“CREATE SECURITY LABEL ” on page 1326	Defines a security label.
“CREATE SECURITY POLICY ” on page 1327	Defines a security policy.
“CREATE SEQUENCE ” on page 1328	Defines a sequence.
“CREATE SERVER ” on page 1343	Defines a data source to a federated database.
“CREATE SERVICE CLASS ” on page 1333	Defines a service class.
“CREATE STOGROUP ” on page 1349	Defines a new storage group within the database.
“CREATE SYNONYM ” on page 1351	Defines a synonym for a module, nickname, sequence, table, view, or another synonym.
“CREATE TABLE ” on page 1351	Defines a table.
“CREATE TABLESPACE ” on page 1428	Defines a table space.
“CREATE THRESHOLD ” on page 1443	Defines a threshold.
“CREATE TRANSFORM ” on page 1457	Defines transformation functions.
“CREATE TRIGGER ” on page 1460	Defines a trigger.
“CREATE TRUSTED CONTEXT ” on page 1474	Defines a trusted context at the current server.
“CREATE TYPE ” on page 1479	Defines a user-defined data type at the current server.

Table 114. SQL schema statements (continued)

SQL Statement	Purpose
“CREATE TYPE (array) ” on page 1480	Defines an array type.
“CREATE TYPE (cursor) ” on page 1485	Defines a cursor type.
“CREATE TYPE (distinct) ” on page 1487	Defines a distinct data type.
“CREATE TYPE (row) ” on page 1495	Defines a row type.
“CREATE TYPE (structured) ” on page 1500	Defines a structured data type.
“CREATE TYPE MAPPING ” on page 1521	Defines a mapping between data types.
“CREATE USAGE LIST” on page 1527	Defines a usage list in order to monitor all unique sections (DML statements) that have referenced a particular table or index during their execution.
“CREATE USER MAPPING ” on page 1529	Defines a mapping between user authorizations.
“CREATE VARIABLE ” on page 1531	Defines a global variable.
“CREATE VIEW ” on page 1539	Defines a view of one or more table, view or nickname.
“CREATE WORK ACTION SET ” on page 1552	Defines a work action set and work actions within the work action set.
“CREATE WORK CLASS SET ” on page 1560	Defines a work class set.
“CREATE WORKLOAD ” on page 1564	Defines a workload.
“CREATE WRAPPER ” on page 1579	Registers a wrapper.
“DROP ” on page 1616	Deletes objects in the database.
“GRANT (database authorities) ” on page 1675	Grants authorities on the entire database.
“GRANT (exemption) ” on page 1680	Grants an exemption on an access rule for a specified label-based access control (LBAC) security policy.
“GRANT (global variable privileges) ” on page 1682	Grants one or more privileges on a created global variable.
“GRANT (index privileges) ” on page 1684	Grants the CONTROL privilege on indexes in the database.
“GRANT (module privileges) ” on page 1686	Grants privileges on a module.
“GRANT (package privileges) ” on page 1687	Grants privileges on packages in the database.
“GRANT (role) ” on page 1690	Grants roles to users, groups, or to other roles.
“GRANT (routine privileges) ” on page 1692	Grants privileges on a routine (function, method, or procedure).
“GRANT (schema privileges and authorities) ” on page 1696	Grants privileges on a schema.
“GRANT (security label) ” on page 1701	Grants a label-based access control (LBAC) security label for read access, write access, or for both read and write access.
“GRANT (sequence privileges) ” on page 1703	Grants privileges on a sequence.
“GRANT (server privileges) ” on page 1705	Grants privileges to query a specific data source.

Table 114. SQL schema statements (continued)

SQL Statement	Purpose
“GRANT (SETSESSIONUSER privilege) ” on page 1707	Grants the privilege to use the SET SESSION AUTHORIZATION statement.
“GRANT (table space privileges) ” on page 1708	Grants privileges on a table space.
“GRANT (table, view, or nickname privileges) ” on page 1710	Grants privileges on tables, views and nicknames.
“GRANT (workload privileges) ” on page 1716	Grants the USAGE privilege on a workload.
“GRANT (XSR object privileges) ” on page 1717	Grants the USAGE privilege on an XSR object.
“REFRESH TABLE ” on page 1757	Refreshes the data in a materialized query table.
“RENAME ” on page 1762	Renames an existing table.
“RENAME STOGROUP ” on page 1764	Renames an existing storage group.
“RENAME TABLESPACE ” on page 1765	Renames an existing table space.
“REVOKE (database authorities) ” on page 1771	Revokes authorities from the entire database.
“REVOKE (exemption) ” on page 1775	Revokes the exemption on an access rule for a specified label-based access control (LBAC) security policy.
“REVOKE (global variable privileges) ” on page 1777	Revokes one or more privileges on a created global variable.
“REVOKE (index privileges) ” on page 1778	Revokes the CONTROL privilege on given indexes.
“REVOKE (module privileges) ” on page 1780	Revokes privileges on a module.
“REVOKE (package privileges) ” on page 1781	Revokes privileges from given packages in the database.
“REVOKE (role) ” on page 1783	Revokes roles from users, groups, or other roles.
“REVOKE (routine privileges) ” on page 1785	Revokes privileges on a routine (function, method, or procedure).
“REVOKE (schema privileges and authorities) ” on page 1789	Revokes privileges on a schema.
“REVOKE (security label) ” on page 1792	Revokes a label-based access control (LBAC) security label for read access, write access, or for both read and write access.
“REVOKE (sequence privileges)” on page 1793	Revokes privileges on a sequence.
“REVOKE (server privileges) ” on page 1795	Revokes privileges to query a specific data source.
“REVOKE (SETSESSIONUSER privilege) ” on page 1797	Revokes the privilege to use the SET SESSION AUTHORIZATION statement.
“REVOKE (table space privileges) ” on page 1798	Revokes the USE privilege on a given table space.

Table 114. SQL schema statements (continued)

SQL Statement	Purpose
"REVOKE (table, view, or nickname privileges) " on page 1799	Revokes privileges from given tables, views or nicknames.
"REVOKE (workload privileges) " on page 1804	Revokes the USAGE privilege on a workload.
"REVOKE (XSR object privileges) " on page 1805	Revokes the USAGE privilege on an XSR object.
"SET INTEGRITY " on page 1851	Sets the set integrity pending state and checks data for constraint violations.
"TRANSFER OWNERSHIP " on page 1892	Transfers ownership of a database object.

Table 115. SQL data change statements

SQL Statement	Purpose
"DELETE " on page 1599	Deletes one or more rows from a table.
"INSERT " on page 1721	Inserts one or more rows into a table.
"MERGE " on page 1735	Updates a target (a table or view) using data from a source (result of a table reference).
"TRUNCATE " on page 1902	Deletes all rows from a table.
"UPDATE " on page 1905	Updates the values of one or more columns in one or more rows of a table.

Table 116. SQL data statements

SQL Statement	Purpose
"ALLOCATE CURSOR " on page 749	Allocates a cursor for the result set identified by the result set locator variable.
"ASSOCIATE LOCATORS " on page 956	Gets the result set locator value for each result set returned by a procedure.
"CLOSE " on page 971	Closes a cursor.
"DECLARE CURSOR " on page 1581	Defines an SQL cursor.
"FETCH " on page 1659	Assigns values of a row to host variables.
"FLUSH AUTHENTICATION CACHE " on page 1668	Removes cached users in the authentication cache
"FLUSH BUFFERPOOLS " on page 1663	Writes out the dirty pages in the buffer pools to disk.
"FLUSH EVENT MONITOR " on page 1663	Writes out the active internal buffer of an event monitor.
"FLUSH FEDERATED CACHE " on page 1664	The FLUSH FEDERATED CACHE statement flushes the federated cache, allowing fresh metadata to be obtained the next time an SQL statement is issued against the remote table or view using a federated three part name.
"FLUSH OPTIMIZATION PROFILE CACHE " on page 1665	Removes the cached optimization profiles.

Table 116. SQL data statements (continued)

SQL Statement	Purpose
“FLUSH PACKAGE CACHE ” on page 1667	Removes all cached dynamic SQL statements currently in the package cache.
“FREE LOCATOR ” on page 1671	Removes the association between a locator variable and its value.
“LOCK TABLE ” on page 1732	Either prevents concurrent processes from changing a table or prevents concurrent processes from using a table.
“OPEN ” on page 1746	Prepares a cursor that will be used to retrieve values when the FETCH statement is issued.
“SELECT INTO ” on page 1810	Specifies a result table of no more than one row and assigns the values to host variables.
“SET variable ” on page 1878	Assigns values to variables.
“VALUES INTO ” on page 1921	Specifies a result table of no more than one row and assigns the values to host variables.

Table 117. SQL transaction statements

SQL Statement	Purpose
“COMMIT ” on page 982	Terminates a unit of work and commits the database changes made by that unit of work.
“RELEASE SAVEPOINT ” on page 1761	Releases a savepoint within a transaction.
“ROLLBACK ” on page 1806	Terminates a unit of work and backs out the database changes made by that unit of work.
“SAVEPOINT ” on page 1808	Sets a savepoint within a transaction.

Table 118. SQL connection statements

SQL Statement	Purpose
“CONNECT (type 1) ” on page 1006	Connects to an application server according to the rules for remote unit of work.
“CONNECT (type 2) ” on page 1012	Connects to an application server according to the rules for application-directed distributed unit of work.
“DISCONNECT ” on page 1614	Terminates one or more connections when there is no active unit of work.
“RELEASE (connection) ” on page 1760	Places one or more connections in the release-pending state.
“SET CONNECTION ” on page 1814	Changes the state of a connection from dormant to current, making the specified location the current server.

Table 119. SQL dynamic statements

SQL Statement	Purpose
“DESCRIBE ” on page 1608	Obtains information about an object.
“DESCRIBE INPUT ” on page 1608	Obtains information about the input parameter markers of a prepared statement.
“DESCRIBE OUTPUT ” on page 1611	Obtains information about a prepared statement or information about the select list columns in a prepared SELECT statement.

Table 119. SQL dynamic statements (continued)

SQL Statement	Purpose
“EXECUTE ” on page 1645	Executes a prepared SQL statement.
“EXECUTE IMMEDIATE ” on page 1653	Prepares and executes an SQL statement.
“PREPARE ” on page 1752	Prepares an SQL statement (with optional parameters) for execution.

Table 120. SQL session statements

SQL Statement	Purpose
“DECLARE GLOBAL TEMPORARY TABLE ” on page 1586	Defines a declared temporary table.
“EXPLAIN ” on page 1655	Captures information about the chosen access plan.
“SET COMPILATION ENVIRONMENT ” on page 1813	Changes the current compilation environment in the connection to match the values contained in the compilation environment provided by a deadlock event monitor.
“SET CURRENT DECFLOAT ROUNDING MODE ” on page 1816	Verifies that the specified rounding mode is the value that is currently set for the CURRENT DECFLOAT ROUNDING MODE special register.
“SET CURRENT DEFAULT TRANSFORM GROUP ” on page 1817	Changes the value of the CURRENT DEFAULT TRANSFORM GROUP special register.
“SET CURRENT DEGREE ” on page 1818	Changes the value of the CURRENT DEGREE special register.
“SET CURRENT EXPLAIN MODE ” on page 1820	Changes the value of the CURRENT EXPLAIN MODE special register.
“SET CURRENT EXPLAIN SNAPSHOT ” on page 1822	Changes the value of the CURRENT EXPLAIN SNAPSHOT special register.
“SET CURRENT FEDERATED ASYNCHRONY ” on page 1824	Changes the value of the CURRENT FEDERATED ASYNCHRONY special register.
“SET CURRENT IMPLICIT XMLPARSE OPTION ” on page 1825	Changes the value of the CURRENT IMPLICIT XMLPARSE OPTION special register.
“SET CURRENT ISOLATION ” on page 1826	Changes the value of the CURRENT ISOLATION special register.
“SET CURRENT LOCALE LC_MESSAGES ” on page 1827	Changes the value of the CURRENT LOCALE LC_MESSAGES special register.
“SET CURRENT LOCALE LC_TIME ” on page 1828	Changes the value of the CURRENT LOCALE LC_TIME special register.
“SET CURRENT LOCK TIMEOUT ” on page 1829	Changes the value of the CURRENT LOCK TIMEOUT special register.
“SET CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION ” on page 1830	Changes the value of the CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION special register.
“SET CURRENT MDC ROLLOUT MODE ” on page 1832	Assigns a value to the CURRENT MDC ROLLOUT MODE special register.
“SET CURRENT OPTIMIZATION PROFILE ” on page 1834	Assigns a value to the CURRENT OPTIMIZATION PROFILE special register.

Table 120. SQL session statements (continued)

SQL Statement	Purpose
“SET CURRENT PACKAGE PATH ” on page 1836	Assigns a value to the CURRENT PACKAGE PATH special register.
“SET CURRENT PACKAGESET ” on page 1839	Sets the schema name for package selection.
“SET CURRENT QUERY OPTIMIZATION ” on page 1841	Changes the value of the CURRENT QUERY OPTIMIZATION special register.
“SET CURRENT REFRESH AGE ” on page 1843	Changes the value of the CURRENT REFRESH AGE special register.
“SET CURRENT SQL_CCFLAGS ” on page 1845	Changes the value of the CURRENT SQL_CCFLAGS special register.
“SET CURRENT TEMPORAL BUSINESS_TIME ” on page 1846	Changes the value of the CURRENT TEMPORAL BUSINESS_TIME special register.
“SET CURRENT TEMPORAL SYSTEM_TIME ” on page 1847	Changes the value of the CURRENT TEMPORAL SYSTEM_TIME special register.
“SET ENCRYPTION PASSWORD ” on page 1848	Sets the password for encryption.
“SET EVENT MONITOR STATE ” on page 1850	Activates or deactivates an event monitor.
“SET PASSTHRU ” on page 1867	Opens a session for submitting data source native SQL directly to the data source.
“SET PATH ” on page 1868	Changes the value of the CURRENT PATH special register.
“SET ROLE ” on page 1870	Verifies that the authorization ID of the session is a member of a specific role.
“SET SCHEMA ” on page 1871	Changes the value of the CURRENT SCHEMA special register.
“SET SERVER OPTION ” on page 1873	Sets server option settings.
“SET SESSION AUTHORIZATION ” on page 1874	Changes the value of the SESSION USER special register.
“SET USAGE LIST STATE” on page 1876	Manages the state of a usage list and the associated data and memory.

Table 121. SQL embedded host language statements

SQL Statement	Purpose
“BEGIN DECLARE SECTION ” on page 961	Marks the beginning of a host variable declaration section.
“END DECLARE SECTION ” on page 1645	Marks the end of a host variable declaration section.
“GET DIAGNOSTICS ” on page 1671	Used to obtain information about the previously executed SQL statement.
“INCLUDE ” on page 1719	Inserts code or declarations into a source program.
“RESIGNAL ” on page 1767	Used to resignal an error or warning condition.
“SIGNAL ” on page 1889	Used to signal an error or warning condition.
“WHENEVER ” on page 1924	Defines actions to be taken on the basis of SQL return codes.

Table 122. SQL control statements

SQL Statement	Purpose
“CALL ” on page 962	Calls a procedure.
“CASE ” on page 969	Selects an execution path based on multiple conditions.
“Compound SQL ” on page 984	Encloses SQL statements with BEGIN and END keywords.
“Compound SQL (inlined) ” on page 984	Combines one or more other SQL statements into an dynamic block.
“Compound SQL (embedded) ” on page 988	Combines one or more other SQL statements into an executable block.
“Compound SQL (compiled) ” on page 991	Groups other statements together in an SQL procedure.
“FOR ” on page 1668	Executes a statement or group of statements for each row of a table.
“GOTO ” on page 1674	Used to branch to a user-defined label within an SQL procedure.
“IF ” on page 1718	Selects an execution path based on the evaluation of a condition.
“ITERATE ” on page 1730	Causes the flow of control to return to the beginning of a labelled loop.
“LEAVE ” on page 1731	Transfers program control out of a loop or a compound statement.
“LOOP ” on page 1733	Repeats the execution of a statement or a group of statements.
“PIPE ” on page 1750	Returns a row from a compiled table function.
“REPEAT ” on page 1766	Executes a statement or group of statements until a search condition is true.
“RESIGNAL ” on page 1767	Used to resignal an error or warning condition.
“RETURN ” on page 1769	Used to return from a routine.
“SIGNAL ” on page 1889	Used to signal an error or warning condition.
“WHILE ” on page 1926	Repeats the execution of a statement or group of statements while a specified condition is true.

How SQL statements are invoked

SQL statements are classified as executable or non-executable.

An *executable statement* can be invoked in four ways. It can be:

- Issued interactively
- Prepared and executed dynamically
- Embedded in an application program
- Embedded in an SQL procedure, trigger, compound SQL (compiled), or compound SQL (inlined) with some restrictions:
  - Refer to "SQL-procedure-statement" in “Compound SQL (compiled) ” on page 991 for the set of executable statements supported in SQL procedures and compound SQL (compiled) statements.
  - Refer to "SQL-statement" in “Compound SQL (inlined) ” on page 984 statement for the set of executable statements supported in compound SQL (inlined) statements.
  - Refer to "SQL-procedure-statement" in “CREATE TRIGGER ” on page 1460 for the set of executable statements supported in a trigger.

Depending on the statement, some or all of these methods can be used. Statements embedded in REXX are prepared and executed dynamically.

A *non-executable statement* can only be embedded in an application program.

Another SQL statement construct is the select-statement. A *select-statement* can be invoked in three ways. It can be:

- Issued interactively
- Prepared dynamically, referenced in DECLARE CURSOR, and executed implicitly by OPEN, FETCH and CLOSE (dynamic invocation)
- Included in DECLARE CURSOR, and executed implicitly by OPEN, FETCH and CLOSE (static invocation)

Embedding a statement in an application program

SQL statements can be included in a source program that will be submitted to a precompiler. Such statements are said to be *embedded* in the program.

An embedded statement can be placed anywhere in the program where a host language statement is allowed. Each embedded statement must be preceded by the keywords EXEC SQL.

An executable statement embedded in an application program is executed every time a statement of the host language would be executed if it were specified in the same place. Thus, a statement within a loop is executed every time the loop is executed, and a statement within a conditional construct is executed only when the condition is satisfied.

An embedded statement can contain references to host variables. A host variable referenced in this way can be used in two ways. It can be used:

- As input (the current value of the host variable is used in the execution of the statement)
- As output (the variable is assigned a new value as a result of executing the statement)

In particular, all references to host variables in expressions and predicates are effectively replaced by current values of the variables; that is, the variables are used as input.

All executable statements should be followed by a test of the SQL return code. Alternatively, the WHENEVER statement (which is itself non-executable) can be used to change the flow of control immediately after the execution of an embedded statement.

All objects referenced in data manipulation language (DML) statements must exist when the statements are bound to a database.

An embedded non-executable statement is processed only by the precompiler. The precompiler reports any errors encountered in the statement. The statement is *never* processed during program execution; therefore, such statements should not be followed by a test of the SQL return code.

Statements can be included in the SQL-procedure-body portion of the CREATE PROCEDURE statement. Such statements are said to be embedded in the SQL procedure. Whenever an SQL statement description refers to a *host-variable*, an *SQL-variable* can be used if the statement is embedded in an SQL procedure.

Dynamic preparation and execution

An application program can dynamically build an SQL statement in the form of a character string placed in a host variable.

In general, the statement is built from some data available to the program (for example, input from a workstation). The statement (not a select-statement) constructed can be prepared for execution by means of the (embedded) PREPARE statement, and executed by means of the (embedded) EXECUTE statement. Alternatively, an (embedded) EXECUTE IMMEDIATE statement can be used to prepare and execute the statement in one step.

A statement that is going to be dynamically prepared must not contain references to host variables. It can instead contain parameter markers. (For rules concerning parameter markers, see "PREPARE".) When the prepared statement is executed, the parameter markers are effectively replaced by current values of the

host variables specified in the EXECUTE statement. Once prepared, a statement can be executed several times with different values for the host variables. Parameter markers are not allowed in the EXECUTE IMMEDIATE statement.

Successful or unsuccessful execution of the statement is indicated by the setting of an SQL return code in the SQLCA after the EXECUTE (or EXECUTE IMMEDIATE) statement completes. The SQL return code should be checked, as previously described. For more information, see "Detecting and processing error and warning conditions in host language applications" on page 739.

Static invocation of a select-statement

A select-statement can be included as a part of the (non-executable) DECLARE CURSOR statement.

Such a statement is executed every time the cursor is opened by means of the (embedded) OPEN statement. After the cursor is open, the result table can be retrieved, one row at a time, by successive executions of the FETCH statement.

Used in this way, the select-statement can contain references to host variables. These references are effectively replaced by the values that the variables have when the OPEN statement executes.

Dynamic invocation of a select-statement

An application program can dynamically build a select-statement in the form of a character string placed in a host variable.

In general, the statement is built from some data available to the program (for example, a query obtained from a workstation). The statement so constructed can be prepared for execution by means of the (embedded) PREPARE statement, and referenced by a (non-executable) DECLARE CURSOR statement. The statement is then executed every time the cursor is opened by means of the (embedded) OPEN statement. After the cursor is open, the result table can be retrieved, one row at a time, by successive executions of the FETCH statement.

Used in this way, the select-statement must not contain references to host variables. It can contain parameter markers instead. The parameter markers are effectively replaced by the values of the host variables specified in the OPEN statement.

Interactive invocation

A capability for entering SQL statements from a workstation is part of the architecture of the database manager. A statement entered in this way is said to be issued interactively.

Such a statement must be an executable statement that does not contain parameter markers or references to host variables, because these make sense only in the context of an application program.

SQL use with other host systems

SQL statement syntax exhibits minor variations among different types of host systems (Db2 for z/OS, Db2 for IBM i, Db2).

Regardless of whether the SQL statements in an application are static or dynamic, it is important - if the application is meant to access different database host systems - to ensure that the SQL statements and precompile/bind options are supported on the database systems that the application will access.

Further information about SQL statements used in other host systems can be found in the *SQL Reference* manuals for Db2 for z/OS and Db2 for IBM i.

Detecting and processing error and warning conditions in host language applications

An application program containing executable SQL statements can use either SQLCODE or SQLSTATE values to handle return codes from SQL statements.

There are two ways in which an application can get access to these values.

- Include a structure named SQLCA. The SQLCA includes an integer variable named SQLCODE and a character string variable named SQLSTATE. In REXX, an SQLCA is provided automatically. In other languages, an SQLCA can be obtained by using the INCLUDE SQLCA statement.
- If LANGLEVEL SQL92E is specified as a precompile option, a variable named SQLCODE or SQLSTATE can be declared in the SQL declare section of the program. If neither of these variables is declared in the SQL declare section, it is assumed that a variable named SQLCODE is declared elsewhere in the program. With LANGLEVEL SQL92E, the program should not have an INCLUDE SQLCA statement.

An SQLCODE is set by the database manager after each SQL statement executes. All database managers conform to the ISO/ANSI SQL standard, as follows:

- If SQLCODE = 0 and SQLWARN0 is blank, execution was successful.
- If SQLCODE = 100, "no data" was found. For example, a FETCH statement returned no data, because the cursor was positioned after the last row of the result table.
- If SQLCODE > 0 and not = 100, execution was successful with a warning.
- If SQLCODE = 0 and SQLWARN0 = 'W', execution was successful, but one or more warning indicators were set.
- If SQLCODE < 0, execution was not successful.

The meaning of SQLCODE values other than 0 and 100 is product-specific.

An SQLSTATE is set by the database manager after each SQL statement executes. Application programs can check the execution of SQL statements by testing SQLSTATE instead of SQLCODE. SQLSTATE provides common codes for common error conditions. Application programs can test for specific errors or classes of errors. The coding scheme is the same for all IBM database managers, and is based on the ISO/ANSI SQL92 standard.

SQL comments

Static SQL statements can include host language or SQL comments. Dynamic SQL statements can include SQL comments.

There are two types of SQL comments:

simple comments
Simple comments are introduced by two consecutive hyphens (--) and end with the end of line.

bracketed comments
Bracketed comments are introduced by /* and end with */.

The following rules apply to the use of simple comments:

- The two hyphens must be on the same line and must not be separated by a space.
- Simple comments can be started wherever a space is valid (except within a delimiter token or between 'EXEC' and 'SQL').
- Simple comments cannot be continued to the next line.
- In COBOL, the hyphens must be preceded by a space.

The following rules apply to the use of bracketed comments:

- The /* must be on the same line and must not be separated by a space.
- The */ must be on the same line and must not be separated by a space.
- Bracketed comments can be started wherever a space is valid (except within a delimiter token or between 'EXEC' and 'SQL').
- Bracketed comments can be continued to subsequent lines.

Examples

- *Example 1:* This example shows how to include simple comments in a statement:

```
CREATE VIEW PRJ_MAXPER       -- PROJECTS WITH MOST SUPPORT PERSONNEL
  AS SELECT PROJNO, PROJNAME -- NUMBER AND NAME OF PROJECT
    FROM PROJECT
    WHERE DEPTNO = 'E21'     -- SYSTEMS SUPPORT DEPT CODE
    AND PRSTAFF > 1
```

- *Example 2:* This example shows how to include bracketed comments in a statement:

```
CREATE VIEW PRJ_MAXPER       /* PROJECTS WITH MOST SUPPORT
                                  PERSONNEL                */
  AS SELECT PROJNO, PROJNAME /* NUMBER AND NAME OF PROJECT  */
    FROM PROJECT
    WHERE DEPTNO = 'E21'     /* SYSTEMS SUPPORT DEPT CODE   */
    AND PRSTAFF > 1
```

Conditional compilation in SQL

Conditional compilation allows SQL to include compiler directives which are used to determine the actual SQL that gets compiled.

There are two types of compiler directives that can be used for conditional compilation:

Selection directive
A compiler control statement used to determine the selection of a code fragment. The _IF directive can reference inquiry directives or global variables that are defined as a constant.

Inquiry directive
A reference to a compiler named constant that is assigned by the system or specified as a conditional compilation named constant in CURRENT SQL_CCFLAGS. An inquiry directive can be used directly or in a selection directive.

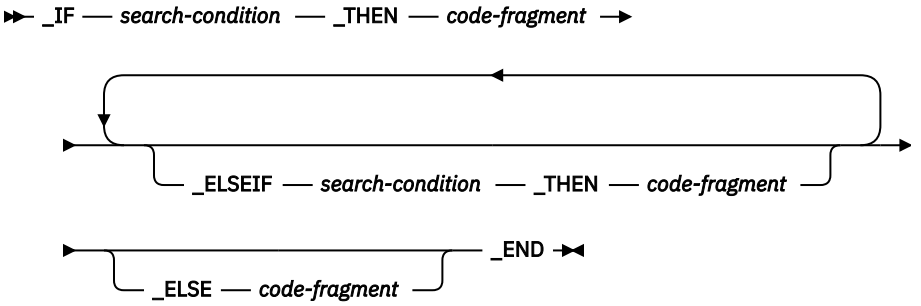
These directives can be used in the following contexts:

- SQL procedure definitions
- Compiled SQL function definitions
- Compiled trigger definitions
- Oracle PL/SQL package definitions

A directive can only appear after the object type (FUNCTION, PACKAGE, PACKAGE BODY, PROCEDURE, or TRIGGER) has been identified in the data definition language statement.

Selection directive

The selection directive is very similar to the IF statement except there are prefixes on the keywords to indicate use of conditional compilation and the terminating keyword is _END.



search-condition
Specifies the condition that is evaluated to determine what *code-fragment*, if any, is included. If the condition is unknown or false, evaluation continues with the next search condition, until a condition

is true, the _ELSE clause is reached, or the end of the selection directive is reached. The search condition can include only the following elements (SQLSTATE 428HV):

- Constants of type BOOLEAN, INTEGER, or VARCHAR
- NULL constants
- Inquiry directives
- Global constants, where the defined constant value is a simple literal of type BOOLEAN, INTEGER, or VARCHAR
- Basic predicates
- NULL predicates
- Predicates that are a Boolean constant or a Boolean inquiry directive
- Logical operators (AND, OR, and NOT)

code-fragment
A portion of SQL code that can be included in the context of the SQL statement where the selection directive appears. There must not be a selection directive in *code-fragment* (SQLSTATE 428HV).

Inquiry directive

An inquiry directive is used to inquire about the compilation environment. An inquiry directive is specified in an SQL statement as an ordinary identifier prefixed with two underscore characters. The actual identifier can represent one of the following values:

- A compilation environment value defined by the system
- A compilation value defined by a user at the database level or at the individual session level

The only compilation environment variable defined by the system is __SQL_LINE, which provides the line number of SQL that is currently being compiled.

A user-defined compilation value can be defined at the database level using the **sql_ccflags** database configuration parameter or at a session level by assigning it to the CURRENT SQL_CCFLAGS special register.

If an inquiry directive is referenced but is not defined, processing continues assuming that the value for the inquiry directive is the null value.

Notes

- **References to global variables defined as constants:** A reference to a global variable (which can also be a reference to a module variable published in a module) in a selection directive is used to provide a value based on a constant at the time of compilation only. The referenced global variable must meet the following requirements:
  - Exist at the current server (SQLSTATE 42704)
  - Have a data type of BOOLEAN, INTEGER, or VARCHAR (SQLSTATE 428HV)
  - Be defined using the CONSTANT clause with a single constant value (SQLSTATE 428HV)

  Such a global variable is known as a global constant. Subsequent changes to the global constant do not have any impact on statements that are already compiled.
- **Syntax alternatives:** If the data server environment is enabled for PL/SQL statement execution:
  - ELSIF can be specified instead of ELSEIF
  - A dollar character ($) can be used instead of an underscore character (_) as the prefix for the keywords for conditional compilation
  - Two dollar characters ($$) can be used instead of two underscore characters (__) as the prefix for an inquiry directive

The dollar character prefix is intended only to support existing SQL statements that use inquiry directives and is not recommended for use when writing new SQL statements.

Example

Specify a database-wide setting for a compilation value called DBV97 that has a value of TRUE.

```
UPDATE DATABASE CONFIGURATION USING SQL_CCFLAGS DB2V97:TRUE
```

The value is available as the default for any subsequent connection to the database.

If a particular session needed a maximum number of years compilation value for use in defining some routines in the current session, the default SQL_CCFLAGS can be extended using the SET CURRENT SQL_CCFLAGS statement.

```
BEGIN
  DECLARE CCFLAGS_LIST VARCHAR(1024);
  SET CCFLAGS_LIST = CURRENT SQL_CCFLAGS CONCAT ',max_years:50';
  SET CURRENT SQL_CCFLAGS = CCFLAGS_LIST;
END
```

The use of CURRENT SQL_CCFLAGS on the right side of the assignment to the CCFLAGS_LIST variable keeps the existing SQL_CCFLAGS settings, while the string constant provides the additional compilation values.

Here is an example of a CREATE PROCEDURE statement that uses the contents of the CURRENT SQL_CCFLAGS.

```
CREATE PROCEDURE CHECK_YEARS (IN YEARS_WORKED INTEGER)
BEGIN
   _IF __DB2V97 _THEN
      IF YEARS_WORKED > __MAX_YEARS THEN
      ...
      END IF;
   _END
```

The inquiry directive __DB2V97 is used as a Boolean value to determine if the code can be included. The inquiry directive __MAX_YEARS is replaced during compilation by the constant value 50.

About SQL control statements

SQL control statements, also called SQL Procedural Language (SQL PL), are SQL statements that allow SQL to be used in a manner similar to writing a program in a structured programming language.

SQL control statements provide the capability to control the logic flow, declare, and set variables, and handle warnings and exceptions. Some SQL control statements include other nested SQL statements. SQL control statements can be used in the body of a routine, trigger or a compound statement.

References to SQL parameters, SQL variables, and global variables

SQL parameters, SQL variables, and global variables can be referenced anywhere in an SQL procedure statement where an expression or variable can be specified.

Host variables cannot be specified in SQL routines, SQL triggers or dynamic compound statements. SQL parameters can be referenced anywhere in the routine body, and can be qualified with the routine name. SQL variables can be referenced anywhere in the compound statement in which they are declared, and can be qualified with the label name specified at the beginning of the compound statement. If an SQL parameter or SQL variable has a row data type, fields can be referenced anywhere an SQL parameter or SQL variable can be referenced. Global variables can be referenced within any expression as long as the expression is not required to be deterministic. The following scenarios require deterministic expressions, which preclude the use of global variables:

- Check constraints
- Definitions of generated columns

- Refresh immediate MQTs

All SQL parameters, SQL variables, row variable fields, and global variables are considered nullable. The name of an SQL parameter, SQL variable, row variable field, or global variable in an SQL routine can be the same as the name of a column in a table or view referenced in the routine. The name of an SQL variable or row variable field can also be the same as the name of another SQL variable or row variable field declared in the same routine. This can occur when the two SQL variables are declared in different compound statements. The compound statement that contains the declaration of an SQL variable determines the scope of that variable. For more information, see “Compound SQL (compiled) ” on page 991.

The name of an SQL variable or SQL parameter in an SQL routine can be the same as the name of an identifier used in certain SQL statements. If the name is not qualified, the following rules describe whether the name refers to the identifier or to the SQL parameter or SQL variable:

- In the SET PATH and SET SCHEMA statements, the name is checked as an SQL parameter or SQL variable. If not found as an SQL variable or SQL parameter, it is used as an identifier.
- In the CONNECT, DISCONNECT, RELEASE, and SET CONNECTION statements, the name is used as an identifier.

Names that are the same should be explicitly qualified. Qualifying a name clearly indicates whether the name refers to a column, SQL variable, SQL parameter, row variable field, or global variable. If the name is not qualified, or qualified but still ambiguous, the following rules describe whether the name refers to a column, an SQL variable, an SQL parameter, or a global variable:

- If the tables and views specified in an SQL routine body exist at the time the routine is created, the name is first checked as a column name. If not found as a column, it is then checked as an SQL variable in the compound statement, then checked as an SQL parameter, and then, finally, checked as a global variable.
- If the referenced tables or views do not exist at the time the routine is created, the name is first checked as an SQL variable in the compound statement, then as an SQL parameter, and then as a global variable. The variable can be declared within the compound statement that contains the reference, or within a compound statement in which that compound statement is nested. If two SQL variables are within the same scope and have the same name, which can happen if they are declared in different compound statements, the SQL variable that is declared in the innermost compound statement is used. If not found, it is assumed to be a column.

References to SQL labels

Labels can be specified on most SQL procedure statements.

The compound statement that contains the statement that defines a label determines the scope of that label name. A label name must be unique within the compound statement in which it is defined, including any labels defined in compound statements that are nested within that compound statement (SQLSTATE 42734). The label must not be the same as a label specified on the compound statement itself (SQLSTATE 42734), or the same as the name of the routine that contains the SQL procedure statement (SQLSTATE 42734).

A label name can only be referenced within the compound statement in which it is defined, including any compound statements that are nested within that compound statement. A label can be used to qualify the name of an SQL variable, or it can be specified as the target of a GOTO, LEAVE, or ITERATE statement.

References to SQL condition names

The name of an SQL condition can be the same as the name of another SQL condition declared in the same routine.

This can occur when the two SQL conditions are declared in different compound statements. The compound statement that contains the declaration of an SQL condition name determines the scope of that condition name. A condition name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement (SQLSTATE 42734). A condition name can only be referenced within the compound statement

in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a condition name, the condition that is declared in the innermost compound statement is the condition that is used. For more information, see "Compound SQL (inlined)".

References to SQL statement names

The name of an SQL statement can be the same as the name of another SQL statement declared in the same routine.

This can occur when the two SQL statements are declared in different compound statements. The compound statement that contains the declaration of an SQL statement name determines the scope of that statement name. A statement name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement (SQLSTATE 42734). A statement name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a statement name, the statement that is declared in the innermost compound statement is the statement that is used. For more information, see "Compound SQL (inlined)".

References to SQL cursor names

Cursor names include the names of declared cursors and the names of cursor variables.

The name of an SQL cursor can be the same as the name of another SQL cursor declared in the same routine. This can occur when the two SQL cursors are declared in different compound statements.

The compound statement that contains the declaration of an SQL cursor determines the scope of that cursor name. A cursor name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement (SQLSTATE 42734). A cursor name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement. When there is a reference to a cursor name, the cursor that is declared in the innermost compound statement is the cursor that is used. For more information, see "Compound SQL (inlined)".

If the cursor constructor assigned to a cursor variable contains a reference to a local SQL variable, then any OPEN statement that uses the cursor variable must be within the scope where the local SQL variable was declared.

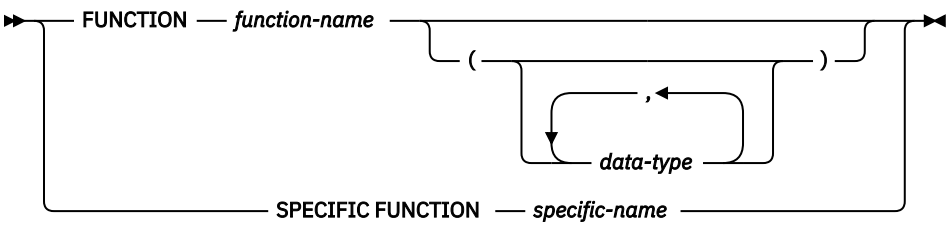
Function, method, and procedure designators

This topic describes syntax fragments that are used to uniquely identify a function, method, or procedure that is not defined in a module.

Function designator

A function designator uniquely identifies a single function. Function designators typically appear in DDL statements for functions (such as DROP or ALTER). A function designator must not identify a module function (SQLSTATE 42883).

function-designator



FUNCTION *function-name*

Identifies a particular function, and is valid only if there is exactly one function instance with the name *function-name* in the schema. The identified function can have any number of parameters defined for it. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. If no function by this name exists in the named or implied schema, an error (SQLSTATE 42704) is raised. If there is more than one instance of the function in the named or implied schema, an error (SQLSTATE 42725) is raised.

FUNCTION *function-name (data-type,...)*

Provides the function signature, which uniquely identifies the function. The function resolution algorithm is not used.

function-name

Specifies the name of the function. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names.

(data-type,...)

Values must match the data types that were specified (in the corresponding position) on the CREATE FUNCTION statement. The number of data types, and the logical concatenation of the data types, is used to identify the specific function instance.

If a data type is unqualified, the type name is resolved by searching the schemas on the SQL path. This also applies to data type names specified for a REFERENCE type.

It is not necessary to specify the length, precision, or scale for the parameterized data types. Instead, an empty set of parentheses can be coded to indicate that these attributes are to be ignored when looking for a data type match.

FLOAT() cannot be used (SQLSTATE 42601), because the parameter value indicates different data types (REAL or DOUBLE).

If length, precision, or scale is coded, the value must exactly match that specified in the CREATE FUNCTION statement. When length is specified for character and graphic string data types, the string unit of the length attribute must exactly match that specified in the CREATE FUNCTION statement.

A type of FLOAT(*n*) does not need to match the defined value for *n*, because $0 < n < 25$ means REAL, and $24 < n < 54$ means DOUBLE. Matching occurs on the basis of whether the type is REAL or DOUBLE.

If no function with the specified signature exists in the named or implied schema, an error (SQLSTATE 42883) is raised.

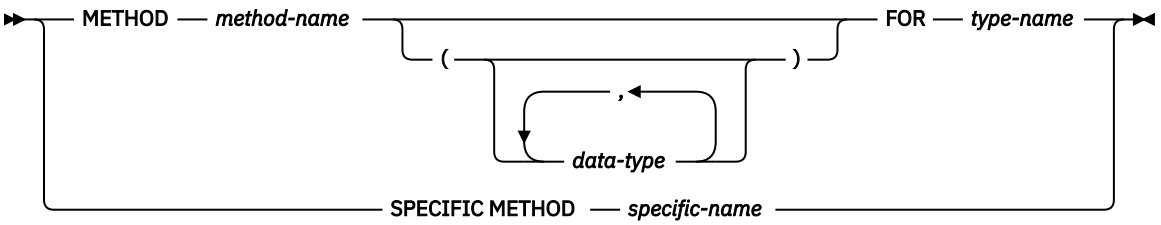
SPECIFIC FUNCTION *specific-name*

Identifies a particular user-defined function, using the name that is specified or defaulted to at function creation time. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The *specific-name* must identify a specific function instance in the named or implied schema; otherwise, an error (SQLSTATE 42704) is raised.

Method designator

A method designator uniquely identifies a single method. Method designators typically appear in DDL statements for methods (such as DROP or ALTER).

method-designator



METHOD *method-name*
Identifies a particular method, and is valid only if there is exactly one method instance with the name *method-name* for the type *type-name*. The identified method can have any number of parameters defined for it. If no method by this name exists for the type, an error (SQLSTATE 42704) is raised. If there is more than one instance of the method for the type, an error (SQLSTATE 42725) is raised.

METHOD *method-name (data-type,...)*
Provides the method signature, which uniquely identifies the method. The method resolution algorithm is not used.

method-name
Specifies the name of the method for the type *type-name*.

(data-type,...)
Values must match the data types that were specified (in the corresponding position) on the CREATE TYPE statement. The number of data types, and the logical concatenation of the data types, is used to identify the specific method instance.

If a data type is unqualified, the type name is resolved by searching the schemas on the SQL path. This also applies to data type names specified for a REFERENCE type.

It is not necessary to specify the length, precision, or scale for the parameterized data types. Instead, an empty set of parentheses can be coded to indicate that these attributes are to be ignored when looking for a data type match.

FLOAT() cannot be used (SQLSTATE 42601), because the parameter value indicates different data types (REAL or DOUBLE).

If length, precision, or scale is coded, the value must exactly match that specified in the CREATE TYPE statement. When length is specified for character and graphic string data types, the string unit of the length attribute must exactly match that specified in the CREATE TYPE statement.

A type of FLOAT(*n*) does not need to match the defined value for *n*, because $0 < n < 25$ means REAL, and $24 < n < 54$ means DOUBLE. Matching occurs on the basis of whether the type is REAL or DOUBLE.

If no method with the specified signature exists for the type in the named or implied schema, an error (SQLSTATE 42883) is raised.

