the implicitly or explicitly specified SQL schema, an error is returned (SQLSTATE 42704).

URI *XML-uri1*
Specifies the target namespace URI of the XML schema. The value of *XML-uri1* specifies a URI as a character string constant that is not empty. The URI must be the target namespace of a registered XML schema (SQLSTATE 4274A) and, if no LOCATION clause is specified, it must uniquely identify the registered XML schema (SQLSTATE 4274B).

NO NAMESPACE
Specifies that the XML schema has no target namespace. The target namespace URI is equivalent to an empty character string that cannot be specified as an explicit target namespace URI.

LOCATION *XML-uri2*
Specifies the XML schema location URI of the XML schema. The value of *XML-uri2* specifies a URI as a character string constant that is not empty. The XML schema location URI, combined with the target namespace URI, must identify a registered XML schema (SQLSTATE 4274A), and there must be only one such XML schema registered (SQLSTATE 4274B).

Examples

Example 1: Assume that column XMLCOL is defined in table T1. Retrieve only the XML values that have been validated by any XML schema.

```
SELECT XMLCOL FROM T1
  WHERE XMLCOL IS VALIDATED
```

Example 2: Assume that column XMLCOL is defined in table T1. Enforce the rule that values cannot be inserted or updated unless they have been validated.

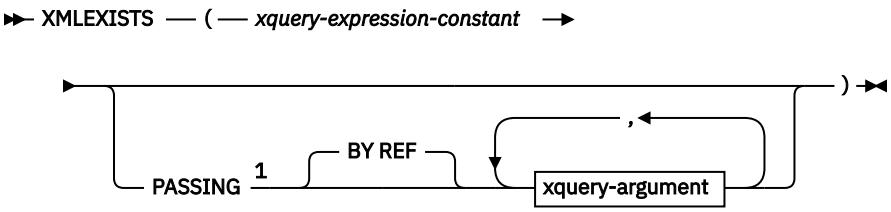
```
ALTER TABLE T1 ADD CONSTRAINT CK_VALIDATED
  CHECK (XMLCOL IS VALIDATED)
```

Example 3: Assume that you want to select only those rows from table T1 with XML column XMLCOL that have been validated with the XML schema URI http://www.posample.org.

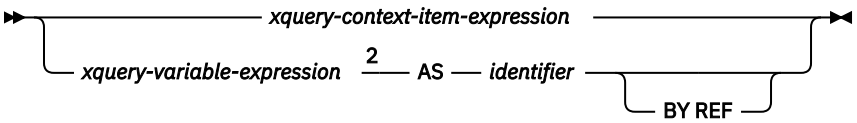
```
SELECT XMLCOL FROM T1
  WHERE XMLCOL IS VALIDATED
   ACCORDING TO XMLSCHEMA URI
   'http://www.posample.org'
```

XMLEXISTS predicate

The XMLEXISTS predicate tests whether an XQuery expression returns a sequence of one or more items.



xquery-argument



Notes:

[1] The data type cannot be DECFLOAT.
[2] The data type of the expression cannot be DECFLOAT.

xquery-expression-constant
Specifies an SQL character string constant that is interpreted as an XQuery expression. The constant string is converted directly to UTF-8 without conversion to the database or section code page. The XQuery expression executes using an optional set of input XML values, and returns an output sequence that is tested to determine the result of the XMLEXISTS predicate. The value for *xquery-expression-constant* must not be an empty string or a string of blank characters (SQLSTATE 10505).

PASSING
Specifies input values and the manner in which these values are passed to the XQuery expression specified by *xquery-expression-constant*. By default, every unique column name that is in the scope where the function is invoked is implicitly passed to the XQuery expression using the name of the column as the variable name. If an *identifier* in a specified xquery-argument matches an in-scope column name, then the explicit xquery-argument is passed to the XQuery expression overriding that implicit column.

BY REF
Specifies that the default passing mechanism is by reference for any *xquery-variable-expression* of data type XML. When XML values are passed by reference, the XQuery evaluation uses the input node trees, if any, directly from the specified input expressions, preserving all properties, including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons involving some nodes contained between the two input arguments might refer to nodes within the same XML node tree.

This clause has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

xquery-argument
Specifies an argument that is to be passed to the XQuery expression specified by *row-xquery-expression-constant*. The method through which *row-xquery-argument* is used in the XQuery expression depends on whether the argument is specified as an *xquery-context-item-expression* or *an xquery-variable-expression*.

- If the resulting value is of type XML, it becomes an *input-xml-value*. A null XML value is converted to an XML empty sequence.
- If the resulting value is not of type XML, it must be castable to the XML data type. A null value is converted to an XML empty sequence. The converted value becomes an *input-xml-value*.

When the *xquery-expression-constant* is evaluated, an XQuery variable is presented with a value equal to *input-xml-value* and a name specified by the AS clause.

xquery-context-item-expression
xquery-context-item-expression specifies the initial context item in the XQuery expression specified by *xquery-expression-constant*. The value of the initial context item is the result of *xquery-context-item-expression* cast to XML. *xquery-context-item-expression* must not be specified more than one time.

xquery-context-item-expression must not be a sequence of more than one item. If the result of *xquery-context-item-expression* is an empty string, the XQuery expression is evaluated with the initial context item set to an XML empty string.

If the *xquery-context-item-expression* is not specified or is an empty string, the initial context item in the XQuery expression is undefined, and the XQuery expression must not reference the initial context item. An XQuery variable is not created for the context item expression.

If the *xquery-context-expression* is not specified or the *input-xml-value* that results from the *xquery-context-expression* is an XML empty sequence, the initial context item is undefined. If the XQuery expression refers to the initial context item, it must be specified with a value that is not an XML empty sequence.

xquery-variable-expression
Specifies an SQL expression whose value is available to the XQuery expression specified by *xquery-expression-constant* during execution. The expression cannot contain a sequence reference (SQLSTATE 428F9) or an OLAP function (SQLSTATE 42903). The data type of the expression cannot be DECFLOAT.

AS *identifier*
Specifies that the value generated by *xquery-variable-expression* will be passed to *xquery-expression-constant* as an XQuery variable. The variable name will be *identifier*. The leading dollar sign ($) that precedes variable names in the XQuery language is not included in *identifier*. The identifier must be a valid XQuery variable name and is restricted to an XML NCName. The identifier must not be greater than 128 bytes in length. Two arguments within the same PASSING clause cannot use the same identifier (SQLSTATE 42711).

BY REF
Indicates that an XML input value is to be passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees, if any, directly from the specified input expressions, preserving all properties, including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons involving some nodes contained between the two input arguments might refer to nodes within the same XML node tree. If BY REF is not specified following an *xquery-variable-expression*, XML arguments are passed by way of the default passing mechanism that is provided through the syntax that follows the PASSING keyword. This option cannot be specified for non-XML values. When a non-XML value is passed, the value is converted to XML; this process creates a copy.

Notes

The XMLEXISTS predicate cannot be:

- Part of the ON clause that is associated with a JOIN operator or a MERGE statement (SQLSTATE 42972)
- Part of the GENERATE KEY USING or RANGE THROUGH clause in the CREATE INDEX EXTENSION statement (SQLSTATE 428E3)
- Part of the FILTER USING clause in the CREATE FUNCTION (External Scalar) statement, or the FILTER USING clause in the CREATE INDEX EXTENSION statement (SQLSTATE 428E4)
- Part of a check constraint or a column generation expression (SQLSTATE 42621)
- Part of a group-by-clause (SQLSTATE 42822)
- Part of an argument for an aggregate function (SQLSTATE 42607)

An XMLEXISTS predicate that involves a subquery might be restricted by statements that restrict subqueries.

Example

```
SELECT c.cid FROM customer c
  WHERE XMLEXISTS('$d/*:customerinfo/*:addr[ *:city = "Aurora" ]'
    PASSING info AS "d")
```

Built-in global variables

Built-in global variables are provided with the database manager and are used in SQL statements to retrieve scalar values associated with the variables.

As an example, the ROUTINE_TYPE global variable is referenced in an SQL statement to retrieve the current routine type.

For most built-in global variables, the authorization ID of any statement that retrieves the value of the global variable is required to have the READ privilege on the global variable or DATAACCESS authority. However, there are exceptions where an authorization ID with other database authorities also has access to the global variable. Exceptions to the authorization required to retrieve the value of a global variable are specified within the descriptions of the built-in global variables.

In a non-restrictive database, the READ privilege is granted to PUBLIC for most built-in global variables at creation time. Exceptions to granting this privilege are specified within the descriptions of the built-in global variables.

Examples

- To access the global variable CLIENT_HOST, run the following query:

```
VALUES SYSIBM.CLIENT_HOST
```

  This query returns the host name of the current client:

```
1
----------
hotellnx93
```

  An alternative way to call the global variable is to use it in a SELECT statement:

```
SELECT C1, C2
  FROM T1
  WHERE C3 = CLIENT_HOST
```

- For read/write global variables, set the value with the "SET variable" statement:

```
SET NLS_STRING_UNITS = 'CODEUNITS32'
```

CLIENT_HOST global variable

This built-in global variable contains the host name of the current client, as returned by the operating system.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(255).
- The schema is SYSIBM.
- The scope of this global variable is session.

If the client connection originated from an application running on the local system, the value of the variable is NULL. The database manager obtains the client IP address from the network when the connection is accepted. The client host name is obtained from the client IP address by invoking the TCP/IP `GetAddrInfo` function. If the processes did not originate from a remote system using TCP/IP, the value of the variable is NULL.

CLIENT_IPADDR global variable

This built-in global variable contains the IP address of the current client, as returned by the operating system.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(128).
- The schema is SYSIBM.
- The scope of this global variable is session.

The value of the CLIENT_IPADDR global variable is NULL if the client did not connect by using the TCP/IP or SSL protocol.

CLIENT_ORIGUSERID global variable

This built-in global variable contains the original user identifier, as supplied by an application, usually from a multiple-tier server environment.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.

- The type is VARCHAR(1024).
- The schema is SYSIBM.
- The scope of this global variable is session.

If an application does not supply a value, the value of the CLIENT_ORIGUSERID global variable is NULL.

The value that is used for CLIENT_ORIGUSERID can be set with the following APIs:

- the originalUser variable of the getDB2Connection (trusted reuse) and reuseDB2Connection (trusted connection reuse) APIs of the IBM® Data Server Driver for JDBC and SQLJ.

Notes

No privileges are granted to PUBLIC when the CLIENT_ORIGUSERID global variable is created.

CLIENT_USRSECTOKEN global variable

This built-in global variable contains a security token, as supplied by an application, usually from a multiple-tier server environment.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is BLOB(4K).
- The schema is SYSIBM.
- The scope of this global variable is session.

If an application does not supply a value, the value of the CLIENT_USRSECTOKEN global variable is NULL.

The value that is used for CLIENT_USERSECTOKEN can be set with the following APIs:

- the userSecToken variable of the getDB2Connection (trusted reuse) and reuseDB2Connection (trusted connection reuse) APIs of the IBM® Data Server Driver for JDBC and SQLJ.

Notes

No privileges are granted to PUBLIC when the CLIENT_USRSECTOKEN global variable is created.

MON_INTERVAL_ID global variable

This built-in global variable contains the identifier for the current monitoring interval.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is BIGINT.
- The schema is SYSIBM.
- The scope of this global variable is database.

The MON_INTERVAL_ID global variable facilitates the collection and aggregation of monitoring data by external monitoring applications. The value of this global variable is intended to be set by monitoring tools. However, you can increment the value by using the MON_INCREMENT_INTERVAL_ID procedure.

The value of the MON_INTERVAL_ID global variable is 0 if there is no current monitoring interval.

The **mon_interval_id** monitor element contains the value of the monitor interval ID at the time that the monitoring data was captured. You can use the value of the **mon_interval_id** monitor element to correlate data that you gather over a specific monitoring interval.

Notes

In addition to the typical authorization groups or IDs that can read built-in global variables, an authorization ID with either DBADM or SQLADM authority has read access to the MON_INTERVAL_ID global variable.

NLS_STRING_UNITS global variable

This built-in global variable specifies the default string units that are used when defining character and graphic data types in a Unicode database.

This global variable has the following characteristics:

- It is a read/write variable, with values maintained by the user.
- The type is VARCHAR(11 OCTETS).
- The schema is SYSIBM.
- The scope of this global variable is session.
- It has a default value of NULL.

This global variable is only applicable to a Unicode database and must have a value of NULL, 'SYSTEM', or 'CODEUNITS32' (SQLSTATE 42815).

NULL
The STRING_UNITS database configuration parameter is used to determine the default string units

SYSTEM
CHAR, VARCHAR, and CLOB data types defined without specifying the CODEUNITS32 keyword will default to OCTETS.

GRAPHIC, VARGRAPHIC, and DBCLOB data types defined without specifying the CODEUNITS32 keyword will default to CODEUNITS16.

CODEUNITS32
CHAR, VARCHAR, and CLOB data types defined without specifying the OCTETS keyword will default to CODEUNITS32.

GRAPHIC, VARGRAPHIC, and DBCLOB data types defined without specifying the CODEUNITS16 keyword will default to CODEUNITS32.

PACKAGE_NAME global variable

This built-in global variable contains the name of the currently executing package.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(128).
- The schema is SYSIBM.
- The scope of this global variable is session.

In a nested execution scenario, where one package invokes another, the PACKAGE_NAME global variable contains the name of the immediate package context. For example, if package A checks the value of the PACKAGE_NAME variable, the value is A. If package A invokes package B and package B checks the value of the PACKAGE_NAME variable, the value is B.

PACKAGE_SCHEMA global variable

This built-in global variable contains the schema name of the currently executing package.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.

- The type is VARCHAR(128).
- The schema is SYSIBM.
- The scope of this global variable is session.

In a nested execution scenario, where one package invokes another, the PACKAGE_SCHEMA global variable contains the schema name of the immediate package context. For example, if package X.A checks the value of the PACKAGE_SCHEMA variable, the schema value is X. If package X.A invokes package Y.B and package B checks the value of the PACKAGE_SCHEMA variable, the schema value is Y.

PACKAGE_VERSION global variable

This built-in global variable contains the version identifier of the currently executing package.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(64).
- The schema is SYSIBM.
- The scope is session.

If the current executing package does not have a version identifier, the value is NULL.

In a nested execution scenario, where one package invokes another, the PACKAGE_VERSION global variable contains the version identifier of the immediate package context. For example, if package A checks the value of the PACKAGE_VERSION variable, then the value is 1.0. If package A invokes package B and package B checks the value of the PACKAGE_VERSION variable, then the value is 1.8.

ROUTINE_MODULE global variable

This built-in global variable contains the module name of the currently executing routine.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(128).
- The schema is SYSIBM.
- The scope of this global variable is session.

If the currently executing routine does not belong to a module or if the variable is referenced outside a routine execution context, the value of the ROUTINE_MODULE global variable is NULL.

Notes

The value of the ROUTINE_MODULE global variable is set only for procedures and compiled functions: the value always reflects the name of the currently executing routine.

The value does not change for inline functions or methods: the value remains the same as it was when the inline function or method was invoked.

ROUTINE_SCHEMA global variable

This built-in global variable contains the schema name of the currently executing routine.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(128).
- The schema is SYSIBM.
- The scope of this global variable is session.

If the ROUTINE_SCHEMA global variable is referenced outside a routine execution context, the value of the variable is NULL.

Notes

The value of the ROUTINE_SCHEMA global variable is set only for procedures and compiled functions: the value always reflects the schema name of the currently executing routine.

The value does not change for inline functions or methods: the value remains the same as it was when the inline function or method was invoked.

ROUTINE_SPECIFIC_NAME global variable

This built-in global variable contains the specific name of the currently executing routine.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(128).
- The schema is SYSIBM.
- The scope of this global variable is session.

If the ROUTINE_SPECIFIC_NAME global variable is referenced outside a routine execution context, the value of the variable is NULL.

Notes

The value of the ROUTINE_SPECIFIC_NAME global variable is set only for procedures and compiled functions: the value always reflects the specific name of the currently executing routine.

The value is not changed for inline functions or methods: the value remains the same as it was when the inline function or method was invoked.

ROUTINE_TYPE global variable

This built-in global variable contains the type of the currently executing routine.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is CHAR(1).
- The schema is SYSIBM.
- The scope of this global variable is session.

If the ROUTINE_TYPE global variable is referenced outside a routine execution context, the value of the variable is NULL.

The value of the ROUTINE_TYPE global variable is P for a stored procedure and F for a function.

Notes

The value of the ROUTINE_TYPE global variable is set only for procedures and compiled functions: the value always reflects the type of the currently executing routine.

The value does not change for inline functions or methods: the value remains the same as it was when the inline function or method was invoked.

SQL_COMPAT global variable

This built-in global variable specifies the SQL compatibility mode. Its value determines which set of syntax rules are applied to SQL queries.

This global variable has the following characteristics:

- It is a read/write variable, with values maintained by the user.
- The type is VARCHAR(3).
- The schema is SYSIBM.
- The scope of this global variable is session.
- It has a default value of NULL.

This global variable must have a value of NULL, 'DB2', or 'NPS' (SQLSTATE 42815).

NULL
The default setting ('DB2') is used.

'DB2'
Db2 syntax rules are applied to SQL queries.

'NPS'
Netezza syntax rules are applied to SQL queries. If you use this setting, some SQL behavior will differ from what is documented in the SQL reference information. To determine the potential effects of a compatibility feature on your SQL applications, see Compatibility features for Netezza .

TRUSTED_CONTEXT global variable

This built-in global variable contains the name of the trusted context that was matched to establish the current trusted connection.

This global variable has the following characteristics:

- It is read-only, with values maintained by system.
- The type is VARCHAR(128).
- The schema is SYSIBM.
- The scope is session.

If no trusted connection is established, the value of the TRUSTED_CONTEXT global variable is NULL.

Built-in functions

Built-in functions are functions provided with the database manager and are classified as aggregate functions, scalar functions, or table functions.

This topic lists the supported built-in functions classified by type:

- Aggregate functions (Table 38 on page 225)
- Array functions (Table 39 on page 227)
- Cast scalar functions (Table 40 on page 227)
- Datetime scalar functions (Table 41 on page 228)
- JSON scalar functions (Table 42 on page 231)
- Miscellaneous scalar functions (Table 43 on page 232)
- Numeric scalar functions (Table 44 on page 233)
- Partitioning scalar functions (Table 45 on page 235)
- Regular expression functions (Table 46 on page 235)
- Security scalar functions (Table 47 on page 235)
- String scalar functions (Table 48 on page 236)

- Table functions (Table 49 on page 238)
- XML functions (Table 50 on page 239)

The “OLAP specification” on page 163 topic documents the following OLAP functions which are sometimes referred to as built-in functions:

- FIRST_VALUE and LAST_VALUE
- LAG and LEAD
- NTILE
- RANK and DENSE_RANK
- RATIO_TO_REPORT
- ROW_NUMBER

There are additional built-in functions documented under the following headings:

- ADMIN_CMD procedure and associated SQL routines
- Audit routines and procedures
- Configuration SQL routines and views
- Db2 pureScale instance views
- Environment views
- Explain routines
- Monitor routines
- MQSeries® SQL routines
- Security SQL routines and views
- Snapshot SQL routines and views
- SQL procedures SQL routines
- Workload management routines
- Miscellaneous SQL routines and views

For details about these additional built-in functions, see "Supported built-in SQL routines and views" in *Administrative Routines and Views*.

Table 38. Aggregate functions

Function	**Description**
“ARRAY_AGG ” on page 240	Aggregates a set of elements into an array.
“AVG ” on page 244	Returns the average of a set of numbers.
“CORRELATION ” on page 245	Returns the coefficient of correlation of a set of number pairs.
“COUNT ” on page 246	Returns the number of rows or values in a set of rows or values.
“COUNT_BIG ” on page 247	Returns the number of rows or values in a set of rows or values. The result can be greater than the maximum value of INTEGER.
“COVARIANCE ” on page 248	Returns the covariance of a set of number pairs.
“COVARIANCE_SAMP ” on page 249	Returns the sample covariance of a set of number pairs.
“CUME_DIST ” on page 250	Returns the cumulative distribution of a row that is hypothetically inserted into a group of rows.

Table 38. Aggregate functions (continued)	
Function	**Description**
“GROUPING ” on page 251	Used with grouping-sets and super-groups to indicate sub-total rows generated by a grouping set. The value returned is 0 or 1. A value of 1 means that the value of the argument in the returned row is a null value, and the row was generated for a grouping set. This generated row provides a sub-total for a grouping set.
“LISTAGG ” on page 255	Aggregates a set string elements into one string by concatenating the strings.
“MAX ” on page 257	Returns the maximum value in a set of values.
“MEDIAN ” on page 258	Returns the median value in a set of values.
“MIN ” on page 259	Returns the minimum value in a set of values.
“PERCENTILE_CONT ” on page 260	Returns the value that corresponds to the specified percentile, given a sort specification by using a continuous distribution model.
“PERCENTILE_DISC ” on page 261	Returns the value that corresponds to the specified percentile given a sort specification by using a discrete distribution model.
“PERCENT_RANK ” on page 262	Returns the relative percentile rank of a row that is hypothetically inserted into a group of rows.
“Regression functions (REGR_AVGX, REGR_AVGY, REGR_COUNT, ...)” on page 264	The regression functions fit an ordinary-least-squares regression line of the form y = a * x + b to a set of number pairs: • REGR_AVGX returns quantities used to compute diagnostic statistics. • REGR_AVGY returns quantities used to compute diagnostic statistics. • REGR_COUNT returns the number of non-null number pairs used to fit the regression line. • REGR_INTERCEPT or REGR_ICPT returns the y-intercept of the regression line. • REGR_R2 returns the coefficient of determination for the regression. • REGR_SLOPE returns the slope of the line. • REGR_SXX returns quantities used to compute diagnostic statistics. • REGR_SXY returns quantities used to compute diagnostic statistics. • REGR_SYY returns quantities used to compute diagnostic statistics.
“STDDEV ” on page 266	Returns the biased standard deviation (division by *n*) of a set of numbers.
“STDDEV_SAMP ” on page 267	Returns the sample standard deviation (division by [*n*-1]) of a set of numbers.
“SUM ” on page 268	Returns the sum of a set of numbers.
“VARIANCE ” on page 269	Returns the biased variance (division by *n*) of a set of numbers.
“VARIANCE_SAMP ” on page 270	Returns the sample variance (division by [*n*-1]) of a set of numbers.
“XMLAGG ” on page 271	Returns an XML sequence containing an item for each non-null value in a set of XML values.
“XMLGROUP ” on page 273	Returns an XML value with a single XQuery document node containing one top-level element node.

Table 39. Array functions	
Function	**Description**
“ARRAY_AGG ” on page 240	Aggregates a set of elements into an array.
“ARRAY_DELETE ” on page 284	Deletes an element or range of elements from an associative array.
“ARRAY_FIRST ” on page 285	Returns the smallest array index value of the array.
“ARRAY_LAST ” on page 286	Returns the largest array index value of the array.
“ARRAY_NEXT ” on page 286	Returns the next larger array index value for an array relative to the specified array index argument.
“ARRAY_PRIOR ” on page 287	Returns the next smaller array index value for an array relative to the specified array index argument.
“CARDINALITY ” on page 298	Returns a value of type BIGINT representing the number of elements of an array
“MAX_CARDINALITY ” on page 419	Returns a value of type BIGINT representing the maximum number of elements that an array can contain.
“TRIM_ARRAY ” on page 546	Returns a value with the same array type as *array-variable* but with the cardinality reduced by the value of *numeric-expression*.
“UNNEST ” on page 624	Returns a result table that includes a row for each element of the specified array.

Table 40. Cast scalar functions	
Function	**Description**
“BIGINT ” on page 290	Returns a 64-bit integer representation of a value in the form of an integer constant.
“BINARY ” on page 292	Returns a fixed-length binary string representation of a string of any data type.
“BLOB ” on page 295	Returns a BLOB representation of a string of any type.
“BPCHAR ” on page 296	Returns a VARCHAR representation of a value.
“CHAR ” on page 300	Returns a CHARACTER representation of a value.
“CLOB ” on page 308	Returns a CLOB representation of a value.
“DATE ” on page 315	Returns a DATE from a value.
“DATETIME ” on page 316	Returns a TIMESTAMP from a value or a pair of values.
“DBCLOB ” on page 325	Returns a DBCLOB representation of a string.
“DECFLOAT ” on page 327	Returns the decimal floating-point representation of a value.
“DECIMAL or DEC ” on page 331	Returns a DECIMAL representation of a value.
“DOUBLE_PRECISION or DOUBLE” on page 339	Returns the floating-point representation of a value.
EMPTY_BLOB, EMPTY_CLOB, and EMPTY_DBCLOB scalar functions	Return a zero-length value of the associated data type.
“FLOAT ” on page 348	Returns a DOUBLE representation of a value.
“FLOAT4 ” on page 349	Returns a REAL representation of a value.

Table 40. Cast scalar functions (continued)	
Function	**Description**
“FLOAT8 ” on page 349	Returns a DOUBLE representation of a value.
“GRAPHIC ” on page 353	Returns a GRAPHIC representation of a string.
“INT ” on page 376	Returns an INTEGER representation of a value.
“INTEGER ” on page 379	Returns an INTEGER representation of a value.
“INTERVAL ” on page 376	Returns a DECIMAL duration that corresponds to a duration specified as a string.
“INT2 ” on page 381	Returns a SMALLINT representation of a value.
“INT4 ” on page 381	Returns a INTEGER representation of a value.
“INT8 ” on page 381	Returns a BIGINT representation of a value.
“NCHAR ” on page 429	Returns a fixed-length national character string representation of a value.
“NCLOB ” on page 431	Returns an NCLOB representation of a national character string.
“NUMERIC ” on page 438	Returns a DECIMAL representation of a value.
“NVARCHAR ” on page 431	Returns a varying-length national character string representation of a value.
“REAL ” on page 455	Returns the single-precision floating-point representation of a value.
“SMALLINT ” on page 502	Returns a SMALLINT representation of a value.
“TIME ” on page 525	Returns a TIME from a value.
“TIMESTAMP ” on page 525	Returns a TIMESTAMP from a value or a pair of values.
“TO_CLOB” on page 537	Returns a CLOB representation of a character string type.
“TO_NCLOB ” on page 539	Returns an NCLOB representation of a character string.
“VARBINARY ” on page 556	Returns a VARBINARY (varying-length binary string) representation of a string of any data type.
“VARCHAR ” on page 557	Returns a VARCHAR representation of a value.
“VARGRAPHIC ” on page 573	Returns a VARGRAPHIC representation of a value.

Table 41. Datetime scalar functions	
Function	**Description**
“ADD_DAYS ” on page 277	Returns a datetime value that represents the first argument plus a specified number of days.
“ADD_HOURS ” on page 278	Returns a timestamp value that represents the first argument plus a specified number of hours.
“ADD_MINUTES ” on page 279	Returns a timestamp value that represents the first argument plus a specified number of minutes.
“ADD_MONTHS ” on page 280	Returns a datetime value that represents *expression* plus a specified number of months.
“ADD_SECONDS ” on page 281	Returns a timestamp value that represents the first argument plus a specified number of seconds and fractional seconds.

Table 41. Datetime scalar functions (continued)	
Function	**Description**
“ADD_YEARS ” on page 282	Returns a datetime value that represents the first argument plus a specified number of years.
“AGE ” on page 283	Returns a numeric value that specifies the number of full years, full months, and full days between the current timestamp and the argument.
“DATE_PART ” on page 316	Returns portion of a datetime based on its argument.
“DATE_TRUNC ” on page 318	Returns a timestamp expression rounded to the specified unit.
“DAY ” on page 320	Returns the day part of a value.
“DAYNAME ” on page 321	Returns a character string containing the name of the day (for example, Friday) for the day portion of expression, based on locale-name or the value of the special register CURRENT LOCALE LC_TIME.
“DAYOFMONTH ” on page 322	Returns an integer between 1 and 31 that represents the day of the month.
“DAYOFWEEK ” on page 322	Returns the day of the week in the first argument as an integer value. The integer value is in the range 1-7, where 1 represents the first day of the week, as specified in the second argument.
“DAYOFWEEK_ISO ” on page 323	Returns the day of the week from a value, where 1 is Monday and 7 is Sunday.
“DAYOFYEAR ” on page 323	Returns the day of the year from a value.
“DAYS ” on page 323	Returns an integer representation of a date.
“DAYS_BETWEEN ” on page 324	Returns the number of full days between the specified arguments.
“DAYS_TO_END_OF_MONTH ” on page 325	Returns the number of days to the end of the month.
“EXTRACT ” on page 344	Returns a portion of a date or timestamp based on the arguments.
“FIRST_DAY ” on page 348	Returns a date or timestamp that represents the first day of the month of the argument.
“FROM_UTC_TIMESTAMP ” on page 350	Returns a TIMESTAMP that is converted from Coordinated Universal Time to the timezone that is specified by the timezone string.
“HOUR ” on page 364	Returns the hour part of a value.
“HOURS_BETWEEN ” on page 365	Returns the number of full hours between the specified arguments.
“JULIAN_DAY ” on page 396	Returns an integer value representing the number of days from January 1, 4712 B.C. to the date specified in the argument.
“LAST_DAY ” on page 396	Returns a datetime value that represents the last day of the month of the argument.
“MICROSECOND ” on page 419	Returns the microsecond part of a value.
“MIDNIGHT_SECONDS ” on page 420	Returns an integer value representing the number of seconds between midnight and a specified time value.
“MINUTE ” on page 421	Returns the minute part of a value.
“MINUTES_BETWEEN ” on page 422	Returns the number of full minutes between the specified arguments.
“MONTH ” on page 425	Returns the month part of a value.

Table 41. Datetime scalar functions (continued)	
Function	**Description**
“MONTHNAME ” on page 425	Returns a character string containing the name of the month (for example, January) for the month portion of expression, based on locale-name or the value of the special register CURRENT LOCALE LC_TIME.
“MONTHS_BETWEEN ” on page 426	Returns an estimate of the number of months between *expression1* and *expression2*.
“NEXT_DAY ” on page 433	Returns a datetime value that represents the first weekday, named by *string-expression*, that is later than the date in *expression*.
“NEXT_MONTH ” on page 434	Returns the first day of the next month after the specified date.
“NEXT_QUARTER ” on page 435	Returns the first day of the next quarter after the specified date.
“NEXT_WEEK ” on page 435	Returns the first day of the next week after the specified date.
“NEXT_YEAR ” on page 436	Returns the first day of the next year after the specified date.
“NOW ” on page 437	Returns a timestamp based on when the SQL statement is executed at the current server.
“QUARTER ” on page 450	Returns an integer that represents the quarter of the year in which a date resides.
“ROUND ” on page 485	Returns a datetime value, rounded to the unit specified by *format-string*.
“ROUND_TIMESTAMP ” on page 490	Returns a timestamp that is the *expression* rounded to the unit specified by the *format-string*.
“SECOND ” on page 499	Returns the seconds part of a value.
“SECONDS_BETWEEN ” on page 500	Returns the number of full seconds between the specified arguments.
“THIS_MONTH ” on page 523	Returns the first day of the month in the specified date.
“THIS_QUARTER ” on page 523	Returns the first day of the quarter in the specified date.
“THIS_WEEK ” on page 524	Returns the first day of the week in the specified date.
“THIS_YEAR ” on page 524	Returns the first day of the year in the specified date.
“TIMESTAMP_FORMAT ” on page 527	Returns a timestamp from a character string (*argument1*) that has been interpreted using a format template (*argument2*).
“TIMESTAMP_ISO ” on page 532	Returns a timestamp value based on a date, time, or timestamp argument. If the argument is a date, it inserts zero for all the time elements. If the argument is a time, it inserts the value of CURRENT DATE for the date elements, and zero for the fractional time element.
“TIMESTAMPDIFF ” on page 533	Returns an estimated number of intervals of type *argument1*, based on the difference between two timestamps. The second argument is the result of subtracting two timestamp types and converting the result to CHAR.
“TIMEZONE ” on page 535	Converts a date and time in one timezone into a timestamp in another timezone.
“TO_CHAR ” on page 536	Returns a CHARACTER representation of a timestamp.
“TO_DATE ” on page 537	Returns a timestamp from a character string.

Table 41. Datetime scalar functions (continued)	
Function	**Description**
“TO_NCHAR ” on page 539	Returns a national character representation of an input expression that has been formatted using a character template.
“TO_TIMESTAMP ” on page 540	Returns a timestamp that is based on the interpretation of the input string using the specified format.
“TO_UTC_TIMESTAMP ” on page 541	Returns a TIMESTAMP that is converted from Coordinated Universal Time to the timezone specified by the timezone string.
“TRUNCATE or TRUNC ” on page 548	Returns a datetime value, truncated to the unit specified by *format-string*.
“TRUNC_TIMESTAMP ” on page 547	Returns a timestamp that is the *expression* truncated to the unit specified by the *format-string*.
“VARCHAR_FORMAT ” on page 564	Returns a CHARACTER representation of a timestamp (*argument1*), formatted according to a template (*argument2*).
“WEEK ” on page 580	Returns the week of the year from a value, where the week starts with Sunday.
“WEEK_ISO ” on page 581	Returns the week of the year from a value, where the week starts with Monday.
“WEEKS_BETWEEN ” on page 581	Returns the number of full weeks between the specified arguments.
“YEAR ” on page 615	Returns the year part of a value.
“YEARS_BETWEEN ” on page 615	Returns the number of full years between the specified arguments.
“YMD_BETWEEN ” on page 616	Returns a numeric value that specifies the number of full years, full months, and full days between two datetime values.

Table 42. JSON scalar functions	
Function	**Description**
“BSON_TO_JSON ” on page 296	Converts a string that contains data that is formatted as BSON to a character string that contains data that is formatted as JSON.
“JSON_ARRAY ” on page 383	Generates a JSON array by explicitly listing the array elements by using an expression or by using a query.
“JSON_OBJECT ” on page 386	Generates a JSON object by using the specified key:value pairs. If no key:value pairs are provided, an empty object is returned.
“JSON_QUERY ” on page 389	Returns an SQL/JSON value from the specified JSON text by using an SQL/JSON path expression.
“JSON_TO_BSON ” on page 392	Converts a string that contains data that is formatted for JSON to a binary string that contains data that is formatted as BSON.
“JSON_VALUE ” on page 393	Returns an SQL scalar value from JSON text, by using an SQL/JSON path expression.

Table 43. Miscellaneous scalar functions	
Function	**Description**
“BITAND, BITANDNOT, BITOR, BITXOR, and BITNOT ” on page 293	These bitwise functions operate on the "two's complement" representation of the integer value of the input arguments and return the result as a corresponding base 10 integer value in a data type based on the data type of the input arguments.
“COALESCE ” on page 308	Returns the first argument that is not null.
“CURSOR_ROWCOUNT ” on page 314	Returns the cumulative count of all rows fetched by the specified cursor since the cursor was opened.
“DECODE ” on page 334	Compares each specified *expression2* to *expression1*. If *expression1* is equal to *expression2*, or both *expression1* and *expression2* are null, the value of the following *result-expresssion* is returned. If no *expression2* matches *expression1*, the value of *else-expression* is returned; otherwise a null value is returned.
“DEREF ” on page 337	Returns an instance of the target type of the reference type argument.
“EVENT_MON_STATE ” on page 343	Returns the operational state of particular event monitor.
“GREATEST ” on page 358	Returns the maximum value in a set of values.
“HEX ” on page 362	Returns a hexadecimal representation of a value.
“IDENTITY_VAL_LOCAL ” on page 366	Returns the most recently assigned value for an identity column.
“ INTNAND, INTNOR, INTNXOR, and INTNNOT ” on page 381	These bitwise functions operate on the "two's complement" representation of the integer value of the input arguments and return the result as a corresponding base 10 integer value.
“LEAST ” on page 398	Returns the minimum value in a set of values.
“LENGTH ” on page 402	Returns the length of a value.
“MAX ” on page 418	Returns the maximum value in a set of values.
“MIN ” on page 421	Returns the minimum value in a set of values.
“NULLIF ” on page 437	Returns a null value if the arguments are equal; otherwise, it returns the value of the first argument.
“NVL ” on page 438	Returns the first argument that is not null.
“RAISE_ERROR ” on page 452	Raises an error in the SQLCA. The sqlstate that is to be returned is indicated by *argument1*. The second argument contains any text that is to be returned.
“RAWTOHEX ” on page 454	Returns a hexadecimal representation of a value as a character string.
“REC2XML ” on page 456	Returns a string formatted with XML tags, containing column names and column data.
“RID and RID_BIT ” on page 479	The RID_BIT scalar function returns the row identifier (RID) of a row in a character string format. The RID scalar function returns the RID of a row in large integer format. The RID function is not supported in partitioned database environments. The RID_BIT function is preferred over the RID function.
“TABLE_NAME ” on page 520	Returns an unqualified name of a table or view based on the object name specified in *argument1*, and the optional schema name specified in *argument2*. The returned value is used to resolve aliases.

Table 43. Miscellaneous scalar functions (continued)	
Function	**Description**
“TABLE_SCHEMA ” on page 521	Returns the schema name portion of a two-part table or view name (given by the object name in *argument1* and the optional schema name in *argument2*). The returned value is used to resolve aliases.
“TO_HEX ” on page 537	Converts a numeric expression into the hexadecimal representation.
“TYPE_ID ” on page 550	Returns the internal data type identifier of the dynamic data type of the argument. The result of this function is not portable across databases.
“TYPE_NAME ” on page 551	Returns the unqualified name of the dynamic data type of the argument.
“TYPE_SCHEMA ” on page 552	Returns the schema name of the dynamic data type of the argument.
“VALUE ” on page 556	Returns the first argument that is not null.

Table 44. Numeric scalar functions	
Function	**Description**
“ABS or ABSVAL ” on page 276	Returns the absolute value of a number.
“ACOS ” on page 276	Returns the arc cosine of a number, in radians.
“ASIN ” on page 289	Returns the arc sine of a number, in radians.
“ATAN ” on page 289	Returns the arc tangent of a number, in radians.
“ATANH ” on page 290	Returns the hyperbolic arc tangent of a number, in radians.
“ATAN2 ” on page 289	Returns the arc tangent of x and y coordinates as an angle expressed in radians.
“CEILING or CEIL ” on page 299	Returns the smallest integer value that is greater than or equal to a number.
“COMPARE_DECFLOAT ” on page 311	Returns a SMALLINT value that indicates whether the two arguments are equal or unordered, or whether one argument is greater than the other.
“COS ” on page 313	Returns the cosine of a number.
“COSH ” on page 313	Returns the hyperbolic cosine of a number.
“COT ” on page 314	Returns the cotangent of the argument, where the argument is an angle expressed in radians.
“DECFLOAT_FORMAT ” on page 329	Returns a DECFLOAT(34) from a character string.
“DEGREES ” on page 337	Returns the number of degrees of an angle.
“DIGITS ” on page 338	Returns a character-string representation of the absolute value of a number.
“EXP ” on page 343	Returns a value that is the base of the natural logarithm (e) raised to a power specified by the argument.
“FLOOR ” on page 349	Returns the largest integer value that is less than or equal to a number.
“LN ” on page 404	Returns the natural logarithm of a number.
“LOG10 ” on page 410	Returns the common logarithm (base 10) of a number.
“MOD ” on page 423	Returns the remainder of the first argument divided by the second argument.

Table 44. Numeric scalar functions (continued)	
Function	**Description**
“MOD (SYSFUN schema) ” on page 424	Returns the remainder of the first argument divided by the second argument.
“MULTIPLY_ALT ” on page 427	Returns the product of two arguments as a decimal value. This function is useful when the sum of the argument precisions is greater than 31.
“NORMALIZE_ DECFLOAT ” on page 436	Returns a decimal floating-point value that is the result of the argument set to its simplest form.
“POW ” on page 448	Returns the result of raising the first argument to the power of the second argument.
“POWER ” on page 448	Returns the result of raising the first argument to the power of the second argument.
“QUANTIZE ” on page 448	Returns a decimal floating-point number that is equal in value and sign to the first argument, and whose exponent is equal to the exponent of the second argument.
“RADIANS ” on page 451	Returns the number of radians for an argument that is expressed in degrees.
“RANDOM ” on page 454	Returns a floating point value between 0 and 1.
“RAND (SYSFUN schema) ” on page 453	Returns a random number.
“RAND (SYSIBM schema) ” on page 453	Returns a floating point value between 0 and 1.
“ROUND ” on page 485	Returns a numeric value that has been rounded to the specified number of decimal places.
“SIGN ” on page 501	Returns the sign of a number.
“SIN ” on page 501	Returns the sine of a number.
“SINH ” on page 502	Returns the hyperbolic sine of a number.
“SQRT ” on page 504	Returns the square root of a number.
“TAN ” on page 522	Returns the tangent of a number.
“TANH ” on page 523	Returns the hyperbolic tangent of a number.
“TO_NUMBER ” on page 539	Returns a DECFLOAT(34) from a character string.
“TOTALORDER ” on page 542	Returns a SMALLINT value of -1, 0, or 1 that indicates the comparison order of two arguments.
“TRUNCATE or TRUNC ” on page 548	Returns a number value that has been truncated at a specified number of decimal places.
“VARCHAR_FORMAT ” on page 564	Returns a CHARACTER representation of a timestamp (*argument1*), formatted according to a template (*argument2*).
“WIDTH_BUCKET ” on page 582	Creates equal-width histograms.

Table 45. Partitioning scalar functions	
Function	**Description**
“DATAPARTITIONNUM ” on page 314	Returns the sequence number (SYSDATAPARTITIONS.SEQNO) of the data partition in which the row resides. The argument is any column name within the table.
“DBPARTITIONNUM ” on page 326	Returns the database partition number of the row. The argument is any column name within the table.
“HASH ” on page 359	Returns the 128-bit, 160-bit, 256-bit or 512-bit hash of the input data.
“HASH4 ” on page 360	Returns the 32-bit hash of the input data.
“HASH8 ” on page 361	Returns the 64-bit hash of the input data.
“HASHEDVALUE ” on page 361	Returns the distribution map index (0 to 32767) of the row. The argument is a column name within a table.

Table 46. Regular expression scalar functions	
Function	**Description**
“REGEXP_COUNT ” on page 460	Returns a count of the number of times that a regular expression pattern is matched in a string.
“REGEXP_EXTRACT ” on page 462	Returns one occurrence of a substring of a string that matches the regular expression pattern.
“REGEXP_INSTR ” on page 462	Returns the starting or ending position of the matched substring, depending on the value of the return_option argument.
“REGEXP_LIKE ” on page 465	Returns a boolean value indicating if the regular expression pattern is found in a string. The function can be used only where a predicate is supported.
“REGEXP_MATCH_COUNT ” on page 467	Returns a count of the number of times that a regular expression pattern is matched in a string.
“REGEXP_REPLACE ” on page 468	Returns a modified version of the source string where occurrences of the regular expression pattern found in the source string are replaced with the specified replacement string.
“REGEXP_SUBSTR ” on page 470	Returns one occurrence of a substring of a string that matches the regular expression pattern.

Table 47. Security scalar functions	
Function	**Description**
“SECLABEL ” on page 496	Returns an unnamed security label.
“SECLABEL_BY_NAME ” on page 497	Returns a specific security label.
“SECLABEL_TO_CHAR ” on page 497	Accepts a security label and returns a string that contains all elements in the security label.
VERIFY_GROUP_FOR_USER	Returns a value that indicates whether any of the groups associated with **authorization-id-expression** are in the group names specified by the list of **group-name-expression** arguments.

Table 47. Security scalar functions (continued)	
Function	**Description**
“VERIFY_ROLE_FOR_USER ” on page 579	Returns a value that indicates whether any of the roles associated with **authorization-id-expression** are in, or contain any of, the role names specified by the list of **role-name-expression** arguments.
VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER	Returns a value that indicates whether **authorization-id-expression** has acquired a role under a trusted connection associated with some trusted context and that role is in, or contained in any of, the role names specified by the list of **role-name-expression** arguments.

Table 48. String scalar functions	
Function	**Description**
“ASCII ” on page 288	Returns the ASCII code value of the leftmost character of the argument as an integer.
“BTRIM ” on page 297	Removes characters from the beginning and end of a string expression.
“CHARACTER_LENGTH ” on page 306	Returns the length of an expression in the specified *string-unit*.
“CHR ” on page 307	Returns the character that has the ASCII code value specified by the argument.
“COLLATION_KEY” on page 309	Returns a VARBINARY string representing the collation key of the specified *string-expression* in the specified *collation-name*.
“COLLATION_KEY_BIT ” on page 310	Returns a VARCHAR FOR BIT DATA string representing the collation key of the specified *string-expression* in the specified *collation-name*.
“CONCAT ” on page 312	Returns a string that is the concatenation of two strings.
“DECRYPT_BIN and DECRYPT_CHAR ” on page 335	Returns a value that is the result of decrypting encrypted data using a password string.
“DIFFERENCE ” on page 338	Returns the difference between the sounds of the words in two argument strings, as determined by the SOUNDEX function. A value of 4 means the strings sound the same.
“ENCRYPT ” on page 341	Returns a value that is the result of encrypting a data string expression.
“GENERATE_UNIQUE ” on page 351	Returns a bit data character string that is unique compared to any other execution of the same function.
“GETHINT ” on page 352	Returns the password hint if one is found.
“INITCAP” on page 369	Returns a string with the first character of each word converted to uppercase and the rest to lowercase.
“INSERT ” on page 371	Returns a string, where *argument3* bytes have been deleted from *argument1* (beginning at *argument2*), and *argument4* has been inserted into *argument1* (beginning at *argument2*).
“INSTR ” on page 374	Returns the starting position of a string within another string.
“INSTRB ” on page 376	Returns the starting position, in bytes, of a string within another string.

Table 48. String scalar functions (continued)	
Function	**Description**
“LCASE ” on page 397	Returns a string in which all the SBCS characters have been converted to lowercase characters.
“LCASE (locale sensitive) ” on page 397	Returns a string in which all characters have been converted to lowercase characters using the rules from the Unicode standard associated with the specified locale.
“LCASE (SYSFUN schema) ” on page 397	Returns a string in which all the SBCS characters have been converted to lowercase characters.
“LOWER (locale sensitive) ” on page 412	Returns a string in which all characters have been converted to lowercase characters using the rules from the Unicode standard associated with the specified locale.
“LEFT ” on page 398	Returns the leftmost characters from a string.
“LOCATE ” on page 405	Returns the starting position of one string within another string.
“LOCATE_IN_STRING ” on page 408	Returns the starting position of the first occurrence of one string within another string.
“LOWER ” on page 411	Returns a string in which all the characters have been converted to lowercase characters.
“LPAD” on page 414	Returns a string that is padded on the left with the specified character, or with blanks.
“LTRIM ” on page 416	Removes blanks from the beginning of a string expression.
“LTRIM (SYSFUN schema) ” on page 418	Removes blanks from the beginning of a string expression.
“OCTET_LENGTH ” on page 439	Returns the length of an expression in octets (bytes).
“OVERLAY ” on page 440	Returns a string in which, beginning at *start* in the specified *source-string*, *length* of the specified code units have been deleted and *insert-string* has been inserted.
“POSITION ” on page 444	Returns the starting position of *argument2* within *argument1*.
“POSSTR ” on page 446	Returns the starting position of one string within another string.
“QUOTE_IDENT ” on page 450	Returns a string that can be used as an identifier in an SQL statement.
“QUOTE_LITERAL ” on page 451	Returns a string that can be used as a string constant in an SQL statement.
“REPEAT ” on page 473	Returns a character string composed of the first argument repeated the number of times specified by the second argument.
“REPEAT (SYSFUN schema) ” on page 474	Returns a character string composed of the first argument repeated the number of times specified by the second argument.
“REPLACE ” on page 475	Replaces all occurrences of *argument2* in *argument1* with *argument3*.
“REPLACE (SYSFUN schema) ” on page 478	Replaces all occurrences of *expres sion2* in *expression1* with *e xpression3*.
“RIGHT ” on page 481	Returns the rightmost characters from a string.
“RPAD” on page 491	Returns a string that is padded on the right with the specified character, string, or with blanks.

Table 48. String scalar functions (continued)	
Function	**Description**
“RTRIM ” on page 494	Removes blanks from the end of a string expression.
“RTRIM (SYSFUN schema) ” on page 496	Removes blanks from the end of a string expression.
“SOUNDEX ” on page 503	Returns a 4-character code representing the sound of the words in the argument. This result can be compared with the sound of other strings.
“SPACE ” on page 504	Returns a character string that consists of a specified number of blanks.
“STRIP ” on page 505	Removes blanks or another specified character from the end, the beginning, or both ends of a string expression.
“STRLEFT ” on page 506	Returns the leftmost string of *string-expression* of length *length*, expressed in the specified string unit.
“STRPOS ” on page 506	Returns the starting position of one string within another string.
“STRRIGHT ” on page 506	Returns the rightmost string of *string-expression* of length *length*, expressed in the specified string unit.
“SUBSTR ” on page 506	Returns a substring of a string.
“SUBSTRB ” on page 515	Returns a substring of a string.
“SUBSTRING ” on page 518	Returns a substring of a string.
“TO_SINGLE_BYTE ” on page 540	Returns a string in which multi-byte characters are converted to the equivalent single-byte character where an equivalent character exists.
“TRANSLATE ” on page 543	Returns a string in which one or more characters in a string are converted to other characters.
“TRIM ” on page 545	Removes blanks or another specified character from the end, the beginning, or both ends of a string expression.
“UCASE ” on page 552	The UCASE function is identical to the TRANSLATE function except that only the first argument (*char-string-exp*) is specified.
“UCASE (locale sensitive) ” on page 552	Returns a string in which all characters have been converted to uppercase characters using the rules from the Unicode standard associated with the specified locale.
“UPPER ” on page 554	Returns a string in which all the characters have been converted to uppercase characters.
“UPPER (locale sensitive) ” on page 554	Returns a string in which all characters have been converted to uppercase characters using the rules from the Unicode standard associated with the specified locale.

Table 49. Table functions	
Function	**Description**
“BASE_TABLE ” on page 618	Returns both the object name and schema name of the object found after any alias chains have been resolved.
“JSON_TABLE ” on page 619	Returns a result table from the evaluation of SQL/JSON path expressions. Each item in the result sequence of the row SQL/JSON path expression represents one or more rows in the result table.

Table 49. Table functions (continued)	
Function	**Description**
“UNNEST ” on page 624	Returns a result table that includes a row for each element of the specified array.
“XMLTABLE ” on page 626	Returns a table from the evaluation of XQuery expressions, possibly using specified input arguments as XQuery variables. Each sequence item in the result sequence of the row XQuery expression represents a row of the result table.

Table 50. XML functions	
Function	**Description**
“PARAMETER ” on page 443	Represents a position in an SQL statement where the value is provided dynamically by XQuery as part of the invocation of the db2-fn:sqlquery function.
“XMLAGG ” on page 271	Returns an XML sequence containing an item for each non-null value in a set of XML values.
“XMLATTRIBUTES ” on page 585	Constructs XML attributes from the arguments.
“XMLCOMMENT ” on page 586	Returns an XML value with a single XQuery comment node with the input argument as the content.
“XMLCONCAT ” on page 586	Returns a sequence containing the concatenation of a variable number of XML input arguments.
“XMLDOCUMENT ” on page 587	Returns an XML value with a single XQuery document node with zero or more children nodes.
“XMLELEMENT ” on page 588	Returns an XML value that is an XML element node.
“XMLFOREST ” on page 594	Returns an XML value that is a sequence of XML element nodes.
“XMLGROUP ” on page 273	Returns an XML value with a single XQuery document node containing one top-level element node.
“XMLNAMESPACES ” on page 596	Constructs namespace declarations from the arguments.
“XMLPARSE ” on page 597	Parses the argument as an XML document and returns an XML value.
“XMLPI ” on page 599	Returns an XML value with a single XQuery processing instruction node.
“XMLQUERY ” on page 600	Returns an XML value from the evaluation of an XQuery expression possibly using specified input arguments as XQuery variables.
“XMLROW ” on page 603	Returns an XML value with a single XQuery document node containing one top-level element node.
“XMLSERIALIZE ” on page 605	Returns a serialized XML value of the specified data type generated from the argument.
“XMLTABLE ” on page 626	Returns a table from the evaluation of XQuery expressions, possibly using specified input arguments as XQuery variables. Each sequence item in the result sequence of the row XQuery expression represents a row of the result table.
“XMLTEXT ” on page 606	Returns an XML value with a single XQuery text node having the input argument as the content.
“XMLVALIDATE ” on page 607	Returns a copy of the input XML value augmented with information obtained from XML schema validation, including default values.

Table 50. XML functions (continued)	
Function	**Description**
“XMLXSROBJECTID ” on page 611	Returns the XSR object identifier of the XML schema used to validate the XML document that is specified in the argument
“XSLTRANSFORM ” on page 612	Converts XML data into other formats, including the conversion of XML documents that conform to one XML schema into documents that conform to another schema.

Aggregate functions

An aggregate function (formerly known as a column function) accepts arguments and returns a single scalar value that is the result of an evaluation of a set of like values, such as those in a column within a set of one or more rows.

The argument of an aggregate function is a set of values derived from an expression. The expression can include columns, but cannot include a *scalar-fullselect*, another aggregate function, or an XMLQUERY or XMLEXISTS expression (SQLSTATE 42607). The scope of the set is a group or an intermediate result table.

If a GROUP BY clause is specified in a query, and the intermediate result of the FROM, WHERE, GROUP BY, and HAVING clauses is the empty set, the aggregate functions are not applied; the result of the query is the empty set; the SQLCODE is set to +100; and the SQLSTATE is set to '02000'.

If a GROUP BY clause is *not* specified in a query, and the intermediate result of the FROM, WHERE, and HAVING clauses is the empty set, the aggregate functions are applied to the empty set.

For example, the result of the following SELECT statement is the number of distinct values of JOBCODE for employees in department D01:

```
SELECT COUNT(DISTINCT JOBCODE)
  FROM CORPDATA.EMPLOYEE
  WHERE WORKDEPT = 'D01'
```

The keyword DISTINCT is not considered to be an argument of the function, but rather a specification of an operation that is performed before the function is applied. If DISTINCT is specified, duplicate values are eliminated. When interpreting the DISTINCT clause for decimal floating-point values that are numerically equal, the number of significant digits in the value is not considered. For example, the decimal floating-point number 123.00 is not distinct from the decimal floating-point number 123. The representation of the number returned from the query will be any one of the representations encountered (for example, either 123.00 or 123).

If ALL is implicitly or explicitly specified, duplicate values are not eliminated.

For compatibility with other SQL implementations, UNIQUE can be specified as a synonym for DISTINCT in aggregate functions.

Expressions can be used in aggregate functions. For example:

```
SELECT MAX(BONUS + 1000)
  INTO :TOP_SALESREP_BONUS
  FROM EMPLOYEE
  WHERE COMM > 5000
```

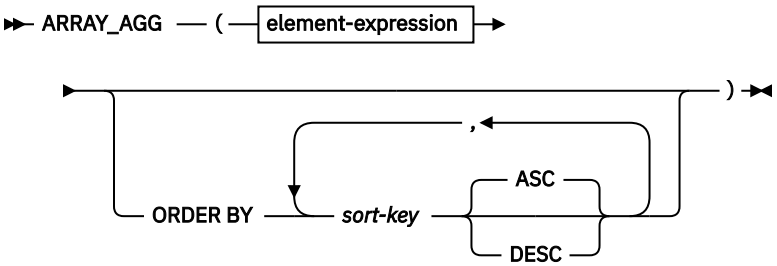
Aggregate functions can be qualified with a schema name (for example, SYSIBM.COUNT(*)).

ARRAY_AGG

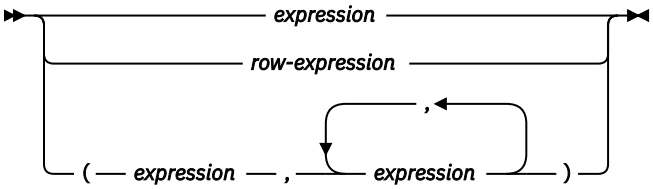
The ARRAY_AGG function aggregates a set of elements into an array.

Invocation of the ARRAY_AGG aggregate function is based on the result array type.

Ordinary array aggregation

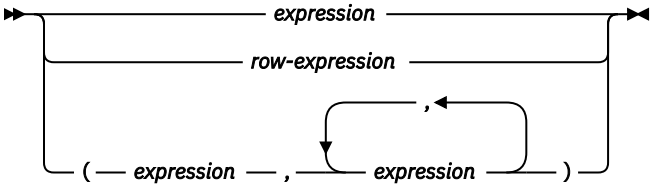


element-expression



Associative array aggregation

element-expression



The schema is SYSIBM.

Ordinary array aggregation

element-expression

Specifies the source for the elements of the array.

expression

An expression that specifies the element value for the array. The data type of the expression must be a data type that can be specified in a CREATE TYPE (array) statement (SQLSTATE 429C2).

row-expression

A row expression that specifies the value that has a row data type as the element of the array.

(*expression,expression...*)

A list of two or more expressions that specify the fields for a value that has a row data type as the element of the array. The data type of each expression must be a valid data type for a row field as described in CREATE TYPE (row) statement (SQLSTATE 429C5).

ORDER BY

Specifies the order of the rows from the same grouping set that are processed in the aggregation of an ordinary array. If the ORDER BY clause cannot distinguish the order of the column data, the rows in the same grouping set are arbitrarily ordered.

If ORDER BY is specified, it determines the order of the aggregated elements in the ordinary array. If ORDER BY is not specified and no other ARRAY_AGG, LISTAGG or XMLAGG is included in the same SELECT clause with ordering specified, the ordering of elements within the ordinary array is not deterministic. If ORDER BY is not specified and the same SELECT clause has multiple

occurrences of ARRAY_AGG, LISTAGG, or XMLAGG that specify ordering the same ordering of elements within the ordinary array is used for each result of ARRAY_AGG.

sort-key
The sort key can be a column name or a *sort-key-expression*. If the sort key is a constant, it does not refer to the position of the output column (as in the ORDER BY clause of a query), but it is simply a constant that implies no sort key.

ASC
Processes the *sort-key* in ascending order. This is the default option.

DESC
Processes the *sort-key* in descending order.

The result data type is an ordinary array. If the element values are specified using a single *expression* or *row-expression*, then the data type of the array element is the same as the type of the *expression* or *row-expression*. If the element values are specified with a list of expressions, then the array element is a row type with field types that correspond to the expressions.

If a SELECT clause includes an ARRAY_AGG function, then all invocations of ARRAY_AGG, LISTAGG, XMLAGG, and XMLGROUP functions in the same SELECT clause must specify the same order or not specify an order (SQLSTATE 428GZ).

Associative array aggregation

index-expression
Specifies the index of an associative array. When used in a context where there is a target user-defined array data type in the same statement or the result of the ARRAY_AGG is explicitly cast to a user-defined array data type, the data type of *index-expression* must be castable to the index data type of the target associative array data type. Otherwise, the data type of the *index-expression* must be a data type that can be specified for the index of an associative array in a CREATE TYPE (array) statement (SQLSTATE 429C2).

There cannot be any duplicate *index-expression* values in the grouping set that is processed to aggregate the associative array (SQLSTATE 22545).

element-expression
Specifies the source for the elements of the array.

expression
An expression that specifies the element value for the array. The data type of the expression must be a data type that can be specified in a CREATE TYPE (array) statement (SQLSTATE 429C2).

row-expression
A row expression that specifies the value that has a row data type as the element of the array.

(*expression,expression...*)
A list of two or more expressions that specify the fields for a value that has a row data type as the element of the array. The data type of each expression must be a valid data type for a row field as described in CREATE TYPE (row) statement (SQLSTATE 429C5).

The result data type is an associative array. If the ARRAY_AGG is used in a context where there is a target user-defined array data type in the same statement or the result of the ARRAY_AGG is explicitly cast to a user-defined array data type, the data type of the index matches the data type of the target associative array. If the element values are specified using a single *expression* or *row-expression*, then the data type of the array element is the same as the type of the expression or row-expression. If the element values are specified with a list of expressions, then the array element is a row type with field types that correspond to the expressions.

Notes

- The ARRAY_AGG function can only be specified within an SQL procedure, compiled SQL function, or compound SQL (compiled) statement the following specific contexts (SQLSTATE 42887):

  - The select-list of a SELECT INTO statement
  - The select-list of a fullselect in the definition of a cursor that is not scrollable
  - The select-list of a scalar subquery on the right side of a SET statement
- ARRAY_AGG cannot be used as part of an OLAP function (SQLSTATE 42887).
- The SELECT statement that uses ARRAY_AGG cannot contain an ORDER BY clause or a DISTINCT clause, and the SELECT clause or HAVING clause cannot contain a subquery or invoke an inlined SQL function that returns a subquery (SQLSTATE 42887).

Examples

- *Example 1:* Given the following DDL:

```
CREATE TYPE PHONELIST AS DECIMAL(10, 0)ARRAY[10]

CREATE TABLE EMPLOYEE (
  ID          INTEGER NOT NULL,
  PRIORITY    INTEGER NOT NULL,
  PHONENUMBER DECIMAL(10, 0),
  PRIMARY KEY(ID, PRIORITY))
```

  Create a procedure that uses a SELECT INTO statement to return the prioritized list of contact numbers under which an employee can be reached.

```
CREATE PROCEDURE GETPHONENUMBERS
  (IN  EMPID   INTEGER,
   OUT NUMBERS PHONELIST)
BEGIN
  SELECT ARRAY_AGG(PHONENUMBER ORDER BY PRIORITY)
    INTO NUMBERS
  FROM EMPLOYEE
  WHERE ID = EMPID;
END
```

  Create a procedure that uses a SET statement to return the list of contact numbers for an employee, in an arbitrary order.

```
CREATE PROCEDURE GETPHONENUMBERS
   (IN  EMPID   INTEGER,
    OUT NUMBERS PHONELIST)
 BEGIN
   SET NUMBERS =
     (SELECT ARRAY_AGG(PHONENUMBER)
     FROM EMPLOYEE
     WHERE ID = EMPID);
 END
```

- *Example 2:* Create a procedure that uses a SELECT INTO statement to aggregate priority 1 phone numbers into an associative array indexed by IDs from the EMPLOYEE table.

```
CREATE TYPE EMPPHONES AS DECIMAL(10,0) ARRAY[INTEGER]

CREATE PROCEDURE GETPHONES
(OUT EMPLOYEES EMPPHONES)
 BEGIN
  SELECT ARRAY_AGG(ID, PHONENUMBER)
  INTO EMPLOYEES
  FROM EMPLOYEE WHERE PRIORITY=1;
 END
```

- *Example 3:* Create a procedure that uses a SELECT INTO statement to aggregate the EMPLOYEE table into an array of row variable.

```
CREATE TYPE EMPROW AS ROW ANCHOR ROW EMPLOYEE

CREATE TYPE EMPARRAY AS EMPROW ARRAY[]

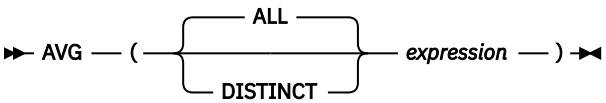
CREATE PROCEDURE GETEMPLOYEES
   (OUT EMPLOYEES EMPARRAY)
BEGIN
  SELECT ARRAY_AGG((ID, PRIORITY, PHONENUMBER) ORDER BY ID)
```

```
  INTO EMPLOYEES
  FROM EMPLOYEE;
END
```

AVG

The AVG function returns the average of a set of numbers.

Note: The result of the function can be affected by the enablement of the large_aggregation configuration parameter.



The schema is SYSIBM.

expression
An expression that returns a set of built-in numeric or Boolean values. The AVG function ignores any null values the input expression might contain.

ALL or DISTINCT
If ALL is specified, all values returned by the expression, including duplicate values, are used to calculate the average (this is the default). If DISTINCT is specified, duplicate values are ignored. Decimal floating-point values that are numerically equal are treated as duplicates even if they have different numbers of significant digits. For example, if the set of values returned by an expression includes the decimal floating-point numbers 123, 123.0, and 123.00, only one of these values is used to calculate the average.

Result

The data type of the result is the same as the data type of the input expression, with the following exceptions:

- If the data type of the input expression is SMALLINT, the data type of the result is INTEGER.
- If the data type of the input expression is BOOLEAN, the data type of the result is BIGINT. The result is 1 only if all values returned by the input expression are also 1; otherwise, the result is 0.
- If the data type of the input expression is single-precision floating point (REAL), the data type of the result is double-precision floating point (DOUBLE).
- If the data type of the input expression is DECFLOAT(*n*), the data type of the result is DECFLOAT(34).
- If the input expression is a DECIMAL value with precision *p* and scale *s*, the result is a DECIMAL with precision and scale as follows:

Table 51. Result precision and scale of the AVG aggregate function with DECIMAL input

DECIMAL arithmetic mode [1]	***p***	**Result precision**	**Result scale**
default	n/a	31	31-p+s
DEC15	<=15	15	15-p+s
DEC15	>15	31	MAX(0,28-p+s)
DEC31	n/a	31	MAX(0,28-p+s)

Note:

1. These modes are determined by the **dec_arithmetic** configuration parameter.

If the data type of the result is SMALLINT, INTEGER, or BIGINT, the fractional part of the average is truncated. It is not rounded up.

During evaluation, the order in which the input values are added together is undefined, but every intermediate result must be within the range of the data type of the result.

The result can be null. If the function is applied to an empty set, the result is a null value; otherwise, the result is the average value of the set.

Examples

- *Example 1*: Using the PROJECT table, set the host variable AVERAGE (decimal(5,2)) to the average staffing level (PRSTAFF) of projects in department (DEPTNO) 'D11'.

```
SELECT AVG(PRSTAFF)
  INTO :AVERAGE
  FROM PROJECT
  WHERE DEPTNO = 'D11'
```

  Results in AVERAGE being set to 4.25 (that is 17/4) when using the sample table.

- *Example 2*: Using the PROJECT table, set the host variable ANY_CALC (decimal(5,2)) to the average of each unique staffing level value (PRSTAFF) of projects in department (DEPTNO) 'D11'.

```
SELECT AVG(DISTINCT PRSTAFF)
  INTO :ANY_CALC
  FROM PROJECT
  WHERE DEPTNO = 'D11'
```

  Results in ANY_CALC being set to 4.66 (that is 14/3) when using the sample table.

CORRELATION

The CORRELATION function returns the coefficient of correlation of a set of number pairs.

The schema is SYSIBM.

expression1
An expression that returns a value of any built-in numeric data type.

expression2
An expression that returns a value of any built-in numeric data type.

If either argument is decimal floating-point, the result is DECFLOAT(34); otherwise, the result is a double-precision floating-point number. The result can be null. When not null, the result is between -1 and 1.

The function is applied to the set of (*expression1*, *expression2*) pairs derived from the argument values by the elimination of all pairs for which either *expression1* or *expression2* is null.

If the function is applied to an empty set, or if either STDDEV(*expression1*) or STDDEV(*expression2*) is equal to zero, the result is a null value. Otherwise, the result is the correlation coefficient for the value pairs in the set. The result is equivalent to the following expression:

```
COVARIANCE(expression1,expression2)/
(STDDEV(expression1)*
STDDEV(expression2))
```

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

CORR can be specified in place of CORRELATION.

Example

Using the EMPLOYEE table, set the host variable CORRLN (double-precision floating point) to the correlation between salary and bonus for those employees in department (WORKDEPT) 'A00'.

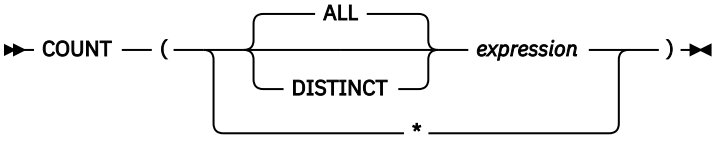
```
SELECT CORRELATION(SALARY, BONUS)
  INTO :CORRLN
  FROM EMPLOYEE
  WHERE WORKDEPT = 'A00'
```

CORRLN is set to approximately 9.99853953399538E-001 when using the sample table.

COUNT

The COUNT function returns the number of rows or values in a set of rows or values.

Note: The result of the function can be affected by the enablement of the large_aggregation configuration parameter.



The schema is SYSIBM.

expression

If ALL is implied or specified, an expression that returns a value of any built-in data type. If DISTINCT is specified, an expression that returns a value of any built-in data type except BLOB, CLOB, DBCLOB, or XML.

The result of the function is a large integer. The result cannot be null.

The argument of COUNT(*) is a set of rows. The result is the number of rows in the set. A row that includes only null values is included in the count.

The argument of COUNT(DISTINCT *expression*) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null and duplicate values. The result is the number of different non-null values in the set.

The argument of COUNT(*expression*) or COUNT(ALL *expression*) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values. The result is the number of non-null values in the set, including duplicates.

Examples

- *Example 1*: Using the EMPLOYEE table, set the host variable FEMALE (int) to the number of rows where the value of the SEX column is 'F'.

  ```
  SELECT COUNT(*)
    INTO :FEMALE
    FROM EMPLOYEE
    WHERE SEX = 'F'
  ```

  Results in FEMALE being set to 13 when using the sample table.

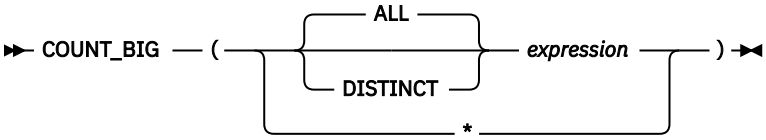
- *Example 2*: Using the EMPLOYEE table, set the host variable FEMALE_IN_DEPT (int) to the number of departments (WORKDEPT) that have at least one female as a member.

  ```
  SELECT COUNT(DISTINCT WORKDEPT)
    INTO :FEMALE_IN_DEPT
    FROM EMPLOYEE
    WHERE SEX = 'F'
  ```

  Results in FEMALE_IN_DEPT being set to 5 when using the sample table. (There is at least one female in departments A00, C01, D11, D21, and E11.)

COUNT_BIG

The COUNT_BIG function returns the number of rows or values in a set of rows or values. It is similar to COUNT except that the result can be greater than the maximum value of integer.



The schema is SYSIBM.

expression

If ALL is implied or specified, an expression that returns a value of any built-in data type. If DISTINCT is specified, an expression that returns a value of any built-in data type except BLOB, CLOB, DBCLOB, or XML.

The result of the function is a decimal with precision 31 and scale 0. The result cannot be null.

The argument of COUNT_BIG(*) is a set of rows. The result is the number of rows in the set. A row that includes only null values is included in the count.

The argument of COUNT_BIG(DISTINCT *expression*) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null and duplicate values. The result is the number of different non-null values in the set.

The argument of COUNT_BIG(*expression*) or COUNT_BIG(ALL *expression*) is a set of values. The function is applied to the set of values derived from the argument values by the elimination of null values. The result is the number of non-null values in the set, including duplicates.

Examples

- *Example 1*: Refer to COUNT examples and substitute COUNT_BIG for occurrences of COUNT. The results are the same except for the data type of the result.
- *Example 2*: Some applications may require the use of COUNT but need to support values larger than the largest integer. This can be achieved by use of sourced user-defined functions and setting the SQL path. The following series of statements shows how to create a sourced function to support COUNT(*) based on COUNT_BIG and returning a decimal value with a precision of 15. The SQL path is set such that the sourced function based on COUNT_BIG is used in subsequent statements such as the query shown.

```
CREATE FUNCTION RICK.COUNT() RETURNS DECIMAL(15,0)
  SOURCE SYSIBM.COUNT_BIG();
SET CURRENT PATH RICK, SYSTEM PATH;
SELECT COUNT(*) FROM EMPLOYEE;
```

Note how the sourced function is defined with no parameters to support COUNT(*). This only works if you name the function COUNT and do not qualify the function with the schema name when it is used. To get the same effect as COUNT(*) with a name other than COUNT, invoke the function with no parameters. Thus, if RICK.COUNT had been defined as RICK.MYCOUNT instead, the query would have to be written as follows:

```
SELECT MYCOUNT() FROM EMPLOYEE;
```

If the count is taken on a specific column, the sourced function must specify the type of the column. The following statements created a sourced function that will take any CHAR column as a argument and use COUNT_BIG to perform the counting.

```
CREATE FUNCTION RICK.COUNT(CHAR()) RETURNS DOUBLE
  SOURCE SYSIBM.COUNT_BIG(CHAR());
SELECT COUNT(DISTINCT WORKDEPT) FROM EMPLOYEE;
```

COVARIANCE

The COVARIANCE function returns the (population) covariance of a set of number pairs.

The schema is SYSIBM.

expression1
An expression that returns a value of any built-in numeric data type.

expression2
An expression that returns a value of any built-in numeric data type.

If either argument is decimal floating-point, the result is DECFLOAT(34); otherwise, the result is a double-precision floating-point number. The result can be null.

The function is applied to the set of (*expression1*,*expression2*) pairs derived from the argument values by the elimination of all pairs for which either *expression1* or *expression2* is null.

If the function is applied to an empty set, the result is a null value. Otherwise, the result is the covariance of the value pairs in the set.

The calculation that is used to determine the biased covariance is logically equivalent to the following formula:

```
COVARIANCE = SUM(
   ( expression1 - AVG(expression1) ) *
   ( expression2 - AVG(expression2) ) ) / COUNT(expression1)
```

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

COVAR or COVAR_POP can be specified in place of COVARIANCE.

Example

Set the host variable COVARNCE to the covariance between salary and bonus for those employees in department 'A00' in the EMPLOYEE table. The data type of the host variable COVARNCE is double-precision floating point.

```
   SELECT COVARIANCE(SALARY, BONUS)
     INTO :COVARNCE
     FROM EMPLOYEE
     WHERE WORKDEPT = 'A00'
```

COVARNCE is set to approximately 1.68888888888889E+006 when using the sample table.

The following result set is shown for reference.

```
SELECT SALARY, BONUS FROM EMPLOYEE WHERE WORKDEPT = 'A00'
```

```
SALARY      BONUS
----------- -----------
  152750.00     1000.00
   66500.00      900.00
   49250.00      600.00
   46500.00     1000.00
   39250.00      600.00

5 record(s) selected.
```

COVARIANCE_SAMP

The COVARIANCE_SAMP function returns the sample covariance of a set of number pairs.

The schema is SYSIBM.

expression1
An expression that returns a value of any built-in numeric data type.

expression2
An expression that returns a value of any built-in numeric data type.

If either argument is decimal floating-point, the result is DECFLOAT(34); otherwise, the result is a double-precision floating-point number. The result can be null.

The function is applied to the set of (*expression1*, *expression2*) pairs that are derived from the argument values by the elimination of all pairs for which either *expression1* or *expression2* is null.

If the function is applied to an empty set or a set with only one row, the result is a null value. Otherwise, the result is the sample covariance of the value pairs in the set.

The calculation that is used to determine the sample covariance is logically equivalent to the following formula:

```
COVARIANCE_SAMP = SUM(
   ( expression1 - AVG(expression1) ) *
   ( expression2 - AVG(expression2) ) ) / ( COUNT(expression1) – 1 )
```

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

COVAR_SAMP can be specified in place of COVARIANCE_SAMP.

Example

Set the host variable COVARNCE to the sample covariance between the salary and bonus for those employees in department 'A00' of the EMPLOYEE table. The data type of the host variable COVARNCE is double-precision floating point.

```
   SELECT COVARIANCE_SAMP(SALARY, BONUS)
     INTO :COVARNCE
     FROM EMPLOYEE
     WHERE WORKDEPT = 'A00'
```

COVARNCE is set to approximately +5.42875000000000E+006 when the sample table is used.

The following result set is shown for reference.

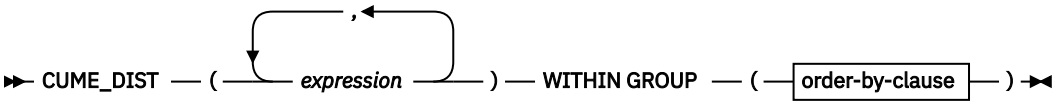
```
SELECT SALARY, BONUS FROM EMPLOYEE WHERE WORKDEPT = 'A00'
```

```
SALARY      BONUS
----------- -----------
  152750.00     1000.00
   66500.00      900.00
   49250.00      600.00
   46500.00     1000.00
   39250.00      600.00

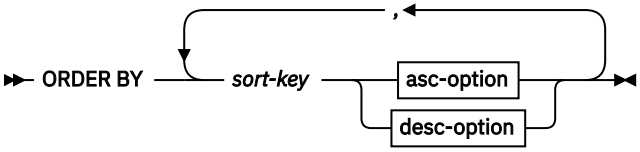
5 record(s) selected.
```

CUME_DIST

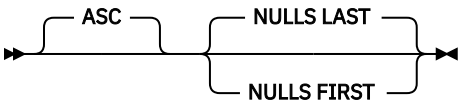
The CUME_DIST function returns the cumulative distribution of a row that is hypothetically inserted into a group of rows.



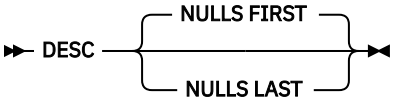
order-by-clause



asc-option



desc-option



The schema is SYSIBM.

expression
An expression that specifies a row that is hypothetically inserted into a group of rows. The expression must return a value that is a built-in data type. The expression must be a constant, a variable, or a cast of a constant or variable (SQLSTATE 428I9).

WITHIN GROUP
Indicates that the aggregation follows the specified ordering within the grouping set.

order-by-clause

ORDER BY
Specifies the order of the rows from the same grouping set that are processed in the aggregation.

sort-key
The sort key can be a column name or a sort-key-expression. If the sort key is a constant, it does not refer to the position of the output column (as in the ordinary ORDER BY clause), but it is a constant, which implies no sort key.

ASC
Uses the values of the *sort-key* in ascending order.

DESC
Uses the values of the *sort-key* in descending order.

NULLS FIRST
The ordering considers null values before all non-null values in the sort order.

NULLS LAST
The ordering considers null values after all non-null values in the sort order.

The number of expressions must be the same as the number of sort-key expressions (SQLSTATE 42822). The data type of each expression and the data type of the corresponding sort-key expression must be compatible (SQLSTATE 42822).

The data type of the result is DECFLOAT(34). The actual result is greater than 0.0 and less than or equal to 1.0.

Example

Set the host variable CD to the cumulative distribution of a hypothetical new employee's salary of 47000 within the salaries of the employees in department 'A00'.

```
SELECT CUME_DIST(47000) WITHIN GROUP (ORDER BY SALARY)
   INTO :CD FROM EMPLOYEE WHERE WORKDEPT = 'A00'
```

GROUPING

Used in conjunction with grouping-sets and super-groups, the GROUPING function returns a value that indicates whether or not a row returned in a GROUP BY answer set is a row generated by a grouping set that excludes the column represented by *expression*.

The schema is SYSIBM.

expression

An expression that matches a *grouping-expression* from the GROUP BY clause of the same subselect.

The result of the function is a small integer. It is set to one of the following values:

1
The value of *expression* in the returned row is a null value, and the row was generated by the super-group. This generated row can be used to provide sub-total values for the GROUP BY expression.

0
The value is other than the previously listed value.

Example

The following query:

```
SELECT SALES_DATE, SALES_PERSON,
    SUM(SALES) AS UNITS_SOLD,
    GROUPING(SALES_DATE) AS DATE_GROUP,
    GROUPING(SALES_PERSON) AS SALES_GROUP
  FROM SALES
  GROUP BY CUBE (SALES_DATE, SALES_PERSON)
  ORDER BY SALES_DATE, SALES_PERSON
```

results in:

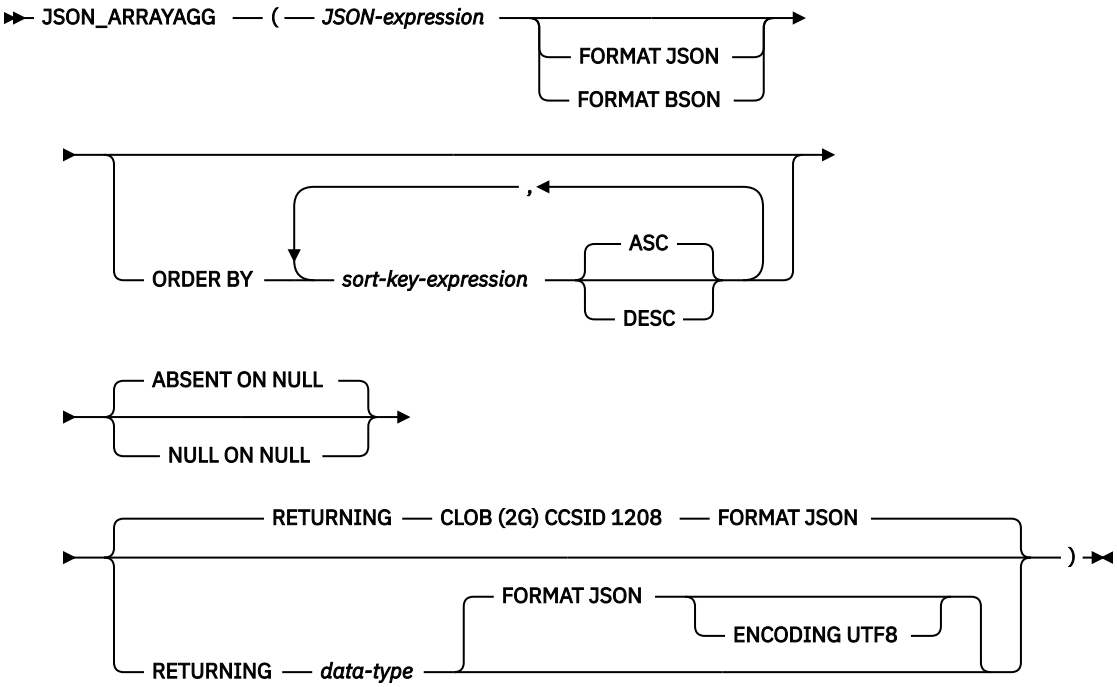
```
SALES_DATE SALES_PERSON    UNITS_SOLD  DATE_GROUP  SALES_GROUP
---------- --------------- ----------- ----------- -----------
12/31/1995 GOUNOT                    1           0           0
12/31/1995 LEE                       6           0           0
12/31/1995 LUCCHESSI                 1           0           0
12/31/1995 -                         8           0           1
03/29/1996 GOUNOT                   11           0           0
03/29/1996 LEE                      12           0           0
03/29/1996 LUCCHESSI                 4           0           0
03/29/1996 -                        27           0           1
03/30/1996 GOUNOT                   21           0           0
03/30/1996 LEE                      21           0           0
03/30/1996 LUCCHESSI                 4           0           0
03/30/1996 -                        46           0           1
03/31/1996 GOUNOT                    3           0           0
03/31/1996 LEE                      27           0           0
03/31/1996 LUCCHESSI                 1           0           0
03/31/1996 -                        31           0           1
04/01/1996 GOUNOT                   14           0           0
04/01/1996 LEE                      25           0           0
04/01/1996 LUCCHESSI                 4           0           0
04/01/1996 -                        43           0           1
-          GOUNOT                   50           1           0
-          LEE                      91           1           0
```

```
-           LUCCHESSI                14           1           0
-           -                       155           1           1
```

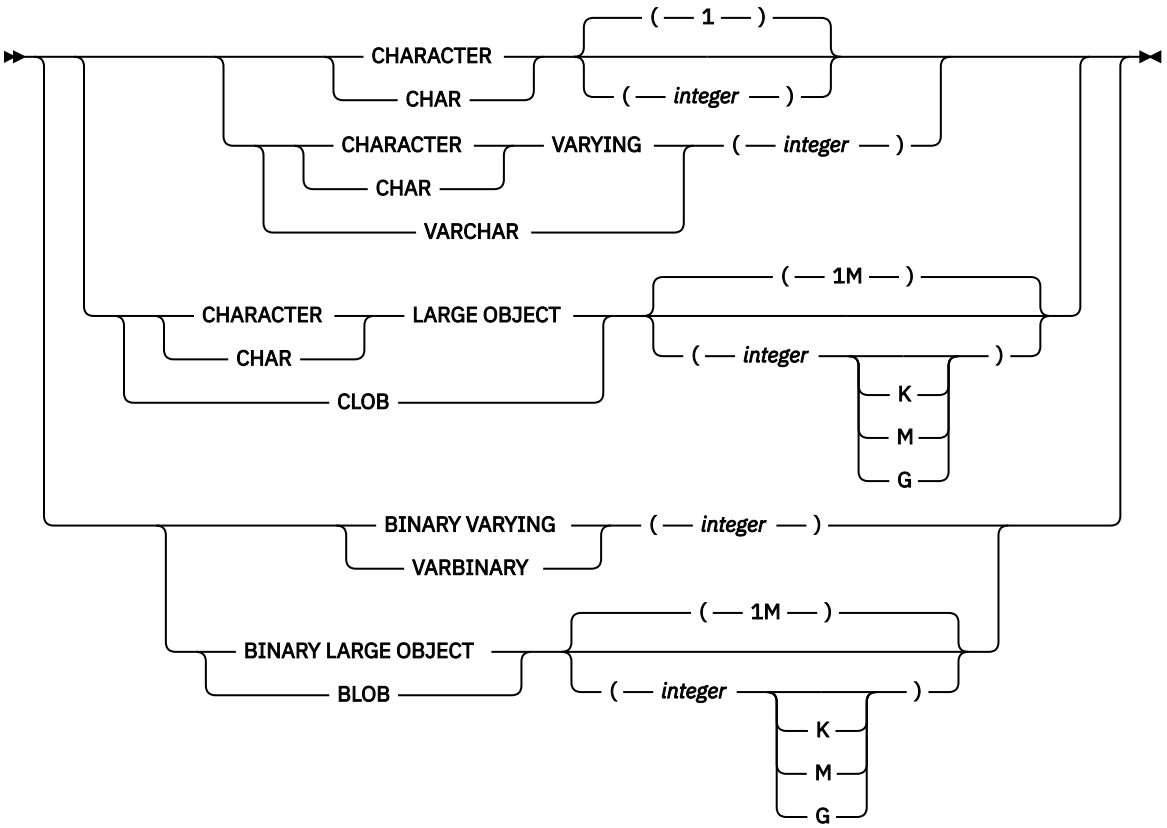
An application can recognize a SALES_DATE sub-total row by the fact that the value of DATE_GROUP is 0 and the value of SALES_GROUP is 1. A SALES_PERSON sub-total row can be recognized by the fact that the value of DATE_GROUP is 1 and the value of SALES_GROUP is 0. A grand total row can be recognized by the value 1 for both DATE_GROUP and SALES_GROUP.

JSON_ARRAYAGG

The JSON_ARRAYAGG function returns a JSON array that contains an array element for each value in a set of JSON or SQL values.



data-type



Note: The schema is SYSIBM. The function name cannot be specified as a qualified name.

JSON-expression

The expression to use to generate a value in the JSON array. The result type of this expression can be any built-in data type. It cannot be CHAR or VARCHAR bit data. It cannot be a user-defined type that is sourced on any of these data types.

FORMAT JSON or FORMAT BSON

Specifies whether the JSON expression is already formatted data.

FORMAT JSON

The JSON expression is formatted as JSON data. If the JSON expression is a character or graphic string data type, it is treated as JSON data. If the JSON expression is a binary string data type, it is interpreted as UTF-8 data.

FORMAT BSON

The JSON expression is formatted as the BSON representation of JSON data and must be a binary string data type.

If either the FORMAT JSON or FORMAT BSON properties are omitted from the statement, the format of the JSON expression is determined in the following ways:

- By the explicit or implicit FORMAT value of the JSON expression. This method applies when the JSON expression is one of the following built-in functions:
  - JSON_ARRAY
  - JSON_OBJECT
  - JSON_QUERY
  - JSON_ARRAYAGG
  - JSON_OBJECTAGG
- As FORMAT BSON when the JSON expression is a binary string type.

- As unformatted data in all other situations. If the generated value is not numeric, the result string is constructed with strings that are enclosed in quotation marks, and escape sequences for any special characters. A numeric value that is not a valid JSON number, such as INFINITY or NAN, results in an error.

ORDER BY
Specifies the order of the rows from the same grouping set that is processed in the aggregation. Rows in the same grouping are arbitrarily ordered when the ORDER BY clause is not specified, or if the ORDER BY clause cannot differentiate the order of the sort key value.

sort-key-expression
Specifies a sort key value that is either a column name or an expression. The data type of the column or expression must not be a DATALINK or XML value.

ASC
Processes the sort key expression in ascending order. This setting is the default.

DESC
Processes the sort key expression in descending order.

The ordering is based on the values of the sort keys, which might or might not be used in the JSON expression.

When you are running a statement that contains the JSON_ARRAYAGG function, weighted values are sometimes used to return the result. These values are used under the following circumstances:

- When a collating sequence other than *HEX is in effect.
- When the sort-key-expressions contain SBCS data, mixed data, or Unicode data.

The weighted values are derived by applying the collating sequence to the sort key expressions.

ABSENT ON NULL or NULL ON NULL
Specifies what to return when an array element that is produced by the JSON expression is the null value.

ABSENT ON NULL
A null array element is not included in the JSON array. This setting is the default.

NULL ON NULL
A null array element is included in the JSON array.

RETURNING *data-type*
Specifies the format of the result.

data-type
The data type of the result. The default data type is Character Large Object [CLOB (2G)]

FORMAT JSON
JSON data is returned as a JSON string.

ENCODING UTF8
The encoding to use when *data-type* is a binary string type. This clause is only allowed for binary string types. The result can be null. If the set of values is empty, the result is the null value.

The result can be null. If the set of values is empty, the result is the null value.

Notes

The JSON_ARRAYAGG aggregate function cannot be used as part of an OLAP specification.

Example

- The following example shows the command syntax for returning a JSON array containing all the department numbers.

```
SELECT JSON_ARRAYAGG(deptno) AS deptlist FROM dept;
```

The result is the following JSON array.

```
DEPT_NAME
-----------------------------
["sales","Procurment","finance","Eng","Design","Labour"]

1 record(s) selected.
```

- The following example shows the command syntax for returning a JSON array for each department that contains a list of employees that are assigned to that department.

```
SELECT deptno, JSON_ARRAYAGG(id) AS employe_id from employe group by deptno
```

The result is the following two rows.

```
DEPTN  EMPLOYE_ID
---------- ---------------------------------------
       102 [102001,102002,102003,102004]
       103 [103001,103002,103003,103004]
      2 record(s) selected.
```

- The following example shows the command syntax for returning a JSON array for each department number and its corresponding department name.

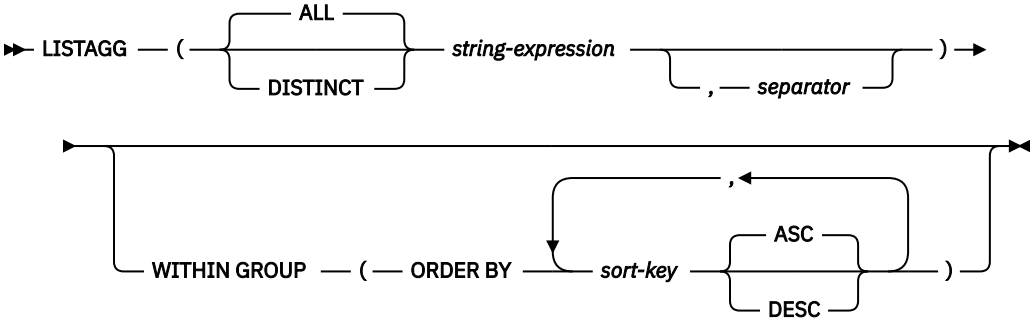
```
SELECT num as dept_num, JSON_ARRAYAGG (deptname) as dept_name FROM dept group by num
```

The result is the following JSON array.

```
DEPT_NUM    DEPT_NAME
----------- ---------------------------------------
        101 ["sales"]
        102 ["Procurment"]
        103 ["finance"]
        104 ["Eng"]
        105 ["Design"]
        106 ["Labour"]
6 record(s) selected.
```

LISTAGG

The LISTAGG function aggregates a set of string elements into one string by concatenating the strings. Optionally, a separator string can be provided which is inserted between contiguous input strings.



The schema is SYSIBM.

The LISTAGG function aggregates a set of string values for the group into one string by appending the *string-expression* values based on the order specified in the WITHIN GROUP clause.

The function is applied to the set of values that are derived from the first argument by the elimination of null values. If DISTINCT is specified, duplicate *string-expression* values are eliminated. If a *separator* argument is specified that is not the null value, the value is inserted between each pair of non-null *string-expression* values.

string-expression
An expression that specifies the string values to be aggregated. The expression must return a built-in character string, graphic string, binary string, numeric value, Boolean value, or datetime value:

- If the value is not a character, graphic, or, binary string, or if it is a CLOB, it is implicitly cast to VARCHAR before the function is evaluated.
- If the value is a DBCLOB, it is implicitly cast to VARGRAPHIC before the function is evaluated.
- The value cannot be a BLOB (SQLSTATE 42815).

separator
A constant expression that defines the separation string that is used between non-null *string-expression* values. The expression must return a value that is a built-in string, numeric, or datetime data type. If the value is not a string data type, it is implicitly cast to VARCHAR before the function is evaluated. CLOB and DBCLOB are supported through implicit casting. If the value is a CLOB, it is implicitly cast to VARCHAR before the function is evaluated. If the value is a DBCLOB, it is implicitly cast to VARGRAPHIC before the function is evaluated. The data type of *separator* cannot be a BLOB (SQLSTATE 42815).

The separator can be a constant, special register, variable, or an expression based on constants, special registers, or variables, provided that the expression does not include a non-deterministic function or a function that takes external action.

WITHIN GROUP
Indicates that the aggregation will follow the specified ordering within the grouping set.

If WITHIN GROUP is not specified and no other LISTAGG, ARRAY_AGG, or XMLAGG is included in the same SELECT clause with ordering specified, the ordering of strings within the result is not deterministic. If WITHIN GROUP is not specified, and the same SELECT clause has multiple occurrences of XMLAGG, ARRAY_AGG, or LISTAGG that specify ordering, the same ordering is used for the result of the LISTAGG function invocation.

ORDER BY
Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause cannot distinguish the order of the column data, the rows in the same grouping set are arbitrarily ordered.

sort-key
The sort key can be a column name or a *sort-key-expression*. If the sort key is a constant, it does not refer to the position of the output column (as in the ORDER BY clause of a query); it is a constant, which implies no sort key.

ASC
Processes the *sort-key* in ascending order. This is the default option.

DESC
Processes the *sort-key* in descending order.

Result

The result data type of LISTAGG is based on the data type of *string-expression*:

Table 52. Determining the result data type and length

Data type of *string-expression*	**Result data type and length**
CHAR(*n*) or VARCHAR(*n*)	VARCHAR(MAX(4000, *n*))
GRAPHIC(*n*) or VARGRAPHIC(*n*)	VARGRAPHIC(MAX(2000, *n*))
BINARY(*n*) or VARBINARY(*n*)	VARBINARY(MAX(4000, *n*))

The string unit of the result data type is the same as the string units of the data type of *string-expression*.

The result data type can exceed VARCHAR(4000), VARBINARY(4000), or VARGRAPHIC(2000) if a derived size is used to determine the size of the result, to a maximum for the result data type. The following example successfully yields a return data type of VARCHAR(10000):

```
LISTAGG(CAST(NAME AS VARCHAR(10000)), ',')
```

If the actual length of the aggregated result string exceeds the maximum for the result data type, an error is returned (SQLSTATE 22001).

The result can be null. If the function is applied to an empty set or all of the *string-expression* values in the set are null values, the result is a null value.

Rules

- If DISTINCT is specified for LISTAGG, the *sort-key* of the ORDER BY specification must match *string-expression* (SQLSTATE 42822). If *string-expression* is implicitly cast, the *sort-key* must explicitly include a corresponding matching cast specification.
- If a SELECT clause includes an ARRAY_AGG function, then all invocations of ARRAY_AGG, LISTAGG, XMLAGG, and XMLGROUP functions in the same SELECT clause must meet one of the following criteria (SQLSTATE 428GZ):
  - Specify the same order
  - Not specify an order
  - Have the *string-expression* argument of a LISTAGG with DISTINCT match the *sort-key* expression of the ORDER BY clause in ARRAY_AGG
- LISTAGG cannot be used as part of an OLAP specification (SQLSTATE 42887).

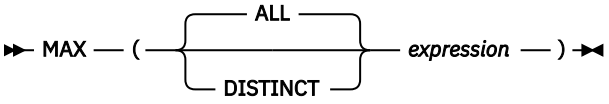
Example

Produce an alphabetical list of comma-separated names, grouped by department.

```
SELECT workdept,
      LISTAGG(lastname, ', ') WITHIN GROUP(ORDER BY lastname)
      AS employees
   FROM emp
   GROUP BY workdept
```

MAX

The MAX function returns the maximum value in a set of values.



The schema is SYSIBM.

expression
An expression that returns a value of any built-in data type other than BLOB, CLOB, DBCLOB, ROWID, or XML.

The data type, length and code page of the result are the same as the data type, length and code page of the argument values. The result is considered to be a derived value and can be null.

The function is applied to the set of values derived from the argument values by the elimination of null values.

If the function is applied to an empty set, the result is a null value. Otherwise, the result is the maximum value in the set.

The specification of DISTINCT has no effect on the result and therefore is not recommended. It is included for compatibility with other relational systems.

Notes

- ***Results involving DECFLOAT special values:*** If the data type of the argument is decimal floating-point and positive or negative infinity, sNaN, or NaN is found, the maximum value is determined using decimal floating-point ordering rules. If multiple representations of the same decimal floating-point value are found (for example, 2.00 and 2.0), it is unpredictable which representation will be returned.

Examples

- *Example 1*: Using the EMPLOYEE table, set the host variable MAX_SALARY (decimal(7,2)) to the maximum monthly salary (SALARY/12) value.

```
SELECT MAX(SALARY) / 12
  INTO :MAX_SALARY
  FROM EMPLOYEE
```

  Results in MAX_SALARY being set to 4395.83 when using the sample table.

- *Example 2*: Using the PROJECT table, set the host variable LAST_PROJ(char(24)) to the project name (PROJNAME) that comes last in the collating sequence.

```
SELECT MAX(PROJNAME)
  INTO :LAST_PROJ
  FROM PROJECT
```

  Results in LAST_PROJ being set to "WELD LINE PLANNING" when using the sample table.

- *Example 3*: Similar to the previous example, set the host variable LAST_PROJ (char(40)) to the project name that comes last in the collating sequence when a project name is concatenated with the host variable PROJSUPP. PROJSUPP is "_Support"; it has a char(8) data type.

```
SELECT MAX(PROJNAME CONCAT PROJSUPP)
  INTO :LAST_PROJ
  FROM PROJECT
```

  Results in LAST_PROJ being set to "WELD LINE PLANNING_SUPPORT" when using the sample table.

MEDIAN

The MEDIAN function returns the median value in a set of values.

The schema is SYSIBM.

expression
An expression that specifies the set of values from which the median is determined. The expression must return a value that is a built-in numeric data type, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported through implicit casting. If the expression is not a numeric data type, it is cast to DECFLOAT(34) before the function is evaluated.

If the data type of *expression* is DECFLOAT(*n*), the data type of the result is DECFLOAT(34). Otherwise, the data type of the result is DOUBLE.

The function is applied to the set of values that are derived from the argument values by the elimination of null values.

The result can be null. If *expression* is null or if the function is applied to an empty set, the result is a null value.

The MEDIAN function is a synonym for the following expression:

```
PERCENTILE_CONT( 0.5 ) WITHIN GROUP( ORDER BY expression )
```

Example

Set the host variable MED to the value that corresponds to the median of the salaries of the employees in department 'E21'.

```
   SELECT MEDIAN(SALARY) INTO :MED FROM EMPLOYEE WHERE WORKDEPT = 'E21'
```

MED is set to a value of 41895.00.

The following result set is shown for reference.

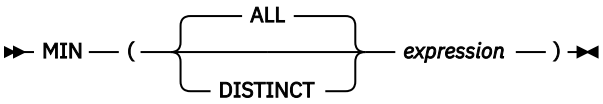
```
   SELECT SALARY FROM EMPLOYEE WHERE WORKDEPT = 'E21' ORDER BY SALARY
```

```
SALARY
-----------
   31840.00
   35370.00
   39950.00
   43840.00
   45370.00
   86150.00

  6 record(s) selected.
```

MIN

The MIN function returns the minimum value in a set of values.



expression
An expression that returns a value of any built-in data type other than a BLOB, CLOB, DBCLOB, or XML.

The data type, length, and code page of the result are the same as the data type, length, and code page of the argument values. The result is considered to be a derived value and can be null.

The function is applied to the set of values derived from the argument values by the elimination of null values.

If this function is applied to an empty set, the result of the function is a null value. Otherwise, the result is the minimum value in the set.

The specification of DISTINCT has no effect on the result and therefore is not recommended. It is included for compatibility with other relational systems.

Notes

- ***Results involving DECFLOAT special values:*** If the data type of the argument is decimal floating-point and positive or negative infinity, sNaN, or NaN is found, the minimum value is determined using decimal floating-point ordering rules. If multiple representations of the same decimal floating-point value are found (for example, 2.00 and 2.0), it is unpredictable which representation will be returned.

Examples

- *Example 1*: Using the EMPLOYEE table, set the host variable COMM_SPREAD (decimal(7,2)) to the difference between the maximum and minimum commission (COMM) for the members of department (WORKDEPT) 'D11'.

```
SELECT MAX(COMM) - MIN(COMM)
  INTO :COMM_SPREAD
  FROM EMPLOYEE
  WHERE WORKDEPT = 'D11'
```

  Results in COMM_SPREAD being set to 1118 (that is, 2580 - 1462) when using the sample table.

- *Example 2*: Using the PROJECT table, set the host variable (FIRST_FINISHED (char(10)) to the estimated ending date (PRENDATE) of the first project scheduled to be completed.

```
SELECT MIN(PRENDATE)
  INTO :FIRST_FINISHED
  FROM PROJECT
```

  Results in FIRST_FINISHED being set to '1982-09-15' when using the sample table.

PERCENTILE_CONT

The PERCENTILE_CONT function returns the value that corresponds to the specified percentile given a sort specification by using a continuous distribution model.

The schema is SYSIBM.

percentile
An expression that specifies the percentile. The expression must return a value that is a built-in numeric data type, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported through implicit casting. If the expression is not a numeric data type, it is cast to DECFLOAT(34) before the function is evaluated. The expression must be a constant, a variable, or a cast of a constant or variable (SQLSTATE 428I9). The value must be 0 - 1 (SQLSTATE 22003).

WITHIN GROUP
Indicates that the aggregation follows the specified ordering within the grouping set.

ORDER BY
Specifies the order of the rows from the same grouping set that are processed in the aggregation.

sort-key
The sort key must be a column name or an expression that contains a column reference. *sort-key* must be a built-in numeric data type (SQLSTATE 42822). If the single column result set specified by *sort-key* contains one or more NULL values, they are not considered and a warning is returned (SQLSTATE 01003).

ASC
Processes the *sort-key* in ascending order.

DESC
Processes the *sort-key* in descending order.

If the data type of *sort-key* is DECFLOAT(*n*), the data type of the result is DECFLOAT(34). Otherwise, the data type of the result is DOUBLE.

The result can be null. If *percentile* is null or the single column result set specified by *sort-key* is empty, the result is NULL.

When used in an OLAP specification, only the *window-partition-clause* can be specified.

Example

Set the host variable PC to the value that corresponds to the 75th percentile of the salaries of the employees in department 'E21' using a continuous distribution model.

```
SELECT PERCENTILE_CONT(0.75) WITHIN GROUP (ORDER BY SALARY)
   INTO :PC FROM EMPLOYEE
   WHERE WORKDEPT = 'E21'
```

PC is set to a value of 44987.50.

The following result set is shown for reference:

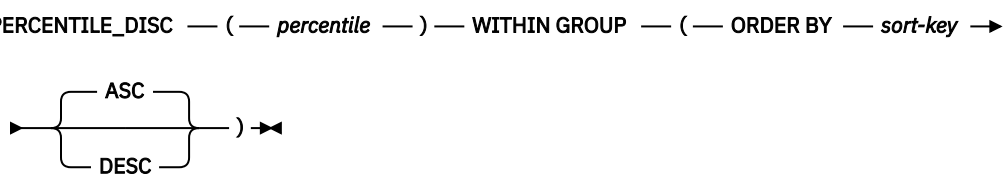
```
SELECT SALARY FROM EMPLOYEE WHERE WORKDEPT = 'E21'
   ORDER BY SALARY

SALARY
-----------
   31840.00
   35370.00
   39950.00
   43840.00
   45370.00
   86150.00

  6 record(s) selected.
```

PERCENTILE_DISC

The PERCENTILE_DISC function returns the value that corresponds to the specified percentile given a sort specification by using a discrete distribution model.



The schema is SYSIBM.

percentile
An expression that specifies the percentile. The expression must return a value that is a built-in numeric data type, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the expression is not a numeric data type, it is cast to DECFLOAT(34) before the function is evaluated. The expression must be a constant, a variable, or a cast of a constant or variable (SQLSTATE 428I9). The value must be 0 - 1 (SQLSTATE 22003).

WITHIN GROUP
Indicates that the aggregation follows the specified ordering within the grouping set.

ORDER BY
Specifies the order of the rows from the same grouping set that are processed in the aggregation.

sort-key
The sort key must be a column name or an expression that contains a column reference. *sort-key* must be a built-in numeric data type (SQLSTATE 42822). If the single column result set specified by *sort-key* contains one or more NULL values, they are not considered and a warning is returned (SQLSTATE 01003).

ASC
Processes the *sort-key* in ascending order.

DESC
Processes the *sort-key* in descending order.

The data type of the result is the same as the data type of *sort-key*.

The result can be null. If *percentile* is null or the single column result set specified by *sort-key* is empty, the result is NULL.

When used in an OLAP specification, only the *window-partition-clause* can be specified.

Example

Set the host variable PD to the value that corresponds to the 75th percentile of the salaries of the employees in department 'E21' using a discrete distribution model.

```
   SELECT PERCENTILE_DISC(0.75) WITHIN GROUP (ORDER BY SALARY)
      INTO :PD FROM EMPLOYEE WHERE WORKDEPT = 'E21'
```

PD is set to a value of 45370.00.

The following result set is shown for reference.

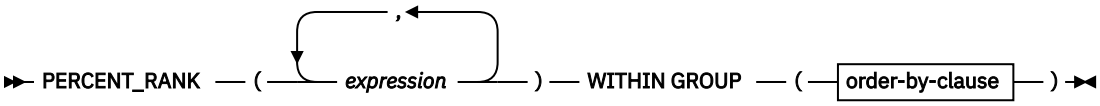
```
   SELECT SALARY FROM EMPLOYEE WHERE WORKDEPT = 'E21' ORDER BY SALARY

SALARY
-----------
   31840.00
   35370.00
   39950.00
   43840.00
   45370.00
   86150.00

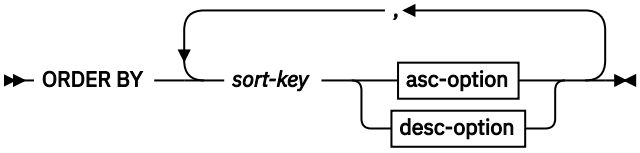
  6 record(s) selected.
```

PERCENT_RANK

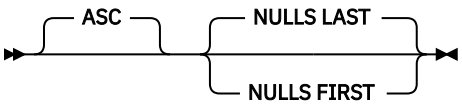
The PERCENT_RANK function returns the relative percentile rank of a row that is hypothetically inserted into a group of rows.



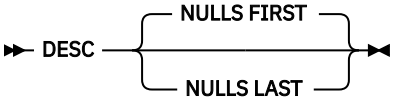
order-by-clause



asc-option



desc-option



The schema is SYSIBM.

expression
An expression that specifies a row that is hypothetically inserted into a group of rows. The expression must return a value that is a built-in data type. The expression must be a constant, a variable, or a cast of a constant or variable (SQLSTATE 428I9).

order-by-clause

ORDER BY
Specifies the order of the rows from the same grouping set that are processed in the aggregation.

sort-key
The sort key can be a column name or a *sort-key-expression*. If the sort key is a constant, it does not refer to the position of the output column. A constant implies no sort key, unlike a constant in the ordinary ORDER BY clause.

ASC
Uses the values of the *sort-key* in ascending order.

DESC
Uses the values of the *sort-key* in descending order.

NULLS FIRST
The ordering considers null values before all non-null values in the sort order.

NULLS LAST
The ordering considers null values after all non-null values in the sort order.

The number of expressions must be the same as the number of *sort-key* expressions (SQLSTATE 42822). The data type of each expression and the data type of the corresponding *sort-key* expression must be compatible (SQLSTATE 42822).

The data type of the result is DECFLOAT(34). The actual result is greater than 0.0 and less than or equal to 1.0.

Example

Set the host variable PR to the relative percentile rank of a hypothetical new employee's salary of 47000 within the salaries of the employees in department 'A00'.

```
   SELECT PERCENT_RANK(47000) WITHIN GROUP (ORDER BY SALARY)
      INTO :PR FROM EMPLOYEE WHERE WORKDEPT = 'A00'
```

PR is set to a value of 0.4.

The following result set is shown for reference.

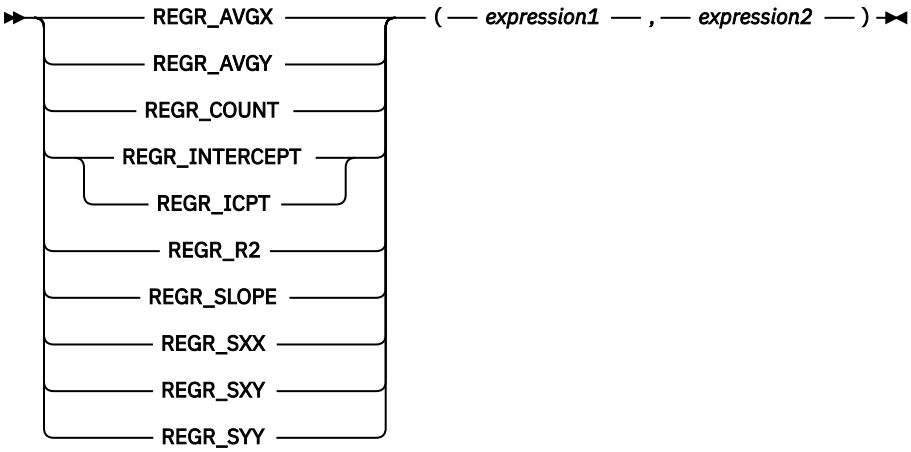
```
   SELECT SALARY FROM EMPLOYEE WHERE WORKDEPT = 'A00' ORDER BY SALARY

SALARY
-----------
   39250.00
   46500.00
   49250.00
   66500.00
  152750.00

  5 record(s) selected.
```

Regression functions (REGR_AVGX, REGR_AVGY, REGR_COUNT, ...)

The regression functions support the fitting of an ordinary-least-squares regression line of the form y = a * x + b to a set of number pairs.



The schema is SYSIBM.

expression1
An expression that returns a value of any built-in numeric data type. It is interpreted as a value of the dependent variable (that is, a "y value").

expression2
An expression that returns a value of any built-in numeric data type. It is interpreted as a value of the independent variable (that is, an "x value").

The REGR_COUNT function returns the number of non-null number pairs used to fit the regression line.

The REGR_INTERCEPT (or REGR_ICPT) function returns the y-intercept of the regression line ("b" in the equation mentioned previously).

The REGR_R2 function returns the coefficient of determination ("R-squared" or "goodness-of-fit") for the regression.

The REGR_SLOPE function returns the slope of the line ("a" in the equation mentioned previously).

The REGR_AVGX, REGR_AVGY, REGR_SXX, REGR_SXY, and REGR_SYY functions return quantities that can be used to compute various diagnostic statistics needed for the evaluation of the quality and statistical validity of the regression model.

The data type of the result of REGR_COUNT is integer. For the remaining functions, if either argument is DECFLOAT(*n*), the data type of the result is DECFLOAT(34); otherwise, the data type of the result is double-precision floating-point. If either argument is a special decimal floating-point value, the rules for general arithmetic operations for decimal floating-point apply. See "General arithmetic operation rules for decimal floating-point" in “General arithmetic operation rules for decimal floating-point” on page 142.

The result can be null. When not null, the result of REGR_R2 is between 0 and 1, and the result of both REGR_SXX and REGR_SYY is non-negative.

Each function is applied to the set of (*expression1*, *expression2*) pairs derived from the argument values by the elimination of all pairs for which either *expression1* or *expression2* is null.

If the set is not empty and VARIANCE(*expression2*) is positive, REGR_COUNT returns the number of non-null pairs in the set, and the remaining functions return results that are defined as follows:

```
REGR_SLOPE(expression1,expression2) =
COVARIANCE(expression1,expression2)/VARIANCE(expression2)
```

```
REGR_INTERCEPT(expression1, expression2) =
AVG(expression1) - REGR_SLOPE(expression1, expression2) * AVG(expression2)
```

```
REGR_R2(expression1, expression2) =
POWER(CORRELATION(expression1, expression2), 2) if VARIANCE(expression1)>0
REGR_R2(expression1, expression2) = 1 if VARIANCE(expression1)=0
```

```
REGR_AVGX(expression1, expression2) = AVG(expression2)
```

```
REGR_AVGY(expression1, expression2) = AVG(expression1)
```

```
REGR_SXX(expression1, expression2) =
REGR_COUNT(expression1, expression2) * VARIANCE(expression2)
```

```
REGR_SYY(expression1, expression2) =
REGR_COUNT(expression1, expression2) * VARIANCE(expression1)
```

```
REGR_SXY(expression1, expression2) =
REGR_COUNT(expression1, expression2) * COVARIANCE(expression1, expression2)
```

If the set is not empty and VARIANCE(*expression2*) is equal to zero, then the regression line either has infinite slope or is undefined. In this case, the functions REGR_SLOPE, REGR_INTERCEPT, and REGR_R2 each return a null value, and the remaining functions return values as defined previously. If the set is empty, REGR_COUNT returns zero and the remaining functions return a null value.

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

The regression functions are all computed simultaneously during a single pass through the data. In general, it is more efficient to use the regression functions to compute the statistics needed for a regression analysis than to perform the equivalent computations using ordinary column functions such as AVERAGE, VARIANCE, COVARIANCE, and so forth.

The usual diagnostic statistics that accompany a linear-regression analysis can be computed in terms of the functions listed previously. For example:

Adjusted R2
1 - ((1 - REGR_R2) * ((REGR_COUNT - 1) / (REGR_COUNT - 2)))

Standard error
SQRT((REGR_SYY-(POWER(REGR_SXY,2)/REGR_SXX))/(REGR_COUNT-2))

Total sum of squares
REGR_SYY

Regression sum of squares
POWER(REGR_SXY,2) / REGR_SXX

Residual sum of squares
(Total sum of squares)-(Regression sum of squares)

t statistic for slope
REGR_SLOPE * SQRT(REGR_SXX) / (Standard error)

t statistic for y-intercept
REGR_INTERCEPT/((Standard error) * SQRT((1/REGR_COUNT)+(POWER(REGR_AVGX,2)/REGR_SXX))

Example

Using the EMPLOYEE table, compute an ordinary-least-squares regression line that expresses the bonus of an employee in department (WORKDEPT) `'A00'` as a linear function of the employee's salary. Set the host variables SLOPE, ICPT, RSQR (double-precision floating point) to the slope, intercept, and coefficient of determination of the regression line, respectively. Also set the host variables AVGSAL and AVGBONUS to the average salary and average bonus, respectively, of the employees in department `'A00'`, and set the host variable CNT (integer) to the number of employees in department `'A00'` for whom both salary

and bonus data are available. Store the remaining regression statistics in host variables SXX, SYY, and SXY.

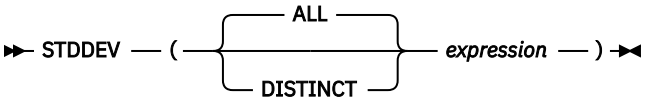
```
SELECT REGR_SLOPE(BONUS,SALARY), REGR_INTERCEPT(BONUS,SALARY),
REGR_R2(BONUS,SALARY), REGR_COUNT(BONUS,SALARY),
REGR_AVGX(BONUS,SALARY), REGR_AVGY(BONUS,SALARY),
REGR_SXX(BONUS,SALARY), REGR_SYY(BONUS,SALARY),
REGR_SXY(BONUS,SALARY)
INTO    :SLOPE, :ICPT,
:RSQR, :CNT,
:AVGSAL, :AVGBONUS,
:SXX, :SYY,
:SXY
FROM EMPLOYEE
WHERE WORKDEPT = 'A00'
```

When using the sample table, the host variables are set to the following approximate values:

```
SLOPE:  +1.71002671916749E-002
ICPT:  +1.00871888623260E+002
RSQR:  +9.99707928128685E-001
CNT:  3
AVGSAL:  +4.28333333333333E+004
AVGBONUS:  +8.33333333333333E+002
SXX:  +2.96291666666667E+008
SYY:  +8.66666666666667E+004
SXY:  +5.06666666666667E+006
```

STDDEV

The STDDEV function returns the biased standard deviation (division by *n*) of a set of numbers.



The schema is SYSIBM.

expression
An expression that returns a value of any built-in numeric data type.

If the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*); otherwise, the result is double-precision floating-point. The result can be null.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are eliminated. When interpreting the DISTINCT clause for decimal floating-point values that are numerically equal, the number of significant digits in the value is not considered. For example, the decimal floating-point number 123.00 is not distinct from the decimal floating-point number 123. The representation of the number returned from the query will be any one of the representations encountered (for example, either 123.00 or 123).

If the function is applied to an empty set, the result is a null value. Otherwise, the result is the standard deviation of the values in the set.

The calculation that is used to determine the biased standard deviation is logically equivalent to the following formula:

```
STDDEV = SQRT(VARIANCE(expression))
```

where SQRT(VARIANCE(*expression*)) is the square root of the biased variance.

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

STDDEV_POP can be specified in place of STDDEV.

Example

Set the host variable DEV to the standard deviation of the salaries of employees in department 'A00' in the EMPLOYEE table. The data type for the host variable DEV is double-precision floating point.

```
   SELECT STDDEV(SALARY)
     INTO :DEV
     FROM EMPLOYEE
     WHERE WORKDEPT = 'A00'
```

DEV is set to a number with an approximate value of 9938.00.

The following result set is shown for reference.

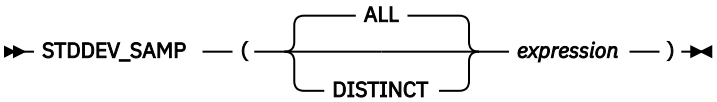
```
   SELECT SALARY FROM EMPLOYEE WHERE WORKDEPT = 'A00'
```

```
SALARY
-----------
  152750.00
   66500.00
   49250.00
   46500.00
   39250.00

  5 record(s) selected.
```

STDDEV_SAMP

The STDDEV_SAMP function returns the sample standard deviation (division by [*n*-1]) of a set of numbers.



The schema is SYSIBM.

expression
An expression that returns a value of any built-in numeric data type.

If the argument is DECFLOAT(*n*), the result is DECFLOAT(34); otherwise, the result is double-precision floating-point. The result can be null.

The function is applied to the set of values that are derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are eliminated. When the DISTINCT clause is interpreted for decimal floating-point values that are numerically equal, the number of significant digits in the value is not considered. For example, the decimal floating-point number 123.00 is not distinct from the decimal floating-point number 123. The representation of the number that is returned from the query is any one of the representations encountered (for example, either 123.00 or 123).

If the function is applied to an empty set or a set with only one row, the result is a null value. Otherwise, the result is the sample standard deviation of the values in the set.

The calculation that is used to determine the sample standard deviation is logically equivalent to the following formula:

```
   STDDEV_SAMP = SQRT(VARIANCE_SAMP(expression))
```

where SQRT(VARIANCE_SAMP(*expression*)) is the square root of the sample variance.

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

Example

Set the host variable DEV to the sample standard deviation of the salaries for those employees in department 'A00' of the EMPLOYEE table. The data type for the host variable DEV is double-precision floating point.

```
SELECT STDDEV_SAMP(SALARY)
  INTO :DEV
  FROM EMPLOYEE
  WHERE WORKDEPT = 'A00'
```

DEV is set to a number with an approximate value of +4.68630318054647E+004.

The following result set is shown for reference.

```
SELECT SALARY FROM EMPLOYEE WHERE WORKDEPT = 'A00'
```

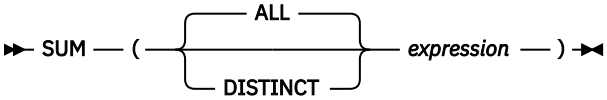
```
SALARY
-----------
  152750.00
   66500.00
   49250.00
   46500.00
   39250.00

  5 record(s) selected.
```

SUM

The SUM function returns the sum of a set of numbers.

Note: The result of the function can be affected by the enablement of the large_aggregation configuration parameter.



The schema is SYSIBM.

expression
An expression that returns a value of any built-in numeric data type.

The data type of the result is the same as the data type of the input expression, with the following exceptions:

- If the data type of the input expression is SMALLINT, the data type of the result is INTEGER.
- If the data type of the input expression is single-precision floating point (REAL), the data type of the result is double-precision floating point (DOUBLE).
- If the data type of the input expression is DECFLOAT(*n*), the data type of the result is DECFLOAT(34).
- If the input expression is a DECIMAL value with precision *p* and scale *s*, the result is a DECIMAL with scale *s* and precision as follows:

Table 53. Result precision of the SUM aggregate function with DECIMAL input

DECIMAL arithmetic mode [1]	*p*	Result precision
default	n/a	31
DEC15	<=15	15
DEC15	>15	MIN(31,p+10)
DEC31	n/a	MIN(31,p+10)

Note:

1. These modes are determined by the **dec_arithmetic** configuration parameter.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are also eliminated. When interpreting the DISTINCT clause for decimal floating-point values that are numerically equal, the number of significant digits in the value is not considered. For example, the decimal floating-point number 123.00 is not distinct from the decimal floating-point number 123. The representation of the number returned from the query will be any one of the representations encountered (for example, either 123.00 or 123).

The result can be null. If the function is applied to an empty set, the result is a null value. Otherwise, the result is the sum of the values in the set.

The order in which the values are aggregated is undefined, but every intermediate result must be within the range of the result data type.

Example

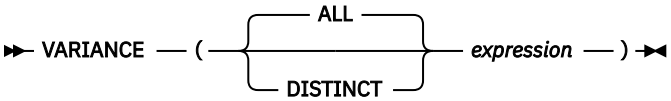
Using the EMPLOYEE table, set the host variable JOB_BONUS (decimal(9,2)) to the total bonus (BONUS) paid to clerks (JOB='CLERK').

```
SELECT SUM(BONUS)
  INTO :JOB_BONUS
  FROM EMPLOYEE
  WHERE JOB = 'CLERK'
```

Results in JOB_BONUS being set to 2800 when using the sample table.

VARIANCE

The VARIANCE function returns the biased variance (division by *n*) of a set of numbers.



The schema is SYSIBM.

expression
An expression that returns a value of any built-in numeric data type.

If the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*); otherwise, the result is double-precision floating-point. The result can be null.

The function is applied to the set of values derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are eliminated. When interpreting the DISTINCT clause for decimal floating-point values that are numerically equal, the number of significant digits in the value is not considered. For example, the decimal floating-point number 123.00 is not distinct from the decimal floating-point number 123. The representation of the number returned from the query will be any one of the representations encountered (for example, either 123.00 or 123).

If the function is applied to an empty set, the result is a null value. Otherwise, the result is the variance of the values in the set.

The calculation that is used to determine the biased variance is logically equivalent to the following formula:

```
VARIANCE = SUM(expression**2)/COUNT(expression) - (SUM(expression)/
COUNT(expression))**2
```

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

VAR or VAR_POP can be specified in place of VARIANCE.

Example

Set the host variable VARNCE, whose data type is double-precision floating point, to the variance of the salaries for those employees in department 'A00' of the EMPLOYEE table.

```
SELECT VARIANCE(SALARY)
  INTO :VARNCE
  FROM EMPLOYEE
  WHERE WORKDEPT = 'A00'
```

Results in VARNCE being set to approximately 98763888.88 when using the sample table.

The following result set is shown for reference.

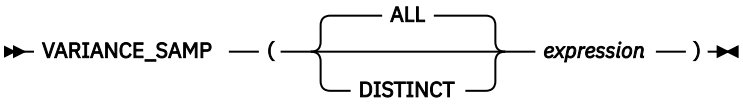
```
SELECT SALARY FROM EMPLOYEE WHERE WORKDEPT = 'A00'
```

```
SALARY
-----------
  152750.00
   66500.00
   49250.00
   46500.00
   39250.00

  5 record(s) selected.
```

VARIANCE_SAMP

The VARIANCE_SAMP function returns the sample variance (division by [*n*-1]) of a set of numbers.



The schema is SYSIBM.

expression
An expression that returns a value of any built-in numeric data type.

If the argument is DECFLOAT(*n*), the result is DECFLOAT(34); otherwise, the result is double-precision floating-point. The result can be null.

The function is applied to the set of values that are derived from the argument values by the elimination of null values. If DISTINCT is specified, redundant duplicate values are eliminated. When the DISTINCT clause is interpreted for decimal floating-point values that are numerically equal, the number of significant digits in the value is not considered. For example, the decimal floating-point number 123.00 is not distinct from the decimal floating-point number 123. The representation of the number that is returned from the query is any one of the representations encountered (for example, 123.00 or 123).

If the function is applied to an empty set or a set with only one row, the result is a null value. Otherwise, the result is the sample variance of the values in the set.

The calculation that is used to determine the sample variance is logically equivalent to the following formula:

```
VARIANCE_SAMP = ( SUM(expression**2) - ((SUM(expression)**2) /
(COUNT(expression))) ) /
                  (COUNT(expression) - 1)
```

The order in which the values are added is undefined, but every intermediate result must be within the range of the result data type.

VAR_SAMP can be specified in place of VARIANCE_SAMP.

Example

Set the host variable VARNCE to the sample variance of the salaries for those employees in department 'A00' of the EMPLOYEE table. The data type for the host variable VARNCE is double-precision floating point.

```
SELECT VARIANCE_SAMP(SALARY)
  INTO :VARNCE
  FROM EMPLOYEE
  WHERE WORKDEPT = 'A00'
```

This statement results in VARNCE being set to approximately +2.19614375000000E+009 when the sample table is used.

The following result set is shown for reference.

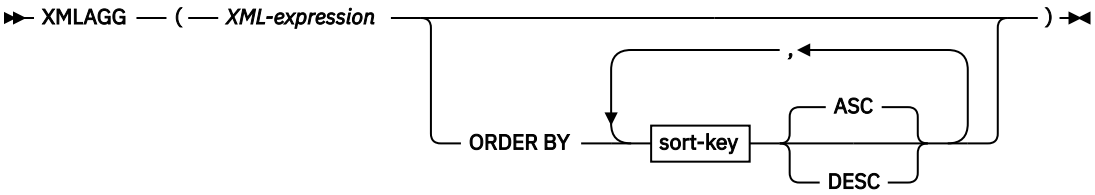
```
SELECT SALARY FROM EMPLOYEE WHERE WORKDEPT = 'A00'
```

```
SALARY
-----------
  152750.00
   66500.00
   49250.00
   46500.00
   39250.00

  5 record(s) selected.
```

XMLAGG

The XMLAGG function returns an XML sequence containing an item for each non-null value in a set of XML values.



The schema is SYSIBM. The function name cannot be specified as a qualified name.

XML-expression
Specifies an expression of data type XML. The data type of *XML-expression* cannot be a BINARY or VARBINARY type (SQLSTATE 42884).

ORDER BY
Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause is omitted, or if the ORDER BY clause cannot distinguish the order of the column data, the rows in the same grouping set are arbitrarily ordered.

sort-key
The sort key can be a column name or a *sort-key-expression*. Note that if the sort key is a constant, it does not refer to the position of the output column (as in the ordinary ORDER BY clause), but it is simply a constant, which implies no sort key.

The data type of the result is XML.

The function is applied to the set of values derived from the argument values by the elimination of null values.

If the *XML-expression* argument can be null, the result can be null. If the set of values is empty, the result is the null value. Otherwise, the result is an XML sequence containing an item for each value in the set.

If a SELECT clause includes an ARRAY_AGG function, then all invocations of ARRAY_AGG, LISTAGG, XMLAGG, and XMLGROUP functions in the same SELECT clause must specify the same order or not specify an order (SQLSTATE 428GZ).

Notes

- **Support in OLAP expressions**: XMLAGG cannot be used as a column function of an OLAP aggregation function (SQLSTATE 42601).

Example

Construct a department element for each department, containing a list of employees sorted by last name.

```
SELECT XMLSERIALIZE(
  CONTENT XMLELEMENT(
    NAME "Department", XMLATTRIBUTES(
      E.WORKDEPT AS "name"
    ),
    XMLAGG(
      XMLELEMENT(
        NAME "emp", E.LASTNAME
      )
      ORDER BY E.LASTNAME
    )
  )
  AS CLOB(110)
)
AS "dept_list"
FROM EMPLOYEE E
WHERE E.WORKDEPT IN ('C01','E21')
GROUP BY WORKDEPT
```

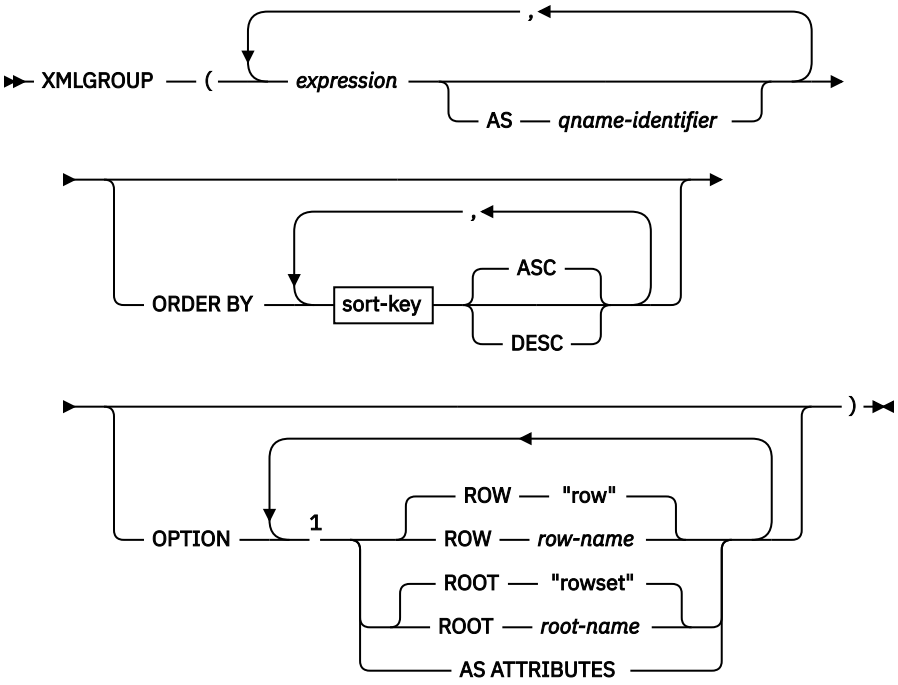
This query produces the following result:

```
dept_list
------------------------...
<Department name="C01">
  <emp>KWAN</emp>
  <emp>NICHOLLS</emp>
  <emp>QUINTANA</emp>
</Department>
<Department name="E21">
  <emp>GOUNOT</emp>
  <emp>LEE</emp>
  <emp>MEHTA</emp>
  <emp>SPENSER</emp>
</Department>
```

Note: XMLAGG does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

XMLGROUP

The XMLGROUP function returns an XML value with a single XQuery document node containing one top-level element node. This is an aggregate expression that will return a single-rooted XML document from a group of rows where each row is mapped to a row subelement.



Notes:

[1] The same clause must not be specified more than once.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

expression
The content of each generated XML element node (or the value of each generated attribute) is specified by an expression. The data type of *expression* cannot be a BINARY type, a VARBINARY type, or a structured type (SQLSTATE 42884). The expression can be any SQL expression. If the expression is not a simple column reference, a *qname-identifier* must be specified.

AS *qname-identifier*
Specifies the XML element name or attribute name as an SQL identifier. The *qname-identifier* must be of the form of an XML qualified name, or QName (SQLSTATE 42634). See the W3C XML namespace specifications for more details on valid names. If the name is qualified, the namespace prefix must be declared within the scope (SQLSTATE 42635). If *qname-identifier* is not specified, *expression* must be a column name (SQLSTATE 42703). The element name or attribute name is created from the column name using the fully escaped mapping from a column name to an QName.

OPTION
Specifies additional options for constructing the XML value. If no OPTION clause is specified, the default behavior applies.

ROW *row-name*
Specifies the name of the element to which each row is mapped. If this option is not specified, the default element name is "row".

ROOT *root-name*
Specifies the name of the root element node. If this option is not specified, the default root element name is "rowset"

AS ATTRIBUTES
Specifies that each expression is mapped to an attribute value with column name or *qname-identifier* serving as the attribute name.

ORDER BY
Specifies the order of the rows from the same grouping set that are processed in the aggregation. If the ORDER BY clause is omitted, or if the ORDER BY clause cannot distinguish the order of the column data, the rows in the same grouping set are arbitrarily ordered.

sort-key
The sort key can be a column name or a *sort-key-expression*. Note that if the sort key is a constant, it does not refer to the position of the output column (as in the ordinary ORDER BY clause), but it is simply a constant, which implies no sort key.

Rules

- If a SELECT clause includes an ARRAY_AGG function, then all invocations of ARRAY_AGG, LISTAGG, XMLAGG, and XMLGROUP functions in the same SELECT clause must specify the same order or not specify an order (SQLSTATE 428GZ).

Notes

The default behavior defines a simple mapping between a result set and an XML value. Some additional notes about function behavior apply:

- By default, each row is transformed into an XML element named "row" and each column is transformed into a nested element with the column name serving as the element name.
- The null handling behavior is NULL ON NULL. A null value in a column maps to the absence of the subelement. If all column values are null, no row element will be generated.
- The binary encoding scheme for BLOB and FOR BIT DATA data types is base64Binary encoding.
- By default, the elements corresponding to the rows in a group are children of a root element named "rowset".
- The order of the row subelements in the root element will be the same as the order in which the rows are returned in the query result set.
- A document node will be added implicitly to the root element to make the XML result a well-formed single-rooted XML document

Examples

The provided examples are based on the following table, T1, with integer columns C1 and C2 that contain numeric data stored in a relational format.

```
C1          C2
----------- -----------
          1           2
          -           2
          1           -
          -           -

  4 record(s) selected.
```

- *Example 1*: The following example shows an XMLGroup query and output fragment with default behavior, using a single top-level element to represent the table:

```
SELECT XMLGROUP(C1, C2)FROM T1
```

```
<rowset>
   <row>
      <C1>1</C1>
      <C2>2</C2>
   </row>
   <row>
      <C2>2</C2>
   </row>
   <row>
      <C1>1</C1>
   </row>
```

```
</rowset>

  1 record(s) selected.
```

- *Example 2*: The following example shows an XMLGroup query and output fragment with attribute centric mapping. Instead of appearing as nested elements as in the previous example, relational data is mapped to element attributes:

```
SELECT XMLGROUP(C1, C2 OPTION AS ATTRIBUTES) FROM T1
```

```
<rowset>
   <row C1="1" C2="2"/>
   <row C2="2"/>
   <row C1="1"/>
</rowset>

  1 record(s) selected.
```

- *Example 3*: The following example shows an XMLGroup query and output fragment with the default <rowset> root element replaced by <document> and the default <row> element replaced by <entry>. Columns C1 and C2 are returned as <column1> and <column2> elements, and the return set is ordered by column C1:

```
SELECT XMLGROUP(
   C1 AS "column1", C2 AS "column2"
   ORDER BY C1 OPTION ROW "entry" ROOT "document")
FROM T1
```

```
<document>
   <entry>
      <column1>1</column1>
      <column2>2</column2>
   </entry>
   <entry>
      <column1>1</column1>
   </entry>
   <entry>
      <column2>2</column2>
    </entry>
</document>
```

Scalar functions

A scalar function optionally accepts arguments and returns a single scalar value each time the function is called.

A scalar function can be used wherever an expression can be used. However, the restrictions that apply to the use of expressions and aggregate functions also apply when an expression or aggregate function is used within a scalar function. For example, the argument of a scalar function can be an aggregate function only if an aggregate function is allowed in the context in which the scalar function is used.

The restrictions on the use of aggregate functions do not apply to scalar functions, because a scalar function is applied to a single value rather than to a set of values.

The result of the following SELECT statement has as many rows as there are employees in department D01:

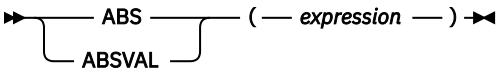
```
SELECT EMPNO, LASTNAME, YEAR(CURRENT DATE - BRTHDATE)
  FROM EMPLOYEE
  WHERE WORKDEPT = 'D01'
```

Scalar functions can be qualified with a schema name (for example, SYSIBM.CHAR(123)).

In a Unicode database, all scalar functions that accept a character or graphic string will accept any string types for which conversion is supported.

ABS or ABSVAL

Returns the absolute value of the argument.



The schema is SYSIBM.

The SYSFUN version of the ABS (or ABSVAL) function continues to be available.

expression
An expression that returns a value of any built-in numeric data type.

The result has the same data type and length attribute as the argument. The result can be null; if the argument is null, the result is the null value. If the argument is the maximum negative value for SMALLINT, INTEGER or BIGINT, the result is an overflow error.

Notes

Results involving DECFLOAT special values: For decimal floating-point values, the special values are treated as follows:

- ABS(NaN) and ABS(-NaN) return NaN.
- ABS(Infinity) and ABS(-Infinity) return Infinity.
- ABS(sNaN) and ABS(-sNaN) return sNaN.

Example

```
ABS(-51234)
```

returns an INTEGER with a value of 51234.

ACOS

Returns the arccosine of the argument as an angle expressed in radians.

The schema is SYSIBM. (The SYSFUN version of the ACOS function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

The result of the function is a double-precision floating-point number. The result can be null if the argument can be null or the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

Example

Assume that the host variable ACOSINE is a DECIMAL(10,9) host variable with a value of 0.070737202.

```
SELECT ACOS(:ACOSINE)
  FROM SYSIBM.SYSDUMMY1
```

This statement returns the approximate value 1.49.

ADD_DAYS

The ADD_DAYS function returns a datetime value that represents the first argument plus a specified number of days.

The schema is SYSIBM.

expression
An expression that specifies the starting date. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

numeric-expression
An expression that specifies the number of days to add to the starting date specified by *expression*. The expression must return a value that is a built-in numeric, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the expression is not an INTEGER, it is cast to INTEGER before the function is evaluated. A negative numeric value can be used to subtract days.

The result of the function is a timestamp with the same precision as *expression* , if *expression* is a timestamp. Otherwise, the result of the function is a date. If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

1. Assume that today is January 31, 2007. Set the host variable ADD_DAY with the current day plus 1 day.

   ```
   SET :ADD_DAY = ADD_DAYS(CURRENT_DATE, 1)
   ```

   The host variable ADD_DAY is set with the value representing 2007-02-01.

2. Assume that DATE is a host variable with the value July 27, 1965. Set the host variable ADD_DAY with the value of that day plus 3 days.

   ```
   SET :ADD_DAY = ADD_DAYS(:DATE,3)
   ```

   The host variable ADD_DAY is set with the value representing the day plus 3 days, 1965-07-30.

3. The ADD_DAYS function and datetime arithmetic can be used to achieve the same results. The following examples demonstrate this.

   ```
   SET :DATEHV = DATE('2008-2-28') + 4 DAYS
   SET :DATEHV = ADD_DAYS('2008-2-28', 4)
   ```

   In both cases, the host variable DATEHV is set with the value '2008-03-03'.

   Now consider the same examples but with the date '2008-2-29' as the argument.

   ```
   SET :DATEHV = DATE('2008-2-29') + 4 DAYS
   SET :DATEHV = ADD_DAYS('2008-2-29', 4)
   ```

   In both cases, the host variable DATEHV is set with the value '2008-03-04'.

4. Assume that DATE is a host variable with the value July 27, 1965. Set the host variable ADD_DAY with the value of that day minus 3 days.

   ```
   SET :ADD_DAY = ADD_DAYS(:DATE,-3)
   ```

   The host variable ADD_DAY is set to 1965-07-24; the value representing July 27, 1965 minus 3 days.

ADD_HOURS

The ADD_HOURS function returns a timestamp value that represents the first argument plus a specified number of hours.

The schema is SYSIBM.

expression
An expression that specifies the starting timestamp. The expression must return a value that is a TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. The expression must not return a value that is a DATE (SQLSTATE 42815). If *expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

numeric-expression
An expression that specifies the number of hours to add to the starting timestamp specified by *expression*. The expression must return a value that is a built-in numeric, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the expression is not an INTEGER, it is cast to INTEGER before the function is evaluated. A negative numeric value can be used to subtract hours.

The result of the function is a timestamp with the same precision as *expression*, if *expression* is a timestamp. Otherwise, the result is a TIMESTAMP(12). If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

1. Assume that the current timestamp is January 31, 2007, 01:02:03.123456. Set the host variable ADD_HOUR with the current timestamp plus 1 hour.

   ```
   SET :ADD_HOUR = ADD_HOURS(CURRENT TIMESTAMP, 1)
   ```

   The host variable ADD_HOUR is set with the value representing 2007-01-31-02.02.03.123456.

2. Assume that TIMESTAMP is a host variable with the value July 27, 1965 23:58:59. Set the host variable ADD_HOUR with the value of that timestamp plus 3 hours.

   ```
   SET :ADD_HOUR = ADD_HOURS(:TIMESTAMP,3)
   ```

   The host variable ADD_HOUR is set with the value representing the timestamp plus 3 hours, 1965-07-28-02.58.59.

3. The ADD_HOURS function and datetime arithmetic can be used to achieve the same results. The following examples demonstrate this.

   ```
   SET :TIMESTAMPHV = TIMESTAMP '2008-2-28-22.58.59' + 4 HOURS
   SET :TIMESTAMPHV = ADD_HOURS( TIMESTAMP '2008-2-28-22.58.59', 4)
   ```

   In both cases, the host variable TIMESTAMPHV is set with the value '2008-02-29-02.58.59'.

   Now consider the same examples but with 28 hours added.

   ```
   SET :TIMESTAMPHV = TIMESTAMP '2008-2-28-22.58.59' + 28 HOURS
   SET :TIMESTAMPHV = ADD_HOURS(TIMESTAMP '2008-2-28-22.58.59', 28)
   ```

   In both cases, the host variable TIMESTAMPHV is set with the value '2008-03-01-02.58.59'.

4. Assume that TIMESTAMP is a host variable with the value July 27, 1965 23:58:59. Set the host variable ADD_HOUR with the value of that timestamp minus 3 hours.

```
SET :ADD_HOUR = ADD_HOURS(:TIMESTAMP,-3)
```

The host variable ADD_HOUR is set to 1965-07-27-20.58.59; the value representing July 27, 1965 23:58:59 minus 3 hours.

ADD_MINUTES

The ADD_MINUTES function returns a timestamp value that represents the first argument plus a specified number of minutes.

The schema is SYSIBM.

expression
An expression that specifies the starting timestamp. The expression must return a value that is a TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. The expression must not return a value that is a DATE (SQLSTATE 42815). If *expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

numeric-expression
An expression that specifies the number of minutes to add to the starting timestamp specified by *expression*. The expression must return a value that is a built-in numeric, CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the expression is not a BIGINT, it is cast to BIGINT before the function is evaluated. A negative numeric value can be used to subtract minutes.

The result of the function is a timestamp with the same precision as *expression*, if *expression* is a timestamp. Otherwise, the result is a TIMESTAMP(12). If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

1. Assume that the current timestamp is January 31, 2007, 01:02:03.123456. Set the host variable ADD_MINUTE with the current timestamp plus 1 minute.

   ```
   SET :ADD_MINUTE = ADD_MINUTES(CURRENT TIMESTAMP, 1)
   ```

   The host variable ADD_MINUTE is set with the value representing 2007-01-31-01.03.03.123456.

2. Assume that TIMESTAMP is a host variable with the value July 27, 1965 23:58:59. Set the host variable ADD_MINUTE with the value of that timestamp plus 3 minutes.

   ```
   SET :ADD_MINUTE = ADD_MINUTES(:TIMESTAMP,3)
   ```

   The host variable ADD_MINUTE is set with the value representing the timestamp plus 3 minutes, 1965-07-28-00.01.59.

3. The ADD_MINUTES function and datetime arithmetic can be used to achieve the same results. The following examples demonstrate this.

   ```
   SET :TIMESTAMPHV = TIMESTAMP '2008-2-28-23.58.59' + 4 MINUTES
   SET :TIMESTAMPHV = ADD_MINUTES( TIMESTAMP '2008-2-28-23.58.59', 4)
   ```

   In both cases, the host variable TIMESTAMPHV is set with the value '2008-02-29-00.02.59'.

   Now consider the same examples but with 1442 minutes added.

   ```
   SET :TIMESTAMPHV = TIMESTAMP '2008-2-28-23.58.59' + 1442 MINUTES
   SET :TIMESTAMPHV = ADD_MINUTES(TIMESTAMP '2008-2-28-23.58.59', 1442)
   ```

In both cases, the host variable TIMESTAMPHV is set with the value '2008-03-01-00.00.59'.

4. Assume that TIMESTAMP is a host variable with the value July 27, 1965 23:58:59. Set the host variable ADD_MINUTE with the value of that timestamp minus 3 minutes.

```
SET :ADD_MINUTE = ADD_MINUTES(:TIMESTAMP,-3)
```

The host variable ADD_MINUTE is set to 1965-07-27-23.55.59; the value representing July 27, 1965 23:58:59 minus 3 minutes.

ADD_MONTHS

The ADD_MONTHS function returns a datetime value that represents *expression* plus a specified number of months.

The schema is SYSIBM.

expression
An expression that specifies the starting date. The expression must return a value of one of the following built-in data types: a DATE or a TIMESTAMP.

numeric-expression
An expression that returns a value of any built-in numeric data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. The *numeric-expression* specifies the number of months to add to the starting date specified by *expression*. A negative numeric value is allowed.

The result of the function has the same data type as *expression*, unless *expression* is a string, in which case the result data type is DATE. The result can be null; if any argument is null, the result is the null value.

If *expression* is the last day of the month or if the resulting month has fewer days than the day component of *expression*, the result is the last day of the resulting month. Otherwise, the result has the same day component as *expression*. Any hours, minutes, seconds or fractional seconds information included in *expression* is not changed by the function.

Examples

- *Example 1*: Assume today is January 31, 2007. Set the host variable ADD_MONTH with the last day of January plus 1 month.

```
SET :ADD_MONTH = ADD_MONTHS(LAST_DAY(CURRENT_DATE), 1);
```

The host variable ADD_MONTH is set with the value representing the end of February, 2007-02-28.

- *Example 2*: Assume DATE is a host variable with the value July 27, 1965. Set the host variable ADD_MONTH with the value of that day plus 3 months.

```
SET :ADD_MONTH = ADD_MONTHS(:DATE,3);
```

The host variable ADD_MONTH is set with the value representing the day plus 3 months, 1965-10-27.

- *Example 3*: The ADD_MONTHS function can be used to achieve similar results as datetime arithmetic. The following examples demonstrate the similarities and contrasts.

```
SET :DATEHV = DATE('2008-2-28') + 4 MONTHS;
SET :DATEHV = ADD_MONTHS('2008-2-28', 4);
```

In both cases, the host variable DATEHV is set with the value '2008-06-28'.

Now consider the same examples but with the date '2008-2-29' as the argument.

```
SET :DATEHV = DATE('2008-2-29') + 4 MONTHS;
```

The host variable DATEHV is set with the value '2008-06-29'.

```
SET :DATEHV = ADD_MONTHS('2008-2-29', 4);
```

The host variable DATEHV is set with the value '2008-06-30'.

In this case, the ADD_MONTHS function returns the last day of the month, which is June 30, 2008, instead of June 29, 2008. The reason is that February 29 is the last day of the month. So, the ADD_MONTHS function returns the last day of June.

ADD_SECONDS

The ADD_SECONDS function returns a timestamp value that represents the first argument plus a specified number of seconds and fractional seconds.

The schema is SYSIBM.

expression
An expression that specifies the starting timestamp. The expression must return a value that is a TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. The *expression* must not return a value that is a DATE (SQLSTATE 42815). If expression is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function

numeric-expression
An expression that specifies the number of seconds and fractional seconds to add to the starting timestamp specified by *expression*. The expression must return a value that is a built-in numeric, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the expression is not a DECIMAL(27,12), it is cast to DECIMAL(27,12) before the function is evaluated. A negative numeric value can be used to subtract seconds and fractional seconds.

The result of the function is a timestamp with the same precision as *expression*, if *expression* is a timestamp. Otherwise, the result is a TIMESTAMP(12). If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

1. Assume that the current timestamp is January 31, 2007, 01:02:03.123456. Set the host variable ADD_SECOND with the current timestamp plus 1 second.

   ```
   SET :ADD_SECOND = ADD_SECONDS(CURRENT TIMESTAMP, 1)
   ```

   The host variable ADD_SECOND is set with the value representing 2007-01-31-01.02.04.123456.
2. Assume that TIMESTAMP is a host variable with the value July 27, 1965 23:59:59.123456. Set the host variable ADD_SECOND with the value of that timestamp plus 3.123 seconds.

   ```
   SET :ADD_SECOND = ADD_SECONDS(:TIMESTAMP,3.123)
   ```

   The host variable ADD_SECOND is set with the value representing the timestamp plus 3.123 seconds, 1965-07-28-00.00.02.246456.

3. The ADD_SECONDS function and datetime arithmetic can be used to achieve the same results. The following examples demonstrate this.

```
SET :TIMESTAMPHV = TIMESTAMP '2008-2-28-23.58.59.123456' + 61.654321 SECONDS
```

```
SET :TIMESTAMPHV = ADD_SECONDS(
   TIMESTAMP '2008-2-28-23.58.59.123456', 61.654321)
```

   In both cases, the host variable TIMESTAMPHV is set with the value '2008-02-29-00.00.00.777777'.

   Now consider the same examples but with the timestamp '2008-2-29-23.59.59.123456' as the argument.

```
SET :TIMESTAMPHV = TIMESTAMP '2008-2-29-23.59.59.123456' + 61.654321 SECONDS
```

```
SET :TIMESTAMPHV = ADD_SECONDS(
   TIMESTAMP '2008-2-29-23.59.59.123456', 61.654321)
```

   In both cases, the host variable TIMESTAMPHV is set with the value '2008-03-01-00.01.00.777777'.

4. Assume that TIMESTAMP is a host variable with the value July 27, 1965 23:59:59.123456. Set the host variable ADD_SECOND with the value of that timestamp minus 3.123 seconds.

```
SET :ADD_SECOND = ADD_SECONDS(:TIMESTAMP,-3.123)
```

   The host variable ADD_SECOND is set to 1965-07-27-23.59.56.000456; the value representing July 27, 1965 23:59:59.123456 minus 3.123 seconds.

ADD_YEARS

The ADD_YEARS function returns a datetime value that represents the first argument plus a specified number of years.

The schema is SYSIBM.

expression
An expression that specifies the starting date. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

numeric-expression
An expression that specifies the number of years to add to the starting date specified by *expression*. The expression must return a value that is a built-in numeric, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the expression is not an INTEGER, it is cast to INTEGER before the function is evaluated. A negative numeric value can be used to subtract years.

The result of the function is a timestamp with the same precision as *expression*, if *expression* is a timestamp. Otherwise, the result of the function is a date. If any argument can be null, the result can be null; if any argument is null, the result is the null value.

If the result would be February 29 of a non-leap-year, the day is changed to 28, and a warning indicator in the SQLCA is set to indicate the adjustment.

Examples

1. Assume that today is January 31, 2007. Set the host variable ADD_YEAR with the current day plus 1 year.

```
SET :ADD_YEAR = ADD_YEARS(CURRENT_DATE, 1)
```

The host variable ADD_YEAR is set with the value representing 2008-01-31.

2. Assume that DATE is a host variable with the value July 27, 1965. Set the host variable ADD_YEAR with the value of that day plus 3 years.

```
SET :ADD_YEAR = ADD_YEARS(:DATE,3)
```

The host variable ADD_YEAR is set with the value representing the day plus 3 years, 1968-07-27.

3. The ADD_YEARS function and datetime arithmetic can be used to achieve the same results. The following examples demonstrate this.

```
SET :DATEHV = DATE('2008-2-29') + 4 YEARS
SET :DATEHV = ADD_YEARS('2008-2-29', 4)
```

In both cases, the host variable DATEHV is set with the value '2012-02-29'.

Now consider the same examples but with 3 years added.

```
SET :DATEHV = DATE('2008-2-29') + 3 YEARS
SET :DATEHV = ADD_YEARS('2008-2-29', 3)
```

In both cases, the host variable DATEHV is set with the value '2011-02-28'.

4. Assume that DATE is a host variable with the value July 27, 1965. Set the host variable ADD_YEAR with the value of that day minus 3 years.

```
SET :ADD_YEAR = ADD_YEARS(:DATE,-3)
```

The host variable ADD_YEAR is set to 1962-07-27; the value representing July 27, 1965 minus 3 years.

AGE

The AGE function returns a numeric value that represents the number of full years, full months, and full days between the current timestamp and the argument.

The schema is SYSIBM.

expression
An expression that specifies the datetime value for which the age is computed. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function

If there is less than a full day between the current timestamp and *expression*, the result is zero. If *expression* is earlier than the current timestamp, the result is positive. If *expression* is later than the current timestamp, the result is negative.

The result of the function is an INTEGER. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

The AGE function is a synonym of the following expression:

```
INTEGER( ( CURRENT TIMESTAMP(12) - TIMESTAMP( expression, 12 ) ) / 1000000 )
```

The result is the integer representation of the extraction of the year, month, and day components of a timestamp duration.

Notes

- **Determinism**: AGE is a deterministic function. However, the invocation of the function depends on the value of the special register CURRENT TIMESTAMP. The AGE function can be used wherever special registers are supported (SQLSTATE 42621, 428EC, or 429BX).

Examples

1. Assume the CURRENT TIMESTAMP(12) is 2013-09-24-11.28.00.123456789012. Set the host variable AGE1 to the number of full years, full months, and full days between the current timestamp and 2012-02-28-12.00.00.

   ```
   SET :AGE1 = AGE(TIMESTAMP '2012-02-28-12.00.00')
   ```

   The host variable AGE1 is set to 10624.
2. Assume the CURRENT TIMESTAMP(12) is 2013-09-24-11.28.00.123456789012. Set the host variable AGE1 to the number of full years, full months, and full days between the current timestamp and 2013-09-23-12.00.00.

   ```
   SET :AGE1 = AGE(TIMESTAMP '2013-09-23-12.00.00')
   ```

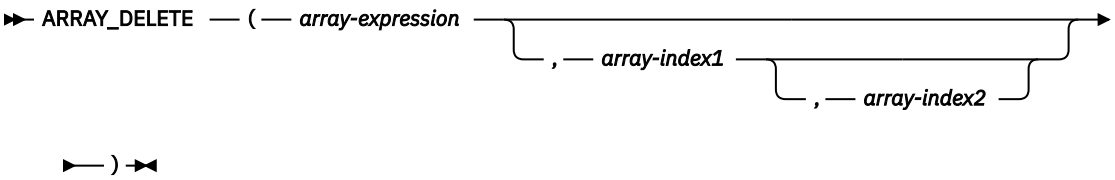
   The host variable AGE1 is set to 0.
3. Assume the CURRENT TIMESTAMP(12) is 2013-09-24-11.28.00.123456789012. Set the host variable AGE1 to the number of full years, full months, and full days between the current timestamp and 2020-01-01.

   ```
   SET :AGE1 = AGE(DATE '2020-01-01')
   ```

   The host variable AGE1 is set to -60306.

ARRAY_DELETE

The ARRAY_DELETE function deletes elements from an array.



The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification of a parameter marker to an array type.

array-index1
An expression that results in a value that can be assigned to the data type of the array index. If *array-expression* is an ordinary array, *array-index1* must be the null value (SQLTATE 42815).

array-index2
An expression that results in a value that can be assigned to the data type of the array index. If *array-expression* is an ordinary array, *array-index2* must be the null value. If *array-index2* is specified and is a non-null value, then *array-index1* must be a non-null value that is less than the value of *array-index2* (SQLSTATE 42815).

The result of the function has the same data type as *array-expression*. The result array is a copy of *array-expression*, with the following modifications:

- If the optional arguments are not specified or they are the null value, all of the elements of *array-expression* are deleted and the cardinality of the result array value is 0.

- If only *array-index1* is specified with a non-null value, the array element at index value *array-index1* is deleted.
- If *array-index2* is also specified with a non-null value, then the elements ranging from index value *array-index1* to *array-index2* (inclusive) are deleted.

The result can be null; if *array-expression* is null, the result is the null value.

Examples

1. Delete all the elements from the ordinary array variable RECENT_CALLS of array type PHONENUMBERS .

```
SETRECENT_CALLS = ARRAY_DELETE(RECENT_CALLS)
```

2. A supplier has discontinued some of their products. Delete the elements from the associative array variable FLOOR_TILES of array type PRODUCTS from index value 'PK5100' to index value 'PS2500'.

```
SETFLOOR_TILES = ARRAY_DELETE(FLOOR_TILES,'PK5100','PS2500')
```

ARRAY_FIRST

The ARRAY_FIRST function returns the minimum array index value of the array.

The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification of a parameter marker to an array type.

The data type of the result is the data type of the array index, which is INTEGER for an ordinary array. If *array-expression* is not null and the cardinality of the array is greater than zero, the value of the result is the minimum array index value, which is 1 for an ordinary array.

The result can be null; if *array-variable* is null or the cardinality of the array is zero, the result is the null value.

Examples

1. Return the first index value in the ordinary array variable SPECIALNUMBERS to the SQL variable E_CONSTIDX.

```
SET E_CONSTIDX = ARRAY_FIRST(SPECIALNUMBERS)
```

   The result is 1.

2. Given the associative array variable PHONELIST with index values and phone numbers: 'Home' is '4163053745', 'Work' is '4163053746', and 'Mom' is '416-4789683', assign the value of the minimum index in the array to the character string variable named X.

```
SET X = ARRAY_FIRST(PHONELIST)
```

   The value of 'Home' is assigned to X. Access the element value associated with index value 'Home' and assign it to the SQL variable NUMBER_TO_CALL:

```
SET NUMBER_TO_CALL = PHONELIST[X]
```

ARRAY_LAST

The ARRAY_LAST function returns the maximum array index value of the array.

The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification of a parameter marker to an array type.

The data type of the result is the data type of the array index, which is INTEGER for an ordinary array. If *array-expression* is not null and the cardinality of the array is greater than zero, the value of the result is the maximum array index value, which is the cardinality of the array for an ordinary array.

The result can be null; if array-variable is null or the cardinality of the array is zero, the result is the null value.

Examples

1. Return the last index value in the ordinary array variable SPECIALNUMBERS to the SQL variable PI_CONSTIDX.

   ```
   SET PI_CONSTIDX = ARRAY_LAST(SPECIALNUMBERS)
   ```

   The result is 10.
2. Given the associative array variable PHONELIST with index values and phone numbers: 'Home' is '4163053745', 'Work' is '4163053746', and 'Mom' is '4164789683', assign the value of the maximum index in the array to the character string variable named X.

   ```
   SET X = ARRAY_LAST(PHONELIST)
   ```

   The value of 'Work' is assigned to X. Access the element value associated with index value 'Work' and assign it to the SQL variable NUMBER_TO_CALL:

   ```
   SET NUMBER_TO_CALL = PHONELIST[X]
   ```

ARRAY_NEXT

The ARRAY_NEXT function returns the next larger array index value for an array relative to the specified array index argument.

The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification of a parameter marker to an array type.

array-index
Specifies a value that is assignable to the data type of the index of the array. Valid values include any valid value for the data type.

The result is the next larger array index value defined in the array relative to the specified *array-index* value. If *array-index* is less than the minimum index array value in the array, the result is the first array index value defined in the array.

The data type of the result of the function is the data type of the array index. The result can be null; if either argument is null, the cardinality of the first argument is zero, or the value of *array-index* is greater than or equal to the value of the last index in the array, the result is the null value.

Examples

1. Return the next index value after the 9th index position in the ordinary array variable SPECIALNUMBERS to the SQL variable NEXT_CONSTIDX.

```
SET NEXT_CONSTIDX = ARRAY_NEXT(SPECIALNUMBERS,9)
```

   The result is 10.

2. Given the associative array variable PHONELIST with index values and phone numbers: 'Home' is '4163053745', 'Work' is '4163053746', and 'Mom' is '416-4789683', assign the value of the index in the array that is the next index after index value 'Dad', which does not exist for the array value, to the character string variable named X:

```
SET X = ARRAY_NEXT(PHONELIST, 'Dad')
```

   The value of 'Home' is assigned to X, since the value 'Dad' is a value smaller than any index value for the array variable. Assign the value of the index in the array that is the next index after index value'Work':

```
SET X = ARRAY_NEXT(PHONELIST, 'Work')
```

   The null value is assigned to X.

ARRAY_PRIOR

The ARRAY_PRIOR function returns the next smaller array index value for an array relative to the specified array index argument.

The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification of a parameter marker to an array type.

array-index
Specifies a value that is assignable to the data type of the index of the array. Valid values include any valid value for the data type.

The result is the next smaller array index value defined in the array relative to the specified *array-index* value. If *array-index* is greater than the maximum index array value in the array, the result is the last array index value defined in the array.

The data type of the result of the function is the data type the array index. The result can be null; if either argument is null, the cardinality of the first argument is zero, or the value of *array-index* is less than or equal to the value of the first index in the array, the result is the null value.

Examples

1. Return the previous index value before the 2nd index position in the ordinary array variable SPECIALNUMBERS to the SQL variable PREV_CONSTIDX.

```
SET PREV_CONSTIDX = ARRAY_PRIOR(SPECIALNUMBERS,2)
```

   The result is 1.

2. Given the associative array variable PHONELIST with index values and phone numbers: 'Home' is '4163053745', 'Work' is '4163053746', and 'Mom' is '416-4789683', assign the value of the index in the array that is the previous index before index value 'Work' to the character string variable named X:

```
SET X = ARRAY_PRIOR(PHONELIST, 'Work')
```

The value of 'Mom' is assigned to X. Assign the value of the index in the array that is the previous index before index value'Home':

```
SET X = ARRAY_PRIOR(PHONELIST, 'Home')
```

The null value is assigned to X.

ASCII

The ASCII function returns the ASCII code value of the leftmost character of the argument as an integer.

The schema is SYSFUN.

expression
An expression that returns a built-in character string or Boolean value. In a Unicode database, the expression can also return a graphic string, in which case it is first converted to a character string before the function is evaluated. The maximum length is:

- 4000 bytes for a VARCHAR
- 1,048,576 bytes for a CLOB

Result

The result of the function is always INTEGER.

The result can be null; if the argument is null, the result is the null value.

ASCII_STR

The ASCII_STR function returns an ASCII version of the string.

The schema is SYSIBM.

string-expression
An expression that returns a value of a built-in character or graphic string.

A character string must not be bit data (SQLSTATE 42815).

The argument can also be a numeric data type. The numeric argument is implicitly cast to a VARCHAR data type.

ASCII_STR returns an ASCII version of the string. Non-ASCII characters are converted to UTF-16 characters and appear in the result in the form of *xxxx* (or *xxxx**yyyy* for surrogate characters), where *xxxx* and *yyyy* represent a UTF-16 code unit. A backslash in a string-expression is converted to a double backslash.

The string unit of the result is OCTETS.

The length attribute of the result is MIN((5**n*),32672), where *n* is determined as follows:

- If a string-expression has the string units OCTETS or CODEUNITS16, *n* is the length attribute of the input string.
- If a string-expression has the string units CODEUNITS32, *n* is twice the length attribute of the input string.

Result

The result of the function is a varying-length character string.

If the actual length of the result string exceeds the maximum for the return type, an error occurs(SQLSTATE 54006).

If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Notes

As a syntax alternative, you can specify ASCIISTR as a synonym for ASCII_STR.

The following example returns the ASCII string equivalent of the Unicode (UTF-8) string, '4869206D616D6520697320D090D0BDD0B4D180D0B5D0B9202020F0908080':

```
SET :HV1 = ASCII_STR(X'4869206D616D6520697320D090D0BDD0B4D180D0B5D0B9202020F0908080');
```

:HV1 is assigned the value 'Hi, my name is \0410\043D\0434\0440\0435\0439 \D800\DC00'.

In this example, the UTF-8 characters D090, D0BD, D0B4, D180, D0B5, and D0B9 are converted to \0410\043D\0434\0440\0435\0439, and the non-ASCII character F0908080 is converted to \D800\DC00.

```
SET :HV1 = ASCII_STR('Hi, my name is Андрей(Andrei)');
```

:HV1 is assigned the value "Hi, my name is \0410\043D\0434\0440\0435\0439 (Andrei)"

ASIN

Returns the arcsine on the argument as an angle expressed in radians.

The schema is SYSIBM. (The SYSFUN version of the ASIN function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

The result of the function is a double-precision floating-point number. The result can be null if the argument can be null or the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

ATAN

Returns the arctangent of the argument as an angle expressed in radians.

The schema is SYSIBM. (The SYSFUN version of the ATAN function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

The result of the function is a double-precision floating-point number. The result can be null if the argument can be null or the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

ATAN2

Returns the arctangent of x and y coordinates as an angle expressed in radians. The x and y coordinates are specified by the first and second arguments, respectively.

The schema is SYSIBM. (The SYSFUN version of the ATAN2 function continues to be available.)

expression1
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

expression2
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

The result of the function is a double-precision floating-point number. The result can be null if the argument can be null or the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

ATANH

Returns the hyperbolic arctangent of the argument, where the argument is an angle expressed in radians.

The schema is SYSIBM.

expression
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

The result of the function is a double-precision floating-point number. The result can be null if the argument can be null or the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

BIGINT

The BIGINT function returns a big integer (a binary integer with a precision of 63 bits) representation of a value of a different data type.

Numeric to BIGINT

String to BIGINT

Datetime to BIGINT

Boolean to BIGINT

The schema is SYSIBM.

Numeric to BIGINT

numeric-expression
An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a big integer column or variable. The fractional part of the argument is truncated. If the whole part of the argument is not within the range of big integers, an error is returned (SQLSTATE 22003).

String to BIGINT

string-expression
An expression that returns a value that is a character-string or Unicode graphic-string representation of a number with a length not greater than the maximum length of a character constant.

The result is the same number that would result from CAST(*string-expresssion* AS BIGINT). Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an integer, decimal, floating-point, or decimal floating-point constant (SQLSTATE 22018). If the whole part of the argument is not within the range of big integers, an error is returned (SQLSTATE 22003). The data type of *string-expresssion* must not be CLOB or DBCLOB (SQLSTATE 42884).

Datetime to BIGINT

datetime-expression
An expression that is of one of the following data types:

- DATE. The result is a BIGINT value representing the date as *yyyymmdd*.
- TIME. The result is a BIGINT value representing the time as *hhmmss*.
- TIMESTAMP. The result is a BIGINT value representing the timestamp as *yyyymmddhhmmss*. The fractional seconds portion of the timestamp value is not included in the result.

Boolean to BIGINT

boolean-expression
An expression that returns a Boolean value (TRUE or FALSE). The result is either 1 (for TRUE) or 0 (for FALSE).

Result

The result of the function is a big integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Notes

- **Increasing portability of applications:** If the first argument is numeric, or if the first argument is a string and the length argument is specified, use the "CAST specification" on page 152 instead of this function to increase the portability of your applications.

Examples

- *Example 1*: From ORDERS_HISTORY table, count the number of orders and return the result as a big integer value.

```
SELECT BIGINT (COUNT_BIG(*))
  FROM ORDERS_HISTORY
```

- *Example 2*: Using the EMPLOYEE table, select the EMPNO column in big integer form for further processing in the application.

```
SELECT BIGINT (EMPNO) FROM EMPLOYEE
```

- *Example 3*: Assume that the column RECEIVED (whose data type is TIMESTAMP) has an internal value equivalent to '1988-12-22-14.07.21.136421'.

```
BIGINT(RECEIVED)
```

results in the value 19 881 222 140 721.

- *Example 4*: Assume that the column STARTTIME (whose data type is TIME) has an internal value equivalent to '12:03:04'.

```
BIGINT(STARTTIME)
```

  results in the value 120 304.

- *Example 5*: The following statement returns the value 1 of data type BIGINT.

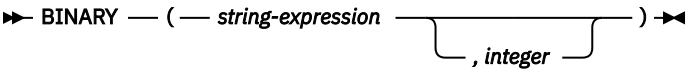
```
values BIGINT(TRUE)
```

- *Example 6*: The following statement returns the value 0 of data type BIGINT.

```
values BIGINT(3>3)
```

BINARY

The BINARY function returns a fixed-length binary string representation of a string of any data type.



The schema is SYSIBM.

string-expression
An expression that returns a value of a character string, graphic string, or binary string data type.

integer
An integer constant value, which specifies the length attribute of the resulting BINARY data type. The value must be 1 - 255. If *integer* is not specified, the length attribute of the result is the lower of the following values:

- The maximum length for the BINARY data type
- The length attribute for the data type of *string-expression* expressed in bytes:
  - The length attribute, if *string-expression* is a binary string, a character string that is FOR BIT DATA, or a character string with string units of OCTETS
  - The length attribute multiplied by 2, if *string-expression* is a graphic string with string units of CODEUNITS16 or double bytes
  - The length attribute multiplied by 4, if *string-expression* is a character or graphic string with string units of CODEUNITS32

If *string-expression* is an empty string and the *integer* argument is not specified, an error is returned (SQLSTATE 42815).

The result of the function is a BINARY. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The actual length is the same as the length attribute of the result. If the length of *string-expression* that is converted to a binary string is less than the length attribute of the result, the result is padded with hexadecimal zeros up to the length of the result. If the length of *string-expression* that is converted to a binary string is greater than the length attribute of the result, truncation occurs.

A warning (SQLSTATE 01004) is returned in the following situations:

- The first argument is a character or graphic string (other than a CLOB or DBCLOB) and non-blank characters are truncated.
- The first argument is a binary string (other than BLOB) and non-hexadecimal zeros are truncated.

Examples

1. The following function returns a fixed-length binary string with a length attribute 1 and a value BX'00'.

```
SELECT BINARY('',1)
  FROM SYSIBM.SYSDUMMY1
```

2. The following function returns a fixed-length binary string with a length attribute 5 and a value BX'4B42480000'.

```
SELECT BINARY('KBH',5)
  FROM SYSIBM.SYSDUMMY1
```

3. The following function returns a fixed-length binary string with a length attribute 3 and a value BX'4B4248'.

```
SELECT BINARY('KBH')
  FROM SYSIBM.SYSDUMMY1
```

4. The following function returns a fixed-length binary string with a length attribute 3 and a value BX'4B4248'.

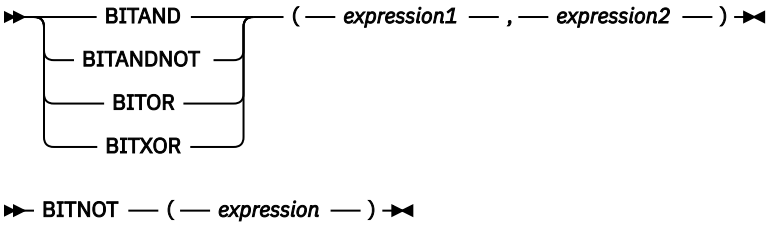
```
SELECT BINARY('KBH ',3)
  FROM SYSIBM.SYSDUMMY1
```

5. The following function returns a fixed-length binary string with a length attribute 3, a value BX'4B4248', and a warning (SQLSTATE 01004).

```
SELECT BINARY('KBH 93',3)
  FROM SYSIBM.SYSDUMMY1
```

BITAND, BITANDNOT, BITOR, BITXOR, and BITNOT

These bitwise functions operate on the "two's complement" representation of the integer value of the input arguments and return the result as a corresponding base 10 integer value in a data type based on the data type of the input arguments.



The schema is SYSIBM.

Table 54. The bit manipulation functions

Function	Description	A bit in the two's complement representation of the result is:
BITAND	Performs a bitwise AND operation.	1 only if the corresponding bits in both arguments are 1.
BITANDNOT	Clears any bit in the first argument that is in the second argument.	Zero if the corresponding bit in the second argument is 1; otherwise, the result is copied from the corresponding bit in the first argument.
BITOR	Performs a bitwise OR operation.	1 unless the corresponding bits in both arguments are zero.

Table 54. The bit manipulation functions (continued)		
Function	**Description**	**A bit in the two's complement representation of the result is:**
BITXOR	Performs a bitwise exclusive OR operation.	1 unless the corresponding bits in both arguments are the same.
BITNOT	Performs a bitwise NOT operation.	Opposite of the corresponding bit in the argument.

expression* or *expression1* or *expression2
The arguments must be integer values represented by the data types SMALLINT, INTEGER, BIGINT, or DECFLOAT. Arguments of type DECIMAL, REAL, or DOUBLE are cast to DECFLOAT. The value is truncated to a whole number.

The bit manipulation functions can operate on up to 16 bits for SMALLINT, 32 bits for INTEGER, 64 bits for BIGINT, and 113 bits for DECFLOAT. The range of supported DECFLOAT values includes integers from -2^{112} to 2^{112} -1, and special values such as NaN or INFINITY are not supported (SQLSTATE 42815). If the two arguments have different data types, the argument supporting fewer bits is cast to a value with the data type of the argument supporting more bits. This cast impacts the bits that are set for negative values. For example, -1 as a SMALLINT value has 16 bits set to 1, which when cast to an INTEGER value has 32 bits set to 1.

The result of the functions with two arguments has the data type of the argument that is highest in the data type precedence list for promotion. If either argument is DECFLOAT, the data type of the result is DECFLOAT(34). If either argument can be null, the result can be null; if either argument is null, the result is the null value.

The result of the BITNOT function has the same data type as the input argument, except that DECIMAL, REAL, DOUBLE, or DECFLOAT(16) returns DECFLOAT(34). If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Due to differences in internal representation between data types and on different hardware platforms, using functions (such as HEX) or host language constructs to view or compare internal representations of BIT function results and arguments is data type-dependent and not portable. The data type- and platform-independent way to view or compare BIT function results and arguments is to use the actual integer values.

Use of the BITXOR function is recommended to toggle bits in a value. Use the BITANDNOT function to clear bits. BITANDNOT(val, pattern) operates more efficiently than BITAND(val, BITNOT(pattern)).

Examples

The following examples are based on an ITEM table with a PROPERTIES column of type INTEGER.

- *Example 1*: Return all items for which the third property bit is set.

```
SELECT ITEMID FROM ITEM
  WHERE BITAND(PROPERTIES, 4) = 4
```

- *Example 2*: Return all items for which the fourth or the sixth property bit is set.

```
SELECT ITEMID FROM ITEM
  WHERE BITAND(PROPERTIES, 40) <> 0
```

- *Example 3*: Clear the twelfth property of the item whose ID is 3412.

```
UPDATE ITEM
    SET PROPERTIES = BITANDNOT(PROPERTIES, 2048)
  WHERE ITEMID = 3412
```

- *Example 4*: Set the fifth property of the item whose ID is 3412.

```
UPDATE ITEM
    SET PROPERTIES = BITOR(PROPERTIES, 16)
  WHERE ITEMID = 3412
```

- *Example 5*: Toggle the eleventh property of the item whose ID is 3412.

```
UPDATE ITEM
    SET PROPERTIES = BITXOR(PROPERTIES, 1024)
  WHERE ITEMID = 3412
```

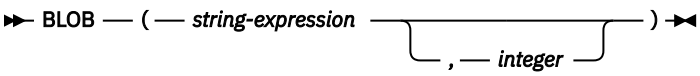
- *Example 6*: Switch all the bits in a 16-bit value that has only the second bit on.

```
VALUES BITNOT(CAST(2 AS SMALLINT))
```

returns -3 (with a data type of SMALLINT).

BLOB

The BLOB function returns a BLOB representation of a string of any type.



The schema is SYSIBM.

string-expression
An expression that returns a value of a character string, graphic string, or binary string data type.

integer
An integer value specifying the length attribute of the resulting BLOB data type. If *integer* is not specified, the length attribute of the result is the same as the length of the input, except where the input is graphic. In this case, the length attribute of the result is twice the length of the input.

The result of the function is a BLOB. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

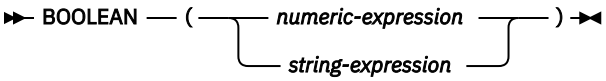
Example

Given a table with a BLOB column named TOPOGRAPHIC_MAP and a VARCHAR column named MAP_NAME, locate any maps that contain the string 'Pellow Island' and return a single binary string with the map name concatenated in front of the actual map.

```
SELECT BLOB(MAP_NAME  CONCAT ':  ') CONCAT TOPOGRAPHIC_MAP
  FROM ONTARIO_SERIES_4
  WHERE TOPOGRAPHIC_MAP LIKE BLOB('%Pellow Island%')
```

BOOLEAN

The BOOLEAN function returns the actual Boolean value that corresponds to a non-Boolean representation of a Boolean value.



The schema is SYSIBM.

numeric-expression
An expression that returns a binary integer or floating decimal value. The result is TRUE if the returned value is non-zero and FALSE if it is zero.

string-expression
An expression that returns a character-string or Unicode graphic-string representation of a Boolean value. Leading and trailing blanks are eliminated from the string before it is evaluated.

The returned string must be a valid representation of a Boolean value as described in "Boolean values" on page 41 (SQLSTATE 22018).

The result of the function is the same BOOLEAN value that would result from the expression:

```
CAST(string-expression AS BOOLEAN)
```

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

- *Example 1*: The following statement returns a value of data type BOOLEAN with the value TRUE.

```
values BOOLEAN(1)
```

- *Example 2*: The following statement returns a value of data type BOOLEAN with the value FALSE.

```
values BOOLEAN('NO')
```

- *Example 3*: The following statement returns a value of data type BOOLEAN with the value TRUE.

```
values BOOLEAN('Yes')
```

BPCHAR

The BPCHAR function returns a varying-length character string representation of a value of a different data type.

The schema is SYSIBM.

The BPCHAR scalar function is a synonym for the VARCHAR scalar function.

BSON_TO_JSON

The BSON_TO_JSON function converts a string that contains data that is formatted as BSON to a character string that contains data that is formatted as JSON.

Although the schema for this function is SYSIBM, the function cannot be specified as a qualified name.

JSON-expression
Specifies an expression that returns a binary string value. It must contain formatted BSON data (SQLSTATE 22032).

If *JSON-expression* can be null, the result can be null; if *JSON-expression* is null, the result is the null value.

Notes

- If parameter markers are not explicitly cast to a supported data type, an error is returned (SQLSTATE 42815)

Example

1. Retrieve a JSON document in string format, from a table where the data is stored in binary representation.

```
SELECT JSON_FIELD FROM TESTJSON;

JSON_FIELD
--------------------
x'16000000024E616D65000700000047656F7267650000'
```

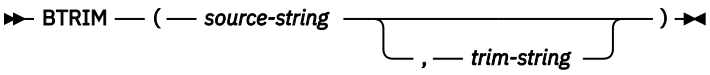
   To extract the contents of a JSON field, use the BSON_TO_JSON function.

```
SELECT BSON_TO_JSON(JSON_FIELD) FROM TESTJSON;

1
--------------------
{ "Name" : "George" }
```

BTRIM

The BTRIM function removes the characters that are specified in a trim string from the beginning and end of a source string.



The schema is SYSIBM.

This function compares the binary representation of each character (consisting of one or more bytes) in the trim-string to the binary representation of each character (consisting of one or more bytes) at the beginning and end of the source string. The database collation does not affect the search. If the string-expression is defined as FOR BIT DATA, the search compares each byte in the trim-expression to the byte at the beginning and end of the string-expression.

source-string
An expression that specifies the string from which characters are to be removed. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. If the source string is:

- A numeric, Boolean, or datetime value, it is implicitly cast to VARCHAR before the function is evaluated
- A CLOB value, the length of the value is limited to the maximum size of a VARCHAR (SQLSTATE 22001)
- A DBCLOB value, the actual length of the value is limited to the maximum size of a VARGRAPHIC (SQLSTATE 22001)

trim-string
An expression that specifies the characters that are to be removed from the beginning and end of the source string. The expression must return a built-in character string, graphic string, numeric value, or datetime value. If the trim string is:

- Not a character string or graphic string, it is implicitly cast to VARCHAR before the function is evaluated
- A CLOB, the actual length of the value is limited to the maximum size of a VARCHAR (SQLSTATE 22001)
- A DBCLOB, the actual length of the value is limited to the maximum size of a VARGRAPHIC (SQLSTATE 22001)

The type of the source string determines the default trim string:

Type of source string	Default trim string
A graphic string in a DBCS or EUC database	double-byte blank
A graphic string in a Unicode database	UCS-2 blank
A FOR BIT DATA string	X'20'
All other cases	single-byte blank

Restrictions:

- If the source string is not defined as FOR BIT DATA, then the trim string cannot be defined as FOR BIT DATA (SQLSTATE 42815).
- If one parameter (source string or trim string) is character FOR BIT DATA, then the other parameter cannot be a graphic (SQLSTATE 42846).
- A combination of character string and graphic string arguments can be used only in a Unicode database (SQLSTATE 42815).

Result

The data type of the source string determines the data type of the result:

Data type of source string	Data type of result
VARCHAR or CHAR	VARCHAR
CLOB	CLOB
VARGRAPHIC or GRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB

The length attribute of the data type of the result is the same as the length attribute of the data type of the source string. The length of the result is the length of the source string minus the number of string units that were removed. If all of the characters are removed, the result is an empty string with a length of zero.

If any argument can be null, the result can be null. If any argument is null, the result is the null value.

Example

The host variable BALANCE1 is of type CHAR(9) and has the value `'000345.50'`. The following statement returns the value `'345.5'`:

```
SELECT BTRIM(:BALANCE1, '0')
  FROM SYSIBM.SYSDUMMY1
```

The host variable BALANCE2 is of type CHAR(9) and has the value `'  345.50'`. The following statement returns the value `'345.50'`.

```
SELECT BTRIM(:BALANCE2)
  FROM SYSIBM.SYSDUMMY1
```

CARDINALITY

The CARDINALITY function returns a value of type BIGINT representing the number of elements of an array.

The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification of a parameter marker to an array type.

Result

For an:

- Ordinary array, the returned value is the highest array index for which the array has an assigned element. This includes elements that have been assigned the null value.
- Associative array, the returned value is the actual number of unique array index values defined in the array expression.

The function returns 0 if the array is empty. The result can be null; if the argument is null, the result is the null value.

Examples

1. Return the number of calls that have been stored in the recent calls list so far:

   ```
   SET HOWMANYCALLS = CARDINALITY(RECENT_CALLS)
   ```

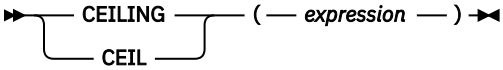
   The SQL variable HOWMANYCALLS contains the value 3.
2. Assume that the associative array variable CAPITALS of array type CAPITALSARRAY contains all of the capitals for the 10 provinces and 3 territories in Canada as well as the capital of the country, Ottawa. Return the cardinality of the array variable:

   ```
   SET NUMCAPITALS = CARDINALITY(CAPITALS)
   ```

   The SQL variable NUMCAPITALS contains the value 14.

CEILING or CEIL

Returns the smallest integer value greater than or equal to the argument.



The schema is SYSIBM. (The SYSFUN version of the CEILING function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type.

The result of the function has the same data type and length attribute as the argument except that the scale is 0 if the argument is DECIMAL. For example, an argument with a data type of DECIMAL(5,5) returns DECIMAL(5,0).

The result can be null if the argument can be null or if the argument is not a decimal floating-point number and the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

Notes

- **Results involving DECFLOAT special values:** For decimal floating-point values, the special values are treated as follows:
  - CEILING(NaN) returns NaN.
  - CEILING(-NaN) returns -NaN.
  - CEILING(Infinity) returns Infinity.
  - CEILING(-Infinity) returns -Infinity.

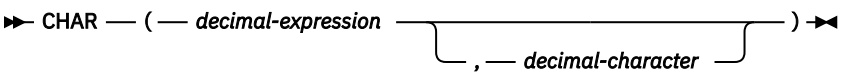
– CEILING(sNaN) returns NaN and a warning.
– CEILING(-sNaN) returns -NaN and a warning.

CHAR

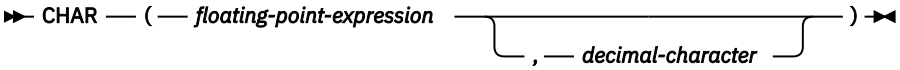
The CHAR function returns a fixed-length character string representation of a value of a different data type.

Integer to CHAR

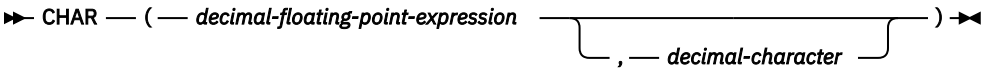
Decimal to CHAR



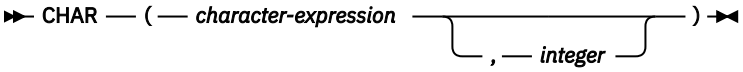
Floating-point to CHAR



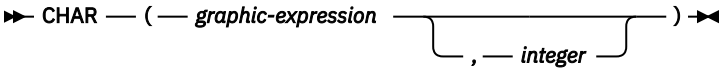
Decimal floating-point to CHAR



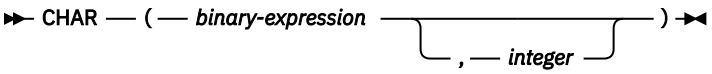
Character string to CHAR



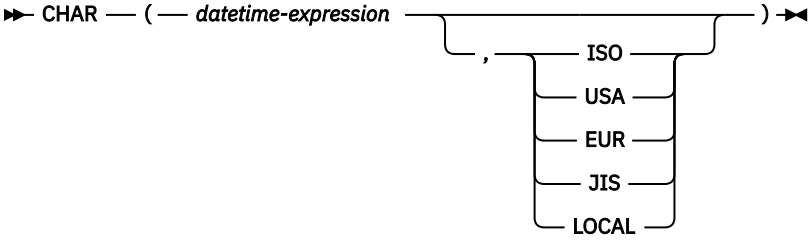
Graphic string to CHAR



Binary string to CHAR



Datetime to CHAR



Boolean to CHAR

The schema is SYSIBM. The function name cannot be specified as a qualified name when keywords are used in the function signature. The SYSFUN.CHAR(*floating-point-expression*) signature continues to be available. In this case, the decimal character is locale sensitive, and therefore returns either a period or a comma, depending on the locale of the database server.

Integer to CHAR

integer-expression
An expression that returns a value that is of an integer data type (SMALLINT, INTEGER, or BIGINT).

The result is a fixed-length character string representation of *integer-expression* in the form of an SQL integer constant. The result consists of *n* characters, which represent the significant digits in the argument, and is preceded by a minus sign if the argument is negative. The result is left-aligned. If the data type of the first argument is:

- SMALLINT, the length of the result is 6
- INTEGER, the length of the result is 11
- BIGINT, the length of the result is 20

If the number of bytes in the result is less than the defined length of the result, the result is padded on the right with single-byte blanks.

The code page of the result is the code page of the section.

Decimal to CHAR

decimal-expression
An expression that returns a value that is a decimal data type. If a different precision and scale are required, the DECIMAL scalar function can be used first to make the change.

decimal-character
Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character constant cannot be a digit, the plus sign (+), the minus sign (-), or a blank (SQLSTATE 42815). The default is the period (.) character.

The result is a fixed-length character string representation of *decimal-expression* in the form of an SQL decimal constant. The length of the result is 2+*p*, where *p* is the precision of *decimal-expression*. Leading zeros are not included. Trailing zeros are included. If *decimal-expression* is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the decimal character. If the scale of *decimal-expression* is zero, the decimal character is not returned. If the number of bytes in the result is less than the defined length of the result, the result is padded on the right with single-byte blanks.

The code page of the result is the code page of the section.

Floating-point to CHAR

floating-point-expression
An expression that returns a value that is a floating-point data type (DOUBLE or REAL).

decimal-character
Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character constant cannot be a digit, the plus sign (+), the minus sign (-), or a blank (SQLSTATE 42815). The default is the period (.) character.

The result is a fixed-length character string representation of *floating-point-expression* in the form of an SQL floating-point constant. The length of the result is 24. The result is the smallest number of characters that can represent the value of *floating-point-expression* such that the mantissa consists of a single digit other than zero followed by a period and a sequence of digits. If *floating-point-expression* is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If

floating-point-expression is zero, the result is 0E0. If the number of bytes in the result is less than 24, the result is padded on the right with single-byte blanks.

The code page of the result is the code page of the section.

Decimal floating-point to CHAR

decimal-floating-point-expression
An expression that returns a value that is a decimal floating-point data type (DECFLOAT).

decimal-character
Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character constant cannot be a digit, the plus sign (+), the minus sign (-), or a blank (SQLSTATE 42815). The default is the period (.) character.

The result is a fixed-length character string representation of *decimal-floating-point-expression* in the form of an SQL decimal floating-point constant. The length attribute of the result is 42. The result is the smallest number of characters that can represent the value of *decimal-floating-point-expression*. If *decimal-floating-point-expression* is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If *decimal-floating-point-expression* is zero, the result is 0.

If the value of *decimal-floating-point-expression* is the special value Infinity, sNaN, or NaN, the strings 'INFINITY', 'SNAN', and 'NAN', respectively, are returned. If the special value is negative, the first character of the result is a minus sign. The decimal floating-point special value sNaN does not result in warning when converted to a string. If the number of characters in the result is less than 42, the result is padded on the right with single-byte blanks.

The code page of the result is the code page of the section.

Character string to CHAR

character-expression
An expression that returns a value that is a built-in character string data type.

integer
An integer constant that specifies the length attribute for the resulting fixed-length character string. The value must be between 0 and the maximum length for the CHAR data type in the string units of the result.

If the second argument is not specified:

- If the *character-expression* is the empty string constant, the length attribute of the result is 0.
- Otherwise, the length attribute of the result is the lower of the following values:
  - The maximum length for the CHAR data type in the string units of the result
  - The length attribute of the first argument.

The result is a fixed-length character string. If *character-expression* is FOR BIT DATA, the result is FOR BIT DATA.

The length of the result is the same as the length attribute of the result. If the length of *character-expression* is:

- Less than the length attribute of the result, the result is padded with blanks up to the length attribute of the result
- Greater than the length attribute of the result:
  - If the string unit of the result is CODEUNITS32, truncation is performed. If only blank characters are truncated and *character-expression* is CHAR or VARCHAR, no warning is returned. Otherwise, a warning is returned (SQLSTATE 01004).
  - If *integer* is specified, truncation is performed. If only blank characters are truncated and *character-expression* is CHAR or VARCHAR, no warning is returned. Otherwise, a warning is returned (SQLSTATE 01004). When part of a multi-byte character is truncated, that partial character is replaced with the blank character. Do not rely on this behavior because it might change in a future release.

- If *integer* is not specified and *character-expression* is VARCHAR, truncation behavior is:
  - If only blank characters must be truncated, truncation is performed with no warning returned.
  - If non-blank characters must be truncated, an error is returned (SQLSTATE 22001).
- If *integer* is not specified and *character-expression* is CLOB, an error is returned (SQLSTATE 22001).

Graphic string to CHAR

graphic-expression
An expression that returns a value that is a built-in graphic string data type.

integer
An integer constant that specifies the length attribute for the resulting fixed-length character string. The value must be between 0 and the maximum length for the CHAR data type in the string units of the result.

If the second argument is not specified:

- If the *graphic-expression* is the empty string constant, the length attribute of the result is 0.
- If the string units of *graphic-expression* is CODEUNITS32, the length attribute of the result is the lower of the following values:
  - The maximum length for the CHAR data type in the string units of the result.
  - The length attribute of the first argument.
- Otherwise, the length attribute of the result is the lower of the following values:
  - The maximum length for the CHAR data type in the string units of the result.
  - 3 * length attribute of the first argument.

The result is a fixed-length character string that is converted from *graphic-expression*. The length of the result is the same as the length attribute of the result.

If the length of *graphic-expression* that is converted to a character string is:

- Less than the length attribute of the result, the result is padded with blanks up to the length attribute of the result.
- Greater than the length attribute of the result:
  - If the string unit of the result is CODEUNITS32, truncation is performed. If only blank characters are truncated and *graphic-expression* is GRAPHIC or VARGRAPHIC, no warning is returned. Otherwise, a warning is returned (SQLSTATE 01004).
  - If *integer* is specified and *graphic-expression* is a GRAPHIC or VARGRAPHIC, truncation is performed with no warning returned.
  - If *integer* is specified and graphic-expression is a DBCLOB, truncation is performed with a warning returned (SQLSTATE 01004).
  - If *integer* is not specified, an error is returned (SQLSTATE 22001).

Binary string to CHAR

binary-expression
An expression that returns a value that is a built-in binary string data type.

integer
An integer constant that specifies the length attribute for the resulting fixed-length character string.

The result is a fixed-length FOR BIT DATA character string, padded with blanks if necessary.

Datetime to CHAR

datetime-expression
An expression that is of one of the following data types:

DATE
The result is the character string representation of the date in the format specified by the second argument. The length of the result is 10. An error is returned if the second argument is specified and is not a valid value (SQLSTATE 42703).

TIME
The result is the character string representation of the time in the format specified by the second argument. The length of the result is 8. An error is returned if the second argument is specified and is not a valid value (SQLSTATE 42703).

TIMESTAMP
The result is the character string representation of the timestamp. If the data type of *datetime-expression* is TIMESTAMP(0), the length of the result is 19. If the data type of *datetime-expression* is TIMESTAMP(*n*), where *n* is between 1 and 12, the length of the result is 20+*n*. Otherwise, the length of the result is 26. The second argument is not applicable and must not be specified (SQLSTATE 42815).

The code page of the result is the code page of the section.

Boolean to CHAR

boolean-expression
An expression that returns a Boolean value (TRUE or FALSE). The result is either 'TRUE ' (note the blank after the E) or 'FALSE'.

Result

The CHAR function returns a fixed-length character string representation of:

- An integer number, if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number, if the first argument is a decimal number
- A double-precision floating-point number, if the first argument is a DOUBLE or REAL
- A decimal floating-point number, if the first argument is a DECFLOAT
- A character string, if the first argument is any type of character string
- A graphic string (Unicode databases only), if the first argument is any type of graphic string
- A datetime value, if the first argument is a DATE, TIME, or TIMESTAMP
- A Boolean value (TRUE or FALSE)

In a non-Unicode database, the string units of the result is OCTETS. Otherwise, the string units of the result are determined by the data type of the first argument.

- OCTETS, if the first argument is character string or a graphic string with string units of OCTETS, CODEUNITS16, or double bytes.
- CODEUNITS32, if the first argument is character string or a graphic string with string units of CODEUNITS32.
- Determined by the default string unit of the environment, if the first argument is not a character string or a graphic string.

In a Unicode database, when the output string is truncated part-way through a multiple-byte character:

- If the input was a character string, the partial character is replaced with one or more blanks
- If the input was a graphic string, the partial character is replaced by the empty string

Do not rely on either of these behaviors because they might change in a future release.

If the first argument can be null, the result can be null. If the first argument is null, the result is the null value.

Notes

- **Increasing portability of applications:** If the first argument is numeric, or if the first argument is a string and the length argument is specified, use the "CAST specification" on page 152 instead of this function to increase the portability of your applications.
- **Decimal to character and leading zeros**: In versions previous to version 9.7, the result for decimal input to this function includes leading zeros and a trailing decimal character. The database configuration parameter *dec_to_char_fmt* can be set to "V95" to have this function return the version 9.5 result for decimal input. The default value of the *dec_to_char_fmt* database configuration parameter for new databases is "NEW", which has this function return results which match the SQL standard casting rules and is consistent with results from the VARCHAR function.

Examples

- *Example 1*: Assume that the PRSTDATE column has an internal value equivalent to 1988-12-25. The following function returns the value '12/25/1988'.

```
CHAR(PRSTDATE, USA)
```

- *Example 2*: Assume that the STARTING column has an internal value equivalent to 17:12:30, and that the host variable HOUR_DUR (decimal(6,0)) is a time duration with a value of 050000 (that is, 5 hours). The following function returns the value '5:12 PM'.

```
CHAR(STARTING, USA)
```

  The following function returns the value '10:12 PM'.

```
CHAR(STARTING + :HOUR_DUR, USA)
```

- *Example 3*: Assume that the RECEIVED column (TIMESTAMP) has an internal value equivalent to the combination of the PRSTDATE and STARTING columns. The following function returns the value '1988-12-25-17.12.30.000000'.

```
CHAR(RECEIVED)
```

- *Example 4*: The LASTNAME column is defined as VARCHAR(15). The following function returns the values in this column as fixed-length character strings that are 10 bytes long. LASTNAME values that are more than 10 bytes long (excluding trailing blanks) are truncated and a warning is returned.

```
SELECT CHAR(LASTNAME,10) FROM EMPLOYEE
```

- *Example 5*: The EDLEVEL column is defined as SMALLINT. The following function returns the values in this column as fixed-length character strings. An EDLEVEL value of 18 is returned as the CHAR(6) value '18' followed by four blanks.

```
SELECT CHAR(EDLEVEL) FROM EMPLOYEE
```

- *Example 6*: The SALARY column is defined as DECIMAL with a precision of 9 and a scale of 2. The current value (18357.50) is to be displayed with a comma as the decimal character (18357,50). The following function returns the value '18357,50' followed by three blanks.

```
CHAR(SALARY, ',')
```

- *Example 7*: Values in the SALARY column are to be subtracted from 20000.25 and displayed with the default decimal character. The following function returns the value '-0001642.75' followed by three blanks.

```
CHAR(20000.25 - SALARY)
```

- *Example 8*: Assume that the host variable SEASONS_TICKETS is defined as INTEGER and has a value of 10000. The following function returns the value '10000.00'.

```
CHAR(DECIMAL(:SEASONS_TICKETS,7,2))
```

- *Example 9*: Assume that the host variable DOUBLE_NUM is defined as DOUBLE and has a value of -987.654321E-35. The following function returns the value '-9.87654321E-33' followed by nine trailing blanks because the result data type is CHAR(24).

```
CHAR(:DOUBLE_NUM)
```

- *Example 10*: The following statement returns a string of data type CHAR with the value 'TRUE '.

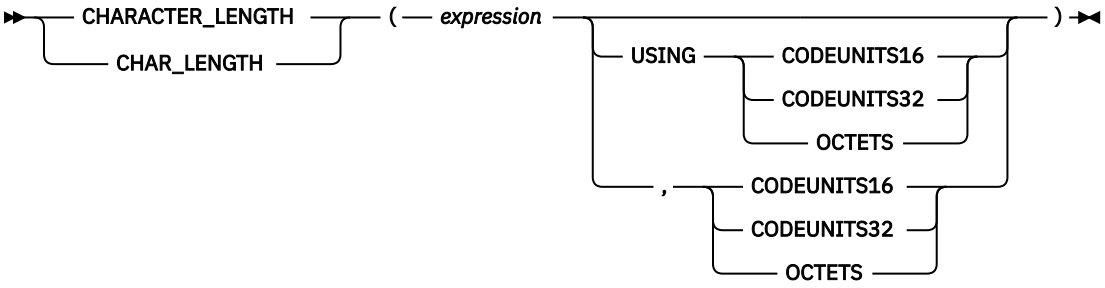
```
values CHAR(3=3)
```

- *Example 11*: The following statement returns a string of data type CHAR with the value 'FALSE'.

```
values CHAR(3>3)
```

CHARACTER_LENGTH

The CHARACTER_LENGTH function returns the length, in the specified string unit, of an expression.



The schema is SYSIBM.

expression
An expression that returns a built-in character, binary, or graphic string, or a Boolean value.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of the result:

- CODEUNITS16 specifies that the result is to be expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the result is to be expressed in 32-bit UTF-32 code units.
- OCTETS specifies that the result is to be expressed in bytes.

If a string unit is specified as CODEUNITS16 or CODEUNITS32, and *expression* is a binary string or a FOR BIT DATA string, an error is returned (SQLSTATE 428GC).

If a string unit argument is not specified and *expression* is a character string that is not FOR BIT DATA or is a graphic string, the default is CODEUNITS32. Otherwise, the default is OCTETS.

For more information, see "String units in built-in functions" in "Character strings".

Result

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The length of character and graphic strings includes trailing blanks. The length of varying-length strings is the actual length and not the maximum length.

Examples

- Assume that NAME is a VARCHAR(128) column, encoded in Unicode UTF-8, that contains the value 'Jürgen'. The following two queries return the value 6:

```
SELECT CHARACTER_LENGTH(NAME, CODEUNITS32)
FROM T1 WHERE NAME = 'Jürgen'

SELECT CHARACTER_LENGTH(NAME, CODEUNITS16)
FROM T1 WHERE NAME = 'Jürgen'
```

  The following two queries return the value 7:

```
SELECT CHARACTER_LENGTH(NAME, OCTETS)
FROM T1 WHERE NAME = 'Jürgen'

SELECT LENGTH(NAME)
FROM T1 WHERE NAME = 'Jürgen'
```

- The following examples work with the Unicode string '&N~AB', where '&' is the musical symbol G clef character, and '~' is the combining tilde character. This string is shown in different Unicode encoding forms in the following example:

	'&'	'N'	'~'	'A'	'B'
UTF-8	X'F09D849E'	X'4E'	X'CC83'	X'41'	X'42'
UTF-16BE	X'D834DD1E'	X'004E'	X'0303'	X'0041'	X'0042'
UTF-32BE	X'0001D11E'	X'0000004E'	X'00000303'	X'00000041'	X'00000042'

  Assume that the variable UTF8_VAR contains the UTF-8 representation of the string.

```
SELECT CHARACTER_LENGTH(UTF8_VAR, CODEUNITS16),
  CHARACTER_LENGTH(UTF8_VAR, CODEUNITS32),
  CHARACTER_LENGTH(UTF8_VAR, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

  returns the values 6, 5, and 9, respectively.

  Assume that the variable UTF16_VAR contains the UTF-16BE representation of the string.

```
SELECT CHARACTER_LENGTH(UTF16_VAR, CODEUNITS16),
   CHARACTER_LENGTH(UTF16_VAR, CODEUNITS32),
   CHARACTER_LENGTH(UTF16_VAR, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

  returns the values 6, 5, and 12, respectively.

CHR

Returns the character that has the ASCII code value specified by the argument.

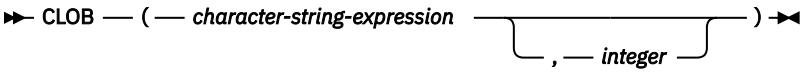
The schema is SYSFUN.

expression
An expression that returns a value of INTEGER or SMALLINT data type.

The result of the function is CHAR(1). The result can be null; if the argument is null, the result is the null value. If the argument value is between 1 and 255, the result is the character that has the ASCII code value corresponding to the argument. If the argument value is 0, the result is the blank character (X'20'). Otherwise the result is the same as CHR(255).

CLOB

The CLOB function returns a CLOB representation of a character string type.



The schema is SYSIBM.

In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string data type before the function is executed.

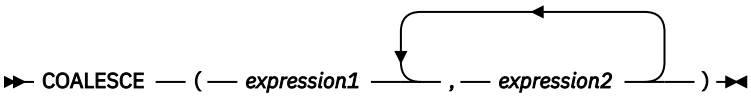
character-string-expression
An expression that returns a value that is a character string. The expression cannot be a character string defined as FOR BIT DATA (SQLSTATE 42846).

integer
An integer value specifying the length attribute of the resulting CLOB data type. If the *character-string-expression* string unit is OCTETS, the value must be between 0 and 2 147 483 647. If the *character-string-expression* string unit is CODEUNITS32, the value must be between 0 and 536 870 911. If a value for *integer* is not specified, the length of the result is the same as the length of the first argument.

The result of the function is a CLOB in the string units of *character-string-expression*. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

COALESCE

The COALESCE function returns the first non-null expression in a list of expressions.



The schema is SYSIBM.

expression1
An expression that returns a value of any built-in or user-defined data type.

expression2
An expression that returns a value of any built-in or user-defined data type and that is compatible with the data type of *expression1*. Which data types are compatible with each other is described in "Rules for result data types" on page 71.

The arguments are evaluated in the order in which they are specified, and the result of the function is the first argument that is not null. If all the arguments are null, the result is null.

Notes

- The COALESCE function cannot be used as a source function when creating a user-defined function. Because this function accepts any compatible data types as arguments, it is not necessary to create additional signatures to support user-defined data types.

Examples

- *Example 1*: When selecting all the values from all the rows in the DEPARTMENT table, if the department manager (MGRNO) is missing (that is, null), then return a value of 'ABSENT'.

```
SELECT DEPTNO, DEPTNAME, COALESCE(MGRNO, 'ABSENT'), ADMRDEPT
  FROM DEPARTMENT
```

- *Example 2*: When selecting the employee number (EMPNO) and salary (SALARY) from all the rows in the EMPLOYEE table, if the salary is missing (that is, null), then return a value of zero.

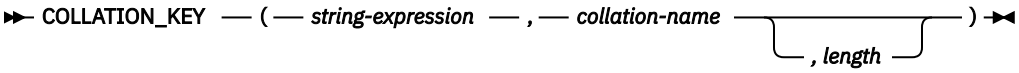
```
   SELECT EMPNO, COALESCE(SALARY, 0)
     FROM EMPLOYEE
```

- *Example 3*: In the following COALESCE statement, if the value of c1 is:
  - 5, the statement returns a value of 5
  - NULL, the statement returns a value of 10
  - 'AB', the statement returns an error, because the data types of the two expressions are incompatible

```
COALESCE(c1,10)
```

COLLATION_KEY

The COLLATION_KEY function returns a VARBINARY string that represents the collation key of the expression argument, in the specified collation.



The schema is SYSIBM.

The results of COLLATION_KEY for two strings can be binary compared to determine their order within the specified *collation-name*. For the comparison to be meaningful, the results that are used must be from the same *collation-name*.

string-expression
An expression for which the collation key is determined. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. Numeric and datetime data types are supported through implicit casting. The expression must not be a FOR BIT DATA subtype (SQLSTATE 429BM). If the expression is a CLOB, numeric, or datetime data type, the expression is cast to VARCHAR before the function is evaluated. If the expression is a DBCLOB, it is cast to VARGRAPHIC before the function is evaluated. If *string-expression* is not in UTF-16, this function converts the code page of *string-expression* to UTF-16. If the result of the code page conversion contains at least one substitution character, this function returns a collation key of the UTF-16 string with the substitution character or characters. In such cases, the warning flag SQLWARN8 in the SQLCA is set to 'W'.

collation-name
An expression that specifies the collation to use when the collation key is determined. The expression must return a value that is a CHAR or VARCHAR. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC. The expression must be a constant (SQLSTATE 428I9). The value of *collation-name* is not case-sensitive and must be one of the Unicode Collation Algorithm-based collations or language-aware collations for Unicode data (SQLSTATE 42704).

length
An expression that specifies the length attribute of the result in bytes. The expression must return a value that is a built-in numeric data type, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported through implicit casting. If the expression is not an INTEGER, it is cast to INTEGER before the function is evaluated. The value must be 1 - 32 672 (SQLSTATE 42815). The expression must be a constant (SQLSTATE 428I9).

If a value for *length* is not specified, the length of the result is determined as described in the following table:

Table 55. Determining the result length	
Data type of *string-expression*	**Result data type length**
CHAR(*n*) or VARCHAR(*n*)	Minimum of 12*n* bytes and 32 672 bytes
GRAPHIC(*n*) or VARGRAPHIC(*n*)	Minimum of 12*n* bytes and 32 672 bytes

Regardless of whether *length* is specified, if the length of the collation key is longer than the length of the result data type, an error is returned (SQLSTATE 42815). The actual result length of the collation key is approximately six times the length of *string-expression* after it is converted to UTF-16.

If *string-expression* is an empty string, the result is a valid collation key that can have a nonzero length.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

1. The following query orders employees by their surnames by using the language-aware collation for German in code page 923:

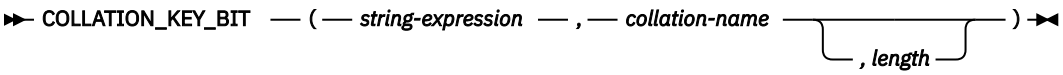
```
SELECT FIRSTNME, LASTNAME
   FROM EMPLOYEE
      ORDER BY COLLATION_KEY (LASTNAME, 'SYSTEM_923_DE')
```

2. The following query uses a culturally correct comparison to find the departments of employees in the province of Québec:

```
SELECT E.WORKDEPT
   FROM EMPLOYEE AS E INNER JOIN SALES AS S
   ON COLLATION_KEY(E.LASTNAME, 'CLDR181_LFR') =
      COLLATION_KEY(S.SALES_PERSON, 'CLDR181_LFR')
      WHERE S.REGION = 'Quebec'
```

COLLATION_KEY_BIT

The COLLATION_KEY_BIT function returns a VARCHAR FOR BIT DATA string that represents the collation key of the *string-expression* in the specified *collation-name*.



The schema is SYSIBM.

The results of COLLATION_KEY_BIT for two strings can be binary compared to determine their order within the specified *collation-name*. For the comparison to be meaningful, the results used must be from the same *collation-name*.

string-expression
An expression that returns a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC string for which the collation key should be determined. If *string-expression* is a CHAR or VARCHAR, the expression must not be FOR BIT DATA (SQLSTATE 429BM).

If *string-expression* is not in UTF-16, this function performs code page conversion of *string-expression* to UTF-16. If the result of the code page conversion contains at least one substitution character, this function returns a collation key of the UTF-16 string with the substitution character or characters and the warning flag SQLWARN8 in the SQLCA is set to 'W'.

collation-name
A character constant that specifies the collation to use when determining the collation key.

The value of *collation-name* is not case sensitive and must be one of the "Unicode Collation Algorithm-based collations" in *Globalization Guide* or "language-aware collations for Unicode data" in *Globalization Guide* (SQLSTATE 42616).

length
An expression that specifies the length attribute of the result in bytes. If specified, *length* must be an integer between 1 and 32 672 (SQLSTATE 42815).

If a value for *length* is not specified, the length of the result is determined as follows:

Table 56. Determining the result length

Data type of *string-expression*	**Result data type length**
CHAR(*n*) or VARCHAR(*n*)	Minimum of 12*n* bytes and 32 672 bytes
GRAPHIC(*n*) or VARGRAPHIC(*n*)	Minimum of 12*n* bytes and 32 672 bytes

Regardless of whether *length* is specified or not, if the length of the collation key is longer than the length of the result data type, an error is returned (SQLSTATE 42815). The actual result length of the collation key is approximately six times the length of *string-expression* after it is converted to UTF-16.

If *string-expression* is an empty string, the result is a valid collation key that can have a nonzero length.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: The following query orders employees by their family names by using the language-aware collation for German in code page 923:

```
SELECT FIRSTNME, LASTNAME
  FROM EMPLOYEE
  ORDER BY COLLATION_KEY_BIT (LASTNAME, 'SYSTEM_923_DE')
```

- *Example 2*: The following query uses a culturally correct comparison to find the departments of employees in the province of Québec:

```
SELECT E.WORKDEPT
 FROM EMPLOYEE AS E INNER JOIN SALES AS S
 ON COLLATION_KEY_BIT(E.LASTNAME, 'CLDR181_LFR') =
   COLLATION_KEY_BIT(S.SALES_PERSON, 'CLDR181_LFR')
 WHERE S.REGION = 'Quebec'
```

COMPARE_DECFLOAT

The COMPARE_DECFLOAT function returns a SMALLINT value that indicates whether the two arguments are equal or unordered, or whether one argument is greater than the other.

The schema is SYSIBM.

expression1
An expression that returns a value of any built-in numeric data type. If the argument is not DECFLOAT(34), it is logically converted to DECFLOAT(34) for processing.

expression2
An expression that returns a value of any built-in numeric data type. If the argument is not DECFLOAT(34), it is logically converted to DECFLOAT(34) for processing.

The value of *expression1* is compared with the value of *expression2*, and the result is returned according to the following rules:

- If both arguments are finite, the comparison is algebraic and follows the procedure for decimal floating-point subtraction. If the difference is exactly zero with either sign, the arguments are equal. If a nonzero difference is positive, the first argument is greater than the second argument. If a nonzero difference is negative, the first argument is less than the second.
- Positive zero and negative zero compare as equal.

- Positive infinity compares equal to positive infinity.
- Positive infinity compares greater than any finite number.
- Negative infinity compares equal to negative infinity.
- Negative infinity compares less than any finite number.
- Numeric comparison is exact. The result is determined for finite operands as if range and precision were unlimited. No overflow or underflow condition can occur.
- If either argument is NaN or sNaN (positive or negative), the result is unordered.

The result value is as follows:

- 0 if the arguments are exactly equal
- 1 if *expression1* is less than *expression2*
- 2 if *expression1* is greater than *expression2*
- 3 if the arguments are unordered

The result of the function is a SMALLINT value. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Examples

The following examples show the values that are returned by the COMPARE_DECFLOAT function, given a variety of input decimal floating-point values:

```
COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(2.17)) = 0
COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(2.170)) = 2
COMPARE_DECFLOAT(DECFLOAT(2.170), DECFLOAT(2.17)) = 1
COMPARE_DECFLOAT(DECFLOAT(2.17), DECFLOAT(0.0)) = 2
COMPARE_DECFLOAT(INFINITY,INFINITY) = 0
COMPARE_DECFLOAT(INFINITY,-INFINITY) = 2
COMPARE_DECFLOAT(DECFLOAT(-2),INFINITY) = 1
COMPARE_DECFLOAT(NAN,NAN) = 3
COMPARE_DECFLOAT(DECFLOAT(-0.1),SNAN) = 3
```

CONCAT

The CONCAT function combines two arguments to form a string expression.

The schema is SYSIBM.

expression1* or *expression2
An expression that returns a value of one of the following data types:

- Character, binary, or graphic string
- Numeric value (this is implicitly cast to VARCHAR)
- Datetime value (this is implicitly cast to VARCHAR)
- Boolean value (this is implicitly cast to VARCHAR)

The following restrictions apply:

- A binary string can be concatenated only with another binary string or with a character string that is defined as FOR BIT DATA.
- A character string and a graphic string can be concatenated only in a Unicode database. The character string is converted to a graphic string before concatenation. The character string cannot be defined as FOR BIT DATA, because such a character string cannot be cast to a graphic data string.
- If an argument is defined with CODEUNITS32, the other argument cannot be defined as FOR BIT DATA.

Result

The result of the function is a string that consists of the first argument followed by the second argument. The data type and the length of the result is determined by the data types and lengths of the arguments, after any applicable casting is done. For more information, refer to the "Data Type and Length of Concatenated Operands" table in “Expressions” on page 132.

If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Notes

- No check is made for improperly formed mixed data when doing concatenation.
- The CONCAT function is identical to the CONCAT operator. For more information, see “Expressions” on page 132.

Example

Concatenate the column FIRSTNME with the column LASTNAME.

```
SELECT CONCAT(FIRSTNME, LASTNAME)
FROM EMPLOYEE
WHERE EMPNO = '000010'
```

Returns the value "CHRISTINEHAAS".

COS

Returns the cosine of the argument, where the argument is an angle expressed in radians.

The schema is SYSIBM. (The SYSFUN version of the COS function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

The result of the function is a double-precision floating-point number. The result can be null if the argument can be null or the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

COSH

Returns the hyperbolic cosine of the argument, where the argument is an angle expressed in radians.

The schema is SYSIBM.

expression
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

The result of the function is a double-precision floating-point number. The result can be null if the argument can be null or the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

COT

Returns the cotangent of the argument, where the argument is an angle expressed in radians.

The schema is SYSIBM. (The SYSFUN version of the COT function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

The result of the function is a double-precision floating-point number. The result can be null if the argument can be null or the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

CURSOR_ROWCOUNT

The CURSOR_ROWCOUNT function returns the cumulative count of all rows fetched by the specified cursor since the cursor was opened.

The schema is SYSIBM.

cursor-variable-name
The name of a SQL variable or SQL parameter of a cursor type. The underlying cursor of the *cursor-variable-name* must be open (SQLSTATE 24501).

The result is 0 if no FETCH action on the underlying cursor of the cursor-variable-name was performed before the evaluation of the function.

This function can only be used within a compound SQL (compiled) statement.

The data type of the result is BIGINT. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

The following example shows how to use the function to retrieve the count of rows associated with the cursor *curEmp* and assign it to a variable named *rows_fetched*:

```
SET rows_fetched = CURSOR_ROWCOUNT(curEmp);
```

DATAPARTITIONNUM

The DATAPARTITIONNUM function returns the sequence number (SYSDATAPARTITIONS.SEQNO) of the data partition in which the row resides.

The schema is SYSIBM.

column-name
The qualified or unqualified name of any column in the table. Because row-level information is returned, the result is the same regardless of which column is specified. The column can have any data type.

If the column is a column of a view, the expression for the column in the view must reference a column of the underlying base table, and the view must be deletable. A nested or common table expression follows the same rules as a view.

Result

The data type of the result is INTEGER and is never null.

Data partitions are sorted by range, and sequence numbers start at 0. For example, the DATAPARTITIONNUM function returns 0 for a row that resides in the data partition with the lowest range.

Notes

- This function cannot be used as a source function when creating a user-defined function. Because the function accepts any data type as an argument, it is not necessary to create additional signatures to support user-defined distinct types.
- The DATAPARTITIONNUM function cannot be used within check constraints or in the definition of generated columns (SQLSTATE 42881). The DATAPARTITIONNUM function cannot be used in a materialized query table (MQT) definition (SQLSTATE 428EC).
- The DATAPARTITIONNUM function cannot be used as part of an expression-based key in a CREATE INDEX statement.

Examples

- *Example 1:* Retrieve the sequence number of the data partition in which the row for EMPLOYEE.EMPNO resides.

```
SELECT DATAPARTITIONNUM (EMPNO)
FROM EMPLOYEE
```

- *Example 2:* To convert a sequence number that is returned by DATAPARTITIONNUM (for example, 0) to a data partition name that can be used in other SQL statements (such as ALTER TABLE...DETACH PARTITION), you can query the SYSCAT.DATAPARTITIONS catalog view. Include the SEQNO obtained from DATAPARTITIONNUM in the WHERE clause, as shown in the following example.

```
SELECT DATAPARTITIONNAME
FROM SYSCAT.DATAPARTITIONS
WHERE TABNAME = 'EMPLOYEE' AND SEQNO = 0
```

  results in the value 'PART0'.

DATE

The DATE function returns a date from a value.

The schema is SYSIBM.

The special behavior of DATE with the Db2 compatibility features for Oracle applications is described in DATE data type based on TIMESTAMP(0).

expression
An expression that returns a value of one of the following built-in data types: DATE, TIMESTAMP, numeric, or character string that is not a CLOB.

A value with a numeric data type must be a positive number with an integral value less than or equal to 3 652 059.

A character string must be a valid string representation of a date or timestamp or a string of length 7. If the value is a string of length 7, it must represent a valid date in the form *yyyynnn* , where *yyyy* are digits denoting a year, and *nnn* are digits between 001 and 366, denoting a day of that year.

In a Unicode database, if an expression returns a value of a graphic string data type, the value is first converted to a character string before the function is executed.

The result of the function is a DATE. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a DATE, TIMESTAMP, or valid string representation of a date or timestamp:
  - The result is the date part of the value.
- If the argument is a number:
  - The result is the date that is *n*-1 days after January 1, 0001, where *n* is the integral part of the number.
- If the argument is a string with a length of 7:
  - The result is the date represented by the string.

Examples

Assume that the column RECEIVED (whose data type is TIMESTAMP) has an internal value equivalent to '1988-12-25-17.12.30.000000'.

- *Example 1*: This example results in an internal representation of '1988-12-25'.

```
DATE(RECEIVED)
```

- *Example 2*: This example results in an internal representation of '1988-12-25'.

```
DATE('1988-12-25')
```

- *Example 3*: This example results in an internal representation of '1988-12-25'.

```
DATE('25.12.1988')
```

- *Example 4*: This example results in an internal representation of '0001-02-04'.

```
DATE(35)
```

DATETIME

The DATETIME function returns a timestamp from a value or a pair of values.

The schema is SYSIBM.

The DATETIME scalar function is a synonym for the TIMESTAMP scalar function.

DATE_PART

The DATE_PART function returns a portion of a datetime based on its arguments. It extracts the subfield that is specified from the date, time, timestamp, and duration values.

The schema is SYSIBM.

format-string

An expression that represents which unit of datetime is to be extracted from the *date-expression*. The expression that returns a built-in character string data type with an actual length that is not greater than 255 bytes. The format element in *format-string* specifies how the datetime-expression should be truncated. Leading and trailing blanks are removed from the string, and the resulting substring must

be a valid format element for the type of *datetime-expression* (SQLSTATE 22007). Table 57 on page 317 lists the allowable values for *format-string*.

datetime-expression
An expression that specifies the datetime value from which the unit specified by *format-string* is extracted. The expression must return a value that is a DATE, TIME, TIMESTAMP, date duration, time duration, or timestamp duration.

Table 57. Allowable values for format-string

format-string	**Description**
EPOCH	
MILLENNIUM/ MILLENNIUMS	
CENTURY/CENTURIES	
DECADE/DECADES	
YEAR/YEARS	
QUARTER	
MONTH/MONTHS	
WEEK	
DAY/DAYS	
DOW	
DOY	
HOUR/HOURS	
MINUTE/MINUTES	
SECOND/SECONDS	
MILLISECOND/ MILLISECONDS	
MICROSECOND/ MICROSECONDS	

The format-string values are case insensitive.

The data type of the result of this function is BIGINT. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

- *Example 1*: Extracting the day part from a date value.

```
values DATE_PART('DAY', DATE('2007-02-18'));
    Result: 18
```

- *Example 2*: Extracting the year part from a date duration.

```
values DATE_PART('YEAR', cast(20130710 as decimal(8,0)));
    Result: 2013
```

- *Example 3*: Extracting the hour part from a time duration.

```
values DATE_PART('HOUR', cast(075559 as decimal(6,0)));
    Result: 7
```

DATE_TRUNC

THE DATE_TRUNC function truncates a date, time, or timestamp value to the specified time unit.

The schema is SYSIBM.

format-string

An expression that returns a character string that does not exceed 255 bytes and that, after all leading and trailing blanks are removed, is one of the character strings listed in Table 58 on page 318. The resulting substring must be a valid format element for the type of the specified datetime expression (SQLSTATE 22007). For example, a DATE value cannot be truncated to its first hour, minute, or second, and a TIME value cannot be truncated to the first day of its year.

datetime-expression

An expression that returns a DATE, TIME, or TIMESTAMP value, or a DECIMAL value representing a date, time, or timestamp duration. String representations of these data types must be explicitly cast to a DATE, TIME, TIMESTAMP, or DECIMAL value. For more information about durations, see "Datetime operations and durations" on page 145.

Table 58. Allowed values for a format string

If the format string is...	the datetime expression is truncated to the...	For example...	is truncated to...
'MILLENNIUM' or 'MILLENNIUMS'	First day of its millennium	1999-02-14	1000-01-01
'CENTURY' or 'CENTURIES'	First day of its century	1999-02-14	1900-01-01
'DECADE' or 'DECADES'	First day of its decade	1999-02-14	1990-01-01
'YEAR' or 'YEARS'	First day of its year	1999-02-14	1999-01-01
'QUARTER'	First day of its quarter	2017-05-14 20:38:40.24	2017-04-01 00:00:00
'MONTH' or 'MONTHS'	First day of its month	2017-05-14 20:38:40.24	2017-05-01 00:00:00
'WEEK'	First day of its week	2017-05-14 20:38:40.24	2017-05-08 00:00:00
'DAY' or 'DAYS'	Beginning of its day	2017-05-14 20:38:40.24	2017-05-14 00:00:00
'HOUR' or 'HOURS'	Beginning of its hour	2017-05-14 20:38:40.24	2017-05-14 20:00:00
'MINUTE' or 'MINUTES'	Beginning of its minute	20:38:40.24576985	20:38:00

Table 58. Allowed values for a format string (continued)			
If the format string is...	**the datetime expression is truncated to the...**	**For example...**	**is truncated to...**
'SECOND' or 'SECONDS'	Beginning of its second	20:38:40.24576985	20:38:40
'MILLISECOND' or 'MILLISECONDS'	Beginning of its millisecond	20:38:40.24576985	20:38:40.245
'MICROSECOND' or 'MICROSECOND'	Beginning of its microsecond	20:38:40.24576985	20:38:40.245769

The format-string values are case insensitive.

Result

If the specified datetime expression is:

- A DATE or TIMESTAMP value, the result is a TIMESTAMP value
- A TIME value, the result is a TIME value
- A DECIMAL value representing a date, time, or timestamp duration, the result is a DECIMAL value of the same type

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

- *Example 1*: Truncate a DATE value to the beginning of the month.

```
values date_trunc('MONTH', DATE('2007-02-18'))
      Result: 2007-02-01 00:00:00
```

- *Example 2*: Truncate a TIMESTAMP value to the beginning of the hour.

```
values date_trunc('HOUR', TIMESTAMP('2017-02-14 20:38:40.24'));
     Result: 2017-02-14 20:00:00
```

- *Example 3*: Truncate a TIME value to the beginning of the minute.

```
 values date_trunc('MINUTE', TIME('20:38:40'));
     Result: 20:38:00
```

- *Example 4*: A date duration has the data type DECIMAL(8,0). For example, the value 00200203 represents a duration of 20 years, 2 months, and 3 days. Truncate a date duration to the beginning of the month.

```
db2 "values date_trunc('MONTH', cast ('00200203' AS DECIMAL(8,0)))"

1
----------
   200200.

  1 record(s) selected.
```

- *Example 5*: A time duration has the data type DECIMAL(6,0). For example, the value 102930 represents a duration of 10 hours, 29 minutes, and 30 seconds. Truncate a time duration to the beginning of the minute.

```
db2 "values date_trunc('MINUTE',  cast ('102930' AS DECIMAL(6,0)))"

1
--------
 102900.

  1 record(s) selected.
```

- *Example 6*: A timestamp duration has the data type DECIMAL(14+s,*s*), where *s* is the timestamp precision. For example, the DECIMAL(20,6) value 00070005032040.000301 represents a duration of 7 years, 0 months, 5 days, 3 hours, 20 minutes, and 40.000301 seconds. Truncate a timestamp duration to the beginning of the hour.

```
db2 "values date_trunc('HOUR', cast ('00070005032040.000301' AS DECIMAL(15,1)))"

1
-----------------
    70005030000.0

  1 record(s) selected.
```

DAY

The DAY function returns the day part of a value.

The schema is SYSIBM.

expression
An expression that returns a value of one of the following built-in data types: DATE, TIMESTAMP, numeric, or character string that is not a CLOB.

If the value is a number, it must be a date duration or timestamp duration (SQLSTATE 42815).

If the value is a character string, it must be a valid string representation of a date or timestamp. In a Unicode database, if the value is a graphic string (except DBCLOB), it is first converted to a character string before the function is executed.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a DATE, TIMESTAMP, or valid string representation of a date or timestamp:
  - The result is the day part of the value, which is an integer between 1 and 31.
- If the argument is a date duration or timestamp duration:
  - The result is the day part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

Examples

- *Example 1*: Using the PROJECT table, set the host variable END_DAY (smallint) to the day that the WELD LINE PLANNING project (PROJNAME) is scheduled to stop (PRENDATE).

```
SELECT DAY(PRENDATE)
  INTO :END_DAY
  FROM PROJECT
  WHERE PROJNAME = 'WELD LINE PLANNING'
```

Results in END_DAY being set to 15 when using the sample table.

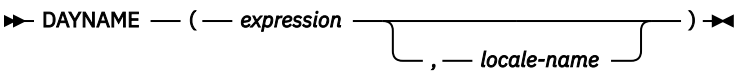
- *Example 2*: Assume that the column DATE1 (whose data type is DATE) has an internal value equivalent to 2000-03-15 and the column DATE2 (whose data type is DATE) has an internal value equivalent to 1999-12-31.

```
DAY(DATE1 - DATE2)
```

Results in the value 15.

DAYNAME

The DAYNAME function returns a character string containing the name of the day (for example, Friday) for the day portion of the input value.



The schema is SYSIBM. The SYSFUN version of the DAYNAME function continues to be available

The character string returned is based on *locale-name* or the value of the special register CURRENT LOCALE LC_TIME.

expression
An expression that returns a value of one of the following built-in data types: a DATE, TIMESTAMP, or a valid character string representation of a date or timestamp that is not a CLOB. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

locale-name
A character constant that specifies the locale used to determine the language of the result. The value of *locale-name* is not case-sensitive and must be a valid locale (SQLSTATE 42815). For information about valid locales and their naming, see "Locale names for SQL and XQuery". If *locale-name* is not specified, the value of the special register CURRENT LOCALE LC_TIME is used.

The result is a varying-length character string. The length attribute is 100. If the resulting string exceeds the length attribute of the result, the result will be truncated. If the *expression* argument can be null, the result can be null; if the *expression* argument is null, the result is the null value. The code page of the result is the code page of the section. The string units of the result is determined by the string units of the environment

Notes

- **Julian and Gregorian calendar**: The transition from the Julian calendar to the Gregorian calendar on 15 October 1582 is taken into account by this function. However, the SYSFUN version of the DAYNAME function assumes the Gregorian calendar for all calculations.
- **Determinism**: DAYNAME is a deterministic function. However, when *locale-name* is not explicitly specified, the invocation of the function depends on the value of the special register CURRENT LOCALE LC_TIME. This invocation that depends on the value of a special register cannot be used wherever special registers cannot be used (SQLSTATE 42621, 428EC, or 429BX).

Example

Assume that the variable TMSTAMP is defined as TIMESTAMP and has the following value: 2007-03-09-14.07.38.123456. The following examples show several invocations of the function and the resulting string values. The result type in each case is VARCHAR(100).

```
Function invocation                          Result
--------------------------                   ----------
DAYNAME (TMSTAMP, 'CLDR181_en_US')           Friday
DAYNAME (TSMTAMP, 'CLDR181_de_DE')           Freitag
DAYNAME (TMSTAMP, 'CLDR181_fr_FR')           vendredi
```

DAYOFMONTH

The DAYOFMONTH function returns an integer between 1 and 31 that represents the day of the month.

The schema is SYSIBM.

expression
An expression that specifies the datetime value from which the day of the month is determined. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

The result of the function is an INTEGER. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

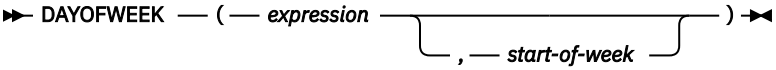
Set the host variable END_DAY to the day that the WELD LINE PLANNING project is scheduled to stop, by querying the PRENDATE column of the PROJECT table.

```
SELECT DAYOFMONTH(PRENDATE) INTO :END_DAY
   FROM PROJECT WHERE PROJNAME = 'WELD LINE PLANNING'
```

The host variable END_DAY is set to 15.

DAYOFWEEK

The DAYOFWEEK function returns the day of the week in the first argument as an integer value. The integer value is in the range 1-7, where 1 represents the first day of the week, as specified in the second argument.



The schema is SYSIBM. The SYSFUN version of the DAYOFWEEK function continues to be available.

expression
An expression that specifies the datetime value from which the day of the week is determined. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. If *expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string representation of a date or timestamp.

start-of-week
An expression that specifies the starting day of the week. The expression must return a value that is a built-in numeric, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. The value must be in the range 1 - 7 (SQLSTATE 42815), where 1 represents Sunday. If not specified, the default value is 1.

The result of the function is INTEGER. If any argument can be null, the result can be null; if any argument is null, the result is the null value.

DAYOFWEEK_ISO

Returns the day of the week in the argument as an integer value in the range 1-7, where 1 represents Monday.

The schema is SYSFUN.

expression
An expression that returns a value of one of the following built-in data types: a DATE, TIMESTAMP, or a valid character string representation of a date or timestamp that is not a CLOB. In a Unicode database, if a supplied argument is a graphic string (except DBCLOB), it is first converted to a character string before the function is executed.

The result of the function is INTEGER. The result can be null; if the argument is null, the result is the null value.

DAYOFYEAR

Returns the day of the year in the argument as an integer value in the range 1-366.

The schema is SYSFUN.

expression
An expression that returns a value of one of the following built-in data types: a DATE, TIMESTAMP, or a valid character string representation of a date or timestamp that is not a CLOB. In a Unicode database, if a supplied argument is a graphic string (except DBCLOB), it is first converted to a character string before the function is executed.

The result of the function is INTEGER. The result can be null; if the argument is null, the result is the null value.

DAYS

The DAYS function returns an integer representation of a date.

The schema is SYSIBM.

expression
An expression that returns a value of one of the following built-in data types: a DATE, TIMESTAMP, or a valid character string representation of a date or timestamp that is not a CLOB. In a Unicode database, if a supplied argument is a graphic string (except DBCLOB), it is first converted to a character string before the function is executed.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result is 1 more than the number of days from January 1, 0001 to *D*, where *D* is the date that would occur if the DATE function were applied to the argument.

Examples

- *Example 1*: Using the PROJECT table, set the host variable EDUCATION_DAYS (int) to the number of elapsed days (PRENDATE - PRSTDATE) estimated for the project (PROJNO) 'IF2000'.

```
SELECT DAYS(PRENDATE) - DAYS(PRSTDATE)
  INTO :EDUCATION_DAYS
```

```
    FROM PROJECT
    WHERE PROJNO = 'IF2000'
```

Results in EDUCATION_DAYS being set to 396.

- *Example 2*: Using the PROJECT table, set the host variable TOTAL_DAYS (int) to the sum of elapsed days (PRENDATE - PRSTDATE) estimated for all projects in department (DEPTNO) 'E21'.

```
SELECT SUM(DAYS(PRENDATE) - DAYS(PRSTDATE))
  INTO :TOTAL_DAYS
  FROM PROJECT
  WHERE DEPTNO = 'E21'
```

Results in TOTAL_DAYS being set to 1584 when using the sample table.

DAYS_BETWEEN

The DAYS_BETWEEN function returns the number of full days between the specified arguments.

The schema is SYSIBM.

expression1
An expression that specifies the first datetime value to compute the number of full days between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression1* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

expression2
An expression that specifies the second datetime value to compute the number of full days between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression2* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

If there is less than a full day between *expression1* and *expression2*, the result is zero. If *expression1* is later than *expression2*, the result is positive. If *expression1* is earlier than *expression2*, the result is negative. In NPS compatibility mode, this function always returns a positive number. If *expression1* or *expression2* contains time information, this information is also used to determine the number of full days. If *expression1* or *expression2* does not contain time information, a time of midnight (00.00.00) is used for the argument that is missing time information.

The result of the function is an INTEGER. If either argument can be null, the result can be null. If either argument is null, the result is the null value.

Examples

1. Set the host variable NUM_DAYS with the number of full days between 2012-03-03 and 2012-02-28.

```
SET :NUM_DAYS = DAYS_BETWEEN(DATE '2012-03-03',
   DATE '2012-02-28')
```

The host variable NUM_DAYS is set to 4 because an additional day is incurred for February 29, 2012.

2. Set the host variable NUM_DAYS with the number of full days between 2013-09-11-23.59.59 and 2013-09-01-00.00.00.

```
SET :NUM_DAYS = DAYS_BETWEEN(TIMESTAMP '2013-09-11-23.59.59',
   TIMESTAMP '2013-09-01-00.00.00')
```

The host variable NUM_DAYS is set to 10 because there is 1 second less than a full 11 days between the arguments. It is positive because the first argument is later than the second argument.

3. Set the host variable NUM_DAYS with the number of full days between 2013-09-01-00.00.00 and 2013-09-11-23.59.59.

```
SET :NUM_DAYS = DAYS_BETWEEN(TIMESTAMP '2013-09-01-00.00.00',
   TIMESTAMP '2013-09-11-23.59.59')
```

The host variable NUM_DAYS is set to -10 because there is 1 second less than a full 11 days between the arguments. It is negative because the first argument is earlier than the second argument.

DAYS_TO_END_OF_MONTH

The DAYS_TO_END_OF_MONTH function returns the number of days to the end of the month.

The schema is SYSIBM.

expression
An expression that specifies the datetime value for which the number of days to the end of the month is computed. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

The result of the function is INTEGER. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

1. Set the host variable NUMDAYS as the number of days to the end of the month for the date February 20, 2012.

```
SET :NUMDAYS = DAYS_TO_END_OF_MONTH(DATE '2012-02-20')
```

The host variable NUMDAYS is set with the value 9.

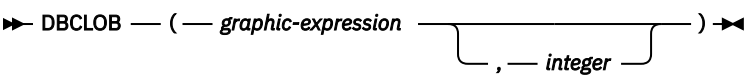
2. The DAYS_TO_END_OF_MONTH function and datetime arithmetic with DAYS and LAST_DAY functions can be used to achieve the same results. The following examples demonstrate this.

```
SET :NUMDAYS = DAYS(LAST_DAY(date '2013-02-20')) - DAYS(date '2013-02-20')
SET :NUMDAYS = DAYS_TO_END_OF_MONTH(DATE '2013-02-20')
```

In both cases, the host variable NUMDAYS is set with the value 8.

DBCLOB

The DBCLOB function returns a DBCLOB representation of a graphic string type.



The schema is SYSIBM.

graphic-expression
An expression that returns a value that is a graphic string.

integer
An integer value specifying the length attribute of the resulting DBCLOB data type. The value must be between 0 and 1 073 741 823 if the *graphic-expression* string unit is double bytes or CODEUNITS16,

or between 0 and 536 870 911 if *graphic-expression* string unit is CODEUNITS32. If *integer* is not specified, the length of the result is the same as the length of the first argument.

In a Unicode database, if a supplied argument is a character string, it is first converted to a graphic string before the function is executed. When the output string is truncated, such that the last character is a high surrogate, that surrogate is either:

- Left as is, if the supplied argument is a character string
- Converted to the blank character (X'0020'), if the supplied argument is a graphic string

Do not rely on these behaviors, because they might change in a future release.

The result of the function is a DBCLOB in the string units of *graphic-expression*. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

DBPARTITIONNUM

The DBPARTITIONNUM function returns the database partition number for a row. For example, if used in a SELECT clause, it returns the database partition number for each row in the result set.

The schema is SYSIBM.

column-name
The qualified or unqualified name of any column in the table. Because row-level information is returned, the result is the same regardless of which column is specified. The column can have any data type.

If the column is a column of a view, the expression for the column in the view must reference a column of the underlying base table, and the view must be deletable. A nested or common table expression follows the same rules as a view.

The specific row (and table) for which the database partition number is returned by the DBPARTITIONNUM function is determined from the context of the SQL statement that uses the function.

The database partition number returned on transition variables and tables is derived from the current transition values of the distribution key columns. For example, in a before insert trigger, the function returns the projected database partition number, given the current values of the new transition variables. However, the values of the distribution key columns might be modified by a subsequent before insert trigger. Thus, the final database partition number of the row when it is inserted into the database might differ from the projected value.

Result

The data type of the result is INTEGER and is never null. If there is no `db2nodes.cfg` file, the result is 0.

Notes

- The DBPARTITIONNUM function cannot be used on replicated tables, within check constraints, or in the definition of generated columns (SQLSTATE 42881).
- The DBPARTITIONNUM function cannot be used as a source function when creating a user-defined function. Because it accepts any data type as an argument, it is not necessary to create additional signatures to support user-defined distinct types.
- The DBPARTITIONNUM function cannot be used as part of an expression-based key in a CREATE INDEX statement.
- ***Syntax alternatives:*** For compatibility with previous versions of Db2 products, the function name NODENUMBER is a synonym for DBPARTITIONNUM.

Examples

- *Example 1*: Count the number of instances in which the row for a given employee in the EMPLOYEE table is on a different database partition than the description of the employee's department in the DEPARTMENT table.

```
SELECT COUNT(*) FROM DEPARTMENT D, EMPLOYEE E
  WHERE D.DEPTNO=E.WORKDEPT
  AND DBPARTITIONNUM(E.LASTNAME) <> DBPARTITIONNUM(D.DEPTNO)
```

- *Example 2*: Join the EMPLOYEE and DEPARTMENT tables so that the rows of the two tables are on the same database partition.

```
SELECT * FROM DEPARTMENT D, EMPLOYEE E
  WHERE DBPARTITIONNUM(E.LASTNAME) = DBPARTITIONNUM(D.DEPTNO)
```

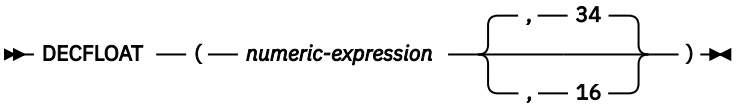
- *Example 3*: Using a before trigger on the EMPLOYEE table, log the employee number and the projected database partition number of any new row in the EMPLOYEE table in a table named EMPINSERTLOG1.

```
CREATE TRIGGER EMPINSLOGTRIG1
BEFORE INSERT ON EMPLOYEE
REFERENCING NEW AW NEWTABLE
FOR EACH ROW
INSERT INTO EMPINSERTLOG1
VALUES(NEWTABLE.EMPNO, DBPARTITIONNUM
(NEWTABLE.EMPNO))
```

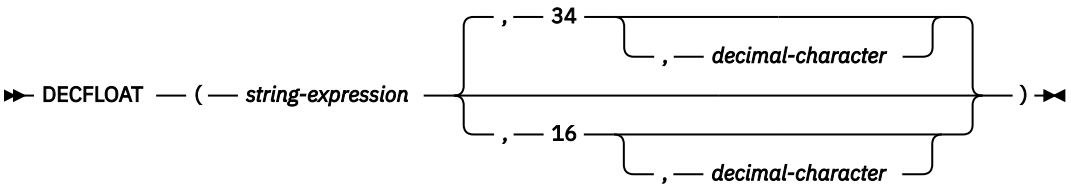
DECFLOAT

The DECFLOAT function returns a decimal floating-point representation of a value of a different data type.

Numeric to decimal floating-point



Character to decimal floating-point



Boolean to decimal floating-point

The schema is SYSIBM.

numeric-expression
An expression that returns a value of any built-in numeric data type.

string-expression
An expression that returns a value that is a character-string or Unicode graphic-string representation of a number with a length not greater than the maximum length of a character constant. The data type of string-expression must not be CLOB or DBCLOB (SQLSTATE 42884). Leading and trailing blanks are

removed from the string. The resulting substring is folded to uppercase and must conform to the rules for forming an integer, decimal, floating-point, or decimal floating-point constant (SQLSTATE 22018) and not be greater than 42 bytes (SQLSTATE 42820).

boolean-expression
An expression that returns a Boolean value (TRUE or FALSE). The result is either 1 (for TRUE) or 0 (for FALSE).

34 or 16
Specifies the number of digits of precision for the result. The default is 34.

decimal-character
Specifies the single-byte character constant used to delimit the decimal digits in *character-expression* from the whole part of the number. The character cannot be a digit, plus (+), minus (-), or blank, and it can appear at most once in *character-expression*.

Result

The result is the same number that would result from CAST(*string-expression* AS DECFLOAT(*n*)) or CAST(*numeric-expression* AS DECFLOAT(*n*)). Leading and trailing blanks are removed from the string.

The result of the function is a decimal floating-point number with the implicitly or explicitly specified number of digits of precision. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

If necessary, the source is rounded to the precision of the target. The CURRENT DECFLOAT ROUNDING MODE special register determines the rounding mode.

Notes

- **Increasing portability of applications:** If the first argument is numeric, or if the first argument is a string and the length argument is specified, use the "CAST specification" on page 152 instead of this function to increase the portability of your applications.
- All numeric values are interpreted as integer, decimal, or floating-point constants and then cast to decimal floating-point. The use of a floating-point constant can result in round-off errors and is therefore strongly discouraged. Use the string to decimal floating-point version of the DECFLOAT function instead.

Examples

- *Example 1*: Use the DECFLOAT function in order to force a DECFLOAT data type to be returned in a select-list for the EDLEVEL column (data type = SMALLINT) in the EMPLOYEE table. The EMPNO column should also appear in the select list.

```
SELECT EMPNO, DECFLOAT(EDLEVEL,16)
FROM EMPLOYEE
```

- *Example 2*: The following statement returns the value 1 of data type DECFLOAT.

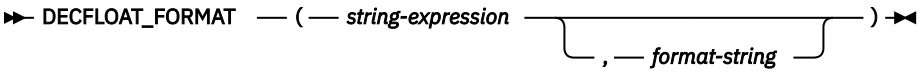
```
   values DECFLOAT(TRUE)
```

- *Example 3*: The following statement returns the value 0 of data type DECFLOAT.

```
   values DECFLOAT(3>3)
```

DECFLOAT_FORMAT

The DECFLOAT_FORMAT function returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format.



The schema is SYSIBM.

string-expression
An expression that returns a value that is a CHAR and VARCHAR data type. In a Unicode database, if a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function.Leading and trailing blanks are removed from the string. If *format-string* is not specified, the resulting substring must conform to the rules for forming an SQL integer, decimal, floating-point, or decimal floating-point constant (SQLSTATE 22018) and not be greater than 42 bytes (SQLSTATE 42820); otherwise, the resulting substring must contain the components of a number that correspond to the format specified by *format-string* (SQLSTATE 22018).

format-string
An expression that returns a value that is a built-in character string data type (except CLOB). In a Unicode database, if a supplied argument is a graphic string (except DBCLOB), it is first converted to a character string before evaluating the function. The actual length must not be greater than 255 bytes (SQLSTATE 22018). The value is a template for how *string-expression* is to be interpreted for conversion to a DECFLOAT value. Format elements specified as a prefix can be used only at the beginning of the template. Format elements specified as a suffix can be used only at the end of the template. The format elements are case sensitive. The template must not contain more than one of the MI, S, or PR format elements (SQLSTATE 22018).

Table 59. Format elements for the DECFLOAT_FORMAT function

Format element	**Description**
0 or 9	Each 0 or 9 represents a digit.
MI	Suffix: If *string-expression* is to represent a negative number, a trailing minus sign (-) is expected. If *string-expression* is to represent a positive number, a trailing blank can be specified.
S	Prefix: If *string-expression* is to represent a negative number, a leading minus sign (-) is expected. If *string-expression* is to represent a positive number, a leading plus sign (+) or leading blank can be specified.
PR	Suffix: If *string-expression* is to represent a negative number, a leading less than character (<) and a trailing greater than character (>) are expected. If *string-expression* is to represent a positive number, a leading space and a trailing space can be specified.
$	Prefix: A leading dollar sign ($) must be specified.
,	Specifies the expected location of a comma. This comma is used as a group separator.
.	Specifies the expected location of the period. This period is used as a decimal point.

If *format-string* is not specified, *string-expression* must conform to the rules for forming an SQL integer, decimal, floating-point, or decimal floating-point constant (SQLSTATE 22018) and have a length not greater than 42 bytes (SQLSTATE 42820).

The result is a DECFLOAT(34). If the first or second argument can be null, the result can be null; if the first or second argument is null, the result is the null value.

Notes

- Syntax alternatives: TO_NUMBER is a synonym for DECFLOAT_FORMAT.

Examples

- *Example 1*: The following example returns 123.45

```
DECFLOAT_FORMAT( '123.45' )
```

- *Example 2*: The following example returns -123456.78

```
DECFLOAT_FORMAT( '-123456.78' )
```

- *Example 3*: The following example returns 123456.78

```
DECFLOAT_FORMAT( '+123456.78' )
```

- *Example 4*: The following example returns 12300

```
DECFLOAT_FORMAT( '1.23E4' )
```

- *Example 5*: The following example returns 123.40

```
DECFLOAT_FORMAT( '123.4', '9999.99' )
```

- *Example 6*: The following example returns 1234

```
DECFLOAT_FORMAT( '001,234', '000,000' )
```

- *Example 7*: The following example returns 1234

```
DECFLOAT_FORMAT( '1234 ', '9999MI' )
```

- *Example 8*: The following example returns -1234

```
DECFLOAT_FORMAT( '1234-', '9999MI' )
```

- *Example 9*: The following example returns 1234

```
DECFLOAT_FORMAT( '+1234', 'S9999' )
```

- *Example 10*: The following example returns -1234

```
DECFLOAT_FORMAT( '-1234', 'S9999' )
```

- *Example 11*: The following example returns 1234

```
DECFLOAT_FORMAT( ' 1234 ', '9999PR' )
```

- *Example 12*: The following example returns -1234

```
DECFLOAT_FORMAT( '<1234>', '9999PR' )
```

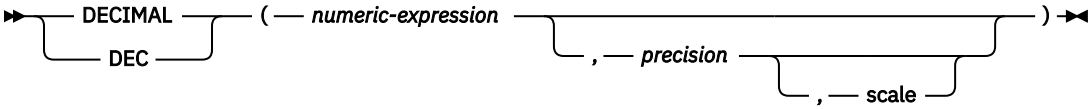
- *Example 13*: The following example returns 123456.78

```
DECFLOAT_FORMAT( '$123,456.78', '$999,999.99' )
```

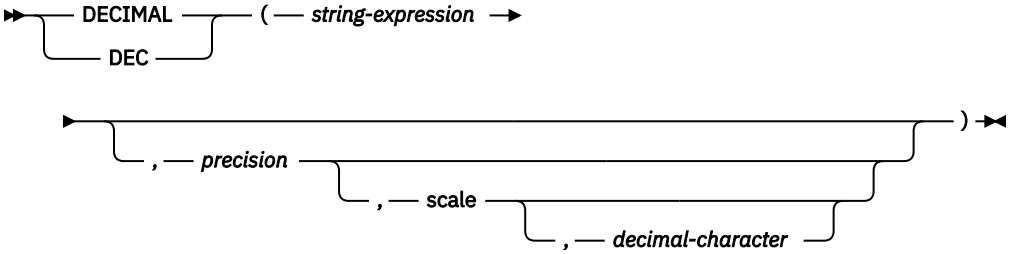
DECIMAL or DEC

The DECIMAL function returns a decimal representation of a number, a string representation of a number, or a datetime value.

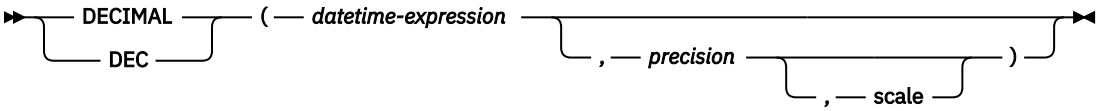
Numeric to DECIMAL



String to DECIMAL



Datetime to DECIMAL



The schema is SYSIBM.

Numeric to DECIMAL

numeric-expression
An expression that returns a value of any built-in numeric data type.

precision
An integer constant with a value in the range 1 - 31. The default precision depends on the data type of the input expression:

- 31 for decimal floating point (DECFLOAT)
- 15 for floating point (REAL or DOUBLE) or decimal (DECIMAL)
- 19 for big integer (BIGINT)
- 11 for large integer (INTEGER)
- 5 for small integer (SMALLINT)

scale
An integer constant in the range of 0 to the precision value. The default scale is zero.

The result is the same number that would occur if the first argument were assigned to a decimal column or variable with a precision of *precision* and a scale of *scale*. Digits are truncated from the end of the decimal number if the number of digits to the right of the decimal separator character is greater than the scale *scale*. An error is returned if the number of significant decimal digits required to represent the whole part of the number is greater than *precision* - *scale* (SQLSTATE 22003).

String to DECIMAL

string-expression
An *expression* that returns a value that is a character string or a Unicode graphic-string representation of a number with a length not greater than the maximum length of a character

constant. The data type of *string-expression* must not be CLOB or DBCLOB (SQLSTATE 42884). Leading and trailing blanks are eliminated from the string and the resulting string must conform to the rules for forming an integer, decimal, floating-point, or decimal floating-point constant (SQLSTATE 22018).

The *string-expression* is converted to the section code page if required to match the code page of the constant *decimal-character*.

precision
An integer constant with a value in the range 1 to 31 that specifies the precision of the result. If not specified, the default is 15.

scale
An integer constant with a value in the range 0 to *precision* that specifies the scale of the result. If not specified, the default is 0.

decimal-character
Specifies the single-byte character constant used to delimit the decimal digits in *string-expression* from the whole part of the number. The character cannot be a digit, plus (+), minus (-), or blank, and it can appear at most once in *string-expression* (SQLSTATE 42815).

The result is the same number that would result from CAST(*string-expression* AS DECIMAL(*precision*, *scale*)). Digits are truncated from the end of the decimal number if the number of digits to the right of the decimal separator character is greater than the scale *scale*. An error is returned if the number of significant digits to the left of the decimal character (the whole part of the number) in *string-expression* is greater than *precision* - *scale* (SQLSTATE 22003). The default decimal character is not valid in the substring if a different value for the *decimal-character* argument is specified (SQLSTATE 22018).

In NPS mode, casting an empty string to DECIMAL returns 0.

Datetime to DECIMAL

datetime-expression
An expression that returns a value of type DATE, TIME or TIMESTAMP.

precision
An integer constant with a value in the range 1 to 31 that specifies the precision of the result. If not specified, the default for the precision and scale depends on the data type of *datetime-expression* as follows:

- Precision is 8 and scale is 0 for a DATE. The result is a DECIMAL(8,0) value representing the date as *yyyymmdd*.
- Precision is 6 and scale is 0 for a TIME. The result is a DECIMAL(6,0) value representing the time as *hhmmss*.
- Precision is 14+*tp* and scale is *tp* for a TIMESTAMP(*tp*). The result is a DECIMAL(14+*tp*,*tp*) value representing the timestamp as *yyyymmddhhmmss.nnnnnnnnnnn*.

scale
An integer constant with a value in the range 0 to *precision* that specifies the scale of the result. If not specified and a *precision* is specified, the default is 0.

The result is the same number that would result from CAST(*datetime* - *expression* AS DECIMAL(*precision*, *scale*)). Digits are truncated from the end of the decimal number if the number of digits to the right of the decimal separator character is greater than the scale *scale*. An error is returned if the number of significant digits to the left of the decimal character (the whole part of the number) in *string-expression* is greater than *precision* - *scale* (SQLSTATE 22003).

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Note: The CAST specification should be used to increase the portability of applications. For more information, see "CAST specification".

Examples

- *Example 1*: Use the DECIMAL function in order to force a DECIMAL data type (with a precision of 5 and a scale of 2) to be returned in a select-list for the EDLEVEL column (data type = SMALLINT) in the EMPLOYEE table. The EMPNO column should also appear in the select list.

```
SELECT EMPNO, DECIMAL(EDLEVEL,5,2)
  FROM EMPLOYEE
```

- *Example 2*: Assume the host variable PERIOD is of type INTEGER. Then, in order to use its value as a date duration it must be "cast" as decimal(8,0).

```
SELECT PRSTDATE + DECIMAL(:PERIOD,8)
  FROM PROJECT
```

- *Example 3*: Assume that updates to the SALARY column are input through a window as a character string using comma as a decimal character (for example, the user inputs 21400,50). Once validated by the application, it is assigned to the host variable *newsalary* which is defined as CHAR(10).

```
UPDATE STAFF
  SET SALARY = DECIMAL(:newsalary, 9, 2, ',')
  WHERE ID = :empid;
```

  The value of *newsalary* becomes 21400.50.

- *Example 4*: Add the default decimal character (.) to a value.

```
DECIMAL('21400,50', 9, 2, '.')
```

  This fails because a period (.) is specified as the decimal character, but a comma (,) appears in the first argument as a delimiter.

- *Example 5*: Assume that the column STARTING (whose data type is TIME) has an internal value equivalent to '12:10:00'.

```
DECIMAL(STARTING)
```

  results in the value `121 000`.

- *Example 6*: Assume that the column RECEIVED (whose data type is TIMESTAMP) has an internal value equivalent to '1988-12-22-14.07.21.136421'.

```
DECIMAL(RECEIVED)
```

  results in the value `19 881 222 140 721.136421`.

- *Example 7*: This example shows the decimal result and resulting precision and scale for various datetime input values. Assume the existence of the following columns with associated values:

Column name	Data type	Value
ENDDT	DATE	2000-03-21
ENDTM	TIME	12:02:21
ENDTS	TIMESTAMP	2000-03-21-12.02.21.123456
ENDTS0	TIMESTAMP(0)	2000-03-21-12.02.21
ENDTS9	TIMESTAMP(9)	2000-03-21-12.02.21.123456789

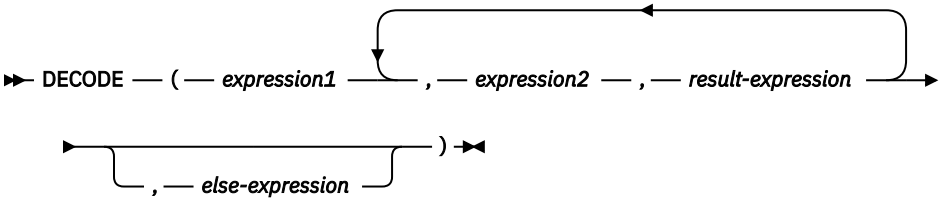
  The following table shows the decimal result and resulting precision and scale for various datetime input values.

DECIMAL(arguments)	Precision and Scale	Result
DECIMAL(ENDDT)	(8,0)	20000321.

DECIMAL(arguments)	Precision and Scale	Result
DECIMAL(ENDDT, 10)	(10,0)	20000321.
DECIMAL(ENDDT, 12, 2)	(12,2)	20000321.00
DECIMAL(ENDTM)	(6,0)	120221.
DECIMAL(ENDTM, 10)	(10,0)	120221.
DECIMAL(ENDTM, 10, 2)	(10,2)	120221.00
DECIMAL(ENDTS)	(20, 6)	20000321120221.123456
DECIMAL(ENDTS, 23)	(23, 0)	20000321120221.
DECIMAL(ENDTS, 23, 4)	(23, 4)	20000321120221.1234
DECIMAL(ENDTS0)	(14,0)	20000321120221.
DECIMAL(ENDTS9)	(23,9)	20000321120221.123456789

DECODE

The DECODE function does equality comparisons between arguments, also treating null values as equal, to determine which argument to return as the result.



The schema is SYSIBM.

The DECODE function compares each *expression2* to *expression1*. If *expression1* is equal to *expression2*, or both *expression1* and *expression2* are null, the value of the following *result-expresssion* is returned. If no *expression2* matches *expression1*, the value of *else-expression* is returned; otherwise a null value is returned.

The DECODE function is similar to the CASE expression except for the handling of null values:

- A null value of *expression1* will match a corresponding null value of *expression2*.
- If the NULL keyword is used as an argument in the DECODE function, it must be cast to an appropriate data type.

The rules for determining the result type of a DECODE expression are based on the corresponding CASE expression.

Examples

- *Example 1*: The DECODE expression:

```
DECODE (c1, 7, 'a', 6, 'b', 'c')
```

  achieves the same result as the following CASE expression:

```
CASE c1
  WHEN 7 THEN 'a'
  WHEN 6 THEN 'b'
  ELSE 'c'
END
```

- *Example 2*: The DECODE expression:

```
DECODE (c1, var1, 'a', var2, 'b')
```

  where the values of c1, var1, and var2 could be null values, achieves the same result as the following CASE expression:

```
CASE
  WHEN c1 = var1 OR (c1 IS NULL AND var1 IS NULL) THEN 'a'
  WHEN c1 = var2 OR (c1 IS NULL AND var2 IS NULL) THEN 'b'
  ELSE NULL
END
```

- *Example 3*: Consider also the following query:

```
SELECT ID, DECODE(STATUS, 'A', 'Accepted',
                          'D', 'Denied',
                          CAST(NULL AS VARCHAR(1)), 'Unknown',
                          'Other')
FROM CONTRACTS
```

  Here is the same statement using a CASE expression:

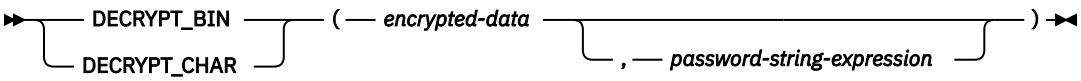
```
SELECT ID,
  CASE
    WHEN STATUS = 'A' THEN 'Accepted'
    WHEN STATUS = 'D' THEN 'Denied'
    WHEN STATUS IS NULL THEN 'Unknown'
    ELSE 'Other'
  END
FROM CONTRACTS
```

DECRYPT_BIN and DECRYPT_CHAR

The DECRYPT_BIN and DECRYPT_CHAR functions both return a value that is the result of decrypting *encrypted-data*.

Important: The DECRYPT_BIN and DECRYPT_CHAR functions are deprecated and might not appear in future releases.

Note: If using this feature on AIX, review the following for performance considerations.



The schema is SYSIBM.

The password used for decryption is either the *password-string-expression* value or the encryption password value that was assigned by the SET ENCRYPTION PASSWORD statement. To maintain the best level of security on your system, it is recommended that you do not pass the encryption password explicitly with the DECRYPT_BIN and DECRYPT_CHAR functions in your query; instead, use the SET ENCRYPTION PASSWORD statement to set the password, and use a host variable or dynamic parameter markers when you use the SET ENCRYPTION PASSWORD statement, rather than a literal string.

The DECRYPT_BIN and DECRYPT_CHAR functions can only decrypt values that are encrypted using the ENCRYPT function (SQLSTATE 428FE).

encrypted-data
An expression that returns a CHAR FOR BIT DATA or VARCHAR FOR BIT DATA value as a complete, encrypted data string. The data string must have been encrypted using the ENCRYPT function.

password-string-expression
An expression that returns a CHAR or VARCHAR value with at least 6 bytes and no more than 127 bytes (SQLSTATE 428FC). This expression must be the same password used to encrypt the data (SQLSTATE 428FD). If the value of the password argument is null or not provided, the data will

be decrypted using the encryption password value that was assigned for the session by the SET ENCRYPTION PASSWORD statement (SQLSTATE 51039).

The result of the DECRYPT_BIN function is VARCHAR FOR BIT DATA. The result of the DECRYPT_CHAR function is VARCHAR. If *encrypted-data* included a hint, the hint is not returned by the function. The length attribute of the result is the length of the data type of *encrypted-data* minus 8 bytes. The actual length of the value returned by the function will match the length of the original string that was encrypted. If *encrypted-data* includes bytes beyond the encrypted string, these bytes are not returned by the function.

If the first argument can be null, the result can be null. If the first argument is null, the result is the null value.

If the data is decrypted on a different system, which uses a code page that is different from the code page in which the data was encrypted, expansion might occur when converting the decrypted value to the database code page. In such situations, the *encrypted-data* value should be cast to a VARCHAR string with a larger number of bytes.

Examples

- *Example 1*: The following example demonstrates the use of the DECRYPT_CHAR function by showing code fragments from an embedded SQL application.

```
EXEC SQL BEGIN DECLARE SECTION;
      char hostVarCreateTableStmt[100];
      char hostVarSetEncPassStmt[200];
      char hostVarPassword[128];
      char hostVarInsertStmt1[200];
      char hostVarInsertStmt2[200];
      char hostVarSelectStmt1[200];
      char hostVarSelectStmt2[200];
EXEC SQL END DECLARE SECTION;

/* prepare the statement */
strcpy(hostVarCreateTableStmt, "CREATE TABLE EMP (SSN VARCHAR(24) FOR BIT DATA)");
EXEC SQL PREPARE hostVarCreateTableStmt FROM :hostVarCreateTableStmt;

/* execute the statement */
EXEC SQL EXECUTE hostVarCreateTableStmt;
```

- *Example 2*: Use the SET ENCRYPTION PASSWORD statement to set an encryption password for the session:

```
/* prepare the statement with a parameter marker */
strcpy(hostVarSetEncPassStmt, "SET ENCRYPTION PASSWORD = ?");
EXEC SQL PREPARE hostVarSetEncPassStmt FROM :hostVarSetEncPassStmt;

/* execute the statement for hostVarPassword = 'Pac1f1c' */
strcpy(hostVarPassword, "Pac1f1c");
EXEC SQL EXECUTE hostVarSetEncPassStmt USING :hostVarPassword;

/* prepare the statement */
strcpy(hostVarInsertStmt1, "INSERT INTO EMP(SSN) VALUES ENCRYPT('289-46-8832')");
EXEC SQL PREPARE hostVarInsertStmt1 FROM :hostVarInsertStmt1;

/* execute the statement */
EXEC SQL EXECUTE hostVarInsertStmt1;

/* prepare the statement */
strcpy(hostVarSelectStmt1, "SELECT DECRYPT_CHAR(SSN) FROM EMP");
EXEC SQL PREPARE hostVarSelectStmt1 FROM :hostVarSelectStmt1;

/* execute the statement */
EXEC SQL EXECUTE hostVarSelectStmt1;
```

This query returns the value '289-46-8832'.

- *Example 3*: Pass the encryption password explicitly:

```
/* prepare the statement */
strcpy(hostVarInsertStmt2, "INSERT INTO EMP (SSN) VALUES
ENCRYPT('289-46-8832',?)");
EXEC SQL PREPARE hostVarInsertStmt2 FROM :hostVarInsertStmt2;

/* execute the statement for hostVarPassword = 'Pac1f1c' */
strcpy(hostVarPassword, "Pac1f1c");
EXEC SQL EXECUTE hostVarInsertStmt2 USING :hostVarPassword;

/* prepare the statement */
strcpy(hostVarSelectStmt2, "SELECT DECRYPT_CHAR(SSN,?) FROM EMP");
EXEC SQL PREPARE hostVarSelectStmt2 FROM :hostVarSelectStmt2;

/* execute the statement for hostVarPassword = 'Pac1f1c' */
strcpy(hostVarPassword, "Pac1f1c");
EXEC SQL EXECUTE hostVarSelectStmt2 USING :hostVarPassword;
```

This query returns the value '289-46-8832'.

DEGREES

The DEGREES function returns the number of degrees of the argument, which is an angle expressed in radians.

The schema is SYSIBM. (The SYSFUN version of the DEGREES function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type. If the value is of decimal floating-point data type, the operation is performed in decimal floating-point; otherwise, the value is converted to double-precision floating-point for processing by the function.

If the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*); otherwise, the result is a double-precision floating-point number. The result can be null; if the argument is null, the result is the null value.

Example

Assume that RAD is a DECIMAL(4,3) host variable with a value of 3.142.

```
VALUES DEGREES(:RAD)
```

Returns the approximate value 180.0.

DEREF

The DEREF function returns an instance of the target type of the argument.

expression
An expression that returns a value with a reference data type that has a defined scope (SQLSTATE 428DT).

The static data type of the result is the target type of the argument. The dynamic data type of the result is a subtype of the target type of the argument. The result can be null. The result is the null value if *expression* is a null value or if *expression* is a reference that has no matching OID in the target table.

The result is an instance of the subtype of the target type of the reference. The result is determined by finding the row of the target table or target view of the reference that has an object identifier that matches the reference value. The type of this row determines the dynamic type of the result. Since the type of the result can be based on a row of a subtable or subview of the target table or target view, the authorization

ID of the statement must have SELECT privilege on the target table and all of its subtables or the target view and all of its subviews (SQLSTATE 42501).

Example

Assume that EMPLOYEE is a table of type EMP, and that its object identifier column is named EMPID. Then the following query returns an object of type EMP (or one of its subtypes), for each row of the EMPLOYEE table (and its subtables). This query requires SELECT privilege on EMPLOYEE and all its subtables.

```
SELECT DEREF(EMPID) FROM EMPLOYEE
```

DIFFERENCE

Returns a value from 0 to 4 representing the difference between the sounds of two strings based on applying the SOUNDEX function to the strings. A value of 4 is the best possible sound match.

The schema is SYSFUN.

expression
An expression that returns a character string or a Boolean value. In a Unicode database, the expression can also return a graphic string. If the returned value is not a character string, it is cast to a character string before the function is evaluated. The character string to be evaluated cannot exceed 4000 bytes. This function interprets data that is passed to it as if the data were made up of ASCII characters, even if it is encoded in UTF-8.

Result

The result of the function is INTEGER. The result can be null; if the argument is null, the result is the null value.

Example

The following code:

```
VALUES (DIFFERENCE('CONSTRAINT','CONSTANT'),SOUNDEX('CONSTRAINT'),
SOUNDEX('CONSTANT')),
(DIFFERENCE('CONSTRAINT','CONTRITE'),SOUNDEX('CONSTRAINT'),
SOUNDEX('CONTRITE'))
```

returns the following output:

```
1           2    3
----------- ---- ----
          4 C523 C523
          2 C523 C536
```

In the first row, the words have the same result from SOUNDEX while in the second row the words have only some similarity.

DIGITS

The DIGITS function returns a character-string representation of a number.

The schema is SYSIBM.

expression

An expression that returns a value of one of the following built-in data types: SMALLINT, INTEGER, BIGINT, DECIMAL, CHAR, or VARCHAR. In a Unicode database, if a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to a character string before the function is executed. A CHAR or VARCHAR value is implicitly cast to DECIMAL(31,6) before evaluating the function.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The result of the function is a fixed-length character string representing the absolute value of the argument without regard to its scale. The result does not include a sign or a decimal character. Instead, it consists exclusively of digits, including, if necessary, leading zeros to fill out the string. The length of the string is:

- 5 if the argument is a small integer
- 10 if the argument is a large integer
- 19 if the argument is a big integer
- *p* if the argument is a decimal number with a precision of *p*.

Examples

- *Example 1*: Assume that a table called TABLEX contains an INTEGER column called INTCOL containing 10-digit numbers. List all distinct four digit combinations of the first four digits contained in column INTCOL.

```
SELECT DISTINCT SUBSTR(DIGITS(INTCOL),1,4)
  FROM TABLEX
```

- *Example 2*: Assume that COLUMNX has the DECIMAL(6,2) data type, and that one of its values is -6.28. Then, for this value:

```
DIGITS(COLUMNX)
```

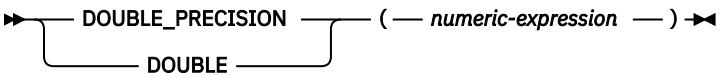
  returns the value '000628'.

  The result is a string of length six (the precision of the column) with leading zeros padding the string out to this length. Neither sign nor decimal point appear in the result.

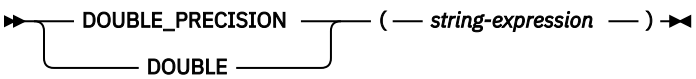
DOUBLE_PRECISION or DOUBLE

The DOUBLE_PRECISION and DOUBLE functions return a double-precision floating-point representation of either a number or a string representation of a number.

Numeric to DOUBLE



String to DOUBLE



The schema is SYSIBM.

Numeric to DOUBLE

numeric-expression
An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a double-precision floating-point column or variable. If the numeric value of the argument is not within the range of double-precision floating-point, an error is returned (SQLSTATE 22003).

String to DOUBLE

string-expression
An expression that returns a string, including FOR BIT DATA, that represents a number. The data type of this expression cannot be CLOB, BLOB, or DBCLOB (SQLSTATE 42884).

The result is the same number that would result from the statement CAST(*string-expression* AS DOUBLE PRECISION). Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a valid numeric constant (SQLSTATE 22018). If the numeric value of the argument is not within the range of double-precision floating-point, an error is returned (SQLSTATE 22003).

The result of the function is a double-precision floating-point number. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Notes

- The CAST specification should be used to increase the portability of applications.
- FLOAT is a synonym for DOUBLE_PRECISION and DOUBLE.
- The SYSFUN version of DOUBLE (*string_expression*) continues to be available.

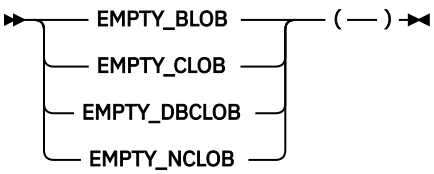
Example

Using the EMPLOYEE table, find the ratio of salary to commission for employees whose commission is not zero. The columns involved (SALARY and COMM) have DECIMAL data types. To eliminate the possibility of out-of-range results, DOUBLE is applied to SALARY so that the division is carried out in floating point:

```
SELECT EMPNO, DOUBLE(SALARY)/COMM
  FROM EMPLOYEE
  WHERE COMM > 0
```

EMPTY_BLOB, EMPTY_CLOB, EMPTY_DBCLOB, and EMPTY_NCLOB

These functions return a zero-length value with a data type of BLOB, CLOB, or DBCLOB.



The schema is SYSIBM.

The empty value functions return a zero-length value of the associated data type. There are no arguments to these functions (the empty parentheses must be specified).

- The EMPTY_BLOB function returns a zero-length value with a data type of BLOB(1).
- The EMPTY_CLOB function returns a zero-length value with a data type of CLOB(1).
- The EMPTY_DBCLOB and EMPTY_NCLOB functions return a zero-length value with a data type of DBCLOB(1).

The result of these functions can be used in assignments to provide zero-length values where needed.

The EMPTY_NCLOB function can be specified only in a Unicode database (SQLSTATE 560AA).

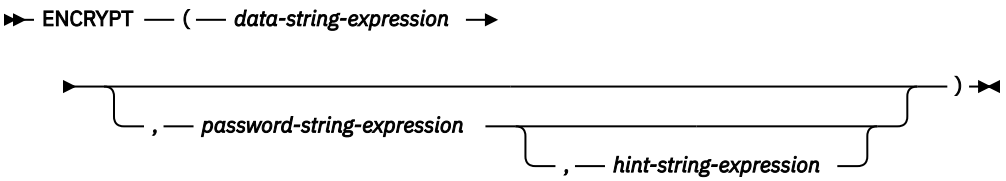
ENCRYPT

The ENCRYPT function returns a value that is the result of encrypting *data-string-expression*.

Important: The ENCRYPT function is deprecated and might not appear in future releases.

The algorithms used are not compliant with **NIST SP 800-131A**.

Note: If using this feature on AIX, review the following for performance considerations.



The schema is SYSIBM.

The password used for encryption is either the *password-string-expression* value or the encryption password value that was assigned by the SET ENCRYPTION PASSWORD statement. To maintain the best level of security on your system, it is recommended that you do not pass the encryption password explicitly with the ENCRYPT function in your query; instead, use the SET ENCRYPTION PASSWORD statement to set the password, and use a host variable or dynamic parameter markers when you use the SET ENCRYPTION PASSWORD statement, rather than a literal string.

In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

data-string-expression
An expression that returns a CHAR or a VARCHAR value that is to be encrypted. The length attribute for the data type of *data-string-expression* is limited to 32663 without a *hint-string-expression* argument, and 32631 when the *hint-string-expression* argument is specified (SQLSTATE 42815).

password-string-expression
An expression that returns a CHAR or a VARCHAR value with at least 6 bytes and no more than 127 bytes (SQLSTATE 428FC). The value represents the password used to encrypt *data-string-expression*. If the value of the password argument is null or not provided, the data is encrypted using the encryption password value that was assigned for the session by the SET ENCRYPTION PASSWORD statement (SQLSTATE 51039).

hint-string-expression
An expression that returns a CHAR or a VARCHAR value with at most 32 bytes that will help data owners remember passwords (for example, 'Ocean' as a hint to remember 'Pacific'). If a hint value is given, the hint is embedded into the result and can be retrieved using the GETHINT function. If this argument is null or not provided, no hint will be embedded in the result.

The result data type of the function is VARCHAR FOR BIT DATA.

- When the optional hint parameter is specified, the length attribute of the result is equal to the length attribute of the unencrypted data + 8 bytes + the number of bytes until the next 8-byte boundary + 32 bytes for the length of the hint.
- When the optional hint parameter is not specified, the length attribute of the result is equal to the length attribute of the unencrypted data + 8 bytes + the number of bytes until the next 8-byte boundary.

If the first argument can be null, the result can be null. If the first argument is null, the result is the null value.

Note that the encrypted result is longer than the *data-string-expression* value. Therefore, when assigning encrypted values, ensure that the target is declared with sufficient size to contain the entire encrypted value.

Notes

- ***Encryption algorithm:*** The internal encryption algorithm is RC2 block cipher with padding; the 128-bit secret key is derived from the password using an MD5 message digest.
- ***Encryption passwords and data:*** Password management is the user's responsibility. Once the data is encrypted, only the password that was used when encrypting it can be used to decrypt it (SQLSTATE 428FD).

  The encrypted result might contain null terminator and other unprintable characters. Any assignment or cast to a length that is shorter than the suggested data length might result in failed decryption in the future, and lost data. Blanks are valid encrypted data values that might be truncated when stored in a column that is too short.
- ***Administration of encrypted data:*** Encrypted data can only be decrypted on servers that support the decryption functions corresponding to the ENCRYPT function. Therefore, replication of columns with encrypted data should only be done to servers that support the DECRYPT_BIN or the DECRYPT_CHAR function.
- ***Avoid encrypted data in predicates:*** The ENCRYPT function does not always produce the same encrypted data when given the same input. Do not use encrypted data in search conditions or comparison operations. For example, do not use encrypted data in a predicate.

Examples

- *Example 1*: The following example demonstrates the use of the ENCRYPT function by showing code fragments from an embedded SQL application.

```
EXEC SQL BEGIN DECLARE SECTION;
      char hostVarCreateTableStmt[100];
      char hostVarSetEncPassStmt[200];
      char hostVarPassword[128];
      char hostVarInsertStmt1[200];
      char hostVarInsertStmt2[200];
      char hostVarInsertStmt3[200];
EXEC SQL END DECLARE SECTION;

/* prepare the statement */
strcpy(hostVarCreateTableStmt, "CREATE TABLE EMP (SSN VARCHAR(24) FOR BIT DATA)");
EXEC SQL PREPARE hostVarCreateTableStmt FROM :hostVarCreateTableStmt;

/* execute the statement */
EXEC SQL EXECUTE hostVarCreateTableStmt;
```

- *Example 2*: Use the SET ENCRYPTION PASSWORD statement to set an encryption password for the session:

```
/* prepare the statement with a parameter marker */
strcpy(hostVarSetEncPassStmt, "SET ENCRYPTION PASSWORD = ?");
EXEC SQL PREPARE hostVarSetEncPassStmt FROM :hostVarSetEncPassStmt;

/* execute the statement for hostVarPassword = 'Pac1f1c' */
strcpy(hostVarPassword, "Pac1f1c");
EXEC SQL EXECUTE hostVarSetEncPassStmt USING :hostVarPassword;

/* prepare the statement */
strcpy(hostVarInsertStmt1, "INSERT INTO EMP(SSN) VALUES ENCRYPT('289-46-8832')");
EXEC SQL PREPARE hostVarInsertStmt1 FROM :hostVarInsertStmt1;

/* execute the statement */
EXEC SQL EXECUTE hostVarInsertStmt1;
```

- *Example 3*: Pass the encryption password explicitly:

```
/* prepare the statement */
strcpy(hostVarInsertStmt2, "INSERT INTO EMP(SSN) VALUES
ENCRYPT('289-46-8832',?)");
```

```
EXEC SQL PREPARE hostVarInsertStmt2 FROM :hostVarInsertStmt2;

/* execute the statement for hostVarPassword = 'Pac1f1c' */
strcpy(hostVarPassword, "Pac1f1c");
EXEC SQL EXECUTE hostVarInsertStmt2 USING :hostVarPassword;
```

- *Example 4*: Define a password hint:

```
/* prepare the statement */
strcpy(hostVarInsertStmt3, "INSERT INTO EMP(SSN) VALUES ENCRYPT('289-46-8832',?,'Ocean')");
EXEC SQL PREPARE hostVarInsertStmt3 FROM :hostVarInsertStmt3;

/* execute the statement for hostVarPassword = 'Pac1f1c' */
strcpy(hostVarPassword, "Pac1f1c");
EXEC SQL EXECUTE hostVarInsertStmt3 USING :hostVarPassword;
```

EVENT_MON_STATE

The EVENT_MON_STATE function returns the current state of an event monitor.

The schema is SYSIBM.

string-expression
An expression that returns a value of CHAR or VARCHAR data type. In a Unicode database, if the value is a graphic string, it is first converted to a character string before the function is executed. The value must be the name of an event monitor that is equal to an event monitor name in the SYSCAT.EVENMONITORS catalog view (SQLSTATE 42704).

The result is an integer with one of the following values:

0
The event monitor is inactive.

1
The event monitor is active.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

The following example selects all of the defined event monitors, and indicates whether each is active or inactive:

```
SELECT EVMONNAME,
  CASE
    WHEN EVENT_MON_STATE(EVMONNAME) = 0 THEN 'Inactive'
    WHEN EVENT_MON_STATE(EVMONNAME) = 1 THEN 'Active'
  END
  FROM SYSCAT.EVENTMONITORS
```

EXP

The EXP function returns a value that is the base of the natural logarithm (e) raised to a power specified by the argument. The EXP and LN functions are inverse operations.

The schema is SYSIBM. (The SYSFUN version of the EXP function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type. If the value is of decimal floating-point data type, the operation is performed in decimal floating-point; otherwise, the value is converted to double-precision floating-point for processing by the function.

If the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*); otherwise, the result is a double-precision floating-point number. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Notes

- **Results involving DECFLOAT special values:** For decimal floating-point values, the special values are treated as follows:
  - EXP(NaN) returns NaN.
  - EXP(-NaN) returns -NaN.
  - EXP(Infinity) returns Infinity.
  - EXP(-Infinity) returns 0.
  - EXP(sNaN) returns NaN and a warning.
  - EXP(-sNaN) returns -NaN and a warning.

Example

Assume that E is a DECIMAL(10,9) host variable with a value of 3.453789832.

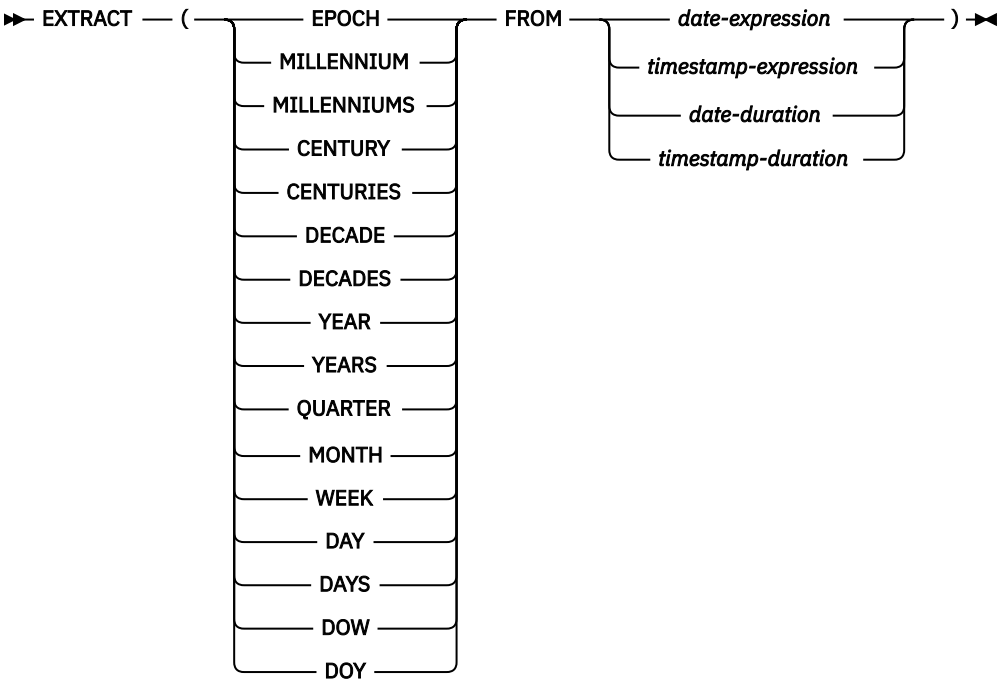
```
VALUES EXP(:E)
```

Returns the DOUBLE value +3.16200000069145E+001.

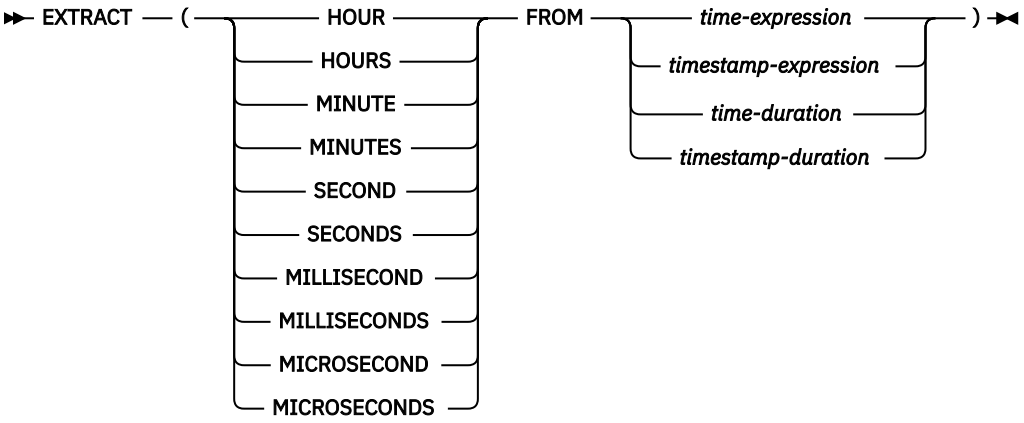
EXTRACT

The EXTRACT function returns a portion of a datetime based on its arguments.

Extract date values



Extract time values



The schema is SYSIBM.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Extract date values

EPOCH
The number of seconds since 1970-01-01 00:00:00.00 for the specified date or timestamp expression is returned. A duration cannot be specified (SQLCODE SQL0171, SQLSTATE 22546). The value is positive if the expression represents a date or timestamp that is after 1970-01-01 00:00:00.00; the value is negative for a date or timestamp that is before 1970-01-01 00:00:00.00.

MILLENNIUM or MILLENNIUMS
The ordinal number of the full 1000-year period of the specified date or timestamp expression or duration is returned; for example, 2 for a date between 01 Jan 2000 and 31 Dec 2999

CENTURY or CENTURIES
The ordinal number of the full 100-year period of the specified date or timestamp expression or duration is returned; for example, 20 for a date between 01 Jan 2000 and 31 Dec 2099. Not to be confused with the ordinal system that counts dates up to the year 100 as being in the "first century", dates between 01 Jan 2000 and 31 Dec 2099 as being in the "21st century", etc.

DECADE or DECADES
The ordinal number of the full 10-year period of the specified date or timestamp expression or duration is returned; for example, 201 for a date between 01 Jan 2010 and 31 Dec 2019.

YEAR or YEARS
The years portion of the specified date or timestamp expression or duration is returned. The result is identical to that returned by the YEAR scalar function.

QUARTER
The quarter (1, 2, 3, or 4) of the year of the specified date or timestamp expression or duration is returned.

MONTH
The number (1 - 12) of the month of the specified date or timestamp expression or duration is returned. The result is identical to that returned by the MONTH scalar function.

WEEK
The number (1 - 53) of the week of the year of the specified date or timestamp expression or duration is returned. The value uses the ISO-8601 definition of a week, which begins on Monday; as a result, some years might have 53 weeks, and sometimes the first few days of January can be included as part of the 52nd or 53rd week of the previous year.

DAY or DAYS
The number (1 - 31) of the day of the specified date or timestamp expression or duration is returned. The result is identical to that returned by the DAY scalar function.

DOW
A number (1 for Sunday, 2 for Monday, ..., 7 for Saturday) indicating the day of the week of the specified date or timestamp expression is returned. A duration cannot be specified (SQLCODE SQL0171, SQLSTATE 22546).

DOY
A number (1 - 366) indicating the day of the year of the specified date or timestamp expression is returned. A duration cannot be specified (SQLCODE SQL0171, SQLSTATE 22546).

date-expression
An expression that returns the value of either a built-in DATE or built-in character string data type.

If a date expression is a character string, it must be a valid string representation of a date that is not a CLOB. In a Unicode database, if a date expression is a graphic string, it is first converted to a character string before the function is executed.

timestamp-expression
An expression that returns the value of either a built-in TIMESTAMP or built-in character string data type.

If a timestamp expression is a character string, it must be a valid string representation of a timestamp that is not a CLOB. In a Unicode database, if a timestamp expression is a graphic string, it is first converted to a character string before the function is executed.

date-duration
A DECIMAL(8,0) number that specifies a date duration (see "Datetime operations and durations" on page 145).

timestamp-duration
A DECIMAL(14+*s*,*s*) number that specifies a timestamp duration, where *s* represents the number of digits of fractional seconds ranging from 0 to 12 (see "Datetime operations and durations" on page 145).

Extract time values

HOUR or HOURS
The hours portion of the specified time or timestamp expression or duration is returned. The result is identical to that returned by the HOUR scalar function.

MINUTE or MINUTES
The minutes portion of the specified time or timestamp expression or duration is returned. The result is identical to that returned by the MINUTE scalar function.

SECOND or SECONDS
The seconds portion of the specified time or timestamp expression or duration is returned. The result is identical to that returned by:

- SECOND(*expression*, 6) when the data type of the expression or duration is a TIME value or a string representation of a TIME or TIMESTAMP
- SECOND(*expression*, *s*) when the data type of the expression or duration is a TIMESTAMP(*s*) value

MILLISECOND or MILLISECONDS
The seconds portion of the specified timestamp expression or duration, including fractional parts to one thousandth of a second, multiplied by 1000 (0 - 59999) is returned. A time expression or duration cannot be specified (SQLCODE SQL0180, SQLSTATE 22007).

MICROSECOND or MICROSECONDS
The seconds portion of the specified timestamp expression or duration, including fractional parts to one millionth of a second, multiplied by 1000000 (0 - 59999999) is returned. A time expression or duration cannot be specified (SQLCODE SQL0180, SQLSTATE 22007).

time-expression
An expression that returns the value of either a built-in TIME or built-in character string data type.

If a time expression is a character string, it must be a valid string representation of a time that is not a CLOB. In a Unicode database, if a time expression is a graphic string, it is first converted to a character string before the function is executed.

timestamp-expression
An expression that returns the value of a built-in DATE, TIMESTAMP or character string data type.

If *timestamp-expression* is a DATE, it is converted to a TIMESTAMP(0) value, assuming a time of exactly midnight (00.00.00).

If a timestamp expression is a character string, it must be a valid string representation of a timestamp or date that is not a CLOB. In a Unicode database, if a timestamp expression is a graphic string, it is first converted to a character string before the function is executed. The string is converted to a TIMESTAMP(6) value.

time-duration
A DECIMAL(6,0) number that specifies a time duration (see "Datetime operations and durations" on page 145).

timestamp-duration
A DECIMAL(14+*s*,*s*) number that specifies a timestamp duration, where *s* represents the number of digits of fractional seconds ranging from 0 to 12 (see "Datetime operations and durations" on page 145).

The data type of the result of the function depends on the part of the datetime value that is specified:

- If MILLENNIUM, CENTURY, DECADE, YEAR, QUARTER, MONTH, WEEK, DAY, DOW, DOY, HOUR, or MINUTE is specified, the data type of the result is INTEGER.
- If SECOND is specified with a TIMESTAMP(*p*) value, the data type of the result is DECIMAL(2+*p*, *p*) where *p* is the fractional seconds precision.
- If SECOND is specified with a TIME value or a string representation of a TIME or TIMESTAMP, the data type of the result is DECIMAL(8,6).
- If MILLISECOND, MILLISECONDS, MICROSECOND, or MICROSECONDS is specified with a TIMESTAMP(p) value, the data type of the result is INTEGER.
- If EPOCH is specified, the data type of result is BIGINT.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

In a table with the name PROJECT:

- Column col1 contains the date value '1988-12-25'. The following statement returns the integer value 12:

```
SELECT EXTRACT(MONTH FROM col1) FROM PROJECT;
```

- Column col2 contains the timestamp value '2007-02-14 12:15:06.123456'. The following statement returns the integer value 6123:

```
SELECT EXTRACT(MILLISECONDS FROM col2) FROM PROJECT;
```

  The following statement returns the integer value 6123456:

```
SELECT EXTRACT(MICROSECONDS FROM col2) FROM PROJECT;
```

- Column col3 contains the date value '2013-02-14'. The following statement returns the integer value 201:

```
SELECT EXTRACT(DECADE FROM col3) FROM PROJECT;
```

- Column col4 has a data type of DECIMAL(8,0) and contains the value 12301000. Because the data type is DECIMAL(8,0), this value will be interpreted as a date duration (1230 years, 10 months, 00 days). The following statement returns the integer value 10:

```
SELECT EXTRACT(MONTH FROM col4) FROM PROJECT;
```

- Column col5 has a data type of DECIMAL(6,0) and contains the value 123010. Because the data type is DECIMAL(6,0), this value will be interpreted as a time duration (12 hours, 30 minutes, 10 seconds). The following statement returns the integer value 10:

```
SELECT EXTRACT(SECONDS FROM col5) FROM PROJECT;
```

- Column col6 has a data type of DECIMAL(16,2) and contains the value 12301000123010.45. Because the data type is DECIMAL(16,2), this value will be interpreted as a timestamp duration (1230 years, 10 months, 00 days, 12 hours, 30 minutes, 10.45 seconds). The following statement returns the integer value 10450:

```
SELECT EXTRACT(MILLISECOND FROM col6) FROM PROJECT;
```

FIRST_DAY

The FIRST_DAY function returns a date or timestamp that represents the first day of the month of the argument.

The schema is SYSIBM.

expression
An expression that specifies the datetime value to compute the first day of the month. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

The result of the function is a timestamp with the same precision as *expression*, if *expression* is a timestamp. Otherwise, the result of the function is a date. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

1. Set the host variable FIRST_OF_MONTH with the first day of the current month.

```
SET :FIRST_OF_MONTH = FIRST_DAY(CURRENT_DATE)
```

   The host variable FIRST_OF_MONTH is set with the value representing the beginning of the current month. If the current day is 2000-02-10, then FIRST_OF_MONTH is set to 2000-02-01.

2. Set the host variable FIRST_OF_MONTH with the first day of the month in IBM European standard format for the given date.

```
SET :FIRST_OF_MONTH = CHAR(FIRST_DAY(DATE '1965-07-07'), EUR)
```

   The host variable FIRST_OF_MONTH is set with the value '01.07.1965'.

FLOAT

The FLOAT function returns a floating-point representation of a number. FLOAT is a synonym for DOUBLE.

The schema is SYSIBM.

FLOAT4

The FLOAT4 function returns a single-precision floating-point representation of either a number or a string representation of a number.

The schema is SYSIBM.

The FLOAT4 scalar function is a synonym for the REAL scalar function.

FLOAT8

The FLOAT8 function returns a double-precision floating-point representation of either a number or a string representation of a number.

The schema is SYSIBM.

The FLOAT8 scalar function is a synonym for the DOUBLE scalar function.

FLOOR

Returns the largest integer value less than or equal to the argument.

The schema is SYSIBM. (The SYSFUN version of the FLOOR function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type.

The result of the function has the same data type and length attribute as the argument except that the scale is 0 if the argument is DECIMAL. For example, an argument with a data type of DECIMAL(5,5) returns DECIMAL(5,0).

The result can be null if the argument can be null or if the argument is not a decimal floating-point number and the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

Notes

- **Results involving DECFLOAT special values:** For decimal floating-point values, the special values are treated as follows:
  - FLOOR(NaN) returns NaN.
  - FLOOR(-NaN) returns -NaN.
  - FLOOR(Infinity) returns Infinity.
  - FLOOR(-Infinity) returns -Infinity.
  - FLOOR(sNaN) returns NaN and a warning.
  - FLOOR(-sNaN) returns -NaN and a warning.

Examples

- *Example 1*: Use the FLOOR function to truncate any digits to the right of the decimal point.

```
SELECT FLOOR(SALARY)
  FROM EMPLOYEE
```

- *Example 2*: Use the FLOOR function on both positive and negative numbers.

```
VALUES FLOOR(3.5), FLOOR(3.1),
  FLOOR(-3.1), FLOOR(-3.5)
```

This example returns 3., 3., -4., and -4., respectively.

FROM_UTC_TIMESTAMP

The FROM_UTC_TIMESTAMP scalar function returns a TIMESTAMP that is converted from Coordinated Universal Time to the time zone specified by the time zone string. FROM_UTC_TIMESTAMP is a statement deterministic function.

The schema is SYSIBM.

expression
An expression that specifies the timestamp that is in the Coordinated Universal Time time zone. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. If *expression* does not contain time information, a time of midnight (00.00.00) is used for the argument. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported through implicit casting. If expression is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

timezone-expression
An expression that specifies the time zone that the expression is to be adjusted to. The expression must return a value that is a built-in character string, numeric, or datetime data type. In a Unicode database, the expression can also be a graphic string data type. Numeric and datetime data types are supported through implicit casting. If the expression is not a VARCHAR, it is cast to VARCHAR before the function is evaluated. The expression must not be a FOR BIT DATA subtype (SQLSTATE 42815). *timezone-expression* must not be null if *expression* is not null (SQLSTATE 42815).

The value of the *timezone-expression* must be a time zone name from the Internet Assigned Numbers Authority (IANA) time zone database. The standard format for a time zone name in the IANA database is `Area/Location`, where:

- `Area` is the English name of a continent, ocean, or the special area 'Etc'.
- `Location` is the English name of a location within the area; usually a city, or small island.

Examples:

- "America/Toronto"
- "Asia/Sakhalin"
- "Etc/UTC" (which represents Coordinated Universal Time)

For complete details on the valid set of time zone names and the rules that are associated with those time zones, refer to the IANA time zone database. The database server uses version **2010c** of the IANA time zone database. Contact IBM support if a newer version of the IANA time zone database is required.

The result of the function is a timestamp with the same precision as *expression*, if *expression* is a timestamp. If expression is a DATE, the result of the function is a TIMESTAMP(0). Otherwise, the result of the function is a TIMESTAMP(6).

The result can be null; if the *expression* is null, the result is the null value. The *timezone-expression* cannot be null if a not-null value was supplied for the *expression* (SQLSTATE 42815).

The result is the *expression*, adjusted from the Coordinated Universal Time time zone to the time zone specified by the *timezone-expression*. If the *timezone-expression* returns a value that is not a time zone in the IANA time zone database, then the value of *expression* is returned without being adjusted.

The timestamp adjustment is done by first applying the raw offset from Coordinated Universal Time of the *timezone-expression*. If Daylight Saving Time is in effect at the adjusted timestamp for the time zone that is specified by the *timezone-expression*, then the Daylight Saving Time offset is also applied to the timestamp.

Time zones that use Daylight Saving Time have ambiguities at the transition dates. When a time zone changes from standard time to Daylight Saving Time, a range of time does not occur as it is skipped during the transition. When a time zone changes from Daylight Saving Time to standard time, a range of time occurs twice. Ambiguous timestamps are treated as if they occurred when standard time was in effect for the time zone.

Examples

1. Convert the Coordinated Universal Time timestamp '2011-12-25 09:00:00.123456' to the 'Asia/Tokyo' time zone. The following returns a TIMESTAMP with the value '2011-12-25 18:00:00.123456'.

```
FROM_UTC_TIMESTAMP(TIMESTAMP '2011-12-25 09:00:00.123456', 'Asia/Tokyo')
```

2. Convert the Coordinated Universal Time timestamp '2014-11-02 06:55:00' to the 'America/Toronto' time zone. The following returns a TIMESTAMP with the value '2014-11-02 01:55:00'.

```
FROM_UTC_TIMESTAMP(TIMESTAMP'2014-11-02 06:55:00', 'America/Toronto')
```

3. Convert the Coordinated Universal Time timestamp '2015-03-02 06:05:00' to the 'America/Toronto' time zone. The following returns a TIMESTAMP with the value '2015-03-02 01:05:00'.

```
FROM_UTC_TIMESTAMP(TIMESTAMP'2015-03-02 06:05:00', 'America/Toronto')
```

GENERATE_UNIQUE

The GENERATE_UNIQUE function returns a bit data character string 13 bytes long (CHAR(13) FOR BIT DATA) that is unique compared to any other execution of the same function.

The schema is SYSIBM.

The system clock is used to generate the internal Universal Time, Coordinated (UTC) timestamp along with the database partition number on which the function executes. Adjustments that move the actual system clock backward could result in duplicate values.

The function is defined as non-deterministic.

There are no arguments to this function (the empty parentheses must be specified).

The result of the function is a unique value that includes the internal form of the Universal Time, Coordinated (UTC) and the database partition number where the function was processed. The result cannot be null.