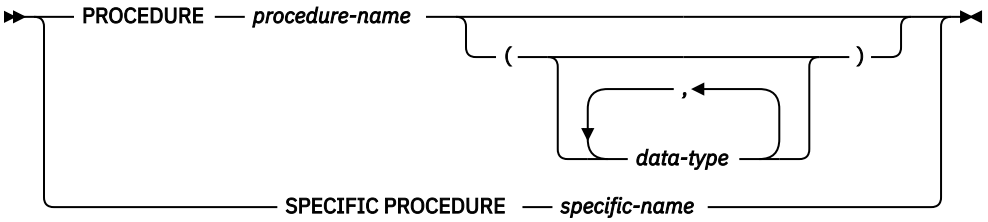
FOR *type-name*
Names the type with which the specified method is to be associated. The name must identify a type already described in the catalog (SQLSTATE 42704). In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names.

SPECIFIC METHOD *specific-name*
Identifies a particular method, using the name that is specified or defaulted to at method creation time. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The *specific-name* must identify a specific method instance in the named or implied schema; otherwise, an error (SQLSTATE 42704) is raised.

Procedure designator

A procedure designator uniquely identifies a single procedure. Procedure designators typically appear in DDL statements for procedures (such as DROP or ALTER). A procedure designator must not identify a module procedure (SQLSTATE 42883).

procedure-designator



PROCEDURE *procedure-name*
Identifies a particular procedure, and is valid only if there is exactly one procedure instance with the name *procedure-name* in the schema. The identified procedure can have any number of parameters defined for it. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. If no procedure by this name exists in the named or implied schema, an error (SQLSTATE 42704) is raised. If there is more than one instance of the procedure in the named or implied schema, an error (SQLSTATE 42725) is raised.

PROCEDURE *procedure-name (data-type,...)*
Provides the procedure signature, which uniquely identifies the procedure. The procedure resolution algorithm is not used.

procedure-name
Specifies the name of the procedure. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names.

(data-type,...)
Values must match the data types that were specified (in the corresponding position) on the CREATE PROCEDURE statement. The number of data types, and the logical concatenation of the data types, is used to identify the specific procedure instance.

If a data type is unqualified, the type name is resolved by searching the schemas on the SQL path. This also applies to data type names specified for a REFERENCE type.

It is not necessary to specify the length, precision, or scale for the parameterized data types. Instead, an empty set of parentheses can be coded to indicate that these attributes are to be ignored when looking for a data type match.

FLOAT() cannot be used (SQLSTATE 42601), because the parameter value indicates different data types (REAL or DOUBLE).

If length, precision, or scale is coded, the value must exactly match that specified in the CREATE PROCEDURE statement. When length is specified for character and graphic string data types, the string unit of the length attribute must exactly match that specified in the CREATE PROCEDURE statement.

A type of FLOAT(*n*) does not need to match the defined value for *n*, because $0 < n < 25$ means REAL, and $24 < n < 54$ means DOUBLE. Matching occurs on the basis of whether the type is REAL or DOUBLE.

If no procedure with the specified signature exists in the named or implied schema, an error (SQLSTATE 42883) is raised.

SPECIFIC PROCEDURE *specific-name*
Identifies a particular procedure, using the name that is specified or defaulted to at procedure creation time. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a

qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The *specific-name* must identify a specific procedure instance in the named or implied schema; otherwise, an error (SQLSTATE 42704) is raised.

ALLOCATE CURSOR

The ALLOCATE CURSOR statement allocates a cursor for the result set identified by the result set locator variable.

For more information about result set locator variables, see the description of the ASSOCIATE LOCATORS statement.

Invocation

This statement can only be embedded in an SQL procedure. It is not an executable statement and cannot be dynamically prepared.

Authorization

None required.

Syntax

Description

cursor-name
Names the cursor. The name must not identify a cursor that has already been declared in the source SQL procedure (SQLSTATE 24502).

CURSOR FOR RESULT SET *rs-locator-variable*

Names a result set locator variable that has been declared in the source SQL procedure, according to the rules for declaring result set locator variables. For more information about declaring SQL variables, see "Compound SQL (Procedure) statement".

The result set locator variable must contain a valid result set locator value, as returned by the ASSOCIATE LOCATORS SQL statement (SQLSTATE 0F001).

Rules

- The following rules apply when using an allocated cursor:
  - An allocated cursor cannot be opened with the OPEN statement (SQLSTATE 24502).
  - An allocated cursor cannot be used in a positioned UPDATE or DELETE statement (SQLSTATE 42828).
  - An allocated cursor can be closed with the CLOSE statement. Closing an allocated cursor closes the associated cursor.
  - Only one cursor can be allocated to each result set.
- Allocated cursors last until a rollback operation, an implicit close, or an explicit close.
- A commit operation destroys allocated cursors that are not defined WITH HOLD.
- Destroying an allocated cursor closes the associated cursor in the SQL procedure.

Example

This SQL procedure example defines and associates cursor C1 with the result set locator variable LOC1 and the related result set returned by the SQL procedure:

```
ALLOCATE C1 CURSOR FOR RESULT SET LOC1;
```

ALTER AUDIT POLICY

The ALTER AUDIT POLICY statement modifies the definition of an audit policy at the current server.

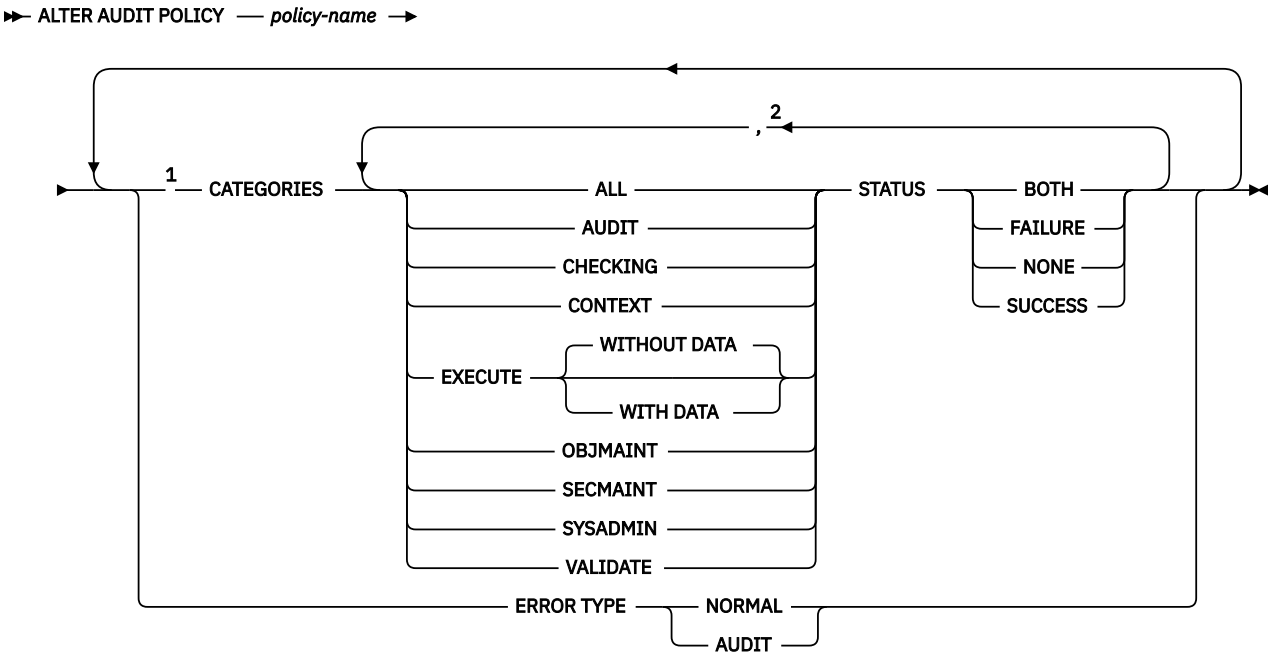
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Notes:

1 Each of the CATEGORIES and ERROR TYPE clauses can be specified at most once (SQLSTATE 42614).

2 Each category can be specified at most once (SQLSTATE 42614), and no other category can be specified if ALL is specified (SQLSTATE 42601).

Description

policy-name

Identifies the audit policy that is to be altered. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The name must uniquely identify an existing audit policy at the current server (SQLSTATE 42704).

CATEGORIES

A list of one or more audit categories for which a new status value is specified. If ALL is not specified, the STATUS of any category that is not explicitly specified remains unchanged.

ALL

Sets all categories to the same status. The EXECUTE category is WITHOUT DATA.

AUDIT
Generates records when audit settings are changed or when the audit log is accessed.

CHECKING
Generates records during authorization checking of attempts to access or manipulate database objects or functions.

CONTEXT
Generates records to show the operation context when a database operation is performed.

EXECUTE
Generates records to show the execution of SQL statements.

WITHOUT DATA or WITH DATA
Specifies whether or not input data values provided for any host variables and parameter markers should be logged as part of the EXECUTE category.

WITHOUT DATA
Input data values provided for any host variables and parameter markers are not logged as part of the EXECUTE category.

WITH DATA
Input data values provided for any host variables and parameter markers are logged as part of the EXECUTE category. Not all input values are logged; specifically, LOB, LONG, XML, and structured type parameters appear as the null value. Date, time, and timestamp fields are logged in ISO format. The input data values are converted to the database code page before being logged. If code page conversion fails, no errors are returned and the unconverted data is logged.

OBJMAINT
Generates records when data objects are created or dropped.

SECMAINT
Generates records when object privileges, database privileges, or DBADM authority is granted or revoked. Records are also generated when the database manager security configuration parameters **sysadm_group**, **sysctrl_group**, or **sysmaint_group** are modified.

SYSADMIN
Generates records when operations requiring SYSADM, SYSMAINT, or SYSCTRL authority are performed.

VALIDATE
Generates records when users are authenticated or when system security information related to a user is retrieved.

STATUS
Specifies a status for the specified category.

BOTH
Successful and failing events will be audited.

FAILURE
Only failing events will be audited.

SUCCESS
Only successful events will be audited.

NONE
No events in this category will be audited.

ERROR TYPE
Specifies whether audit errors are to be returned or ignored.

NORMAL
Any errors generated by the audit are ignored and only the SQLCODEs for errors associated with the operation being performed are returned to the application.

AUDIT
All errors, including errors occurring within the audit facility itself, are returned to the application.

Rules

- An AUDIT-exclusive SQL statement must be followed by a COMMIT or ROLLBACK statement (SQLSTATE 5U021). AUDIT-exclusive SQL statements are:
  - AUDIT
  - CREATE AUDIT POLICY, ALTER AUDIT POLICY, or DROP (AUDIT POLICY)
  - DROP (ROLE) or DROP (TRUSTED CONTEXT) if the role or trusted context is associated with an audit policy
- An AUDIT-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.

Notes

- Only one uncommitted AUDIT-exclusive SQL statement is allowed at a time across all database partitions. If an uncommitted AUDIT-exclusive SQL statement is executing, subsequent AUDIT-exclusive SQL statements wait until the current AUDIT-exclusive SQL statement commits or rolls back.
- Changes are written to the system catalog, but do not take effect until they are committed, even for the connection that issues the statement.
- If the audit policy that is being altered is currently associated with a database object, the changes do not take effect until the next unit of work for the application that is affected by the change. For example, if the audit policy is in use for the database, no current units of work will see the change to the policy until after a COMMIT or a ROLLBACK statement for that unit of work completes.

Example

Alter the SECMAINT, CHECKING, and VALIDATE categories of an audit policy named DBAUDPRF to audit both successes and failures.

```
ALTER AUDIT POLICY DBAUDPRF
  CATEGORIES SECMAINT STATUS BOTH,
             CHECKING STATUS BOTH,
             VALIDATE STATUS BOTH
```

ALTER BUFFERPOOL

The ALTER BUFFERPOOL statement is used to modify the characteristics or behavior of a buffer pool. There are a number of reasons to use the ALTER BUFFERPOOL statement, for example, to enable self-tuning memory.

The ALTER BUFFERPOOL statement can modify a buffer pool in the following ways:

- Modify the size of the buffer pool on all members or on a single member
- Enable or disable automatic sizing of the buffer pool
- Add this buffer pool definition to a new database partition group
- Modify the block area of the buffer pool for block-based I/O

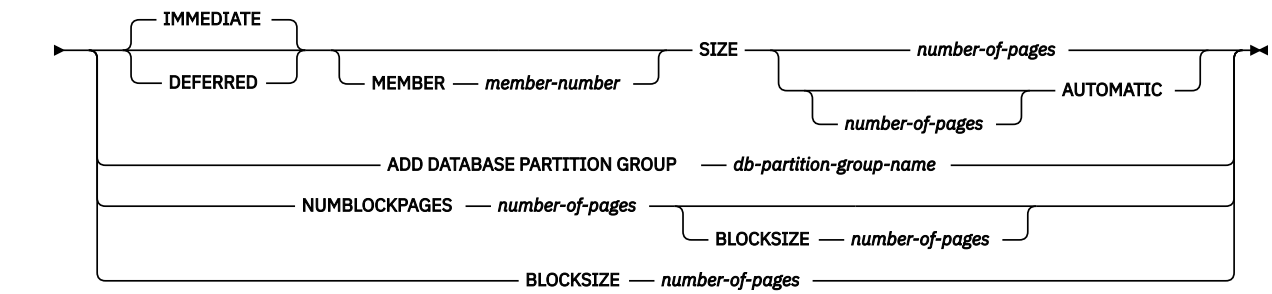
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SYSCTRL or SYSADM authority.

Syntax



Description

bufferpool-name
Names the buffer pool. This is a one-part name. It is an SQL identifier (either ordinary or delimited). It must be a buffer pool described in the catalog.

IMMEDIATE or DEFERRED
Indicates whether or not the buffer pool size will be changed immediately.

IMMEDIATE
The buffer pool size will be changed immediately. If there is not enough reserved space in the database shared memory to allocate new space (SQLSTATE 01657), the statement is executed as DEFERRED.

DEFERRED
The buffer pool size will be changed when the database is reactivated (all applications need to be disconnected from the database). Reserved memory space is not needed; the database will allocate the required memory from the system at activation time.

MEMBER *member-number*
Specifies the member on which the size of the buffer pool is modified. An exception entry is created in the SYSCAT.BUFFERPOOLEXCEPTIONS catalog view. The member must be in one of the database partition groups for the buffer pool (SQLSTATE 42729). If this clause is not specified, the size of the buffer pool is modified on all members except those that have an exception entry in SYSCAT.BUFFERPOOLEXCEPTIONS.

SIZE
Specifies a new size for the buffer pool, or enables or disables self tuning for this buffer pool.

number-of-pages
The number of pages for the new buffer pool size. If the buffer pool is already a self-tuning buffer pool, and the SIZE *number-of-pages* clause is specified, the alter operation disables self-tuning for this buffer pool.

AUTOMATIC
Enables self tuning for this buffer pool. The database manager adjusts the size of the buffer pool in response to workload requirements. If the number of pages is specified, the current buffer pool size is set to that value unless the deferred keyword is also specified, in which case the number of pages will be ignored. On subsequent database activations, the buffer pool size is based on the last tuning value that is determined by the self-tuning memory manager (STMM). The STMM enforces a minimum size for automatic buffer pools, which is the minimum of the current size and 5000 pages. To determine the current size of buffer pools that are enabled for self tuning, use the MON_GET_BUFFERPOOL routine and examine the current size of the buffer pools. The size of the buffer pool is found in the**bp_cur_buffsz** monitor element. When AUTOMATIC is specified, the MEMBER clause cannot be specified (SQLSTATE 42601).

ADD DATABASE PARTITION GROUP *db-partition-group-name*
Adds this database partition group to the list of database partition groups to which the buffer pool definition is applicable. For any member in the database partition group that does not already have

the buffer pool defined, the buffer pool is created on the member using the default size specified for the buffer pool. Table spaces in *db-partition-group-name* may specify this buffer pool. The database partition group must currently exist in the database (SQLSTATE 42704).

NUMBLOCKPAGES ***number-of-pages***
Specifies the number of pages that should exist in the block-based area. The number of pages must not be greater than 98 percent of the number of pages for the buffer pool, based on the NPAGES value in SYSCAT.BUFFERPOOLS (SQLSTATE 54052). Specifying the value 0 disables block I/O. The actual value of NUMBLOCKPAGES used will be a multiple of BLOCKSIZE.

NUMBLOCKPAGES is not supported in a Db2 pureScale environment (SQLSTATE 56038).

BLOCKSIZE ***number-of-pages***
Specifies the number of pages in a block. The block size must be a value between 2 and 256 (SQLSTATE 54053). The default value is 32.

BLOCKSIZE is not supported in a Db2 pureScale environment (SQLSTATE 56038).

Notes

- Only the buffer pool size can be changed dynamically (immediately). All other changes are deferred, and will only come into effect after the database is reactivated.
- If the statement is executed as deferred, although the buffer pool definition is transactional and the changes to the buffer pool definition will be reflected in the catalog tables on commit, no changes to the actual buffer pool will take effect until the next time the database is started. The current attributes of the buffer pool will exist until then, and there will not be any impact to the buffer pool in the interim. Tables created in table spaces of new database partition groups will use the default buffer pool. The statement is IMMEDIATE by default when that keyword applies.
- There should be enough real memory on the machine for the total of all the buffer pools, as well as for the rest of the database manager and application requirements.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - DBPARTITIONNUM or NODE can be specified in place of MEMBER except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - NODEGROUP can be specified in place of DATABASE PARTITION GROUP

ALTER DATABASE PARTITION GROUP

The ALTER DATABASE PARTITION GROUP statement is used to add one or more database partitions to a database partition group, or drop one or more database partitions from a database partition group.

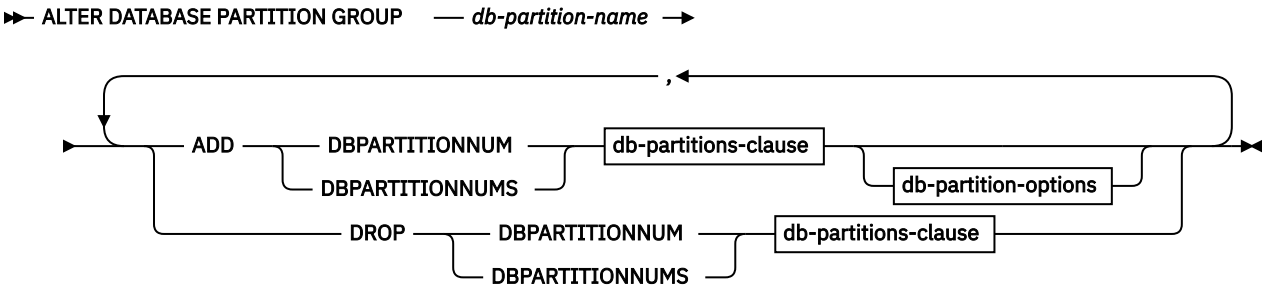
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

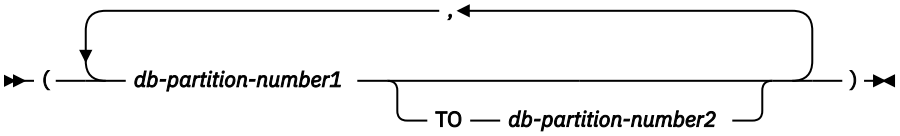
Authorization

The authorization ID of the statement must have SYSCTRL or SYSADM authority.

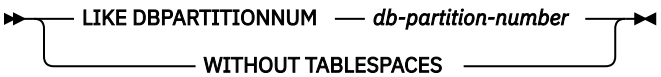
Syntax



db-partitions-clause



db-partition-options



Description

db-partition-name
Names the database partition group. This is a one-part name. It is an SQL identifier (either ordinary or delimited). It must be a database partition group described in the catalog. IBMCATGROUP and IBMTEMPGROUP cannot be specified (SQLSTATE 42832).

ADD DBPARTITIONNUM
Specifies the specific database partition or partitions to add to the database partition group. DBPARTITIONNUMS is a synonym for DBPARTITIONNUM. Any specified database partition must not already be defined in the database partition group (SQLSTATE 42728).

DROP DBPARTITIONNUM
Specifies the specific database partition or partitions to drop from the database partition group. DBPARTITIONNUMS is a synonym for DBPARTITIONNUM. Any specified database partition must already be defined in the database partition group (SQLSTATE 42729).

db-partitions-clause
Specifies the database partition or partitions to be added or dropped.

db-partition-number1
Specify a specific database partition number.

TO *db-partition-number2*
Specify a range of database partition numbers. The value of *db-partition-number2* must be greater than or equal to the value of *db-partition-number1* (SQLSTATE 428A9).

db-partition-options

LIKE DBPARTITIONNUM *db-partition-number*
Specifies that the containers for the existing table spaces in the database partition group will be the same as the containers on the specified *db-partition-number*. The specified database partition must be a partition that existed in the database partition group before this statement, and that is not included in a DROP DBPARTITIONNUM clause of the same statement.

For table spaces that are defined to use automatic storage (that is, table spaces that were created with the MANAGED BY AUTOMATIC STORAGE clause of the CREATE TABLESPACE statement, or for which no MANAGED BY clause was specified at all), the containers will not necessarily match those from the specified partition. Instead, containers will automatically be assigned by the database manager based on the storage paths that are associated with the database, and this

might or might not result in the same containers being used. The size of each table space is based on the initial size that was specified when the table space was created, and might not match the current size of the table space on the specified partition.

WITHOUT TABLESPACES
Specifies that the containers for existing table spaces in the database partition group are not created on the newly added database partition or partitions. The ALTER TABLESPACE statement using the *db-partitions-clause* or the MANAGED BY AUTOMATIC STORAGE clause must be used to define containers for use with the table spaces that are defined on this database partition group. If this option is not specified, the default containers are specified on newly added database partitions for each table space defined on the database partition group.

This option is ignored for table spaces that are defined to use automatic storage (that is, table spaces that were created with the MANAGED BY AUTOMATIC STORAGE clause of the CREATE TABLESPACE statement, or for which no MANAGED BY clause was specified at all). There is no way to defer container creation for these table spaces. Containers will automatically be assigned by the database manager based on the storage paths that are associated with the database. The size of each table space will be based on the initial size that was specified when the table space was created.

Rules

- Each database partition specified by number must be defined in the `db2nodes.cfg` file (SQLSTATE 42729).
- Each *db-partition-number* listed in the *db-partitions-clause* must be for a unique database partition (SQLSTATE 42728).
- A valid database partition number is between 0 and 999 inclusive (SQLSTATE 42729).
- A database partition cannot appear in both the ADD and DROP clauses (SQLSTATE 42728).
- There must be at least one database partition remaining in the database partition group. The last database partition cannot be dropped from a database partition group (SQLSTATE 428C0).
- If neither the LIKE DBPARTITIONNUM clause nor the WITHOUT TABLESPACES clause is specified when adding a database partition, the default is to use the lowest database partition number of the existing database partitions in the database partition group (say it is *2*) and proceed as if LIKE DBPARTITIONNUM *2* had been specified. For an existing database partition to be used as the default, it must have containers defined for all the table spaces in the database partition group (column IN_USE of SYSCAT.DBPARTITIONGROUPDEF is not 'T').
- The ALTER DATABASE PARTITION GROUP statement might fail (SQLSTATE 55071) if an add database partition server request is either pending or in progress. This statement might also fail (SQLSTATE 55077) if a new database partition server is added online to the instance and not all applications are aware of the new database partition server.

Notes

- When a database partition is added to a database partition group, a catalog entry is made for the database partition (see SYSCAT.DBPARTITIONGROUPDEF). The distribution map is changed immediately to include the new database partition, along with an indicator (IN_USE) that the database partition is in the distribution map if either:
  - no table spaces are defined in the database partition group or
  - no tables are defined in the table spaces defined in the database partition group and the WITHOUT TABLESPACES clause was not specified.

  The distribution map is not changed and the indicator (IN_USE) is set to indicate that the database partition is not included in the distribution map if either:
  - Tables exist in table spaces in the database partition group or

  - Table spaces exist in the database partition group and the WITHOUT TABLESPACES clause was specified (unless all of the table spaces are defined to use automatic storage, in which case the WITHOUT TABLESPACES clause is ignored)

  To change the distribution map, the REDISTRIBUTE DATABASE PARTITION GROUP command must be used. This redistributes any data, changes the distribution map, and changes the indicator. Table space containers need to be added before attempting to redistribute data if the WITHOUT TABLESPACES clause was specified.
- When a database partition is dropped from a database partition group, the catalog entry for the database partition (see SYSCAT.DBPARTITIONGROUPDEF) is updated. If there are no tables defined in the table spaces defined in the database partition group, the distribution map is changed immediately to exclude the dropped database partition and the entry for the database partition in the database partition group is dropped. If tables exist, the distribution map is not changed and the indicator (IN_USE) is set to indicate that the database partition is waiting to be dropped. The REDISTRIBUTE DATABASE PARTITION GROUP command must be used to redistribute the data and drop the entry for the database partition from the database partition group.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - NODE can be specified in place of DBPARTITIONNUM
  - NODES can be specified in place of DBPARTITIONNUMS
  - NODEGROUP can be specified in place of DATABASE PARTITION GROUP

Example

Assume that you have a six-partition database that has the following database partitions: 0, 1, 2, 5, 7, and 8. Two database partitions (3 and 6) are added to the system.

- *Example 1*: Assume that you want to add database partitions 3 and 6 to a database partition group called MAXGROUP, and have table space containers like those on database partition 2. The statement is as follows:

```
ALTER DATABASE PARTITION GROUP MAXGROUP
  ADD DBPARTITIONNUMS (3,6)LIKE DBPARTITIONNUM 2
```

- *Example 2*: Assume that you want to drop database partition 1 and add database partition 6 to database partition group MEDGROUP. You will define the table space containers separately for database partition 6 using ALTER TABLESPACE. The statement is as follows:

```
ALTER DATABASE PARTITION GROUP MEDGROUP
  ADD DBPARTITIONNUM(6)WITHOUT TABLESPACES
  DROP DBPARTITIONNUM(1)
```

ALTER DATABASE

The ALTER DATABASE statement adds new storage paths to, or removes existing storage paths from, the collection of paths that are used for automatic storage table spaces.

An automatic storage table space is a table space that has been created using automatic storage; that is, the MANAGED BY AUTOMATIC STORAGE clause has been specified on the CREATE TABLESPACE statement, or no MANAGED BY clause has been specified at all. If a database is enabled for automatic storage, container and space management characteristics of its table spaces can be completely determined by the database manager. If the database is not currently enabled for automatic storage then the act of adding storage paths will enable it.

Important: This statement is deprecated and might be removed in a future release. Use the CREATE STOGROUP or ALTER STOGROUP statements instead.

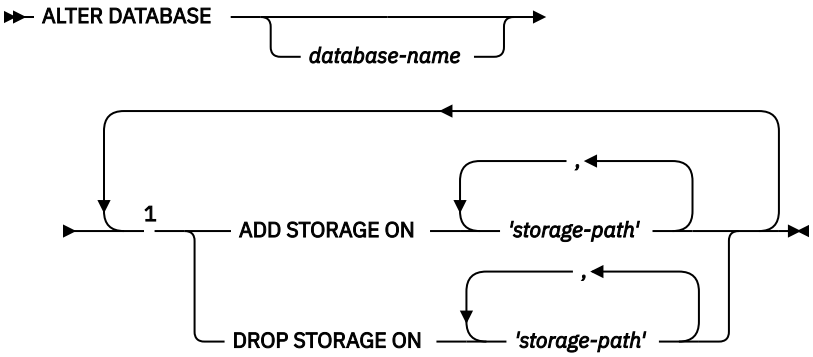
Invocation

The statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include either SYSADM or SYSCTRL authority.

Syntax



Notes:

1 Each clause can be specified only once.

Description

database-name
An optional value specifying the name of the database that is to be altered. If specified, the value must match the name of the database to which the application is currently connected (not the alias that the client might have cataloged); otherwise, an error is returned (SQLSTATE 42961).

ADD STORAGE ON
Specifies that one or more new storage paths are to be added to the collection of storage paths that are used for automatic storage table spaces.

'storage-path'
A string constant that specifies the location where containers for automatic storage table spaces are to be created. The format of the string depends on the operating system, as illustrated in the following table:

Operating system	String format
Linux AIX	An absolute path.
Windows	The letter name of a drive.

DROP STORAGE ON
Specifies that one or more storage paths are to be removed from the collection of storage paths that are used for automatic storage table spaces. If table spaces are actively using a storage path being dropped, then the state of the storage path is changed from "In Use" to "Drop Pending" and future use of the storage path will be prevented.

'storage-path'
A string constant that specifies the location from which storage paths are to be removed. The format of the string depends on the operating system, as illustrated in the following table:

Operating system	String format
Linux AIX	An absolute path.
Windows	The letter name of a drive.

Rules

- For a database that is running on version 10.1 or later, the operations of this statement are applied to the default storage group for the database. If no storage group is defined for the database, the name IBMSTOGROUP is used.
- A storage path being added, must be valid according to the naming rules for paths, and must be accessible (SQLSTATE 57019). Similarly, in a partitioned database environment, the storage path must exist and be accessible on every database partition (SQLSTATE 57019).
- A storage path being dropped must currently exist in the database (SQLSTATE 57019) and cannot already be in the "Drop Pending" state (SQLSTATE 55073).
- A database enabled for automatic storage must have at least one storage path. Dropping all storage paths from the database is not permitted (SQLSTATE 428HH).
- The ALTER DATABASE statement cannot be executed while a database partition server is being added (SQLSTATE 55071).
- DROP STORAGE ON cannot be specified in a Db2 pureScale environment (SQLSTATE 56038).

Notes

- When adding new storage paths:
  - Existing regular and large table spaces using automatic storage will not initially use these new paths. The database manager might choose to create new table space containers on these paths only if an out-of-space condition occurs.
  - Existing temporary table spaces managed by automatic storage do not automatically use new storage paths. The database must be stopped normally then restarted for containers in these table spaces to use the new storage path or paths. As an alternative, the temporary table spaces can be dropped and recreated. When created, these table spaces automatically use all storage paths that have sufficient free space.
- Adding storage paths to the database to enable automatic storage will not cause the database to convert existing non-automatic storage enabled table spaces to use automatic storage.
- Although ADD STORAGE and DROP STORAGE are logged operations, whether they are redone during a rollforward operation depends on how the database was restored. If the restore operation does not redefine the storage paths that are associated with the database, the log record that contains the storage path change is redone, and the storage paths that are described in the log record are added or dropped during the rollforward operation. However, if the storage paths *are* redefined during the restore operation, the rollforward operation will not redo ADD STORAGE or DROP STORAGE log records, because it is assumed that you have already set up the storage paths.
- When free space is calculated for a storage path on a database partition, the database manager checks for the existence of the following directories or mount points within the storage path, and will use the first one that is found.

```
<storage path>/<instance name>/NODE####/<database name>
<storage path>/<instance name>/NODE####
<storage path>/<instance name>
<storage path>
```

  Where:

  - <storage path> is a storage path associated with the database
  - <instance name> is the instance under which the database resides

  - NODE#### corresponds to the database partition number (for example, NODE0000 or NODE0001)
  - <database name> is the name of the database

  File systems can be mounted at a point beneath the storage path, and the database manager will recognize that the actual amount of free space available for table space containers might not be the same amount that is associated with the storage path directory itself.

  Consider an example in which two logical database partitions exist on one physical machine, and there is a single storage path (/dbdata). Each database partition will use this storage path, but you might want to isolate the data from each partition within its own file system. In this case, a separate file system can be created for each partition and it can be mounted at /dbdata/<instance>/NODE####. When creating containers on the storage path and determining free space, the database manager will not retrieve free space information for /dbdata, but instead will retrieve it for the corresponding /dbdata/<instance>/NODE#### directory.
- In general, the same storage paths must be used for each partition in a partitioned database environment. One exception to this is the case in which database partition expressions are used within the storage path. Doing this allows the database partition number to be reflected in the storage path, such that the resulting path name is different on each partition.
- When dropping a storage path that is in use by one or more table spaces, the state of the path changes from "In Use" to "Drop Pending". Future growth on the path will not occur. Before the path can be fully removed from the database, each affected table space must be rebalanced (using the REBALANCE clause of the ALTER TABLESPACE statement) so that its container data is moved off the storage path. Rebalance is only supported for regular and large table spaces. Temporary table spaces should be dropped and recreated to have their containers removed from the dropped path. When the path is no longer in use by any table space, it will be physically removed from the database.

  For a partitioned database, the path is maintained independently on each partition. When a path is no longer in use on a given database partition, it will be physically removed from that partition. Other partitions may still show the path as being in the "Drop Pending" state.

  The list of automatic storage table spaces using drop pending storage paths can be determined by issuing the following SQL statement:

```
SELECT DISTINCT A.TBSP_NAME, A.TBSP_ID, A.TBSP_CONTENT_TYPE
  FROM TABLE(MON_GET_TABLESPACE(NULL,-2)) AS A
  WHERE A.TBSP_PATHS_DROPPED = 1
```

- When dropping a storage path that was originally specified using a database partition expression, the same storage path string, including the database partition expression, must be used in the drop. If a database partition expression was specified then this path string can be found in the "Path with db partition expression" element (db_storage_path_with_dpe) of a database snapshot. This element is not shown if a database partition expression was not included in the original path specified.
- It is possible for a given storage path to be added to a database multiple times. When using the DROP STORAGE ON clause, specifying that particular path once will drop *all* instances of the path from the database.

Examples

1. Add two paths under the /db directory (/db/filesystem1 and /db/filesystem2) and a third path named /filesystem3 to the space for automatic storage table spaces that is associated with the currently connected database.

   ```
   ALTER DATABASE ADD STORAGE ON '/db/filesystem1', '/db/filesystem2',
     '/filesystem3'
   ```

2. Add drives D and E to the space for automatic storage table spaces that is associated with the SAMPLE database.

   ```
   ALTER DATABASE SAMPLE ADD STORAGE ON 'D:', 'E:\'
   ```

3. Add directory F:\DBDATA and drive G to the space for automatic storage table spaces that is associated with the currently connected database.

```
ALTER DATABASE ADD STORAGE ON 'F:\DBDATA', 'G:'
```

4. Add a storage path that uses a database partition expression to differentiate the storage paths on each of the database partitions.

```
ALTER DATABASE ADD STORAGE ON '/dataForPartition $N'
```

   The storage path that would be used on database partition 0 is /dataForPartition0; on database partition 1, it would be /dataForPartition1; and so on.

5. Add storage paths to a database that is not automatic storage enabled, for the purposes of enabling automatic storage for the database.

```
CREATE DATABASE MYDB AUTOMATIC STORAGE NO
CONNECT TO MYDB
ALTER DATABASE ADD STORAGE ON '/db/filesystem1', '/db/filesystem2'
```

   Database MYDB is now enabled for automatic storage.

6. Remove paths /db/filesystem1 and /db/filesystem2 from the currently connected database.

```
ALTER DATABASE DROP STORAGE ON '/db/filesystem1', '/db/filesystem2'
```

   After the storage is dropped successfully, use the ALTER TABLESPACE statement with the REBALANCE clause for each table space that was using these storage paths to rebalance the table space.

7. A storage path with a database partition expression (/dataForPartition $N) was previously added to the database and now it is to be removed.

```
ALTER DATABASE DROP STORAGE ON '/dataForPartition $N'
```

   After the storage is dropped successfully, use the ALTER TABLESPACE statement with the REBALANCE clause for each table space that was using these storage paths to rebalance the table space.

ALTER EVENT MONITOR

The ALTER EVENT MONITOR statement alters the definition of an event monitor that has a target for the event monitor data of TABLE.

Invocation

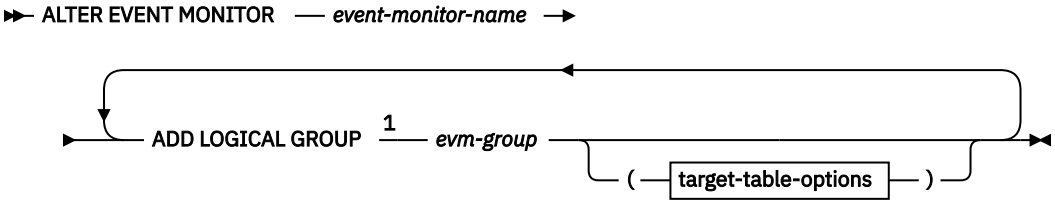
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

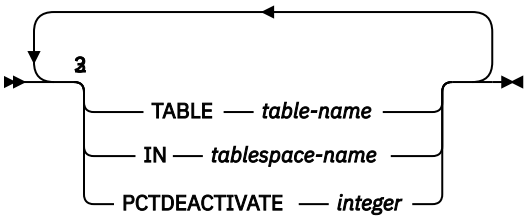
The privileges held by the authorization ID of the statement must include one of the following authorities:

- DBADM authority
- SQLADM authority

Syntax



target-table-options



Notes:

[1] A logical group can be added only to TABLE event monitors (not UNFORMATTED EVENT TABLE event monitors).

[2] Each clause can be specified only once.

[3] Clauses can be separated with a space or a comma.

Description

event-monitor-name

The *event-monitor-name* must identify an event monitor that exists at the current server and has a target for the event monitor data of TABLE.

ADD LOGICAL GROUP

Adds a logical group to the event monitor that has a target for the data of TABLE.

evm-group

Identifies the logical data group for which a target table is being added. The value depends upon the type of event monitor, as shown in the following table:

Table 123. Values for evm-group based on the type of event monitor

Type of Event Monitor	evm-group value
Database	• DB • CONTROL[1] • DBMEMUSE
Tables	• TABLE • CONTROL[1]
Deadlocks	• CONNHEADER • DEADLOCK • DLCONN • CONTROL[1]

Table 123. Values for evm-group based on the type of event monitor (continued)

Type of Event Monitor	evm-group value
Deadlocks with details	• CONNHEADER • DEADLOCK • DLCONN[2] • DLLOCK[3] • CONTROL[1]
Deadlocks with details history	• CONNHEADER • DEADLOCK • DLCONN[2] • DLLOCK[3] • STMTHIST • CONTROL[1]
Deadlocks with details history values	• CONNHEADER • DEADLOCK • DLCONN[2] • DLLOCK[3] • STMTHIST • STMTVALS • CONTROL[1]
Table spaces	• TABLESPACE • CONTROL[1]
Buffer pools	• BUFFERPOOL • CONTROL[1]
Connections	• CONNHEADER • CONN • CONTROL[1] • CONNMEMUSE
Statements	• CONNHEADER • STMT • SUBSECTION[4] • CONTROL[1]
Transactions	• CONNHEADER • XACT • CONTROL[1]

Table 123. Values for evm-group based on the type of event monitor (continued)

Type of Event Monitor	evm-group value
Activities	• ACTIVITY • ACTIVITYMETRICS • ACTIVITYSTMT • ACTIVITYVALS • CONTROL[1]
Statistics	• QSTATS • SCSTATS • SCMETRICS • WCSTATS • WLSTATS • WLMETRICS • HISTOGRAMBIN • CONTROL[1]
Threshold Violations	• THRESHOLDVIOLATIONS • CONTROL[1]
Locking[5]	• LOCK • LOCK_PARTICIPANTS • LOCK_PARTICIPANT_ACTIVITIES • LOCK_ACTIVITY_VALUES • CONTROL[1]
Package Cache[5]	• PKGCACHE • PKGCACHE_METRICS • CONTROL[1]
Unit of Work[5]	• UOW • UOW_METRICS • UOW_PACKGE_LIST • UOW_EXECUTABLE_LIST • CONTROL[1]

Table 123. Values for evm-group based on the type of event monitor (continued)

Type of Event Monitor	evm-group value
Change History	• CHANGESUMMARY • EVMONSTART • TXNCOMPLETION • DDLSTMTEXEC • DBDBMCFG • REGVAR • UTILSTART • UTILSTOP • UTILPHASE • UTILLOCATION • CONTROL[1]

[1] Logical data groups dbheader (conn_time element only), start, and overflow, are all written to the CONTROL group. The overflow group is written if the event monitor is non-blocked and events were discarded.

[2] Corresponds to the DETAILED_DLCONN event.

[3] Corresponds to the LOCK logical data groups that occur within each DETAILED_DLCONN event.

[4] Created only for partitioned database environments.

[5] Refers to the Formatted Event Table version of this event monitor type.

TABLE ***table-name***
Specifies the name of the target table. The target table must be a non-partitioned table. If the name is unqualified, the table schema defaults to the value in the CURRENT SCHEMA special register. If no name is provided, the unqualified name is derived from *evm-group* and *event-monitor-name* as follows:

```
substring(evm-group CONCAT '_'
   CONCAT event-monitor-name,1,128)
```

IN ***tablespace-name***
Defines the table space in which the table is to be created. If no table space name is provided, the table space is chosen using the same process as when a table is created without a table space name using the CREATE TABLE statement.

When specifying the table space name for an activities, locking, package cache, or unit of work event monitor, the table space's page size affects the INLINE LOB lengths used. Therefore, consider specifying a table space with as large a page size as possible to improve the INSERT performance of the event monitor.

PCTDEACTIVATE ***integer***
If a table is being created in a DMS table space, PCTDEACTIVATE specifies how full the table space must be before the event monitor automatically deactivates. The specified value, which represents a percentage, can range from 0 to 100. The default value is 100 (meaning that the event monitor deactivates when the table space becomes completely full). This option is ignored for SMS table spaces. When a target table space has auto-resize enabled, it is recommended that PCTDEACTIVATE be set to 100.

Notes

- **When system catalog changes take effect:** Changes are written to the system catalog, but do not take effect until they are committed and the event monitor is reactivated.