The result of this function can be used to provide unique values in a table. Each successive value will be greater than the previous value, providing a sequence that can be used within a table. The value includes the database partition number where the function executed so that a table partitioned across multiple database partitions also has unique values in some sequence. The sequence is based on the time the function was executed.

This function differs from using the special register CURRENT TIMESTAMP in that a unique value is generated for each row of a multiple row insert statement, an insert statement with a fullselect, or an INSERT operation in a MERGE statement.

The timestamp value that is part of the result of this function can be determined using the TIMESTAMP scalar function with the result of GENERATE_UNIQUE as an argument.

Example

Create a table that includes a column that is unique for each row. Populate this column using the GENERATE_UNIQUE function. Notice that the UNIQUE_ID column has "FOR BIT DATA "specified to identify the column as a bit data character string.

```
CREATE TABLE EMP_UPDATE
  (UNIQUE_ID CHAR(13) FOR BIT DATA,
  EMPNO CHAR(6),
  TEXT VARCHAR(1000))
  INSERT INTO EMP_UPDATE
    VALUES (GENERATE_UNIQUE(), '000020', 'Update entry...'),
    (GENERATE_UNIQUE(), '000050', 'Update entry...')
```

This table will have a unique identifier for each row provided that the UNIQUE_ID column is always set using GENERATE_UNIQUE. This can be done by introducing a trigger on the table.

```
CREATE TRIGGER EMP_UPDATE_UNIQUE
  NO CASCADE BEFORE INSERT ON EMP_UPDATE
  REFERENCING NEW AS NEW_UPD
  FOR EACH ROW
  SNEW_UPD.UNIQUE_ID = GENERATE_UNIQUE()
```

With this trigger defined, the previous INSERT statement could be issued without the first column as follows.

```
INSERT INTO EMP_UPDATE (EMPNO, TEXT)
  VALUES ('000020', 'Update entry 1...'),
  ('000050', 'Update entry 2...')
```

The timestamp (in UTC) for when a row was added to EMP_UPDATE can be returned using:

```
SELECT TIMESTAMP (UNIQUE_ID), EMPNO, TEXT
  FROM EMP_UPDATE
```

Therefore, there is no need to have a timestamp column in the table to record when a row is inserted.

GETHINT

The GETHINT function will return the password hint if one is found in the *encrypted-data*.

Important: The GETHINT function is deprecated and might not appear in future releases.

The schema is SYSIBM.

A password hint is a phrase that will help data owners remember passwords; for example, 'Ocean' as a hint to remember 'Pacific'. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

encrypted-data
An expression that returns a CHAR FOR BIT DATA or VARCHAR FOR BIT DATA value that is a complete, encrypted data string. The data string must have been encrypted using the ENCRYPT function (SQLSTATE 428FE).

The result of the function is VARCHAR(32 OCTETS). The result can be null; if the hint parameter was not added to the *encrypted-data* by the ENCRYPT function or the first argument is null, the result is the null value.

Example

In this example the hint 'Ocean' is stored to help the user remember the encryption password 'Pacific'.

```
INSERT INTO EMP (SSN) VALUES ENCRYPT('289-46-8832', 'Pacific','Ocean');
SELECT GETHINT(SSN)
  FROM EMP;
```

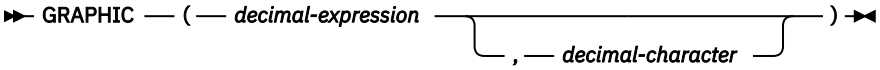
The value returned is 'Ocean'.

GRAPHIC

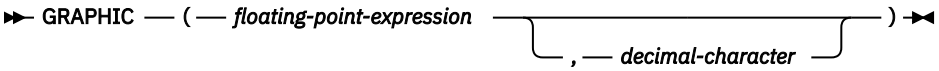
The GRAPHIC function returns a fixed-length graphic string representation of a value of a different data type.

Integer to graphic

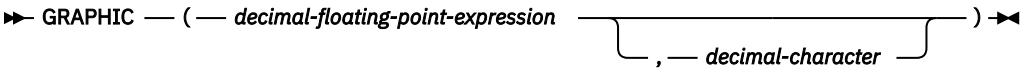
Decimal to graphic



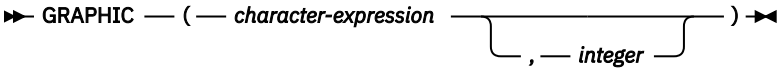
Floating-point to graphic



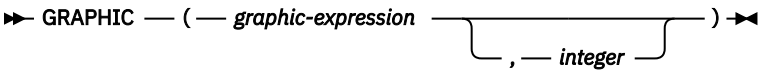
Decimal floating-point to graphic



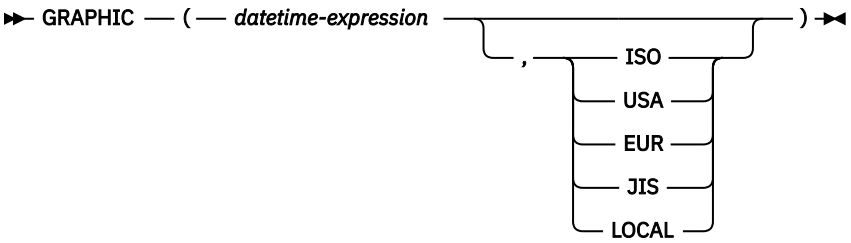
Character to graphic



Graphic to graphic



Datetime to graphic



Boolean to vargraphic

The schema is SYSIBM. The function name cannot be specified as a qualified name when keywords are used in the function signature.

Integer to graphic

integer-expression
An expression that returns a value that is of an integer data type (SMALLINT, INTEGER, or BIGINT).

The result is a fixed-length graphic string representation of *integer-expression* in the form of an SQL integer constant. The result consists of *n* double-byte characters, which represent the significant digits in the argument, and is preceded by a minus sign if the argument is negative. The result is left-aligned.

- If the first argument is a small integer, the length of the result is 6.
- If the first argument is a large integer, the length of the result is 11.
- If the first argument is a big integer, the length of the result is 20.

If the number of double-byte characters in the result is less than the defined length of the result, the result is padded on the right with blanks.

The code page of the result is the DBCS code page of the section.

Decimal to graphic

decimal-expression
An expression that returns a value that is a decimal data type. The DECIMAL scalar function can be used to change the precision and scale.

decimal-character
Specifies the double-byte character constant that is used to delimit the decimal digits in the result graphic string. The double-byte character constant cannot be a digit, the plus sign (+), the minus sign (-), or a blank (SQLSTATE 42815). The default is the period (.) character.

The result is a fixed-length graphic string representation of *decimal-expression* in the form of an SQL decimal constant. The length of the result is 2+*p*, where *p* is the precision of *decimal-expression*. Leading zeros are not included. Trailing zeros are included. If *decimal-expression* is negative, the first double-byte character of the result is a minus sign; otherwise, the first double-byte character is a digit or the decimal character. If the scale of *decimal-expression* is zero, the decimal character is not returned. If the number of double-byte characters in the result is less than the defined length of the result, the result is padded on the right with blanks.

The code page of the result is the DBCS code page of the section.

Floating-point to graphic

floating-point-expression
An expression that returns a value that is a floating-point data type (DOUBLE or REAL).

decimal-character
Specifies the double-byte character constant that is used to delimit the decimal digits in the result graphic string. The double-byte character constant cannot be a digit, the plus sign (+), the minus sign (-), or a blank (SQLSTATE 42815). The default is the period (.) character.

The result is a fixed-length graphic string representation of *floating-point-expression* in the form of an SQL floating-point constant. The length of the result is 24. The result is the smallest number of double-byte characters that can represent the value of *floating-point-expression* such that the mantissa consists of a single digit other than zero followed by a period and a sequence of digits. If *floating-point-expression* is negative, the first double-byte character of the result is a minus sign; otherwise, the first double-byte character is a digit. If *floating-point-expression* is zero, the result is

0E0. If the number of double-byte characters in the result is less than 24, the result is padded on the right with blanks.

The code page of the result is the DBCS code page of the section.

Decimal floating-point to graphic

decimal-floating-point-expression
An expression that returns a value that is a decimal floating-point data type (DECFLOAT).

decimal-character
Specifies the double-byte character constant that is used to delimit the decimal digits in the result graphic string. The double-byte character constant cannot be a digit, the plus sign (+), the minus sign (-), or a blank (SQLSTATE 42815). The default is the period (.) character.

The result is a fixed-length graphic string representation of *decimal-floating-point-expression* in the form of an SQL decimal floating-point constant. The length attribute of the result is 42. The result is the smallest number of double-byte characters that can represent the value of *decimal-floating-point-expression*. If *decimal-floating-point-expression* is negative, the first double-byte character of the result is a minus sign; otherwise, the first double-byte character is a digit. If *decimal-floating-point-expression* is zero, the result is 0.

If the value of *decimal-floating-point-expression* is the special value Infinity, sNaN, or NaN, the strings G'INFINITY', G'SNAN', and G'NAN', respectively, are returned. If the special value is negative, the first double-byte character of the result is a minus sign. The decimal floating-point special value sNaN does not result in a warning when converted to a string. If the number of double-byte characters in the result is less than 42, the result is padded on the right with blanks.

The code page of the result is the DBCS code page of the section.

Character to graphic
In Unicode databases:

character-expression
An expression that returns a value that is a built-in character string data type. The expression must not be a FOR BIT DATA subtype (SQLSTATE 42846).

integer
An integer constant that specifies the length attribute for the resulting fixed-length graphic string. The value must be between 0 and the maximum length for the GRAPHIC data type in the string units of the result.

If the second argument is not specified:

- If the *character-expression* is the empty string constant, the length attribute of the result is 0.
- Otherwise, the length attribute of the result is the lower of the following values:
  - The maximum length for the GRAPHIC data type in the string units of the result
  - The length attribute of the first argument

The result is a fixed-length graphic string that is converted from *character-expression*. The length attribute of the result is determined by the value of *integer*.

The actual length of the result is the same as the length attribute of the result.

If the length of *character-expression* that is converted to a graphic string is less than the length attribute of the result, the result is padded with blanks up to the length attribute of the result.

If the length of *character-expression* that is converted to a graphic string is greater than the length attribute of the result, several scenarios exist:

- If the string unit of the result is CODEUNITS32, truncation is performed. If only blank characters are truncated and *character-expression* is CHAR or VARCHAR, no warning is returned. Otherwise, a warning is returned (SQLSTATE 01004).
- If *integer* is specified, truncation is performed. If only blank characters are truncated and *character-expression* is CHAR or VARCHAR, no warning is returned. Otherwise, a warning is returned

(SQLSTATE 01004). When the output string is truncated, such that the last character is a high surrogate, that surrogate is converted to the blank character (X'0020'). Do not rely on this behavior because it might change in a future release.

- If *integer* is not specified, an error is returned (SQLSTATE 22001).

For details about the conversion process, see "VARGRAPHIC " on page 573.

In non-Unicode databases:

character-expression
An expression that returns a value that is a built-in CHAR or VARCHAR data type.

The result is a fixed-length graphic string that is converted from *character-expression*. The length attribute of the result is the minimum of the length attribute of *character-expression* and the maximum length for the GRAPHIC data type.

The actual length of the result is the same as the length attribute of the result. If the length of *character-expression* that is converted to a graphic string is less than the length attribute of the result, the result is padded with blanks up to the length attribute of the result. If the length of *character-expression* that is converted to a graphic string is greater than the length attribute of the result, an error is returned (SQLSTATE 22001).

For details about the conversion process, see "VARGRAPHIC " on page 573.

Graphic to graphic

graphic-expression
An expression that returns a built-in value that is a graphic string data type.

integer
An integer constant that specifies the length attribute for the resulting fixed-length graphic string. The value must be between 0 and the maximum length for the GRAPHIC data type in the string units of the result.

If the second argument is not specified:

- If the *graphic-expression* is the empty string constant, the length attribute of the result is 0.
- Otherwise, the length attribute of the result is the lower of the following values:
  - The maximum length for the GRAPHIC data type in the string units of the result
  - The length attribute of the first argument

The result is a fixed-length graphic string. The length attribute of the result is determined by the value of *integer*.

The actual length of the result is the same as the length attribute of the result.

If the length of *graphic-expression* is less than the length attribute of the result, the result is padded with blanks up to the length attribute of the result.

If the length of *graphic-expression* is greater than the length attribute of the result, several scenarios exist:

- If the string unit of the result is CODEUNITS32, truncation is performed. If only blank characters are truncated and *graphic-expression* is GRAPHIC or VARGRAPHIC, no warning is returned. Otherwise, a warning is returned (SQLSTATE 01004).
- If *integer* is specified, truncation is performed. If only blank characters are truncated and *graphic-expression* is GRAPHIC or VARGRAPHIC, no warning is returned. Otherwise, a warning is returned (SQLSTATE 01004). In a Unicode database, when the output string is truncated, such that the last character is a high surrogate, that surrogate is converted to the blank character (X'0020'). Do not rely on this behavior because it might change in a future release.
- If *integer* is not specified and *graphic-expression* is VARGRAPHIC, truncation behavior is as follows:
  - If only blank characters must be truncated, truncation is performed with no warning returned.
  - If non-blank characters must be truncated, an error is returned (SQLSTATE 22001).

- If *integer* is not specified and *graphic-expression* is DBCLOB, an error is returned (SQLSTATE 22001).

Datetime to graphic

datetime-expression
An expression that is of one of the following data types:

DATE
The result is the graphic string representation of the date in the format specified by the second argument. The length of the result is 10. An error is returned if the second argument is specified and is not a valid value (SQLSTATE 42703).

TIME
The result is the graphic string representation of the time in the format specified by the second argument. The length of the result is 8. An error is returned if the second argument is specified and is not a valid value (SQLSTATE 42703).

TIMESTAMP
The result is the graphic string representation of the timestamp. If the data type of *datetime-expression* is TIMESTAMP(0), the length of the result is 19. If the data type of *datetime-expression* is TIMESTAMP(*n*), where *n* is between 1 and 12, the length of the result is 20+*n*. Otherwise, the length of the result is 26.

The code page of the string is the code page of the section.

Boolean to graphic

boolean-expression
An expression that returns a Boolean value (TRUE or FALSE). The result is either 'TRUE ' (note the blank after the E) or 'FALSE'.

Result

The GRAPHIC function returns a fixed-length graphic string representation of:

- An integer number (Unicode database only), if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number (Unicode database only), if the first argument is a decimal number
- A double-precision floating-point number (Unicode database only), if the first argument is a DOUBLE or REAL
- A decimal floating-point number (Unicode database only), if the argument is a decimal floating-point number (DECFLOAT)
- A character string, if the first argument is any type of character string
- A graphic string, if the first argument is any type of graphic string
- A datetime value (Unicode database only), if the first argument is a DATE, TIME, or TIMESTAMP
- A Boolean value (TRUE or FALSE)

In a non-Unicode database, the string units of the result is double bytes. Otherwise, the string units of the result are determined by the data type of the first argument.

- CODEUNITS16, if the first argument is character string or a graphic string with string units of OCTETS or CODEUNITS16.
- CODEUNITS32, if the first argument is character string or a graphic string with string units of CODEUNITS32.
- Determined by the default string unit of the environment, if the first argument is not a character string or a graphic string.

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Notes

- **Increasing portability of applications:** If the first argument is numeric, or if the first argument is a string and the length argument is specified, use the "CAST specification" on page 152 instead of this function to increase the portability of your applications.

Examples

- *Example 1*: The EDLEVEL column is defined as SMALLINT. The following returns the value as a fixed-length graphic string.

```
SELECT GRAPHIC(EDLEVEL)
  FROM EMPLOYEE
  WHERE LASTNAME = 'HAAS'
```

  Results in the value G'18 '.

- *Example 2*: The SALARY and COMM columns are defined as DECIMAL with a precision of 9 and a scale of 2. Return the total income for employee Haas using the comma decimal character.

```
SELECT GRAPHIC(SALARY + COMM, ',')
  FROM EMPLOYEE
  WHERE LASTNAME = 'HAAS'
```

  Results in the value G'56970,00 '.

- *Example 3*: The following statement returns a string of data type GRAPHIC with the value 'TRUE '.

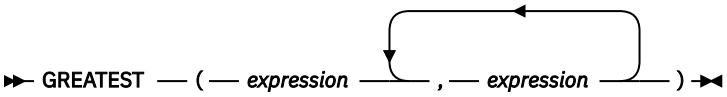
```
values GRAPHIC(3=3)
```

- *Example 4*: The following statement returns a string of data type GRAPHIC with the value 'FALSE'.

```
values GRAPHIC(3>3)
```

GREATEST

The GREATEST function returns the maximum value in a set of values.



The schema is SYSIBM.

expression

An expression that returns a value of any built-in data type or user-defined data type that is comparable with the data type of the other argument. The data type cannot be a LOB, distinct type based on a LOB, XML, array, cursor, row, or structured type.

Result

The result of the function is the largest argument value. The result can be null if at least one argument can be null; the result is the null value if any argument is null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined by the data types of all the arguments as explained in "Rules for result data types".

Notes

- The GREATEST scalar function is a synonym for the MAX scalar function.

- The GREATEST function cannot be used as a source function when creating a user-defined function. Because this function accepts any comparable data types as arguments, it is not necessary to create additional signatures to support user-defined data types.

Example

Assume that table T1 contains three columns C1, C2, and C3 with values 1, 7, and 4, respectively. The query:

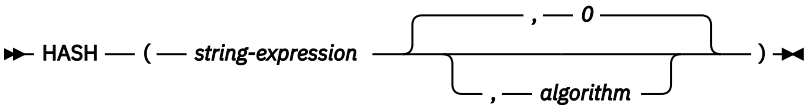
```
SELECT GREATEST (C1, C2, C3) FROM T1
```

returns 7.

If column C3 has a value of null instead of 4, the same query returns the null value.

HASH

The HASH function returns a 128-bit, 160-bit, 256-bit or 512-bit hash of the input data, depending on the algorithm selected, and is intended for cryptographic purposes.



The schema is SYSIBM.

string-expression
An expression that represents the string value to be hashed. This expression must return a built-in character string, graphic string, binary string, numeric value, Boolean value, or datetime value. If the value is not a character, graphic, or binary string, it is implicitly cast to VARCHAR before the function is evaluated.

algorithm
An expression that returns a value that indicates which algorithm is to be used for hashing. The expression must return a value that has a built-in numeric, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also return a GRAPHIC or VARGRAPHIC data type. If the value is not an INTEGER, it is cast to INTEGER before the function is evaluated. If no algorithm is specified, the default algorithm value of 0 is used.

Table 60 on page 359 shows the algorithm used, the result size, and the number of return values for each algorithm value.

Table 60. Resulting size from each algorithm

Algorithm value	Algorithm	Result size	Number of return values
0	MD5	128 bit	2^{128}
1	SHA1	160 bit	2^{160}
2	SHA2_256	256 bit	2^{256}
3	SHA2_512	512 bit	2^{512}

Note that security flaws have been identified in both the SHA1 and MD5 algorithms. You can find acceptable hash algorithms in applicable compliance documentation, such as National Institute of Standards and Technology (NIST) Special Publication 800-131A.

Result

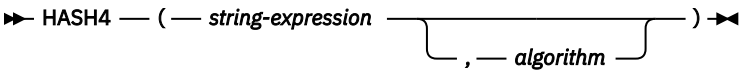
The data type of the result is VARBINARY. If any argument can be null, the result can be null. If any argument is null, the result is the null value.

Example

```
values  hash('Charlie at IBM', 1)
result is x'D6E42303462491FC696EAC53C1B086A5034735A7'
```

HASH4

The HASH4 function returns the 32-bit checksum hash of the input data. The function provides 2^{32} distinct return values and is intended for data retrieval (lookups).



The schema is SYSIBM.

string-expression
An expression that represents the string value to be hashed. This expression must return a built-in character string, graphic string, binary string, numeric value, Boolean value, or datetime value. If the value is not a character, graphic, or binary string, it is implicitly cast to VARCHAR before the function is evaluated.

algorithm
An expression that specifies the algorithm to use for hashing. The expression must return a value that is a built-in numeric, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported using implicit casting. If the expression is not a INTEGER, it is cast to INTEGER before evaluating the function.

The algorithm value can be either `0` or `1`. `0` is the default value and indicates the Adler algorithm. `1` indicates the CRC32 algorithm. The Adler algorithm provides a faster checksum hash; however, it has poor coverage when the messages are less than a few hundred bytes (poor coverage means that two different integers hash to the same value, referred to as a "collision"). In this case, use the CRC32 algorithm, or switch to hash8 instead.

Result

The data type of the result is INTEGER. If the first argument can be null, the result can be null. If the first argument is null, the result is the null value.

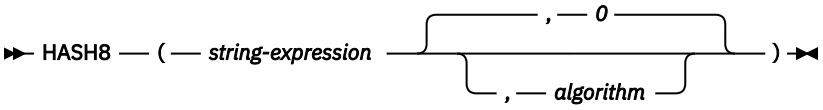
Example

The following example gives a hashed value of a string of text:

```
values hash4('Charlie at IBM', 0)
The result is 622396582
```

HASH8

The HASH8 function returns the 64-bit hash of an input string. The function provides 2^{64} distinct return values and is intended for data retrieval (that is, lookups). The result for a particular input string differs depending on the endianness (big-endian or little-endian) of your system.



The schema is SYSIBM.

string-expression
An expression that represents the string value to be hashed. This expression must return a built-in character string, graphic string, binary string, numeric value, Boolean value, or datetime value. If the value is not a character, graphic, or binary string, it is implicitly cast to VARCHAR before the function is evaluated.

algorithm
An expression that returns a value that indicates which algorithm is to be used for hashing. The expression must return a value that has a built-in numeric, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also return a GRAPHIC or VARGRAPHIC data type. If the value is not an INTEGER, it is cast to INTEGER before the function is evaluated. The returned value must be 0, which indicates the Jenkins algorithm.

Result

The data type of the result is BIGINT. If the first argument can be null, the result can be null. If the first argument is null, the result is the null value.

Example

```
values hash8('Charlie at IBM', 0)
```

- On a little-endian system, the result is 4570902652830829618.
- On a big-endian system, the result is 7187665777530874019.

HASHEDVALUE

The HASHEDVALUE function returns the distribution map index of the row obtained by applying the partitioning function on the distribution key value of the row.

The schema is SYSIBM.

column-name
The qualified or unqualified name of a column in a table. The column can have any data type.

If the column is a column of a view, the expression in the view for the column must reference a column of the underlying base table and the view must be deletable. A nested or common table expression follows the same rules as a view.

An example application for this function is in a SELECT clause, where it returns the distribution map index for each row of the table that was used to form the result of the SELECT statement.

The distribution map index returned on transition variables and tables is derived from the current transition values of the distribution key columns. For example, in a before insert trigger, the function will return the projected distribution map index given the current values of the new transition variables. However, the values of the distribution key columns may be modified by a subsequent before insert

trigger. Thus, the final distribution map index of the row when it is inserted into the database may differ from the projected value.

The specific row (and table) for which the distribution map index is returned by the HASHEDVALUE function is determined from the context of the SQL statement that uses the function.

Result

The data type of the result is INTEGER in the range 0 to 32767. For a table with no distribution key, the result is always 0. A null value is never returned. Since row-level information is returned, the results are the same, regardless of which column is specified for the table.

Notes

- The HASHEDVALUE function cannot be used on replicated tables, within check constraints, or in the definition of generated columns (SQLSTATE 42881).
- The HASHEDVALUE function cannot be used as a source function when creating a user-defined function. Because it accepts any data type as an argument, it is not necessary to create additional signatures to support user-defined distinct types.
- The HASHEDVALUE function cannot be used as part of an expression-based key in a CREATE INDEX statement.
- ***Syntax alternatives:*** For compatibility with previous versions of Db2 products, the function name PARTITION is a synonym for HASHEDVALUE.

Examples

- *Example 1*: List the employee numbers (EMPNO) from the EMPLOYEE table for all rows with a distribution map index of 100.

```
SELECT EMPNO FROM EMPLOYEE
  WHERE HASHEDVALUE(PHONENO) = 100
```

- *Example 2*: Log the employee number and the projected distribution map index of the new row into a table called EMPINSERTLOG2 for any insertion of employees by creating a before trigger on the table EMPLOYEE.

```
CREATE TRIGGER EMPINSLOGTRIG2
  BEFORE INSERT ON EMPLOYEE
  REFERENCING NEW AW NEWTABLE
  FOR EACH ROW
  INSERT INTO EMPINSERTLOG2
    VALUES(NEWTABLE.EMPNO, HASHEDVALUE(NEWTABLE.EMPNO))
```

HEX

The HEX function returns a hexadecimal representation of a value as a character string.

The schema is SYSIBM.

expression
An expression that returns a value of any built-in data type that is not XML, with a maximum length of 16 336 bytes.

The result of the function is a character string with string units of OCTETS. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The code page is the section code page.

The result is a string of hexadecimal digits. The first two represent the first byte of the argument, the next two represent the second byte of the argument, and so forth. If the argument is a datetime value or

a numeric value the result is the hexadecimal representation of the internal form of the argument. The hexadecimal representation that is returned may be different depending on the application server where the function is executed. Cases where differences would be evident include:

- Character string arguments when the HEX function is performed on an ASCII client with an EBCDIC server or on an EBCDIC client with an ASCII server.
- Numeric arguments (in some cases) when the HEX function is performed where client and server systems have different byte orderings for numeric values.

The type and length of the result vary based on the type, length, and string units of the character and graphic string arguments.

Table 61. Data type of the result as a function of the data types of the argument data type and the length attribute

Argument data type[1]	**Length attribute**[2]	**Result data type**
CHAR(A) or BINARY(A)	A<128	CHAR(A*2)
CHAR(A) or BINARY(A)	A>127	VARCHAR(A*2)
VARCHAR(A), VARBINARY(A), CLOB(A), or BLOB(A)	A<16337	VARCHAR(A*2)
GRAPHIC(A)	A<64	CHAR(A*2*2)
GRAPHIC(A)	A>63	VARCHAR(A*2*2)
VARGRAPHIC(A) or DBCLOB(A)	A<8169	VARCHAR(A*2*2)
CHAR(A CODEUNITS32)	A<64	VARCHAR(A*4*2)
VARCHAR(A CODEUNITS32) or CLOB(A CODEUNITS32)	A<4085	VARCHAR(A*4*2)
GRAPHIC(A CODEUNITS32)	A<64	VARCHAR(A*2*2*2)
VARGRAPHIC(A CODEUNITS32) or DBCLOB(A CODEUNITS32)	A<4085	VARCHAR(A*2*2*2)

1. If string units are not specified, then the string units for the data type are not CODEUNITS32.
2. The maximum length attributes reflect a data type limit or the limit of 16336 bytes for the input argument.

Examples

Assume the use of a database application server on AIX® or Linux® for the following examples.

- *Example 1*: Using the DEPARTMENT table set the host variable HEX_MGRNO (char(12)) to the hexadecimal representation of the manager number (MGRNO) for the "PLANNING" department (DEPTNAME).

```
SELECT HEX(MGRNO)
  INTO :HEX_MGRNO
  FROM DEPARTMENT
  WHERE DEPTNAME = 'PLANNING'
```

  HEX_MGRNO will be set to "303030303230" when using the sample table (character value is "000020").
- *Example 2*: Suppose COL_1 is a column with a data type of char(1) and a value of "B". The hexadecimal representation of the letter "B" is X'42'. HEX(COL_1) returns a two byte long string "42".
- *Example 3*: Suppose COL_3 is a column with a data type of decimal(6,2) and a value of 40.1. An eight byte long string "0004010C" is the result of applying the HEX function to the internal representation of the decimal value, 40.1.

HEXTORAW

The HEXTORAW function returns a bit string representation of a hexadecimal character string.

The schema is SYSIBM.

In a Unicode database, if a supplied argument is a graphic string, it is converted to a character string before the function is executed.

character-expression
An expression that returns a value that is a built-in character string that is not a CLOB (SQLSTATE 42815). The length must be an even number of characters from the ranges '0' to '9', 'a' to 'f', and 'A' to 'F' (SQLSTATE 42815).

The result of the function is a VARBINARY. The length attribute of the result is half the length attribute of *character-expression* and the actual length is half the length of the actual length of *character-expression*. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Example

Represent a string of hexadecimal characters in binary form.

```
HEXTORAW('ef01abC9')
```

The result is a VARBINARY(4) data type with a value of BX'EF01ABC9'.

HOUR

The HOUR function returns the hour part of a value.

The schema is SYSIBM.

expression
An expression that returns a value of one of the following built-in data types: a DATE, a TIME, a TIMESTAMP, a character string, or an exact numeric data type.

If *expression* is a character string, it must not be a CLOB and its value must be a valid string representation of a datetime value. For the valid formats of string representations of datetime values, see "String representations of datetime values" in "Datetime values".

If *expression* is an exact numeric value, it must be a time duration or timestamp duration. For information about valid time durations and timestamp durations, see "Datetime operands and durations".

Only Unicode databases support an expression that is a valid graphic string representation of a datetime value that is not a DBCLOB. The graphic string is converted to a character string before the function is executed.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a TIME, TIMESTAMP or valid string representation of a time or timestamp:
  - The result is the hour part of the value, which is an integer between 0 and 24.
- If the argument is a DATE or valid string representation of a date:
  - The result is 0.

- If the argument is a time duration or timestamp duration:
  - The result is the hour part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

Example

Using the CL_SCHED sample table, select all the classes that start in the afternoon.

```
SELECT * FROM CL_SCHED
  WHERE HOUR(STARTING) BETWEEN 12 AND 17
```

HOURS_BETWEEN

The HOURS_BETWEEN function returns the number of full hours between the specified arguments.

The schema is SYSIBM.

expression1
An expression that specifies the first datetime value to compute the number of full hours between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression1* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

expression2
An expression that specifies the second datetime value to compute the number of full hours between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression2* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

If there is less than a full hour between *expression1* and *expression2*, the result is zero. If *expression1* is later than *expression2*, the result is positive. If *expression1* is earlier than *expression2*, the result is negative. In NPS compatibility mode, this function always returns a positive number. If *expression1* or *expression2* contains time information, this information is also used to determine the number of full hours. If *expression1* or *expression2* does not contain time information, a time of midnight (00.00.00) is used for the argument that is missing time information.

The result of the function is an INTEGER. If either argument can be null, the result can be null. If either argument is null, the result is the null value.

Examples

1. Set the host variable NUM_HOURS to the number of full hours between 2012-03-01-01.00.00 and 2012-02-28-00.00.00.

   ```
   SET :NUM_HOURS = HOURS_BETWEEN(TIMESTAMP '2012-03-01-01.00.00',
                                  TIMESTAMP '2012-02-28-00.00.00')
   ```

   The host variable NUM_HOURS is set to 49 because an additional day is incurred for February 29, 2012.

2. Set the host variable NUM_HOURS to the number of full hours between 2013-09-11-23.59.59 and 2013-09-01-00.00.00.

   ```
   SET :NUM_HOURS = HOURS_BETWEEN(TIMESTAMP '2013-09-11-23.59.59',
                                  TIMESTAMP '2013-09-01-00.00.00')
   ```

The host variable NUM_HOURS is set to 263 because there is 1 second less than a full 264 hours between the arguments. It is positive because the first argument is later than the second argument.

3. Set the host variable NUM_HOURS to the number of full hours between 2013-09-01-00.00.00 and 2013-09-11-23.59.59.

```
SET :NUM_HOURS = HOURS_BETWEEN(TIMESTAMP '2013-09-01-00.00.00',
                               TIMESTAMP '2013-09-11-23.59.59')
```

The host variable NUM_HOURS is set to -263 because there is 1 second less than a full 264 hours between the arguments. It is negative because the first argument is earlier than the second argument.

IDENTITY_VAL_LOCAL

The IDENTITY_VAL_LOCAL function is a non-deterministic function that returns the most recently assigned value for an identity column, where the assignment occurred as a result of a single INSERT statement using a VALUES clause.

The schema is SYSIBM.

The function has no input parameters.

The result is a DECIMAL(31,0), regardless of the actual data type of the corresponding identity column.

The value returned by the function is the value assigned to the identity column of the table identified in the most recent single row insert operation. The INSERT statement must contain a VALUES clause on a table containing an identity column. The INSERT statement must also be issued at the same level; that is, the value must be available locally at the level it was assigned, until it is replaced by the next assigned value. (A new level is initiated each time a trigger or routine is invoked.)

The assigned value is either a value supplied by the user (if the identity column is defined as GENERATED BY DEFAULT), or an identity value generated by the database manager.

It is recommended that a SELECT FROM data-change-table-reference statement be used to obtain the assigned value for an identity column. See "table-reference" in "subselect" for more information.

The function returns a null value if a single row INSERT statement with a VALUES clause has not been issued at the current processing level against a table containing an identity column.

The result of the function is not affected by the following operations:

- A single row INSERT statement with a VALUES clause for a table without an identity column
- A multiple row INSERT statement with a VALUES clause
- An INSERT statement with a fullselect
- A ROLLBACK TO SAVEPOINT statement

Notes

- Expressions in the VALUES clause of an INSERT statement are evaluated before the assignments for the target columns of the insert operation. Thus, an invocation of an IDENTITY_VAL_LOCAL function inside the VALUES clause of an INSERT statement will use the most recently assigned value for an identity column from a previous insert operation. The function returns the null value if no previous single row INSERT statement with a VALUES clause for a table containing an identity column has been executed within the same level as the IDENTITY_VAL_LOCAL function.
- The identity column value of the table for which the trigger is defined can be determined within a trigger by referencing the trigger transition variable for the identity column.
- The result of invoking the IDENTITY_VAL_LOCAL function from within the trigger condition of an insert trigger is a null value.

- It is possible that multiple before or after insert triggers exist for a table. In this case, each trigger is processed separately, and identity values assigned by one triggered action are not available to other triggered actions using the IDENTITY_VAL_LOCAL function. This is true even though the multiple triggered actions are conceptually defined at the same level.
- It is not generally recommended to use the IDENTITY_VAL_LOCAL function in the body of a before insert trigger. The result of invoking the IDENTITY_VAL_LOCAL function from within the triggered action of a before insert trigger is the null value. The value for the identity column of the table for which the trigger is defined cannot be obtained by invoking the IDENTITY_VAL_LOCAL function within the triggered action of a before insert trigger. However, the value for the identity column can be obtained in the triggered action by referencing the trigger transition variable for the identity column.
- The result of invoking the IDENTITY_VAL_LOCAL function from within the triggered action of an after insert trigger is the value assigned to an identity column of the table identified in the most recent single row insert operation invoked in the same triggered action that had a VALUES clause for a table containing an identity column. (This applies to both FOR EACH ROW and FOR EACH STATEMENT after insert triggers.) If a single row INSERT statement with a VALUES clause for a table containing an identity column was not executed within the same triggered action, before the invocation of the IDENTITY_VAL_LOCAL function, the function returns a null value.
- Because IDENTITY_VAL_LOCAL is a non-deterministic function, the result of invoking this function within the SELECT statement of a cursor can vary for each FETCH statement.
- The assigned value is the value actually assigned to the identity column (that is, the value that would be returned on a subsequent SELECT statement). This value is not necessarily the value provided in the VALUES clause of the INSERT statement, or a value generated by the database manager. The assigned value could be a value specified in a SET transition variable statement, within the body of a before insert trigger, for a trigger transition variable associated with the identity column.
- ***Scope of IDENTITY_VAL_LOCAL***: The IDENTITY_VAL_LOCAL value persists until the next insert in the current session into a table that has an identity column defined on it, or the application session ends. The value is unaffected by COMMIT or ROLLBACK statements. The IDENTITY_VAL_LOCAL value cannot be directly set and is a result of inserting a row into a table.

  A technique commonly used, especially for performance, is for an application or product to manage a set of connections and route transactions to an arbitrary connection. In these situations, the availability of the IDENTITY_VAL_LOCAL value should be relied on only until the end of the transaction. Examples of where this type of situation can occur include applications that use XA protocols, use connection pooling, use the connection concentrator, and use HADR to achieve failover.
- The value returned by the function following a failed single row INSERT statement with a VALUES clause into a table with an identity column is unpredictable. It could be the value that would have been returned from the function had it been invoked before the failed insert operation, or it could be the value that would have been assigned had the insert operation succeeded. The actual value returned depends on the point of failure, and is therefore unpredictable.

Examples

- *Example 1:* Create two tables, T1 and T2, each with an identity column named C1. Start the identity sequence for table T2 at 10. Insert some values for C2 into T1.

```
CREATE TABLE T1
  (C1 INTEGER GENERATED ALWAYS AS IDENTITY,
   C2 INTEGER)

CREATE TABLE T2
  (C1 DECIMAL(15,0) GENERATED BY DEFAULT AS IDENTITY (START WITH 10),
   C2 INTEGER)

INSERT INTO T1 (C2) VALUES (5)

INSERT INTO T1 (C2) VALUES (6)

SELECT * FROM T1
```

  This query returns:

```
C1          C2
----------- -----------
          1           5
          2           6
```

Insert a single row into table T2, where column C2 gets its value from the IDENTITY_VAL_LOCAL function.

```
   INSERT INTO T2 (C2) VALUES (IDENTITY_VAL_LOCAL())

   SELECT * FROM T2
```

This query returns:

```
C1                C2
----------------- -----------
              10.           2
```

- *Example 2:* In a nested environment involving a trigger, use the IDENTITY_VAL_LOCAL function to retrieve the identity value assigned at a particular level, even though there might have been identity values assigned at lower levels. Assume that there are three tables, EMPLOYEE, EMP_ACT, and ACCT_LOG. There is an after insert trigger defined on EMPLOYEE that results in additional inserts into the EMP_ACT and ACCT_LOG tables.

```
   CREATE TABLE EMPLOYEE
     (EMPNO SMALLINT GENERATED ALWAYS AS IDENTITY (START WITH 1000),
      NAME CHAR(30),
      SALARY DECIMAL(5,2),
      DEPTNO SMALLINT)

   CREATE TABLE EMP_ACT
     (ACNT_NUM SMALLINT GENERATED ALWAYS AS IDENTITY (START WITH 1),
      EMPNO SMALLINT)

   CREATE TABLE ACCT_LOG
     (ID SMALLINT GENERATED ALWAYS AS IDENTITY (START WITH 100),
      ACNT_NUM SMALLINT,
      EMPNO SMALLINT)

   CREATE TRIGGER NEW_HIRE
     AFTER INSERT ON EMPLOYEE
     REFERENCING NEW AS NEW_EMP
     FOR EACH ROW
     BEGIN ATOMIC
       INSERT INTO EMP_ACT (EMPNO) VALUES (NEW_EMP.EMPNO);
       INSERT INTO ACCT_LOG (ACNT_NUM, EMPNO)
         VALUES (IDENTITY_VAL_LOCAL(), NEW_EMP.EMPNO);
     END
```

The first triggered insert operation inserts a row into the EMP_ACT table. The statement uses a trigger transition variable for the EMPNO column of the EMPLOYEE table to indicate that the identity value for the EMPNO column of the EMPLOYEE table is to be copied to the EMPNO column of the EMP_ACT table. The IDENTITY_VAL_LOCAL function could not be used to obtain the value assigned to the EMPNO column of the EMPLOYEE table, because an INSERT statement has not been issued at this level of the nesting. If the IDENTITY_VAL_LOCAL function were invoked in the VALUES clause of the INSERT statement for the EMP_ACT table, it would return a null value. The insert operation against the EMP_ACT table also results in the generation of a new identity value for the ACNT_NUM column.

The second triggered insert operation inserts a row into the ACCT_LOG table. The statement invokes the IDENTITY_VAL_LOCAL function to indicate that the identity value assigned to the ACNT_NUM column of the EMP_ACT table in the previous insert operation in the triggered action is to be copied to the ACNT_NUM column of the ACCT_LOG table. The EMPNO column is assigned the same value as the EMPNO column of the EMPLOYEE table.

After the following INSERT statement and all of the triggered actions have been processed:

```
   INSERT INTO EMPLOYEE (NAME, SALARY, DEPTNO)
     VALUES ('Rupert', 989.99, 50)
```

the contents of the three tables are as follows:

```
   SELECT EMPNO, SUBSTR(NAME,1,10) AS NAME, SALARY, DEPTNO
     FROM EMPLOYEE

EMPNO  NAME       SALARY  DEPTNO
------ ---------- ------- ------
  1000 Rupert      989.99     50

   SELECT ACNT_NUM, EMPNO
     FROM EMP_ACT

ACNT_NUM EMPNO
-------- ------
       1   1000

   SELECT * FROM ACCT_LOG

ID     ACNT_NUM EMPNO
------ -------- ------
   100        1   1000
```

The result of the IDENTITY_VAL_LOCAL function is the most recently assigned value for an identity column at the same nesting level. After processing the original INSERT statement and all of the triggered actions, the IDENTITY_VAL_LOCAL function returns a value of 1000, because this is the value that was assigned to the EMPNO column of the EMPLOYEE table.

IFNULL

The IFNULL function returns the first non-null expression in a list of two expressions.

The schema is SYSIBM.

The IFNULL function is identical to the “COALESCE ” on page 308, except that IFNULL is limited to two arguments.

INITCAP

The INITCAP function returns a string with the first character of each *word* converted to uppercase, using the UPPER function semantics, and the other characters converted to lowercase, using the LOWER function semantics.

The schema is SYSIBM.

A *word* is delimited by any of the following characters:

Table 62. Word delimiter characters

Character or range of characters	Unicode code points or range of Unicode code points
(blank)	U+0020
! " # $ % & ' ( ) * + , -. /	U+0021 to U+002F
: ; < = > ? @	U+003A to U+0040
[\ ] ^ _ `	U+005B to U+0060
{ | } ~	U+007B to U+007E

Table 62. Word delimiter characters (continued)	
Character or range of characters	**Unicode code points or range of Unicode code points**
Control characters, including the following SQL control characters: • tab • new line • form feed • carriage return • line feed	U+0009, U+000A, U+000B, U+000C, U+000D, U+0085

Note: A character listed in the preceding table might not have an allocated code point in a particular database code page.

string-expression
An expression that returns a CHAR or VARCHAR data type. In a Unicode database, the expression can return a GRAPHIC or VARGRAPHIC data type.

The data type of the result depends on the data type of *string-expression*, as described in the following table:

Table 63. Data type of string-expression compared to the data type of the result	
Data type of *string-expression*	**Data type of the result**
CHAR or VARCHAR	VARCHAR
GRAPHIC or VARGRAPHIC	VARGRAPHIC

The length attribute of the result is the same as the length attribute of *string-expression*.

If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Examples

- *Example 1*: Input the string "a prospective book title" to return the string "A Prospective Book Title".

```
VALUES INITCAP ('a prospective book title')
1
------------------------
A Prospective Book Title
```

- *Example 2*: Input the string "YOUR NAME" to return the string "Your Name".

```
VALUES INITCAP ('YOUR NAME')
1
---------
Your Name
```

- *Example 3*: Input the string "my_résumé" to return the string "My_Résumé".

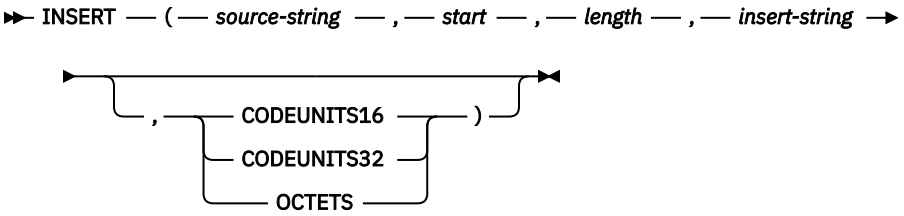
```
VALUES INITCAP ('my_résumé')
1
---------
My_Résumé
```

- *Example 4*: Input the string "élégant" to return the string "Élégant".

```
VALUES INITCAP ('FORMAT:élégant')
1
--------------
Format:Élégant
```

INSERT

The INSERT function returns a string where, beginning at *start* in *source-string*, *length* of the specified code units have been deleted and *insert-string* has been inserted.



The schema is SYSIBM. The SYSFUN version of the INSERT function continues to be available.

The INSERT function is identical to the OVERLAY function, except that the length argument is mandatory.

source-string
An expression that specifies the source string. The expression must return a value that is a built-in string, numeric, boolean, or datetime data type. If the value is not a string data type, it is implicitly cast to VARCHAR before evaluating the function.

start
An expression that returns an integer value. The integer value specifies the starting point within the source string where the deletion of code units and the insertion of another string is to begin. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. The integer value is the starting point in code units using the specified string units. The integer value must be between 1 and the actual length of *source-string* in implicit or explicit string units plus one (SQLSTATE 22001). If OCTETS is specified and the result is graphic data, the value must be an odd number between 1 and the actual octet length of *source-string* plus one (SQLSTATE 428GC or 22011).

length
An expression that specifies the number of code units (in the specified string units) that are to be deleted from the source string, starting at the position identified by *start*. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. The value must be positive integer or zero (SQLSTATE 22011). If OCTETS is specified and the result is graphic data, the value must be an even number or zero (SQLSTATE 428GC).

insert-string
An expression that specifies the string to be inserted into *source-string*, starting at the position identified by *start*. The expression must return a value that is a built-in string, numeric, boolean, or datetime data type. If the value is not a string data type, it is implicitly cast to VARCHAR before evaluating the function.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of *start* and *length*.

CODEUNITS16 specifies that *start* and *length* are expressed in 16-bit UTF-16 code units. CODEUNITS32 specifies that *start* and *length* are expressed in 32-bit UTF-32 code units. OCTETS specifies that *start* and *length* are expressed in bytes.

If the string unit is specified as CODEUNITS16 or CODEUNITS32, and the result is a binary string or bit data, an error is returned (SQLSTATE 428GC). If the string unit is specified as CODEUNITS16 or OCTETS, and the string units of source-string is CODEUNITS32, an error is returned (SQLSTATE 428GC). If the string unit is specified as OCTETS, the operation is performed in the code page of the *source-string*. If a string unit is not explicitly specified, the string unit of the *source-string* determines the unit that is used. For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String units in built-in functions" in "Character strings".

The data type of the result depends on the data types of *source-string* and *insert-string*, as shown in the following tables of supported type combinations. The string unit of the result is the string unit of *source-string*. If either *source-string* or *insert-string* is defined as FOR BIT DATA the other argument cannot be defined with string units of CODEUNITS32.The second table applies only to Unicode databases.

Table 64. Data type of the result as a function of the data types of source-string and insert-string

source-string	***insert-string***	**Result**
CHAR or VARCHAR	CHAR or VARCHAR	VARCHAR
GRAPHIC or VARGRAPHIC	GRAPHIC or VARGRAPHIC	VARGRAPHIC
CLOB	CHAR, VARCHAR, or CLOB	CLOB
CHAR or VARCHAR	CLOB	CLOB
DBCLOB	GRAPHIC, VARGRAPHIC, or DBCLOB	DBCLOB
GRAPHIC or VARGRAPHIC	DBCLOB	DBCLOB
CHAR or VARCHAR	CHAR FOR BIT DATA or VARCHAR FOR BIT DATA	VARCHAR FOR BIT DATA
CHAR FOR BIT DATA or VARCHAR FOR BIT DATA	CHAR, VARCHAR, CHAR FOR BIT DATA, or VARCHAR FOR BIT DATA	VARCHAR FOR BIT DATA
BINARY or VARBINARY	BINARY or VARBINARY	VARBINARY
BLOB	BINARY, VARBINARY, or BLOB	BLOB
BINARY or VARBINARY	BLOB	BLOB

Note: If *source-string* or *insert-string* is a binary data type and the other is a FOR BIT DATA string, the argument that is not a binary data type is handled as if it was cast to the corresponding binary data type.

Table 65. Data type of the result as a function of the data types of source-string and insert-string (Unicode databases only)

source-string	***insert-string***	**Result**
CHAR or VARCHAR	GRAPHIC or VARGRAPHIC	VARCHAR
GRAPHIC or VARGRAPHIC	CHAR or VARCHAR	VARGRAPHIC
CLOB	GRAPHIC, VARGRAPHIC, or DBCLOB	CLOB
DBCLOB	CHAR, VARCHAR, or CLOB	DBCLOB

A *source-string* can have a length of 0; in this case, *start* must be 1 (as implied by the bounds for *start* described previously), and the result of the function is a copy of the *insert-string*.

An *insert-string* can also have a length of 0. This has the effect of deleting the code units identified by *start* and *length* from the *source-string*.

The length attribute of the result is the length attribute of *source-string* plus the length attribute of *insert-string* when the string units of the *source-string* and *insert-string* are the same or the result string units is CODEUNITS32. Special cases are listed in the following table.

Table 66. Data type of the result as a function of the data types of source-string and insert-string (special cases)

source-string		***insert-string***		**Result**	
Data type	**String units**	**Data type**	**String units**	**Length attribute**	**String units**

Table 66. Data type of the result as a function of the data types of source-string and insert-string (special cases) (continued)					
source-string		***insert-string***		**Result**	
Character string with length attribute A	OCTETS	Graphic string with length attribute B	CODEUNITS16	A+3*B	OCTETS
Character string with length attribute A	OCTETS	Graphic string with length attribute B	CODEUNITS32	A+4*B	OCTETS
Character string with length attribute A	OCTETS	Character with length attribute B	CODEUNITS32	A+4*B	OCTETS
Graphic string with length attribute A	CODEUNITS16	Character with length attribute B	OCTETS	A+B	CODEUNITS16
Graphic string with length attribute A	CODEUNITS16	Character with length attribute B	CODEUNITS32	A+2*B	CODEUNITS16
Graphic string with length attribute A	CODEUNITS16	Graphic string with length attribute B	CODEUNITS32	A+2*B	CODEUNITS16

The actual length of the result depends on the actual length of *source-string*, the actual length of the of the deleted string, the actual length of the *insert-string*, and string units used for the *start* and *length* arguments. For example, if the string arguments are character strings in OCTETS and the OCTETS is used as the fourth argument, the actual length of the result is A1 - MIN((A1 - V2 + 1), V3) + A4, where:

- A1 is the actual length of *source-string*
- V2 is the value of *start*
- V3 is the value of *length*
- A4 is the actual length of *insert-string*

If the actual length of the result string exceeds the maximum for the return data type, an error is returned (SQLSTATE 54006).

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: Create the strings "INSISTING", "INSISERTING", and "INSTING" from the string "INSERTING" by inserting text into the middle of the existing text.

```
SELECT INSERT('INSERTING',4,2,'IS'),
  INSERT('INSERTING',4,0,'IS'),
  INSERT('INSERTING',4,2,'')
  FROM SYSIBM.SYSDUMMY1
```

- *Example 2*: Create the strings "XXINSERTING", "XXNSERTING", "XXSERTING", and "XXERTING" from the string "INSERTING" by inserting text before the existing text, using 1 as the starting point.

```
SELECT INSERT('INSERTING',1,0,'XX'),
  INSERT('INSERTING',1,1,'XX'),
  INSERT('INSERTING',1,2,'XX'),
  INSERT('INSERTING',1,3,'XX')
  FROM SYSIBM.SYSDUMMY1
```

- *Example 3*: Create the string "ABCABCXX" from the string "ABCABC" by inserting text after the existing text. Because the source string is 6 characters long, set the starting position to 7 (one plus the length of the source string).

```
SELECT INSERT('ABCABC',7,0,'XX')
  FROM SYSIBM.SYSDUMMY1
```

- *Example 4*: Change the string "Hegelstraße" to "Hegelstrasse".

```
SELECT INSERT('Hegelstraße',10,1,'ss',CODEUNITS16)
  FROM SYSIBM.SYSDUMMY1
```

- *Example 5*: The following example works with the Unicode string "&N~AB", where "&" is the musical symbol G clef character, and "~ " is the combining tilde character. This string is shown in different Unicode encoding forms in the following example:

	"&"	"N"	"~"	"A"	"B"
UTF-8	X'F09D849E'	X'4E'	X'CC83'	X'41'	X'42'
UTF-16BE	X'D834DD1E'	X'004E'	X'0303'	X'0041'	X'0042'

Assume that the variables UTF8_VAR and UTF16_VAR contain the UTF-8 and the UTF-16BE representations of the string, respectively. Use the INSERT function to insert a "C" into the Unicode string "&N~AB".

```
SELECT INSERT(UTF8_VAR, 1, 4, 'C', CODEUNITS16),
  INSERT(UTF8_VAR, 1, 4, 'C', CODEUNITS32),
  INSERT(UTF8_VAR, 1, 4, 'C', OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values "CAB", "CB", and "CN~AB", respectively.

```
SELECT INSERT(UTF8_VAR, 5, 1, 'C', CODEUNITS16),
  INSERT(UTF8_VAR, 5, 1, 'C', CODEUNITS32),
  INSERT(UTF8_VAR, 5, 1, 'C', OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values "&N~CB", "&N~AC", and "&C~AB", respectively.

```
SELECT INSERT(UTF16_VAR, 1, 4, 'C', CODEUNITS16),
  INSERT(UTF16_VAR, 1, 4, 'C', CODEUNITS32),
  INSERT(UTF16_VAR, 1, 4, 'C', OCTETS)
FROM SYSIBM.SYSDUMMY1
```

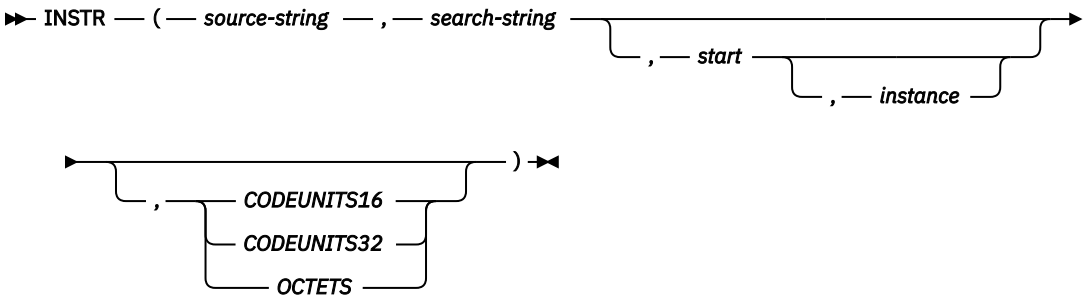
returns the values "CAB", "CB", and "CN~AB", respectively.

```
SELECT INSERT(UTF16_VAR, 5, 2, 'C', CODEUNITS16),
  INSERT(UTF16_VAR, 5, 1, 'C', CODEUNITS32),
  INSERT(UTF16_VAR, 5, 4, 'C', OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values "&N~C", "&N~AC", and "&CAB", respectively.

INSTR

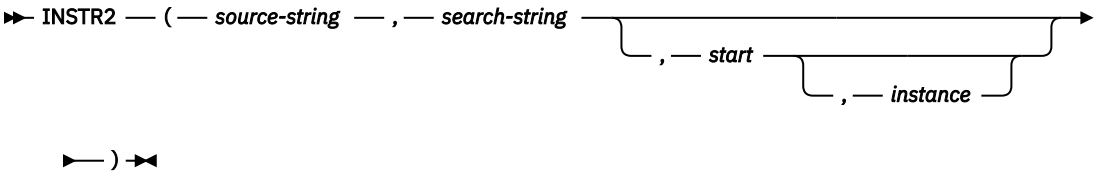
The INSTR function returns the starting position of a string (the *search string*) within another string (the *source string*). The INSTR scalar function is a synonym for the LOCATE_IN_STRING scalar function.



The schema is SYSIBM

INSTR2

The INSTR2 function returns the starting position, in 16-bit UTF-16 string units (CODEUNITS16), of a string within another string.



The schema is SYSIBM.

source-string
An expression that specifies the string in which the search is to take place.

search-string
An expression that specifies the string that is the object of the search.

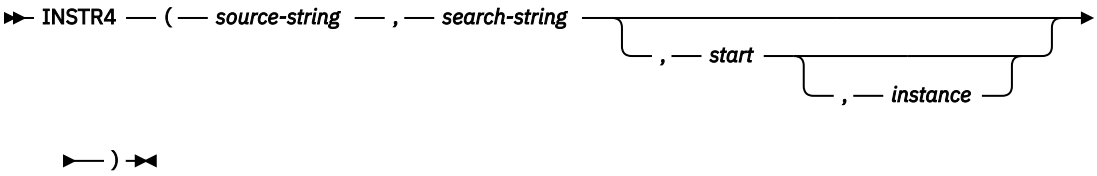
start
An expression that specifies the position within *source-string* at which the search for a match is to start.

instance
An expression that specifies which instance of *search-string* to search for within *source-string*.

The INSTR2 scalar function invoked with character or graphic strings as the first two arguments is equivalent to invoking the LOCATE_IN_STRING function with CODEUNITS16 specified. The INSTR2 scalar function invoked with binary strings as the first two arguments is equivalent to invoking the LOCATE_IN_STRING function without a string units argument.

INSTR4

The INSTR4 function returns the starting position, in 32-bit UTF-32 string units (CODEUNITS32), of a string within another string.



The schema is SYSIBM.

source-string
An expression that specifies the string in which the search is to take place.

search-string
An expression that specifies the string that is the object of the search.

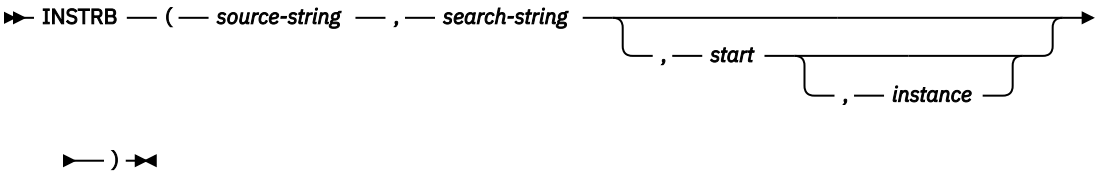
start
An expression that specifies the position within *source-string* at which the search for a match is to start.

instance
An expression that specifies which instance of *search-string* to search for within *source-string*.

The INSTR4 scalar function invoked with character or graphic strings as the first two arguments is equivalent to invoking the LOCATE_IN_STRING function with CODEUNITS32 specified. The INSTR4 scalar function invoked with binary strings as the first two arguments is equivalent to invoking the LOCATE_IN_STRING function without a string units argument.

INSTRB

The INSTRB function returns the starting position, in bytes, of a string within another string.



The schema is SYSIBM.

source-string
An expression that specifies the string in which the search is to take place.

search-string
An expression that specifies the string that is the object of the search.

start
An expression that specifies the position within the source string at which the search for a match is to start.

instance
An expression that specifies which instance of the search string to search for within the source string.

The INSTRB scalar function invoked with character or graphic strings as the first two arguments is equivalent to invoking the LOCATE_IN_STRING function with OCTETS specified. The INSTRB scalar function invoked with binary strings as the first two arguments is equivalent to invoking the LOCATE_IN_STRING function without a string units argument.

INT

The INT function returns a large integer (a binary integer with a precision of 31 bits) representation of a value of a different data type.

The schema is SYSIBM.

The INT scalar function is a synonym for the INTEGER scalar function.

INTERVAL

The INTERVAL function converts a character string representation of an interval to a decimal duration.

The schema is SYSIBM.

Syntax

string-constant
A character string representation of an interval, for example:

```
'4 years 2 months 3 days'
'3 day 4 year 2 month'
'-4y -2 m -3d'
'-2 hr -21 min -34sec'
'4years 2months 3 days 2 hours 21minutes 34seconds 75 milliseconds 27 microseconds'
'2 mons 3 days 4 yrs 2 hrs 20 mins 30 secs 75 ms 27 us'
```

Note:

- The input must be a string constant, not an expression or column value (sqlcode SQL0171N with SQLSTATE=42815).
- A blank between each value and its unit keyword is optional.
- Values must be either all positive or all negative.
- The unit keywords are case-insensitive.
- The order of the unit keywords is unimportant.
- A unit keyword cannot be used more than once.
- The number that is specified for each unit must be a whole number.
- The following statements are equivalent:

```
INTERVAL (string-constant)
CAST (string-constant as INTERVAL)
```

The specified interval can be of one of the following types:

time interval
The input value does not contain units other than hours, minutes, or seconds, and cannot exceed the equivalent of `'99h 99m 99s'` (sqlcode SQL0105N with SQLSTATE=42604). A minutes value that exceeds 99 is converted to hours, and a seconds value that exceeds 99 is converted to minutes. For example, 100 seconds is converted to 1 minute and 40 seconds.

date interval
The input value does not contain units other than years, months, or days, and cannot exceed the equivalent of `'9999y 99m 99d'` (sqlcode SQL0105N with SQLSTATE=42604). A months value that exceeds 99 is converted to years, and a days value that exceeds 99 is converted to 30-day months. For example, 100 days is converted to 3 months and 10 days.

timestamp interval
The input value cannot exceed the equivalent of `'9999y 99m 99d 99h 99m 99s 999999us'` (sqlcode SQL0105N with SQLSTATE=42604). The millisecond and microsecond values are combined into a single microsecond value before they are evaluated. If the resulting value exceeds 999999 microseconds, it is converted to seconds. For example, `'88 ms 5000000 us'` is converted to 5088000 microseconds. This exceeds 999999 microseconds, so it is converted to 5.088000 seconds. A seconds value that exceeds 99 is converted to minutes. A minutes value that exceeds 99 is converted to hours. An hours value that exceeds 99 is converted to days. A days value that exceeds 99 is converted to 30-day months. A months value that exceeds 99 is converted to years.

Table 67. Keywords for representing time units

Keywords	**Maximum value allowed when specifying a...**		
	time interval	**date interval**	**timestamp interval**
year, years, yrs, yr, y	(not allowed)	9999	9999
month, months, mons, mon	(not allowed)	119999	119999
day, days, d	(not allowed)	3599999	3599999
hour, hours, hrs, hr, h	99	(not allowed)	86399999
minute, minutes, mins, min, m	5999	(not allowed)	2147483647
second, seconds, secs, sec, s	359999	(not allowed)	2147483647
millisecond, milliseconds, ms	(not allowed)	(not allowed)	2147483647

Table 67. Keywords for representing time units (continued)			
Keywords	**Maximum value allowed when specifying a...**		
	time interval	**date interval**	**timestamp interval**
microsecond, microseconds, us	(not allowed)	(not allowed)	2147483647

Result

The data type of the result depends on the type of the input interval. If the input value represents:

- A date interval, the result is a date duration, which is a DECIMAL(8,0) value.
- A time interval, the result is a time duration, which is a DECIMAL(6,0) value.
- A timestamp interval, the result is a timestamp duration, which is a DECIMAL value. The precision of this value depends on whether, after combining millisecond and microsecond values into a single microsecond value, and after then converting any microseconds in excess of 999999 to seconds, the number of microseconds remaining is zero:
  - If so, the result is DECIMAL(14,0)
  - If not, the result is DECIMAL(20,6)

Examples

- The following statement returns the DECIMAL(8,0) value 40203:

```
interval('4years 2months 3days')
```

- The following statement returns the DECIMAL(6,0) value -122030:

```
interval('-12 hours -20 minutes -30 seconds')
```

- The following statement returns the DECIMAL(20,6) value 40801092630.007055:

```
interval('4 years 9 hour 26min 30 seconds 7 ms 55us 8months 1d')
```

- The following statement returns the DECIMAL(14,0) value 22035:

```
interval('2 hours 20 minutes 30 seconds 1500 ms 3500000 us')
```

  The millisecond (1500) and microsecond (3500000) values are combined into a single microsecond value (5000000) before they are evaluated. The resulting value exceeds 999999 microseconds, so it is converted to 5 seconds, which are added to the specified 30 seconds for a total of 35 seconds.

- The following statement returns the DECIMAL(8,0) value 90714, which corresponds to 9 years, 7 months, and 14 days.

```
interval('1 years 100 months 104 days')
```

  Because the number of days exceeds 99, the 104 days are converted to 3 30-day months, plus a remainder of 14 days. The 3 months are added to the specified 100 months for a total of 103 months. Because the number of months exceeds 99, the 103 months are converted to 8 12-month years, plus a remainder of 7 months. The 8 years are added to the specified 1 year for a total of 9 years.

- The following statement returns the DECIMAL(6,0) value 230120, which corresponds to 23 hours, 1 minute, and 20 seconds.

```
interval('20 hours 181 minutes 20 seconds')
```

  Because the number of minutes exceeds 99, the 181 minutes are converted to 3 60-minute hours, plus a remainder of 1 minute. The 3 hours are added to the specified 20 hours for a total of 23 hours.

Related reference

"Datetime operations and durations" on page 145
Datetime values can be incremented, decremented, and subtracted. These operations can involve decimal numbers called durations.

INTEGER

The INTEGER function returns a large integer (a binary integer with a precision of 31 bits) representation of a value of a different data type.

Numeric to INTEGER

String to INTEGER

Date to INTEGER

Time to INTEGER

Boolean to INTEGER

The schema is SYSIBM.

Numeric to INTEGER

numeric-expression
An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a large integer column or variable. The fractional part of the argument is truncated. If the whole part of the argument is not within the range of integers, an error is returned (SQLSTATE 22003).

String to INTEGER

string-expression
An expression that returns a value that is a character-string or Unicode graphic-string representation of a number with a of length not greater than the maximum length of a character constant.

The result is the same number that would result from CAST(*string-expresssion* AS INTEGER). Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an integer, decimal, floating-point, or decimal floating-point constant (SQLSTATE 22018). If the whole part of the argument is not within the range of integers, an error is returned (SQLSTATE 22003). The data type of *string-expression* must not be CLOB or DBCLOB (SQLSTATE 42884).

Date to INTEGER

date-expression
An expression that returns a value of the DATE data type. The result is an INTEGER value representing the date as *yyyymmdd*.

Time to INTEGER

time-expression
An expression that returns a value of the TIME data type. The result is an INTEGER value representing the time as *hhmmss*.

Boolean to INTEGER

boolean-expression
An expression that returns a Boolean value (TRUE or FALSE). The result is either 1 (for TRUE) or 0 (for FALSE).

Result

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Notes

- **Increasing portability of applications:** If the first argument is numeric, or if the first argument is a string and the length argument is specified, use the "CAST specification" on page 152 instead of this function to increase the portability of your applications.

Examples

- *Example 1*: Using the EMPLOYEE table, select a list containing salary (SALARY) divided by education level (EDLEVEL). Truncate any decimal in the calculation. The list should also contain the values used in the calculation and employee number (EMPNO). The list should be in descending order of the calculated value.

```
SELECT INTEGER (SALARY / EDLEVEL), SALARY, EDLEVEL, EMPNO
  FROM EMPLOYEE
  ORDER BY 1 DESC
```

- *Example 2*: Using the EMPLOYEE table, select the EMPNO column in integer form for further processing in the application.

```
SELECT INTEGER(EMPNO) FROM EMPLOYEE
```

- *Example 3*: Assume that the column BIRTHDATE (whose data type is DATE) has an internal value equivalent to '1964-07-20'.

```
INTEGER(BIRTHDATE)
```

  results in the value `19 640 720`.

- *Example 4*: Assume that the column STARTTIME (whose data type is TIME) has an internal value equivalent to '12:03:04'.

```
INTEGER(STARTTIME)
```

  results in the value `120 304`.

- *Example 5*: The following statement returns the value 1 of data type INTEGER.

```
values INTEGER(TRUE)
```

- *Example 6*: The following statement returns the value 0 of data type INTEGER.

```
values INTEGER(3>3)
```

INT2

The INT2 function returns a small integer (a binary integer with a precision of 15 bits) representation of a value of a different data type.

The schema is SYSIBM.

The INT2 scalar function is a synonym for the SMALLINT scalar function.

INT4

The INT4 function returns a large integer (a binary integer with a precision of 31 bits) representation of a value of a different data type.

The schema is SYSIBM.

The INT4 scalar function is a synonym for the INTEGER scalar function.

INT8

The INT8 function returns a big integer (a binary integer with a precision of 63 bits) representation of a value of a different data type.

The schema is SYSIBM.

The INT8 scalar function is a synonym for the BIGINT scalar function.

INTNAND, INTNOR, INTNXOR, and INTNNOT

These bitwise functions operate on the "two's complement" representation of the integer value of the input arguments and return the result as a corresponding base 10 integer value.

The schema is SYSIBM.

In each function, the placeholder *N* represents the byte size of the integer data type that the function operates on and returns, as shown in Table 69 on page 382.

Table 68. The bit manipulation functions		
Function	**Description**	**A bit in the two's complement representation of the result is:**
INTNAND	Performs a bitwise AND operation.	1 only if the corresponding bits in both arguments are 1.
INTNOR	Performs a bitwise OR operation.	1 unless the corresponding bits in both arguments are zero.
INTNXOR	Performs a bitwise exclusive OR operation.	1 unless the corresponding bits in both arguments are the same.
INTNNOT	Performs a bitwise NOT operation.	Opposite of the corresponding bit in the argument.

Table 69. Meaning of placeholder N	
Value of *N*	**Data type function operates on and returns**
2	SMALLINT
4	INTEGER
8	BIGINT

expression* or *expression1* or *expression2

The arguments must be integer values represented by the data types SMALLINT, INTEGER, BIGINT, DECFLOAT, DECIMAL, REAL, or DOUBLE. If the input argument is not of the same data type as represented by N, then the input is implicitly cast to the data type represented by *N*. As a result, if a value larger than the maximum value supported by the data type represented by *N* is passed as input to the function, then an overflow can occur (SQLSTATE=22003).

If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Due to differences in internal representation between data types and on different hardware platforms, using functions (such as HEX) or host language constructs to view or compare internal representations of BIT function results and arguments is data type-dependent and not portable. The data type- and platform-independent way to view or compare BIT function results and arguments is to use the actual integer values.

Examples

- *Example 1*: A value larger than the maximum supported by 2 byte SMALLINT is passed as input to the function INT2AND.

```
select INT2AND(1234567,1) from SYSIBM.SYSDUMMY1
SQL0413N  Overflow occurred during numeric data type conversion.
SQLSTATE=22003
```

- *Example 2*: Assume BIGINT columns col1 and col2 have values 137266 and 123825 respectively.

```
SELECT INT8AND(col1,col2) from TAB1
returns the value 48
```

- *Example 3*: Assume SMALLINT columns col1 and col2 have values 12 and 13 respectively.

```
SELECT INT2AND(col1,col2) from TAB1
returns the value 12
```

ISNULL

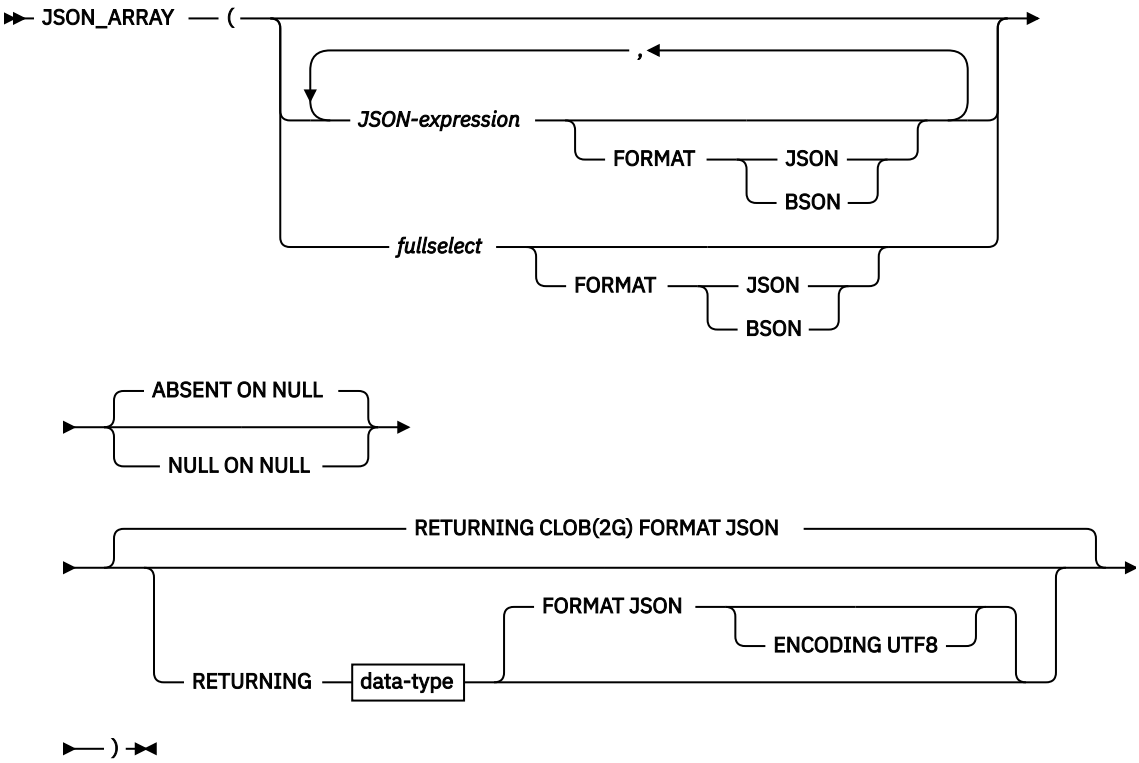
The ISNULL function returns the first non-null expression in a list of two expressions.

The schema is SYSIBM.

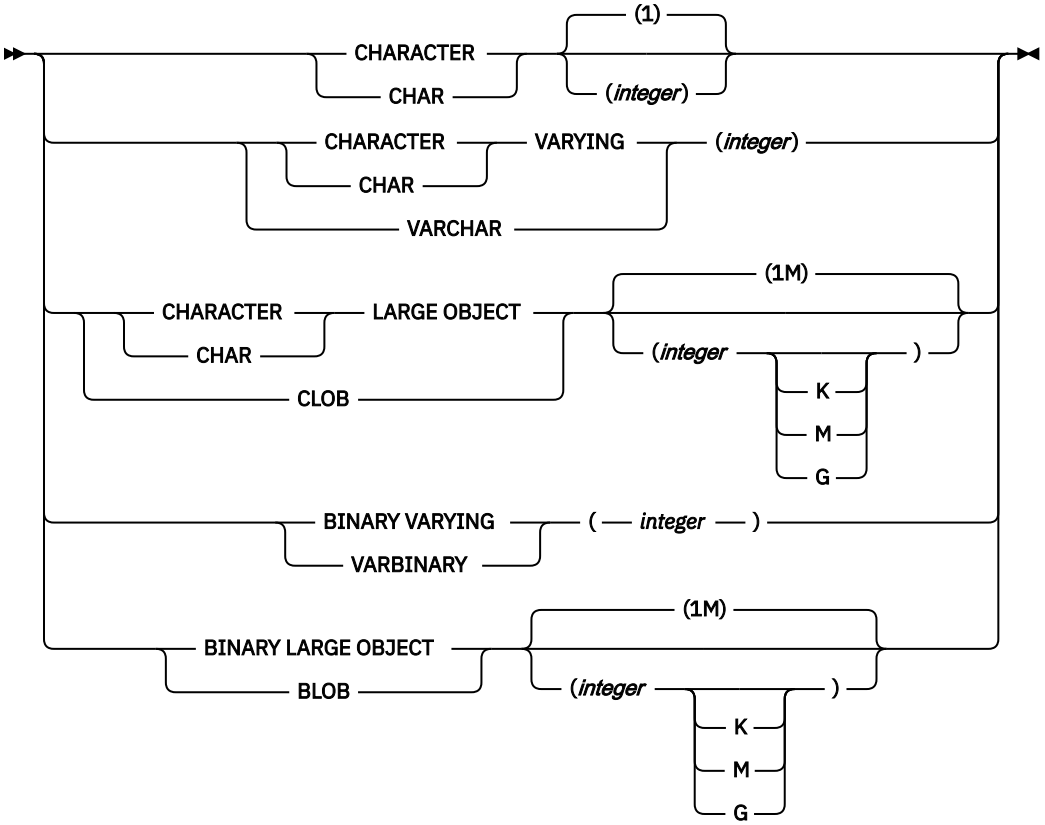
The ISNULL function is identical to the “COALESCE ” on page 308, except that ISNULL is limited to two arguments.

JSON_ARRAY

The JSON_ARRAY function generates a JSON array by explicitly listing the array elements by using *JSON-expression*, or by using a query.



data-type



Although the schema for this function is SYSIBM, the function cannot be specified as a qualified name.

JSON-expression
The expression that is used to generate a value in the JSON array.

The result type of this expression can be any built-in data type, except the following data types (SQLSTATE 42815):

- GRAPHIC
- VARGRAPHIC
- DBCLOB
- BINARY
- CHAR FOR BIT DATA
- VARCHAR FOR BIT DATA
- XML
- A user-defined type that is sourced on any of the previously listed data types

If the generated value is numeric, it cannot be Infinity, NaN, or sNaN (SQLSTATE 22023).

If FORMAT JSON or FORMAT BSON is not specified, and the generated value is not numeric, any special characters (for example, backslash or double quotation marks) within the result string are escaped.

If FORMAT JSON or FORMAT BSON is not specified and *JSON-expression* is binary string type, it is interpreted as FORMAT BSON.

FORMAT JSON
JSON-expression is formatted as JSON data.

If *JSON-expression* is a character string data type, it is treated as JSON data.

If *JSON-expression* is a binary string data type, it is interpreted as UTF-8 data.

FORMAT BSON
Specifies that *JSON-expression* is formatted as the BSON representation of JSON data (SQLSTATE 22032). *JSON-expression* must be a binary string data type (SQLSTATE 42815).

fullselect
Specifies a fullselect that returns a single column to be used to generate the values in the array (SQLSTATE 42823). The value of each row is used to generate a value in the JSON array.

The result type of this column cannot be any of the following data types (SQLSTATE 42815):

- GRAPHIC
- VARGRAPHIC
- DBCLOB
- BINARY
- CHAR FOR BIT DATA
- VARCHAR FOR BIT DATA
- XML
- A user-defined type that is sourced on any of the previously listed data types

If the generated value is numeric, it cannot be Infinity, NaN, or sNaN (SQLSTATE 22023).

If FORMAT JSON or FORMAT BSON is not specified and the generated value is not numeric, any special characters (for example, backslash or double quotation marks) within the result string are escaped.

If FORMAT JSON or FORMAT BSON is not specified and the *fullselect* is binary string type, it is interpreted as FORMAT BSON.

FORMAT JSON
fullselect is formatted as JSON data.

If *fullselect* is a character string data type, it is treated as JSON data.

If *fullselect* is a binary string data type, it is interpreted as UTF-8 data.

FORMAT BSON
Specifies that *fullselect* is formatted as the BSON representation of JSON data (SQLSTATE 22032). *fullselect* must be a binary string data type (SQLSTATE 42815).

ON NULL
Specifies what to return when an array element produced by *JSON-expression* or *fullselect* is the null value.

ABSENT ON NULL
A null array element is not included in the JSON array. This clause is the default.

NULL ON NULL
A null array element is included in the JSON array.

RETURNING data-type
The data type of the result can be CHAR, VARCHAR, CLOB, VARBINARY, or BLOB (SQLSTATE 42815). The default is CLOB (2 GB).

See "CREATE TABLE " on page 1351 for the description of built-in data types.

FORMAT JSON
The returned data is formatted as JSON data.

ENCODING UTF8
Specifies the encoding to use when *data-type* is a binary string type. This clause is allowed only for binary string types. The default for binary strings is UTF-8.

Notes

- If parameter markers are not explicitly cast to a supported data type, an error is returned (SQLSTATE 42815)

Examples

1. Generate a JSON array that contains the values 'Washington', 'Jefferson', and 'Hamilton'.

```
VALUES JSON_ARRAY('Washington', 'Jefferson', 'Hamilton');

1
-------------------------------------
["Washington","Jefferson","Hamilton"]
```

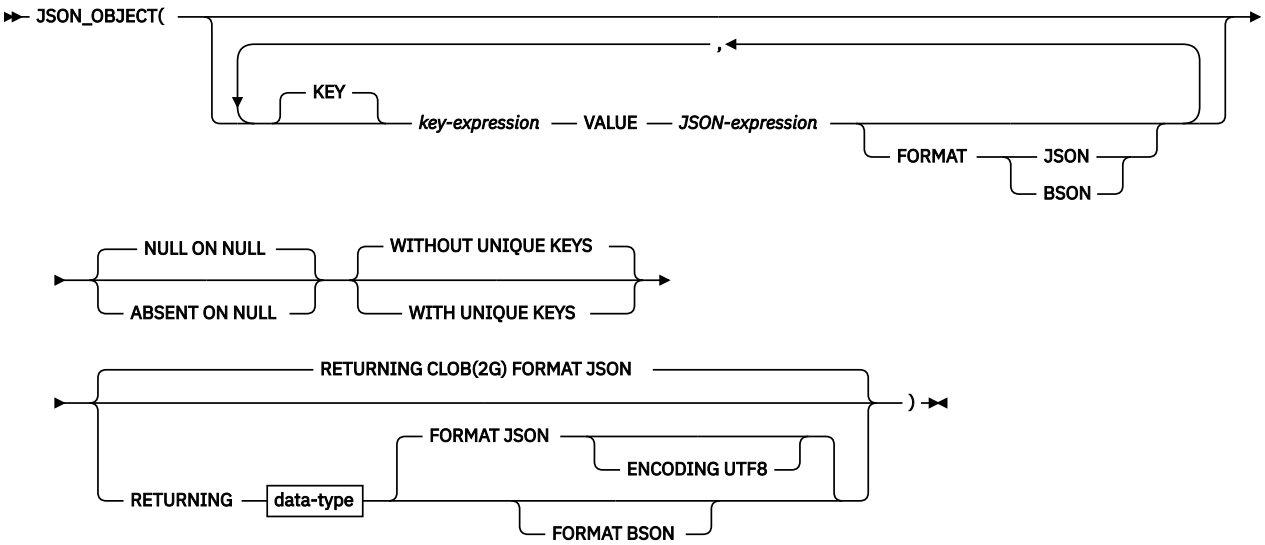
2. Generate a JSON array that includes all department numbers.

```
VALUES JSON_ARRAY(SELECT DEPTNO FROM DEPT);

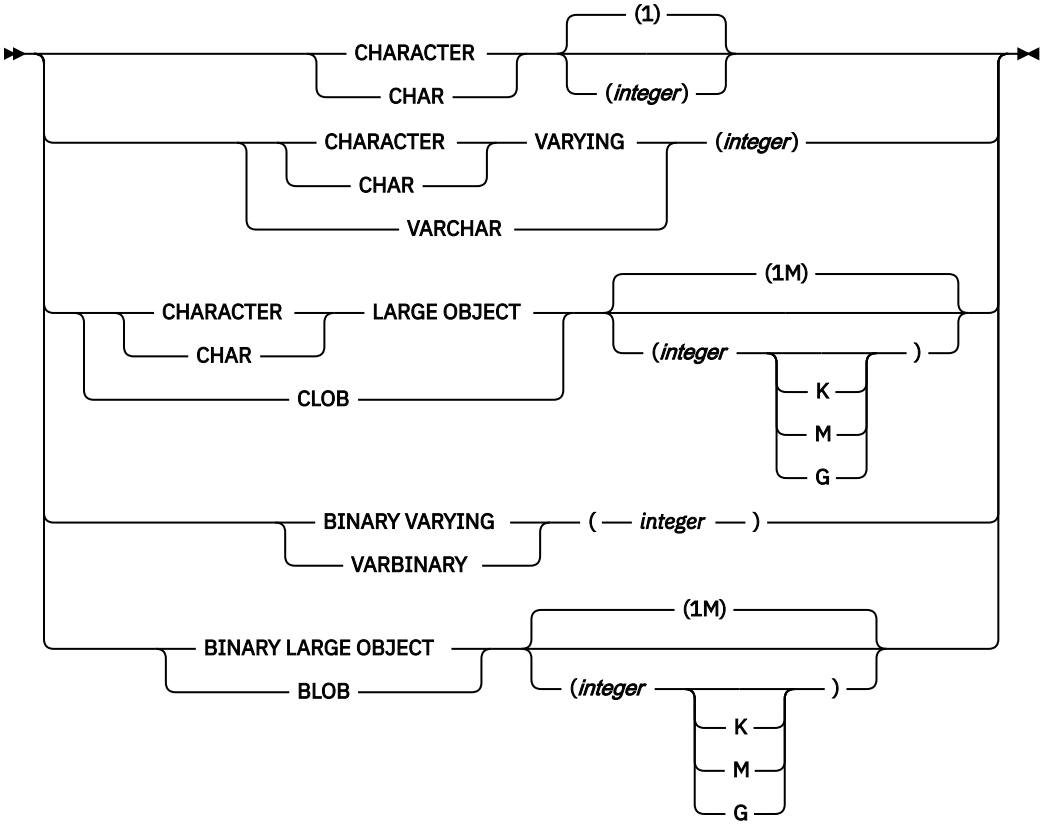
1
------------------------------
["F22","G22","H22","I22","J22"]
```

JSON_OBJECT

The JSON_OBJECT function generates a JSON object by using the specified key:value pairs. If no key:value pairs are provided, an empty object is returned.



data-type



Although the schema for this function is SYSIBM, the function cannot be specified as a qualified name.

key-expression
The name of the JSON key. The name must not be null (SQLSTATE 22004). The result of *key-expression* must be a built-in character string data type, except the following data types (SQLSTATE 42815):

- GRAPHIC
- VARGRAPHIC
- DBCLOB
- CHAR FOR BIT DATA
- VARCHAR FOR BIT DATA

JSON-expression
The expression that is used to generate the JSON value that is associated with *key-expression*.

The result type of this expression can be any built-in data type, except the following data types (SQLSTATE 42815):

- GRAPHIC
- VARGRAPHIC
- DBCLOB
- BINARY
- CHAR FOR BIT DATA
- VARCHAR FOR BIT DATA
- XML
- A user-defined type that is sourced on any of the previously listed data types

If the generated value is numeric, it cannot be Infinity, NaN, or sNaN (SQLSTATE 22023).

If FORMAT JSON or FORMAT BSON is not specified, and the generated value is not numeric, any special characters (for example, backslash or double quotation marks) within the result string are escaped.

If FORMAT JSON or FORMAT BSON is not specified and the expression is binary string type, it is interpreted as FORMAT BSON.

FORMAT JSON
JSON-expression is formatted as JSON data.

If *JSON-expression* is a character string data type, it is treated as JSON data.

If *JSON-expression* is a binary string data type, it is interpreted as UTF-8 data.

FORMAT BSON
Specifies that *JSON-expression* is formatted as the BSON representation of JSON data (SQLSTATE 22032). *JSON-expression* must be a binary string data type (SQLSTATE 42815).

ON NULL
Specifies what to return when *JSON-expression* is the null value.

NULL ON NULL
A character string that represents the null value is returned. This clause is the default.

ABSENT ON NULL
The key:value pair is omitted from the JSON object.

WITHOUT UNIQUE KEYS or WITH UNIQUE KEYS
Specifies whether the key values for the resulting JSON object must be unique.

WITHOUT UNIQUE KEYS
The resulting JSON object is not checked for duplicate keys. This clause is the default.

WITH UNIQUE KEYS
The resulting JSON object must have unique key values (SQLSTATE 22037).

Generating a JSON object with unique keys is considered best practice. If *key-expression* generates unique key names, omit WITH UNIQUE KEYS to improve performance.

RETURNING data-type
The data type of the result can be CHAR, VARCHAR, CLOB, VARBINARY, or BLOB (SQLSTATE 42815). The default is CLOB (2 GB).

See “CREATE TABLE ” on page 1351 for the description of built-in data types.

FORMAT JSON
The returned data is formatted as JSON data.

ENCODING UTF8
Specifies the encoding to use when *data-type* is a binary string type. This clause is allowed only for binary string types. The default for binary strings is UTF-8.

FORMAT BSON
The returned data is formatted as the BSON representation of JSON data (SQLSTATE 22032). *data-type* must be a binary string data type (SQLSTATE 42815).

Notes

- If parameter markers are not explicitly cast to a supported data type, an error is returned (SQLSTATE 42815)

Examples

1. Generate a JSON object for a person’s name.

```
VALUES JSON_OBJECT(KEY 'first' VALUE 'John', KEY 'last' VALUE 'Doe')

1
```

```
----------------------------
{"first":"John","last":"Doe"}
```

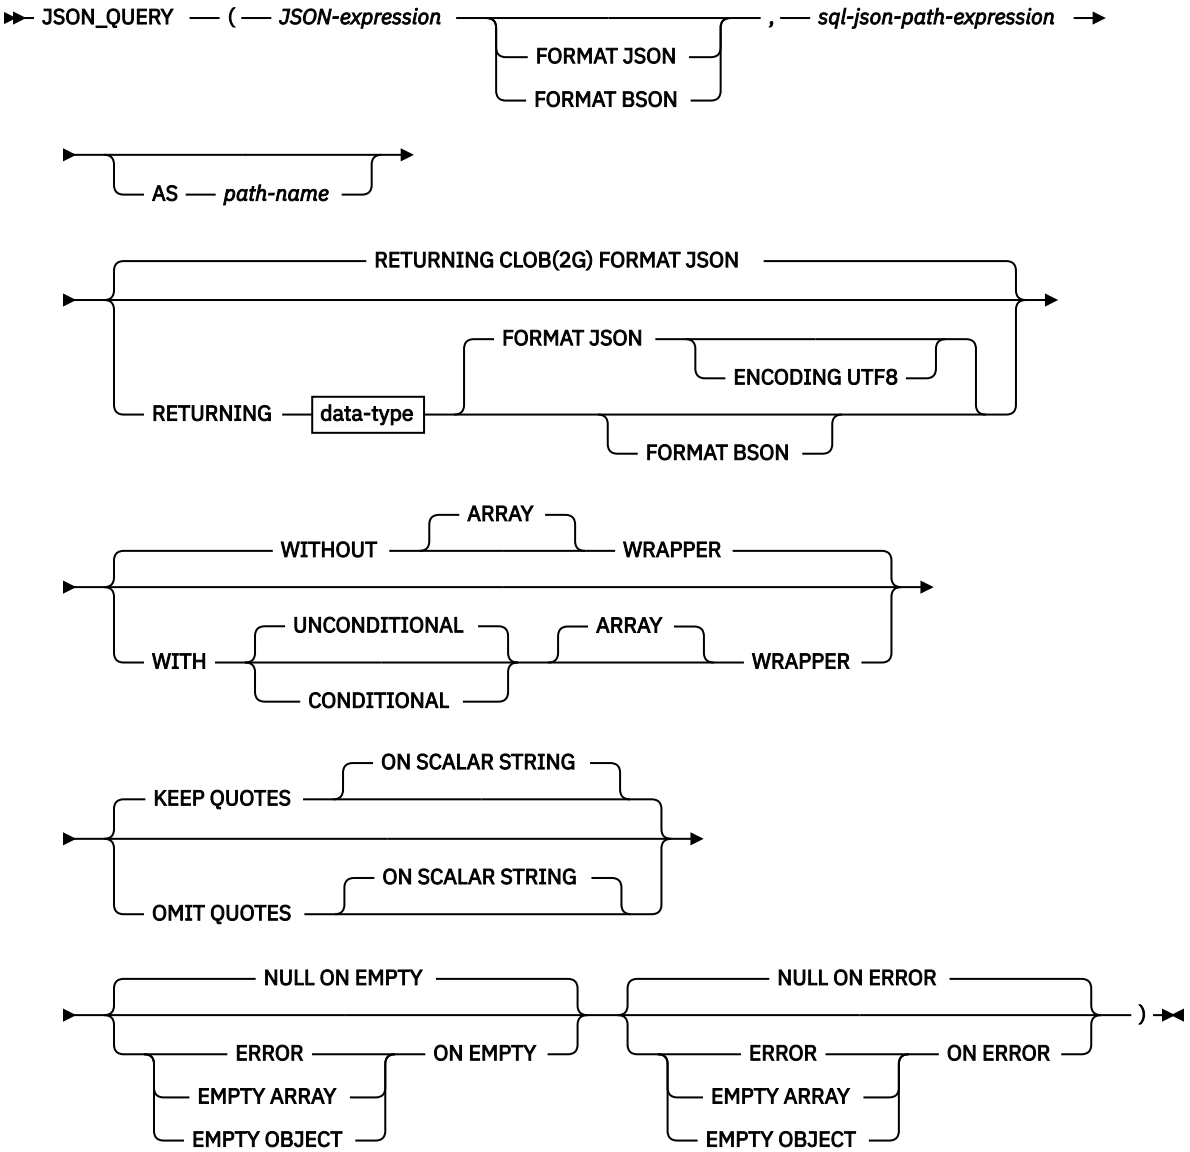
2. Generate a JSON object that contains the surname, hire date, and salary for the employee with an employee number of '000020'.

```
SELECT JSON_OBJECT(KEY 'Last name' VALUE LASTNAME,
                   KEY 'Hire date' VALUE HIREDATE,
                   KEY 'Salary' VALUE SALARY)
   FROM EMPLOYEE
   WHERE EMPNO  = '000020';

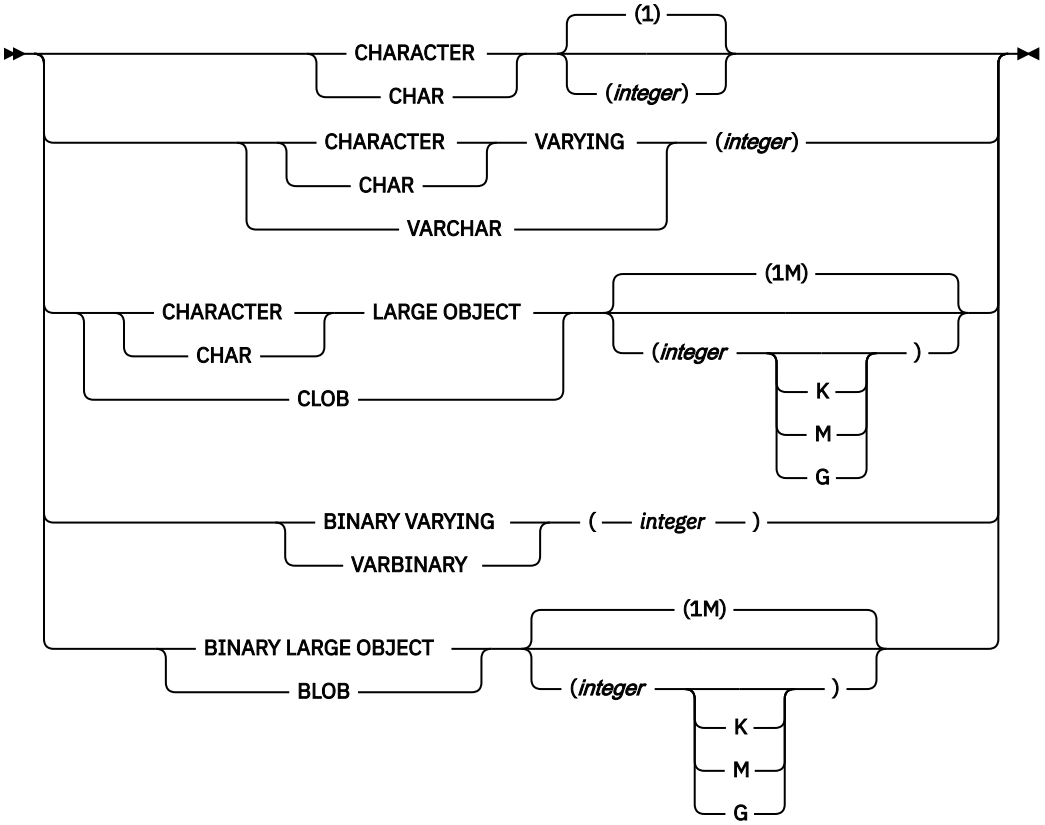
1
--------------------------------------------------------------------
{"Last name":"THOMPSON","Hire date":"1973-10-10","Salary":41250.00}
```

JSON_QUERY

The JSON_QUERY function returns an SQL/JSON value from the specified JSON text by using an SQL/JSON path expression.



data-type



Although the schema for this function is SYSIBM, the function cannot be specified as a qualified name.

JSON-expression
An expression that returns a value that is a built-in string data type, except the following data types (SQLSTATE 42815):

- GRAPHIC
- VARGRAPHIC
- DBCLOB
- BINARY
- CHAR FOR BIT DATA
- VARCHAR FOR BIT DATA
- A user-defined type that is sourced on any of the previously listed data types

If a character value is returned, it must contain correctly formatted JSON data (SQLSTATE 22032). If a binary data type is returned, it is interpreted according to the explicit or implicit FORMAT clause.

FORMAT JSON
JSON-expression is formatted as JSON data.

If *JSON-expression* is a character string data type, it is treated as JSON data.

If *JSON-expression* is a binary string data type, it is interpreted as UTF-8 data.

FORMAT BSON
Specifies that *JSON-expression* is formatted as the BSON representation of JSON data (SQLSTATE 22032). *JSON-expression* must be a binary string data type (SQLSTATE 42815).

sql-json-path-expression
An expression that returns a value that is a built-in character string data type. The string is interpreted as an SQL/JSON path expression and is used to locate a JSON value within the JSON data that

is specified by *JSON-expression*. For more information about the SQL/JSON path expression, see "sql-json-path-expression" on page 179.

AS *path-name*
Specifies a name to be used to identify *sql-json-path-expression*.

RETURNING *data-type*
The data type of the result can be CHAR, VARCHAR, CLOB, VARBINARY, or BLOB (SQLSTATE 42815). The default is CLOB (2 GB).

See "CREATE TABLE " on page 1351 for the description of built-in data types.

FORMAT JSON
The returned data is formatted as JSON data.

ENCODING UTF8
Specifies the encoding to use when *data-type* is a binary string type. This clause is allowed only for binary string types. The default for binary strings is UTF-8.

FORMAT BSON
The returned data is formatted as the BSON representation of JSON data (SQLSTATE 22032). *data-type* must be a binary string data type (SQLSTATE 42815).

WITHOUT ARRAY WRAPPER or WITH ARRAY WRAPPER
Specifies whether the output value is wrapped in a JSON array.

WITHOUT ARRAY WRAPPER
The result is not wrapped. This clause is the default. Using a strict SQL/JSON path definition that resolves to a sequence of two or more SQL/JSON elements results in an error (SQLSTATE 2203A). Using a lax SQL/JSON path definition with the ON EMPTY that resolves to a sequence of two or more SQL/JSON elements will result in an error (SQLSTATE 22035).

WITH UNCONDITIONAL ARRAY WRAPPER
The result is enclosed in square brackets to create a JSON array.

WITH CONDITIONAL ARRAY WRAPPER
Indicates that the result is enclosed in square brackets to create a JSON array for either of the following scenarios:

- More than one SQL/JSON element is returned.
- A single SQL/JSON element that is not a JSON array or a JSON object is returned.

KEEP QUOTES or OMIT QUOTES
Specifies whether the surrounding quotation marks should be removed when a scalar string is returned.

KEEP QUOTES
Quotation marks are not removed from scalar strings. This clause is the default.

OMIT QUOTES
Quotation marks are removed from scalar strings. When OMIT QUOTES is specified, the WITH ARRAY WRAPPER clause cannot be specified (SQLSTATE 42601).

ON EMPTY
Specifies the behavior when an empty sequence is returned by *sql-json-path-expression*.

NULL ON EMPTY
A null value is returned. This clause is the default.

ERROR ON EMPTY
An error is returned.

EMPTY ARRAY ON EMPTY
An empty array is returned.

EMPTY OBJECT ON EMPTY
An empty object is returned.

ON ERROR
Specifies the behavior when an error is encountered by JSON_QUERY.

NULL ON ERROR
A null value is returned. This clause is the default.

ERROR ON ERROR
An error is returned.

EMPTY ARRAY ON ERROR
An empty array is returned.

EMPTY OBJECT ON ERROR
An empty object is returned.

The result can be null. If *JSON-expression* is null, the result is the null value.

Notes

- If parameter markers are not explicitly cast to a supported data type, an error is returned (SQLSTATE 42815)

Example

1. Return the JSON object that is associated with the name key from JSON text.

```
VALUES JSON_QUERY('{"id":"701", "name":{"first":"John", "last":"Doe"}}', '$.name');
```

The result is the following string that represents a JSON object:

```
{"first":"John", "last":"Doe"}
```

See the example at "sql-json-path-expression" on page 179 for different array wrapper options with JSON_QUERY.

JSON_TO_BSON

The JSON_TO_BSON function converts a string that contains data that is formatted for JSON to a binary string that contains data that is formatted as BSON.

Although the schema for this function is SYSIBM, the function cannot be specified as a qualified name.

JSON-expression
Specifies an expression that returns a character string value. It must contain formatted JSON data (SQLSTATE 22032).

If *JSON-expression* can be null, the result can be null; if *JSON-expression* is null, the result is the null value.

Notes

- If parameter markers are not explicitly cast to a supported data type, an error is returned (SQLSTATE 42815)

Examples

1. Convert a valid JSON document to BSON format and insert it into in a table.

```
INSERT INTO TESTJSON VALUES (JSON_TO_BSON('{"Name":"George"}'));
```

This example inserts x'16000000024E616D65000700000047656F7267650000' into the table named TESTJSON.

2. Convert an incorrectly formatted JSON document, which is missing a value for the key "Name".

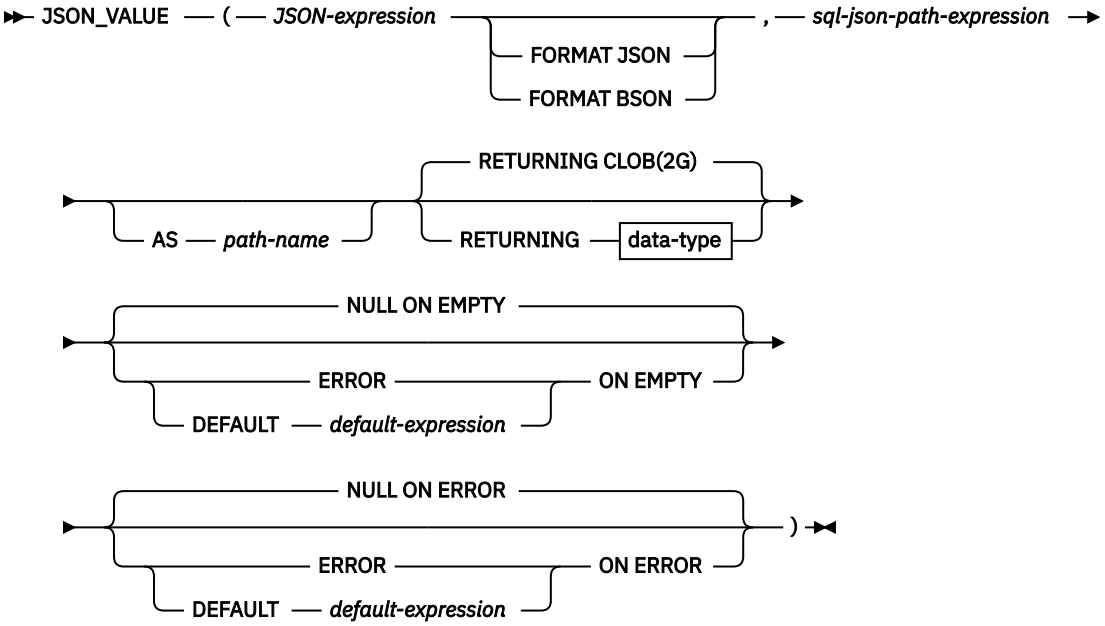
```
INSERT INTO TESTJSON VALUES (JSON_TO_BSON('{"Name":, "Age" : 32}'));

SQL16402N  JSON data is not valid.  SQLSTATE=22032
```

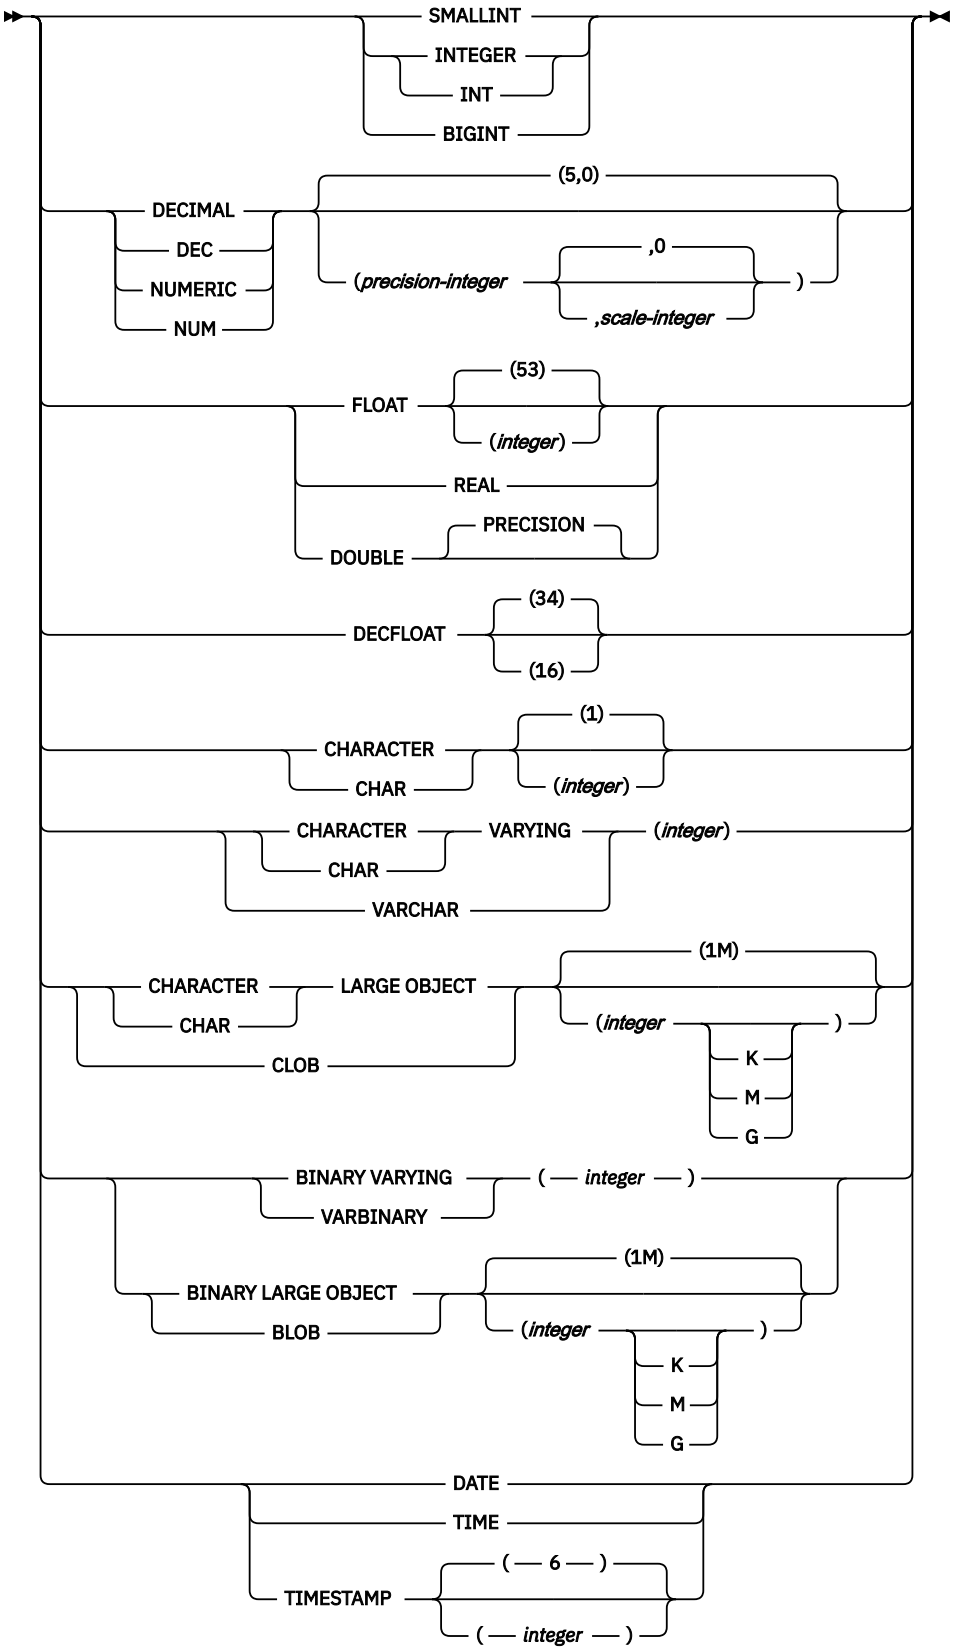
This example results in an error.

JSON_VALUE

The JSON_VALUE function returns an SQL scalar value from JSON text, by using an SQL/JSON path expression.



data-type



Although the schema for this function is SYSIBM, the function cannot be specified as a qualified name.

JSON-expression

An expression that returns a value that is a built-in string data type, except the following data types (SQLSTATE 42815):

- GRAPHIC
- VARGRAPHIC
- DBCLOB
- BINARY
- CHAR FOR BIT DATA
- VARCHAR FOR BIT DATA
- A user-defined type that is sourced on any of the previously listed data types

If a character value is returned, it must contain correctly formatted JSON data (SQLSTATE 22032). If a binary data type is returned, it is interpreted according to the explicit or implicit FORMAT clause.

FORMAT JSON
JSON-expression is formatted as JSON data.

If *JSON-expression* is a character string data type, it is treated as JSON data.

If *JSON-expression* is a binary string data type, it is interpreted as UTF-8 data.

FORMAT BSON
Specifies that *JSON-expression* is formatted as the BSON representation of JSON data (SQLSTATE 22032). *JSON-expression* must be a binary string data type (SQLSTATE 42815).

sql-json-path-expression
An expression that returns a value that is a built-in character string data type. The string is interpreted as an SQL/JSON path expression and is used to locate a JSON value within the JSON data that is specified by *JSON-expression*. For more information about the SQL/JSON path expression, see "sql-json-path-expression" on page 179.

AS *path-name*
Specifies a name to be used to identify *sql-json-path-expression*.

RETURNING *data-type*
Specifies the data type of the result. The default is CLOB (2 GB). The default encoding used when data-type is a binary string type is UTF-8.

See "CREATE TABLE " on page 1351 for the description of built-in data types.

ON EMPTY
Specifies the behavior when an empty sequence is returned by *sql-json-path-expression*.

NULL ON EMPTY
A null value is returned. This clause is the default.

ERROR ON EMPTY
An error is returned.

DEFAULT *default-expression* ON EMPTY
The value that is specified by *default-expression* is returned. The data type of *default-expression* must be the same as the returning data type (SQLSTATE 42815).

ON ERROR
Specifies the behavior when an error is encountered by JSON_VALUE.

NULL ON ERROR
A null value is returned. This clause is the default.

ERROR ON ERROR
An error is returned.

DEFAULT *default-expression* ON ERROR
The value that is specified by *default-expression* is returned. The data type of *default-expression* must be the same as the returning data type (SQLSTATE 42815).

The result can be null. If *JSON-expression* is null, the result is the null value.

Notes

- If parameter markers are not explicitly cast to a supported data type, an error is returned (SQLSTATE 42815)

Examples

1. Return a value from JSON text as an integer.

```
VALUES (JSON_VALUE('{"id":"987"}', 'strict $.id' RETURNING INTEGER));
```

   The result is 987.

2. Get the value for the bonus field from JSON text. Return it as an integer.

```
VALUES (JSON_VALUE('{"pay":{"salary":94250.00,"bonus":800.00,"comm":3300.00}}',
                   'strict $.pay.bonus' RETURNING INTEGER));
```

   The result is 800.

JULIAN_DAY

Returns an integer value representing the number of days from January 1, 4713 B.C. (the start of the Julian date calendar) to the date value specified in the argument.

The schema is SYSFUN.

expression
An expression that returns a value of one of the following built-in data types: a DATE, TIMESTAMP, or a valid character string representation of a date or timestamp that is not a CLOB. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

The result of the function is INTEGER. The result can be null; if the argument is null, the result is the null value.

LAST_DAY

The LAST_DAY scalar function returns a date or timestamp value that represents the last day of the month of the argument.

The schema is SYSIBM.

expression
An expression that specifies the starting date. The expression must return a value of one of the following built-in data types: a DATE or a TIMESTAMP.

The result of the function has the same data type as *expression*, unless *expression* is a string, in which case the result data type is DATE. The result can be null; if the value of *date-expression* is null, the result is the null value.

Any hours, minutes, seconds or fractional seconds information included in *expression* is not changed by the function.

Examples

- *Example 1*: Set the host variable *END_OF_MONTH* with the last day of the current month.

```
SET :END_OF_MONTH = LAST_DAY(CURRENT_DATE);
```

  The host variable *END_OF_MONTH* is set with the value representing the end of the current month. If the current day is 2000-02-10, then *END_OF_MONTH* is set to 2000-02-29.

- *Example 2*: Set the host variable *END_OF_MONTH* with the last day of the month in EUR format for the given date.

```
SET :END_OF_MONTH = CHAR(LAST_DAY('1965-07-07'), EUR);
```

  The host variable *END_OF_MONTH* is set with the value '31.07.1965'.

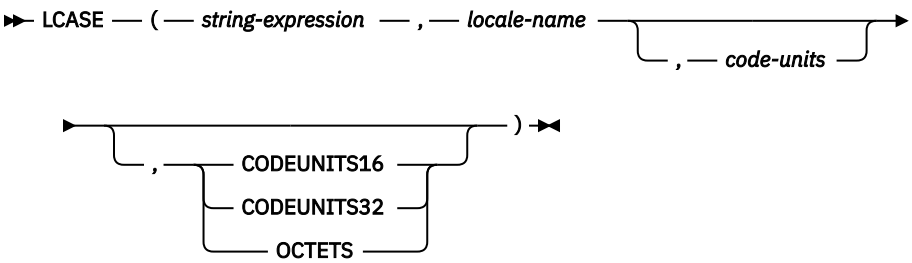
LCASE

The LCASE function returns a string in which all the SBCS characters of the input string have been converted to lowercase characters. The LCASE scalar function is a synonym for the LOWER scalar function.

The schema is SYSIBM.

LCASE (locale sensitive)

The LCASE function returns a string in which all characters have been converted to lowercase characters using the rules associated with the specified locale. The LCASE scalar function is a synonym for the LOWER scalar function.



The schema is SYSIBM.

LCASE (SYSFUN schema)

The LCASE function returns a string in which all SBCS characters have been converted to lowercase characters, that is, the characters A-Z have been converted to the characters a-z. Characters with diacritical marks are not converted. Consequently, a statement of the form LCASE(UCASE(*string*)) will not necessarily return the same result as LCASE(*string*).

The schema is SYSFUN.

expression
An expression that returns a built-in character string or Boolean value. In a Unicode database, the expression can also return a graphic string, in which case it is first converted to a character string before the function is evaluated. For a VARCHAR, the maximum length is 4000 bytes. For a CLOB, the maximum length is 1,048,576 bytes.

Result

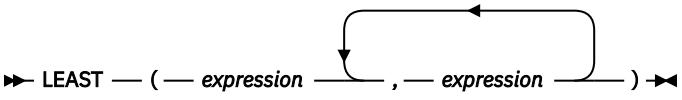
The data type of the result depends on the data type of the input expression:

- VARCHAR(4000) if the input expression is VARCHAR or CHAR
- CLOB(1M) if the input expression is CLOB or LONG VARCHAR

The result can be null; if the input expression is null, the result is the null value.

LEAST

The LEAST function returns the minimum value in a set of values.



The schema is SYSIBM.

expression
An expression that returns a value of any built-in data type or user-defined data type that is comparable with the data type of the other argument. The data type cannot be a LOB, distinct type base on a LOB, XML, array, cursor, row, or structured type.

Result

The result of the function is the smallest argument value. The result can be null if at least one argument can be null; the result is the null value if any argument is null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined by the data types of all the arguments as explained in "Rules for result data types".

Notes

- The LEAST scalar function is a synonym for the MIN scalar function.
- The LEAST function cannot be used as a source function when creating a user-defined function. Because this function accepts any comparable data types as arguments, it is not necessary to create additional signatures to support user-defined data types.

Example

Assume that table T1 contains three columns C1, C2, and C3 with values 1, 7, and 4, respectively. The query:

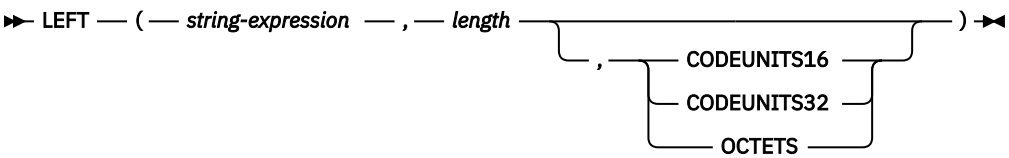
```
SELECT LEAST (C1, C2, C3) FROM T1
```

returns 1.

If column C3 has a value of null instead of 4, the same query returns the null value.

LEFT

The LEFT function returns the leftmost string of *string-expression* of length *length*, expressed in the specified string unit.



The schema is SYSIBM. The SYSFUN version of the LEFT function continues to be available.

string-expression
An expression that specifies the string from which the result is derived. The expression must return a built-in string, numeric value, Boolean value, or datetime value. If the value is not a string, it is implicitly cast to VARCHAR before the function is evaluated. Zero or more contiguous code points of the string comprise a substring of the string.

The *string-expression* is padded on the right with the necessary number of padding characters so that the specified substring of *string-expression* always exists. The character used for padding is the same character that is used to pad the string in contexts where padding would occur. For more information about padding, see "String assignments" in "Assignments and comparisons".

length

An expression that specifies the length of the result. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. *length* must be greater than or equal to 0 (SQLSTATE 22011). If OCTETS is specified and the result is graphic data, the value must be an even number (SQLSTATE 428GC).

If *length* is not a constant and a string unit is not specified, *length* must be less than or equal to the length attribute of *string-expression* (SQLSTATE 22011).

If *length* is not a constant and a string unit is specified, *length* must be less than or equal to the corresponding value from the following table (SQLSTATE 22011):

Table 70. Maximum value of length when length is not a constant and a string unit is specified

String unit of *string-expression*	**Specified string unit**	**Maximum value of *length*** **L = length attribute of *string-expression***
OCTETS	OCTETS	L
OCTETS	CODEUNITS16	L/2
OCTETS	CODEUNITS32	L/4
CODEUNITS16	OCTETS	L*2
CODEUNITS16	CODEUNITS16	L
CODEUNITS16	CODEUNITS32	L/2
CODEUNITS32	OCTETS	L*4
CODEUNITS32	CODEUNITS16	L*2
CODEUNITS32	CODEUNITS32	L

If *length* is a constant and the data type of *string-expression* is:

CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC
length must be less than or equal to 32,672 OCTETS, 16,336 CODEUNITS16 or 8168 CODEUNITS32 (SQLSTATE 22011).

CLOB or DBCLOB
length must be less than or equal to 2,147,483,647 OCTETS, 1,073,741,823 CODEUNITS16, or 53,6870,911 CODEUNITS32 (SQLSTATE 22011).

BLOB
length must be less than or equal to 2,147,483,647 OCTETS (SQLSTATE 22011).

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of *length*.

CODEUNITS16 specifies that *length* is expressed in 16-bit UTF-16 code units. CODEUNITS32 specifies that *length* is expressed in 32-bit UTF-32 code units. OCTETS specifies that *length* is expressed in bytes.

If the string unit is specified as CODEUNITS16 or CODEUNITS32, and *string-expression* is a binary string or bit data, an error is returned (SQLSTATE 428GC). If the string unit is specified as OCTETS and *string-expression* is a graphic string, *length* must be an even number; otherwise, an error is returned (SQLSTATE 428GC). If a string unit is not explicitly specified, the string unit of *string-expression* determines the unit that is used. For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String units in built-in functions" in "Character strings".

Result

The result of the function is a varying-length string that depends on the data type of *string-expression*:

- VARCHAR if *string-expression* is CHAR or VARCHAR
- CLOB if *string-expression* is CLOB
- VARGRAPHIC if *string-expression* is GRAPHIC or VARGRAPHIC
- DBCLOB if *string-expression* is DBCLOB
- VARBINARY if *string-expression* is BINARY or VARBINARY
- BLOB if *string-expression* is BLOB

The string unit of the result is the string unit of *string-expression*.The length attribute of the result depends on how *length* and string unit are specified:

- If *length* is not a constant, then the length attribute of the result is the same as the length attribute of *string-expression*.
- If *length* is a constant and a string unit is not specified, then the length attribute of the result is the maximum of length and the length attribute of *string-expression*.
- If *length* is a constant and a string unit is specified, then the length attribute of the result is shown in Table 2:

Table 71. Length attribute of result when length is a constant and a string unit is specified

String unit of *string-expression*	**Specified string unit**	**Maximum value of *length*** **L = length attribute of *string-expression***
OCTETS	OCTETS	max(L, *length*)
OCTETS	CODEUNITS16	max(L, *length* * 2)
OCTETS	CODEUNITS32	max(L, *length* * 4)
CODEUNITS16	OCTETS	max(L, *length* / 2)
CODEUNITS16	CODEUNITS16	max(L, *length*)
CODEUNITS16	CODEUNITS32	max(L, *length* * 2)
CODEUNITS32	OCTETS	max(L, *length* / 4)
CODEUNITS32	CODEUNITS16	max(L, *length* / 2)
CODEUNITS32	CODEUNITS32	max(L, *length*)

The actual length of the result (in string units) is *length*.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: Assume that variable ALPHA has a value of "ABCDEF". The following statement:

```
SELECT LEFT(ALPHA,3)
  FROM SYSIBM.SYSDUMMY1
```

  returns "ABC", which are the three leftmost characters in ALPHA.

- *Example 2*: Assume that variable NAME, which is defined as VARCHAR(50), has a value of "KATIE AUSTIN", and that the integer variable FIRSTNAME_LEN has a value of 5. The following statement:

```
SELECT LEFT(NAME,FIRSTNAME_LEN)
  FROM SYSIBM.SYSDUMMY1
```

  returns the value "KATIE".

- *Example 3*: The following statement returns a zero-length string.

```
SELECT LEFT('ABCABC',0)
  FROM SYSIBM.SYSDUMMY1
```

- *Example 4*: The FIRSTNME column in the EMPLOYEE table is defined as VARCHAR(12). Find the first name of an employee whose last name is "BROWN" and return the first name in a 10-byte string.

```
SELECT LEFT(FIRSTNME, 10)
  FROM EMPLOYEE
  WHERE LASTNAME = 'BROWN'
```

  returns a VARCHAR(12) string that has the value "DAVID" followed by five blank characters.

- *Example 5*: In a Unicode database, FIRSTNAME is a VARCHAR(12) column. One of its values is the 6-character string "Jürgen". When FIRSTNAME has this value:

```
Function...                      Returns...

LEFT(FIRSTNAME,2,CODEUNITS32)   'Jü' -- x'4AC3BC'
LEFT(FIRSTNAME,2,CODEUNITS16)   'Jü' -- x'4AC3BC'
LEFT(FIRSTNAME,2,OCTETS)        'J'  -- x'4A20', a truncated string
```

- *Example 6*: The following example works with the Unicode string "&N~AB", where "&" is the musical symbol G clef character, and "~" is the combining tilde character. This string is shown in different Unicode encoding forms in the following example:

	"&"	"N"	"~"	"A"	"B"
UTF-8	X'F09D849E'	X'4E'	X'CC83'	X'41'	X'42'
UTF-16BE	X'D834DD1E'	X'004E'	X'0303'	X'0041'	X'0042'

  Assume that the variable UTF8_VAR, with a length attribute of 20 bytes, contains the UTF-8 representation of the string.

```
SELECT LEFT(UTF8_VAR, 2, CODEUNITS16),
  LEFT(UTF8_VAR, 2, CODEUNITS32),
  LEFT(UTF8_VAR, 2, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

  returns the values "&", "&N", and "bb", respectively, where "b" represents the blank character.

```
SELECT LEFT(UTF8_VAR, 5, CODEUNITS16),
  LEFT(UTF8_VAR, 5, CODEUNITS32),
  LEFT(UTF8_VAR, 5, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

  returns the values "&N~A", "&N~AB", and "&N", respectively.

```
SELECT LEFT(UTF8_VAR, 10, CODEUNITS16),
  LEFT(UTF8_VAR, 10, CODEUNITS32),
```

```
    LEFT(UTF8_VAR, 10, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values "&N~ABbbbb", "&N~ABbbbbb", and "&N~ABb", respectively, where "b" represents the blank character.

Assume that the variable UTF16_VAR, with a length attribute of 20 code units, contains the UTF-16BE representation of the string.

```
SELECT LEFT(UTF16_VAR, 2, CODEUNITS16),
  LEFT(UTF16_VAR, 2, CODEUNITS32),
  HEX (LEFT(UTF16_VAR, 2, OCTETS))
FROM SYSIBM.SYSDUMMY1
```

returns the values "&", "&N", and X'D834', respectively, where X'D834' is an unmatched high surrogate.

```
SELECT LEFT(UTF16_VAR, 5, CODEUNITS16),
  LEFT(UTF16_VAR, 5, CODEUNITS32),
  LEFT(UTF16_VAR, 6, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

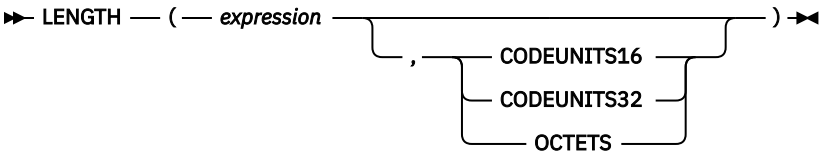
returns the values "&N~A", "&N~AB", and "&N", respectively.

```
SELECT LEFT(UTF16_VAR, 10, CODEUNITS16),
  LEFT(UTF16_VAR, 10, CODEUNITS32),
  LEFT(UTF16_VAR, 10, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values "&N~ABbbbb", "&N~ABbbbbb", and "&N~A", respectively, where "b" represents the blank character.

LENGTH

The LENGTH function returns the length of *expression* in the implicit or explicit string unit.



The schema is SYSIBM.

expression
An expression that returns a value that is a built-in data type. If *expression* can be null, the result can be null; if *expression* is null, the result is the null value.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of the result. CODEUNITS16 specifies that the result is to be expressed in 16-bit UTF-16 code units. CODEUNITS32 specifies that the result is to be expressed in 32-bit UTF-32 code units. OCTETS specifies that the result is to be expressed in bytes.

If a string unit is explicitly specified, and if *expression* is not string data, an error is returned (SQLSTATE 428F5). If a string unit is specified as CODEUNITS16 or CODEUNITS32, and *expression* is a binary string or bit data, an error is returned (SQLSTATE 428GC). If a string unit is specified as OCTETS and *expression* is a binary string, an error is returned (SQLSTATE 42815). For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String units in built-in functions" in "Character strings".

If a string unit argument is not explicitly specified and if *expression* is a character or graphic string, the string units of *expression* determines the string unit that is used for the result. Otherwise, the value returned specifies the length in bytes.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The length of character and graphic strings includes trailing blanks. The length of binary strings includes binary zeros. The length of varying-length strings is the actual length and not the maximum length. The length of all other values is the number of bytes used to represent the value:

- 2 for small integer (SMALLINT)
- 4 for large integer (INTEGER)
- 8 for big integer (BIGINT)
- (*p*/2)+1 for decimal numbers with precision *p*
- 8 for DECFLOAT(16)
- 16 for DECFLOAT(34)
- The length of the string for binary strings
- The length of the string for character strings
- 4 for single-precision floating-point
- 8 for double-precision floating-point
- 4 for DATE
- 3 for TIME
- 7+(*p*+1)/2 for TIMESTAMP(*p*)

Examples

- *Example 1*: Assume that the host variable ADDRESS is a varying-length character string with a value of '895 Don Mills Road'.

```
LENGTH(:ADDRESS)
```

  returns the value 18.

- *Example 2*: Assume that START_DATE is a column of type DATE.

```
LENGTH(START_DATE)
```

  returns the value 4.

- *Example 3*: The following example returns the value 10.

```
LENGTH(CHAR(START_DATE, EUR))
```

- *Example 4*: The following examples work with the Unicode string '&N~AB', where '&' is the musical symbol G clef character, and '~' is the combining tilde character. This string is shown in different Unicode encoding forms in the following example:

	'&'	'N'	'~'	'A'	'B'
UTF-8	X'F09D849E'	X'4E'	X'CC83'	X'41'	X'42'
UTF-16BE	X'D834DD1E'	X'004E'	X'0303'	X'0041'	X'0042'
UTF-32BE	X'0001D11E'	X'0000004E'	X'00000303'	X'00000041'	X'00000042'

  Assume that the variable UTF8_VAR contains the UTF-8 representation of the string.

```
SELECT LENGTH(UTF8_VAR, CODEUNITS16),
  LENGTH(UTF8_VAR, CODEUNITS32),
  LENGTH(UTF8_VAR, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

  returns the values 6, 5, and 9, respectively.

  Assume that the variable UTF16_VAR contains the UTF-16BE representation of the string.

```
SELECT LENGTH(UTF16_VAR, CODEUNITS16),
   LENGTH(UTF16_VAR, CODEUNITS32),
   LENGTH(UTF16_VAR, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values 6, 5, and 12, respectively.

LENGTH2

The LENGTH2 function returns the length of *expression* in 16-bit UTF-16 string units (CODEUNITS16).

The schema is SYSIBM.

expression
An expression that returns a value that is a built-in data type.

The LENGTH2 scalar function invoked with a character or graphic string as the argument is equivalent to invoking the LENGTH function with CODEUNITS16 specified. The LENGTH2 scalar function invoked with any other data type as the argument is equivalent to invoking the LENGTH function without a string units argument.

LENGTH4

The LENGTH4 function returns the length of *expression* in 32-bit UTF-32 string units (CODEUNITS32).

The schema is SYSIBM.

expression
An expression that returns a value that is a built-in data type.

The LENGTH4 scalar function invoked with a character or graphic string as the argument is equivalent to invoking the LENGTH function with CODEUNITS32 specified. The LENGTH4 scalar function invoked with any other data type as the argument is equivalent to invoking the LENGTH function without a string units argument.

LENGTHB

The LENGTHB function returns the length of *expression* in bytes.

The schema is SYSIBM.

expression
An expression that returns a value that is a built-in data type.

The LENGTHB scalar function invoked with a character or graphic string as the argument is equivalent to invoking the LENGTH function with OCTETS specified. The LENGTHB scalar function invoked with any other data type as the argument is equivalent to invoking the LENGTH function without a string units argument.

LN

The LN function returns the natural logarithm of a number. The LN and EXP functions are inverse operations.

The schema is SYSIBM. (The SYSFUN version of the LN function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type. If the value is of decimal floating-point data type, the operation is performed in decimal floating-point; otherwise, the value is converted to double-precision floating-point for processing by the function. The value of the argument must be greater than zero (SQLSTATE 22003).

If the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*); otherwise, the result is a double-precision floating-point number. The result can be null; if the argument is null, the result is the null value.

Notes

- ***Results involving DECFLOAT special values:*** For decimal floating-point values, the special values are treated as follows:
  - LN(NaN) returns NaN.
  - LN(-NaN) returns -NaN.
  - LN(Infinity) returns Infinity.
  - LN(-Infinity) returns NaN and a warning.
  - LN(sNaN) returns NaN and a warning.
  - LN(-sNaN) returns -NaN and a warning.
  - LN(DECFLOAT('0') returns -Infinity.
- ***Syntax alternatives:*** For compatibility with other SQL dialects, LOG can be specified in place of LN. However, because some database managers and applications use LOG to mean a common logarithm rather than a natural logarithm, use LN instead of LOG whenever possible.

Example

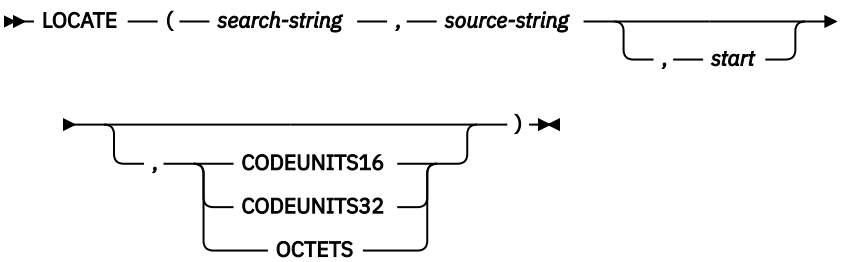
Assume that NATLOG is a DECIMAL(4,2) host variable with a value of 31.62.

```
VALUES LN(:NATLOG)
```

Returns the approximate value 3.45.

LOCATE

The LOCATE function returns the starting position of the first occurrence of one string (called the *search-string*) within another string (called the *source-string*).



The schema is SYSIBM. The SYSFUN version of the LOCATE function continues to be available, but it is not sensitive to the database collation.

If the *search-string* is not found and neither argument is null, the result is zero. If the *search-string* is found, the result is a number from 1 to the actual length of the *source-string*. The search is done using the collation of the database, unless *search-string* or *source-string* is defined as a binary string or as FOR BIT DATA , in which case the search is done using a binary comparison.

If the optional *start* is specified, it indicates the character position in the *source-string* at which the search is to begin. An optional string unit can be specified to indicate in what units the *start* and result of the function are expressed.

If the *search-string* has a length of zero, the result returned by the function is 1. Otherwise, if the *source-string* has a length of zero, the result returned by the function is 0. Otherwise:

- If the value of *search-string* is equal to an identical length of substring of contiguous positions within the value of *source-string*, the result returned by the function is the starting position of the first such substring within the *source-string* value.
- Otherwise, the result returned by the function is 0.

search-string
An expression that specifies the string that is the object of the search. The expression must return a value that is a built-in CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, binary string, numeric, Boolean, or datetime data type. If the value is not a CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, or binary string data type, it is implicitly cast to VARCHAR before evaluating the function. The expression cannot be specified by a LOB file reference variable.

source-string
An expression that specifies the string in which the search is to take place. The expression must return a value that is a built-in string, numeric, Boolean, or datetime data type. If the value is not a string data type, it is implicitly cast to VARCHAR before evaluating the function.

start
An expression that specifies the position within *source-string* at which the search is to start. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. The value of the integer must be greater than or equal to zero. If *start* is specified, the LOCATE function is similar to:

```
POSITION(search-string,
  SUBSTRING(source-string, start, string-unit),
  string-unit) + start - 1
```

where *string-unit* is either CODEUNITS16, CODEUNITS32, or OCTETS.

If *start* is not specified, the search begins at the first position of the source string, and the LOCATE function is similar to:

```
POSITION(search-string, source-string, string-unit)
```

If OCTETS is specified and *source-string* is graphic data, the value of the integer must be odd (SQLSTATE 428GC).

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of *start* and the result. CODEUNITS16 specifies that *start* and the result are to be expressed in 16-bit UTF-16 code units. CODEUNITS32 specifies that *start* and the result are to be expressed in 32-bit UTF-32 code units. OCTETS specifies that *start* and the result are to be expressed in bytes.

If a string unit is specified as CODEUNITS16 or CODEUNITS32, and *search-string* or *source-string* is a binary string or FOR BIT DATA, an error is returned (SQLSTATE 428GC). If the string unit is specified as CODEUNITS16 or OCTETS, and the string units of *source-string* is CODEUNITS32, an error is returned (SQLSTATE 428GC).

If a string unit is not explicitly specified and if *source-string* is a character or graphic string, the string units of *source-string* determines the unit that is used for the result and for *start* (if specified). Otherwise, they are expressed in bytes.

If a locale-sensitive UCA-based collation is used for this function, then the CODEUNITS16 option offers the best performance characteristics.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String units in built-in functions" in "Character strings".

The first and second arguments must have compatible string types. For more information about compatibility, see "Rules for string conversions". In a Unicode database, if one string argument is character (not FOR BIT DATA) and the other string argument is graphic, then the *search-string* is converted to the data type of the *source-string* for processing. If one argument is character FOR BIT DATA, the other argument must not be graphic (SQLSTATE 42846).

The result of the function is a large integer. If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: Find the location of the first occurrence of the character "N" in the string "DINING".

```
SELECT LOCATE('N', 'DINING')
FROM SYSIBM.SYSDUMMY1
```

  The result is the value 3.

- *Example 2*: For all the rows in the table named IN_TRAY, select the RECEIVED column, the SUBJECT column, and the starting position of the string "GOOD" within the NOTE_TEXT column.

```
SELECT RECEIVED, SUBJECT, LOCATE('GOOD', NOTE_TEXT)
FROM IN_TRAY
WHERE LOCATE('GOOD', NOTE_TEXT) <> 0
```

- *Example 3*: Locate the character "ß" in the string "Jürgen lives on Hegelstraße", and set the host variable LOCATION with the position, as measured in CODEUNITS32 units, within the string.

```
SET :LOCATION = LOCATE('ß', 'Jürgen lives on Hegelstraße', 1, CODEUNITS32)
```

  The value of host variable LOCATION is set to 26.

- *Example 4*: Locate the character '"ß" in the string "Jürgen lives on Hegelstraße", and set the host variable LOCATION with the position, as measured in CODEUNITS16 units, within the string.

```
SET :LOCATION = LOCATE('ß', 'Jürgen lives on Hegelstraße', 1, CODEUNITS16)
```

  The value of host variable LOCATION is set to 26.

- *Example 5*: Locate the character "ß" in the string "Jürgen lives on Hegelstraße", and set the host variable LOCATION with the position, as measured in OCTETS, within the string.

```
SET :LOCATION = LOCATE('ß', 'Jürgen lives on Hegelstraße', 1, OCTETS)
```

  The value of host variable LOCATION is set to 27.

- *Example 6*: The following examples work with the Unicode string "&N~AB", where "&" is the musical symbol G clef character, and "~" is the non-spacing combining tilde character. This string is shown in different Unicode encoding forms in the following example:

	"&"	"N"	"~"	"A"	"B"
UTF-8	X'F09D849E'	X'4E'	X'CC83'	X'41'	X'42'
UTF-16BE	X'D834DD1E'	X'004E'	X'0303'	X'0041'	X'0042'

  Assume that the variable UTF8_VAR contains the UTF-8 representation of the string.

```
SELECT LOCATE('~', UTF8_VAR, CODEUNITS16),
  LOCATE('~', UTF8_VAR, CODEUNITS32),
  LOCATE('~', UTF8_VAR, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

  returns the values 4, 3, and 6, respectively.

Assume that the variable UTF16_VAR contains the UTF-16BE representation of the string.

```
SELECT LOCATE('~', UTF16_VAR, CODEUNITS16),
   LOCATE('~', UTF16_VAR, CODEUNITS32),
   LOCATE('~', UTF16_VAR, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values 4, 3, and 7, respectively.

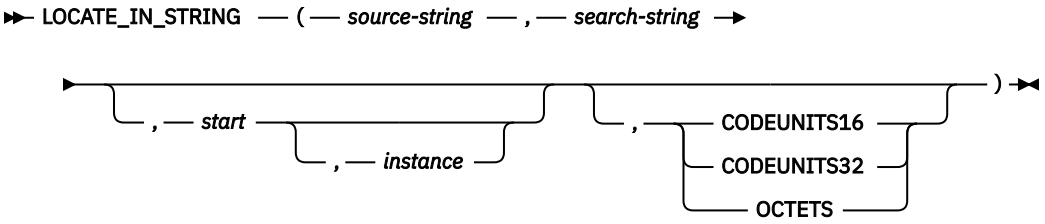
- *Example 7*: In a Unicode database created with the case insensitive collation CLDR181_LEN_S1, find the position of the word "Brown" in the phrase "The quick brown fox".

```
SET :LOCATION = LOCATE('Brown', 'The quick brown fox', CODEUNITS16)
```

The value of the host variable LOCATION is set to 11.

LOCATE_IN_STRING

The LOCATE_IN_STRING function returns the starting position of a string (called the *search-string*) within another string (called the *source-string*).



The schema is SYSIBM

If the *search-string* is not found and neither argument is null, the result is zero. If the *search-string* is found, the result is a number from 1 to the actual length of the *source-string*. The search is done using the collation of the database, unless *search-string* or *source-string* is defined as a binary string or as FOR BIT DATA, in which case the search is done using a binary comparison.

If the optional *start* is specified, it indicates the character position in the *source-string* at which the search is to begin. If the *start* is specified, an instance number can also be specified. The *instance* argument is used to determine the position of a specific occurrence of *search-string* within *source-string*. An optional string unit can be specified to indicate in what units the *start* and result of the function are expressed.

If the *search-string* has a length of zero, the result returned by the function is 1. If the *source-string* has a length of zero, the result returned by the function is 0. If neither condition exists, and if the value of *search-string* is equal to an identical length of a substring of contiguous positions within the value of *source-string*, the result returned by the function is the starting position of that substring within the *source-string* value; otherwise, the result returned by the function is 0.

source-string
An expression that specifies the string in which the search is to take place. The expression must return a value that is a built-in string, numeric, Boolean, or datetime data type. If the value is not a string data type, it is implicitly cast to VARCHAR before evaluating the function.

search-string
An expression that specifies the string that is the object of the search. The expression must return a value that is a built-in CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, binary string, numeric, Boolean, or datetime data type. If the value is not a CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, or binary string data type, it is implicitly cast to VARCHAR before evaluating the function. The expression cannot be specified by a LOB file reference variable.

start
An expression that specifies the position within *source-string* at which the search for a match is to start. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC or

VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

If the value of the integer is greater than zero, the search begins at *start* and continues for each position to the end of the string. If the value of the integer is less than zero, the search begins at LENGTH(*source-string*) + *start* + 1 and continues for each position to the beginning of the string.

If *start* is not specified, the default is 1. If OCTETS is specified and *source-string* is graphic data, the value of the integer must be odd (SQLSTATE 428GC). If the value of the integer is zero, an error is returned (SQLSTATE 42815).

instance
An expression that specifies which instance of *search-string* to search for within *source-string*. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. If *instance* is not specified, the default is 1. The value of the integer must be greater than or equal to 1 (SQLSTATE 42815).

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of *start* and the result. CODEUNITS16 specifies that *start* and the result are to be expressed in 16-bit UTF-16 code units. CODEUNITS32 specifies that *start* and the result are to be expressed in 32-bit UTF-32 code units. OCTETS specifies that *start* and the result are to be expressed in bytes.

If a string unit is specified as CODEUNITS16 or CODEUNITS32, and *search-string* or *source-string* is a binary string or FOR BIT DATA, an error is returned (SQLSTATE 428GC). If the string unit is specified as CODEUNITS16 or OCTETS, and the string units of *source-string* is CODEUNITS32, an error is returned (SQLSTATE 428GC).

If a string unit is not explicitly specified and if *source-string* is a character or graphic string, the string units of *source-string* determines the unit that is used for the result and for *start* (if specified). Otherwise, they are expressed in bytes.

If a locale-sensitive UCA-based collation is used for this function, then the CODEUNITS16 option offers the best performance characteristics.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String units in built-in functions" in "Character strings".

The first and second arguments must have compatible string types. For more information about compatibility, see "Rules for string conversions". In a Unicode database, if one string argument is character (not FOR BIT DATA) and the other string argument is graphic, then the *search-string* is converted to the data type of the *source-string* for processing. If one argument is character FOR BIT DATA, the other argument must not be graphic (SQLSTATE 42846).

At each search position, a match is found when the substring at that position and LENGTH(*search-string*) - 1 values to the right of the search position in *source-string*, is equal to *search-string*.

The result of the function is a large integer. The result is the starting position of the instance of *search-string* within *source-string*. The value is relative to the beginning of the string (regardless of the specification of *start*). If any argument can be null, the result can be null; if any argument is null, the result is the null value.

INSTR can be used as a synonym for LOCATE_IN_STRING.

The INSTRB scalar function is equivalent to invoking the LOCATE_IN_STRING function with OCTETS (where allowed) specified to indicate that start position and the result are expressed in bytes.

Examples

- *Example 1*: Locate the character "ß" in the string "Jürgen lives on Hegelstraße" by searching from the end of the string, and set the host variable POSITION with the position, as measured in CODEUNITS32 units, within the string.

```
SET :POSITION = LOCATE_IN_STRING('Jürgen lives on Hegelstraße',
                                 'ß',-1,CODEUNITS32);
```

  The value of host variable POSITION is set to 26.

- *Example 2*: Find the location of the third occurrence of the character "N" in the string "WINNING" by searching from the start of the string and then set the host variable POSITION with the position of the character, as measured in bytes, within the string.

```
SET :POSITION =
LOCATE_IN_STRING('WINNING','N',1,3,OCTETS);
```

  The value of host variable POSITION is set to 6.

LOG10

The LOG10 function returns the common logarithm (base 10) of a number.

The schema is SYSIBM. (The SYSFUN version of the LOG10 function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type. If the value is of decimal floating-point data type, the operation is performed in decimal floating-point; otherwise, the value is converted to double-precision floating-point for processing by the function. The value of the argument must be greater than zero (SQLSTATE 22003).

If the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*); otherwise, the result is a double-precision floating-point number. The result can be null; if the argument is null, the result is the null value.

Notes

- ***Results involving DECFLOAT special values:*** For decimal floating-point values, the special values are treated as follows:
  - LOG10(NaN) returns NaN.
  - LOG10(-NaN) returns -NaN.
  - LOG10(Infinity) returns Infinity.
  - LOG10(-Infinity) returns NaN and a warning.
  - LOG10(sNaN) returns NaN and a warning.
  - LOG10(-sNaN) returns -NaN and a warning.
  - LOG10(DECFLOAT('0') returns -Infinity.

Example

Assume that L is a DECIMAL(4,2) host variable with a value of 31.62.

```
VALUES LOG10(:L)
```

Returns the DOUBLE value +1.49996186559619E+000.

LONG_VARCHAR

The LONG_VARCHAR function is deprecated and might be removed in a future release.

The function is compatible with earlier Db2 versions.

LONG_VARGRAPHIC

The LONG_VARGRAPHIC function is deprecated and might be removed in a future release.

The function is compatible with earlier Db2 versions.

LOWER

The LOWER function returns a string in which all the SBCS characters have been converted to lowercase characters.

The schema is SYSIBM. (The SYSFUN version of this function continues to be available with support for CLOB arguments.)

string-expression
An expression that returns a built-in character string or Boolean value. In a Unicode database, the expression can also return a graphic string, in which case it is first converted to a character string before the function is evaluated.

Result

The characters A-Z are converted to the characters a-z, and other characters are converted to their lowercase equivalents, if they exist. For example, in code page 850, É maps to é. If the code point length of the result character is not the same as the code point length of the source character, the source character is not converted. Because not all characters are converted, LOWER(UPPER(*string-expression*)) does not necessarily return the same result as LOWER(*string-expression*).

The result of the function has the same data type, string unit, and length attribute as the argument. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Example

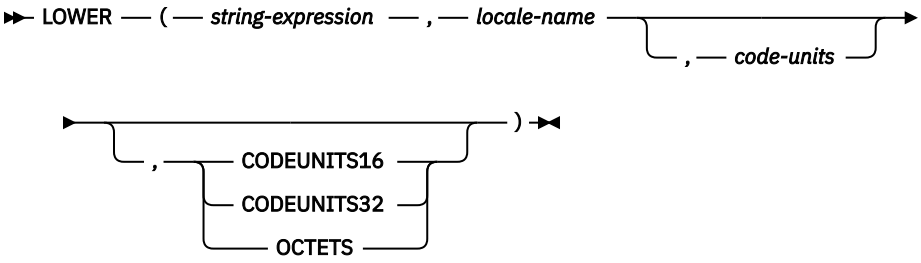
Ensure that the characters in the value of column JOB in the EMPLOYEE table are returned in lowercase characters.

```
SELECT LOWER(JOB)
  FROM EMPLOYEE
  WHERE EMPNO = '000020';
```

The result is the value 'manager'.

LOWER (locale sensitive)

The LOWER function returns a string in which all characters have been converted to lowercase characters using the rules associated with the specified locale.



The schema is SYSIBM.

string-expression
An expression that returns a built-in character string, , Boolean value, or graphic string. If the expression returns a character string, the expression cannot specify FOR BIT DATA (SQLSTATE 42815).

locale-name
A character constant that specifies the locale that defines the rules for conversion to lowercase characters. This value is not case sensitive and must be a valid locale (SQLSTATE 42815). For information about valid locales and their naming, see "Locale names for SQL and XQuery".

Attention: In the container-only release of Db2 Version 11.5 Mod Pack 1 and later versions, passing UNI_SIMPLE as locale-name will enable use of simple case folding mapping.

code-units
An integer constant that specifies the number of code units in the result. If specified, this must be an integer between:

- 1 and 32672, if the string unit of the result is OCTETS
- 1 and 16336, if the string unit of the result is double bytes or CODEUNITS16
- 1 and 8168, if the string unit of the result is CODEUNITS32

Otherwise, an error is returned (SQLSTATE 42815). The default is the length attribute of *string-expression*.

The value that can be specified for *code-units* depends on which string units are used:

- If the string unit OCTETS is specified for the string expression and the result is graphic data, the value must be even (SQLSTATE 428GC).
- If the string unit OCTETS is specified for the string expression and the string unit of the result is CODEUNIT32, the value must be a multiple of 4 (SQLSTATE 428GC).
- If the string unit CODEUNITS16 is specified for the string expression and the string unit of the result is CODEUNITS32, the value must be a multiple of 2 (SQLSTATE 428GC).

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of *code-units*.

CODEUNITS16 specifies that *code-units* is expressed in 16-bit UTF-16 code units. CODEUNITS32 specifies that *code-units* is expressed in 32-bit UTF-32 code units. OCTETS specifies that *code-units* is expressed in bytes.

If a string unit is not explicitly specified, the string unit of *string-expression* determines the unit that is used. For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String units in built-in functions" in "Character strings".

Result

The result of the function is VARCHAR if *string-expression* is CHAR or VARCHAR, and VARGRAPHIC if *string-expression* is GRAPHIC or VARGRAPHIC. The string units of the result is the same as the string units of *string-expression*.

The length attribute of the result is determined by the implicit or explicit value of *code-units*, the implicit or explicit string unit, the result data type, and the result string units, as shown in the following table:

Table 72. Length attribute of the result of LOWER as a function of string unit and result type

Data type and string units of result	**Length attribute for *code-units* in CODEUNITS16**	**Length attribute for *code-units* in CODEUNITS32**	**Length attribute for *code-units* in OCTETS**
VARCHAR in OCTETS	MIN(*code-units* * 3, 32672)	MIN(*code-units* * 4, 32672)	*code-units*
VARCHAR in CODEUNITS32	MIN(*code-units* / 2, 8168)	MIN(*code-units*, 8168)	MIN(*code-units* / 4, 8168)
VARGRAPHIC in CODEUNITS16 or double bytes	*code-units*	MIN(*code-units* * 2, 16336)	MIN(*code-units* / 2, 16336)
VARGRAPHIC in CODEUNITS32	MIN(*code-units* / 2, 8168)	MIN(*code-units*, 8168)	MIN(*code-units* / 4, 8168)

The actual length of the result might be greater than the length of *string-expression*. If the actual length of the result is greater than the length attribute of the result, an error is returned (SQLSTATE 42815). If the number of code units in the result exceeds the value of *code-units*, an error is returned (SQLSTATE 42815).

If *string-expression* is not in UTF-16, this function performs code page conversion of *string-expression* to UTF-16, and of the result from UTF-16 to the code page of *string-expression*. If either code page conversion results in at least one substitution character, the result includes the substitution character, a warning is returned (SQLSTATE 01517), and the warning flag SQLWARN8 in the SQLCA is set to 'W'.

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Examples

- *Example 1*: Ensure that the characters in the value of column JOB in the EMPLOYEE table are returned in lowercase characters.

```
SELECT LOWER(JOB, 'en_US')
  FROM EMPLOYEE
  WHERE EMPNO = '000020'
```

  The result is the value 'manager'.

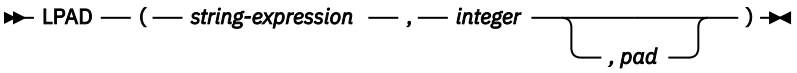
- *Example 2*: Find the lowercase characters for all the 'I' characters in a Turkish string.

```
VALUES LOWER('IİıI', 'tr_TR', CODEUNITS16)
```

  The result is the string 'ıiiı'.

LPAD

The LPAD function pads a string on the left with a specified character string or with blanks.



The schema is SYSIBM.

The LPAD function treats leading or trailing blanks in the string expression as significant. Padding will only occur if the actual length of *string-expression* is less than *integer*, and *pad* is not an empty string.

string-expression
An expression that specifies the source string. The expression must return a built-in character string, graphic string, binary string, CLOB or DBCLOB value, numeric value, Boolean value, or datetime value. If the value is:

- A CLOB, numeric, Boolean, or datetime value, it is implicitly cast to VARCHAR before the function is evaluated
- A DBCLOB value, it is implicitly cast to VARGRAPHIC before the function is evaluated

The data type of the value cannot be a BLOB (SQLSTATE 42815).

integer
An expression that specifies the actual length of the result in the string units of the string expression. The expression must return a built-in numeric value, Boolean value, or character string. In a Unicode database, the expression can also return a graphic string, in which case it is first converted to a character string before the function is evaluated. If the value returned by the expression is not an integer, it is cast to INTEGER before the function is evaluated. The value must be zero or a positive integer that is less than or equal to the maximum length for the result data type in the units of the string expression.

pad
An expression that specifies the string with which to pad. The expression must return a built-in character string, graphic string, binary string, CLOB or DBCLOB value, numeric value, Boolean value, or datetime value. If the value is:

- A CLOB, numeric, Boolean, or datetime value, it is implicitly cast to VARCHAR before the function is evaluated
- A DBCLOB value, it is implicitly cast to VARGRAPHIC before the function is evaluated

The data type of *pad* cannot be a BLOB (SQLSTATE 42815).

The data type of the string expression determines the default pad string:

- The SBCS blank character, if the string expression is a character string.
- The ideographic blank character, if the string expression is a graphic string. For graphic string in an EUC database, X'3000' is used. For graphic string in a Unicode database, X'0020' is used.
- Hexadecimal zero (X'00'), if the string expression is a binary string.

Result

The data type of the result depends on the data type of the string expression:

- VARCHAR if the data type is VARCHAR or CHAR
- VARGRAPHIC if the data type is VARGRAPHIC or GRAPHIC
- VARBINARY if the data type is VARBINARY or BINARY

The result of the function is a varying length string that has the same string unit and code page as the string expression. The values for the string expression and the pad expression must have compatible data types. If the string expression and pad expression have different code pages, then the pad expression is

converted to the code page of the string expression. If either the string expression or the pad expression is FOR BIT DATA or a binary string, no character conversion occurs.

The length attribute of the result depends on whether the value for *integer* is available when the SQL statement containing the function invocation is compiled (for example, if it is specified as a constant or a constant expression) or available only when the function is executed (for example, if it is specified as the result of invoking a function). When the value is available when the SQL statement containing the function invocation is compiled, if *integer* is greater than zero, the length attribute of the result is *integer*. If *integer* is 0, the length attribute of the result is 1. When the value is available only when the function is executed, the length attribute of the result is determined according to the following table:

Table 73. Determining the result length when integer is available only when the function is executed

Data type of *string-expression*	**Result data type length**
CHAR(*n*), VARCHAR(*n*), BINARY(*n*), or VARBINARY(*n*)	Minimum of *n*+100 and 32 672
GRAPHIC(*n*) or VARGRAPHIC(*n*)	Minimum of *n*+100 and 16 336
CHAR(n) or VARCHAR(*n*) or GRAPHIC(*n*) or VARGRAPHIC(*n*) with string units of CODEUNITS32 (Unicode database only)	Minimum of *n*+100 and 8 168

The actual length of the result is determined from *integer*. If *integer* is 0 the actual length is 0, and the result is the empty result string. If *integer* is less than the actual length of *string-expression*, the actual length is *integer* and the result is truncated.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: Assume that NAME is a VARCHAR(15) column that contains the values "Chris", "Meg", and "Jeff". The following query will completely pad out a value on the left with periods:

```
SELECT LPAD(NAME,15,'.' ) AS NAME FROM T1;
```

  returns:

```
NAME
---------------
.........Chris
............Meg
...........Jeff
```

- *Example 2*: Assume that NAME is a VARCHAR(15) column that contains the values "Chris", "Meg", and "Jeff". The following query will only pad each value to a length of 5:

```
SELECT LPAD(NAME,5,'.' ) AS NAME FROM T1;
```

  returns:

```
NAME
-----
Chris
..Meg
.Jeff
```

- *Example 3*: Assume that NAME is a CHAR(15) column containing the values "Chris", "Meg", and "Jeff". The LPAD function does not pad because NAME is a fixed length character field and is blank padded already. However, since the length of the result is 5, the columns are truncated:

```
SELECT LPAD(NAME,5,'.' ) AS NAME FROM T1;
```

  returns:

```
NAME
-----
Chris
Meg
Jeff
```

- *Example 4*: Assume that NAME is a VARCHAR(15) column containing the values "Chris", "Meg", and "Jeff". In some cases, a partial instance of the pad specification is returned:

```
SELECT LPAD(NAME,15,'123' ) AS NAME FROM T1;
```

returns:

```
NAME
---------------
1231231231Chris
123123123123Meg
12312312312Jeff
```

- *Example 5*: Assume that NAME is a VARCHAR(15) column containing the values "Chris", "Meg", and "Jeff". Note that "Chris" is truncated, "Meg" is padded, and "Jeff" is unchanged:

```
SELECT LPAD(NAME,4,'.' ) AS NAME FROM T1;
```

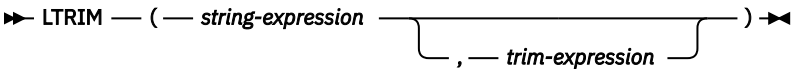
returns:

```
NAME
----
Chri
.Meg
Jeff
```

LTRIM

The LTRIM function removes any of the specified characters from the beginning of a string.

The character search compares the binary representation of each character (consisting of one or more bytes) in the trim expression to the binary representation of each character (consisting of one or more bytes) at the beginning of the string expression. The database collation does not affect the search. If the string expression is defined as FOR BIT DATA or is a binary string, the search compares each byte in the trim expression to the byte at the beginning of the string expression.



The schema is SYSIBM. (The SYSFUN version of this function is also available. That version uses a single parameter, removes leading blanks only, and accepts CLOB arguments.)

string-expression

An expression that specifies the string to be trimmed.

- If only one argument is specified, the expression must return a built-in character string, graphic string, binary string, CLOB or DBCLOB value, numeric value, Boolean value, or datetime value. If the value is:
  - A CLOB, numeric, Boolean, or datetime value, it is implicitly cast to VARCHAR before the function is evaluated
  - A DBCLOB value, it is implicitly cast to VARGRAPHIC before the function is evaluated

  The data type of the value cannot be a BLOB (SQLSTATE 42815).
- If both arguments are specified, the expression must return a value that is a built-in character string, numeric value, Boolean value, or datetime value. If the data type of the value is numeric or datetime, the value is implicitly cast to VARCHAR before the function is evaluated. The actual length of a CLOB value is limited to the maximum size of a VARCHAR data type (SQLSTATE 22001). The

actual length of a BLOB value is limited to the maximum size of a VARBINARY (SQLSTATE 22001). The actual length of a DBCLOB value is limited to the maximum size of a VARGRAPHIC data type (SQLSTATE 22001).

trim-expression

An expression that specifies the characters that are to be removed from the beginning of a string expression. The expression must return a built-in character string, numeric value, Boolean value, or datetime value.

- If the data type of the trim expression is not a string, then the value is implicitly cast to VARCHAR before the function is evaluated.
- If the data type of the trim expression is a CLOB, then the actual length of the value is limited to the maximum size of a VARCHAR (SQLSTATE 22001).
- If the data type of the trim expression is a DBCLOB, then the actual length of the value is limited to the maximum size of a VARGRAPHIC (SQLSTATE 22001).
- If the data type of the trim expression is BLOB, then the actual length of the value is limited to the maximum size of a VARBINARY (SQLSTATE 22001).
- If the string expression is not defined as FOR BIT DATA, then the trim expression cannot be defined as FOR BIT DATA (SQLSTATE 42815).

The data type of the string expression determines the default trim expression:

- A double byte blank, if the string expression is a graphic string in a DBCS or EUC database
- A UCS-2 blank, if the string expression is a graphic string in a Unicode database
- The value X'20', if the string expression is a FOR BIT DATA string
- The value X'00', if the string expression is a binary string
- A single-byte blank in all other cases

The values for the string expression and trim expression must have compatible data types. If one function argument is character FOR BIT DATA, then the other argument cannot be a graphic (SQLSTATE 42846). A combination of character string and graphic string arguments can be used only in a Unicode database (SQLSTATE 42815).

Result

The data type of the result depends on the data type of the string expression:

- VARCHAR if the data type is VARCHAR or CHAR
- CLOB if the data type is CLOB
- VARBINARY if the data type is VARBINARY or BINARY
- BLOB if the data type is BLOB
- VARGRAPHIC if the data type is VARGRAPHIC or GRAPHIC
- DBCLOB if the data type is DBCLOB

The length attribute of the result data type is the same as the length attribute of the data type of the string expression.

The actual length of the result is the length of *string-expression* minus the number of string units removed. If all of the characters are removed, the result is an empty string with a length of zero.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: Use the LTRIM function when the host variable HELLO is defined as CHAR(6) and has a value of " Hello".

```
VALUES LTRIM(:HELLO)
```

  The result is 'Hello'. When a *trim-expression* is not specified only blanks are removed.

- *Example 2*: Use the LTRIM function to remove the characters specified in the *trim-expression* from the beginning of the *string-expression*.

```
VALUES LTRIM('...$V..$AR', '$.')
```

  The result is `'V..$AR'`. The function stops when it encounters a character not in the *trim-expression*.

- *Example 3*: Use the LTRIM function to remove the characters specified in the *trim-expression* from the beginning of the *string-expression*

```
VALUES LTRIM('[[ -78]]', '- []')
```

  The result is `'78]]'`. When removing characters and blanks, you must include a blank in the *trim-expression*.

LTRIM (SYSFUN schema)

Returns the characters of the argument with leading blanks removed.

The schema is SYSFUN.

expression
An expression that returns the built-in character string or Boolean value that is to be trimmed. The maximum length is:

- 4000 bytes for a VARCHAR
- 1,048,576 bytes for a CLOB

Result

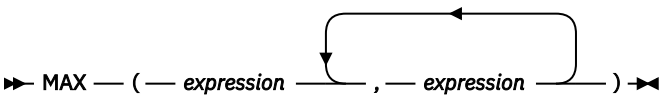
The data type of the result is:

- VARCHAR(4000) if the data type of the expression is CHAR or VARCHAR
- CLOB(1M) if the data type of the expression is CLOB or LONG VARCHAR

The result can be null; if the expression is null, the result is the null value.

MAX

The MAX function returns the maximum value in a set of values.



The schema is SYSIBM.

expression
An expression that returns a value of any built-in data type or user-defined data type that is comparable with data type of the other arguments. The data type cannot be a LOB, distinct type base on a LOB, XML, array, cursor, row, or structured type.

The result of the function is the largest argument value. The result can be null if at least one argument can be null; the result is the null value if any argument is null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined by the data types of all the arguments as explained in "Rules for result data types".

Notes

- The MAX scalar function is a synonym for the GREATEST scalar function.
- The MAX function cannot be used as a source function when creating a user-defined function. Because this function accepts any comparable data types as arguments, it is not necessary to create additional signatures to support user-defined data types.

Example

Return the bonus for an employee, the greater of 500 and 5% of the employee's salary.

```
SELECT EMPNO, MAX(SALARY * 0.05, 500)
  FROM EMPLOYEE
```

MAX_CARDINALITY

The MAX_CARDINALITY function returns a value of type BIGINT representing the maximum number of elements that an array can contain. This is the cardinality that was specified in the CREATE TYPE statement for the ordinary array type.

The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an array type, or a CAST specification of a parameter marker to an array type.

Result

The result can be null; if the argument is an associative array, the result is the null value.

Example

1. Return the maximum cardinality of the RECENT_CALLS array variable of array type PHONENUMBERS:

   ```
   SET LIST_SIZE = MAX_CARDINALITY(RECENT_CALLS)
   ```

   The SQL variable LIST_SIZE is set to 50, which is the maximum cardinality that the array type PHONENUMBERS was defined with.

MICROSECOND

The MICROSECOND function returns the microsecond part of a value.

The schema is SYSIBM.

expression
An expression that returns a value of one of the following built-in data types: DATE, TIMESTAMP, timestamp duration, or a valid character string representation of a date or timestamp that is not a CLOB. If a supplied argument is a DATE, it is first converted to a TIMESTAMP(0) value, assuming a

time of exactly midnight (00.00.00). In a Unicode database, if a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to a character string before the function is executed.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a DATE, TIMESTAMP, or a valid string representation of a date or timestamp:
  - The integer ranges from 0 through 999 999.
  - If the precision of the timestamp exceeds 6, the value is truncated.
- If the argument is a duration:
  - The result reflects the microsecond part of the value which is an integer between -999 999 through 999 999. A nonzero result has the same sign as the argument.

Example

Assume a table TABLEA contains two columns, TS1 and TS2, of type TIMESTAMP. Select all rows in which the microseconds portion of TS1 is not zero and the seconds portion of TS1 and TS2 are identical.

```
SELECT * FROM TABLEA
  WHERE MICROSECOND(TS1) <> 0
    AND
  SECOND(TS1) = SECOND(TS2)
```

MIDNIGHT_SECONDS

Returns an integer value in the range 0 to 86 400, representing the number of seconds between midnight and the time value specified in the argument.

The schema is SYSFUN.

expression
An expression that returns a value of one of the following built-in data types: DATE, TIME, TIMESTAMP, or a valid character string representation of a date, time, or timestamp that is not a CLOB. If the expression is a DATE or a valid string representation of a date, it is first converted to a TIMESTAMP(0) value, assuming a time of exactly midnight (00.00.00). In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

The result of the function is INTEGER. The result can be null; if the argument is null, the result is the null value.

Examples

- *Example 1*: Find the number of seconds between midnight and 00:10:10, and midnight and 13:10:10.

  ```
  VALUES (MIDNIGHT_SECONDS('00:10:10'), MIDNIGHT_SECONDS('13:10:10'))
  ```

  This example returns the following:

  ```
  1           2
  ----------- -----------
          610       47410
  ```

  Since a minute is 60 seconds, there are 610 seconds between midnight and the specified time. The same follows for the second example. There are 3600 seconds in an hour, and 60 seconds in a minute, resulting in 47 410 seconds between the specified time and midnight.

- *Example 2*: Find the number of seconds between midnight and 24:00:00, and midnight and 00:00:00.

```
   VALUES (MIDNIGHT_SECONDS('24:00:00'), MIDNIGHT_SECONDS('00:00:00'))
```

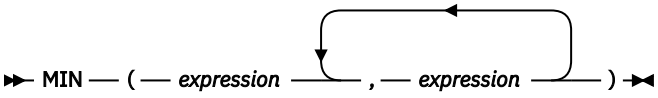
This example returns the following:

```
1           2
----------- -----------
      86400           0
```

Note that these two values represent the same point in time, but return different MIDNIGHT_SECONDS values.

MIN

The MIN function returns the minimum value in a set of values.



The schema is SYSIBM.

expression
An expression that returns a value of any built-in data type or user-defined data type that is comparable with data type of the other arguments. The data type cannot be a LOB, distinct type base on a LOB, XML, array, cursor, row, or structured type.

The result of the function is the smallest argument value. The result can be null if at least one argument can be null; the result is the null value if any argument is null.

The selected argument is converted, if necessary, to the attributes of the result. The attributes of the result are determined by the data types of all the arguments as explained in "Rules for result data types".

Notes

- The MIN scalar function is a synonym for the LEAST scalar function.
- The MIN function cannot be used as a source function when creating a user-defined function. Because this function accepts any comparable data types as arguments, it is not necessary to create additional signatures to support user-defined data types.

Example

Return the bonus for an employee, the LESSER of 5000 and 5% of the employee's salary.

```
  SELECT EMPNO, MIN(SALARY * 0.05, 5000)
    FROM EMPLOYEE
```

MINUTE

The MINUTE function returns the minute part of a value.

The schema is SYSIBM.

expression
An expression that returns a value of one of the following built-in data types: DATE, TIME, TIMESTAMP, time duration, timestamp duration, or a valid character string representation of a date, time, or timestamp that is not a CLOB. If a supplied argument is a DATE, it is first converted to a TIMESTAMP(0) value, assuming a time of exactly midnight (00.00.00). In a Unicode database, if a

supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to a character string before the function is executed.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a DATE, TIME, TIMESTAMP, or valid string representation of a date, time or timestamp:
  - The result is the minute part of the value, which is an integer between 0 and 59.
- If the argument is a time duration or timestamp duration:
  - The result is the minute part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

Examples

Using the CL_SCHED sample table, select all classes with a duration less than 50 minutes.

```
SELECT * FROM CL_SCHED
  WHERE HOUR(ENDING - STARTING) = 0
    AND
  MINUTE(ENDING - STARTING) < 50
```

MINUTES_BETWEEN

The MINUTES_BETWEEN function returns the number of full minutes between the specified arguments.

The schema is SYSIBM.

expression1
An expression that specifies the first datetime value to compute the number of full minutes between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression1* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

expression2
An expression that specifies the second datetime value to compute the number of full minutes between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression2* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

If there is less than a full minute between *expression1* and *expression2*, the result is zero. If *expression1* is later than *expression2*, the result is positive. If *expression1* is earlier than *expression2*, the result is negative. In NPS compatibility mode, this function always returns a positive number. If *expression1* or *expression2* contains time information, this information is also used to determine the number of full minutes. If *expression1* or *expression2* does not contain time information, a time of midnight (00.00.00) is used for the argument that is missing time information.

The result of the function is a BIGINT. If either argument can be null, the result can be null. If either argument is null, the result is the null value.

Examples

1. Set the host variable NUM_MINUTES to the number of full minutes between 2012-03-01-01.00.00 and 2012-02-28-00.00.00.

```
SET :NUM_MINUTES = MINUTES_BETWEEN(TIMESTAMP '2012-03-01-01.07.00',
                                   TIMESTAMP '2012-02-28-00.00.00')
```

   The host variable NUM_MINUTES is set to 2940; 1440 of those minutes are incurred due to February 29, 2012.

2. Set the host variable NUM_MINUTES to the number of full minutes between 2013-09-11-23.59.59 and 2013-09-01-00.00.00.

```
SET :NUM_MINUTES = MINUTES_BETWEEN(TIMESTAMP '2013-09-11-23.59.59',
                                   TIMESTAMP '2013-09-01-00.00.00')
```

   The host variable NUM_MINUTES is set to 15839 because there is 1 second less than a full 15840 minutes between the arguments. It is positive because the first argument is later than the second argument.

3. Set the host variable NUM_MINUTES to the number of full minutes between 2013-09-01-00.00.00 and 2013-09-11-23.59.59.

```
SET :NUM_MINUTES = MINUTES_BETWEEN(TIMESTAMP '2013-09-01-00.00.00',
                                   TIMESTAMP '2013-09-11-23.59.59')
```

   The host variable NUM_MINUTES is set to -15839 because there is 1 second less than a full 15840 minutes between the arguments. It is negative because the first argument is earlier than the second argument.

MOD

Returns the remainder of the first argument divided by the second argument.

The schema is SYSIBM. (The SYSFUN version of this function continues to be available.)

expression1
An expression that returns a value of any built-in numeric data type.

expression2
An expression that returns a value of any built-in numeric data type. This expression can only be zero when at least one of the function arguments is a decimal floating point.

The formula for calculating the remainder is:

```
MOD(x,y) = x-(x/y)*y
```

where x/y is the truncated integer result of the division.

The result only is negative when the first argument is negative.

The result can be null if either argument can be null or if neither argument is a decimal floating-point number and the dft_sqlmathwarn database configuration parameter is set to YES; the result is the null value when either argument is NULL.

The data type of the result depends on the data types of the arguments.

- Small integer if both arguments are small integers.
- Large integer if one argument is a large integer and the other argument is either a small integer or a large integer.
- Big integer if both arguments are integers and at least one argument is a big integer.

- Decimal if one argument is an integer and the other argument is a decimal. The result has the same precision as the decimal argument.
- Decimal if both arguments are decimals. The precision of the result is `MIN (p-s,p'-s')+ (MAX(s,s')` and the scale is `(MAX(s,s')`. Where p and s represent the precision and scale of the first argument and `p'` and `s'` represent the precision and scale of the second argument.
- Double-precision floating point if one argument is a floating-point number and the other is not a DECFLOAT. The arguments are converted to double-precision floating point numbers before performing the MOD function. For example, if one argument is a floating-point number and the other is an integer or decimal, the function is performed with a temporary copy of the integer or decimal, which has been converted to double-precision floating-point. The result must be in the range of floating-point numbers.
- Double-precision floating point if both arguments are floating-point numbers. The result must be in the range of floating-point numbers.
- DECFLOAT(34) if either argument is a decimal floating-point. If *expression2* evaluates to zero, the result is not a number (NaN) and an invalid operation warning with the associated SQLSTATE is issued.

  If either argument is a special decimal floating-point value, the general arithmetic operation rules for decimal floating-point apply (see Expressions).
- Results when arguments include infinity:
  - `MOD(x, +/-INFINITY)` returns the value x.
  - `MOD(+/-INFINITY, +/-INFINITY)` returns NaN and an invalid operation warning with the associated SQLSTATE.
  - `MOD(+/-INFINITY, x)` returns NaN and an invalid operation warning with the associated SQLSTATE.

Examples

- *Example 1*: Assume the host variable M1 is an INTEGER with a value of 5 and host variable M2 is an INTEGER with a value of 2

```
SELECT MOD(:M1, :M2)
   FROM SYSIBM.SYSDUMMY1
```

  The result is 1 with a data type of INTEGER.
- *Example 2*: Assume the host variable M1 is an INTEGER with a value of 5 and host variable M2 is a DECIMAL(3,2) with a value of 2.20

```
SELECT MOD(:M1, :M2)
   FROM SYSIBM.SYSDUMMY1
```

  The result is 0.60 with a data type of DECIMAL(3,2).
- *Example 3*: Assume the host variable M1 is a DECIMAL(4,2) with a value of 5.5 and host variable M2 is a DECIMAL(4,1) with a value of 2.0

```
SELECT MOD(:M1, :M2)
   FROM SYSIBM.SYSDUMMY1
```

  The result is 1.50 with a data type of DECIMAL(4,2).

MOD (SYSFUN schema)

Returns the remainder of the first argument divided by the second argument.

The schema is SYSFUN.

The result is negative only if first argument is negative. The result of the function is:

- SMALLINT if both arguments are SMALLINT
- INTEGER if one argument is INTEGER and the other is INTEGER or SMALLINT
- BIGINT if one argument is BIGINT and the other argument is BIGINT, INTEGER or SMALLINT.

The result can be null; if any argument is null, the result is the null value.

MONTH

The MONTH function returns the month part of a value.

The schema is SYSIBM.

expression
An expression that returns a value of one of the following built-in data types: DATE, TIMESTAMP, date duration, timestamp duration, or a valid character string representation of a date or timestamp that is not a CLOB. In a Unicode database, if a supplied argument is a graphic string (except DBCLOB), it is first converted to a character string before the function is executed.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a DATE, TIMESTAMP, or a valid string representation of a date or timestamp:
  - The result is the month part of the value, which is an integer between 1 and 12.
- If the argument is a date duration or timestamp duration:
  - The result is the month part of the value, which is an integer between -99 and 99. A nonzero result has the same sign as the argument.

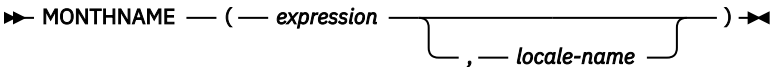
Example

Select all rows from the EMPLOYEE table for people who were born (BIRTHDATE) in DECEMBER.

```
SELECT * FROM EMPLOYEE
  WHERE MONTH(BIRTHDATE) = 12
```

MONTHNAME

The MONTHNAME function returns a character string containing the name of the month (for example, January) for the month portion of the input value.



The schema is SYSIBM. The SYSFUN version of the MONTHNAME function continues to be available.

The character string returned is based on *locale-name* or the value of the special register CURRENT LOCALE LC_TIME.

expression
An expression that returns a value of one of the following built-in data types: a DATE, TIMESTAMP, or a valid character string representation of a date or timestamp that is not a CLOB. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

locale-name
A character constant that specifies the locale used to determine the language of the result. The value of *locale-name* is not case-sensitive and must be a valid locale (SQLSTATE 42815). For information

about valid locales and their naming, see "Locale names for SQL and XQuery". If *locale-name* is not specified, the value of the special register CURRENT LOCALE LC_TIME is used.

The result is a varying-length character string. The length attribute is 100. If the resulting string exceeds the length attribute of the result, the result will be truncated. If the *expression* argument can be null, the result can be null; if the *expression* argument is null, the result is the null value. The code page of the result is the code page of the section. The string units of the result is determined by the string units of the environment.

Notes

- **Julian and Gregorian calendar**: The transition from the Julian calendar to the Gregorian calendar on 15 October 1582 is taken into account by this function. However, the SYSFUN version of the MONTHNAME function assumes the Gregorian calendar for all calculations.
- **Determinism**: MONTHNAME is a deterministic function. However, when *locale-name* is not explicitly specified, the invocation of the function depends on the value of the special register CURRENT LOCALE LC_TIME. This invocation that depends on the value of a special register cannot be used wherever special registers cannot be used (SQLSTATE 42621, 428EC, or 429BX).

Example

Assume that the variable TMSTAMP is defined as TIMESTAMP and has the following value: 2007-03-09-14.07.38.123456. The following examples show several invocations of the function and the resulting string values. The result type in each case is VARCHAR(100).

```
Function invocation                          Result
-------------------------                   ----------
MONTHNAME (TMSTAMP, 'CLDR181_en_US')          March
MONTHNAME (TSMTAMP, 'CLDR181_de_DE')          Marz
MONTHNAME (TMSTAMP, 'CLDR181_fr_FR')          mars
```

MONTHS_BETWEEN

The MONTHS_BETWEEN function returns an estimate of the number of months between *expression1* and *expression2*.

The schema is SYSIBM.

expression1* or *expression2
Expressions that return a value of either a DATE or TIMESTAMP data type.

If *expression1* represents a date that is later than *expression2*, the result is positive. If *expression1* represents a date that is earlier than expression2, the result is negative.

- If *expression1* and *expression2* represent dates or timestamps with the same day of the month, or both arguments represent the last day of their respective months, the result is a the whole number difference based on the year and month values ignoring any time portions of timestamp arguments.
- Otherwise, the whole number part of the result is the difference based on the year and month values. The fractional part of the result is calculated from the remainder based on an assumption that every month has 31 days. If either argument represents a timestamp, the arguments are effectively processed as timestamps with maximum precision, and the time portions of these values are also considered when determining the result.

The result of the function is a DECIMAL(31,15). If either argument can be null, the result can be null. If either argument is null, the result is the null value.

Examples

- *Example 1*: Calculate the number of months that project AD3100 will take. Assume that the start date is 1982-01-01 and the end date is 1983-02-01.

```
SELECT MONTHS_BETWEEN (PRENDATE, PRSDATE)
   FROM PROJECT
   WHERE PROJNO='AD3100'
```

  The result is 13.000000000000000.

- *Example 2*: Here are some additional examples to consider:

Table 74. Additional examples using MONTHS_BETWEEN

Value for argument *e1*	Value for argument *e2*	Value returned by MONTHS_BETWEEN (*e1*,*e2*)	Value returned by ROUND (MONTHS_BETWEEN (*e1*,*e2*)*31,2)	Comment
2005-02-02	2005-01-01	1.032258064516129	32.00	
2007-11-01-09.00.00.00000	2007-12-07-14.30.12.12345	-1.200945386592741	-37.23	
2007-12-13-09.40.30.00000	2007-11-13-08.40.30.00000	1.000000000000000	31.00	See Note 1
2007-03-15	2007-02-20	0.838709677419354	26.00	See Note 2
2008-02-29	2008-02-28-12.00.00	0.016129032258064	0.50	
2008-03-29	2008-02-29	1.000000000000000	31.00	
2008-03-30	2008-02-29	1.032258064516129	32.00	
2008-03-31	2008-02-29	1.000000000000000	31.00	See Note 3

Note:

1. The time difference is ignored because the day of the month is the same for both values.
2. The result is not 23 because, even though February has 28 days, the assumption is that all months have 31 days.
3. The result is not 33 because both dates are the last day of their respective month, and so the result is only based on the year and month portions.

MULTIPLY_ALT

The MULTIPLY_ALT scalar function returns the product of the two arguments.

The schema is SYSIBM.

numeric_expression1
An expression that returns a value of any built-in numeric data type.

numeric_expression2
An expression that returns a value of any built-in numeric data type.

The MULTIPLY_ALT function is provided as an alternative to the multiplication operator, especially when the sum of the decimal precisions of the arguments exceeds 31.

The result of the function is DECIMAL when both arguments are exact numeric data types (DECIMAL, BIGINT, INTEGER, or SMALLINT); otherwise the operation is carried out using decimal floating-point arithmetic and the result of the function is decimal floating-point with a precision determined by the data

type of the arguments in the same way the precision is determined for decimal floating-point arithmetic. A floating-point or string argument is cast to DECFLOAT(34) before evaluating the function.

When the result of the function is DECIMAL, the precision and scale of the result are determined as follows, using the symbols *p* and *s* to denote the precision and scale of the first argument, and the symbols *p*' and *s*' to denote the precision and scale of the second argument.

- The precision is MIN(31, *p* + *p*')
- The scale is:
  - 0 if the scale of both arguments is 0
  - MIN(31, *s* + *s*') if *p* + *p*' is less than or equal to 31
  - MAX(MIN(3, *s* + *s*'), 31 - (*p* - *s* + *p*' - *s*')) if *p* + *p*' is greater than 31.

The result can be null if at least one argument can be null, or if the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if one of the arguments is null.

The MULTIPLY_ALT function is a preferable choice to the multiplication operator when performing decimal arithmetic where a scale of at least 3 is required and the sum of the precisions exceeds 31. In these cases, the internal computation is performed so that overflows are avoided. The final result is then assigned to the result data type, using truncation where necessary to match the scale. Note that overflow of the final result is still possible when the scale is 3.

The following table is a sample comparing the result types using MULTIPLY_ALT and the multiplication operator.

Type of argument 1	Type of argument 2	Result using MULTIPLY_ALT	Result using multiplication operator
DECIMAL(31,3)	DECIMAL(15,8)	DECIMAL(31,3)	DECIMAL(31,11)
DECIMAL(26,23)	DECIMAL(10,1)	DECIMAL(31,19)	DECIMAL(31,24)
DECIMAL(18,17)	DECIMAL(20,19)	DECIMAL(31,29)	DECIMAL(31,31)
DECIMAL(16,3)	DECIMAL(17,8)	DECIMAL(31,9)	DECIMAL(31,11)
DECIMAL(26,5)	DECIMAL(11,0)	DECIMAL(31,3)	DECIMAL(31,5)
DECIMAL(21,1)	DECIMAL(15,1)	DECIMAL(31,2)	DECIMAL(31,2)

Example

Multiply two values where the data type of the first argument is DECIMAL(26,3) and the data type of the second argument is DECIMAL(9,8). The data type of the result is DECIMAL(31,7).

```
values multiply_alt(98765432109876543210987.654,5.43210987)
1
--------------------------------
536504678578875294857887.5277415
```

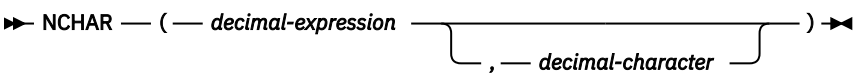
Note that the complete product of these two numbers is 536504678578875294857887.52774154498, but the last 4 digits are truncated to match the scale of the result data type. Using the multiplication operator with the same values will cause an arithmetic overflow, since the result data type is DECIMAL(31,11) and the result value has 24 digits left of the decimal, but the result data type only supports 20 digits.

NCHAR

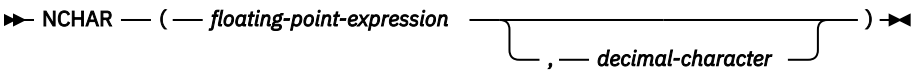
The NCHAR function returns a fixed-length national character string representation of a variety of data types.

Integer to nchar

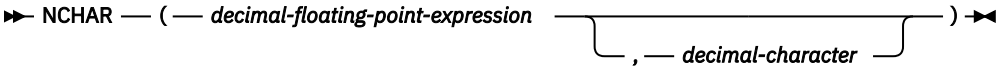
Decimal to nchar



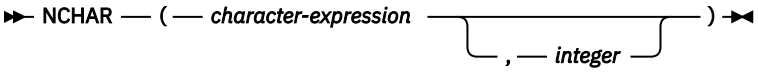
Floating-point to nchar



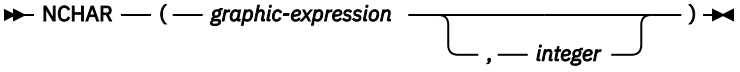
Decimal floating-point to nchar



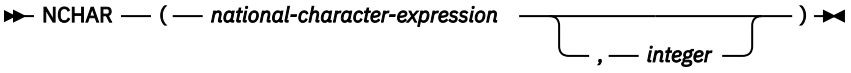
Character to nchar



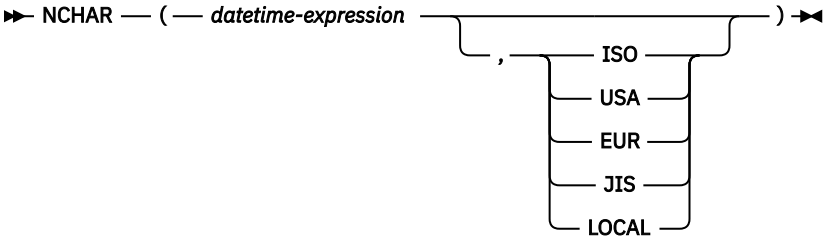
Graphic to nchar



Nchar to nchar



Datetime to nchar



Boolean to nvarchar

The schema is SYSIBM. The function name cannot be specified as a qualified name when keywords are used in the function signature.

The NCHAR function can be specified only in a Unikode database (SQLSTATE 560AA).

Result

The NCHAR function returns a fixed-length national character string representation of:

- An integer number, if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number, if the first argument is a decimal number
- A double-precision floating-point number, if the first argument is a DOUBLE or REAL
- A decimal floating-point number, if the argument is a decimal floating-point number (DECFLOAT)
- A character string, if the first argument is any type of character string
- A graphic string, if the first argument is any type of graphic string
- A national character string, if the first argument is any type of national character string
- A datetime value, if the first argument is a DATE, TIME, or TIMESTAMP
- A Boolean value (TRUE or FALSE)

The NCHAR scalar function is a synonym for a scalar cast function with result string units as specified in the following table.

Table 75. NCHAR scalar function synonyms

NCHAR_MAPPING value	Synonym function	Result string units
CHAR_CU32	CHAR	CODEUNITS32
GRAPHIC_CU32	GRAPHIC	CODEUNITS32
GRAPHIC_CU16	GRAPHIC[1]	CODEUNITS16

1. When the first argument has string units of CODEUNITS32 and the second argument is not specified, the length attribute of the result is different from the GRAPHIC function because the string units of the result is CODEUNITS16. In this case, the length attribute of the result is 2 times the length attribute of the result that is determined by the GRAPHIC function.

NCHR

The NCHR function returns a Unicode character with the specified UTF-32 Unicode code point.

The schema is SYSIBM.

Note: The NCHR function can be specified only in a Unicode database (SQLSTATE 560AA).

integer-expression

An expression that specifies the UTF-32 Unicode code point.

The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type.

If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated.

The integer-expression must be greater than or equal to 0 (SQLSTATE 42815).

The integer-expression must represent a valid UTF-32 Unicode character (SQLSTATE 22021).

Result

The result of the function is a Unicode character with the CHAR data type and a length of 1 CODEUNITS32.

If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Notes

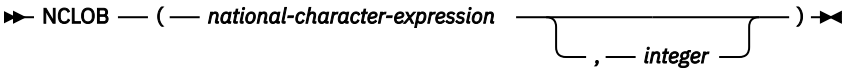
As a syntax alternative, you can specify UNICHR as a synonym for NCHR.

In the following example, the variable GCLEF is assigned the value '𝄞' (UTF-32 Unicode value U&'\+01d11e'= 119070):SET GCLEF=NCHR(119070):

```
SET GCLEF=NCHR(119070);
```

NCLOB

The NCLOB function returns a NCLOB representation of any type of national character string.



The schema is SYSIBM.

The NCLOB function can be specified only in a Unicode database (SQLSTATE 560AA).

The NCLOB scalar function is a synonym for a scalar cast function with result string units as specified in the following table.

Table 76. NCLOB scalar function synonyms

NCLOB_MAPPING value	Synonym function	Result string units
CHAR_CU32	CLOB	CODEUNITS32
GRAPHIC_CU32	DCLOB	CODEUNITS32
GRAPHIC_CU16	DCLOB[1]	CODEUNITS16

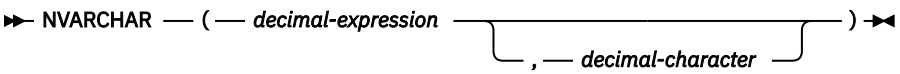
1. When the first argument has string units CODEUNITS32 and the second argument is not specified, the length attribute of the result is different from the DCLOB function because the string units of the result is CODEUNITS16. In this case, the length attribute of the result is 2 times the length attribute of the result that is otherwise determined by the DCLOB function.

NVARCHAR

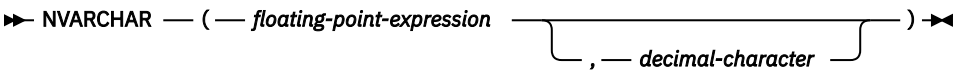
The NVARCHAR function returns a varying-length national character string representation of a variety of data types.

Integer to nvarchar

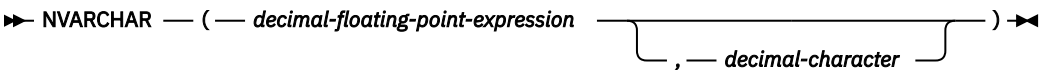
Decimal to nvarchar



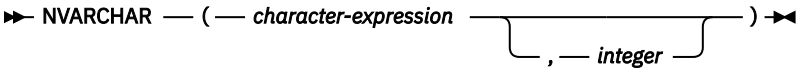
Floating-point to nvarchar



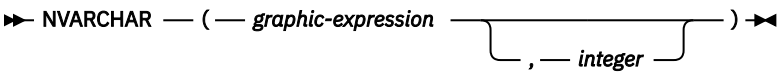
Decimal floating-point to nvarchar



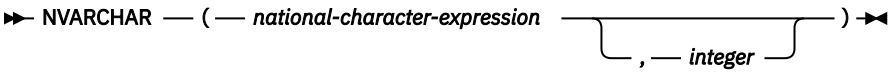
Character to nvarchar



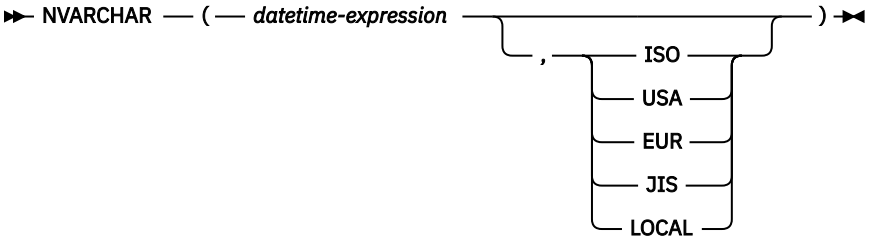
Graphic to nvarchar



Nchar to nvarchar



Datetime to nvarchar



Boolean to nvarchar

The schema is SYSIBM.

The function name cannot be specified as a qualified name when keywords are used in the function signature.

NVARCHAR can be specified only in a Unicode database (SQLSTATE 560AA).

Result

The NVARCHAR function returns a varying-length national character string representation of:

- An integer number, if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number, if the first argument is a decimal number
- A double-precision floating-point number, if the first argument is a DOUBLE or REAL

- A decimal floating-point number, if the first argument is a decimal floating-point number (DECFLOAT)
- A character string, if the first argument is any type of character string
- A graphic string, if the first argument is any type of graphic string
- An national character string, if the first argument is any type of national character string
- A datetime value, if the first argument is a DATE, TIME, or TIMESTAMP
- A Boolean value (TRUE or FALSE)

The NVARCHAR scalar function is a synonym for a scalar cast function with result string units as specified in the following table.

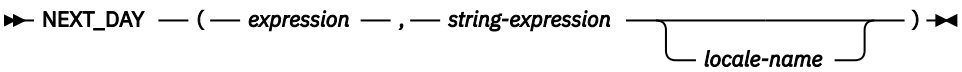
Table 77. NVARCHAR scalar function synonyms

NCHAR_MAPPING	Synonym function	Result string units
CHAR_CU32	VARCHAR	CODEUNITS32
GRAPHIC_CU32	VARGRAPHIC	CODEUNITS32
GRAPHIC_CU16	VARGRAPHIC[1]	CODEUNITS16

1. When the first argument has string units CODEUNITS32 and the second argument is not specified, the length attribute of the result is different from the VARGRAPHIC function because the string units of the result is CODEUNITS16. In this case, the length attribute of the result is 2 times the length attribute of the result that is otherwise determined by the VARGRAPHIC function.

NEXT_DAY

The NEXT_DAY scalar function returns a datetime value that represents the first weekday, named by *string-expression*, that is later than the date in *expression*.



The schema is SYSIBM.

expression
An expression that returns a value of one of the following built-in data types: a DATE or a TIMESTAMP.

string-expression
An expression that returns a built-in character data type. The value must be a valid day of the week for the *locale-name*. The value can be specified either as the full name of the day or the associated abbreviation. For example, if the locale is 'en_US' then the following values are valid:

Table 78. Valid day names and abbreviations for the 'en_US' locale

Day of week	Abbreviation
MONDAY	MON
TUESDAY	TUE
WEDNESDAY	WED
THURSDAY	THU
FRIDAY	FRI
SATURDAY	SAT
SUNDAY	SUN

The minimum length of the input value is the length of the abbreviation. The characters can be specified in lower or upper case and any characters immediately following a valid abbreviation are ignored.

locale-name
A character constant that specifies the locale used to determine the language of the *string-expression* value. The value of *locale-name* is not case sensitive and must be a valid locale (SQLSTATE 42815). For information about valid locales and their naming, see "Locale names for SQL and XQuery". If *locale-name* is not specified, the value of the special register CURRENT LOCALE LC_TIME is used.

The result of the function has the same data type as *expression*, unless *expression* is a string, in which case the result data type is TIMESTAMP(6) . The result can be null; if any argument is null, the result is the null value.

Any hours, minutes, seconds or fractional seconds information included in *expression* is not changed by the function. If *expression* is a string representing a date, the time information in the resulting TIMESTAMP value is all set to zero.

Notes

- **Determinism:** NEXT_DAY is a deterministic function. However, when locale-name is not explicitly specified, the invocation of the function depends on the value of the special register CURRENT LOCALE LC_TIME. Invocations of the function that depend on the value of a special register cannot be used wherever special registers cannot be used (SQLSTATE 42621, 428EC, or 429BX).

Examples

- *Example 1*: Set the variable NEXTDAY with the date of the Tuesday following April 24, 2007.

```
SET NEXTDAY = NEXT_DAY(DATE '2007-04-24', 'TUESDAY')
```

  The variable NEXTDAY is set with the value of '2007-05-01', since April 24, 2007 is itself a Tuesday.
- *Example 2*: Set the variable vNEXTDAY with the timestamp of the first Monday in May, 2007. Assume the variable vDAYOFWEEK = 'MON'.

```
SET vNEXTDAY = NEXT_DAY(LAST_DAY(CURRENT_TIMESTAMP),vDAYOFWEEK)
```

  The variable vNEXTDAY is set with the value of '2007-05-07-12.01.01.123456', assuming that the value of the CURRENT_TIMESTAMP special register is '2007-04-24-12.01.01.123456'.

NEXT_MONTH

The NEXT_MONTH function returns the first day of the next month after the specified date.

The schema is SYSIBM.

datetime-expression
An expression that specifies a date after which the first day of the next month is to be returned. The expression must return a value that is a DATE, a TIMESTAMP, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported using implicit casting. If *datetime-expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string accepted by the TIMESTAMP scalar function.

The result of the function is DATE. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Example

The following example returns the date value of the first day of the next month after the date specified by the input:

```
values next_month('2007-02-18')
      Result: 2007-03-01
```

NEXT_QUARTER

The NEXT_QUARTER function returns the first day of the next quarter after the date specified by the input.

The schema is SYSIBM.

datetime-expression
An expression that specifies a date after which the first day of the next quarter is to be returned. The expression must return a value that is a DATE, a TIMESTAMP, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported using implicit casting. If *datetime-expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string accepted by the TIMESTAMP scalar function.

The result of the function is DATE. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Example

The following example returns the date value of the first day of the next quarter after the date specified by the input:

```
values next_quarter('2007-02-18')
      Result: 2007-04-01
```

NEXT_WEEK

The NEXT_WEEK function returns the first day of the next week after the specified date. Sunday is considered the first day of that new week.

The schema is SYSIBM.

datetime-expression
An expression that specifies a date after which the first day of the next week is to be returned. The expression must return a value that is a DATE, a TIMESTAMP, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported using implicit casting. If *datetime-expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string accepted by the TIMESTAMP scalar function.

The result of the function is DATE. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Example

The following example returns the date value of the first day of the next week after the date specified by the input:

```
values next_week('2007-02-18')
      Result: 2007-02-25
```

NEXT_YEAR

The NEXT_YEAR function returns the first day of the year follows the year containing the date specified by the input.

The schema is SYSIBM.

datetime-expression
An expression that specifies a date after which first day of the next year is to be returned. The expression must return a value that is a DATE, a TIMESTAMP, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported using implicit casting. If *datetime-expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string accepted by the TIMESTAMP scalar function.

The result of the function is DATE. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Example

Returns the date value of the first day of the year that follows the year containing the date specified by the input.

```
values next_year('2007-02-18')
      Result: 2008-01-01
```

NORMALIZE_ DECFLOAT

The NORMALIZE_DECFLOAT function returns a decimal floating-point value equal to the input argument set to its simplest form; that is, a nonzero number with trailing zeros in the coefficient has those zeros removed.

The schema is SYSIBM.

Returning a decimal floating-point value equal to the input argument set to its simplest form may require representing the number in normalized form by dividing the coefficient by the appropriate power of ten and adjusting the exponent accordingly. A zero value has its exponent set to 0.

expression
An expression that returns a value of any built-in numeric data type. Arguments of type SMALLINT, INTEGER, REAL, DOUBLE, or DECIMAL(*p*,*s*), where *p* <= 16, are converted to DECFLOAT(16) for processing. Arguments of type BIGINT or DECIMAL(*p*,*s*), where *p* > 16, are converted to DECFLOAT(34) for processing.

The result of the function is a DECFLOAT(16) value if the data type of expression after conversion to decimal floating-point is DECFLOAT(16). Otherwise, the result of the function is a DECFLOAT(34) value. If the argument is a special decimal floating-point value, the result is the same special decimal floating-point value. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

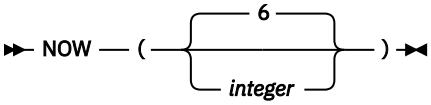
Examples

The following examples show the values that are returned by the NORMALIZE_DECFLOAT function, given a variety of input decimal floating-point values:

```
NORMALIZE_DECFLOAT(DECFLOAT(2.1)) = 2.1
NORMALIZE_DECFLOAT(DECFLOAT(-2.0)) = -2
NORMALIZE_DECFLOAT(DECFLOAT(1.200)) = 1.2
NORMALIZE_DECFLOAT(DECFLOAT(-120)) = -1.2E+2
NORMALIZE_DECFLOAT(DECFLOAT(120.00)) = 1.2E+2
NORMALIZE_DECFLOAT(DECFLOAT(0.00)) = 0
NORMALIZE_DECFLOAT(-NAN) = -NaN
NORMALIZE_DECFLOAT(-INFINITY) = -Infinity
```

NOW

The NOW function returns a timestamp based on a reading of the time-of-day clock when the SQL statement is executed at the current server.



The schema is SYSIBM.

integer
Specifies the precision of the timestamp. Valid values are 0 to 12, inclusive. If you do not specify an integer, the default precision of 6 is used.

The value returned by the NOW function is the same as the value returned by the CURRENT TIMESTAMP special register. If this function is used more than once within a single SQL statement or used with CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP special registers within a single statement, all values are based on a single clock reading.

The precision of the clock reading varies by platform and the resulting value is padded with zeros if the precision of the retrieved clock reading is less than the precision of the request.

The data type of the result is a timestamp. The result cannot be null.

Example

Return the timestamp for the current time.

```
values now().
           Result: 2015-04-01-03.17.04.579645.
```

NULLIF

The NULLIF function returns a null value if the arguments are equal, otherwise it returns the value of the first argument.

The schema is SYSIBM.

expression1
An expression that returns a value of any built-in or user-defined data type.

expression2
An expression that returns a value of any built-in or user-defined data type that is comparable with the data type of the other argument according to the rules for equality comparison.

The result of using NULLIF(e1,e2) is the same as using the following expression:

```
CASE WHEN e1=e2 THEN NULL ELSE e1 END
```

When e1=e2 evaluates to unknown (because one or both arguments is NULL), CASE expressions consider this not true. Therefore, in this situation, NULLIF returns the value of the first argument.

Notes

- The NULLIF function cannot be used as a source function when creating a user-defined function. Because this function accepts any comparable data types as arguments, it is not necessary to create additional signatures to support user-defined data types.

Example

Assume host variables PROFIT, CASH, and LOSSES have DECIMAL data types with the values 4500.00, 500.00, and 5000.00 respectively:

```
NULLIF (:PROFIT + :CASH , :LOSSES )
```

Returns a null value.

NUMERIC

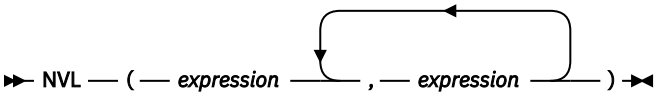
The NUMERIC function returns a decimal representation of a number, a string representation of a number, or a datetime value.

The schema is SYSIBM.

The NUMERIC scalar function is a synonym for the DECIMAL scalar function.

NVL

The NVL function returns the first argument that is not null.



The schema is SYSIBM.

NVL is a synonym for COALESCE.

NVL2

The NVL2 function returns the second argument when the first argument is not NULL. If the first argument is NULL, the third argument is returned.

The schema is SYSIBM.

The NVL2 function is a synonym for the following statement:

```
CASE WHEN expression IS NOT NULL
     THEN result-expression
     ELSE else-expression
END
```

OCTET_LENGTH

The OCTET_LENGTH function returns the length of *expression* in octets (bytes).

The schema is SYSIBM.

expression
An expression that returns a value that is a built-in string data type.

The result of the function is INTEGER. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The length of character or graphic strings includes trailing blanks. The length of binary strings includes binary zeros. The length of varying-length strings is the actual length and not the maximum length.

For greater portability, code your application to be able to accept a result of data type DECIMAL(31).

Examples

- *Example 1*: Assume that table T1 has a GRAPHIC(10) column named C1.

```
SELECT OCTET_LENGTH(C1) FROM T1
```

  returns the value 20.

- *Example 2*: The following example works with the Unicode string '&N~AB', where '&' is the musical symbol G clef character, and '~' is the combining tilde character. This string is shown in different Unicode encoding forms in the following example:

	'&'	'N'	'~'	'A'	'B'
UTF-8	X'F09D849E'	X'4E'	X'CC83'	X'41'	X'42'
UTF-16BE	X'D834DD1E'	X'004E'	X'0303'	X'0041'	X'0042'

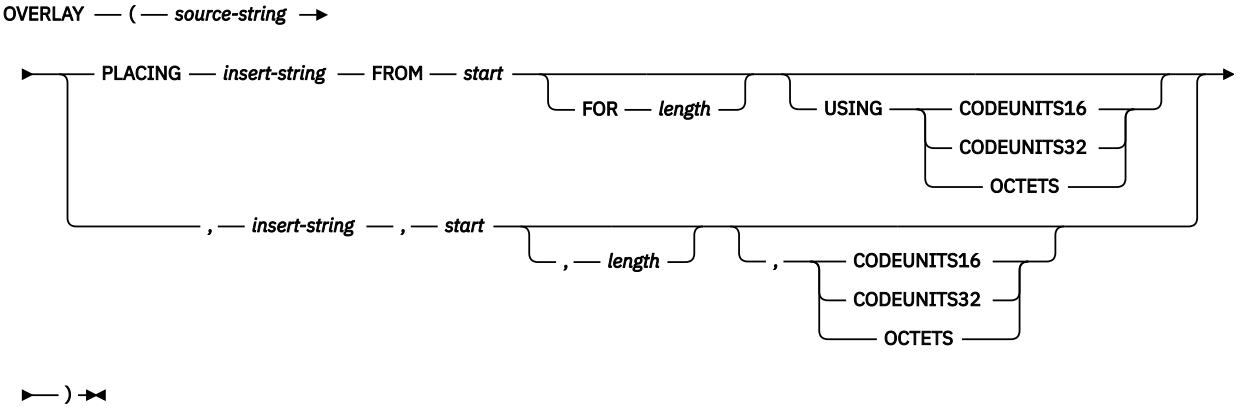
  Assume that the variables UTF8_VAR and UTF16_VAR contain the UTF-8 and the UTF-16BE representations of the string, respectively.

```
SELECT OCTET_LENGTH(UTF8_VAR),
  OCTET_LENGTH(UTF16_VAR)
FROM SYSIBM.SYSDUMMY1
```

  returns the values 9 and 12, respectively.

OVERLAY

The OVERLAY function returns a string in which, beginning at *start* in *source-string*, *length* of the specified code units have been deleted and *insert-string* has been inserted.



The schema is SYSIBM.

source-string
An expression that specifies the source string. The expression must return a value that is a built-in string, numeric, boolean, or datetime data type. If the value is not a string data type, it is implicitly cast to VARCHAR before evaluating the function.

insert-string
An expression that specifies the string to be inserted into *source-string*, starting at the position identified by *start*. The expression must return a value that is a built-in string, numeric, boolean, or datetime data type. If the value is not a string data type, it is implicitly cast to VARCHAR before evaluating the function. If the code page of the *insert-string* differs from that of the *source-string*, *insert-string* is converted to the code page of the *source-string*.

start
An expression that returns an integer value. The integer value specifies the starting point within the source string where the deletion and the insertion of another string is to begin. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. The integer value is the starting point in code units using the specified string units. The integer value must be between 1 and the actual length of *source-string* in the specified string units plus one (SQLSTATE 42815). If OCTETS is specified and the result is graphic data, the value must be an odd number between 1 and the actual octet length of *source-string* plus one (SQLSTATE 428GC or 22011).

length
An expression that specifies the number of code units (in the specified string units) that are to be deleted from the source string, starting at the position identified by *start*. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. The value must be a positive integer or zero (SQLSTATE 22011). If OCTETS is specified and the result is graphic data, the value must be an even number or zero (SQLSTATE 428GC).

Not specifying *length* is equivalent to specifying a value of 1, except when OCTETS is specified and the result is graphic data, in which case, not specifying *length* is equivalent to specifying a value of 2.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of *start* and *length*.

CODEUNITS16 specifies that *start* and *length* are expressed in 16-bit UTF-16 code units. CODEUNITS32 specifies that *start* and *length* are expressed in 32-bit UTF-32 code units. OCTETS specifies that *start* and *length* are expressed in bytes.

If the string unit is specified as CODEUNITS16 or CODEUNITS32, and the result is a binary string or a FOR BIT DATA string, an error is returned (SQLSTATE 428GC). If the string unit is specified as

CODEUNITS16 or OCTETS, and the string units of *source-string* is CODEUNITS32, an error is returned (SQLSTATE 428GC). If the string unit is specified as OCTETS, the operation is performed in the code page of the *source-string*.

If a string unit argument is not specified and both *source-string* and *insert-string* are either a character string that is not FOR BIT DATA or is a graphic string, the default is CODEUNITS32. Otherwise, the default is OCTETS.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String units in built-in functions" in "Character strings".

The data type of the result depends on the data types of *source-string* and *insert-string*, as shown in the following tables of supported type combinations. The string unit of the result is the string unit of *source-string*. If either *source-string* or *insert-string* is defined as FOR BIT DATA the other argument cannot be defined with string units of CODEUNITS32. The second table applies to Unicode databases only.

Table 79. Data type of the result as a function of the data types of source-string and insert-string

source-string	***insert-string***	**Result**
CHAR or VARCHAR	CHAR or VARCHAR	VARCHAR
GRAPHIC or VARGRAPHIC	GRAPHIC or VARGRAPHIC	VARGRAPHIC
CLOB	CHAR, VARCHAR, or CLOB	CLOB
CHAR or VARCHAR	CLOB	CLOB
DBCLOB	GRAPHIC, VARGRAPHIC, or DBCLOB	DBCLOB
GRAPHIC or VARGRAPHIC	DBCLOB	DBCLOB
CHAR or VARCHAR	CHAR FOR BIT DATA or VARCHAR FOR BIT DATA	VARCHAR FOR BIT DATA
CHAR FOR BIT DATA or VARCHAR FOR BIT DATA	CHAR, VARCHAR, CHAR FOR BIT DATA, or VARCHAR FOR BIT DATA	VARCHAR FOR BIT DATA
BINARY or VARBINARY	BINARY or VARBINARY	VARBINARY
BLOB	BLOB	BLOB
BINARY or VARBINARY	BLOB	BLOB

Note: If the data types for *source-string* and *insert-string* are a combination of binary and FOR BIT DATA string, the argument that is not a binary data type is handled as if it was cast to the corresponding binary data type.

Table 80. Data type of the result as a function of the data types of source-string and insert-string (Unicode databases only)

source-string	***insert-string***	**Result**
CHAR or VARCHAR	GRAPHIC or VARGRAPHIC	VARCHAR
GRAPHIC or VARGRAPHIC	CHAR or VARCHAR	VARGRAPHIC
CLOB	GRAPHIC, VARGRAPHIC, or DBCLOB	CLOB
DBCLOB	CHAR, VARCHAR, or CLOB	DBCLOB

A *source-string* can have a length of 0; in this case, *start* must be 1 (as implied by the bounds provided in the description for *start*), and the result of the function is a copy of the *insert-string*.

An *insert-string* can also have a length of 0. This has the effect of deleting the code units identified by *start* and *length* from the *source-string*.

The length attribute of the result is the length attribute of *source-string* plus the length attribute of *insert-string* when the string units of the *source-string* and *insert-string* are the same or the result string units is CODEUNITS32. Special cases are listed in the following table.

Table 81. Data type of the result as a function of the data types of source-string and insert-string (special cases, Unicode databases only)

source-string		***insert-string***		**Result**	
Data type	**String units**	**Data type**	**String units**	**Length attribute**	**String units**
Character string with length attribute A	OCTETS	Graphic string with length attribute B	CODEUNITS16	A+3*B	OCTETS
			CODEUNITS32	A+4*B	
		Character with length attribute B	CODEUNITS32	A+4*B	
Graphic string with length attribute A	CODEUNITS16	Character with length attribute B	OCTETS	A+B	CODEUNITS16
			CODEUNITS32	A+2*B	
		Graphic string with length attribute B	CODEUNITS32	A+2*B	

The actual length of the result depends on the actual length of *source-string*, the actual length of the deleted string, the actual length of the *insert-string*, and string units used for the *start* and *length* arguments. For example, if the string arguments are character strings in OCTETS and the OCTETS is used as the fourth argument, the actual length of the result is A1 - MIN((A1 - V2 + 1), V3) + A4, where:

- A1 is the actual length of *source-string*
- V2 is the value of *start*
- V3 is the value of *length*
- A4 is the actual length of *insert-string*

If the actual length of the result string exceeds the maximum for the return data type, an error is returned (SQLSTATE 54006).

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: Create the strings 'INSISTING', 'INSISERTING', and 'INSTING' from the string 'INSERTING' by inserting text into the middle of the existing text.

```
SELECT OVERLAY('INSERTING','IS',4,2,OCTETS),
  OVERLAY('INSERTING','IS',4,0,OCTETS),
  OVERLAY('INSERTING','',4,2,OCTETS)
  FROM SYSIBM.SYSDUMMY1
```

- *Example 2*: Create the strings 'XXINSERTING', 'XXNSERTING', 'XXSERTING', and 'XXERTING' from the string 'INSERTING' by inserting text before the existing text, using 1 as the starting point.

```
SELECT OVERLAY('INSERTING','XX',1,0,CODEUNITS16)),
  OVERLAY('INSERTING','XX',1,1,CODEUNITS16)),
  OVERLAY('INSERTING','XX',1,2,CODEUNITS16)),
  OVERLAY('INSERTING','XX',1,3,CODEUNITS16))
  FROM SYSIBM.SYSDUMMY1
```

- *Example 3*: Create the string 'ABCABCXX' from the string 'ABCABC' by inserting text after the existing text. Because the source string is 6 characters long, set the starting position to 7 (one plus the length of the source string).

```
SELECT OVERLAY('ABCABC','XX',7,0,CODEUNITS16))
  FROM SYSIBM.SYSDUMMY1
```

- *Example 4*: Change the string 'Hegelstraße' to 'Hegelstrasse'.

```
SELECT OVERLAY('Hegelstraße','ss',10,1,CODEUNITS16))
  FROM SYSIBM.SYSDUMMY1
```

- *Example 5*: The following example works with the Unicode string '&N~AB', where '&' is the musical symbol G clef character, and '~' is the combining tilde character. This string is shown in different Unicode encoding forms in the following example:

	'&'	'N'	'~'	'A'	'B'
UTF-8	X'F09D849E'	X'4E'	X'CC83'	X'41'	X'42'
UTF-16BE	X'D834DD1E'	X'004E'	X'0303'	X'0041'	X'0042'

Assume that the variables UTF8_VAR and UTF16_VAR contain the UTF-8 and the UTF-16BE representations of the string, respectively. Use the OVERLAY function to insert a 'C' into the Unicode string '&N~AB'.

```
SELECT OVERLAY(UTF8_VAR, 'C', 1, CODEUNITS16),
  OVERLAY(UTF8_VAR, 'C', 1, CODEUNITS32),
  OVERLAY(UTF8_VAR, 'C', 1, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values 'C?N~AB', 'CN~AB', and 'CbbbN~AB', respectively, where '?' represents X'EDB49E', which corresponds to the X'DD1E' in the intermediate UTF-16 form, and 'bbb' replaces the UTF-8 incomplete characters X'9D849E'.

```
SELECT OVERLAY(UTF8_VAR, 'C', 5, CODEUNITS16),
  OVERLAY(UTF8_VAR, 'C', 5, CODEUNITS32),
  OVERLAY(UTF8_VAR, 'C', 5, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values '&N~CB', '&N~AC', and '&N~AB', respectively.

```
SELECT OVERLAY(UTF16_VAR, 'C', 1, CODEUNITS16),
  OVERLAY(UTF16_VAR, 'C', 1, CODEUNITS32)
FROM SYSIBM.SYSDUMMY1
```

returns the values 'C?N~AB' and 'CN~AB', respectively, where '?' represents the unmatched low surrogate U+DD1E.

```
SELECT OVERLAY(UTF16_VAR, 'C', 5, CODEUNITS16),
  OVERLAY(UTF16_VAR, 'C', 5, CODEUNITS32)
FROM SYSIBM.SYSDUMMY1
```

returns the values '&N~CB' and '&N~AC', respectively.

PARAMETER

The PARAMETER function represents a position in an SQL statement where the value is provided dynamically by XQuery as part of the invocation of the db2-fn:sqlquery function.

The schema is SYSIBM.

integer-constant
An integer constant that specifies a position index of a value in the arguments of db2-fn:sqlquery. The value must be between 1 and the total number of the arguments specified in the db2-fn:sqlquery SQL statement (SQLSTATE 42815).

The PARAMETER function represents a position in an SQL statement where the value is provided dynamically by XQuery as part of the invocation of the db2-fn:sqlquery function. The argument of the PARAMETER function determines which value is substituted for the PARAMETER function when the db2-fn:sqlquery function is executed. The value supplied by the PARAMETER function can be referenced multiple times within the same SQL statement.

This function can only be used in a fullselect contained in the string literal argument of the db2-fn:sqlquery function in an XQuery expression (SQLSTATE 42887).

Example

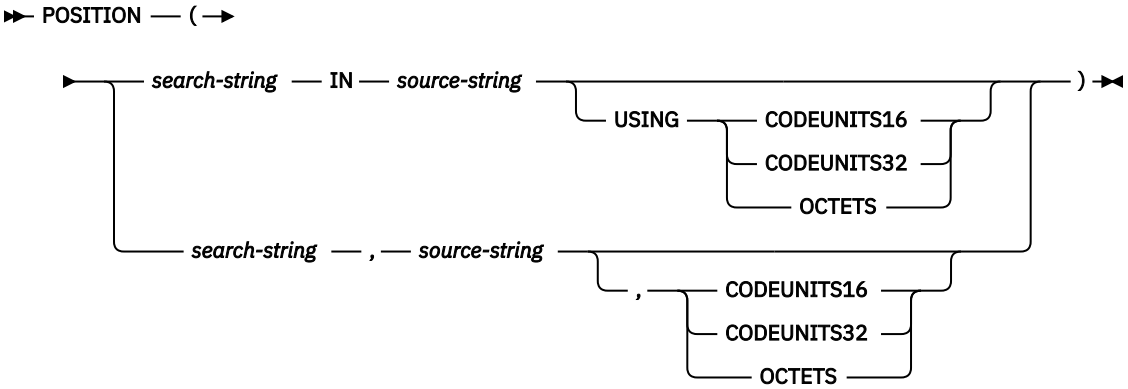
In the following example, the db2-fn:sqlquery function call uses one PARAMETER function call and the XQuery expression `$po/@OrderDate`, the order date attribute. The PARAMETER function call returns the value of order date attribute:

```
xquery
declare default element namespace "http://posample.org";
for $po in db2-fn:xmlcolumn('PURCHASEORDER.PORDER')/PurchaseOrder,
  $item in $po/item/partid
for $p in db2-fn:sqlquery(
  "select description from product where promostart < PARAMETER(1)",
    $po/@OrderDate )
where $p//@pid = $item
return
<RESULT>
  <PoNum>{data($po/@PoNum)}</PoNum>
  <PartID>{data($item)} </PartID>
  <PoDate>{data($po/@OrderDate)}</PoDate>
</RESULT>
```

The example returns the purchase ID, part ID, and the purchase date for all the parts sold after the promotional start date.

POSITION

The POSITION function returns the starting position of the first occurrence of one string within another string.



The schema is SYSIBM.

The string the POSITION function searches for is called the *search-string*. The string it searches in is called the *source-string*. The POSITION function returns the starting position of the first occurrence of one string (called the *search-string*) within another string (called the *source-string*). If *search-string* is not found and neither argument is null, the result is zero. If the *search-string* is found, the result is a number from 1 to the actual length of *source-string*, expressed in the string unit that is explicitly specified. The

search is done using the collation of the database, unless *search-string* or *source-string* is defined as a binary string or as FOR BIT DATA, in which case the search is done using a binary comparison.

If *source-string* has an actual length of 0, the result of the function is 0. If *search-string* has an actual length of 0 and *source-string* is not null, the result of the function is 1.

search-string
An expression that specifies the string that is to be searched for. This expression must return a value that is a built-in character string, graphic string, binary string, numeric value, Boolean value, or datetime value. If the value is not a character string, graphic string, or binary string, it is implicitly cast to VARCHAR before the function is evaluated. The expression cannot be a LOB file reference variable.

source-string
An expression that specifies the string to be searched through. This expression must return a value that is a built-in character string, numeric value, Boolean value, or datetime value. If the value is not a string data type, it is implicitly cast to VARCHAR before evaluating the function.

CODEUNITS16 or CODEUNITS32 or OCTETS
Specifies the string unit of the result. CODEUNITS16 specifies that the result is to be expressed in 16-bit UTF-16 code units. CODEUNITS32 specifies that the result is to be expressed in 32-bit UTF-32 code units. OCTETS specifies that the result is to be expressed in bytes.

If a string unit is specified as CODEUNITS16 or CODEUNITS32, and *search-string* or *source-string* is a binary string or a FOR BIT DATA string, an error is returned (SQLSTATE 428GC).

If a string unit argument is not specified and both *search-string* and *source-string* are either a character string that is not FOR BIT DATA or is a graphic string, the default is CODEUNITS32. Otherwise, the default is OCTETS.

If a locale-sensitive UCA-based collation is used for this function, then the CODEUNITS16 option offers the best performance characteristics.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String units in built-in functions" in "Character strings".

The first and second arguments must have compatible string types. For more information about compatibility, see "Rules for string conversions". In a Unicode database, if one string argument is character (not FOR BIT DATA) and the other string argument is graphic, then the *search-string* is converted to the data type of the *source-string* for processing. If one argument is character FOR BIT DATA, the other argument must not be graphic (SQLSTATE 42846).

Result

The result of the function is a large integer. If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: Select the RECEIVED column, the SUBJECT column, and the starting position of the string 'GOOD BEER' within the NOTE_TEXT column for all rows in the IN_TRAY table that contain that string.

```
SELECT RECEIVED, SUBJECT, POSITION('GOOD BEER', NOTE_TEXT, OCTETS)
FROM IN_TRAY
WHERE POSITION('GOOD BEER', NOTE_TEXT, OCTETS) <> 0
```

- *Example 2*: Find the position of the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in CODEUNITS32 units, within the string.

```
SET :LOCATION = POSITION(
  'ß', 'Jürgen lives on Hegelstraße', CODEUNITS32
)
```

The value of host variable LOCATION is set to 26.

- *Example 3*: Find the position of the character 'ß' in the string 'Jürgen lives on Hegelstraße', and set the host variable LOCATION with the position, as measured in OCTETS, within the string.

```
SET :LOCATION = POSITION(
  'ß', 'Jürgen lives on Hegelstraße', OCTETS
)
```

  The value of host variable LOCATION is set to 27.

- *Example 4*: The following examples work with the Unicode string '&N~AB', where '&' is the musical symbol G clef character, and '~' is the non-spacing combining tilde character. This string is shown in different Unicode encoding forms in the following example:

	'&'	'N'	'~'	'A'	'B'
UTF-8	X'F09D849E'	X'4E'	X'CC83'	X'41'	X'42'
UTF-16BE	X'D834DD1E'	X'004E'	X'0303'	X'0041'	X'0042'

  Assume that the variable UTF8_VAR contains the UTF-8 representation of the string.

```
SELECT POSITION('N', UTF8_VAR, CODEUNITS16),
  POSITION('N', UTF8_VAR, CODEUNITS32),
  POSITION('N', UTF8_VAR, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

  returns the values 3, 2, and 5, respectively.

  Assume that the variable UTF16_VAR contains the UTF-16BE representation of the string.

```
SELECT POSITION('B', UTF16_VAR, CODEUNITS16),
   POSITION('B', UTF16_VAR, CODEUNITS32),
   POSITION('B', UTF16_VAR, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

  returns the values 6, 5, and 11, respectively.

- *Example 5*: In a Unicode database created with the case insensitive collation CLDR181_LEN_S1, find the position of the word 'Brown' in the phrase 'The quick brown fox'.

```
SET :LOCATION = POSITION('Brown', 'The quick brown fox', CODEUNITS16)
```

  The value of the host variable LOCATION is set to 11.

POSSTR

The POSSTR function returns the starting position of the first occurrence of one string (called the *search-string*) within another string (called the *source-string*).

The schema is SYSIBM.

Numbers for the *search-string* position start at 1 (not 0).

The result of the function is a large integer. If either of the arguments can be null, the result can be null; if either of the arguments is null, the result is the null value.

source-string
An expression that specifies the string to be searched through. This expression must return a built-in character string, numeric value, Boolean value, or datetime value. If the value is not a character string, it is implicitly cast to VARCHAR before the function is evaluated.

search-string
An expression that specifies the string that is to be searched for. This expression must return a value that is a built-in string, signed numeric, Boolean, or datetime value. If the value is not a string, it is

implicitly cast to VARCHAR before the function is evaluated. The actual length must not exceed the maximum length of a VARCHAR.

The expression cannot include any of the following elements (SQLSTATE 42824):

- A LOB file reference variable
- A parameter of an inlined SQL user-defined function
- A transition variable in an inlined trigger
- A local variable in a compound SQL (inlined) statement
- A user-defined function
- A non-deterministic built-in function
- A scalar fullselect

In a Unicode database, if one argument is character (not FOR BIT DATA) and the other argument is graphic, then the *search-string* is converted to the data type of the *source-string* for processing. If one argument is character FOR BIT DATA, the other argument must not be graphic (SQLSTATE 42846).

Both *search-string* and *source-string* have zero or more contiguous positions. If the strings are character or binary strings, a position is a byte. If the strings are graphic strings, a position is a double byte. POSSTR operates on a strict byte-count basis, without awareness of either the database collation or changes between single and multi-byte characters. The POSITION, LOCATE, or LOCATE_IN_STRING functions can be used to operate with awareness of the database collation and the string units.

The following rules apply:

- The data types of *source-string* and *search-string* must be compatible, otherwise an error is raised (SQLSTATE 42884).
  - If *source-string* is a character string, then *search-string* must be a character string, but not a CLOB, with an actual length of 32672 bytes or less.
  - If *source-string* is a graphic string, then *search-string* must be a graphic string, but not a DBCLOB, with an actual length of 16336 double-byte characters or less.
  - If *source-string* is a binary string, then *search-string* must be a binary string with an actual length of 32672 bytes or less.
- If *search-string* has a length of zero, the result returned by the function is 1.
- Otherwise:
  - If *source-string* has a length of zero, the result returned by the function is zero.
  - Otherwise:
    - If the value of *search-string* is equal to an identical length substring of contiguous positions from the value of *source-string*, then the result returned by the function is the starting position of the first such substring within the *source-string* value.
    - Otherwise, the result returned by the function is 0.

Example

Select RECEIVED and SUBJECT columns as well as the starting position of the words 'GOOD BEER' within the NOTE_TEXT column for all entries in the IN_TRAY table that contain these words.

```
SELECT RECEIVED, SUBJECT, POSSTR(NOTE_TEXT, 'GOOD BEER')
  FROM IN_TRAY
  WHERE POSSTR(NOTE_TEXT, 'GOOD BEER') <> 0
```

POW

The POW function returns the result of raising the first argument to the power of the second argument.

The schema is SYSIBM.

POW is a synonym for POWER.

POWER

The POWER function returns the result of raising the first argument to the power of the second argument.

The schema is SYSIBM. (The SYSFUN version of the POWER function continues to be available.)

expression1
An expression that returns a value of any built-in numeric data type.

expression2
An expression that returns a value of any built-in numeric data type.

If the value of expression1 is equal to zero, then expression2 must be greater than or equal to zero. If both arguments are 0, the result is 1. If the value of expression1 is less than zero, then expression2 must be an integer value.

The result of the function is:

- INTEGER if both arguments are INTEGER or SMALLINT
- BIGINT if one argument is BIGINT and the other argument is BIGINT, INTEGER or SMALLINT
- DECFLOAT(34) if one of the arguments is decimal floating-point. If either argument is a DECFLOAT and one of the following statements is true, the result is NAN and an invalid operation condition:
  - Both arguments are zero
  - The second argument has a nonzero fractional part
  - The second argument has more than 9 digits
  - The second argument is INFINITY
- DOUBLE otherwise

If the argument is a special decimal floating-point value, the rules for general arithmetic operations for decimal floating-point apply. See "General arithmetic operation rules for decimal floating-point" on page 142 in "Expressions" on page 132.

The result can be null; if any argument is null, the result is the null value.

Example

Assume that the host variable HPOWER is an integer with a value of 3.

```
VALUES POWER(2,:HPOWER)
```

Returns the value 8.

QUANTIZE

The QUANTIZE function returns a decimal floating-point value that is equal in value (except for any rounding) and sign to *numeric-expression* and that has an exponent equal to the exponent of *exp-expression*.

The number of digits (16 or 34) is the same as the number of digits in *numeric-expression*.

The schema is SYSIBM.

numeric-expression
An expression that returns a value of any built-in numeric data type. If the argument is not a decimal floating-point value, it is converted to DECFLOAT(34) for processing.

exp-expression
An expression that returns a value of any built-in numeric data type. If the argument is not a decimal floating-point value, it is converted to DECFLOAT(34) for processing. The *exp-expression* is used as an example pattern for rescaling *numeric-expression*. The sign and coefficient of *exp-expression* are ignored.

The coefficient of the result is derived from that of *numeric-expression*. It is rounded, if necessary (if the exponent is being increased), multiplied by a power of ten (if the exponent is being decreased), or remains unchanged (if the exponent is already equal to that of *exp-expression*).

The CURRENT DECFLOAT ROUNDING MODE special register determines the rounding mode.

Unlike other arithmetic operations on the decimal floating-point data type, if the length of the coefficient after the quantize operation is greater than the precision specified by *exp-expression*, the result is NaN and a warning is returned (SQLSTATE 0168D). This ensures that, unless there is a warning condition, the exponent of the result of QUANTIZE is always equal to that of *exp-expression*.

- if either argument is NaN, NaN is returned
- if either argument is sNaN, NaN is returned and a warning is returned (SQLSTATE 01565)
- if both arguments are infinity (positive or negative), infinity with the same sign as the first argument is returned
- if one argument is infinity (positive or negative) and the other argument is not infinity, NaN is returned and a warning is returned (SQLSTATE 0168D)

The result of the function is a DECFLOAT(16) value if both arguments are DECFLOAT(16). Otherwise, the result of the function is a DECFLOAT(34) value. The result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: The following examples show the values that are returned by the QUANTIZE function given a variety of input decimal floating-point values and assuming a rounding mode of ROUND_HALF_UP:

```
QUANTIZE(2.17, DECFLOAT(0.001)) = 2.170
QUANTIZE(2.17, DECFLOAT(0.01)) = 2.17
QUANTIZE(2.17, DECFLOAT(0.1)) = 2.2
QUANTIZE(2.17, DECFLOAT('1E+0')) = 2
QUANTIZE(2.17, DECFLOAT('1E+1')) = 0E+1
QUANTIZE(2, DECFLOAT(INFINITY)) = NaN    -- warning
QUANTIZE(0, DECFLOAT('1E+5')) = 0E+5
QUANTIZE(217, DECFLOAT('1E-1')) = 217.0
QUANTIZE(217, DECFLOAT('1E+0')) = 217
QUANTIZE(217, DECFLOAT('1E+1')) = 2.2E+2
QUANTIZE(217, DECFLOAT('1E+2')) = 2E+2
```

- *Example 2*: In the following example the value -0 is returned for the QUANTIZE function. The CHAR function is used to avoid the potential removal of the minus sign by a client program:

```
CHAR(QUANTIZE(-0.1, DECFLOAT(1))) = -0
```

QUARTER

Returns an integer value in the range 1 to 4, representing the quarter of the year for the date specified in the argument.

The schema is SYSFUN.

expression
An expression that returns a value of one of the following built-in data types: DATE, TIMESTAMP, or a valid character string representation of a date or timestamp that is not a CLOB. In a Unicode database, if a supplied argument is a graphic string (except DBCLOB), it is first converted to a character string before the function is executed.

The result of the function is INTEGER. The result can be null; if the argument is null, the result is the null value.

QUOTE_IDENT

The QUOTE_IDENT function returns a string that can be used as an identifier in an SQL statement.

The schema is SYSIBM.

Syntax

string-expression

An expression that specifies the input string. The expression must return a character string, signed numeric value, or datetime value. If the data type of the input string is not VARCHAR, it is implicitly cast to VARCHAR before the function is evaluated. If the data type of the input string is CHAR or VARCHAR, the expression must not be FOR BIT DATA (SQLSTATE 42815).

Result

The data type of the result is VARCHAR, and the result has the same codepage and string units as the input string. The length attribute of the result depends on the length attribute of the input string:

Length attribute of the input string	Length attribute of the result
L OCTETS	`min(32672,(L*2)+2)` OCTETS
L CODEUNITS32	`min(8168,(L*2)+2)` CODEUNITS32

If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Examples

Statement	Result
`quote_ident('HELLO WORLD')`	`"HELLO WORLD"`
`quote_ident('HELLOWORLD')`	`HELLOWORLD`
`quote_ident('HELLO_WORLD')`	`HELLO_WORLD`
`quote_ident('hello world')`	`"hello world"`
`quote_ident('hello"world')`	`"hello""world"`
`quote_ident('hello''world')`	`"hello'world"`

Statement	Result
`quote_ident('')`	`""`

Related reference

“Identifiers” on page 5
An *identifier* is a token that is used to form a name. An identifier in an SQL statement is either an SQL identifier or a host identifier.

QUOTE_LITERAL

The QUOTE_LITERAL function returns a string that can be used as a string constant in an SQL statement.

The schema is SYSIBM.

Syntax

string-expression

An expression that specifies the input string. The expression must return a character string, signed numeric value, or datetime value. If the data type of the input string is not VARCHAR, it is implicitly cast to VARCHAR before the function is evaluated. If the data type of the input string is CHAR or VARCHAR, the expression must not be FOR BIT DATA (SQLSTATE 42815).

Result

The data type of the result is VARCHAR, and the result has the same codepage and string units as the input string. The length attribute of the result depends on the length attribute of the input string:

Length attribute of the input string	Length attribute of the result
L OCTETS	`min(32672,(L*2)+2)` OCTETS
L CODEUNITS32	`min(8168,(L*2)+2)` CODEUNITS32

If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Examples

Statement	Result
`quote_literal(42.5)`	`'42.5'`
`quote_literal('You''re here!')`	`'You''re here!'`

Related reference

“Identifiers” on page 5
An *identifier* is a token that is used to form a name. An identifier in an SQL statement is either an SQL identifier or a host identifier.

RADIANS

The RADIANS function returns the number of radians for an argument that is expressed in degrees.

The schema is SYSIBM. (The SYSFUN version of the RADIANS function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type. If the argument is decimal floating-point, the operation is performed in decimal floating-point; otherwise, the argument is converted to double-precision floating-point for processing by the function.

If the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*); otherwise, the result is a double-precision floating-point number. The result can be null; if the argument is null, the result is the null value.

Example

Assume that host variable HDEG is an INTEGER with a value of 180. The following statement:

```
VALUES RADIANS(:HDEG)
```

Returns the value +3.14159265358979E+000.

RAISE_ERROR

The RAISE_ERROR function causes the statement that includes the function to return an error with the specified SQLSTATE, SQLCODE -438, and *diagnostic-string*.

The schema is SYSIBM.

sqlstate
A character string containing exactly 5 bytes. It must be of type CHAR defined with a length of 5 or type VARCHAR defined with a length of 5 or greater. In a Unicode database, the expression can also return a graphic string. If the returned value is not a character string, it is cast to a character string before the function is evaluated.

The *sqlstate* value must obey the following rules for application-defined SQLSTATEs:

- Each character must be from the set of digits ("0" through "9") or non-accented upper case letters ("A" through "Z")
- The SQLSTATE class (first two characters) cannot be "00", "01", or "02" because these are not error classes.
- If the SQLSTATE class (first two characters) starts with the character "0" through "6" or "A" through "H", then the subclass (last three characters) must start with a letter in the range "I" through "Z".
- If the SQLSTATE class (first two characters) starts with the character "7", "8", "9" or "I" though "Z", then the subclass (last three characters) can be any of "0" through "9" or "A" through "Z".

If the SQLSTATE does not conform to these rules, an error occurs (SQLSTATE 428B3).

diagnostic-string
An expression that returns a character string that describes the error condition, or a Boolean value. In a Unicode database, the expression can also return a graphic string. If the returned value is not a character string, it is cast to a character string before the function is evaluated. If the string exceeds 70 bytes, it is truncated.

Result

The RAISE_ERROR function always returns the null value with an undefined data type. To use this function in a context where the data type cannot be determined, a cast specification must be used to give the null returned value a data type. A CASE expression is where the RAISE_ERROR function will be most useful.

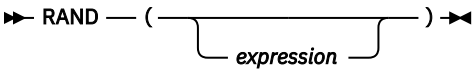
Example

List employee numbers and education levels as Post Graduate, Graduate and Diploma. If an education level is greater than 20, raise an error.

```
SELECT EMPNO,
  CASE WHEN EDUCLVL < 16 THEN 'Diploma'
       WHEN EDUCLVL < 18 THEN 'Graduate'
       WHEN EDUCLVL < 21 THEN 'Post Graduate'
       ELSE RAISE_ERROR('70001',
         'EDUCLVL has a value greater than 20')
  END
FROM EMPLOYEE
```

RAND (SYSFUN schema)

The RAND function returns a floating point value between 0 and 1. RAND is a non-deterministic function.



The schema is SYSFUN.

expression
An expression that returns a value of data type SMALLINT, INTEGER, or BOOLEAN. The value must be between 0 and 2,147,483,647. The returned value is used as a seed value.

A specific seed value produces the same sequence of random numbers for a specific instance of a RAND function in a query each time the query is executed. The seed value is used only for the first invocation of an instance of the RAND function within a statement. If a seed value is not specified, a different sequence of random numbers is produced each time the query is executed within the same session. To produce a set of random numbers that varies from session to session, specify a random seed; for example, one that is based on the current time.

The RAND scalar function does not guarantee the uniqueness of the random numbers. Use the GENERATE_UNIQUE scalar function to generate a series unique numbers.

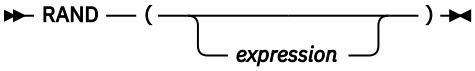
The RAND function relies on the random number facilities of the host operating system. The random number facility of each host might vary in factors such as the number of potential distinct values and the quality of the randomness. For these reasons, the output of this function is not suitable as a source of randomness in a cryptographic system.

Result

The data type of the result is double-precision floating point. If the argument is null, the result is the null value. If either argument can be null, the result can be null. If either argument is null, the result is the null value.

RAND (SYSIBM schema)

The RAND function returns a floating point value between 0 and 1. RAND is a non-deterministic function.



The schema is SYSIBM.

expression
The expression represents the value of a seed which is used to initialize the random number generator. The expression must return a built-in character string, Boolean value, or numeric value. In a Unicode database, the expression can also return a graphic string, in which case it is first converted to

a character string before the function is evaluated. If the returned value is not a INTEGER, it is cast to INTEGER before evaluating the function. The value must be between 0 and 2,147,483,647.

A specific seed value produces the same sequence of random numbers for a specific instance of a RAND function in a query each time the query is executed. The seed value is used only for the first invocation of an instance of the RAND function within a statement. If a seed value is not specified, a different sequence of random numbers is produced each time the query is executed within the same session. To produce a set of random numbers that varies from session to session, specify a random seed; for example, one that is based on the current time.

The RAND scalar function does not guarantee the uniqueness of the random numbers. Use the GENERATE_UNIQUE scalar function to generate a series unique numbers.

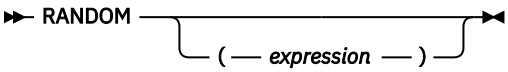
The RAND function relies on the random number facilities of the host operating system. The random number facility of each host might vary in factors such as the number of potential distinct values and the quality of the randomness. For these reasons, the output of this function is not suitable as a source of randomness in a cryptographic system.

Result

The data type of the result is double-precision floating point. If the argument is null, the result is the null value. If either argument can be null, the result can be null. If either argument is null, the result is the null value.

RANDOM

The RANDOM function returns a floating point value between 0 and 1. RANDOM is a non-deterministic function.



The schema is SYSIBM.

The RANDOM scalar function is a synonym for the “RAND (SYSIBM schema) ” on page 453.

RAWTOHEX

The RAWTOHEX function returns a hexadecimal representation of a value as a character string.

The schema is SYSIBM.

expression
An expression that specifies the string for which the hexadecimal value is to be returned. The expression must return a built-in character string, graphic string, binary string, numeric value, Boolean value, or datetime value. If the value is not a character, graphic, or, binary string, it is implicitly cast to VARCHAR before the function is evaluated.

Result

The result of the function is VARCHAR. If the argument can be null, the result can be null. If the argument is null, the result is the null value. The length of the result is computed based on the following table:

Table 82. Data type of the result as a function of the data types of the argument data type and the length attribute

Argument data type[1]	**Length attribute**[2]	**Result data type**
CHAR(A) or BINARY(A)	A<128	CHAR(A*2)

Table 82. Data type of the result as a function of the data types of the argument data type and the length attribute (continued)

Argument data type[1]	Length attribute[2]	Result data type
CHAR(A) or BINARY(A)	A>127	VARCHAR(A*2)
VARCHAR(A), VARBINARY(A), CLOB(A), or BLOB(A)	A<16337	VARCHAR(A*2)
GRAPHIC(A)	A<64	CHAR(A*2*2)
GRAPHIC(A)	A>63	VARCHAR(A*2*2)
VARGRAPHIC(A) or DBCLOB(A)	A<8169	VARCHAR(A*2*2)
CHAR(A CODEUNITS32)	A<64	VARCHAR(A*4*2)
VARCHAR(A CODEUNITS32) or CLOB(A CODEUNITS32)	A<4085	VARCHAR(A*4*2)
GRAPHIC(A CODEUNITS32)	A<64	VARCHAR(A*2*2*2)
VARGRAPHIC(A CODEUNITS32) or DBCLOB(A CODEUNITS32)	A<4085	VARCHAR(A*2*2*2)

1. If string units are not specified, then the string units for the data type are not CODEUNITS32.
2. The maximum length attributes reflect a data type limit or the limit of 16336 bytes for the input argument.

Example

```
values rawtohex('hello')
    returns 68656C6C6F
```

REAL

The REAL function returns a single-precision floating-point representation of either a number or a string representation of a number.

Numeric to REAL

String to REAL

The schema is SYSIBM.

Numeric to REAL

numeric-expression
An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a single-precision floating-point column or variable. If the numeric value of the argument is not within the range of single-precision floating-point, an error is returned (SQLSTATE 22003).

String to REAL

string-expression
An expression that returns a value that is character-string or Unicode graphic-string representation of a number. The data type of string-expression must not be a CLOB or a DBCLOB (SQLSTATE 42884).

The result is the same number that would result from CAST(string-expression AS REAL). Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming a valid numeric constant (SQLSTATE 22018). If the numeric value of the argument is not within the range of single-precision floating-point, an error is returned (SQLSTATE 22003).

The result of the function is a single-precision floating-point number. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Notes

- The CAST specification should be used to increase the portability of applications.

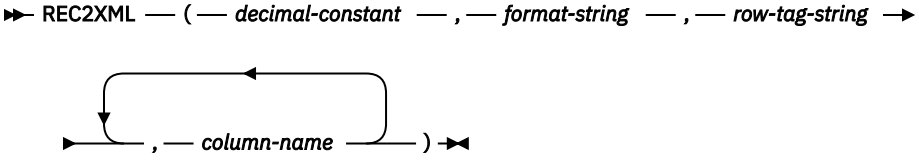
Example

Using the EMPLOYEE table, find the ratio of salary to commission for employees whose commission is not zero. The columns involved (SALARY and COMM) have DECIMAL data types. The required result is in single-precision floating point. Therefore, REAL is applied to SALARY so that the division is carried out in floating point (actually double-precision) and then REAL is applied to the complete expression to return the result in single-precision floating point.

```
SELECT EMPNO, REAL(REAL(SALARY)/COMM)
  FROM EMPLOYEE
  WHERE COMM > 0
```

REC2XML

The REC2XML function returns a string formatted with XML tags, containing column names and column data.



The schema is SYSIBM.

In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

decimal-constant
The expansion factor for replacing column data characters. The decimal value must be greater than 0.0 and less than or equal to 6.0. (SQLSTATE 42820).

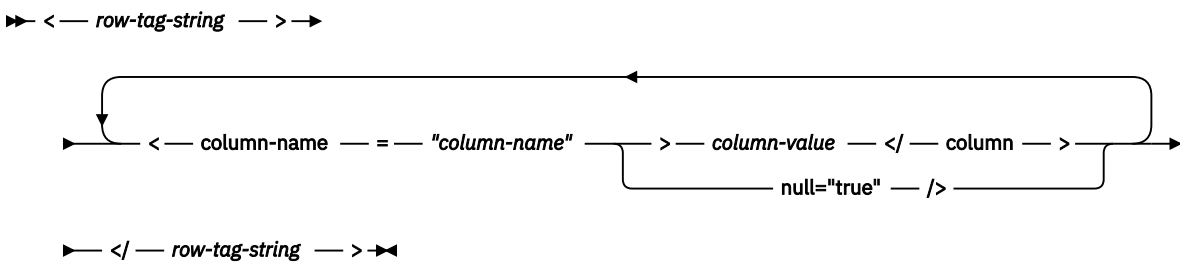
The *decimal-constant* value is used to calculate the result length of the function. For every column with a character data type, the length attribute of the column is multiplied by this expansion factor before it is added in to the result length.

To specify no expansion, use a value of 1.0. Specifying a value less than 1.0 reduces the calculated result length. If the actual length of the result string is greater than the calculated result length of the function, then an error is raised (SQLSTATE 22001).

format-string
The string constant that specifies which format the function is to use during execution.

The *format-string* is case-sensitive, so the following values must be specified in uppercase to be recognized.

COLATTVAL or COLATTVAL_XML
These formats return a string with columns as attribute values.



Column names may or may not be valid XML attribute values. For column names which are not valid XML attribute values, character replacement is performed on the column name before it is included in the result string.

Column values may or may not be valid XML element names. If the *format-string* COLATTVAL is specified, then for the column names which are not valid XML element values, character replacement is performed on the column value before it is included in the result string. If the *format-string* COLATTVAL_XML is specified, then character replacement is not performed on column values (although character replacement is still performed on column names).

row-tag-string
A string constant that specifies the tag used for each row. If an empty string is specified, then a value of "row" is assumed.

If a string of one or more blank characters is specified, then no beginning *row-tag-string* or ending *row-tag-string* (including the angle bracket delimiters) will appear in the result string.

column-name
A qualified or unqualified name of a table column. The column must have one of the following data types (SQLSTATE 42815):

- numeric (SMALLINT, INTEGER, BIGINT, DECIMAL, REAL, DOUBLE)
- character string (CHAR, VARCHAR; a character string with a subtype of BIT DATA is not allowed)
- datetime (DATE, TIME, TIMESTAMP)
- a user-defined type based on one of the previously listed data types

The same column name cannot be specified more than once (SQLSTATE 42734).

The result of the function is VARCHAR in OCTETS, regardless of the string units of the environment or the specified columns. The maximum length is 32 672 bytes (SQLSTATE 54006).

Consider the following invocation:

```
REC2XML (dc, fs, rt, c1, c2, ..., cn)
```

If the value of "fs" is either "COLATTVAL" or "COLATTVAL_XML", then the result is the same as this expression:

```
'<' CONCAT rt CONCAT '>' CONCAT y1 CONCAT y2
CONCAT ... CONCAT yn CONCAT '</' CONCAT rt CONCAT '>'
```

where y_n is equivalent to:

```
'<column name="' CONCAT xvcn CONCAT vn
```

and vn is equivalent to:

```
'">' CONCAT rn CONCAT '</column>'
```

if the column is not null, and

```
'" null="true"/>'
```

if the column value is null.

xvc_n is equivalent to a string representation of the column name of c_n, where any characters appearing in Table 84 on page 458 are replaced with the corresponding representation. This ensures that the resulting string is a valid XML attribute or element value token.

The r_n is equivalent to a string representation as indicated in Table 83 on page 458

Table 83. Column Values String Result	
Data type of c_n	**r_n**
CHAR, VARCHAR	The value is a string. If the *format-string* does not end in the characters "_XML", then each character in c_n is replaced with the corresponding replacement representation from Table 84 on page 458, as indicated. The length attribute is: dc * the length attribute of c_n.
SMALLINT, INTEGER, BIGINT, DECIMAL, NUMERIC, REAL, DOUBLE	The value is LTRIM(RTRIM(CHAR(c_n))). The length attribute is the result length of CHAR(c_n). The decimal character is always the period (".") character.
DATE	The value is CHAR(c_n,ISO). The length attribute is the result length of CHAR(c_n,ISO).
TIME	The value is CHAR(c_n,JIS). The length attribute is the result length of CHAR(c_n,JIS)
TIMESTAMP	The value is CHAR(c_n). The length attribute is the result length of CHAR(c_n).

Character replacement:

Depending on the value specified for the *format-string*, certain characters in column names and column values will be replaced to ensure that the column names form valid XML attribute values and the column values form valid XML element values.

Table 84. Character Replacements for XML Attribute Values and Element Values	
Character	**Replacement**
<	&lt;
>	&gt;
"	&quot;
&	&amp;
'	&apos;

Examples

Note: REC2XML does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

- *Example 1*: Using the DEPARTMENT table in the sample database, format the department table row, except the DEPTNAME and LOCATION columns, for department 'D01' into an XML string. Since the data

does not contain any of the characters which require replacement, the expansion factor will be 1.0 (no expansion). Also note that the MGRNO value is null for this row.

```
SELECT REC2XML (1.0, 'COLATTVAL', '', DEPTNO, MGRNO, ADMRDEPT)
  FROM DEPARTMENT
  WHERE DEPTNO = 'D01'
```

This example returns the following VARCHAR(117) string:

```
<row>
<column name="DEPTNO">D01</column>
<column name="MGRNO" null="true"/>
<column name="ADMRDEPT">A00</column>
</row>
```

- *Example 2*: A 5-day university schedule introduces a class named "&43<FIE" to a table called CL_SCHED, with a new format for the CLASS_CODE column. Using the REC2XML function, this example formats an XML string with this new class data, except for the class end time.

  The length attribute for the REC2XML call with an expansion factor of 1.0 would be 128 (11 for the "<row>" and "</row>" overhead, 21 for the column names, 75 for the "<column name=", ">", "</column>" and double quotation marks, 7 for the CLASS_CODE data, 6 for the DAY data, and 8 for the STARTING data). Since the "&" and "<" characters will be replaced, an expansion factor of 1.0 will not be sufficient. The length attribute of the function will need to support an increase from 7 to 14 bytes for the new format CLASS_CODE data.

  However, since it is known that the DAY value will never be more than 1 digit long, an unused extra 5 units of length are added to the total. Therefore, the expansion only needs to handle an increase of 2. Since CLASS_CODE is the only character string column in the argument list, this is the only column data to which the expansion factor applies. To get an increase of 2 for the length, an expansion factor of 9/7 (approximately 1.2857) would be needed. An expansion factor of 1.3 will be used.

  ```
  SELECT REC2XML (1.3, 'COLATTVAL', 'record', CLASS_CODE, DAY, STARTING)
    FROM CL_SCHED
    WHERE CLASS_CODE = '&43<FIE'
  ```

  This example returns the following VARCHAR(167) string:

  ```
  <record>
  <column name="CLASS_CODE">&amp;43&lt;FIE</column>
  <column name="DAY">5</column>
  <column name="STARTING">06:45:00</column>
  </record>
  ```

- *Example 3*: Assume that new rows have been added to the EMP_RESUME table in the sample database. The new rows store the resumes as strings of valid XML. The COLATTVAL_XML *format-string* is used so character replacement will not be carried out. None of the resumes are more than 3500 bytes in length. The following query is used to select the XML version of the resumes from the EMP_RESUME table and format it into an XML document fragment.

  ```
  SELECT REC2XML (1.0, 'COLATTVAL_XML', 'row', EMPNO, RESUME_XML)
    FROM (SELECT EMPNO, CAST(RESUME AS VARCHAR(3500)) AS RESUME_XML
      FROM EMP_RESUME
      WHERE RESUME_FORMAT = 'XML')
    AS EMP_RESUME_XML
  ```

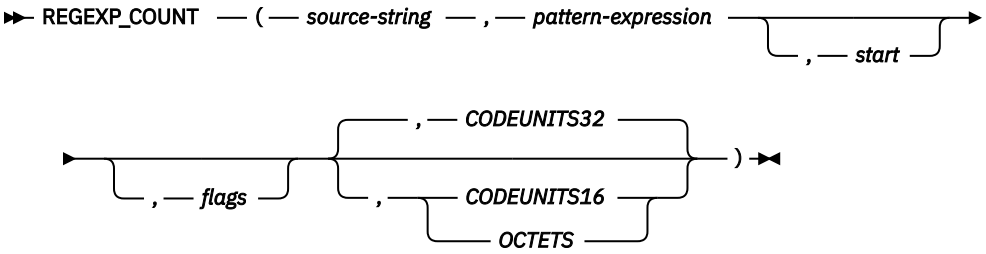
  This example returns a row for each employee who has a resume in XML format. Each returned row will be a string with the following format:

  ```
  <row>
  <column name="EMPNO">{employee number}</column>
  <column name="RESUME_XML">{resume in XML}</column>
  </row>
  ```

  Where "{employee number}" is the actual EMPNO value for the column and "{resume in XML}" is the actual XML fragment string value that is the resume.

REGEXP_COUNT

The REGEXP_COUNT scalar function returns a count of the number of times that a regular expression pattern is matched in a string.



The schema is SYSIBM.

source-string
An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815).

pattern-expression
An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. The length of a CLOB or DBCLOB expression must not be greater than the maximum length of a VARCHAR or VARGRAPHIC data type. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815).

start
An expression that specifies the position within *source-string* at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd (SQLSTATE 428GC). The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

flags
An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute (SQLSTATE 42815). The string can include one or more valid flag values and the combination of flag values must be valid (SQLSTATE 2201T). An empty string is the same as the value 'c'. The default flag value is 'c'.

Table 85. Supported flag values

Flag value	Description
c	Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.
i	Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.
m	Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, "^" and "$" also matches at the start and end of each line within the input string.

Table 85. Supported flag values (continued)	
Flag value	**Description**
n	Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator, and matches a single "." in a pattern.
s	Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.
x	Specifies that white space characters in a pattern are ignored, unless escaped.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of the start value:

- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string unit of the source string is CODEUNITS32, an error is returned (SQLSTATE 428GC).

For more information, see "String units in built-in functions" in “Character strings” on page 31.

Result

The result of the function is an INTEGER that represents the number of occurrences of the pattern expression within the source string. If the pattern expression is not found and no argument is null, the result is 0.

If any argument of the REGEXP_COUNT function can be null, the result can be null. If any argument is null, the result is the null value.

Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- **Considerations for non-Unicode databases**:
  - A regular expression pattern supports only half-width control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.

Example

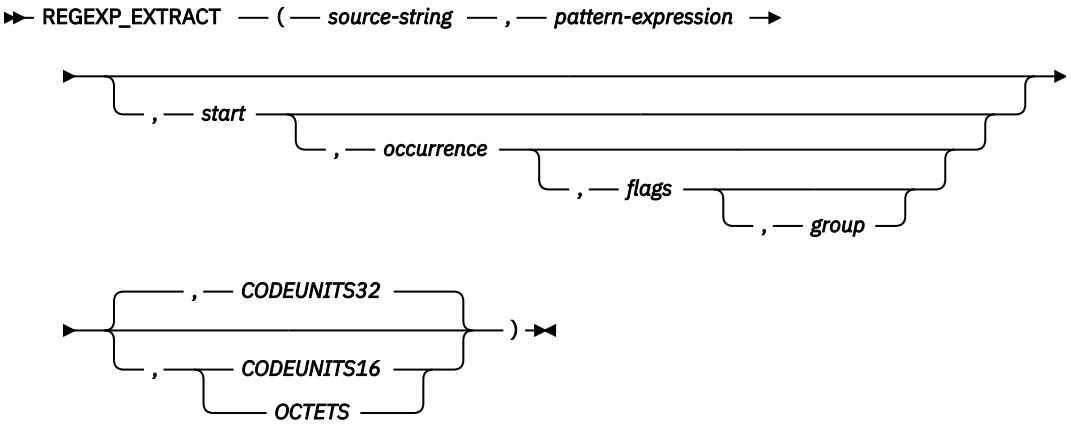
Count the number of times "Steven" or "Stephen" occurs in the string "Steven Jones and Stephen Smith are the best players".

```
SELECT REGEXP_COUNT(
   'Steven Jones and Stephen Smith are the best players', 'Ste(v|ph)en')
     FROM sysibm.sysdummy1
```

The result is 2.

REGEXP_EXTRACT

The REGEXP_EXTRACT scalar function returns one occurrence of a substring of a string that matches the regular expression pattern.



The schema is SYSIBM.

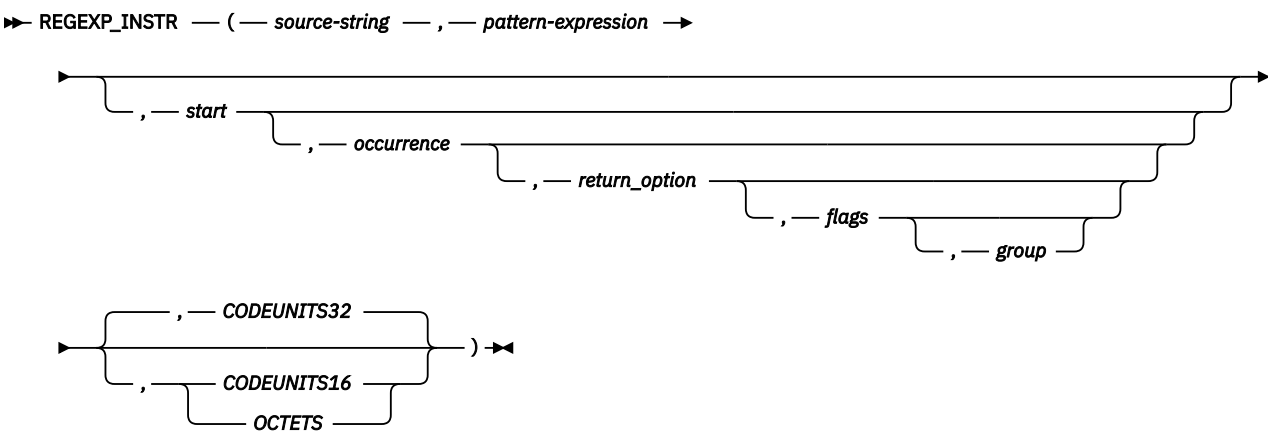
The REGEXP_EXTRACT scalar function is a synonym for the REGEXP_SUBSTR scalar function.

Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- **Considerations for non-Unicode databases**:
  - A regular expression pattern supports only half-width control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.
  - The source string and replacement string arguments must both be character string data types or both be graphic string data types.

REGEXP_INSTR

The REGEXP_INSTR scalar function returns the starting or ending position of the matched substring, depending on the value of the **`return_option`** argument.



The schema is SYSIBM.

source-string
An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815).

pattern-expression
An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. The length of a CLOB or DBCLOB expression must not be greater than the maximum length of a VARCHAR or VARGRAPHIC data type. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815).

start
An expression that specifies the position within *source-string* at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd (SQLSTATE 428GC). The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

occurrence
An expression that specifies which occurrence of the pattern expression within the source string to search for. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. This value must be greater than or equal 1. The default occurrence value is 1, which indicates that only the first occurrence of the pattern expression is considered.

return-option
An expression that specifies what is returned relative to the occurrence. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. This value must be 0 or 1 (SQLSTATE 22546):

- A value of 0 returns the position of the first string unit of the occurrence.
- A value of 1 returns the position of the string unit that follows the occurrence.

The default return option value is 0.

flags
An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute (SQLSTATE 42815). The string can include one or more valid flag values and the combination of flag values must be valid (SQLSTATE 2201T). An empty string is the same as the value 'c'. The default flag value is 'c'.

Table 86. Supported flag values

Flag value	Description
c	Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.
i	Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.
m	Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, "^" and "$" also matches at the start and end of each line within the input string.

Table 86. Supported flag values (continued)	
Flag value	**Description**
n	Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator, and matches a single "." in a pattern.
s	Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.
x	Specifies that white space characters in a pattern are ignored, unless escaped.

group
An expression that specifies which capture group of the pattern expression is used to determine the position within source string to return. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. This value must be greater than or equal to 0 and must not be greater than the number of capture groups in the pattern expression (SQLSTATE 22546). The default group value is 0, which indicates that the position is based on the string that matches the entire pattern.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of both the start value and the result:

- CODEUNITS16 specifies that the start value and result are expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value and result are expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value and result are expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and the string unit of the source string is CODEUNITS32, an error is returned (SQLSTATE 428GC).

For more information, see "String units in built-in functions" in “Character strings” on page 31.

Result

The result of the function is a large integer. If the pattern expression is found, the result is a number from 1 to n, where n is the actual length of the source string plus 1. The result value represents the position expressed in the string units used to process the function. If the pattern expression is not found and no argument is null, the result is 0.

If any argument of the REGEXP_INSTR function can be null, the result can be null. If any argument is null, the result is the null value.

Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- **Considerations for non-Unicode databases**:
  - A regular expression pattern supports only half-width control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.

Examples

1. Find the first occurrence of a 'o' that has a character that is preceding it.

```
SELECT REGEXP_INSTR('hello to you', '.o',1,1)
   FROM sysibm.sysdummy1
```

The result is 4, which is the position of the second 'l' character.

2. Find the second occurrence of a 'o' that has a character that is preceding it.

```
SELECT REGEXP_INSTR('hello to you', '.o',1,2)
   FROM sysibm.sysdummy1
```

The result is 7, which is the position of the character 't'.

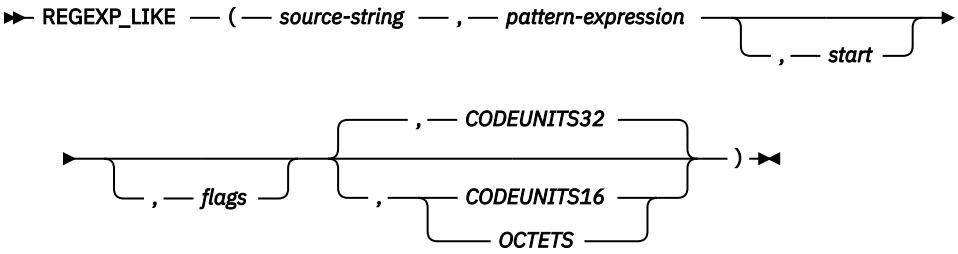
3. Find the position after the third occurrence of the first capture group of the regular expression '(.o).' using case insensitive matching.

```
SELECT REGEXP_INSTR('hello TO you', '(.o).', 1,3,1,'i',1)
   FROM sysibm.sysdummy1
```

The result is 12, which is the position of the character 'u' at the end of the string.

REGEXP_LIKE

The REGEXP_LIKE scalar function returns a boolean value indicating if the regular expression pattern is found in a string. The function can be used only where a predicate is supported.



The schema is SYSIBM.

source-string
An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815).

pattern-expression
An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. The length of a CLOB or DBCLOB expression must not be greater than the maximum length of a VARCHAR or VARGRAPHIC data type. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815).

start
An expression that specifies the position within *source-string* at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd (SQLSTATE 428GC). The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

flags
An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute (SQLSTATE 42815).

The string can include one or more valid flag values and the combination of flag values must be valid (SQLSTATE 2201T). An empty string is the same as the value 'c'. The default flag value is 'c'.

Table 87. Supported flag values

Flag value	Description
c	Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.
i	Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.
m	Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, "^" and "$" also matches at the start and end of each line within the input string.
n	Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator, and matches a single "." in a pattern.
s	Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.
x	Specifies that white space characters in a pattern are ignored, unless escaped.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of the start value:

- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string unit of the source string is CODEUNITS32, an error is returned (SQLSTATE 428GC).

For more information, see "String units in built-in functions" in “Character strings” on page 31.

Result

The result of the function is a BOOLEAN value. If the pattern expression is found, the result is true. If the pattern expression is not found, the result is false. If the value of any of the arguments is null, the result is unknown.

Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- **Considerations for non-Unicode databases**:
  - A regular expression pattern supports only half-width control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.
  - The source string and replacement string arguments must both be character string data types or both be graphic string data types.

Examples

1. Select the employee number where the last name is spelled LUCCHESSI, LUCHESSI, or LUCHESI from the EMPLOYEE table without considering upper or lower case letters.

```
SELECT EMPNO FROM EMPLOYEE
   WHERE REGEXP_LIKE(LASTNAME,'luc+?hes+?i','i')
```

   The result is 1 row with EMPNO value '000110'.

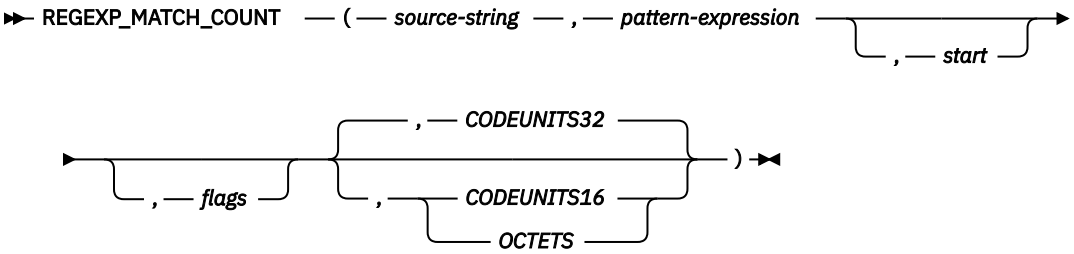
2. Select any invalid product identifier values from the PRODUCT table. The expected format is 'nnn-nnn-nn' where 'n' is a digit 0 - 9.

```
SELECT PID FROM PRODUCT
   WHERE NOT REGEXP_LIKE(pid,'[0-9]{3}-[0-9]{3}-[0-9]{2}')
```

   The result is 0 rows because all the product identifiers match the pattern.

REGEXP_MATCH_COUNT

The REGEXP_MATCH_COUNT scalar function returns a count of the number of times that a regular expression pattern is matched in a string.



The schema is SYSIBM.

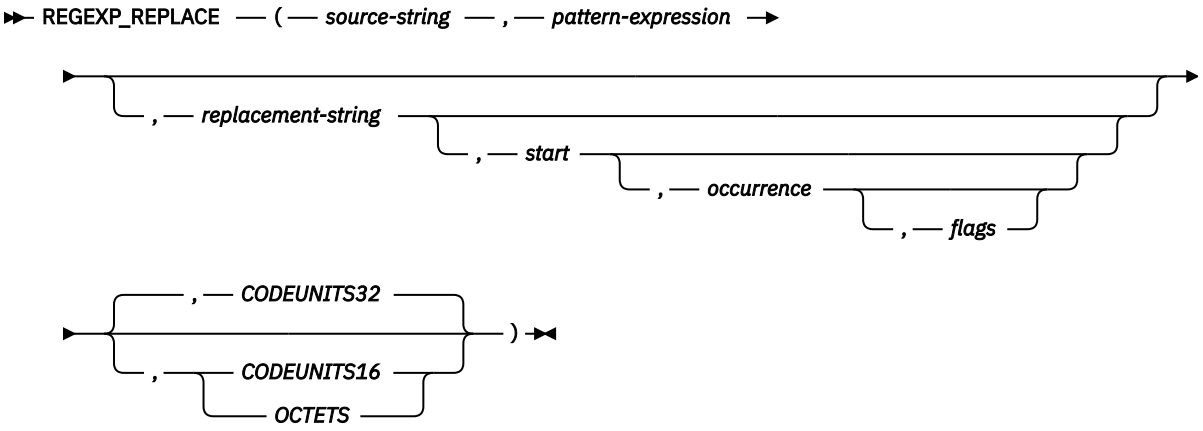
The REGEXP_MATCH_COUNT scalar function is a synonym for the REGEXP_COUNT scalar function.

Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- **Considerations for non-Unicode databases**:
  - A regular expression pattern supports only half-width control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.
  - The source string and replacement string arguments must both be character string data types or both be graphic string data types.

REGEXP_REPLACE

The REGEXP_REPLACE scalar function returns a modified version of the source string where occurrences of the regular expression pattern found in the source string are replaced with the specified replacement string.



The schema is SYSIBM.

source-string
An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815).

pattern-expression
An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. The length of a CLOB or DBCLOB expression must not be greater than the maximum length of a VARCHAR or VARGRAPHIC data type. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815).

replacement-string
An expression that specifies the replacement string for matching substrings. The expression must return a value that is a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815). The default replacement string is the empty string.

The content of the replacement string can include references to capture group text from the search to use in the replacement text. These references are of the form '$n' or '\n', where n is the number of the capture group and 0 represents the entire string that matches the pattern. The value for n must be in the range 0-9 and not greater than the number of capture groups in the pattern (SQLSTATE 2201V). For example, either '$2' or '\2' can be used to refer to the content found in the source string for the second capture group that is specified in the pattern expression. If the pattern expression must include a literal reference to a '$' or '\' character, that character must be preceded with an '/' character as an escape character ('\$' or '\\').

start
An expression that specifies the position within *source-string* at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd (SQLSTATE 428GC). The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

occurrence
An expression that specifies which occurrence of the pattern expression within the source string is to be searched for and replaced. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The occurrence value must be greater than or equal to 0. The default occurrence value is 0, which indicates that all occurrences of the pattern expression in the source string are replaced.

flags
An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute (SQLSTATE 42815). The string can include one or more valid flag values and the combination of flag values must be valid (SQLSTATE 2201T). An empty string is the same as the value 'c'. The default flag value is 'c'.

Table 88. Supported flag values

Flag value	Description
c	Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.
i	Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.
m	Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, "^" and "$" also matches at the start and end of each line within the input string.
n	Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator, and matches a single "." in a pattern.
s	Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.
x	Specifies that white space characters in a pattern are ignored, unless escaped.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of the start value:

- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string unit of the source string is CODEUNITS32, an error is returned (SQLSTATE 428GC).

For more information, see "String units in built-in functions" in “Character strings” on page 31.

Result

The result of the function is a string. If there are no occurrences of the pattern to be replaced and no argument is null, the original string is returned. The data type of the string is the same data type as the source string, except for CHAR, which becomes VARCHAR; and VARGRAPHIC, which becomes GRAPHIC.

The length attribute of the result data type is determined based on the length attributes of the source string and the replacement string by using the following calculation:

```
MIN(MaxTypeLen, LAS+(LAS+1)*LAR)
```

where *MaxTypeLen* represents the maximum length attribute for the data type of the result, *LAS* represents the length attribute for the data type of the source-string, and *LAR* represents the length attribute for the data type of the replacement string. If the replacement string is not specified, the value for *LAR* is 0. If the actual length of the result string exceeds the maximum for the return data type, an error is returned (SQLSTATE 54006).

If any argument of the REGEXP_REPLACE function can be null, the result can be null. If any argument is null, the result is the null value.

Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- **Considerations for non-Unicode databases**:
  - A regular expression pattern supports only half-width control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.
  - The source string and replacement string arguments must both be character string data types or both be graphic string data types.

Example

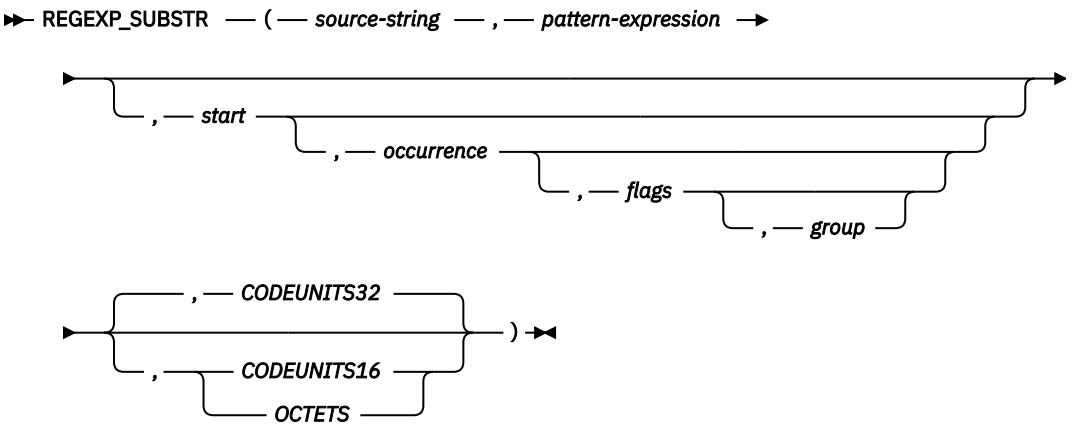
Replace the second occurrence of the pattern 'R.d' with 'Orange' using a case sensitive search.

```
SELECT REGEXP_REPLACE(
   'Red Yellow RED Blue Red Green Blue', 'R.d','Orange',1,2,'c')
      FROM sysibm.sysdummy1
```

The result is 'Red Yellow RED Blue Orange Green Blue'.

REGEXP_SUBSTR

The REGEXP_SUBSTR scalar function returns one occurrence of a substring of a string that matches the regular expression pattern.



The schema is SYSIBM.

source-string
An expression that specifies the string in which the search is to take place. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815).

pattern-expression
An expression that specifies the regular expression string that is the pattern for the search. This expression must return a built-in character string, graphic string, numeric value, Boolean value, or datetime value. A numeric, Boolean, or datetime value is implicitly cast to VARCHAR before the function is evaluated. The length of a CLOB or DBCLOB expression must not be greater than the maximum length of a VARCHAR or VARGRAPHIC data type. A character string cannot specify the FOR BIT DATA attribute (SQLSTATE 42815).

start
An expression that specifies the position within *source-string* at which the search is to start. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The value of the integer must be greater than or equal to 1. If OCTETS is specified and the source string is graphic data, the value of the integer must be odd (SQLSTATE 428GC). The default start value is 1. See parameter description for CODEUNITS16, CODEUNITS32, or OCTETS for the string unit that applies to the start position.

occurrence
An expression that specifies which occurrence of the pattern expression within *source-string* to search for. The expression must return a built-in character string, graphic string, Boolean, or numeric value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The occurrence value must be greater than or equal 1. The default occurrence value is 1, which indicates that only the first occurrence of the pattern expression is considered.

flags
An expression that specifies flags that controls aspects of the pattern matching. The expression must return a built-in character string that does not specify the FOR BIT DATA attribute (SQLSTATE 42815). The string can include one or more valid flag values and the combination of flag values must be valid (SQLSTATE 2201T). An empty string is the same as the value 'c'. The default flag value is 'c'.

Table 89. Supported flag values

Flag value	Description
c	Specifies that matching is case-sensitive. This flag is the default value if 'c' or 'i' is not specified. This value must not be specified with a value of 'i'.
i	Specifies that matching is case insensitive. This value must not be specified with a value of 'c'.
m	Specifies that the input data can contain more than one line. By default, the '^' in a pattern matches only the start of the input string; the '$' in a pattern matches only the end of the input string. If this flag is set, "^" and "$" also matches at the start and end of each line within the input string.
n	Specifies that the '.' character in a pattern matches a line terminator in the input string. By default, the '.' character in a pattern does not match a line terminator. A carriage-return and line-feed pair in the input string behaves as a single-line terminator, and matches a single "." in a pattern.
s	Specifies that the '.' character in a pattern matches a line terminator in the input string. This value is a synonym for the 'n' value.
x	Specifies that white space characters in a pattern are ignored, unless escaped.

group
An expression that specifies which capture group of the pattern expression within source string to return. The expression must return a built-in character, binary, or graphic string, or a Boolean value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before the function is evaluated. The group value must be greater than or equal to 0 and must not be greater than the number of capture groups in the pattern expression (SQLSTATE 22546). The default group value is 0, which indicates that the string that matches the entire pattern is to be returned.

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of the start value:

- CODEUNITS16 specifies that the start value is expressed in 16-bit UTF-16 code units.
- CODEUNITS32 specifies that the start value is expressed in 32-bit UTF-32 code units. This is the default.
- OCTETS specifies that the start value is expressed in bytes.

If the string unit is specified as CODEUNITS16 or OCTETS, and if the string unit of the source string is CODEUNITS32, an error is returned (SQLSTATE 428GC).

For more information, see "String units in built-in functions" in “Character strings” on page 31.

Result

The result of the function is a string. The data type of the string is the same data type as the source string, except for CHAR, which becomes VARCHAR; and GRAPHIC, which becomes and VARGRAPHIC. The length attribute of the result data type is same as the length attribute of the source string. The actual length of the result is the length of the occurrence in the string that matches the pattern expression. If the pattern expression is not found, the result is the null value.

The result of the REGEXP_SUBSTR function can be null. If any argument is null, the result is the null value.

Notes

- The regular expression processing is done by using the International Components for Unicode (ICU) regular expression interface.
- **Considerations for non-Unicode databases**:
  - A regular expression pattern supports only half-width control characters; use a character string data type for the pattern expression argument. A character string data type can be used for the pattern expression argument even when a graphic string data type is used for the source string argument.
  - The source string argument must be a graphic string data type if the pattern expression argument is a graphic string data type.

Examples

1. Return the string which matches any character preceding a 'o'.

```
SELECT REGEXP_SUBSTR('hello to you', '.o',1,1)
   FROM sysibm.sysdummy1
```

   The result is 'lo'.
2. Return the second string occurrence which matches any character preceding a 'o'.

```
SELECT REGEXP_SUBSTR('hello to you', '.o',1,2)
   FROM sysibm.sysdummy1
```

   The result is 'to'.
3. Return the third string occurrence which matches any character preceding a 'o'.

```
SELECT REGEXP_SUBSTR('hello to you', '.o',1,3)
   FROM sysibm.sysdummy1
```

   The result is 'yo'.

REPEAT

The REPEAT function returns a character string that is composed of the first argument repeated the number of times that are specified by the second argument.

The schema is SYSIBM. The SYSFUN version of the REPEAT function continues to be available.

expression1
An expression that specifies the string to be repeated. The expression must return a built-in character string, numeric value, Boolean value, or datetime value. If the value is not a character string, it is implicitly cast to VARCHAR before the function is evaluated.

expression2
An expression that is a positive integer value or zero that specifies the number of times to repeat the string. The expression must return a built-in character string, graphic string, or numeric value. If the value is not an integer, it is implicitly cast to INTEGER before the function is evaluated.

Result

The result of the function is one of the following data types:

- VARBINARY if *expression1* is a BINARY or VARBINARY string
- VARCHAR if *expression1* is a CHAR or VARCHAR string
- VARGRAPHIC if *expression1* is GRAPHIC or VARGRAPHIC string
- CLOB if *expression1* is CLOB
- BLOB if *expression1* is BLOB
- DBCLOB if *expression1* is a DBCLOB

If *expression2* is a constant, the length attribute of the result is minimum of the length attribute of *expression1* times *expression2* and the maximum length of the result data type. Otherwise, the length attribute depends on the data type of the result:

- 4000 for VARBINARY and VARCHAR
- 2000 for VARGRAPHIC
- 1 MB for CLOB, DBCLOB, and BLOB

The actual length of the result is the actual length of *expression1* times *expression2*. If the actual length of the result string exceeds the length attribute for the return type, an error is returned (SQLSTATE 54006).

If the result data type is a character string or graphic string, the string units of the result are the string units of *expression1*.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

1. Repeat 'abc' two times to create 'abcabc'.

```
SELECT REPEAT('abc',2)
  FROM SYSIBM.SYSDUMMY1
```

2. List the phrase 'REPEAT THIS' five times. Use the CHAR function to limit the output to 60 bytes.

```
SELECT CHAR(REPEAT('REPEAT THIS',5), 60)
  FROM SYSIBM.SYSDUMMY1
```

This example outputs the following string:

```
'REPEAT THISREPEAT THISREPEAT THISREPEAT THISREPEAT THIS     '
```

3. For the following query, the LENGTH function returns a value of 0 because the result of repeating a string zero times is an empty string, which is a zero-length string.

```
SELECT LENGTH(REPEAT('REPEAT THIS',0))
  FROM SYSIBM.SYSDUMMY1
```

4. For the following query, the LENGTH function returns a value of 0. A value of 0 because the result of repeating an empty string any number of times is an empty string, which is a zero-length string.

```
SELECT LENGTH(REPEAT('', 5))
  FROM SYSIBM.SYSDUMMY1
```

REPEAT (SYSFUN schema)

Returns a character string composed of the first argument repeated the number of times specified by the second argument.

The schema is SYSFUN.

expression1
An expression that returns a value of built-in character string, graphic string, or binary string data type. In a Unicode database, the expression can also return a graphic string, in which case it is first converted to a character string before the function is evaluated. The maximum length is:

- 4000 bytes for a VARCHAR
- 1,048,576 bytes for a CLOB or binary string

expression2
An expression that returns a value of data type SMALLINT or INTEGER. The returned value specifies the number of times to repeat the string returned by *expression1*.

Result

The data type of the result is:

- VARCHAR(4000 OCTETS) if the first expression returns a CHAR or VARCHAR value
- CLOB(1M OCTETS) if the first expression returns a CLOB value
- BLOB(1M) if the first expression returns a BLOB value

The result can be null; if any argument is null, the result is the null value.

Examples

List the phrase 'REPEAT THIS' five times.

```
VALUES REPEAT('REPEAT THIS', 5)
```

This example returns the following VARCHAR(4000 OCTETS) output:

```
1
------------------------------------------------------------
REPEAT THISREPEAT THISREPEAT THISREPEAT THISREPEAT THIS
```

List the phrase 'REPEAT THIS' five times and limit the output to 60 bytes:

```
VALUES CHAR(REPEAT('REPEAT THIS', 5), 60)
```

This example returns the following CHAR(60) output:

```
1
-------------------------------------------------------------
REPEAT THISREPEAT THISREPEAT THISREPEAT THISREPEAT THIS
```

REPLACE

Replaces all occurrences of *search-string* in *source-string* with *replace-string*.

The schema is SYSIBM. The SYSFUN version of the REPLACE function continues to be available but it is not sensitive to the database collation.

If the search string is not found in the source string, the search string is returned unchanged. If the Unicode database is defined with a locale-sensitive UCA-based collation and none of the *source-string*, *search-string*, or *replace-string* arguments are defined as FOR BIT DATA or as a binary string, a linguistically correct search is done. Otherwise, the search is done using a binary comparison with no special consideration for multi-byte characters.

source-string
An expression that specifies the source string. The expression must return a value that is a built-in character string, numeric value, DBCLOB value, Boolean value, or datetime value. If the value is:

- A numeric, datetime, or CLOB value, it is implicitly cast to VARCHAR before the function is evaluated
- A DBCLOB value, it is implicitly cast to VARGRAPHIC before the function is evaluated

The actual length of binary strings cannot exceed 1,048,576 bytes (SQLSTATE 42815).

search-string
An expression that specifies the string to be removed from the source string. The expression must return a value that is a built-in character string, numeric value, DBCLOB value, Boolean value, or datetime value. If the value is:

- A numeric, datetime, or CLOB value, it is implicitly cast to VARCHAR before the function is evaluated
- A DBCLOB value, it is implicitly cast to VARGRAPHIC before the function is evaluated

The actual length of binary strings cannot exceed 1,048,576 bytes (SQLSTATE 42815).

replace-string
An expression that specifies the replacement string. The expression must return a value that is a built-in character string, numeric value, DBCLOB value, Boolean value, or datetime value. If the value is:

- A numeric, datetime, or CLOB value, it is implicitly cast to VARCHAR before the function is evaluated
- A DBCLOB value, it is implicitly cast to VARGRAPHIC before the function is evaluated

The actual length of binary strings cannot exceed 1,048,576 bytes (SQLSTATE 42815). If the expression is an empty string or is not specified, nothing replaces the string that is removed from the source string.

All three arguments must have compatible data types.

Result

The data type of the result depends on the data type of the arguments:

- If any argument is a BLOB, the result is a BLOB.
- If the arguments are binary strings and not BLOB, the result is a VARBINARY.
- If the arguments are character strings, the result is a VARCHAR. If any argument is defined as FOR BIT DATA, the result is defined as FOR BIT DATA.

- If the arguments are graphic strings, the result is a VARGRAPHIC.

In a Unicode database, if both character strings and graphic strings are used as arguments, then the result data type is based on the string type of the *source-string* argument. If the *source-string* argument is a character string type, then the result data type is VARCHAR. If the *source-string* argument is a graphic string type, then the result data type is VARGRAPHIC.

The string unit of the result is the string unit of *source-string*. If any argument is defined as FOR BIT DATA, the other arguments cannot be defined with string units of CODEUNITS32.

The string units of the result is the same as the string units of *source-string*. The length attribute of the result depends on the arguments:

- The length attribute of the result is the length attribute of the source-string (with the same string units) in the following cases:
  - The *replace-string* argument is not specified or is specified as an empty string constant.
  - The search-string is a constant and the number of bytes in the search-string constant is greater than or equal to:
    - The number of bytes of a constant *replace-string*.
    - The length attribute of a non-constant character string type *replace-string* in OCTETS.
    - The length attribute times 2 of a non-constant graphic string type *replace-string* in double bytes or CODEUNITS16.
    - The length attribute times 4 of a non-constant *replace-string* in CODEUNITS32.
    - The length attribute of a non-constant binary string type *replace-string*.
- Otherwise, the length attribute of the result is determined by the following calculation depending on the data type of the result (that allows for the smallest possible *search-string* to be replaced by the largest possible *replace-string*):
  - For VARCHAR with string units of OCTETS:
    - If L1 < = 4000, the length attribute of the result is `MIN(4000, (L3*(L1/L2)) + MOD(L1,L2))`
    - Otherwise, the length attribute of the result is `MIN(32672, (L3*(L1/L2)) + MOD(L1,L2))`
  - For VARCHAR with string units of CODEUNITS32, the length attribute of the result is `MIN(8168, (L3*(L1/L2)) + MOD(L1,L2))`.
  - For VARGRAPHIC with string units of double bytes or CODEUNITS16:
    - If L1 < = 2000, the length attribute of the result is `MIN(2000, (L3*(L1/L2)) + MOD(L1,L2))`
    - Otherwise, the length attribute of the result is `MIN(16336, (L3*(L1/L2)) + MOD(L1,L2))`
  - For VARGRAPHIC with string units of CODEUNITS32, the length attribute of the result is `MIN(8168, (L3*(L1/L2)) + MOD(L1,L2))`.
  - For VARBINARY, the length attribute of the result is `MIN(32672, (L3*(L1/L2)) + MOD(L1,L2))`
  - For BLOB, the length attribute of the result is `MIN(2G, (L3*(L1/L2)) + MOD(L1,L2))`

where the length values for L1, L2, and L3 are given in the following table based on the string units of the result:

Table 90. Length values of L1, L2, and L3

String units of the result	L1	L2	L3
OCTETS (a character string)	Length attribute of *source-string*	One (1) if not a constant, otherwise the actual number of bytes in the constant expressed as a character string type.	• If *replace-string* is a constant, the actual number of bytes in the constant expressed as a character string type. • If *replace-string* is a character string in OCTETS then the length attribute of *replace-string*. • If *replace-string* is a character string or a graphic string in CODEUNITS32, then 4 times the length attribute of *replace-string*. • If *replace-string* is a graphic string in double bytes or CODEUNITS16, then 3 times the length attribute of *replace-string*.
CODEUNITS16 or double bytes (a graphic string)	Length attribute of *source-string*	One (1) if not a constant, otherwise the actual number of double bytes or CODEUNITS16 string units in the constant expressed as a graphic string type.	• If *replace-string* is a constant, the actual number of double bytes or CODEUNITS16 string units in the constant expressed as a graphic string type. • If *replace-string* is a character string in OCTETS or a graphic string in double bytes or CODEUNITS16 then the length attribute of *replace-string*. • If *replace-string* is a character string or graphic string in CODEUNITS32 then the 2 times the length attribute of *replace-string*.

Table 90. Length values of L1, L2, and L3 (continued)			
String units of the result	**L1**	**L2**	**L3**
CODEUNITS32 (a character string or a graphic string)	Length attribute of *source-string*	One (1) if not a constant, otherwise length attribute of *search-string*.	Length attribute of *replace-string*
Not applicable (a binary string)	Length attribute of *source-string*	One (1) if not a constant, otherwise the actual number of bytes in the constant expressed as a binary string type.	• If *replace-string* is a constant, the actual number of bytes in the constant expressed as a binary string type. • If *replace-string* is a binary string or character string that is FOR BIT DATA, then the length attribute of *replace-string*.

If the result is a character string, the length attribute of the result must not exceed the maximum length of the VARCHAR data type in the string units of the result. If the result is a graphic string, the length attribute of the result must not exceed the maximum length of the VARGRAPHIC data type in the string units of the result.

The actual length of the result is the actual length of *source-string* plus the number of occurrences of *search-string* that exist in *source-string* multiplied by the actual length of *replace-string* minus the actual length of *search-string*. If the actual length of the result would exceed the length attribute of the result or would exceed 1,048,576 bytes, an error is returned (SQLSTATE 22001).

If the actual length of the *replace-string* exceeds the maximum for the return data type, an error is returned. If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: Replace all occurrences of the letter 'N' in the word 'DINING' with 'VID'.

```
VALUES CHAR (REPLACE ('DINING', 'N', 'VID'), 10)
```

  The result is the string 'DIVIDIVIDG'.

- *Example 2*: In a Unicode database with case-insensitive collation CLDR181_LEN_S1, replace the word 'QUICK' with the word 'LARGE'.

```
VALUES REPLACE ('The quick brown fox', 'QUICK', 'LARGE')
```

  The result is the string 'The LARGE brown fox'.

REPLACE (SYSFUN schema)

Replaces all occurrences of *expression2* in *expression1* with *expression3*.

The schema is SYSFUN.

The search is done using a binary comparison with no special consideration for multi-byte characters.

expression1* or *expression2* or *expression3
The data type for the arguments can be of any built-in character string or binary string type.

The expression must return a built-in character string, Boolean value, or binary string. In a Unicode database, the expression can also return a graphic string, in which case it is first converted to a character string before the function is evaluated. The maximum length is:

- 4000 bytes for a VARCHAR
- 1,048,576 bytes for a CLOB or binary string

A CHAR value is converted to VARCHAR and a LONG VARCHAR value is converted to CLOB(1M).

Result

The data type of the result is VARCHAR(4000).

The result can be null; if any argument is null, the result is the null value.

Examples

Replace all occurrences of the letter 'N' in the word 'DINING' with 'VID':

```
VALUES REPLACE ('DINING', 'N', 'VID')
```

This example returns the following VARCHAR(4000) output:

```
1
----------
DIVIDIVIDG
```

Replace all occurrences of the letter 'N' in the word 'DINING' with 'VID', and limit the output to 9 bytes:

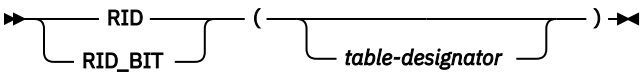
```
VALUES CHAR (REPLACE ('DINING', 'N', 'VID'), 9)
```

This example returns the following CHAR(9) output:

```
1
----------
DIVIDIVID
```

RID and RID_BIT

The RID and RID_BIT functions are used to uniquely identify a row. Each returns the row identifier (RID) of a row. The result of the RID_BIT function, unlike the result of the RID function, contains table information to help you avoid inadvertently using it with the wrong table. Both functions are non-deterministic.



The schema is SYSIBM. The function name cannot be specified as a qualified name.

RID
Indicates that the RID function is to be run. Starting from Db2 version 11.5.3, the RID function can be used in partitioned database environment. The value provided by the RID function does not include database partition information. In a partitioned database environment, use **DBPARTITIONNUM** to make the value unique.

RID_BIT
Indicates that the RID_BIT function is to be run.

table-designator
Uniquely identifies a base table, view, or nested table expression (SQLSTATE 42703). If the table designator specifies a view or nested table expression, the RID_BIT and RID functions return the RID of the base table of the view or nested table expression. The specified view or nested table expression must contain only one base table in its outer subselect (SQLSTATE 42703). The table designator must be deletable (SQLSTATE 42703). For information about deletable views, see the "Notes" section of "CREATE VIEW".

If a table designator is not specified, the FROM clause must contain only one element which can be derived to be the table designator (SQL STATE 42703).

Result

The data type of the result is either BIGINT (for RID) or VARCHAR (16) FOR BIT DATA (for RID_BIT). The result can be null.

The RID or RID_BIT function might return different values when invoked several times for a single row. For example, if RID or RID_BIT is run both before and after the reorg utility is run against the specified table, the function might return a different value each time.

Notes

- To implement optimistic locking in an application, use the values returned by the ROW CHANGE TOKEN expression as arguments to the RID_BIT scalar function.
- Starting from Db2 version 11.5.3, the RID scalar functions can be used with column-organized tables.
- ***Syntax alternatives***: The following alternatives are non-standard. They are supported for compatibility with earlier product versions or with other database products.
  - The pseudocolumn "ROWID" can be used to refer to the RID. An unqualified ROWID reference is equivalent to RID_BIT() and a qualified ROWID such as EMPLOYEE.ROWID is equivalent to RID_BIT(EMPLOYEE).

Examples

- *Example 1*: Return the RID and last name of employees in department 20 from the EMPLOYEE table.

```
SELECT RID_BIT (EMPLOYEE), ROW CHANGE TOKEN FOR EMPLOYEE, LASTNAME
  FROM EMPLOYEE
  WHERE DEPTNO = '20'
```

- *Example 2*: Given table EMP1, which is defined as follows:

```
CREATE TABLE EMP1 (
  EMPNO   CHAR(6),
  NAME    CHAR(30),
  SALARY  DECIMAL(9,2),
  PICTURE BLOB(250K),
  RESUME  CLOB(32K)
)
```

Set host variable HV_EMP_RID to the value of the RID_BIT built-in scalar function, and HV_EMP_RCT to the value of the ROW CHANGE TOKEN expression for the row corresponding to employee number 3500.

```
SELECT RID_BIT(EMP1), ROW CHANGE TOKEN FOR EMP1
  INTO :HV_EMP_RID, :HV_EMP_RCT FROM EMP1
  WHERE EMPNO = '3500'
```

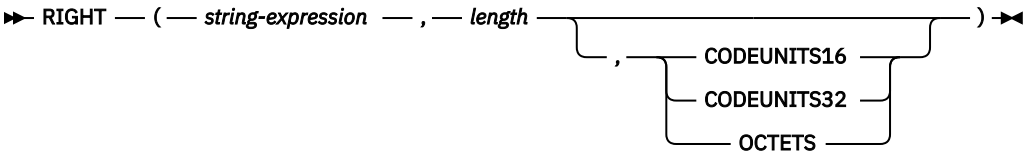
Using that RID value to identify the employee, and user-defined function UPDATE_RESUME, increase the employee's salary by $1000 and update the employee's resume.

```
UPDATE EMP1 SET
  SALARY = SALARY + 1000,
  RESUME = UPDATE_RESUME(:HV_RESUME)
```

```
WHERE RID_BIT(EMP1) = :HV_EMP_RID
AND ROW CHANGE TOKEN FOR EMP1 = :HV_EMP_RCT
```

RIGHT

The RIGHT function returns the rightmost string of *string-expression* of length *length*, expressed in the specified string unit.



The schema is SYSIBM. The SYSFUN version of the RIGHT function continues to be available.

If *string-expression* is a character string, the result is a character string. If *string-expression* is a graphic string, the result is a graphic string

string-expression
An expression that specifies the string from which the result is derived. The expression must return a value that is a built-in string, numeric, Boolean, or datetime data type. If the value is not a string data type, it is implicitly cast to VARCHAR before evaluating the function. A substring of *string-expression* is zero or more contiguous code points of *string-expression*.

length

An expression that specifies the length of the result. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. *length* must be greater than or equal to 0 (SQLSTATE 22011). If OCTETS is specified and the result is graphic data, the value must be an even number (SQLSTATE 428GC).

If *length* is not a constant and a string unit is not specified, then *length* must be less than or equal to the length attribute of *string-expression* (SQLSTATE 22011).

If *length* is not a constant and a string unit is specified, then *length* must be less than or equal to the value from table 1 (SQLSTATE 22011):

Table 91. Maximum value of length when a string unit is specified

String unit of *string-expression*	**Specified string unit**	**Maximum value of *length*** **L = length attribute of *string-expression***
String unit of *string-expression*	Specified string unit	Maximum value of *length* L = length attribute of *string-expression*
OCTETS	OCTETS	L
OCTETS	CODEUNITS16	L/2
OCTETS	CODEUNITS32	L/4
CODEUNITS16	OCTETS	L*2
CODEUNITS16	CODEUNITS16	L
CODEUNITS16	CODEUNITS32	L/2
CODEUNITS32	OCTETS	L*4
CODEUNITS32	CODEUNITS16	L*2

Table 91. Maximum value of length when a string unit is specified (continued)		
String unit of *string-expression*	**Specified string unit**	**Maximum value of *length*** **L = length attribute of *string-expression***
CODEUNITS32	CODEUNITS32	L

If *length* is a constant:

- if *string-expression*is CHAR, VARCHAR, GRAPHIC or VARGRAPHIC, *length* must be less than or equal to 32 672 OCTETS, 16 336 CODEUNITS16 or 8 168 CODEUNITS32 (SQLSTATE 22011)
- if *string-expression* is CLOB or DBCLOB, *length* must be less than or equal to 2147483647 OCTETS, 1 073 741 823 CODEUNITS16 or 536870911 CODEUNITS32 (SQLSTATE 22011)
- if *string-expression* is BLOB, *length* must be less than or equal to 2147483647 OCTETS (SQLSTATE 22011)

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of *length*.

CODEUNITS16 specifies that *length* is expressed in 16-bit UTF-16 code units. CODEUNITS32 specifies that *length* is expressed in 32-bit UTF-32 code units. OCTETS specifies that *length* is expressed in bytes.

If the string unit is specified as CODEUNITS16 or CODEUNITS32, and *string-expression* is a binary string or bit data, an error is returned (SQLSTATE 428GC). If the string unit is specified as OCTETS and *string-expression* is a graphic string, *length* must be an even number; otherwise, an error is returned (SQLSTATE 428GC). If a string unit is not explicitly specified, the string unit of *string-expression* determines the unit that is used. For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String units in built-in functions" in "Character strings".

The *string-expression* is padded on the right with the necessary number of padding characters so that the specified substring of *string-expression* always exists. The character used for padding is the same character that is used to pad the string in contexts where padding would occur. For more information about padding, see "String assignments" in "Assignments and comparisons".

The result of the function is a varying-length string that depends on the data type of *string-expression*:

- VARCHAR if *string-expression* is CHAR or VARCHAR
- CLOB if *string-expression* is CLOB
- VARGRAPHIC if *string-expression* is GRAPHIC or VARGRAPHIC
- DBCLOB if *string-expression* is DBCLOB
- VARBINARY if *string-expression* is BINARY or VARBINARY
- BLOB if *string-expression* is BLOB

The string unit of the result is the string unit of *string-expression*.The length attribute of the result depends on how *length* and string unit are specified:

- If *length* is not a constant, then the length attribute of the result is the same as the length attribute of *string-expression*.
- If *length* is a constant and a string unit is not specified, then the length attribute of the result is the maximum of length and the length attribute of *string-expression*.
- If *length* is a constant and a string unit is specified, then the length attribute of the result is shown in Table 2:

Table 92. Length attribute of result when length is a constant and a string unit is specified		
String unit of *string-expression*	**Specified string unit**	**Maximum value of *length*** **L = length attribute of *string-expression***
OCTETS	OCTETS	max(L, *length*)
OCTETS	CODEUNITS16	max(L, *length* * 2)
OCTETS	CODEUNITS32	max(L, *length* * 4)
CODEUNITS16	OCTETS	max(L, *length* / 2)
CODEUNITS16	CODEUNITS16	max(L, *length*)
CODEUNITS16	CODEUNITS32	max(L, *length* * 2)
CODEUNITS32	OCTETS	max(L, *length* / 4)
CODEUNITS32	CODEUNITS16	max(L, *length* / 2)
CODEUNITS32	CODEUNITS32	max(L, *length*)

The actual length of the result (in string units) is *length*.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: Assume that variable ALPHA has a value of "ABCDEF". The following statement:

```
SELECT RIGHT(ALPHA,3)
  FROM SYSIBM.SYSDUMMY1
```

  returns "DEF", which are the three rightmost characters in ALPHA.

- *Example 2*: Assume that variable NAME, which is defined as VARCHAR(50), has a value of "KATIE AUSTIN", and that the integer variable LASTNAME_LEN has a value of 6. The following statement:

```
SELECT RIGHT(NAME,LASTNAME_LEN)
  FROM SYSIBM.SYSDUMMY1
```

  returns the value "AUSTIN".

- *Example 3*: The following statement returns a zero-length string.

```
SELECT RIGHT('ABCABC',0)
  FROM SYSIBM.SYSDUMMY1
```

- *Example 4*: The FIRSTNME column in the EMPLOYEE table is defined as VARCHAR(12). Find the first name of an employee whose last name is "BROWN" and return the first name in a 10-byte string.

```
SELECT RIGHT(FIRSTNME, 10)
  FROM EMPLOYEE
  WHERE LASTNAME = 'BROWN'
```

  returns a VARCHAR(12) string that has the value "DAVID" followed by five blank characters.