Example

The event monitor ACT is missing the ACTIVITYMETRICS group. Alter the event monitor to add this group and give the table the name "ACTMETRICS".

```
ALTER EVENT MONITOR ACT
   ADD LOGICAL GROUP ACTIVITYMETRICS TABLE ACTMETRICS
```

ALTER FUNCTION

The ALTER FUNCTION statement modifies the properties of an existing function.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- ALTERIN privilege on the schema of the function
- Owner of the function, as recorded in the OWNER column of the SYSCAT.ROUTINES catalog view
- SCHEMAADM authority on the schema of the function
- DBADM authority

To alter the EXTERNAL NAME of a function, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

- CREATE_EXTERNAL_ROUTINE authority on the database
- DBADM authority

To alter a function to be not fenced, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

- CREATE_NOT_FENCED_ROUTINE authority on the database
- DBADM authority

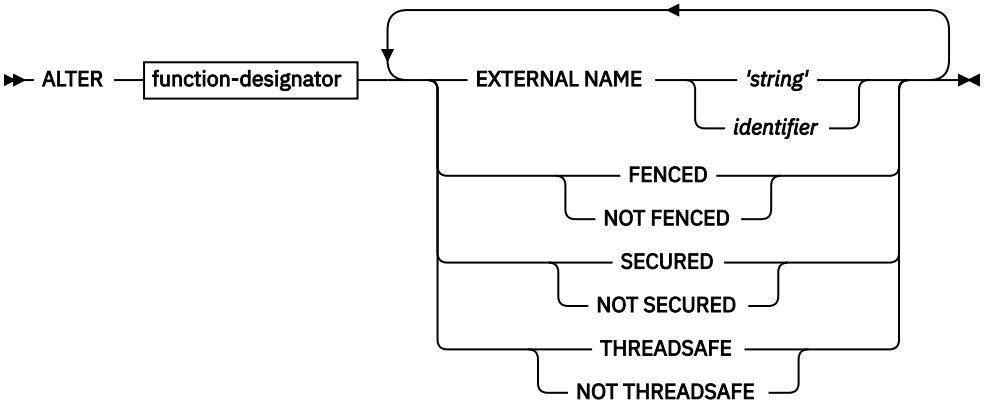
To alter a function to be fenced, no additional authorities or privileges are required.

To alter a function to be SECURED or NOT SECURED the privileges held by the authorization ID of the statement must include at least one of the following authorities:

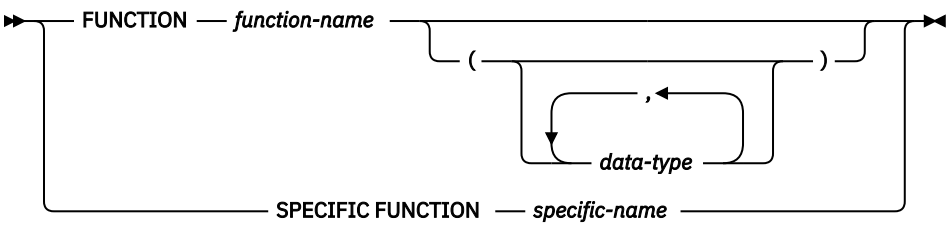
- SECADM authority
- CREATE_SECURE_OBJECT authority

If no other clauses are specified, then no other privileges are required to process the statement.

Syntax



function-designator



Description

function-designator
Uniquely identifies the function to be altered. For more information, see "Function, method, and procedure designators" on page 745.

EXTERNAL NAME *'string'* or *identifier*
Identifies the name of the user-written code that implements the function. This option can only be specified when altering external functions (SQLSTATE 42849).

FENCED or NOT FENCED
Specifies whether the function is considered safe to run in the database manager operating environment's process or address space (NOT FENCED), or not (FENCED). Most functions have the option of running as FENCED or NOT FENCED.

If a function is altered to be FENCED, the database manager insulates its internal resources (for example, data buffers) from access by the function. In general, a function running as FENCED will not perform as well as a similar one running as NOT FENCED.

CAUTION: Use of NOT FENCED for functions that were not adequately coded, reviewed, and tested can compromise the integrity of a Db2 database. Db2 databases take some precautions against many of the common types of inadvertent failures that might occur, but cannot guarantee complete integrity when NOT FENCED user-defined functions are used.

A function declared as NOT THREADSAFE cannot be altered to be NOT FENCED (SQLSTATE 42613).

If a function has any parameters defined AS LOCATOR, and was defined with the NO SQL option, the function cannot be altered to be FENCED (SQLSTATE 42613).

This option cannot be altered for LANGUAGE OLE, OLEDB, or CLR functions (SQLSTATE 42849).

This option cannot be altered for a function that is registered as a component routine of an aggregate interface function (SQLSTATE 42849).

SECURED or NOT SECURED
Specifies whether the function is considered secure for row and column access control.

NOT SECURED
Indicates that the function is not considered secure. When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled and column level access control is activated for its table (SQLSTATE 428HA). This rule applies to the non secure user-defined functions that are invoked anywhere in the statement.

SECURED
Indicates that the function is considered secure.

The function must be secure when it is referenced in a row permission or a column mask (SQLSTATE 428H8).

The function must be secure when it is referenced in a materialized query table and the materialized query table references any table that has row or column level access control activated (SQLSTATE 428H8).

This option cannot be altered for a function that is registered as a component routine of an aggregate interface function (SQLSTATE 42849).

THREADSAFE or NOT THREADSAFE
Specifies whether the function is considered safe to run in the same process as other routines (THREADSAFE), or not (NOT THREADSAFE).

If the function is defined with LANGUAGE other than OLE and OLEDB:

- If the function is defined as THREADSAFE, the database manager can invoke the function in the same process as other routines. In general, to be threadsafe, a function should not use any global or static data areas. Most programming references include a discussion of writing threadsafe routines. Both FENCED and NOT FENCED functions can be THREADSAFE.
- If the function is defined as NOT THREADSAFE, the database manager will never simultaneously invoke the function in the same process as another routine. Only a fenced function can be NOT THREADSAFE (SQLSTATE 42613).

This option may not be altered for LANGUAGE OLE or OLEDB functions (SQLSTATE 42849).

This option cannot be altered for a function that is registered as a component routine of an aggregate interface function (SQLSTATE 42849).

Notes

- It is not possible to alter a function that is in the following schema (SQLSTATE 42832):
  - SYSIBM
  - SYSFUN
  - SYSPROC
- Functions declared as LANGUAGE SQL, sourced functions, or template functions cannot be altered (SQLSTATE 42917).
- ***Altering a function from NOT SECURED to SECURED***: Normally users with SECADM authority do not have privileges to alter database objects such as user-defined functions and triggers. Typically they will examine the actions taken by a function, ensure it is secure, then grant the CREATE_SECURE_OBJECT authority to someone who has required privileges to alter the user-defined function to be secure. After the function is altered, they will revoke the CREATE_SECURE_OBJECT authority from the user who was granted this authority.

  The function is considered secure. The SECURED attribute is considered to be an assertion that declares the user has established a change control audit procedure for all changes to the user-defined function. The database manager assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages.

  Packages and dynamically cached SQL statements that depend on the function might be invalidated because the secure attribute affects the access path selection for statements involving tables for which row or column level access control is activated and the function being replaced.

- ***Altering a function from SECURED to NOT SECURED***: The function is considered not secure. Packages and dynamically cached SQL statements that depend on the function might be invalidated because the secure attribute affects the access path selection for statements involving tables for which row or column level access control is activated.
- ***Invoking other user-defined functions in a secure function***: When a secure user-defined function is referenced in a data manipulation statement where a row or column access control enforced table is referenced, if the secure user-defined function invokes other user-defined functions, the database manager does not validate whether those nested user-defined functions are secure. If those nested functions can access sensitive data, the user with SECADM authority needs to ensure those functions are allowed to access those data and a change control audit procedure has been established for all changes to those functions.

Example

The function MAIL() has been thoroughly tested. To improve its performance, alter the function to be not fenced.

```
ALTER FUNCTION MAIL() NOT FENCED
```

ALTER HISTOGRAM TEMPLATE

The ALTER HISTOGRAM TEMPLATE statement is used to modify the template describing the type of histogram that can be used to override one or more of the default histograms of a service class or a work class.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include WLMADM or DBADM authority.

Syntax

Description

template-name
Names the histogram template. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The name must identify an existing histogram template at the current server (SQLSTATE 42704). The template name can be the default system histogram template SYSDEFAULTHISTOGRAM.

HIGH BIN VALUE ***bigint-constant***
Specifies the top value of the second to last bin (the last bin has an unbounded top value). The units depend on how the histogram is used. The maximum value is 268 435 456.

Rules

- A workload management (WLM)-exclusive SQL statement must be followed by a COMMIT or a ROLLBACK statement (SQLSTATE 5U021). WLM-exclusive SQL statements are:
  - CREATE HISTOGRAM TEMPLATE, ALTER HISTOGRAM TEMPLATE, or DROP (HISTOGRAM TEMPLATE)
  - CREATE SERVICE CLASS, ALTER SERVICE CLASS, or DROP (SERVICE CLASS)
  - CREATE THRESHOLD, ALTER THRESHOLD, or DROP (THRESHOLD)

  - CREATE WORK ACTION SET, ALTER WORK ACTION SET, or DROP (WORK ACTION SET)
  - CREATE WORK CLASS SET, ALTER WORK CLASS SET, or DROP (WORK CLASS SET)
  - CREATE WORKLOAD, ALTER WORKLOAD, or DROP (WORKLOAD)
  - GRANT (Workload Privileges) or REVOKE (Workload Privileges)
- A WLM-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.

Notes

- Only one uncommitted WLM-exclusive SQL statement at a time is allowed across all partitions. If an uncommitted WLM-exclusive SQL statement is executing, subsequent WLM-exclusive SQL statements will wait until the current WLM-exclusive SQL statement commits or rolls back.
- Changes are written to the system catalog, but do not take effect until they are committed, even for the connection that issues the statement.

Example

Change the high bin value of a histogram template named LIFETIMETEMP.

```
ALTER HISTOGRAM TEMPLATE LIFETIMETEMP
  HIGH BIN VALUE 90000
```

ALTER INDEX

The ALTER INDEX statement alters the definition of an index.

Invocation

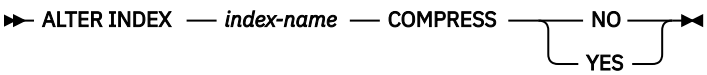
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- ALTERIN privilege on the schema of the index
- ALTER privilege on the table on which the index is defined
- CONTROL privilege on the index
- SCHEMAADM authority on the schema of the index
- DBADM authority

Syntax



Description

INDEX *index-name*
Identifies the index to be altered. The name must identify an index that exists at the current server (SQLSTATE 42704).

COMPRESS
Specifies whether index compression is to be enabled or disabled. The index must not be an MDC or ITC block index, catalog index, XML path index, index specification, or an index on a created temporary table or declared temporary table (SQLSTATE 56090).

NO
Specifies that index compression is disabled. A compressed index will remain compressed until the index is rebuilt via index reorganization or recreation.

YES
Specifies that index compression is enabled. An uncompressed index will remain uncompressed until the index is rebuilt via index reorganization or recreation.

Example

Alter index JOB_BY_DPT to be compressed index.

```
ALTER INDEX JOB_BY_DPT
COMPRESS YES
```

Related reference
“CREATE INDEX ” on page 1240
The CREATE INDEX statement is used to define an index on a database table.

Related information
BIND command

ALTER MASK

The ALTER MASK statement alters a column mask that exists at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax

Description

mask-name
Identifies the column mask to be altered. The name must identify a mask that exists at the current server (SQLSTATE 42704).

ENABLE

Enables the column mask. If column level access control is not currently activated on the table, the column mask will become effective when column level access control is activated on the table. If column level access control is currently activated on the table, the column mask becomes effective immediately and all packages and dynamically cached statements that reference the table are invalidated.

ENABLE is ignored if the column mask is already enabled.

DISABLE

Disables the column mask. If column level access control is not currently activated on the table, the column mask will remain ineffective when column level access control is activated on the table. If column level access control is currently activated on the table, the column mask becomes ineffective immediately and all packages and dynamically cached statements that reference the table are invalidated.

DISABLE is ignored if the column mask is already disabled.

Examples

- *Example 1*: Enable column mask M1.

```
ALTER MASK M1 ENABLE
```

- *Example 2*: Disable column mask M1.

```
ALTER MASK M1 DISABLE
```

ALTER METHOD

The ALTER METHOD statement modifies an existing method by changing the method body associated with the method.

Invocation

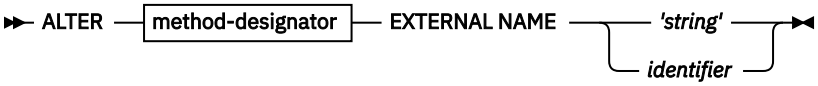
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

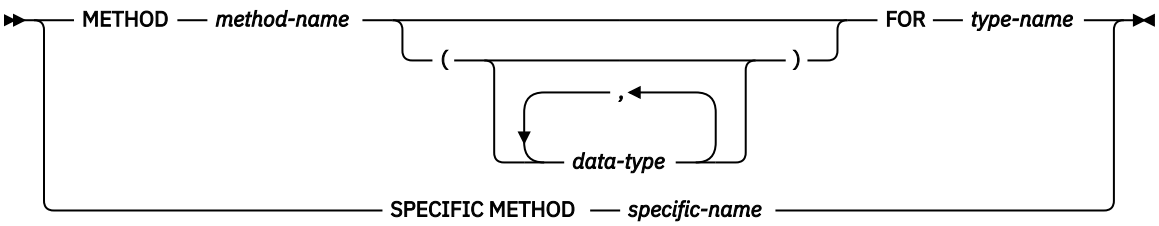
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CREATE_EXTERNAL_ROUTINE authority on the database, and at least one of:
  - ALTERIN privilege on the schema of the type
  - SCHEMAADM privilege on the schema of the type
  - Owner of the type, as recorded in the OWNER column of the SYSCAT.DATATYPES catalog view
- DBADM authority

Syntax



method-designator



Description

method-designator
Uniquely identifies the method to be altered. For more information, see "Function, method, and procedure designators" on page 745.

EXTERNAL NAME *'string'* or *identifier*
Identifies the name of the user-written code that implements the method. This option can only be specified when altering external methods (SQLSTATE 42849).

Notes

- It is not possible to alter a method that is in the SYSIBM, SYSFUN, or SYSPROC schema (SQLSTATE 42832).
- Methods declared as LANGUAGE SQL cannot be altered (SQLSTATE 42917).
- Methods declared as LANGUAGE CLR cannot be altered (SQLSTATE 42849).
- The specified method must have a body before it can be altered (SQLSTATE 42704).

Example

Alter the method DISTANCE() in the structured type ADDRESS_T to use the library newaddresslib.

```
ALTER METHOD DISTANCE()
  FOR ADDRESS_T
  EXTERNAL NAME 'newaddresslib!distance2'
```

ALTER MODULE

The ALTER MODULE statement alters the definition of a module.

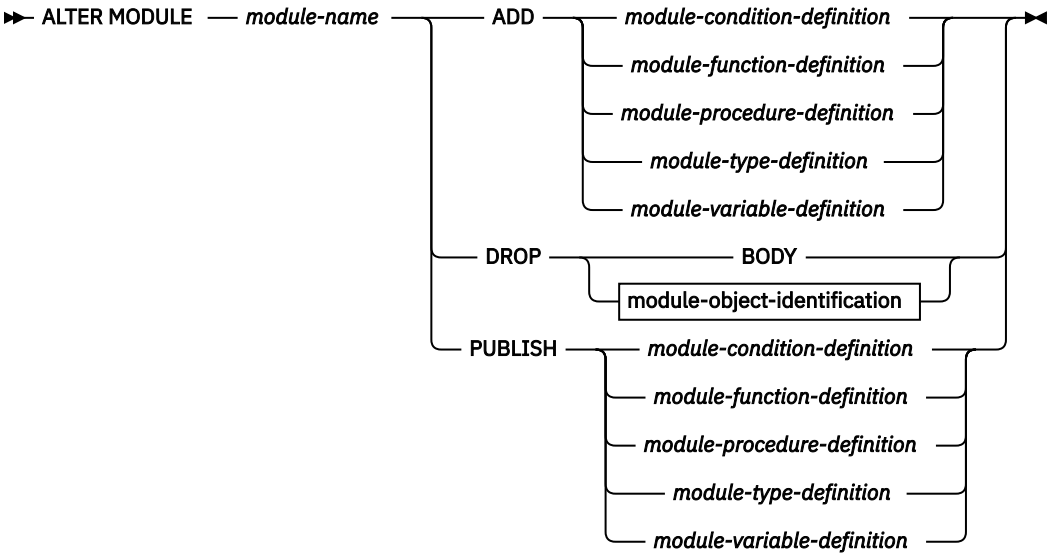
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

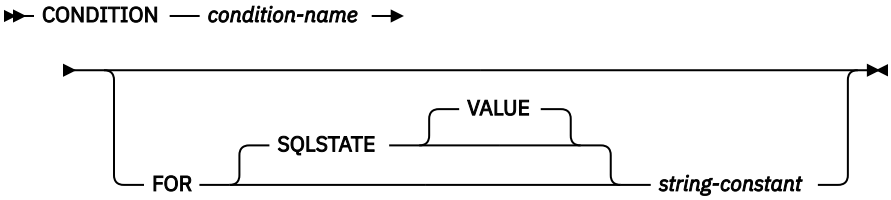
Authorization

The privileges held by the authorization ID of the statement must include ownership of the module and also include all of the privileges necessary to invoke the SQL statements that are specified within the ALTER MODULE statement.

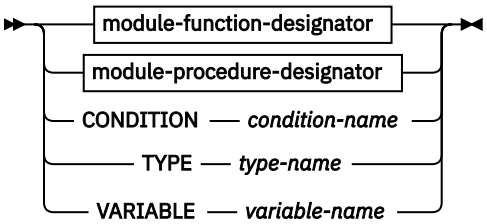
Syntax



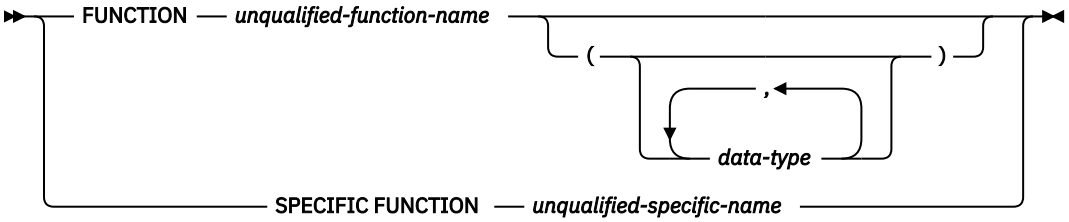
module-condition-definition



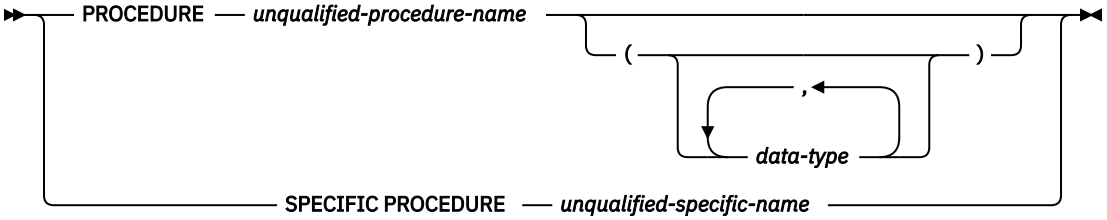
module-object-identification



module-function-designator



module-procedure-designator



Description

module-name
Identifies the module to be altered. The module-name must identify a module that exists at the current server (SQLSTATE 42704). The specified name must not be an alias for a module (SQLSTATE 560CT).

ADD
Adds an object to the module or adds the body to a routine definition that already exists in the module without a body. If adding a user-defined type or a global variable, the object must not identify a user-defined type or global variable that already exists in the module. If the user-defined type or global variable did not exist, it is added to the module for use within the module only.

If adding a routine and the specified routine does not exist, the routine is added. If adding a routine and the specified routine exists, the existing routine definition must not include a routine body (SQLSTATE 42723). This routine prototype is completely replaced by the new routine definition, including the routine attributes and the routine body, except that the published attribute is retained. The specified routine is considered to exist if one of the following conditions is true:

- There is a routine in the module with the same specific name and same routine name.
- The specified routine is a procedure and there is a procedure in the module with the same procedure name and the same number of parameters. The names and data types of the parameters do not need to match.
- The specified routine is a function and there is a function in the module with the same function name and the same number of parameters with matching data types. The length, precision, and scale of parameter data types are not compared and can be different when determining if the specified routine exists. The names of the parameters do not need to match.

module-condition-definition
Adds a module condition.

condition-name
Name of the condition. The name must not identify an existing condition in the module. The condition-name must be specified without any qualification (SQLSTATE 42601). The name of the condition must be unique within the module.

FOR SQLSTATE *string-constant*
Specifies the SQLSTATE that is associated with the condition. The string-constant must be specified as five characters enclosed in single quotation marks, and the SQLSTATE class (the first two characters) must not be '00'. This is an optional clause.

module-function-definition
The syntax to add a function is the same as the CREATE FUNCTION statement excluding the CREATE keyword and both the function-name and specific-name must be specified without any qualification (SQLSTATE 42601). If the function is unique within the module, a new function is added. If the function matches an existing function that does not include a body (SQL-routine-body or EXTERNAL NAME clause), then this function prototype is replaced by the new definition except that the published attribute is retained.

The module function definition must not specify the SOURCE clause, the TEMPLATE clause, or the LANGUAGE OLEDEB option (SQLSTATE 42613).

module-procedure-definition
The syntax to define the procedure is the same as the CREATE PROCEDURE statement excluding the CREATE keyword and both the procedure-name and specific-name must be specified without any qualification (SQLSTATE 42601). If the procedure signature is unique within the module, a new procedure is added. If the procedure matches an existing procedure that does not include a body (SQL-routine-body or EXTERNAL NAME clause), then this procedure prototype is replaced by the new definition except that the published attribute is retained. The name of the procedure can begin with "SYS_" only to add the module initialization procedure called SYS_INIT. See Notes for details.

module-type-definition
The syntax to define the user-defined type is the same as the CREATE TYPE statement excluding the CREATE keyword and the type-name must be specified without any qualification (SQLSTATE 42601). The name of the user-defined type must be unique within the module. A structured type cannot be defined in a module. Any generated functions required to support the type definition are also defined in the module. If the module user-defined type is published then so are the generated functions.

module-variable-definition
The syntax to define the variable is the same as the CREATE VARIABLE statement excluding the CREATE keyword and the variable-name must be specified without any qualification (SQLSTATE 42601). The name of the variable must be unique within the module.

DROP
Drops a specified part of a module. The module-object-identification syntax is used to identify the object to be dropped unless the body of the module is being dropped.

BODY
Drops the module body, which includes:

- all objects that are not published.
- the routine body of any published SQL routines
- the EXTERNAL reference for any published external routines.

PUBLISH
Adds a new object to the module and makes it available for use outside the module. In the case of routines, a routine prototype can be specified that does not include the executable body of the routine.

module-condition-definition
Adds a module condition that is available for use outside the module.

condition-name
Name of the condition. The name must not identify an existing condition in the module. The condition-name must be specified without any qualification (SQLSTATE 42601). The name of the condition must be unique within the module.

FOR SQLSTATE ***string-constant***
Specifies the SQLSTATE that is associated with the condition. The string-constant must be specified as five characters enclosed in single quotation marks, and the SQLSTATE class (the first two characters) must not be '00'. This is an optional clause.

module-function-definition
The syntax to define the function is the same as the CREATE FUNCTION statement excluding the CREATE keyword and both the function-name and specific-name must be specified without any qualification (SQLSTATE 42601). The definition of the function must include the function name, full specification of any parameters and the returns clause. Module user-defined data types that are not published are not candidates for the parameter data types or the RETURNS clause data type. Module variables that are not published are not candidates for the anchor object in an ANCHOR clause of a parameter data type or a returns data type. A function prototype can be specified by omitting the LANGUAGE clause (or specifying LANGUAGE SQL) and the SQL-routine-body. The function signature must be unique within the module. The name of the function must not begin with "SYS_" (SQLSTATE 42939). All SQL functions added to a module are processed as if a compound SQL (compiled) statement was used.

The module function definition can only specify the RETURNS TABLE clause when the SQL-routine-body is an compound SQL (compiled) statement that specifies NOT ATOMIC. The module function definition must not specify the SOURCE clause, the TEMPLATE clause, or the LANGUAGE OLEDEB option (SQLSTATE 42613).

module-procedure-definition
The syntax to define the procedure is the same as the CREATE PROCEDURE statement excluding the CREATE keyword and both the procedure-name and specific-name must be specified without

any qualification (SQLSTATE 42601). The definition of the procedure must include the procedure name and full specification of any parameters. Module user-defined data types that are not published are not candidates for the parameter data types. Module variables that are not published are not candidates for the anchor object in an ANCHOR clause of a parameter definition. A function prototype can be specified by omitting the LANGUAGE clause (or specifying LANGUAGE SQL) and the SQL-routine-body. The procedure signature must be unique within the module. The name of the procedure must not begin with "SYS_" (SQLSTATE 42939).

module-type-definition
The syntax to define the user-defined type is the same as the CREATE TYPE statement excluding the CREATE keyword and the type-name must be specified without any qualification (SQLSTATE 42601). Module user-defined data types that are not published are not candidates for any data type referenced in the module user-defined data type definition. Module variables that are not published are not candidates for the anchor object in an ANCHOR clause. The name of the user-defined type must not begin with "SYS_" (SQLSTATE 42939) and must be unique within the module. A structured type cannot be defined in a module. Any generated functions required to support the type definition are also defined in the module as published functions.

module-variable-definition
The syntax to define the variable is the same as the CREATE VARIABLE statement excluding the CREATE keyword and the variable-name must be specified without any qualification (SQLSTATE 42601). Module user-defined data types that are not published are not candidates for the any data type referenced in the variable definition. Module variables that are not published are not candidates for the anchor object in an ANCHOR clause. The name of the variable must not begin with "SYS_" (SQLSTATE 42939) and must be unique within the module.

module-object-identification
Identifies a unique module object.

module-function-designator
Uniquely identifies a single module function.

FUNCTION ***unqualified-function-name***
Identifies a particular function, and is valid only if there is exactly one function instance with the name unqualified-function-name in the module. The identified function can have any number of parameters defined for it. If no function by this name exists in the module, an error (SQLSTATE 42704) is raised. If there is more than one instance of the function in the module, an error (SQLSTATE 42725) is raised.

FUNCTION ***unqualified-function-name (data type,...)***
Provides the function signature, which uniquely identifies the function. The function resolution algorithm is not used.

unqualified-function-name
Specifies the name of the function.

(data-type,...)
Values must match the data types that were specified (in the corresponding position) when the function was originally defined. The number of data types, and the logical concatenation of the data types, is used to identify the specific function instance.

If a data type is unqualified, the type name is resolved by searching the schemas on the SQL path. This also applies to data type names specified for a REFERENCE type.

It is not necessary to specify the length, precision, or scale for the parameterized data types. Instead, an empty set of parentheses can be coded to indicate that these attributes are to be ignored when looking for a data type match. FLOAT() cannot be used (SQLSTATE 42601), because the parameter value indicates different data types (REAL or DOUBLE). If length, precision, or scale is coded, the value must exactly match that specified when the function was defined.

A type of FLOAT(n) does not need to match the defined value for n, because 0 < n < 25 means REAL, and 24 < n < 54 means DOUBLE. Matching occurs on the basis of whether the type

is REAL or DOUBLE. If no function with the specified signature exists in the module, an error (SQLSTATE 42883) is raised.

SPECIFIC FUNCTION ***unqualified-specific-name***
Identifies a particular user-defined function, using the name that is specified or defaulted to at function definition time. The unqualified-specific-name must identify a specific function instance in the module; otherwise, an error is returned (SQLSTATE 42704).

module-procedure-designator
Uniquely identifies a single module procedure.

PROCEDURE ***unqualified-procedure-name***
Identifies a particular procedure, and is valid only if there is exactly one procedure instance with the name unqualified-procedure-name in the module. The identified procedure can have any number of parameters defined for it. If no procedure by this name exists in the module, an error is returned (SQLSTATE 42704). If there is more than one instance of the procedure in the module, an error is returned (SQLSTATE 42725).

PROCEDURE ***unqualified-procedure-name (data-type,...)***
Provides the procedure signature, which uniquely identifies the procedure. The procedure resolution algorithm is not used.

unqualified-procedure-name
Specifies the name of the procedure.

(data-type,...)
Values must match the data types that were specified (in the corresponding position) when the procedure was originally defined. The number of data types, and the logical concatenation of the data types, is used to identify the specific procedure instance.

If a data type is unqualified, the type name is resolved by searching the schemas on the SQL path. This also applies to data type names specified for a REFERENCE type.

It is not necessary to specify the length, precision, or scale for the parameterized data types. Instead, an empty set of parentheses can be coded to indicate that these attributes are to be ignored when looking for a data type match.

FLOAT() cannot be used (SQLSTATE 42601), because the parameter value indicates different data types (REAL or DOUBLE). If length, precision, or scale is coded, the value must exactly match that specified in when the procedure was defined.

A type of FLOAT(n) does not need to match the defined value for n, because 0 < n < 25 means REAL, and 24 < n < 54 means DOUBLE. Matching occurs on the basis of whether the type is REAL or DOUBLE.

If no procedure with the specified signature exists in the module, an error is returned (SQLSTATE 42883).

SPECIFIC PROCEDURE ***unqualified-specific-name***
Identifies a particular procedure, using the name that is specified or defaulted to at procedure definition time. The unqualified-specific-name must identify a specific procedure instance in the module; otherwise, an error is returned (SQLSTATE 42704).

TYPE ***type-name***
Identifies a user-defined type from the module. The type-name must be specified without any qualification (SQLSTATE 42601) and must identify a user-defined type that exists in the module (SQLSTATE 42704).

VARIABLE ***variable-name***
Identifies a global variable from the module. The variable-name must be specified without any qualification (SQLSTATE 42601) and must identify a global variable that exists in the module (SQLSTATE 42704).

CONDITION ***condition-name***
Identifies a condition from the module. The condition-name must be specified without any qualification and must identify a condition that exists in the module (SQLSTATE 42737).

Rules

- Names of objects in the module cannot begin with "SYS_" with the exception of specifically designated SYS_INIT procedure name (SQLSTATE 42939).
- **ALTER MODULE DROP FUNCTION**: If the function is referenced in the definition of a row permission or column mask, the function cannot be dropped (SQLSTATE 42893).
- **ALTER MODULE DROP VARIABLE**: If the variable is referenced in the definition of a row permission or column mask, the variable cannot be dropped (SQLSTATE 42893).
- **ALTER MODULE DROP BODY**: If the module is referenced in the definition of a row permission or column mask, the module cannot be dropped (SQLSTATE 42893).

Notes

- ***Module initialization*:** A module can have a special initialization procedure called SYS_INIT that is implicitly executed when the first reference is made to a module routine or module global variable. The SYS_INIT procedure must be implemented with no parameters, cannot return result sets, and can be an SQL or external procedure that cannot be published (SQLSTATE 428HP). If the SYS_INIT procedure fails, an error is returned for the statement that caused the module initialization (SQLSTATE 56098).
- ***Use of module conditions*:** A module condition can only be used with a SIGNAL statement, RESIGNAL statement or a handler declaration that is within a compound SQL (compiled) statement.
- ***Invalidation*:** If a routine prototype is replaced using the ADD action, all objects that depended on the published module routine are invalidated. If DROP BODY is issued, all objects dependent on published module routines are invalidated.
- ***Obfuscation*:** The ALTER MODULE ADD FUNCTION, ALTER MODULE ADD PROCEDURE, ALTER MODULE PUBLISH FUNCTION, and ALTER MODULE PUBLISH PROCEDURE statements can be submitted in obfuscated form. In an obfuscated statement, only the routine name and its parameters are readable. The rest of the statement is encoded in such a way that is not readable but can be decoded by the database server. Obfuscated statements can be produced by calling the DBMS_DDL.WRAP function.

Example

The following statements create a module named INVENTORY containing an associative array type, a variable of that data type, a procedure that adds elements to the array and a function that extracts elements from the array. Only the function and the procedure can be referenced from outside of the module based on the PUBLISH keyword in the corresponding ALTER MODULE statements. The data type and the variable can only be referenced by other objects in the module.

```
CREATE MODULE INVENTORY

ALTER MODULE INVENTORY ADD
TYPE ITEMLIST AS INTEGER ARRAY[VARCHAR(100)]

ALTER MODULE INVENTORY ADD
VARIABLE ITEMS ITEMLIST

ALTER MODULE INVENTORY PUBLISH
PROCEDURE UPDATE_ITEM(NAME VARCHAR(100), QUANTITY INTEGER)
BEGIN
SET ITEMS[NAME] = QUANTITY;
END

ALTER MODULE INVENTORY PUBLISH
FUNCTION CHECK_ITEM(NAME VARCHAR(100)) RETURNS INTEGER
RETURN ITEMS[NAME]
```

ALTER NICKNAME

The ALTER NICKNAME statement modifies the nickname information associated with a data source object (such as a table, view, or file).

This statement modifies the information that is stored in the federated database in the following ways:

- Altering the local column names for the columns of the data source object
- Altering the local data types for the columns of the data source object
- Adding, setting, or dropping nickname and column options
- Adding or dropping a primary key
- Adding or dropping one or more unique, referential, or check constraints
- Altering one or more referential or check constraint attributes
- Altering the caching of data at a federated server

Invocation

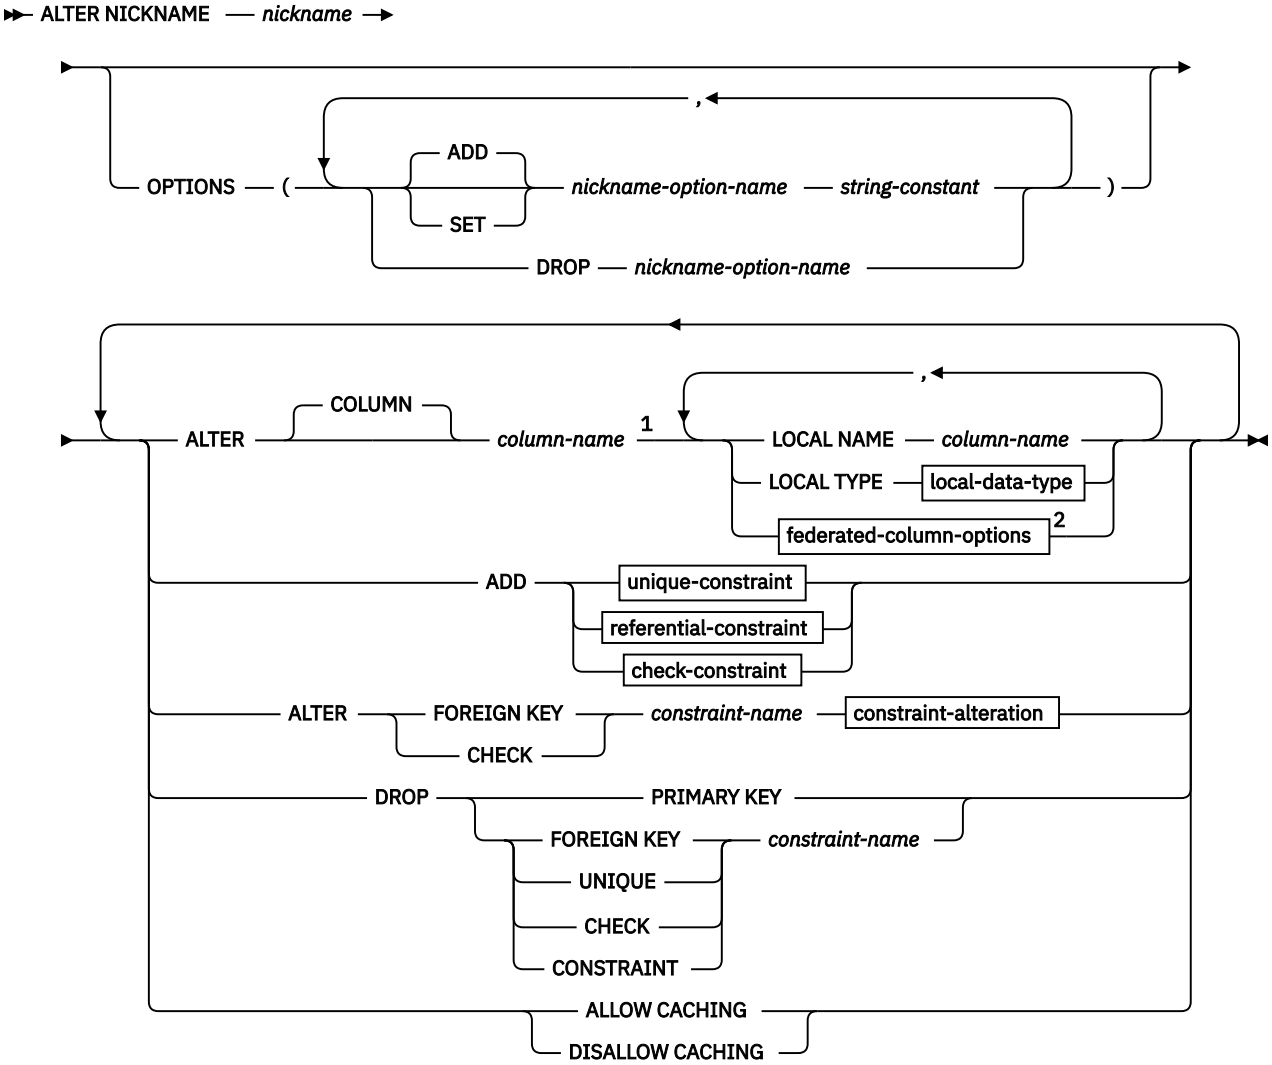
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

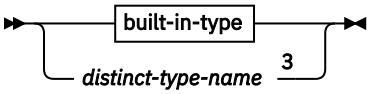
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- ALTER privilege on the nickname specified in the statement
- CONTROL privilege on the nickname specified in the statement
- ALTERIN privilege on the schema, if the schema name of the nickname exists
- SCHEMAADM authority on the schema, if the schema name of the nickname exists
- Owner of the nickname, as recorded in the OWNER column of the SYSCAT.TABLES catalog view
- DBADM authority