- *Example 5*: In a Unicode database, FIRSTNAME is a VARCHAR(12) column. One of its values is the 6-character string "Jürgen". When FIRSTNAME has this value:

```
Function...                      Returns...

RIGHT(FIRSTNAME,5,CODEUNITS32)  'ürgen' -- x'C3BC7267656E'
RIGHT(FIRSTNAME,5,CODEUNITS16)  'ürgen' -- x'C3BC7267656E'
RIGHT(FIRSTNAME,5,OCTETS)       'rgen'  -- x'207267656E', a truncated string
```

- *Example 6*: The following example works with the Unicode string "&N~AB," where "&" is the musical symbol G clef character, and "~" is the combining tilde character. This string is shown in different Unicode encoding forms in the following example:

	"&"	**"N"**	**"~"**	**"A"**	**"B"**
UTF-8	X'F09D849E'	X'4E'	X'CC83'	X'41'	X'42'
UTF-16BE	X'D834DD1E'	X'004E'	X'0303'	X'0041'	X'0042'

Assume that the variable UTF8_VAR, with a length attribute of 20 bytes, contains the UTF-8 representation of the string.

```
SELECT RIGHT(UTF8_VAR, 2, CODEUNITS16),
  RIGHT(UTF8_VAR, 2, CODEUNITS32),
  RIGHT(UTF8_VAR, 2, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values "AB", "AB", and "AB"', respectively.

```
SELECT RIGHT(UTF8_VAR, 5, CODEUNITS16),
  RIGHT(UTF8_VAR, 5, CODEUNITS32),
  RIGHT(UTF8_VAR, 5, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values "?N~AB", "&N~AB", and "N~AB", respectively, where ?'is X'EDB49E'.

```
SELECT RIGHT(UTF8_VAR, 10, CODEUNITS16),
  RIGHT(UTF8_VAR, 10, CODEUNITS32),
  RIGHT(UTF8_VAR, 10, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values "&N~ABbbbb", "&N~ABbbbbb", and "&N~ABb", respectively, where "b" represents the blank character.

Assume that the variable UTF16_VAR, with a length attribute of 20 code units, contains the UTF-16BE representation of the string.

```
SELECT RIGHT(UTF16_VAR, 2, CODEUNITS16),
  RIGHT(UTF16_VAR, 2, CODEUNITS32),
  RIGHT(UTF16_VAR, 2, OCTETS))
FROM SYSIBM.SYSDUMMY1
```

returns the values "AB", "AB", and "B", respectively.

```
SELECT RIGHT(UTF16_VAR, 5, CODEUNITS16),
  RIGHT(UTF16_VAR, 5, CODEUNITS32),
  RIGHT(UTF16_VAR, 6, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values "?N~AB", "&N~AB", and "~AB", respectively, where ? is the stand-alone low surrogate X'DD1E'.

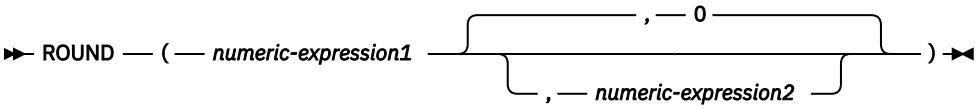
```
SELECT RIGHT(UTF16_VAR, 10, CODEUNITS16),
  RIGHT(UTF16_VAR, 10, CODEUNITS32),
  RIGHT(UTF16_VAR, 10, OCTETS)
FROM SYSIBM.SYSDUMMY1
```

returns the values "&N~ABbbbb", "&N~ABbbbbb", and "?N~AB", respectively, where "b" represents the blank character and ? is X'DD1E'.

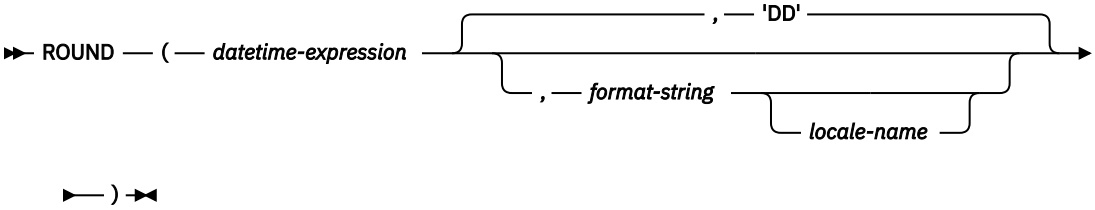
ROUND

The ROUND function returns a rounded value of a number or a datetime value.

ROUND numeric



ROUND datetime



The schema is SYSIBM. The SYSFUN version of the ROUND numeric function continues to be available.

The return value depends on the first argument:

- If the result of the first argument is a numeric value, the ROUND functions returns a number, rounded to the specified number of places to the right or left of the decimal point.
- If the first argument is a DATE, TIME, or TIMESTAMP the ROUND functions returns a datetime value, rounded to the unit specified by *format-string*.

ROUND numeric

If *numeric-expression1* is positive, a digit value of 5 or greater is an indication to round to the next higher positive number. For example, ROUND(3.5,0) = 4. If *numeric-expression1* is negative, a digit value of 5 or greater is an indication to round to the next lower negative number. For example, ROUND(-3.5,0) = -4.

numeric-expression1
An expression that must return a value that is a built-in CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, or numeric data type. If the value is not a numeric data type, it is implicitly cast to DECFLOAT(34) before evaluating the function.

If the expression is a decimal floating-point data type, the DECFLOAT rounding mode will not be used. The rounding behavior of ROUND corresponds to a value of ROUND_HALF_UP. If a different rounding behavior is wanted, use the QUANTIZE function.

numeric-expression2
An expression that returns a value that is a built-in numeric data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

If *numeric-expression2* is not negative, *numeric-expression1* is rounded to the absolute value of *numeric-expression2* number of places to the right of the decimal point.

If *numeric-expression2* is negative, *numeric-expression1* is rounded to the absolute value of *numeric-expression2*+1 number of places to the left of the decimal point.

If the absolute value of a negative *numeric-expression2* is larger than the number of digits to the left of the decimal point, the result is 0. For example, ROUND(748.58,-4) = 0. If *numeric-expression1* is positive, a digit value of 5 is rounded to the next higher positive number. If *numeric-expression1* is negative, a digit value of 5 is rounded to the next lower negative number.

The data type and length attribute of the result are the same as the data type and length attribute of the first argument, except that the precision is increased by one if the *numeric-expression1*

is DECIMAL and the precision is less than 31. For example, an argument with a data type of DECIMAL(5,2) results in DECIMAL(6,2). An argument with a data type of DECIMAL(31,2) results in DECIMAL(31,2). The scale is the same as the scale of the first argument.

If either argument can be null or if the argument is not a decimal floating-point number and the database is configured with **dft_sqlmathwarn** set to YES, the result can be null. If either argument is null, the result is the null value.

This function is not affected by the setting of the CURRENT DECFLOAT ROUNDING MODE special register, even for decimal floating-point arguments. The rounding behavior of ROUND corresponds to a value of ROUND_HALF_UP. If you want behavior for a decimal floating-point value that conforms to the rounding mode specified by the CURRENT DECFLOAT ROUNDING MODE special register, use the QUANTIZE function instead.

ROUND datetime

If *datetime-expression* has a datetime data type, the ROUND function returns *datetime-expression* rounded to the unit specified by the *format-string*. If *format-string* is not specified, *datetime-expression* is rounded to the nearest day, as if 'DD' is specified for *format-string*.

datetime-expression

An expression that must return a value that is a date, a time, or a timestamp. String representations of these data types are not supported and must be explicitly cast to a DATE, TIME, or TIMESTAMP for use with this function; alternatively, you can use the ROUND_TIMESTAMP function for a string representation of a date or timestamp.

format-string

An expression that returns a built-in character string data type with an actual length that is not greater than 255 bytes. The format element in *format-string* specifies how *datetime-expression* should be rounded. For example, if *format-string* is 'DD', a timestamp that is represented by *datetime-expression* is rounded to the nearest day. Leading and trailing blanks are removed from the string, and the resulting substring must be a valid format element for the type of *datetime-expression* (SQLSTATE 22007). The default is 'DD', which cannot be used if the data type of *datetime-expression* is TIME.

Allowable values for *format-string* are listed in the table of format elements listed in the Table 1.

locale-name

A character constant that specifies the locale used to determine the first day of the week when using format element values DAY, DY, or D. The value of *locale-name* is not case sensitive and must be a valid locale (SQLSTATE 42815). For information about valid locales and their naming, see "Locale names for SQL and XQuery". If *locale-name* is not specified, the value of the special register CURRENT LOCALE LC_TIME is used.

The result of the function has the same DATE type as *datetime-expression*. The result can be null; if any argument is null, the result is the null value.

The following format elements are used to identify the rounding or truncation unit of the datetime value in the ROUND, ROUND_TIMESTAMP, TRUNCATE and TRUNC_TIMESTAMP functions.

Table 93. Format elements for ROUND, ROUND_TIMESTAMP, TRUNCATE, and TRUNC_TIMESTAMP

Format element	Rounding or truncating unit	ROUND example	TRUNCATE example
CC SCC	Century Rounds up to the start of the next century after the 50th year of the century (for example on 1951-01-01-00.00.00). Not valid for TIME argument.	Input Value: 1897-12-04-12.22.22.000000 Result: 1901-01-01-00.00.00.000000	Input Value: 1897-12-04-12.22.22.000000 Result: 1801-01-01-00.00.00.000000

Table 93. Format elements for ROUND, ROUND_TIMESTAMP, TRUNCATE, and TRUNC_TIMESTAMP (continued)

Format element	Rounding or truncating unit	ROUND example	TRUNCATE example
SYYYY YYYY YEAR SYEAR YYY YY Y	Year Rounds up on July 1st to January 1st of the next year. Not valid for TIME argument.	Input Value: 1897-12-04-12.22.22.000000 Result: 1898-01-01-00.00.00.000000	Input Value: 1897-12-04-12.22.22.000000 Result: 1897-01-01-00.00.00.000000
IYYY IYY IY I	ISO Year Rounds up on July 1st to the first day of the next ISO year. The first day of the ISO year is defined as the Monday of the first ISO week. Not valid for TIME argument.	Input Value: 1897-12-04-12.22.22.000000 Result: 1898-01-03-00.00.00.000000	Input Value: 1897-12-04-12.22.22.000000 Result: 1897-01-04-00.00.00.000000
Q	Quarter Rounds up on the 16th day of the second month of the quarter. Not valid for TIME argument.	Input Value: 1999-06-04-12.12.30.000000 Result: 1999-07-01-00.00.00.000000	Input Value: 1999-06-04-12.12.30.000000 Result: 1999-04-01-00.00.00.000000
MONTH MON MM RM	Month Rounds up on the 16th day of the month. Not valid for TIME argument.	Input Value: 1999-06-18-12.12.30.000000 Result: 1999-07-01-00.00.00.000000	Input Value: 1999-06-18-12.12.30.000000 Result: 1999-06-01-00.00.00.000000
WW	Same day of the week as the first day of the year. Rounds up on the 12th hour of the 4th day of the week, with respect to the first day of the year. Not valid for TIME argument.	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-06-00.00.00.000000	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-04-29-00.00.00.000000

Table 93. Format elements for ROUND, ROUND_TIMESTAMP, TRUNCATE, and TRUNC_TIMESTAMP (continued)

Format element	Rounding or truncating unit	ROUND example	TRUNCATE example
IW	Same day of the week as the first day of the ISO year. See "WEEK_ISO scalar function" for details. Rounds up on the 12th hour of the 4th day of the week, with respect to the first day of the ISO year. Not valid for TIME argument.	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-08-00.00.00.000000	Input Value: 2000-05-05-12.12.30.000000 Result: 2000-05-01-00.00.00.000000
W	Same day of the week as the first day of the month. Rounds up on the 12th hour of the 4th day of the week, with respect to the first day of the month. Not valid for TIME argument.	Input Value: 2000-06-21-12.12.30.000000 Result: 2000-06-22-00.00.00.000000	Input Value: 2000-06-21-12.12.30.000000 Result: 2000-06-15-00.00.00.000000
DDD DD J	Day Rounds up on the 12th hour of the day. Not valid for TIME argument.	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-18-00.00.00.000000	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-17-00.00.00.000000
DAY DY D	Starting day of the week. Rounds up with respect to the 12th hour of the 4th day of the week. The first day of the week is based on the locale (see *locale-name*). Not valid for TIME argument.	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-21-00.00.00.000000	Input Value: 2000-05-17-12.59.59.000000 Result: 2000-05-14-00.00.00.000000

Table 93. Format elements for ROUND, ROUND_TIMESTAMP, TRUNCATE, and TRUNC_TIMESTAMP (continued)

Format element	Rounding or truncating unit	ROUND example	TRUNCATE example
HH HH12 HH24	Hour Rounds up at 30 minutes.	Input Value: 2000-05-17-23.59.59.000000 Result: 2000-05-18-00.00.00.000000	Input Value: 2000-05-17-23.59.59.000000 Result: 2000-05-17-23.00.00.000000
MI	Minute Rounds up at 30 seconds.	Input Value: 2000-05-17-23.58.45.000000 Result: 2000-05-17-23.59.00.000000	Input Value: 2000-05-17-23.58.45.000000 Result: 2000-05-17-23.58.00.000000
SS	Second Rounds up at half a second.	Input Value: 2000-05-17-23.58.45.500000 Result: 2000-05-17-23.58.46.000000	Input Value: 2000-05-17-23.58.45.500000 Result: 2000-05-17-23.58.45.000000

Note: The format elements in Table 93 on page 486 must be specified in uppercase.

If a format element that applies to a time part of a value is specified for a date argument, the date argument is returned unchanged. If a format element that is not valid for a time argument is specified for a time argument, an error is returned (SQLSTATE 22007).

Notes

- **Determinism:** ROUND is a deterministic function. However, the following invocations of the function depend on the value of the special register CURRENT LOCALE LC_TIME.
  - Round of a datetime value when *locale-name* is not explicitly specified and one of the following is true:
    - *format-string* is not a constant
    - *format-string* is a constant and includes format elements that are locale sensitive

    Invocations of the function that depend on the value of a special register cannot be used wherever special registers cannot be used (SQLSTATE 42621, 428EC, or 429BX).

Examples

- *Example 1*: Calculate the value of 873.726, rounded to 2, 1, 0, -1, -2, -3, and -4 decimal places, respectively.

```
VALUES (
  ROUND(873.726, 2),
  ROUND(873.726, 1),
  ROUND(873.726, 0),
  ROUND(873.726,-1),
  ROUND(873.726,-2),
  ROUND(873.726,-3),
  ROUND(873.726,-4) )
```

This example returns:

```
1         2         3         4         5         6         7
--------- --------- --------- --------- --------- --------- ---------
  873.730   873.700   874.000   870.000   900.000  1000.000     0.000
```

- *Example 2*: Calculate using both positive and negative numbers.

```
   VALUES (
     ROUND(3.5, 0),
     ROUND(3.1, 0),
     ROUND(-3.1, 0),
     ROUND(-3.5,0) )
```

This example returns:

```
1    2    3    4
---- ---- ---- ----
 4.0  3.0 -3.0 -4.0
```

- *Example 3*: Calculate the decimal floating-point number 3.12350 rounded to three decimal places.

```
   VALUES (
     ROUND(DECFLOAT('3.12350'), 3))
```

This example returns:

```
1
-----
3.12400
```

- *Example 4*: Set the host variable RND_DT with the input date rounded to the nearest month value.

```
   SET :RND_DATE = ROUND(DATE('2000-08-16'), 'MONTH');
```

The value set is 2000-09-01.

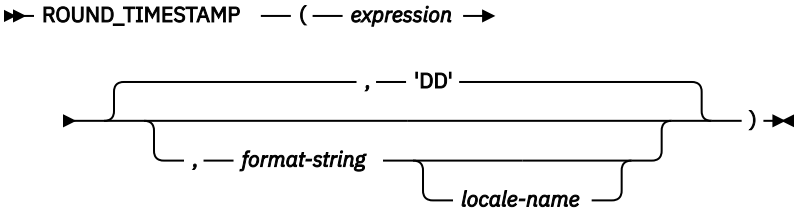
- *Example 5*: Set the host variable RND_TMSTMP with the input timestamp rounded to the nearest year value.

```
   SET :RND_TMSTMP = ROUND(TIMESTAMP('2000-08-14-17.30.00'),
                           'YEAR');
```

The value set is 2001-01-01-00.00.00.000000.

ROUND_TIMESTAMP

The ROUND_TIMESTAMP scalar function returns a TIMESTAMP based on a provided argument (*expression*), rounded to the unit specified in another argument (*format-string*).



The schema is SYSIBM.

If *format-string* is not specified, *expression* is rounded to the nearest day, as if `'DD'` is specified for *format-string*.

expression
An expression that returns a value of one of the following built-in data types: a DATE or a TIMESTAMP.

format-string
An expression that returns a built-in character string data type with an actual length that is not greater than 255 bytes. The format element in *format-string* specifies how *expression* should be rounded. For example, if format-string is `'DD'`, the timestamp that is represented by *expression* is rounded to the nearest day. Leading and trailing blanks are removed from the string, and the resulting substring must be a valid format element for a timestamp (SQLSTATE 22007). The default is `'DD'`.

Allowable values for *format-string* are listed in the table of format elements found in the description of the ROUND function.

locale-name
A character constant that specifies the locale used to determine the first day of the week when using format model values DAY, DY, or D. The value of *locale-name* is not case sensitive and must be a valid locale (SQLSTATE 42815). For information about valid locales and their naming, see "Locale names for SQL and XQuery". If *locale-name* is not specified, the value of the special register CURRENT LOCALE LC_TIME is used.

The result of the function is a TIMESTAMP with a timestamp precision of:

- *p* when the data type of *expression* is TIMESTAMP(*p*)
- 0 when the data type of *expression* is DATE
- 6 otherwise.

The result can be null; if any argument is null, the result is the null value.

Notes

- **Determinism:** ROUND_TIMESTAMP is a deterministic function. However, the following invocations of the function depend on the value of the special register CURRENT LOCALE LC_TIME.
  - Round of a date or timestamp value when *locale-name* is not explicitly specified and one of the following is true:
    - *format-string* is not a constant
    - *format-string* is a constant and includes format elements that are locale sensitive

    Invocations of the function that depend on the value of a special register cannot be used wherever special registers cannot be used (SQLSTATE 42621, 428EC, or 429BX).

Example

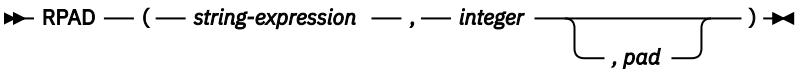
Set the host variable *RND_TMSTMP* with the input timestamp rounded to the nearest year value.

```
SET :RND_TMSTMP = ROUND_TIMESTAMP('2000-08-14-17.30.00', 'YEAR');
```

The value set is 2001-01-01-00.00.00.000000.

RPAD

The RPAD function returns a string composed of *string-expression* padded on the right, with *pad* or blanks.



The schema is SYSIBM.

The RPAD function treats leading or trailing blanks in *string-expression* as significant. Padding will only occur if the actual length of *string-expression* is less than *integer*, and *pad* is not an empty string.

string-expression
An expression that specifies the source string. The expression must return a value that is a built-in character string, graphic string, BINARY, VARBINARY, numeric, or datetime data type. CLOB and DBCLOB are supported through implicit casting. If the value is a CLOB, it is implicitly cast to VARCHAR before the function is evaluated. If the value is a DBCLOB, it is implicitly cast to VARGRAPHIC before the function is evaluated. If the data type of the *string-expression* value is numeric or datetime, the value is implicitly cast to VARCHAR before the function is evaluated. The data type of *string-expression* cannot be a BLOB (SQLSTATE 42815).

integer
An expression that specifies the actual length of the result in the string units of *string-expression*. The expression must return a value that is a built-in numeric, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported through implicit casting. If the expression is not of type INTEGER, it is cast to INTEGER before the function is evaluated. The value must be zero or a positive integer that is less than or equal to the maximum length for the result data type in the string units of *string-expression*.

pad
An expression that specifies the string with which to pad. The expression must return a value that is a built-in character string, graphic string, BINARY, VARBINARY, numeric, or datetime data type. CLOB and DBCLOB are supported through implicit casting. If the value is a CLOB, it is implicitly cast to VARCHAR before the function is evaluated. If the value is a DBCLOB, it is implicitly cast to VARGRAPHIC before the function is evaluated. If the data type of the *pad* value is numeric or datetime, the value is implicitly cast to VARCHAR before the function is evaluated. The data type of *pad* cannot be a BLOB (SQLSTATE 42815).

If *pad* is not specified, the pad character is determined as follows:

- SBCS blank character if *string-expression* is a character string.
- Ideographic blank character, if *string-expression* is a graphic string. For graphic string in an EUC database, X'3000' is used. For graphic string in a Unicode database, X'0020' is used.
- Hexadecimal zero (X'00'), if *string-expression* is a binary string.

The data type of the result depends on the data type of the *string-expression*:

- VARCHAR if the data type is VARCHAR or CHAR
- VARGRAPHIC if the data type is VARGRAPHIC or GRAPHIC
- VARBINARY if the data type is VARBINARY or BINARY

The result of the function is a varying length string that has the same string unit and code page as *string-expression*. The value of *string-expression* and the value of *pad* must have compatible data types. If the *string-expression* and *pad* have different code pages, then *pad* is converted to the code page of *string-expression*. If either *string-expression* or *pad* is FOR BIT DATA or binary, no character conversion occurs.

The length attribute of the result depends on whether the value for *integer* is available when the SQL statement containing the function invocation is compiled (for example, if it is specified as a constant or a constant expression) or available only when the function is executed (for example, if it is specified as the result of invoking a function). When the value is available when the SQL statement containing the function invocation is compiled, if *integer* is greater than zero, the length attribute of the result is *integer*. If *integer* is 0, the length attribute of the result is 1. When the value is available only when the function is executed, the length attribute of the result is determined according to the following table:

Table 94. Determining the result length when integer is available only when the function is executed

Data type of *string-expression*	**Result data type length**
CHAR(*n*) or VARCHAR(*n*), BINARY(*n*) or VARBINARY(*n*)	Minimum of *n*+100 and 32 672
GRAPHIC(*n*) or VARGRAPHIC(*n*)	Minimum of *n*+100 and 16 336

Table 94. Determining the result length when integer is available only when the function is executed (continued)

Data type of *string-expression*	Result data type length
CHAR(*n*) or VARCHAR(*n*) or GRAPHIC(*n*) or VARGRAPHIC(*n*) with string units of CODEUNITS32 (Unicode database only)	Minimum of *n*+100 and 8 168

The actual length of the result is determined from *integer*. If *integer* is 0 the actual length is 0, and the result is the empty result string. If *integer* is less than the actual length of *string-expression*, the actual length is *integer* and the result is truncated.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: Assume that NAME is a VARCHAR(15) column containing the values "Chris", "Meg", and "Jeff". The following query will completely pad out a value on the right with periods:

```
SELECT RPAD(NAME,15,'.' ) AS NAME FROM T1;
```

  returns:

```
NAME
---------------
Chris..........
Meg............
Jeff...........
```

- *Example 2*: Assume that NAME is a VARCHAR(15) column containing the values "Chris", "Meg", and "Jeff". The following query will completely pad out a value on the right with *pad* (note that in some cases there is a partial instance of the padding specification):

```
SELECT RPAD(NAME,15,'123' ) AS NAME FROM T1;
```

  returns:

```
NAME
---------------
Chris1231231231
Meg123123123123
Jeff12312312312
```

- *Example 3*: Assume that NAME is a VARCHAR(15) column containing the values "Chris", "Meg", and "Jeff". The following query will only pad each value to a length of 5:

```
SELECT RPAD(NAME,5,'.' ) AS NAME FROM T1;
```

  returns:

```
NAME
-----
Chris
Meg..
Jeff.
```

- *Example 4*: Assume that NAME is a CHAR(15) column containing the values "Chris", "Meg", and "Jeff". Note that the result of RTRIM is a varying length string with the blanks removed:

```
SELECT RPAD(RTRIM(NAME),15,'.' ) AS NAME FROM T1;
```

  returns:

```
NAME
---------------
```

```
Chris.....
Meg.......
Jeff......
```

- *Example 5*: Assume that NAME is a VARCHAR(15) column containing the values "Chris", "Meg", and "Jeff". Note that "Chris" is truncated, "Meg" is padded, and "Jeff" is unchanged:

```
SELECT RPAD(NAME,4,'.' ) AS NAME FROM T1;
```

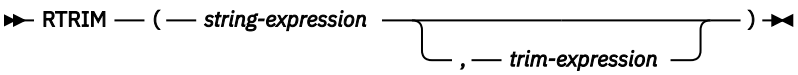
returns:

```
NAME
----
Chri
Meg.
Jeff
```

RTRIM

The RTRIM function removes any of the specified characters from the end of a string.

The RTRIM function removes any of the characters contained in a trim expression from the end of a string expression. The character search compares the binary representation of each character (consisting of one or more bytes) in the trim expression to the binary representation of each character (consisting of one or more bytes) at the end of the string expression. The database collation does not affect the search. If the string expression is defined as FOR BIT DATA or is a binary type, the search compares each byte in the trim expression to the byte at the end of the string expression.



The schema is SYSIBM. (The SYSFUN version of this function that uses a single parameter continues to be available with support for CLOB arguments.)

string-expression

An expression that specifies the source string.

- If only one argument is specified, the expression must return a built-in character string, graphic string, binary string, CLOB or DBCLOB value, Boolean value, numeric value, or datetime value. If the value is:
  - Not a CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, BINARY, VARBINARY, or DBCLOB value, it is implicitly cast to VARCHAR before the function is evaluated
  - A DBCLOB value, it is implicitly cast to VARGRAPHIC before the function is evaluated

  The data type of the string expression cannot be BLOB (SQLSTATE 42815).
- If both arguments are specified, the expression must return a built-in character string, Boolean value, numeric value, or datetime value. If the data type of the *string-expression* value is not a string data type, the value is implicitly cast to VARCHAR before the function is evaluated. The actual length of a CLOB value is limited to the maximum size of a VARCHAR data type (SQLSTATE 22001). The actual length of a BLOB value is limited to the maximum size of a VARBINARY data type (SQLSTATE 22001). The actual length of a DBCLOB value is limited to the maximum size of a VARGRAPHIC data type (SQLSTATE 22001).

trim-expression

An expression that specifies the characters that are being removed from the end of a *string-expression*. The expression must be a value that is a built-in string, numeric, or datetime data type.

- If the data type of the *trim-expression* is not a string, then the value is implicitly cast to VARCHAR before the function is evaluated.
- If the data type of the *trim-expression* is a CLOB, then the actual length of the value is limited to the maximum size of a VARCHAR (SQLSTATE 22001).

- If the data type of the *trim-expression* is a DBCLOB, then the actual length of the value is limited to the maximum size of a VARGRAPHIC (SQLSTATE 22001).
- If the data type of *trim-expression* is a BLOB, then the actual length of the value is limited to the maximum size of a VARBINARY (SQLSTATE 22001).
- If the *string-expression* is not defined as FOR BIT DATA, then the *trim-expression* cannot be defined as FOR BIT DATA (SQLSTATE 42815).

When a *trim-expression* is not specified, the data type of the *string-expression* determines the default value used:

- A double byte blank if the *string-expression* is a graphic string in a DBCS or EUC database
- A UCS-2 blank if the *string-expression* is a graphic string in a Unicode database
- A value of X'20' if the *string-expression* is a FOR BIT DATA string
- A value of X'00' if the *string-expression* is a binary string
- A single-byte blank for all other cases

The *string-expression* and *trim-expression* values must have compatible data types. If one of these arguments is a FOR BIT DATA character string, the other argument cannot be a graphic string (SQLSTATE 42846). A combination of character string and graphic string arguments can be used only in a Unicode database (SQLSTATE 42815).

Result

The data type of the result depends on the data type of the *string-expression*.

- VARCHAR if the data type is VARCHAR or CHAR
- CLOB if the data type is CLOB
- VARBINARY if the data type is VARBINARY or BINARY
- BLOB if the data type is BLOB
- VARGRAPHIC if the data type is VARGRAPHIC or GRAPHIC
- DBCLOB if the data type is DBCLOB

The length attribute of the result data type is the same as the length attribute of the *string-expression* data type.

The actual length of the result for character or binary strings is the length of *string-expression* minus the number of string units removed. The actual length of the result for graphic strings is the length of *string-expression* minus the number of string units removed. If all of the characters are removed, the result is an empty string with a length of zero.

If any argument can be null, the result can be null; if any argument is null, the result is the null value.

Examples

- *Example 1*: Use the RTRIM function when the host variable HELLO is defined as CHAR(6) and has a value of 'Hello '.

```
VALUES RTRIM(:HELLO)
```

  The result is 'Hello'. When a *trim-expression* is not specified only blanks are removed. The host variable is declared as CHAR(9) and is blank-padded up to 9 bytes.
- *Example 2*: Use the RTRIM function to remove the characters specified in the *trim-expression* from the end of the *string-expression*.

```
VALUES RTRIM('...$VAR$...', '$.')
```

  The result is `'...$VAR'`.

- *Example 3*: Use the RTRIM function to remove the characters specified in the *trim-expression* from the end of the *string-expression*.

```
VALUES RTRIM('((-78.0) )', '-0. ()')
```

The result is `'((-78'`. When removing characters and blanks, you must include a blank in the *trim-expression*.

RTRIM (SYSFUN schema)

Returns the characters of the argument with trailing blanks removed.

The schema is SYSFUN.

expression
The *expression* can be of any built-in character string data type. For a VARCHAR the maximum length is 4 000 bytes and for a CLOB the maximum length is 1 048 576 bytes.

The result of the function is:

- VARCHAR(4000) if *expression* is VARCHAR (not exceeding 4 000 bytes) or CHAR
- CLOB(1M) if *expression* is CLOB or LONG VARCHAR

The result can be null; if *expression* is null, the result is the null.

SECLABEL

The SECLABEL function returns an unnamed security label with a data type of DB2SECURITYLABEL. Use the SECLABEL function to insert a security label with given component values without having to create a named security label.

The schema is SYSIBM.

security-policy-name
A string that specifies a security policy that exists at the current server (SQLSTATE 42704). The string must be a character or graphic string constant or host variable.

security-label-string
An expression that returns a valid representation of a security label for the security policy named by *security-policy-name* (SQLSTATE 4274I). The expression must return a value that is a built-in CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type.

Examples

- *Example 1*: The following statement inserts a row in table REGIONS which is protected by the security policy named CONTRIBUTIONS. The security label for the row to be inserted is given by the SECLABEL function. The security policy CONTRIBUTIONS has two components. The security label given has the element LIFE MEMBER for first component, the elements BLUE and YELLOW for the second component.

```
INSERT INTO REGIONS
  VALUES (SECLABEL('CONTRIBUTIONS', 'LIFE MEMBER:(BLUE,YELLOW)'),
    1, 'Northeast')
```

- *Example 2*: The following statement inserts a row in table CASE_IDS which is protected by the security policy named TS_SECPOLICY, which has three components. The security label is provided by the

SECLABEL function. The security label inserted has the element HIGH PROFILE for the first component, the empty value for the second component and the element G19 for the third component.

```
INSERT INTO CASE_IDS
  VALUES (SECLABEL('TS_SECPOLICY', 'HIGH PROFILE:():G19') , 3, 'KLB')
```

SECLABEL_BY_NAME

The SECLABEL_BY_NAME function returns the specified security label. The security label returned has a data type of DB2SECURITYLABEL. Use this function to insert a named security label.

The schema is SYSIBM.

security-policy-name
A string that specifies a security policy that exists at the current server (SQLSTATE 42704). The string must be a character or graphic string constant or host variable.

security-label-name
An expression that returns the name of a security label that exists at the current server for the security policy named by *security-policy-name* (SQLSTATE 4274I). The expression must return a value that is a built-in CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type.

Examples

In the following examples, Tina is trying to insert a row in table REGIONS which is protected by the security policy named CONTRIBUTIONS. Tina wants the row to be protected by the security label named EMPLOYEESECLABEL.

- *Example 1*: This statement fails because CONTRIBUTIONS.EMPLOYEESECLABEL is an unknown identifier:

```
INSERT INTO REGIONS
VALUES (CONTRIBUTIONS.EMPLOYEESECLABEL, 1, 'Southwest')   -- incorrect
```

- *Example 2*: This statement fails because the first value is a string, it does not have a data type of DB2SECURITYLABEL:

```
INSERT INTO REGIONS
VALUES ('CONTRIBUTIONS.EMPLOYEESECLABEL', 1, 'Southwest') -- incorrect
```

- *Example 2*: This statement succeeds because the SECLABEL_BY_NAME function returns a security label that has a data type of DB2SECURITYLABEL:

```
INSERT INTO REGIONS
VALUES (SECLABEL_BY_NAME('CONTRIBUTIONS', 'EMPLOYEESECLABEL'),
  1, 'Southwest')                                        -- correct
```

SECLABEL_TO_CHAR

The SECLABEL_TO_CHAR function accepts a security label and returns a string that contains all elements in the security label. The string is in the security label string format.

The schema is SYSIBM.

security-policy-name
A string that specifies a security policy that exists at the current server (SQLSTATE 42704). The string must be a character or graphic string constant or host variable.

security-label
An expression that returns a security label value that is valid for the security policy named by *security-policy-name* (SQLSTATE 4274I). The expression must return a value that is a built-in SYSPROC.DB2SECURITYLABEL distinct type.

The result of the function is VARCHAR(32672 OCTETS). The result can be null; if the second argument is null, the result is the null value.

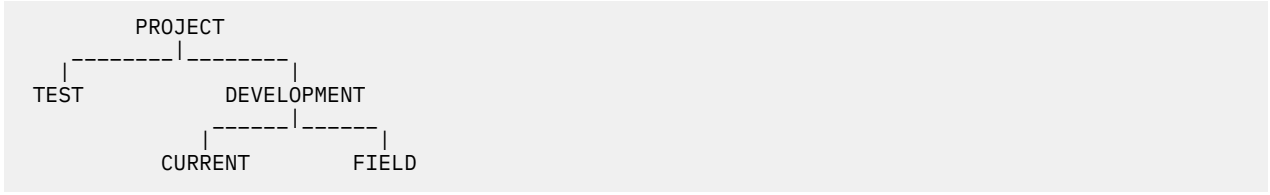
Notes

- If the authorization ID of the statement executes this function on a security label being read from a column with a data type of DB2SECURITYLABEL then that authorization ID's LBAC credentials might affect the output of the function. In such a case an element is not included in the output if the authorization ID does not have read access to that element. An authorization ID has read access to an element if its LBAC credentials would allow it to read data that was protected by a security label containing only that element, and no others.

  For the rule set DB2LBACRULES only components of type TREE can contain elements that you do not have read access to. For other types of component, if any one of the elements block read access then you will not be able to read the row at all. So only components of type tree will have elements excluded in this way.

Example

The EMP table has two columns, RECORDNUM and LABEL; RECORDNUM has data type INTEGER, and LABEL has type DB2SECURITYLABEL. Table EMP is protected by security policy DATA_ACCESSPOLICY, which uses the DB2LBACRULES rule set and has only one component (GROUPS, of type TREE). GROUPS has five elements: PROJECT, TEST, DEVELOPMENT, CURRENT, AND FIELD. The following diagram shows the relationship of these elements to one another:



The EMP table contains the following data:

```
RECORDNUM  LABEL
---------  ----------------
        1  PROJECT
        2  (TEST, FIELD)
        3  (CURRENT, FIELD)
```

The user whose ID is Djavan holds a security label for reading that contains only the DEVELOPMENT element. This means that Djavan has read access to the DEVELOPMENT, CURRENT, and FIELD elements:

```
   SELECT RECORDNUM, SECLABEL_TO_CHAR('DATA_ACCESSPOLICY', LABEL) FROM EMP
```

returns:

```
RECORDNUM  LABEL
---------  ----------------
        2  FIELD
        3  (CURRENT, FIELD)
```

The row with a RECORDNUM value of 1 is not included in the output, because Djavan's LBAC credentials do not allow him to read that row. In the row with a RECORDNUM value of 2, element TEST is not included in the output, because Djavan does not have read access to that element; Djavan would not have been able to access the row at all if TEST were the only element in the security label. Because Djavan has read access to elements CURRENT and FIELD, both elements appear in the output.

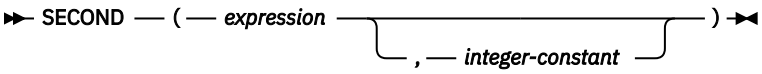
Now Djavan is granted an exemption to the DB2LBACREADTREE rule. This means that no element of a TREE type component will block read access. The same query returns:

```
RECORDNUM  LABEL
---------  ----------------
        1  PROJECT
        2  (TEST, FIELD)
        3  (CURRENT, FIELD)
```

This time the output includes all rows and all elements, because the exemption gives Djavan read access to all of the elements.

SECOND

The SECOND function returns the seconds part of a value with optional fractional seconds.



The schema is SYSIBM.

expression
An expression that returns a value of one of the following built-in data types: DATE, TIME, TIMESTAMP, time duration, timestamp duration, or a valid character string representation of a date, time, or timestamp that is not a CLOB. If *expression* is a DATE or a valid string representation of a date, it is first converted to a TIMESTAMP(0) value, assuming a time of exactly midnight (00.00.00). If expression is a valid string representation of a timestamp, it is first converted to a TIMESTAMP(12) value. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

integer-constant
An integer constant representing the scale for the fractional seconds. The value must be in the range 0 through 12.

The result of the function with a single argument is a large integer. The result of the function with two arguments is DECIMAL(2+*s*,*s*) where *s* is the value of the *integer-constant*. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The other rules depend on the data type of the first argument and the number of arguments:

- If the first argument is a DATE, TIME, TIMESTAMP, or valid string representation of a date, time, or timestamp:
  - If only one argument is specified, the result is the seconds part of the value (0 and 59).
  - If both arguments are specified, the result is the seconds part of the value (0 to 59) and *integer-constant* digits of the fractional seconds part of the value where applicable. If there are no fractional seconds in the value, then zeros are returned.
- If the first argument is a time duration or timestamp duration:
  - If only one argument is specified, the result is the seconds part of the value (-99 to 99).
  - If both arguments are specified, the result is the seconds part of the value (-99 to 99) and *integer-constant* digits of the fractional seconds part of the value where applicable. If there are no fractional seconds in the value then zeros are returned. A nonzero result has the same sign as the argument.

Examples

- *Example 1*: Assume that the host variable TIME_DUR (decimal(6,0)) has the value 153045.

```
SELECT SECOND(:TIME_DUR)
  FROM SYSIBM.SYSDUMMY1
```

  Returns the value 45.

- *Example 2*: Assume that the column RECEIVED (whose data type is TIMESTAMP) has an internal value equivalent to 1988-12-25-17.12.30.000000.

```
SELECT SECOND(RECEIVED)
  FROM IN_TRAY
```

  Returns the value 30.

- *Example 3*: Get the seconds with fractional seconds from a current timestamp with milliseconds.

```
SELECT SECOND (CURRENTTIMESTAMP(3), 3)
  FROM SYSIBM.SYSDUMMY1
```

  Returns a DECIMAL(5,3) value based on the current timestamp that could be something like 54.321.

SECONDS_BETWEEN

The SECONDS_BETWEEN function returns the number of full seconds between the specified arguments.

The schema is SYSIBM.

expression1
An expression that specifies the first datetime value to compute the number of full seconds between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression1* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

expression2
An expression that specifies the second datetime value to compute the number of full seconds between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression2* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

If there is less than a full second between *expression1* and *expression2*, the result is zero. If *expression1* is later than *expression2*, the result is positive. If *expression1* is earlier than *expression2*, the result is negative. In NPS compatibility mode, this function always returns a positive number. If *expression1* or *expression2* contains time information, this information is also used to determine the number of full seconds. If *expression1* or *expression2* does not contain time information, a time of midnight (00.00.00) is used for the argument that is missing time information.

The result of the function is a BIGINT. If either argument can be null, the result can be null. If either argument is null, the result is the null value.

Examples

1. Set the host variable NUM_SECONDS to the number of full seconds between 2012-03-01-01.00.00 and 2012-02-28-00.00.00.

```
SET :NUM_SECONDS = SECONDS_BETWEEN(TIMESTAMP '2012-03-01-01.00.00',
                                   TIMESTAMP '2012-02-28-00.00.00')
```

   The host variable NUM_SECONDS is set to 176400; 86400 of the seconds are incurred because of February 29, 2012.

2. Set the host variable NUM_SECONDS to the number of full seconds between 2013-09-11-23.59.59.999999 and 2013-09-01-00.00.00.000000.

```
SET :NUM_SECONDS = SECONDS_BETWEEN(TIMESTAMP '2013-09-11-23.59.59.999999',
                                   TIMESTAMP '2013-09-01-00.00.00.000000')
```

The host variable NUM_SECONDS is set to 950399 because there are 0.000001 seconds less than a full 950400 seconds between the arguments. It is positive because the first argument is later than the second argument.

3. Set the host variable NUM_SECONDS to the number of full seconds between 2013-09-01-00.00.00.000000 and 2013-09-11-23.59.59.999999.

```
SET :NUM_SECONDS = SECONDS_BETWEEN(TIMESTAMP '2013-09-01-00.00.00.000000',
                                   TIMESTAMP '2013-09-11-23.59.59.999999')
```

The host variable NUM_SECONDS is set to -950399 because there are 0.000001 seconds less than a full 950400 seconds between the arguments. It is negative because the first argument is earlier than the second argument.

SIGN

Returns an indicator of the sign of the argument.

The schema is SYSIBM. (The SYSFUN version of the SIGN function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type. DECIMAL and REAL values are converted to double-precision floating-point numbers for processing by the function.

If the argument is less than zero, -1 is returned. If the argument is the decimal floating-point value of -0, the decimal floating-point value of -0 is returned. If argument equals zero, 0 is returned. If argument is greater than zero, 1 is returned.

The result of the function is:

- SMALLINT if the argument is SMALLINT
- INTEGER if the argument is INTEGER
- BIGINT if the argument is BIGINT
- DECFLOAT(*n*) if the argument is DECFLOAT(*n*)
- DOUBLE otherwise.

The result can be null; if the argument is null, the result is the null value.

Example

Assume that host variable PROFIT is a large integer with a value of 50000.

```
VALUES SIGN(:PROFIT)
```

Returns the value 1.

SIN

Returns the sine of the argument, where the argument is an angle expressed in radians.

The schema is SYSIBM. (The SYSFUN version of the SIN function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

The result of the function is a double-precision floating-point number. The result can be null if the argument can be null or the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

SINH

Returns the hyperbolic sine of the argument, where the argument is an angle expressed in radians.

The schema is SYSIBM.

expression
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

The result of the function is a double-precision floating-point number. The result can be null if the argument can be null or the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

SMALLINT

The SMALLINT function returns a small integer (a binary integer with a precision of 15 bits) representation of a value of a different data type.

Numeric to SMALLINT

String to SMALLINT

Boolean to SMALLINT

The schema is SYSIBM.

Numeric to SMALLINT

numeric-expression
An expression that returns a value of any built-in numeric data type.

The result is the same number that would occur if the argument were assigned to a small integer column or variable. The fractional part of the argument is truncated. If the whole part of the argument is not within the range of small integers, an error is returned (SQLSTATE 22003).

String to SMALLINT

string-expression
An expression that returns a value that is a character-string or Unicode graphic-string representation of a number with a length not greater than the maximum length of a character constant.

The result is the same number that would result from CAST(*string-expresssion* AS SMALLINT). Leading and trailing blanks are eliminated and the resulting string must conform to the rules for forming an integer, decimal, floating-point, or decimal floating-point constant (SQLSTATE 22018). If the whole part of the argument is not within the range of small integers, an error is returned (SQLSTATE 22003). The data type of *string-expression* must not be CLOB or DBCLOB (SQLSTATE 42884).

Boolean to SMALLINT

boolean-expression
An expression that returns a Boolean value (TRUE or FALSE). The result is either 1 (for TRUE) or 0 (for FALSE).

Result

The result of the function is a small integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

Notes

- **Increasing portability of applications:** If the first argument is numeric, or if the first argument is a string and the length argument is specified, use the "CAST specification" on page 152 instead of this function to increase the portability of your applications.

Examples

- *Example 1*: Using the EMPLOYEE table, select a list containing salary (SALARY) divided by education level (EDLEVEL). Truncate any decimal in the calculation. The list should also contain the values used in the calculation and the employee number (EMPNO).

```
SELECT SMALLINT(SALARY / EDLEVEL), SALARY, ESDLEVEL, EMPNO
  FROM EMPLOYEE
```

- *Example 2*: The following statement returns the value 1 of data type SMALLINT.

```
values SMALLINT(TRUE)
```

- *Example 3*: The following statement returns the value 0 of data type SMALLINT.

```
values SMALLINT(3>3)
```

SOUNDEX

Returns a 4-character code representing the sound of the words in the argument. The result can be used to compare with the sound of other strings.

The schema is SYSFUN.

expression
An expression that returns a value of CHAR or VARCHAR data type. The length of the value must not exceed 4 000 bytes. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed. The function interprets data that is passed to it as if it were ASCII characters, even if it is encoded in UTF-8.

The result of the function is CHAR(4). The result can be null; if the argument is null, the result is the null value.

The SOUNDEX function is useful for finding strings for which the sound is known but the precise spelling is not. It makes assumptions about the way that letters and combinations of letters sound that can help to search out words with similar sounds. The comparison can be done directly or by passing the strings as arguments to the DIFFERENCE function.

Example

Using the EMPLOYEE table, find the EMPNO and LASTNAME of the employee with a surname that sounds like 'Loucesy'.

```
SELECT EMPNO, LASTNAME FROM EMPLOYEE
  WHERE SOUNDEX(LASTNAME) = SOUNDEX('Loucesy')
```

This example returns the following output:

```
EMPNO  LASTNAME
------ ---------------
000110 LUCCHESSI
```

SPACE

Returns a character string consisting of blanks with length specified by the argument.

The schema is SYSFUN.

expression
An expression that returns a value of built-in SMALLINT or INTEGER data type.

The result of the function is VARCHAR(4000 OCTETS). The result can be null; if the argument is null, the result is the null value.

SQRT

The SQRT function returns the square root of a number.

The schema is SYSIBM. (The SYSFUN version of the SQRT function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type. If the argument is decimal floating-point, the operation is performed in decimal floating-point; otherwise, the argument is converted to double-precision floating-point for processing by the function.

If the argument is DECFLOAT(*n*), the result is DECFLOAT(*n*); otherwise, the result is a double-precision floating-point number.

The result can be null; if the argument is null, the result is the null value.

Notes

- ***Results involving DECFLOAT special values:*** If the argument is a special decimal floating-point value, the rules for general arithmetic operations for decimal floating-point apply. See "General arithmetic operation rules for decimal floating-point" on page 142 in "Expressions" on page 132.

Example

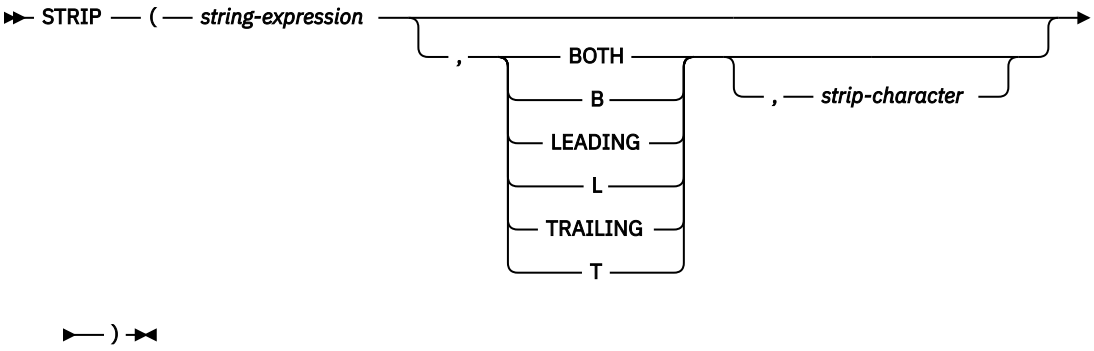
Assume that SQUARE is a DECIMAL(2,1) host variable with a value of 9.0.

```
VALUES SQRT(:SQUARE)
```

Returns the approximate value 3.00.

STRIP

The STRIP function removes blanks or another specified character from the end, the beginning, or both ends of a string expression.



The schema is SYSIBM. The function name cannot be specified as a qualified name when keywords are used in the function signature.

The STRIP function is identical to the TRIM scalar function.

string-expression
An expression that specifies the string from which the result is derived. The expression must return a value that is a built-in CHAR, VARCHAR, BINARY, VARBINARY, GRAPHIC, VARGRAPHIC, numeric, or datetime data type. If the value is not a CHAR, VARCHAR, BINARY, VARBINARY, GRAPHIC, or VARGRAPHIC data type, it is cast to VARCHAR before the function is evaluated.

BOTH, LEADING, or TRAILING
Specifies whether characters are removed from the beginning, the end, or from both ends of the string expression. If this argument is not specified, the characters are removed from both the end and the beginning of the string.

strip-character
A single-character constant that specifies the character that is to be removed. The *strip-character* can be any character whose UTF-32 encoding is a single character or a single digit numeric value. The binary representation of the character is matched.

If *strip-character* is not specified and:

- If the *string-expression* is a DBCS graphic string, the default *strip-character* is a DBCS blank, whose code point is dependent on the database code page
- If the *string-expression* is a UCS-2 graphic string, the default *strip-character* is a UCS-2 blank (X'0020')
- If the *string-expression* is a binary string, the default *strip-character* is a hexadecimal zero (X'00')
- Otherwise, the default *strip-character* is an SBCS blank (X'20')

The value for *string-expression* and the value for *strip-character* must have compatible data types.

The data type of the result depends on the data type of the *string-expression*:

- VARCHAR if the data type is VARCHAR or CHAR
- VARGRAPHIC if the data type is VARGRAPHIC or GRAPHIC
- VARBINARY if the data type is VARBINARY or BINARY

The result is a varying-length string with the same maximum length as the length attribute of the *string-expression*. The actual length of the result is the length of the *string-expression* minus the number of string units that are removed. If all of the characters are removed, the result is an empty varying-length string. The code page of the result is the same as the code page of the *string-expression*.

Example

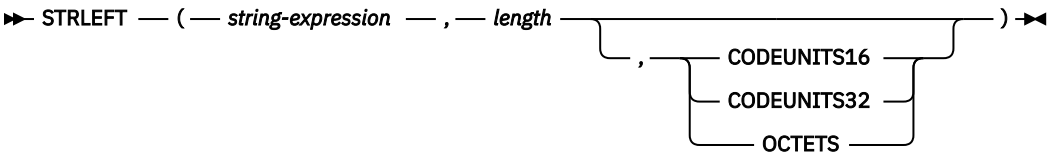
Assume that the host variable BALANCE of type CHAR(9) has a value of '000345.50'.

```
SELECT STRIP(:BALANCE, LEADING, '0'),
FROM SYSIBM.SYSDUMMY1
```

returns the value '345.50'.

STRLEFT

The STRLEFT function returns the leftmost string of *string-expression* of length *length*, expressed in the specified string unit.



The schema is SYSIBM.

The STRLEFT scalar function is a synonym for the LEFT scalar function.

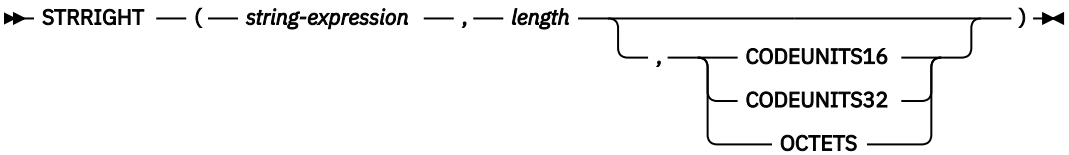
STRPOS

The schema is SYSIBM.

STRPOS is a synonym for POSSTR.

STRRIGHT

The STRRIGHT function returns the right most string of *string-expression* of length *length*, expressed in the specified string unit.

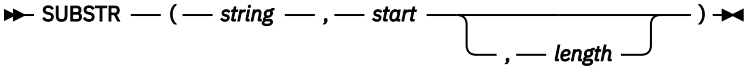


The schema is SYSIBM.

The STRRIGHT scalar function is a synonym for the RIGHT scalar function.

SUBSTR

The SUBSTR function returns a substring of a string.



The schema is SYSIBM.

string
The input expression, which specifies the string from which the substring is to be derived. The expression must return a value that is a built-in character string, numeric value, Boolean value, or datetime value. If the value is not a character string, it is implicitly cast to VARCHAR before the

function is evaluated. Any number (zero or more) contiguous string units of this expression constitute a substring of this expression.

start
An expression that specifies the position, relative to the beginning of the input expression, from which the substring is to be calculated. For example:

- Position 1 is the first string unit of the input expression. The statement SUBSTR('abcd',1,2) returns 'ab'.
- Position 2 is one position to the right of position 1. The statement SUBSTR('abcd',2,2) returns 'bc'.

The expression must return a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

length
An expression that specifies the length of the result. If specified, the expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. The value of the integer must be in the range of 0 to *n*, where *n* equals (the length attribute of *string* in string units) - *start* + 1 (SQLSTATE 22011 if out of range).

If *length* is explicitly specified, *string* is effectively padded on the right with the necessary number of blank characters (single-byte for character strings; double-byte for graphic strings) or hexadecimal zero characters (for binary strings) so that the specified substring exists. The default length is the number of string units from the string unit specified by *start* to the last string unit of *string*. However, if *string* is a varying-length string with a length less than *start*, the default is zero and the result is the empty string. It must be specified as number of string units in the context of the database code page and not the application code page. (For example, the column NAME with a data type of VARCHAR(18) and a value of 'MCKNIGHT' will yield an empty string with SUBSTR(NAME,10)).

If *string* is:

- A fixed-length string, the default length is LENGTH(*string*) - *start* + 1
- A varying-length string, the default length is either zero or LENGTH(*string*) - *start* + 1, whichever is greater.

Result

If *string* is a character string, the result is a character string represented in the code page and string units of its first argument. If it is a binary string, the result is a binary string. If it is a graphic string, the result is a graphic string represented in the code page and string units of its first argument. If the first argument is a host variable that is not a binary string and not a FOR BIT DATA character string, the code page of the result is the database code page. If any argument of the SUBSTR function can be null, the result can be null; if any argument is null, the result is the null value.

Table 95 on page 507 shows that the result type and length of the SUBSTR function depend on the type and attributes of its inputs.

Table 95. Data Type and Length of SUBSTR Result

String Argument Data Type	Length Argument	Result Data Type
CHAR(A)	constant (*l*<*n*) If the units of *string* are: • OCTETS, *n*=256 • CODEUNITS32, *n*=64	CHAR(*l*)
CHAR(A)	not specified but *start* argument is a constant	CHAR(A-*start*+1)
CHAR(A)	not a constant	VARCHAR(A)

Table 95. Data Type and Length of SUBSTR Result (continued)

String Argument Data Type	Length Argument	Result Data Type
VARCHAR(A)	constant (*l*<*n*) If the units of *string* are: • OCTETS, *n*=256 • CODEUNITS32, *n*=64	CHAR(*l*)
VARCHAR(A)	constant (*m*<*l*<*n*) If the units of *string* are: • OCTETS, *m*=256 and *n*=32673 • CODEUNITS32, *m*=63 and *n*=8169	VARCHAR(*l*)
VARCHAR(A)	not a constant or not specified	VARCHAR(A)
CLOB(A)	constant (*l*)	CLOB(*l*)
CLOB(A)	not a constant or not specified	CLOB(A)
GRAPHIC(A)	constant (*l*<*n*) If the units of *string* are: • double-bytes or CODEUNITS16, *n*=128 • CODEUNITS32, *n*=64	GRAPHIC(*l*)
GRAPHIC(A)	not specified but *start* argument is a constant	GRAPHIC(A-*start*+1)
GRAPHIC(A)	not a constant	VARGRAPHIC(A)
VARGRAPHIC(A)	constant (*l*<*n*) If the units of *string* are: • double-bytes or CODEUNITS16, *n*=128 • CODEUNITS32, *n*=64	GRAPHIC(*l*)
VARGRAPHIC(A)	constant (*m*<*l*<*n*) If the units of *string* are: • double-bytes or CODEUNITS16, *m*=127 and *n*=16337 • CODEUNITS32, *m*=63 and *n*=8169	VARGRAPHIC(*l*)
VARGRAPHIC(A)	not a constant	VARGRAPHIC(A)
DBCLOB(A)	constant (*l*)	DBCLOB(*l*)
DBCLOB(A)	not a constant or not specified	DBCLOB(A)
BINARY(A)	constant (*l*<256)	BINARY(*l*)
BINARY(A)	not specified but *start* argument is a constant	BINARY(A-*start*+1)
BINARY(A)	not a constant	VARBINARY(A)
VARBINARY(A)	constant (*l*<256)	BINARY(*l*)
VARBINARY(A)	constant (255<*l*<32673)	VARBINARY(*l*)
VARBINARY(A)	not a constant or not specified	VARBINARY(A)
BLOB(A)	constant (*l*)	BLOB(*l*)

Table 95. Data Type and Length of SUBSTR Result (continued)

String Argument Data Type	Length Argument	Result Data Type
BLOB(A)	not a constant or not specified	BLOB(A)

Note: The LONG VARCHAR and LONG VARGRAPHIC data types continue to be supported but are deprecated and not recommended.

Notes

- In dynamic SQL, *string*, *start*, and *length* can be represented by a parameter marker. If a parameter marker is used for *string*, the data type of the operand will be VARCHAR, and the operand will be nullable.
- Though not explicitly stated in the result definitions mentioned previously, the semantics imply that if *string* is a mixed single- and multi-byte character string, the result might contain fragments of multi-byte characters, depending upon the values of *start* and *length*. For example, the result could possibly begin with the second byte of a multi-byte character, or end with the first byte of a multi-byte character. The SUBSTR function does not detect such fragments, nor provide any special processing should they occur.

Examples

- *Example 1*: Assume that the host variable `NAME (VARCHAR(50))` has the value `'BLUE JAY'`:
  - The following statement returns the value `'BLUE'`:

    ```
    SUBSTR(:NAME,1,4)
    ```

  - The following statement returns the value `'JAY'`:

    ```
    SUBSTR(:NAME,6)
    ```

  - The following statement returns the value `'JA'`:

    ```
    SUBSTR(:NAME,6,2)
    ```

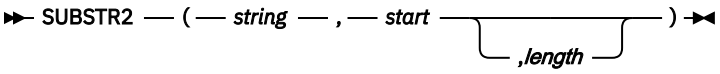
- *Example 2*: Select all rows from the PROJECT table for which the project name (PROJNAME) starts with the word 'OPERATION'.

  ```
  SELECT * FROM PROJECT
    WHERE SUBSTR(PROJNAME,1,10) = 'OPERATION '
  ```

  The space at the end of the constant is necessary to exclude words such as 'OPERATIONAL'.

SUBSTR2

The SUBSTR2 function returns a substring from a string. The resulting substring starts at a specified position in the string and continues for a specified or default length. The start and length arguments are expressed in 16-bit UTF-16 string units (CODEUNITS16).



The schema is SYSIBM.

string
An expression that specifies the string from which the resulting substring is derived. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. A character string cannot have the FOR BIT DATA attribute (SQLSTATE 428GC). If the value is not a

string data type, it is implicitly cast to VARCHAR before evaluating the function. A substring of *string* is zero or more contiguous bytes of *string*.

start
An expression that specifies the starting position in *string* for the beginning of the result substring in 16-bit UTF-16 string units. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

If *start* is positive, then the starting position is calculated from the beginning of the string. If *start* is greater than the length of *string* in 16-bit UTF-16 string units, then a zero length string is returned.

If *start* is negative, then the starting position is calculated from the end of the string by counting backwards. If the absolute value of *start* is greater than the length of *string* in 16-bit UTF-16 string units, then a zero length string is returned.

If *start* is 0, then a starting position of 1 is used.

length
An expression that specifies the length of the resulting substring in 16-bit UTF-16 string units. If *length* is specified, the expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

If the value for *length* is greater than the number of 16-bit UTF-16 string units from the starting position to the end of the string, then the length of the resulting substring is the length of the first argument in 16-bit UTF-16 string units minus the starting position plus one.

If the value for *length* is less than or equal to zero, the result is a zero length string.

The default value for *length* is the number of CODEUNITS16 from the position specified by *start* to the last byte of *string*.

If *string* is a CHAR or VARCHAR data type, the result of the function is a VARCHAR data type. If *string* is a CLOB, the result of the function is a CLOB. If *string* is a GRAPHIC or VARGRAPHIC data type, the result of the function is a VARGRAPHIC data type. If *string* is a DBCLOB, the result of the function is a DBCLOB. If the first argument is a host variable, the code page of the result is the section code page; otherwise, it is the code page of the first argument.

The length attribute of the result is the same as the length attribute of the first argument, unless the start or length arguments are specified as constants. When a constant is specified, the length attribute of the result is based on the first applicable row in the following table.

Table 96. Length Attribute of SUBSTR2 Result when Arguments Include Constants

String Argument	Start Argument[1]	Length Argument	Length Attribute of Result[2]
character type with length attribute A	any valid argument	constant value L<=0	0
character type with length attribute A	constant value S and |(S)|>A	not specified or any valid argument	0
character type with length attribute A	not a constant	constant value L>0	MIN(A, L×4)
character type with length attribute A	constant value S>0	not specified or not a constant	A-S+1
character type with length attribute A	constant value S<0	not specified or not a constant	MIN(A, |(S)×4|)
character type with length attribute A	constant value S>0	constant value L>0	MIN(A-S+1, L×4)

Table 96. Length Attribute of SUBSTR2 Result when Arguments Include Constants (continued)

String Argument	Start Argument[1]	Length Argument	Length Attribute of Result[2]
character type with length attribute A	constant value S<0	constant value L>0	MIN(A,|(S)×4|, L×4)
graphic type with length attribute A	any valid argument	constant value L<=0	0
graphic type with length attribute A	constant value S and |(S)|>A	not specified or any valid argument	0
graphic type with length attribute A	not a constant	constant value L>0	MIN(A, L)
graphic type with length attribute A	constant value S>0	not specified or not a constant	A-S+1
graphic type with length attribute A	constant value S<0	not specified or not a constant	|(S)|
graphic type with length attribute A	constant value S>0	constant value L>0	MIN(A-S+1, L)
graphic type with length attribute A	constant value S<0	constant value L>0	MIN(|(S)|, L)|

Notes:

[1] If a start argument value of 0 is specified, then use a value of 1 for S when referencing this table.

[2] The length attribute of the result for some of the character result types involves a constant that is multiplied by a factor of 4. This multiplier covers the worst case expansion derived from the following factors:

- Multiplying by 2 to switch from counting in 16-bit UTF-16 string units to counting in bytes used for the length attributes of a character data type.
- Multiplying by 2 again because a 2-byte character in UTF-16 can be represented by up to 4 bytes in a character string.

If any argument of the SUBSTR2 function can be null, the result can be null. If any argument is null, the result is the null value.

Notes

- In dynamic SQL, *string*, *start*, and *length* can be represented by a parameter marker. If an untyped parameter marker is used for string, the operand will be nullable and if the database supports graphic data types the data type of the operand will be VARGRAPHIC(16336). Otherwise, the data type will be VARCHAR(32672).
- If *string* is a mixed single-byte and multi-byte character string, the result might contain fragments of multi-byte characters depending on the values of *start* and *length*. For example, the result might begin with the third byte of a multi-byte character, or end with the first byte of a multi-byte character. The SUBSTR2 function detects these partial characters and replaces each byte of an incomplete character with a single blank character.
- SUBSTR2 is similar to the SUBSTR function, with the following exceptions:
  - SUBSTR2 supports a negative start value, which indicates that processing is to start from the end of the string.

- SUBSTR2 supports a *length* value that is greater than the calculated result length. In such cases, a shorter string is returned, rather than an error.
- SUBSTR2 returns a result data type of VARCHAR if the input data type is CHAR. VARGRAPHIC is the result data type returned if the input type is GRAPHIC.
- The length attribute of the result for SUBSTR2 is either the same as the length attribute of the first argument, or it is derived based on the start or length attributes, if either of these are constants.
- SUSTR2 returns a result with a length attribute that is the same as the length attribute of the first argument, unless the start or length arguments are specified as constants. When a constant is specified, the length attribute of the result is derived based on the start or length attributes (see the preceding table).

Examples

- *Example 1*: Given the following host variables:
  - `NAME (VARGRAPHIC(50)` with a value of 'Roméo Jürgen'
  - `SURNAME POS (INTEGER)` with a value of 7

```
SUBSTR2(:NAME, :SURNAME_POS)
```

  returns the value `Jürgen`

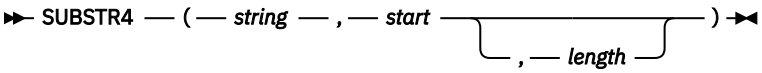
```
SUBSTR2(:NAME, :SURNAME_POS,2)
```

  returns the value `Jü`
- *Example 2*: Select all rows from the PROJECT table which end in 'ING'

```
SELECT * FROM PROJECT
   WHERE SUBSTR2(PROJNAME,-3) = 'ING'
```

SUBSTR4

The SUBSTR4 function returns a substring from a string. The resulting substring starts at a specified position in the string and continues for a specified or default length. The start and length arguments are expressed in 32-bit UTF-32 string units (CODEUNITS32).



The schema is SYSIBM.

string
An expression that specifies the string from which the resulting substring is derived. The expression must return a value that is a built-in character string, graphic string, numeric, or datetime data type. A character string cannot have the FOR BIT DATA attribute (SQLSTATE 428GC). If the value is not a string data type, it is implicitly cast to VARCHAR before evaluating the function. A substring of *string* is zero or more contiguous string units of *string*.

start
An expression that specifies the starting position in *string* for the beginning of the result substring in 32-bit UTF-32 string units. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

If *start* is positive, then the starting position is calculated from the beginning of the string. If *start* is greater than the length of *string* in 32-bit UTF-32 string units, then a zero length string is returned.

If *start* is negative, then the starting position is calculated from the end of the string by counting backwards. If the absolute value of *start* is greater than the length of *string* in 32-bit UTF-32 string units, then a zero length string is returned.

If *start* is 0, then a starting position of 1 is used.

length

An expression that specifies the length of the resulting substring in 32-bit UTF-32 string units. If *length* is specified, the expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

If the value for *length* is greater than the number of 32-bit UTF-32 string units from the starting position to the end of the string, then the length of the resulting substring is the length of the first argument in 32-bit UTF-32 string units minus the starting position plus one.

If the value for *length* is less than or equal to zero, the result is a zero length string.

The default value for *length* is the number of CODEUNITS32 from the position specified by *start* to the last string unit of *string*.

If *string* is a CHAR or VARCHAR data type, the result of the function is a VARCHAR data type. If *string* is a CLOB, the result of the function is a CLOB. If *string* is a GRAPHIC or VARGRAPHIC data type, the result of the function is a VARGRAPHIC data type. If *string* is a DBCLOB, the result of the function is a DBCLOB. If the first argument is a host variable, the code page of the result is the section code page; otherwise, it is the code page of the first argument.

The length attribute of the result is the same as the length attribute of the first argument, unless the start or length arguments are specified as constants. When a constant is specified, the length attribute of the result is based on the first applicable row in the following table. The string unit of the result is the same as the string unit of the first argument.

Table 97. Length attribute of SUBSTR4 result when arguments include constants

String Argument	Start Argument[1]	Length Argument	Length Attribute of Result[2]
character type with length attribute A	any valid argument	constant value L<=0	0
character type with length attribute A	constant value S and |(S)|>A	not specified or any valid argument	0
character type with length attribute A	not a constant	constant value L>0	MIN(A, L×4) if the string units of *string* is OCTETS MIN(A, L) if the string units of *string* is CODEUNITS32
character type with length attribute A	constant value S>0	not specified or not a constant	A-S+1
character type with length attribute A	constant value S<0	not specified or not a constant	MIN(A, |(S)×4|) if the string units of *string* is OCTETS MIN(A, |S|) if the string units of *string* is CODEUNITS32
character type with length attribute A	constant value S>0	constant value L>0	MIN(A-S+1, L×4) if the string units of *string* is OCTETS MIN(A-S+1, L) if the string units of *string* is CODEUNITS32

Table 97. Length attribute of SUBSTR4 result when arguments include constants (continued)

String Argument	Start Argument[1]	Length Argument	Length Attribute of Result[2]
character type with length attribute A	constant value S<0	constant value L>0	MIN(A,|(S)×4|, L×4) if the string units of *string* is OCTETS MIN(A, |S|, L) if the string units of *string* is CODEUNITS32
graphic type with length attribute A	any valid argument	constant value L<=0	0
graphic type with length attribute A	constant value S and |(S)|>A	not specified or any valid argument	0
graphic type with length attribute A	not a constant	constant value L>0	MIN(A, L*2) if the string units of *string* is double-bytes or CODEUNITS16 MIN(A, L) if the string units of *string* is CODEUNITS32
graphic type with length attribute A	constant value S>0	not specified or not a constant	A-S+1
graphic type with length attribute A	constant value S<0	not specified or not a constant	MIN(A, |(S) * 2|) if the string units of *string* is double-bytes or CODEUNITS16 MIN(A, |S|) if the string units of *string* is CODEUNITS32
graphic type with length attribute A	constant value S>0	constant value L>0	MIN(A-S+1, L*2) if the string units of *string* is double-bytes or CODEUNITS16 MIN(A-S+1, L) if the string units of *string* is CODEUNITS32
graphic type with length attribute A	constant value S<0	constant value L>0	MIN(A, |(S)*2|, L*2) if the string units of *string* is double-bytes or CODEUNITS16 MIN(A, |S|, L) if the string units of *string* is CODEUNITS32

Table 97. Length attribute of SUBSTR4 result when arguments include constants (continued)

String Argument	Start Argument[1]	Length Argument	Length Attribute of Result[2]

Notes:

[1] If a start argument value of 0 is specified, then use a value of 1 for S when referencing this table.

[2] The length attribute of the result for some of the character result types involves a constant that is multiplied by a factor of 4. This multiplier covers the worst case expansion derived from multiplying by 4 to switch from counting in 32-bit UTF-32 string units to counting in bytes used for the length attributes of a character data type with string units of OCTETS.
The length attribute of the result for some of the graphic result types involves a constant that is multiplied by a factor of 2. This multiplier covers the worst case expansion derived from multiplying by 2 because a 4-byte character in UTF-32 could be represented by up to 2 double-byte characters in a graphic string.

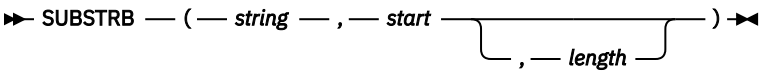
If any argument of the SUBSTR4 function can be null, the result can be null. If any argument is null, the result is the null value.

Notes

- If *string* contains combining characters, the result might contain base characters without their combining characters or combining characters without their base characters depending on the values of start and length.
- SUBSTR4 is similar to the SUBSTR function, with the following exceptions:
  - SUBSTR4 supports a negative start value, which indicates that processing is to start from the end of the string.
  - SUBSTR4 supports a *length* value that is greater than the calculated result length. In such cases, a shorter string is returned, rather than an error.
  - SUBSTR4 returns a result data type of VARCHAR if the input data type is CHAR. VARGRAPHIC is the result data type returned if the input type is GRAPHIC.
  - The length attribute of the result for SUBSTR4 is either the same as the length attribute of the first argument, or it is derived based on the start or length attributes, if either of these are constants.
  - SUBSTR4 returns a result with a length attribute that is the same as the length attribute of the first argument, unless the start or length arguments are specified as constants. When a constant is specified, the length attribute of the result is derived based on the start or length attributes (see the preceding table).

SUBSTRB

The SUBSTRB function returns a substring of a string, beginning at a specified position in the string. Lengths are calculated in bytes.



The schema is SYSIBM.

The SUBSTRB function is available starting with version 9.7 Fix Pack 1.

string
An expression that specifies the string from which the result is derived.

The expression must return a value that is a built-in character string, numeric value, Boolean value, or datetime value. If the value is not a character string, it is implicitly cast to VARCHAR before the

function is evaluated. In a Unicode database, if the value is a graphic data type, it is implicitly cast to a character string data type before the function is evaluated. Any number (zero or more) contiguous bytes of this expression constitute a substring of this expression.

start
An expression that specifies the start position in *string* of the beginning of the result substring. The expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

If *start* is positive, then the start position is calculated from the beginning of the string. If *start* is greater than the length of *string*, then a zero length string is returned.

If *start* is negative, then the start position is calculated from the end of the string and by counting backwards. If the absolute value of *start* is greater than the length of *string*, then a zero length string is returned.

If *start* is 0, then a start position of 1 is used.

length
An expression that specifies the length of the result in bytes. If specified, the expression must return a value that is a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

If the length is:

- Greater than the number of bytes from the start position to the end of the string, the result length is the length of the first argument minus the start position plus one
- Less than or equal to zero, the result of SUBSTRB is a zero length string

The default length is the number of bytes from the position specified by *start* to the last byte of *string*.

Result

If *string* is a CHAR or VARCHAR data type, the result of the function is a VARCHAR data type. If *string* is a CLOB, the result of the function is a CLOB. If *string* is a BINARY or VARBINARY data type, the result of the function is a VARBINARY data type. If *string* is a BLOB, the result of the function is a BLOB. If the first argument is a host variable that is not a binary string and not a FOR BIT DATA character string, the code page of the result is the section code page; otherwise, it is the code page of the first argument.

The length attribute of the result is the same as the length attribute of the first argument unless both *start* and *length* arguments are specified and defined as constants. In this case, the length attribute of the result is determined as follows:

- If *length* is a constant which is less than or equal to zero, the length attribute of the result is zero.
- If *start* is not a constant, but *length* is a constant, the length attribute of the result is the minimum of the length attribute of the first argument and *length*.
- If *start* is a constant, but *length* is not a constant or not specified, the length attribute of the result is the length attribute of the first argument minus the start position, plus one.
- If *start* and *length* are constants, the length attribute of the result is the minimum of the following values:
  - *length*
  - The length attribute of the first argument minus the start position plus one

If any argument of the SUBSTRB function can be null, the result can be null; if any argument is null, the result is the null value.

Notes

- In dynamic SQL, *string*, *start*, and *length* can be represented by a parameter marker. If a parameter marker is used for *string*, the data type of the operand will be VARCHAR, and the operand will be nullable.
- Though not explicitly stated in the previously mentioned result definitions, the semantics imply that if *string* is a mixed single-byte and multi-byte character string, the result might contain fragments of multi-byte characters, depending on the values of *start* and *length*. For example, the result could possibly begin with the second byte of a multi-byte character, or end with the first byte of a multi-byte character. The SUBSTRB function will detect these partial characters and will replace each byte of an incomplete character with a single blank character.
- SUBSTRB is similar to the existing SUBSTR function, with the following exceptions:
  - SUBSTRB supports a negative *start* value, which indicates the processing should start from the end of the string.
  - SUBSTRB allows *length* to be greater than the calculated result length. In this case, a shorter string will be returned, rather than returning an error.
  - Graphic input data is not natively supported for the first argument of SUBSTRB. In a Unicode database, graphic data is supported, but it is first converted to character data before evaluating the function, and lengths are calculated in bytes.
  - The result data type of SUBSTRB is VARCHAR if the input data type is CHAR.
  - The length attribute of the result for SUBSTRB is either the same as the length attribute of the first argument, or it is derived based on the *start* or *length* attributes, if either of these are constants.

Examples

- *Example 1*: Assume the host variable NAME (VARCHAR(50)) has a value of 'BLUE JAY' and the host variable SURNAME_POS (INTEGER) has a value of 6.

```
SUBSTRB(:NAME, :SURNAME_POS)
```

  Returns the value 'JAY'.

```
SUBSTRB(:NAME, :SURNAME_POS,1)
```

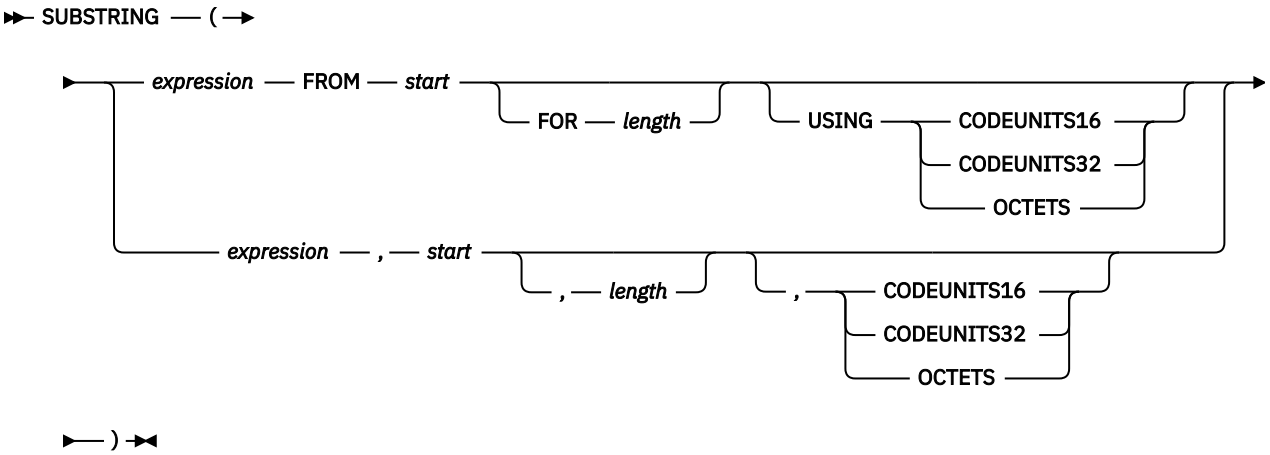
  Returns the value 'J'.

- *Example 2*: Select all rows from the PROJECT table which end in 'ING'.

```
SELECT * FROM PROJECT
   WHERE SUBSTRB(PROJNAME,-3) = 'ING'
```

SUBSTRING

The SUBSTRING function returns a substring of a string.



The schema is SYSIBM.

expression
An expression that specifies the string from which the result is derived. The expression must return a built-in character string, numeric value, Boolean value, or datetime value. If the value is not a character string, it is implicitly cast to VARCHAR before the function is evaluated.

A substring of the input expression comprises zero or more contiguous string units of the input expression.

start
An expression that specifies the position, relative to the beginning of the input expression, from which the substring is to be calculated. For example:

- Position 1 is the first string unit of the input expression. The statement `SUBSTRING('abc',1,2)` returns `'ab'`.
- Position 2 is one position to the right of position 1. The statement `SUBSTRING('abc',2,2)` returns `'bc'`.
- Position 0 is one position to the left of position 1. The statement `SUBSTRING('abc',0,2)` returns `'a'`.
- Position -1 is two positions to the left of position 1. The statement `SUBSTRING('abc',-1,2)` returns a zero-length string.

The expression must return a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

The start value can be positive, negative, or zero. If OCTETS is specified and the input expression contains graphic data, the start value must be odd (SQLSTATE 428GC).

length
An expression that specifies the length of the result. The expression must return a built-in numeric, CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC value. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

If the input expression is:

- A fixed-length string, the default length is `CHARACTER_LENGTH(`*expression* `USING` *string-unit*`) - ` *start* ` + 1`. This is the number of string units (CODEUNITS16, CODEUNITS32, or OCTETS) from the start position to the final position of the input expression.
- A varying-length string, the default length is zero or `CHARACTER_LENGTH(`*expression* `USING` *string-unit*`) - ` *start* ` + 1`, whichever is greater.

If the specified length is zero, the result is the empty string.

If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function. The value must be greater than or equal to zero. If a value greater than *n* is specified, where *n* is the (length attribute of *expression*) - *start* + 1, then *n* is used as the length of the resulting substring. The value is expressed in the string units that are explicitly specified. If OCTETS is specified, and if the input expression contains graphic data, the length must be an even number (SQLSTATE 428GC).

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string units of *start* and *length*. CODEUNITS16 specifies that *start* and *length* are to be expressed in 16-bit UTF-16 code units. CODEUNITS32 specifies that *start* and *length* are to be expressed in 32-bit UTF-32 code units. OCTETS specifies that *start* and *length* are to be expressed in bytes.

If string units are specified as CODEUNITS16 or CODEUNITS32, and *expression* is a binary string or a FOR BIT DATA string, an error is returned (SQLSTATE 428GC).

If a string units argument is not specified and *expression* is a character string that is not FOR BIT DATA or is a graphic string, the default is CODEUNITS32. Otherwise, the default is OCTETS.

For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String units in built-in functions" in "Character strings".

When the SUBSTRING function is invoked using OCTETS, and the *source-string* is encoded in a code page that requires more than one byte per code point (mixed or MBCS), the SUBSTRING operation might split a multi-byte code point and the resulting substring might begin or end with a partial code point. If this occurs, the function replaces the bytes of leading or trailing partial code points with blanks in a way that does not change the byte length of the result. (See a related example in the Examples section.)

Result

The data type of the result depends on the data type of the first argument, as shown in the following table.

Table 98. Data type of the result of SUBSTRING

Data type of the first argument	**Data type of the result**
CHAR or VARCHAR	VARCHAR
CLOB	CLOB
GRAPHIC or VARGRAPHIC	VARGRAPHIC
DBCLOB	DBCLOB
BINARY or VARBINARY	VARBINARY
BLOB	BLOB

The length attribute of the result is equal to the length attribute of the input expression. If any argument of the function can be null, the result can be null; if any argument is null, the result is the null value. The result is not padded with any character. If the input expression has an actual length of 0, the result also has an actual length of 0.

Notes

- The length attribute of the result is equal to the length attribute of the input expression. This behavior is different from the behavior of the SUBSTR function, where the length attribute is derived from the *start* and the *length* arguments of the function.

Examples

- *Example 1*: FIRSTNAME is a VARCHAR(12) column in table T1. One of its values is the 6-character string 'Jürgen'. When FIRSTNAME has this value:

```
Function ...                          Returns ...
------------------------------------  ------------------------------------
SUBSTRING(FIRSTNAME,1,2,CODEUNITS32)  'Jü' -- x'4AC3BC'
SUBSTRING(FIRSTNAME,1,2,CODEUNITS16)  'Jü' -- x'4AC3BC'
SUBSTRING(FIRSTNAME,1,2,OCTETS)       'J ' -- x'4A20' (a truncated string)
SUBSTRING(FIRSTNAME,8,CODEUNITS16)    a zero-length string
SUBSTRING(FIRSTNAME,8,4,OCTETS)       a zero-length string
SUBSTRING(FIRSTNAME,0,2,CODEUNITS32)  'J' -- x'4AC3BC'
```

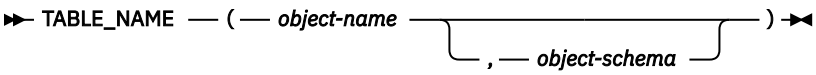
- *Example 2*: The following example illustrates how SUBSTRING replaces the bytes of leading or trailing partial multi-byte code points with blanks when the string length unit is OCTETS. Assume that UTF8_VAR contains the UTF-8 representation of the Unicode string '&N~AB', where '&' is the musical symbol G clef and '~' is the combining tilde character.

```
   SUBSTRING(UTF8_VAR, 2, 5, OCTETS)
```

  Three blank bytes precede the 'N', and one blank byte follows the 'N'.

TABLE_NAME

The TABLE_NAME function returns an unqualified name of the object found after any alias chains have been resolved.



The schema is SYSIBM.

The specified *object-name* (and *object-schema*) are used as the starting point of the resolution. If the starting point does not refer to an alias, the unqualified name of the starting point is returned. The resulting name may be of a table, view, or undefined object. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

object-name
A character expression representing the unqualified name (usually of an existing alias) to be resolved. *object-name* must have a data type of CHAR or VARCHAR and a length greater than 0 and less than 129 bytes.

object-schema
A character expression representing the schema used to qualify the supplied *object-name* value before resolution. *object-schema* must have a data type of CHAR or VARCHAR and a length greater than 0 and less than 129 bytes.

If *object-schema* is not supplied, the default schema is used for the qualifier.

The data type of the result of the function is VARCHAR(128 OCTETS). If *object-name* can be null, the result can be null; if *object-name* is null, the result is the null value. If *object-schema* is the null value, the default schema name is used. The result is the character string representing an unqualified name. The result name could represent one of the following objects:

table
The value for *object-name* was either a table name (the input value is returned) or an alias name that resolved to the table whose name is returned.

view
The value for *object-name* was either a view name (the input value is returned) or an alias name that resolved to the view whose name is returned.

undefined object

The value for *object-name* was either an undefined object (the input value is returned) or an alias name that resolved to the undefined object whose name is returned.

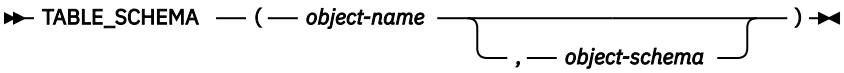
Therefore, if a non-null value is given to this function, a value is always returned, even if no object with the result name exists.

Notes

- To improve performance in partitioned database configurations by avoiding the unnecessary communication that occurs between the coordinator partition and catalog partition when using the TABLE_SCHEMA and TABLE_NAME scalar functions, the BASE_TABLE table function can be used instead.

TABLE_SCHEMA

The TABLE_SCHEMA function returns the schema name of the object found after any alias chains have been resolved.



The schema is SYSIBM.

The specified *object-name* (and *object-schema*) are used as the starting point of the resolution. If the starting point does not refer to an alias, the schema name of the starting point is returned. The resulting schema name may be of a table, view, or undefined object. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

object-name
A character expression representing the unqualified name (usually of an existing alias) to be resolved. *object-name* must have a data type of CHAR or VARCHAR and a length greater than 0 and less than 129 bytes.

object-schema
A character expression representing the schema used to qualify the supplied *object-name* value before resolution. *object-schema* must have a data type of CHAR or VARCHAR and a length greater than 0 and less than 129 bytes.

If *object-schema* is not supplied, the default schema is used for the qualifier.

The data type of the result of the function is VARCHAR(128 OCTETS). If *object-name* can be null, the result can be null; if *object-name* is null, the result is the null value. If *object-schema* is the null value, the default schema name is used. The result is the character string representing a schema name. The result schema could represent the schema name for one of the following objects:

table
The value for *object-name* was either a table name (the input or default value of *object-schema* is returned) or an alias name that resolved to a table for which the schema name is returned.

view
The value for *object-name* was either a view name (the input or default value of *object-schema* is returned) or an alias name that resolved to a view for which the schema name is returned.

undefined object
The value for *object-name* was either an undefined object (the input or default value of *object-schema* is returned) or an alias name that resolved to an undefined object for which the schema name is returned.

Therefore, if a non-null *object-name* value is given to this function, a value is always returned, even if the object name with the result schema name does not exist. For example, `TABLE_SCHEMA('DEPT', 'PEOPLE')` returns 'PEOPLE ' if the catalog entry is not found.

Notes

- To improve performance in partitioned database configurations by avoiding the unnecessary communication that occurs between the coordinator partition and catalog partition when using the TABLE_SCHEMA and TABLE_NAME scalar functions, the BASE_TABLE table function can be used instead.

Examples

- *Example 1*: PBIRD tries to select the statistics for a given table from SYSCAT.TABLES using an alias PBIRD.A1 defined on the table HEDGES.T1.

```
SELECT NPAGES, CARD FROM SYSCAT.TABLES
  WHERE TABNAME = TABLE_NAME ('A1')
  AND TABSCHEMA = TABLE_SCHEMA ('A1')
```

  The requested statistics for HEDGES.T1 are retrieved from the catalog.

- *Example 2*: Select the statistics for an object called HEDGES.X1 from SYSCAT.TABLES using HEDGES.X1. Use TABLE_NAME and TABLE_SCHEMA since it is not known whether HEDGES.X1 is an alias or a table.

```
SELECT NPAGES, CARD FROM SYSCAT.TABLES
  WHERE TABNAME = TABLE_NAME ('X1','HEDGES')
  AND TABSCHEMA = TABLE_SCHEMA ('X1','HEDGES')
```

  Assuming that HEDGES.X1 is a table, the requested statistics for HEDGES.X1 are retrieved from the catalog.

- *Example 3*: Select the statistics for a given table from SYSCAT.TABLES using an alias PBIRD.A2 defined on HEDGES.T2 where HEDGES.T2 does not exist.

```
SELECT NPAGES, CARD FROM SYSCAT.TABLES
  WHERE TABNAME = TABLE_NAME ('A2','PBIRD')
  AND TABSCHEMA = TABLE_SCHEMA ('A2',PBIRD')
```

  The statement returns 0 records as no matching entry is found in SYSCAT.TABLES where TABNAME = 'T2' and TABSCHEMA = 'HEDGES'.

- *Example 4*: Select the qualified name of each entry in SYSCAT.TABLES along with the final referenced name for any alias entry.

```
SELECT TABSCHEMA AS SCHEMA,  TABNAME AS NAME,
  TABLE_SCHEMA (BASE_TABNAME, BASE_TABSCHEMA) AS REAL_SCHEMA,
  TABLE_NAME (BASE_TABNAME, BASE_TABSCHEMA) AS REAL_NAME
  FROM SYSCAT.TABLES
```

  The statement returns the qualified name for each object in the catalog and the final referenced name (after alias has been resolved) for any alias entries. For all non-alias entries, BASE_TABNAME and BASE_TABSCHEMA are null so the REAL_SCHEMA and REAL_NAME columns will contain nulls.

TAN

Returns the tangent of the argument, where the argument is an angle expressed in radians.

The schema is SYSIBM. (The SYSFUN version of the TAN function continues to be available.)

expression
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

The result of the function is a double-precision floating-point number. The result can be null if the argument can be null or the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

TANH

Returns the hyperbolic tangent of the argument, where the argument is an angle expressed in radians.

The schema is SYSIBM.

expression
An expression that returns a value of any built-in numeric data type except for DECFLOAT. The value is converted to a double-precision floating-point number for processing by the function.

The result of the function is a double-precision floating-point number. The result can be null if the argument can be null or the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

THIS_MONTH

The THIS_MONTH function returns the first day of the month in the specified date.

The schema is SYSIBM.

datetime-expression
An expression that specifies a date for which first day of the month is to be returned. The expression must return a value that is a DATE, a TIMESTAMP, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported using implicit casting. If *datetime-expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string accepted by the TIMESTAMP scalar function.

The result of the function is DATE. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Example

Returns the date value of the first day of the month specified by the input.

```
values this_month('2007-02-18')
      Result: 2007-02-01
```

THIS_QUARTER

The THIS_QUARTER function returns the first day of the quarter that contains the specified date.

The schema is SYSIBM.

datetime-expression
An expression that specifies a date for which first day of the quarter is to be returned. The expression must return a value that is a DATE, a TIMESTAMP, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported using implicit casting. If *datetime-expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string accepted by the TIMESTAMP scalar function.

The result of the function is DATE. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Example

Returns the date value of the first day of the quarter of the date specified by the input.

```
values this_quarter('2007-05-18')
      Result: 2007-04-01
```

THIS_WEEK

The THIS_WEEK function returns the first day of the week that contains the specified date. Sunday is considered the first day of that week.

The schema is SYSIBM.

datetime-expression
An expression that specifies a date for which first day of the week is to be returned. The expression must return a value that is a DATE, a TIMESTAMP, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported using implicit casting. If *datetime-expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string accepted by the TIMESTAMP scalar function.

This function returns a value of data type DATE. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Example

```
values this_week ('1996-02-29')
      Result: 1996-02-25
```

THIS_YEAR

The THIS_YEAR function returns the first day of the year in the specified date.

The schema is SYSIBM.

datetime-expression
An expression that specifies a date for which first day of the year is to be returned. The expression must return a value that is a DATE, a TIMESTAMP, a CHAR, or a VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported using implicit casting. If *datetime-expression* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string accepted by the TIMESTAMP scalar function.

The result of the function is DATE. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Example

The following example returns the date value of the first day of the year of the date specified by the input.

```
values this_year('2007-02-18')
      Result: 2007-01-01
```

TIME

The TIME function returns a time from a value.

The schema is SYSIBM.

expression
An expression that returns a value of one of the following built-in data types: DATE, TIME, TIMESTAMP, or a valid character string representation of a date, time, or timestamp that is not a CLOB. In a Unicode database, if an expression returns a value of a graphic string data type, the value is first converted to a character string before the function is executed.

The result of the function is a TIME. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument:

- If the argument is a DATE or string representation of a date:
  - The result is midnight.
- If the argument is a TIME:
  - The result is that time.
- If the argument is a TIMESTAMP:
  - The result is the time part of the timestamp.
- If the argument is a string representation of time or timestamp:
  - The result is the time represented by the string.

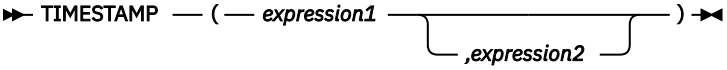
Example

Select all notes from the IN_TRAY sample table that were received at least one hour later in the day (any day) than the current time.

```
SELECT * FROM IN_TRAY
  WHERE TIME(RECEIVED) >= CURRENT TIME + 1 HOUR
```

TIMESTAMP

The TIMESTAMP function returns a timestamp from a value or a pair of values.



The schema is SYSIBM.

Only Unicode databases support an argument that is a graphic string representation of a date, a time, or a timestamp. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

expression1* and *expression2

The rules for the arguments depend on whether **expression2** is specified and the data type of **expression2**.

- If only one argument is specified it must be an expression that returns a value of one of the following built-in data types: a DATE, a TIMESTAMP, or a character string that is not a CLOB. If **expression1** is a character string, it must be one of the following:

  - A valid character string representation of a date or a timestamp. For the valid formats of string representations of date or timestamp values, see "String representations of datetime values" in Datetime values.
  - A character string with an actual length of 13 that is assumed to be a result from the GENERATE_UNIQUE function.
  - A string of length 14 that is a string of digits that represents a valid date and time in the form *yyyyxxddhhmmss*, where *yyyy* is the year, *xx* is the month, *dd* is the day, *hh* is the hour, *mm* is the minute, and *ss* is the seconds.
- If **expression1** and **expression2** are specified:
  - If the data type of **expression2** is not an integer:
    - **expression1** must be a DATE or a valid string representation of a date and the **expression2** must be a TIME or a valid string representation of a time.
  - If the data type of **expression2** is an integer:
    - **expression1** must be a DATE, TIMESTAMP, or a valid string representation of a timestamp or date. **expression2** must be an integer constant in the range 0 to 12 representing the timestamp precision.

The result of the function is a TIMESTAMP.

The timestamp precision and other rules depend on whether the second argument is specified:

- If both arguments are specified and the second argument is not an integer:
  - The result is a TIMESTAMP(6) with the date specified by the first argument and the time specified by the second argument. The fractional seconds part of the timestamp is zero.
- If both arguments are specified and the second argument is an integer:
  - The result is a TIMESTAMP with the precision specified in the second argument.
- If only one argument is specified and it is a TIMESTAMP(*p*):
  - The result is that TIMESTAMP(*p*).
- If only one argument is specified and it is a DATE:
  - The result is that date with an assumed time of midnight cast to TIMESTAMP(0).
- If only one argument is specified and it is a string:
  - The result is the TIMESTAMP(6) value represented by that string extended as described earlier with any missing time information. If the argument is a string of length 14, the TIMESTAMP has a fractional seconds part of zero.

If the arguments include only date information, the time information in the result value is all zeros. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Examples

- *Example 1*: Assume the column START_DATE (whose data type is DATE) has a value equivalent to 1988-12-25, and the column START_TIME (whose data type is TIME) has a value equivalent to 17.12.30.

```
TIMESTAMP(START_DATE, START_TIME)
```

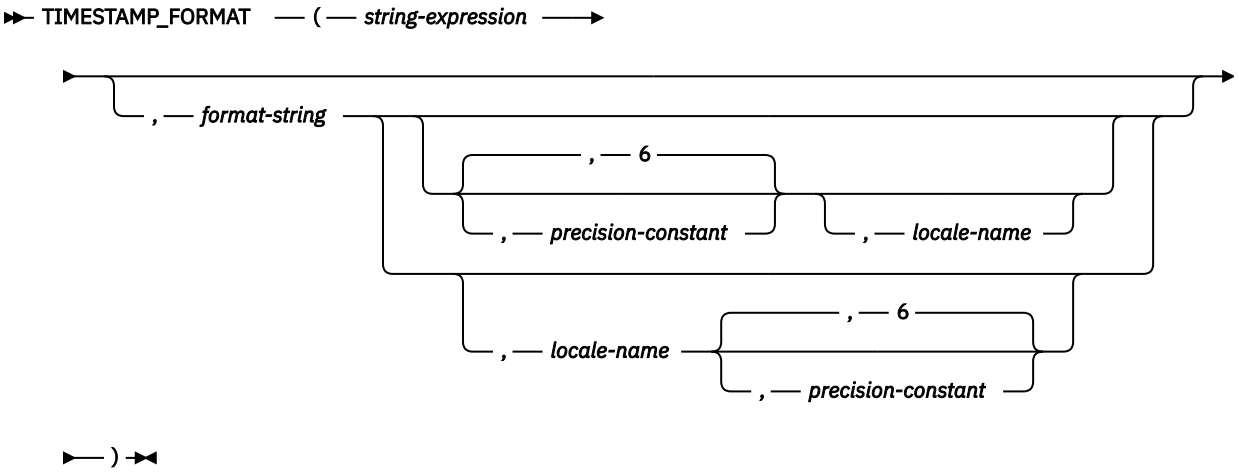
  Returns the value '1988-12-25-17.12.30.000000'.
- *Example 2*: Convert a timestamp string with 7 digits of fractional seconds to a TIMESTAMP(9) value.

```
TIMESTAMP('2007-09-24-15.53.37.2162474',9)
```

  Returns the value '2007-09-24-15.53.37.216247400'.

TIMESTAMP_FORMAT

The TIMESTAMP_FORMAT function returns a timestamp that is based on the interpretation of the input string using the specified format.



The schema is SYSIBM.

string-expression
The expression must return a value that is a built-in CHAR or VARCHAR data type. In a Unicode database, if a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function. The *string-expression* must contain the components of a timestamp that correspond to the format specified by *format-string*.

format-string
The expression must return a value that is a built-in CHAR or VARCHAR data type. In a Unicode database, if a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function. The actual length must not be greater than 255 bytes (SQLSTATE 22007). The value is a template for how *string-expression* is interpreted and then converted to a timestamp value.

A valid *format-string* must contain at least one format element, must not contain multiple specifications for any component of a timestamp, and can contain any combination of the format elements, unless otherwise noted in Table 99 on page 528 (SQLSTATE 22007). For example, *format-string* cannot contain both YY and YYYY, because they are both used to interpret the year component of *string-expression*. Refer to the table to determine which format elements cannot be specified together. Two format elements can optionally be separated by one or more of the following separator characters:

- minus sign (-)
- period (.)
- slash (/)
- comma (,)
- apostrophe (')
- semi-colon (;)
- colon (:)
- blank ( )

Separator characters can also be specified at the start or end of *format-string*. These separator characters can be used in any combination in the format string, for example 'YYYY/MM-DD HH:MM.SS'. Separator characters specified in a *string-expression* are used to separate components and are not required to match the separator characters specified in the *format-string*.

Table 99. Format elements for the TIMESTAMP_FORMAT function

Format element	Related components of a timestamp	Description
AM or PM	hour	Meridian indicator (morning or evening) without periods. This format element is dependent on *locale-name*, if specified. Otherwise, it is dependent on the value of the special register CURRENT LOCALE LC_TIME.
A.M. or P.M.	hour	Meridian indicator (morning or evening) with periods. This format element uses the exact strings "A.M." or "P.M." and is independent of the locale name in effect.
DAY, Day, or day	none	Name of the day in uppercase, titlecase, or lowercase format. The language used is dependent on *locale-name*, if specified; otherwise, it is dependent on the value of the special register CURRENT LOCALE LC_TIME.
DY, Dy, or dy	none	Abbreviated name of the day in uppercase, titlecase, or lowercase format. The language used is dependent on *locale-name*, if specified; otherwise, it is dependent on the value of the special register CURRENT LOCALE LC_TIME.
D	none	Day of the week (1-7). The first day of the week is dependent on *locale-name*, if specified; otherwise, it is dependent on the value of the special register CURRENT LOCALE LC_TIME.
DD	day	Day of month (01-31).
DDD	month, day	Day of year (001-366).

Table 99. Format elements for the TIMESTAMP_FORMAT function (continued)

Format element	Related components of a timestamp	Description
FF or FF*n*	fractional seconds	Fractional seconds (0-999999999999). The number *n* is used to specify the number of digits expected in the *string-expression*. Valid values for *n* are 1-12 with no leading zeros. Specifying FF is equivalent to specifying FF6. When the component in *string-expression* corresponding to the FF format element is followed by a separator character or is the last component, the number of digits for the fractional seconds can be less than what is specified by the format element. In this case zero digits are padded onto the right of the specified digits.
HH	hour	HH behaves the same as HH12.
HH12	hour	Hour of the day (01-12) in 12-hour format. AM is the default meridian indicator.
HH24	hour	Hour of the day (00-24) in 24-hour format.
J	year, month, and day	Julian day (number of days since January 1, 4713 BC).
MI	minute	Minute (00-59).
MM	month	Month (01-12).
MONTH, Month, or month	month	Name of the month in uppercase, titlecase, or lowercase format. The language used is dependent on *locale-name*, if specified; otherwise, it is dependent on the value of the special register CURRENT LOCALE LC_TIME.
MON, Mon, or mon	month	Abbreviated name of the month in uppercase, titlecase, or lowercase format. The language used is dependent on *locale-name*, if specified; otherwise, it is dependent on the value of the special register CURRENT LOCALE LC_TIME.
NNNNNN	microseconds	Microseconds (000000-999999). Same as FF6.

Table 99. Format elements for the TIMESTAMP_FORMAT function (continued)		
Format element	**Related components of a timestamp**	**Description**
RR	year	Last two digits of the adjusted year (00-99).
RRRR	year	4-digit adjusted year (0000-9999).
SS	seconds	Seconds (00-59).
SSSSS	hours, minutes, and seconds	Seconds since previous midnight (00000-86400).
Y	year	Last digit of the year (0-9). First three digits of the current year are used to determine the full 4-digit year.
YY	year	Last two digits of the year (00-99). First two digits of the current year are used to determine the full 4-digit year.
YYY	year	Last three digits of the year (000-999). First digit of the current year is used to determine the full 4-digit year.
YYYY	year	4-digit year (0000-9999).

Note: The format elements in Table 99 on page 528 are not case sensitive, except for the following:

- AM, PM
- A.M., P.M.
- DAY, Day, day
- DY, Dy, dy
- D
- MONTH, Month, month
- MON, Mon, mon

The DAY, Day, day, DY, Dy, dy, and D format elements do not contribute to any components of the resulting timestamp. However, a specified value for any of these format elements must be correct for the combination of the year, month, and day components of the resulting timestamp (SQLSTATE 22007). For example, assuming a value of 'en_US' is used for *locale-name*, a value of 'Monday 2008-10-06' for *string-expression* is valid for a value of 'Day YYYY-MM-DD'. However, value of 'Tuesday 2008-10-06' for *string-expression* would result in error for the same *format-string*.

The RR and RRRR format elements can be used to alter how a specification for a year is to be interpreted by adjusting the value to produce a 2-digit value or a 4-digit value depending on the leftmost two digits of the current year according to the following table.

Last two digits of the current year	**Two-digit year in *string-expression***	**First two digits of the year component of timestamp**
00-50	00-49	First two digits of the current year
51-99	00-49	First two digits of the current year + 1

Last two digits of the current year	Two-digit year in *string-expression*	First two digits of the year component of timestamp
00-50	50-99	First two digits of the current year - 1
51-99	50-99	First two digits of the current year

For example, if the current year is 2007, '86' with format 'RR' means 1986, but if the current year is 2052, it means 2086.

The following defaults are used when a *format-string* does not include a format element for one of the following components of a timestamp:

Timestamp component	Default
year	current year, as 4 digits
month	current month, as 2 digits
day	01 (first day of the month)
hour	00
minute	00
second	00
fractional seconds	a number of zeros matching the timestamp precision of the result

Leading zeros can be specified for any component of the timestamp value (that is, month, day, hour, minutes, seconds) that does not have the maximum number of significant digits for the corresponding format element in the *format-string*.

A substring of the *string-expression* representing a component of a timestamp (such as year, month, day, hour, minutes, seconds) can include less than the maximum number of digits for that component of the timestamp indicated by the corresponding format element. Any missing digits default to zero. For example, with a *format-string* of 'YYYY-MM-DD HH24:MI:SS', an input value of '999-3-9 5:7:2' would produce the same result as '0999-03-09 05:07:02'.

If *format-string* is not specified, *string-expression* will be interpreted using a default format based on the value of the special register CURRENT LOCALE LC_TIME.

precision-constant
An integer constant that specifies the timestamp precision of the result. The value must be in the range 0 to 12. If not specified, the timestamp precision defaults to 6.

locale-name
A character constant that specifies the locale used for the following format elements:

- AM, PM
- DAY, Day, day
- DY, Dy, dy
- D
- MONTH, Month, month
- MON, Mon, mon

The value of *locale-name* is not case sensitive and must be a valid locale (SQLSTATE 42815).

For information about valid locales and their naming, see "Locale names for SQL and XQuery" in the *Globalization Guide* .

If *locale-name* is not specified, the value of the special register CURRENT LOCALE LC_TIME is used.

The result of the function is a TIMESTAMP with a precision based on *precision-constant*. If either of the first two arguments can be null, the result can be null; if either of the first two arguments is null, the result is the null value.

Notes

- ***Julian and Gregorian calendar***: The transition from the Julian calendar to the Gregorian calendar on 15 October 1582 is taken into account by this function.
- ***Determinism:*** TIMESTAMP_FORMAT is a deterministic function. However, the following invocations of the function depend on the value of either the special register CURRENT LOCALE LC_TIME or CURRENT TIMESTAMP.
  - When *format-string* is not explicitly specified, or when *locale-name* is not explicitly specified and one of the following is true:
    - *format-string* is not a constant
    - *format-string* is a constant and includes format elements that are locale sensitive
    - *format-string* is a constant and does not include a format element that fully defines the year (that is, J or YYYY) and so uses the value of the current year
    - *format-string* is a constant and does not include a format element that fully defines the month (for example, J, MM, MONTH, or MON) and so uses the value of the current month

  These invocations that depend on the value of a special register cannot be used wherever special registers cannot be used (SQLSTATE 42621, 428EC, or 429BX).
- ***Syntax alternatives:*** TO_DATE is a synonym for TIMESTAMP_FORMAT. TO_TIMESTAMP is a similar function, and the only difference is that the default value for *precision-constant* is 12.

Examples

- *Example 1*: Insert a row into the IN_TRAY table with a receiving timestamp that is equal to one second before the beginning of the year 2000 (December 31, 1999 at 23:59:59).

```
INSERT INTO IN_TRAY (RECEIVED)
  VALUES (TIMESTAMP_FORMAT('1999-12-31 23:59:59',
    'YYYY-MM-DD HH24:MI:SS'))
```

- *Example 2*: An application receives strings of date information into a variable called INDATEVAR. This value is not strictly formatted and might include two or four digits for years, and one or two digits for months and days. Date components might be separated with minus sign (-) or slash (/) characters and are expected to be in day, month, and year order. Time information consists of hours (in 24-hour format) and minutes, and is usually separated by a colon. Sample values include '15/12/98 13:48' and '9-3-2004 8:02'. Insert such values into the IN_TRAY table.

```
INSERT INTO IN_TRAY (RECEIVED)
  VALUES (TIMESTAMP_FORMAT(:INDATEVAR,
    'DD/MM/RRRR HH24:MI'))
```

  The use of RRRR in the format allows for 2- and 4-digit year values and assigns missing first two digits based on the current year. If YYYY were used, input values with a 2-digit year would have leading zeros. The slash separator also allows the minus sign character. Assuming a current year of 2007, resulting timestamps from the sample values are:

```
'15/12/98 13:48' --> 1998-12-15-13.48.00.000000
'9-3-2004 8:02'     --> 2004-03-09-08.02.00.000000
```

TIMESTAMP_ISO

Returns a timestamp value based on a date, time, or timestamp argument.

The schema is SYSFUN.

expression
An expression that returns a value of one of the following built-in data types: CHAR, VARCHAR, DATE, TIME, or TIMESTAMP data type. In a Unicode database, if a supplied argument has a GRAPHIC or VARGRAPHIC data type, it is first converted to a character string before evaluating the function. A string expression must return a valid character string representation of a date or timestamp.

If the argument is a date value, TIMESTAMP_ISO inserts zero for all the time elements. If the argument is a time value, TIMESTAMP_ISO inserts the value of the CURRENT DATE special register for the date elements, and zero for the fractional seconds element. The result of the function is a TIMESTAMP(6). The result can be null; if the argument is null, the result is the null value.

The TIMESTAMP_ISO function is generally defined as deterministic. If the first argument has the TIME data type, then the function is not deterministic because the CURRENT DATE is used for the date portion of the timestamp value.

The result of the function is a TIMESTAMP. The result can be null; if the argument is null, the result is the null value.

TIMESTAMPDIFF

Returns an estimated number of intervals of the type defined by the first argument, based on the difference between two timestamps.

The schema is SYSIBM. The SYSFUN version of the TIMESTAMPDIFF function continues to be available.

numeric-expression
An expression that returns a value of built-in INTEGER or SMALLINT data type. Valid values represent an interval as defined in the following table.

Table 100. Valid interval values

Value	Interval
1	Microseconds
2	Seconds
4	Minutes
8	Hours
16	Days
32	Weeks
64	Months
128	Quarters
256	Years

string-expression
An expression that returns a value of built-in CHAR or VARCHAR data type. The value is expected to be the result of subtracting two timestamps and converting the result to CHAR. If the value is not a CHAR or VARCHAR data type, it is implicitly cast to VARCHAR before evaluating the function. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed

If a positive or negative sign is present, it is the first character of the string. The following table describes the elements of the character string duration.

Table 101. TIMESTAMPDIFF string elements		
String Elements	**Valid Values**	**Character position from the decimal point (negative is left)**
Years	1-9998 or blank	-14 to -11
Months	0-11 or blank	-10 to -9
Days	0-30 or blank	-8 to -7
Hours	0-24 or blank	-6 to -5
Minutes	0-59 or blank	-4 to -3
Seconds	0-59	-2 to -1
Decimal Points	Period	0
Microseconds	000000-999999	1 to 6

The result of the function is INTEGER with the same sign as the second argument. The result can be null; if the argument is null, the result is the null value.

The returned value is determined for each interval as indicated by the following table:

Table 102. TIMESTAMPDIFF computations	
Result interval	**Computation using duration elements**
Years	Years
Quarters	integer value of (months+(years*12))/3
Months	months + (years*12)
Weeks	integer value of ((days+(months*30))/7)+ (years*52)
Days	days + (months*30)+(years*365)
Hours	hours + ((days+(months*30)+(years*365))*24)
Minutes (the absolute value of the duration must not exceed 40850913020759.999999)	minutes + (hours+ ((days+(months*30)+(years*365))*24)) *60
Seconds (the absolute value of the duration must be less than 680105031408.000000)	seconds + (minutes+(hours+ ((days+(months*30)+(years*365)) *24))*60)*60
Microseconds (the absolute value of the duration must be less than 3547.483648)	microseconds + (seconds+(minutes*60))*1000000

The following assumptions may be used in estimating a difference:

- There are 365 days in a year.
- There are 30 days in a month.
- There are 24 hours in a day.
- There are 60 minutes in an hour.
- There are 60 seconds in a minute.

These assumptions are used when converting the information in the second argument, to the interval type specified in the first argument. The returned estimate may vary by a number of days. For example, if the number of days (interval 16) is requested for the difference between '1997-03-01-00.00.00' and

'1997-02-01-00.00.00', the result is 30. This is because the difference between the timestamps is 1 month, and the assumption of 30 days in a month applies.

Example

The following example returns 4277, the number of minutes between two timestamps:

```
TIMESTAMPDIFF(4,CHAR(TIMESTAMP('2001-09-29-11.25.42.483219') -
  TIMESTAMP('2001-09-26-12.07.58.065497')))
```

TIMEZONE

The TIMEZONE scalar function converts a date and time in one timezone into a timestamp in another timezone.

The schema is SYSIBM.

datetime-expression
An expression that returns a value of data type DATE, TIMESTAMP, CHAR, or VARCHAR. In a Unicode database, the expression can also be of data type GRAPHIC or VARGRAPHIC. A value of data type CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC must be a valid string that is accepted by the “TIMESTAMP ” on page 525 scalar function. Such a string is implicitly cast to a timestamp before conversion.

from-timezone
An expression that specifies the time zone of the value returned by the input datetime expression.

to-timezone

An expression that specifies the time zone of the output timestamp.

The value returned by a to-timezone or from-timezone expression:

- Must be a built-in character string data type (in a Unicode database, it can also be a graphic string data type) that contains a time zone name as specified in the Internet Assigned Numbers Authority (IANA) time zone database (SQLSTATE 22546).
- Cannot be a FOR BIT DATA subtype (SQLSTATE 42815).

If the value is not of data type VARCHAR, it is cast to VARCHAR before the TIMEZONE function is evaluated.

The standard format for a time zone name in the IANA database is *area*/*location*, where:

area
The English name of a continent or ocean, or the special area **Etc**.

location
The English name of a location within the specified area. This is usually a city or a small island.

For example:

```
"America/Toronto"  [The North American city of Toronto]
"Asia/Sakhalin"    [The Asian island of Sakhalin]
"Etc/UTC"          [Coordinated Universal Time]
```

For a complete list of valid time zone names and the rules associated with those time zones, refer to the IANA time zone database. The database server uses version 2010c of the IANA time zone database. If a newer version of the IANA time zone database is required, contact IBM support.

The precision of the output timestamp depends on the data type of the value returned by the input datetime expression:

- If the input value is a timestamp, the output value is a timestamp with the same precision as the input value.
- If the data type of the input value is DATE, the data type of the output value is TIMESTAMP(0).
- Otherwise, the data type of the output value is TIMESTAMP(6).

If any argument of the function can be null, the result can be null. If any argument is null, the result is the null value.

Examples

- The data type of column col1 of table T1 is TIMESTAMP(3), so the data type of the output of the following statement is also TIMESTAMP(3):

```
select TIMEZONE(col1, 'America/New_York', 'America/Los_Angeles')from T1;
```

  This statement returns: `2016-12-19-14.00.00.123`.
- The data type of column col3 of table T5 is DATE, so the data type of the output of the following statement is TIMESTAMP(0):

```
select TIMEZONE(col3, 'America/New_York', 'America/Los_Angeles')from T5;
```

  This statement returns: `2016-07-14-23.00.00`.
- The input of each of the following statements is a string literal, so the data type of their output is TIMESTAMP(6):

```
values TIMEZONE('2016-09-24 17:00:00.12345678', 'America/New_York', 'America/Los_Angeles');
```

  This statement returns: `2016-09-24-17.00.00.123456`.

```
values TIMEZONE('2016-09-24 17:00:00.123', 'America/New_York', 'America/Los_Angeles');
```

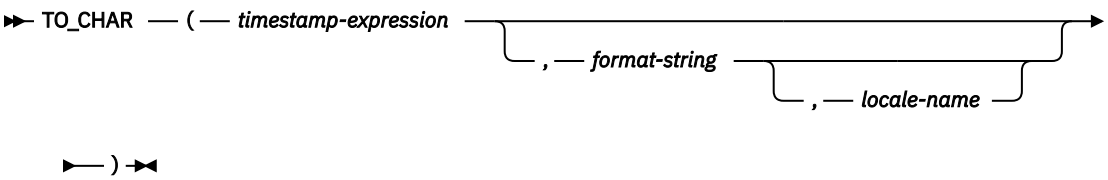
  This statement returns: `2016-09-24-17.00.00.123000`.

TO_CHAR

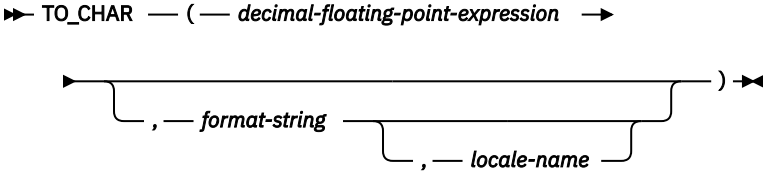
The TO_CHAR function returns a character representation of an input expression.

Character to varchar

Timestamp to varchar



Decimal floating-point to varchar

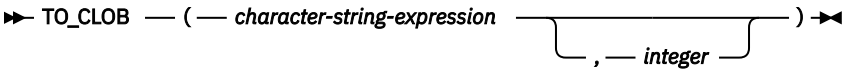


The schema is SYSIBM.

The TO_CHAR scalar function is a synonym for the VARCHAR_FORMAT scalar function.

TO_CLOB

The TO_CLOB function returns a CLOB representation of a character string type.

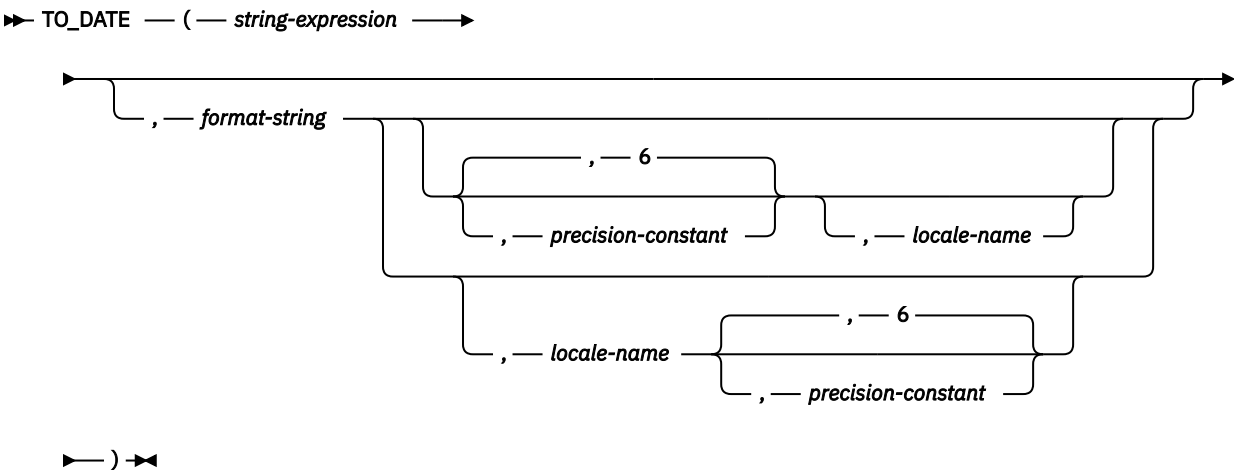


The schema is SYSIBM.

The TO_CLOB scalar function is a synonym for the CLOB scalar function.

TO_DATE

The TO_DATE function returns a timestamp that is based on the interpretation of the input string using the specified format.



The schema is SYSIBM.

The TO_DATE scalar function is a synonym for the TIMESTAMP_FORMAT scalar function.

TO_HEX

The TO_HEX function converts a numeric expression into the hexadecimal representation.

The schema is SYSIBM.

expression
The expression must return a value that is a built-in character string, Boolean value, or numeric value. In a Unicode database, the expression can also return a graphic string, in which case it is first converted to a character string before the function is evaluated. If the data type of the input is not SMALLINT, INTEGER, or BIGINT, it is implicitly cast to BIGINT before the function is evaluated.

Result

The data type of the result depends on the data type of the input expression:

- For SMALLINT input, the result is VARCHAR(4).
- For INTEGER input, the result is VARCHAR(8).

- For BIGINT input, the result is VARCHAR(16).

If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Example

```
values to_hex(565);
     returns value 235.
```

TO_MULTI_BYTE

The TO_MULTI_BYTE function returns a Unicode string in which the single-byte characters in a string-expression are converted to their multi-byte (full width) equivalents.

The schema is SYSIBM.

string-expression
An expression that returns a value of a built-in character string.

A character string must not be bit data.

The argument can be also a numeric data type.

The numeric argument is implicitly cast to a VARCHAR data type.

Result

The result of the function is VARCHAR.

The result string unit is the same as string-expression.

The result length attribute depends on the string units as follows:

- If string unit is OCTETS, the result length attribute is the minimum of three times the length attribute of string-expression and the maximum length for the result data type.
- Otherwise, the result length attribute is the same as string-expression.

If the actual length of the result string exceeds the maximum for the return type, an error occurs (SQLSTATE 54006).

If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Example

In the following example, the query returns the original single-byte string ‘ABC’, the full width equivalent, and the hexadecimal representation of the full width equivalent:

```
SELECT S, TO_MULTI_BYTE(S) MB, HEX(TO_MULTI_BYTE(S)) HEX
FROM (VALUES 'ABC') T(S)
S   MB        HEX

------------------------------
ABC  A B C EFBCA1EFBCA2EFBCA3

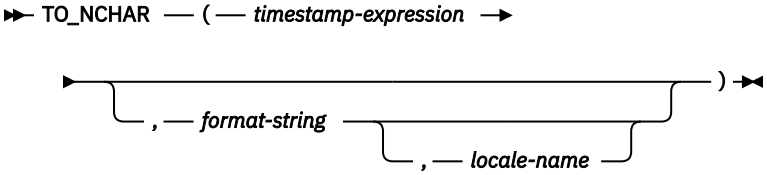
1 record(s) selected.
```

TO_NCHAR

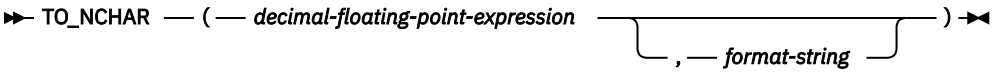
The TO_NCHAR function returns a national character representation of an input expression that has been formatted using a character template.

Character to nvarchar

Timestamp to nvarchar



Decimal floating-point to nvarchar



The schema is SYSIBM.

The TO_NCHAR function can be specified only in a Unicode database (SQLSTATE 560AA).

The TO_NCHAR scalar function is equivalent to invoking the TO_CHAR function and casting its result to NVARCHAR.

For more information about TO_NCHAR refer to VARCHAR_FORMAT.

TO_NCLOB

The TO_NCLOB function returns any type of national character string.

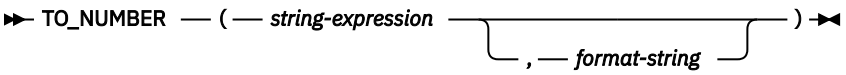
The schema is SYSIBM.

The TO_NCLOB scalar function is a synonym for the NCLOB scalar function.

The TO_NCLOB function can be specified only in a Unicode database (SQLSTATE 560AA).

TO_NUMBER

The TO_NUMBER function returns a DECFLOAT(34) value that is based on the interpretation of the input string using the specified format.



The schema is SYSIBM.

The TO_NUMBER scalar function is a synonym for the DECFLOAT_FORMAT scalar function.

TO_SINGLE_BYTE

The TO_SINGLE_BYTE function returns a string in which multi-byte characters are converted to the equivalent single-byte character where an equivalent character exists.

The schema is SYSIBM.

Only characters that have an equivalent to the single-byte characters represented by the characters in the UTF-8 code point range U+0020 to U+007E will be converted. If a multi-byte character does not have a single-byte equivalent, then it remains unchanged.

string-expression
An expression that specifies the string which gets converted. The expression must return a value that is a built-in CHAR or VARCHAR data type. In a Unicode database, if a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function. The expression cannot be a character string defined as FOR BIT DATA (SQLSTATE 42815).

The data type, code page and length attribute of the result is the same as the data type, code page and length attribute of the argument. If the argument can be null, the result can be null. If the argument is null, the result is the null value.

Example

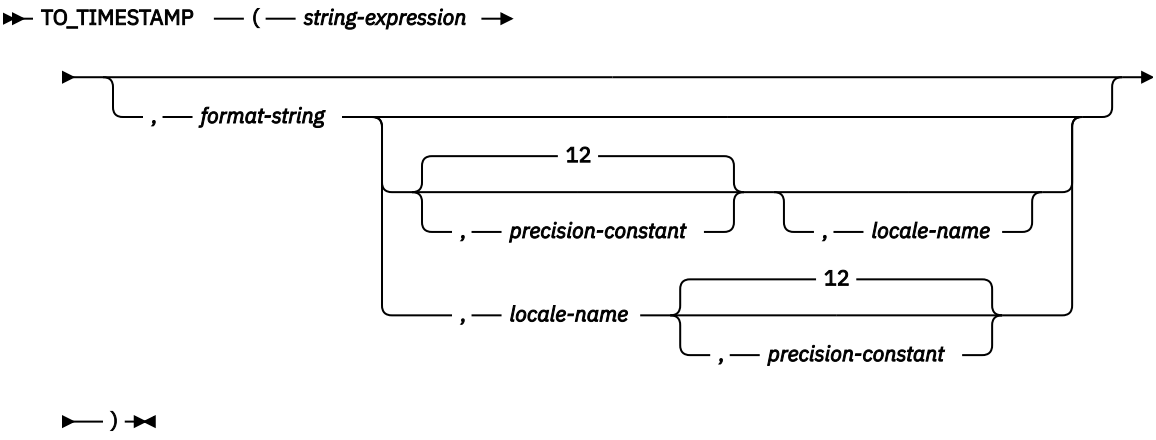
Convert the full width UTF-8 characters 'ABC' (x'efbca1efbca2efbca3' in hex format) to their single byte equivalents.

```
VALUES TO_SINGLE_BYTE(x'efbca1efbca2efbca3')
```

The result is the value 'ABC' (x'414243' in hex format).

TO_TIMESTAMP

The TO_TIMESTAMP function returns a timestamp that is based on the interpretation of the input string using the specified format.



The schema is SYSIBM.

The TO_TIMESTAMP scalar function is a synonym for the TIMESTAMP_FORMAT scalar function except that the default value for *precision-constant* is 12.

TO_UTC_TIMESTAMP

The TO_UTC_TIMESTAMP scalar function returns a TIMESTAMP that is converted to Coordinated Universal Time from the timezone that is specified by the timezone string. TO_UTC_TIMESTAMP is a a statement deterministic function.

The schema is SYSIBM.

expression
An expression that specifies the timestamp that is in the *timezone-expression* time zone. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. If *expression* does not contain time information, a time of midnight (00.00.00) is used for the argument. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported through implicit casting. If expression is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

timezone-expression
An expression that specifies the time zone that the expression is to be adjusted from. The expression must return a value that is a built-in character string, numeric, or datetime data type. In a Unicode database, the expression can also be a graphic string data type. Numeric and datetime data types are supported through implicit casting. If the expression is not a VARCHAR, it is cast to VARCHAR before the function is evaluated. The expression must not be a FOR BIT DATA subtype (SQLSTATE 42815). *timezone-expression* must not be null if *expression* is not null (SQLSTATE 42815).

The value of the *timezone-expression* must be a time zone name from the Internet Assigned Numbers Authority (IANA) time zone database. The standard format for a time zone name in the IANA database is `Area/Location`, where:

- `Area` is the English name of a continent, ocean, or the special area 'Etc'.
- `Location` is the English name of a location within the area; usually a city, or small island.

Examples:

- "America/Toronto"
- "Asia/Sakhalin"
- "Etc/UTC" (which represents Coordinated Universal Time)

For complete details on the valid set of time zone names and the rules that are associated with those time zones, refer to the IANA time zone database. The database server uses version **2010c** of the IANA time zone database. Contact IBM support if a newer version of the IANA time zone database is required.

The result of the function is a timestamp with the same precision as *expression*, if *expression* is a timestamp. If expression is a DATE, the result of the function is a TIMESTAMP(0). Otherwise, the result of the function is a TIMESTAMP(6).

The result can be null; if the *expression* is null, the result is the null value. The *timezone-expression* cannot be null if a not-null value was supplied for the *expression* (SQLSTATE 42815).

The result is the *expression*, adjusted to the Coordinated Universal Time time zone from the time zone specified by the *timezone-expression*. If the *timezone-expression* returns a value that is not a time zone in the IANA time zone database, then the value of *expression* is returned without being adjusted.

The timestamp adjustment is done by first applying the raw offset from Coordinated Universal Time of the *timezone-expression*. If Daylight Saving Time is in effect at the adjusted timestamp for the time zone that is specified by the *timezone-expression*, then the Daylight Saving Time offset is also applied to the timestamp.

Time zones that use Daylight Saving Time have ambiguities at the transition dates. When a time zone changes from standard time to Daylight Saving Time, a range of time does not occur as it is skipped during

the transition. When a time zone changes from Daylight Saving Time to standard time, a range of time occurs twice. Ambiguous timestamps are treated as if they occurred when standard time was in effect for the time zone.

Examples

1. Convert the timestamp '1970-01-01 00:00:00' to the Coordinated Universal Time timezone from the 'America/Denver' timezone. The following returns a TIMESTAMP with the value '1970-01-01 07:00:00'.

   ```
   TO_UTC_TIMESTAMP(TIMESTAMP'1970-01-01 00:00:00', 'America/Denver')
   ```

2. The database administrator created a read-only global variable, SERVER_TIMEZONE, which contains the server's timezone. In this example, the SERVER_TIMEZONE user-defined global variable is set to 'America/Denver'.

   Convert the timestamp '1970-01-01 00:00:00' to the Coordinated Universal Time timezone from the server's timezone. The following returns a TIMESTAMP with the value '1970-01-01 07:00:00'.

   ```
   TO_UTC_TIMESTAMP(TIMESTAMP'1970-01-01 00:00:00', SERVER_TIMEZONE)
   ```

TOTALORDER

The TOTALORDER function returns a SMALLINT value of -1, 0, or 1 that indicates the comparison order of two arguments.

The schema is SYSIBM.

decfloat-expression1
An expression that returns a value of any built-in numeric data type. If the argument is not DECFLOAT(34), it is logically converted to DECFLOAT(34) for processing.

decfloat-expression2
An expression that returns a value of any built-in numeric data type. If the argument is not a decimal floating-point value, it is converted to DECFLOAT(34) for processing.

Numeric comparison is exact, and the result is determined for finite operands as if range and precision were unlimited. An overflow or underflow condition cannot occur.

If one value is DECFLOAT(16) and the other is DECFLOAT(34), the DECFLOAT(16) value is converted to DECFLOAT(34) before the comparison is made.

The semantics of the TOTALORDER function are based on the total order predicate rules of IEEE 754R. TOTALORDER returns the following values:

- -1 if *decfloat-expression1* is lower in order compared to *decfloat-expression2*
- 0 if both *decfloat-expression1* and *decfloat-expression2* have the same order
- 1 if *decfloat-expression1* is higher in order compared to *decfloat-expression2*

The ordering of the special values and finite numbers is as follows:

```
-NAN<-SNAN<-INFINITY<-0.10<-0.100<-0<0<0.100<0.10<INFINITY<SNAN<NAN
```

The result of the function is a SMALLINT value. If either argument can be null, the result can be null; if either argument is null, the result is the null value.

Examples

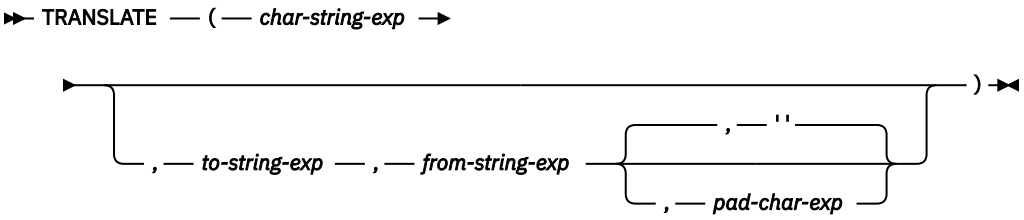
The following examples show the use of the TOTALORDER function to compare decimal floating point values:

```
TOTALORDER(-INFINITY, -INFINITY) = 0
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-1.0)) = 0
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-1.00)) = -1
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(-0.5)) = -1
TOTALORDER(DECFLOAT(-1.0), DECFLOAT(0.5)) = -1
TOTALORDER(DECFLOAT(-1.0), INFINITY) = -1
TOTALORDER(DECFLOAT(-1.0), SNAN) = -1
TOTALORDER(DECFLOAT(-1.0), NAN) = -1
TOTALORDER(NAN, DECFLOAT(-1.0)) = 1
TOTALORDER(-NAN, -NAN) = 0
TOTALORDER(-SNAN, -SNAN) = 0
TOTALORDER(NAN, NAN) = 0
TOTALORDER(SNAN, SNAN) = 0
TOTALORDER(-1.0, -1.0) = 0
TOTALORDER(-1.0, -1.00) = -1
TOTALORDER(-1.0, -0.5) = -1
TOTALORDER(-1.0, 0.5) = -1
TOTALORDER(-1.0, INFINITY) = -1
TOTALORDER(-1.0, SNAN) = -1
TOTALORDER(-1.0, NAN) = -1
```

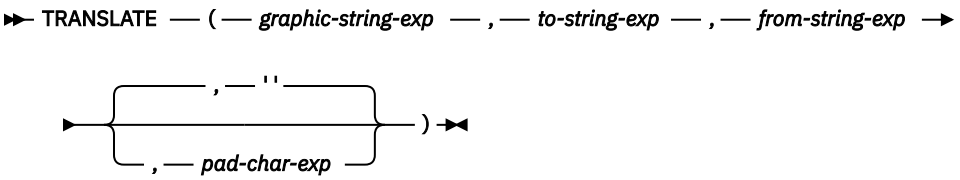
TRANSLATE

The TRANSLATE function returns a value in which one or more characters in a string expression might have been converted to other characters.

character string expression:



graphic string expression:



The schema is SYSIBM.

The function converts all the characters in *char-string-exp* or *graphic-string-exp* that also occur in *from-string-exp* to the corresponding characters in *to-string-exp* or, if no corresponding characters exist, to the pad character specified by *pad-char-exp*.

char-string-exp* or *graphic-string-exp
The string that is to be converted. The expression must return a value that is a built-in CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, numeric, or datetime data type. If the value is not a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it is implicitly cast to VARCHAR before evaluating the function.

to-string-exp
A string of characters to which certain characters in *char-string-exp* are to be converted.

The expression must return a value that is a built-in CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, numeric, or datetime data type. If the value is not a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it is implicitly cast to VARCHAR before evaluating the function. If a value for *to-string-exp* is not specified, and the data type is not graphic, all characters in *char-string-exp* will be in monocase; that

is, the characters a-z will be converted to the characters A-Z, and other characters will be converted to their uppercase equivalents, if they exist. For example, in code page 850, é maps to É, but ÿ is not mapped, because code page 850 does not include Ÿ. If the code point length of the result character is not the same as the code point length of the source character, the source character is not converted.

from-string-exp
A string of characters that, if found in *char-string-exp*, are to be converted to the corresponding character in *to-string-exp*.

The expression must return a value that is a built-in CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, numeric, or datetime data type. If the value is not a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it is implicitly cast to VARCHAR before evaluating the function. If *from-string-exp* contains duplicate characters, the first one found will be used, and the duplicates will be ignored. If *to-string-exp* is longer than *from-string-exp*, the surplus characters will be ignored. If *to-string-exp* is specified, *from-string-exp* must also be specified.

pad-char-exp
A single character used to pad *to-string-exp* if *to-string-exp* is shorter than *from-string-exp*. The expression must return a value that is a built-in CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, numeric, or datetime data type. If the value is not a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it is implicitly cast to VARCHAR before evaluating the function. The value must have a length attribute of zero or one. If a zero-length string is specified, characters in the *from-string-exp* with no corresponding character in the *to-string-exp* are removed from *char-string-exp* or *graphic-string-exp*. If a value is not specified a single-byte blank character is assumed.

With *graphic-string-exp*, only *pad-char-exp* is optional (if a value is not specified, the double-byte blank character is assumed), and each argument, including the pad character, must be of a graphic data type.

The data type and code page of the result is the same as the data type and code page of the first argument. If the first argument is a host variable, the code page of the result is the database code page. In a non-Unicode database, if any argument is graphic string, then all the arguments must be graphic strings (SQLSTATE 42815). In a Unicode database: if the first argument is a FOR BIT DATA character string, then no other argument can be a graphic string (SQLSTATE 42846); if the first argument is a graphic string, then no other argument can be a FOR BIT DATA character string (SQLSTATE 42846).

The length attribute and string units of the result is the same as that of the first argument. If any argument can be null, the result can be null. If any argument is null, the result is the null value.

If the arguments are of data type CHAR or VARCHAR, the corresponding characters in *to-string-exp* and *from-string-exp* must have the same number of bytes (except in the case of a zero-length string). For example, it is not valid to convert a single-byte character to a multi-byte character, or to convert a multi-byte character to a single-byte character. The *pad-char-exp* argument cannot be the first byte of a valid multi-byte character (SQLSTATE 42815).

The characters are matched using a binary comparison. The database collation is not used.

If only *char-string-exp* is specified, single-byte characters will be monocased, and multi-byte characters will remain unchanged.

Examples

For the provided examples, assume that the host variable SITE (VARCHAR(30)) has a value of 'Hanauma Bay'.

- *Example 1*: The following example returns the value 'HANAUMA BAY'.

```
TRANSLATE(:SITE)
```

- *Example 2*: The following example returns the value 'Hanauma jay'.

```
TRANSLATE(:SITE, 'j', 'B')
```

- *Example 3*: The following example returns the value 'Heneume Bey'.

```
TRANSLATE(:SITE, 'ei', 'aa')
```

- *Example 4*: The following example returns the value 'HAnAumA bA%'.

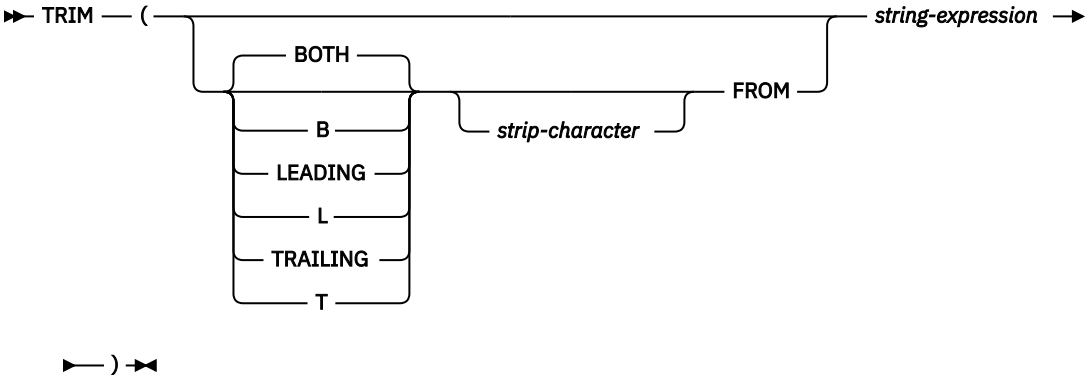
```
TRANSLATE(:SITE, 'bA', 'Bay', '%')
```

- *Example 5*: The following example returns the value 'Hana ma ray'.

```
TRANSLATE(:SITE, 'r', 'Bu')
```

TRIM

The TRIM function removes blanks or another specified character from the end, the beginning, or both ends of a string expression.



The schema is SYSIBM. The function name cannot be specified as a qualified name when keywords are used in the function signature.

BOTH, LEADING, or TRAILING
Specifies whether characters are removed from the beginning, the end, or from both ends of the string expression. If this argument is not specified, the characters are removed from both the end and the beginning of the string.

strip-character
A single-character constant that specifies the character that is to be removed. The *strip-character* can be any character whose UTF-32 encoding is a single character or a single digit numeric value. The binary representation of the character is matched.

If *strip-character* is not specified and:

- If the *string-expression* is a DBCS graphic string, the default *strip-character* is a DBCS blank, whose code point is dependent on the database code page
- If the *string-expression* is a UCS-2 graphic string, the default *strip-character* is a UCS-2 blank (X'0020')
- If the *string-expression* is a binary string, the default *strip-character* is a hexadecimal zero (X'00')
- Otherwise, the default *strip-character* is an SBCS blank (X'20')

FROM *string-expression*
An expression that specifies the string from which the result is derived. The expression must return a value that is a built-in CHAR, VARCHAR, BINARY, VARBINARY, GRAPHIC, VARGRAPHIC, numeric, or datetime data type. If the value is not a CHAR, VARCHAR, BINARY, VARBINARY, GRAPHIC, or VARGRAPHIC data type, it is implicitly cast to VARCHAR before the function is evaluated.

The value for *string-expression* and the value for *strip-character* must have compatible data types.

The data type of the result depends on the data type of the string-expression:

- VARCHAR if the data type is VARCHAR or CHAR
- VARGRAPHIC if the data type is VARGRAPHIC or GRAPHIC
- VARBINARY if the data type is VARBINARY or BINARY

The result is a varying-length string with the same maximum length as the length attribute of the *string-expression*. The actual length of the result is the length of the *string-expression* minus the number of string units that are removed. If all of the characters are removed, the result is an empty varying-length string. The code page of the result is the same as the code page of the *string-expression*.

Examples

- *Example 1*: Assume that the host variable HELLO of type CHAR(9) has a value of ' Hello'.

```
SELECT TRIM(:HELLO),
  TRIM(TRAILING FROM :HELLO)
FROM SYSIBM.SYSDUMMY1
```

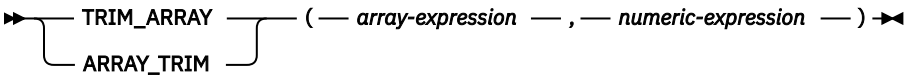
  returns the values 'Hello' and ' Hello', respectively.
- *Example 2*: Assume that the host variable BALANCE of type CHAR(9) has a value of '000345.50'.

```
SELECT TRIM(L '0' FROM :BALANCE),
FROM SYSIBM.SYSDUMMY1
```

  returns the value '345.50'.

TRIM_ARRAY

The TRIM_ARRAY function deletes elements from the end of an array.



The schema is SYSIBM.

array-expression
An SQL variable, SQL parameter, or global variable of an ordinary array type, or a CAST specification of a parameter marker to an ordinary array type. An associative array data type cannot be specified (SQLSTATE 42884).

numeric-expression
Specifies the number of elements trimmed from the end of the array. The numeric expression can be of any numeric data type with a value that can be cast to INTEGER. The value of the numeric expression must be between 0 and the cardinality of the array expression (SQLSTATE 2202E).

Result

The function returns a value with the same array type as the array expression but with the cardinality reduced by the value of INTEGER(*numeric-expression*).

The result can be null; if either argument is null, the result is the null value.

Rules

- The TRIM_ARRAY function is not supported for associative arrays (SQLSTATE 42884).
- The TRIM_ARRAY function can only be used on the right side of an assignment statement in contexts where arrays are supported (SQLSTATE 42884).

Examples

1. *Example 1*: Remove the last element from the array variable RECENT_CALLS.

```
SET RECENT_CALLS = TRIM_ARRAY(RECENT_CALLS, 1)
```

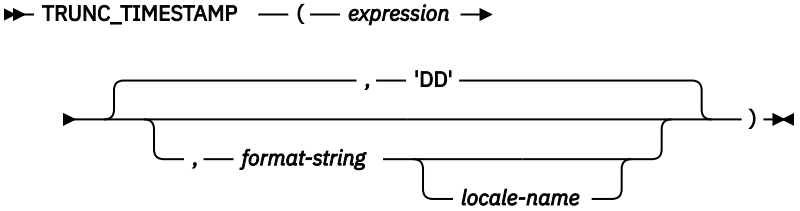
2. *Example 2*: Assign only the first two elements from the array variable SPECIALNUMBERS to the SQL array variable EULER_CONST:

```
SET EULER_CONST = TRIM_ARRAY(SPECIALNUMBERS, 8)
```

   The result is that EULER_CONST will be assigned an array with two elements, the first element value is 2.71828183 and the second element value is the null value.

TRUNC_TIMESTAMP

The TRUNC_TIMESTAMP scalar function returns a TIMESTAMP that is an argument (*expression*) truncated to the unit specified by another argument (*format-string*).



The schema is SYSIBM.

If *format-string* is not specified, *expression* is truncated to the nearest day, as if 'DD' was specified for *format-string*.

expression
An expression that returns a value of one of the following built-in data types: a DATE or a TIMESTAMP.

format-string
An expression that returns a built-in character string data type with an actual length that is not greater than 255 bytes. The format element in *format-string* specifies how *expression* should be truncated. For example, if *format-string* is 'DD', a timestamp that is represented by *expression* is truncated to the nearest day. Leading and trailing blanks are removed from the string, and the resulting substring must be a valid format element for a timestamp (SQLSTATE 22007). The default is 'DD'.

Allowable values for *format-string* are listed in the table of format elements found in the description of the ROUND function.

locale-name
A character constant that specifies the locale used to determine the first day of the week when using format model values DAY, DY, or D. The value of *locale-name* is not case sensitive and must be a valid locale (SQLSTATE 42815). For information about valid locales and their naming, see "Locale names for SQL and XQuery". If *locale-name* is not specified, the value of the special register CURRENT LOCALE LC_TIME is used.

The result of the function is a TIMESTAMP with the same timestamp precision as *expression*. The result can be null; if any argument is null, the result is the null value.

The result of the function is a TIMESTAMP with a timestamp precision of:

- *p* when the data type of expression is TIMESTAMP(*p*)
- 0 when the data type of expression is DATE
- 6 otherwise

The result can be null; if any argument is null, the result is the null value.

Notes

- **Determinism:** TRUNC_TIMESTAMP is a deterministic function. However, the following invocations of the function depend on the value of the special register CURRENT LOCALE LC_TIME.
  - Truncate of a date or timestamp value when *locale-name* is not explicitly specified and one of the following is true:
    - *format-string* is not a constant
    - *format-string* is a constant and includes format elements that are locale sensitive

    Invocations of the function that depend on the value of a special register cannot be used wherever special registers cannot be used (SQLSTATE 42621, 428EC, or 429BX).

Example

Set the host variable TRNK_TMSTMP with the current year rounded to the nearest year value.

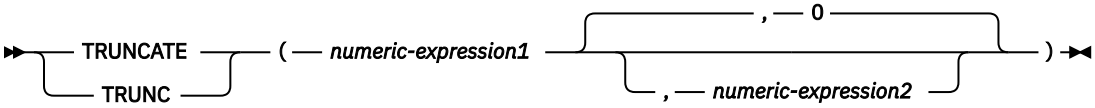
```
SET :TRNK_TMSTMP = TRUNC_TIMESTAMP('2000-03-14-17.30.00', 'YEAR');
```

The host variable TRNK_TMSTMP is set with the value 2000-01-01-00.00.00.000000.

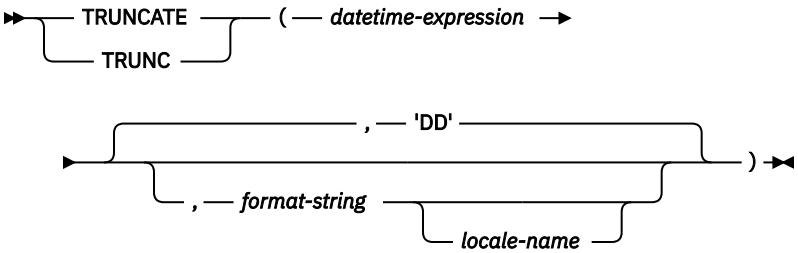
TRUNCATE or TRUNC

The TRUNCATE function returns a truncated value of a number or a datetime value.

TRUNCATE numeric:



TRUNCATE datetime:



The schema is SYSIBM. The SYSFUN version of the TRUNCATE numeric function continues to be available.

The data type of the return value depends on the first argument:

- If the result of the first argument is a numeric value, a number is returned, truncated to the specified number of places to the right or left of the decimal point.
- If the first argument is a DATE, TIME, or TIMESTAMP, a datetime value, truncated to the unit specified by *format-string*.

TRUNCATE numeric

If *numeric-expression1* has a numeric data type, the TRUNCATE function returns *numeric-expression1* truncated to *numeric-expression2* places to the right of the decimal point if *numeric-expression2* is positive, or to the left of the decimal point if *numeric-expression2* is zero or negative. If *numeric-expression2* is not specified, *numeric-expression1* is truncated to zero places left of the decimal point.

numeric-expression1
An expression that must return a value that is a built-in CHAR, VARCHAR, GRAPHIC, VARGRAPHIC, or numeric data type. If the value is not a numeric data type, it is implicitly cast to DECFLOAT(34) before evaluating the function.

If the expression is a decimal floating-point data type, the DECFLOAT rounding mode will not be used. The rounding behavior of TRUNCATE corresponds to a value of ROUND_DOWN. If a different rounding behavior is wanted, use the QUANTIZE function.

numeric-expression2
An expression that returns a value that is a built-in numeric data type. If the value is not of type INTEGER, it is implicitly cast to INTEGER before evaluating the function.

If *numeric-expression2* is not negative, *numeric-expression1* is truncated to the absolute value of *numeric-expression2* number of places to the right of the decimal point.

If *numeric-expression2* is negative, *numeric-expression1* is truncated to the absolute value of *numeric-expression2* + 1 number of places to the left of the decimal point. If the absolute value of a negative *numeric-expression2* is larger than the number of digits to the left of the decimal point, the result is 0. For example:

```
TRUNCATE(748.58,-4) = 0
```

The data type, length, and scale attributes of the result are the same as the data type, length, and scale attributes of the first argument.

If either argument can be null, the result can be null. If either argument is null, the result is the null value.

TRUNCATE datetime
If *datetime-expression* has a datetime data type, the TRUNCATE function returns *datetime-expression* rounded to the unit specified by the *format-string*. If *format-string* is not specified, *datetime-expression* is truncated to the nearest day, as if 'DD' is specified for *format-string*.

datetime-expression
An expression that must return a value that is a DATE, a TIME, or a TIMESTAMP. String representations of these data types are not supported and must be explicitly cast to a DATE, TIME, or TIMESTAMP for use with this function; alternatively, you can use the TRUNC_TIMESTAMP function for a string representation of a date or timestamp.

format-string
An expression that returns a built-in character string data type with an actual length that is not greater than 255 bytes. The format element in *format-string* specifies how *datetime-expression* should be truncated. For example, if *format-string* is 'DD', a timestamp that is represented by *datetime-expression* is truncated to the nearest day. Leading and trailing blanks are removed from the string, and the resulting substring must be a valid format element for the type of *datetime-expression* (SQLSTATE 22007). The default is 'DD', which cannot be used if the data type of *datetime-expression* is TIME.