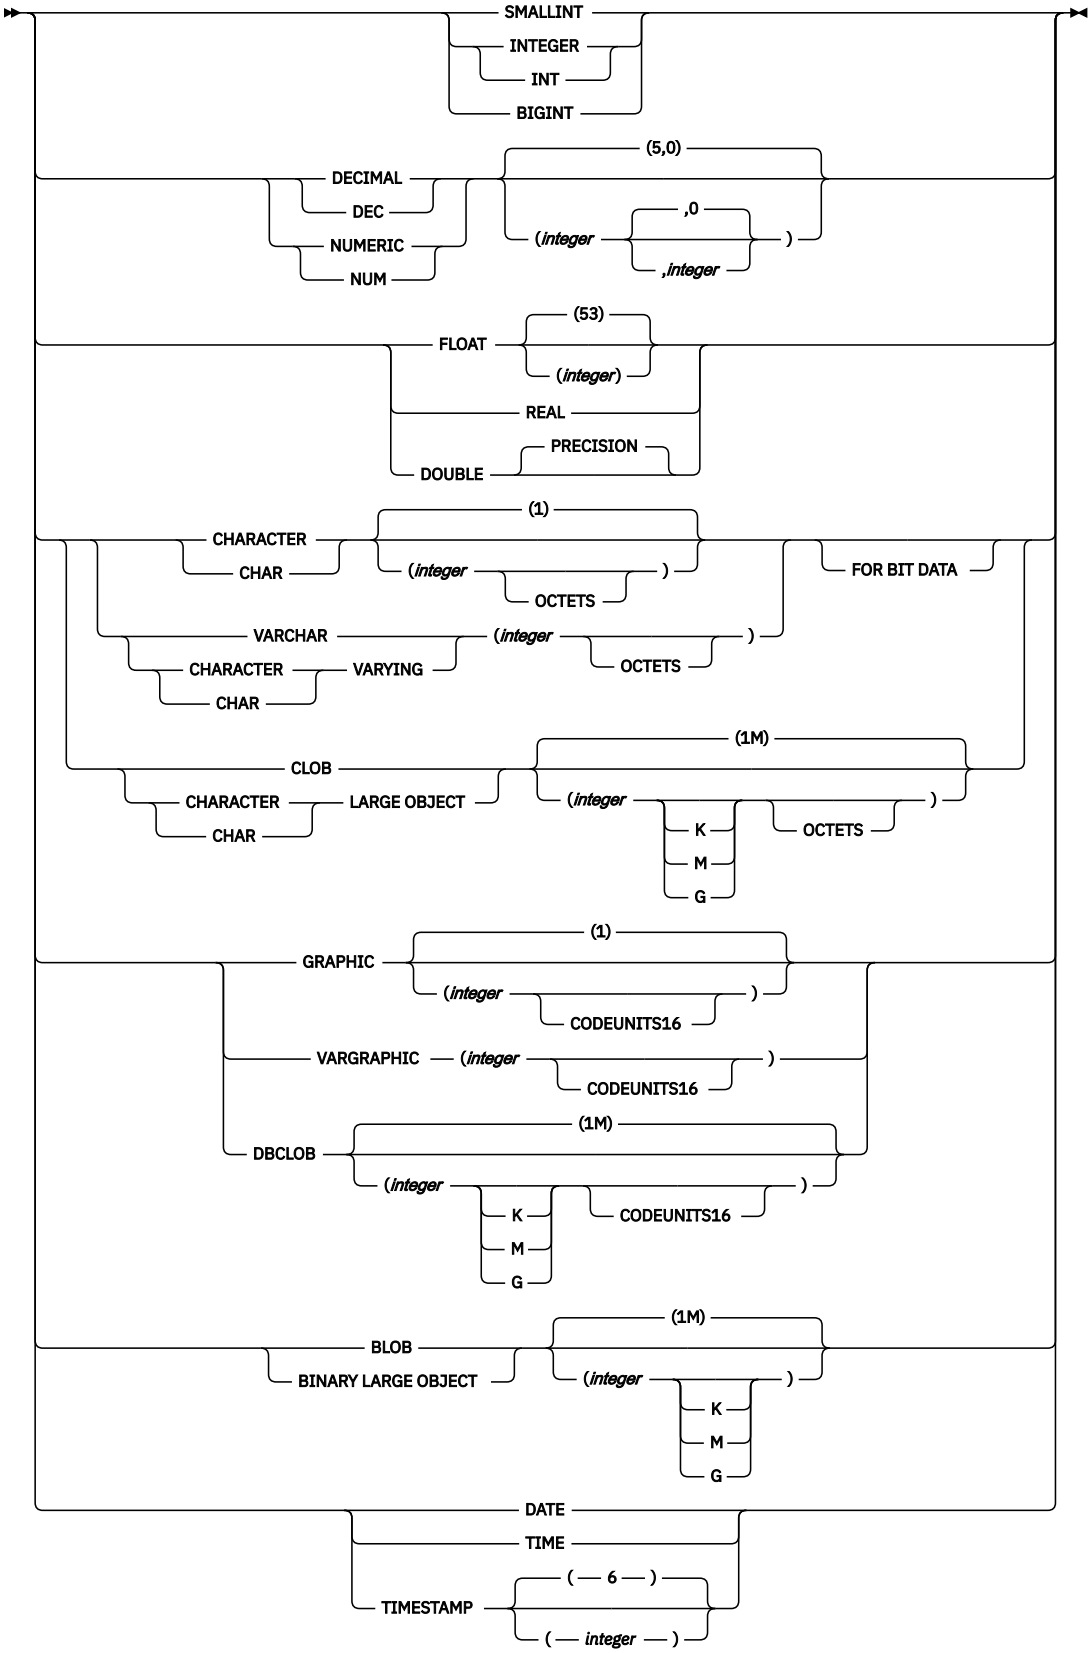
Syntax



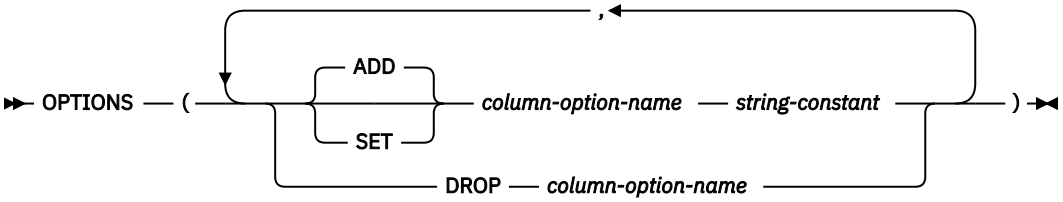
local-data-type



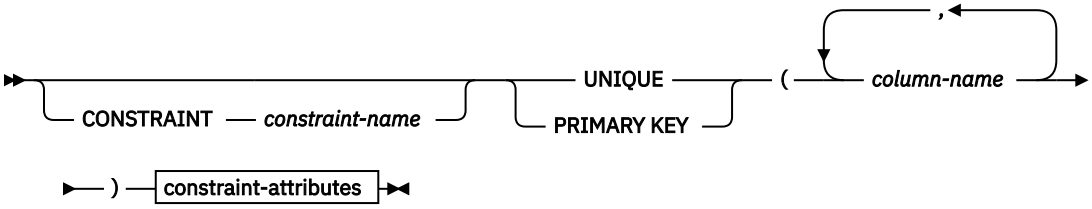
built-in-type



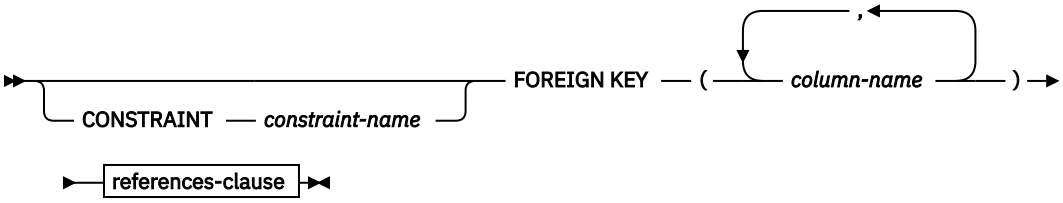
federated-column-options



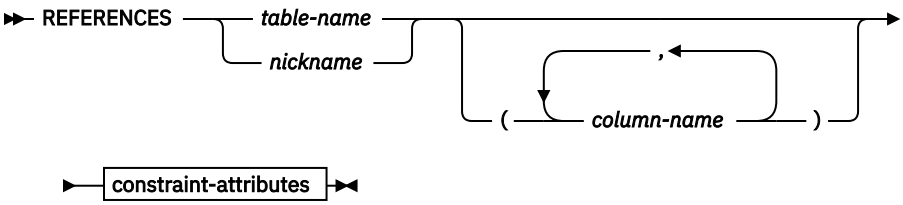
unique-constraint



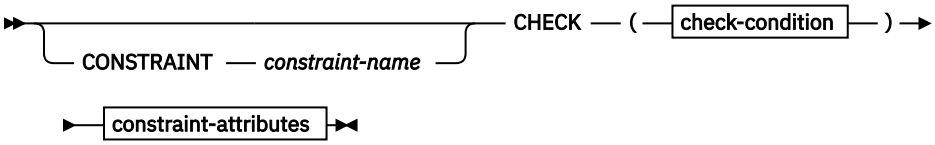
referential-constraint



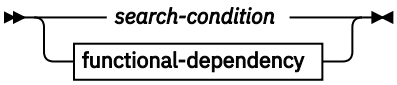
references-clause



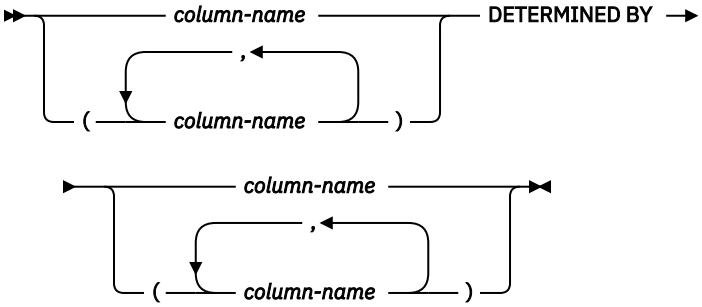
check-constraint



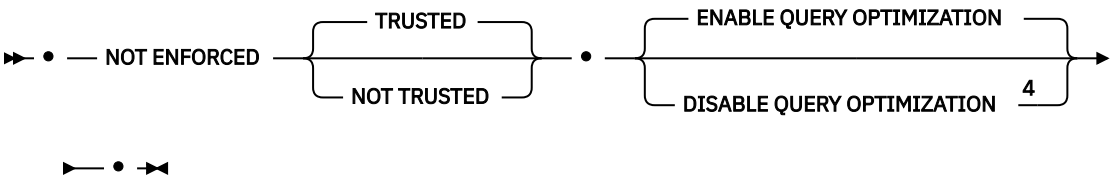
check-condition



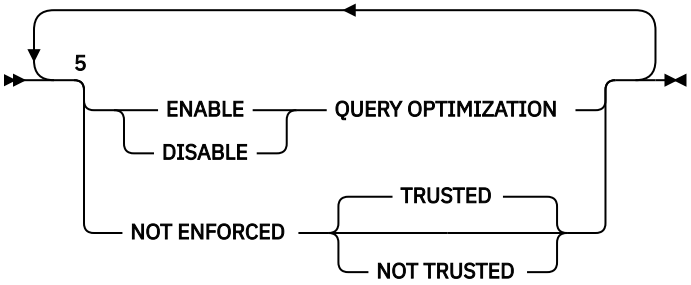
functional-dependency



constraint-attributes



constraint-alteration



Notes:

[1] You cannot specify both the ALTER COLUMN clause and an ADD, ALTER, or DROP informational constraint clause in the same ALTER NICKNAME statement.

[2] If you need to specify the federated-column-options clause in addition to the LOCAL NAME parameter, the LOCAL TYPE parameter, or both, you must specify the federated-column-options clause last.

[3] The specified distinct type cannot have any data type constraints and the source type cannot be an anchored data type (SQLSTATE 428H2).

[4] DISABLE QUERY OPTIMIZATION is not supported for a unique or primary key constraint.

[5] The same clause must not be specified more than once.

Description

nickname
Identifies the nickname for the data source object (such as a table, view, or file) that contains the column being altered. It must be a nickname described in the catalog.

OPTIONS
Indicates the nickname options that are added, set, or dropped when the nickname is altered.

ADD
Adds a nickname option.

SET
Changes the setting of a nickname option.

nickname-option-name
The nickname option that is to be added or set. Which options you can specify depends on the data source of the object for which a nickname is being created. For a list of data sources and the nickname options that apply to each, see Data source options.

string-constant
The nickname option setting as a character string constant enclosed in single quotation marks.

DROP *nickname-option-name*
Drops a nickname option.

ALTER COLUMN *column-name*
Names the column to be altered. The *column-name* is the federated server's current name for the column of the table or view at the data source. The *column-name* must identify an existing column of the nickname (SQLSTATE 42703). You cannot reference the same column name multiple times in the same ALTER NICKNAME statement (SQLSTATE 42711).

LOCAL NAME *column-name*
Specifies a new name, *column-name*, by which the federated server is to reference the column to be altered. The new name cannot be qualified, and the same name cannot be used for more than one column of the nickname (SQLSTATE 42711).

LOCAL TYPE *local-data-type*
Specifies a new local data type to which the data type of the column that is to be altered will map. The new type is denoted by *local-data-type*.

Some wrappers only support a subset of the SQL data types. For descriptions of specific data types, see the description of the "CREATE TABLE" statement.

built-in-type
See "CREATE TABLE" for the description of built-in data types.

OPTIONS
Indicates what column options are to be added, set, or dropped for the column specified after the COLUMN keyword.

ADD
Adds a column option.

SET
Changes the setting of a column option.

column-option-name
Names a column option that is to be added or set.

string-constant
Specifies the setting for *column-option-name* as a character string constant.

DROP *column-option-name*
Drops a column option.

ADD *unique-constraint*
Defines a unique constraint. See the description of the "CREATE NICKNAME" statement.

ADD *referential-constraint*
Defines a referential constraint. See the description of the "CREATE NICKNAME" statement.

ADD *check-constraint*
Defines a check constraint. See the description of the "CREATE NICKNAME" statement.

ALTER FOREIGN KEY *constraint-name*
Alters the constraint attributes of the referential constraint *constraint-name*. For a description of the constraint attributes, see the "CREATE NICKNAME" statement. The *constraint-name* must identify an existing referential constraint (SQLSTATE 42704).

ALTER CHECK *constraint-name*
Alters the constraint attributes of the check constraint *constraint-name*. The *constraint-name* must identify an existing check constraint (SQLSTATE 42704).

constraint-alteration
Provides options for changing the attributes associated with referential or check constraints.

ENABLE QUERY OPTIMIZATION
The constraint can be used for query optimization under appropriate circumstances.

DISABLE QUERY OPTIMIZATION
The constraint cannot be used for query optimization.

NOT ENFORCED
Specifies that the constraint is not enforced by the database manager during normal operations such as insert, update, or delete.

TRUSTED
The data can be trusted to conform to the constraint. TRUSTED must be used only if the data in the table is independently known to conform to the constraint. Query results might be unpredictable if the data does not actually conform to the constraint. This is the default option.

NOT TRUSTED
The data cannot be trusted to conform to the constraint. NOT TRUSTED is intended for cases where the data conforms to the constraint for most rows, but it is not independently known that all the rows or future additions will conform to the constraint. If a constraint is NOT TRUSTED and enabled for query optimization, then it will not be used to perform optimizations that depend on the data conforming completely to the constraint. NOT TRUSTED can be specified only for referential integrity constraints (SQLSTATE 42613).

DROP PRIMARY KEY
Drops the definition of the primary key and all referential constraints that are dependent upon this primary key. The nickname must have a primary key.

DROP FOREIGN KEY *constraint-name*
Drops the referential constraint *constraint-name*. The *constraint-name* must identify an existing referential constraint defined on the nickname.

DROP UNIQUE *constraint-name*
Drops the definition of the unique constraint *constraint-name* and all referential constraints that are dependent upon this unique constraint. The *constraint-name* must identify an existing unique constraint.

DROP CHECK *constraint-name*
Drops the check constraint *constraint-name*. The *constraint-name* must identify an existing check constraint defined on the nickname.

DROP CONSTRAINT *constraint-name*
Drops the constraint *constraint-name*. The *constraint-name* must identify an existing check constraint, referential constraint, primary key, or unique constraint defined on the nickname.

ALLOW CACHING or DISALLOW CACHING
Specifies whether the nickname can be referenced in a query that defines a materialized query table, which could be used to cache data from the data source at the federated server.

ALLOW CACHING
Specifies that the nickname can be referenced in a query that defines a materialized query table, which allows data from the data source to be cached in the materialized query table at the federated server. The refreshable options defined for the materialized query table specify how the cached data in the materialized query table is maintained.

DISALLOW CACHING
Specifies that the nickname cannot be referenced in a query that defines a materialized query table. DISALLOW CACHING cannot be specified for a nickname that is referenced in the fullselect of a materialized query table definition (SQLSTATE 42917).

Rules

- If a nickname is used in a view, SQL method, or SQL function, or informational constraints are defined on it, the ALTER NICKNAME statement cannot be used to change the local names or data types for the columns in the nickname (SQLSTATE 42893). The statement can be used, however, to add, set, or drop column options, nickname options, or informational constraints.
- If a nickname is referenced by a materialized query table definition, the ALTER NICKNAME statement cannot be used to change the local names, data types, column options, or nickname options (SQLSTATE 42893). Moreover, the statement cannot be used to disable caching (SQLSTATE 42917). The statement can be used, however, to add, alter, or drop informational constraints.
- A column option cannot be specified more than once in the same ALTER NICKNAME statement (SQLSTATE 42853). When a column option is enabled, reset, or dropped, any other column options that are in use are not affected.
- For relational nicknames, the ALTER NICKNAME statement within a given unit of work (UOW) cannot be processed under either of the following conditions (SQLSTATE 55007):
  - A nickname referenced in this statement has a cursor open on it in the same UOW

  - Either an INSERT, DELETE, or UPDATE statement is already issued in the same UOW against the nickname that is referenced in this statement
- For non-relational nicknames, the ALTER NICKNAME statement within a given unit of work (UOW) cannot be processed under any of the following conditions (SQLSTATE 55007):
  - A nickname referenced in this statement has a cursor open on it in the same UOW
  - A nickname referenced in this statement is already referenced by a SELECT statement in the same UOW
  - Either an INSERT, DELETE, or UPDATE statement has already been issued in the same UOW against the nickname that is referenced in this statement

Notes

- If the ALTER NICKNAME statement is used to change the local name for a column of a nickname, queries against that column must reference it by its new name.
- When the local specification of a column's data type is changed, the database manager invalidates any statistics (HIGH2KEY, LOW2KEY, and so on) gathered for that column.
- ***Caching and protected objects:*** For nicknames whose data source object is protected, specify `DISALLOW CACHING`. This ensures that each time the nickname is used, data for the appropriate authorization ID is returned from the data source at query execution time. This is done by restricting the nickname from being used in the definition of a materialized query table at the federated server, which might be being used to cache the nickname data.
- BINARY and VARBINARY types are not supported in a Federated system.

Examples

1. The nickname NICK1 references a Db2 for IBM i table called T1. Also, COL1 is the local name that references this table's first column, C1. Rename the local name for C1 from COL1 to NEWCOL.

```
ALTER NICKNAME NICK1
  ALTER COLUMN COL1
  LOCAL NAME NEWCOL
```

2. The nickname EMPLOYEE references a Db2 for z/OS table called EMP. Also, SALARY is the local name that references EMP_SAL, one of this table's columns. The column's data type, FLOAT, maps to the local data type, DOUBLE. Change the mapping so that FLOAT maps to DECIMAL (10, 5).

```
ALTER NICKNAME EMPLOYEE
  ALTER COLUMN SALARY
  LOCAL TYPE DECIMAL(10,5)
```

3. Indicate that in an Oracle table, a column with the data type of VARCHAR does not have trailing blanks. The nickname for the table is NICK2, and the local name for the column is COL1.

```
ALTER NICKNAME NICK2
  ALTER COLUMN COL1
  OPTIONS (ADD VARCHAR_NO_TRAILING_BLANKS 'Y')
```

4. Alter the fully qualified path for the table-structured file, drugdata1.txt, for the nickname DRUGDATA1. Use the FILE_PATH nickname option and change the path from the current value of '/user/pat/drugdata1.txt' to '/usr/kelly/data/drugdata1.txt'.

```
ALTER NICKNAME DRUGDATA1
  OPTIONS (SET FILE_PATH '/usr/kelly/data/drugdata1.txt')
```

ALTER PACKAGE

The ALTER PACKAGE statement alters bind options for a package at the current server without having to bind or rebind the package.

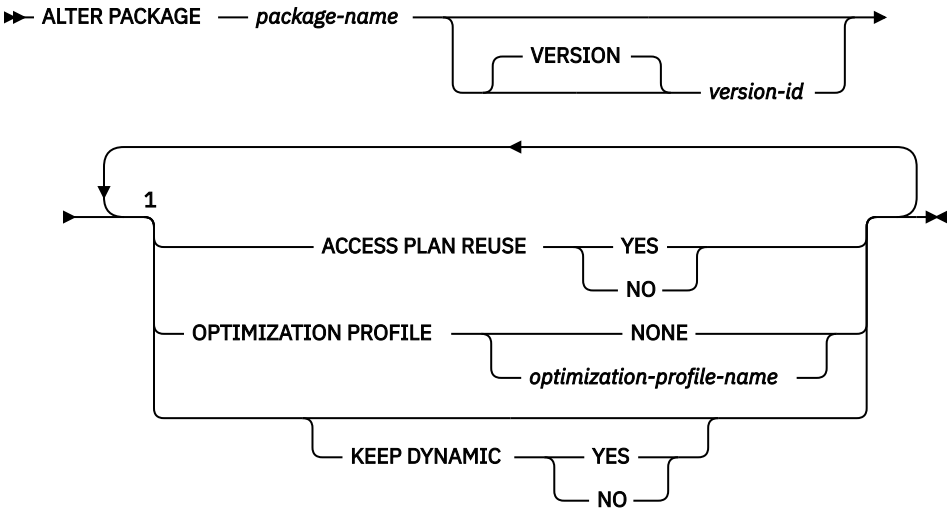
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- ALTERIN privilege on the schema
- BIND privilege on the package
- SCHEMAADM authority on the schema
- DBADM authority



Notes:

[1] The same clause must not be specified more than once.

Description

package-name

Identifies the package that is to be altered. The package name must identify a package that exists at the current server (SQLSTATE 42704).

VERSION *version-id*

Identifies which package version is to be altered. If a value is not specified, the version defaults to the empty string. If multiple packages with the same package name but different versions exist, only one package version can be altered in one invocation of the ALTER PACKAGE statement. Delimit the version identifier with double quotation marks when it:

- Is generated by the VERSION(AUTO) precompiler option
- Begins with a digit
- Contains lowercase or mixed-case letters

If the statement is invoked from an operating system command prompt, precede each double quotation mark delimiter with a back slash character to ensure that the operating system does not strip the delimiters.

ACCESS PLAN REUSE
Indicates whether the query compiler should attempt to reuse the access plans for static statements in the package during future implicit and explicit rebinds.

NO
Specifies not to reuse access plans.

YES
Specifies to attempt to reuse access plans.

OPTIMIZATION PROFILE
Indicates what, if any, optimization profile to associate with the package.

NONE
Associates no optimization profile with the package. If an optimization profile is already associated with the package, the association is removed.

optimization-profile-name
Associates the optimization profile *optimization-profile-name* with the package. The optimization profile is a two-part name. If the specified *optimization-profile-name* is unqualified, the value of the CURRENT DEFAULT SCHEMA special register is used as the implicit qualifier. If an optimization profile is already associated with the package, the association is replaced with *optimization-profile-name*.

While the ALTER PACKAGE statement removes the current copy of the package from the Db2 package cache, it does not invalidate the package and does not cause an implicit rebind to take place. This means that although dynamic SQL is affected by the changes made by the statement, query execution plans for static statements are not be affected until the next implicit or explicit rebind.

KEEP DYNAMIC

Starting with Db2 Version 9.8 Fix Pack 2, you can modify the value of the KEEPDYNAMIC bind option for a package without requiring a fresh bind operation, thereby avoiding unnecessary recompilation until the next bind operation occurs. This option controls how long the statement text and section associated with a prepared statement are kept in the SQL context. It takes effect after all applications that are using the package have completed the transactions that were running when the **ALTER PACKAGE** statement was executed.

YES

Instructs the SQL context to keep the statement text and section associated with prepared statements indefinitely. Dynamic SQL statements are kept across transactions. All packages bound with KEEPDYNAMIC YES are by default compatible with the existing package cache behavior.

NO

Instructs the SQL context to remove the statement text and section associated with prepared statements at the end of each unit of work. The executable versions of prepared statements and the statement text in packages bound with the KEEP DYNAMIC NO option are removed from the SQL context at transaction boundaries. The client, driver, or application needs to prepare any dynamic SQL statement it wishes to reuse in a new unit of work again.

For remote applications that use an IBM non-embedded API, once you have ensured that statements will be prepared in new transactions, you can use this option so that WLB will not be disallowed solely based on the KEEP DYNAMIC behavior. However even with this option, WLB may be disallowed for other reasons.

SELECT statements issued by cursors with the WITH HOLD option are disassociated from the SQL context at the next transaction boundary where the cursor is closed. As a result, workload balancing is allowed as long as there are no executable versions of prepared statements associated with the application in the SQL context.

Note: Workload balancing is not restricted for dynamic SQL applications that use IBM non-embedded APIs, such as JDBC, .NET, or CLI/ODBC, to run SQL within the common client packages. These interfaces implicitly re-prepare SQL statements before executing them in transactions where their connection might have been moved to a new executable version of prepared statements.

Notes

- **Catalog view values may not reflect the settings that were in effect for the package:** Because this statement does not trigger a rebind of the package, the settings for a package as shown in the SYSCAT.PACKAGES catalog view might not reflect what was actually in effect during the last BIND or REBIND. If the ALTER_TIME is greater than the LAST_BIND_TIME, then this might be the case.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with the BIND and REBIND commands. These alternatives are non-standard and should not be used.
  - APREUSE can be specified in place of ACCESS PLAN REUSE.
  - OPTPROFILE can be specified in place of OPTIMIZATION PROFILE.
  - KEEPDYNAMIC can be specified in place of KEEP DYNAMIC.

Examples

Example 1: Enable access plan reuse for package TRUUVERT.EMPADMIN.

```
ALTER PACKAGE TRUUVERT.EMPADMIN ACCESS PLAN REUSE YES
```

Example 2: Assume access plan reuse has been enabled for package TRUUVERT.EMPADMIN. Assume also that optimization profile AYYANG.INDEXHINTS contains a statement profile for a specific statement within the package. Associate the optimization profile with this package so that it will override the reuse of the access plan for the statement.

```
ALTER PACKAGE TRUUVERT.EMPADMIN OPTIMIZATION PROFILE AYYANG.INDEXHINTS
```

Dynamic statements will be affected after the statement commits; static statements will be affected at the next rebind. When the package is rebound, the query compiler will attempt to reuse the access plans for all static statements in the package, with the exception of the statement identified by the optimization profile. When recompiling this statement, the query compiler will instead attempt to apply the statement profile.

Example 3: The following statement will result in no optimization profile being associated with package TRUUVERT.EMPADMIN.

```
ALTER PACKAGE TRUUVERT.EMPADMIN OPTIMIZATION PROFILE NONE
```

ALTER PERMISSION

The ALTER PERMISSION statement alters a row permission that exists at the current server.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax

Description

permission-name
This is the name of the row permission to be altered. The name must identify a row permission that already exists at the current server (SQLSTATE 42704). The name must not identify a default row permission that is created implicitly by the database manager (SQLSTATE 428H9).

ENABLE

Enables the row permission. If row level access control is not currently activated on the table, the row permission will become effective when row level access control is activated on the table. If row level access control is currently activated on the table, the row permission becomes effective immediately and all packages and dynamic cached statements that reference the table are invalidated.

ENABLE is ignored if the row permission is already defined as enabled.

DISABLE

Disables the row permission. If row level access control is not currently activated on the table, the row permission will remain ineffective when row level access control is activated on the table. If row level access control is currently activated on the table, the row permission becomes ineffective immediately and all packages and dynamic cached statements that reference the table are invalidated.

DISABLE is ignored if the row permission is already defined as disabled.

Examples

- *Example 1*: Enable permission P1.

```
ALTER PERMISSION P1 ENABLE
```

- *Example 2*: Disable permission P1.

```
ALTER PERMISSION P1 DISABLE
```

ALTER PROCEDURE (external)

The ALTER PROCEDURE (External) statement modifies an existing external procedure by changing the properties of the procedure.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- ALTERIN privilege on the schema of the procedure
- Owner of the procedure, as recorded in the OWNER column of the SYSCAT.ROUTINES catalog view
- SCHEMAADM authority on the schema of the procedure
- DBADM authority

To alter the EXTERNAL NAME of a procedure, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

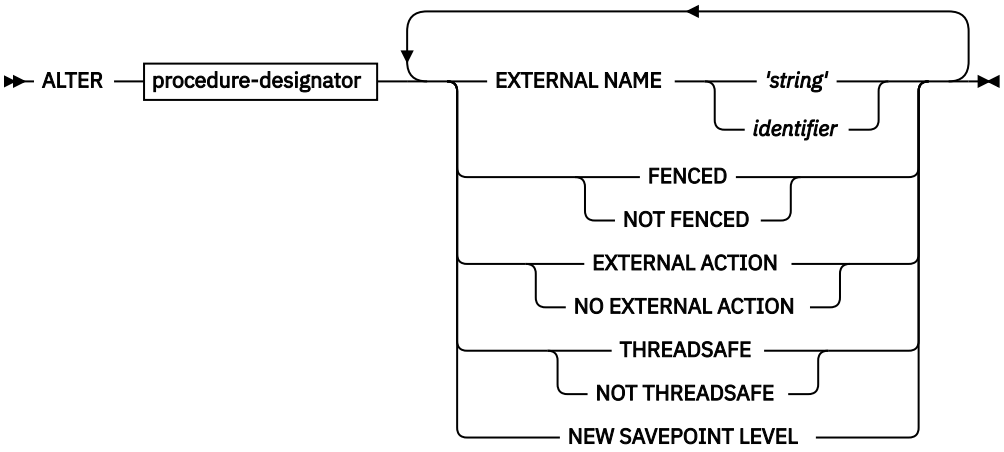
- CREATE_EXTERNAL_ROUTINE authority on the database
- DBADM authority

To alter a procedure to be not fenced, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

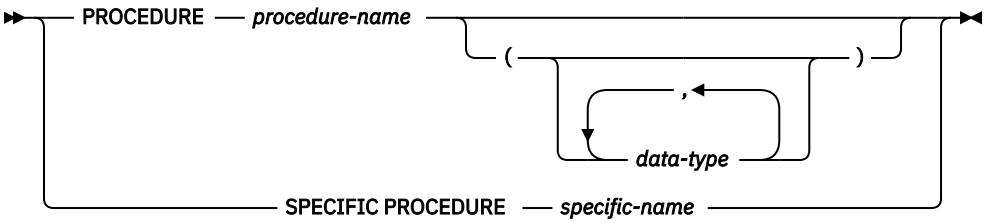
- CREATE_NOT_FENCED_ROUTINE authority on the database
- DBADM authority

To alter a procedure to be fenced, no additional authorities or privileges are required.

Syntax



procedure-designator



Description

procedure-designator
Identifies the procedure to alter. The *procedure-designator* must identify a procedure that exists at the current server. The owner of the procedure and all privileges on the procedure are preserved. For more information, see "Function, method, and procedure designators" on page 745.

EXTERNAL NAME *'string'* or *identifier*
Identifies the name of the user-written code that implements the procedure.

FENCED or NOT FENCED
Specifies whether the procedure is considered safe to run in the database manager operating environment's process or address space (NOT FENCED), or not (FENCED). Most procedures have the option of running as FENCED or NOT FENCED.

If a procedure is altered to be FENCED, the database manager insulates its internal resources (for example, data buffers) from access by the procedure. In general, a procedure running as FENCED will not perform as well as a similar one running as NOT FENCED.

CAUTION: Use of NOT FENCED for procedures that were not adequately coded, reviewed, and tested can compromise the integrity of a Db2 database. Db2 databases take some

precautions against many of the common types of inadvertent failures that might occur, but cannot guarantee complete integrity when NOT FENCED stored procedures are used.

A procedure declared as NOT THREADSAFE cannot be altered to be NOT FENCED (SQLSTATE 42613).

If a procedure has any parameters defined AS LOCATOR, and was defined with the NO SQL option, the procedure cannot be altered to be FENCED (SQLSTATE 42613).

This option cannot be altered for LANGUAGE OLE or CLR procedures (SQLSTATE 42849).

This option cannot be altered for a procedure that is registered as a component routine of an aggregate interface function (SQLSTATE 42849).

EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the procedure takes some action that changes the state of an object not managed by the database manager (EXTERNAL ACTION), or not (NO EXTERNAL ACTION). If NO EXTERNAL ACTION is specified, the system can use certain optimizations that assume the procedure has no external impact.

This option cannot be altered for a procedure that is registered as a component routine of an aggregate interface function (SQLSTATE 42849).

THREADSAFE or NOT THREADSAFE
Specifies whether the procedure is considered safe to run in the same process as other routines (THREADSAFE), or not (NOT THREADSAFE).

If the procedure is defined with LANGUAGE other than OLE:

- If the procedure is defined as THREADSAFE, the database manager can invoke the procedure in the same process as other routines. In general, to be threadsafe, a procedure should not use any global or static data areas. Most programming references include a discussion of writing threadsafe routines. Both FENCED and NOT FENCED procedures can be THREADSAFE.
- If the procedure is defined as NOT THREADSAFE, the database manager will never invoke the procedure in the same process as another routine. Only a fenced procedure can be NOT THREADSAFE (SQLSTATE 42613).

This option cannot be altered for LANGUAGE OLE procedures (SQLSTATE 42849).

This option cannot be altered for a procedure that is registered as a component routine of an aggregate interface function (SQLSTATE 42849).

NEW SAVEPOINT LEVEL
Specifies that a new savepoint level is to be created for the procedure. A savepoint level refers to the scope of reference for any savepoint-related statement, as well as to the name space used for comparison and reference of any savepoint names.

The savepoint level for a procedure can only be altered to NEW SAVEPOINT LEVEL.

This option cannot be altered for a procedure that is registered as a component routine of an aggregate interface function (SQLSTATE 42849).

Rules

- It is not possible to alter a procedure that is in the following schema (SQLSTATE 42832):
  - SYSIBM
  - SYSFUN
  - SYSPROC

Example

Alter the procedure PARTS_ON_HAND() to be not fenced.

```
ALTER PROCEDURE PARTS_ON_HAND() NOT FENCED
```

ALTER PROCEDURE (sourced)

The ALTER PROCEDURE (Sourced) statement modifies an existing sourced procedure by changing the data type of one or more parameters of the sourced procedure.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

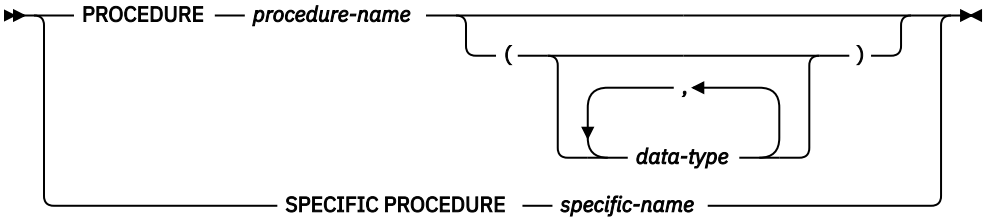
Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- ALTERIN privilege on the schema of the procedure
- Owner of the procedure, as recorded in the OWNER column of the SYSCAT.ROUTINES catalog view
- SCHEMAADM authority on the schema of the procedure
- DBADM authority

Syntax

procedure-designator



parameter-alteration

Description

procedure-designator
Uniquely identifies the procedure to be altered. The identified procedure must be a sourced procedure (SQLSTATE 42849). For more information, see "Function, method, and procedure designators" on page 745.

parameter-name
Identifies the parameter to be altered. The *parameter-name* must identify an existing parameter of the procedure (SQLSTATE 42703). The name must not identify a parameter that is otherwise being altered in the same ALTER PROCEDURE statement (SQLSTATE 42713).

data-type
Specifies the new local data type of the parameter. SQL data type specifications and abbreviations that are valid for the *data-type* definition of a CREATE TABLE statement can be specified. BLOB, CLOB, DBCLOB, DECFLOAT, XML, REFERENCE, and user-defined types are not supported (SQLSTATE 42815).

Example

Assume that federated procedure FEDEMPLOYEE has been created for a remote Oracle procedure named 'EMPLOYEE'. The data type of an input parameter named SALARY maps to a DOUBLE(8) in Db2. Alter the data type of this parameter to DECIMAL(5,2).

```
ALTER PROCEDURE FEDEMPLOYEE
  ALTER PARAMETER SALARY
  SET DATA TYPE DECIMAL(5,2)
```

ALTER PROCEDURE (SQL)

The ALTER PROCEDURE (SQL) statement modifies an existing SQL procedure by changing the properties of the procedure.

Invocation

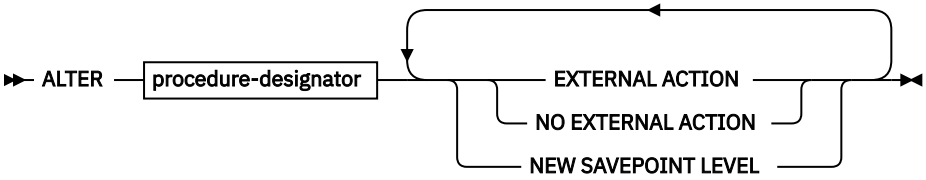
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

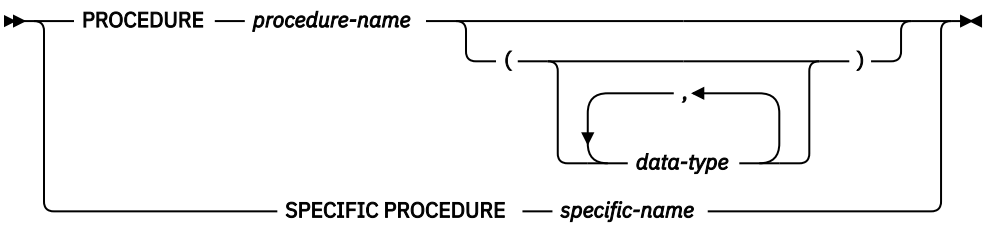
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- ALTERIN privilege on the schema of the procedure
- Owner of the procedure, as recorded in the OWNER column of the SYSCAT.ROUTINES catalog view
- SCHEMAADM authority on the schema of the procedure
- DBADM authority

Syntax



procedure-designator



Description

procedure-designator

Identifies the procedure to alter. The *procedure-designator* must identify a procedure that exists at the current server. The owner of the procedure and all privileges on the procedure are preserved. For more information, see "Function, method, and procedure designators" on page 745.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the procedure takes some action that changes the state of an object not managed by the database manager (EXTERNAL ACTION), or not (NO EXTERNAL ACTION). If NO EXTERNAL

ACTION is specified, the system can use certain optimizations that assume the procedure has no external impact.

NEW SAVEPOINT LEVEL
Specifies that a new savepoint level is to be created for the procedure. A savepoint level refers to the scope of reference for any savepoint-related statement, as well as to the name space used for comparison and reference of any savepoint names.

The savepoint level for a procedure can only be altered to NEW SAVEPOINT LEVEL.

Rules

- It is not possible to alter a procedure that is in the following schema (SQLSTATE 42832):
  - SYSIBM
  - SYSFUN
  - SYSPROC

Example

Alter the procedure MEDIAN_RESULT_SET to indicate that it has no external action.

```
ALTER PROCEDURE MEDIAN_RESULT_SET(DOUBLE)
  NO EXTERNAL ACTION
```

ALTER SCHEMA

The ALTER SCHEMA statement modifies the data capture attribute of an existing schema.

Invocation

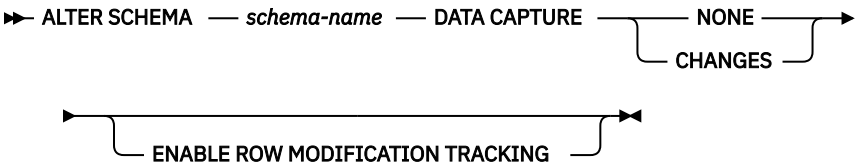
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- Owner of the schema, as recorded in the OWNER column of SYSCAT.SCHEMATA catalog view
- DBADM authority

Syntax



Description

schema-name
Identifies the schema to be altered. The *schema-name* must identify a schema that exists at the current server (SQLSTATE 42704).

DATA CAPTURE
Indicates whether extra information for data replication is to be written to the log.

NONE
Indicates that no extra information for data replication will be logged.

CHANGES
Indicates that extra information regarding SQL changes to this schema will be written to the log. This option is required if this schema will be replicated and a replication capture program is used to capture changes for this schema from the log.

ENABLE ROW MODIFICATION TRACKING
Indicates tables created in the schema are to be enabled for logical backup. This only applies to columnar organized tables. For a list of restrictions, see Schema enabled for row modification tracking.

Notes

- Altering the DATA CAPTURE attribute at the schema level causes newly created tables to inherit the DATA CAPTURE attribute from the schema if one is not specified at the table level. Altering the DATA CAPTURE attribute at the schema level does not affect the DATA CAPTURE attribute of existing tables within that schema. If the DATA CAPTURE attribute is changed and any existing tables do not match the new attribute, a warning is returned (SQLSTATE 01696).
- To find the list of tables that have the DATA CAPTURE attribute set to CHANGES, issue the following query:

```
SELECT TABNAME, TABSCHEMA FROM SYSCAT.TABLES
  WHERE TYPE IN ('T','S','L')
    AND DATACAPTURE <> 'N'
```

- To find the list of tables that have the DATA CAPTURE attribute set to NONE, issue the following query:

```
SELECT TABNAME, TABSCHEMA FROM SYSCAT.TABLES
  WHERE TYPE IN ('T','S','L')
    AND DATACAPTURE = 'N'
```

Related information
Schema enabled for row modification tracking

ALTER SECURITY LABEL COMPONENT

The ALTER SECURITY LABEL COMPONENT statement modifies a security label component.

Invocation

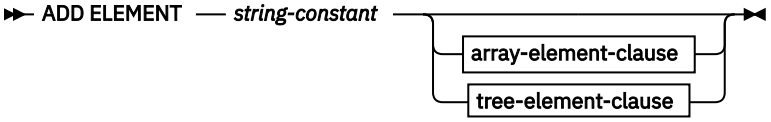
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

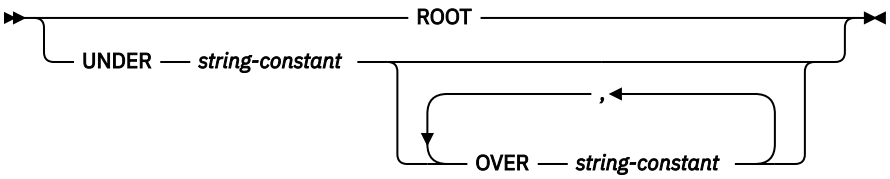
Syntax

add-element-clause



array-element-clause

tree-element-clause



Description

component-name
Specifies the name of the security label component to be altered. The named component must exist at the current server (SQLSTATE 42704).

ADD ELEMENT
Specifies the element to be added to the security label component. If *array-element-clause* and *tree-element-clause* are not specified, the element is added to a set component.

string-constant
The string constant value to be added to the set of valid values for the security label component. The value cannot be the same as any other value in the set of valid values for the security label component (SQLSTATE 42713).

BEFORE or AFTER
For an array component, specifies where the element is to be added in the ordered set of element values for the security label component.

BEFORE
The element to be added is to be ranked immediately before the identified existing element.

AFTER
The element to be added is to be ranked immediately after the identified existing element.

string-constant
Specifies a string constant value of an existing element in the array component (SQLSTATE 42704).

ROOT or UNDER
For a tree component, specifies where the element is to be added in the tree structure of node element values for the security label component.

ROOT
The element to be added is to be considered the root node of the tree.

UNDER *string-constant*
The element to be added is an immediate child of the element identified by the *string-constant*. The *string-constant* value must be an existing element in the tree component (SQLSTATE 42704).

OVER *string-constant*,...
The element to be added is an immediate child of every element identified by the list of *string-constant* values. Each *string-constant* value must be an existing element in the tree component (SQLSTATE 42704).

Rules

- Element names cannot contain any of these characters (SQLSTATE 42601):
  - Opening parenthesis - (
  - Closing parenthesis -)
  - Comma - ,

  - Colon - :
- An element name can have no more than 32 bytes (SQLSTATE 42622).
- If a security label component is a set or a tree, no more than 64 elements can be part of that component.
- If the component is an array, it might or might not be possible to arrive at an array whose total number of elements matches the total number of elements that could be specified when creating a security label component of type array (65 535). The database manager assigns an encoded value to the new element from within the interval into which the new element is added. Depending on the pattern followed when adding elements to an array component, the number of possible values that can be assigned from within a particular interval might be quickly exhausted if several elements are inserted into that interval.
- BEFORE and AFTER must only be specified for a security label component that is an array (SQLSTATE 42613).
- ROOT and UNDER must only be specified for a security label component that is a tree (SQLSTATE 42613).

Notes

- For a set component, there is no order to the elements in the set.

Examples

- *Example 1:* Add the element 'High classified' to the LEVEL security label array component between the elements 'Secret' and 'Classified'.

```
ALTER SECURITY LABEL COMPONENT LEVEL
  ADD ELEMENT 'High classified' BEFORE 'Classified'
```

- *Example 2:* Add the element 'Funding' to the COMPARTMENTS security label set component.

```
ALTER SECURITY LABEL COMPONENT COMPARTMENTS
  ADD ELEMENT 'Funding'
```

- *Example 3:* Add the elements 'ENGINE' and 'TOOLS' to the GROUPS security label array component. The following diagram shows where these new elements are to be placed.

```
                    PROJECT
                 ___|_____
                |         |
           ENGINE         TOOLS
        ___|_____
       |        |
    TEST      DEVELOPMENT
           ____|____
          |         |
       CURRENT    FIELD

ALTER SECURITY LABEL COMPONENT GROUPS
  ADD ELEMENT 'TOOLS' UNDER 'PROJECT'

ALTER SECURITY LABEL COMPONENT GROUPS
  ADD ELEMENT 'ENGINE' UNDER 'PROJECT'
    OVER 'TEST', 'DEVELOPMENT'
```

ALTER SECURITY POLICY

The ALTER SECURITY POLICY statement modifies a security policy.

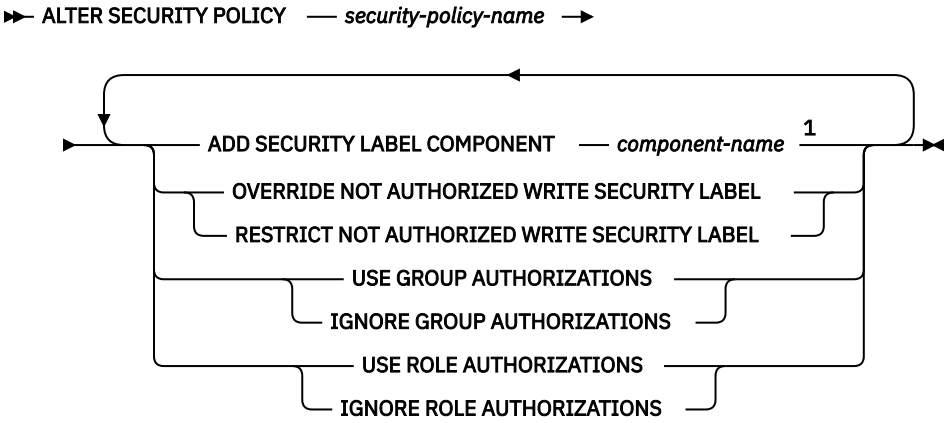
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Notes:

[1] Only the ADD SECURITY LABEL COMPONENT clause can be specified more than once.

Description

security-policy-name
Specifies the name of the security policy to be altered. The name must identify an existing security policy at the current server (SQLSTATE 42710).

ADD SECURITY LABEL COMPONENT *component-name*
Adds a security label component to the security policy. The same security component must not be specified more than once for the security policy (SQLSTATE 42713). The security policy cannot currently be in use by a table (SQLSTATE 42893).

OVERRIDE NOT AUTHORIZED WRITE SECURITY LABEL or RESTRICT NOT AUTHORIZED WRITE SECURITY LABEL
Specifies the action taken when a user is not authorized to write the explicitly specified security label that is provided in the INSERT or UPDATE statement issued against a table that is protected with this security policy. A user's security label and exemption credentials determine the user's authorization to write an explicitly provided security label.

OVERRIDE NOT AUTHORIZED WRITE SECURITY LABEL
Indicates that the value of the user's security label, rather than the explicitly specified security label, is used for write access during an insert or update operation.

RESTRICT NOT AUTHORIZED WRITE SECURITY LABEL
Indicates that the insert or update operation will fail if the user is not authorized to write the explicitly specified security label that is provided in the INSERT or UPDATE statement (SQLSTATE 42519).

USE GROUP AUTHORIZATION or IGNORE GROUP AUTHORIZATION
Specifies whether or not security labels and exemptions granted to groups, directly or indirectly, are considered for any access attempt.

USE GROUP AUTHORIZATION
Indicates that any security labels or exemptions granted to groups, directly or indirectly, are considered.

IGNORE GROUP AUTHORIZATION
Indicates that any security labels or exemptions granted to groups are not considered.

USE ROLE AUTHORIZATION or IGNORE ROLE AUTHORIZATION
Specifies whether or not security labels and exemptions granted to roles, directly or indirectly, are considered for any access attempt.

USE ROLE AUTHORIZATION
Indicates that any security labels or exemptions granted to roles, directly or indirectly, are considered.

IGNORE ROLE AUTHORIZATION
Indicates that any security labels or exemptions granted to roles are not considered.

Rules

- If a user does not directly hold a security label for write access, an error is returned in the following situations (SQLSTATE 42519):
  - A value for the row security label column is not explicitly provided as part of the SQL statement
  - The OVERRIDE NOT AUTHORIZED WRITE SECURITY LABEL option is in effect for the security policy, and the user is not allowed to write a data object with the provided security label

Notes

- New components are logically added at the end of the existing security label definition contained by the modified policy. Existing security labels defined for this security policy are modified to contain the new component as part of their definition with no element in their value for this component.
- ***Cache invalidation when changing NOT AUTHORIZED WRITE SECURITY LABEL:*** Changing the NOT AUTHORIZED WRITE SECURITY LABEL to a new value will cause the invalidation of any cached dynamic or static SQL statements that are dependent on any table that is protected by the security policy being altered.
- Because the session authorization ID is the focus authorization ID for label-based access control, security labels granted to groups or to roles that are accessible through groups are eligible for consideration for all types of SQL statements, including static SQL.
- If more than one security label or exemption is available to a user with associated groups or roles at the time of a read or write access attempt, those security labels and exemptions will be evaluated for eligibility based on the following rules:
  - If the security policy enables only role authorizations for consideration, all security labels and exemptions granted to roles of which the user authorization ID is a direct or indirect member will be considered. Security labels and exemptions granted to roles for which membership is only accessible through the groups associated with the user authorization ID will not be considered.
  - If the security policy enables only group authorizations for consideration, all security labels and exemptions granted to groups associated with the user authorization ID will be considered. Security labels and exemptions granted to roles for which membership is only accessible through the groups associated with the user authorization ID will not be considered.
  - If the security policy enables both group and role authorizations for consideration, any security labels and exemptions granted to roles accessible to the user indirectly through groups associated with the user authorization ID will be considered.

  - Role authorizations that are accessible to the user only through PUBLIC will not be considered at any time.
- If more than one security label is eligible for consideration during an access attempt, the values provided for each security label are merged at the individual component level to form a security label that reflects the combination of all available values at each component piece of the security policy. This is the security label value that will be used for the access attempt.

  The mechanisms for combining security labels vary by component type. The components of the resultant security label are as follows:

  - Set components contain the union of all unique values encountered in the eligible security labels
  - Array components contain the highest order element encountered in the eligible security labels
  - Tree components contain the union of all unique values encountered in the eligible security labels
- If more than one exemption is eligible for consideration during an access attempt, all found exemptions are applied to the access attempt.

Examples

- *Example 1:* Alter a security policy named DATA_ACCESS to add a new component named REGION.

```
ALTER SECURITY POLICY DATA_ACCESS
  ADD COMPONENT REGION
```

- *Example 2:* Alter a security policy named DATA_ACCESS to allow access through security labels granted to roles.

```
ALTER SECURITY POLICY DATA_ACCESS
  USE ROLE AUTHORIZATIONS
```

- *Example 3:* Show the eligible security labels that would be considered depending on the settings for group or role authorizations in a security policy. The security policy SECUR_POL has an array component and a set component, consisting of the following elements:

  Array = {TS, S, C, U}
  Set = {A, B, X, Y}

  The following security labels are defined for SECUR_POL:

  Security label L1 = C:A
  Security label L2 = S:B
  Security label L3 = TS:X
  Security label L4 = U:Y

  User Paul is a member of role R1 and group G1. Group G1 is a member of role R2. Security label L1 is granted to Paul. Security label L2 is granted to role R1. Security label L3 is granted to group G1. Security label L4 is granted to role R2. The following table shows what security labels would be considered for any access attempt by Paul, depending on the different possible settings of the security policy SECUR_POL.

Table 124. Security labels considered as a function of security policy settings

	Roles Enabled	**Roles Disabled**
Groups Enabled	L1, L2, L3, L4	L1, L3
Groups Disabled	L1, L2	L1

  The following table shows the value of the combined security label for any access attempt by Paul, depending on the different settings of the security policy SECUR_POL.

Table 125. Combined security labels as a function of security policy settings		
	Roles Enabled	**Roles Disabled**
Groups Enabled	TS:(A, B, X, Y)	TS:(A, X)
Groups Disabled	S:(A, B)	C:A

ALTER SEQUENCE

The ALTER SEQUENCE statement can be used to change a sequence.

A sequence can be changed in the following ways:

- Restarting the sequence
- Changing the increment between future sequence values
- Setting or eliminating the minimum or maximum values
- Changing the number of cached sequence numbers
- Changing the attribute that determines whether the sequence can cycle or not
- Changing whether sequence numbers must be generated in order of request

Invocation

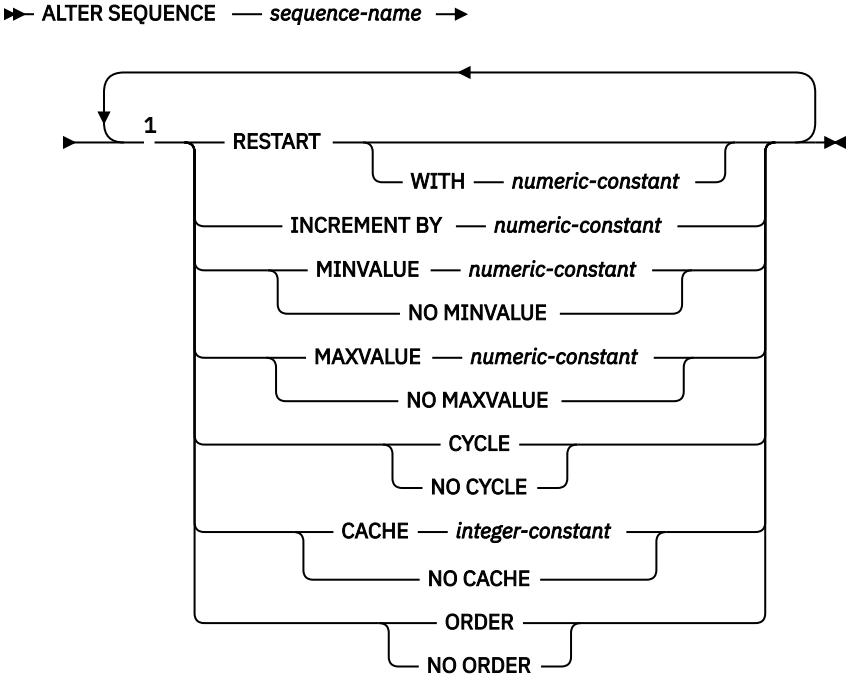
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- ALTER privilege on the sequence to be altered
- ALTERIN privilege on the schema implicitly or explicitly specified
- SCHEMAADM authority on the schema implicitly or explicitly specified
- DBADM authority

Syntax



Notes:

[1] The same clause must not be specified more than once.

Description

sequence-name
Identifies the sequence that is to be changed. The name, including the implicit or explicit schema qualifier, must uniquely identify an existing sequence at the current server. If no sequence by this name exists in the explicitly or implicitly specified schema, an error (SQLSTATE 42704) is returned. *sequence-name* must not be a sequence generated by the system for an identity column (SQLSTATE 428FB).

RESTART
Restarts the sequence. If *numeric-constant* is not specified, the sequence is restarted at the value specified implicitly or explicitly as the starting value on the CREATE SEQUENCE statement that originally created the sequence.

WITH *numeric-constant*
Restarts the sequence with the specified value. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence (SQLSTATE 42815), without nonzero digits existing to the right of the decimal point (SQLSTATE 428FA).

INCREMENT BY *numeric-constant*
Specifies the interval between consecutive values of the sequence. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence (SQLSTATE 42815). The value must not exceed the value of a large integer constant (SQLSTATE 42820) and must not contain nonzero digits to the right of the decimal point (SQLSTATE 428FA).

If this value is negative, then this is a descending sequence. If this value is 0 or positive, this is an ascending sequence after the ALTER statement.

MINVALUE or NO MINVALUE
Specifies the minimum value at which a descending sequence either cycles or stops generating values, or an ascending sequence cycles to after reaching the maximum value.

MINVALUE *numeric-constant*
Specifies the numeric constant that is the minimum value. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence (SQLSTATE 42815), without nonzero digits existing to the right of the decimal point (SQLSTATE 428FA), but the value must be less than or equal to the maximum value (SQLSTATE 42815).

NO MINVALUE
For an ascending sequence, the value is the original starting value. For a descending sequence, the value is the minimum value of the data type associated with the sequence.

MAXVALUE or NO MAXVALUE
Specifies the maximum value at which an ascending sequence either cycles or stops generating values, or a descending sequence cycles to after reaching the minimum value.

MAXVALUE *numeric-constant*
Specifies the numeric constant that is the maximum value. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence (SQLSTATE 42815), without nonzero digits existing to the right of the decimal point (SQLSTATE 428FA), but the value must be greater than or equal to the minimum value (SQLSTATE 42815).

NO MAXVALUE
For an ascending sequence, the value is the maximum value of the data type associated with the sequence. For a descending sequence, the value is the original starting value.

CYCLE or NO CYCLE
Specifies whether the sequence should continue to generate values after reaching either its maximum or minimum value. The boundary of the sequence can be reached either with the next value landing exactly on the boundary condition, or by overshooting the value.

CYCLE
Specifies that values continue to be generated for this sequence after the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches its maximum value, it generates its minimum value; or after a descending sequence reaches its minimum value, it generates its maximum value. The maximum and minimum values for the sequence determine the range that is used for cycling.

When CYCLE is in effect, then duplicate values can be generated for the sequence.

NO CYCLE
Specifies that values will not be generated for the sequence once the maximum or minimum value for the sequence has been reached.

CACHE or NO CACHE
Specifies whether to keep some preallocated values in memory for faster access. This is a performance and tuning option.

CACHE *integer-constant*
Specifies the maximum number of sequence values that are preallocated and kept in memory. Preallocating and storing values in the cache reduces synchronous I/O to the log when values are generated for the sequence.

In the event of a system failure, all cached sequence values that have not been used in committed statements are lost (that is, they will never be used).The maximum number of sequence values that can be lost is calculated as follows:

- If ORDER is specified, the maximum is the value specified for the CACHE option.
- In a multi-partition or Db2 pureScale environment, the maximum is the value specified for the CACHE option times the number of members that generate new identity values.

The minimum value is 2 (SQLSTATE 42815).

NO CACHE
Specifies that values of the sequence are not to be preallocated. It ensures that there is not a loss of values in the case of a system failure, shutdown or database deactivation. When this option is

specified, the values of the sequence are not stored in the cache. In this case, every request for a new value for the sequence results in synchronous I/O to the log.

ORDER or NO ORDER
Specifies whether the sequence numbers must be generated in order of request.

ORDER
Specifies that the sequence numbers are generated in order of request.

NO ORDER
Specifies that the sequence numbers do not need to be generated in order of request.

Notes

- Only future sequence numbers are affected by the ALTER SEQUENCE statement.
- The data type of a sequence cannot be changed. Instead, drop and re-create the sequence specifying the required data type for the new sequence.
- All cached values are lost when a sequence is altered.
- After restarting a sequence or changing to CYCLE, it is possible for sequence numbers to be duplicate values of ones generated by the sequence previously.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - A comma can be used to separate multiple sequence options.
  - NOMINVALUE, NOMAXVALUE, NOCYCLE, NOCACHE, and NOORDER can be specified in place of NO MINVALUE, NO MAXVALUE, NO CYCLE, NO CACHE, and NO ORDER, respectively

Example

A possible reason for specifying RESTART without a numeric value would be to reset the sequence to the START WITH value. In this example, the goal is to generate the numbers from 1 up to the number of rows in the table and then inserting the numbers into a column added to the table using temporary tables. Another use would be to get results back where all the resulting rows are numbered:

```
ALTER SEQUENCE ORG_SEQ RESTART
SELECT NEXT VALUE FOR ORG_SEQ, ORG.* FROM ORG
```

ALTER SERVER

The ALTER SERVER statement is used to modify the definition or configuration of a data source.

This statement can be used to make the following changes:

- Modify the definition of a specific data source, or the definition of a category of data sources.
- Make changes in the configuration of a specific data source, or the configuration of a category of data sources-changes that will persist over multiple connections to the federated database.

In this statement, the word SERVER and the parameter names that start with *server-* refer only to data sources in a federated system. They do not refer to the federated server in such a system, or to DRDA application servers.

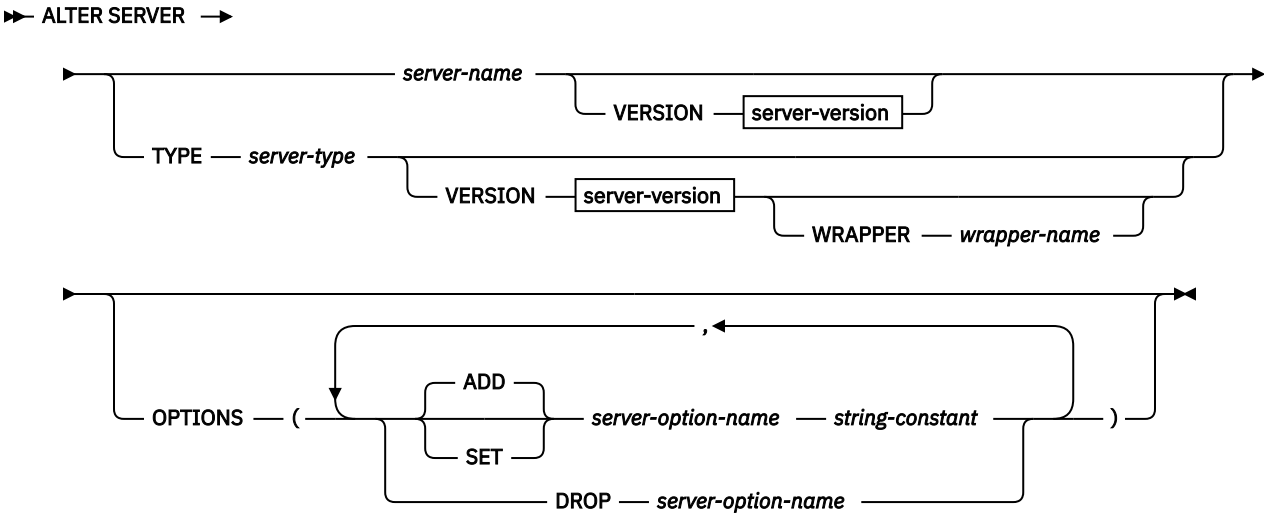
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

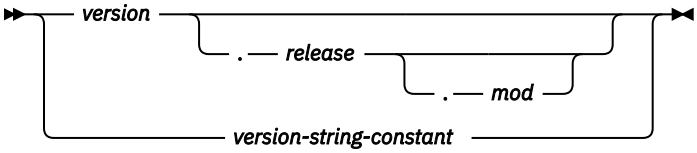
Authorization

The privileges held by the authorization ID of the statement must include DBADM authority.

Syntax



server-version



Description

server-name
Identifies the federated server's name for the data source to which the changes being requested are to apply. The data source must be one that is described in the catalog.

VERSION
After *server-name*, VERSION and its parameter specify a new version of the data source that *server-name* denotes.

version
Specifies the version number. The value must be an integer.

release
Specifies the number of the release of the version denoted by *version.* The value must be an integer.

mod
Specifies the number of the modification of the release denoted by *release.* The value must be an integer.

version-string-constant
Specifies the complete designation of the version. The *version-string-constant* can be a single value (for example, '8i'); or it can be the concatenated values of *version*, *release* and, if applicable, *mod* (for example, '8.0.3').

TYPE *server-type*
Specifies the type of data source to which the changes being requested are to apply.

VERSION
After *server-type*, VERSION and its parameter specify the version of the data sources for which server options are to be enabled, reset, or dropped.

WRAPPER *wrapper-name*
Specifies the name of the wrapper that the federated server uses to interact with data sources of the type and version denoted by *server-type* and *server-version*. The wrapper must be listed in the catalog.

OPTIONS
Indicates what server options are to be enabled, reset, or dropped for the data source denoted by *server-name*, or for the category of data sources denoted by *server-type* and its associated parameters.

ADD
Enables a new server option.

SET
Changes the setting of a server option.

server-option-name
The server option that is to be added or reset. Which options you can specify depends on the data source of the object for which a wrapper is being created. For a list of data sources and the server options that apply to each, see Data source options.

string-constant
The server option setting as a character string constant enclosed in single quotation marks.

DROP *server-option-name*
Drops a server option.

Notes

- A server option cannot be specified more than once in the same ALTER SERVER statement (SQLSTATE 42853). When a server option is enabled, reset, or dropped, any other server options that are in use are not affected.
- An ALTER SERVER statement within a given unit of work (UOW) cannot be processed (SQLSTATE 55007) under either of the following conditions:
  - The statement references a single data source, and the UOW already includes one of the following:
    - A SELECT statement that references a nickname for a table or view within this data source
    - An open cursor on a nickname for a table or view within this data source
    - Either an INSERT, DELETE, or UPDATE statement issued against a nickname for a table or view within this data source
  - The statement references a category of data sources (for example, all data sources of a specific type and version), and the UOW already includes one of the following:
    - A SELECT statement that references a nickname for a table or view within one of these data sources
    - An open cursor on a nickname for a table or view within one of these data sources
    - Either an INSERT, DELETE, or UPDATE statement issued against a nickname for a table or view within one of these data sources
- If the server option is set to one value for a type of data source, and set to another value for an instance of this type, the second value overrides the first one for the instance. For example, assume that PLAN_HINTS is set to 'Y' for server type ORACLE, and to 'N' for an Oracle data source named DELPHI. This configuration causes plan hints to be enabled at all Oracle data sources except DELPHI.
- You can only alter set or alter drop server options for a category of data sources that was enabled by a prior alter add server option operation (SQLSTATE 42704).
- When altering the server version, no verification occurs to ensure that the specified server version matches the remote server version. Specifying an incorrect server version can result in SQL errors when you access nicknames that belong to the database server definition. This is most likely when you specify a server version that is later than the remote server version. In that case, when you access nicknames that belong to the server definition, the database server might send SQL that the remote server does not recognize.
- Server option HOST and NODE cannot be dropped at the same time (SQLSTATE 428EG).

- Both HOST and NODE keywords are included in the server option list, NODE is used even if NODE specified an unrecognized data source.
- PORT option is not mandatory. When PORT is dropped, ODBC wrapper uses default PORT number according to remote data source. The default PORT number is listed in CREATE SERVER.

Examples

- *Example 1:* Ensure that when authorization IDs are sent to your Oracle 8.0.3 data sources, the case of the IDs will remain unchanged. Also, assume that the local federated server CPU is twice as fast as the data source CPU. Inform the optimizer of this statistic.

```
   ALTER SERVER
     TYPE ORACLE
     VERSION 8.0.3
     OPTIONS
        (ADD FOLD_ID 'N',
        SET CPU_RATIO '2.0')
```

- *Example 2:* Indicate that the Documentum data source called DCTM_SVR_ASIA has been changed to Version 4.

```
   ALTER SERVER DCTM_SVR_ASIA
     VERSION 4
```

- *Example 3:* Drop the NODE option, add new HOST option. ODBC driver uses DSN-less mode instead of DSN connection to access a Hive server.

```
   ALTER SERVER HIVE
OPTIONS (add HOST ‘9.123.111.214’, DROP NODE)
```

ALTER SERVICE CLASS

The ALTER SERVICE CLASS statement alters the definition of a service class.

Invocation

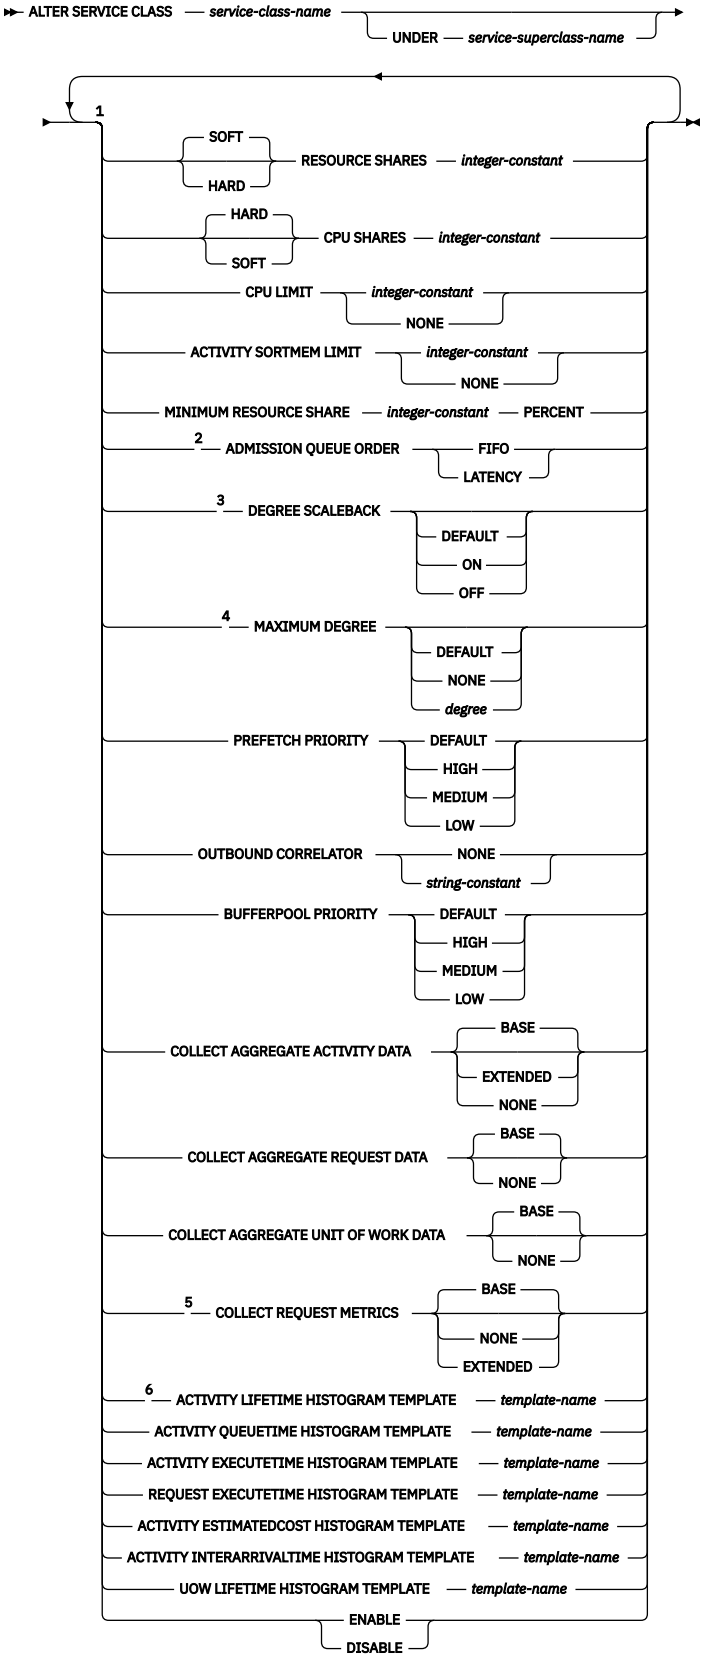
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

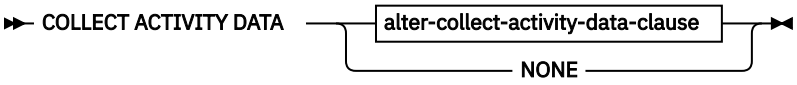
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- SQLADM authority, only if every alteration clause is a COLLECT clause
- WLMADM authority
- DBADM authority

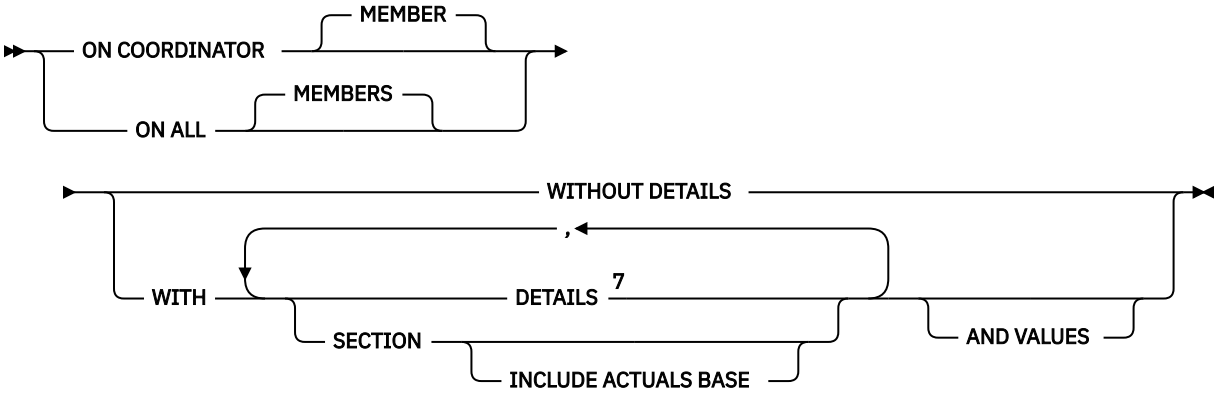
Syntax



collect-activity-data-clause



alter-collect-activity-data-clause



Notes:

[1] The same clause must not be specified more than once (SQLSTATE 42613).
[2] The ADMISSION QUEUE ORDER clause is valid only for a service subclass (SQLSTATE 5U043).
[3] The DEGREE SCALEBACK DEFAULT option is valid only for a service subclass (SQLSTATE 5U043).
[4] The MAXIMUM DEGREE DEFAULT option is valid only for a service subclass (SQLSTATE 5U043).
[5] The COLLECT REQUEST METRICS clause is valid only for a service superclass (SQLSTATE 05U44).
[6] The REQUEST EXECUTETIME AND UOW LIFETIME HISTOGRAM TEMPLATE clauses are valid only for a service subclass (SQLSTATE 05U43).
[7] The DETAILS keyword is the minimum to be specified, followed by the option separated by a comma.

Description

service-class-name
Identifies the service class that is to be altered. This is a one-part name. It is an SQL identifier (either ordinary or delimited).The *service-class-name* must identify a service class that exists in the database (SQLSTATE 42704). To alter a service subclass, the *service-superclass-name* must be specified using the UNDER clause.

UNDER *service-superclass-name*
This clause is used only for altering a service subclass. The *service-superclass-name* identifies the service superclass of the service subclass and must identify a service superclass that exists in the database (SQLSTATE 42704).

RESOURCE SHARES
Specifies the number of shares of resources to which this service class is entitled, and whether the service class is allowed to exceed this number when other service classes in the same scope are not using their full entitlements. This value affects the amount of work the workload manager (WLM) adaptive admission control allows into the system.

HARD
The service class is not allowed to exceed its resource share entitlement.

SOFT
The service class is allowed to exceed its resource share entitlement when other service classes are not using their full entitlements.

Valid values are integers 1 - 65535.

Note: To use resource shares with WLM, you must enable the **wlm_admission_ctrl** configuration parameter.

CPU SHARES
Specifies the number of CPU shares that the workload manager (WLM) dispatcher allocates to this service class when work is executing within this service class, and whether the service class is allowed to exceed this number when other service classes in the same scope are not using their full entitlement.

HARD
The service class is not allowed to exceed its CPU share entitlement.

SOFT
The service class is allowed to exceed its CPU share entitlement when other service classes are not using their full entitlements.

Valid values are integers 1 - 65535.

Note: To use CPU shares with WLM dispatcher, you must enable the **wlm_disp_cpu_shares** database manager configuration parameter.

CPU LIMIT
Specifies the maximum percentage of the CPU resources that the WLM dispatcher can assign to this service class. Valid values for the *integer-constant* are integers between 1 and 100. You can also specify CPU LIMIT NONE to indicate that there is no CPU limit.

ACTIVITY SORTMEM LIMIT

Specifies the maximum percentage of the configured shared sort memory (**SHEAPTHRES_SHR**) that individual queries executing in the service class are allowed to consume. Queries requiring more memory than the configured limit will have individual per-operator **SORTHEAP** values reduced at runtime. Memory requests that exceed the limit will be throttled. Valid values for the integer-constant are integers ranging between 10 and 100. You can also specify NONE to indicate there is no activity sort memory limit. The default is NONE.

The effective sort memory limit for a query will be the most restrictive of the limit defined at the subclass, superclass and database via the **ACT_SORTMEM_LIMIT** database configuration parameter. The sort memory limit applied to an activity is determined when the activity is first admitted for execution. The applied sort memory limit will not change if a query is remapped at runtime to a different service subclass.

The activity sort memory limit will only be enforced for queries that are managed by the adaptive workload manager. If the adaptive workload manager is disabled (**WLM_ADMISSION_CTRL** database config parameter is set to NO,) or a query bypasses the adaptive workload manager, no sort memory limit is applied to the query regardless of which service class it runs in.

Note: Setting an activity sort memory limit too low may result in reduced performance for queries.

MINIMUM RESOURCE SHARE *integer-constant* PERCENT
Specifies the percentage of entitled resources managed by WLM adaptive admission control that is held in reserve for the service class when other service classes exceed their admission resource entitlement. Valid values for the *integer-constant* are integers 0 - 100.

ADMISSION QUEUE ORDER
Specifies the queue order for activities queued by WLM adaptive admission control.

FIFO
Requests are queued in a first-in first-out order. This is the default.

LATENCY
The position of a request in the queue is based on its estimated execution time (that is, its latency) relative to the amount of time that has elapsed since it joined the queue.

DEGREE SCALEBACK
Specifies whether work running in this service class may have its degree scaled back. Queries set to DEGREE ANY may have their actual runtime degree scaled back by the database manager based on current CPU loads.

Scaling back the degree for service classes running simple queries may result in less contention and improved throughput. Disabling degree scale back for service classes with complex queries can

help ensure more consistent and predictable response times. A setting of DEFAULT means a service subclass inherits its DEGREE SCALEBACK setting from the parent superclass. The DEFAULT setting is only applicable to service subclasses. The default setting for a service superclass is ON. The default value for a service subclass is DEFAULT.

MAXIMUM DEGREE
Specifies the maximum runtime degree of parallelism for activities running in this service class. The MAXIMUM DEGREE DEFAULT option is only valid for a service subclass (SQLSTATE 5U043).

DEFAULT
This service subclass should inherit its maximum degree value from its parent superclass. This setting is only applicable to service subclass.

NONE
This service class does not specify a maximum runtime degree for assigned applications. The actual runtime degree is determined as the lower of the value of **max_querydegree** configuration parameter, the value set by SET RUNTIME DEGREE command, the SQL statement compilation degree and the MAXIMUM DEGREE value set on the Workload.

degree
Specifies the maximum degree of parallelism for this service class. Valid values are 1 to 32767. The actual runtime degree is determined as the lower of this degree, the value of **max_querydegree** configuration parameter, the value set by SET RUNTIME DEGREE command, the SQL statement compilation degree and the MAXIMUM DEGREE set on the Workload.

PREFETCH PRIORITY
This parameter controls the priority with which agents in the service class can submit their prefetch requests:

HIGH
Prefetch requests are submitted to the high priority queue.

MEDIUM
Prefetch requests are submitted to the medium low priority queue.

LOW
Prefetch requests are submitted to the low priority queue.

DEFAULT
The default value is DEFAULT, which is internally mapped to MEDIUM for service superclasses. If DEFAULT is specified for a service subclass, it inherits the PREFETCH PRIORITY of its parent superclass.

Other values are not valid (SQLSTATE 42615).

Prefetchers empty the priority queue in order from high to low. Agents in the service class submit their prefetch requests at the PREFETCH PRIORITY level when the next activity begins. If PREFETCH PRIORITY is altered after a prefetch request is submitted, the request priority does not change. PREFETCH PRIORITY cannot be altered for a default subclass (SQLSTATE 5U032).

OUTBOUND CORRELATOR
Specifies whether or not to associate threads from this service class to an external workload manager service class.

If OUTBOUND CORRELATOR is set to a *string-constant* for the service superclass and OUTBOUND CORRELATOR NONE is set for a service subclass, the service subclass inherits the OUTBOUND CORRELATOR of its parent.

OUTBOUND CORRELATOR NONE
For a service superclass, specifies that there is no external workload manager service class association with this service class, and for a service subclass, specifies that the external workload manager service class association is the same as its parent.

OUTBOUND CORRELATOR *string-constant*
Specifies the *string-constant* that is to be used as a correlator to associate threads from this service class to an external workload manager service class. The external workload manager must

be active (SQLSTATE 5U030). The external workload manager should be set up to recognize the value of the specified string constant.

BUFFERPOOL PRIORITY
This parameter controls the bufferpool priority (HIGH, MEDIUM, or LOW) of pages fetched by activities in this service class. If DEFAULT is specified for a service subclass, it inherits the BUFFERPOOL PRIORITY from its parent superclass. Other values are not valid (SQLSTATE 42615).

Pages fetched by activities in a service class with higher bufferpool priority are less likely to be swapped out than pages fetched by activities in a service class with lower bufferpool priority. BUFFERPOOL PRIORITY cannot be altered for a default subclass (SQLSTATE 5U032).

COLLECT ACTIVITY DATA
Specifies that information about each activity that executes in this service class is to be sent to any active activities event monitor when the activity completes.

alter-collect-activity-data-clause

ON COORDINATOR MEMBER
Specifies that activity data is to be collected only at the coordinator member of the activity.

ON ALL MEMBERS
Specifies that activity data is to be collected at all members where the activity is processed. On remote members, a record for the activity may be captured multiple times as the activity comes and goes on those members. If the AND VALUES clause is specified, activity input values will be collected only for the members of the coordinator.

WITHOUT DETAILS
Specifies that data about each activity that executes in the service class is to be sent to any active activities event monitor, when the activity completes execution. Details about statement, compilation environment, and section environment data are not sent.

WITH DETAILS
Specifies that statement and compilation environment data is to be sent to any active activities event monitor, for those activities that have them. Section environment data is not sent.

SECTION
Specifies that statement, compilation environment, section environment data, and section actuals are to be sent to any active activities event monitor for those activities that have them. DETAILS must be specified if SECTION is specified. Section actuals will be collected on any partition where the activity data is collected.

INCLUDE ACTUALS BASE
Specifies that section actuals should also be collected on any partition where the activity data is collected. For section actuals to be collected, either INCLUDE ACTUALS clause must be specified or the **section_actuals** database configuration parameter must be set.

The effective setting for the collection of section actuals is the combination of the INCLUDE ACTUALS clause (specified on the WORK ACTION, SERVICE CLASS, or WORKLOAD), the **section_actuals** database configuration parameter, and the <collectsectionactuals> setting specified on the WLM_SET_CONN_ENV routine. For example, if INCLUDE ACTUALS BASE is specified, yet the **section_actuals** database configuration parameter value is NONE and <collectsectionactuals> is set to NONE, then the effective setting for the collection of section actuals is BASE.

BASE specifies that the following actuals should be enabled and collected during the activity's execution:

- Basic operator cardinality counts
- Statistics for each object referenced (DML statements only)

AND VALUES
Specifies that input data values are to be sent to any active activities event monitor, for those activities that have them. This data does not include SQL statements that are compiled by using the REOPT ALWAYS bind option.

NONE
Specifies that activity data should not be collected for each activity that executes in this service class.

COLLECT AGGREGATE ACTIVITY DATA
Specifies that aggregate activity data should be captured for this service class and sent to the statistics event monitor, if one is active. This information is collected periodically on an interval that is specified by the **wlm_collect_int** database configuration parameter. The default is COLLECT AGGREGATE ACTIVITY DATA BASE.

BASE
Specifies that basic aggregate activity data should be captured for this service class and sent to the statistics event monitor, if one is active. Basic aggregate activity data includes:

- Estimated activity cost high watermark
- Rows returned high watermark
- Temporary table space usage high watermark

  Note: Only activities that have an SQLTEMPSPACE threshold applied to them participate in this high watermark.
- Activity life time histogram
- Activity queue time histogram
- Activity execution time histogram

EXTENDED
Specifies that all aggregate activity data should be captured for this service class and sent to the statistics event monitor, if one is active. This includes all basic aggregate activity data plus:

- Activity data manipulation language (DML) estimated cost histogram
- Activity DML inter-arrival time histogram

NONE
Specifies that no aggregate activity data should be captured for this service class.

COLLECT AGGREGATE REQUEST DATA
Specifies that aggregate request data should be captured for this service class and sent to the statistics event monitor, if one is active. This information is collected periodically on an interval specified by the **wlm_collect_int** database configuration parameter. The default is COLLECT AGGREGATE REQUEST DATA NONE. The COLLECT AGGREGATE REQUEST DATA clause is valid only for a service subclass.

BASE
Specifies that basic aggregate request data should be captured for this service class and sent to the statistics event monitor, if one is active.

NONE
Specifies that no aggregate request data should be captured for this service class.

COLLECT AGGREGATE UNIT OF WORK DATA
Specifies that aggregate unit of work data is to be captured for this service class and sent to the statistics event monitor, if one is active. This information is collected periodically on an interval that is specified by the **wlm_collect_int** database configuration parameter. The default, when COLLECT AGGREGATE UNIT OF WORK DATA is specified, is COLLECT AGGREGATE UNIT OF WORK DATA BASE.

BASE
Specifies that basic aggregate unit of work data is to be captured for this service class and sent to the statistics event monitor, if one is active. Basic aggregate unit of work data includes:

- Unit of work lifetime histogram

NONE
Specifies that no aggregate unit of work data is to be collected for this service class.

COLLECT REQUEST METRICS
Specifies that monitor metrics should be collected for any request submitted by a connection that is associated with the specified service superclass and sent to the statistics and unit of work event monitors, if active. The default is COLLECT REQUEST METRICS NONE. The COLLECT REQUEST METRICS clause is only valid for a service superclass (SQLSTATE 50U44).

Note: The effective request metrics collection setting is the combination of the attribute specified by the COLLECT REQUEST METRICS clause on the service superclass associated with the connection submitting the request, and the **mon_req_metrics** database configuration parameter. If either the service superclass attribute or the configuration parameter has a value other than NONE, metrics will be collected for the request.

BASE
Specifies that basic metrics will be collected for any request submitted by a connection associated with the service superclass.

EXTENDED
Specifies that basic metrics will be collected for any request submitted by a connection associated with the service superclass. In addition, specifies that the values for the following monitor elements should be determined with additional granularity:

- **total_section_time**
- **total_section_proc_time**
- **total_routine_user_code_time**
- **total_routine_user_code_proc_time**
- **total_routine_time**

NONE
Specifies that no metrics will be collected for any request submitted by a connection associated with the service superclass.