Allowable values for *format-string* are listed in the table of format elements found in the description of the ROUND function.

locale-name
A character constant that specifies the locale used to determine the first day of the week when using format element values DAY, DY, or D. The value of *locale-name* is not case sensitive and must be a valid locale (SQLSTATE 42815). For information about valid locales and their naming, see "Locale names for SQL and XQuery". If *locale-name* is not specified, the value of the special register CURRENT LOCALE LC_TIME is used.

The result of the function has the same date type as *datetime-expression*. The result can be null; if any argument is null, the result is the null value.

The data type and length attribute of the result are the same as the data type and length attribute of the first argument.

The result can be null if the argument can be null or if the argument is not a decimal floating-point number and the database is configured with **dft_sqlmathwarn** set to YES; the result is the null value if the argument is null.

Notes

- **Determinism:** TRUNCATE is a deterministic function. However, the following invocations of the function depend on the value of the special register CURRENT LOCALE LC_TIME.
  - Truncate of a datetime value when *locale-name* is not explicitly specified and one of the following is true:
    - *format-string* is not a constant
    - *format-string* is a constant and includes format elements that are locale sensitive

    Invocations of the function that depend on the value of a special register cannot be used wherever special registers cannot be used (SQLSTATE 42621, 428EC, or 429BX).

Examples

- *Example 1*: Using the EMPLOYEE table, calculate the average monthly salary for the highest paid employee. Truncate the result two places to the right of the decimal point.

```
SELECT TRUNCATE(MAX(SALARY)/12,2)
  FROM EMPLOYEE;
```

  Assuming the highest paid employee earns $52750.00 per year, the example returns 4395.83.
- *Example 2*: Display the number 873.726 truncated 2, 1, 0, -1, and -2 decimal places, respectively.

```
VALUES (
  TRUNCATE(873.726,2),
  TRUNCATE(873.726,1),
  TRUNCATE(873.726,0),
  TRUNCATE(873.726,-1),
  TRUNCATE(873.726,-2),
  TRUNCATE(873.726,-3) );
```

  This example returns 873.720, 873.700, 873.000, 870.000, 800.000, and 0.000.
- *Example 3*: Display the decimal-floating point number 873.726 truncated 0 decimal places.

```
VALUES(TRUNCATE(DECFLOAT(873.726),0))
```

  Returns the value 873.
- *Example 4*: Set the variable vTRNK_DT with the input date rounded to the nearest month value.

```
SET vTRNK_DT = TRUNC(DATE('2000-08-16'), 'MONTH');
```

  The value set is 2000-08-01.
- *Example 5*: Set the host variable TRNK_TMSTMP with the current year rounded to the nearest year value.

```
SET :TRNK_TMSTMP = TRUNCATE(DATE('2000-03-14-17.30.00'), 'YEAR');
```

  The value set is 2000-01-01-00.00.00.000000.

TYPE_ID

The TYPE_ID function returns the internal type identifier of the dynamic data type of the *expression*.

The schema is SYSIBM.

expression
An expression that returns a value of a user-defined structured data type.

The data type of the result of the function is INTEGER. If *expression* can be null, the result can be null; if *expression* is null, the result is the null value.

The value returned by the TYPE_ID function is not portable across databases. The value may be different, even though the type schema and type name of the dynamic data type are the same. When coding for portability, use the TYPE_SCHEMA and TYPE_NAME functions to determine the type schema and type name.

Notes

- This function cannot be used as a source function when creating a user-defined function. Because it accepts any structured data type as an argument, it is not necessary to create additional signatures to support different user-defined types.

Example

A table hierarchy exists having root table EMPLOYEE of type EMP and subtable MANAGER of type MGR. Another table ACTIVITIES includes a column called WHO_RESPONSIBLE that is defined as REF(EMP) SCOPE EMPLOYEE. For each reference in ACTIVITIES, display the internal type identifier of the row that corresponds to the reference.

```
SELECT TASK, WHO_RESPONSIBLE->NAME,
    TYPE_ID(DEREF(WHO_RESPONSIBLE))
  FROM ACTIVITIES
```

The DEREF function is used to return the object corresponding to the row.

TYPE_NAME

The TYPE_NAME function returns the unqualified name of the dynamic data type of the *expression*.

The schema is SYSIBM.

expression
An expression that returns a value of a user-defined structured data type.

The data type of the result of the function is VARCHAR(128 OCTETS). If *expression* can be null, the result can be null; if *expression* is null, the result is the null value. Use the TYPE_SCHEMA function to determine the schema name of the type name returned by TYPE_NAME.

Notes

- This function cannot be used as a source function when creating a user-defined function. Because it accepts any structured data type as an argument, it is not necessary to create additional signatures to support different user-defined types.

Example

A table hierarchy exists having root table EMPLOYEE of type EMP and subtable MANAGER of type MGR. Another table ACTIVITIES includes a column called WHO_RESPONSIBLE that is defined as REF(EMP) SCOPE EMPLOYEE. For each reference in ACTIVITIES, display the type of the row that corresponds to the reference.

```
SELECT TASK, WHO_RESPONSIBLE->NAME,
    TYPE_NAME(DEREF(WHO_RESPONSIBLE)),
    TYPE_SCHEMA(DEREF(WHO_RESPONSIBLE))
  FROM ACTIVITIES
```

The DEREF function is used to return the object corresponding to the row.

TYPE_SCHEMA

The TYPE_SCHEMA function returns the schema name of the dynamic data type of the *expression*.

The schema is SYSIBM.

expression
An expression that returns a value of a user-defined structured data type.

The data type of the result of the function is VARCHAR(128 OCTETS). If *expression* can be null, the result can be null; if *expression* is null, the result is the null value. Use the TYPE_NAME function to determine the type name associated with the schema name returned by TYPE_SCHEMA.

Notes

- This function cannot be used as a source function when creating a user-defined function. Because it accepts any structured data type as an argument, it is not necessary to create additional signatures to support different user-defined types.

UCASE

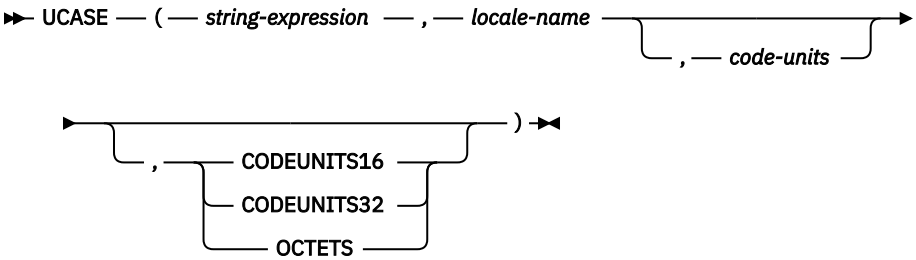
The UCASE function is identical to the TRANSLATE function except that only the first argument (*char-string-exp*) is specified.

The schema is SYSIBM.

UCASE is a synonym for UPPER.

UCASE (locale sensitive)

The UCASE function returns a string in which all characters have been converted to uppercase characters using the rules associated with the specified locale.

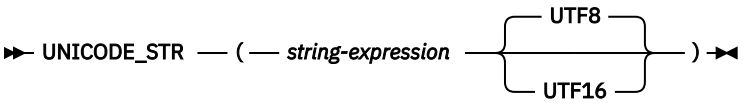


The schema is SYSIBM.

UCASE is a synonym for UPPER.

UNICODE_STR

The UNICODE_STR function returns a string in Unicode UTF-8 or UTF-16, depending on the specified option. The string represents a Unicode encoding of the input string.



The schema is SYSIBM.

string-expression

An expression that returns a value of a built-in character or graphic string.

A character string must not be bit data.

Values that are preceded by a backslash ('\') are treated as Unicode UTF-16 characters, for example, '\0041' is the Unicode UTF-16 representation for 'A').

A double backslash '\\' indicates a backslash in the string.

A backslash that is not part of a double backslash must be following by four hexadecimal digits (SQLSTATE 42815).

A partial surrogate character in the expression is replaced with a blank.

The argument can also be a numeric data type.

The numeric argument is implicitly cast to a VARCHAR data type.

UTF8 or UTF16

Specifies the Unicode encoding of the result.

- If UTF8 is specified, the result is returned as a Unicode UTF-8 character string.
- If UTF16 is specified, the result is returned as a Unicode UTF-16 graphic string.

UTF8 is the default.

Result

The result of the function depends on the second argument:

- If UTF8 is specified, the result is VARCHAR.
- If UTF16 is specified, the result is VARGRAPHIC.

The length attribute of the result depends on the second argument (UTF8 or UTF16).

- If the second argument is UTF8, the length attribute of the result is MIN(*n*,32672) OCTETS, where *n* depends on the length attribute and string units of the string-expression as follows:
  - If the string-expression contains the string unit OCTETS, *n* is the length attribute of the input string.
  - If the string-expression contains the string unit CODEUNITS16, *n* is twice the length attribute of the input string.
  - If the string-expression contains the string unit CODEUNITS32, *n* is four times the length attribute of the input string.
- If the second argument is UTF16, the length attribute of the result is MIN(*n*,16336) CODEUNITS16, where *n* depends on the length attribute and string units of the string-expression as follows:
  - If the string-expression contains the string units OCTETS or CODEUNITS16, *n* is the length attribute of the input string.
  - If the string-expression contains the string unit CODEUNITS32, *n* is twice the length attribute of the input string.

Notes

As a syntax alternative, you can specify UNISTR as a synonym for UNICODE_STR.

The following example sets the host variable *HV1* to a VARCHAR value that represents the Unicode UTF-8 string that corresponds to the argument:

```
SET :HV1 = UNICODE_STR('Hi, my name is \5CF0');
```

HV1 is assigned a Unicode UTF-8 string with the following value 'Hi, my name is 峰'.

UPPER

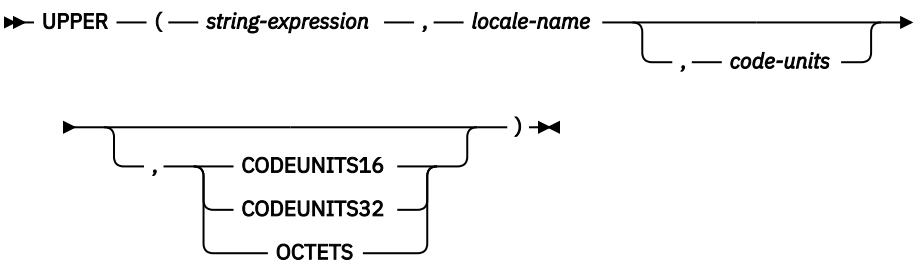
The UPPER function is identical to the TRANSLATE function except that only the first argument (*char-string-exp*) is specified.

The schema is SYSIBM. (The SYSFUN version of this function continues to be available for upward compatibility.)

expression
An expression that returns either a Boolean value or a built-in character string that is not FOR BIT DATA. In a Unicode database, the expression can also return a graphic string, in which case it is first converted to a character string before the function is evaluated.

UPPER (locale sensitive)

The UPPER function returns a string in which all characters have been converted to uppercase characters using the rules associated with the specified locale.



The schema is SYSIBM.

string-expression
An expression that returns a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC string. If *string-expression* is CHAR or VARCHAR, the expression must not be FOR BIT DATA (SQLSTATE 42815).

locale-name
A character constant that specifies the locale that defines the rules for conversion to uppercase characters. The value of *locale-name* is not case sensitive and must be a valid locale (SQLSTATE 42815). For information about valid locales and their naming, see "Locale names for SQL and XQuery".

Attention: In the container-only release of Db2 Version 11.5 Mod Pack 1 and later versions, passing UNI_SIMPLE as locale-name will enable use of simple case folding mapping.

code-units
An integer constant that specifies the number of code units in the result. If specified, *code-units* must be an integer between:

- 1 and 32 672 if the string unit of the result is OCTETS
- 1 and 16 336 if the string unit of the result is double bytes or CODEUNITS16

- 1 and 8 168 if the string unit of the result is CODEUNITS32

otherwise an error (SQLSTATE 42815). If *code-units* is not explicitly specified, it is implicitly the length attribute of *string-expression*. If OCTETS is specified and the result is graphic data, the value of *code-units* must be even, otherwise an error is returned (SQLSTATE 428GC). If OCTETS is specified and the string units of the result is CODEUNIT32, the value of *code-units* must be a multiple of 4 (SQLSTATE 428GC). If CODEUNITS16 is specified and the string units of the result is CODEUNITS32, the value of *code-units* must be a multiple of 2 (SQLSTATE 428GC).

CODEUNITS16, CODEUNITS32, or OCTETS
Specifies the string unit of *code-units*.

CODEUNITS16 specifies that *code-units* is expressed in 16-bit UTF-16 code units. CODEUNITS32 specifies that *code-units* is expressed in 32-bit UTF-32 code units. OCTETS specifies that *code-units* is expressed in bytes.

If a string unit is not explicitly specified, the string unit of *string-expression* determines the unit that is used. For more information about CODEUNITS16, CODEUNITS32, and OCTETS, see "String units in built-in functions" in "Character strings".

The result of the function is VARCHAR if *string-expression* is CHAR or VARCHAR, and VARGRAPHIC if *string-expression* is GRAPHIC or VARGRAPHIC. The string units of the result is the same as the string units of *string-expression*

The length attribute of the result is determined by the implicit or explicit value of *code-units*, the implicit or explicit string unit, the result data type, and the result string units, as shown in the following table:

Table 103. Length attribute of the result of UPPER as a function of string unit and result type

Data type and string units of result	**Length attribute for *code-units* in CODEUNITS16**	**Length attribute for *code-units* in CODEUNITS32**	**Length attribute for *code-units* in OCTETS**
VARCHAR in OCTETS	MIN(*code-units* * 3, 32672)	MIN(*code-units* * 4, 32672)	*code-units*
VARCHAR in CODEUNITS32	MIN(*code-units* / 2, 8168)	MIN(*code-units*, 8168)	MIN(*code-units* / 4, 8168)
VARGRAPHIC in CODEUNITS16 or double bytes	*code-units*	MIN(*code-units* * 2, 16336)	MIN(*code-units* / 2, 16336)
VARGRAPHIC in CODEUNITS32	MIN(*code-units* / 2, 8168)	MIN(*code-units*, 8168)	MIN(*code-units* / 4, 8168)

The actual length of the result might be greater than the length of *string-expression*. If the actual length of the result is greater than the length attribute of the result, an error is returned (SQLSTATE 42815). If the number of code units in the result exceeds the value of *code-units*, an error is returned (SQLSTATE 42815).

If *string-expression* is not in UTF-16, this function performs code page conversion of *string-expression* to UTF-16, and of the result from UTF-16 to the code page of *string-expression*. If either code page conversion results in at least one substitution character, the result includes the substitution character, a warning is returned (SQLSTATE 01517), and the warning flag SQLWARN8 in the SQLCA is set to 'W'.

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Examples

- *Example 1*: Ensure that the characters in the value of column JOB in the EMPLOYEE table are returned in uppercase characters.

```
SELECT UPPER(JOB, 'en_US')
  FROM EMPLOYEE
  WHERE EMPNO = '000020'
```

  The result is the value 'MANAGER'.

- *Example 2*: Find the uppercase characters for all the 'I' characters in a Turkish string.

```
VALUES UPPER('Iİıi', 'tr_TR', CODEUNITS16)
```

  The result is the string 'IİIİ'.

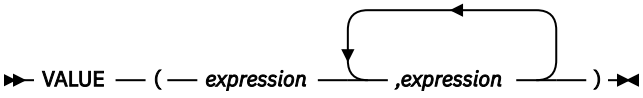
- *Example 3*: Find the uppercase form of the German 'ß' (sharp S).

```
VALUES UPPER('ß', 'de', 2, CODEUNITS16)
```

  The result is the string 'SS'. Note that *code-units* must be specified in this example, because there are more code units in the result than in *string-expression*.

VALUE

The VALUE function returns the first argument that is not null.

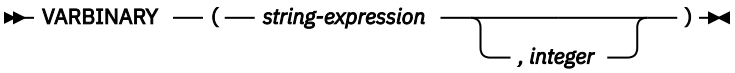


The schema is SYSIBM.

VALUE is a synonym for COALESCE.

VARBINARY

The VARBINARY function returns a VARBINARY (varying-length binary string) representation of a string of any data type.



The schema is SYSIBM.

string-expression
An expression that returns a value of a string data type.

integer
An integer constant value, which specifies the length attribute of the resulting VARBINARY data type. The value must be 1 - 32672. If *integer* is not specified, the length attribute of the result is the lower of the following values:

- The maximum length for the VARBINARY data type
- The length attribute for the data type of *string-expression* expressed in bytes:
  - The length attribute, if *string-expression* is a binary string, a character string that is FOR BIT DATA, or a character string with string units of OCTETS
  - The length attribute multiplied by 2, if *string-expression* is a graphic string with string units of CODEUNITS16 or double bytes
  - The length attribute multiplied by 4, if *string-expression* is a character or graphic string with string units of CODEUNITS32

If the length attribute of *string-expression* is zero and the *integer* argument is not specified, the length attribute of the result is 1.

The result of the function is a VARBINARY. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

The actual length of the result is the minimum of the length attribute of the result and the actual length in bytes of the *string-expression*. If the length of *string-expression* that is converted to a binary string is greater than the length attribute of the result, truncation occurs. A warning (SQLSTATE 01004) is returned in the following situations:

- The first argument is a character or graphic string (other than a CLOB or DBCLOB) and non-blank characters are truncated.
- The first argument is a binary string (other than BLOB) and non-hexadecimal zeros are truncated.

Examples

1. The following function returns a varying-length binary string with a length attribute 1, actual length 0, and a value of empty string.

```
SELECT VARBINARY('',1)
  FROM SYSIBM.SYSDUMMY1
```

2. The following function returns a varying-length binary string with a length attribute 5, actual length 3, and a value BX'4B4248'.

```
SELECT VARBINARY('KBH',5)
  FROM SYSIBM.SYSDUMMY1
```

3. The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'4B4248'.

```
SELECT VARBINARY('KBH')
  FROM SYSIBM.SYSDUMMY1
```

4. The following function returns a varying-length binary string with a length attribute 3, actual length 3, and a value BX'4B4248'.

```
SELECT VARBINARY('KBH ',3)
  FROM SYSIBM.SYSDUMMY1
```

5. The following function returns a varying-length binary string with a length attribute 3, actual length 3, a value BX'4B4248', and a warning (SQLSTATE 01004).

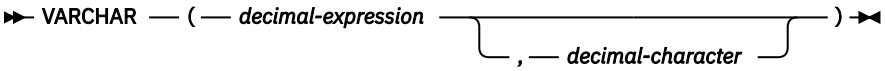
```
SELECT VARBINARY('KBH 93',3)
  FROM SYSIBM.SYSDUMMY1
```

VARCHAR

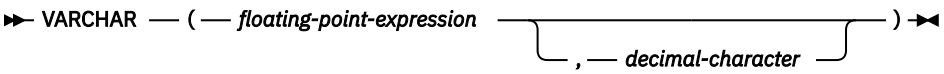
The VARCHAR function returns a varying-length character string representation of a value of a different data type.

Binary integer to VARCHAR

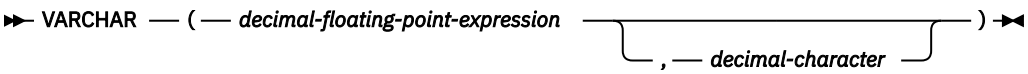
Decimal to VARCHAR



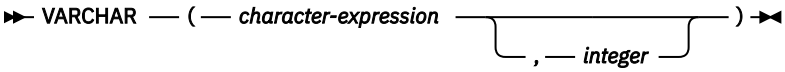
Floating-point to VARCHAR



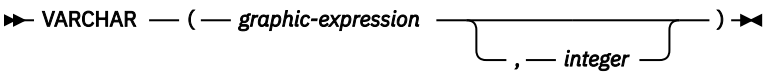
Decimal floating-point to VARCHAR



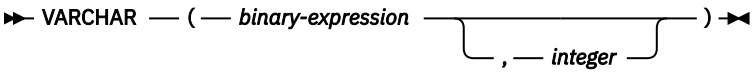
Character string to VARCHAR



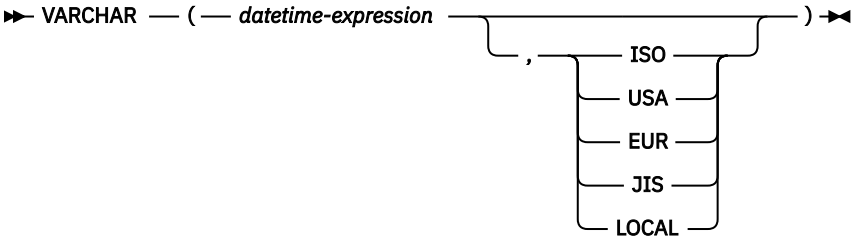
Graphic string to VARCHAR



Binary string to VARCHAR



Datetime to VARCHAR



Boolean to VARCHAR

The schema is SYSIBM. The function name cannot be specified as a qualified name when keywords are used in the function signature.

Binary integer to VARCHAR

integer-expression
An expression that returns a value that is of an integer data type (SMALLINT, INTEGER, or BIGINT).

The result is the varying-length string representation of *integer-expression* in the form of an SQL integer constant. The length attribute of the result depends on whether *integer-expression* is a small, large or big integer as follows:

- If the first argument is a small integer, the maximum length of the result is 6.
- If the first argument is a large integer, the maximum length of the result is 11.

- If the first argument is a big integer, the maximum length of the result is 20.

The actual length of the result is the smallest number of characters that can be used to represent the value of the argument. Leading zeros are not included. If the argument is negative, the first character of the result is a minus sign. Otherwise, the first character is a digit.

The code page of the result is the code page of the section.

Decimal to VARCHAR

decimal-expression
An expression that returns a value that is a decimal data type. The DECIMAL scalar function can be used to change the precision and scale.

decimal-character
Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character constant cannot be a digit, the plus sign (+), the minus sign (-), or a blank (SQLSTATE 42815). The default is the period (.) character.

The result is a varying-length character string representation of *decimal-expression* in the form of an SQL decimal constant. The length attribute of the result is 2+*p*, where *p* is the precision of *decimal-expression*. The actual length of the result is the smallest number of characters that can be used to represent the result, except that trailing zeros are included. Leading zeros are not included. If decimal-expression is negative, the first character of the result is a minus sign; otherwise, the first character is a digit or the decimal character. If the scale of *decimal-expression* is zero, the decimal character is not returned.

The code page of the result is the code page of the section.

Floating-point to VARCHAR

floating-point-expression
An expression that returns a value that is a floating-point data type (DOUBLE or REAL).

decimal-character
Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character constant cannot be a digit, the plus sign (+), the minus sign (-), or a blank (SQLSTATE 42815). The default is the period (.) character.

The result is a varying-length character string representation of *floating-point-expression* in the form of an SQL floating-point constant.

The maximum length of the result is 24. The actual length of the result is the smallest number of characters that can represent the value of floating-point-expression such that the mantissa consists of a single digit other than zero followed by the *decimal-character* and a sequence of digits. If *floating-point-expression* is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If *floating-point-expression* is zero, the result is 0E0.

The code page of the result is the code page of the section.

Decimal floating-point to VARCHAR

decimal-floating-point-expression
An expression that returns a value that is a decimal floating-point data type (DECFLOAT).

decimal-character
Specifies the single-byte character constant that is used to delimit the decimal digits in the result character string. The character constant cannot be a digit, the plus sign (+), the minus sign (-), or a blank (SQLSTATE 42815). The default is the period (.) character.

The result is a varying-length character string representation of *decimal-floating-point-expression* in the form of an SQL decimal floating-point constant. The maximum length of the result is 42. The actual length of the result is the smallest number of characters that can represent the value of *decimal-floating-point-expression*. If *decimal-floating-point-expression* is negative, the first character of the result is a minus sign; otherwise, the first character is a digit. If *decimal-floating-point-expression* is zero, the result is 0.

If the value of *decimal-floating-point-expression* is the special value Infinity, sNaN, or NaN, the strings "INFINITY", "SNAN", and "NAN", respectively, are returned. If the special value is negative, the first character of the result is a minus sign. The decimal floating-point special value sNaN does not result in a warning when converted to a string.

The code page of the result is the code page of the section.

Character string to VARCHAR

character-expression
An expression that returns a value that is a built-in character string data type.

integer
An integer constant that specifies the length attribute for the resulting varying-length character string. The value must be between 0 and the maximum length for the VARCHAR data type in the string units of the result.

If the second argument is not specified:

- If the *character-expression* is the empty string constant, the length attribute of the result is 0.
- Otherwise, the length attribute of the result is the lower of the following values:
  - The maximum length for the VARCHAR data type in the string units of the result
  - The length attribute of the first argument

The result is a varying-length character string. The length attribute of the result is determined by the value of *integer*. If *character-expression* is the FOR BIT DATA subtype, the result is FOR BIT DATA.

If the length of *character-expression* is greater than the length attribute of the result, several scenarios exist:

- If the string unit of the result is CODEUNITS32, truncation is performed. If only blank characters are truncated and *character-expression* is CHAR or VARCHAR, no warning is returned. Otherwise, a warning is returned (SQLSTATE 01004).
- If *integer* is specified, truncation is performed. If only blank characters are truncated and *character-expression* is CHAR or VARCHAR, no warning is returned. Otherwise, a warning is returned (SQLSTATE 01004). When part of a multi-byte character is truncated, that partial character is replaced with the blank character. Do not rely on this behavior because it might change in a future release.
- If *integer* is not specified, an error is returned (SQLSTATE 22001).

Graphic string to VARCHAR

graphic-expression
An expression that returns a value that is a built-in graphic string data type.

integer
An integer constant that specifies the length attribute for the resulting varying-length character string. The value must be between 0 and the maximum length for the VARCHAR data type in the string units of the result.

If the second argument is not specified:

- If the *graphic-expression* is the empty string constant, the length attribute of the result is 0.
- If the string units of *graphic-expression* is CODEUNITS32, the length attribute of the result is the lower of the following values:
  - The maximum length for the VARCHAR data type in the string units of the result
  - The length attribute of the first argument
- Otherwise, the length attribute of the result is the lower of the following values:
  - The maximum length for the VARCHAR data type in the string units of the result
  - 3 * length attribute of the first argument

The result is a varying-length character string that is converted from *graphic-expression*. The length attribute of the result is determined by the value of *integer*.

If the length of *graphic-expression* that is converted to a character string is greater than the length attribute of the result, several scenarios exist:

- If the string unit of the result is CODEUNITS32, truncation is performed. If only blank characters are truncated and *graphic-expression* is GRAPHIC or VARGRAPHIC, no warning is returned. Otherwise, a warning is returned (SQLSTATE 01004).
- If *integer* is specified and *graphic-expression* is a GRAPHIC or VARGRAPHIC, truncation is performed with no warning returned.
- If *integer* is specified and *graphic-expression* is a DBCLOB, truncation is performed with a warning returned (SQLSTATE 01004).
- If *integer* is not specified and *graphic-expression* is a GRAPHIC or VARGRAPHIC, truncation is performed with no warning returned.
- If *integer* is not specified and *graphic-expression* is a DBCLOB, an error is returned (SQLSTATE 22001).

Binary string to VARCHAR

binary-expression
An expression that returns a value that is a built-in binary string data type.

integer
An integer constant that specifies the length attribute for the resulting varying-length character string. The value must be between 0 and the maximum length for the VARCHAR data type in the string units of the result.

The result is a FOR BIT DATA character string.

Datetime to VARCHAR

datetime-expression
An expression that is of one of the following data types:

DATE
The result is the character string representation of the date in the format specified by the second argument. The length of the result is 10. An error is returned if the second argument is specified and is not a valid value (SQLSTATE 42703).

TIME
The result is the character string representation of the time in the format specified by the second argument. The length of the result is 8. An error is returned if the second argument is specified and is not a valid value (SQLSTATE 42703).

TIMESTAMP
The result is the character string representation of the timestamp. If the data type of *datetime-expression* is TIMESTAMP(0), the length of the result is 19. If the data type of *datetime-expression* is TIMESTAMP(*n*), where *n* is between 1 and 12, the length of the result is 20+*n*. Otherwise, the length of the result is 26. The second argument must not be specified (SQLSTATE 42815).

The code page of the result is the code page of the section.

Boolean to VARCHAR

boolean-expression
An expression that returns a Boolean value (TRUE or FALSE). The result is either 'TRUE' or 'FALSE'.

Result

The VARCHAR function returns a varying-length character string representation of:

- An integer number, if the only argument is a SMALLINT, INTEGER, or BIGINT value

- A decimal number, if the first argument is a DECIMAL value
- A double-precision floating-point number, if the first argument is a floating-point (DOUBLE or REAL) value
- A decimal floating-point number, if the first argument is a decimal floating-point (DECFLOAT) value
- A character string, if the first argument is a character string (CHAR, VARCHAR, or CLOB) value
- A graphic string (Unicode databases only), if the first argument is a graphic string (GRAPHIC, VARGRAPHIC, or DBCLOB) value
- A datetime value, if the first argument is a datetime (DATE, TIME, or TIMESTAMP) value
- A Boolean value ('TRUE' or 'FALSE'), if the only argument is a BOOLEAN value (TRUE or FALSE)

In a non-Unicode database, the string units of the result is OCTETS. Otherwise, the string units of the result is determined by the data type of the first argument.

- OCTETS, if the first argument is character string or a graphic string with string units of OCTETS, CODEUNITS16, or double bytes.
- CODEUNITS32, if the first argument is character string or a graphic string with string units of CODEUNITS32.
- Determined by the default string unit of the environment, if the first argument is not a character string or a graphic string.

In a Unicode database, when the output string is truncated part-way through a multiple-byte character:

- If the input was a character string, the partial character is replaced with one or more blanks
- If the input was a graphic string, the partial character is replaced by the empty string

Do not rely on either of these behaviors, because they might change in a future release.

If the first argument can be null, the result can be null. If the first argument is null, the result is the null value.

Notes

- **Increasing portability of applications:** If the first argument is numeric, or if the first argument is a string and the length argument is specified, use the “CAST specification” on page 152 instead of this function to increase the portability of your applications.

Examples

- *Example 1:* Make EMPNO varying-length with a length of 10.

```
SELECT VARCHAR(EMPNO,10)
  INTO :VARHV
  FROM EMPLOYEE
```

- *Example 2:* Set the host variable JOB_DESC, defined as VARCHAR(8), to the VARCHAR equivalent of the job description (which is the value of the JOB column), defined as CHAR(8), for employee Dolores Quintana.

```
SELECT VARCHAR(JOB)
  INTO :JOB_DESC
  FROM EMPLOYEE
  WHERE LASTNAME = 'QUINTANA'
```

- *Example 3:* The EDLEVEL column is defined as SMALLINT. The following returns the value as a varying-length character string.

```
SELECT VARCHAR(EDLEVEL)
  FROM EMPLOYEE
  WHERE LASTNAME = 'HAAS'
```

  Results in the value '18'.

- *Example 4:* The SALARY and COMM columns are defined as DECIMAL with a precision of 9 and a scale of 2. Return the total income for employee Haas using the comma decimal character.

```
SELECT VARCHAR(SALARY + COMM, ',')
  FROM EMPLOYEE
  WHERE LASTNAME = 'HAAS'
```

  Results in the value '56970,00'.

- *Example 5*: The following statement returns a string of data type VARCHAR with the value 'TRUE'.

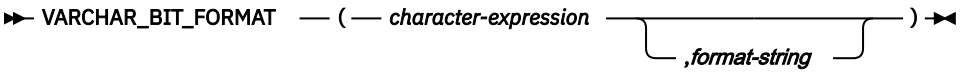
```
values VARCHAR(3=3)
```

- *Example 6*: The following statement returns a string of data type VARCHAR with the value 'FALSE'.

```
values VARCHAR(3>3)
```

VARCHAR_BIT_FORMAT

The VARCHAR_BIT_FORMAT function returns a bit string representation of a character string that has been formatted using a character template.



The schema is SYSIBM.

In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

character-expression
An expression that returns a value that is a built-in character string that is not a CLOB (SQLSTATE 42815). The required length is determined by the specified format string and how the value is interpreted. If a *format-string* argument is not specified, the length must be an even number of characters from the ranges '0' to '9', 'a' to 'f', and 'A' to 'F' (SQLSTATE 42815).

format-string
A character constant that contains a template for how the bytes of *character-expression* are to be interpreted.

Valid format strings include: `'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx'` and `'XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX'` (SQLSTATE 42815) where each 'x' or 'X' corresponds to one hexadecimal digit in the result.

The result of the function is a varying-length character string FOR BIT DATA with the length attribute and actual length based on the format string. For the two valid format strings listed previously, the length attribute of the result is 36 and the actual length is 16. If a *format-string* argument is not specified, the length attribute of the result is half the length attribute of *character-expression* and the actual length is half the length of the actual length of *character-expression*. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Examples

- *Example 1*: Represent a Universal Unique Identifier in its binary form:

```
VARCHAR_BIT_FORMAT('d83d6360-1818-11db-9804-b622a1ef5492',
                   'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx')
```

  Result returned:

```
x'D83D6360181811DB9804B622A1EF5492'
```

- *Example 2*: Represent a Universal Unique Identifier in its binary form:

```
VARCHAR_BIT_FORMAT('D83D6360-1818-11DB-9804-B622A1EF5492',
                   'XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX')
```

  Result returned:

```
    x'D83D6360181811DB9804B622A1EF5492'
```

- *Example 3*: Represent a string of hexadecimal characters in binary form.

```
VARCHAR_BIT_FORMAT('ef01abC9')
```

  Result returned as a VARCHAR(4) FOR BIT DATA value:

```
    x'EF01ABC9'
```

- *Example 4*: Represent a string of hexadecimal characters as a character string in the code page of the database. The result needs to be cast to a VARCHAR data type with the FOR MIXED DATA clause, assuming the database supports graphic types. Otherwise the result needs to be cast to a VARCHAR data type with the FOR SBCS clause. The following example assumes a Unicode database:

```
VALUES CAST(VARCHAR_BIT_FORMAT(HEX('abcdefg')) AS VARCHAR(10) FOR MIXED DATA)
```

  Result returned:

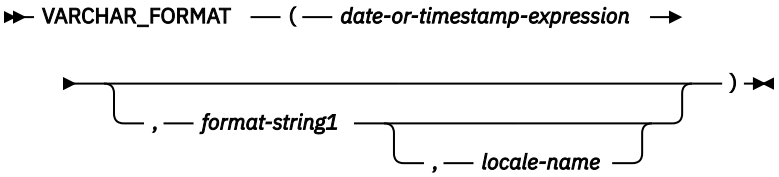
```
abcdefg
```

VARCHAR_FORMAT

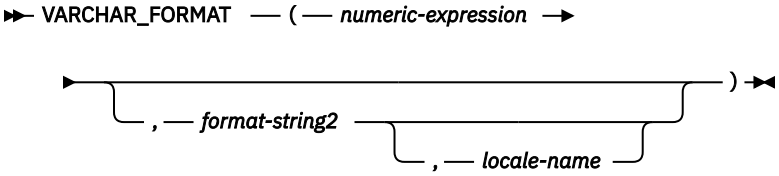
The VARCHAR_FORMAT function returns a character representation of an input expression.

Character string to VARCHAR

DATE or TIMESTAMP to VARCHAR



Signed numeric to VARCHAR



The schema is SYSIBM.

If any argument of the VARCHAR_FORMAT function can be null, the result can be null; if any argument is null, the result is the null value.

Character string to VARCHAR

character-expression
An expression that returns a value that must be a built-in CHAR or VARCHAR data type. In a Unicode database, if a supplied argument is a GRAPHIC or VARGRAPHIC data type, it is first converted to VARCHAR before evaluating the function.

The result is a VARCHAR with a length attribute that matches the length attribute of the argument. The value of the result is the same as the value of *character-expression*.

The code page of the result is the code page of the section.

DATE or TIMESTAMP to VARCHAR

date-or-timestamp-expression
An expression that returns a value that must be a DATE or TIMESTAMP, or a valid string representation of a date or timestamp that is not a CLOB or DBCLOB. In a Unicode database, if the expression returns a graphic string representation of a date or timestamp, the returned value is first converted to a character string before the function is evaluated.

If the input expression returns:

- A string, the *format-string* argument must also be specified.
- A DATE or a string representation of a date, the returned value is first converted to a TIMESTAMP(0) value with a time component of exactly midnight (00.00.00).
- A string representation of a timestamp, it is first converted to a TIMESTAMP(12) value

For a list of valid formats for string representations of datetime values, see "String representations of datetime values" on page 39.

format-string1
An expression that returns a value with one of the following built-in data types:

- CHAR or VARCHAR
- Signed numeric
- Datetime
- GRAPHIC or VARGRAPHIC (Unicode databases only)

If the data type is not CHAR or VARCHAR, it is implicitly cast to VARCHAR before the function is evaluated. The actual length must not be greater than 255 bytes (SQLSTATE 22007). The value is a template for how *timestamp-expression* is to be formatted.

The default format string is based on the value of the special register CURRENT LOCALE LC_TIME.

A valid format string must contain a combination of the format elements listed in Table 1 (SQLSTATE 22007). Two format elements can optionally be separated by one or more of the following separator characters:

- minus sign (-)
- period (.)
- slash (/)
- comma (,)
- apostrophe (')
- semi-colon (;)
- colon (:)
- blank ( )

Separator characters can also be specified at the start or end of *format-string*.

Table 104. Format elements for DATE or TIMESTAMP to VARCHAR	
Format element	**Description**
AM or PM	Meridian indicator (morning or evening) without periods. This format element is dependent on *locale-name*, if specified; otherwise, it is dependent on the value of the special register CURRENT LOCALE LC_TIME.
A.M. or P.M.	Meridian indicator (morning or evening) with periods. This format element uses the exact strings 'A.M.' or 'P.M.' and is independent of the locale name in effect.
CC	Century (01-99). If the last two digits of the four-digit year are zero, the result is the first two digits of the year; otherwise, the result is the first two digits of the year plus one.
DAY, Day, or day	Name of the day in uppercase, titlecase, or lowercase format. The language used is dependent on *locale-name*, if specified; otherwise, it is dependent on the value of the special register CURRENT LOCALE LC_TIME.
DY, Dy, or dy	Abbreviated name of the day in uppercase, titlecase, or lowercase format. The language used is dependent on *locale-name*, if specified; otherwise, it is dependent on the value of the special register CURRENT LOCALE LC_TIME.
D	Day of the week (1-7). The first day of the week is dependent on *locale-name*, if specified; otherwise, it is dependent on the value of the special register CURRENT LOCALE LC_TIME.
DD	Day of month (01-31).
DDD	Day of year (001-366).
FF or FF*n*	Fractional seconds (0-999999999), where *n* specifies the scale of the returned value. Valid values for *n* are 1 - 12 with no leading zeros. Specifying FF is equivalent to specifying FF6. If the scale of the input timestamp is less than *n*, the result is padded with trailing zeros.
HH	HH behaves the same as HH12.
HH12	Hour of the day (01-12) in 12-hour format.
HH24	Hour of the day (00-24) in 24-hour format.
I	ISO year (0-9). The last digit of the year based on the ISO week that is returned.
ID	ISO day of the week (1-7). 1 is Monday and 7 is Sunday.

Table 104. Format elements for DATE or TIMESTAMP to VARCHAR (continued)	
Format element	**Description**
IW	ISO week of the year (01-53). The week starts on Monday and includes seven days. Week 1 is the first week of the year to contain a Thursday, which is equivalent to the first week of the year to contain January 4.
IY	ISO year (00-99). The last two digits of the year based on the ISO week that is returned.
IYY	ISO year (000-999). The last three digits of the year based on the ISO week that is returned.
IYYY	ISO year (0000-9999). The 4-digit year based on the ISO week that is returned.
J	Julian day (number of days since January 1, 4713 BC).
MI	Minute (00-59).
MM	Month (01-12).
MONTH, Month, or month	Name of the month in uppercase, titlecase, or lowercase format. The language used is dependent on *locale-name*, if specified; otherwise, it is dependent on the value of the special register CURRENT LOCALE LC_TIME.
MON, Mon, or mon	Abbreviated name of the month in uppercase, titlecase, or lowercase format. The language used is dependent on *locale-name*, if specified; otherwise, it is dependent on the value of the special register CURRENT LOCALE LC_TIME.
MS	Milleseconds (000-999). Same as FF3.
NNNNNN	Microseconds (000000-999999). Same as FF6.
Q	Quarter (1-4), where the months January through March return 1.
RR	RR behaves the same as YY.
RRRR	RRRR behaves the same as YYYY.
SS	Seconds (00-59).
SSSSS	Seconds since previous midnight (00000-86400).
US	Microseconds (000000-999999). Same as FF6.
W	Week of the month (1-5), where week 1 starts on the first day of the month and ends on the seventh day.
WW	Week of the year (01-53), where week 1 starts on January 1 and ends on January 7.
Y	Last digit of the year (0-9).
YY	Last two digits of the year (00-99).

Table 104. Format elements for DATE or TIMESTAMP to VARCHAR (continued)	
Format element	**Description**
YYY	Last three digits of the year (000-999).
YYYY	4-digit year (0000-9999).

The format elements in Table 104 on page 566 are not case sensitive, with the following exceptions:

- AM, PM
- A.M., P.M.
- DAY, Day, day
- DY, Dy, dy
- D
- MONTH, Month, month
- MON, Mon, mon

In cases where format elements are ambiguous, the case insensitive format elements will be considered first. For example, 'DDYYYY' would be interpreted as "DD followed by YYYY", not "D followed by DY followed by YYY".

locale-name
A character constant that specifies the locale used for the following format elements:

- AM, PM
- DAY, Day, day
- DY, Dy, dy
- D
- MONTH, Month, month
- MON, Mon, mon

The specified locale name is not case sensitive and must be a valid locale (SQLSTATE 42815). For information about valid locales and their naming,, see "Locale names for SQL and XQuery" in the *Globalization Guide* . The default is the value of the CURRENT LOCALE LC_TIME special register.

The result is a representation of the input timestamp expression in the format specified by the format string. The format string is interpreted as a series of format elements that can be separated by one or more separator characters. A string of characters in the format string is interpreted as the longest matching format element in Table 104 on page 566. If two format elements that contain the same characters are not delimited by a separator character, the specification is interpreted, starting from the left, as the longest matching format element in the table, and continues until matches are found for the remainder of the format string. For example, 'YYYYYYDD' is interpreted as the format elements 'YYYY', 'YY', and 'DD'.

The result is a varying-length character string. The length attribute is 255. If the string units of the environment or *format-string* is CODEUNITS32, the string units of the result is CODEUNITS32. Otherwise, the string units of the result is OCTETS. The *format-string* determines the actual length of the result. If the resulting string exceeds the length attribute of the result, the result is truncated.

The code page of the result is the code page of the section.

Signed numeric to VARCHAR

numeric-expression
An expression that returns a value of any built-in signed numeric data type. If the data type of the value is not DECFLOAT, it is converted to DECFLOAT(34) for processing.

format-string2
An expression that returns a value that has one of the following built-in data types:

- CHAR or VARCHAR
- Signed numeric
- Datetime
- GRAPHIC or VARGRAPHIC (Unicode databases only)

If the data type is not CHAR or VARCHAR, it is implicitly cast to VARCHAR before the function is evaluated. The actual length cannot be greater than 255 bytes (SQLSTATE 22018). The value is used as a template to format the input decimal floating-point expression. Format elements specified as a prefix can be used only at the beginning of the template. Format elements specified as a suffix can be used only at the end of the template. The template cannot contain more than one of the MI, S, or PR format elements (SQLSTATE 22018).

If a format string is not specified, the function is equivalent to VARCHAR(DECFLOAT(numeric-expression)).

Table 105. Format elements for decimal floating-point to varchar

Format element	**Description**
0	Each 0 represents a significant digit. Leading zeros in a number are displayed as zeros.
9	Each 9 represents a significant digit. Leading zeros in a number are displayed as blanks.
PL or pl	If the input decimal floating-point expression returns a positive number, a plus sign (+) is added at the specified position.
G or g	The group separator specified by the locale is added at the specified position.
D or d	The decimal delimiter specified by the locale is added at the specified position.
,	A comma is added at the specified position, for example as a group separator.
.	A period is added at the specified position, for example as a decimal point.
S or s	Prefix: If the input decimal floating-point expression returns: • A negative number, a leading minus sign (-) is added to the result • A positive number, a leading plus sign (+) is added to the result
$	Prefix: A leading dollar sign ($) is added to the result.
MI or mi	Suffix: If the input decimal floating-point expression returns: • A negative number, a trailing minus sign (-) is added to the result • A positive number, a trailing blank is added to the result
PR or pr	Suffix: If the input decimal floating-point expression returns: • A negative number, a leading less than character (<) and a trailing greater than character (>) are added to the result • A positive number, a leading space and a trailing space are added to the result

The format elements are case sensitive.

locale-name
A character constant that specifies the locale used to determine the group separator and decimal delimiter.

The specified locale name is not case sensitive and must be a valid locale (SQLSTATE 42815). For information about valid locales and their naming,, see "Locale names for SQL and XQuery" in the *Globalization Guide* . The default is the value of the CURRENT LOCALE LC_TIME special register.

The result is a varying-length character string representation of the input decimal floating-point expression. If a single argument is specified the length attribute is 42. Otherwise the length attribute is 254. If the string units of the environment or the format string is CODEUNITS32, the string units of the result is CODEUNITS32; otherwise, the string units of the result is OCTETS. The actual length of the result is determined by the format string, if specified; otherwise, the actual length of the result is the smallest number of characters that can represent the value of the input decimal floating-point expression. If the resulting string exceeds the length attribute of the result, the result is truncated.

If the value of the input decimal floating-point expression is the special value:

- Infinity, the string "INFINITY" is returned
- sNaN, the string "SNAN" is returned
- NaN, the string "NAN" is returned

If the special value is negative, the first character of the result is a minus sign (-). The decimal floating-point special value sNaN does not result in an exception when converted to a string.

If the format string does not include any of the format elements MI, S, or PR, and if the value of the input expression is negative, then a minus sign (-) is included in the result; otherwise, a blank is included in the result.

If the number of digits to the left of the decimal point in the input expression is greater than the number of digits to the left of the decimal point in the format string, the result is a string of one or more number sign (#) characters. If the number of digits to the right of the decimal point in the input expression is greater than the number of digits to the right of the decimal point in the format string, the result is rounded to the number of digits to the right of the decimal point in the format string. The DECFLOAT rounding mode will not be used. The rounding behavior of VARCHAR_FORMAT corresponds to a value of ROUND_HALF_UP.

The code page of the result is the code page of the section.

Notes

- ***Julian and Gregorian calendar***: For Timestamp to varchar, the transition from the Julian calendar to the Gregorian calendar on 15 October 1582 is taken into account by this function.
- ***Determinism:*** VARCHAR_FORMAT is a deterministic function. However, the following invocations of the function depend on the value of the special register CURRENT LOCALE LC_TIME.
  - Timestamp to varchar, when format-string is not explicitly specified, or when locale-name is not explicitly specified and one of the following statements is true:
    - *format-string* is not a constant
    - *format-string* is a constant and includes format elements that are locale sensitive

    These invocations that depend on the value of a special register cannot be used wherever special registers cannot be used (SQLSTATE 42621, 428EC, or 429BX).
- ***Syntax alternatives:*** TO_CHAR is a synonym for VARCHAR_FORMAT.

Examples

- *Example 1*: Display the names and creation timestamps for all system tables that have names that start with **SYSU**.

```
SELECT VARCHAR(TABNAME, 20) AS TABLE_NAME,
  VARCHAR_FORMAT(CREATE_TIME, 'YYYY-MM-DD HH24:MI:SS')
    AS CREATION_TIME
  FROM SYSCAT.TABLES
  WHERE TABNAME LIKE 'SYSU%'
```

This example returns the following output:

```
TABLE_NAME           CREATION_TIME
-------------------- --------------------
SYSUSERAUTH          2000-05-19 08:18:56
SYSUSEROPTIONS       2000-05-19 08:18:56
```

- *Example 2*: The variable TMSTMP is defined as a TIMESTAMP and has the value 2007-03-09-14.07.38.123456. The following examples show invocations of the VARCHAR_FORMAT function and the resulting string values. The data type of each result is VARCHAR(255).

```
Function invocation                          Result
-------------------                          ------
VARCHAR_FORMAT(TMSTMP,'YYYYMMDDHHMISSFF3')   20070309020738123
VARCHAR_FORMAT(TMSTMP,'YYYYMMDDHH24MISS')    20070309140738
VARCHAR_FORMAT(TMSTMP,'YYYYMMDDHHMI')        200703090207
```

```
VARCHAR_FORMAT(TMSTMP,'HH12:MI:SS.MS AM')    02:07:38.123 PM
VARCHAR_FORMAT(TMSTMP,'HH24:MI:SS.US')       14:07:38.123456
```

```
VARCHAR_FORMAT(TMSTMP,'DD/MM/YY')            09/03/07
VARCHAR_FORMAT(TMSTMP,'MM-DD-YYYY')          03-09-2007
VARCHAR_FORMAT(TMSTMP,'J')                   2454169
VARCHAR_FORMAT(TMSTMP,'Q')                   1
VARCHAR_FORMAT(TMSTMP,'W')                   2
VARCHAR_FORMAT(TMSTMP,'IW')                  10
VARCHAR_FORMAT(TMSTMP,'WW')                  10
VARCHAR_FORMAT(TMSTMP,'Month','en_US')       March
VARCHAR_FORMAT(TMSTMP,'MONTH','en_US')       MARCH
VARCHAR_FORMAT(TMSTMP,'MON','en_US')         MAR
VARCHAR_FORMAT(TMSTMP,'Day','en_US')         Friday
VARCHAR_FORMAT(TMSTMP,'DAY','en_US')         FRIDAY
VARCHAR_FORMAT(TMSTMP,'Dy','en_US')          Fri
VARCHAR_FORMAT(TMSTMP,'Month','de_DE')       März
VARCHAR_FORMAT(TMSTMP,'MONTH','de_DE')       MÄRZ
VARCHAR_FORMAT(TMSTMP,'MON','de_DE')         MÄRZ
VARCHAR_FORMAT(TMSTMP,'Day','de_DE')         Freitag
VARCHAR_FORMAT(TMSTMP,'DAY','de_DE')         FREITAG
VARCHAR_FORMAT(TMSTMP,'Dy','de_DE')          Fr.
```

- *Example 3*: The variable DTE is defined as a DATE and has the following value: 2007-03-09. The following examples show several invocations of the function and the resulting string values. The data type of each result is VARCHAR(255).

```
Function invocation                          Result
-------------------                          ------
VARCHAR_FORMAT(DTE,'YYYYMMDD')               20070309
VARCHAR_FORMAT(DTE,'YYYYMMDDHH24MISS')       20070309000000
```

- *Example 4*: The variables POSNUM and NEGNUM are both defined as DECFLOAT(34), and the value of POSNUM is 1234.56 and the value of NEGNUM is -1234.56. The following examples show several invocations of the VARCHAR_FORMAT and the resulting string values. The data type of the first two results is VARCHAR(42) and the rest are VARCHAR(254).

```
Function invocation                           Result
-------------------                           ------
VARCHAR_FORMAT(POSNUM)                        '1234.56'
VARCHAR_FORMAT(NEGNUM)                        '-1234.56'
VARCHAR_FORMAT(POSNUM,'9999.99')              ' 1234.56'
VARCHAR_FORMAT(NEGNUM,'9999.99')              '-1234.56'
VARCHAR_FORMAT(POSNUM,'99999.99')             '  1234.56'
VARCHAR_FORMAT(NEGNUM,'99999.99')             ' -1234.56'
VARCHAR_FORMAT(POSNUM,'00000.00')             ' 01234.56'
VARCHAR_FORMAT(NEGNUM,'00000.00')             '-01234.56'
VARCHAR_FORMAT(POSNUM,'9999.99MI')            '1234.56 '
VARCHAR_FORMAT(NEGNUM,'9999.99MI')            '1234.56-'
VARCHAR_FORMAT(POSNUM,'S9999.99')             '+1234.56'
VARCHAR_FORMAT(NEGNUM,'S9999.99')             '-1234.56'
VARCHAR_FORMAT(POSNUM,'9999.99PR')            ' 1234.56 '
VARCHAR_FORMAT(NEGNUM,'9999.99PR')            '<1234.56>'
VARCHAR_FORMAT(POSNUM,'S$9,999.99')           '+$1,234.56'
VARCHAR_FORMAT(NEGNUM,'S$9,999.99')           '-$1,234.56'
```

```
VARCHAR_FORMAT(POSNUM,'99,99,99')             '    12,35'
VARCHAR_FORMAT(NEGNUM,'99,99,99')             '   -12,35'
VARCHAR_FORMAT(POSNUM,'PL9999.99')            '+1234.56'
VARCHAR_FORMAT(NEGNUM,'PL9999.99')            ' 1234.56'
VARCHAR_FORMAT(POSNUM,'9999PL')               ' 1234+'
VARCHAR_FORMAT(NEGNUM,'9999PL')               '-1234 '
VARCHAR_FORMAT(POSNUM,'9999.9')               ' 1234.6'
VARCHAR_FORMAT(NEGNUM,'9999.9')               '-1234.6'
VARCHAR_FORMAT(POSNUM,'9999')                 ' 1235'
VARCHAR_FORMAT(NEGNUM,'9999')                 '-1235'
VARCHAR_FORMAT(POSNUM,'99.99')                '######'
VARCHAR_FORMAT(NEGNUM,'99.99')                '######'
VARCHAR_FORMAT(POSNUM,'9999D99', 'en_US')     ' 1234.56'
VARCHAR_FORMAT(POSNUM,'9999D99', 'fr_FR')     ' 1234,56'
VARCHAR_FORMAT(POSNUM,'9G999D99', 'en_US')    ' 1,234.56'
VARCHAR_FORMAT(POSNUM,'9G999D99', 'de_DE')    ' 1.234,56'
```

VARCHAR_FORMAT_BIT

The VARCHAR_FORMAT_BIT function returns a character representation of a bit string that has been formatted using a character template.

The schema is SYSIBM.

bit-data-expression
An expression that returns a value that is a built-in character-string FOR BIT DATA data type (SQLSTATE 42815). The required length is determined by the specified format string and how the value is interpreted.

format-string
A character constant that contains a template for how the result is to be formatted.

Valid format strings include: `'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx'` and `'XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX'` (SQLSTATE 42815) where each 'x' or 'X' corresponds to one hexadecimal digit from *bit-data-expression*.

The result of the function is a varying-length character string with the length attribute and actual length based on the format string. If the string units of the environment or *format-string* is CODEUNITS32, the string units of the result is CODEUNITS32. Otherwise, the string units of the result is OCTETS For the two valid format strings listed previously, the length attribute is 36 and the actual length is 36 bytes. If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Examples

- *Example 1*: Represent a Universal Unique Identifier in its formatted form:

```
VARCHAR_FORMAT_BIT(CAST(x'd83d6360181811db9804b622a1ef5492'
                        AS VARCHAR(16) FOR BIT DATA),
                   'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx')
```

  Result returned:

```
'd83d6360-1818-11db-9804-b622a1ef5492'
```

- *Example 2*: Represent a Universal Unique Identifier in its formatted form:

```
VARCHAR_FORMAT_BIT(CAST(x'd83d6360181811db9804b622a1ef5492'
                        AS CHAR(16) FOR BIT DATA),
                   'XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX')
```

  Result returned:

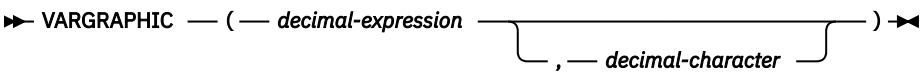
```
'D83D6360-1818-11DB-9804-B622A1EF5492'
```

VARGRAPHIC

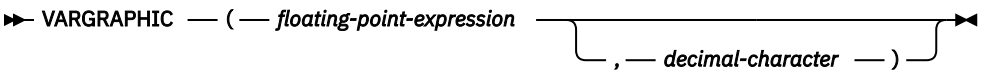
The VARGRAPHIC function returns a varying-length graphic string representation of a value of a different data type.

Integer to vargraphic

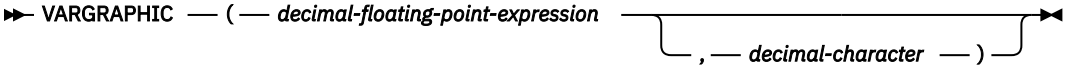
Decimal to vargraphic



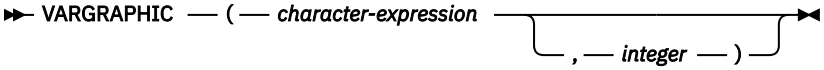
Floating-point to vargraphic



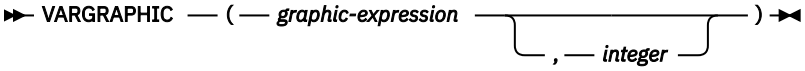
Decimal floating-point to vargraphic



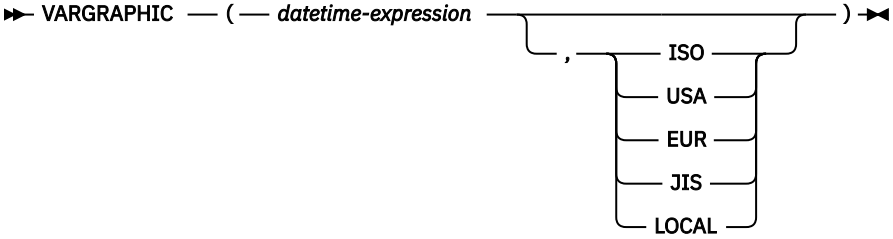
Character to vargraphic



Graphic to vargraphic



Datetime to vargraphic



Boolean to vargraphic

The schema is SYSIBM. The function name cannot be specified as a qualified name when keywords are used in the function signature.

Integer to vargraphic

integer-expression
An expression that returns a value that is of an integer data type (SMALLINT, INTEGER, or BIGINT).

The result is the varying-length graphic string representation of *integer-expression* in the form of an SQL integer constant. The length attribute of the result depends on whether *integer-expression* is a small, large or big integer as follows:

- If the first argument is a small integer, the maximum length of the result is 6.
- If the first argument is a large integer, the maximum length of the result is 11.
- If the first argument is a big integer, the maximum length of the result is 20.

The actual length of the result is the smallest number of double-byte characters that can be used to represent the value of the argument. Leading zeros are not included. If the argument is negative, the first double-byte character of the result is a minus sign; otherwise, the first double-byte character is a digit.

The code page of the result is the DBCS code page of the section.

Decimal to vargraphic

decimal-expression
An expression that returns a value that is a decimal data type. The DECIMAL scalar function can be used to change the precision and scale.

decimal-character
Specifies the double-byte character constant that is used to delimit the decimal digits in the result graphic string. The double-byte character constant cannot be a digit, the plus sign (+), the minus sign (-), or a blank (SQLSTATE 42815). The default is the period (.) character.

The result is a varying-length graphic string representation of *decimal-expression* in the form of an SQL decimal constant. The length attribute of the result is 2+*p*, where *p* is the precision of *decimal-expression*. The actual length of the result is the smallest number of double-byte characters that can be used to represent the result, except that trailing zeros are included. Leading zeros are not included. If *decimal-expression* is negative, the first double-byte character of the result is a minus sign; otherwise, the first double-byte character is a digit or the decimal character. If the scale of *decimal-expression* is zero, the decimal character is not returned.

The code page of the result is the DBCS code page of the section.

Floating-point to vargraphic

floating-point-expression
An expression that returns a value that is a floating-point data type (DOUBLE or REAL).

decimal-character
Specifies the double-byte character constant that is used to delimit the decimal digits in the result graphic string. The double-byte character constant cannot be a digit, the plus sign (+), the minus sign (-), or a blank (SQLSTATE 42815). The default is the period (.) character.

The result is a varying-length graphic string representation of *floating-point-expression* in the form of an SQL floating-point constant.

The maximum length of the result is 24. The actual length of the result is the smallest number of double-byte characters that can represent the value of *floating-point-expression* such that the mantissa consists of a single digit other than zero followed by the *decimal-character* and a sequence of digits. If *floating-point-expression* is negative, the first double-byte character of the result is a minus sign; otherwise, the first double-byte character is a digit. If *floating-point-expression* is zero, the result is 0E0.

The code page of the result is the DBCS code page of the section.

Decimal floating-point to vargraphic

decimal-floating-point-expression
An expression that returns a value that is a decimal floating-point data type (DECFLOAT).

decimal-character
Specifies the double-byte character constant that is used to delimit the decimal digits in the result graphic string. The double-byte character constant cannot be a digit, the plus sign (+), the minus sign (-), or a blank (SQLSTATE 42815). The default is the period (.) character.

The result is a varying-length graphic string representation of *decimal-floating-point-expression* in the form of an SQL decimal floating-point constant. The maximum length of the result is 42. The actual length of the result is the smallest number of double-byte characters that can represent the value of *decimal-floating-point-expression*. If *decimal-floating-point-expression* is negative, the first double-byte character of the result is a minus sign; otherwise, the first double-byte character is a digit. If *decimal-floating-point-expression* is zero, the result is 0.

If the value of *decimal-floating-point-expression* is the special value Infinity, sNaN, or NaN, the strings G'INFINITY', G'SNAN', and G'NAN', respectively, are returned. If the special value is negative, the first double-byte character of the result is a minus sign. The decimal floating-point special value sNaN does not result in a warning when converted to a string.

The code page of the result is the DBCS code page of the section.

Character to vargraphic
In Unicode databases:

character-expression
An expression that returns a value that is a built-in character string data type. The expression must not be a FOR BIT DATA subtype (SQLSTATE 42846).

integer
An integer constant that specifies the length attribute for the resulting varying-length graphic string. The value must be between 0 and the maximum length for the VARGRAPHIC data type in the string units of the result.

If the second argument is not specified:

- If the *character-expression* is the empty string constant, the length attribute of the result is 0.
- Otherwise, the length attribute of the result is the lower of the following values:
  - The maximum length for the VARGRAPHIC data type in the string units of the result.
  - The length attribute of the first argument.

The result is a varying-length graphic string that is converted from *character-expression*. The length attribute of the result is determined by the value of *integer*.

If the length of *character-expression* that is converted to a graphic string is greater than the length attribute of the result, several scenarios exist:

- If the string unit of the result is CODEUNITS32, truncation is performed. If only blank characters are truncated and *character-expression* is CHAR or VARCHAR, no warning is returned. Otherwise, a warning is returned (SQLSTATE 01004).
- If *integer* is specified, truncation is performed with a warning returned (SQLSTATE 01004). When the output string is truncated, such that the last character is a high surrogate, that surrogate is deleted. Do not rely on this behavior because it might change in a future release.
- If *integer* is not specified and *character-expression* is a VARCHAR, truncation is performed with a warning returned (SQLSTATE 01004).
- If *integer* is not specified and character-expression is a CLOB, an error is returned (SQLSTATE 22001).

This function converts *character-expression* from UTF-8 to UTF-16. Every character of *character-expression* is converted.

In non-Unicode databases:

character-expression
An expression that returns a value that is a built-in CHAR or VARCHAR data type.

The result is a varying-length graphic string that is converted from *character-expression*. The length attribute of the result is the minimum of the length attribute of *character-expression* and the maximum length for the VARGRAPHIC data type.

If the length of *character-expression* that is converted to a graphic string is greater than the length attribute of the result, an error is returned (SQLSTATE 22001).

For databases with a code set that is not Japanese EUC (code page 954) or Traditional Chinese (code page 964), each single-byte character in *character-expression* is converted to its equivalent double-byte representation or to the double-byte substitution character in the result. Each double-byte character in *character-expression* is mapped without extra conversion. If the first byte of a double-byte character appears as the last byte of *character-expression*, it is converted to the double-byte substitution character. The sequential order of the characters in *character-expression* is preserved. No warning or error code is generated if one or more double-byte substitution characters are returned in the result.

For details about the conversion process for databases with a code set that is Japanese EUC (code page 954) or Traditional Chinese (code page 964), refer to the topic "Japanese and traditional-Chinese extended UNIX code (EUC) considerations" in Globalization Guide.

Graphic to vargraphic

graphic-expression
An expression that returns a value that is a built-in graphic string data type.

integer
An integer constant that specifies the length attribute for the resulting varying-length graphic string. The value must be between 0 and the maximum length for the VARGRAPHIC data type in the string units of the result. If the second argument is not specified:

- If the *graphic-expression* is the empty string constant, the length attribute of the result is 0.
- Otherwise, the length attribute of the result is the lower of the following values:
  - The maximum length for the VARGRAPHIC data type in the string units of the result
  - The length attribute of the first argument

The result is a varying-length graphic string. The length attribute of the result is determined by the value of *integer*.

If the length of *graphic-expression* is greater than the length attribute of the result, several scenarios exist:

- If the string unit of the result is CODEUNITS32, truncation is performed. If only blank characters are truncated and *graphic-expression* is GRAPHIC or VARGRAPHIC, no warning is returned. Otherwise, a warning is returned (SQLSTATE 01004).
- If integer is specified, truncation is performed. If only blank characters are truncated and *graphic-expression* is GRAPHIC or VARGRAPHIC, no warning is returned. Otherwise, a warning is returned (SQLSTATE 01004). In a Unicode database, when the output string is truncated, such that the last character is a high surrogate, that surrogate is converted to the blank character (X'0020'). Do not rely on this behavior, because it might change in a future release.
- If *integer* is not specified, an error is returned (SQLSTATE 22001).

Datetime to vargraphic

datetime-expression
An expression that is one of the following data types:

DATE
The result is the graphic string representation of the date in the format specified by the second argument. The length of the result is 10. An error is returned if the second argument is specified and is not a valid value (SQLSTATE 42703).

TIME
The result is the graphic string representation of the time in the format specified by the second argument. The length of the result is 8. An error is returned if the second argument is specified and is not a valid value (SQLSTATE 42703).

TIMESTAMP
The result is the graphic string representation of the timestamp. If the data type of *datetime-expression* is TIMESTAMP(0), the length of the result is 19. If the data type of *datetime-expression* is TIMESTAMP(*n*), where *n* is between 1 and 12, the length of the result is 20+*n*. Otherwise, the length of the result is 26. The second argument must not be specified (SQLSTATE 42815).

The code page of the result is the DBCS code page of the section.

Boolean to vargraphic

boolean-expression
An expression that returns a Boolean value (TRUE or FALSE). The result is either 'TRUE' or 'FALSE'.

Result

The VARGRAPHIC function returns a varying-length graphic string representation of:

- An integer number (Unicode database only), if the first argument is a SMALLINT, INTEGER, or BIGINT
- A decimal number (Unicode database only), if the first argument is a decimal number
- A double-precision floating-point number (Unicode database only), if the first argument is a DOUBLE or REAL
- A decimal floating-point number (Unicode database only), if the first argument is a decimal floating-point number (DECFLOAT)
- A character string, if the first argument is any type of character string
- A graphic string, if the first argument is any type of graphic string
- A datetime value (Unicode databases only), if the first argument is a DATE, TIME, or TIMESTAMP
- A Boolean value (TRUE or FALSE)

In a non-Unicode database, the string units of the result is double bytes. Otherwise, the string units of the result is determined by the data type of the first argument.

- CODEUNITS16, if the first argument is character string or a graphic string with string units of OCTETS or CODEUNITS16.
- CODEUNITS32, if the first argument is character string or a graphic string with string units of CODEUNITS32.
- Determined by the default string unit of the environment, if the first argument is not a character string or a graphic string.

If the first argument can be null, the result can be null; if the first argument is null, the result is the null value.

Notes

- **Increasing portability of applications:** If the first argument is numeric, or if the first argument is a string and the length argument is specified, use the "CAST specification" on page 152 instead of this function to increase the portability of your applications.

Examples

- *Example 1*: The EDLEVEL column is defined as SMALLINT. The following statement returns the value as a varying-length graphic string.

```
SELECT VARGRAPHIC(EDLEVEL)
  FROM EMPLOYEE
  WHERE LASTNAME = 'HAAS'
```

  Results in the value G'18'.

- *Example 2*: The SALARY and COMM columns are defined as DECIMAL with a precision of 9 and a scale of 2. Return the total income for employee Haas using the comma decimal character.

```
SELECT VARGRAPHIC(SALARY + COMM, ',')
  FROM EMPLOYEE
  WHERE LASTNAME = 'HAAS'
```

  Results in the value G'56970,00'.

- *Example 3*: The following statement returns a string of data type VARGRAPHIC with the value 'TRUE'.

```
values VARGRAPHIC(3=3)
```

- *Example 4*: The following statement returns a string of data type VARGRAPHIC with the value 'FALSE'.

```
values VARGRAPHIC(3>3)
```

VERIFY_GROUP_FOR_USER

The VERIFY_GROUP_FOR_USER function returns a value that indicates whether any of the groups associated with the authorization ID identified by the SESSION_USER special register are in the group names specified by the list of *group-name-expression* arguments.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

group-name-expression
An expression that specifies an authorization name (SQLSTATE 42815). The existence of the authorization name at the current server is not verified. *group-name-expression* must return a built-in character string data type or graphic string data type that is not a LOB (SQLSTATE 42815). The content of the string is not folded to uppercase and is not left-aligned.

The result of the function is an integer. The result cannot be null. The result is 1 if any of the groups associated with the authorization ID identified by the SESSION_USER special register are in the list of *group-name-expression* arguments. Otherwise, the result is 0.

Example 1

The tellers in a bank can only access customers from their own branch. All tellers are members in the group TELLER. A row permission is created by a user with SECADM authority to enforce this rule.

```
CREATE PERMISSION TELLER_ROW_ACCESS ON CUSTOMER
  FOR ROWS WHERE VERIFY_GROUP_FOR_USER(SESSION_USER,'TELLER') = 1 AND
      BRANCH = (SELECT HOME_BRANCH FROM INTERNAL_INFO
          WHERE EMP_ID = USER)
ENFORCED FOR ALL ACCESS
ENABLE
```

Example 2

The determination on whether the user can see the row is determined by the name of the role in the ACCESS_ROLE column of the table being protected. A row permission is created by a user with the SECADM authority to check the session user is in this role.

```
CREATE PERMISSION ROLEACCESS ON CUSTOMER
FOR ROWS WHERE ( VERIFY_GROUP_FOR_USER(SESSION_USER, ACCESS_ROLE ) = 1 )
ENFORCED FOR ALL ACCESS
ENABLE
```

VERIFY_ROLE_FOR_USER

The VERIFY_ROLE_FOR_USER function returns a value that indicates whether any of the roles associated with the authorization ID identified by the SESSION_USER special register are in (or contain any of) the role names specified by the list of *role-name-expression* arguments.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

role-name-expression

An expression that specifies a role name (SQLSTATE 42815). The existence of the role name at the current server is not verified. *role-name-expression* must return a built-in character string data type or graphic string data type that is not a LOB (SQLSTATE 42815). The content of the string is not folded to uppercase and is not left-aligned.

The result of the function is an integer. The result cannot be null. The result is 1 if any of the roles associated with the authorization ID identified by the SESSION_USER special register are in (or contain any of) the role names specified by the list of *role-name-expression* arguments. Otherwise, the result is 0.

Example 1

The tellers in a bank can only access customers from their own branch. All tellers are members in the role TELLER. A row permission is created by a user with the SECADM authority to enforce this rule.

```
CREATE PERMISSION TELLER_ROW_ACCESS ON CUSTOMER
  FOR ROWS WHERE VERIFY_ROLE_FOR_USER(SESSION_USER,'TELLER') = 1 AND
      BRANCH = (SELECT HOME_BRANCH FROM INTERNAL_INFO
          WHERE EMP_ID = USER)
ENFORCED FOR ALL ACCESS
ENABLE
```

Example 2

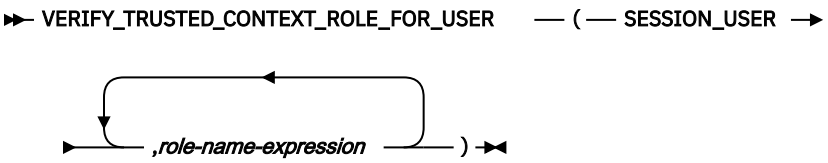
The determination on whether the user can see the row is determined by the name of the role in the ACCESS_ROLE column of the table being protected. A row permission is created by a user with the SECADM authority to check the session user is in this role.

```
CREATE PERMISSION ROLEACCESS ON CUSTOMER
FOR ROWS WHERE (VERIFY_ROLE_FOR_USER(SESSION_USER, ACCESS_ROLE) = 1)
ENFORCED FOR ALL ACCESS
ENABLE
```

VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER

The VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER function returns a value that indicates whether the authorization ID identified by the SESSION_USER special register has acquired a role under a trusted

connection associated with some trusted context and that role is in (or part of) the role names specified by the list of *role-name-expression* arguments.



The schema is SYSIBM. The function name cannot be specified as a qualified name.

role-name-expression
An expression that specifies a role name (SQLSTATE 42815). The existence of the role name at the current server is not verified. *role-name-expression* must return a built-in character string data type or graphic string data type that is not a LOB (SQLSTATE 42815). The content of the string is not folded to uppercase and is not left-aligned.

The result of the function is an integer. The result cannot be null. The result is 1 if the authorization ID identified by the SESSION_USER special register has acquired a role under a trusted connection associated with some trusted context and that role is in (or contained in any of) the role names specified by the list of *role-name-expression* arguments. Otherwise, the result is 0.

Example 1

The tellers in a bank can only access customers from their own branch. All tellers are members in the role TELLER, which can only be acquired through a trusted connection. A row permission is created by a user with SECADM authority to enforce this rule.

```
CREATE PERMISSION TELLER_ROW_ACCESS ON CUSTOMER
  FOR ROWS WHERE
     VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER,'TELLER') = 1 AND
         BRANCH = (SELECT HOME_BRANCH FROM INTERNAL_INFO
             WHERE EMP_ID = USER)
ENFORCED FOR ALL ACCESS
ENABLE
```

Example 2

The determination on whether the user can see the row is determined by the name of the role in the ACCESS_ROLE column of the table being protected. A row permission is created by a user with the SECADM authority to check the session user is in this role.

```
CREATE PERMISSION ROLEACCESS ON CUSTOMER
FOR ROWS WHERE ( VERIFY_TRUSTED_CONTEXT_ROLE_FOR_USER(SESSION_USER, ACCESS_ROLE ) = 1 )
ENFORCED FOR ALL ACCESS
ENABLE
```

WEEK

The WEEK scalar function returns the week of the year of the argument as an integer value in range 1-54. The week starts with Sunday.

The schema is SYSFUN.

expression
An expression that returns a value of one of the following built-in data types: DATE, TIMESTAMP, or a valid character string representation of a date or timestamp that is not a CLOB. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

The result of the function is INTEGER. The result can be null; if the argument is null, the result is the null value.

WEEK_ISO

The WEEK_ISO function returns the week of the year of the argument as an integer value in the range 1-53.

The schema is SYSFUN.

expression
An expression that returns a value of one of the following built-in data types: DATE, TIMESTAMP, or a valid character string representation of a date or timestamp that is not a CLOB. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

The week starts with Monday and always includes 7 days. Week 1 is the first week of the year to contain a Thursday, which is equivalent to the first week containing January 4. It is therefore possible to have up to 3 days at the beginning of a year appear in the last week of the previous year. Conversely, up to 3 days at the end of a year may appear in the first week of the next year.

The result of the function is INTEGER. The result can be null; if the argument is null, the result is the null value.

Example

The following list shows examples of the result of WEEK_ISO and DAYOFWEEK_ISO.

```
DATE       WEEK_ISO    DAYOFWEEK_ISO
---------- ----------- -------------
1997-12-28          52             7
1997-12-31           1             3
1998-01-01           1             4
1999-01-01          53             5
1999-01-04           1             1
1999-12-31          52             5
2000-01-01          52             6
2000-01-03           1             1
```

WEEKS_BETWEEN

The WEEKS_BETWEEN function returns the number of full weeks between the specified arguments.

The schema is SYSIBM.

expression1
An expression that specifies the first datetime value to compute the number of full weeks between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression1* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

expression2
An expression that specifies the second datetime value to compute the number of full weeks between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If

expression2 is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

If there is less than a full week between *expression1* and *expression2*, the result is zero. If *expression1* is later than *expression2*, the result is positive. If *expression1* is earlier than *expression2*, the result is negative. In NPS compatibility mode, this function always returns a positive number. If *expression1* or *expression2* contains time information, this information is also used to determine the number of full weeks. If *expression1* or *expression2* does not contain time information, a time of midnight (00.00.00) is used for the argument that is missing time information.

The result of the function is an INTEGER. If either argument can be null, the result can be null. If either argument is null, the result is the null value.

Examples

1. Set the host variable NUM_WEEKS with the number of full weeks between 2012-03-06 and 2012-02-28.

   ```
   SET :NUM_WEEKS = WEEKS_BETWEEN(DATE '2012-03-06', DATE '2012-02-28')
   ```

   The host variable NUM_WEEKS is set to 1 because there are 7 days between the arguments, including February 29, 2012.
2. Set the host variable NUM_WEEKS with the number of full weeks between 2012-03-05 and 2012-02-28.

   ```
   SET :NUM_WEEKS = WEEKS_BETWEEN(DATE '2012-03-05', DATE '2012-02-28')
   ```

   The host variable NUM_WEEKS is set to 0 because there are only 6 days between the arguments.
3. Set the host variable NUM_WEEKS with the number of full weeks between 2013-09-21-23.59.59 and 2013-09-01-00.00.00.

   ```
   SET :NUM_WEEKS = WEEKS_BETWEEN(TIMESTAMP '2013-09-21-23.59.59',
                                  TIMESTAMP '2013-09-01-00.00.00')
   ```

   The host variable NUM_WEEKS is set to 2 because there is 1 second less than 3 full weeks between the arguments. It is positive because the first argument is later than the second argument.
4. Set the host variable NUM_WEEKS with the number of full weeks between 2013-09-01-00.00.00 and 2013-09-21-23.59.59.

   ```
   SET :NUM_WEEKS = WEEKS_BETWEEN(TIMESTAMP '2013-09-01-00.00.00',
                                  TIMESTAMP '2013-09-21-23.59.59')
   ```

   The host variable NUM_WEEKS is set to -2 because there is 1 second less than 3 full weeks between the arguments. It is negative because the first argument is earlier than the second argument.

WIDTH_BUCKET

The WIDTH_BUCKET function is used to create equal-width histograms.

The schema is SYSIBM.

expression
An expression that specifies the value to be assigned into a bucket. The expression must return a value that is a built-in numeric, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the data type is DECFLOAT, the value must not be a special value such as NaN or INFINITY (SQLSTATE 42815).

bound1
An expression that specifies the left end point. The expression must return a value that is a built-in numeric, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the data type is DECFLOAT, the value must not be a special value such as NaN or INFINITY (SQLSTATE 42815).

bound2
An expression that specifies the right end point. The expression must return a value that is a built-in numeric, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the data type is DECFLOAT, the value must not be a special value such as NaN or INFINITY (SQLSTATE 42815). *bound1* must not be equal to *bound2* (SQLSTATE 2201G).

num-buckets
An expression that specifies the number of buckets between *bound1* and *bound2*. The expression must return a value that is a SMALLINT, INTEGER, BIGINT, DECIMAL, DECFLOAT, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If the expression is a CHAR, VARCHAR, a GRAPHIC, or VARGRAPHIC, it is cast to DECFLOAT(34) before the function is evaluated. If the value is a DECIMAL or DECFLOAT, it is truncated to zero places to the left of the decimal point. The value must be greater than 0 (SQLSTATE 2201G). If the data type is DECFLOAT, the value must not be a special value such as NaN or INFINITY (SQLSTATE 42815).

The data type of the result is based on the data type of *num-buckets*.

Table 106. Data type of the result

Data type of *num-buckets*	**Data type of result**
SMALLINT	SMALLINT
INTEGER	INTEGER
BIGINT	BIGINT
DECIMAL(p,s)	DECIMAL(MIN(31, p-s+1), 0)
DECFLOAT(n)	DECFLOAT(n)

This function returns the bucket number that *expression* falls into given *bound1*, *bound2*, and *num-buckets*. The range from *bound1* to *bound2* is divided into *num-buckets* buckets starting from bucket 1 to bucket *num-buckets*.

If any argument can be null, the result can be null. If any argument is null, the result is the null value.

Notes

- If *bound1* is less than *bound2*, each bucket is a left-closed, right-open interval on the real line. If *expression* is less than *bound1*, the result is 0, which represents an underflow bucket. If *expression* is greater than or equal to *bound2*, the result is *num-buckets* + 1, which represents an overflow bucket.
- If *bound1* is greater than *bound2*, each bucket is a left-closed, right-open interval on the real line. If *expression* is greater than *bound1*, the result is 0, which represents an underflow bucket. If *expression* is less than or equal to *bound2*, the result is *num-buckets* + 1, which represents an overflow bucket.
- When *num-buckets* is the maximum value for the data type, an error is returned if the result is *num-buckets* + 1 (SQLSTATE 22003).
- Several arithmetic operations are used to compute the result. If any of these arithmetic operations result in an overflow, an error is returned (SQLSTATE 22003).

Example

Using the EMPLOYEE table, assign a bucket to each employee's salary using a range of 35000 to 100000 divided into 13 buckets.

```
   SELECT EMPNO, SALARY, WIDTH_BUCKET(SALARY, 35000, 100000, 13)
      FROM EMPLOYEE ORDER BY EMPNO
```

15 buckets are assigned with the following ranges:

- Bucket 0: salary < 35000
- Bucket 1: 35000 <= salary < 40000
- Bucket 2: 40000 <= salary < 45000
- Bucket 3: 45000 <= salary < 50000
- Bucket 4: 50000 <= salary < 55000
- Bucket 5: 55000 <= salary < 60000
- Bucket 6: 60000 <= salary < 65000
- Bucket 7: 65000 <= salary < 70000
- Bucket 8: 70000 <= salary < 75000
- Bucket 9: 75000 <= salary < 80000
- Bucket 10: 80000 <= salary < 85000
- Bucket 11: 85000 <= salary < 90000
- Bucket 12: 90000 <= salary < 95000
- Bucket 13: 95000 <= salary < 100000
- Bucket 14: salary >= 100000

The query has the following output:

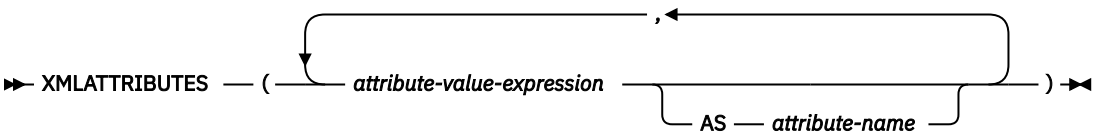
```
EMPNO  SALARY      3
------ ----------- -----------
000010   152750.00          14
000020    94250.00          12
000030    98250.00          13
000050    80175.00          10
000060    72250.00           8
000070    96170.00          13
000090    89750.00          11
000100    86150.00          11
000110    66500.00           7
000120    49250.00           3
000130    73800.00           8
000140    68420.00           7
000150    55280.00           5
000160    62250.00           6
000170    44680.00           2
000180    51340.00           4
000190    50450.00           4
000200    57740.00           5
000210    68270.00           7
000220    49840.00           3
000230    42180.00           2
000240    48760.00           3
000250    49180.00           3
000260    47250.00           3
000270    37380.00           1
000280    36250.00           1
000290    35340.00           1
000300    37750.00           1
000310    35900.00           1
000320    39950.00           1
000330    45370.00           3
000340    43840.00           2
200010    46500.00           3
200120    39250.00           1
200140    68420.00           7
200170    64680.00           6
```

```
200220    69840.00          7
200240    37760.00          1
200280    46250.00          3
200310    35900.00          1
200330    35370.00          1
200340    31840.00          0

  42 record(s) selected.
```

XMLATTRIBUTES

The XMLATTRIBUTES function constructs XML attributes from the arguments.



The schema is SYSIBM. The function name cannot be specified as a qualified name.

This function can only be used as an argument of the XMLELEMENT function. The result is an XML sequence containing an XQuery attribute node for each non-null input value.

attribute-value-expression
An expression whose result is the attribute value. The data type of *attribute-value-expression* cannot be an XML type, a BINARY type, a VARBINARY type, or a structured type (SQLSTATE 42884). The expression can be any SQL expression. If the expression is not a simple column reference, an attribute name must be specified.

attribute-name
Specifies an attribute name. The name is an SQL identifier that must be in the form of an XML qualified name, or QName (SQLSTATE 42634). See the W3C XML namespace specifications for more details on valid names. The attribute name cannot be `xmlns` or prefixed with `xmlns:`. A namespace is declared using the function XMLNAMESPACES. Duplicate attribute names, whether implicit or explicit, are not allowed (SQLSTATE 42713).

If *attribute-name* is not specified, *attribute-value-expression* must be a column name (SQLSTATE 42703). The attribute name is created from the column name using the fully escaped mapping from a column name to an XML attribute name.

The data type of the result is XML. If the result of *attribute-value-expression* can be null, the result can be null; if the result of every *attribute-value-expression* is null, the result is the null value.

Examples

Note: XMLATTRIBUTES does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

- *Example 1*: Produce an element with attributes.

```
SELECT E.EMPNO, XMLELEMENT(
  NAME "Emp",
  XMLATTRIBUTES(
    E.EMPNO, E.FIRSTNME ||' '|| E.LASTNAME AS "name"
  )
)
AS "Result"
FROM EMPLOYEE E WHERE E.EDLEVEL = 12
```

This query produces the following result:

```
EMPNO  Result
000290 <Emp EMPNO="000290" name="JOHN PARKER"></Emp>
000310 <Emp EMPNO="000310" name="MAUDE SETRIGHT"></Emp>
200310 <Emp EMPNO="200310" name="MICHELLE SPRINGER"></Emp>
```

- *Example 2*: Produce an element with a namespace declaration that is not used in any QName. The prefix is used in an attribute value.

```
VALUES XMLELEMENT(
  NAME "size",
  XMLNAMESPACES(
    'http://www.w3.org/2001/XMLSchema-instance' AS "xsi",
    'http://www.w3.org/2001/XMLSchema' AS "xsd"
  ),
  XMLATTRIBUTES(
    'xsd:string' AS "xsi:type"
  ), '1'
)
```

This query produces the following result:

```
<size xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xsi:type="xsd:string">1</size>
```

XMLCOMMENT

The XMLCOMMENT function returns an XML value with a single XQuery comment node with the input argument as the content.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

string-expression
An expression whose value has a character string type: CHAR, VARCHAR or CLOB. The result of the *string-expression* is parsed to check for conformance to the requirements for an XML comment, as specified in the XML 1.0 rule. The result of the *string-expression* must conform to the following regular expression:

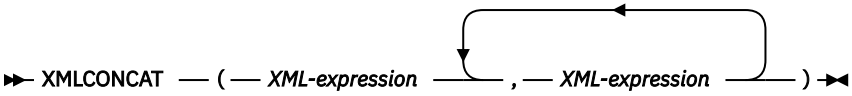
```
((Char - '-') | ('-' (Char - '-')))*
```

where `Char` is defined as any Unicode character excluding surrogate blocks X'FFFE' and X'FFFF'. Basically, the XML comment cannot contain two adjacent hyphens, and cannot end with a hyphen (SQLSTATE 2200S).

The data type of the result is XML. If the result of *string-expression* can be null, the result can be null; if the input value is null, the result is the null value.

XMLCONCAT

The XMLCONCAT function returns a sequence containing the concatenation of a variable number of XML input arguments.



The schema is SYSIBM. The function name cannot be specified as a qualified name.

XML-expression
Specifies an expression of data type XML.

The data type of the result is XML. The result is an XML sequence containing the concatenation of the non-null input XML values. Null values in the input are ignored. If the result of any *XML-expression* can be null, the result can be null; if the result of every input value is null, the result is the null value.

Example

Note: XMLCONCAT does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

Construct a department element for departments A00 and B01, containing a list of employees sorted by first name. Include an introductory comment immediately preceding the department element.

```
SELECT XMLCONCAT(
  XMLCOMMENT(
    'Confirm these employees are on track for their product schedule'
  ),
  XMLELEMENT(
    NAME "Department",
    XMLATTRIBUTES(
      E.WORKDEPT AS "name"
    ),
    XMLAGG(
      XMLELEMENT(
        NAME "emp", E.FIRSTNME
      )
    ORDER BY E.FIRSTNME
    )
  )
)
FROM EMPLOYEE E
WHERE E.WORKDEPT IN ('A00', 'B01')
GROUP BY E.WORKDEPT
```

This query produces the following result:

```
<!--Confirm these employees are on track for their product schedule-->
<Department name="A00">
<emp>CHRISTINE</emp>
<emp>DIAN</emp>
<emp>GREG</emp>
<emp>SEAN</emp>
<emp>VINCENZO</emp>
</Department>
<!--Confirm these employees are on track for their product schedule-->
<Department name="B01">
<emp>MICHAEL</emp>
</Department>
```

XMLDOCUMENT

The XMLDOCUMENT function returns an XML value with a single XQuery document node with zero or more children nodes.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

XML-expression
An expression that returns an XML value. A sequence item in the XML value must not be an attribute node (SQLSTATE 10507).

The data type of the result is XML. If the result of *XML-expression* can be null, the result can be null; if the input value is null, the result is the null value.

The children of the resulting document node are constructed as described in the following steps. The input expression is a sequence of nodes or atomic values, which is referred to in these steps as the content sequence.

1. If the content sequence contains a document node, the document node is replaced in the content sequence by the children of the document node.
2. Each adjacent sequence of one or more atomic values in the content sequence are replaced with a text node containing the result of casting each atomic value to a string with a single blank character inserted between adjacent values.

3. For each node in the content sequence, a new deep copy of the node is constructed. A deep copy of a node is a copy of the whole subtree rooted at that node, including the node itself and its descendants. Each copied node has a new node identity.
4. The nodes in the content sequence become the children of the new document node.

The XMLDOCUMENT function effectively executes the XQuery computed document constructor. The result of

```
XMLQUERY('document {$E}' PASSING BY REF XML-expression AS "E")
```

is equivalent to

```
XMLDOCUMENT( XML-expression )
```

with the exception of the case where *XML-expression* is null and XMLQUERY returns the empty sequence compared to XMLDOCUMENT which returns the null value.

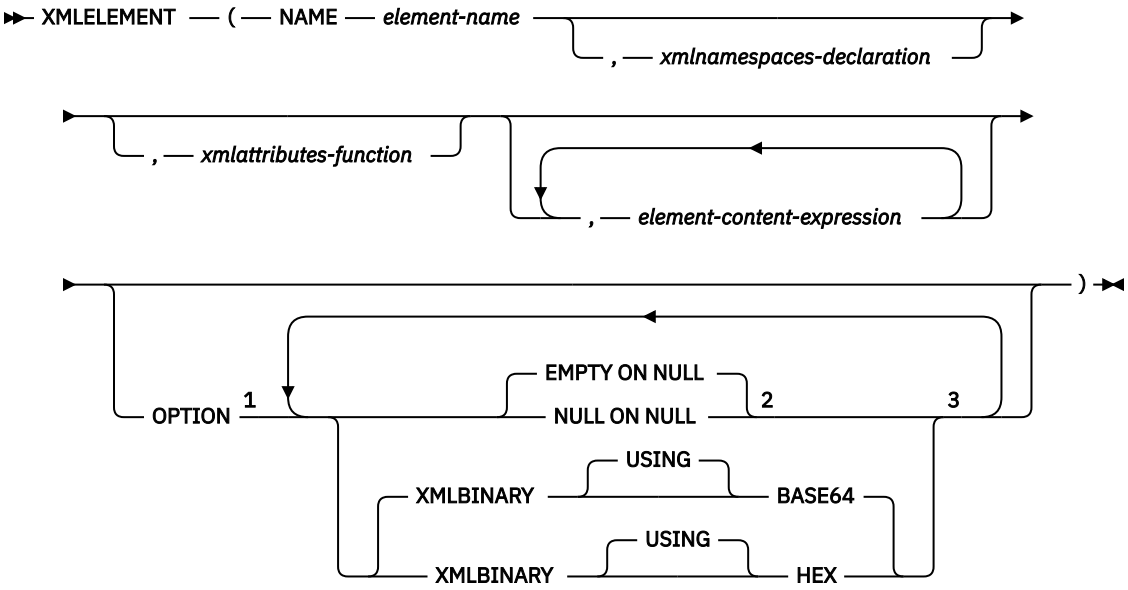
Example

Insert a constructed document into an XML column.

```
INSERT INTO T1 VALUES(
  123, (
    SELECT XMLDOCUMENT(
      XMLELEMENT(
        NAME "Emp", E.FIRSTNME || ' ' || E.LASTNAME, XMLCOMMENT(
          'This is just a simple example'
        )
      )
    )
    FROM EMPLOYEE E
    WHERE E.EMPNO = '000120'
  )
)
```

XMLELEMENT

The XMLELEMENT function returns an XML value that is an XQuery element node.



Notes:

[1] The OPTION clause can only be specified if at least one *xmlattributes-function* or *element-content-expression* is specified.

[2] NULL ON NULL or EMPTY ON NULL can only be specified if at least one *element-content-expression* is specified.

[3] The same clause must not be specified more than once.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

NAME *element-name*

Specifies the name of an XML element. The name is an SQL identifier that must be in the form of an XML qualified name, or QName (SQLSTATE 42634). See the W3C XML namespace specifications for more details on valid names. If the name is qualified, the namespace prefix must be declared within the scope (SQLSTATE 42635).

xmlnamespaces-declaration

Specifies the XML namespace declarations that are the result of the XMLNAMESPACES declaration. The namespaces that are declared are in the scope of the XMLELEMENT function. The namespaces apply to any nested XML functions within the XMLELEMENT function, regardless of whether or not they appear inside another subselect.

If *xmlnamespaces-declaration* is not specified, namespace declarations are not associated with the constructed element.

xmlattributes-function

Specifies the XML attributes for the element. The attributes are the result of the XMLATTRIBUTES function.

element-content-expression

The content of the generated XML element node is specified by an expression or a list of expressions. The data type of *element-content-expression* cannot be a BINARY type, a VARBINARY type, or a structured type (SQLSTATE 42884). The expression can be any SQL expression.

If *element-content-expression* is not specified, an empty string is used as the content for the element and OPTION NULL ON NULL or EMPTY ON NULL must not be specified.

OPTION

Specifies additional options for constructing the XML element. If no OPTION clause is specified, the default is EMPTY ON NULL XMLBINARY USING BASE64. This clause has no impact on nested XMLELEMENT invocations specified in *element-content-expression*.

EMPTY ON NULL or NULL ON NULL

Specifies whether a null value or an empty element is to be returned if the values of each *element-content-expression* is a null value. This option only affects null handling of element contents, not attribute values. The default is EMPTY ON NULL.

EMPTY ON NULL

If the value of each *element-content-expression* is null, an empty element is returned.

NULL ON NULL

If the value of each *element-content-expression* is null, a null value is returned.

XMLBINARY USING BASE64 or XMLBINARY USING HEX

Specifies the assumed encoding of binary input data, character string data with the FOR BIT DATA attribute, or a distinct type that is based on one of these types. The encoding applies to element content or attribute values. The default is XMLBINARY USING BASE64.

XMLBINARY USING BASE64

Specifies that the assumed encoding is base64 characters, as defined for XML schema type xs:base64Binary encoding. The base64 encoding uses a 65-character subset of US-ASCII (10 digits, 26 lowercase characters, 26 uppercase characters, '+', and '/') to represent every six bits of the binary or bit data with one printable character in the subset. These characters are selected so that they are universally representable. Using this method, the size of the encoded data is 33 percent larger than the original binary or bit data.

XMLBINARY USING HEX

Specifies that the assumed encoding is hexadecimal characters, as defined for XML schema type xs:hexBinary encoding. The hexadecimal encoding represents each byte (8 bits) with two

hexadecimal characters. Using this method, the encoded data is twice the size of the original binary or bit data.

This function takes an element name, an optional collection of namespace declarations, an optional collection of attributes, and zero or more arguments that make up the content of the XML element. The result is an XML sequence containing an XML element node or the null value.

The data type of the result is XML. If any of the *element-content-expression* arguments can be null, the result can be null; if all the *element-content-expression* argument values are null and the NULL ON NULL option is in effect, the result is the null value.

Notes

- When constructing elements that will be copied as content of another element that defines default namespaces, default namespaces should be explicitly undeclared in the copied element to avoid possible errors that could result from inheriting the default namespace from the new parent element. Predefined namespace prefixes ('xs', 'xsi', 'xml', and 'sqlxml') must also be declared explicitly when they are used.
- **Constructing an element node**: The resulting element node is constructed as follows:
  1. The *xmlnamespaces-declaration* adds a set of in-scope namespaces for the constructed element. Each in-scope namespace associates a namespace prefix (or the default namespace) with a namespace URI. The in-scope namespaces define the set of namespace prefixes that are available for interpreting QNames within the scope of the element.
  2. If the xmlattributes-function is specified, it is evaluated and the result is a sequence of attribute nodes.
  3. Each *element-content-expression* is evaluated and the result is converted into a sequence of nodes as follows:
     - If the result type is not XML, it is converted to an XML text node whose content is the result of *element-content-expression* mapped to XML according to the rules of mapping SQL data values to XML data values (see the table that describes supported casts from non-XML values to XML values in "Casting between data types").
     - If the result type is XML, then in general the result is a sequence of items. Some of the items in that sequence might be document nodes. Each document node in the sequence is replaced by the sequence of its top-level children. Then for each node in the resulting sequence, a new deep copy of the node is constructed, including its children and attributes. Each copied node has a new node identity. Copied element and attribute nodes preserve their type annotation. For each adjacent sequence of one or more atomic values returned in the sequence, a new text node is constructed, containing the result of casting each atomic value to a string, with a single blank character inserted between adjacent values. Adjacent text nodes in the content sequence are merged into a single text node by concatenating their contents, with no intervening blanks. After concatenation, any text node whose content is a zero-length string is deleted from the content sequence.
  4. The result sequence of XML attributes and the resulting sequences of all *element-content-expression* specifications are concatenated into one sequence which is called the content sequence. Any sequence of adjacent text nodes in the content sequence is merged into a single text node. If all the *element-content-expression* arguments are empty strings, or an *element-content-expression* argument is not specified, an empty element is returned.
  5. The content sequence must not contain an attribute node following a node that is not an attribute node (SQLSTATE 10507). Attribute nodes occurring in the content sequence become attributes of the new element node. Two or more of these attribute nodes must not have the same name (SQLSTATE 10503). A namespace declaration is created corresponding to any namespace used in the names of the attribute nodes if the namespace URI is not in the in-scope namespaces of the constructed element.
  6. Element, text, comment, and processing instruction nodes in the content sequence become the children of the constructed element node.

7. The constructed element node is given a type annotation of `xs:anyType`, and each of its attributes is given a type annotation of `xdt:untypedAtomic`. The node name of the constructed element node is element-name specified after the NAME keyword.

- **Rules for using namespaces within XMLELEMENT**: Consider the following rules about scoping of namespaces:
  - The namespaces declared in the XMLNAMESPACES declaration are the in-scope namespaces of the element node constructed by the XMLELEMENT function. If the element node is serialized, then each of its in-scope namespaces will be serialized as a namespace attribute unless it is an in-scope namespace of the parent of the element node and the parent element is serialized too.
  - If an XMLQUERY or XMLEXISTS is in an *element-content-expression*, then the namespaces becomes the statically known namespaces of the XQuery expression of the XMLQUERY or XMLEXISTS. Statically known namespaces are used to resolve the QNames in the XQuery expression. If the XQuery prolog declares a namespace with the same prefix, within the scope of the XQuery expression, the namespace declared in the prolog will override the namespaces declared in the XMLNAMESPACES declaration.
  - If an attribute of the constructed element comes from an *element-content-expression*, its namespace might not already be declared as an in-scope namespace of the constructed element, in this case, a new namespace is created for it. If this would result in a conflict, which means that the prefix of the attribute name is already bound to a different URI by a in-scope namespace, a prefix is generated that does not cause such a conflict and the prefix used in the attribute name is changed to the new prefix, and a namespace is created for this new prefix. The generated new prefix follows the following pattern: "db2ns-xx", where "x" is a character chosen from the set [A-Z,a-z,0-9]. For example:

```
VALUES XMLELEMENT(
  NAME "c", XMLQUERY(
    'declare namespace ipo="www.ipo.com"; $m/ipo:a/@ipo:b'
      PASSING XMLPARSE(
        DOCUMENT '<tst:a xmlns:tst="www.ipo.com" tst:b="2"/>'
      ) AS "m"
  )
)
```

returns:

```
<c xmlns:tst="www.ipo.com" tst:b="2"/>
```

A second example:

```
VALUES XMLELEMENT(
  NAME "tst:c", XMLNAMESPACES(
    'www.tst.com' AS "tst"
  ),
  XMLQUERY(
    'declare namespace ipo="www.ipo.com"; $m/ipo:a/@ipo:b'
      PASSING XMLPARSE(
        DOCUMENT '<tst:a xmlns:tst="www.ipo.com" tst:b="2"/>'
      ) AS "m"
  )
)
```

returns:

```
<tst:c xmlns:tst="www.tst.com" xmlns:db2ns-a1="www.ipo.com"
  db2ns-a1:b="2"/>
```

Examples

Note: XMLELEMENT does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

- *Example 1*: Construct an element with the NULL ON NULL option.

```
SELECT E.FIRSTNME, E.LASTNAME, XMLELEMENT(
  NAME "Emp", XMLELEMENT(
```

```
      NAME "firstname", E.FIRSTNME
    ),
    XMLELEMENT(
      NAME "lastname", E.LASTNAME
    )
    OPTION NULL ON NULL
  )
  AS "Result"
  FROM EMPLOYEE E
  WHERE E.EDLEVEL = 12
```

This query produces the following result:

```
FIRSTNME     LASTNAME        Emp
JOHN         PARKER          <Emp><firstname>JOHN</firstname>
                               <lastname>PARKER</lastname></Emp>
MAUDE        SETRIGHT        <Emp><firstname>MAUDE</firstname>
                               <lastname>SETRIGHT</lastname></Emp>
MICHELLE     SPRINGER        <Emp><firstname>MICHELLE</firstname>
                               <lastname>SPRINGER</lastname></Emp>
```

- *Example 2*: Produce an element with a list of elements nested as child elements.

```
  SELECT XMLELEMENT(
    NAME "Department", XMLATTRIBUTES(
      E.WORKDEPT AS "name"
    ),
    XMLAGG(
      XMLELEMENT(
        NAME "emp", E.FIRSTNME
      )
      ORDER BY E.FIRSTNME
    )
  )
  AS "dept_list"
  FROM EMPLOYEE E
  WHERE E.WORKDEPT IN ('A00', 'B01')
  GROUP BY WORKDEPT
```

This query produces the following result:

```
dept_list
<Department name="A00">
<emp>CHRISTINE</emp>
<emp>SEAN</emp>
<emp>VINCENZO</emp>
</Department>
<Department name="B01">
<emp>MICHAEL</emp>
</Department>
```

- *Example 3*: Creating nested XML elements specifying a default XML element namespace and using a subselect.

```
SELECT XMLELEMENT(
         NAME "root",
         XMLNAMESPACES(DEFAULT 'http://mytest.uri'),
         XMLATTRIBUTES(cid),
            (SELECT
               XMLAGG(
                 XMLELEMENT(
                   NAME "poid", poid
                 )
               )
             FROM purchaseorder
             WHERE purchaseorder.custid = customer.cid
            )
       )
FROM customer
WHERE cid = '1002'
```

The statement returns the following XML document with the default element namespace declared in the root element:

```
<root xmlns="http://mytest.uri" CID="1002">
  <poid>5000</poid>
```

```
  <poid>5003</poid>
  <poid>5006</poid>
</root>
```

- *Example 4*: Using a common table expression with XML namespaces.

  When an XML element is constructed with a common table expression and the element is used in elsewhere in the same SQL statement, any namespace declarations should be specified as part of the element construction. The following statement specifies the default XML namespace in both the common table expression that uses the PURCHASEORDER table to create the poid elements and the SELECT statement that uses the CUSTOMER table to create the root element.

```
WITH tempid(id, elem) AS
  (SELECT custid, XMLELEMENT(NAME "poid",
     XMLNAMESPACES(DEFAULT 'http://mytest.uri'),
       poid)
   FROM purchaseorder )
SELECT XMLELEMENT(NAME "root",
         XMLNAMESPACES(DEFAULT 'http://mytest.uri'),
            XMLATTRIBUTES(cid),
            (SELECT XMLAGG(elem)
             FROM tempid
             WHERE tempid.id = customer.cid )
        )
FROM customer
WHERE cid = '1002'
```

  The statement returns the following XML document with a default element namespace declared in the root element.

```
<root xmlns="http://mytest.uri" CID="1002">
  <poid>5000</poid>
  <poid>5003</poid>
  <poid>5006</poid>
</root>
```

  In the following statement, the default element namespace is declared only in the SELECT statement that uses the CUSTOMER table to create the root element:

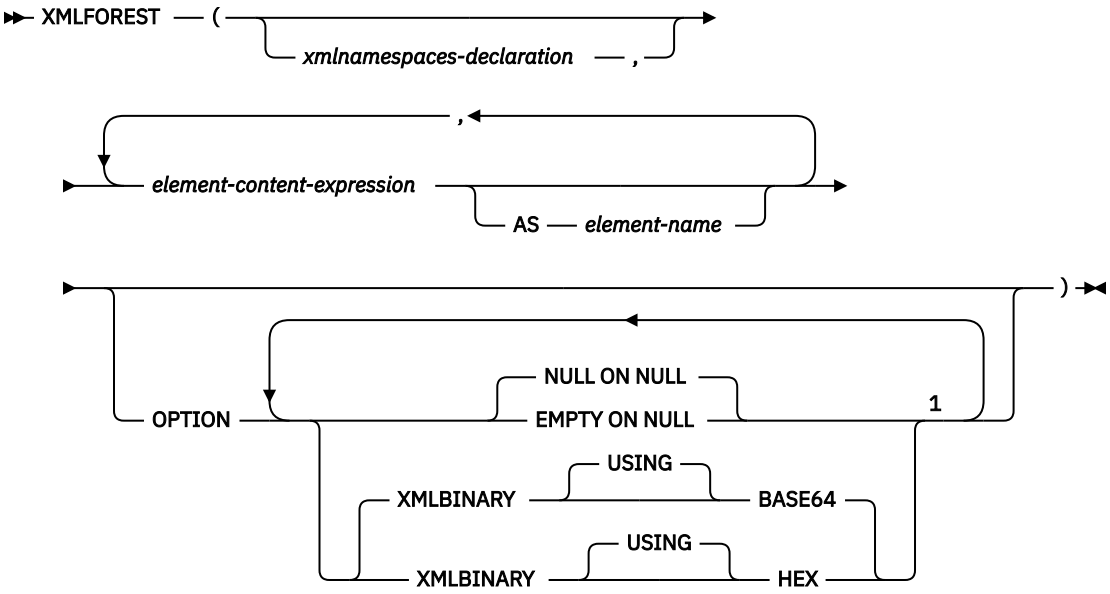
```
WITH tempid(id, elem) AS
    (SELECT custid, XMLELEMENT(NAME "poid", poid)
     FROM purchaseorder )
SELECT XMLELEMENT(NAME "root",
         XMLNAMESPACES(DEFAULT 'http://mytest.uri'),
            XMLATTRIBUTES(cid),
            (SELECT XMLAGG(elem)
             FROM tempid
             WHERE tempid.id = customer.cid )
       )
FROM customer
WHERE cid = '1002'
```

  The statement returns the following XML document with the default element namespace declared in the root element. Because the poid elements are created in the common table expression without a default element namespace declaration, the default element namespace for the poid elements is not defined. In the XML document, the default element namespace for the poid elements is set to an empty string "" because the default element namespace for the poid elements is not defined, and the poid elements do not belong to the default element namespace of the root element `xmlns="http://mytest.uri"`.

```
<root xmlns="http://mytest.uri" CID="1002">
  <poid xmlns="">5000</poid>
  <poid xmlns="">5003</poid>
  <poid xmlns="">5006</poid>
</root>
```

XMLFOREST

The XMLFOREST function returns an XML value that is a sequence of XQuery element nodes.



Notes:

[1] The same clause must not be specified more than once.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

xmlnamespaces-declaration
Specifies the XML namespace declarations that are the result of the XMLNAMESPACES declaration. The namespaces that are declared are in the scope of the XMLFOREST function. The namespaces apply to any nested XML functions within the XMLFOREST function, regardless of whether or not they appear inside another subselect.

If *xmlnamespaces-declaration* is not specified, namespace declarations are not associated with the constructed elements.

element-content-expression
The content of the generated XML element node is specified by an expression. The data type of *element-content-expression* cannot be a BINARY type, a VARBINARY type, or a structured type (SQLSTATE 42884). The expression can be any SQL expression. If the expression is not a simple column reference, an element name must be specified.

AS *element-name*
Specifies the XML element name as an SQL identifier. The element name must be of the form of an XML qualified name, or QName (SQLSTATE 42634). See the W3C XML namespace specifications for more details on valid names. If the name is qualified, the namespace prefix must be declared within the scope (SQLSTATE 42635). If *element-name* is not specified, *element-content-expression* must be a column name (SQLSTATE 42703). The element name is created from the column name using the fully escaped mapping from a column name to an QName.

OPTION
Specifies additional options for constructing the XML element. If no OPTION clause is specified, the default is NULL ON NULL XMLBINARY USING BASE64. This clause has no impact on nested XMLELEMENT invocations specified in *element-content-expression*.

EMPTY ON NULL or NULL ON NULL
Specifies whether a null value or an empty element is to be returned if the values of each *element-content-expression* is a null value. This option only affects null handling of element contents, not attribute values. The default is NULL ON NULL.

EMPTY ON NULL
If the value of each *element-content-expression* is null, an empty element is returned.

NULL ON NULL
If the value of each *element-content-expression* is null, a null value is returned.

XMLBINARY USING BASE64 or XMLBINARY USING HEX
Specifies the assumed encoding of binary input data, character string data with the FOR BIT DATA attribute, or a distinct type that is based on one of these types. The encoding applies to element content or attribute values. The default is XMLBINARY USING BASE64.

XMLBINARY USING BASE64
Specifies that the assumed encoding is base64 characters, as defined for XML schema type xs:base64Binary encoding. The base64 encoding uses a 65-character subset of US-ASCII (10 digits, 26 lowercase characters, 26 uppercase characters, '+', and '/') to represent every six bits of the binary or bit data with one printable character in the subset. These characters are selected so that they are universally representable. Using this method, the size of the encoded data is 33 percent larger than the original binary or bit data.

XMLBINARY USING HEX
Specifies that the assumed encoding is hexadecimal characters, as defined for XML schema type xs:hexBinary encoding. The hexadecimal encoding represents each byte (8 bits) with two hexadecimal characters. Using this method, the encoded data is twice the size of the original binary or bit data.

This function takes an optional set of namespace declarations and one or more arguments that make up the name and element content for one or more element nodes. The result is an XML sequence containing a sequence of XQuery element nodes or the null value.

The data type of the result is XML. If any of the *element-content-expression* arguments can be null, the result can be null; if all the *element-content-expression* argument values are null and the NULL ON NULL option is in effect, the result is the null value.

The XMLFOREST function can be expressed by using XMLCONCAT and XMLELEMENT. For example, the following two expressions are semantically equivalent.

```
XMLFOREST(xmlnamespaces-declaration, arg1 AS name1, arg2 AS name2 ...)
```

```
XMLCONCAT(
  XMLELEMENT(
    NAME name1, xmlnamespaces-declaration, arg1
  ),
  XMLELEMENT(
    NAME name2, xmlnamespaces-declaration, arg2
  )
  ...
)
```

Notes

- When constructing elements that will be copied as content of another element that defines default namespaces, default namespaces should be explicitly undeclared in the copied element to avoid possible errors that could result from inheriting the default namespace from the new parent element. Predefined namespace prefixes ('xs', 'xsi', 'xml', and 'sqlxml') must also be declared explicitly when they are used.

Example

Note: XMLFOREST does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

Construct a forest of elements with a default namespace.

```
   SELECT EMPNO,
     XMLFOREST(
```

```
      XMLNAMESPACES(
        DEFAULT 'http://hr.org', 'http://fed.gov' AS "d"
      ),
      LASTNAME, JOB AS "d:job"
    )
  AS "Result"
  FROM EMPLOYEE
  WHERE EDLEVEL = 12
```

This query produces the following result:

```
EMPNO  Result
000290 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">PARKER
  </LASTNAME>
<d:job xmlns="http://hr.org" xmlns:d="http://fed.gov">OPERATOR</d:job>

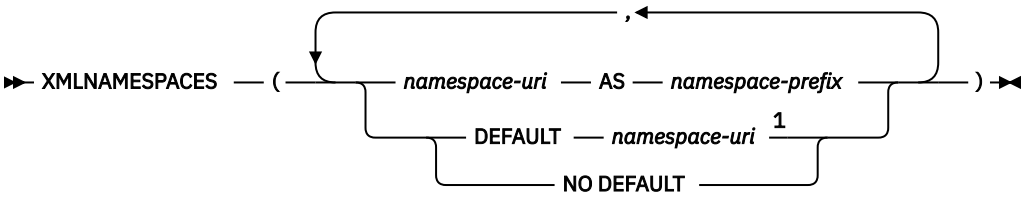
000310 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">SETRIGHT
  </LASTNAME>
<d:job xmlns="http://hr.org" xmlns:d="http://fed.gov">OPERATOR</d:job>

200310 <LASTNAME xmlns="http://hr.org" xmlns:d="http://fed.gov">SPRINGER
  </LASTNAME>
<d:job xmlns="http://hr.org" xmlns:d="http://fed.gov">OPERATOR</d:job>
```

XMLNAMESPACES

The XMLNAMESPACES declaration constructs namespace declarations from the arguments.

xmlnamespaces-declaration



Notes:

1 DEFAULT or NO DEFAULT can only be specified once in arguments of XMLNAMESPACES.

The schema is SYSIBM. The declaration name cannot be specified as a qualified name.

This declaration can only be used as an argument for specific functions such as XMLELEMENT, XMLFOREST and XMLTABLE. The result is one or more XML namespace declarations containing in-scope namespaces for each non-null input value.

namespace-uri
Specifies the namespace universal resource identifier (URI) as an SQL character string constant. This character string constant must not be empty if it is used with a *namespace-prefix* (SQLSTATE 42815).

namespace-prefix
Specifies a namespace prefix. The prefix is an SQL identifier that must be in the form of an XML NCName (SQLSTATE 42634). See the W3C XML namespace specifications for more details on valid names. The prefix cannot be `xml` or `xmlns` and the prefix must be unique within the list of namespace declarations (SQLSTATE 42635).

DEFAULT *namespace-uri*
Specifies the default namespace to use within the scope of this namespace declaration. The *namespace-uri* applies for unqualified names in the scope unless overridden in a nested scope by another DEFAULT declaration or a NO DEFAULT declaration.

NO DEFAULT
Specifies that no default namespace is to be used within the scope of this namespace declaration. There is no default namespace in the scope unless overridden in a nested scope by a DEFAULT declaration.

The data type of the result is XML. The result is an XML namespace declaration for each specified namespace. The result cannot be null.

Examples

Note: XMLNAMESPACES does not insert blank spaces or new line characters in the output. All example output has been formatted to enhance readability.

- *Example 1*: Produce an XML element named adm:employee and an XML attribute adm:department, both associated with a namespace whose prefix is adm.

```
SELECT EMPNO, XMLELEMENT(
  NAME "adm:employee", XMLNAMESPACES(
    'http://www.adm.com' AS "adm"
  ),
  XMLATTRIBUTES(
    WORKDEPT AS "adm:department"
  ),
LASTNAME
)
FROM EMPLOYEE
WHERE JOB = 'ANALYST'
```

This query produces the following result:

```
000130 <adm:employee xmlns:adm="http://www.adm.com" adm:department="C01">
  QUINTANA</adm:employee>
000140 <adm:employee xmlns:adm="http://www.adm.com" adm:department="C01">
  NICHOLLS</adm:employee>
200140 <adm:employee xmlns:adm="http://www.adm.com" adm:department="C01">
  NATZ</adm:employee>
```

- *Example 2*: Produce an XML element named 'employee', which is associated with a default namespace, and a sub-element named 'job', which does not use a default namespace, but whose sub-element named 'department' does use a default namespace.

```
SELECT EMP.EMPNO, XMLELEMENT(
  NAME "employee", XMLNAMESPACES(
    DEFAULT 'http://hr.org'
  ),
  EMP.LASTNAME, XMLELEMENT(
    NAME "job", XMLNAMESPACES(
      NO DEFAULT
    ),
    EMP.JOB, XMLELEMENT(
      NAME "department", XMLNAMESPACES(
        DEFAULT 'http://adm.org'
      ),
      EMP.WORKDEPT
    )
  )
)
FROM EMPLOYEE EMP
WHERE EMP.EDLEVEL = 12
```

This query produces the following result:

```
000290 <employee xmlns="http://hr.org">PARKER<job xmlns="">OPERATOR
  <department xmlns="http://adm.org">E11</department></job></employee>
000310 <employee xmlns="http://hr.org">SETRIGHT<job xmlns="">OPERATOR
  <department xmlns="http://adm.org">E11</department></job></employee>
200310 <employee xmlns="http://hr.org">SPRINGER<job xmlns="">OPERATOR
  <department xmlns="http://adm.org">E11</department></job></employee>
```

XMLPARSE

The XMLPARSE function parses the argument as an XML document and returns an XML value.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

DOCUMENT
Specifies that the character string expression to be parsed must evaluate to a well-formed XML document that conforms to XML 1.0, as modified by the XML Namespaces recommendation (SQLSTATE 2200M).

string-expression
Specifies an expression that returns a character string or BLOB value. If a parameter marker is used, it must explicitly be cast to one of the supported data types.

STRIP WHITESPACE or PRESERVE WHITESPACE
Specifies whether or not whitespace in the input argument is to be preserved. If neither is specified, STRIP WHITESPACE is the default.

STRIP WHITESPACE
Specifies that text nodes containing only whitespace characters up to 1000 bytes in length will be stripped, unless the nearest containing element has the attribute xml:space='preserve'. If any text node begins with more that 1000 bytes of whitespace, an error is returned (SQLSTATE 54059).

The whitespace characters in the CDATA section are also affected by this option. DTDs may have DOCTYPE declarations for elements, but the content models of elements are not used to determine if whitespace is stripped or not.

PRESERVE WHITESPACE
Specifies that all whitespace is to be preserved, even when the nearest containing element has the attribute xml:space='default'.

The data type of the result is XML. If the result of *string-expression* can be null, the result can be null; if the result of *string-expression* is null, the result is the null value.

Notes

- **Encoding of the input string**: The input string may contain an XML declaration that identifies the encoding of the characters in the XML document. If the string is passed to the XMLPARSE function as a character string, it will be converted to the code page at the database server. This code page may be different from the originating code page and the encoding identified in the XML declaration.

  Therefore, applications should avoid direct use of XMLPARSE with character string input and should send strings containing XML documents directly using host variables to maintain the match between the external code page and the encoding in the XML declaration. If XMLPARSE must be used in this situation, a BLOB type should be specified as the argument to avoid code page conversion.
- **Handling of DTDs**: External document type definitions (DTDs) and entities must be registered in a database. Both internal and external DTDs are checked for valid syntax. During the parsing process, the following actions are also performed:
  - Default values that are defined by the internal and external DTDs are applied.
  - Entity references and parameter entities are replaced by their expanded forms.
  - If an internal DTD and an external DTD define the same element, an error is returned (SQLSTATE 2200M).
  - If an internal DTD and an external DTD define the same entity or attribute, the internal definition is chosen.

  After parsing, internal DTDs and entities, as well as references to external DTDs and entities, are not preserved in the stored representation of the value.
- **Character conversion in non-UTF-8 databases**: Code page conversion occurs when an XML document is parsed into a non-Unicode database server, if the document is passed in from a host variable or parameter marker of a character data type, or from a character string literal. Parsing an XML document using a host variable or parameter marker of type XML, BLOB or FOR BIT DATA (CHAR FOR BIT DATA or VARCHAR FOR BIT DATA) prevents code page conversion. When a character data type is used, care must be taken to ensure that all characters in the XML document have a matching code point in the target database code page, otherwise substitution characters may be introduced. The configuration parameter **enable_xmlchar** can be used to help ensure the integrity of XML data stored

in a non-Unicode database. Setting this parameter to "NO" blocks the insertion of XML documents from character data types. The BLOB and FOR BIT DATA data types are still allowed, as documents passed into a database using these data types avoid code page conversion.

Example

Using the PRESERVE WHITESPACE option preserves the white space characters in the XML document inserted into the table, including the white space characters in the description element.

```
INSERT INTO PRODUCT VALUES ('100-103-99','Tool bag',14.95,NULL,NULL,NULL,
XMLPARSE( DOCUMENT
  '<product xmlns="http://posample.org" pid="100-103-99">
    <description>
     <name>Tool bag</name>
     <details>
      Super Deluxe tool bag:
      - 26 inches long, 12 inches wide
      - Curved padded handle
      - Locking latch
      - Reinforced exterior pockets
     </details>
     <price>14.95</price>
     <weight>3 kg</weight>
    </description>
  </product>' PRESERVE WHITESPACE ));
```

Running the following select statement

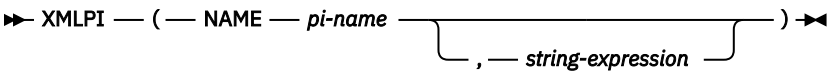
```
SELECT XMLQUERY ('$d/*:product/*:description/*:details' PASSING DESCRIPTION as "d" )
FROM PRODUCT WHERE PID = '100-103-99' ;
```

returns the details element with the white space characters:

```
<details xmlns="http://posample.org">
  Super Deluxe tool bag:
  - 26 inches long, 12 inches wide
  - Curved padded handle
  - Locking latch
  - Reinforced exterior pockets
</details>
```

XMLPI

The XMLPI function returns an XML value with a single XQuery processing instruction node.



The schema is SYSIBM. The function name cannot be specified as a qualified name.

NAME *pi-name*
Specifies the name of a processing instruction. The name is an SQL identifier that must be in the form of an XML NCName (SQLSTATE 42634). See the W3C XML namespace specifications for more details on valid names. The name cannot be the word 'xml' in any case combination (SQLSTATE 42634).

string-expression
An expression that returns a value that is a character string. The resulting string is converted to UTF-8 and must conform to the content of an XML processing instruction as specified in XML 1.0 rules (SQLSTATE 2200T):

- The string must not contain the substring '?>' since this substring terminates a processing instruction
- Each character of the string can be any Unicode character excluding the surrogate blocks, X'FFFE' and X'FFFF'.

The resulting string becomes the content of the constructed processing instruction node.

The data type of the result is XML. If the result of *string-expression* can be null, the result can be null; if the result of *string-expression* is null, the result is the null value. If *string-expression* is an empty string or is not specified, an empty processing instruction node is returned.

Examples

- *Example 1*: Generate an XML processing instruction node.

```
SELECT XMLPI(
  NAME "Instruction", 'Push the red button'
)
FROM SYSIBM.SYSDUMMY1
```

This query produces the following result:

```
<?Instruction Push the red button?>
```

- *Example 2*: Generate an empty XML processing instruction node.

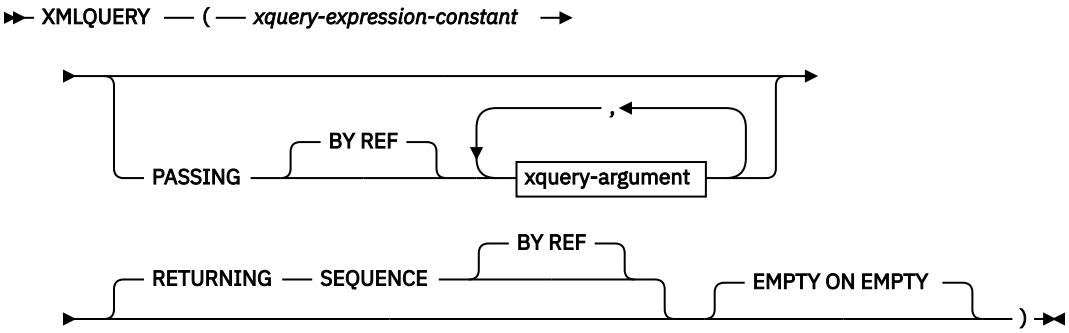
```
SELECT XMLPI(
  NAME "Warning"
)
FROM SYSIBM.SYSDUMMY1
```

This query produces the following result:

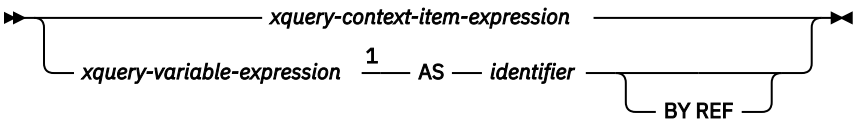
```
<?Warning ?>
```

XMLQUERY

The XMLQUERY function returns an XML value from the evaluation of an XQuery expression possibly using specified input arguments as XQuery variables.



xquery-argument



Notes:

[1] The data type of the expression cannot be DECFLOAT.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

xquery-expression-constant
Specifies an SQL character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. The constant string is converted to UTF-8 before being parsed as an XQuery statement. The XQuery expression executes using an optional set of input XML values, and returns an output sequence that is also returned as the value of the XMLQUERY expression. The value for *xquery-expression-constant* must not be an empty string or a string of blank characters (SQLSTATE 10505).

PASSING

Specifies input values and the manner in which these values are passed to the XQuery expression specified by *xquery-expression-constant*. By default, every unique column name that is in the scope where the function is invoked is implicitly passed to the XQuery expression using the name of the column as the variable name. If an *identifier* in a specified xquery-argument matches an in-scope column name, then the explicit xquery-argument is passed to the XQuery expression overriding that implicit column.

BY REF

Specifies that the default passing mechanism is by reference for any *xquery-variable-expression* of data type XML and for the returned value. When XML values are passed by reference, the XQuery evaluation uses the input node trees, if any, directly from the specified input expressions, preserving all properties, including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons involving some nodes contained between the two input arguments might refer to nodes within the same XML node tree.

This clause has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

xquery-argument

Specifies an argument that is to be passed to the XQuery expression specified by *xquery-expression-constant*. An argument specifies a value and the manner in which that value is to be passed. *xquery-argument* specifies both a value and the manner in which that value is to be passed. The method through which an argument, in the PASSING clause, is used in the XQuery expression depends on whether the argument is specified as *xquery-context-item-expression* or *xquery-variable-expression*. *xquery-argument* includes an SQL expression that is evaluated before it passes the result to the XQuery expression.

- If the resulting value is of type XML, it becomes an *input-xml-value*. A null XML value is converted to an XML empty sequence.
- If the resulting value is not of type XML, it must be castable to the XML data type. A null value is converted to an XML empty sequence. The converted value becomes an *input-xml-value*.

When the *xquery-expression-constant* is evaluated, an XQuery variable is presented with a value equal to *input-xml-value* and a name specified by the AS clause.

xquery-context-item-expression

xquery-context-item-expression specifies the initial context item in the XQuery expression that is specified by *xquery-expression-constant*. The value of the initial context item is the result of *xquery-context-item-expression* to XML. *xquery-context-item-expression* must not be specified more than one time. *xquery-context-item-expression* must not be a sequence of more than one item.

If *input-xml-value* is an empty XML string, the XQuery expression is evaluated with the initial context item set to an empty XML string. If the value of *input-xml-value* is null, the function returns a null value. If the *xquery-context-item-expression* is not specified or is an empty sequence, the initial context item in the XQuery expression is undefined and the XQuery expression must not reference the initial context item.

An XQuery variable is not created for the context item expression.

xquery-variable-expression

Specifies an SQL expression whose value is available to the XQuery expression specified by *xquery-expression-constant* during execution. The expression cannot contain a sequence reference (SQLSTATE 428F9) or an OLAP function (SQLSTATE 42903). The data type of the expression cannot be DECFLOAT.

AS *identifier*

Specifies that the value generated by *xquery-variable-expression* will be passed to *xquery-expression-constant* as an XQuery variable. The variable name will be *identifier*. The leading dollar sign ($) that precedes variable names in the XQuery language is not included in *identifier*. The identifier must be a valid XQuery variable name and is restricted to an XML

NCName (SQLSTATE 42634). The identifier must not be greater than 128 bytes in length. Two arguments within the same PASSING clause cannot use the same identifier (SQLSTATE 42711).

BY REF
Indicates that an XML input value is to be passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees, if any, directly from the specified input expressions, preserving all properties, including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons involving some nodes contained between the two input arguments might refer to nodes within the same XML node tree. If BY REF is not specified following an *xquery-variable-expression*, XML arguments are passed by way of the default passing mechanism that is provided through the syntax that follows the PASSING keyword. This option cannot be specified for non-XML values. When a non-XML value is passed, the value is converted to XML; this process creates a copy.

RETURNING SEQUENCE
Indicates that the XMLQUERY expression returns a sequence.

BY REF
Indicates that the result of the XQuery expression is returned by reference. If this value contains nodes, any expression using the return value of the XQuery expression will receive node references directly, preserving all node properties, including the original node identities and document order. Referenced nodes will remain connected within their node trees. If the BY REF clause is not specified and the PASSING is specified, the default passing mechanism is used. If BY REF is not specified and PASSING is not specified, the default returning mechanism is BY REF.

EMPTY ON EMPTY
Specifies that an empty sequence result from processing the XQuery expression is returned as an empty sequence.

The data type of the result is XML; it cannot be null.

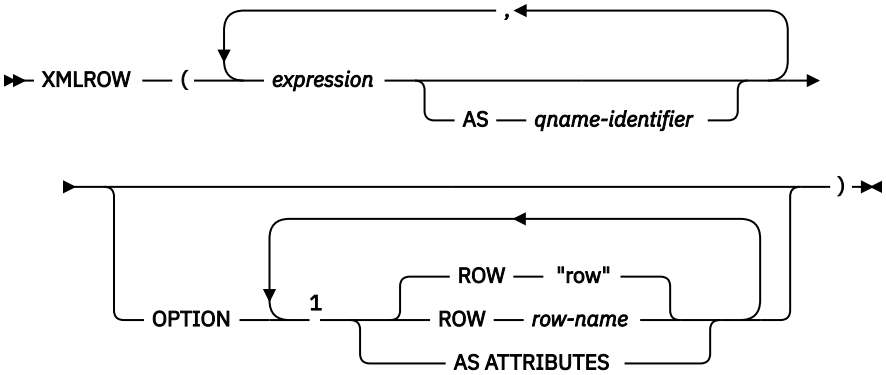
If the evaluation of the XQuery expression results in an error, then the XMLQUERY function returns the XQuery error (SQLSTATE class '10').

Notes

- **XMLQUERY usage restrictions**: The XMLQUERY function cannot be:
  - Part of the ON clause that is associated with a JOIN operator or a MERGE statement (SQLSTATE 42972)
  - Part of the GENERATE KEY USING or RANGE THROUGH clause in the CREATE INDEX EXTENSION statement (SQLSTATE 428E3)
  - Part of the FILTER USING clause in the CREATE FUNCTION (External Scalar) statement, or the FILTER USING clause in the CREATE INDEX EXTENSION statement (SQLSTATE 428E4)
  - Part of a check constraint or a column generation expression (SQLSTATE 42621)
  - Part of a group-by-clause (SQLSTATE 42822)
  - Part of an argument for an aggregate function (SQLSTATE 42607)
- **XMLQUERY as a subquery**: An XMLQUERY expression that acts as a subquery can be restricted by statements that restrict subqueries.

XMLROW

The XMLROW function returns an XML value with a single XQuery document node containing one top-level element node.



Notes:

[1] The same clause must not be specified more than once.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

expression
The content of each generated XML element node is specified by an expression. The data type of the expression cannot be a BINARY type, a VARBINARY type, or a structured type (SQLSTATE 42884). The expression can be any SQL expression. If the expression is not a simple column reference, an element name must be specified.

AS *qname-identifier*
Specifies the XML element name or attribute name as an SQL identifier. The *qname-identifier* must be of the form of an XML qualified name, or QName (SQLSTATE 42634). See the W3C XML namespace specifications for more details on valid names. If the name is qualified, the namespace prefix must be declared within the scope (SQLSTATE 42635). If *qname-identifier* is not specified, *expression* must be a column name (SQLSTATE 42703). The element name or attribute name is created from the column name using the fully escaped mapping from a column name to an QName.

OPTION
Specifies additional options for constructing the XML value. If no OPTION clause is specified, the default behavior applies.

AS ATTRIBUTES
Specifies that each expression is mapped to an attribute value with column name or *qname-identifier* serving as the attribute name.

ROW *row-name*
Specifies the name of the element to which each row is mapped. If this option is not specified, the default element name is "row".

Notes

By default, each row in the result set is mapped to an XML value as follows:

- Each row is transformed into an XML element named "row" and each column is transformed into a nested element with the column name as the element name.
- The null handling behavior is NULL ON NULL. A null value in a column maps to the absence of the subelement. If all column values are null, a null value is returned by the function.
- The binary encoding scheme for BLOB and FOR BIT DATA data types is base64Binary encoding.
- A document node will be added implicitly to the row element to make the XML result a well-formed single-rooted XML document.

Examples

Assume the following table T1 with columns C1 and C2 that contain numeric data stored in a relational format:

```
C1          C2
----------- -----------
          1           2
          -           2
          1           -
          -           -

  4 record(s) selected.
```

- *Example 1*: The following example shows an XMLRow query and output fragment with default behavior, using a sequence of row elements to represent the table:

```
SELECT XMLROW(C1, C2) FROM T1
```

```
<row><C1>1</C1><C2>2</C2></row>
<row><C2>2</C2></row>
<row><C1>1</C1></row>

  4 record(s) selected.
```

- *Example 2*: The following example shows an XMLRow query and output fragment with attribute centric mapping. Instead of appearing as nested elements as in the previous example, relational data is mapped to element attributes:

```
SELECT XMLROW(C1, C2 OPTION AS ATTRIBUTES) FROM T1
```

```
<row C1="1" C2="2"/>
<row C2="2"/>
<row C1="1"/>

  4 record(s) selected.
```

- *Example 3*: The following example shows an XMLRow query and output fragment with the default <row> element replaced by <entry>. Columns C1 and C2 are returned as <column1> and <column2> elements, and the total of C1 and C2 is returned inside a <total> element:

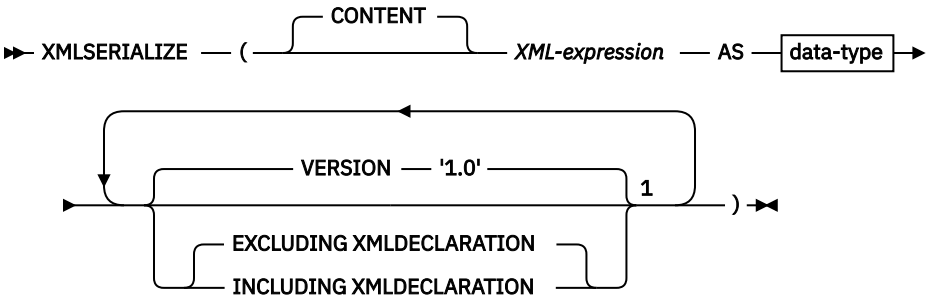
```
SELECT XMLROW(
   C1 AS "column1", C2 AS "column2",
   C1+C2 AS "total" OPTION ROW "entry")
FROM T1
```

```
<entry><column1>1</column1><column2>2</column2><total>3</total></entry>
<entry><column2>2</column2></entry>
<entry><column1>1</column1></entry>

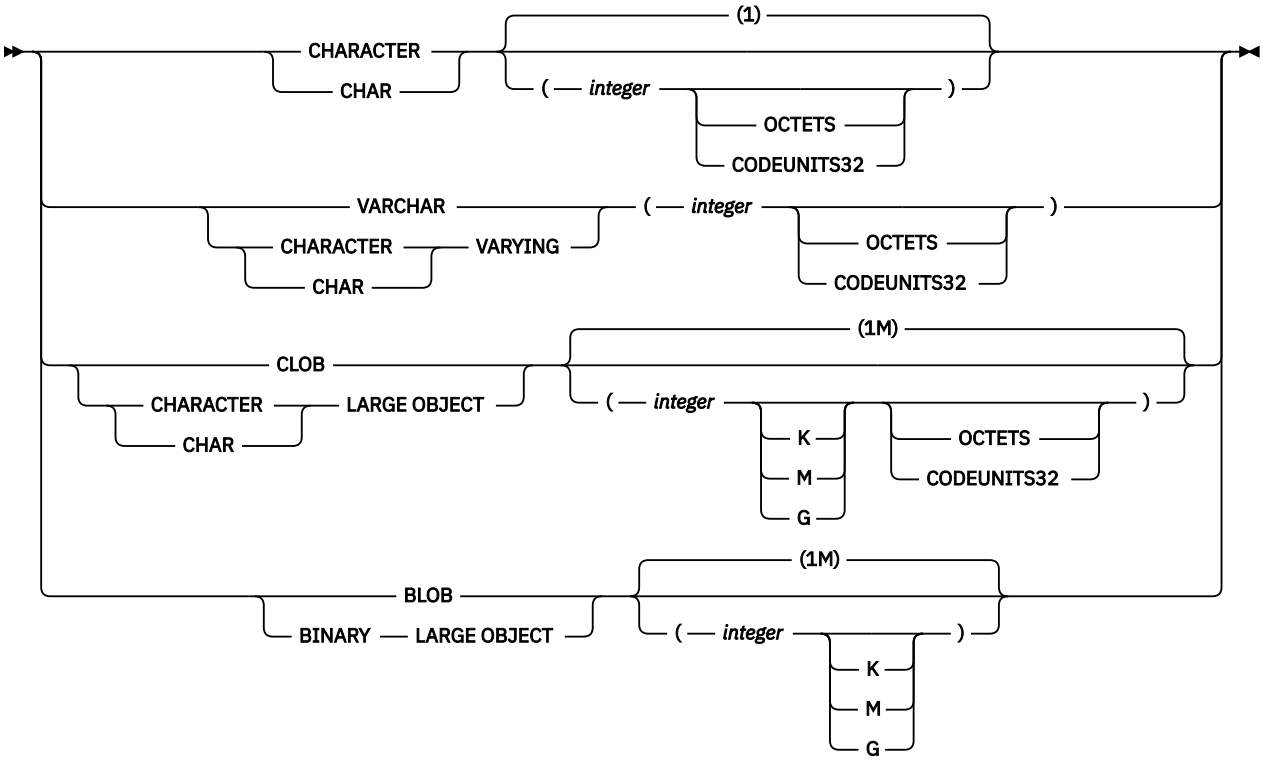
  4 record(s) selected.
```

XMLSERIALIZE

The XMLSERIALIZE function returns a serialized XML value of the specified data type generated from the *XML-expression* argument.



data-type



Notes:

[1] The same clause must not be specified more than once.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

CONTENT
Specifies that any XML value can be specified and the result of the serialization is based on this input value.

XML-expression
Specifies an expression that returns a value of data type XML. The XML sequence value must not contain an item that is an attribute node (SQLSTATE 2200W). This is the input to the serialization process.

AS *data-type*
Specifies the result type. The implicit or explicit length attribute of the specified result data type must be sufficient to contain the serialized output (SQLSTATE 22001).

VERSION '1.0'
Specifies the XML version of the serialized value. The only version supported is '1.0' which must be specified as a string constant (SQLSTATE 42815).

EXCLUDING XMLDECLARATION or INCLUDING XMLDECLARATION
Specifies whether an XML declaration is included in the result. The default is EXCLUDING XMLDECLARATION.

EXCLUDING XMLDECLARATION
Specifies that an XML declaration is not included in the result.

INCLUDING XMLDECLARATION
Specifies that an XML declaration is included in the result. The XML declaration is the string '<?xml version="1.0" encoding="UTF-8"?>'.

AS *data-type*
Specifies the result data type. The implicit or explicit length attribute of the specified result data type must be sufficient to contain the transformed output (SQLSTATE 22001).

If either the *xml-document* argument or the *xsl-stylesheet* argument is null, the result will be null.

Code page conversion might occur when storing any of the previously mentioned documents in a CHAR, VARCHAR, or CLOB column, which might result in a character loss.

The result has the data type specified by the user. An XML sequence is effectively converted to have a single document node by applying XMLDOCUMENT to *XML-expression* before serializing the resulting XML nodes. If the result of *XML-expression* can be null, the result can be null; if the result of *XML-expression* is null, the result is the null value.

Notes

- **Encoding in the serialized result**: The serialized result is encoded with UTF-8. If XMLSERIALIZE is used with a character data type, and the INCLUDING XMLDECLARATION clause is specified, the resulting character string containing serialized XML might have an XML encoding declaration that does not match the code page of the character string. Following serialization, which uses UTF-8 encoding, the character string that is returned from the server to the client is converted to the code page of the client, and that code page might be different from UTF-8.

  Therefore, applications should avoid direct use of XMLSERIALIZE INCLUDING XMLDECLARATION that return character string types and should retrieve XML values directly into host variables to maintain the match between the external code page and the encoding in the XML declaration. If XMLSERIALIZE must be used in this situation, a BLOB type should be specified to avoid code page conversion.
- **Syntax alternative**: XML2CLOB(*XML-expression*) can be specified in place of XMLSERIALIZE(*XML-expression* AS CLOB(2G)). It is supported only for compatibility with previous Db2 releases.

XMLTEXT

The XMLTEXT function returns an XML value with a single XQuery text node having the input argument as the content.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

string-expression
An expression whose value has a character string type: CHAR, VARCHAR or CLOB.

The data type of the result is XML. If the result of *string-expression* can be null, the result can be null; if the input value is null, the result is the null value. If the result of *string-expression* is an empty string, the result value is an empty text node.

Examples

- *Example 1*: Create a simple XMLTEXT query.

```
   VALUES(
     XMLTEXT(
       'The stock symbol for Johnson&Johnson is JNJ.'
     )
   )
```

This query produces the following serialized result:

```
1
--------------------------------------------------
The stock symbol for Johnson&amp;Johnson is JNJ.
```

Note that the '&' sign is mapped to '&' when a text node is serialized.

- *Example 2*: Use XMLTEXT with XMLAGG to construct mixed content. Suppose that the content of table T is as follows:

```
seqno  plaintext
                                                    emphtext
------ ------------------------------------------------------------
-------------
1      This query shows how to construct
 mixed content
2       using XMLAGG and XMLTEXT. Without
 XMLTEXT
3      XMLAGG will not have text nodes to group with other nodes,
 mixed content
       therefore, cannot generate
```

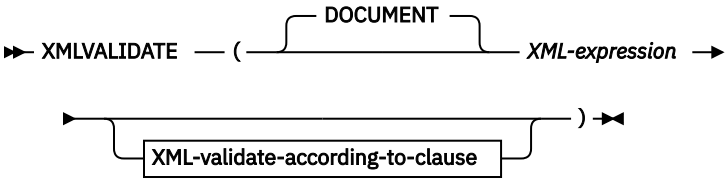
```
   SELECT
XMLELEMENT(
     NAME "para", XMLAGG(
       XMLCONCAT(
         XMLTEXT(
           PLAINTEXT
         ),
         XMLELEMENT(
           NAME "emphasis", EMPHTEXT
         )
       )
       ORDER BY SEQNO
     ), '.'
   ) AS "result"
   FROM T
```

This query produces the following result:

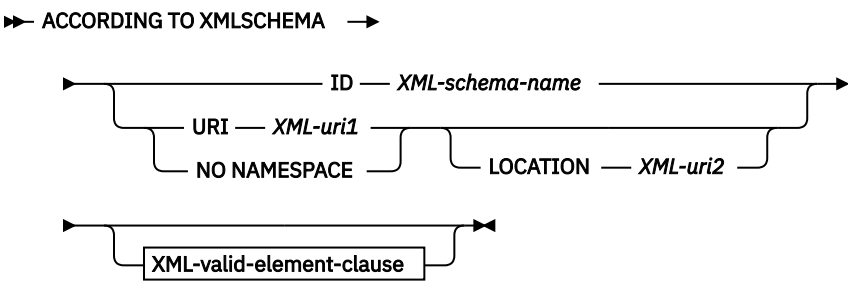
```
result
--------------------------------------------------------------------------------
<para>This query shows how to construct <emphasis>mixed content</emphasis>
using XMLAGG and XMLTEXT. Without <emphasis>XMLTEXT</emphasis>
, XMLAGG
will not have text nodes to group with other nodes, therefore, cannot
generate
<emphasis>mixed content</emphasis>.</para>
```

XMLVALIDATE

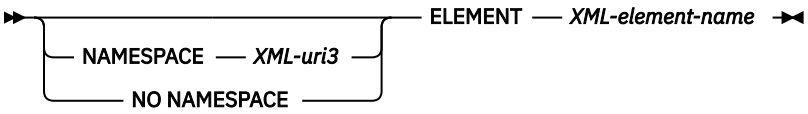
The XMLVALIDATE function returns a copy of the input XML value augmented with information obtained from XML schema validation, including default values.



XML-validate-according-to-clause



XML-valid-element-clause



The schema is SYSIBM. The function name cannot be specified as a qualified name.

DOCUMENT
Specifies that the XML value resulting from *XML-expression* must be a well-formed XML document that conforms to XML Version 1.0 (SQLSTATE 2200M).

XML-expression
An expression that returns a value of data type XML. If *XML-expression* is an XML host variable or an implicitly or explicitly typed parameter marker, the function performs a validating parse that strips ignorable whitespace and the CURRENT IMPLICIT XMLPARSE OPTION setting is not considered.

XML-validate-according-to-clause
Specifies the information that is to be used when validating the input XML value.

ACCORDING TO XMLSCHEMA
Indicates that the XML schema information for validation is explicitly specified. If this clause is not included, the XML schema information must be provided in the content of the *XML-expression* value.

ID *XML-schema-name*
Specifies an SQL identifier for the XML schema that is to be used for validation. The name, including the implicit or explicit SQL schema qualifier, must uniquely identify an existing XML schema in the XML schema repository at the current server. If no XML schema by this name exists in the implicitly or explicitly specified SQL schema, an error is returned (SQLSTATE 42704).

URI *XML-uri1*
Specifies the target namespace URI of the XML schema that is to be used for validation. The value of *XML-uri1* specifies a URI as a character string constant that is not empty. The URI must be the target namespace of a registered XML schema (SQLSTATE 4274A) and, if no LOCATION clause is specified, it must uniquely identify the registered XML schema (SQLSTATE 4274B).

NO NAMESPACE
Specifies that the XML schema for validation has no target namespace. The target namespace URI is equivalent to an empty character string that cannot be specified as an explicit target namespace URI.

LOCATION *XML-uri2*
Specifies the XML schema location URI of the XML schema that is to be used for validation. The value of *XML-uri2* specifies a URI as a character string constant that is not empty. The XML schema location URI, combined with the target namespace URI, must identify a registered XML schema (SQLSTATE 4274A), and there must be only one such XML schema registered (SQLSTATE 4274B).

XML-valid-element-clause
Specifies that the XML value in *XML-expression* must have the specified element name as the root element of the XML document.

NAMESPACE *XML-uri3* or NO NAMESPACE
Specifies the target namespace for the element that is to be validated. If neither clause is specified, the specified element is assumed to be in the same namespace as the target namespace of the registered XML schema that is to be used for validation.

NAMESPACE *XML-uri3*
Specifies the namespace URI for the element that is to be validated. The value of *XML-uri3* specifies a URI as a character string constant that is not empty. This can be used when the registered XML schema that is to be used for validation has more than one namespace.

NO NAMESPACE
Specifies that the element for validation has no target namespace. The target namespace URI is equivalent to an empty character string which cannot be specified as an explicit target namespace URI.

ELEMENT *xml-element-name*
Specifies the name of a global element in the XML schema that is to be used for validation. The specified element, with implicit or explicit namespace, must match the root element of the value of *XML-expression* (SQLSTATE 22535 or 22536).

The data type of the result is XML. If the value of *XML-expression* can be null, the result can be null; if the value of *XML-expression* is null, the result is the null value.

The XML validation process is performed on a serialized XML value. Because XMLVALIDATE is invoked with an argument of type XML, this value is automatically serialized before validation processing with the follow two exceptions.

- If the argument to XMLVALIDATE is an XML host variable or an implicitly or explicitly typed parameter marker, then a validating parse operation is performed on the input value (no implicit non-validating parse is performed and CURRENT IMPLICIT XMLPARSE OPTION setting is not considered).
- If the argument to XMLVALIDATE is an XMLPARSE invocation using the option PRESERVE WHITESPACE, then the XML parsing and XML validation of the document may be combined into a single validating parse operation.

If an XML value has previously been validated, the annotated type information from the previous validation is removed by the serialization process. However, any default values and entity expansions from the previous validation remain unchanged. If validation is successful, all ignorable whitespace characters are stripped from the result.

To validate a document whose root element does not have a namespace, an xsi:noNamespaceSchemaLocation attribute must be present on the root element.

Notes

- **Determining the XML schema**: The XML schema can be either specified explicitly with the `ACCORDING TO XMLSCHEMA` clause as part of the XMLVALIDATE invocation, or determined implicitly from the XML schema location information in the input XML value. The explicit or implicit XML schema information must identify an XML schema registered in the XML schema repository (SQLSTATE 42704, 4274A, or 22532), and there must be only one such registered XML schema (SQLSTATE 4274B or 22533).

  If an XML schema for validation is explicitly specified with the `ACCORDING TO XMLSCHEMA` clause, the schema location information specified in the input XML value is ignored.

  If the XML schema information is not specified with the `ACCORDING TO XMLSCHEMA` clause, the input XML value must contain XML schema location information (SQLSTATE 2200M). The schema location information in the input XML value, a namespace name, and a schema location specifies the XML schema document in the XML schema repository used for validation.

- **XML schema authorization**: The XML schema used for validation must be registered in the XML schema repository before use. The privileges held by the authorization ID of the statement must include at least one of the following authorities:
  - USAGE privilege on the XML schema that is to be used during validation
  - DBADM authority
- **Using a maxOccurs attribute value that is greater than 5000 in XML schemas:** In Db2 Version 9.7 Fix Pack 1 and later, if an XML schema that is registered in the XSR uses the maxOccurs attribute where the value is greater than 5000, the maxOccurs attribute value is treated as if you specified "unbounded". Because document elements that have a maxOccurs attribute value that is greater than 5000 are processed as if you specified "unbounded", an XML document might pass validation when you use the XMLVALIDATE function even if the number of occurrences of an element exceeds the maximum according to the XML schema that you used to validate the document.

  If you use an XML schema that defines an element that has a maxOccurs attribute value that is greater than 5000 and you want to reject XML documents that have a maxOccurs attribute value greater than 5000, you can define a trigger or procedure to check for that condition. In the trigger or procedure, use an XPath expression to count the number of occurrences of the element and return an error if the number of elements exceeds the maxOccurs attribute value.

  For example, the following trigger ensures that a document never has more than 6500 phone elements:

```
CREATE TRIGGER CUST_INSERT
  AFTER INSERT ON CUSTOMER
  REFERENCING NEW AS NEWROW
  FOR EACH ROW MODE DB2SQL
BEGIN ATOMIC
  SELECT CASE WHEN X <= 6500 THEN 'OK - Do Nothing'
              ELSE RAISE_ERROR('75000', 'TooManyPhones')  END

  FROM (
    SELECT XMLCAST(XMLQUERY('$INFO/customerinfo/count(phone)') AS INTEGER) AS X
    FROM CUSTOMER
    WHERE CUSTOMER.CID = NEWROW.CID );
END
```

Examples

- *Example 1*: Validate using the XML schema identified by the XML schema hint in the XML instance document.

```
   INSERT INTO T1(XMLCOL)
     VALUES (XMLVALIDATE(?))
```

  Assume that the input parameter marker is bound to an XML value that contains the XML schema information.

```
   <po:order
      xmlns:po="http://my.world.com"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://my.world.com http://my.world.com/world.xsd" >
   ...
   </po:order>
```

  Further, assume that the XML schema that is associated with the target namespace "http://my.world.com" and by schemaLocation hint "http://my.world.com/world.xsd" is found in the XML schema repository.

  Based on these assumptions, the input XML value will be validated according to that XML schema.

- *Example 2*: Validate using the XML schema identified by the SQL name PODOCS.WORLDPO.

```
   INSERT INTO T1(XMLCOL)
     VALUES (
       XMLVALIDATE(
         ? ACCORDING TO XMLSCHEMA ID PODOCS.WORLDPO
```

```
    )
  )
```

Assuming that the XML schema that is associated with SQL name FOO.WORLDPO is found in the XML repository, the input XML value will be validated according to that XML schema.

- *Example 3*: Validate a specified element of the XML value.

```
INSERT INTO T1(XMLCOL)
  VALUES (
    XMLVALIDATE(
      ? ACCORDING TO XMLSCHEMA ID FOO.WORLDPO
      NAMESPACE 'http://my.world.com/Mary'
      ELEMENT "po"
    )
  )
```

Assuming that the XML schema that is associated with SQL name FOO.WORLDPO is found in the XML repository, the XML schema will be validated against the element "po", whose namespace is 'http://my.world.com/Mary'.

- *Example 4*: XML schema is identified by target namespace and schema location.

```
INSERT INTO T1(XMLCOL)
  VALUES (
    XMLVALIDATE(
      ? ACCORDING TO XMLSCHEMA URI 'http://my.world.com'
      LOCATION 'http://my.world.com/world.xsd'
    )
  )
```

Assuming that an XML schema associated with the target namespace "http://my.world.com" and by schemaLocation hint "http://my.world.com/world.xsd" is found in the XML schema repository, the input XML value will be validated according to that schema.

XMLXSROBJECTID

The XMLXSROBJECTID function returns the XSR object identifier of the XML schema used to validate the XML document specified in the argument. The XSR object identifier is returned as a BIGINT value and provides the key to a single row in SYSCAT.XSROBJECTS.

The schema is SYSIBM.

xml-value-expression
Specifies an expression that results in a value with a data type of XML. The resulting XML value must be an XML sequence with a single item that is an XML document or the null value (SQLSTATE 42815). If the argument is null, the function returns null. If *xml-value-expression* does not specify a validated XML document, the function returns 0.

Notes

- The XML schema corresponding to an XSR object ID returned by the function might no longer exist, because an XML schema can be dropped without affecting XML values that were validated using the XML schema. Therefore, queries that use the XSR object ID to fetch further XML schema information from the catalog views might return an empty result set.
- Applications can use the XSR object identifier to retrieve additional information about the XML schema. For example, the XSR object identifier can be used to return the individual XML schema documents that make up a registered XML schema from SYSCAT.SYSXSROBJECTCOMPONENTS, and the hierarchy of XML schema documents in the XML schema from SYSCAT.XSROBJECTHIERARCHIES.

Examples

- *Example 1*: Retrieve the XML schema identifier for the XML document XMLDOC stored in the table MYTABLE.

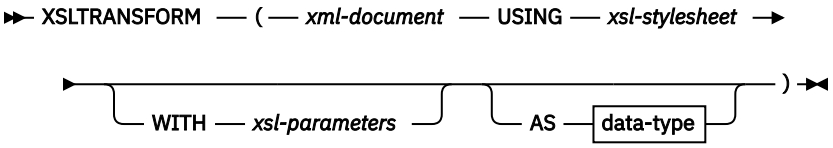
```
SELECT XMLXSROBJECTID(XMLDOC) FROM MYTABLE
```

- *Example 2*: Retrieve the XML schema documents associated with the XML document that has a specific ID (in this case where DOCKEY = 1) in the table MYTABLE, including the hierarchy of the XML schema documents that make up the XML schema.

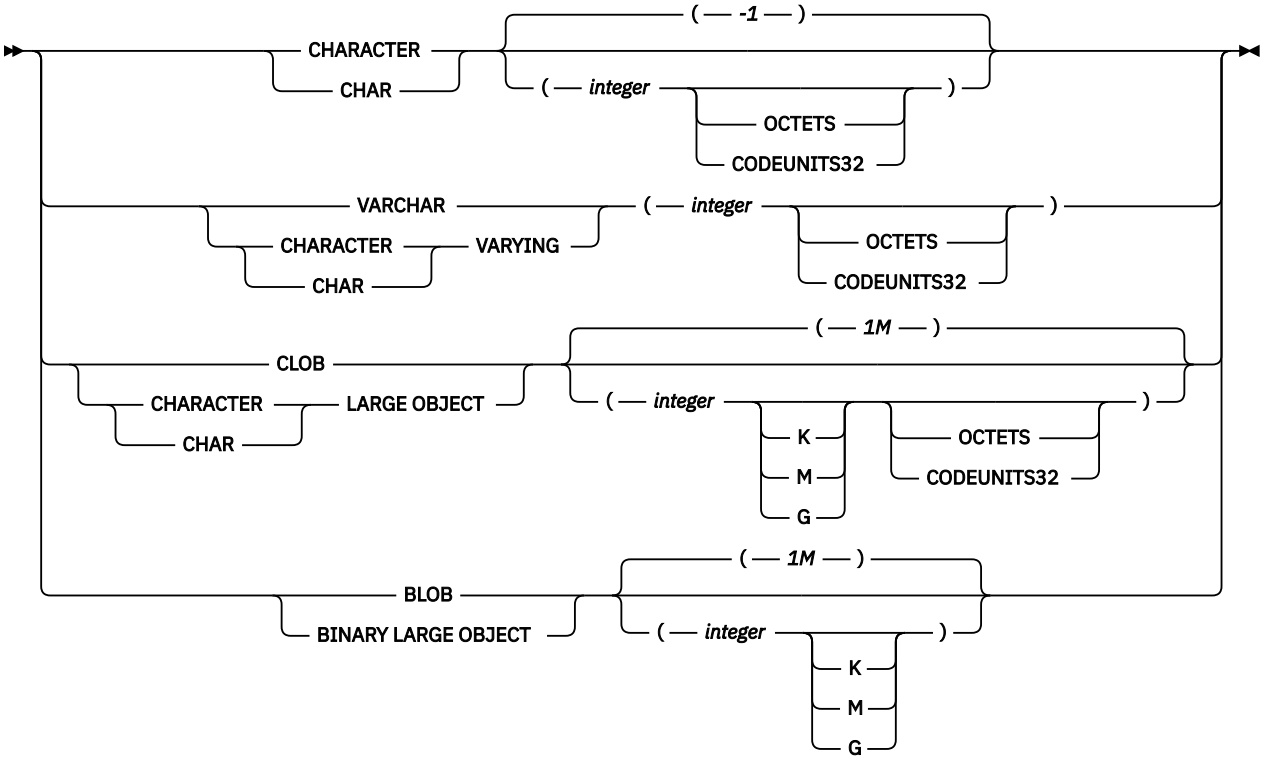
```
SELECT H.HTYPE, C.TARGETNAMESPACE, C.COMPONENT
FROM SYSCAT.XSROBJECTCOMPONENTS C, SYSCAT.XSROBJECTHIERARCHIES H
WHERE C.OBJECTID =
  (SELECT XMLXSROBJECTID(XMLDOC) FROM MYTABLE
   WHERE DOCKEY = 1)
AND C.OBJECTID = H.OBJECTID
```

XSLTRANSFORM

Use XSLTRANSFORM to convert XML data into other formats, including the conversion of XML documents that conform to one XML schema into documents that conform to another schema.



data-type



The schema is SYSIBM. This function cannot be specified as a qualified name.

The XSLTRANSFORM function transforms an XML document into a different data format. The data can be transformed into any form possible for the XSLT processor, including but not limited to XML, HTML, or plain text.

All paths used by XSLTRANSFORM are internal to the database system. This command cannot currently be used directly with files or stylesheets residing in an external file system.

xml-document
An expression that returns a well-formed XML document with a data type of XML, CHAR, VARCHAR, CLOB, or BLOB. This is the document that is transformed using the XSL style sheet specified in *xsl-stylesheet*.

The XML document must at minimum be single-rooted and well-formed.

xsl-stylesheet
An expression that returns a well-formed XML document with a data type of XML, CHAR, VARCHAR, CLOB, or BLOB. The document is an XSL style sheet that conforms to the W3C XSLT Version 1.0 Recommendation. Style sheets incorporating XQUERY statements or the `xsl:include` declaration are not supported. This stylesheet is applied to transform the value specified in *xml-document*.

xsl-parameters
An expression that returns a well-formed XML document or null with a data type of XML, CHAR, VARCHAR, CLOB, or BLOB. This is a document that provides parameter values to the XSL stylesheet specified in *xsl-stylesheet*. The value of the parameter can be specified as an attribute, or as a text node.

The syntax of the parameter document is as follows:

```
<params xmlns="http://www.ibm.com/XSLTransformParameters">
<param name="..." value="..."/>
<param name="...">enter value here</param>
        ...
</params>
```

The stylesheet document must have `xsl:param` element(s) in it with name attribute values that match the ones specified in the parameter document.

AS *data-type*
Specifies the result data type. The implicit or explicit length attribute of the specified result data type must be sufficient to contain the transformed output (SQLSTATE 22001). The default result data type is CLOB(2G OCTETS) except in a Unicode database where the string units of the environment is set to CODEUNITS32 when the default is CLOB(536870911 CODEUNITS32).

If either the *xml-document* argument or the *xsl-stylesheet* argument is null, the result will be null.

Code page conversion might occur when storing any of the previously mentioned documents in a CHAR, VARCHAR, or CLOB column, which might result in a character loss.

Example

This example illustrates how to use XSLT as a formatting engine. To get set up, first create the XML_TAB table and insert a row that includes an XML document and an XSL style sheet into the table.

```
CREATE TABLE XML_TAB (DOC_ID INTEGER, XML_DOC XML, XSL_DOC XML);

INSERT INTO XML_TAB VALUES
(1,
'<?xml version="1.0"?>
 <students xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation = "/home/steffen/xsd/xslt.xsd">
  <student studentID="1" firstName="Steffen" lastName="Siegmund"
    age="23" university="Rostock"/>
 </students>',
'<?xml version="1.0" encoding="UTF-8"?>
 <xsl:stylesheet version="1.0"
            xmlns:xsl="http://www.w3.org/1999/XSL/Transform">
 <xsl:param name="headline"/>
 <xsl:param name="showUniversity"/>
 <xsl:template match="students">
  <html>
  <head/>
  <body>
    <h1><xsl:value-of select="$headline"/></h1>
      <table border="1">
```

```
        <th>
         <tr>
          <td width="80">StudentID</td>
          <td width="200">First Name</td>
          <td width="200">Last Name</td>
          <td width="50">Age</td>
        <xsl:choose>
         <xsl:when test="$showUniversity =''true''">
          <td width="200">University</td>
         </xsl:when>
        </xsl:choose>
         </tr>
        </th>
       <xsl:apply-templates/>
      </table>
  </body>
  </html>
 </xsl:template>
 <xsl:template match="student">
         <tr>
          <td><xsl:value-of select="@studentID"/></td>
          <td><xsl:value-of select="@firstName"/></td>
          <td><xsl:value-of select="@lastName"/></td>
          <td><xsl:value-of select="@age"/></td>
        <xsl:choose>
         <xsl:when test="$showUniversity = ''true''">
          <td><xsl:value-of select="@university"/></td>
         </xsl:when>
        </xsl:choose>
        </tr>
 </xsl:template>
 </xsl:stylesheet>'
);
```

Next, call the XSLTRANSFORM function to convert the XML data into HTML and display it.

```
SELECT XSLTRANSFORM (XML_DOC USING XSL_DOC AS CLOB(1M)) FROM XML_TAB;
```

The result is this document:

```
<html>
<head>
<META http-equiv="Content-Type" content="text/html; charset=UTF-8">
</head>
<body>
<h1></h1>
<table border="1">
<th>
<tr>
<td width="80">StudentID</td>
<td width="200">First Name</td>
<td width="200">Last Name</td>
<td width="50">Age</td>
</tr>
</th>
 <tr>
<td>1</td>
<td>Steffen</td><td>Siegmund</td>
<td>23</td>
</tr>
              </table>
</body>
</html>
```

In this example, the output is HTML and the parameters influence only what HTML is produced and what data is brought over to it. As such it illustrates the use of XSLT as a formatting engine for end-user output.

Usage note

There are many methods you can use to transform XML documents including the XSLTRANSFORM function, an XQuery update expression, and XSLT processing by an external application server. For documents stored in an XML column of a database table, many transformations can be performed more efficiently by using an XQuery update expression rather than with XSLT because XSLT always requires parsing of the XML documents that are being transformed. If you decide to transform XML documents

with XSLT, you should make careful decisions about whether to transform the document in the database or in an application server.

YEAR

The YEAR function returns the year part of a value.

The schema is SYSIBM.

expression
An expression that returns a value of one of the following built-in data types: DATE, TIMESTAMP, date duration, timestamp duration, or a valid character string representation of a date or timestamp that is not a CLOB. In a Unicode database, if a supplied argument is a graphic string, it is first converted to a character string before the function is executed.

The result of the function is a large integer. If the argument can be null, the result can be null; if the argument is null, the result is the null value.

The other rules depend on the data type of the argument specified:

- If the argument is a DATE, TIMESTAMP, or valid string representation of a date or timestamp:
  - The result is the year part of the value, which is an integer between 1 and 9999.
- If the argument is a date duration or timestamp duration:
  - The result is the year part of the value, which is an integer between -9999 and 9999. A nonzero result has the same sign as the argument.

Examples

- *Example 1*: Select all the projects in the PROJECT table that are scheduled to start (PRSTDATE) and end (PRENDATE) in the same calendar year.

```
SELECT * FROM PROJECT
  WHERE YEAR(PRSTDATE) = YEAR(PRENDATE)
```

- *Example 2*: Select all the projects in the PROJECT table that are scheduled to take less than one year to complete.

```
SELECT * FROM PROJECT
  WHERE YEAR(PRENDATE - PRSTDATE) < 1
```

YEARS_BETWEEN

The YEARS_BETWEEN function returns the number of full years between the specified arguments.

The schema is SYSIBM.

expression1
An expression that specifies the first datetime value to compute the number of full years between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression1* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

expression2
An expression that specifies the second datetime value to compute the number of full years between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or

VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression2* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

If there is less than a full year between *expression1* and *expression2*, the result is zero. If *expression1* is later than *expression2*, the result is positive. If *expression1* is earlier than *expression2*, the result is negative. If *expression1* or *expression2* contains time information, this information is also used to determine the number of full years. If *expression1* or *expression2* does not contain time information, a time of midnight (00.00.00) is used for the argument that is missing time information.

The result of the function is an INTEGER. If either argument can be null, the result can be null. If either argument is null, the result is the null value.

The YEARS_BETWEEN function is a synonym of the following expression:

```
YEAR( TIMESTAMP( expression1, 12 ) - TIMESTAMP( expression2, 12 ) )
```

Examples

1. Set the host variable NUM_YEARS with the number of full years between 2013-02-28 and 2012-02-29.

   ```
   SET :NUM_YEARS = YEARS_BETWEEN(DATE '2013-02-28', DATE '2012-02-29')
   ```

   The host variable NUM_YEARS is set to 0 because there is 1 day less than a full year between the arguments due to the existence of February 29, 2012.
2. Set the host variable NUM_YEARS with the number of full years between 2013-12-31 and 2001-01-01.

   ```
   SET :NUM_YEARS = YEARS_BETWEEN(DATE '2013-12-31', DATE '2001-01-01')
   ```

   The host variable NUM_YEARS is set to 12 because there is 1 day less than 13 full years between the arguments. It is positive because the first argument is later than the second argument.
3. Set the host variable NUM_YEARS with the number of full years between 2001-01-01-00.00.00 and 2013-12-31-23.59.59.

   ```
   SET :NUM_YEARS = YEARS_BETWEEN(TIMESTAMP '2001-01-01-00.00.00',
      TIMESTAMP '2013-12-31-23.59.59')
   ```

   The host variable NUM_YEARS is set to -12 because there is 1 day less than 13 full years between the arguments. It is negative because the first argument is earlier than the second argument.

YMD_BETWEEN

The YMD_BETWEEN function returns a numeric value that specifies the number of full years, full months, and full days between two datetime values.

The schema is SYSIBM.

expression1
An expression that specifies the first datetime value to compute the number of full years, full months, and full days between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression1* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

expression2
An expression that specifies the second datetime value to compute the number of full years, full months, and full days between two datetime values. The expression must return a value that is a DATE, TIMESTAMP, CHAR, or VARCHAR data type. In a Unicode database, the expression can also be a GRAPHIC or VARGRAPHIC data type. CHAR, VARCHAR, GRAPHIC, and VARGRAPHIC are supported by using implicit casting. If *expression2* is a CHAR, VARCHAR, GRAPHIC, or VARGRAPHIC data type, it must be a valid string that is accepted by the TIMESTAMP scalar function.

If there is less than a full day between *expression1* and *expression2*, the result is zero. If *expression1* is later than *expression2*, the result is positive. If *expression1* is earlier than *expression2*, the result is negative. If *expression1* or *expression2* contains time information, this information is also used to determine the number of full years, full months, and full days. If *expression1* or *expression2* does not contain time information, a time of midnight (00.00.00) is used for the argument that is missing time information.

The result of the function is an INTEGER. If either argument can be null, the result can be null. If either argument is null, the result is the null value.

The YMD_BETWEEN function is a synonym of the following expression:

```
INTEGER( ( TIMESTAMP(expression1, 12) – TIMESTAMP(expression2, 12) ) / 1000000 )
```

The result is the integer representation of the extraction of the year, month, and day components of a timestamp duration.

Examples

1. Set the host variable YMD to the number of full years, full months, and full days between 2013-09-23-23.59.59.123456789012 and 2013-09-24-23.59.59.123456789011.

   ```
   SET :YMD = YMD_BETWEEN(TIMESTAMP '2013-09-24-23.59.59.123456789011',
      TIMESTAMP '2013-09-23-23.59.59.123456789012')
   ```

   The host variable YMD is set to 0 because there are 0.000000000001 seconds less than a full day between the arguments. It is positive because the first argument is later than the second argument.
2. Set the host variable YMD to the number of full years, full months, and full days between 2013-09-23-23.59.59.123456789012 and 2013-09-24-23.59.59.123456789012.

   ```
   SET :YMD = YMD_BETWEEN(TIMESTAMP '2013-09-24-23.59.59.123456789012',
      TIMESTAMP '2013-09-23-23.59.59.123456789012')
   ```

   The host variable YMD is set to 1 because there is exactly 1 day between the arguments. It is positive because the first argument is later than the second argument.
3. Set the host variable YMD to the number of full years, full months, and full days between 2013-09-23-23.59.59.123456789012 and 2016-03-01-23.59.59.123456789011.

   ```
   SET :YMD = YMD_BETWEEN(TIMESTAMP '2013-09-23-23.59.59.123456789012',
      TIMESTAMP '2016-03-01-23.59.59.123456789011')
   ```

   The host variable YMD is set to -20507 because there are 0.000000000001 seconds less than 2 full years, 5 full months, and 8 full days between the arguments. It is negative because the first argument is earlier than the second argument.

Table functions

Table functions return columns of a table, resembling a table created through a simple CREATE TABLE statement.

A table function can be used only in the FROM clause of a statement.

Table functions can be qualified with a schema name.

BASE_TABLE

The BASE_TABLE function returns both the object name and schema name of the object found after any alias chains have been resolved.

The schema is SYSPROC.

The specified objectname (and objectschema) are used as the starting point of the resolution. If the starting point does not refer to an alias, the schema name and the unqualified name of the starting point are returned. The function returns a single row table consisting of the following columns:

Table 107. Information returned by the BASE_TABLE function

Column name	Data type	Description
BASESCHEMA	VARCHAR(128)	Schema name of the object found after any alias chains have been resolved. Matches objectschema if no matching alias was found.
BASENAME	VARCHAR(128)	Unqualified name of the object found after any alias chains have been resolved. Matches objectname if no matching alias was found. The name may identify a table, a view, or an undefined object.

objectschema
A character expression representing the schema used to qualify the supplied *objectname* value before resolution. *objectschema* must have a data type of CHAR or VARCHAR and a length greater than 0 and less than 129 bytes.

objectname
A character expression representing the unqualified name to be resolved. *objectname* must have a data type of CHAR or VARCHAR and a length greater than 0 and less than 129 bytes.

Note: The BASE_TABLE table function improves performance in partitioned database configurations by avoiding the unnecessary communication that occurs between the coordinator partition and catalog partition when using the TABLE_SCHEMA and TABLE_NAME scalar functions.

Example

The following statement using the TABLE_SCHEMA and TABLE_NAME functions is written as:

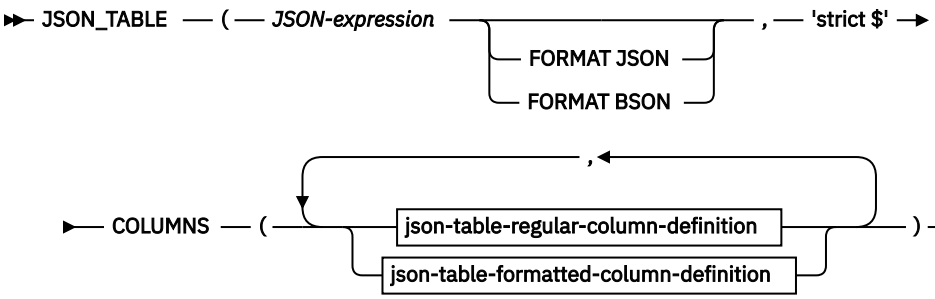
```
SELECT COLCOUNT INTO :H00030
FROM SYSCAT.TABLES
WHERE OWNER = TABLE_SCHEMA(:H00031 ,:H00032 )
AND TABNAME = TABLE_NAME(:H00031 ,:H00032 )
```

The equivalent statement using the BASE_TABLE function can be written as:

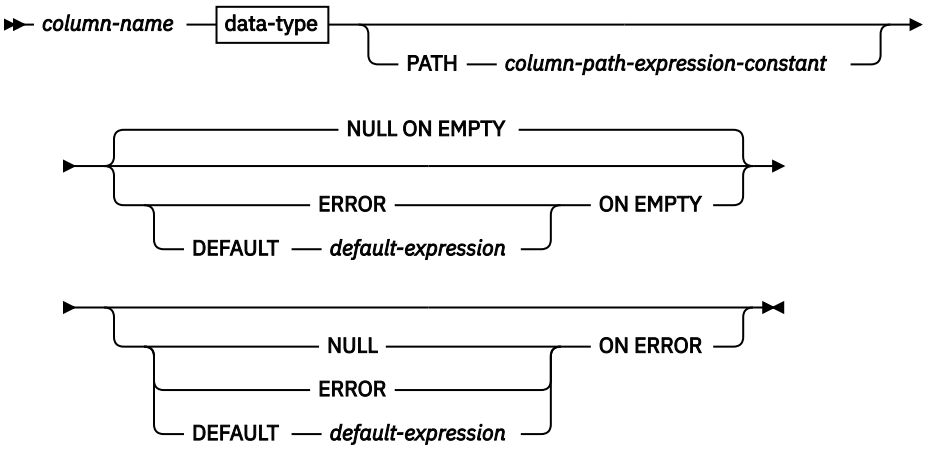
```
SELECT COLCOUNT INTO :H00030
FROM SYSCAT.TABLES A, TABLE(SYSPROC.BASE_TABLE(:H00032, :H00031)) AS B
WHERE A.OWNER = B.BASESCHEMA
AND A.TABNAME = B.BASENAME
```

JSON_TABLE

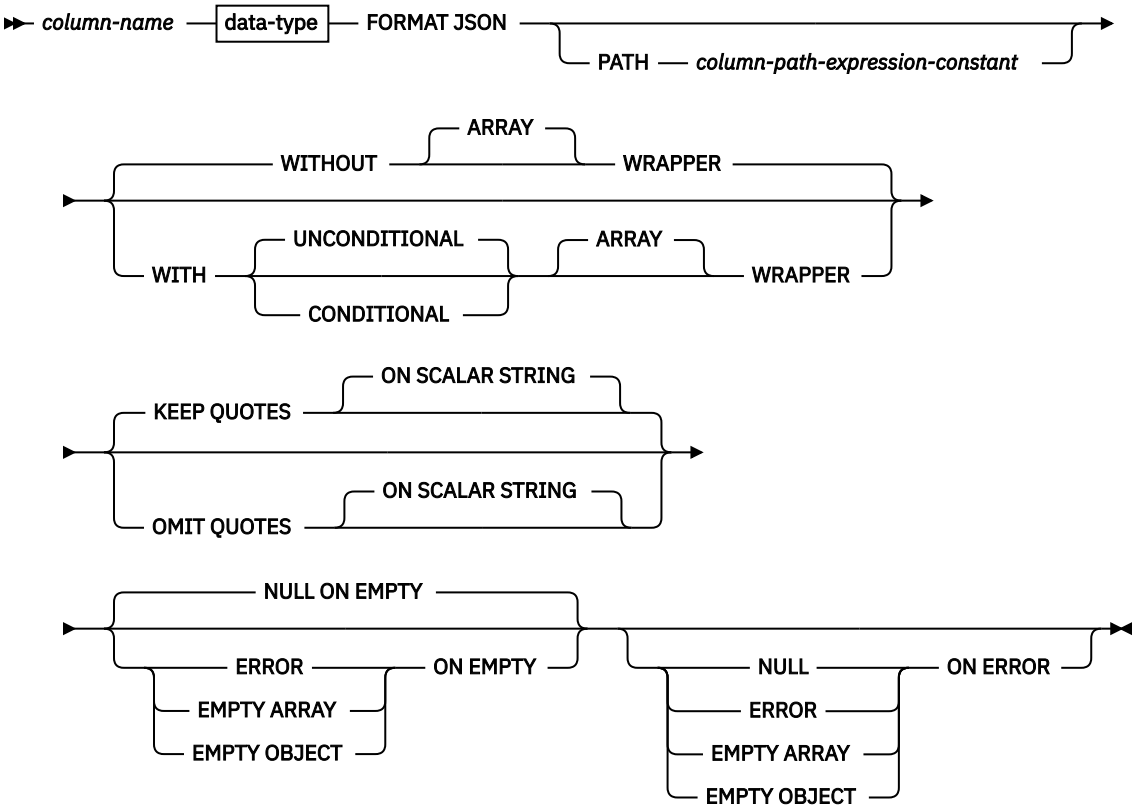
The JSON_TABLE table function returns a result table from the evaluation of SQL/JSON path expressions. Each item in the result sequence of the row SQL/JSON path expression represents one or more rows in the result table.



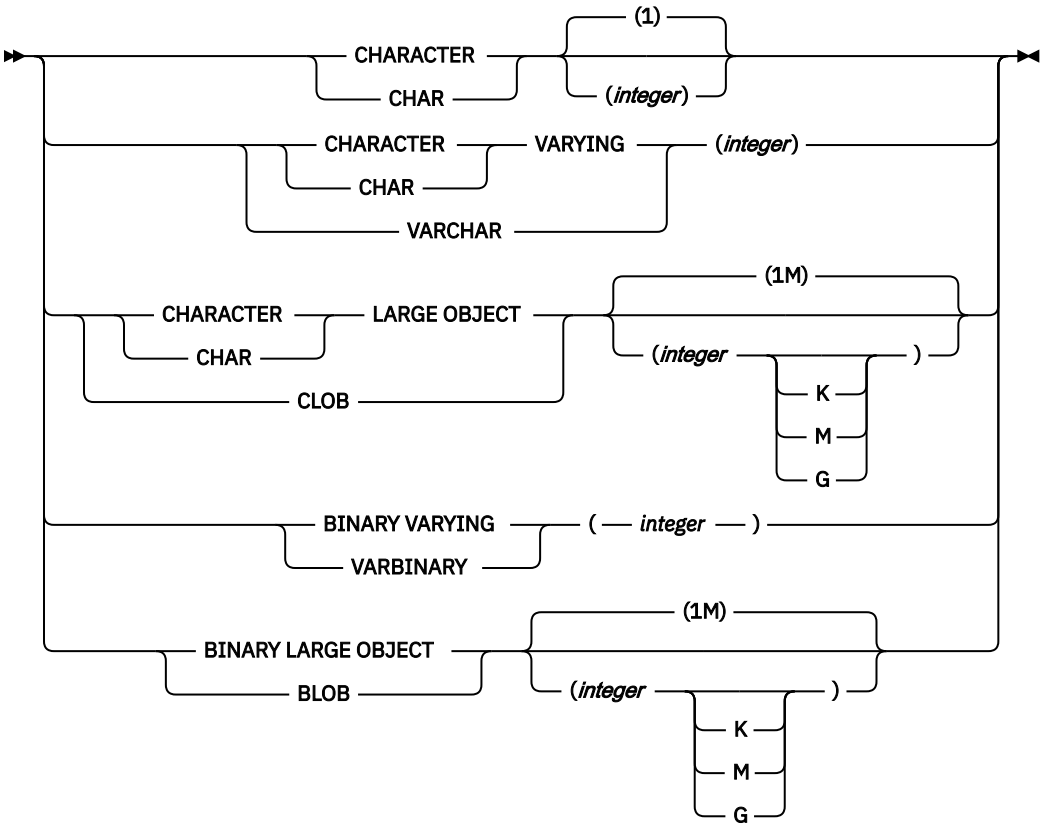
json-table-regular-column-definition



json-table-formatted-column-definition



data-type



The schema is SYSIBM. The function name cannot be specified as a qualified name.

JSON-expression
An expression that returns a value that is a built-in string data type, except the following data types (SQLSTATE 42815):

- GRAPHIC
- VARGRAPHIC
- DBCLOB
- BINARY
- CHAR FOR BIT DATA
- VARCHAR FOR BIT DATA
- A user-defined type that is sourced on any of the previously listed data types

If a character value is returned, it must contain correctly formatted JSON data (SQLSTATE 22032). If a binary data type is returned, it is interpreted according to the explicit or implicit FORMAT clause.

FORMAT JSON
JSON-expression is formatted as JSON data.

If *JSON-expression* is a character string data type, it is treated as JSON data.

If *JSON-expression* is a binary string data type, it is interpreted as UTF-8 data.

FORMAT BSON
Specifies that *JSON-expression* is formatted as the BSON representation of JSON data (SQLSTATE 22032). *JSON-expression* must be a binary string data type (SQLSTATE 42815).

'strict $'
Specifies that an error is reported when the specified path expression cannot be used to navigate the current JSON document from the start of the context item. The error is handled according to the current ON ERROR clause.

COLUMNS
Specifies the output columns of the result table, including the column name, data type, and how the column value is computed for each row. The sum of the result column lengths cannot exceed 64 KB.

json-table-regular-column-definition
Specifies an output column of the result table, including the column name, data type, and an SQL/JSON path expression to extract the value from the sequence item for the row.

column-name
Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the result table (SQLSTATE 42711).

data-type
Specifies the data type of the column.

See “CREATE TABLE ” on page 1351 for the description of built-in data types.

PATH *column-path-expression-constant*
Specifies a character string constant that is interpreted as an SQL/JSON path. The *column-path-expression-constant* specifies an SQL/JSON path expression that determines the column value regarding an item that is the result of evaluating the SQL/JSON path expression in *sql-json-path-expression*.

For more information about the content of an SQL/JSON path expression, see “sql-json-path-expression” on page 179.

Given an item from the result of processing the *sql-json-path-expression* as the externally provided context item, the *column-path-expression-constant* is evaluated and returns an output sequence. The column value is determined based on this output sequence as follows:

- If an empty sequence is returned, the ON EMPTY clause provides the value of the column.
- If ERROR ON EMPTY is specified, an error is returned.

- If an empty sequence is returned and the ON EMPTY clause is not specified, the null value is assigned to the column.
- If a single element sequence is returned and the type of the element is not a JSON array or a JSON object, the value is converted to the data type that was specified for the column.
- If a single element sequence is returned and the type of the element is a JSON array or a JSON object, an error is returned.
- If a sequence with more than one element is returned, an error is returned.
- If an error occurs, the ON ERROR clause specifies the value of the column.

The value of *column-path-expression-constant* must not be an empty string or a string of all blanks. If the PATH clause is not specified, the *column-path-expression-constant* is defined as `'$.'` prefixed to *column-name*.

ON EMPTY
Specifies the behavior when an empty sequence is returned for the column.

NULL ON EMPTY
An SQL null value is returned. This clause is the default.

ERROR ON EMPTY
An error is returned.

DEFAULT *default-expression* ON EMPTY
The value that is specified by *default-expression* is returned. The data type of *default-expression* must be the same as the return data type (SQLSTATE 42815).

ON ERROR
Specifies the behavior when an error is returned for the column. If this clause is not specified, the behavior specified for the table-level ON ERROR clause is followed.

NULL ON ERROR
A null value is returned.

ERROR ON ERROR
An error is returned.

DEFAULT *default-expression* ON ERROR
The value that is specified by *default-expression* is returned. The data type of *default-expression* must be the same as the return data type (SQLSTATE 42815).

json-table-formatted-column-definition
Specifies an output column of the result table. The definition includes the column name, data type, and an SQL/JSON path expression. This definition is used to extract the value from the sequence item for the row. The extracted value is formatted as a JSON string.

column-name
Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the result table (SQLSTATE 42711).

data-type
Specifies the data type of the column. The data type can be CHAR, VARCHAR, CLOB, VARBINARY, or BLOB (SQLSTATE 42815).

See “CREATE TABLE ” on page 1351 for the description of built-in data types.

FORMAT JSON
Indicates that the data that is retrieved is formatted as a JSON string.

PATH *column-path-expression-constant*
Specifies a character string constant that is interpreted as an SQL/JSON path.

The *column-path-expression-constant* specifies an SQL/JSON path expression that determines the column value regarding the result of evaluating the SQL/JSON path expression in *sql-json-path-expression*.

For more information about the content of an SQL/JSON path expression, see "sql-json-path-expression" on page 179.

Given an item from the result of processing the *sql-json-path-expression* as the externally provided context item, the *column-path-expression-constant* is evaluated and returns an output sequence. The column value is determined based on this output sequence as follows:

- If an empty sequence is returned, the ON EMPTY clause provides the value of the column.
- If ERROR ON EMPTY is specified, an error is returned.
- If an empty sequence is returned and the ON EMPTY clause is not specified, the null value is assigned to the column.
- If an error occurs, the ON ERROR clause specifies the value of the column.

The value for *column-path-expression-constant* must not be an empty string or a string of all blanks. If the PATH clause is not specified, the *column-path-expression-constant* is defined as `'$.'` prefixed to *column-name*.

WITHOUT ARRAY WRAPPER or WITH ARRAY WRAPPER
Specifies whether the output value is wrapped in a JSON array.

WITHOUT ARRAY WRAPPER
Indicates that the result is not wrapped. This clause is the default. Using a strict SQL/JSON path definition that resolves to a sequence of two or more SQL/JSON elements results in an error (SQLSTATE 2203A). Using a lax SQL/JSON path definition with the ON EMPTY that resolves to a sequence of two or more SQL/JSON elements results in an error (SQLSTATE 22035).

WITH UNCONDITIONAL ARRAY WRAPPER
Indicates that the result is enclosed in square brackets to create a JSON array.

WITH CONDITIONAL ARRAY WRAPPER
Indicates that the result is enclosed in square brackets to create a JSON array for either of the following scenarios:

- More than one SQL/JSON element is returned.
- A single SQL/JSON element that is not a JSON array or a JSON object is returned.

KEEP QUOTES or OMIT QUOTES
Specifies whether the surrounding quotation marks are removed when a scalar string is returned.

KEEP QUOTES
Quotation marks are not removed from scalar strings. This clause is the default.

OMIT QUOTES
Quotation marks are removed from scalar strings. When OMIT QUOTES is specified, the WITH ARRAY WRAPPER clause cannot be specified (SQLSTATE 42601).

ON EMPTY
Specifies the behavior when an empty sequence is returned for a column.

NULL ON EMPTY
An SQL null value is returned. This clause is the default.

ERROR ON EMPTY
An error is returned.

EMPTY ARRAY ON EMPTY
An empty JSON array is returned.

EMPTY OBJECT ON EMPTY
An empty JSON object is returned.

ON ERROR
Specifies the behavior when an error is returned for the column. If this clause is not specified, the behavior specified for the table-level ON ERROR clause is followed.

NULL ON ERROR
An SQL null value is returned. This clause is the default.

ERROR ON ERROR
An error is returned.

EMPTY ARRAY ON ERROR
An empty JSON array is returned.

EMPTY OBJECT ON ERROR
An empty JSON object is returned.

ERROR ON ERROR
An error is returned when a table level error is encountered.

Notes

- If parameter markers are not explicitly cast to a supported data type, an error is returned (SQLSTATE 42815)

Example

1. This example is based on the following JSON document:

```
{
  "id" : 901,
  "firstname" : "John",
  "lastname"  : "Doe",
  "phoneno"   : "555-3762"
}
```

List the employee ID, given name, surname, and phone number:

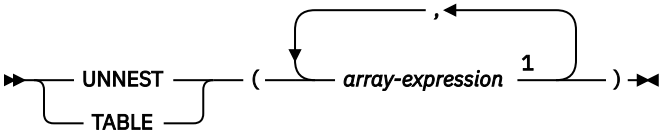
```
SELECT U."id", U."first name", U."last name", U."phone number"
  FROM EMPLOYEE_TABLE E
    JSON_TABLE(E.jsondoc, 'strict $'
                COLUMNS( "id" INTEGER,
                         "firstname"  VARCHAR(20),
                         "lastname"   VARCHAR(20),
                         "phoneno"    VARCHAR(20))
                        ERROR ON ERROR) AS U
```

This query returns the following table:

id	firstname	lastname	phoneno
901	John	Doe	555-3762

UNNEST

The UNNEST function returns a result table that includes a row for each element of the specified array. If there are multiple ordinary array arguments specified, the number of rows will match the array with the largest cardinality.



Notes:

[1] Only a single *array-expression* argument can be specified if the expression returns an associative array type or an array type with row type elements

The schema is SYSIBM.

array-expression
An expression that returns an array data type. The expression must be one of the following expressions:

- An SQL variable
- An SQL parameter
- A global variable
- A function invocation
- A CAST specification of a parameter marker
- A CASE expression

Names for the result columns produced by the UNNEST function can be provided as part of the *correlation-clause* of the *collection-derived-table* clause.

The UNNEST function can only be used in a *collection-derived-table* clause in a context where arrays are supported (SQLSTATE 42887).

The result table depends on the input arguments.

- If a single *array-expression* that returns an ordinary array is specified:
  - If the array element is not a row data type, the result is a single column table with a column data type that matches the array element data type.
  - If the array element is a row data type, the result is a table with one column for each row field in the element data type. The result table column data types match the corresponding array element row field data types.
- If more than one ordinary array argument is specified and none of the array elements have a row data type, the first array provides the first column in the result table, the second array provides the second column, and so on. The data type of each column matches the data type of the array elements of the corresponding array argument. If the cardinalities of the arrays are not identical, the cardinality of the resulting table is the same as the array with the largest cardinality. The column values in the table are set to the null value for all rows whose array index value is greater than the cardinality of the corresponding array. In other words, if each array is viewed as a table with two columns, one for the array indexes and one for the data, then UNNEST performs an OUTER JOIN among the arrays, using equality on the array indexes as a join predicate.
- If a single *array-expression* that returns an associative array is specified:
  - If the array element is not a row data type, the result is a table with 2 columns where the first column data type matches the array index data type and the second column data type matches the array element data type.
  - If the array element is a row data type, the result is a table with one more column than the number of fields in the row data type, where the first column data type matches the array index data type and the remaining column data types match the array element row field data types.
- An error is returned (SQLSTATE 42884):
  - If more than one associative array argument is specified.
  - If more than one array argument is specified and at least one of the arrays has a element data type that is a row type.
  - If both ordinary array arguments and associative array arguments are specified.

This special table function is only used in *collection-derived-table* of *table-reference* in a FROM clause.

If more than one array is provided and at least one of the arguments is an associative array, an error is returned (SQLSTATE 42884).

If the WITH ORDINALITY clause is used when unnesting an associative array, an error is returned (SQLSTATE 428HT).

Examples

1. Assume the ordinary array variable RECENT_CALLS of array type PHONENUMBERS contains only the three element values 9055553907, 4165554213, and 4085553678.The following query:

```
SELECT T.ID, T.NUM
FROM UNNEST(RECENT_CALLS) WITH ORDINALITY AS T(NUM, ID)
```

   returns a table formatted as follows:

```
ID    NUM
----------
1     9055553907
2     4165554213
3     4085553678
```

2. Return the list of personal phone numbers from the array variable PHONELIST of array type PERSONAL_PHONENUMBERS along with the index string values The following query:

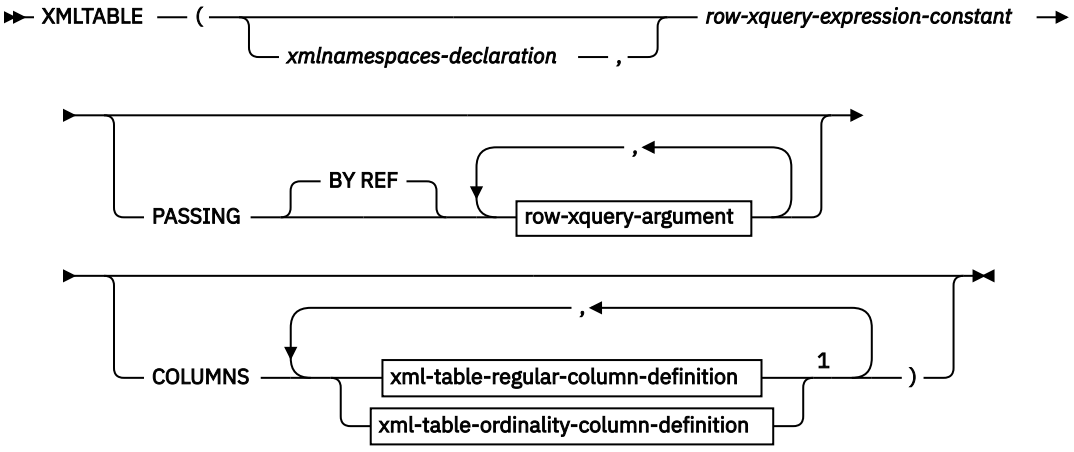
```
SELECT T.ID, T.PHONE
FROM UNNEST(PHONELIST) AS T(ID, PHONE)
```

   returns a table formatted as follows:

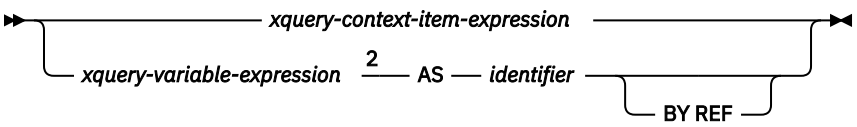
```
ID    PHONE
---------------
Home  4163053745
Work  4163053746
Mom   4164789683
```

XMLTABLE

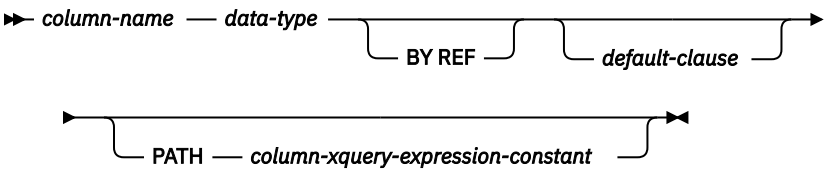
The XMLTABLE function returns a result table from the evaluation of XQuery expressions, possibly using specified input arguments as XQuery variables. Each sequence item in the result sequence of the row XQuery expression represents a row of the result table.



row-xquery-argument



xml-table-regular-column-definition



xml-table-ordinality-column-definition

Notes:

[1] The xml-table-ordinality-column-definition clause must not be specified more than once (SQLSTATE 42614).

[2] The data type of the expression cannot be DECFLOAT.

The schema is SYSIBM. The function name cannot be specified as a qualified name.

xmlnamespaces-declaration
Specifies one or more XML namespace declarations that become part of the static context of the *row-xquery-expression-constant* and the *column-xquery-expression-constant*. The set of statically known namespaces for XQuery expressions which are arguments of XMLTABLE is the combination of the pre-established set of statically known namespaces and the namespace declarations specified in this clause. The XQuery prolog within an XQuery expression may override these namespaces.

If *xmlnamespaces-declaration* is not specified, only the pre-established set of statically known namespaces apply to the XQuery expressions.

row-xquery-expression-constant
Specifies an SQL character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. The constant string is converted directly to UTF-8 without conversion to the database or section code page. The XQuery expression executes using an optional set of input XML values, and returns an output XQuery sequence where a row is generated for each item in the sequence. The value for *row-xquery-expression-constant* must not be an empty string or a string of all blanks (SQLSTATE 10505).

PASSING
Specifies input values and the manner in which these values are passed to the XQuery expression specified by *row-xquery-expression-constant*. By default, every unique column name that is in the scope where the function is invoked is implicitly passed to the XQuery expression using the name of the column as the variable name. If an *identifier* in a specified row-xquery-argument matches an in-scope column name, then the explicit row-xquery-argument is passed to the XQuery expression overriding that implicit column.

BY REF
Specifies that any XML input arguments are, by default, passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees, if any, directly from the specified input expressions, preserving all properties, including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons involving some nodes contained between the two input arguments might refer to nodes within the same XML node tree.

This clause has no impact on how non-XML values are passed. The non-XML values create a new copy of the value during the cast to XML.

row-xquery-argument
Specifies an argument that is to be passed to the XQuery expression that is specified by *row-xquery-expression-constant*. The method through which *row-xquery-argument* is used in the XQuery expression depends on whether the argument is specified as an *xquery-context-item-expression* or an *xquery-variable-expression*.

- If the resulting value is of type XML, it becomes an *input-xml-value*. A null XML value is converted to an XML empty sequence.

- If the resulting value is not of type XML, it must be castable to the XML data type. A null value is converted to an XML empty sequence. The converted value becomes an *input-xml-value*.

When the *row-xquery-expression-constant* is evaluated, an XQuery variable is presented with a value equal to *input-xml-value* and a name specified by the AS clause.

xquery-context-item-expression
An expression that returns a value that is XML, integer, decimal, or a character or graphic string that is not a LOB. *xquery-context-item-expression* must not be a character string that is bit data.

xquery-context-item-expression specifies the initial context item for the *row-xquery-expression*. The value of the initial context item is the result of *xquery-context-item-expression* cast to XML. *xquery-context-item-expression* must not be specified more than one time.

xquery-variable-expression
Specifies an SQL expression whose value is available to the XQuery expression specified by *row-xquery-expression-constant* during execution. The expression cannot contain a NEXT VALUE expression, PREVIOUS VALUE expression (SQLSTATE 428F9), or an OLAP function (SQLSTATE 42903). The data type of the expression cannot be DECFLOAT.

AS *identifier*
Specifies that the value generated by *xquery-variable-expression* will be passed to *row-xquery-expression-constant* as an XQuery variable. The variable name will be *identifier*. The leading dollar sign ($) that precedes variable names in the XQuery language is not included in *identifier*. The identifier must be a valid XQuery variable name and is restricted to an XML NCName. The identifier must not be greater than 128 bytes in length. Two arguments within the same PASSING clause cannot use the same identifier (SQLSTATE 42711).

BY REF
Indicates that an XML input value is to be passed by reference. When XML values are passed by reference, the XQuery evaluation uses the input node trees, if any, directly from the specified input expressions, preserving all properties, including the original node identities and document order. If two arguments pass the same XML value, node identity comparisons and document ordering comparisons involving some nodes contained between the two input arguments might refer to nodes within the same XML node tree. If BY REF is not specified following an *xquery-expression-variable*, XML arguments are passed by way of the default passing mechanism that is provided through the syntax that follows the PASSING keyword. This option cannot be specified for non-XML values (SQLSTATE 42636). When a non-XML value is passed, the value is converted to XML; this process creates a copy.

COLUMNS
Specifies the output columns of the result table. If this clause is not specified, a single unnamed column of data type XML is returned by reference, with the value based on the sequence item from evaluating the XQuery expression in the *row-xquery-expression-constant* (equivalent to specifying PATH '.'). To reference the result column, a *column-name* must be specified in the *correlation-clause* following the function.

xml-table-regular-column-definition
Specifies the output columns of the result table including the column name, data type, XML passing mechanism and an XQuery expression to extract the value from the sequence item for the row

column-name
Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the table (SQLSTATE 42711).

data-type
Specifies the data type of the column. See CREATE TABLE for the syntax and a description of types available. A *data-type* may be used in XMLTable if there is a supported XMLCAST from the XML data type to the specified *data-type*.

BY REF
Specifies that XML values are returned by reference for columns of data type XML. By default, XML values are returned BY REF. When XML values are returned by reference, the XML value includes the input node trees, if any, directly from the result values, and preserves all properties, including the original node identities and document order. This option cannot be specified for non-XML columns (SQLSTATE 42636). When a non-XML column is processed, the value is converted from XML; this process creates a copy.

default-clause
Specifies a default value for the column. See CREATE TABLE for the syntax and a description of the *default-clause*. For XMLTABLE result columns, the default is applied when the processing the XQuery expression contained in *column-xquery-expression-constant* returns an empty sequence.

PATH *column-xquery-expression-constant*
Specifies an SQL character string constant that is interpreted as an XQuery expression using supported XQuery language syntax. The constant string is converted directly to UTF-8 without conversion to the database or section code page. The *column-xquery-expression-constant* specifies an XQuery expression that determines the column value with respect to an item that is the result of evaluating the XQuery expression in *row-xquery-expression-constant*. Given an item from the result of processing the *row-xquery-expression-constant* as the externally provided context item, the *column-xquery-expression-constant* is evaluated, returning an output sequence. The column value is determined based on this output sequence as follows.

- If the output sequence contains zero items, the *default-clause* provides the value of the column.
- If an empty sequence is returned and no *default-clause* was specified, a null value is assigned to the column.
- If a non-empty sequence is returned, the value is XMLCAST to the *data-type* specified for the column. An error could be returned from processing this XMLCAST.

The value for *column-xquery-expression-constant* must not be an empty string or a string of all blanks (SQLSTATE 10505). If this clause is not specified, the default XQuery expression is simply the *column-name*.

xml-table-ordinality-column-definition
Specifies the ordinality column of the result table.

column-name
Specifies the name of the column in the result table. The name cannot be qualified and the same name cannot be used for more than one column of the table (SQLSTATE 42711).

FOR ORDINALITY
Specifies that *column-name* is the ordinality column of the result table. The data type of this column is BIGINT. The value of this column in the result table is the sequential number of the item for the row in the resulting sequence from evaluating the XQuery expression in *row-xquery-expression-constant*.

If the evaluation of any of the XQuery expressions results in an error, then the XMLTABLE function returns the XQuery error (SQLSTATE class '10').

Example

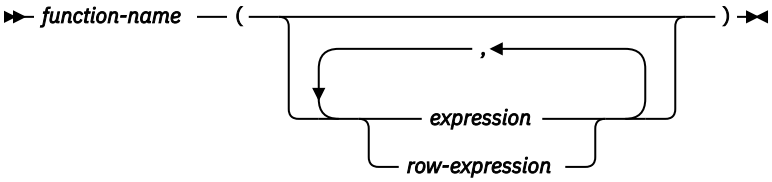
List as a table result the purchase order items for orders with a status of 'NEW'.

```
SELECT U."PO ID", U."Part #", U."Product Name",
     U."Quantity", U."Price", U."Order Date"
  FROM PURCHASEORDER P,
     XMLTABLE('$po/PurchaseOrder/item' PASSING P.PORDER AS "po"
              COLUMNS "PO ID"         INTEGER       PATH '../@PoNum',
                      "Part #"        CHAR(10)      PATH 'partid',
                      "Product Name"  VARCHAR(50)   PATH 'name',
                      "Quantity"      INTEGER       PATH 'quantity',
                      "Price"         DECIMAL(9,2)  PATH 'price',
```

```
                        "Order Date"    DATE          PATH '../@OrderDate'
                ) AS U
      WHERE P.STATUS = 'Unshipped'
```

User-defined functions

User-defined functions (UDFs) are extensions or additions to the existing built-in functions of the SQL language.



A user-defined function can be a scalar function, which returns a single value each time it is called; an aggregate function, which is passed a set of like values and returns a single value for the set; a row function, which returns one row; or a table function, which returns a table.

A number of user-defined functions are provided in the SYSFUN and SYSPROC schemas.

A UDF can be an aggregate function only if it is sourced on an existing aggregate function. A UDF is referenced by means of a qualified or unqualified function name, followed by parentheses enclosing the function arguments (if any). A user-defined column or scalar function registered with the database can be referenced in the same contexts in which any built-in function can appear. A user-defined row function can be referenced only implicitly when registered as a transform function for a user-defined type. A user-defined table function registered with the database can be referenced only in the FROM clause of a SELECT statement.

Function arguments must correspond in number and position to the parameters specified for the user-defined function when it was registered with the database. In addition, the arguments must be of data types that are promotable to the data types of the corresponding defined parameters.

The result of the function is specified in the RETURNS clause. The RETURNS clause, defined when the UDF was registered, determines whether or not a function is a table function. If the RETURNS NULL ON NULL INPUT clause is specified (or defaulted to) when the function is registered, the result is null if any argument is null. In the case of table functions, this is interpreted to mean a return table with no rows (that is, an empty table).

See "Row expressions" for more information about rules and row data types.

Following are some examples of user-defined functions:

- A scalar UDF called ADDRESS extracts the home address from resumes stored in script format. The ADDRESS function expects a CLOB argument and returns a VARCHAR(4000) value:

  ```
  SELECT EMPNO, ADDRESS(RESUME) FROM EMP_RESUME
    WHERE RESUME_FORMAT = 'SCRIPT'
  ```

- Table T2 has a numeric column A. Invoking the scalar UDF called ADDRESS from the previous example:

  ```
  SELECT ADDRESS(A) FROM T2
  ```

  raises an error (SQLSTATE 42884), because no function with a matching name and with a parameter that is promotable from the argument exists.

- A table UDF called WHO returns information about the sessions on the server machine that were active at the time that the statement is executed. The WHO function is invoked from within a FROM clause that includes the keyword TABLE and a mandatory correlation variable. The column names of the WHO() table were defined in the CREATE FUNCTION statement.

  ```
  SELECT ID, START_DATE, ORIG_MACHINE
    FROM TABLE( WHO() ) AS QQ
    WHERE START_DATE LIKE 'MAY%'
  ```

Built-in procedures

A procedure is an application program that can be started through the SQL CALL statement. The procedure is specified by a procedure name, which may be followed by arguments that are enclosed within parentheses. *Built-in procedures* are procedures provided with the database manager.

This topic lists the supported built-in procedures for managing XML schema repository (XSR) objects. See Table 108 on page 631.

There are additional built-in procedures documented under the following headings:

- ADMIN_CMD procedure and associated SQL routines
- Administrative task scheduler routines and views
- Audit routines and procedures
- Automatic maintenance SQL routines and views
- Common SQL API stored procedures
- Explain routines
- Monitor routines
- Snapshot SQL routines and views
- SQL procedures SQL routines
- Stepwise redistribute SQL routines
- Storage management tool SQL routines
- Text search SQL routines
- Workload management routines
- Miscellaneous SQL routines and views

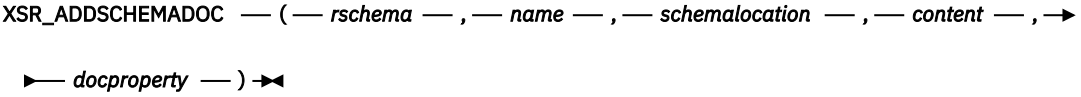
For details about these additional built-in procedures, see "Supported built-in SQL routines and views" in *Administrative Routines and Views* .

Table 108. XML schema repository procedures

Function	Description
“XSR_ADDSCHEMADOC” on page 631	Add an XML schema document to an XML schema.
“XSR_COMPLETE” on page 632	Complete the XML schema registration process for an XML schema.
“XSR_DTD” on page 633	Register a document type declaration.
“XSR_EXTENTITY” on page 634	Register an external entity.
“XSR_REGISTER” on page 635	Register an XML schema.
“XSR_UPDATE” on page 637	Update an existing XML schema.

XSR_ADDSCHEMADOC

Each XML schema in the XML schema repository (XSR) can consist of one or more XML schema documents. Where an XML schema consists of multiple documents, the XSR_ADDSCHEMADOC procedure is used to add every XML schema other than the primary XML schema document.



The schema is SYSPROC.

Authorization

The authorization ID of the caller of the procedure must be the owner of the XSR object as recorded in the catalog view SYSCAT.XSROBJECTS.

rschema
An input argument of type VARCHAR (128) that specifies the SQL schema for the XML schema. The SQL schema is one part of the SQL identifier used to identify this XML schema in the XSR, which is to be moved to the complete state. (The other part of the SQL identifier is supplied by the name argument.) This argument can have a null value, which indicates that the default SQL schema, as defined in the CURRENT SCHEMA special register, is used. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument. XSR objects will not experience name collisions with database objects that exist outside of the XSR, because XSR objects occur in a different namespace than objects outside of the XML schema repository.

name
An input argument of type VARCHAR (128) that specifies the name of the XML schema. The complete SQL identifier for the XML schema is *rschema.name*. The XML schema name must already exist as a result of calling the XSR_REGISTER procedure, and XML schema registration cannot yet be completed. This argument cannot have a null value. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

schemalocation
An input argument of type VARCHAR (1000), which can have a null value, that indicates the schema location of the primary XML schema document to which the XML schema document is being added. This argument is the external name of the XML schema, that is, the primary document can be identified in the XML instance documents with the xsi:schemaLocation attribute.

content
An input parameter of type BLOB (30M) that contains the content of the XML schema document being added. This argument cannot have a null value; an XML schema document must be supplied.

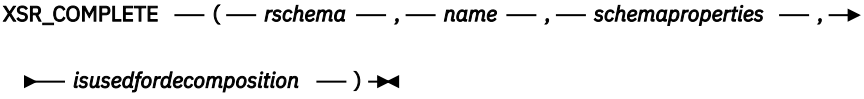
docproperty
An input parameter of type BLOB (5M) that indicates the properties for the XML schema document being added. This parameter can have a null value; otherwise, the value is an XML document.

Example

```
CALL SYSPROC.XSR_ADDSCHEMADOC(
  'user1',
  'POschema',
  'http://myPOschema/address.xsd',
  :content_host_var,
  0)
```

XSR_COMPLETE

The XSR_COMPLETE procedure is the final procedure to be called as part of the XML schema registration process, which registers XML schemas with the XML schema repository (XSR). An XML schema is not available for validation until the schema registration completes through a call to this procedure.



The schema is SYSPROC.

Authorization:

The authorization ID of the caller of the procedure must be the owner of the XSR object as recorded in the catalog view SYSCAT.XSROBJECTS.

rschema
An input argument of type VARCHAR (128) that specifies the SQL schema for the XML schema. The SQL schema is one part of the SQL identifier used to identify this XML schema in the XSR, which is to be moved to the complete state. (The other part of the SQL identifier is supplied by the name argument.) This argument can have a null value, which indicates that the default SQL schema, as defined in the CURRENT SCHEMA special register, is used. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument. XSR objects will not experience name collisions with database objects that exist outside of the XSR, because XSR objects occur in a different namespace than objects outside of the XML schema repository.

name
An input argument of type VARCHAR (128) that specifies the name of the XML schema. The complete SQL identifier for the XML schema, for which a completion check is to be performed, is *rschema.name*. The XML schema name must already exist as a result of calling the XSR_REGISTER procedure, and XML schema registration cannot yet be completed. This argument cannot have a null value. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

schemaproperties
An input argument of type BLOB (5M) that specifies properties, if any, associated with the XML schema. The value for this argument is either the null value, if there are no associated properties, or an XML document representing the properties for the XML schema.

isusedfordecomposition
An input parameter of type integer that indicates if an XML schema is to be used for decomposition. If an XML schema is to be used for decomposition, this value should be set to 1; otherwise, it should be set to zero.

Example

```
CALL SYSPROC.XSR_COMPLETE(
  'user1',
  'POschema',
  :schemaproperty_host_var,
  0)
```

XSR_DTD

The XSR_DTD procedure registers a document type declaration (DTD) with the XML schema repository (XSR).

The schema is SYSPROC.

Authorization

The authorization ID of the caller of the procedure must have at least one of the following:

- DBADM authority.
- IMPLICIT_SCHEMA database authority if the SQL schema does not exist.
- CREATEIN privilege if the SQL schema exists.

rschema
An input and output argument of type VARCHAR (128) that specifies the SQL schema for the DTD. The SQL schema is one part of the SQL identifier used to identify this DTD in the XSR. (The other part of the SQL identifier is supplied by the *name* argument.) This argument can have a null value, which indicates that the default SQL schema, as defined in the CURRENT SCHEMA special register, is used. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument. Relational schemas that begin with the string 'SYS' must not be used for this value. XSR objects will not experience name collisions with database objects that exist outside of the XSR, because XSR objects occur in a different namespace than objects outside of the XML schema repository.

name
An input and output argument of type VARCHAR (128) that specifies the name of the DTD. The complete SQL identifier for the DTD is *rschema.name* and should be unique among all objects in the XSR. This argument accepts a null value. When a null value is provided for this argument, a unique value is generated and stored within the XSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

systemid
An input parameter of type VARCHAR (1000) that specifies the system identifier of the DTD. The system ID of the DTD should match the uniform resource identifier of the DTD in the DOCTYPE declaration of the XML instance document or in an ENTITY declaration (as prefixed by the SYSTEM keyword, if used). This argument cannot have a null value. The system ID can be specified together with a public ID.

publicid
An input parameter of type VARCHAR (1000) that specifies the public identifier of the DTD. The public ID of a DTD should match the uniform resource identifier of the DTD in the DOCTYPE declaration of the XML instance document or in an ENTITY declaration (as prefixed by the PUBLIC keyword, if used). This argument accepts a null value and should be used only if also specified in the DOCTYPE declaration of the XML instance document or in an ENTITY declaration.

content
An input parameter of type BLOB (30M) that contains the content of the DTD document. This argument cannot have a null value.

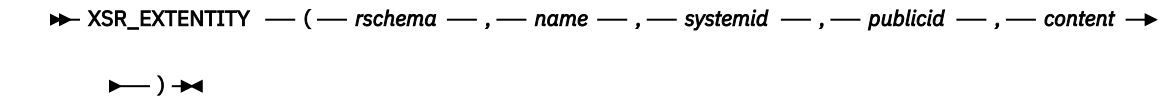
Example

Register the DTD identified by the system ID *http://www.test.com/person.dtd* and public ID *http://www.test.com/person*:

```
CALL SYSPROC.XSR_DTD ( 'MYDEPT' ,
   'PERSONDTD' ,
   'http://www.test.com/person.dtd' ,
   'http://www.test.com/person',
   :content_host_variable
   )
```

XSR_EXTENTITY

The XSR_EXTENTITY procedure registers an external entity with the XML schema repository (XSR).



The schema is SYSPROC.

Authorization

The authorization ID of the caller of the procedure must have at least one of the following:

- DBADM authority.
- IMPLICIT_SCHEMA database authority if the SQL schema does not exist.
- CREATEIN privilege if the SQL schema exists.

rschema
An input and output argument of type VARCHAR (128) that specifies the SQL schema for the external entity. The SQL schema is one part of the SQL identifier used to identify this external entity in the XSR. (The other part of the SQL identifier is supplied by the *name* argument.) This argument can have a null value, which indicates that the default SQL schema, as defined in the CURRENT SCHEMA special register, is used. Rules for valid characters and delimiters that apply to any SQL identifier also

apply to this argument. Relational schemas that begin with the string 'SYS' must not be used for this value. XSR objects will not experience name collisions with database objects that exist outside of the XSR, because XSR objects occur in a different namespace than objects outside of the XML schema repository.

name
An input and output argument of type VARCHAR (128) that specifies the name of the external entity. The complete SQL identifier for the external entity is *rschema.name* and should be unique among all objects in the XSR. This argument accepts a null value. When a null value is provided for this argument, a unique value is generated and stored within the XSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

systemid
An input parameter of type VARCHAR (1000) that specifies the system identifier of the external entity. The system ID of the external entity should match the uniform resource identifier of the external entity in the ENTITY declaration (as prefixed by the SYSTEM keyword, if used). This argument cannot have a null value. The system ID can be specified together with a public ID.

publicid
An input parameter of type VARCHAR (1000) that specifies the public identifier of the external entity. The public ID of a external entity should match the uniform resource identifier of the external entity in the ENTITY declaration (as prefixed by the PUBLIC keyword, if used). This argument accepts a null value and should be used only if also specified in the DOCTYPE declaration of the XML instance document or in an ENTITY declaration.

content
An input parameter of type BLOB (30M) that contains the content of the external entity document. This argument cannot have a null value.

Example

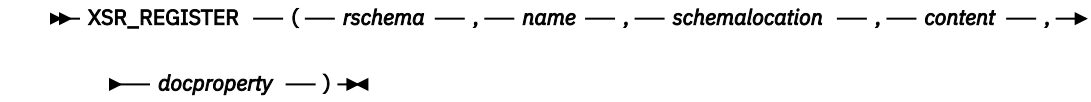
Register the external entities identified by the system identifiers *http://www.test.com/food/chocolate.txt* and *http://www.test.com/food/cookie.txt*:

```
CALL SYSPROC.XSR_EXTENTITY ( 'FOOD' ,
   'CHOCLATE' ,
   'http://www.test.com/food/chocolate.txt' ,
   NULL ,
   :content_of_chocolate.txt_as_a_host_variable
   )

CALL SYSPROC.XSR_EXTENTITY ( 'FOOD' ,
   'COOKIE' ,
   'http://www.test.com/food/cookie.txt' ,
   NULL ,
   :content_of_cookie.txt_as_a_host_variable
   )
```

XSR_REGISTER

The XSR_REGISTER procedure is the first procedure to be called as part of the XML schema registration process, which registers XML schemas with the XML schema repository (XSR).



The schema is SYSPROC.

Authorization

The authorization ID of the caller of the procedure must have at least one of the following authorities:

- DBADM authority.

- IMPLICIT_SCHEMA database authority if the SQL schema does not exist.
- CREATEIN privilege if the SQL schema exists.

rschema
An input and output argument of type VARCHAR (128) that specifies the SQL schema for the XML schema. The SQL schema is one part of the SQL identifier used to identify this XML schema in the XSR. (The other part of the SQL identifier is supplied by the name argument.) This argument can have a null value, which indicates that the default SQL schema, as defined in the CURRENT SCHEMA special register, is used. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument. Relational schemas that begin with the string 'SYS' must not be used for this value. XSR objects will not experience name collisions with database objects that exist outside of the XSR, because XSR objects occur in a different namespace than objects outside of the XML schema repository.

name
An input and output argument of type VARCHAR (128) that specifies the name of the XML schema. The complete SQL identifier for the XML schema is *rschema.name* and should be unique among all objects in the XSR. This argument accepts a null value. When a null value is provided for this argument, a unique value is generated and stored within the XSR. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

schemalocation
An input argument of type VARCHAR (1000), which can have a null value, that indicates the schema location of the primary XML schema document. This argument is the external name of the XML schema, that is, the primary document can be identified in the XML instance documents with the xsi:schemaLocation attribute.

content
An input parameter of type BLOB (30M) that contains the content of the primary XML schema document. This argument cannot have a null value; an XML schema document must be supplied.

docproperty
An input parameter of type BLOB (5M) that indicates the properties for the primary XML schema document. This parameter can have a null value; otherwise, the value is an XML document.

Examples

- *Example 1*: The following example shows how to call the XSR_REGISTER procedure from the command line:

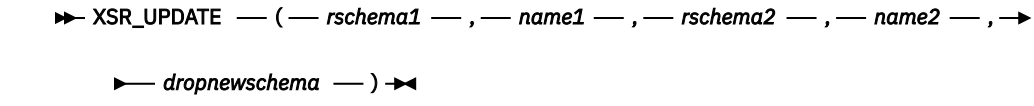
```
CALL SYSPROC.XSR_REGISTER(
  'user1',
  'POschema',
  'http://myPOschema/PO.xsd',
  :content_host_var,
  :docproperty_host_var)
```

- *Example 2*: The following example shows how to call the XSR_REGISTER procedure from a Java application program:

```
stmt = con.prepareCall("CALL SYSPROC.XSR_REGISTER (?, ?, ?, ?, ?)");
String xsrObjectName = "myschema1";
String xmlSchemaLocation = "po.xsd";
stmt.setNull(1, java.sql.Types.VARCHAR);
stmt.setString(2, xsrObjectName);
stmt.setString(3, xmlSchemaLocation);
stmt.setBinaryStream(4, buffer, (int)length);
stmt.setNull(5, java.sql.Types.BLOB);
stmt.registerOutParameter(1, java.sql.Types.VARCHAR);
stmt.registerOutParameter(2, java.sql.Types.VARCHAR);
stmt.execute();
```

XSR_UPDATE

The XSR_UPDATE procedure is used to evolve an existing XML schema in the XML schema repository (XSR). This enables you to modify or extend an existing XML schema so that it can be used to validate both already existing and newly inserted XML documents.



The schema is SYSPROC.

The original XML schema and the new XML schema specified as arguments to XSR_UPDATE must both be registered and completed in the XSR before the procedure is called. These XML schemas must also be compatible. For details about the compatibility requirements see *Compatibility requirements for evolving an XML schema*.

Authorization

The privileges held by the authorization ID of the caller of the procedure must include at least one of the following:

- DBADM authority.
- SELECT privilege on the catalog views SYSCAT.XSROBJECTS and SYSCAT.XSROBJECTCOMPONENTS and one of the following sets of privileges:
  - OWNER of the XML schema specified by the SQL schema *rschema1* and the object name *name1*
  - ALTERIN privilege on the SQL schema specified by the *rschema1* argument and, if the *dropnewschema* argument is not equal to zero, DROPIN privilege on the SQL schema specified by the *rschema2* argument.

rschema1
An input argument of type VARCHAR (128) that specifies the SQL schema for the original XML schema to be updated. The SQL schema is one part of the SQL identifier used to identify this XML schema in the XSR. (The other part of the SQL identifier is supplied by the *name1* argument.) This argument cannot have a null value. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

name1
An input argument of type VARCHAR (128) that specifies the name of the original XML schema to be updated. The complete SQL identifier for the XML schema is *rschema1.name1* . This XML schema must already be registered and completed in the XSR. This argument cannot have a null value. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

rschema2
An input argument of type VARCHAR (128) that specifies the SQL schema for the new XML schema that will be used to update the original XML schema. The SQL schema is one part of the SQL identifier used to identify this XML schema in the XSR. (The other part of the SQL identifier is supplied by the *name2* argument.) This argument cannot have a null value. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

name2
An input argument of type VARCHAR (128) that specifies the name of the new XML schema that will be used to update the original XML schema. The complete SQL identifier for the XML schema is *rschema2.name2*. This XML schema must already be registered and completed in the XSR. This argument cannot have a null value. Rules for valid characters and delimiters that apply to any SQL identifier also apply to this argument.

dropnewschema
An input parameter of type integer that indicates whether the new XML schema should be dropped after it is used to update the original XML schema. Setting this parameter to any nonzero value will cause the new XML schema to be dropped. This argument cannot have a null value.

Example

```
CALL SYSPROC.XSR_UPDATE(
  'STORE',
  'PROD',
  'STORE',
  'NEWPROD',
  1)
```

The contents of the XML schema STORE.PROD is updated with the contents of STORE.NEWPROD, and the XML schema STORE.NEWPROD is dropped.

SQL queries

A *query* specifies a result table. A query is a component of certain SQL statements.

The three forms of a query are:

- subselect
- fullselect
- select-statement.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- For each table or view identified in the query, one of the following authorities:
  - SELECT privilege on the table or view
  - SELECTIN privilege on the schema of the table or view
  - DATAACCESS privilege on the schema of the table or view
  - CONTROL privilege on the table or view
- DATAACCESS authority

For each global variable used as an expression in the query, the privileges held by the authorization ID of the statement must include one of the following authorities:

- READ privilege on the global variable that is not defined in a module
- EXECUTE privilege on the module of the global variable that is defined in a module
- EXECUTEIN privilege on the schema containing the module of the global variable that is defined in a module
- DATAACCESS authority on the schema containing the module of the global variable that is defined in a module

If the query contains an SQL data change statement, the authorization requirements of that statement also apply to the query.

Group privileges, with the exception of PUBLIC, are not checked for queries that are contained in static SQL statements or DDL statements.

For nicknames, authorization requirements of the data source for the object referenced by the nickname are applied when the query is processed. The authorization ID of the statement may be mapped to a different authorization ID at the data source.

Queries and table expressions

A *query* is a component of certain SQL statements; it specifies a (temporary) result table.

A *table expression* creates a temporary result table from a simple query. Clauses further refine the result table. For example, you can use a table expression as a query to select all of the managers from several

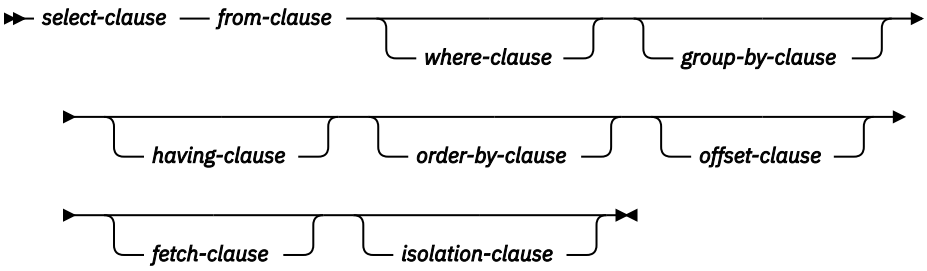
departments, specify that they must have over 15 years of working experience, and be located at the New York branch office.

A *common table expression* is like a temporary view within a complex query. It can be referenced in other places within the query, and can be used in place of a view. Each use of a specific common table expression within a complex query shares the same temporary view.

Recursive use of a common table expression within a query can be used to support applications such as airline reservation systems, bill of materials (BOM) generators, and network planning.

subselect

The *subselect* is a component of the fullselect.



A subselect specifies a result table derived from the tables, views or nicknames identified in the FROM clause. The derivation can be described as a sequence of operations in which the result of each operation is input for the next. (This is only a way of describing the subselect. The method used to perform the derivation can be quite different from this description. If portions of the subselect do not actually need to be executed for the correct result to be obtained, they might or might not be executed.)

The authorization for a *subselect* is described in the Authorization section in "SQL queries".

The clauses of the subselect are processed in the following sequence:

1. FROM clause
2. WHERE clause
3. GROUP BY clause
4. HAVING clause
5. SELECT clause
6. ORDER BY clause
7. OFFSET clause
8. FETCH clause

A subselect that contains an ORDER BY clause, OFFSET clause, or FETCH clause cannot be specified:

- In the outermost fullselect of a view.
- In the outer fullselect of a materialized query table.
- Unless the subselect is enclosed in parenthesis.

For example, the following is not valid (SQLSTATE 428FJ):

```
SELECT * FROM T1
   ORDER BY C1
UNION
SELECT * FROM T2
   ORDER BY C1
```

The following example *is* valid:

```
(SELECT * FROM T1
   ORDER BY C1)
UNION
```

```
(SELECT * FROM T2
   ORDER BY C1)
```

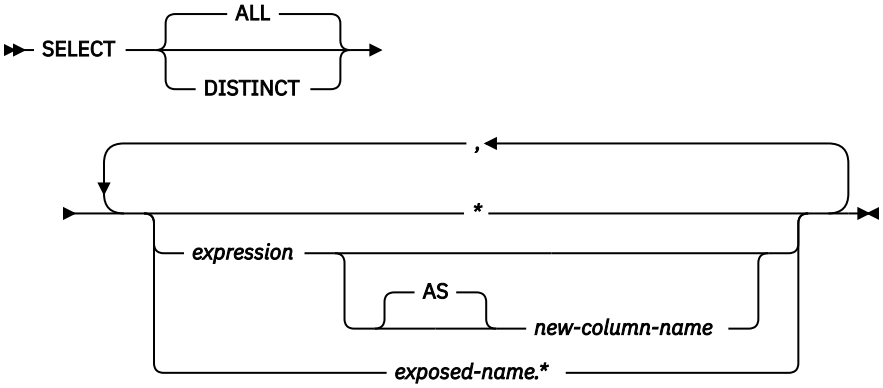
Note: An ORDER BY clause in a subselect does not affect the order of the rows returned by a query. An ORDER BY clause only affects the order of the rows returned if it is specified in the outermost fullselect.

For details about the clauses in the subselect query, refer to the following topics:

- “select-clause” on page 640
- “from-clause” on page 643
- “where-clause” on page 690
- “group-by-clause” on page 691
- “having-clause” on page 702
- “order-by-clause” on page 703
- “offset-clause” on page 706
- “fetch-clause” on page 705
- “isolation-clause (subselect query)” on page 707

select-clause

The SELECT clause specifies the columns of the final result table.



The column values are produced by the application of the *select list* to the final result table, *R*. The select list is the names or expressions specified in the SELECT clause, and *R* is the result of the previous operation of the subselect. For example, if the only clauses specified are SELECT, FROM, and WHERE, *R* is the result of that WHERE clause.

ALL
Retains all rows of the final result table, and does not eliminate redundant duplicates. This is the default.

DISTINCT
Eliminates all but one of each set of duplicate rows of the final result table. If DISTINCT is used, no string column of the result table can be a LOB type, distinct type based on LOB, or structured type. DISTINCT can be used more than once in a subselect. This includes SELECT DISTINCT, the use of DISTINCT in an aggregate function of the select list or HAVING clause, and subqueries of the subselect.

Two rows are duplicates of one another only if each value in the first is equal to the corresponding value in the second. For determining duplicates, two null values are considered equal, and two different decimal floating-point representations of the same number are considered equal. For example, -0 is equal to +0 and 2.0 is equal to 2.00. Each of the decimal floating-point special values are also considered equal: -NAN equals -NAN, -SNAN equals -SNAN, -INFINITY equals -INFINITY, INFINITY equals INFINITY, SNAN equals SNAN, and NAN equals NAN.

When the data type of a column is decimal floating-point, and multiple representations of the same number exist in the column, the particular value that is returned for a SELECT DISTINCT can be any one of the representations in the column. For more information, see "Numeric comparisons" on page 65.

For compatibility with other SQL implementations, UNIQUE can be specified as a synonym for DISTINCT.

Select list notation

***

Represents a list of names that identify the columns of table *R*, excluding any columns defined as IMPLICITLY HIDDEN. The first name in the list identifies the first column of *R*, the second name identifies the second column of *R*, and so on.

The list of names is established when the program containing the SELECT clause is bound. Hence the asterisk (*) does not identify any columns that have been added to a table after the statement containing the table reference has been bound.

expression

Specifies the values of a result column. Can be any expression that is a valid SQL language element, but commonly includes column names. Each column name used in the select list must unambiguously identify a column of R. The result type of the expression cannot be a row type (SQLSTATE 428H2).

new-column-name* or AS *new-column-name

Names or renames the result column. The name must not be qualified and does not have to be unique. Subsequent usage of column-name is limited as follows:

- A *new-column-name* specified in the AS clause can be used in the order-by-clause, provided the name is unique.
- A *new-column-name* specified in the AS clause of the select list cannot be used in any other clause within the subselect (where-clause, group-by-clause or having-clause).
- A *new-column-name* specified in the AS clause cannot be used in the update-clause.
- A *new-column-name* specified in the AS clause is known outside the fullselect of nested table expressions, common table expressions and CREATE VIEW.

exposed-name.*

Represents the list of names that identify the columns of the result table identified by *exposed-name*, excluding any columns defined as IMPLICITLY HIDDEN. The *exposed-name* can be a table name, view name, nickname, or correlation name, and must designate a table, view or nickname named in the FROM clause. The first name in the list identifies the first column of the table, view or nickname, the second name in the list identifies the second column of the table, view or nickname, and so on.

The list of names is established when the statement containing the SELECT clause is bound. Therefore, * does not identify any columns that have been added to a table after the statement has been bound.

The number of columns in the result of SELECT is the same as the number of expressions in the operational form of the select list (that is, the list established when the statement is prepared), and cannot exceed 500 for a 4K page size or 1012 for an 8K, 16K, or 32K page size.

Limitations on string columns

For restrictions using varying-length character strings on the select list, see "Character strings" on page 31.

Applying the select list

Some of the results of applying the select list to R depend on whether GROUP BY or HAVING is used. The results are described in two separate lists.

If GROUP BY or HAVING is used

- An expression *X* (not an aggregate function) used in the select list must have a GROUP BY clause with:
  - a *grouping-expression* in which each expression or column-name unambiguously identifies a column of R (see "group-by-clause" on page 691) or
  - each column of R referenced in *X* as a separate *grouping-expression*.
- The select list is applied to each group of R, and the result contains as many rows as there are groups in R. When the select list is applied to a group of R, that group is the source of the arguments of the aggregate functions in the select list.

If neither GROUP BY nor HAVING is used

- Either the select list must not include any aggregate functions, or each *column-name* in the select list must be specified within an aggregate function or must be a correlated column reference.
- If the select does not include aggregate functions, then the select list is applied to each row of R and the result contains as many rows as there are rows in R.
- If the select list is a list of aggregate functions, then R is the source of the arguments of the functions and the result of applying the select list is one row.

In either case the *n*th column of the result contains the values specified by applying the *n*th expression in the operational form of the select list.

Null attributes of result columns

Result columns do not allow null values if they are derived from:

- A column that does not allow null values
- A constant
- The COUNT or COUNT_BIG function
- A host variable that does not have an indicator variable
- A scalar function or expression that does not include an operand where nulls are allowed
- An expression with a result type that is a weakly typed distinct type defined with a NOT NULL data type constraint

Result columns allow null values if they are derived from:

- Any aggregate function except COUNT or COUNT_BIG
- A column where null values are allowed
- A scalar function or expression that includes an operand where nulls are allowed
- A NULLIF function with arguments containing equal values
- A host variable that has an indicator variable, an SQL parameter, an SQL variable, or a global variable
- A result of a set operation if at least one of the corresponding items in the select list is nullable
- An arithmetic expression or view column that is derived from an arithmetic expression and the database is configured with **dft_sqlmathwarn** set to Yes
- A scalar subselect
- A dereference operation
- A GROUPING SETS *grouping-expression*

Names of result columns

- If the AS clause is specified, the name of the result column is the name specified on the AS clause.
- If the AS clause is not specified and if a column list is specified in the correlation clause, the name of the result column is the corresponding name in the correlation column list.

- If neither an AS clause nor a column list in the correlation clause is specified and if the result column is derived only from a single column (without any functions or operators), the name of the result column is the unqualified name of that column.
- If neither an AS clause nor a column list in the correlation clause is specified and if the result column is derived only from a single SQL variable or SQL parameter (without any functions or operators), the name of the result column is the unqualified name of that SQL variable or SQL parameter.
- If neither an AS clause nor a column list in the correlation clause is specified and if the result column is derived using a dereference operation, the name of the result column is the unqualified name of the target column of the dereference operation.
- All other result columns are unnamed. The system assigns temporary numbers (as character strings) to these columns.

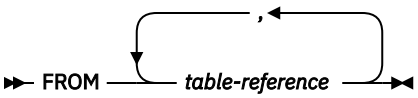
Data types of result columns

Each column of the result of SELECT acquires a data type from the expression from which it is derived.

When the expression is ...	The data type of the result column is ...
the name of any numeric column	the same as the data type of the column, with the same precision and scale for DECIMAL columns, or the same precision for DECFLOAT columns.
a constant	the same as the data type of the constant.
the name of any numeric variable	the same as the data type of the variable, with the same precision and scale for DECIMAL variables, or the same precision for DECFLOAT variables.
the name of any string column	the same as the data type of the column, with the same length attribute.
the name of any string variable	the same as the data type of the variable, with the same length attribute; if the data type of the variable is not identical to an SQL data type (for example, a NUL-terminated string in C), the result column is a varying-length string.
the name of a datetime column	the same as the data type of the column.
the name of a user-defined type column	the same as the data type of the column.
the name of a reference type column	the same as the data type of the column.

from-clause

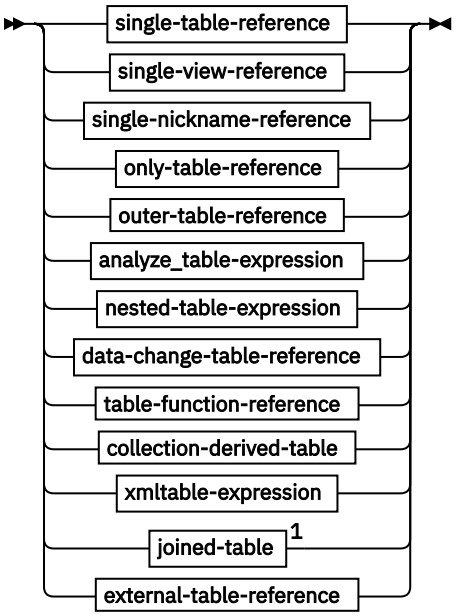
The FROM clause specifies an intermediate result table.



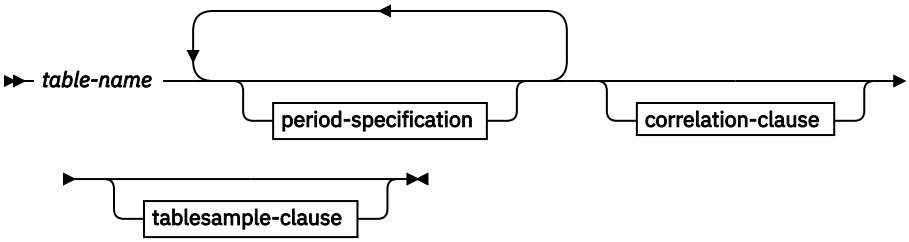
If only one *table-reference* is specified, the intermediate result table is the result of that *table-reference*. If more than one *table-reference* is specified, the intermediate result table consists of all possible combinations of the rows of the specified *table-reference* (the Cartesian product). Each row of the result is a row from the first *table-reference* concatenated with a row from the second *table-reference*, concatenated in turn with a row from the third, and so on. The number of rows in the result is the product of the number of rows in all the individual table references. For a description of *table-reference*, see "table-reference" on page 644.

table-reference

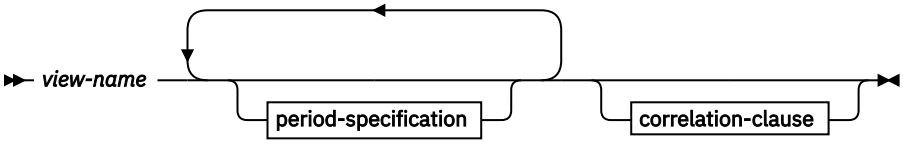
A *table-reference* specifies an intermediate result table.



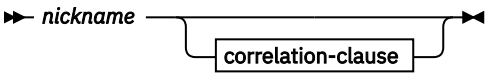
single-table-reference



single-view-reference



single-nickname-reference



only-table-reference

outer-table-reference

implementation-clause

continue-handler

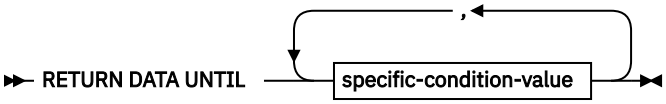

table-UDF-cardinality-clause

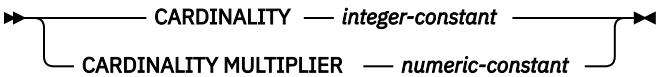
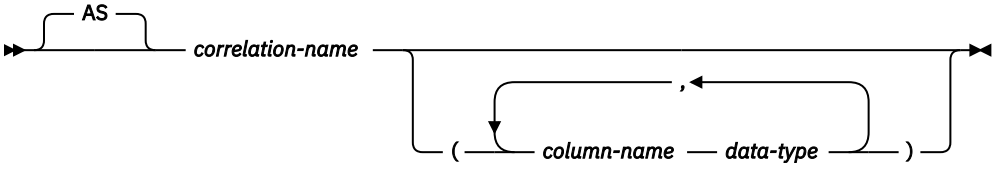
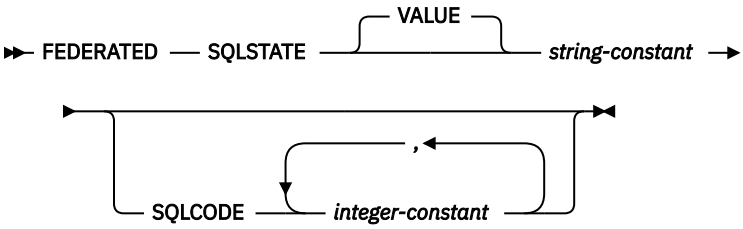


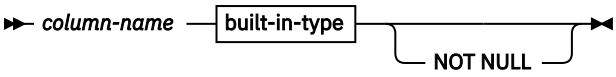
typed-correlation-clause



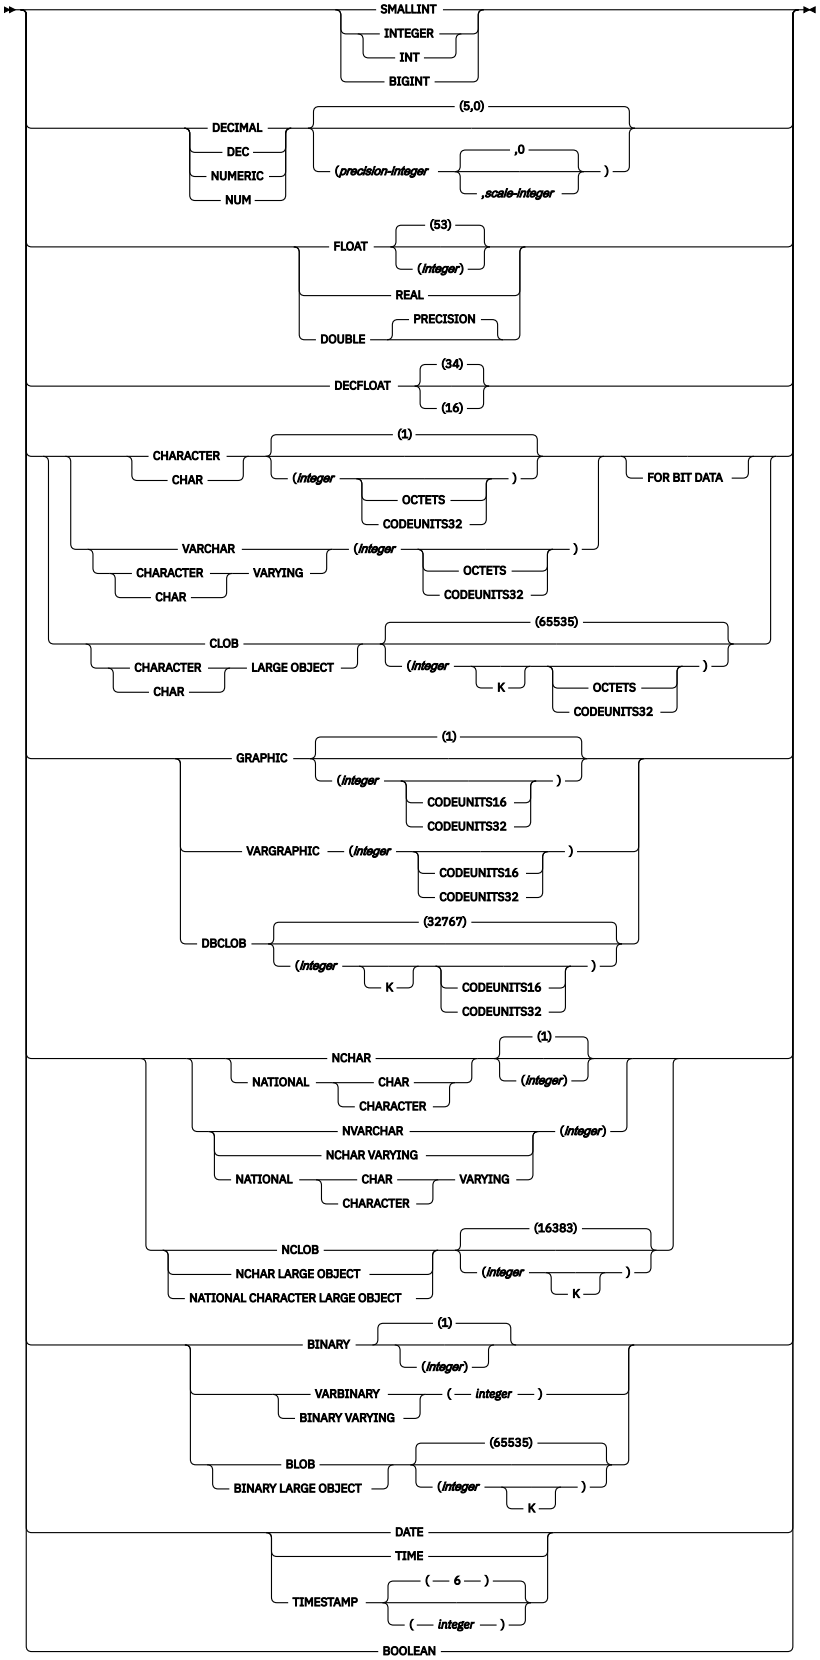
specific-condition-value



column-definition



built-in-type



Notes:

[1] The syntax for joined-table is covered in a separate topic; refer to "joined-table" on page 685.

[2] TABLE can be specified in place of LATERAL.

[3] The typed-correlation-clause is required for generic table functions. This clause cannot be specified for any other table functions.

[4] WITH ORDINALITY can be specified only if the argument to the UNNEST table function is one or more ordinary array variables or functions with ordinary array return types; an associative array variable or function with an associative array return type cannot be specified (SQLSTATE 428HT).

[5] An XMLTABLE function can be part of a table-reference. In this case, subexpressions within the XMLTABLE expression are in-scope of prior range variables in the FROM clause. For more information, see the description of "XMLTABLE".

[6] Specifying a LIKE clause or at least one column definition is not mandatory for an `INSERT INTO <table> SELECT FROM` statement, which acts as an implicit LIKE with respect to the INSERT target table.

A *table-reference* specifies an intermediate result table.

- If a single-table-reference is specified without a period-specification or a tablesample-clause, the intermediate result table is the rows of the table. If a period-specification is specified, the intermediate result table consists of the rows of the temporal table where the period matches the specification. If a tablesample-clause is specified, the intermediate result table consists of a sampled subset of the rows of the table.
- If a single-view-reference is specified without a period-specification, the intermediate result table is that view. If a period-specification is specified, temporal table references in the view consider only the rows where the period matches the specification.
- If a single-nickname-reference is specified, the intermediate result table is the data from the data source for that nickname.
- If an only-table-reference is specified, the intermediate result table consists of only the rows of the specified table or view without considering the applicable subtables or subviews.
- If an outer-table-reference is specified, the intermediate result table represents a virtual table based on all the subtables of a typed table or the subviews of a typed view.
- If an analyze_table-expression is specified, the result table contains the result of executing a specific data mining model by using an in-database analytics provider, a named model implementation, and input data.
- If a nested-table-expression is specified, the result table is the result of the specified fullselect.
- If a data-change-table-reference is specified, the intermediate result table is the set of rows that are directly changed by the searched UPDATE, searched DELETE, or INSERT statement that is included in the clause.
- If a table-function-reference is specified, the intermediate result table is the set of rows that are returned by the table function.
- If a collection-derived-table is specified, the intermediate result table is the set of rows that are returned by the UNNEST function.
- If an xmltable-expression is specified, the intermediate result table is the set of rows that are returned by the XMLTABLE function.
- If a joined-table is specified, the intermediate result table is the result of one or more join operations. For more information, see “joined-table” on page 685.
- If an external-table-reference is specified without a tablesample-clause, the intermediate result table is the rows of the external table that is represented by the specified file. If a tablesample-clause is specified, the intermediate result table consists of a sampled subset of the rows of the external table that is represented by the specified file.

single-table-reference

Each *table-name* specified as a table-reference must identify an existing table at the application server or an existing table at a remote server specified using a remote-object-name. The intermediate result table is the result of the table. If the *table-name* references a typed table, the intermediate result table is the UNION ALL of the table with all its subtables, with only the columns of the *table-name*. A period-specification can be used with a temporal table to specify the period from which

the rows are returned as the intermediate result table. A tablesample-clause can be used to specify that a sample of the rows be returned as the intermediate result table.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value *CTST* and *table-name* identifies a system-period temporal table, the table reference is executed as if it contained the following specification with the special register set to the null value:

```
table-name FOR SYSTEM_TIME AS OF CTST
```

If the CURRENT TEMPORAL BUSINESS_TIME special register is set to a non-null value *CTBT* and *table-name* identifies an application-period temporal table, the table reference is executed as if it contained the following specification with the special register set to the null value:

```
table-name FOR BUSINESS_TIME AS OF CTBT
```

single-view-reference

Each *view-name* specified as a table-reference must identify one of the following objects:

- An existing view at the application server
- A view at a remote server specified using a remote-object-name
- The *table-name* of a common table expression

The intermediate result table is the result of the view or common table expression. If the *view-name* references a typed view, the intermediate result table is the UNION ALL of the view with all its subviews, with only the columns of the *view-name*. A period-specification can be used with a view defined over a temporal table to specify the period from which the rows are returned as the intermediate result table.

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a non-null value *CTST*, and *view-name* identifies a system-period temporal table, the table reference is executed as if it contained the following specification with the special register set to the null value:

```
view-name FOR SYSTEM_TIME AS OF CTST
```

If the CURRENT TEMPORAL BUSINESS_TIME special register is set to a non-null value *CTBT*, and *view-name* identifies an application-period temporal table, the table reference is executed as if it contained the following specification with the special register set to the null value:

```
view-name FOR BUSINESS_TIME AS OF CTBT
```

single-nickname-reference

Each *nickname* specified as a table-reference must identify an existing nickname at the application server. The intermediate result table is the result of the nickname.

only-table-reference

The use of ONLY(*table-name*) or ONLY(*view-name*) means that the rows of the applicable subtables or subviews are not included in the intermediate result table. If the *table-name* used with ONLY does not have subtables, then ONLY(*table-name*) is equivalent to specifying *table-name*. If the *view-name* used with ONLY does not have subviews, then ONLY(*view-name*) is equivalent to specifying *view-name*.

The use of ONLY requires the SELECT privilege on every subtable of *table-name* or subview of *view-name*.

outer-table-reference

The use of OUTER(*table-name*) or OUTER(*view-name*) represents a virtual table. If the *table-name* or *view-name* used with OUTER does not have subtables or subviews, then specifying OUTER is equivalent to not specifying OUTER. If the *table-name* does have subtables, the intermediate result table from OUTER(*table-name*) is derived from *table-name* as follows:

- The columns include the columns of *table-name* followed by the additional columns introduced by each of its subtables, if any. The additional columns are added on the right, traversing the subtable

hierarchy in depth-first order. Subtables that have a common parent are traversed in creation order of their types.

- The rows include all the rows of *table-name* and all the rows of its subtables. Null values are returned for columns that are not in the subtable for the row.

If the *view-name* does have subviews, the intermediate result table from OUTER(*view-name*) is derived from *view-name* as follows:

- The columns include the columns of *view-name* followed by the additional columns introduced by each of its subviews, if any. The additional columns are added on the right, traversing the subview hierarchy in depth-first order. Subviews that have a common parent are traversed in creation order of their types.
- The rows include all the rows of *view-name* and all the rows of its subviews. Null values are returned for columns that are not in the subview for the row.

The use of OUTER requires the SELECT privilege on every subtable of *table-name* or subview of *view-name*.

analyze_table-expression

table-name | view-name
The *table-name* or *view-name* variable must identify an existing table or view or identify the *table-name* of a common table expression that you define preceding the fullselect containing the table-reference. You can specify a nickname. However, in-database analytics are intended for local data, and retrieving the data for a nickname from another data source does not take advantage of the intended performance benefits.

ANALYZE_TABLE
Returns the result of executing a specific data mining model by using an in-database analytics provider, a named model implementation, and input data. A query referencing the ANALYZE_TABLE parameter cannot be a static SQL statement or a data definition language (DDL) statement. Input or output values cannot be of the following types:

- CHAR FOR BIT DATA or VARCHAR FOR BIT DATA
- BINARY or VARBINARY
- BLOB, CLOB, DBCLOB, or NCLOB
- BOOLEAN
- XML
- DB2SECURITYLABEL

IMPLEMENTATION '*string*'
Specifies how the expression is to be evaluated. The *string* parameter is a string constant whose maximum length is 1024 bytes. The specified value is used to establish a session with an in-database analytic provider. When you specify SAS as the provider, you must specify values for the following case-insensitive parameters:

PROVIDER
Currently, the only supported provider value is SAS.

ROUTINE_SOURCE_TABLE
Specifies a user table containing the DS2 code (and, optionally, any required format or metadata) to implement the algorithm that is specified by the ROUTINE_SOURCE_NAME parameter. DS2 is a procedural language processor for SAS, designed for data modeling, stored procedures, and data extraction, transformation, and load (ETL) processing.

The routine source table has a defined structure (see the examples at the end of the "*analyze_table-expression*" section) and, in a partitioned database environment, must be on the catalog database partition. The table cannot be a global temporary table. The MODELDS2 column for a particular row must not be empty or contain the null value. If the value of the MODELFORMATS or MODELMETADATA column is not null, the value must have a length greater

than 0. If you do not specify a table schema name, the value of the CURRENT SCHEMA special register is used.

ROUTINE_SOURCE_NAME
Specifies the name of the algorithm to use.

For example:

```
IMPLEMENTATION
  'PROVIDER=SAS;
  ROUTINE_SOURCE_TABLE=ETLIN.SOURCE_TABLE;
  ROUTINE_SOURCE_NAME=SCORING_FUN1;'
```

If the table name, schema name, or algorithm name contains lowercase or mixed-case letters, specify delimited identifiers, as shown in the following example:

```
IMPLEMENTATION
  'PROVIDER=SAS;
  ROUTINE_SOURCE_TABLE="ETLin"."Source_Table";
  ROUTINE_SOURCE_NAME="Scoring_Fun1";'
```

The following examples show you how to use the ANALYZE_TABLE expression.

SAS tooling helps you to define a table to store model implementations for scoring functions. A row in this table stores an algorithm that is written in DS2, with any required SAS format information and metadata. The MODELNAME column serves as the primary key. For a particular value of the ROUTINE_SOURCE_NAME parameter, at most one row is retrieved from the table that the ROUTINE_SOURCE_TABLE parameter specifies. For example:

```
CREATE TABLE ETLIN.SOURCE_TABLE (
  MODELNAME VARCHAR(128) NOT NULL PRIMARY KEY,
  MODELDS2 BLOB(4M) NOT NULL,
  MODELFORMATS BLOB(4M),
  MODELMETADATA BLOB(4M)
);
```

The MODELNAME column contains the name of the algorithm. The MODELDS2 column contains the DS2 source code that implements the algorithm. The MODELFORMATS column contains the aggregated SAS format definition that the algorithm requires. If the algorithm does not require a SAS format, this column contains the null value. The MODELMETADATA column contains any additional metadata that the algorithm requires. If the algorithm does not require any additional metadata, this column contains the null value. If the SAS EP installer creates the table, it might include additional columns.

- Use the data in columns C1 and C2 in table T1 as input data with the scoring model SCORING_FUN1, whose implementation is stored in ETLIN.SOURCE_TABLE:

```
WITH sas_score_in (c1,c2) AS
  (SELECT c1,c2 FROM t1)
  SELECT *
    FROM sas_score_in ANALYZE_TABLE(
      IMPLEMENTATION
        'PROVIDER=SAS;
         ROUTINE_SOURCE_TABLE=ETLIN.SOURCE_TABLE;
         ROUTINE_SOURCE_NAME=SCORING_FUN1;');
```

- Use all the data in the table T2 with the scoring model SCORING_FUN2, whose implementation is stored in ETLIN.SOURCE_TABLE:

```
SELECT *
  FROM t2 ANALYZE_TABLE(
    IMPLEMENTATION
      'PROVIDER=SAS;
       ROUTINE_SOURCE_TABLE=ETLIN.SOURCE_TABLE;
       ROUTINE_SOURCE_NAME=SCORING_FUN2;');
```

- Use all the data in view V1 with the scoring model SCORING_FUN3, whose implementation is stored in ETLIN.SOURCE_TABLE, and return the output in ascending order of the first output column:

```
SELECT *
  FROM v1 ANALYZE_TABLE(
    IMPLEMENTATION
      'PROVIDER=SAS;
       ROUTINE_SOURCE_TABLE=ETLIN.SOURCE_TABLE;
       ROUTINE_SOURCE_NAME=SCORING_FUN3;')
  ORDER BY 1;
```

nested-table-expression

A fullselect in parentheses is called a *nested table expression*. The intermediate result table is the result of that fullselect. The columns of the result do not need unique names, but a column with a non-unique name cannot be explicitly referenced. If LATERAL is specified, the fullselect can include correlated references to results columns of table references specified to the left of the nested table expression. If the nested table expression involves data from a federated data source, a continue-handler can be specified to tolerate certain error conditions from the data source.

An expression in the select list of a nested table expression that is referenced within, or is the target of, a data change statement within a fullselect is valid only when it does not include:

- A function that reads or modifies SQL data
- A function that is non-deterministic
- A function that has external action
- An OLAP function

If a view is referenced directly in, or as the target of a nested table expression in a data change statement within a FROM clause, the view must meet either of the following conditions:

- Be symmetric (have WITH CHECK OPTION specified)
- Satisfy the restriction for a WITH CHECK OPTION view

If the target of a data change statement within a FROM clause is a nested table expression, the following restrictions apply:

- Modified rows are not requalified
- WHERE clause predicates are not reevaluated
- ORDER BY or FETCH FIRST operations are not redone

A nested table expression can be used in the following situations:

- In place of a view to avoid creating the view (when general use of the view is not required)
- When the required intermediate result table is based on host variables

data-change-table-reference

A *data-change-table-reference* clause specifies an intermediate result table. This table is based on the rows that are directly changed by the searched UPDATE, searched DELETE, or INSERT statement that is included in the clause. A *data-change-table-reference* can be specified as the only *table-reference* in the FROM clause of the outer fullselect that is used in a *select-statement*, a SELECT INTO statement, or a common table expression. A *data-change-table-reference* can be specified as the only table reference in the only fullselect in a SET Variable statement (SQLSTATE 428FL). The target table or view of the data change statement is considered to be a table or view that is referenced in the query; therefore, the authorization ID of the query must have SELECT privilege on that target table or view. A *data-change-table-reference* clause cannot be specified in a view definition, materialized query table definition, or FOR statement (SQLSTATE 428FL).

The target of the UPDATE, DELETE, or INSERT statement cannot be a temporary view defined in a common table expression (SQLSTATE 42807) or a nickname (SQLSTATE 25000).

Expressions in the select list of a view or fullselect as target of a data change statement in a *table-reference* can be selected only if OLD TABLE is specified or the expression does not include the following elements (SQLSTATE 428G6):

- A subquery

- A function that reads or modifies SQL data
- A function is that is non-deterministic or has an external action
- An OLAP function
- A NEXT VALUE FOR *sequence* reference

FINAL TABLE
Specifies that the rows of the intermediate result table represent the set of rows that are changed by the SQL data change statement as they exist at the completion of the data change statement. If there are AFTER triggers or referential constraints that result in further operations on the table that is the target of the SQL data change statement, an error is returned (SQLSTATE 560C6). If the target of the SQL data change statement is a view that is defined with an INSTEAD OF trigger for the type of data change, an error is returned (SQLSTATE 428G3).

NEW TABLE
Specifies that the rows of the intermediate result table represent the set of rows that are changed by the SQL data change statement before the application of referential constraints and AFTER triggers. Data in the target table at the completion of the statement might not match the data in the intermediate result table because of additional processing for referential constraints and AFTER triggers.

OLD TABLE
Specifies that the rows of the intermediate result table represent the set of rows that are changed by the SQL data change statement as they existed before the application of the data change statement.

(searched-update-statement)
Specifies a searched UPDATE statement. A WHERE clause or a SET clause in the UPDATE statement cannot contain correlated references to columns outside of the UPDATE statement.

(searched-delete-statement)
Specifies a searched DELETE statement. A WHERE clause in the DELETE statement cannot contain correlated references to columns outside of the DELETE statement.

(insert-statement)
Specifies an INSERT statement. A fullselect in the INSERT statement cannot contain correlated references to columns outside of the fullselect of the INSERT statement.

The content of the intermediate result table for a *data-change-table-reference* is determined when the cursor opens. The intermediate result table contains all manipulated rows, including all the columns in the specified target table or view. All the columns of the target table or view for an SQL data change statement are accessible using the column names from the target table or view. If an INCLUDE clause was specified within a data change statement, the intermediate result table will contain these additional columns.

table-function-reference

In general, a table function, together with its argument values, can be referenced in the FROM clause of a SELECT in exactly the same way as a table or view. Each *function-name* together with the types of its arguments, specified as a table reference must resolve to an existing table function at the application server. There are, however, some special considerations which apply.

- **Table function column names**: Unless alternative column names are provided following the *correlation-name*, the column names for the table function are those specified in the RETURNS or RETURNS GENERIC TABLE clause of the CREATE FUNCTION statement. This is analogous to the names of the columns of a table, which are defined in the CREATE TABLE statement.
- **Table function resolution**: The arguments specified in a table function reference, together with the function name, are used by an algorithm called *function resolution* to determine the exact function to be used. This is no different from what happens with other functions (such as scalar functions) that are used in a statement.

- **Table function arguments**: As with scalar function arguments, table function arguments can generally be any valid SQL expression. The following examples are valid syntax:

```
Example 1:  SELECT c1
            FROM TABLE( tf1('Zachary') ) AS z
            WHERE c2 = 'FLORIDA';

Example 2:  SELECT c1
            FROM TABLE( tf2 (:hostvar1, CURRENT DATE) ) AS z;

Example 3:  SELECT c1
            FROM t
            WHERE c2 IN
                     (SELECT c3 FROM
                      TABLE( tf5(t.c4) ) AS z  -- correlated reference
                     )                         -- to previous FROM clause
```

```
Example 4:  SELECT c1
            FROM TABLE( tf6('abcd') )                -- tf6 is a generic
                AS z (c1 int, c2 varchar(100)) -- java table function
```

- **Table functions that modify SQL data**: Table functions that are specified with the MODIFIES SQL DATA option can be used only as the last table reference in a *select-statement*, *common-table-expression*, or RETURN statement that is a subselect, a SELECT INTO, or a *row-fullselect* in a SET statement. Only one table function is allowed in one FROM clause, and the table function arguments must be correlated to all other table references in the subselect (SQLSTATE 429BL). The following examples have valid syntax for a table function with the MODIFIES SQL DATA property:

```
Example 1:  SELECT c1
            FROM TABLE( tfmod('Jones') ) AS z

Example 2:  SELECT c1
            FROM t1, t2, TABLE( tfmod(t1.c1, t2.c1) ) AS z

Example 3:  SET var =
            (SELECT c1
            FROM TABLE( tfmod('Jones') ) AS z

Example 4:  RETURN SELECT c1
            FROM TABLE( tfmod('Jones') ) AS z

Example 5:  WITH v1(c1) AS
            (SELECT c1
            FROM TABLE( tfmod(:hostvar1) ) AS z)
            SELECT c1
            FROM v1, t1 WHERE v1.c1 = t1.c1
```

```
Example 6: SELECT z.*
           FROM t1, t2, TABLE( tfmod(t1.c1, t2.c1) )
           AS z (col1 int)
```

collection-derived-table

A *collection-derived-table* can be used to convert the elements of an array into values of a column in separate rows. If WITH ORDINALITY is specified, an extra column of data type INTEGER is appended. This column contains the position of the element in the array. The columns can be referenced in the select list and the in rest of the subselect by using the names specified for the columns in the correlation-clause. The *collection-derived-table* clause can be used only in a context where arrays are supported (SQLSTATE 42887). See the "UNNEST table function" for details.

xmltable-expression

An *xmltable-expression* specifies an invocation of the built-in XMLTABLE function which determines the intermediate result table. See XMLTABLE for more information.

external-table-reference

An external table resides in a text-based, delimited or non-delimited file outside of a database. An *external-table-reference* specifies the name of the file that contains an external table.

column-definition

The attributes of a column.

column-name
Names a column of the table. The name cannot be qualified, and the same name cannot be used for more than one column of the table (SQLSTATE 42711).

built-in-type
One of the following built-in data types:

SMALLINT
A small integer.

[INTEGER | INT]
A large integer.

BIGINT
A big integer.

[DECIMAL | DEC | NUMERIC | NUM](*precision-integer, scale-integer*)
A decimal number.

- The precision integer specifies the total number of digits. It must be in the range 1 - 31. The default is 5.
- The scale integer specifies the number of digits to the right of the decimal point. It cannot be negative and cannot exceed the precision. The default is 0.

FLOAT(*integer*)
A single or double-precision floating-point number. If the specified length is in the range:

- 1 - 24, the number uses single precision
- 25 - 53, the number uses double-precision

Instead of FLOAT, you can specify:

REAL
For single precision floating-point.

DOUBLE
For double-precision floating-point.

DOUBLE PRECISION
For double-precision floating-point.

FLOAT
For double-precision floating-point.

DECFLOAT*(precision-integer)*
A decimal floating-point number. The precision integer specifies the total number of digits, which can be either 16 or 34. The default is 34.

[CHARACTER | CHAR](*integer* [OCTETS | CODEUNITS32])
A fixed-length character string of the specified number of code units. This number can range from 1 - 255 OCTETS or from 1 - 63 CODEUNITS32. The default is 1.

[VARCHAR | CHARACTER VARYING | CHAR VARYING](*integer* [OCTETS | CODEUNITS32])
A varying-length character string with a maximum length of the specified number of code units. This number can range from 1 - 32672 OCTETS or from 1 - 8168 CODEUNITS32.

FOR BIT DATA
Specifies that the contents of the column are to be treated as bit (binary) data. During data exchange with other systems, code page conversions are not performed. Comparisons are done in binary, irrespective of the database collating sequence.

The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

[CLOB | CHARACTER LARGE OBJECT | CHAR LARGE OBJECT](*integer* [K] [OCTETS | CODEUNITS32])
A character large object string with a maximum length of the specified number of code units. The default maximum length is 65,535 bytes.

If you want to multiply the length integer by 1024, specify a K (kilo) multiplier.

- Regardless of whether you use a K multiplier, the resulting length is limited by the maximum length of a CLOB column in an external table, which is 65,535 OCTETS, 32,767 CODEUNITS16, or 16,383 CODEUNITS32. Note that 64K OCTETS and 16K CODEUNITS32 each exceed the maximum length by one, and so are not allowed.
- Any number of spaces (including zero spaces) are allowed between the data type and the length specification or between the length integer and the K multiplier. For example, the following specifications are all equivalent and valid:

```
CLOB(50K)
CLOB(50 K)
CLOB (50   K)
```

- The K multiplier can be specified in either uppercase or lowercase.

In a Unicode database, the default string units for a character string data type are determined by the value of the NLS_STRING_UNITS global variable or *string_units* database configuration parameter. In a non-Unicode database, the default string units for character string data types are OCTETS.

OCTETS
Specifies that the units of the length attribute are bytes.

CODEUNITS32
Specifies that the units of the length attribute are Unicode UTF-32 code units, which approximates counting in characters. This does not affect the underlying code page of the data type. The actual length of a data value is determined by counting the UTF-32 code units as if the data were converted to UTF-32. CODEUNITS32 can be specified only in a Unicode database (SQLSTATE 560AA).

GRAPHIC(*integer* [CODEUNITS16 | CODEUNITS32])
A fixed-length graphic string of the specified length, which can range from 1 - 127 double bytes, 1 - 127 CODEUNITS16, or 1 - 63 CODEUNITS32. The default length is 1.

VARGRAPHIC(*integer* [CODEUNITS16 | CODEUNITS32])
A varying-length graphic string of the specified maximum length, which can range from 1 - 16336 double bytes, 1 - 16336 CODEUNITS16, or 1 - 8168 CODEUNITS32.

DBCLOB(*integer* [K] [CODEUNITS16 | CODEUNITS32])
A character large object string of the specified maximum length in double bytes, Unicode UTF-16 code units, or Unicode UTF-32 code units. The default maximum length is 32,767 double bytes.

If you want to multiply the length integer by 1024, specify a K (kilo) multiplier.

- Regardless of whether you use a K multiplier, the resulting length is limited by the maximum length of a DBCLOB column in an external table, which is 32,767 CODEUNITS16 or 16,383 CODEUNITS32. Note that 32K CODEUNITS16 and 16K CODEUNITS32 each exceed the maximum length by one, and so are not allowed.
- Any number of spaces (including zero spaces) are allowed between the data type and the length specification or between the length integer and the K multiplier. For example, the following specifications are all equivalent and valid:

```
DBCLOB(50K)
DBCLOB(50 K)
DBCLOB (50   K)
```

- The K multiplier can be specified in either uppercase or lowercase.

In a Unicode database, the default string units for a character string data type are determined by the value of the NLS_STRING_UNITS global variable or *string_units* database configuration parameter. In a non-Unicode database, the default string units for character string data types is CODEUNITS16.

CODEUNITS16
Specifies that the units of the length attribute are Unicode UTF-16 code units, which is the same as counting in double bytes. CODEUNITS16 can be specified only in a Unicode database (SQLSTATE 560AA).

CODEUNITS32
Specifies that the units of the length attribute are Unicode UTF-32 code units. This does not affect the underlying code page of the data type. The actual length of a data value is determined by counting the UTF-32 code units as if the data were converted to UTF-32. CODEUNITS32 can be specified only in a Unicode database (SQLSTATE 560AA).

[NATIONAL CHARACTER | NATIONAL CHAR | NCHAR](*integer*)
A fixed-length string of the specified length. The default length is 1.

The NATIONAL CHARACTER type maps to either a fixed-length character or a fixed-length graphic string, depending on the value of the *nchar_mapping* database configuration parameter, which also defines the string units.

[NATIONAL CHARACTER VARYING | NATIONAL CHAR VARYING | NCHAR VARYING | NVARCHAR](*integer*)
A varying-length string of the specified maximum length.

The NATIONAL CHARACTER VARYING type maps to either a varying-length character or a varying-length graphic string, depending on the value of the *nchar_mapping* database configuration parameter, which also defines the string units.

[NATIONAL CHARACTER LARGE OBJECT | NCHAR LARGE OBJECT | NCLOB](*integer* [K])
A large object string of the specified maximum length. The default maximum length is 16,383 double bytes.

This data type maps to either a character large object (CLOB) or a double-byte character large object (DBCLOB), depending on the current value of the *nchar_mapping* database configuration parameter, which also defines the string units. See the description of the CLOB or DBCLOB parameter (whichever applies) for information about possible values for the length integer and how to use a K (kilo) multiplier.

BINARY(*integer*)
A fixed-length binary string of the specified length, which must be in the range 1 - 255 bytes. The default length is 1.

[VARBINARY | BINARY VARYING](*integer*)
A varying-length binary string of the specified maximum length, which must be in the range 1 - 32672 bytes.

[BLOB | BINARY LARGE OBJECT](*integer* [K])
A binary large object string with a maximum length of the specified number of code units. The default maximum length is 65,535 bytes.

If you want to multiply the length integer by 1024, specify a K (kilo) multiplier.

- Regardless of whether you use a K multiplier, the resulting length is limited by the maximum length of a BLOB column in an external table, which is 65,535 bytes. Note that 64K exceeds the maximum length by one, and so is not allowed.
- Any number of spaces (including zero spaces) are allowed between the data type and the length specification or between the length integer and the K multiplier. For example, the following specifications are all equivalent and valid:

```
BLOB(50K)
BLOB(50 K)
BLOB (50   K)
```

- The K multiplier can be specified in either uppercase or lowercase.

DATE
A date.

TIME
A time.

TIMESTAMP(*integer*) or TIMESTAMP
A timestamp. The integer specifies the number of decimal places for fractions of seconds, from 0 (seconds) to 12 (picoseconds). The default is 6 (microseconds).

BOOLEAN
A Boolean value.

LIKE *table-name1* or *view-name* or *nickname*
Specifies that the columns of the table have the same name and description as the columns of the specified table (*table-name1*), view (*view-name*), or nickname (*nickname*). The specified table, view, or nickname must either exist in the catalog or must be a declared temporary table. A typed table or typed view cannot be specified (SQLSTATE 428EC).

The use of LIKE is an implicit definition of *n* columns, where *n* is the number of columns in the identified table (including implicitly hidden columns), view, or nickname. A column of the new table that corresponds to an implicitly hidden column in the existing table will also be defined as implicitly hidden. The implicit definition depends on what is specified after LIKE:

- If a table is specified, then the implicit definition includes the column name, data type, hidden attribute, and nullability characteristic of each of the columns of that table. If EXCLUDING COLUMN DEFAULTS is not specified, then the column default is also included.
- If a view is specified, then the implicit definition includes the column name, data type, and nullability characteristic of each of the result columns of the fullselect defined in that view. The data types of the view columns must be data types that are valid for columns of a table.
- If a nickname is specified, then the implicit definition includes the column name, data type, and nullability characteristic of each column of that nickname.
- If a protected table is specified, the new table inherits the same security policy and protected columns as the identified table.
- If a table is specified and if that table contains a row-begin column, row-end column, or transaction-start-ID column, the corresponding column of the new table inherits only the data type of the source column. The new column is not considered a generated column.
- If a table that includes a period is specified, the new table does not inherit the period definition.
- If a system-period temporal table is specified, the new table is not a system-period temporal table.
- If a random distribution table that uses the **random by generation** method is specified, and if the new table that is being created does not share the same table distribution, the **RANDOM_DISTRIBUTION_KEY** column that is used to generate the random distribution values is not included.

Column default and identity column attributes can be included or excluded, based on the copy-attributes clauses. The implicit definition does not include any other attributes of the identified table, view, or nickname. Consequently, the new table does not have any primary key, unique constraints, foreign key constraints, referential integrity constraints, triggers, indexes, ORGANIZE BY specification, or PARTITIONING KEY specification. The table is created in the table space implicitly or explicitly specified by the IN clause, and the table has any other optional clause only if the optional clause is specified.

When a table is identified in the LIKE clause and that table contains a ROW CHANGE TIMESTAMP column, the corresponding column of the new table inherits only the data type of the ROW CHANGE TIMESTAMP column. The new column is not considered to be a generated column.

If a table is specified, and if row or column level access control is activated for that table, it is not inherited by the new table.

option
The following options control the loading of data to or retrieval of data from an external-table file. The value of each option is a text string and is not case-sensitive.

BOOLSTYLE or BOOLEAN_STYLE
During a load operation, all Boolean values must use the same style. This option specifies the Boolean style that is to be used:

- 1_0 (this is the default)
- T_F
- Y_N
- YES_NO
- TRUE_FALSE

CARDINALITY
Non-zero positive integer value to override the estimation of the expected number of returned rows.

CCSID
The coded character set identifier (CCSID) of the input data file. The value can be any valid integer value from the CCSID specification. There is no default value. The CCSID and ENCODING options are mutually exclusive when the value of the ENCODING option is UTF8, LATIN9, or INTERNAL.

Which styles are used for dates and times depends on whether a CCSID is specified:

- When a CCSID is specified, and when DATESTYLE, TIMESTYLE, DATEDELIM, or TIMEDELIM are not specified, the values or defaults for DATE_FORMAT, TIME_FORMAT, and TIMESTAMP_FORMAT are used.
- When a CCSID is not specified, and when TIMESTAMP_FORMAT, DATE_FORMAT or TIME_FORMAT are not specified, the values or defaults for DATESTYLE, TIMESTYLE, DATEDELIM, and TIMEDELIM are used.

COMPRESS
For a load operation or an unload operation, whether the data file data is compressed:

GZIP
The data file data is compressed by using the GZIP compression algorithm.

NO
The data file data is not compressed. This is the default.

LZ4
The data file data is compressed by using the LZ4 compression algorithm.

The COMPRESS option cannot be specified if the value of the REMOTESOURCE option is GZIP or LZ4.

CRINSTRING
How to interpret an unescaped carriage-return (CR) or carriage-return line-feed (CRLF) character:

TRUE or ON
An unescaped CR character is interpreted as data, not as a record delimiter.

FALSE or OFF
An unescaped CR is interpreted as a record delimiter. This is the default.

Use fixed-length format for **CRINSTRING** only if the value of the **CtrlChars** option is set to OFF.

CTRLCHARS
Whether to allow an ASCII value 1 - 31 in a CHAR or VARCHAR field. Any NULL, CR, or LF characters must be escaped. Allowed values are:

TRUE or ON
An ASCII value 1 - 31 in a CHAR or VARCHAR field is allowed.

If fixed-length format is enabled, all unescaped characters are allowed.

FALSE or OFF
An ASCII value 1 - 31 in a CHAR or VARCHAR field is not allowed. This is the default.

If fixed-length format is enabled, unescaped characters cause an error.

Exceptions for fixed-length format:

- \t, \n
- \r if the CRinString option is set to ON

DATAOBJECT or FILE_NAME

The fully-qualified name of the file (or any medium that can be treated as a file) that is to contain the external table to be created. This option is mandatory when the name of the file is not specified immediately after the table name; otherwise, it is not allowed.

When both the REMOTESOURCE option is set to LOCAL (this is its default value) and the **extbl_strict_io** configuration parameter is set to NO, the path to the external table file is an absolute path and must be one of the paths specified by the **extbl_location** configuration parameter. Otherwise, the path to the external table file is relative to the path that is specified by the **extbl_location** configuration parameter followed by the authorization ID of the table definer. For example, if **extbl_location** is set to `/home/xyz` and the authorization ID of the table definer is `user1`, the path to the external table file is relative to `/home/xyz/user1/`.

The file name must be a valid UTF-8 string.
For a load operation, the following conditions apply:

- The file must already exist.
- Required permissions:
  - If the external table is a named external table, the owner must have read permission for the file and write permission for the LOGDIR directory.
  - If the external table is a transient external table, the authorization ID of the statement must have read permission for the file and write permission for the LOGDIR directory.

For an unload operation, the following conditions apply:

- If the file exists, it is overwritten.
- Required permissions:
  - If the external table is a named external table, the owner must have read and write permission for the directory of this file.
  - If the external table is transient, the authorization ID of the statement must have read and write permission for the directory of this file.

DATEDELIM

The delimiter character that separates the components of a date, according to the format specified by the DATESTYLE option. If you specify an empty string, there is no delimiter between the date components, and days and months must be specified as two-digit numbers. When DATESTYLE is set to MONDY or MONDY2, the default DATEDELIM value is a space. The TIMESTAMP_FORMAT and DATEDELIM options are mutually exclusive.

DATESTYLE

How to interpret the date format. For days or months in the range 1 - 9, use 1 digit, 2 digits, or a space followed by a single digit. When the DATEDELIM option is a space, you can specify a comma after the day. An error occurs if you:

- Specify zero for a day, month, or year
- Specify a nonexistent date (for example, 32 August or 30 February)

The DATESTYLE option and the DATE_FORMAT or TIMESTAMP_FORMAT option are mutually exclusive.

Table 109. Possible values for the DateStyle option. The example shows how the date 21 March 2014 would be represented when DATEDELIM is set to '-'.

Value	Description	Example
YMD	4-digit year, 2-digit month, 2-digit day. This is the default.	2014-03-21
DMY	2-digit day, 2-digit month, 4-digit year.	21-03-2014
MDY	2-digit month, 2-digit day, 4-digit year.	03-21-2014
MONDY	3-character month, 2-digit day, 4-digit year.	Mar 21 2014
DMONY	2-digit day, 3-character month, 4-digit year.	21-Mar-2014
Y2MD	2-digit year, 2-digit month, 2-digit day. Not supported for unloads.	14-03-21
DMY2	2-digit day, 2-digit month, 2-digit year. Not supported for unloads.	21-03-14
MDY2	2-digit month, 2-digit day, 2-digit year. Not supported for unloads.	03-21-14
MONDY2	3-character month, 2-digit day, 2-digit year. Not supported for unloads.	Mar 21 14
DMONY2	2-digit day, 3-character month, 2-digit year. Not supported for unloads.	21-Mar-14

DATETIMEDELIM
A single-byte character that separates the date component and time component of the timestamp data type.

The default delimiter is a space (' ').

Between the date component and the time component, a delimiter is not required. For example, both of the following values are valid:

```
2010-10-10 10:10:10
2010-10-1010:10:10
```

DATE_FORMAT
The format of the date field in the data file. The value can be any of the date format strings that are accepted by the "TIMESTAMP_FORMAT " on page 527. The default is YYYY-MM-DD. The DATE_FORMAT option and the DATEDELIM or DATESTYLE option are mutually exclusive.

DECIMALDELIM or DECIMAL_CHARACTER
The decimal delimiter for the data types FLOAT, DOUBLE, TIME, and TIMESTAMP. Allowed values are ',' and '.'.

DECPLUSBLANK
Specifies how the positive decimal value is represented during the unload operation.

You can specify one of the following values for this option:

NONE
This is the default.

This value represents a positive decimal value without a sign.

PLUS
Specifies that a positive decimal value is represented by a '+' sign.

BLANK
Specifies that a positive decimal value is represented by a blank sign instead of a '+' sign.

If you specify the DECPLUSBLANK option for the load operation, the output is not affected.

Examples for a table test with ddl (decimal (6,2)) and all the available values for the DECPLUSBLANK option:

```
1234
-4563
```

- Create external table '/tmp/unload.txt' using (DECPLUSBLANK NONE) as select * from test:

```
unload.txt
1234.00
-4563.00
```

- Create external table '/tmp/unload.txt' using (DECPLUSBLANK PLUS) as select * from test:

```
unload.txt
+1234.00
-4563.00
```

- Create external table '/tmp/unload.txt' using (DECPLUSBLANK BLANK) as select * from test:

```
unload.txt
 1234.00
-4563.00
```

DELIMITER or COLUMN_DELIMITER

The character that is used to delimit the fields of an input or output record. The default is a vertical bar (`'|'`).

You can specify a character in the 7-bit ASCII range (decimal 1 - 127) in any of the following ways:

- As a single character (for example `DELIMITER ';'`)
- By specifying its corresponding ASCII decimal value (for example, `DELIMITER 59` or `DELIMITER '59'`)
- By specifying its corresponding ASCII hex value (for example, `DELIMITER x'3B'`)

The decimal range 128 - 255 is supported only with the ISO character set input file by specifying its corresponding ASCII decimal value or hex value. If the input file is in the UTF8 character set, this delimiter value range is not supported.

ENCODING

The type of data in the file:

UTF8

The file uses UTF8 encoding for all character data.

LATIN9

The file uses LATIN9 encoding for all character data.

INTERNAL

This is the default option.

The file uses a mixture of both UTF8 and LATIN9 encoding.

Files are encoded in Netezza internal format and therefore should be used only for files that are extracted from Netezza by using ENCODING (INTERNAL).

When the target column is CODEUINTS32 (NCHAR/VARCHAR), the input data is validated to be valid UTF-8 characters.

This option is supported only in a Unicode database.

DBCS_GRAPHIC

This value is allowed only for a load operation, not an unload operation. If this value is specified, the CCSID option must also be specified. During the load operation, fields of type GRAPHIC or VARGRAPHIC are encoded using the double-byte character set of the specified CCSID; fields of all other types are encoded using the mixed-byte character set of the specified CCSID.

Note: ENCODING cannot be set to DBCS_GRAPHIC for a DEL file that was created by the EXPORT utility, because such DEL files are encoded using a single character set.

The CCSID and ENCODING options are mutually exclusive when the value of the ENCODING option is UTF8, LATIN9, or INTERNAL.

ESCAPECHAR or ESCAPE_CHARACTER
Which character is to be regarded as an escape character. An escape character indicates that the character that follows it, which would otherwise be treated as a field-delimiter character or end-of-row sequence character, is instead treated as part of the value in the field. The escape character is ignored for graphic-string data. There is no default.

FILLRECORD
For a load operation, the field of a record are loaded into the columns of a target table from left to right. This option specifies whether an input record can contain fewer fields than there are columns defined for the target table:

TRUE or ON
An input line can contain fewer fields, provided that all columns for which a value is missing are nullable. Missing values are set to NULL. If one or more columns for which a value is missing is not nullable, the record is rejected.

FALSE or OFF
An input line that contains fewer columns is rejected. This is the default.

FORMAT or FILE_FORMAT
The data format of the source file:

TEXT
The data to be loaded or unloaded is in text-delimited format. This is the default.

INTERNAL
The data is in an internal format used by Netezza Platform Software (NPS). This value is valid only when loading data from a file to the database, not when unloading data to a file. If this value is specified for the FORMAT option, the following options, and only these options, must also be specified:

- DATAOBJECT or FILE_NAME.
- REMOTESOURCE, SWIFT or S3. If the REMOTESOURCE option is specified, it must have the value LOCAL or YES.

  Attention: In the container-only release of Db2 Version 11.5 Mod Pack 1 or later releases, AZURE is compatible, in addition to SWIFT and S3.
- COMPRESS. This must be set to GZIP.

BINARY
The data is in an internal format that is used by Db2.

FIXED
The data is in fixed-length format.

Fixed-length format is supported only for load operations.

Files in fixed-length format use ordinal positions, which are offsets, to identify where fields are within the record.

Note:

- The following external table options are not supported for the fixed-length format:
  - Delimiter
  - Encoding
  - EscapeChar
  - FillRecord
  - IgnoreZero

  - IncludeZeroSeconds
  - Lfinstring
  - QuotedValue
  - RequireQuotes
  - TimeExtraZeros
  - TruncString
- There are no field delimiters.
- An end-of-record delimiter is required even for the last record.
- Usually, data in fixed-length format files does not have decimal delimiters or time delimiters because delimiters are not necessary and use space.
- The locations of delimiters are fixed and specified in the layout definition because the fields are fixed in size. This definition comes with the fixed-length format data file.
- To load fixed-format data into the database, you must define the target data type for the fields and the locations within the record.
- You do not have to load all fields in a fixed-length format file. You can skip them by using the *filler* specification.
- The order of fields in the data file must match the order in the target table. Alternatively, you must create an external table definition that specifies the order of the fields as database columns.
- You can change the field order by using an external table definition in combination with an insert-select statement.
- Typically, unknown values or null values are represented by known data patterns that are classified as representing null.

The following parameters apply when the FORMAT option of the external table is set to FIXED:

LAYOUT
Mandatory.

A layout is an ordered collection of zone or field definitions. It defines the location of the fields of the input record.

Specify comma-separated zone definitions within braces { }.

Each zone definition is made up of mutually exclusive, non-overlapping clauses.

No default value.

The clauses must be in the following order, even if some of them are optional and can be empty:

USE TYPE
Optional.

Indicates whether a zone is a normal data zone, a reference zone, or a filler zone.

For data zones, this value is omitted.

A reference zone is specified as **REF**. This specification implies that the zone is referred by another zone for zone length or null values.

A filler zone is specified as **FILLER**. Filler zones specify that the bytes or characters are treated as fillers in a data file.

NAME
Optional.

The name of the zone.

Currently, this definition is not used. Typically, it is provided to identify the field.

TYPE
Optional.

Defines the type of the zone.

If you do not specify the type, it gets the default value of the corresponding type of a table column.

Valid values are as follows:

- CHAR
- VARCHAR
- NCHAR
- NVARCHAR
- SMALLINT
- BIGINT
- BINARY
- VARBINARY
- GRAPHIC
- VARGRAPHIC
- FLOAT
- DOUBLE
- DEC, NUM, or NUMERIC
- DECFLOAT
- BOOLEAN
- DATE
- TIME
- TIMESTAMP

STYLE

Optional.

Defines the zone representation.

The default representation is based on zone type and format option.

All other styles are valid only for their corresponding non-textual zone types.

Valid values are as follows:

- INTERNAL

  Valid only for textual zones, that is, char, varchar, nchar, and nvarchar.
- DECIMAL

  Valid for integer and numeric zone types.
- DECIMALDELIM <'decimal-delim'>

  Valid for numeric, float, double, and time style (time and timestamp) zone types.
- FLOATING

  Valid for float or double zone types.
- EXPONENTIAL

  Valid for float or double zone types.
- YMD <'date-delim'>

  Valid for date zones, including other date styles that are supported for the DateStyle and DateDelim external table options.
- 12Hour <'time-delim'>

Valid for time zones, including other time styles that are supported for the TimeStyle and TimeDelim external table options.

- 24Hour <'time-delim'>

  Valid for time zones, including other time styles that are supported for the TimeStyle and TimeDelim external table options.

- YMD <'date-delim'> 24Hour <'time-delim'>

  Valid for timestamp zones, including other combinations of date and time styles that are supported for the DateStyle, DateDelim, TimeStyle, and TimeDelim external table options.

- TRUE_FALSE, Y_N, 1_0

  Valid for boolean zones, including other boolean styles that are supported for the BoolStyle external table option. The style must be in accordance with the format.

LENGTH

Optional.

Specified as bytes or characters followed by the number or the internal reference to the reference zone.

Number of bytes or characters as provided or as referenced by the reference zone.

For reference zones or filler zones, you cannot use internal references. For reference zones, the number of bytes specifies how the data is read from the data file to get the referred value.

You can use plus signs and minus signs as follows:

```
BYTES @2 + 10
BYTES @2 - 10
```

NULLIF

Optional.

Definition of the zone NULLESS attribute.

Specifies a known data pattern within the field that, when it is present, signifies that the field is null.

The length is equal to or less than the column width. The maximum length is 39 bytes.

You can use the following types of references:

@

Internal reference to numeric zones.

Exact match of the numeric value.

&

External reference.

Exact match of the specified value.

&&

Isolated reference.

Leading spaces and trailing spaces are to be skipped with the exact string match.

Nulls are detailed in the following examples:

Table 110. Layout example

Use type	Name	Type	Style	Length	Nullif
NA	f1	int4	DECIMAL	Bytes 10	Nullif & = 0

Table 110. Layout example (continued)					
Use type	**Name**	**Type**	**Style**	**Length**	**Nullif**
NA	f2	date	YMD	Bytes 10	Nullif &= '2000-10-10'
NA	f3	char(20)	INTERNAL	Chars 10	Nullif &&='ab'
Filler	f4	char(10)	NA	Bytes 10	NA

Remember:

- The referred zone in a length clause must be of type integer.
- You must not specify the NULLIF option for reference zones or filler zones.
- Reference zones and filler zones cannot have variable lengths.
- Variable length zones cannot refer themselves.
- Define the referred zone in a length clause as REF.
- Length-clause references can use only the INTERNAL (@) reference. External or isolated references are not supported.
- Between the referred zone of a length clause and the zone itself, reference zones are not allowed.
- If the reference type is INTERNAL (@), the NULLIF clause cannot refer to itself.
- If the column is non-nullable, it may not have the NULLIF clause.
- Variable length is allowed only for the string type of zones.
- The NULLIF clause can refer only to REF zones or the zones themselves.
- Between the zone that is referred by the NULLIF clause and the zone itself, other referred zones are not allowed, except for the zone that is referred in the length clause.
- The record length can point to zone 1 only for reference.
- A REF must have a zone that refers it.
- The NULLIF clause can have external references only if the REF zone is non-integer.

Recordlength
Specifies the length of the entire record, where null-indicator bytes are included if they exist, and the record delimiter is excluded if it exists.

The value is a constant integer.

The value can also be an internal reference to the reference zone in the layout definition.

There is no default value.

You can use plus signs and minus signs for an internal reference as follows:

```
RECORDLENGTH @1 + 10
RECORDLENGTH @1 - 10
```

IGNOREZERO or TRIM_NULLS
Specifies whether the binary value zero in CHAR fields and VARCHAR fields is to be discarded.

TRUE or ON
The byte value zero is ignored.

FALSE or OFF
The byte value zero is not ignored. This is the default.

KEEP
The binary value zero is accepted and allowed as part of the input field.

INCLUDEHEADER or COLUMN_NAMES
For an unload operation, whether the table column names are to be included as headers in the external-table file:

TRUE or ON
The table column names are to be included as headers.

FALSE or OFF
The table column names are not to be included as headers. This is the default.

INCLUDEZEROSECONDS
For an unload operation, whether to specify **00** as the value for seconds when no value for seconds is available:

TRUE or ON
Specify **00** as the value for seconds.

FALSE or OFF
Do not specify a value for seconds. This is the default.

INCLUDEHIDDEN
For a load operation, specify whether hidden column values are present in a data file.

The `INCLUDEHIDDEN` option works when you are creating an external table by using the LIKE or SAMEAS clause, and base table has hidden columns.

TRUE
A data file contains values against hidden column.

FALSE
A data file does not contain values against hidden column. This is the default. You can change the default value by using the registry variable `DB2_EXTBL_INCLUDE_HIDDEN_COLS`.

LFINSTRING
Specifies how to interpret an unescaped line-feed (sometimes called an LF or newline) character within string data:

TRUE or ON
An unescaped LF character is interpreted as a record delimiter only if it is in the last field of a record; otherwise, it is treated as data. To cause an LF character that is in the last field of a record to be treated as data, enclose the value of that field in single or double quotation marks.

FALSE or OFF
An unescaped LF character is interpreted as a record delimiter regardless of its position. This is the default.

This option is not supported for unload operations.

Attention: This SQL compatibility enhancement is only available in Db2 Version 11.5 Mod Pack 2 and later versions.

LOGDIR or ERROR_LOG
The directory to which the following files are written:

<database>.<schema>.<external-table-name>.<file-name>.<application-handle>.<id>.bad
A file containing rejected records (that is, records that could not be processed).

<database>.<schema>.<external-table-name>.<file-name>.<application-handle>.<id>.log
A log file.

The default is the directory to which the external-table file is written. If the length of the name that is constructed for a .bad or .log file would exceed the allowed maximum, the name of the file that contains the external table (indicated by `<file-name>`) is truncated so that the maximum is not exceeded.

If a .log or .bad file is generated while carrying out an operation on a partition, the name of the generated file is suffixed with a period followed by the 3-digit partition number.

MAXERRORS or MAX_ERRORS
For a load operation, the threshold for the number of rejected records at which the system stops processing and immediately rolls back the load. The default is 1 (that is, a single rejected record results in a rollback).

For fixed-length format, the following conditions apply:

- The parser reports errors for each field or zone rather than one error for the row.
- Multiple errors can be reported for the same row.
- When the parser detects an error in a field or zone, it recovers by using the field length or zone length. It then continues from the next field or zone until the end of record is reached, or an unrecoverable error occurs, or the MaxErrors limit is reached.
- Unrecoverable errors include the following errors:
  - RecordLength mismatch.
  - RecordDelimiter is not found.
  - The RecordLength value is not valid, that is, the value is a negative value or zero.
  - The zone length is not valid, that is, the value is a negative value.
  - The UTF-8 initial byte is not valid.
  - The UTF-8 continuation bytes are not valid.

MULTIPARTSIZEMB

When the DB2_ENABLE_COS_SDK registry variable is set to ON, Db2 remote storage communication with cloud object storage is facilitated through an embedded vendor COS SDK which allows Db2 to stream objects/files to cloud object storage in multiple parts (aka 'multipart upload'). This parameter specifies the part size for multipart upload, in megabytes (MB), for the file being unloaded, and overrides the value specified in the MULTIPARTSIZEMB dbm config parameter. This option is available starting in Version 11.5 Modification Pack 7, in Linux (x86) environments only.

MAXROWS or MAX_ROWS
If set to a positive integer, this specifies the maximum number of records (rows) in the external table that are to be processed. If set to 0 (the default), there is no limit and all rows are processed. During a load operation, if MAXROWS is set to a positive value, after that number of rows are processed, regardless of whether some of the rows were rejected or skipped, the system ends the load operation and commits all inserted records.

MERIDIANDELIM
A single-byte character that separates the seconds component from the AM token or PM token in the 12-hour delimited and undelimited formats of a time value.

The default delimiter is a space (`' '`).

Between the seconds component and the AM token or PM token, a delimiter is not required. For example, both of the following values are valid:

```
1:02:46.12345 AM
1:02:46.12345AM
```

NOLOG
Specifies whether the `.log` file for the external table is created.

This option does not apply to `.bad` files.

Possible values are:

TRUE
No `.log` file is created.

FALSE
The `.log` file is created.

This is the default.

NULLVALUE or NULL_VALUE
The UTF-8 string of at most 4 bytes that is to be used to indicate a null value. The default is `'NULL'`.

PARTITION
If the Database Partitioning Feature (DPF) is enabled for the database, an external table can be partitioned into several files. The name of each of the data files that comprise an external table are suffixed with a period followed by a 3-digit number from 000 to 999 that indicates the number of the partition. For example, if an external table with the name **dataFile.txt** is divided into three partitions, the files that comprise it have the names **dataFile.txt.000**, **dataFile.txt.001**, and **dataFile.txt.002**. These files must be accessible from all members.

For a partitioned external table, the PARTITION option specifies to which partition or partitions the statement applies:

PARTITION ALL
The statement applies to all of the partitions that comprise the external table. For an unload operation, this is the only value that is allowed.

PARTITION (*n* TO *n*)
The statement applies to all of the partitions in the specified range, for example, **PARTITION (54 TO 62)**.

PARTITION (*n*,*n*,...)
The statement applies only to the specified partition or partitions, for example, **PARTITION (53)** or **PARTITION (51,57,58)**. If more than one partition number is specified, they must be in ascending order (sqlcode SQL0263N with SQLSTATE=42615) and there can be no duplicates (sqlcode SQL0265N with SQLSTATE=42615).

If a .log or .bad file is generated while carrying out an operation on a partitioned external table, the name of the generated file is suffixed with a period followed by the 3-digit partition number.

If the DPF is enabled and the PARTITION option is not specified, the external table is treated as single-partitioned table on the coordinator member. The names of the external table file and the .log and .bad files are not suffixed with a partition number.

If the DPF is not enabled, the PARTITION option can be specified, but only with the value ALL, (0 to 0), or (0) (SQL0644N). It will have no effect.

The REMOTESOURCE and PARTITION options are mutually exclusive.

QUOTEDNULL
For a load operation, how to interpret a value that is enclosed in single or double quotation marks and that matches the null value specified by the NULLVALUE or NULL_VALUE option (for example, "NULL" or 'NULL'):

TRUE or ON
The value is interpreted as a null value. This is the default.

FALSE or OFF
The value is interpreted as a character string.

QUOTEDVALUE or STRING_DELIMITER
Whether data values are enclosed in quotation marks:

SINGLE or YES
Data values are enclosed in single quotation marks (').

DOUBLE
Data values are enclosed in double quotation marks (").

NO
Data values are not enclosed in quotation marks. This is the default.

RECORDDELIM or RECORD_DELIMITER
The string literal that is to be interpreted as a row (record) delimiter. The default is `'\n'`.

When CRINSTRING is set to TRUE, RECORDDELIM cannot contain a CR ('\r') character - with the sole exception of a CRLF ('\r\n') delimiter allowed with CRINSTRING for text format only.

REMOTESOURCE
Where the external-table file resides and, if it resides on a remote system, whether the file data is to be compressed:

LOCAL
The file resides on the local server, that is, the system that hosts the database. This is the default.

YES
The file resides on a system other than the local server. For example, specify YES if a client system is connected to the database and the file resides on that system. File data is not compressed before it is transferred.

GZIP
Similar to YES, except that the file data is compressed using the GZIP compression algorithm before the data is transferred, and is decompressed after it is received. This improves overall performance when a large amount of compressible data is being transferred.

LZ4
Similar to YES, except that the file data is compressed using the LZ4 compression algorithm before the data is transferred, and is decompressed after it is received. This improves overall performance when a large amount of compressible data is being transferred.

The REMOTESOURCE, SWIFT, and S3 options are mutually exclusive.

Attention: In the container-only release of Db2 Version 11.5 Mod Pack 1 or later versions, AZURE is compatible and its options are mutually exclusive with REMOTESOURCE, SWIFT, and S3.

The REMOTESOURCE and PARTITION options are mutually exclusive. The COMPRESS option cannot be specified if the value of the REMOTESOURCE option is GZIP or LZ4.

REQUIREQUOTES
Whether quotation marks are mandatory:

TRUE or ON
Quotation marks are mandatory. The QUOTEDVALUE option must be set to YES, SINGLE, or DOUBLE.

FALSE or OFF
Quotation marks are not mandatory. This is the default.

SKIPROWS or SKIP_ROWS
For a load operation, the number of rows to skip before beginning to load the data. The default is 0. Because skipped rows are processed before they are skipped, a skipped row is still capable of causing a processing error.