ACTIVITY LIFETIME HISTOGRAM TEMPLATE
Specifies the template that describes the histogram used to collect statistical data about the duration, in milliseconds, of database activities running in the service class during a specific interval. This time includes both time queued and time executing. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY QUEUETIME HISTOGRAM TEMPLATE
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities running in the service class are queued during a specific interval. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY EXECUTETIME HISTOGRAM TEMPLATE
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities running in the service class are executing during a specific interval. This time does not include the time spent queued. Activity execution time is collected in this histogram at the coordinator member only. The time does not include idle time. Idle time is the time between the execution of requests belonging to the same activity when no work is being done. An example of idle time is the time between the end of opening a cursor and the start of fetching from that cursor. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

REQUEST EXECUTETIME HISTOGRAM TEMPLATE
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database requests running in the service class are executing during a specific interval. This time does not include the time spent queued. Request execution time is collected in this histogram on each member where the request executes. This information is only

collected when the COLLECT AGGREGATE REQUEST DATA clause is specified with the BASE option. This clause is only valid for a service subclass.

ACTIVITY ESTIMATEDCOST HISTOGRAM TEMPLATE
Specifies the template that describes the histogram used to collect statistical data about the estimated cost, in timerons, of DML activities running in the service class. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option.

ACTIVITY INTERARRIVALTIME HISTOGRAM TEMPLATE
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, between the arrival of one DML activity and the arrival of the next DML activity. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option.

UOW LIFETIME HISTOGRAM TEMPLATE
Specifies the template that describes the histogram used to collect statistical data about the duration, in milliseconds, of units of work running in the service class during a specific interval. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE UNIT OF WORK DATA clause is specified with the BASE option.

ENABLE or DISABLE
Specifies whether or not connections and activities can be mapped to the service class.

ENABLE
Connections and activities can be mapped to the service class.

DISABLE
Connections and activities cannot be mapped to the service class. New connections or activities that are mapped to a disabled service class will be rejected (SQLSTATE 5U028). When a service superclass is disabled, its service subclasses are also disabled. When the service superclass is re-enabled, its service subclasses return to states that are defined in the system catalog. A default service class cannot be disabled (SQLSTATE 5U032).

Rules

- A workload management (WLM)-exclusive SQL statement must be followed by a COMMIT or a ROLLBACK statement (SQLSTATE 5U021). WLM-exclusive SQL statements are:
  - CREATE HISTOGRAM TEMPLATE, ALTER HISTOGRAM TEMPLATE, or DROP (histogram template)
  - CREATE SERVICE CLASS, ALTER SERVICE CLASS, or DROP (service class)
  - CREATE THRESHOLD, ALTER THRESHOLD, or DROP (threshold)
  - CREATE WORK ACTION SET, ALTER WORK ACTION SET, or DROP (work action set)
  - CREATE WORK CLASS SET, ALTER WORK CLASS SET, or DROP (work class set)
  - CREATE WORKLOAD, ALTER WORKLOAD, or DROP (workload)
  - GRANT (workload privileges) or REVOKE (workload privileges)
- A WLM-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.

Notes

- Only one uncommitted WLM-exclusive SQL statement at a time is allowed across all members. If an uncommitted WLM-exclusive SQL statement is executing, subsequent WLM-exclusive SQL statements will wait until the current WLM-exclusive SQL statement commits or rolls back.
- Changes are written to the system catalog, but do not take effect until after a COMMIT statement, even for the connection that issues the statement.
- After the ALTER SERVICE CLASS statement is committed, changes to PREFETCH PRIORITY, OUTBOUND CORRELATOR, and COLLECT take effect for the next new activity in the service class. Existing activities in the service class continue to complete their work using the old settings.

- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - o DATABASE PARTITION can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - o DATABASE PARTITIONS can be specified in place of MEMBERS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.

Examples

- *Example 1:* Alter the amount of CPU that can be consumed by work running in service superclass PETSALES to a maximum of 50%.

```
ALTER SERVICE CLASS PETSALES CPU LIMIT 50
```

- *Example 2:* Alter service superclass BARNSALES and add an outbound correlator 'osLowPriority'. Threads running in the service superclass and its service subclasses will have the outbound correlator 'osLowPriority' associated with them.

```
ALTER SERVICE CLASS BARNSALES OUTBOUND CORRELATOR 'osLowPriority'
```

ALTER STOGROUP

The ALTER STOGROUP statement is used to alter the definition of a storage group.

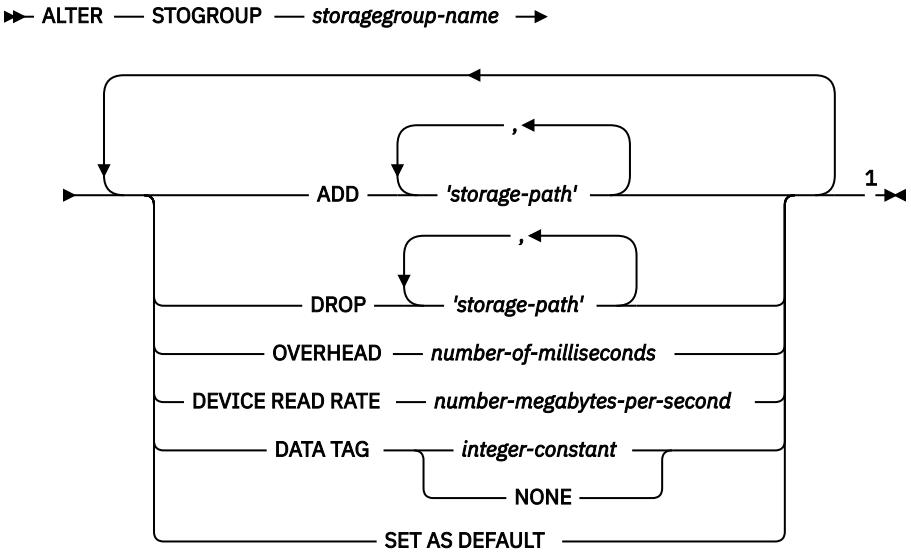
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SYSCTRL or SYSADM authority.

Syntax



Notes:

[1] Each clause can be specified only once.

Description

storagegroup-name
Identifies the storage group to be altered; *storagegroup-name* must identify a storage group that exists at the current server (SQLSTATE 42704). This is a one-part name.

ADD
Specifies that one or more new storage paths are to be added to the specified storage group.

storage-path
A string constant that specifies containers the location where automatic storage table spaces are to be created. The format of the string depends on the operating system, as illustrated in the following table:

Operating system	Format of storage path string
Linux AIX	An absolute path
Windows	The letter name of a drive

The string can include database partition expressions to specify database partition number information in the storage path. For predictable performance, ensure the storage paths added to a storage group have similar media characteristics.

The maximum length of a storage path is 175 characters (SQLSTATE 54036).

A storage path being added must be valid according to the naming rules for paths, and must be accessible (SQLSTATE 57019). Similarly, in a partitioned database environment, the storage path must exist and be accessible on every database partition (SQLSTATE 57019).

DROP
Specifies that one or more storage paths are to be removed from the given storage group. If table spaces are actively using a storage path being dropped, then the state of the storage path is changed from "In Use" to "Drop Pending" and future use of the storage path will be prevented.

The DROP *storage-path* clause is not supported in a Db2 pureScale environment (SQLSTATE 56038).

storage-path
A string constant that specifies the storage path from which storage groups are to be dropped. The format of the string depends on the operating system, as illustrated in the following table:

Operating system	Format of storage path string
Linux AIX	An absolute path
Windows	The letter name of a drive

The string can include database partition expressions to specify database partition number information in the storage path.

A storage path being dropped must currently exist in the storage group (SQLSTATE 57019) and cannot already be in the "Drop Pending" state (SQLSTATE 55073).

OVERHEAD *number-of-milliseconds*
Specifies the I/O controller usage and disk seek and latency time. This value is used to determine the cost of I/O during query optimization. The value of *number-of-milliseconds* is any numeric literal (integer, decimal, or floating point). If this value is not the same for all storage paths, set the value to a numeric literal which represents the average for all storage paths that belong to the storage group.

DEVICE READ RATE *number-megabytes-per-second*
Represents the device specification for the read transfer rate in megabytes per second. This value is used to determine the cost of I/O during query optimization. The value of *number-megabytes-per-second* is any numeric literal (integer, decimal, or floating point). If this value is not the same for all

storage paths, set the value to a numeric literal which represents the average for all storage paths that belong to the storage group.

DATA TAG *integer-constant* or DATA TAG NONE
Specifies a tag for the data in a given storage group. This value can be used as part of a WLM configuration in a work class definition or referenced within a threshold definition. For more information, see the CREATE WORK CLASS SET, ALTER WORK CLASS SET, CREATE THRESHOLD, and ALTER THRESHOLD statements.

integer-constant
Valid values for *integer-constant* are integers from 1 to 9.

NONE
If NONE is specified, there is no data tag.

SET AS DEFAULT
Specifies that the storage group being altered is designated as the default storage group. There can be only one storage group designated as the default storage group. There is no affect to the existing table spaces using that storage group. The designated default storage group is used by automatic storage table spaces when no storage group is specified at table space creation and a database managed table space is converted to automatic storage managed during redirected restore.

Rules

- A storage group must have at least one storage path. Dropping all storage paths from the storage group is not permitted (SQLSTATE 428HH).
- The ALTER STOGROUP statement cannot be executed while a database partition server is being added (SQLSTATE 55071).
- A storage group can have up to 128 defined storage paths (SQLSTATE 5U009).
- A transaction can have at most one ALTER STOGROUP statement per storage group. In the case of the default storage group, there can be at most one ALTER DATABASE statement or one ALTER STOGROUP statement on the default storage group (SQLSTATE 25502).

Notes

- ***Adding new storage paths:*** When adding new storage paths:
  - Existing REGULAR and LARGE table spaces using this storage group will not initially use these new paths. The database manager might choose to create new table space containers on these paths only if an out-of-space condition occurs. You can issue ALTER TABLESPACE REBALANCE statements for existing table spaces to stripe them over the newly added storage paths.
  - Existing temporary table spaces managed by automatic storage do not automatically use new storage paths. The database must be stopped normally then restarted for containers in these table spaces to use the new storage path or paths. As an alternative, the temporary table spaces can be dropped and re-created. When created, these table spaces automatically use all storage paths that have sufficient free space.
- ***Calculation of free space:*** When free space is calculated for a storage path on a database partition, the database manager checks for the existence of the following directories or mount points within the storage path, and will use the first one that is found.

```
<storage path>/<instance name>/NODE####/<database name>
<storage path>/<instance name>/NODE####
<storage path>/<instance name>
<storage path>
```

Where:

  - `<storage path>` is a storage path associated with the database.
  - `<instance name>` is the instance under which the database resides.
  - `NODE####` corresponds to the database partition number (for example, NODE0000 or NODE0001).

– <database name> is the name of the database.

- ***Isolating multiple database partitions under one storage path:*** File systems can be mounted at a point beneath the storage path, and the database manager will recognize that the actual amount of free space available for table space containers might not be the same amount that is associated with the storage path directory itself.

  Consider an example in which two logical database partitions exist on one physical computer, and there is a single storage path (/dbdata). Each database partition will use this storage path, but you might want to isolate the data from each partition within its own file system. In this case, a separate file system can be created for each partition and it can be mounted at /dbdata/<instance>/NODE####. When creating containers on the storage path and determining free space, the database manager will not retrieve free space information for /dbdata, but instead will retrieve it for the corresponding /dbdata/<instance>/NODE#### directory.
- ***Dropping a storage path that is in use by one or more table spaces:*** When dropping a storage path that is in use by one or more table spaces, the state of the path changes from "In Use" to "Drop Pending". Future growth on the path will not occur.

  Before the path can be fully removed from the storage group, each affected table space must be rebalanced (using the REBALANCE clause of the ALTER TABLESPACE statement) so that its container data is moved off the storage path. Rebalance is supported only for REGULAR and LARGE table spaces. Drop and re-create temporary table spaces to have their containers removed from the dropped path. When the path is no longer in use by any table space, it will be physically removed from the database.

  For a partitioned database environment, the path is maintained independently on each partition. When a path is no longer in use on a given database partition, it will be physically removed from that partition. Other partitions might still show the path as being in the "Drop Pending" state. The list of automatic storage table spaces using drop pending storage paths can be determined by issuing the following SQL statement:

```
SELECT DISTINCT TBSP_NAME, TBSP_ID, TBSP_CONTENT_TYPE
  FROM TABLE(MON_GET_TABLESPACE(NULL,-2)) AS T
  WHERE TBSP_PATHS_DROPPED = 1
```

- ***Dropping a storage path that was added to a storage group multiple times:*** It is possible for a given storage path to be added to a storage group multiple times. When using the DROP clause, specifying that particular path once will drop all instances of the path from the storage group.

Examples

1. Add drives D and E to the storage group named COMPLIANCE.

```
ALTER STOGROUP COMPLIANCE ADD 'D:\', 'E:\'
```

2. Add storage paths to the storage group named COMPLIANCE.

```
ALTER STOGROUP COMPLIANCE ADD '/db/filesystem3', '/db/filesystem4'
```

3. Change the data tag for the OPERATIONAL storage group and designate it as the default storage group.

```
ALTER STOGROUP OPERATIONAL DATA TAG 3 SET AS DEFAULT
```

4. Add a storage path that uses a database partition expression to differentiate the storage paths on each of the database partitions.

```
ALTER STOGROUP TESTDATA ADD '/dataForPartition $N'
```

5. Remove paths /db/filesystem1 and /db/filesystem2 from storage group TESTDATA.

```
ALTER STOGROUP TESTDATA DROP '/db/filesystem1', '/db/filesystem2'
```

ALTER TABLE

The ALTER TABLE statement alters the definition of a table.

Invocation

This statement can be embedded in an application program or issued by using dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges that are held by the authorization ID of the statement must include at least one of the following authorities:

- ALTER privilege on the table to be altered
- CONTROL privilege on the table to be altered
- ALTERIN privilege on the schema of the table
- SCHEMAADM authority on the schema of the table
- DBADM authority

To create or drop a foreign key, the privileges that are held by the authorization ID of the statement must include one of the following authorities on the parent table:

- REFERENCES privilege on the table
- REFERENCES privilege on each column of the specified parent key
- CONTROL privilege on the table
- SCHEMAADM authority on the schema of the table
- DBADM authority

To drop the primary key or a unique constraint on table T, the privileges of the authorization ID of the statement must include at least one of the following authorities on every table that is a dependent of T's parent key:

- ALTER privilege on the table
- CONTROL privilege on the table
- ALTERIN privilege on the schema of the table
- SCHEMAADM authority on the schema of the table
- DBADM authority

To alter a table to become a materialized query table (by using a fullselect), the privileges that are held by the authorization ID of the statement must include at least one of the following authorities:

- CONTROL privilege on the table
- SCHEMAADM authority on the schema of the table
- DBADM authority

and at least one of the following authorities on each table or view that is identified in the fullselect (excluding group privileges):

- All of the following:
  - SELECT privilege on the table or view or SELECTIN privilege on the schema of the table or view
  - ALTER privilege on the table or view or ALTERIN privilege (including group privileges) on the schema of the table or view
- CONTROL privilege on the table or view
- DATAACCESS on the schema of the table or view

- DATAACCESS authority on the database

To alter a table so that it is no longer a materialized query table, the privileges of the authorization ID of the statement must include at least one of the following authorities on each table or view that is identified in the fullselect that is used to define the materialized query table:

- ALTER privilege on the table or view
- CONTROL privilege on the table or view
- ALTERIN privilege on the schema of the table or view
- SCHEMAADM authority on the schema of the table
- DBADM authority

To add a column of type DB2SECURITYLABEL to a table, the privileges of the authorization ID of the statement must include at least a security label from the security policy that is associated with the table.

To remove the security policy from a table, the privileges that are held by the authorization ID of the statement must include SECADM authority.

To alter a table to attach a data partition, the privileges of the authorization ID of the statement must also include at least one of the following authorities on the source table:

- SELECT privilege on the table or SELECTIN privilege on the schema containing the source table and DROPIN privilege on the schema of the table
- CONTROL privilege on the table
- DATAACCESS authority on the schema of the table
- DATAACCESS authority on the database

and at least one of the following authorities on the target table:

- All of the following:
  - ALTER privilege on the table or ALTERIN privilege on the schema of the table
  - INSERT privilege on the table or INSERTIN privilege on the schema of the table
- CONTROL privilege on the table
- DATAACCESS authority on the schema of the table
- DATAACCESS authority on the database

To alter a table to detach a data partition, the privileges of the authorization ID of the statement must also include at least one of the following authorities on the target table of the detached partition:

- CREATETAB authority on the database, and USE privilege on the table spaces used by the table, and one of:
  - IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the new table does not exist
  - CREATEIN privilege on the schema, if the schema name of the new table refers to an existing schema
  - SCHEMAADM authority on the schema of the table and USE privilege on the table spaces that are used by the table
- DBADM authority

and at least one of the following authorities on the source table:

- All of the following:
  - SELECT privilege on the table or SELECTIN privilege on the schema of the table
  - ALTER privilege on the table or ALTERIN privilege on the schema of the table
  - DELETE privilege on the table or DELETEIN privilege on the schema of the table
- CONTROL privilege on the table
- DATAACCESS authority on the schema of the table

- DATAACCESS authority on the database

To alter a table to activate not logged initially with empty table, the privileges that are held by the authorization ID of the statement must include at least one of the following authorities:

- All of the following:
  - ALTER privilege on the table or ALTERIN privilege on the schema of the table
  - DELETE privilege on the table or DELETEIN privilege on the schema of the table
- CONTROL privilege on the table
- SCHEMAADM authority on the schema of the table
- DBADM authority

To alter a table that is protected by a security policy to activate not logged initially with empty table, the privileges that are held by the authorization ID of the statement must include at least one of the following authorities:

- CONTROL privilege on the table
- SCHEMAADM authority on the schema of the table
- DBADM authority

To alter a table to ACTIVATE and DEACTIVATE row and column access control, the privileges that are held by the authorization ID of the statement must include the SECADM authority.

To alter a table with ACTIVATE NOT LOGGED INITIALLY WITH EMPTY TABLE, if that table activated row access control, the privileges that are held by the authorization ID of the statement must include at least one of the following authorities:

- CONTROL privilege on the table
- SCHEMAADM authority on the schema of the table
- DBADM authority

When altering system period temporal tables, one of the following authorities is required by the authorization ID of the statement:

- ALTER privilege on the history table
- CONTROL privilege on the history table
- ALTERIN privilege on the schema of the history table
- SCHEMAADM authority on the schema of the history table
- DBADM authority

This condition applies when altering a table to become a system-period temporal table (with the ADD VERSIONING clause). It also applies when altering a system-period temporal table where one or more changes result in changes to the associated history table.

Notes:

[1] The same clause must not be specified more than once (SQLSTATE 42614).
[2] If an ACTIVATE or DEACTIVATE clause is specified for row access control, no other clause except ACTIVATE or DEACTIVATE column access control can be specified in the same ALTER TABLE statement (SQLSTATE 42613).
[3] If an ACTIVATE or DEACTIVATE clause is specified for column access control, no other clause except ACTIVATE or DEACTIVATE row access control can be specified in the same ALTER TABLE statement (SQLSTATE 42613).
[4] If the first column option chosen is *generated-clause*, *data-type* can be omitted; it is computed by the generation expression.
[5] The *lob-options* clause applies to large object types (CLOB, DBCLOB, and BLOB), and to distinct types that are based on large object types only.
[6] The SCOPE clause applies to the REF type only.
[7] The default-clause and generated-clause cannot both be specified for the same column definition (SQLSTATE 42614).
[8] Data type is optional for a row change timestamp column if the first column-option specified is a generated-clause. The data type default is TIMESTAMP(6). Data type is optional for row-begin, row-end, and transaction-start-ID columns if the first column-option is a generated-clause; the data type default is TIMESTAMP(12).
[9] The same clause must not be specified more than once.
[10] The specified distinct type cannot have any data type constraints and the source type cannot be an anchored data type (SQLSTATE 428H2).
[11] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

Description

table-name
The *table-name* must identify a table that exists at the current server. It cannot be a nickname (SQLSTATE 42809) and must not be a view, a catalog table, a created temporary table, or a declared temporary table (SQLSTATE 42995).

If *table-name* identifies a materialized query table, alterations are limited to adding or dropping the materialized query, starting the ACTIVATING NOT LOGGED INITIALLY clause, adding or dropping RESTRICT ON DROP, modifying data capture, pctfree, locksize, append, volatile, data row compression, value compression, and activating or deactivating row and column access control.

If *table-name* identifies a shadow table, alterations can include adding or dropping primary keys in addition to the alterations that are supported for a materialized query table.

If *table-name* identifies a range-clustered table, alterations are limited to adding, changing, or dropping constraints, activating not logged initially, adding or dropping RESTRICT ON DROP, changing locksize, data capture, or volatile, and setting column default values.

ADD *column-definition*
Adds a column to the table.

A column cannot be added to the following tables:

- A history table for a system-period temporal table (SQLSTATE 428HZ)
- A typed table (SQLSTATE 428DH)
- A table whose compression dictionary is being created in an asynchronous background operation (SQL20054N)

For all existing rows in the table, the value of the new column is set to its default value. The new column is the last column of the table; that is, if initially *n* columns exist, the added column is column *n*+1.

Adding the new column must not cause the total byte count of all columns to exceed the maximum record size.

If the table is a column-organized table, a LOB column can not be added to an existing table.

Note: This restriction has been removed starting from Db2version 11.5.1

If the table is a system-period temporal table, the column is added to the associated history table as well.

If the added column is a generated column that is based on an expression, the expression must not reference a column for which a column mask is defined (SQLSTATE 42621).

If a column is added to a table on which a mask or a permission is defined, or to a table that is referenced in the definition of a mask or a permission, that mask or permission is invalidated. Access to a table that activates column access control and a defined invalid mask on it is blocked until the invalid mask is either disabled, dropped, or re-created (SQLSTATE 560D0). Access to a table that activates row access control and a defined invalid row permission on it is blocked until the invalid permission is either disabled, dropped, or re-created (SQLSTATE 560D0).

column-name
Is the name of the column to be added to the table. The name cannot be qualified. Existing column names or period names in the table cannot be used (SQLSTATE 42711).

data-type
Is one of the data types that are listed under "CREATE TABLE".

NOT NULL
Prevents the column from containing null values. The *default-clause* must also be specified (SQLSTATE 42601).

lob-options
Specifies options for LOB data types. See *lob-options* in "CREATE TABLE".

SCOPE
Specify a scope for a reference type column.

typed-table-name2
The name of a typed table. The data type of *column-name* must be REF(*S*), where *S* is the type of *typed-table-name2* (SQLSTATE 428DM). No checking is done of the default value for *column-name* to ensure that the value references an existing row in *typed-table-name2*.

typed-view-name2
The name of a typed view. The data type of *column-name* must be REF(*S*), where *S* is the type of *typed-view-name2* (SQLSTATE 428DM). No checking is done of the default value for *column-name* to ensure that the values reference an existing row in *typed-view-name2*.

CONSTRAINT *constraint-name*
Names the constraint. A *constraint-name* must not identify a constraint that was already specified within the same ALTER TABLE statement, or as the name of any other existing constraint on the table (SQLSTATE 42710).

If the constraint name is not specified by the user, an 18-byte long identifier unique within the identifiers of the existing constraints that are defined on the table is generated by the system. (The identifier consists of "SQL" followed by a sequence of 15 numeric characters that are generated by a timestamp-based function).

When used with a PRIMARY KEY or UNIQUE constraint:

- the *constraint-name* might be used as the name of an index that is created to support the constraint. See Notes for details on index names that are associated with unique constraints.
- you can use an existing index that is defined with RANDOM columns for the key index if applicable. If there is more than one index that can satisfy the primary or unique requirement,

then the index that is chosen cannot be predicted. An existing primary or unique key index cannot be altered to be an index with random ordering. If a primary or unique key index with random ordering is required, a suitable index must first be defined with the RANDOM keyword. Then, the table must be altered to add the primary or unique key.

PRIMARY KEY
Provides a shorthand method of defining a primary key that is composed of a single column. Thus, if PRIMARY KEY is specified in the definition of column C, the effect is the same as if the PRIMARY KEY(C) clause were specified as a separate clause. The column cannot contain null values, so the NOT NULL attribute must also be specified (SQLSTATE 42831).

See PRIMARY KEY within the *unique-constraint* description.

UNIQUE
Provides a shorthand method of defining a unique key that is composed of a single column. Thus, if UNIQUE is specified in the definition of column C, the effect is the same as if the UNIQUE(C) clause were specified as a separate clause.

See UNIQUE within the *unique-constraint* description.

references-clause
Provides a shorthand method of defining a foreign key that is composed of a single column. Thus, if a references-clause is specified in the definition of column C, the effect is the same as if that references-clause were specified as part of a FOREIGN KEY clause in which C is the only identified column.

See *references-clause* in "CREATE TABLE".

rule-clause
See *rule-clause* in "CREATE TABLE".

CHECK (*check-condition*)
Provides a shorthand method of defining a check constraint that applies to a single column. See *check-condition* in "CREATE TABLE".

constraint-attributes
See *constraint-attributes* in "CREATE TABLE".

default-clause
Specifies a default value for the column.

WITH
An optional keyword.

DEFAULT
Provides a default value when a value is not supplied on INSERT or is specified as DEFAULT on INSERT or UPDATE. If a specific default value is not specified following the DEFAULT keyword, the default value depends on the data type of the column as shown in Table 126 on page 835. If a column is defined as an XML or structured type, then a DEFAULT clause cannot be specified.

If a column is defined that uses a distinct type, then the default value of the column is the default value of the source data type cast to the distinct type.

Table 126. Default Values (when no value specified)

Data Type	Default Value
Numeric	0
Fixed-length character string	A string of blanks
Varying-length character string	A string of length 0
Fixed-length graphic string	A string of double-byte blanks
Varying-length graphic string	A string of length 0

Table 126. Default Values (when no value specified) (continued)

Data Type	Default Value
Fixed-length binary string	A string of hexadecimal zeros
Varying-length binary string	A string of length 0
Date	For existing rows, a date corresponding to January 1, 0001. For added rows, the current date.
Time	For existing rows, a time corresponding to 0 hours, 0 minutes, and 0 seconds. For added rows, the current time.
Timestamp	For existing rows, a date corresponding to 01 January 0001, and a time corresponding to 0 hours, 0 minutes, 0 seconds, and 0 microseconds. For added rows, the current time stamp.
Binary string (blob)	A string of length 0
Boolean	FALSE

Omission of DEFAULT from a *column-definition* results in the use of the null value as the default for the column.

Specific types of values that can be specified with the DEFAULT keyword are as follows.

constant
Specifies the constant as the default value for the column. The specified constant must:

- Represent a value that might be assigned to the column in accordance with the rules of assignment as described in Chapter 3
- Not be a floating-point constant unless the column is defined with a floating-point data type
- Be a numeric constant or a decimal floating-point special value if the data type of the column is decimal floating-point. Floating-point constants are first interpreted as DOUBLE and then converted to decimal floating-point. For DECFLOAT(16) columns, decimal constants must have a precision value less than or equal to 16.
- Not have nonzero digits beyond the scale of the column data type if the constant is a decimal constant (for example, 1.234 cannot be the default for a DECIMAL(5,2) column)
- The constant must be expressed with no more than 254 bytes including the quotation characters, any introducer character such as the X for a hexadecimal constant, and characters from the fully qualified function name and parentheses when the constant is the argument of a *cast-function*.

datetime-special-register
Specifies the value of the datetime special register (CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP) at the time of INSERT, UPDATE, or LOAD as the default for the column. The data type of the column must be the data type that corresponds to the special register specified (for example, data type must be DATE when CURRENT DATE is specified). For existing rows, the value is the current date, current time, or current time stamp when the ALTER TABLE statement is processed.

user-special-register
Specifies the value of the user special register (CURRENT USER, SESSION_USER, SYSTEM_USER) at the time of INSERT, UPDATE, or LOAD as the default for the column. The data type of the column must be a character string with a length not less than the length attribute of a user special register. USER can be specified in place of SESSION_USER and

CURRENT_USER can be specified in place of CURRENT USER. For existing rows, the value is the CURRENT USER, SESSION_USER, or SYSTEM_USER of the ALTER TABLE statement.

CURRENT SCHEMA
Specifies the value of the CURRENT SCHEMA special register at the time of INSERT, UPDATE, or LOAD as the default for the column. If CURRENT SCHEMA is specified, the data type of the column must be a character string with a length greater than or equal to the length attribute of the CURRENT SCHEMA special register. For existing rows, the value of the CURRENT SCHEMA special register at the time the ALTER TABLE statement is processed.

CURRENT MEMBER
Specifies the value of the CURRENT MEMBER special register at the time of INSERT, UPDATE, or LOAD as the default for the column. If CURRENT MEMBER is specified, the data type of the column must allow assignment from an integer. For existing rows, the value of the CURRENT MEMBER special register at the time the ALTER TABLE statement is processed.

NULL
Specifies NULL as the default for the column. If NOT NULL was specified, DEFAULT NULL must not be specified within the same column definition.

cast-function
This form of a default value can be used with columns defined as a distinct type, BLOB, or datetime (DATE, TIME, or TIMESTAMP) data type. For distinct type only, except for distinct types based on BLOB or datetime types, the name of the function must match the name of the distinct type for the column. If qualified with a schema name, it must be the same as the schema name for the distinct type. If not qualified, the schema name from function resolution must be the same as the schema name for the distinct type. For a distinct type based on a datetime type, where the default value is a constant, a function must be used and the name of the function must match the name of the source type of the distinct type with an implicit or explicit schema name of SYSIBM. For other datetime columns, the corresponding datetime function can also be used. For a BLOB or a distinct type based on BLOB, a function must be used and the name of the function must be BLOB with an implicit or explicit schema name of SYSIBM.

constant
Specifies one constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type or for the data type if not a distinct type. If the *cast-function* is BLOB, the constant must be a string constant.

datetime-special-register
Specifies CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP. The source type of the distinct type of the column must be the data type that corresponds to the specified special register.

user-special-register
Specifies CURRENT USER, SESSION_USER, or SYSTEM_USER. The data type of the source type of the distinct type of the column must be a string data type with a length of at least 8 bytes. If the *cast-function* is BLOB, the length attribute must be at least 8 bytes.

CURRENT SCHEMA
Specifies the value of the CURRENT SCHEMA special register. The data type of the source type of the distinct type of the column must be a character string with a length greater than or equal to the length attribute of the CURRENT SCHEMA special register. If the *cast-function* is BLOB, the length attribute must be at least 8 bytes.

EMPTY_CLOB(), EMPTY_DBCLOB(), or EMPTY_BLOB()
Specifies a zero-length string as the default for the column. The column must have the data type that corresponds to the result data type of the function.

If the value specified is not valid, an error (SQLSTATE 42894) is returned.

generated-clause

Specifies a generated value for the column. This clause must not be specified with *default-clause* in a column definition (SQLSTATE 42623). A generated column cannot be added to a system-period temporal table (SQLSTATE 428HZ). For details on column generation, see "CREATE TABLE".

GENERATED

Specifies that the database manager generates values for the column. GENERATED must be specified whether the column is to be considered an identity column, row change timestamp column, row-begin column, row-end column, transaction start-ID column, or generated expression column.

If the column is nullable, the null value is assigned as the value for the column in existing rows. Otherwise, the value for the column in existing rows depends on the definition of the column:

- ROW CHANGE TIMESTAMP uses a date that corresponds to January 1, 0001 and a time that corresponds to 0 hours, 0 minutes, 0 seconds, and 0 fractional seconds
- ROW BEGIN uses a date that corresponds to January 1, 0001 and a time that corresponds to 0 hours, 0 minutes, 0 seconds, and 0 fractional seconds
- ROW END uses a date that corresponds to December 30, 9999, and a time that corresponds to 0 hours, 0 minutes, 0 seconds, and 0 fractional seconds
- TRANSACTION START ID uses a date that corresponds to January 1, 0001, and a time that corresponds to 0 hours, 0 minutes, 0 seconds, and 0 fractional seconds
- Expressions use the value that is derived from the expression

ALWAYS

Specifies that the database manager always generates a value for the column when a row is inserted or updated and a value must be generated. The result of the expression is stored in the table. GENERATED ALWAYS is the recommended option unless data propagation or unload and reload operations are running. GENERATED ALWAYS is the default for generated columns.

BY DEFAULT

Specifies that the database manager generates a value for the column when a row is inserted into the table, or updated, specifying DEFAULT for the column, unless an explicit value is specified. BY DEFAULT can be specified with *as-row-change-timestamp-clause* only. BY DEFAULT is the recommended option when you use data propagation or running unload and reload operations.

FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP

Specifies that the column is a timestamp column with values that are generated by the database manager. A value is generated for the column in each row that is inserted, and for any row in which any column is updated. The value that is generated for a ROW CHANGE TIMESTAMP column is a timestamp that corresponds to the insert or update time for that row. If multiple rows are inserted or updated with a single statement, the value of the ROW CHANGE TIMESTAMP column might be different for each row.

A table can have one ROW CHANGE TIMESTAMP column (SQLSTATE 428C1) only. If *data-type* is specified, it must be TIMESTAMP or TIMESTAMP(6) (SQLSTATE 42842). A ROW CHANGE TIMESTAMP column cannot have a DEFAULT clause (SQLSTATE 42623). NOT NULL must be specified for a ROW CHANGE TIMESTAMP column (SQLSTATE 42831).

AS (*generation-expression*)

Specifies that the definition of the column is based on an expression. Requires the table to be placed in set integrity pending no access state, by using the SET INTEGRITY statement with the OFF NO ACCESS option. After the ALTER TABLE statement, the SET INTEGRITY statement with the IMMEDIATE CHECKED and FORCE GENERATED options must be used to update and check all the values in that column against the new expression. For details on specifying a column with a *generation-expression*, see "CREATE TABLE".

AS ROW BEGIN

Specifies that the value is assigned by the database manager whenever a row is inserted into the table or any column in the row is updated. The value is generated by using a reading of the time-of-day clock during execution of the first of the following events in the transaction:

- A data change statement that requires a value to be assigned to the row-begin or transaction start-ID column in a table
- A deletion of a row in a system-period temporal table

For a system-period temporal table, the database manager ensures uniqueness of the generated values for a row-begin column across transactions. The timestamp value might be adjusted to ensure that rows that are inserted into an associated history table have the end timestamp value greater than the begin timestamp value (SQLSTATE 01695). This can happen when a conflicting transaction is updating the same row in the system-period temporal table. The database configuration parameter **systime_period_adj** must be set to Yes for this adjustment to the timestamp value to occur otherwise an error is returned (SQLSTATE 57062). If multiple rows are inserted or updated within a single SQL transaction and an adjustment is not needed, the values for the row-begin column are the same for all the rows and are unique from the values that are generated for the column for another transaction. A row-begin column is required as the begin column of a SYSTEM_TIME period, which is the intended use for this type of generated column.

A table can have only one row-begin column (SQLSTATE 428C1). If *data-type* is not specified, the column is defined as a TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12) (SQLSTATE 42842). The column must be defined as NOT NULL (SQLSTATE 42831). A row-begin column cannot be updated.

AS ROW END

Specifies that a value for the data type of the column is assigned by the database manager whenever a row is inserted or any column in the row is updated. The assigned value is TIMESTAMP '9999-12-30-00.00.00.000000000000'.

A row-end column is required as the second column of a SYSTEM_TIME period, which is the intended use for this type of generated column.

A table can have only one row-end column (SQLSTATE 428C1). If *data-type* is not specified, the column is defined as TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12) (SQLSTATE 42842). The column must be defined as NOT NULL (SQLSTATE 42831). A row-end column cannot be updated.

AS TRANSACTION START ID

Specifies that the value is assigned by the database manager whenever a row is inserted into the table or any column in the row is updated. The database manager assigns a unique timestamp value per transaction or the null value. The null value is assigned to the transaction start-ID column if the column is nullable and if a row-begin column in the table for which the value did not need to be adjusted exists. Otherwise, the value is generated by using a reading of the time-of-day clock during execution of the first of the following events in the transaction:

- A data change statement that requires a value to be assigned to the row-begin or transaction start-ID column in a table
- A deletion of a row in a system-period temporal table

If multiple rows are inserted or updated within a single SQL transaction, the values for the transaction start-ID column are the same for all the rows and are unique from the values that are generated for the column for another transaction.

A transaction start-ID column is required for a system-period temporal table, which is the intended use for this type of generated column.

A table can have only one transaction start-ID column (SQLSTATE 428C1). If *data-type* is not specified, the column is defined as TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12). A transaction start-ID column cannot be updated.

COMPRESS SYSTEM DEFAULT
Specifies that system default values (that is, the default values used for the data types when no specific values are specified) are to be stored in minimal space. If the VALUE COMPRESSION clause is not specified, a warning is returned (SQLSTATE 01648) and system default values are not stored in minimal space.

Allowing system default values to be stored in this manner causes a slight performance penalty during insert and update operations on the column because of extra checking that is done.

The base data type must not be a DATE, TIME, TIMESTAMP, XML, or structured data type (SQLSTATE 42842). If the base data type is a varying-length string, this clause is ignored. String values of length 0 are automatically compressed if a table is set with VALUE COMPRESSION.

COLUMN SECURED WITH *security-label-name*
Identifies a security label that exists for the security policy that is associated with the table. The name must not be qualified (SQLSTATE 42601). The table must be associated with a security policy (SQLSTATE 55064). The table must not be a system-period temporal table.

NOT HIDDEN or IMPLICITLY HIDDEN
Specifies whether the column is to be defined as hidden. The hidden attribute determines whether the column is included in an implicit reference to the table, or whether it can be explicitly referenced in SQL statements. The default is NOT HIDDEN.

NOT HIDDEN
Specifies that the column is included in implicit references to the table, and that the column can be explicitly referenced.

IMPLICITLY HIDDEN
Specifies that the column is not visible in SQL statements unless the column is explicitly referenced by name. For example, assuming that a table includes a column that is defined with the IMPLICITLY HIDDEN clause, the result of a SELECT * does not include the implicitly hidden column. However, the result of a SELECT that explicitly refers to the name of an implicitly hidden column includes that column in the result table.

ADD *unique-constraint*
Defines a unique or primary key constraint. A primary key or unique constraint cannot be added to a table that is a subtable (SQLSTATE 429B3). If the table is a supertable at the top of the hierarchy, the constraint applies to the table and all its subtables.

CONSTRAINT *constraint-name*
Names the primary key or unique constraint. For more information, see *constraint-name* in “CREATE TABLE ” on page 1351.

UNIQUE (*column-name*, ... BUSINESS_TIME WITHOUT OVERLAPS)
Defines a unique key that is composed of the identified columns and periods. The identified columns must be defined as NOT NULL. Each *column-name* must identify a column of the table and the same column must not be identified more than once. The name cannot be qualified. The number of identified columns plus two times the number of identified periods must not exceed 64, and the sum of their stored lengths must not exceed the index key length limit for the page size. For column stored lengths, see "Byte Counts" in "CREATE TABLE". For key length limits, see "SQL and XML limits". No LOB, distinct type based on any of these types, or structured type can be used as part of a unique key, even if the length attribute of the column is small enough to fit within the index key length limit for the page size (SQLSTATE 54008). The set of columns in the unique key cannot be the same as the set of columns of the primary key or another unique key (SQLSTATE 01543). If LANGLEVEL is SQL92E or MIA, an error is returned, SQLSTATE 42891. Any existing values in the set of identified columns must be unique (SQLSTATE 23515).

A check is run to determine whether an existing index matches the unique key definition (ignoring any INCLUDE columns in the index). An index definition matches if it identifies the same set of columns without regard to the order of the columns or the direction (ASC/DESC/RANDOM)

specifications. However, for partitioned tables, non-unique partitioned indexes whose columns are not a superset of the table-partitioning key columns are not considered matching indexes.

If a matching index definition is found, the description of the index is changed to indicate that it is required by the system and it is changed to unique after ensuring uniqueness if it was a non-unique index. If the table has more than one matching index, an existing unique index is selected. If multiple unique indexes exist, the selection is arbitrary with one exception:

- For partitioned tables, matching unique partitioned indexes are favored over matching unique nonpartitioned indexes or matching non-unique indexes (partitioned or nonpartitioned).

If no matching index is found, a unique bidirectional index is automatically created for the columns, as described in CREATE TABLE. See Notes for details on index names that are associated with unique constraints.

BUSINESS_TIME WITHOUT OVERLAPS
For a constraint, BUSINESS_TIME indicates the period name in this table. The period must exist in the table (SQLSTATE 42727).

BUSINESS_TIME WITHOUT OVERLAPS specifies that overlapping periods for BUSINESS_TIME are not allowed, and that values for the rest of the keys must be unique regarding any period of BUSINESS_TIME. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the end column and begin column of the period BUSINESS_TIME (in this order of the columns) is automatically added to the index key in ascending order and enforce that no overlaps in time exist. The columns that are used to defined BUSINESS_TIME must not be specified as part of the constraint (SQLSTATE 428HW).

When a partition is attached to a range partitioned application-period temporal table that has a partitioned BUSINESS_TIME WITHOUT OVERLAPS index, the source table must have an index that matches the partitioned BUSINESS_TIME WITHOUT OVERLAPS index. Additionally, the PERIODNAME and PERIODPOLICY attributes on the indexes must also match.

PRIMARY KEY (*column-name*, ... BUSINESS_TIME WITHOUT OVERLAPS)
Defines a primary key that is composed of the identified columns. Each *column-name* must identify a column of the table, and the same column must not be identified more than once. The name cannot be qualified. The number of identified columns must not exceed 64, and the sum of their stored lengths must not exceed the index key length limit for the page size. For column stored lengths, see "Byte Counts" in "CREATE TABLE". For key length limits, see "SQL limits". The table must not have a primary key and the identified columns must be defined as NOT NULL. No LOB, distinct type based on any of these types, or structured type can be used as part of a primary key, even if the length attribute of the column is small enough to fit within the index key length limit for the page size (SQLSTATE 54008). The set of columns in the primary key cannot be the same as the set of columns in a unique key (SQLSTATE 01543). (If LANGLEVEL is SQL92E or MIA, an error is returned, SQLSTATE 42891). Any existing values in the set of identified columns must be unique (SQLSTATE 23515). *column-name* must not be the name of a row change timestamp, or a begin or end column of the period (SQLSTATE 428HW).