SOCKETBUFSIZE
The size, in bytes, of the chunks of data that are read from the source file. Valid values range from 64 KB - 800 MB. If you specify a value outside this range, the value is set to the nearest valid value. The default is 8 MB.

STRICTNUMERIC
For a load operation, how to treat a value that is to be inserted into a DECIMAL field when its scale exceeds that defined for the field:

TRUE or ON
The row containing the value to be inserted is rejected. For example, if any of the following values were to be loaded into a DECIMAL(5,3) field, the row containing that value would be rejected:

```
12.666666666
-98.34496862785
0.00089
```

FALSE or OFF
The row containing the value to be inserted is accepted, and the portion of the decimal fraction that exceeds the scale defined for the field is truncated. This is the default. For example, the values in the previous example would be converted to:

```
12.666
-98.344
0.000
```

SWIFT
Specifies that the source data file is located in a Swift object store. The REMOTESOURCE, SWIFT, and S3 options are mutually exclusive. Use the DATAOBJECT option to specify the file name.

Attention: In the container-only release of Db2 Version 11.5 Mod Pack 1 or later versions, AZURE is compatible and its options are mutually exclusive with REMOTESOURCE, SWIFT, and S3.

Syntax:

```
SWIFT (endpoint, authKey1, authKey2, bucket)
```

where:

endpoint
A character string that specifies the URL of the SWIFT web service.

authKey1
A character string that specifies the access ID or username of the Swift open stack account used to validate the user.

authKey2
A character string that specifies the password of the Swift open stack account used to validate the user.

bucket
The name of the Swift open stack container (bucket) in which the file resides.

Example:

```
CREATE EXTERNAL TABLE exttab1(a int) using
  (dataobject 'datafile1.dat'
   swift('https://dal05.objectstorage.softlayer.net/auth/v1.0/',
    'XXXOS123456-2:xxx123456',
    'b207c6e974020737d92174esdf6d5be9382aa4c335945a14eaa9172c70f8df16',
    'my_dev'
   )
  )
```

S3
Specifies that the source data file is located in an S3 compatible object store. The REMOTESOURCE, SWIFT, and S3 options are mutually exclusive. Use the DATAOBJECT option to specify the file name.

Attention: In the container-only release of Db2 Version 11.5 Mod Pack 1 or later versions, AZURE is compatible and its options are mutually exclusive with REMOTESOURCE, SWIFT, and S3.

Syntax:

```
S3 (endpoint, authKey1, authKey2, bucket)
```

where:

endpoint
A character string that specifies the URL of the S3 compatible web service.

authKey1
A character string that specifies the S3 access key ID of the access keys used to validate the user and all user actions. For IBM Cloud Object Storage, this is the access key ID from the HMAC credentials.

authKey2
A character string that specifies the S3 secret key of the access keys that are used to validate the user and all user actions. For IBM Cloud Object Storage, this is the secret access key from the HMAC credentials.

bucket
The name of the S3 bucket in which the file resides.

Note: For IBM Cloud Object Storage, to create HMAC credentials, when creating new service credentials, specify `{"HMAC:true}` in the **Add Inline Configuration Parameters** field.

Example using AWS S3:

```
CREATE EXTERNAL TABLE exttab2(a int) using
  (dataobject 'datafile2.dat'
   s3('s3.amazonaws.com',
    'XXXOS123456-2:xxx123456',
    'bs07c6e974040737d92174e5e96d5be9382aa4c33xxx5a14eaa9172c70f8df16',
    'my_dev'
   )
  )
```

Example using IBM Cloud Object Storage:

```
CREATE EXTERNAL TABLE exttab2(a int) using
  (dataobject 'datafile2.dat'
   s3('s3-api.us-geo.objectstorage.softlayer.net',
    '1a2bkXXXsaddntLo0xX0',
    'XXxxiEPjJ7T7WBUz74E6abcdABCDE8Q7RgU4gYY9',
    'my_dev'
   )
  )
```

AZURE

Attention: This feature is available in the container-only release of Db2 Version 11.5 Mod Pack 1 or later versions.

Specifies that the source data file is located in Microsoft Azure Blob Storage. The REMOTESOURCE, SWIFT, S3, and AZURE options are mutually exclusive. Use the DATAOBJECT option to specify the file name. Syntax:

Syntax:

```
AZURE (endpoint, authKey1, authKey2, bucket)
```

where:

endpoint
A character string that specifies the URL of the AZURE web service.

authKey1
A character string that specifies the access ID or username of the Azure Blob Storage account used to validate the user.

authKey2
A character string that specifies the access key of the Azure Blob Storage account used to validate the user.

bucket
The name of the Azure Blob Storage container (bucket) in which the file resides.

Example:

```
CREATE EXTERNAL TABLE exttab1(a int) using
  (dataobject 'datafile1.dat'
   azure('https://my_account.blob.core.windows.net',
    'my_account',
    'lW+oHjmZecPS++IKgThAHlMUOaFUA5C6Z2RlFmc9JPpK34RO/ZIOywzILxJnzGPHz6d/
yDrcQDAwH5wySbOZMQ==',
    'my_bucket'
   )
  )
```

Example using IBM Cloud Object Storage:

```
CREATE EXTERNAL TABLE exttab2(a int) using
  (dataobject 'datafile2.dat'
   s3('s3-api.us-geo.objectstorage.softlayer.net',
    '1a2bkXXXsaddntLo0xX0',
    'XXxxiEPjJ7T7WBUz74E6abcdABCDE8Q7RgU4gYY9',
    'my_dev'
   )
  )
```

TIMEDELIM
The single-byte character that is to separate time components (hours, minutes, and seconds). The default is ' : '. If TIMEDELIM is set to an empty string, hours, minutes, and seconds must all be specified as two-digit numbers. The TIMESTAMP_FORMAT and TIMEDELIM options are mutually exclusive.

TIMEROUNDNANOS or TIMEEXTRAZEROS

Note: This option applies only to TIMESTAMP columns.

Specifies whether records that contain time values whose non-zero precision exceeds six decimal places are to be accepted (and rounded to the nearest microsecond) or rejected:

TRUE
All records are accepted. Their time values are rounded to the nearest microsecond.

FALSE
Only those records that can be stored without a loss of precision (for example, '08.15.32.123' or '08.15.32.12345600000', but not '08.15.32.1234567') are accepted. All other records are rejected. This is the default.

TIMESTYLE
The time format that is to be used in the data file:

24HOUR
24-hour format, for example 23:55. This is the default.

12HOUR
12-hour format, for example 11:55 PM. An AM or PM token can be preceded by a single space and is not case-sensitive.

The TIMESTYLE option and the TIME_FORMAT or TIMESTAMP_FORMAT option are mutually exclusive.

TIMESTAMP_FORMAT
The format of the timestamp field in the data file. The value can be any of the format strings that are accepted by the “TIMESTAMP_FORMAT ” on page 527. The default is **'YYYY-MM-DD HH.MI.SS'**. The TIMESTAMP_FORMAT option and the TIMEDELIM, DATEDELIM, TIMESTYLE, or DATESTYLE option are mutually exclusive.

TIME_FORMAT
The format of the time field in the data file. The value can be any of the time format strings that are accepted by the “TIMESTAMP_FORMAT ” on page 527. The default is **HH.MI.SS**. The TIME_FORMAT option and a TIMEDELIM or TIMESTYLE option are mutually exclusive.

TRIMBLANKS
How an external table is to treat leading or trailing blanks (that is, leading or trailing space characters) in a string:

LEADING
All leading blanks (that is, blanks that precede the first non-blank character) are removed.

TRAILING
All trailing blanks (that is, blanks that follow the last non-blank character) are removed.

BOTH
All leading and trailing blanks are removed.

NONE
No blanks are removed. This is the default.

When reading data from a file and loading it into an external table:

- If QUOTEDVALUE or STRING_DELIMITER is specified with the values SINGLE, YES, or DOUBLE, leading and trailing blanks within quotation marks are not removed.
- For CHAR and NCHAR data, the values TRAILING or BOTH will not have any effect on trailing blanks, because the string will automatically be re-padded with trailing blanks.

TRUNCSTRING or TRUNCATE_STRING
How the system processes a CHAR or VARCHAR string that exceeds its declared storage size:

TRUE
The system truncates a string value that exceeds its declared storage size.

FALSE
The system returns an error when a string value exceeds its declared storage size. This is the default.

Y2BASE
The year that is the beginning of the 100-year range. Years that are specified as 2 digits are counted from this year. The default is 2000. This option must be specified when DATESTYLE is set to Y2MD, MDY2, DMY2, MONDY2 or DMONY2.

Table 111. Options

Option	Default	Applies to Load	Applies to Unload
Azure **Attention:** This option only applies to the container-only release of Db2 Version 11.5 Mod Pack 1 or later versions.	(no default)	Y	Y
BOOLSTYLE or BOOLEAN_STYLE	1_0	Y	Y
CARDINALITY	(no default)	Y	Y
CCSID	(no default)	Y	Y
COMPRESS	NO	Y	Y
CRINSTRING	FALSE	Y	Y
CTRLCHARS	FALSE	Y	N
DATAOBJECT or FILE_NAME	(no default)	Y	Y
DATEDELIM	'-'	Y	Y
DATETIMEDELIM	A space (' ')	Y	Y
DATESTYLE	YMD	Y	Y
DATE_FORMAT	YYYY-MM-DD	Y	Y

Table 111. Options (continued)

Option	Default	Applies to Load	Applies to Unload
DECIMALDELIM or DECIMAL_CHARACTER	'.'	Y	Y
DELIMITER	'|'	Y	Y
ENCODING	INTERNAL	Y	Y[1]
ESCAPECHAR or ESCAPE_CHARACTER	(no default)	Y	Y
FILLRECORD	FALSE	Y	N
FORMAT or FILE_FORMAT	TEXT	Y	Y
IGNOREZERO or TRIM_NULLS	FALSE	Y	N
INCLUDEHEADER or COLUMN_NAMES	FALSE	N	Y
INCLUDEZEROSECONDS	FALSE	Y	Y
INCLUDEHIDDEN	FALSE	Y	N
LFINSTRING	FALSE	Y	N
LOGDIR or ERROR_LOG	target directory of external-table file	Y	N
MULTIPARTSIZEMB	value specified by the MULTIPARTSIZEMB dbm config parameter.	Y	N
MAXERRORS or MAX_ERRORS	1	Y	N
MAXROWS or MAX_ROWS	0	Y	N
MERIDIANDELIM	A space (' ')	Y	Y
NOLOG	FALSE	Y	Y
NULLVALUE or NULL_VALUE	'NULL'	Y	Y
PARTITION	(no default)	Y	Y
QUOTEDNULL	TRUE	Y	N
QUOTEDVALUE	NO	Y	N
RECORDDELIM or RECORD_DELIMITER	'\n'	Y	N
REMOTESOURCE	LOCAL	Y	Y
REQUIREQUOTES	FALSE	Y	N
SKIPROWS or SKIP_ROWS	0	Y	N
SOCKETBUFSIZE	8 MB	Y	Y
STRICTNUMERIC	FALSE	Y	N
SWIFT	(no default)	Y	Y
S3	(no default)	Y	Y
TIMEDELIM	':'	Y	Y

Table 111. Options (continued)			
Option	**Default**	**Applies to Load**	**Applies to Unload**
TIMEROUNDNANOS or TIMEEXTRAZEROS	FALSE	Y	N
TIMESTAMP_FORMAT	'YYYY-MM-DD HH.MI.SS'	Y	Y
TIMESTYLE	24HOUR	Y	Y
TIME_FORMAT	HH.MI.SS	Y	Y
TRIMBLANKS	NONE	Y	Y
TRUNCSTRING or TRUNCATE_STRING	FALSE	Y	N
Y2BASE	2000	Y	N
[1] Only for the values INTERNAL, UTF8, and LATIN9.			

joined-table

A *joined-table* specifies an intermediate result set that is the result of one or more join operations. For more information, see "joined-table" on page 685.

period-specification

A *period-specification* identifies an intermediate result table consisting of the rows of the referenced table where the period matches the specification. A *period-specification* can be specified following the name of a temporal table or the name of a view. The same period name must not be specified more than once for the same table reference (SQLSTATE 428HY). The rows of the table reference are derived by application of the period specifications.

If the table is a system-period temporal table and a *period-specification* for the SYSTEM_TIME period is not specified, the table reference includes all current rows and does not include any historical rows of the table. If the table is an application-period temporal table and a *period-specification* for the BUSINESS_TIME period is not specified, the table reference includes all rows of the table. If the table is a bitemporal table and a *period-specification* is not specified for both SYSTEM_TIME and BUSINESS_TIME, the table reference includes all current rows of the table and does not include any historical rows of the table.

If the table reference is a single-view-reference, the rows of the view reference are derived by application of the period specifications to all of the temporal tables accessed when computing the result table of the view. If the view does not access any temporal table, then the *period-specification* has no effect on the result table of the view. If *period-specification* is used, the view definition or any view definitions referenced when computing the result table of the view must not include any references to compiled SQL functions or external functions with a data access indication other than NO SQL (SQLSTATE 428HY).

If the CURRENT TEMPORAL SYSTEM_TIME special register is set to a value other than the null value, then a *period-specification* that references SYSTEM_TIME must not be specified for the table reference or view reference, unless the value in effect for the SYSTIMESENSITIVE bind option is NO (SQLSTATE 428HY).

If the CURRENT TEMPORAL BUSINESS_TIME special register is set to a value other than the null value, then a period specification that references BUSINESS_TIME must not be specified for the table reference or view reference, unless the value in effect for the BUSTIMESENSITIVE bind option is NO (SQLSTATE 428HY).

FOR SYSTEM_TIME

Specifies that the SYSTEM_TIME period is used for the *period-specification*. If the clause is specified following a *table-name*, the table must be a system-period temporal table (SQLSTATE 428HY). FOR SYSTEM_TIME must not be specified if the value of the CURRENT TEMPORAL SYSTEM_TIME special register is not the null value and the SYSTIMESENSITIVE bind option is set to YES (SQLSTATE 428HY).

FOR BUSINESS_TIME

Specifies that the BUSINESS_TIME period is used for the *period-specification*. If the clause is specified following a *table-name*, BUSINESS_TIME must be a period defined in the table (SQLSTATE 4274M). FOR BUSINESS_TIME must not be specified if the value of the CURRENT TEMPORAL BUSINESS_TIME special register is not the null value and the BUSTIMESENSITIVE bind option is set to YES (SQLSTATE 428HY).

value*, *value1*, and *value2

The *value*, *value1*, and *value2* expressions return the null value or a value of one of the following built-in data types (SQLSTATE 428HY): a DATE, a TIMESTAMP, or a character string that is not a CLOB or DBCLOB. If the argument is a character string, it must be a valid character string representation of a timestamp or a date (SQLSTATE 22007). For the valid formats of string representations of timestamp values, see the section "String representations of datetime values" in the topic Datetime values.

Each expression can contain any of the following supported operands (SQLSTATE 428HY):

- Constant
- Special register
- Variable. For details, refer to “References to variables” on page 19.
- Parameter marker
- Scalar function whose arguments are supported operands (user-defined functions and non-deterministic functions cannot be used)
- CAST specification where the cast operand is a supported operand
- Expression using arithmetic operators and operands

AS OF *value*

Specifies that the table reference includes each row for which the value of the begin column for the specified period is less than or equal to *value*, and the value of the end column for the period is greater than *value*. If *value* is the null value, the table reference is an empty table.

Example: The following query returns the insurance coverage information for insurance policy number 100 on August 31, 2010.

```
SELECT coverage FROM policy_info FOR BUSINESS_TIME
        AS OF '2010-08-31' WHERE policy_id = '100'
```

FROM *value1* TO *value2*

Specifies that the table reference includes rows that exist for the period specified from *value1* to *value2*. A row is included in the table reference if the value of the begin column for the specified period in the row is less than *value2*, and the value of the end column for the specified period in the row is greater than *value1*. The table reference contains zero rows if *value1* is greater than or equal to *value2*. If *value1* or *value2* is the null value, the table reference is an empty table.

Example: The following query returns the insurance coverage information for insurance policy 100, during the year 2009 (from January 1, 2009 at 12:00 AM until before January 1, 2010).

```
SELECT coverage FROM policy_info FOR BUSINESS_TIME
        FROM '2009-01-01' TO '2010-01-01' WHERE policy_id = '100'
```

BETWEEN *value1* AND *value2*

Specifies that the table reference includes rows in which the specified period overlaps at any point in time between *value1* and *value2*. A row is included in the table reference if the value of the begin column for the specified period in the row is less than or equal to *value2* and the value of the end column for the specified period in the row is greater than *value1*. The table reference contains zero rows if *value1* is greater than *value2*. If *value1* is equal to *value2*, the expression is equivalent to AS OF *value1*. If *value1* or *value2* is the null value, the table reference is an empty table.

Example: The following query returns the insurance coverage information for insurance policy number 100, during the year 2008 (between January 1, 2008 and December 31, 2008 inclusive).

```
SELECT coverage FROM policy_info FOR BUSINESS_TIME
        BETWEEN '2008-01-01' AND '2008-12-31' WHERE policy_id = '100'
```

Following are syntax alternatives for *period-specification* clauses:

- AS OF TIMESTAMP can be specified in place of FOR SYSTEM_TIME AS OF
- VERSIONS BETWEEN TIMESTAMP can be specified in place of FOR SYSTEM_TIME BETWEEN

correlation-clause

The exposed names of all table references must be unique. An exposed name is:

- A *correlation-name*
- A *table-name* that is not followed by a *correlation-name*
- A *view-name* that is not followed by a *correlation-name*
- A *nickname* that is not followed by a *correlation-name*
- An *alias-name* that is not followed by a *correlation-name*

If a *correlation-clause* clause does not follow a *function-name* reference, *xmltable-expression* expression, nested table expression, or *data-change-table-reference* reference, or if a *typed-correlation-clause* clause does not follow a *function-name* reference, then there is no exposed name for that table reference.

Each *correlation-name* is defined as a designator of the immediately preceding *table-name*, *view-name*, *nickname*, *function-name* reference, *xmltable-expression*, nested table expression, or *data-change-table-reference*. Any qualified reference to a column must use the exposed name. If the same table name, view, or nickname is specified twice, at least one specification must be followed by a *correlation-name*. The *correlation-name* is used to qualify references to the columns of the table, view or nickname. When a *correlation-name* is specified, *column-name*s can also be specified to give names to the columns of the table reference. If the *correlation-clause* does not include *column-name*s, the exposed column names are determined as follows:

- Column names of the referenced table, view, or nickname when the *table-reference* is a *table-name*, *view-name*, *nickname*, or *alias-name*
- Column names specified in the RETURNS clause of the CREATE FUNCTION statement when the *table-reference* is a *function-name* reference
- Column names specified in the COLUMNS clause of the *xmltable-expression* when the *table-reference* is an *xmltable-expression*
- Column names exposed by the fullselect when the *table-reference* is a *nested-table-expression*
- Column names from the target table of the data change statement, along with any defined INCLUDE columns when the *table-reference* is a *data-change-table-reference*

tablesample-clause

The optional *tablesample-clause* can be used to obtain a random subset (a sample) of the rows from the specified *table-name*, rather than the entire contents of that *table-name*, for this query. This sampling is in addition to any predicates that are specified in the *where-clause*. Unless the optional REPEATABLE clause is specified, each execution of the query will usually yield a different sample, except in degenerate cases where the table is so small relative to the sample size that any

sample must return the same rows. The size of the sample is controlled by the *numeric-expression1* in parentheses, representing an approximate percentage (P) of the table to be returned.

TABLESAMPLE

The method by which the sample is obtained is specified after the TABLESAMPLE keyword, and can be either BERNOULLI or SYSTEM. The exact number of rows in the sample might be different for each execution of the query, but on average is approximately P percent of the table, before any predicates further reduce the number of rows.

The *table-name* must be a stored table. It can be a materialized query table (MQT) name, but not a subselect or table expression for which an MQT has been defined, because there is no guarantee that the database manager will route to the MQT for that subselect.

Semantically, sampling of a table occurs before any other query processing, such as applying predicates or performing joins. Repeated accesses of a sampled table within a single execution of a query (such as in a nested-loop join or a correlated subquery) will return the same sample. More than one table can be sampled in a query.

BERNOULLI

BERNOULLI sampling considers each row individually. It includes each row in the sample with probability P/100 (where P is the value of *numeric-expression1*), and excludes each row with probability 1 - P/100, independently of the other rows. So if the *numeric-expression1* evaluated to the value 10, representing a ten percent sample, each row would be included with probability 0.1, and excluded with probability 0.9.

SYSTEM

SYSTEM sampling permits the database manager to determine the most efficient manner in which to perform the sampling. In most cases, SYSTEM sampling applied to a *table-name* means that each page of *table-name* is included in the sample with probability P/100, and excluded with probability 1 - P/100. All rows on each page that is included qualify for the sample. SYSTEM sampling of a *table-name* generally executes much faster than BERNOULLI sampling, because fewer data pages are retrieved. However, SYSTEM sampling can often yield less accurate estimates for aggregate functions, such as SUM(SALES), especially if the rows of *table-name* are clustered on any columns referenced in that query. The optimizer might in certain circumstances decide that it is more efficient to perform SYSTEM sampling as if it were BERNOULLI sampling. An example is when a predicate on *table-name* can be applied by an index and is much more selective than the sampling rate P.

numeric-expression1

The *numeric-expression1* specifies the size of the sample to be obtained from *table-name*, expressed as a percentage. It must be a constant numeric expression that cannot contain columns. The expression must evaluate to a positive number that is less than or equal to 100, but can be between 1 and 0. For example, a value of 0.01 represents one one-hundredth of a percent, meaning that 1 row in 10 000 is sampled, on average. A *numeric-expression1* that evaluates to 100 is handled as if the tablesample-clause were not specified. If *numeric-expression1* evaluates to the null value, or to a value that is greater than 100 or less than 0, an error is returned (SQLSTATE 2202H).

REPEATABLE (*numeric-expression2*)

It is sometimes desirable for sampling to be repeatable from one execution of the query to the next; for example, during regression testing or query debugging. This can be accomplished by specifying the REPEATABLE clause. The REPEATABLE clause requires the specification of a *numeric-expression2* in parentheses, which serves the same role as the seed in a random number generator. Adding the REPEATABLE clause to the tablesample-clause of any *table-name* ensures that repeated executions of that query (using the same value for *numeric-expression2*) return the same sample, assuming that the data itself has not been updated, reorganized, or repartitioned. To guarantee that the same sample of *table-name* is used across multiple queries, use of a global temporary table is recommended. Alternatively, the multiple queries can be combined into one query, with multiple references to a sample that is defined using the WITH clause.

Examples:

1. Request a 10% Bernoulli sample of the Sales table for auditing purposes.

```
SELECT * FROM Sales
  TABLESAMPLE BERNOULLI(10)
```

2. Compute the total sales revenue in the Northeast region for each product category, using a random 1% SYSTEM sample of the Sales table. The semantics of SUM are for the sample itself, so to extrapolate the sales to the entire Sales table, the query must divide that SUM by the sampling rate (0.01).

```
SELECT SUM(Sales.Revenue) / (0.01)
  FROM Sales TABLESAMPLE SYSTEM(1)
  WHERE Sales.RegionName = 'Northeast'
  GROUP BY Sales.ProductCategory
```

3. Using the REPEATABLE clause, modify the previous query to ensure that the same (yet random) result is obtained each time the query is executed. The value of the constant enclosed by parentheses is arbitrary.

```
SELECT SUM(Sales.Revenue) / (0.01)
  FROM Sales TABLESAMPLE SYSTEM(1) REPEATABLE(3578231)
  WHERE Sales.RegionName = 'Northeast'
  GROUP BY Sales.ProductCategory
```

table-UDF-cardinality-clause

The *table-UDF-cardinality* clause can be specified for each user-defined table function reference within the FROM clause. This option indicates the expected number of rows to be returned only for the SELECT statement that contains it. The CARDINALITY and CARDINALITY MULTIPLIER clauses are not allowed if the table function is an inlined SQL table function (SQLSTATE 42887).

CARDINALITY *integer-constant*

Specifies an estimate of the expected number of rows that are returned by the reference to the user-defined function. The value range of *integer-constant* is from 0 to 9 223 372 036 854 775 807 inclusive.

CARDINALITY MULTIPLIER *numeric-constant*

The product of the specified CARDINALITY MULTIPLIER *numeric-constant* and the reference cardinality value are used by the database server as the expected number of rows that are returned by the table function reference.

In this case, *numeric-constant* can be in the integer, decimal, or floating-point format. The value must be greater than or equal to zero. If the decimal number notation is used, the number of digits can be up to 31. An integer value is treated as a decimal number with no fraction. If zero is specified or the computed cardinality is less than 1, the cardinality of the reference to the user-defined table function is assumed to be 1.

The value in the CARDINALITY column of SYSSTAT.ROUTINES for the table function name is used as the reference cardinality value. If no value is set in the CARDINALITY column of SYSSTAT.ROUTINES, a finite value is assumed as its default value for the reference cardinality value. This finite value is the same value that is assumed for tables for which the RUNSTATS utility has not gathered statistics.

Only a numeric constant can follow the keyword CARDINALITY or CARDINALITY MULTIPLIER. A host variable or parameter marker is not supported. Specifying a cardinality value in a table function reference does not change the CARDINALITY column value for the function in the SYSSTAT.ROUTINES catalog view.

The CARDINALITY value for external and compiled SQL user-defined table functions can be changed by updating the CARDINALITY column in the SYSSTAT.ROUTINES catalog view. The CARDINALITY value for an external table function can also be initialized by specifying the CARDINALITY option in the CREATE FUNCTION (external table) statement when a user-defined table function is created.

typed-correlation-clause

A *typed-correlation-clause* clause defines the appearance and contents of the table generated by a generic table function. This clause must be specified when the table-function-references is a generic table function and cannot be specified for any other table reference. The following *data-type* values are supported in generic table functions:

Table 112. Data types supported in generic table functions

SQL column data type	Equivalent Java data type
SMALLINT	short
INTEGER	int
BIGINT	long
REAL	float
DOUBLE	double
DECIMAL(p,s)	java.math.BigDecimal
NUMERIC(p,s)	java.math.BigDecimal
CHAR(n)	java.lang.String
CHAR(n) FOR BIT DATA	COM.ibm.db2.app.Blob
VARCHAR(n)	java.lang.String
VARCHAR(n) FOR BIT DATA	COM.ibm.db2.app.Blob
GRAPHIC(n)	java.lang.String
VARGRAPHIC(n)	String
BLOB(n)	COM.ibm.db2.app.Blob
CLOB(n)	COM.ibm.db2.app.Clob
DBCLOB(n)	COM.ibm.db2.app.Clob
DATE	String
TIME	String
TIMESTAMP	String
XML AS CLOB(n)	COM.ibm.db2.jcc.DB2Xml

continue-handler

Certain errors that occur within a *nested-table-expression* can be tolerated, and instead of returning an error, the query can continue and return a result. This is referred to as an *error tolerant nested-table-expression*.

Specifying the RETURN DATA UNTIL clause will cause any rows that are returned from the fullselect before the indicated condition is encountered to make up the result set from the fullselect. This means that a partial result set (which can also be an empty result set) from the fullselect is acceptable as the result for the *nested-table-expression*.

The FEDERATED keyword restricts the condition to handle only errors that occur at a remote data source.

The condition can be specified as an SQLSTATE value, with a *string-constant* length of 5. You can optionally specify an SQLCODE value for each specified SQLSTATE value. For portable applications, specify SQLSTATE values as much as possible, because SQLCODE values are generally not portable across platforms and are not part of the SQL standard.

Only certain conditions can be tolerated. Errors that do not allow the rest of the query to be executed cannot be tolerated, and an error is returned for the whole query. The *specific-condition-value* might specify conditions that cannot actually be tolerated by the database manager, even if a specific SQLSTATE or SQLCODE value is specified, and for these cases, an error is returned.

A query or view containing an error tolerant *nested-table-expression* is read-only.

The fullselect of an error tolerant *nested-table-expression* is not optimized using materialized query tables.

specific-condition-value

The following SQLSTATE values and SQLCODE values have the potential, when specified, to be tolerated by the database manager:

- SQLSTATE 08001; SQLCODEs -1336, -30080, -30081, -30082
- SQLSTATE 08004
- SQLSTATE 42501
- SQLSTATE 42704; SQLCODE -204
- SQLSTATE 42720
- SQLSTATE 28000

Correlated references in table-references

Correlated references can be used in nested table expressions or as arguments to table functions. The basic rule that applies for both of these cases is that the correlated reference must be from a *table-reference* at a higher level in the hierarchy of subqueries. This hierarchy includes the table-references that have already been resolved in the left-to-right processing of the FROM clause. For nested table expressions, the LATERAL keyword must exist before the fullselect. The following examples have valid syntax:

```
Example 1:  SELECT t.c1, z.c5
            FROM t, TABLE( tf3(t.c2) ) AS z      -- t precedes tf3
            WHERE t.c3 = z.c4;                   -- in FROM, so t.c2
                                                 -- is known

Example 2:  SELECT t.c1, z.c5
            FROM t, TABLE( tf4(2 * t.c2) ) AS z  -- t precedes tf4
            WHERE t.c3 = z.c4;                   -- in FROM, so t.c2
                                                 -- is known

Example 3:  SELECT d.deptno, d.deptname,
                   empinfo.avgsal, empinfo.empcount
            FROM department d,
                 LATERAL (SELECT AVG(e.salary) AS avgsal,
                                 COUNT(*) AS empcount
                            FROM employee e           -- department precedes nested
                            WHERE e.workdept=d.deptno -- table expression and
                          ) AS empinfo;               -- LATERAL is specified,
                                                      -- so d.deptno is known
```

But the following examples are not valid:

```
Example 4:  SELECT t.c1, z.c5
            FROM TABLE( tf6(t.c2) ) AS z, t  -- cannot resolve t in t.c2!
            WHERE t.c3 = z.c4;               -- compare to Example 1 above.

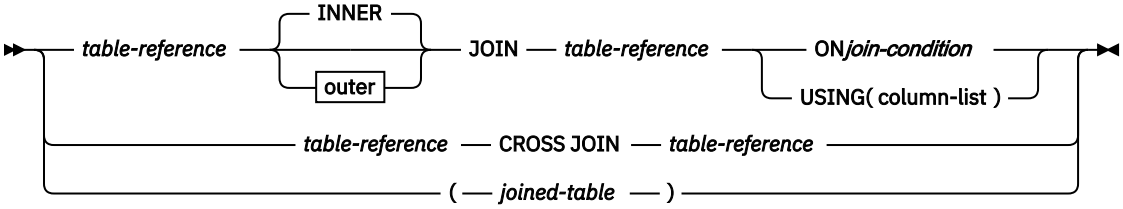
Example 5:  SELECT a.c1, b.c5
            FROM TABLE( tf7a(b.c2) ) AS a, TABLE( tf7b(a.c6) ) AS b
            WHERE a.c3 = b.c4;               -- cannot resolve b in b.c2!

Example 6:  SELECT d.deptno, d.deptname,
                   empinfo.avgsal, empinfo.empcount
            FROM department d,
                 (SELECT AVG(e.salary) AS avgsal,
                                 COUNT(*) AS empcount
                            FROM employee e           -- department precedes nested
                            WHERE e.workdept=d.deptno -- table expression but
```

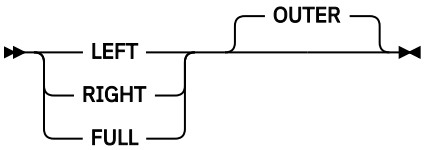
```
                      ) AS empinfo;              -- LATERAL is not specified,
                                                 -- so d.deptno is unknown
```

joined-table

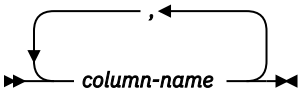
A *joined table* specifies an intermediate result table that is the result of either an inner join or an outer join. The table is derived by applying one of the join operators: CROSS, INNER, LEFT OUTER, RIGHT OUTER, or FULL OUTER to its operands.



outer



column-list



There are several types of joins:

Cross join
Represents the cross product of the tables, where each row of the left table is combined with every row of the right table.

Inner join
Keeps only the rows for which the join condition is true. Rows from either of the joined tables for which the join condition is false are excluded from the result table.

Outer join
Contains the rows for which the join condition is true, plus additional rows:

Left outer join
Also includes rows from the left table for which the join condition is false.

Right outer join
Also includes rows from the right table for which the join condition is false.

Full outer join
Also includes rows from both the left and right tables for which the join condition is false.

The order in which multiple joins are performed can affect the result. Joins can be nested within other joins. The order of processing for joins is generally from left to right, but based on the position of the required join-condition. You can use parentheses to clarify the order of nested joins. For example, the following two statements are equivalent:

```
T1 LEFT JOIN T2 ON T1.C1=T2.C1
  RIGHT JOIN T3 LEFT JOIN T4 ON T3.C1=T4.C1
    ON T1.C1=T3.C1
```

```
(T1 LEFT JOIN T2 ON T1.C1=T2.C1)
  RIGHT JOIN (T3 LEFT JOIN T4 ON T3.C1=T4.C1)
    ON T1.C1=T3.C1
```

A joined table can be used in any context in which any form of the SELECT statement is used. A view or a cursor is read-only if its SELECT statement includes a joined table.

Column references are resolved using the rules for resolution of column name qualifiers. The same rules that apply to predicates apply to join conditions.

Join operations

When a row of T1 is joined with a row of T2, a row in the result consists of the values of that row of T1 concatenated with the values of that row of T2. A join operation might result in the generation of a null row. A null row consists of a null value for each column of a table, regardless of whether null values are allowed in the columns.

The following list summarizes the result of the join operations:

- The result of T1 CROSS JOIN T2 consists of all possible pairings of their rows.
- The result of T1 INNER JOIN T2 consists of their paired rows where the join-condition is true.
- The result of T1 LEFT OUTER JOIN T2 consists of their paired rows where the join-condition is true and, for each unpaired row of T1, the concatenation of that row with the null row of T2. Null values are allowed in all columns derived from T2.
- The result of T1 RIGHT OUTER JOIN T2 consists of their paired rows where the join-condition is true and, for each unpaired row of T2, the concatenation of that row with the null row of T1. Null values are allowed in all columns derived from T1.
- The result of T1 FULL OUTER JOIN T2 consists of their paired rows and, for each unpaired row of T2, the concatenation of that row with the null row of T1 and, for each unpaired row of T1, the concatenation of that row with the null row of T2. Null values are allowed in all columns derived from T1 and T2.

Join conditions

A *join condition* is a qualification expression that involves the two tables to be joined. It specifies pairings of t1 and t2, where t1 and t2 represent the names of the left (t1) and right (t2) operand tables of the JOIN operator. For all possible combinations of rows of t1 and t2, a row of t1 is paired with a row of t2 if the join-condition is true.

A join condition is similar to a search condition, except that:

- It cannot include any dereference operations or the DEREF function, where the reference value is other than the object identifier column
- Any column referenced in an expression of the *join-condition* must be a column of one of the operand tables of the associated join (in the scope of the same joined-table clause)
- Any function referenced in an expression of the *join-condition* of a full outer join must be deterministic and have no external action
- It cannot include an XMLQUERY or XMLEXISTS expression

A join condition must comply with these rules (SQLSTATE 42972).

Join result

You influence which columns are included in the join result by specifying one of the following clauses:

ON <join-condition>
This clause can specify any qualification expression that involves the two tables that are to be joined. For example:

```
SELECT * FROM t1 JOIN t2 ON t1.c1 = t2.c1 AND t1.c2 = t2.c2;
```

The join result contains all columns of t1 followed by all columns of t2.

USING <column-list>

This clause joins the tables on the specified columns. Each column exists in both of the tables to be joined. The tables are joined where the value in a column is the same in both tables. For example:

```
SELECT * FROM t1 JOIN t2 USING (c1, c2);
```

The columns of the join result depend on the join type:

For an inner join or left outer join

The join result contains the join columns from the t1, followed by the non-join columns from t1, followed by the non-join columns from t2.

For a right outer join

The join result contains the join columns from t2, followed by the non-join columns from t1, followed by the non-join columns from t2.

For a full outer join

The join result has a non-null value from the join columns followed by the non-join columns from t1, followed by the non-join columns from t2.

Note that the join columns appear in the join result only once.

Unless a projection column list is explicitly specified, the order of the columns in the output is the same as in the join result.

Any subsequent, unqualified reference to a join column of a USING clause by another clause (such as a WHERE, ON, ORDER BY, GROUP BY, or HAVING clause) resolves to the column from the join result. For example:

```
CREATE TABLE t1 (c1 int, c2 varchar(10), c3 numeric(4,2));
CREATE TABLE t2 (c1 bigint, c2 char(8), c4 numeric(6,3));
CREATE TABLE t3 (c3 bigint, c5 int, c6 numeric(6,3));
```

```
SELECT * FROM t1 FULL JOIN t2 USING (c1, c2) JOIN t3 ON (c1 = t3.c3);
Column projections:
  CASE WHEN (t1.c1 IS NOT NULL) THEN t1.c1 ELSE t2.c1 END AS c1
  CASE WHEN (t1.c2 IS NOT NULL) THEN t1.c2 ELSE t2.c2 END AS c2
  t1.c3
  t2.c4
  t3.c3
  t3.c5
  t3.c6
```

The reference to column c1 in the ON clause resolves to the CASE expression that represents the join column c1 from the full outer join. So, the ON clause is transformed to:

```
ON ((CASE WHEN (t1.c1 IS NOT NULL) THEN t1.c1 ELSE t2.c1 END) = t3.c3)
```

The following restrictions apply:

- The ON and USING clauses are mutually exclusive for a particular join operation, that is, only one of these clauses can be specified when joining two tables. However, a single SQL statement can contain several join operations, and each of these can use either clause.
- An ON or USING clause cannot be used if a plus symbol (+) is used as the outer join operator.

Examples

Assume that the following three tables have been created:

```
CREATE TABLE t1 (c1 int, c2 varchar(10), c3 numeric(4,2));
CREATE TABLE t2 (c1 bigint, c2 char(8), c4 numeric(6,3));
CREATE TABLE t3 (c3 bigint, c5 int, c6 numeric(6,3));
```

- For a join with an ON clause:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.c1 = t2.c1 AND t1.c2 = t2.c2;
Column projections: t1.c1, t1.c2, t1.c3, t2.c1, t2.c2, t2.c4
```

```
SELECT * FROM t1 FULL JOIN t2 ON t1.c1 = t2.c1 AND t1.c2 = t2.c2;
Column projections: t1.c1, t1.c2, t1.c3, t2.c1, t2.c2, t2.c4
```

- For an inner join or left outer join with a USING clause:

```
SELECT * FROM t1 INNER JOIN t2 USING (c1, c2);
Column projections: t1.c1, t1.c2, t1.c3, t2.c4
```

```
SELECT * FROM t1 LEFT JOIN t2 USING (c1, c2);
Column projections: t1.c1, t1.c2, t1.c3, t2.c4
```

- For a right outer join with a USING clause:

```
SELECT * FROM t1 RIGHT JOIN t2 USING (c1, c2);
Column projections: t2.c1, t2.c2, t1.c3, t2.c4
```

- For a full outer join with a USING clause:

```
SELECT * FROM t1 FULL JOIN t2 USING (c1, c2);
Column projections:
  CASE WHEN (t1.c1 IS NOT NULL) THEN t1.c1 ELSE t2.c1 END AS c1
  CASE WHEN (t1.c2 IS NOT NULL) THEN t1.c2 ELSE t2.c2 END AS c2
  t1.c3
  t2.c4
```

Examples of subselect queries with joins
The following examples illustrate the use of joins in a subselect query.

- *Example 1:* This example illustrates the results of the various joins using tables J1 and J2. These tables contain rows as shown.

```
SELECT * FROM J1

W   X
--- ------
A       11
B       12
C       13

SELECT * FROM J2

Y   Z
--- ------
A       21
C       22
D       23
```

The following query does an inner join of J1 and J2 matching the first column of both tables.

```
SELECT * FROM J1 INNER JOIN J2 ON W=Y

W   X      Y   Z
--- ------ --- ------
A       11 A       21
C       13 C       22
```

In this inner join example the row with column W='C' from J1 and the row with column Y='D' from J2 are not included in the result because they do not have a match in the other table. Note that the following alternative form of an inner join query produces the same result.

```
SELECT * FROM J1, J2 WHERE W=Y
```

The following left outer join will get back the missing row from J1 with nulls for the columns of J2. Every row from J1 is included.

```
SELECT * FROM J1 LEFT OUTER JOIN J2 ON W=Y

W   X      Y   Z
--- ------ --- ------
A       11 A       21
```

```
B       12 -        -
C       13 C       22
```

The following right outer join will get back the missing row from J2 with nulls for the columns of J1. Every row from J2 is included.

```
SELECT * FROM J1 RIGHT OUTER JOIN J2 ON W=Y

W   X      Y   Z
--- ------ --- ------
A       11 A       21
C       13 C       22
-        - D       23
```

The following full outer join will get back the missing rows from both J1 and J2 with nulls where appropriate. Every row from both J1 and J2 is included.

```
SELECT * FROM J1 FULL OUTER JOIN J2 ON W=Y

W   X      Y   Z
--- ------ --- ------
A       11 A       21
C       13 C       22
-        - D       23
B       12 -        -
```

- *Example 2:* Using the tables J1 and J2 from the previous example, examine what happens when and additional predicate is added to the search condition.

```
SELECT * FROM J1 INNER JOIN J2 ON W=Y AND X=13

W   X      Y   Z
--- ------ --- ------
C       13 C       22
```

The additional condition caused the inner join to select only 1 row compared to the inner join in Example 1.

Notice what the affect of this is on the full outer join.

```
SELECT * FROM J1 FULL OUTER JOIN J2 ON W=Y AND X=13

W   X      Y   Z
--- ------ --- ------
-        - A       21
C       13 C       22
-        - D       23
A       11 -        -
B       12 -        -
```

The result now has 5 rows (compared to 4 without the additional predicate) because there was only 1 row in the inner join and all rows of both tables must be returned.

The following query illustrates that placing the same additional predicate in WHERE clause has completely different results.

```
SELECT * FROM J1 FULL OUTER JOIN J2 ON W=Y
   WHERE X=13

W   X      Y   Z
--- ------ --- ------
C       13 C       22
```

The WHERE clause is applied after the intermediate result of the full outer join. This intermediate result is the same as the result of the full outer join query in Example 1. The WHERE clause is applied to this intermediate result and eliminates all but the row that has X=13. Choosing the location of a predicate

when performing outer joins can have a significant affect on the results. Consider what happens if the predicate was X=12 instead of X=13. The following inner join returns no rows.

```
SELECT * FROM J1 INNER JOIN J2 ON W=Y AND X=12
```

Hence, the full outer join returns 6 rows, 3 from J1 with nulls for the columns of J2 and 3 from J2 with nulls for the columns of J1.

```
SELECT * FROM J1 FULL OUTER JOIN J2 ON W=Y AND X=12

W   X      Y   Z
--- ------ --- ------
-        - A       21
-        - C       22
-        - D       23
A       11 -        -
B       12 -        -
C       13 -        -
```

If the additional predicate is in the WHERE clause instead, 1 row is returned.

```
SELECT * FROM J1 FULL OUTER JOIN J2 ON W=Y
   WHERE X=12

W   X      Y   Z
--- ------ --- ------
B       12 -        -
```

- *Example 3:* List every department with the employee number and last name of the manager, including departments without a manager.

```
SELECT DEPTNO, DEPTNAME, EMPNO, LASTNAME
  FROM DEPARTMENT LEFT OUTER JOIN EMPLOYEE
       ON MGRNO = EMPNO
```

- *Example 4:* List every employee number and last name with the employee number and last name of their manager, including employees without a manager.

```
SELECT E.EMPNO, E.LASTNAME, M.EMPNO, M.LASTNAME
  FROM EMPLOYEE E LEFT OUTER JOIN
                                        DEPARTMENT INNER JOIN EMPLOYEE M
       ON MGRNO = M.EMPNO
       ON E.WORKDEPT = DEPTNO
```

The inner join determines the last name for any manager identified in the DEPARTMENT table and the left outer join guarantees that each employee is listed even if a corresponding department is not found in DEPARTMENT.

where-clause

The WHERE clause specifies an intermediate result table that consists of those rows of R for which the *search-condition* is true. R is the result of the FROM clause of the subselect.

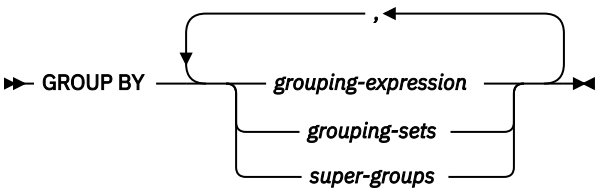
The *search-condition* must conform to the following rules:

- Each *column-name* must unambiguously identify a column of R or be a correlated reference. A *column-name* is a correlated reference if it identifies a column of a *table-reference* in an outer subselect.
- An aggregate function must not be specified unless the WHERE clause is specified in a subquery of a HAVING clause and the argument of the function is a correlated reference to a group.

Any subquery in the *search-condition* is effectively executed for each row of R, and the results are used in the application of the *search-condition* to the given row of R. A subquery is actually executed for each row of R only if it includes a correlated reference. In fact, a subquery with no correlated references might be executed just once, whereas a subquery with a correlated reference might be executed once for each row.

group-by-clause

The GROUP BY clause specifies an intermediate result table that consists of a grouping of the rows of R. R is the result of the previous clause of the subselect.



In its simplest form, a GROUP BY clause contains a *grouping expression*. A grouping expression is an *expression* used in defining the grouping of R. Each expression or *column name* included in grouping-expression must unambiguously identify a column of R (SQLSTATE 42702 or 42703). A grouping expression cannot include a scalar fullselect or an XMLQUERY or XMLEXISTS expression (SQLSTATE 42822), or any expression or function that is not deterministic or has an external action (SQLSTATE 42845).

Note: The following expressions, which do not contain an explicit column reference, can be used in a *grouping-expression* to identify a column of R:

- ROW CHANGE TIMESTAMP FOR *table-designator*
- ROW CHANGE TOKEN FOR *table-designator*
- RID_BIT or RID scalar function

More complex forms of the GROUP BY clause include *grouping-sets* and *super-groups*. For a description of *grouping-sets*, see "grouping-sets" on page 692. For a description of *super-groups*, see "super-groups" on page 692.

The result of GROUP BY is a set of groups of rows. Each row in this result represents the set of rows for which the *grouping-expression* is equal. For grouping, all null values from a *grouping-expression* are considered equal.

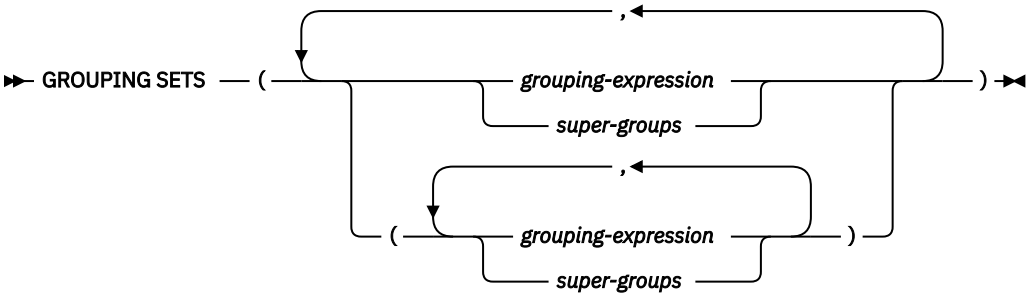
If a *grouping-expression* contains decimal floating-point columns, and multiple representations of the same number exist in these columns, the number that is returned can be any of the representations of the number.

A *grouping-expression* can be used in a search condition in a HAVING clause, in an expression in a SELECT clause, or in a *sort-key-expression* of an ORDER BY clause (see "order-by-clause" on page 703 for details). In each case, the reference specifies only one value for each group. For example, if the *grouping-expression* is *col1+col2*, then an allowed expression in the SELECT list is *col1+col2+3*. Associativity rules for expressions disallow the similar expression, *3+col1+col2*, unless parentheses are used to ensure that the corresponding expression is evaluated in the same order. Thus, *3+(col1+col2)* is also allowed in the SELECT list. If the concatenation operator is used, the *grouping-expression* must be used exactly as the expression was specified in the SELECT list.

If the *grouping-expression* contains varying-length strings with trailing blanks, the values in the group can differ in the number of trailing blanks and might not all have the same length. In that case, a reference to the *grouping-expression* still specifies only one value for each group. However, the value for a group is chosen arbitrarily from the available set of values or a normalized form that might or might not be from the available set of values. Thus, the actual length of the result value is unpredictable.

As noted, there are some cases where the GROUP BY clause cannot refer directly to a column that is specified in the SELECT clause as an expression (scalar-fullselect, not deterministic or external action functions). To group using such an expression, use a nested table expression or a common table expression to first provide a result table with the expression as a column of the result. For an example using nested table expressions, see Example 9 in "Examples of subselect queries" on page 708.

grouping-sets



A *grouping-sets* specification can be used to specify multiple grouping clauses in a single statement. This can be thought of as the union of two or more groups of rows into a single result set. It is logically equivalent to the union of multiple subselects with the group by clause in each subselect corresponding to one grouping set. A grouping set can be a single element or can be a list of elements delimited by parentheses, where an element is either a grouping-expression or a super-group. The groups can be computed with a single pass over the base table using *grouping-sets*.

A simple *grouping-expression* or the more complex forms of *super-groups* are supported by the *grouping-sets* specification. For a description of *super-groups*, see "super-groups" on page 692.

Note that grouping sets are the fundamental building blocks for GROUP BY operations. A simple GROUP BY with a single column can be considered a grouping set with one element. For example:

```
GROUP BY a
```

is the same as

```
GROUP BY GROUPING SETS((a))
```

and

```
GROUP BY a,b,c
```

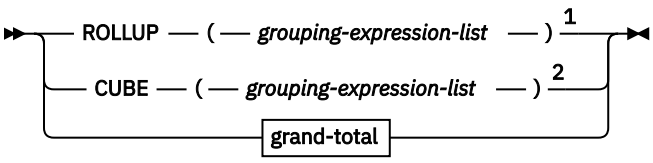
is the same as

```
GROUP BY GROUPING SETS((a,b,c))
```

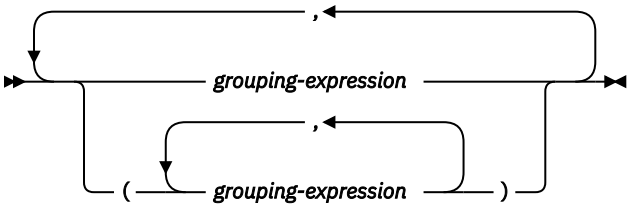
Non-aggregation columns from the SELECT list of the subselect that are excluded from a grouping set will return a null for such columns for each row generated for that grouping set. This reflects the fact that aggregation was done without considering the values for those columns.

The use of grouping sets is illustrated in Example 2 through Example 7 in "Examples of grouping sets, cube, and rollup queries" on page 696.

super-groups



grouping-expression-list



grand-total

Notes:

[1] Alternate specification when used alone in group-by-clause is: grouping-expression-list WITH ROLLUP.

[2] Alternate specification when used alone in group-by-clause is: grouping-expression-list WITH CUBE.

ROLLUP (*grouping-expression-list*)

A *ROLLUP grouping* is an extension to the GROUP BY clause that produces a result set containing *sub-total* rows in addition to the "regular" grouped rows. *Sub-total* rows are "super-aggregate" rows that contain further aggregates whose values are derived by applying the same aggregate functions that were used to obtain the grouped rows. These rows are called sub-total rows, because that is their most common use; however, any aggregate function can be used for the aggregation. For instance, MAX and AVG are used in Example 8 in "Examples of grouping sets, cube, and rollup queries" on page 696. The GROUPING aggregate function can be used to indicate if a row was generated by the super-group.

A ROLLUP grouping is a series of *grouping-sets*. The general specification of a ROLLUP with *n* elements

```
GROUP BY ROLLUP(C1,C2,...,Cn-1,Cn)
```

is equivalent to

```
GROUP BY GROUPING SETS((C1,C2,...,Cn-1,Cn)
                       (C1,C2,...,Cn-1)
                       ...
                       (C1,C2)
                       (C1)
                       () )
```

Note that the *n* elements of the ROLLUP translate to *n*+1 grouping sets. Note also that the order in which the *grouping-expressions* is specified is significant for ROLLUP. For example, the following clause:

```
GROUP BY ROLLUP(a,b)
```

is equivalent to:

```
GROUP BY GROUPING SETS((a,b)
                       (a)
                       () )
```

Similarly, the following clause:

```
GROUP BY ROLLUP(b,a)
```

is equivalent to:

```
GROUP BY GROUPING SETS((b,a)
                       (b)
                       () )
```

The ORDER BY clause is the only way to guarantee the order of the rows in the result set. Example 3 in "Examples of grouping sets, cube, and rollup queries" on page 696 illustrates the use of ROLLUP.

CUBE (*grouping-expression-list*)

A *CUBE grouping* is an extension to the GROUP BY clause that produces a result set that contains all the rows of a ROLLUP aggregation and, in addition, contains "cross-tabulation" rows. *Cross-tabulation* rows are additional "super-aggregate" rows that are not part of an aggregation with sub-totals. The GROUPING aggregate function can be used to indicate if a row was generated by the super-group.

Similar to a ROLLUP, a CUBE grouping can also be thought of as a series of *grouping-sets*. In the case of a CUBE, all permutations of the cubed *grouping-expression-list* are computed along with the grand total. Therefore, the *n* elements of a CUBE translate to 2**n* (2 to the power *n*) *grouping-sets*. For example, a specification of:

```
GROUP BY CUBE(a,b,c)
```

is equivalent to:

```
GROUP BY GROUPING SETS((a,b,c)
                       (a,b)
                       (a,c)
                       (b,c)
                       (a)
                       (b)
                       (c)
                       () )
```

Note that the three elements of the CUBE translate into eight grouping sets.

The order of specification of elements does not matter for CUBE. 'CUBE (DayOfYear, Sales_Person)' and 'CUBE (Sales_Person, DayOfYear)' yield the same result sets. The use of the word 'same' applies to content of the result set, not to its order. The ORDER BY clause is the only way to guarantee the order of the rows in the result set. The use of CUBE is illustrated in Example 4 in “Examples of grouping sets, cube, and rollup queries” on page 696.

grouping-expression-list

A *grouping-expression-list* is used within a CUBE or ROLLUP clause to define the number of elements in the CUBE or ROLLUP operation. This is controlled by using parentheses to delimit elements with multiple *grouping-expression*s.

For example, suppose that a query is to return the total expenses for the ROLLUP of City within a Province but not within a County. However, the clause:

```
GROUP BY ROLLUP(Province, County, City)
```

results in unwanted subtotal rows for the County. In the clause:

```
GROUP BY ROLLUP(Province, (County, City))
```

the composite (County, City) forms one element in the ROLLUP and, therefore, a query that uses this clause will yield the required result. In other words, the two-element ROLLUP:

```
GROUP BY ROLLUP(Province, (County, City))
```

generates:

```
GROUP BY GROUPING SETS((Province, County, City)
                       (Province)
                       () )
```

and the three-element ROLLUP generates:

```
GROUP BY GROUPING SETS((Province, County, City)
                       (Province, County)
                       (Province)
                       () )
```

Example 2 in “Examples of grouping sets, cube, and rollup queries” on page 696 also utilizes composite column values.

grand-total
Both CUBE and ROLLUP return a row which is the overall (grand total) aggregation. This can be separately specified with empty parentheses within the GROUPING SET clause. It can also be specified directly in the GROUP BY clause, although there is no effect on the result of the query. Example 4 in “Examples of grouping sets, cube, and rollup queries” on page 696 uses the grand-total syntax.

Combining grouping sets

This can be used to combine any of the types of GROUP BY clauses. When simple *grouping-expression* fields are combined with other groups, they are "appended" to the beginning of the resulting *grouping sets*. When ROLLUP or CUBE expressions are combined, they operate similarly to "multipliers" on the remaining expression, forming additional grouping set entries according to the definition of either ROLLUP or CUBE.

For instance, combining *grouping-expression* elements acts as follows:

```
GROUP BY a, ROLLUP(b,c)
```

is equivalent to

```
GROUP BY GROUPING SETS((a,b,c)
                       (a,b)
                       (a) )
```

Or similarly,

```
GROUP BY a, b, ROLLUP(c,d)
```

is equivalent to

```
GROUP BY GROUPING SETS((a,b,c,d)
                       (a,b,c)
                       (a,b) )
```

Combining of *ROLLUP* elements acts as follows:

```
GROUP BY ROLLUP(a), ROLLUP(b,c)
```

is equivalent to

```
GROUP BY GROUPING SETS((a,b,c)
                       (a,b)
                       (a)
                       (b,c)
                       (b)
                       () )
```

Similarly,

```
GROUP BY ROLLUP(a), CUBE(b,c)
```

is equivalent to

```
GROUP BY GROUPING SETS((a,b,c)
                       (a,b)
                       (a,c)
                       (a)
                       (b,c)
                       (b)
                       (c)
                       () )
```

Combining of *CUBE* and *ROLLUP* elements acts as follows:

```
GROUP BY CUBE(a,b), ROLLUP(c,d)
```

is equivalent to

```
GROUP BY GROUPING SETS((a,b,c,d)
                       (a,b,c)
                       (a,b)
                       (a,c,d)
                       (a,c)
                       (a)
                       (b,c,d)
                       (b,c)
                       (b)
                       (c,d)
                       (c)
                       () )
```

Similar to a simple *grouping-expression*, combining grouping sets also eliminates duplicates within each grouping set. For instance,

```
GROUP BY a, ROLLUP(a,b)
```

is equivalent to

```
GROUP BY GROUPING SETS((a,b)
                       (a) )
```

A more complete example of combining grouping sets is to construct a result set that eliminates certain rows that might be returned for a full CUBE aggregation.

For example, consider the following GROUP BY clause:

```
GROUP BY Region,
         ROLLUP(Sales_Person, WEEK(Sales_Date)),
         CUBE(YEAR(Sales_Date), MONTH (Sales_Date))
```

The column listed immediately to the right of GROUP BY is grouped, those within the parenthesis following ROLLUP are rolled up, and those within the parenthesis following CUBE are cubed. Thus, the GROUP BY clause results in a cube of MONTH within YEAR which is then rolled up within WEEK within Sales_Person within the Region aggregation. It does not result in any grand total row or any cross-tabulation rows on Region, Sales_Person or WEEK(Sales_Date) so produces fewer rows than the clause:

```
GROUP BY ROLLUP (Region, Sales_Person, WEEK(Sales_Date),
                 YEAR(Sales_Date), MONTH(Sales_Date) )
```

Examples of grouping sets, cube, and rollup queries

The following examples illustrate the grouping, cube, and rollup forms of subselect queries.

The queries in Example 1 through Example 4 use a subset of the rows in the SALES tables based on the predicate 'WEEK(SALES_DATE) = 13'.

```
SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       SALES_PERSON, SALES AS UNITS_SOLD
FROM SALES
WHERE WEEK(SALES_DATE) = 13
```

which results in:

```
WEEK        DAY_WEEK    SALES_PERSON    UNITS_SOLD
----------- ----------- --------------- -----------
         13           6 LUCCHESSI                 3
         13           6 LUCCHESSI                 1
         13           6 LEE                       2
         13           6 LEE                       2
```

```
          13           6 LEE                        3
          13           6 LEE                        5
          13           6 GOUNOT                     3
          13           6 GOUNOT                     1
          13           6 GOUNOT                     7
          13           7 LUCCHESSI                  1
          13           7 LUCCHESSI                  2
          13           7 LUCCHESSI                  1
          13           7 LEE                        7
          13           7 LEE                        3
          13           7 LEE                        7
          13           7 LEE                        4
          13           7 GOUNOT                     2
          13           7 GOUNOT                    18
          13           7 GOUNOT                     1
```

- *Example 1:* Here is a query with a basic GROUP BY clause over 3 columns:

```
SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       SALES_PERSON, SUM(SALES) AS UNITS_SOLD
FROM SALES
WHERE WEEK(SALES_DATE) = 13
GROUP BY WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE), SALES_PERSON
ORDER BY WEEK, DAY_WEEK, SALES_PERSON
```

  This results in:

```
WEEK        DAY_WEEK    SALES_PERSON    UNITS_SOLD
----------- ----------- --------------- -----------
         13           6 GOUNOT                   11
         13           6 LEE                      12
         13           6 LUCCHESSI                 4
         13           7 GOUNOT                   21
         13           7 LEE                      21
         13           7 LUCCHESSI                 4
```

- *Example 2:* Produce the result based on two different grouping sets of rows from the SALES table.

```
SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       SALES_PERSON, SUM(SALES) AS UNITS_SOLD
FROM SALES
WHERE WEEK(SALES_DATE) = 13
GROUP BY GROUPING SETS ( (WEEK(SALES_DATE), SALES_PERSON),
                         (DAYOFWEEK(SALES_DATE), SALES_PERSON))
ORDER BY WEEK, DAY_WEEK, SALES_PERSON
```

  This results in:

```
WEEK        DAY_WEEK    SALES_PERSON    UNITS_SOLD
----------- ----------- --------------- -----------
         13           - GOUNOT                   32
         13           - LEE                      33
         13           - LUCCHESSI                 8
          -           6 GOUNOT                   11
          -           6 LEE                      12
          -           6 LUCCHESSI                 4
          -           7 GOUNOT                   21
          -           7 LEE                      21
          -           7 LUCCHESSI                 4
```

  The rows with WEEK 13 are from the first grouping set and the other rows are from the second grouping set.

- *Example 3:* If you use the 3 distinct columns involved in the grouping sets of Example 2 and perform a ROLLUP, you can see grouping sets for (WEEK,DAY_WEEK,SALES_PERSON), (WEEK, DAY_WEEK), (WEEK) and grand total.

```
SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       SALES_PERSON, SUM(SALES) AS UNITS_SOLD
  FROM SALES
  WHERE WEEK(SALES_DATE) = 13
```

```
GROUP BY ROLLUP ( WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE), SALES_PERSON )
ORDER BY WEEK, DAY_WEEK, SALES_PERSON
```

This results in:

```
WEEK        DAY_WEEK    SALES_PERSON    UNITS_SOLD
----------- ----------- --------------- -----------
         13           6 GOUNOT                   11
         13           6 LEE                      12
         13           6 LUCCHESSI                 4
         13           6 -                        27
         13           7 GOUNOT                   21
         13           7 LEE                      21
         13           7 LUCCHESSI                 4
         13           7 -                        46
         13           - -                        73
          -           - -                        73
```

- *Example 4:* If you run the same query as Example 3 only replace ROLLUP with CUBE, you can see additional grouping sets for (WEEK,SALES_PERSON), (DAY_WEEK,SALES_PERSON), (DAY_WEEK), (SALES_PERSON) in the result.

```
SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       SALES_PERSON, SUM(SALES) AS UNITS_SOLD
FROM SALES
WHERE WEEK(SALES_DATE) = 13
GROUP BY CUBE ( WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE), SALES_PERSON )
ORDER BY WEEK, DAY_WEEK, SALES_PERSON
```

This results in:

```
WEEK        DAY_WEEK    SALES_PERSON    UNITS_SOLD
----------- ----------- --------------- -----------
         13           6 GOUNOT                   11
         13           6 LEE                      12
         13           6 LUCCHESSI                 4
         13           6 -                        27
         13           7 GOUNOT                   21
         13           7 LEE                      21
         13           7 LUCCHESSI                 4
         13           7 -                        46
         13           - GOUNOT                   32
         13           - LEE                      33
         13           - LUCCHESSI                 8
         13           - -                        73
          -           6 GOUNOT                   11
          -           6 LEE                      12
          -           6 LUCCHESSI                 4
          -           6 -                        27
          -           7 GOUNOT                   21
          -           7 LEE                      21
          -           7 LUCCHESSI                 4
          -           7 -                        46
          -           - GOUNOT                   32
          -           - LEE                      33
          -           - LUCCHESSI                 8
          -           - -                        73
```

- *Example 5:* Obtain a result set which includes a grand-total of selected rows from the SALES table together with a group of rows aggregated by SALES_PERSON and MONTH.

```
SELECT SALES_PERSON,
       MONTH(SALES_DATE) AS MONTH,
       SUM(SALES) AS UNITS_SOLD
FROM SALES
GROUP BY GROUPING SETS ( (SALES_PERSON, MONTH(SALES_DATE)),
                         ()
                       )
ORDER BY SALES_PERSON, MONTH
```

This results in:

```
SALES_PERSON    MONTH       UNITS_SOLD
--------------- ----------- -----------
```

```
GOUNOT                   3          35
GOUNOT                   4          14
GOUNOT                  12           1
LEE                      3          60
LEE                      4          25
LEE                     12           6
LUCCHESSI                3           9
LUCCHESSI                4           4
LUCCHESSI               12           1
-                        -         155
```

- *Example 6:* This example shows two simple ROLLUP queries followed by a query which treats the two ROLLUPs as grouping sets in a single result set and specifies row ordering for each column involved in the grouping sets.
  - *Example 6-1:*

```
SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       SUM(SALES) AS UNITS_SOLD
FROM SALES
GROUP BY ROLLUP ( WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE) )
ORDER BY WEEK, DAY_WEEK
```

    results in:

```
WEEK        DAY_WEEK    UNITS_SOLD
----------- ----------- -----------
         13           6          27
         13           7          46
         13           -          73
         14           1          31
         14           2          43
         14           -          74
         53           1           8
         53           -           8
          -           -         155
```

  - *Example 6-2:*

```
SELECT MONTH(SALES_DATE) AS MONTH,
       REGION,
       SUM(SALES) AS UNITS_SOLD
FROM SALES
GROUP BY ROLLUP ( MONTH(SALES_DATE), REGION );
ORDER BY MONTH, REGION
```

    results in:

```
MONTH       REGION          UNITS_SOLD
----------- --------------- -----------
          3 Manitoba                 22
          3 Ontario-North             8
          3 Ontario-South            34
          3 Quebec                   40
          3 -                       104
          4 Manitoba                 17
          4 Ontario-North             1
          4 Ontario-South            14
          4 Quebec                   11
          4 -                        43
         12 Manitoba                  2
         12 Ontario-South             4
         12 Quebec                    2
         12 -                         8
          - -                       155
```

  - *Example 6-3:*

```
SELECT WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       MONTH(SALES_DATE) AS MONTH,
       REGION,
       SUM(SALES) AS UNITS_SOLD
FROM SALES
GROUP BY GROUPING SETS ( ROLLUP( WEEK(SALES_DATE), DAYOFWEEK(SALES_DATE) ),
```

```
                          ROLLUP( MONTH(SALES_DATE), REGION )  )
ORDER BY WEEK, DAY_WEEK, MONTH, REGION
```

results in:

```
  WEEK        DAY_WEEK    MONTH       REGION          UNITS_SOLD
  ----------- ----------- ----------- --------------- -----------
           13           6           - -                        27
           13           7           - -                        46
           13           -           - -                        73
           14           1           - -                        31
           14           2           - -                        43
           14           -           - -                        74
           53           1           - -                         8
           53           -           - -                         8
            -           -           3 Manitoba                 22
            -           -           3 Ontario-North             8
            -           -           3 Ontario-South            34
            -           -           3 Quebec                   40
            -           -           3 -                       104
            -           -           4 Manitoba                 17
            -           -           4 Ontario-North             1
            -           -           4 Ontario-South            14
            -           -           4 Quebec                   11
            -           -           4 -                        43
            -           -          12 Manitoba                  2
            -           -          12 Ontario-South             4
            -           -          12 Quebec                    2
            -           -          12 -                         8
            -           -           - -                       155
            -           -           - -                       155
```

Using the two ROLLUPs as grouping sets causes the result to include duplicate rows. There are even two grand total rows.

Observe how the use of ORDER BY has affected the results:

- In the first grouped set, week 53 has been repositioned to the end.
- In the second grouped set, month 12 has now been positioned to the end and the regions now display in alphabetic order.
- Null values are sorted high.

- *Example 7:* In queries that perform multiple ROLLUPs in a single pass (such as Example 6-3) you might want to be able to indicate which grouping set produced each row. The following steps demonstrate how to provide a column (called GROUP) which indicates the *origin* of each row in the result set. *Origin* means which one of the two grouping sets produced the row in the result set.

  Step 1: Introduce a way of "generating" new data values, using a query which selects from a VALUES clause (which is an alternative form of a fullselect). This query shows how a table can be derived called "X" having 2 columns "R1" and "R2" and 1 row of data.

  ```
  SELECT R1,R2
  FROM (VALUES('GROUP 1','GROUP 2')) AS X(R1,R2);
  ```

  results in:

  ```
  R1      R2
  ------- -------
  GROUP 1 GROUP 2
  ```

  Step 2: Form the cross product of this table "X" with the SALES table. This add columns "R1" and "R2" to every row.

  ```
  SELECT R1, R2, WEEK(SALES_DATE) AS WEEK,
         DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
         MONTH(SALES_DATE) AS MONTH,
         REGION,
         SALES AS UNITS_SOLD
  FROM SALES,(VALUES('GROUP 1','GROUP 2')) AS X(R1,R2)
  ```

  This add columns "R1" and "R2" to every row.

Step 3: Now these columns can be combined with the grouping sets to include these columns in the rollup analysis.

```
SELECT R1, R2,
       WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       MONTH(SALES_DATE) AS MONTH,
       REGION, SUM(SALES) AS UNITS_SOLD
FROM SALES,(VALUES('GROUP 1','GROUP 2')) AS X(R1,R2)
GROUP BY GROUPING SETS ((R1, ROLLUP(WEEK(SALES_DATE),
                         DAYOFWEEK(SALES_DATE))),
                       (R2,ROLLUP( MONTH(SALES_DATE), REGION ) )  )
ORDER BY WEEK, DAY_WEEK, MONTH, REGION
```

results in:

```
R1      R2      WEEK     DAY_WEEK  MONTH     REGION          UNITS_SOLD
------- ------- -------- --------- --------- --------------- -----------
GROUP 1 -             13         6         - -                          27
GROUP 1 -             13         7         - -                          46
GROUP 1 -             13         -         - -                          73
GROUP 1 -             14         1         - -                          31
GROUP 1 -             14         2         - -                          43
GROUP 1 -             14         -         - -                          74
GROUP 1 -             53         1         - -                           8
GROUP 1 -             53         -         - -                           8
-       GROUP 2        -         -         3 Manitoba                   22
-       GROUP 2        -         -         3 Ontario-North               8
-       GROUP 2        -         -         3 Ontario-South              34
-       GROUP 2        -         -         3 Quebec                     40
-       GROUP 2        -         -         3 -                         104
-       GROUP 2        -         -         4 Manitoba                   17
-       GROUP 2        -         -         4 Ontario-North               1
-       GROUP 2        -         -         4 Ontario-South              14
-       GROUP 2        -         -         4 Quebec                     11
-       GROUP 2        -         -         4 -                          43
-       GROUP 2        -         -        12 Manitoba                    2
-       GROUP 2        -         -        12 Ontario-South               4
-       GROUP 2        -         -        12 Quebec                      2
-       GROUP 2        -         -        12 -                           8
-       GROUP 2        -         -         - -                         155
GROUP 1 -              -         -         - -                         155
```

Step 4: Notice that because R1 and R2 are used in different grouping sets, whenever R1 is non-null in the result, R2 is null and whenever R2 is non-null in the result, R1 is null. That means you can consolidate these columns into a single column using the COALESCE function. You can also use this column in the ORDER BY clause to keep the results of the two grouping sets together.

```
SELECT COALESCE(R1,R2) AS GROUP,
       WEEK(SALES_DATE) AS WEEK,
       DAYOFWEEK(SALES_DATE) AS DAY_WEEK,
       MONTH(SALES_DATE) AS MONTH,
       REGION, SUM(SALES) AS UNITS_SOLD
FROM SALES,(VALUES('GROUP 1','GROUP 2')) AS X(R1,R2)
GROUP BY GROUPING SETS ((R1, ROLLUP(WEEK(SALES_DATE),
                         DAYOFWEEK(SALES_DATE))),
                       (R2,ROLLUP( MONTH(SALES_DATE), REGION ) )  )
ORDER BY GROUP, WEEK, DAY_WEEK, MONTH, REGION;
```

results in:

```
GROUP   WEEK        DAY_WEEK    MONTH       REGION          UNITS_SOLD
------- ----------- ----------- ----------- --------------- -----------
GROUP 1          13           6           - -                          27
GROUP 1          13           7           - -                          46
GROUP 1          13           -           - -                          73
GROUP 1          14           1           - -                          31
GROUP 1          14           2           - -                          43
GROUP 1          14           -           - -                          74
GROUP 1          53           1           - -                           8
GROUP 1          53           -           - -                           8
GROUP 1           -           -           - -                         155
GROUP 2           -           -           3 Manitoba                   22
GROUP 2           -           -           3 Ontario-North               8
GROUP 2           -           -           3 Ontario-South              34
GROUP 2           -           -           3 Quebec                     40
```

```
GROUP 2           -           -           3 -                       104
GROUP 2           -           -           4 Manitoba                 17
GROUP 2           -           -           4 Ontario-North             1
GROUP 2           -           -           4 Ontario-South            14
GROUP 2           -           -           4 Quebec                   11
GROUP 2           -           -           4 -                        43
GROUP 2           -           -          12 Manitoba                  2
GROUP 2           -           -          12 Ontario-South             4
GROUP 2           -           -          12 Quebec                    2
GROUP 2           -           -          12 -                         8
GROUP 2           -           -           - -                       155
```

- *Example 8:* The following example illustrates the use of various aggregate functions when performing a CUBE. The example also makes use of cast functions and rounding to produce a decimal result with reasonable precision and scale.

```
SELECT MONTH(SALES_DATE) AS MONTH,
       REGION,
       SUM(SALES) AS UNITS_SOLD,
       MAX(SALES) AS BEST_SALE,
       CAST(ROUND(AVG(DECIMAL(SALES)),2) AS DECIMAL(5,2)) AS AVG_UNITS_SOLD
FROM SALES
GROUP BY CUBE(MONTH(SALES_DATE),REGION)
ORDER BY MONTH, REGION
```

This results in:

```
MONTH       REGION          UNITS_SOLD  BEST_SALE   AVG_UNITS_SOLD
----------- --------------- ----------- ----------- --------------
          3 Manitoba                 22           7           3.14
          3 Ontario-North             8           3           2.67
          3 Ontario-South            34          14           4.25
          3 Quebec                   40          18           5.00
          3 -                       104          18           4.00
          4 Manitoba                 17           9           5.67
          4 Ontario-North             1           1           1.00
          4 Ontario-South            14           8           4.67

         12 Quebec                    2           1           1.00
         12 -                         8           3           1.60
          - Manitoba                 41           9           3.73
          - Ontario-North             9           3           2.25
          - Ontario-South            52          14           4.00
          - Quebec                   53          18           4.42
          - -                       155          18           3.87
```

having-clause

The HAVING clause specifies an intermediate result table that consists of those groups of R for which the *search-condition* is true.

R is the result of the previous clause of the subselect. If this clause is not GROUP BY, R is considered to be a single group with no grouping columns.

Each *column-name* in the search condition must satisfy one of the following conditions:

- Unambiguously identify a grouping column of R.
- Be specified within an aggregate function.
- Be a correlated reference. A *column-name* is a correlated reference if it identifies a column of a *table-reference* in an outer subselect.

A group of R to which the search condition is applied supplies the argument for each aggregate function in the search condition, except for any function whose argument is a correlated reference.

If the search condition contains a subquery, the subquery can be thought of as being executed each time the search condition is applied to a group of R, and the results used in applying the search condition.

In actuality, the subquery is executed for each group only if it contains a correlated reference. For an illustration of the difference, see Example 6 and Example 7 in "Examples of subselect queries" on page 708.

A correlated reference to a group of R must either identify a grouping column or be contained within an aggregate function.

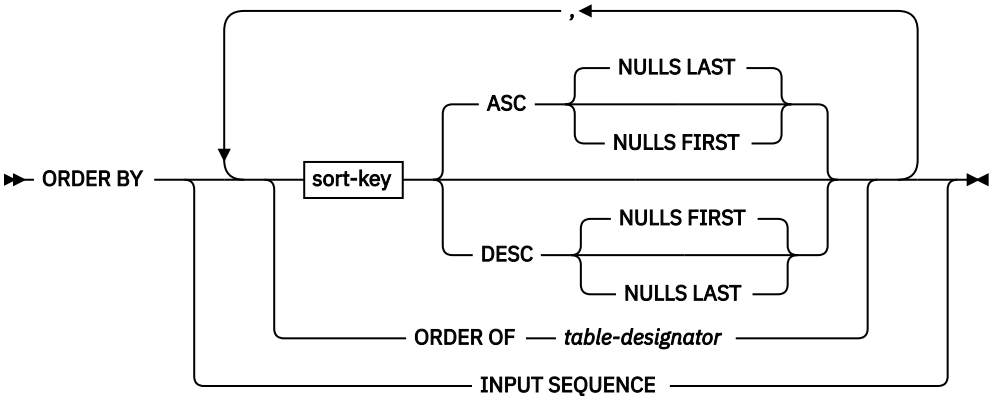
When HAVING is used without GROUP BY, the select list can only include column names when they are arguments to an aggregate function, correlated column references, global variables, host variables, literals, special registers, SQL variables, or SQL parameters.

Note: The following expressions can only be specified in a HAVING clause if they are contained within an aggregate function (SQLSTATE 42803):

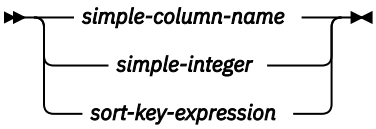
- ROW CHANGE TIMESTAMP FOR *table-designator*
- ROW CHANGE TOKEN FOR *table-designator*
- RID_BIT or RID scalar function

order-by-clause

The ORDER BY clause specifies an ordering of the rows of the result table.



sort-key



If a single sort specification (one *sort-key* with associated direction) is identified, the rows are ordered by the values of that sort specification. If more than one sort specification is identified, the rows are ordered by the values of the first identified sort specification, then by the values of the second identified sort specification, and so on. Each *sort-key* cannot have a data type of CLOB, DBCLOB, BLOB, XML, distinct type on any of these types, or structured type (SQLSTATE 42907).

A named column in the select list can be identified by a *sort-key* that is a *simple-integer* or a *simple-column-name*. An unnamed column in the select list must be identified by an *simple-integer* or, in some cases, by a *sort-key-expression* that matches the expression in the select list (see details of *sort-key-expression*). A column is unnamed if the AS clause is not specified and it is derived from a constant, an expression with operators, or a function.

Ordering is performed in accordance with comparison rules. If an ORDER BY clause contains decimal floating-point columns, and multiple representations of the same number exist in these columns, the ordering of the multiple representations of the same number is unspecified. The null value is higher than all other values. If the ORDER BY clause does not completely order the rows, rows with duplicate values of all identified columns are displayed in an arbitrary order.

simple-column-name
Usually identifies a column of the result table. In this case, *simple-column-name* must be the column name of a named column in the select list.

The *simple-column-name* can also identify a column name of a table, view, or nested table identified in the FROM clause if the query is a subselect. This includes columns defined as implicitly hidden. An error occurs in the following situations:

- If the subselect specifies DISTINCT in the select-clause (SQLSTATE 42822)
- If the subselect produces a grouped result and the *simple-column-name* is not a *grouping-expression* (SQLSTATE 42803)

Determining which column is used for ordering the result is described under "Column names in sort keys" in the "Notes" section.

simple-integer
Must be greater than 0 and not greater than the number of columns in the result table (SQLSTATE 42805). The integer *n* identifies the *n*th column of the result table.

sort-key-expression
An expression that is not simply a column name or an unsigned integer constant. The query to which ordering is applied must be a *subselect* to use this form of sort-key. The *sort-key-expression* cannot include a correlated scalar fullselect (SQLSTATE 42703) or a function with an external action (SQLSTATE 42845).

Any *column-name* within a *sort-key-expression* must conform to the rules described under "Column names in sort keys" in the "Notes" section.

There are a number of special cases that further restrict the expressions that can be specified.

- DISTINCT is specified in the SELECT clause of the subselect (SQLSTATE 42822).

  The sort-key-expression must match exactly with an expression in the select list of the subselect (scalar-fullselects are never matched).
- The subselect is grouped (SQLSTATE 42803).

  The sort-key-expression can:

  – be an expression in the select list of the subselect,
  – include a *grouping-expression* from the GROUP BY clause of the subselect
  – include an aggregate function, constant or host variable.

ASC
Order the rows in ascending order. This is the default.

DESC
Order the rows in descending order.

NULLS FIRST
When ordering rows in ascending or descending order, list null values before all other values.

NULLS LAST
When ordering rows in ascending or descending order, list null values after all other values.

ORDER OF *table-designator*
Specifies that the same ordering used in *table-designator* applies to the result table of the subselect. There must be a table reference matching *table-designator* in the FROM clause of the subselect that specifies this clause (SQLSTATE 42703). The ordering that is applied is the same as if the columns of the ORDER BY clause in the nested subselect (or fullselect) were included in the outer subselect (or fullselect), and these columns were specified in place of the ORDER OF clause.

Note that this form is not allowed in a fullselect (other than the degenerative form of a fullselect). For example, the following is not valid:

```
(SELECT C1 FROM T1
   ORDER BY C1)
```

```
UNION
SELECT C1 FROM T2
   ORDER BY ORDER OF T1
```

The following example *is* valid:

```
SELECT C1 FROM
   (SELECT C1 FROM T1
      UNION
    SELECT C1 FROM T2
    ORDER BY C1 ) AS UTABLE
ORDER BY ORDER OF UTABLE
```

INPUT SEQUENCE
Specifies that, for an INSERT statement, the result table will reflect the input order of ordered data rows. INPUT SEQUENCE ordering can only be specified if an INSERT statement is used in a FROM clause (SQLSTATE 428G4). See "table-reference" on page 644. If INPUT SEQUENCE is specified and the input data is not ordered, the INPUT SEQUENCE clause is ignored.

Notes

- **Column names in sort keys**:
  - The column name is qualified.

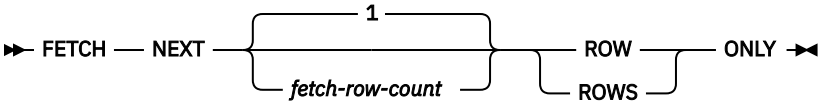
    The query must be a *subselect* (SQLSTATE 42877). The column name must unambiguously identify a column of some table, view or nested table in the FROM clause of the subselect (SQLSTATE 42702). The value of the column is used to compute the value of the sort specification.
  - The column name is unqualified.
    - The query is a subselect.

      If the column name is identical to the name of more than one column of the result table, the column name must unambiguously identify a column of some table, view or nested table in the FROM clause of the ordering subselect (SQLSTATE 42702). If the column name is identical to one column, that column is used to compute the value of the sort specification. If the column name is not identical to a column of the result table, then it must unambiguously identify a column of some table, view or nested table in the FROM clause of the fullselect in the select-statement (SQLSTATE 42702).
    - The query is not a subselect (it includes set operations such as union, except or intersect).

      The column name must not be identical to the name of more than one column of the result table (SQLSTATE 42702). The column name must be identical to exactly one column of the result table (SQLSTATE 42707), and this column is used to compute the value of the sort specification.
- **Limits**: The use of a *sort-key-expression* or a *simple-column-name* where the column is not in the select list might result in the addition of the column or expression to the temporary table used for sorting. This might result in reaching the limit of the number of columns in a table or the limit on the size of a row in a table. Exceeding these limits will result in an error if a temporary table is required to perform the sorting operation.

fetch-clause

The *fetch-clause* sets a maximum number of rows that can be retrieved.



The *fetch-clause* sets a maximum number of rows that can be retrieved. Use this clause to communicate to the database manager that the application is designed in such a way that it is not to retrieve more than *fetch-row-count* rows, regardless of how many rows there are in the intermediate result table. An attempt to fetch beyond *fetch-row-count* rows is handled the same way as normal end of data.

Determining a predictable set of rows to retrieve requires the specification of an ORDER BY clause with sort keys that would uniquely identify the sort order of each row in the intermediate result table. If the intermediate result table includes duplicate sort keys for some rows, the order of these rows is not deterministic. If there is no ORDER BY clause, the intermediate result table is not in a deterministic order. If the order of the intermediate result table is not deterministic, the set of rows that are retrieved is unpredictable.

fetch-row-count
An expression that specifies the maximum number of rows to retrieve. The expression must not contain a column reference, a scalar-fullselect, a function that is not deterministic, a function that has an external action, or a sequence reference (SQLSTATE 428H7). The numeric value must be a positive number or zero (SQLSTATE 2201W). If the data type of the expression is not BIGINT, the result of the expression is cast to a BIGINT value.

Use of the *fetch-clause* with a constant for *fetch-row-count* that is not greater than the maximum large integer influences query optimization of the subselect or fullselect. This influence on query optimization is based on the fact that, at most, a known number of rows will be retrieved. The database manager uses the *integer* from the *optimize-for-clause* to influence query optimization of the outermost fullselect if the following clauses are specified:

- The *fetch-clause* is specified in the outermost fullselect
- The *optimize-for-clause* is specified for the select statement

Limiting the result table to a specified number of rows can improve performance. In some cases, the database manager ceases to process the query when it has determined the specified number of rows. If the *offset-clause* is also specified with a constant for *offset-row-count*, the constant offset value is also considered when a determination is made to cease processing.

If the fullselect contains an SQL data change statement in the FROM clause, all the rows are modified regardless of the limit on the number of rows to fetch.

Notes

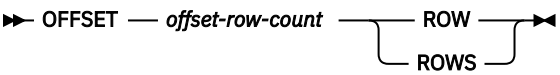
- The keywords FIRST and NEXT can be used interchangeably. The result is unchanged; however, using the keyword NEXT is more readable when the *offset-clause* is used.
- The keywords ROW and ROWS can be used interchangeably. The result is unchanged, however using ROWS is more readable when associated with a number of rows other than 1.
- ***Syntax alternatives***: The following are supported for compatibility with SQL used by other database products. These alternatives are non-standard and should not be used.

Table 113. Syntax alternatives

Alternative syntax	**Equivalent syntax**
LIMIT *x*	FETCH FIRST *x* ROWS ONLY
LIMIT *x* OFFSET *y*	OFFSET *y* ROWS FETCH NEXT *x* ROWS ONLY
LIMIT *y*, *x*	OFFSET *y* ROWS FETCH NEXT *x* ROWS ONLY

offset-clause

The *offset-clause* sets the number of rows to skip.



The *offset-clause* specifies the number of rows to skip before any rows are retrieved. Use this clause to communicate to the database manager that the application does not start retrieving rows until *offset-row-count* rows are skipped. If *offset-clause* is not specified, the default is equivalent to OFFSET 0 ROWS. An

attempt to skip more rows than the number of rows in the intermediate result table is handled the same way as an empty result table.

Determining a predictable set of rows to skip requires the specification of an ORDER BY clause with sort keys that would uniquely identify the sort order of each row in the intermediate result table. If the intermediate result table includes duplicate sort keys for some rows, the order of these rows is not deterministic. If there is no ORDER BY clause, the intermediate result table is not in a deterministic order. If the order of the intermediate result table is not deterministic, the set of skipped rows is unpredictable.

offset-row-count
An expression that specifies the number of rows to skip before any rows are retrieved. The expression must not contain a column reference, a scalar-fullselect, a function that is not deterministic, a function that has an external action, or a sequence reference (SQLSTATE 428H7). The numeric value must be a positive number or zero (SQLSTATE 2201X). If the data type of the expression is not BIGINT, the result of the expression is cast to a BIGINT value.

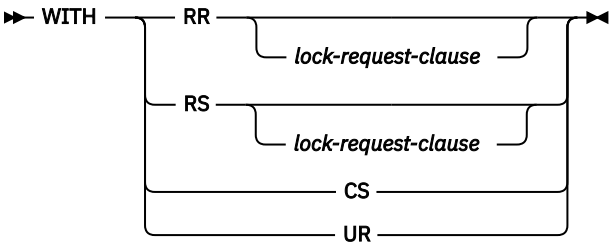
If the fullselect contains an SQL data change statement in the FROM clause, all the rows are modified regardless of the number of rows to skip.

Notes

- The keywords ROW and ROWS can be used interchangeably. The result is unchanged; however, using ROWS is more readable when associated with a number of rows other than 1.
- ***Syntax alternatives***: See the Notes entry that is associated with the fetch-clause for alternative syntax to set the number of rows to skip when the maximum number of rows to retrieve is specified.

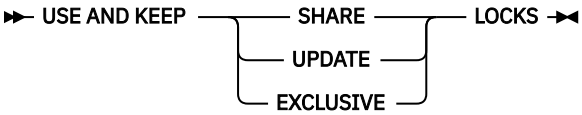
isolation-clause (subselect query)

The optional *isolation-clause* specifies the isolation level at which the subselect or fullselect is run, and whether a specific type of lock is to be acquired.



- RR - Repeatable Read
- RS - Read Stability
- CS - Cursor Stability
- UR - Uncommitted Read

lock-request-clause



The *lock-request-clause* applies only to queries and to positioning read operations within an insert, update, or delete operation. The insert, update, and delete operations themselves will run using locking determined by the database manager.

The optional *lock-request-clause* specifies the type of lock that the database manager is to acquire and hold:

SHARE
Concurrent processes can acquire SHARE or UPDATE locks on the data.

UPDATE
Concurrent processes can acquire SHARE locks on the data, but no concurrent process can acquire an UPDATE or EXCLUSIVE lock.

EXCLUSIVE
Concurrent processes cannot acquire a lock on the data.

***isolation-clause* restrictions**:

- The *isolation-clause* is not supported for a CREATE TABLE or ALTER TABLE statement (SQLSTATE 42601).
- The *isolation-clause* cannot be specified for a subselect or fullselect that will cause trigger invocation, referential integrity scans, or MQT maintenance (SQLSTATE 42601).
- A subselect or fullselect cannot include a *lock-request-clause* if that subselect or fullselect references any SQL functions that are not declared with the option INHERIT ISOLATION LEVEL WITH LOCK REQUEST (SQLSTATE 42601).
- A subselect or fullselect that contains a *lock-request-clause* are not be eligible for MQT routing.
- If an *isolation-clause* is specified for a *subselect* or *fullselect* within the body of an SQL function, SQL method, or trigger, the clause is ignored and a warning is returned.
- If an *isolation-clause* is specified for a *subselect* or *fullselect* that is used by a scrollable cursor, the clause is ignored and a warning is returned.
- Neither *isolation-clause* nor *lock-request-clause* can be specified in the context where they will cause conflict isolation or lock intent on a common table expression (SQLSTATE 42601). This restriction does not apply to aliases or base tables. The following examples create an isolation conflict on *a* and returns an error:
  - View:

    ```
    create view a as (...);
    (select * from a with RR USE AND KEEP SHARE LOCKS)
    UNION ALL
    (select * from a with UR);
    ```

  - Common table expression:

    ```
    WITH a as (...)
    (select * from a with RR USE AND KEEP SHARE LOCKS)
    UNION ALL
    (select * from a with UR);
    ```

- An *isolation-clause* cannot be specified in an XML context (SQLSTATE 2200M).
- The WITH clause specifying isolation cannot be specified at a subselect level in any statement that accesses a column-organized table (SQLSTATE 42858).
- ISOLATION LEVEL UR could behave differently on Column-organized tables and Row-oranized tables.

Examples of subselect queries

The following examples illustrate the susbelect query.

- Example 1 - Select all columns and rows from the EMPLOYEE table.

  ```
  SELECT * FROM EMPLOYEE
  ```

- Example 2 - Join the EMP_ACT and EMPLOYEE tables, select all the columns from the EMP_ACT table and add the employee's surname (LASTNAME) from the EMPLOYEE table to each row of the result.

  ```
  SELECT EMP_ACT.*, LASTNAME
    FROM EMP_ACT, EMPLOYEE
    WHERE EMP_ACT.EMPNO = EMPLOYEE.EMPNO
  ```

- Example 3 - Join the EMPLOYEE and DEPARTMENT tables, select the employee number (EMPNO), employee surname (LASTNAME), department number (WORKDEPT in the EMPLOYEE table, and DEPTNO in the DEPARTMENT table) and department name (DEPTNAME) of all employees who were born (BIRTHDATE) earlier than 1955.

```
SELECT EMPNO, LASTNAME, WORKDEPT, DEPTNAME
   FROM EMPLOYEE, DEPARTMENT
   WHERE WORKDEPT = DEPTNO
   AND YEAR(BIRTHDATE) < 1955
```

- Example 4 - Select the job (JOB) and the minimum and maximum salaries (SALARY) for each group of rows with the same job code in the EMPLOYEE table, but only for groups with more than one row and with a maximum salary greater than or equal to 27000.

```
 SELECT JOB, MIN(SALARY), MAX(SALARY)
   FROM EMPLOYEE
   GROUP BY JOB
   HAVING COUNT(*) > 1
   AND MAX(SALARY) >= 27000
```

- Example 5 - Select all the rows of EMP_ACT table for employees (EMPNO) in department (WORKDEPT) 'E11'. (Employee department numbers are shown in the EMPLOYEE table.)

```
SELECT *
  FROM EMP_ACT
  WHERE EMPNO IN
           (SELECT EMPNO
               FROM EMPLOYEE
               WHERE WORKDEPT = 'E11')
```

- Example 6 - From the EMPLOYEE table, select the department number (WORKDEPT) and maximum departmental salary (SALARY) for all departments whose maximum salary is less than the average salary for all employees.

```
SELECT WORKDEPT, MAX(SALARY)
  FROM EMPLOYEE
  GROUP BY WORKDEPT
  HAVING MAX(SALARY) < (SELECT AVG(SALARY)
                           FROM EMPLOYEE)
```

  The subquery in the HAVING clause is run once in this example.

- Example 7 - Using the EMPLOYEE table, select the department number (WORKDEPT) and maximum departmental salary (SALARY) for all departments whose maximum salary is less than the average salary in all other departments.

```
SELECT WORKDEPT, MAX(SALARY)
   FROM EMPLOYEE EMP_COR
    GROUP BY WORKDEPT
    HAVING MAX(SALARY) < (SELECT AVG(SALARY)
                             FROM EMPLOYEE
                             WHERE NOT WORKDEPT = EMP_COR.WORKDEPT)
```

  In contrast to Example 6, the subquery in the HAVING clause is run for each group.

- Example 8 - Determine the employee number and salary of sales representatives along with the average salary and head count of their departments.

  This query must first create a nested table expression (DINFO) to get the AVGSALARY and EMPCOUNT columns, and the DEPTNO column that is used in the WHERE clause.

```
SELECT THIS_EMP.EMPNO, THIS_EMP.SALARY, DINFO.AVGSALARY, DINFO.EMPCOUNT
 FROM EMPLOYEE THIS_EMP,
       (SELECT OTHERS.WORKDEPT AS DEPTNO,
                          AVG(OTHERS.SALARY) AS AVGSALARY,
                          COUNT(*) AS EMPCOUNT
         FROM EMPLOYEE OTHERS
         GROUP BY OTHERS.WORKDEPT
        ) AS DINFO
 WHERE THIS_EMP.JOB = 'SALESREP'
  AND THIS_EMP.WORKDEPT = DINFO.DEPTNO
```

Using a nested table expression for this case saves the processing resources of creating the DINFO view as a regular view. During statement preparation, accessing the catalog for the view is avoided. Because of the context of the rest of the query, only the rows for the department of the sales representatives are considered by the view.

- Example 9 - Display the average education level and salary for five random groups of employees.

  This query requires the use of a nested table expression to set a random value for each employee so that it can later be used in the GROUP BY clause.

```
SELECT RANDID , AVG(EDLEVEL), AVG(SALARY)
  FROM ( SELECT EDLEVEL, SALARY, INTEGER(RAND()*5) AS RANDID
           FROM EMPLOYEE
       ) AS EMPRAND
  GROUP BY RANDID
```

- Example 10 - Query the EMP_ACT table and return those project numbers that have an employee whose salary is in the top 10 of all employees.

```
SELECT EMP_ACT.EMPNO,PROJNO
   FROM EMP_ACT
   WHERE EMP_ACT.EMPNO IN
       (SELECT EMPLOYEE.EMPNO
        FROM EMPLOYEE
        ORDER BY SALARY DESC
        FETCH FIRST 10 ROWS ONLY)
```

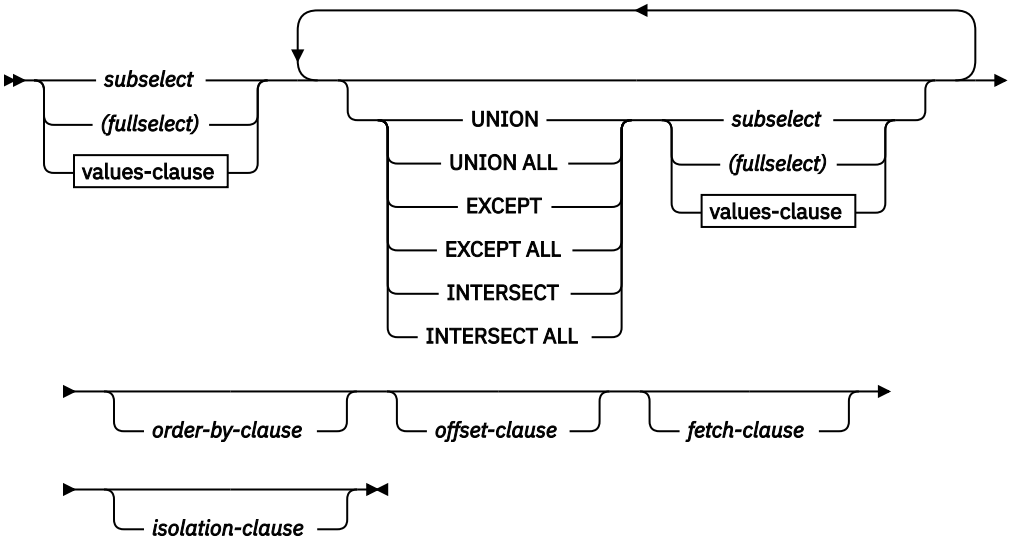
- Example 11 - Assuming that PHONES and IDS are two SQL variables with array values of the same cardinality, turn these arrays into a table with three columns (one for each array and one for the position), and one row per array element.

```
 SELECT T.PHONE, T.ID, T.INDEX FROM UNNEST(PHONES, IDS)
   WITH ORDINALITY AS T(PHONE, ID, INDEX)
   ORDER BY T.INDEX
```

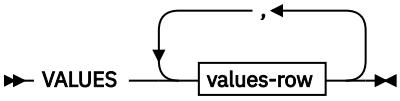
fullselect

The *fullselect* is a component of the select-statement, the INSERT statement, and the CREATE VIEW statement. It is also a component of certain predicates which, in turn, are components of a statement.

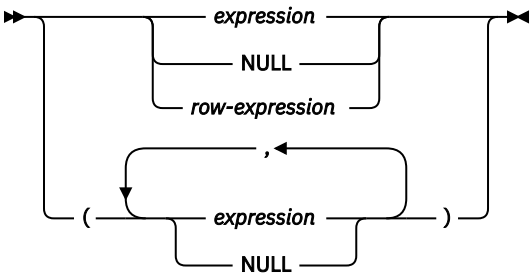
A fullselect that is a component of a predicate is called a *subquery*, and a fullselect that is enclosed in parentheses is sometimes called a subquery.



values-clause



values-row



The set operators UNION, EXCEPT, and INTERSECT correspond to the relational operators union, difference, and intersection.

A fullselect specifies a result table. If a set operator is not used, the result of the fullselect is the result of the specified subselect or values-clause.

The authorization for a *fullselect* is described in the Authorization section in "SQL queries".

values-clause

Derives a result table by specifying the actual values, using expressions or row expressions, for each column of a row in the result table. Multiple rows may be specified. If multiple rows are specified, the extended indicator variable values of DEFAULT and UNASSIGNED must not be used (SQLSTATE 22539). The result type of any expression in the *values-clause* cannot be a row type (SQLSTATE 428H2).

NULL can only be used with multiple specifications of *values-row*, either as the column value of a single column result table or within a *row-expression*, and at least one row in the same column must not be NULL (SQLSTATE 42608).

A *values-row* is specified by:

- A single expression for a single column result table
- *n* expressions (or NULL) separated by commas and enclosed in parentheses, where *n* is the number of columns in the result table or, a row expression for a multiple column result table.

A multiple row VALUES clause must have the same number of columns in each *values-row* (SQLSTATE 42826).

The following examples show *values-clause* and their meaning.

```
VALUES (1),(2),(3)          - 3 rows of 1 column
VALUES 1, 2, 3              - 3 rows of 1 column
VALUES (1, 2, 3)            - 1 row of 3 columns
VALUES (1,21),(2,22),(3,23) - 3 rows of 2 columns
```

A *values-clause* that is composed of *n* specifications of *values-row*, RE_1 to RE_n, where *n* is greater than 1, is equivalent to:

```
RE1 UNION ALL RE2 ... UNION ALL REn
```

This means that the corresponding columns of each *values-row* must be comparable (SQLSTATE 42825).

UNION or UNION ALL

Derives a result table by combining two other result tables (R1 and R2). If UNION ALL is specified, the result consists of all rows in R1 and R2. If UNION is specified without the ALL option, the result is the set of all rows in either R1 or R2, with the duplicate rows eliminated. In either case, however, each row of the UNION table is either a row from R1 or a row from R2.

EXCEPT or EXCEPT ALL
Derives a result table by combining two other result tables (R1 and R2). If EXCEPT ALL is specified, the result consists of all rows that do not have a corresponding row in R2, where duplicate rows are significant. If EXCEPT is specified without the ALL option, the result consists of all rows that are only in R1, with duplicate rows in the result of this operation eliminated.

For compatibility with other SQL implementations, MINUS can be specified as a synonym for EXCEPT.

INTERSECT or INTERSECT ALL
Derives a result table by combining two other result tables (R1 and R2). If INTERSECT ALL is specified, the result consists of all rows that are in both R1 and R2. If INTERSECT is specified without the ALL option, the result consists of all rows that are in both R1 and R2, with the duplicate rows eliminated.

The expression that corresponds to the nth column in R1 and R2 can reference columns with column masks. The nth column of the result of the set operation can be derived from the masked values in R1 or R2.

With the set operation, the elimination of the duplicate rows is based on the unmasked values in R1 and R2. Because all rows are from R1 or R2, the output values in the result table of the set operation may vary when one or more of the following conditions occur:

- The expression corresponding to the nth column in R1 references columns with column masks, but the expression corresponding to the nth column in R2 does not. The opposite is also true.
- The expressions corresponding to the nth column in R1 and R2 reference columns with different column masks.
- The column mask definition references columns that are not the same target column for which the column mask is defined, and those columns are not part of the set operation. It is recommended that the column mask definition does not reference other columns from the target table.

For example, a row in R1 is derived from the masked value, and a row in R2 is derived from the unmasked value. If the row in the result table is from R1, the masked value is returned. If the row in the result table is from R2, the unmasked value is returned.

order-by-clause
Refer to "subselect" on page 639 for details of the *order-by-clause*. A fullselect that contains an ORDER BY clause cannot be specified in (SQLSTATE 428FJ):

- A materialized query table
- The outermost fullselect of a view

Note: An ORDER BY clause in a fullselect does not affect the order of the rows that are returned by a query. An ORDER BY clause affects only the order of the rows that are returned if it is specified in the outermost fullselect. Specify an *order-by-clause* to ensure a predictable order for determining the set of rows from the fullselect if the *offset-clause* or *fetch-clause* are specified.

offset-clause
Refer to "subselect" on page 639 for details of the *offset-clause*. A fullselect that contains an OFFSET clause cannot be specified in the following situations (SQLSTATE 428FJ):

- A materialized query table
- The outermost fullselect of a view

fetch-clause
Refer to "subselect" on page 639 for details of the *fetch-clause*. A fullselect that contains a FETCH clause cannot be specified in the following situations (SQLSTATE 428FJ):

- A materialized query table
- The outermost fullselect of a view

isolation-clause

Refer to "subselect" on page 639 for details of the *isolation-clause*. If *isolation-clause* is specified for a fullselect and it could apply equally to a subselect of the fullselect, *isolation-clause* is applied to the fullselect. For example, consider the following query.

```
SELECT NAME FROM PRODUCT
UNION
SELECT NAME FROM CATALOG
WITH UR
```

Even though the isolation clause WITH UR could apply only to the subselect SELECT NAME FROM CATALOG, it is applied to the whole fullselect.

The number of columns in the result tables R1 and R2 must be the same (SQLSTATE 42826). If the ALL keyword is not specified, R1 and R2 must not include any columns having a data type of CLOB, DBCLOB, BLOB, distinct type on any of these types, or structured type (SQLSTATE 42907).

The column name of the *n*th column of the result table is the name of the *n*th column of R1 if it is named. Otherwise, the *n*th column of the result table is unnamed. If the fullselect is used as a select-statement, a generated name is provided when the statement is described. The generated name cannot be used in other parts of the SQL statement such as the ORDER BY clause or the UPDATE clause. The generated name can be determined by performing a DESCRIBE of the SQL statement and consulting the SQLNAME field.

Duplicate rows: Two rows are duplicates if each value in the first is equal to the corresponding value of the second. For determining duplicates, two null values are considered equal, and two decimal floating-point representations of the same number are considered equal. For example, 2.00 and 2.0 have the same value (2.00 and 2.0 compare as equal) but have different exponents, which allows you to represent both 2.00 and 2.0. So, for example, if the result table of a UNION operation contains a decimal floating-point column and multiple representations of the same number exist, the one that is returned (for example, 2.00 or 2.0) is unpredictable. For more information, see "Numeric comparisons" on page 65.

When multiple operations are combined in an expression, operations within parentheses are performed first. If there are no parentheses, the operations are performed from left to right with the exception that all INTERSECT operations are performed before UNION or EXCEPT operations.

In the following example, the values of tables R1 and R2 are shown on the left. The other headings listed show the values as a result of various set operations on R1 and R2.

R1	R2	UNION ALL	UNION	EXCEPT ALL	EXCEPT	INTER-SECT ALL	INTER-SECT
1	1	1	1	1	2	1	1
1	1	1	2	2	5	1	3
1	3	1	3	2		3	4
2	3	1	4	2		4	
2	3	1	5	4			
2	3	2		5			
3	4	2					
4		2					
4		3					
5		3					
		3					
		3					
		3					

R1	R2	UNION ALL	UNION	EXCEPT ALL	EXCEPT	INTER-SECT ALL	INTER-SECT
		4					
		4					
		4					
		5					

Examples of fullselect queries

The following examples illustrate fullselect queries.

- *Example 1:* Select all columns and rows from the EMPLOYEE table.

```
SELECT * FROM EMPLOYEE
```

- *Example 2:* List the employee numbers (EMPNO) of all employees in the EMPLOYEE table whose department number (WORKDEPT) either begins with 'E' **or** who are assigned to projects in the EMP_ACT table whose project number (PROJNO) equals 'MA2100', 'MA2110', or 'MA2112'.

```
SELECT EMPNO
   FROM EMPLOYEE
   WHERE WORKDEPT LIKE 'E%'
UNION
SELECT EMPNO
   FROM EMP_ACT
   WHERE PROJNO IN('MA2100', 'MA2110', 'MA2112')
```

- *Example 3:* Make the same query as in example 2, and, in addition, "tag" the rows from the EMPLOYEE table with 'emp' and the rows from the EMP_ACT table with 'emp_act'. Unlike the result from example 2, this query might return the same EMPNO more than once, identifying which table it came from by the associated "tag".

```
SELECT EMPNO, 'emp'
   FROM EMPLOYEE
   WHERE WORKDEPT LIKE 'E%'
UNION
SELECT EMPNO, 'emp_act' FROM EMP_ACT
   WHERE PROJNO IN('MA2100', 'MA2110', 'MA2112')
```

- *Example 4:* Make the same query as in example 2, only use UNION ALL so that no duplicate rows are eliminated.

```
SELECT EMPNO
    FROM EMPLOYEE
    WHERE WORKDEPT LIKE 'E%'
UNION ALL
SELECT EMPNO
   FROM EMP_ACT
   WHERE PROJNO IN('MA2100', 'MA2110', 'MA2112')
```

- *Example 5:* Make the same query as in Example 3, only include an additional two employees currently not in any table and tag these rows as "new".

```
SELECT EMPNO, 'emp'
   FROM EMPLOYEE
   WHEREWORKDEPTLIKE 'E%'
UNION
SELECT EMPNO, 'emp_act'
   FROM EMP_ACT
   WHERE PROJNO IN('MA2100', 'MA2110', 'MA2112')
UNION
   VALUES ('NEWAAA', 'new'), ('NEWBBB', 'new')
```

- *Example 6:* This example of EXCEPT produces all rows that are in T1 but not in T2.

```
(SELECT * FROM T1)
EXCEPT ALL
(SELECT * FROM T2)
```

If no null values are involved, this example returns the same results as

```
SELECT ALL *
   FROM T1
   WHERE NOT EXISTS (SELECT * FROM T2
                     WHERE T1.C1 = T2.C1 AND T1.C2 = T2.C2 AND...)
```

- *Example 7:* This example of INTERSECT produces all rows that are in both tables T1 and T2, removing duplicates.

```
(SELECT * FROM T1)
INTERSECT
(SELECT * FROM T2)
```

If no null values are involved, this example returns the same result as

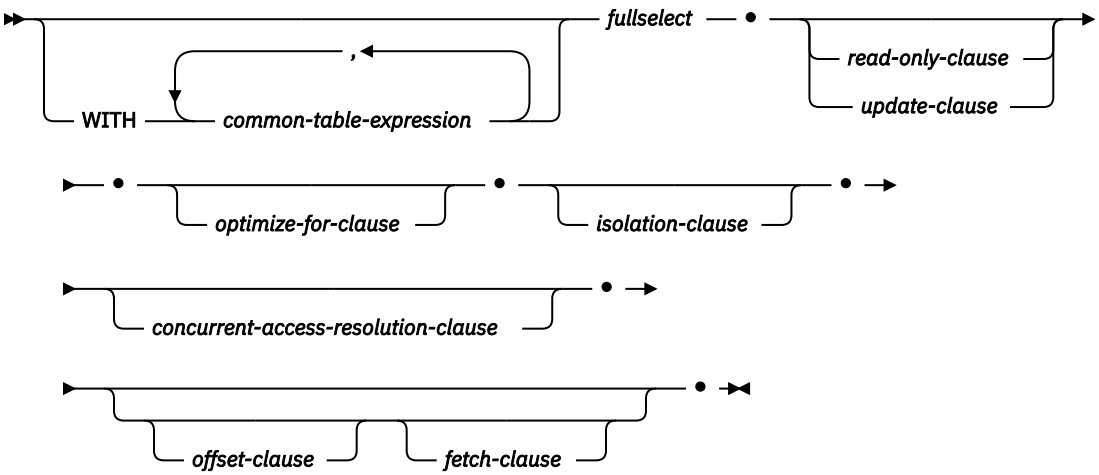
```
SELECT DISTINCT * FROM T1
   WHERE EXISTS (SELECT * FROM T2
                 WHERE T1.C1 = T2.C1 AND T1.C2 = T2.C2 AND...)
```

where C1, C2, and so on represent the columns of T1 and T2.

select-statement

The *select-statement* is the form of a query that can be specified in a DECLARE CURSOR statement, either directly, or prepared and then referenced. It can also be issued through the use of dynamic SQL statements, causing a result table to be displayed on the user's screen.

The table specified by a *select-statement* is the result of the fullselect.



The authorization for a *select-statement* is described in the Authorization section in "SQL queries".

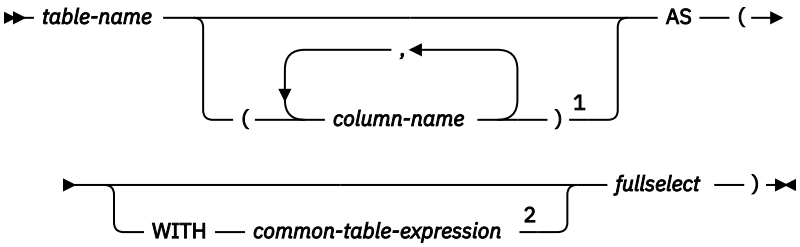
For details about the clauses in the select-statement query, refer to the following topics:

- “common-table-expression” on page 716
- “update-clause” on page 720
- “read-only-clause” on page 721
- “optimize-for-clause” on page 721
- “isolation-clause (select-statement query)” on page 722
- “lock-request-clause” on page 722

- "concurrent-access-resolution-clause" on page 722
- "offset-clause" on page 706
- "fetch-clause" on page 705
- "Retrieval of result sets from an SQL data change statement" on page 725

common-table-expression

A *common table expression* permits defining a result table with a *table-name* that can be specified as a table name in any FROM clause of the fullselect that follows.



Notes:

[1] If a common table expression is recursive, or if the fullselect results in duplicate column names, column names must be specified.

[2] For Netezza compatibility, the WITH clause is supported in common table expressions. This SQL compatibility enhancement is only available in Db2 Version 11.5 Mod Pack 2 and later versions.

Multiple common table expressions can be specified following the single WITH keyword. Each common table expression specified can also be referenced by name in the FROM clause of subsequent common table expressions.

If a list of columns is specified, it must consist of as many names as there are columns in the result table of the fullselect. Each *column-name* must be unique and unqualified. If these column names are not specified, the names are derived from the select list of the fullselect used to define the common table expression.

The *table-name* of a common table expression must be different from any other common table expression *table-name* in the same statement (SQLSTATE 42726). If the common table expression is specified in an INSERT statement the *table-name* cannot be the same as the table or view name that is the object of the insert (SQLSTATE 42726). A common table expression *table-name* can be specified as a table name in any FROM clause throughout the fullselect. A *table-name* of a common table expression overrides any existing table, view or alias (in the catalog) with the same qualified name.

If more than one common table expression is defined in the same statement, cyclic references between the common table expressions are not permitted (SQLSTATE 42835). A *cyclic reference* occurs when two common table expressions *dt1* and *dt2* are created such that *dt1* refers to *dt2* and *dt2* refers to *dt1*.

If the fullselect of a common table expression contains a *data-change-table-reference* in the FROM clause, the common table expression is said to modify data. A common table expression that modifies data is always evaluated when the statement is processed, regardless of whether the common table expression is used anywhere else in the statement. If there is at least one common table expression that reads or modifies data, all common table expressions are processed in the order in which they occur, and each common table expression that reads or modifies data is completely executed, including all constraints and triggers, before any subsequent common table expressions are executed.

The common table expression is also optional before to the fullselect in the CREATE VIEW and INSERT statements.

A common table expression can be used in the following situations:

- In place of a view to avoid creating the view (when general use of the view is not required and positioned updates or deletes are not used)

- To enable grouping by a column that is derived from a scalar subselect or function that is not deterministic or has external action
- When the required result table is based on host variables
- When the same result table must be shared in a fullselect
- When the result must be derived using recursion
- When multiple SQL data change statements must be processed within the query

If the fullselect of a common table expression contains a reference to itself in a FROM clause, the common table expression is a *recursive common table expression*. Queries using recursion are useful in supporting applications such as bill of materials (BOM), reservation systems, and network planning.

The following must be true of a recursive common table expression:

- Each fullselect that is part of the recursion cycle must start with SELECT or SELECT ALL. Use of SELECT DISTINCT is not allowed (SQLSTATE 42925). Furthermore, the unions must use UNION ALL (SQLSTATE 42925).
- The column names must be specified following the *table-name* of the common table expression (SQLSTATE 42908).
- The first fullselect of the first union (the initialization fullselect) must not include a reference to any column of the common table expression in any FROM clause (SQLSTATE 42836).
- If a column name of the common table expression is referred to in the iterative fullselect, the data type, length, and code page for the column are determined based on the initialization fullselect. The corresponding column in the iterative fullselect must have the same data type and length as the data type and length determined based on the initialization fullselect and the code page must match (SQLSTATE 42825). However, for character string types, the length of the two data types can differ. In this case, the column in the iterative fullselect must have a length that will always be assignable to the length determined from the initialization fullselect.
- Each fullselect that is part of the recursion cycle must not include any aggregate functions, group-by-clauses, or having-clauses (SQLSTATE 42836).

  The FROM clauses of these fullselects can include at most one reference to a common table expression that is part of a recursion cycle (SQLSTATE 42836).
- The iterative fullselect and the overall recursive fullselect must not include an order-by-clause (SQLSTATE 42836).
- Subqueries (scalar or quantified) must not be part of any recursion cycles (SQLSTATE 42836).

When developing recursive common table expressions, remember that an infinite recursion cycle (loop) can be created. Check that recursion cycles will stop. This is especially important if the data involved is cyclic. A recursive common table expression is expected to include a predicate that will prevent an infinite loop. The recursive common table expression is expected to include:

- In the iterative fullselect, an integer column incremented by a constant.
- A predicate in the where clause of the iterative fullselect in the form "counter_col < constant" or "counter _col < :hostvar".

A warning is issued if this syntax is not found in the recursive common table expression (SQLSTATE 01605).

Recursion example: bill of materials

Bill of materials (BOM) applications are a common requirement in many business environments. To illustrate the capability of a recursive common table expression for BOM applications, consider a table of parts with associated subparts and the quantity of subparts required by the part.

For this example, create the table as follows:

```
CREATE TABLE PARTLIST
               (PART VARCHAR(8),
                SUBPART VARCHAR(8),
                QUANTITY INTEGER);
```

To give query results for this example, assume that the PARTLIST table is populated with the following values:

```
PART     SUBPART  QUANTITY
-------- -------- -----------
00       01                5
00       05                3
01       02                2
01       03                3
01       04                4
01       06                3
02       05                7
02       06                6
03       07                6
04       08               10
04       09               11
05       10               10
05       11               10
06       12               10
06       13               10
07       14                8
07       12                8
```

Example 1: Single level explosion

The first example is called single level explosion. It answers the question, "What parts are needed to build the part identified by '01'?". The list will include the direct subparts, subparts of the subparts and so on. However, if a part is used multiple times, its subparts are only listed once.

```
WITH RPL (PART, SUBPART, QUANTITY) AS
     (  SELECT ROOT.PART, ROOT.SUBPART, ROOT.QUANTITY
        FROM PARTLIST ROOT
        WHERE ROOT.PART = '01'
      UNION ALL
        SELECT CHILD.PART, CHILD.SUBPART, CHILD.QUANTITY
        FROM RPL PARENT, PARTLIST CHILD
        WHERE  PARENT.SUBPART = CHILD.PART
     )
SELECT DISTINCT PART, SUBPART, QUANTITY
 FROM RPL
  ORDER BY PART, SUBPART, QUANTITY;
```

The preceding query includes a common table expression, identified by the name *RPL*, that expresses the recursive part of this query. It illustrates the basic elements of a recursive common table expression.

The first operand (fullselect) of the UNION, referred to as the *initialization fullselect*, gets the direct children of part '01'. The FROM clause of this fullselect refers to the source table and will never reference itself (*RPL* in this case). The result of this first fullselect goes into the common table expression *RPL* (Recursive PARTLIST). As in this example, the UNION must always be a UNION ALL.

The second operand (fullselect) of the UNION uses *RPL* to compute subparts of subparts by having the FROM clause refer to the common table expression *RPL* and the source table with a join of a part from the source table (child) to a subpart of the current result contained in *RPL* (parent). The result goes back to *RPL* again. The second operand of UNION is then used repeatedly until no more children exist.

The SELECT DISTINCT in the main fullselect of this query ensures the same part/subpart is not listed more than once.

The result of the query is as follows:

```
PART     SUBPART  QUANTITY
-------- -------- -----------
01       02                2
01       03                3
01       04                4
01       06                3
02       05                7
02       06                6
03       07                6
04       08               10
04       09               11
05       10               10
```

```
  05       11               10
  06       12               10
  06       13               10
  07       12                8
  07       14                8
```

Observe in the result that part '01' goes to '02' which goes to '06' and so on. Further, notice that part '06' is reached twice, once through '01' directly and another time through '02'. In the output, however, its subcomponents are listed only once (this is the result of using a SELECT DISTINCT) as required.

It is important to remember that with recursive common table expressions it is possible to introduce an *infinite loop*. In this example, an infinite loop would be created if the search condition of the second operand that joins the parent and child tables was coded as:

```
   PARENT.SUBPART = CHILD.SUBPART
```

This example of causing an infinite loop is obviously a case of not coding what is intended. Exercise care when determining what to code so that there is a definite end of the recursion cycle.

The result produced by this example query can be produced in an application program without using a recursive common table expression. However, this approach would require starting of a new query for every level of recursion. Furthermore, the application needs to put all the results back in the database to order the result. This approach complicates the application logic and does not perform well. The application logic becomes even harder and more inefficient for other bill of material queries, such as summarized and indented explosion queries.

Example 2: Summarized explosion

The second example is a summarized explosion. The question posed here is, what is the total quantity of each part required to build part '01'. The main difference from the single level explosion is the requirement to aggregate the quantities. The first example indicates the quantity of subparts required for the part whenever it is required. It does not indicate how many of the subparts are needed to build part '01'.

```
WITH RPL (PART, SUBPART, QUANTITY) AS
   (
      SELECT ROOT.PART, ROOT.SUBPART, ROOT.QUANTITY
       FROM PARTLIST ROOT
       WHERE ROOT.PART = '01'
    UNION ALL
      SELECT PARENT.PART, CHILD.SUBPART, PARENT.QUANTITY*CHILD.QUANTITY
       FROM RPL PARENT, PARTLIST CHILD
       WHERE PARENT.SUBPART = CHILD.PART
   )
SELECT PART, SUBPART, SUM(QUANTITY) AS "Total QTY Used"
 FROM RPL
  GROUP BY PART, SUBPART
  ORDER BY PART, SUBPART;
```

In the preceding query, the select list of the second operand of the UNION in the recursive common table expression, identified by the name *RPL*, shows the aggregation of the quantity. To find out how much of a subpart is used, the quantity of the parent is multiplied by the quantity per parent of a child. If a part is used multiple times in different places, it requires another final aggregation. This is done by the grouping over the common table expression *RPL* and using the SUM aggregate function in the select list of the main fullselect.

The result of the query is as follows:

```
  PART     SUBPART  Total Qty Used
  -------- -------- --------------
  01       02                   2
  01       03                   3
  01       04                   4
  01       05                  14
  01       06                  15
  01       07                  18
  01       08                  40
  01       09                  44
```

```
  01       10                  140
  01       11                  140
  01       12                  294
  01       13                  150
  01       14                  144
```

Looking at the output, consider the line for subpart '06'. The total quantity used value of 15 is derived from a quantity of 3 directly for part '01' and a quantity of 6 for part '02' which is needed 2 times by part '01'.

Example 3: Controlling depth

The question might come to mind, what happens when there are more levels of parts in the table than you are interested in for your query? That is, how is a query written to answer the question, "What are the first two levels of parts needed to build the part identified by '01'?" For the sake of clarity in the example, the level is included in the result.

```
WITH RPL (LEVEL, PART, SUBPART, QUANTITY) AS
      (
         SELECT 1,               ROOT.PART, ROOT.SUBPART, ROOT.QUANTITY
          FROM PARTLIST ROOT
          WHERE ROOT.PART = '01'
       UNION ALL
         SELECT PARENT.LEVEL+1, CHILD.PART, CHILD.SUBPART, CHILD.QUANTITY
          FROM RPL PARENT, PARTLIST CHILD
          WHERE PARENT.SUBPART = CHILD.PART
            AND PARENT.LEVEL < 2
      )
 SELECT PART, LEVEL, SUBPART, QUANTITY
   FROM RPL;
```

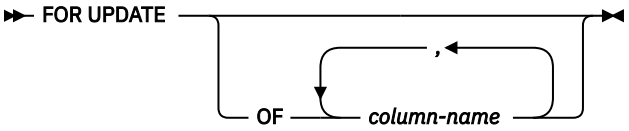
This query is similar to example 1. The column *LEVEL* was introduced to count the levels from the original part. In the initialization fullselect, the value for the *LEVEL* column is initialized to 1. In the subsequent fullselect, the level from the parent is incremented by 1. Then to control the number of levels in the result, the second fullselect includes the condition that the parent level must be less than 2. This ensures that the second fullselect only processes children to the second level.

The result of the query is:

```
  PART     LEVEL       SUBPART  QUANTITY
  -------- ----------- -------- -----------
  01                 1 02                 2
  01                 1 03                 3
  01                 1 04                 4
  01                 1 06                 3
  02                 2 05                 7
  02                 2 06                 6
  03                 2 07                 6
  04                 2 08                10
  04                 2 09                11
  06                 2 12                10
  06                 2 13                10
```

update-clause

The FOR UPDATE clause identifies the columns that can be targets in an assignment clause in a subsequent positioned UPDATE statement. Each *column-name* must be unqualified and must identify a column of the table or view identified in the first FROM clause of the fullselect.



If a FOR UPDATE clause is specified with a *column-name* list, and extended indicator variables are not enabled, then *column-name* must be an updatable column (SQLSTATE 42808).

If a FOR UPDATE clause is specified without a *column-name* list, then the implicit *column-name* list is determined as follows:

- If extended indicator variables are enabled, all of the columns of the table or view identified in the first FROM clause of the fullselect are included.
- If extended indicator variables are not enabled, all of the updatable columns of the table or view identified in the first FROM clause of the fullselect are included.

The FOR UPDATE clause cannot be used if one of the following conditions is true:

- The cursor associated with the select-statement is not deletable .
- One of the selected columns is a non-updatable column of a catalog table and the FOR UPDATE clause has not been used to exclude that column.

read-only-clause

The FOR READ ONLY clause indicates that the result table is read-only and therefore the cursor cannot be referred to in Positioned UPDATE and DELETE statements. FOR FETCH ONLY has the same meaning.

Some result tables are read-only by nature. (For example, a table based on a read-only view.) FOR READ ONLY can still be specified for such tables, but the specification has no effect.

For result tables in which updates and deletes are allowed, specifying FOR READ ONLY (or FOR FETCH ONLY) can possibly improve the performance of FETCH operations by allowing the database manager to do blocking. For example, in programs that contain dynamic SQL statements without the FOR READ ONLY or ORDER BY clause, the database manager might open cursors as if the FOR UPDATE clause were specified. It is recommended, therefore, that the FOR READ ONLY clause be used to improve performance, except in cases where queries will be used in positioned UPDATE or DELETE statements.

A read-only result table must not be referred to in a Positioned UPDATE or DELETE statement, whether it is read-only by nature or specified as FOR READ ONLY (FOR FETCH ONLY).

optimize-for-clause

The OPTIMIZE FOR clause requests special processing of the *select statement*.

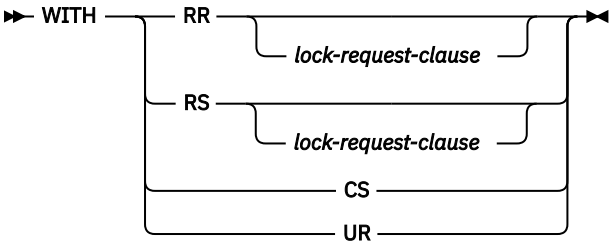
If this clause is omitted, it is assumed that all rows of the result table will be retrieved; if it is specified, it is assumed that the number of rows retrieved will probably not exceed *n*, where *n* is the value of *integer*. The value of *n* must be a positive integer (not zero). Use of the OPTIMIZE FOR clause influences query optimization, based on the assumption that *n* rows will be retrieved. In addition, for cursors that are blocked, this clause will influence the number of rows that will be returned in each block (that is, no more than *n* rows will be returned in each block). If both the *fetch-clause* and the *optimize-for-clause* are specified, the lower of the integer values from these clauses will be used to influence the communications buffer size. The values are considered independently for optimization purposes.

This clause does not limit the number of rows that can be fetched, or affect the result in any other way than performance. Using OPTIMIZE FOR *n* ROWS can improve performance if no more than *n* rows are retrieved, but might degrade performance if more than *n* rows are retrieved.

If the value of *n* multiplied by the size of the row exceeds the size of the communication buffer, the OPTIMIZE FOR clause will have no affect on the data buffers. The size of the communication buffer is defined by the **rqrioblk** or the **aslheapsz** configuration parameter.

isolation-clause (select-statement query)

The optional *isolation-clause* specifies the isolation level at which the statement is executed, and whether a specific type of lock is to be acquired.

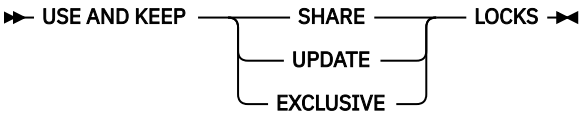


- RR - Repeatable Read (row-organized tables only SQLSTATE 42858)
- RS - Read Stability (row-organized tables only SQLSTATE 42858)
- CS - Cursor Stability
- UR - Uncommitted Read

The default isolation level of the statement is the isolation level of the package in which the statement is bound. When a nickname is used in a *select-statement* to access data in IBM family and Microsoft SQL Server data sources, the *isolation-clause* can be included in the statement to specify the statement isolation level. If the *isolation-clause* is included in statements that access other data sources, the specified isolation level is ignored. The current isolation level on the federated server is mapped to a corresponding isolation level at the data source on each connection to the data source. After a connection is made to a data source, the isolation level cannot be changed for the duration of the connection.

lock-request-clause

The optional *lock-request-clause* specifies the type of lock that the database manager is to acquire and hold.



SHARE
Concurrent processes can acquire SHARE or UPDATE locks on the data.

UPDATE
Concurrent processes can acquire SHARE locks on the data, but no concurrent process can acquire an UPDATE or EXCLUSIVE lock.

EXCLUSIVE
Concurrent processes cannot acquire a lock on the data.

The *lock-request-clause* applies to all base table and index scans required by the query, including those within subqueries, SQL functions and SQL methods. It has no affect on locks placed by procedures, external functions, or external methods. Any SQL function or SQL method called (directly or indirectly) by the statement must be created with INHERIT ISOLATION LEVEL WITH LOCK REQUEST (SQLSTATE 42601). The *lock-request-clause* cannot be used with a modifying query that might activate triggers or that requires referential integrity checks (SQLSTATE 42601).

concurrent-access-resolution-clause

The optional *concurrent-access-resolution-clause* specifies the concurrent access resolution to use for *select-statement*.

WAIT FOR OUTCOME specifies to wait for the commit or rollback when encountering data in the process of being updated or deleted. Rows encountered that are in the process of being inserted are not skipped. The settings for the registry variables DB2_EVALUNCOMMITTED, DB2_SKIPDELETED, and DB2_SKIPINSERTED are ignored. This clause applies when the isolation level is CS or RS. It is ignored when an isolation level of UR or RR is in effect, or when the table is column-organized.

This clause causes the following behavior and settings to be overridden:

- Any higher level setting such as bind options, CLI settings, JDBC settings, or lock modifications.

The SKIP LOCKED DATA clause specifies that rows are skipped when incompatible locks that would block the progress of the statement are held on the rows by other transactions. These rows can belong to any accessed table addressed in the statement, including tables accessed in a subquery. This clause applies when the isolation level is CS or RS and is ignored when an isolation level of UR or RR is in effect. It applies to row and block level locks.

This clause causes the following behavior and settings to be overridden:

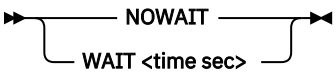
- Any higher level setting such as bind options, CLI settings, JDBC settings, or lock modifications still apply, with the modified behavior that if a lock request is made and there is a conflict, the corresponding row is skipped. SKIP LOCKED DATA specified on a statement does override a higher level WAIT FOR OUTCOME setting.

SKIP LOCKED DATA is ignored if it is specified when WITH RR or WITH UR. The default isolation level of the statement depends on the isolation of the package or plan with which the statement is bound, and whether the result table is read-only. If the default isolation level of the statement is Repeatable Read or Uncommitted Read, then SKIP LOCKED DATA is ignored.

SKIP LOCKED DATA clause is strictly SQL based. Also, it cannot be specified for the following:

- Positioned updates and deletes
- Subquery
- Update/delete statements on column organized table
- **PREPARE** command
- **BIND** command

Attention: The following feature is available in Db2 11.5.6 and later versions.



The NOWAIT and WAIT clauses specify the number of seconds to wait for a lock before returning an error indicating that a lock cannot be obtained.

When using the WAIT clause, `<time sec>` is an integer between -1 and 32767.

Note: For `NOWAIT` and `WAIT 0`, locks are not waited for. If no lock is available at the time of the request, a -911 error is returned.

When a WAIT value of `-1` is specified, lock timeout detection is turned off. In this situation a lock is waited for (if one is not available at the time of the request) until either of the following events occur:

- The lock is granted.
- A deadlock occurs.

Use of the NOWAIT and WAIT clauses overwrites the value of the LOCKTIMEOUT database configuration variable and the value of the CURRENT LOCK TIMEOUT special register for this select statement. This means that adding the NOWAIT/WAIT clause with a wait time value of **t** has

the same effect as executing the select statement with a LOCKTIMEOUT value or CURRENT LOCK TIMEOUT value of **t**.

Examples of select-statement queries

The following examples illustrate the select-statement query.

- *Example 1:* Select all columns and rows from the EMPLOYEE table.

```
SELECT * FROM EMPLOYEE
```

- *Example 2:* Select the project name (PROJNAME), start date (PRSTDATE), and end date (PRENDATE) from the PROJECT table. Order the result table by the end date with the most recent dates appearing first.

```
SELECT PROJNAME, PRSTDATE, PRENDATE
 FROM PROJECT
 ORDER BY PRENDATE DESC
```

- *Example 3:* Select the department number (WORKDEPT) and average departmental salary (SALARY) for all departments in the EMPLOYEE table. Arrange the result table in ascending order by average departmental salary.

```
SELECT WORKDEPT, AVG(SALARY)
   FROM EMPLOYEE
   GROUP BY WORKDEPT
   ORDER BY 2
```

- *Example 4:* Declare a cursor named UP_CUR to be used in a C program to update the start date (PRSTDATE) and the end date (PRENDATE) columns in the PROJECT table. The program must receive both of these values together with the project number (PROJNO) value for each row.

```
EXEC SQL  DECLARE UP_CUR CURSOR FOR
            SELECT PROJNO, PRSTDATE, PRENDATE
              FROM PROJECT
              FOR UPDATE OF PRSTDATE, PRENDATE;
```

- *Example 5:* This example names the expression SAL+BONUS+COMM as TOTAL_PAY

```
 SELECT SALARY+BONUS+COMM AS TOTAL_PAY
   FROM EMPLOYEE
   ORDER BY TOTAL_PAY
```

- *Example 6:* Determine the employee number and salary of sales representatives along with the average salary and head count of their departments. Also, list the average salary of the department with the highest average salary.

  Using a common table expression for this case saves the processing resources of creating the DINFO view as a regular view. During statement preparation, accessing the catalog for the view is avoided and, because of the context of the rest of the fullselect, only the rows for the department of the sales representatives are considered by the view.

```
WITH
   DINFO (DEPTNO, AVGSALARY, EMPCOUNT) AS
       (SELECT OTHERS.WORKDEPT, AVG(OTHERS.SALARY), COUNT(*)
         FROM EMPLOYEE OTHERS
         GROUP BY OTHERS.WORKDEPT
       ),
   DINFOMAX AS
       (SELECT MAX(AVGSALARY) AS AVGMAX FROM DINFO)
SELECT THIS_EMP.EMPNO, THIS_EMP.SALARY,
       DINFO.AVGSALARY, DINFO.EMPCOUNT, DINFOMAX.AVGMAX
 FROM EMPLOYEE THIS_EMP, DINFO, DINFOMAX
 WHERE THIS_EMP.JOB = 'SALESREP'
 AND THIS_EMP.WORKDEPT = DINFO.DEPTNO
```

- *Example 7:* Given two tables, EMPLOYEE and PROJECT, replace employee SALLY with a new employee GEORGE, assign all projects lead by SALLY to GEORGE, and return the names of the updated projects.

```
WITH
  NEWEMP AS (SELECT EMPNO FROM NEW TABLE
               (INSERT INTO EMPLOYEE(EMPNO, FIRSTNME)
                   VALUES(NEXT VALUE FOR EMPNO_SEQ, 'GEORGE'))),
  OLDEMP AS (SELECT EMPNO FROM EMPLOYEE WHERE FIRSTNME = 'SALLY'),
  UPPROJ AS (SELECT PROJNAME FROM NEW TABLE
               (UPDATE PROJECT
                   SET RESPEMP = (SELECT EMPNO FROM NEWEMP)
                   WHERE RESPEMP = (SELECT EMPNO FROM OLDEMP))),
  DELEMP AS (SELECT EMPNO FROM OLD TABLE
               (DELETE FROM EMPLOYEE
                   WHERE EMPNO = (SELECT EMPNO FROM OLDEMP)))
SELECT PROJNAME FROM UPPROJ;
```

- *Example 8:* Retrieve data from the DEPT table. That data will later be updated with a searched update, and will be locked when the query executes.

```
SELECT DEPTNO, DEPTNAME, MGRNO
  FROM DEPT
  WHERE ADMRDEPT ='A00'
  FOR READ ONLY WITH RS USE AND KEEP EXCLUSIVE LOCKS
```

- *Example 9:* Select all columns and rows from the EMPLOYEE table. If another transaction is concurrently updating, deleting, or inserting data in the EMPLOYEE table, the select operation will wait to get the data until after the other transaction is completed.

```
SELECT * FROM EMPLOYEE WAIT FOR OUTCOME
```

Retrieval of result sets from an SQL data change statement

Applications that modify tables with INSERT, UPDATE, or DELETE statements might require additional processing on the modified rows. To facilitate this processing, you can embed SQL data-change operations in the FROM clause of SELECT and SELECT INTO statements.

Within a single unit of work, applications can retrieve a result set containing the modified rows from a table or view modified by an SQL data-change operation.

For example, the following statement updates the salaries of all the records in the EMPLOYEE table in the SAMPLE database and then returns the employee number and new salary for all the updated rows.

```
SELECT empno, salary FROM FINAL TABLE
    (UPDATE employee SET salary = salary * 1.10 WHERE job = 'CLERK')
```

To return data successfully, SELECT statements that retrieve result sets FROM SQL data-change operations require the SQL data-change operations to run successfully. The success of SQL data-change operations includes the processing of all constraints and triggers, if applicable.

For instance, suppose a user with SELECT privileges, but without INSERT privileges on the EMPLOYEE table attempts a SELECT FROM INSERT statement on the EMPLOYEE table. The INSERT operation fails because of the missing privileges, and as a result, the entire SELECT statement fails.

Consider the following query, where records from the EMPLOYEE table are selected and then inserted into a different table, named EMP. This SELECT statement will fail.

```
SELECT empno FROM FINAL TABLE
    (INSERT INTO emp(name, salary)
    SELECT firstnme || midinit || lastname, salary
    FROM employee)
```

If the EMPLOYEE table has 100 rows and row 90 has a SALARY value of $9,999,000.00, then the addition of $10,000.00 would cause a decimal overflow to occur. The overflow would force the database manager to roll back the insertions into the EMP table.

Intermediate result tables

The modified rows of the table or view targeted by an SQL data-change operation in the FROM clause of a SELECT statement compose an intermediate result table. The intermediate result table includes all the columns of the target table or view, in addition to any include columns defined in the SQL data-change operation. You can reference all of the columns in an intermediate result table by name in the select list, the ORDER BY clause, or the WHERE clause.

The contents of the intermediate result table are dependant on the qualifier specified in the FROM clause. You must include one of the following FROM clause qualifiers in SELECT statements that retrieve result sets as intermediate result tables.

OLD TABLE
The rows in the intermediate result table will contain values of the target table rows at the point immediately preceding the execution of before triggers and the SQL data-change operation. The OLD TABLE qualifier applies to UPDATE and DELETE operations.

NEW TABLE
The rows in the intermediate result table will contain values of the target table rows at the point immediately after the SQL data-change statement has been executed, but before referential integrity evaluation and the firing of any after triggers. The NEW TABLE qualifier applies to UPDATE and INSERT operations.

FINAL TABLE
This qualifier returns the same intermediate result table as NEW TABLE. In addition, the use of FINAL TABLE guarantees that no after trigger or referential integrity constraint will further modify the target of the UPDATE or INSERT operation. The FINAL TABLE qualifier applies to UPDATE and INSERT operations.

The FROM clause qualifiers determine what version of the targeted data is in the intermediate result table. These qualifiers do not affect the insertion, deletion, or updates of target table rows.

Target tables and views

When selecting result sets FROM SQL data-change operations, the target can be either a table or a view.

In SQL data-change operations against views, the result table cannot include rows that no longer satisfy the view definition for NEW TABLE and FINAL TABLE. If you embed an INSERT or UPDATE statement that references a view in a SELECT statement, the view must be defined as WITH CASCADED CHECK OPTION. Alternatively, the view must satisfy the restrictions that would allow you to define it as WITH CASCADED CHECK OPTION.

If the target of SQL data-change operations embedded in the FROM clause of a SELECT statement is a fullselect, the result table can include rows that no longer qualify in the fullselect. This is because the predicates in the WHERE clause are not re-evaluated against the updated values.

Result set sorting based on INPUT SEQUENCE

To SELECT rows in the same order as they are inserted into the target table or view, use the INPUT SEQUENCE keywords in the ORDER BY clause. Use of the INPUT SEQUENCE keywords does not force rows to be inserted in the same order they are provided.

The following example demonstrates the use of the INPUT SEQUENCE keywords in the ORDER BY clause to sort the result set of an INSERT operation.

```
CREATE TABLE orders (purchase_date DATE,
                     sales_person VARCHAR(16),
                     region VARCHAR(10),
                     quantity SMALLINT,
                     order_num INTEGER NOT NULL
                       GENERATED ALWAYS AS IDENTITY (START WITH 100,
                                                     INCREMENT BY 1))

SELECT * FROM FINAL TABLE
         (INSERT INTO orders
          (purchase_date, sales_person, region, quantity)
```

```
          VALUES (CURRENT DATE,'Judith','Beijing',6),
                 (CURRENT DATE,'Marieke','Medway',5),
                 (CURRENT DATE,'Hanneke','Halifax',5))
        ORDER BY INPUT SEQUENCE

PURCHASE_DATE SALES_PERSON     REGION     QUANTITY ORDER_NUM
------------- ---------------- ---------- -------- -----------
07/18/2003    Judith           Beijing           6         100
07/18/2003    Marieke          Medway            5         101
07/18/2003    Hanneke          Halifax           5         102
```

You can also sort result set rows using include columns.

SQL statements

This topic contains tables that list the SQL statements classified by type.

- SQL schema statements (Table 114 on page 727)
- SQL data change statements (Table 115 on page 733)
- SQL data statements (Table 116 on page 733)
- SQL transaction statements (Table 117 on page 734)
- SQL connection statements (Table 118 on page 734)
- SQL dynamic statements (Table 119 on page 734)
- SQL session statements (Table 120 on page 735)
- SQL embedded host language statements (Table 121 on page 736)
- SQL control statements (Table 122 on page 737)

Table 114. SQL schema statements

SQL Statement	Purpose
“ALTER AUDIT POLICY ” on page 750	Modifies the definition of an audit policy at the current server.
“ALTER BUFFERPOOL ” on page 752	Changes the definition of a buffer pool.
“ALTER DATABASE ” on page 757	Adds new storage paths to the collection of paths that are used for automatic storage table spaces.
“ALTER EVENT MONITOR ” on page 761	Changes the definition of a TABLE or UNFORMATTED EVENT TABLE event monitor.
“ALTER DATABASE PARTITION GROUP ” on page 754	Changes the definition of a database partition group.
“ALTER FUNCTION ” on page 766	Modifies an existing function by changing the properties of the function.
“ALTER HISTOGRAM TEMPLATE ” on page 769	Modifies the template describing the type of histogram that can be used to override one or more of the default histograms of a service class or a work class.
“ALTER INDEX ” on page 770	Changes the definition of an index.
“ALTER MASK ” on page 771	Changes the definition of a column mask.
“ALTER METHOD ” on page 772	Modifies an existing method by changing the method body associated with the method.
“ALTER MODULE ” on page 773	Changes the definition of a module.
“ALTER NICKNAME ” on page 779	Changes the definition of a nickname.
“ALTER PACKAGE ” on page 788	Alters bind options for a package at the current server without having to bind or rebind the package.

Table 114. SQL schema statements (continued)

SQL Statement	Purpose
“ALTER PERMISSION ” on page 790	Changes the definition of a row permission.
“ALTER PROCEDURE (external) ” on page 791	Modifies an existing external procedure by changing the properties of the procedure.
“ALTER PROCEDURE (sourced) ” on page 794	Modifies an existing sourced procedure by changing the data type of one or more parameters of the sourced procedure.
“ALTER PROCEDURE (SQL) ” on page 795	Modifies an existing SQL procedure by changing the properties of the procedure.
“ALTER SCHEMA ” on page 796	Modifies an existing schema by changing the data capture attribute of the schema.
“ALTER SECURITY LABEL COMPONENT ” on page 797	Modifies a security label component.
“ALTER SECURITY POLICY ” on page 800	Modifies a security policy.
“ALTER SEQUENCE ” on page 803	Changes the definition of a sequence.
“ALTER SERVER ” on page 806	Changes the definition of a data source in a federated system.
“ALTER SERVICE CLASS ” on page 809	Changes the definition of a service class.
“ALTER STOGROUP ” on page 818	Changes the definition of a storage group.
“ALTER TABLE” on page 822	Changes the definition of a table.
“ALTER TABLESPACE ” on page 880	Changes the definition of a table space.
“ALTER THRESHOLD ” on page 893	Changes the definition of a threshold.
“ALTER TRIGGER ” on page 905	Changes the definition of a trigger.
“ALTER TRUSTED CONTEXT ” on page 906	Changes the definition of a trusted context at the current server.
“ALTER TYPE (structured) ” on page 913	Changes the definition of a structured type.
“ALTER USAGE LIST” on page 919	Changes the definition of a usage list.
“ALTER USER MAPPING ” on page 920	Changes the definition of a user authorization mapping.
“ALTER VIEW ” on page 922	Changes the definition of a view by altering a reference type column to add a scope.
“ALTER WORK ACTION SET ” on page 923	Adds, alters, or drops work actions within a work action set.
“ALTER WORK CLASS SET ” on page 936	Adds, alters, or drops work classes within a work class set.
“ALTER WORKLOAD ” on page 941	Changes a workload.
“ALTER WRAPPER ” on page 954	Updates the options that, along with a wrapper module, are used to access data sources of a specific type.
“ALTER XSROBJECT ” on page 955	Enables or disables decomposition support for a specific XML schema.
“AUDIT ” on page 958	Determines the audit policy that is to be used for a particular database or database object at the current server.
“COMMENT ” on page 973	Replaces or adds a comment to the description of an object.
“CREATE ALIAS ” on page 1019	Defines an alias for a module, nickname, sequence, table, view, or another alias.

Table 114. SQL schema statements (continued)

SQL Statement	Purpose
“CREATE AUDIT POLICY ” on page 1022	Defines an auditing policy at the current server.
“CREATE BUFFERPOOL ” on page 1024	Defines a new buffer pool.
“CREATE DATABASE PARTITION GROUP ” on page 1027	Defines a database partition group.
“CREATE EVENT MONITOR ” on page 1029	Specifies events in the database to monitor.
“CREATE EVENT MONITOR (activities) ” on page 1046	Specifies activity events in the database to monitor.
“CREATE EVENT MONITOR (change history) ” on page 1055	Specifies change history events in the database to monitor.
“CREATE EVENT MONITOR (locking) ” on page 1061	Specifies locking events in the database to monitor.
“CREATE EVENT MONITOR (package cache) statement” on page 1065	Specifies package cache statement events in the database to monitor.
“CREATE EVENT MONITOR (statistics) ” on page 1071	Specifies statistics events in the database to monitor.
“CREATE EVENT MONITOR (threshold violations) ” on page 1081	Specifies threshold violation events in the database to monitor.
“CREATE EXTERNAL TABLE ” on page 1095	Defines an external table.
“CREATE FUNCTION ” on page 1123	Registers a user-defined function.
“CREATE FUNCTION ” on page 1123	Registers a user-defined function.
“CREATE FUNCTION (aggregate interface) ” on page 1124	Registers a user-defined aggregate function at the current server.
“CREATE FUNCTION (external scalar) ” on page 1140	Registers a user-defined external scalar function.
“CREATE FUNCTION (external table) ” on page 1166	Registers a user-defined external table function.
“CREATE FUNCTION (OLE DB external table) ” on page 1187	Registers a user-defined OLE DB external table function.
“CREATE FUNCTION (sourced or template) ” on page 1196	Registers a user-defined sourced function or a function template.
“CREATE FUNCTION (SQL scalar, table, or row) ” on page 1208	Defines a user-defined SQL function.
“CREATE FUNCTION MAPPING ” on page 1224	Defines a function mapping.
“CREATE GLOBAL TEMPORARY TABLE ” on page 1228	Defines a created temporary table.
“CREATE HISTOGRAM TEMPLATE ” on page 1239	Defines a template describing the type of histogram that can be used to override one or more of the default histograms of a service class or a work class.
“CREATE INDEX ” on page 1240	Defines an index on a table.

Table 114. SQL schema statements (continued)

SQL Statement	Purpose
“CREATE INDEX EXTENSION ” on page 1261	Defines an extension object for use with indexes on tables with structured or distinct type columns.
“CREATE MASK ” on page 1266	Defines a column mask.
“CREATE METHOD ” on page 1271	Defines a method body to associate with a previously defined method specification.
“CREATE MODULE ” on page 1276	Defines a module.
“CREATE NICKNAME ” on page 1277	Defines a nickname.
“CREATE PERMISSION ” on page 1288	Defines a row permission.
“CREATE PROCEDURE ” on page 1291	Defines a procedure.
“CREATE PROCEDURE (external) ” on page 1292	Defines an external procedure.
“CREATE PROCEDURE (sourced) ” on page 1307	Defines a procedure (the sourced procedure) that is based on another procedure (the source procedure). In a federated system, a federated procedure is a sourced procedure whose source procedure is at a supported data source.
“CREATE PROCEDURE (SQL) ” on page 1312	Defines an SQL procedure.
“CREATE ROLE ” on page 1320	Defines a role at the current server.
“CREATE SCHEMA ” on page 1321	Defines a schema.
“CREATE SECURITY LABEL COMPONENT ” on page 1324	Defines a component that is to be used as part of a security policy.