A check runs to determine whether an existing index matches the primary key definition (ignoring any INCLUDE columns in the index). An index definition matches if it identifies the same set of columns without regard to the order of the columns or the direction (ASC/DESC/RANDOM) specifications. However, for partitioned tables, non-unique partitioned indexes whose columns are not a superset of the table-partitioning key columns are not considered matching indexes.

If a matching index definition is found, the description of the index is changed to indicate that it is the primary index, as required by the system, and it is changed to unique after uniqueness is ensured if it was a non-unique index. If the table has more than one matching index, an existing unique index is selected. If multiple unique indexes exist, the selection is arbitrary with one exception:

- For partitioned tables, matching unique partitioned indexes are favored over matching unique nonpartitioned indexes or matching non-unique indexes (partitioned or nonpartitioned).

If no matching index is found, a unique bidirectional index is automatically created for the columns, as described in CREATE TABLE. See Notes for details on index names that are associated with unique constraints.

If the primary key is being added to a shadow table, the columns of the primary key must match the columns of an enforced primary key constraint or an enforced unique constraint of the base table that is referenced in the *fullselect* of *materizalized-query-definition*.

A primary key cannot be created on a materialized query table that is not defined with MAINTAINED BY REPLICATION.

Only one primary key can be defined on a table.

BUSINESS_TIME WITHOUT OVERLAPS

For a constraint, BUSINESS_TIME indicates the period name in this table. The period must exist in the table (SQLSTATE 42727).

BUSINESS_TIME WITHOUT OVERLAPS specifies that overlapping periods for BUSINESS_TIME are not allowed, and that values for the rest of the keys must be unique regarding any period of BUSINESS_TIME. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the end column and begin column of the period BUSINESS_TIME (in this order of the columns) is automatically added to the index key in ascending order and enforce that no overlaps in time exist. The columns that are used to defined BUSINESS_TIME must not be specified as part of the constraint (SQLSTATE 428HW).

When a partition is attached to a range partitioned application-period temporal table that has a partitioned BUSINESS_TIME WITHOUT OVERLAPS index, the source table must have an index that matches the partitioned BUSINESS_TIME WITHOUT OVERLAPS index. Additionally, the PERIODNAME and PERIODPOLICY attributes on the indexes must also match.

constraint-attributes

See *constraint-attributes* in "CREATE TABLE".

ADD *referential-constraint*

Defines a referential constraint. See *referential-constraint* in "CREATE TABLE".

ADD *check-constraint*

Defines a check constraint or functional dependency. See *check-constraint* in "CREATE TABLE".

constraint-attributes

See *constraint-attributes* in "CREATE TABLE".

ADD *distribution-clause*

Defines a distribution key. The table must be defined in a table space on a single-partition database partition group (SQLSTATE 55037) and must not already have a distribution key (SQLSTATE 42889). If a distribution key exists for the table, the existing key must be dropped before you add the new distribution key. A distribution key cannot be added to a table that is a subtable (SQLSTATE 428DH) .

DISTRIBUTE BY HASH (*column-name*...)

Defines a distribution key by using the specified columns. Each *column-name* must identify a column of the table, and the same column must not be identified more than once. The name cannot be qualified. A column cannot be used as part of a distribution key if the data type of the column is a BLOB, CLOB, DBCLOB, XML, distinct type on any of these types, or structured type.

ADD RESTRICT ON DROP

Specifies that the table cannot be dropped, and that the table space that contains the table cannot be dropped.

ADD MATERIALIZED QUERY

materialized-query-definition

Changes a regular table to a materialized query table for use during query optimization. The table that is specified by *table-name* must not:

- Be previously defined as a materialized query table
- Be a typed table

- Have any constraints, unique indexes, or triggers defined
- Reference a nickname that is marked with caching disabled
- Be referenced in the definition of another materialized query table
- Be referenced in the definition of a view that is enabled for query optimization

If *table-name* does not meet these criteria, an error is returned (SQLSTATE 428EW).

If row level or column level access control is activated for any table that is directly or indirectly referenced in the *fullselect* of *materizalized-query-definition*, and row level access control is not activated for the altered table, row level access control is implicitly activated for the altered table. This restricts direct access to the contents of the materialized query table. A query that explicitly references the table before such a row permission is defined returns a warning that no data in the table exists (SQLSTATE 02000). To provide access to the materialized query table, an appropriate row permission can be created, or an **ALTER TABLE DEACTIVATE ROW ACCESS CONTROL** on the materialized query table can be entered to remove the row level protection if that is appropriate.

If the materialized query table references any table that has row level or column level access control that is activated, the functions that are referenced in the *fullselect* of *materizalized-query-definition* must be defined with the SECURED attribute (SQLSTATE 428EC).

If the table that is altered to a materialized query table has any permissions (excluding the system generated default permission) or masks defined on it, ALTER fails (SQLSTATE 428EW).

fullselect
Defines the query in which the table is based. The columns of the existing table must:

- have the same number of columns
- have the same data types
- have the same column names in the same ordinal positions

As the result columns of *fullselect* (SQLSTATE 428EW). For information about specifying the *fullselect* for a materialized query table, see "CREATE TABLE". One extra restriction is that *table-name* cannot be directly or indirectly referenced in the fullselect.

refreshable-table-options
Specifies the refreshable options for altering a materialized query table.

DATA INITIALLY DEFERRED
The data in the table must be validated by using the REFRESH TABLE or SET INTEGRITY statement.

REFRESH
Indicates how the data in the table is maintained.

DEFERRED
The data in the table can be refreshed at any time by using the REFRESH TABLE statement. The data in the table reflects the result of the query as a snapshot at the time the REFRESH TABLE statement is processed only. Materialized query tables that are defined with this attribute do not allow INSERT, UPDATE, or DELETE statements (SQLSTATE 42807).

IMMEDIATE
The changes that are made to the underlying tables as part of a DELETE, INSERT, or UPDATE are cascaded to the materialized query table. In this case, the content of the table, at any point-in-time, is the same as if the specified subselect is processed. Materialized query tables (MQTs) defined with this attribute do not allow INSERT, UPDATE, or DELETE statements (SQLSTATE 42807). Column-organized MQTs that use the REFRESH IMMEDIATE option are not supported when the MAINTAINED BY SYSTEM clause is specified (SQL20058N).

ENABLE QUERY OPTIMIZATION
The materialized query table can be used for query optimization.

DISABLE QUERY OPTIMIZATION
The materialized query table is not used for query optimization. The table can still be queried directly.

MAINTAINED BY
Specifies whether the data in the materialized query table is maintained by the system, user, or replication tool.

SYSTEM
Specifies that the data in the materialized query table is maintained by the system.

USER
Specifies that the data in the materialized query table is maintained by the user. The user is allowed to run update, delete, or insert operations against user-maintained materialized query tables. The REFRESH TABLE statement, which is used for system-maintained materialized query tables, cannot be started against user-maintained materialized query tables. Only a REFRESH DEFERRED materialized query table can be defined as MAINTAINED BY USER.

REPLICATION
Specifies that the data in the materialized query table is maintained by an external replication technology. The REFRESH TABLE statement, which is used for system-maintained materialized query tables, cannot be issued against replication-maintained materialized query tables, which are referred to as *shadow tables*. Only a REFRESH DEFERRED materialized query table can be defined as MAINTAINED BY REPLICATION, and the altered table must be a column-organized table.

FEDERATED_TOOL
Specifies that the data in the materialized query table is maintained by a federated replication tool. The REFRESH TABLE statement, which is used for system-maintained materialized query tables, cannot be started against federated_tool-maintained materialized query tables. Only a REFRESH DEFERRED materialized query table can be defined as MAINTAINED BY FEDERATED_TOOL.

ALTER FOREIGN KEY *constraint-name*
Alters the constraint attributes of the referential constraint *constraint-name*. The *constraint-name* must identify an existing referential constraint (SQLSTATE 42704).

ALTER CHECK *constraint-name*
Alters the constraint attributes of the check constraint or functional dependency *constraint-name*. The *constraint-name* must identify an existing check constraint or functional dependency (SQLSTATE 42704).

constraint-alteration
Options for changing attributes that are associated with referential or check constraints.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION
Specifies whether the constraint or functional dependency can be used for query optimization under appropriate circumstances.

ENABLE QUERY OPTIMIZATION
The constraint is assumed to be true and can be used for query optimization.

DISABLE QUERY OPTIMIZATION
The constraint cannot be used for query optimization.

ENFORCED or NOT ENFORCED
Specifies whether the constraint is enforced by the database manager during normal operations such as insert, update, or delete. A foreign key constraint cannot be altered from NOT ENFORCED to ENFORCED if the parent key is not enforced (SQLSTATE 42888).

ENFORCED
Change the constraint to ENFORCED. ENFORCED cannot be specified for a functional dependency (SQLSTATE 42621).

NOT ENFORCED
Change the constraint to NOT ENFORCED.

TRUSTED
The data can be trusted to conform to the constraint. TRUSTED must be used only if the data in the table is independently known to conform to the constraint. Query results might be unpredictable if the data does not conform to the constraint. This is the default option.

Informational constraints must not be violated at any time. Informational constraints are used in query optimization, and the incremental processing of REFRESH IMMEDIATE MQT and staging tables. These processes might produce unpredictable results or incorrect MQT and staging table content if the constraints are violated. For example, the order in which parent-child tables are maintained is important. When you want to add rows to a parent-child table, you must insert rows into the parent table first. To remove rows from a parent-child table, you must delete rows from the child table first. This ensures that no orphan rows in the child table exist at any time. If informational constraints are violated, the incremental maintenance of dependent MQT data and staging table data might be optimized based on the violated informational constraints, producing incorrect data.

NOT TRUSTED
The data cannot be trusted to conform to the constraint. NOT TRUSTED is intended for cases where the data conforms to the constraint for most rows, but it is not independently known that all the rows or future additions conform to the constraint. If a constraint is NOT TRUSTED and enabled for query optimization, then it is not used to run optimizations that depend on the data that conforms completely to the constraint. NOT TRUSTED can be specified only for foreign keys (SQLSTATE 42601).

ALTER *column-alteration*
Alters the definition of a column. Only the specified attributes are altered; others remain unchanged. Columns of a typed table cannot be altered (SQLSTATE 428DH). The table must not be defined as a history table (SQLSTATE 428FR). Columns that are used in expression-based index keys cannot be altered (SQLSTATE 42893), unless the operation involves the following column attributes:

- Identity (by using clauses under *identity-alteration*)
- Default compression (by using COMPRESS clause)
- Security (by using SECURED WITH or DROP COLUMN SECURITY clauses)

column-name
Specifies the name of the column that is to be altered. The *column-name* must identify an existing column of the table (SQLSTATE 42703). The name must not be qualified. The name must not identify a column that is otherwise being added, altered, or dropped in the same ALTER TABLE statement (SQLSTATE 42711).

SET DATA TYPE *altered-data-type*
Specifies the new data type of the column. The new data type must be castable from the existing data type of the column (SQLSTATE 42837) except when one of the data types is a distinct type, in which case the source data type of the distinct type is used in determining whether the data types are castable. A LOB column cannot be altered to a different data type (SQLSTATE 42837). A non-LOB column cannot be altered to a LOB data type (SQLSTATE 42837).

Altering a column to a character or graphic string data type that results in the truncation of non-blank characters from existing data is not allowed (SQLSTATE 42837). Similarly, altering a column to a binary string data type that results in truncation of bytes other than hexadecimal zeros is not allowed.

Data type alterations require a classic table reorganization before the table can be fully accessed (SQLSTATE 57007), except in the following situations:

- Increasing the length of a VARCHAR, VARGRAPHIC, or VARBINARY column
- Decreasing the length of a VARCHAR, VARGRAPHIC, or VARBINARY column without truncating trailing blanks from existing data, when no indexes exist on the column

The administrative routine SYSPROC.ADMIN_REVALIDATE_DB_OBJECTS can be called to do table reorganization. A data type alteration that requires a table reorganization cannot be specified if the table is in SET INTEGRITY PENDING state (SQLSTATE 57007).

A string data type cannot be altered if the column is a column of a table-partitioning key.

If the column is a column of a distribution key, then the new data type must meet the following requirements (SQLSTATE 42997):

- Be the same data type as the current column type
- Have the same length of the current column type, except when increasing column length of VARCHAR, VARGRAPHIC, and VARBINARY data type columns
- Cannot be modified to FOR BIT DATA or vice versa in the cases of CHAR and VARCHAR data types

If the data type is LOB, the specified length attribute cannot allow for the possibility of any truncated data (SQLSTATE 42837).

The data type of an identity column cannot be altered (SQLSTATE 42997).

The data type of a column that is defined as ROW BEGIN, ROW END, or TRANSACTION START ID cannot be altered (SQLSTATE 428FR).

The data type and nullability of BUSINESS_TIME period columns cannot be altered (SQLSTATE 428FR).

The table cannot have data capture enabled (SQLSTATE 42997).

The data type of a column cannot be altered if any of the following conditions are true (SQLSTATE 42893):

- The column is a generated expression column and the data of the generated expression column changes if the column is altered
- The column is referenced in an expression of a generated expression column and the data of the generated expression column changes if the column is altered
- The column is referenced in a check constraint and the check constraint is not satisfied if the column is altered
- The column is used in a referential integrity constraint and the referential integrity constraint is not satisfied if the column is altered

Altering a column must not cause the total byte count of all columns to exceed the maximum record size (SQLSTATE 54010). If the column is used in a unique constraint or an index, the new length must not cause the sum of the stored lengths for the unique constraint or index to exceed the index key length limit for the page size (SQLSTATE 54008). For column stored lengths, see "Byte Counts" in "CREATE TABLE". For key length limits, see "SQL and XML limits".

If **auto_reval** is set to DISABLED, the cascaded effects of altering a column is shown in Table 127 on page 846.

If either a row permission or a column mask depends on the column that is altered (as recorded in the SYSCAT.CONTROLDEP catalog view), an error is returned (SQLSTATE 42917).

Table 127. Cascaded effects of altering a column

Operation	Effect
Altering a column that is referenced by a view or check constraint	The object is regenerated during alter processing. If a view, function or method resolution for the object is different after the alter operation, changes the semantics of the object. In the case of a check constraint, if the semantics of the object change as a result of the alter operation, the operation fails.

Table 127. Cascaded effects of altering a column (continued)

Operation	Effect
Altering a column in a table that has a dependent package, trigger, or SQL routine	The object is marked invalid, and is re-validated on next use.
Altering the type of a column in a table that is referenced by an XSROBJECT enabled for decomposition	The XSROBJECT is marked inoperative for decomposition. Reenabling the XSROBJECT might require readjustment of its mappings; afterward, issue an ALTER XSROBJECT ENABLE DECOMPOSITION statement against the XSROBJECT.
Altering a column that is referenced in the default expression of a global variable	The default expression of the global variable is validated during alter processing. If a user-defined function that is used in the default expression cannot be resolved, the operation fails.

If the table is a system-period temporal table, the column is also changed in any associated history table. If the table is a system-period temporal table, string data type columns cannot be altered to a length that requires data truncation, and numeric data type columns cannot be altered to lower precision data types (SQLSTATE 42837).

built-in-type
See "CREATE TABLE" for the description of built-in data types.

SET NOT NULL
Specifies that the column cannot contain null values. No value for this column in existing rows of the table can be the null value (SQLSTATE 23502). This clause is not allowed if the column is specified in the foreign key of a referential constraint with a DELETE rule of SET NULL, and no other nullable columns exist in the foreign key (SQLSTATE 42831).

Altering this attribute for a column requires a classic table reorganization before full table access is allowed (SQLSTATE 57007).

If a row permission or column mask exists, which depends on the column to be altered, an error is issued (SQLSTATE 42917).

If the table is a system-period temporal table, the column is also changed in any associated history table.

SET INLINE LENGTH *integer*
Changes the inline length of an existing structured type, XML, or LOB data type column. The inline length indicates the maximum size in bytes of an instance of a structured type, XML, or LOB data type to store in the base table row. Instances of a structured type or XML data type that cannot be stored inline in the base table row are stored separately, similar to the way that LOB values are stored.

The data type of *column-name* must be a structured type, XML, or LOB data type (SQLSTATE 42842).

The default inline length for a structured type column is the inline length of its data type (specified explicitly or by default in the CREATE TYPE statement). If the inline length of a structured type is less than 292, the value 292 is used for the inline length of the column.

The explicit inline length value can be increased only (SQLSTATE 429B2); it cannot exceed 32673 (SQLSTATE 54010). For a structured type or XML data type column, it must be at least 292. For a LOB data type column, the INLINE LENGTH must not be less than the maximum LOB descriptor size.

Altering the column must not cause the total byte count of all columns to exceed the row size limit (SQLSTATE 54010).

Data that is already stored separately from the rest of the row is not moved inline into the base table row by this statement.

To take advantage of the altered inline length of a structured type column, start the REORG command against the specified table after altering the inline length of its column.

To take advantage of the altered inline length of an XML data type column in an existing table, update all rows with an UPDATE statement.

The REORG command has no effect on the row storage of XML documents.

To take advantage of the altered inline length of a LOB data type column, use the REORG command with the LONGLOBDATA option or UPDATE the corresponding LOB column.

For example:

```
UPDATE table-name SET lob-column = lob-column
   WHERE LENGTH(lob-column) <= chosen-inline-length - 4
```

where *table-name* is the table that had the inline length of the LOB data type column that is altered, *lob-column* is the LOB data type column that was altered, and *chosen-inline-length* is the new value that was chosen for the INLINE LENGTH.

If a row permission or column mask exists, which depends on the column to be altered, an error is returned (SQLSTATE 42917).

If the table is a system-period temporal table, inline length changes are propagated to the history table.

SET *default-clause*
Specifies a new default value for the column that is to be altered. The column must not already be defined as a generated column (SQLSTATE 42623). The specified default value must represent a value that could be assigned to the column in accordance with the rules for assignment as described in "Assignments and comparisons". Altering the default value does not change the value that is associated with this column for existing rows.

SET EXPRESSION AS (*generation-expression*)
Changes the expression for the column to the specified *generation-expression*. SET EXPRESSION requires the table to be put in set integrity pending state by using the SET INTEGRITY statement with the OFF option. After the ALTER TABLE statement, the SET INTEGRITY statement with the IMMEDIATE CHECKED and FORCE GENERATED options must be used to update and check all the values in that column against the new expression. The column must already be defined as a generated column based on an expression (SQLSTATE 42837), and must not have appeared in the PARTITIONING KEY, DIMENSIONS, or KEY SEQUENCE clauses of the table (SQLSTATE 42997). The generation-expression must conform to the same rules that apply when defining a generated column. The result data type of the generation-expression must be assignable to the data type of the column (SQLSTATE 42821).

The *generation-expression* must not reference a column for which a column mask is defined (SQLSTATE 42621).

SET NOT HIDDEN or SET IMPLICITLY HIDDEN
Specifies the hidden attribute for the column.

If the table is a system-period temporal table, the column is also changed in any associated history table.

NOT HIDDEN
Specifies that the column is included in implicit references to the table, and that the column can be explicitly referenced.

IMPLICITLY HIDDEN
Specifies that the column is not visible in SQL statements unless the column is explicitly referenced by name. For example, assuming that a table includes a column that is defined with the IMPLICITLY HIDDEN clause, the result of a SELECT * does not include the implicitly

hidden column. However, the result of a SELECT that explicitly refers to the name of an implicitly hidden column includes that column in the result table.

IMPLICITLY HIDDEN must not be specified for the last column of the table that is not hidden (SQLSTATE 428GU).

SET *generation-alteration*
Specifies that the generation attribute for the column is to be changed. GENERATED might be specified whether the column is an identity column or a row change timestamp column (SQLSTATE 42837). If the table is a system-period temporal table, the column in the associated history table is not affected by the change. If a default for the column exists, that default must be dropped, which can be done in the same *column-alteration* by using one of the DROP DEFAULT clauses. SET GENERATED must not be specified for a column of a temporal history table (SQLSTATE 428FR).

GENERATED ALWAYS
Specifies that the database manager always generates a value for the column when a row is inserted or updated and a value must be generated. GENERATED ALWAYS is the recommended option unless data propagation or unload and reload operations are being performed. ALWAYS is the default for generated columns.

GENERATED BY DEFAULT
Specifies that the database manager generates a value for the column when a row is inserted into the table, or updated, specifying DEFAULT for the column, unless an explicit value is specified. GENERATED BY DEFAULT can be specified with *as-row-change-timestamp-clause* only. GENERATED BY DEFAULT is the recommended option when using data propagation or performing unload and reload operations.

identity-alteration
Alters the identity attributes of the column. The column must be an identity column.

SET INCREMENT BY *numeric-constant*
Specifies the interval between consecutive values of the identity column. The next value to be generated for the identity column will be determined from the last assigned value with the increment applied. The column must already be defined with the IDENTITY attribute (SQLSTATE 42837).

This value can be any positive or negative value that might be assigned to this column (SQLSTATE 42815), and does not exceed the value of a large integer constant (SQLSTATE 42820), without nonzero digits that exist to the right of the decimal point (SQLSTATE 428FA).

If this value is negative, this is a descending sequence after the ALTER statement. If this value is 0 or positive, this is an ascending sequence after the ALTER statement.

SET NO MINVALUE or MINVALUE *numeric-constant*
Specifies the minimum value at which a descending identity column either cycles or stops generating values, or the value to which an ascending identity column cycle after it reaches the maximum value. The column must exist in the specified table (SQLSTATE 42703), and must already be defined with the IDENTITY attribute (SQLSTATE 42837).

NO MINVALUE
For an ascending sequence, the value is the original starting value. For a descending sequence, the value is the minimum value of the data type of the column.

MINVALUE *numeric-constant*
Specifies the numeric constant that is the minimum value. This value can be any positive or negative value that might be assigned to this column (SQLSTATE 42815), without nonzero digits that exist to the right of the decimal point (SQLSTATE 428FA), but the value must be less than or equal to the maximum value (SQLSTATE 42815).

SET NO MAXVALUE or MAXVALUE *numeric-constant*
Specifies the maximum value at which an ascending identity column either cycles or stops generating values, or the value to which a descending identity column cycle after it reaches the minimum value. The column must exist in the specified table (SQLSTATE 42703), and must already be defined with the IDENTITY attribute (SQLSTATE 42837).

NO MAXVALUE
For an ascending sequence, the value is the maximum value of the data type of the column. For a descending sequence, the value is the original starting value.

MAXVALUE *numeric-constant*
Specifies the numeric constant that is the maximum value. This value can be any positive or negative value that might be assigned to this column (SQLSTATE 42815), without nonzero digits that exist to the right of the decimal point (SQLSTATE 428FA), but the value must be greater than or equal to the minimum value (SQLSTATE 42815).

SET NO CYCLE or CYCLE
Specifies whether this identity column continues to generate values after generating either its maximum or minimum value. The column must exist in the specified table (SQLSTATE 42703), and must already be defined with the IDENTITY attribute (SQLSTATE 42837).

NO CYCLE
Specifies that values are not generated for the identity column after the maximum or minimum value is reached.

CYCLE
Specifies that values continue to be generated for this column after the maximum or minimum value is reached. If this option is used, then after an ascending identity column reaches the maximum value, it generates its minimum value; or after a descending sequence reaches the minimum value, it generates its maximum value. The maximum and minimum values for the identity column determine the range that is used for cycling.

When CYCLE is in effect, duplicate values can be generated for an identity column. Although not required, if unique values are wanted, a single-column unique index that is defined by using the identity column ensures uniqueness. If a unique index exists on such an identity column and a non-unique value is generated, an error occurs (SQLSTATE 23505).

SET NO CACHE or CACHE *integer-constant*
Specifies whether to keep some pre-allocated values in memory for faster access. This is a performance and tuning option. The column must already be defined with the IDENTITY attribute (SQLSTATE 42837).

NO CACHE
Specifies that values for the identity column are not to be pre-allocated.

In a Db2 pureScale environment, if the identity values *must* be generated in order of request, the NO CACHE option must be used.

When this option is specified, the values of the identity column are not stored in the cache. In this case, every request for a new identity value results in synchronous I/O to the log.

CACHE *integer-constant*
Specifies how many values of the identity sequence are pre-allocated and kept in memory. When values are generated for the identity column, pre-allocating and storing values in the cache reduces synchronous I/O to the log.

If a new value is needed for the identity column and no unused values available in the cache exist, the allocation of the value requires waiting for I/O to the log. However, when a new value is needed for the identity column and an unused value in the cache exist, the allocation of that identity value can happen more quickly by avoiding the I/O to the log.

If a database deactivates, either normally or due to a system failure, all cached sequence values that are not used in committed statements are lost (that is, they are never used). The maximum number of identity column values that can be lost is calculated as follows:

- If ORDER is specified, the maximum is the value that is specified for the CACHE option.
- In a multi-partition or Db2 pureScale, the maximum is the value that is specified for the CACHE option times the number of members that generate new identity values.

The minimum value is 2 (SQLSTATE 42815).

In a Db2 pureScale environment, if both CACHE and ORDER are specified, the specification of ORDER overrides the specification of CACHE and instead NO CACHE is in effect.

SET NO ORDER or ORDER
Specifies whether the identity column values must be generated in order of request. The column must exist in the specified table (SQLSTATE 42703), and must already be defined with the IDENTITY attribute (SQLSTATE 42837).

NO ORDER
Specifies that the identity column values do not need to be generated in order of request.

ORDER
Specifies that the identity column values must be generated in order of request.

RESTART or RESTART WITH *numeric-constant*
Resets the state of the sequence that is associated with the identity column. If WITH *numeric-constant* is not specified, the sequence for the identity column is restarted at the value that was specified, either implicitly or explicitly, as the starting value when the identity column was originally created.

The column must exist in the specified table (SQLSTATE 42703), and must already be defined with the IDENTITY attribute (SQLSTATE 42837). RESTART does *not* change the original START WITH value.

The *numeric-constant* is an exact numeric constant that can be any positive or negative value that might be assigned to this column (SQLSTATE 42815), without nonzero digits that exist to the right of the decimal point (SQLSTATE 428FA). The *numeric-constant* will be used as the next value for the column.

SET *generation-attribute as-identity-clause*
Changes the column to an identity column. This column alteration must not be specified whether the column has a default or is already a generated column (SQLSTATE 42837). If the table is a system-period temporal table, the column in the associated history table is not affected by the change.

GENERATED ALWAYS
Specifies that the database manager always generates a value for the column when a row is inserted or updated and a value must be generated. ALWAYS is the default for generated columns.

GENERATED BY DEFAULT
Specifies that the database manager generates a value for the column when a row is inserted or updated and a default value must be generated, unless an explicit value is specified.

as-identity-clause
Specifies that the column is the identity column for the table. A table can have a single identity column (SQLSTATE 428C1). The column must be specified as not nullable (SQLSTATE 42997) only, and the data type associated with the column must be an exact numeric data type with a scale of zero (SQLSTATE 42815). An exact numeric data type is one of: SMALLINT, INTEGER, BIGINT, DECIMAL, or NUMERIC with a scale of zero, or a distinct type based on one of these types. For details on identity options, see "CREATE TABLE".

SET GENERATED ALWAYS
Changes the column to a generated expression column, a row-begin column, a row-end column, or a transaction-start-ID column. GENERATED ALWAYS specifies that the database manager always generates a value for the column when a row is inserted or updated and a value must be generated.

AS (*generation-expression*)
Specifies that the definition of the column is based on an expression. The column must not already be defined with a generation expression, cannot be the identity column, or cannot have an explicit default (SQLSTATE 42837). The *generation-expression* must conform to the same rules that apply when defining a generated column. The result data type of the *generation-expression* must be assignable to the data type of the column (SQLSTATE 42821).

The column must not be referenced in the distribution key column or in the multidimensional clustering (MDC) key (SQLSTATE 42997).

The *generation-expression* must not reference a column for which a column mask is defined (SQLSTATE 42621).

AS ROW BEGIN

Specifies that the value is assigned by the database manager whenever a row is inserted into the table or any column in the row is updated. The value is generated by using a reading of the time-of-day clock during execution of the first of the following events in the transaction:

- A data change statement that requires a value to be assigned to the row-begin or transaction start-ID column in a table
- A deletion of a row in a system-period temporal table

For a system-period temporal table, the database manager ensures uniqueness of the generated values for a row-begin column across transactions. The timestamp value might be adjusted to ensure that rows that are inserted into an associated history table have the end timestamp value greater than the begin timestamp value (SQLSTATE 01695). This can happen when a conflicting transaction is updating the same row in the system-period temporal table. The database configuration parameter **systime_period_adj** must be set to Yes for this adjustment to the timestamp value to occur otherwise an error is returned (SQLSTATE 57062). If multiple rows are inserted or updated within a single SQL transaction and an adjustment is not needed, the values for the row-begin column are the same for all the rows and are unique from the values that are generated for the column for another transaction. A row-begin column is required as the begin column of a SYSTEM_TIME period, which is the intended use for this type of generated column.

A table can have only one row-begin column (SQLSTATE 428C1). If *data-type* is not specified, the column is defined as a TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12) (SQLSTATE 42842). The column must be defined as NOT NULL (SQLSTATE 42831). A row-begin column cannot be updated.

AS ROW END

Specifies that the maximum value for the data type of the column is assigned by the database manager whenever a row is inserted or any column in the row is updated.

A row-end column is required as the second column of a SYSTEM_TIME period, which is the intended use for this type of generated column.

A table can have only one row-end column (SQLSTATE 428C1). If *data-type* is not specified, the column is defined as TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12) (SQLSTATE 42842). The column must be defined as NOT NULL (SQLSTATE 42831). A row-end column cannot be updated.

AS TRANSACTION START ID

Specifies that the value is assigned by the database manager whenever a row is inserted into the table or any column in the row is updated. The database manager assigns a unique timestamp value per transaction or the null value. The null value is assigned to the transaction start-ID column if the column is nullable and if a row-begin column exists in the table for which the value did not need to be adjusted. Otherwise, the value is generated by using a reading of the time-of-day clock during execution of the first of the following events in the transaction:

- A data change statement that requires a value to be assigned to the row-begin or transaction start-ID column in a table
- A deletion of a row in a system-period temporal table

If multiple rows are inserted or updated within a single SQL transaction, the values for the transaction start-ID column are the same for all the rows and are unique from the values that are generated for the column for another transaction.

A transaction start-ID column is required for a system-period temporal table, which is the intended use for this type of generated column.

A table can have only one transaction start-ID column (SQLSTATE 428C1). If *data-type* is not specified, the column is defined as TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12). A transaction start-ID column cannot be updated.

DROP DEFAULT
Drops the current default for the column. The specified column must have a default value (SQLSTATE 42837). This action is propagated to the history table for a system-period temporal table.

DROP GENERATED
Drops the generated attributes of the column. The column must be defined as a generated column (SQLSTATE 42837). The column must not be defined as a row-begin column, row-end column, or a transaction-start-ID column in a system-period temporal table (SQLSTATE 428FR).

DROP NOT NULL
Drops the NOT NULL attribute of the column, allowing the column to have the null value. This clause is not allowed if the column is specified in the primary key, in a unique constraint of the table (SQLSTATE 42831), a row-begin column, or a row-end column (SQLSTATE 42837).

Altering this attribute for a column requires a classic table reorganization before full table access is allowed (SQLSTATE 57007).

The table cannot have data capture enabled (SQLSTATE 42997). DROP NOT NULL is blocked for columns that belong to the BUSINESS_TIME period (SQLSTATE 428FR).

If the table is a system-period temporal table, the NOT NULL attribute is also dropped from the corresponding column in any associated history table.

If either a row permission or column mask exists, which depends on the column to be altered, an error is issued (SQLSTATE 42917).

ADD SCOPE
Add a scope to an existing reference type column that does not already define a scope that is defined (SQLSTATE 428DK). If the altered table is a typed table, the column must not be inherited from a supertable (SQLSTATE 428DJ).

typed-table-name
The name of a typed table. The data type of *column-name* must be REF(*S*), where *S* is the type of *typed-table-name* (SQLSTATE 428DM). No checking is done of any existing values in *column-name* to ensure that the values reference existing rows in *typed-table-name*.

typed-view-name
The name of a typed view. The data type of *column-name* must be REF(*S*), where *S* is the type of *typed-view-name* (SQLSTATE 428DM). No checking is done of any existing values in *column-name* to ensure that the values reference existing rows in *typed-view-name*.

COMPRESS
Specifies whether default values for this column are to be stored more efficiently.

SYSTEM DEFAULT
Specifies that system default values (that is, the default values used for the data types when no specific values are specified) are to be stored by using minimal space. If the table is not already set with the VALUE COMPRESSION attribute activated, a warning is returned (SQLSTATE 01648), and system default values are not stored by using minimal space.

Allowing system default values to be stored in this manner causes a slight performance penalty during insert and update operations on the column because of the extra checking that is done.

Existing data in the column is not changed. Consider offline table reorganization to enable existing data to take advantage of storing system default values by using minimal space.

OFF
Specifies that system default values are to be stored in the column as regular values. Existing data in the column is not changed. Offline reorganization is recommended to change existing data.

The base data type must not be DATE, TIME, or TIMESTAMP (SQLSTATE 42842). If the base data type is a varying-length string, this clause is ignored. String values of length 0 are automatically compressed if a table was set with VALUE COMPRESSION.

If the altered table is a typed table, the column must not be inherited from a supertable (SQLSTATE 428DJ).

SECURED WITH *security-label-name*
Identifies a security label that exists for the security policy that is associated with the table. The name must not be qualified (SQLSTATE 42601). The table must be associated with a security (SQLSTATE 55064). The table must not be a system-period temporal table.

DROP COLUMN SECURITY
Alters a column to make it a non-protected column.

ACTIVATE ROW ACCESS CONTROL

Activates row level access control on the table. The table must not be a typed table, a catalog table (SQLSTATE 55019), a created temporary table, a declared temporary table (SQLSTATE 42995), a nickname (SQLSTATE 42809), a view (SQLSTATE 42809), or an external table (SQLSTATE 42858). The table must not identify a shadow table or a base table of a shadow table (SQLSTATE 428HZ).

A default row permission is implicitly created and allows no access to any rows of the table, unless permitted by a row permission that is explicitly created by a user with SECADM authority.

When the table is referenced in a data manipulation statement, all enabled row permissions that were created for the table, including the default row permission, are applied implicitly by the database manager to control the set of rows in the table that are accessible.

If a trigger exists for the table, the trigger must be defined with the SECURED attribute (SQLSTATE 55019).

The table must not be referenced in the definition of a view if an INSTEAD OF trigger that is defined with the NOT SECURED attribute exists for the view (SQLSTATE 55019).

If a materialized query table references the table, the functions that are referenced in the *fullselect* of *materizalized-query-definition* must be defined with the SECURED attribute (SQLSTATE 55019).

If a materialized query table (or a staging table) that depends on the table (directly or indirectly through a view) for which row level access control is being activated and that materialized query table (or a staging table) did not already activate row level access control, row level access control is implicitly activated for the materialized query table (or a staging table). This restricts direct access to the contents of the materialized query table (or a staging table). A query that explicitly references the table before such a row permission is defined returns a warning that no data in the table exists (SQLSTATE 02000). To provide access to the materialized query table (or a staging table), an appropriate row permission can be created, or an ALTER TABLE DEACTIVATE ROW ACCESS CONTROL statement on the materialized query table (or a staging table) can be issued to remove the row level protection if that is appropriate.

ACTIVATE ROW ACCESS CONTROL is ignored if row access control is already defined as activated for the table.

If the table is a system-period temporal table, the database manager automatically activates row access control on the history table and creates a default row permission for the history table.

If the table is a column-organized table, the database manager automatically activates row access control on the synopsis table and creates a default row permission for the synopsis table.

ACTIVATE COLUMN ACCESS CONTROL

Activates column level access control on the table. The table must not be a typed table, a catalog table (SQLSTATE 55019), a created temporary table, a declared temporary table (SQLSTATE 42995), a nickname (SQLSTATE 42809), a view (SQLSTATE 42809), or an external table (SQLSTATE 42858). The table must not identify a shadow table or a base table of a shadow table (SQLSTATE 428HZ).

The access to the table is not restricted but when the table is referenced in a data manipulation statement, all enabled column masks that were created for the table are applied implicitly by the database manager to mask the values that are returned for the referenced columns in the final result table of the queries.

If a trigger exists for the table, the trigger must be defined with the SECURED attribute (SQLSTATE 55019).

If a materialized query table references the table, the functions that are referenced in the *fullselect* of *materizalized-query-definition* must be defined with the SECURED attribute (SQLSTATE 55019).

The table must not be referenced in the definition of a view if an INSTEAD OF trigger that is defined with the NOT SECURED attribute exists for the view (SQLSTATE 55019). If a materialized query table that depends on the table (directly or indirectly through a view) for which column level access control is being activated and that materialized query table did not already activate row level access control, row level access control is implicitly activated for the materialized query table. This restricts direct access to the contents of the materialized query table. A query that explicitly references the table before such a row permission is defined returns a warning that no data in the table exists (SQLSTATE 02000). To provide access to the materialized query table, an appropriate row permission can be created, or an ALTER TABLE DEACTIVATE ROW ACCESS CONTROL statement on the materialized query table can be issued to remove the row level protection if that is appropriate.

ACTIVATE COLUMN ACCESS CONTROL is ignored if column level access control is already defined as activated for the table.

If the table is a system-period temporal table, the database manager automatically activates row access control on the history table and creates a default row permission for the history table.

If the table is a column-organized table, the database manager automatically activates row access control on the synopsis table and creates a default row permission for the synopsis table.

DEACTIVATE ROW ACCESS CONTROL

Deactivates row level access control on the table. When the table is referenced in a data manipulation statement, any existing enabled row permissions that are defined on the table are not applied by the database manager to control the set of rows in the table that are accessible. The table must not identify a shadow table or a base table of a shadow table (SQLSTATE 428HZ).

DEACTIVATE ROW ACCESS CONTROL is ignored if row access control is not activated for the table.

DEACTIVATE COLUMN ACCESS CONTROL

Deactivates column level access control on the table. When the table is referenced in a data manipulation statement, any existing enabled column masks defined on the table are not applied by the database manager to control the values that are returned for the columns that are referenced in the final result table of the queries. The table must not identify a shadow table or a base table of a shadow table (SQLSTATE 428HZ).

DEACTIVATE COLUMN ACCESS CONTROL is ignored if column access control is not activated for the table.

RENAME COLUMN *source-column-name* TO *target-column-name*

Renames the column that is specified in *source-column-name* to the name that is specified in *target-column-name*. If the **auto_reval** database configuration parameter is set to DISABLED, the RENAME COLUMN option of the ALTER TABLE statement behaves like it is under the control of revalidation immediate semantics.

The table must not be defined as a history table (SQLSTATE 42986). If the table is a system-period temporal table, the column is also renamed in any associated history table.

Columns that are used in expression-based index keys cannot be renamed (SQLSTATE 42893).

RENAME COLUMN must not rename a column that is referenced in the definition of a row permission or a column mask. Also, It must not rename a column for which a column mask is defined (SQLSTATE 42917). If you rename a column that belongs to a table on which a mask or a permission is defined, or to a table that is referenced in the definition of a mask or a permission, that mask or permission is invalidated. Access to a table that activated column access control and a defined invalid mask on it is blocked until the invalid mask is either disabled, dropped, or re-created (SQLSTATE 560D0). Access to a table that activated row access control and defined an invalid row permission on it is blocked until the invalid permission is either disabled, dropped, or re-created (SQLSTATE 560D0).

source-column-name
Specifies the name of the column that is to be renamed. The *source-column-name* must identify an existing column of the table (SQLSTATE 42703). The name must not be qualified. The name must not identify a column that is otherwise being added, altered, or dropped in the same ALTER TABLE statement (SQLSTATE 42711).

target-column-name
The new name for the column. The name must not be qualified. Existing column names or period names in the table must not be used (SQLSTATE 42711).

DROP PRIMARY KEY
Drops the definition of the primary key and all referential constraints dependent on this primary key. The table must have a primary key (SQLSTATE 42888).

DROP FOREIGN KEY *constraint-name*
Drops the referential constraint *constraint-name*. The *constraint-name* must identify a referential constraint (SQLSTATE 42704). For information about implications of dropping a referential constraint, see Notes.

DROP UNIQUE *constraint-name*
Drops the definition of the unique constraint *constraint-name* and all referential constraints dependent on this unique constraint. The *constraint-name* must identify an existing UNIQUE constraint (SQLSTATE 42704). For information on implications of dropping a unique constraint, see Notes.

DROP CHECK *constraint-name*
Drops the check constraint *constraint-name*. The *constraint-name* must identify an existing check constraint that is defined on the table (SQLSTATE 42704).

DROP CONSTRAINT *constraint-name*
Drops the constraint *constraint-name*. The *constraint-name* must identify an existing check constraint, referential constraint, primary key, or unique constraint defined on the table (SQLSTATE 42704). For information about implications of dropping a constraint, see Notes.

DROP COLUMN
Drops the identified column from the table. The table must not be a typed table (SQLSTATE 428DH). The table cannot have data capture enabled (SQLSTATE 42997).

Dropping a column requires a classic table reorganization before full table access is allowed (SQLSTATE 57007).

An XML column can be dropped only if all of the other XML columns in the table are dropped at the same time only.

DROP COLUMN must not drop a column that is referenced in the definition of a row permission or a column mask (SQLSTATE 42917). However, a column for which a column mask is defined can be dropped. When the column is dropped, any column mask that is defined on that column is also dropped.

column-name
Identifies the column that is to be dropped. The column name must not be qualified. The name must identify a column of the specified table (SQLSTATE 42703). The name must not identify the only column of the table (SQLSTATE 42814), or a column referenced in the definition of a period (SQLSTATE 42817). The name must not identify the last column of the table that is not

hidden (SQLSTATE 428GU). The name must not identify a column in a table that is defined as a system-period temporal table or history table (SQLSTATE 428FR). The name must not identify a column that is part of the distribution key, table-partitioning key, or organizing dimensions (SQLSTATE 42997).

CASCADE

Specifies the following actions, based on the object:

- Any views that depend on the column that is dropped are marked inoperative
- Any indexes, triggers, SQL functions, constraints, or global variables that depend on the column that is dropped are also dropped
- Any decomposition-enabled XSROBJECTs that depend on the table that contains the column are made inoperative for decomposition.

A trigger depends on the column if it is referenced in the UPDATE OF column list, or anywhere in the triggered action. A decomposition-enabled XSROBJECT depends on a table if it contains a mapping of an XML element or attribute to the table. If an SQL function or global variable depends on another database object, it might not be possible to drop the function or global variable by using the CASCADE option. CASCADE is the default.

RESTRICT

Specifies that the column cannot be dropped if any views, indexes, triggers, constraints, or global variables depend on the column, or if any decomposition-enabled XSROBJECT depends on the table that contains the column (SQLSTATE 42893). A trigger depends on the column if it is referenced in the UPDATE OF column list, or anywhere in the triggered action. A decomposition-enabled XSROBJECT depends on a table if it contains a mapping of an XML element or attribute to the table. The first dependent object that is detected is identified in the administration log.

Table 128. Cascaded Effects of Dropping a Column

Operation	RESTRICT Effect	CASCADE Effect
Dropping a column that is referenced by a view or a trigger	Dropping the column is not allowed.	The object and all objects that depend on that object are dropped.
Dropping a column that is referenced in the key of an index	If all columns that are referenced in the index are dropped in the same ALTER TABLE statement, dropping the index is allowed. Otherwise, dropping the column is not allowed.	The index is dropped.
Dropping a column that is referenced in a unique constraint	If all columns that are referenced in the unique constraint are dropped in the same ALTER TABLE statement, and the unique constraint is not referenced by a referential constraint, the columns and the constraint are dropped. (The index that is used to satisfy the constraint is also dropped). Otherwise, dropping the column is not allowed.	The unique constraint and any referential constraints, which reference that unique constraint, are dropped. (Any indexes that are used by those constraints are also dropped).

Table 128. Cascaded Effects of Dropping a Column (continued)

Operation	RESTRICT Effect	CASCADE Effect
Dropping a column that is referenced in a referential constraint	If all columns that are referenced in the referential constraint are dropped in the same ALTER TABLE statement, the columns and the constraint are dropped. Otherwise, dropping the column is not allowed.	The referential constraint is dropped.
Dropping a column that is referenced by a system-generated column that is not being dropped.	Dropping the column is not allowed.	Dropping the column is not allowed.
Dropping a column that is referenced in a check constraint	Dropping the column is not allowed.	The check constraint is dropped.
Dropping a column that is referenced in a decomposition-enabled XSROBJECT	Dropping the column is not allowed.	The XSROBJECT is marked inoperative for decomposition. Reenabling the XSROBJECT might require readjustment of its mappings; afterward, issue an ALTER XSROBJECT ENABLE DECOMPOSITION statement against the XSROBJECT.
Dropping a column that is referenced in the default expression of a global variable	Dropping the column is not allowed.	The global variable is dropped, unless the dropping of the global variable is disallowed because other objects exist, which do not allow the cascade, that depends on the global variable.

DROP RESTRICT ON DROP
Removes the restriction, if there is one, on dropping the table and the table space that contains the table.

DROP DISTRIBUTION
Drops the distribution definition for the table. The table must have a distribution definition (SQLSTATE 428FT). The table space for the table must be defined on a single partition database partition group.

DROP MATERIALIZED QUERY
Changes a materialized query table so that it is no longer considered to be a materialized query table. The table that is specified by *table-name* must be defined as a materialized query table that is not replicated (SQLSTATE 428EW). The definition of the columns of *table-name* is not changed, but the table can no longer be used for query optimization, and the REFRESH TABLE statement can no longer be used.

If row level access control or column level access control is in effect for the table, this control remains after the table is no longer a materialized query table.

ADD PERIOD period-definition
Adds a period definition to the table.

SYSTEM_TIME (*begin-column-name*, *end-column-name*)

Defines a system period with the name SYSTEM_TIME. There must not be a column in the table with the name SYSTEM_TIME (SQLSTATE 42711). A table can have only one SYSTEM_TIME period

(SQLSTATE 42711). *begin-column-name* must be defined as ROW BEGIN and *end-column-name* must be defined as ROW END (SQLSTATE 428HN).

BUSINESS_TIME (*begin-column-name*, *end-column-name*)

Defines an application period with the name BUSINESS_TIME. There must not be a column in the table with the name BUSINESS_TIME (SQLSTATE 42711). A table can have only one BUSINESS_TIME period (SQLSTATE 42711). *begin-column-name* and *end-column-name* must both be defined as DATE or TIMESTAMP(p) where p is 0 - 12 (SQLSTATE 42842), and the columns must be defined as NOT NULL (SQLSTATE 42831). *begin-column-name* and *end-column-name* must not identify a column that is defined with a GENERATED clause (SQLSTATE 428HZ). Business time period columns cannot be added to a table that is in set integrity pending state.

An implicit check constraint is generated to ensure that the value of *end-column-name* is greater than the value of *begin-column-name*. The name of the implicitly created check constraint is DB2_GENERATED_CHECK_CONSTRAINT_FOR_BUSINESS_TIME and must not be the name of an existing check constraint (SQLSTATE 42710).

DROP PERIOD *period-name*

Drops the identified period from the table. The name must not identify a period that was already added or altered in this ALTER TABLE statement (SQLSTATE 42711). Any implicitly generated check constraints for the period (created when the period was defined) and any indexes that reference the period are also dropped.

period-name

Identifies the period. Valid period names are BUSINESS_TIME or SYSTEM_TIME. The period must exist in the table (SQLSTATE 4274M).

When a BUSINESS_TIME period is dropped, all packages with the application-period temporal table dependency type on that table are invalidated. Other dependent objects like views and triggers that record a dependency on the table are also marked as invalid.

SYSTEM_TIME period cannot be dropped if the table is a system-period temporal table (SQLSTATE 428HZ).

DATA CAPTURE

Indicates whether extra information for data replication is to be written to the log.

If the table is a typed table, then this option is not supported (SQLSTATE 428DH for root tables or 428DR for other subtables).

NONE

Indicates that no extra information is logged.

CHANGES

Indicates that extra information with regards to SQL changes to this table is written to the log. This option is required if this table is replicated and the Capture program is used to capture changes for this table from the log.

INCLUDE LONGVAR COLUMNS

Allows data replication utilities to capture changes that are made to LONG VARCHAR or LONG VARGRAPHIC columns. The clause can be specified for tables that do not have any LONG VARCHAR or LONG VARGRAPHIC columns since it is possible to ALTER the table to include such columns.

ACTIVATE NOT LOGGED INITIALLY

Activates the NOT LOGGED INITIALLY attribute of the table for this current unit of work.

Any changes that are made to the table by an INSERT, DELETE, UPDATE, CREATE INDEX, DROP INDEX, or ALTER TABLE in the same unit of work after the table is altered by this statement are not logged. Any changes that are made to the system catalog by the ALTER statement in which the NOT LOGGED INITIALLY attribute is activated are logged. Any subsequent changes that are made in the same unit of work to the system catalog information are logged.

At the completion of the current unit of work, the NOT LOGGED INITIALLY attribute is deactivated and all operations that are done on the table in subsequent units of work are logged.

If you use this feature to avoid locks on the catalog tables while you insert data, it is important that only this clause is specified on the ALTER TABLE statement. Use of any other clause in the ALTER TABLE statement results in catalog locks. If no other clauses are specified for the ALTER TABLE statement, then only a SHARE lock is acquired on the system catalog tables. This can greatly reduce the possibility of concurrency conflicts during time between when this statement is run and when the unit of work in which it was run is ended.

If the table is a typed table, this option is only supported on the root table of the typed table hierarchy (SQLSTATE 428DR).

If the table is a system-period temporal table or a history table, this option is not supported.

For more information about the NOT LOGGED INITIALLY attribute, see the description of this attribute in "CREATE TABLE " on page 1351.

Note: If non-logged activity occurs against a table that has the NOT LOGGED INITIALLY attribute activated, and if a statement fails (causing a rollback), or a ROLLBACK TO SAVEPOINT is run, the entire unit of work is rolled back (SQL1476N). Furthermore, the table for which the NOT LOGGED INITIALLY attribute was activated is marked inaccessible after the rollback occurs and can be dropped only. Therefore, the opportunity for errors within the unit of work in which the NOT LOGGED INITIALLY attribute is activated is minimized.

WITH EMPTY TABLE
Causes all data currently in table to be removed. When the data is removed, it cannot be recovered except through use of the RESTORE facility. If the unit of work in which this alter statement was issued is rolled back, the table data is not returned to its original state.

When this action is requested, no DELETE triggers defined on the affected table are fired. The index data is also deleted for all indexes that exist on the table.

A partitioned table with attached data partitions or logically detached partitions cannot be emptied (SQLSTATE 42928).

PCTFREE *integer*
Specifies the percentage of each page that is to be left as free space during a load or a table reorganization operation. The first row on each page is added without restriction. When more rows are added to a page, at least *integer* percent of the page is left as free space. The PCTFREE value is considered only by the load and table reorg utilities. The value of *integer* can range 0 - 99. A PCTFREE value of -1 in the system catalog (SYSCAT.TABLES) is interpreted as the default value. The default PCTFREE value for a table page is 0. If the table is a typed table, this option is only supported on the root table of the typed table hierarchy (SQLSTATE 428DR).

LOCKSIZE
Indicates the size (granularity) of locks used when the table is accessed. Use of this option in the table definition does not prevent normal lock escalation from occurring.

If the table is a typed table, this option is only supported on the root table of the typed table hierarchy (SQLSTATE 428DR).

The LOCKSIZE keyword is not supported for column-organized tables (SQLSTATE 42858).

ROW
Indicates the use of row locks. This is the default lock size when a table is created.

BLOCKINSERT
Indicates the use of block locks during insert operations. This means that the appropriate exclusive lock is acquired on the block before insertion, and row locking is not done on the inserted row. This option is useful when separate transactions are inserting into separate cells in the table. Transactions inserting into the same cells can still do so concurrently, but insert into distinct blocks, and this can impact the size of the cell if more blocks are needed. This option is only valid for MDC tables (SQLSTATE 42613).

TABLE
Indicates the use of table locks. This means that the appropriate share or exclusive lock is acquired on the table, and that intent locks (except intent none) are not used. For partitioned

tables, this lock strategy is applied to both the table lock and the data partition locks for any data partitions that are accessed. Use of this value can improve the performance of queries by limiting the number of locks that need to be acquired. However, concurrency is also reduced because all locks are held over the complete table.

APPEND
Indicates whether data is appended to the end of the table data or placed where free space is available in data pages. If the table is a typed table, this option is only supported on the root table of the typed table hierarchy (SQLSTATE 428DR).

ON
Indicates that table data is appended and information about free space on pages is not kept. The table must not have a clustered index (SQLSTATE 428CA).

OFF
Indicates that table data is placed in available space. This is the default when a table is created.

The table is reorganized after you set APPEND OFF since the information about available free space is not accurate and can result in poor performance during insert.

VOLATILE CARDINALITY or NOT VOLATILE CARDINALITY
Indicates to the optimizer whether the cardinality of table *table-name* can vary significantly at run time. Volatility applies to the number of rows in the table, not to the table itself. CARDINALITY is an optional keyword. The default is NOT VOLATILE.

VOLATILE
Specifies that the cardinality of table *table-name* can vary significantly at run time, from empty to large. To access the table, the optimizer uses an index scan (rather than a table scan, regardless of the statistics) if that index is index-only (all referenced columns are in the index), or that index is able to apply a predicate in the index scan. The list prefetch access method is not used to access the table. If the table is a typed table, this option is only supported on the root table of the typed table hierarchy (SQLSTATE 428DR).

NOT VOLATILE
Specifies that the cardinality of *table-name* is not volatile. Access plans to this table continues to be based on existing statistics and on the current optimization level.

COMPRESS
Specifies whether data compression applies to the rows of the table.

YES
Specifies that row and XML compression are enabled. Insert and update operations on the table are subject to compression. Index compression is enabled for new indexes unless explicitly disabled in the CREATE INDEX statement. Existing indexes can be compressed by using the ALTER INDEX statement.

After a table is altered to enable row compression, all rows in the table can be compressed immediately by running one of the following actions:

- REORG command
- Online table move
- Data unload and reload

ADAPTIVE
Enables adaptive compression for the table. Data rows are subject to compression with both table-level and page-level compression dictionaries. XML documents in the XML storage object are subject to compression with a table-level XML compression dictionary. Page-level compression dictionaries are created automatically as rows are inserted or updated. Table-level compression dictionaries are created for both row and XML data automatically after sufficient data is added, unless they exist.

STATIC
Enables classic row compression for the table. Data rows are subject to compression with a table-level compression dictionary, and XML documents in the XML storage object are

subject to compression by using a table-level XML compression dictionary. If no table-level compression dictionaries exist for either row or XML data, they will be created automatically after sufficient data is added.

If neither of the preceding two options are specified along with the COMPRESS YES clause, ADAPTIVE is used implicitly.

NO

Specifies that data row and XML compression are disabled. Inserted and updated data rows and XML documents in the table is no longer subject to compression. Any rows and XML documents in the table that are already in compressed format remain in compressed format until they are converted to non-compressed format when they are updated.

An offline reorganization of the table decompresses any rows that are remain compressed.

If table-level or page-level compression dictionaries exist, they are discarded during table reorganization or truncation (such as a LOAD REPLACE operation). Index compression is disabled for new indexes that are created on that table unless explicitly enabled in the CREATE INDEX statement. Index compression for existing indexes can be explicitly disabled by using the ALTER INDEX statement.

VALUE COMPRESSION

This determines the row format that is to be used. Each data type has a different byte count depending on the row format that is used. For more information, see "Byte Counts" in “CREATE TABLE ” on page 1351. An update operation causes an existing row to be changed to the new row format.

Offline table reorganization is recommended to improve the performance of update operations on existing rows. This can also result in the table to take up less space.

If the row size, which is calculated by using the appropriate column in the table "Byte Counts of Columns by Data Type" (see "CREATE TABLE"), would no longer fit within the row size limit, as indicated in the table "Limits for Number of Columns and Row Size In Each Table Space Page Size", an error is returned (SQLSTATE 54010). If the table is a typed table, this option is only supported on the root table of the typed table hierarchy (SQLSTATE 428DR).

ACTIVATE

The NULL value is stored by using 3 bytes. This is the same or less space than when VALUE COMPRESSION is not active for columns of all data types, except for CHAR(1). Whether a column is defined as nullable has no effect on the row size calculation. The zero-length data values for columns whose data type is VARCHAR, VARGRAPHIC, VARBINARY, CLOB, DBCLOB, or BLOB are to be stored by using 2 bytes only, which is less than the storage required when VALUE COMPRESSION is not active. When a column is defined by using the COMPRESS SYSTEM DEFAULT option, this also allows the system default value for the column to be stored by using 3 bytes of total storage. The row format that is used to support this determines the byte counts for each data type, and tends to cause data fragmentation when updating to or from NULL, a zero-length value, or the system default value.

DEACTIVATE

The null value is stored with space set aside for possible future updates. This space is not set aside for varying-length columns. It also does not support efficient storage of system default values for a column. If columns exist with the COMPRESS SYSTEM DEFAULT attribute, a warning is returned (SQLSTATE 01648).

LOG INDEX BUILD

Specifies the level of logging that is to be performed during create, re-create, or reorganize index operations on this table.

NULL

Specifies that the value of the **logindexbuild** database configuration parameter is used to determine whether index build operations are to be logged. This is the default when the table is created.

OFF
Specifies that any index build operations on this table will be logged minimally. This value overrides the setting of the **logindexbuild** database configuration parameter.

ON
Specifies that any index build operations on this table will be logged completely. This value overrides the setting of the **logindexbuild** database configuration parameter.

ADD PARTITION *add-partition*
Adds one or more data partitions to a partitioned table. If the specified table is not a partitioned table, an error is returned (SQLSTATE 428FT). The number of data partitions must not exceed 32 767.

partition-name
Names the data partition. The name must not be the same as any other data partition for the table (SQLSTATE 42710). If this clause is not specified, the name will be 'PART' followed by the character form of an integer value to make the name unique for the table.

boundary-spec
Specifies the range of values for the new data partition. This range must not overlap that of an existing data partition (SQLSTATE 56016). For a description of the starting-clause and the ending-clause, see "CREATE TABLE".

If the starting-clause is omitted, the new data partition is assumed to be at the end of the table. If the ending-clause is omitted, the new data partition is assumed to be at the start of the table.

IN *tablespace-name*
Specifies the table space where the data partition is to be stored. The named table space must have the same page size, be in the same database partition group, and manage space in the same way as the other table spaces of the partitioned table (SQLSTATE 42838). This can be a table space that is already being used for another data partition of the same table, or a table space that is not being used by this table, but it must be a table space on which the authorization ID of the statement holds the USE privilege (SQLSTATE 42727). If this clause is not specified, the table space of the first visible or attached data partition of the table is used.

INDEX IN *tablespace-name*
Specifies the table space where partitioned indexes on the data partition are stored. If the INDEX IN clause is not specified, partitioned indexes on the data partition are stored in the same table space as the data partition.

The table space that is used by the new index partition, whether default or specified by the INDEX IN clause, must match the type (SMS or DMS), page size, and extent size of the table spaces used by all other index partitions (SQLSTATE 42838).

LONG IN *tablespace-name*
Specifies the table space where the data partition that contains long column data is to be stored. The named table space must have the same page size, be in the same database partition group, and manage space in the same way as the other table spaces and data partitions of the partitioned table (SQLSTATE 42838); it must be a table space on which the authorization ID of the statement holds the USE privilege. The page size and extent size for the named table space can be different from the page size and extent size of the other data partitions of the partitioned table.

For rules that govern the use of the LONG IN clause with partitioned tables, see "Large object behavior in partitioned tables".

ATTACH PARTITION *attach-partition*
Attaches another table as a new data partition. The data object of the table being attached becomes a new partition of the table being attached to. There is no data movement involved. The table is placed in set integrity pending state, and referential integrity checking is deferred until execution of a SET INTEGRITY statement. The ALTER TABLE ATTACH operation does not allow the use of the IN or LONG IN clause. The placement of LOBs for that data partition is determined at the time the source table is created. For rules that govern the use of the LONG IN clause with partitioned tables, see "Large object behavior in partitioned tables".

If the table being attached has either row level access control or column level access control activated, then the table to attach to must have the same controls activated. No row permissions or column masks are automatically carried over from the table being attached to the target table. The column masks and row permissions do not necessarily need to be the same on both tables, although this would be best from a security perspective. But if the table being attached has row level access control activated then the table to attach to must also have row level access control activated (SQLSTATE 428GE). Similarly, if the table being attached has column level access control activated and at least one column mask object that is enabled then the table to attach to must also have column level access control activated and a column mask object that is enabled for the corresponding columns (SQLSTATE 428GE).

partition-name
Names the data partition. The name must not be the same as any other data partition for the table (SQLSTATE 42710). If this clause is not specified, the name is 'PART' followed by the character form of an integer value to make the name unique for the table.

boundary-spec
Specifies the range of values for the new data partition. This range must not overlap that of an existing data partition (SQLSTATE 56016). For a description of the starting-clause and the ending-clause, see "CREATE TABLE".

If the starting-clause is omitted, the new data partition is assumed to be at the end of the table. If the ending-clause is omitted, the new data partition is assumed to be at the start of the table.

FROM *table-name1*
Specifies the table that is to be used as the source of data for the new partition. The table definition of *table-name1* cannot have multiple data partitions, and it must match the altered table in the following ways (SQLSTATE 428GE):

- The number of columns must be the same.
- The data types of the columns in the same ordinal position in the table must be the same.
- The nullability characteristic of the columns in the same ordinal position in the table must be the same.
- If the target table has a row change timestamp column, the corresponding column of the source table must be a row change timestamp column.
- If the data is also distributed, it must be distributed over the same database partition group by using the same distribution keys.
- If either table is a random distribution table that uses the random by generation method, the other table must be one too.
- If the data in either table is organized, the organization must match.
- For structured, XML, or LOB data type, the value for INLINE LENGTH must be the same.
- If the target table has a defined BUSINESS_TIME period, the source table must have a defined BUSINESS_TIME period on the corresponding columns.

After the data from *table-name1* is successfully attached, an operation equivalent to DROP TABLE *table-name1* is performed to remove this table, which no longer has data, from the database.

BUILD MISSING INDEXES
Specifies that if the source table does not have indexes that correspond to the partitioned indexes on the target table, a SET INTEGRITY operation builds partitioned indexes on the new data partition to correspond to the partitioned indexes on the existing data partitions. Indexes on the source table that do not match the partitioned indexes on the target table are dropped during attach processing.

REQUIRE MATCHING INDEXES
Specifies that the source table must have indexes to match the partitioned indexes on the target table; otherwise, an error is returned (SQLSTATE 428GE) and information is written to the administration log about the indexes that do not match.

If the REQUIRE MATCHING INDEXES clause is not specified and the indexes on the source table do not match all the partitioned indexes on the target table, the following behavior occurs:

1. For indexes on the target table that do not have a match on the source table and are either unique indexes or XML indexes that are defined with REJECT INVALID VALUES, the ATTACH operation fails (SQLSTATE 428GE).
2. For all other indexes on the target table that do not have a match on the source table, the index object on the source table is marked invalid during the attach operation. If the source table does not have any indexes, an empty index object is created and marked as invalid. The ATTACH operation succeeds, but the index object on the new data partition is marked as invalid. Typically, SET INTEGRITY is the next operation to run against the data partition. SET INTEGRITY forces a rebuild, if required, of the index object on data partitions that were recently attached. The index rebuild can increase the time that is required to bring the new data online.
3. Information is written to the administration log about the indexes that do not match.

DETACH PARTITION *partition-name* INTO *table-name1*

Detaches the data partition *partition-name* from the altered table, and uses the data partition to create a new table named *table-name1*. The data partition is detached from the altered table and is used to create the new table without any data movement. The specified data partition cannot be the last remaining partition of the table being altered (SQLSTATE 428G2). The table being altered to detach a partition must not be a system-period temporal table (SQLSTATE 428HZ).

When a partition is detached from a table for which either row level access control or column level access control is defined, the new table that is created for the detached data will automatically have row level access control (though not column level access control) activated to protect the detached data. Direct access to this new table returns no rows until appropriate row permissions are defined for the table or row level access control is deactivated for this table.

ADD SECURITY POLICY *policy-name*

Adds a security policy to the table. The security policy must exist at the current server (SQLSTATE 42704). The table must not already have a security policy (SQLSTATE 55065), and must not be a typed table (SQLSTATE 428DH), materialized query table (MQT), or staging table (SQLSTATE 428FG).

DROP SECURITY POLICY

Removes the security policy and all LBAC protection from the table. The table that is specified by *table-name* must be protected by a security policy (SQLSTATE 428GT). If the table has a column with data type DB2SECURITYLABEL, the data type is changed to VARCHAR (128) FOR BIT DATA. If the table has one or more protected columns, those columns become unprotected.

ADD VERSIONING USE HISTORY TABLE *history-table-name*

Specifies that the table is a system-period temporal table. The table must not already be defined as a system-period temporal table or a history table (SQLSTATE 428HM). A SYSTEM_TIME period and a transaction-start-ID column must be defined in the table (SQLSTATE 428HM).

The table must not be a materialized query table (SQLSTATE 428HM).

Historical versions of the rows in the table are retained by the database manager. The database manager records extra information that indicates when a row was inserted into the table, and when it was updated or deleted. When a row in a system-period temporal table is updated, a previous version of the row is kept. When data in a system-period temporal table is deleted, the old version of the row is inserted as a historical record. An associated history table is used to store the historical rows of the table.

References to the table can include a time period search condition to indicate which system versions of the data are to be returned.

history-table-name identifies a history table where historical rows of the system-period temporal table are kept. *history-table-name* must identify a table that exists at the current server (SQLSTATE 42704), and is not a catalog table (SQLSTATE 42832), an existing system-period temporal table, an existing history table, a declared global temporary table, a created global temporary table, a materialized query table, or a view (SQLSTATE 428HX).

The identified history table must not contain an identity column, row change timestamp column, row-begin column, row-end column, transaction start-ID column, generated expression column, or include a period (SQLSTATE 428HX).

The system-period temporal table and the identified history table must have the same number and order of columns (SQLSTATE 428HX). The following attributes for the corresponding columns of the two tables must be the same (SQLSTATE 428HX):

- Column name
- Column data type
- Column length (including inline LOB lengths), precision, and scale
- Column FOR BIT attribute for character string columns
- Column null attribute
- Column hidden attribute

If row access control or column access control is activated for the system-period temporal table and row access control is not activated on the history table, the database manager automatically activates row access control on the history table and creates a default row permission for the history table.

DROP VERSIONING

Specifies that the table is no longer a system-period temporal table. The table must be a system-period temporal table (SQLSTATE 428HZ). Historical data is no longer recorded and maintained for the table. The definition of the columns and data of the table are not changed, but the table is no longer treated as a system-period temporal table. The SYSTEM_TIME period is retained. Subsequent queries that reference the table must not specify a SYSTEM_TIME period specification for the table. The relationship between the system-period temporal table and the associated history table is removed. The history table is not dropped and the contents of the history table are not affected.

When a table is altered with DROP VERSIONING, all packages with the system-period temporal table dependency type on that table are invalidated. Other dependent objects like views and triggers that record a dependency on the table are also marked as invalid.

Rules

- Any enforced unique or primary key constraint that is defined on the table must be a superset of the distribution key, if there is one (SQLSTATE 42997).
- Primary or unique keys cannot be subsets of dimensions (SQLSTATE 429BE).
- A column can be referenced in one ADD, ALTER, or DROP COLUMN clause in a single ALTER TABLE statement only (SQLSTATE 42711).
- A column length, data type, or hidden attribute cannot be altered, nor can the column be dropped, if the table has any materialized query tables that depend on the table (SQLSTATE 42997).
- VARCHAR, VARGRAPHIC, and VARBINARY columns that was altered to be greater than 4000 and 2000, respectively, must not be used as input parameters in functions in the SYSFUN schema (SQLSTATE 22001).
- A column length cannot be altered if the table has any views enabled for query optimization that depend on the table (SQLSTATE 42997).
- The table must be put in set integrity pending state, by using the SET INTEGRITY statement with the OFF option (SQLSTATE 55019) before:
  - Adding a column with a generation expression
  - Altering the generated expression of a column
  - Changing a column to have a generated expression
- An existing column cannot be altered to become of type DB2SECURITYLABEL (SQLSTATE 42837).
- Defining a column of type DB2SECURITYLABEL fails if the table is not associated with a security policy (SQLSTATE 55064).

- A column of type DB2SECURITYLABEL cannot be altered or dropped (SQLSTATE 42817).
- An ALTER TABLE operation to mark a table as protected fails if there exists an MQT that depends on that table (SQLSTATE 55067).
- Attaching a partition to a protected partitioned table fails if the source table and the target table are not protected by using the same security policy, do not have the same row security label column, and do not have the same set of protected columns (SQLSTATE 428GE).
- If a generated column is referenced in a table-partitioning key, the generated column expression cannot be altered (SQLSTATE 42837).
- The *isolation-clause* cannot be specified in the *fullselect* of the *materialized-query-definition* (SQLSTATE 42601).
- Adding or attaching a data partition to a partitioned table fails with SQL0612N after detaching the same partition name, if asynchronous index cleanup has not finished deleting index entries for the partition (SQLSTATE 42711).

Notes

- A *REORG-recommended operation* occurs when changes that result from an ALTER TABLE statement affect the row format of existing data. When this occurs, most subsequent operations on the table are restricted until a table reorganization operation completes successfully (SQLSTATE 57007). Many REORG-recommended ALTER TABLE actions may be run against a table in a single unit of work, either in the same statement or spread over multiple statements. This is considered to be a single REORG-recommended operation. For example, dropping two columns in a single ALTER TABLE statement or in two statements in the same unit of work is considered to be a single REORG-recommended operation. There can be up to three units of work containing REORG-recommended operations before a classic offline table reorganization must be done (SQLTATE 55019). The reorg pending state and the number of REORG-recommended operations are returned from SYSIBMADM.ADMINTABINFO columns reorg_pending and num_reorg_rec_alters respectively.
- The following is the full list of REORG-recommended ALTER statements that cause a version change and place the table into a REORG-pending state:
  - DROP COLUMN
  - ALTER COLUMN SET NOT NULL
  - ALTER COLUMN DROP NOT NULL
  - ALTER COLUMN SET DATA TYPE, except in the following situations:
    - Increasing the length of a VARCHAR or VARGRAPHIC column
    - Decreasing the length of a VARCHAR or VARGRAPHIC column without truncating trailing blanks from existing data, when no indexes exist on the column
- The following table operations are allowed after a successful REORG-recommended operation occurs:
  - ALTER TABLE. However, the following operations are not allowed (SQLSTATE 57007):
    - ADD CHECK CONSTRAINT
    - ADD REFERENTIAL CONSTRAINT
    - ADD UNIQUE CONSTRAINT
  - DROP TABLE
  - RENAME TABLE
  - REORG TABLE
  - TRUNCATE TABLE
  - Table scan access of table data
- Altering a table to make it a materialized query table puts the table in set integrity pending state. If the table is defined as REFRESH IMMEDIATE, the table must be taken out of set integrity pending state before INSERT, DELETE, or UPDATE commands can be started on the table that is referenced by the

fullselect. The table can be taken out of set integrity pending state by using REFRESH TABLE or SET INTEGRITY, with the IMMEDIATE CHECKED option, to completely refresh the data in the table based on the fullselect. If the data in the table accurately reflects the result of the fullselect, the IMMEDIATE UNCHECKED option of SET INTEGRITY can be used to take the table out of set integrity pending state.

- Altering a table to change it to a REFRESH IMMEDIATE materialized query table causes any packages with INSERT, DELETE, or UPDATE usage on the table that is referenced by the fullselect to be invalidated.
- Altering a table to change from a materialized query table to a regular table causes any packages dependent on the table to be invalidated.
- Altering a table to change from a MAINTAINED BY FEDERATED_TOOL materialized query table to a regular table does not cause any change in the subscription setup of the replication tool. Because a subsequent change to a MAINTAINED BY SYSTEM materialized query table causes the replication tool to fail, you must change the subscription setting when you change a MAINTAINED BY FEDERATED_TOOL materialized query table.
- If a deferred materialized query table is associated with a staging table, the staging table is dropped if the materialized query table is altered to a regular table.
- ADD column clauses are processed before all other clauses. Other clauses are processed in the order that they are specified.
- Any columns added through an alter table operation is not automatically added to any existing view of the table.
- Adding or attaching a data partition to a partitioned table, or detaching a data partition from a partitioned table, causes any packages that depend on that table to be invalidated.
- After you detach a data partition from a data partitioned table, the STATUS of the detached partition in the SYSCAT.DATAPARTITIONS catalog can be 'L' when the partition is logically detached and the detach operation is not completed. If the STATUS of the detached partition is 'L', the following operations cannot be performed on the source table (SQLSTATE 55057):
  - Adding a unique or primary key constraint that attempts to create a nonpartitioned index
  - Adding, dropping, or renaming a column
  - Activating value compression or compression
  - Deactivating value compression or compression
- To drop the partitioning for a table, the table must be dropped and then re-created.
- To drop the organization for a table, the table must be dropped and then re-created.
- When an index is automatically created for a unique or primary key constraint, the database manager tries to use the specified constraint name as the index name with a schema name that matches the schema name of the table. If this matches an existing index name or no name for the constraint was specified, the index is created in the SYSIBM schema with a system-generated name that is formed of "SQL" followed by a sequence of 15 numeric characters that are generated by a timestamp-based function.
- When a nonpartitioned index is created on a partitioned table with attached data partitions, the index does not include the data in the attached data partitions. Use the SET INTEGRITY statement to maintain all indexes for all attached data partitions.
- When you create a partitioned index in the presence of attached data partitions (STATUS of 'A' in SYSCAT.DATAPARTITIONS), an index partition for each attached data partition is also created. If the partitioned index is being created as unique, or is an XML index that is created with REJECT INVALID VALUES, then the index creation can fail if an attached data partition contains any violations (duplicates for a unique index, or invalid values for the XML index).
- If a table has a nonpartitioned index, you cannot access a new data partition in that table within the same transaction as the add or attach operation that created the partition, if the transaction does not have the table locked in exclusive mode (SQLSTATE 57007).

- Any table that might be involved in a DELETE operation on table T is said to be *delete-connected* to T. Thus, a table is delete-connected to T if it is a dependent of T or it is a dependent of a table in which deletes from T cascade.
- A package has an insert (update/delete) usage on table T if records are inserted into (updated in/deleted from) T either directly by a statement in the package, or indirectly through constraints or triggers run by the package on behalf of one of its statements. Similarly, a package has an update usage on a column if the column is modified directly by a statement in the package, or indirectly through constraints or triggers run by the package on behalf of one of its statements.
- In a federated system, a remote base table that was created by using transparent DDL can be altered. However, transparent DDL does impose some limitations on the modifications that can be made:
  - A remote base table can be altered by adding new columns or specifying a primary key only.
  - Specific clauses that are supported by transparent DDL include:
    - ADD COLUMN *column-definition*
    - NOT NULL and PRIMARY KEY in the *column-options* clause
    - ADD *unique-constraint* (PRIMARY KEY only)
  - You cannot specify a comment on an existing column in a remote base table.
  - An existing primary key in a remote base table cannot be altered or dropped.
  - Altering a remote base table invalidates any packages that depend on the nickname that is associated with that remote base table.
  - The remote data source must support the changes being requested through the ALTER TABLE statement. Depending on how the data source responds to requests it does not support, an error might be returned or the request might be ignored.
  - An attempt to alter a remote base table that was not created by using transparent DDL returns an error.
- Any changes, whether implicit or explicit, to primary key, unique keys, or foreign keys might have the following effects on packages, indexes, and other foreign keys:

Table 129. Changes to keys, and their effects on packages, indexes, and other foreign keys

Action	**Effect on packages, indexes, and other foreign keys**
Primary key or unique key is added	There is no effect on packages, foreign keys, or existing unique keys. (If the primary or unique key uses an existing unique index that was created in a previous version and was not converted to support deferred uniqueness, the index is converted, and packages with update usage on the associated table are invalidated).
Primary key or unique key is dropped	– The index is dropped if it was automatically created for the constraint. Any packages dependent on the index are invalidated. – The index is set back to non-unique if it was converted to unique for the constraint and it is no longer system-required. Any packages dependent on the index are invalidated. – The index is set to no longer system required if it was an existing unique index that is used for the constraint. There is no effect on packages. – A primary key or unique constraint of the table cannot be dropped if it is the last enforced primary key or unique constraint whose set of columns is in the select list of an associated shadow table. – A primary key or unique constraint cannot be dropped if the table has an associated shadow table, and the primary key of the associated shadow table depends on the constraint being dropped. – All dependent foreign keys are dropped. Further action is taken for each dependent foreign key, as specified in the next row.

Table 129. Changes to keys, and their effects on packages, indexes, and other foreign keys (continued)	
Action	**Effect on packages, indexes, and other foreign keys**
Foreign key is added, dropped, altered from NOT ENFORCED to ENFORCED, or altered from ENFORCED to NOT ENFORCED	– All packages with an insert usage on the object table are invalidated. – All packages with an update usage on at least one column in the foreign key are invalidated. – All packages with a delete usage on the parent table are invalidated. – All packages with an update usage on at least one column in the parent key are invalidated.
Foreign key or a functional dependency is altered from ENABLE QUERY OPTIMIZATION to DISABLE QUERY OPTIMIZATION	All packages with dependencies on the constraint for optimization purposes are invalidated.

- Adding a column to a table results in invalidation of all packages with insert usage on the altered table. If the added column is the first user-defined structured type column in the table, packages with DELETE usage on the altered table is also invalidated.
- Adding a check or referential constraint to a table that exists and that is not in set integrity pending state, or altering the existing check or referential constraint from NOT ENFORCED to ENFORCED on an existing table that is not in set integrity pending state causes the existing rows in the table to be immediately evaluated against the constraint. If the verification fails, an error is returned (SQLSTATE 23512). If a table is in set integrity pending state, adding a check or referential constraint, or altering a constraint from NOT ENFORCED to ENFORCED does not immediately lead to the enforcement of the constraint. Issue the SET INTEGRITY statement with the IMMEDIATE CHECKED option to begin enforcing the constraint.
- Adding, altering, or dropping a check constraint results in invalidation of all packages with either an insert usage on the object table, an update usage on at least one of the columns that are involved in the constraint, or a select usage using the constraint to improve performance.
- Adding a distribution key invalidates all packages with an update usage on at least one of the columns of the distribution key.
- A distribution key that was defined by default is not affected by dropping the primary key and adding a different primary key.
- Dropping a column or changing its data type removes all runstats information from the table being altered. Runstats must be run on the table after it is again accessible. The statistical profile of the table is preserved if the table does not contain a column that was explicitly dropped.
- Altering a column (to change its length, data type, nullability, or hidden attribute) or dropping a column invalidates all packages that reference (directly or indirectly through a referential constraint or trigger) its table.
- Altering a column (to change its length, data type, nullability, or hidden attribute) regenerates views (except typed views) that depend on its table. If a problem occurs while regenerating such a view, an error is returned (SQLSTATE 56098). Any typed views that depend on the table are marked inoperative.
- Altering a column (to change its length, data type, or hidden attribute) marks all dependent triggers and SQL functions as invalid; they are implicitly recompiled on next use. If a problem occurs while regenerating such an object, an error is returned (SQLSTATE 56098).
- Altering a column (to change its length, data type, or nullability attribute) might cause errors (SQLSTATE 54010) while processing a trigger or an SQL function when a statement that involves the trigger or SQL function is prepared or bound. This can occur if the row size based on the sum of the lengths of the transition variables and transition table columns is too long. If such a trigger or SQL function is dropped, a subsequent attempt to re-create it returns an error (SQLSTATE 54040).

- A WLM activity event monitor created in an earlier version must be dropped and re-created to add new table columns that are introduced by this fix pack and any subsequent fix packs or releases.
- Altering a structured or XML type column to increase the inline length invalidates all packages that reference the table, either directly or indirectly through a referential constraint or trigger.
- Altering a structured or XML type column to increase the inline length regenerates views that depend on the table.
- A compression dictionary can be created for the XML storage object of a table only if the XML columns are added to the table, or if the table is migrated the using an online table move.
- Changing the LOCKSIZE for a table results in invalidation of all packages that have a dependency on the altered table.
- Changing VOLATILE or NOT VOLATILE CARDINALITY results in invalidation of all dynamic SQL statements that have a dependency on the altered table.
- ***Replication:*** Exercise caution when you increase the length or changing the data type of a column. The change data table that is associated with an application table might already be at or near the row size limit. The change data table must be altered before the application table, or the two tables must be altered within the same unit of work to ensure that the alteration can be completed for both tables. Consideration should be given to copies, which might also be at or near the row size limit, or reside on platforms that lack the ability to increase the length of an existing column.

  If the change data table is not altered before the Capture program processes log records with the altered attributes, the Capture program will likely fail. If a copy that contains the altered column is not altered before the subscription maintaining the copy runs, the subscription will likely fail.
- When detaching a partition from a protected table, the target table that is automatically created by the database server is protected in the same way the source table is protected.
- When a table is altered such that it becomes protected with row level granularity, any cached dynamic SQL sections that depend on such a table are invalidated. Similarly, any packages that depend on such a table are also invalidated.
- When a column of a table, T, is altered such that it becomes a protected column, any cached dynamic SQL sections that depend on table T are invalidated. Similarly, any packages that depend on table T are also invalidated.
- When a column of a table, T, is altered such that it becomes a non protected column, any cached dynamic SQL sections that depend on table T are invalidated. Similarly, any packages that depend on table T are also invalidated.
- For existing rows in the table, the value of the security label column defaults to the security label for write access of the session authorization ID at the time the ALTER statement that adds a row security label column is executed.
- ***Add materialized query:*** When a base table is altered to become a materialized query table, the label-based access control security attributes (security policy, column security labels, row security label column) are derived in the same way when creating a new materialized query table. If the base table that is altered already has label-based access control security attributes, these attributes are factored in the derivation process as follows:
  - Column access control: The existing security label for a column is aggregated with the corresponding security label that is derived from the query that defines the materialized query table.
  - Row access control: The row access control attributes are set up exactly in the same way as for a new materialized query table.
- In Db2 Version 9.7 Fix Pack 1 or later releases, new multidimensional clustering (MDC) table block indexes are partitioned. Adding a data partition to a data partitioned multidimensional clustering (MDC) table creates the corresponding empty index partitions for the new partition, including the MDC block indexes. Also, a new index partition entry is added to SYSCAT.SYSINDEXPARTITIONS for each MDC block index and for each partitioned index.
- When you attach a data partition to a partitioned MDC table created with Db2 V9.7 Fix Pack 1 or later releases, the source table that is specified by *attach-partition* can be a nonpartitioned MDC table or a single-partition partitioned MDC table.

- **If the source table is nonpartitioned:** MDC block indexes on the source table will be inherited and become the partitioned MDC indexes for the new partition after the ATTACH operation completes.
- **If the source table is partitioned:** If the source table is a partitioned MDC table that is created with Db2 V9.7 Fix Pack 1 or later releases, the block indexes are partitioned. The block indexes become the new block indexes on the partition.
- If the source partitioned MDC table is created at a level lower than Db2 V9.7 Fix Pack 1, the block indexes on the table are nonpartitioned. During the ATTACH operation, the block indexes are dropped and created as partitioned indexes similar to the other partitioned indexes on the source table.

  Issuing the SET INTEGRITY statement on the target table is required to bring the attached partition online.

  If the REQUIRE MATCHING INDEXES clause is specified, and the target table is a partitioned MDC table that is created in Db2 V9.7 Fix Pack 1 or later releases, the ALTER TABLE ... ATTACH PARTITION statement fails and returns SQL20307N (SQLSTATE 428GE). Removing the REQUIRE MATCHING INDEXES clause allows the attach process to proceed.

If the target partitioned MDC table was created at a level lower than Db2 V9.7 Fix Pack 1, the block indexes are nonpartitioned. The block indexes on the source MDC table are dropped during the ATTACH operation. Issuing a SET INTEGRITY statement on the target table is required to bring the attached partition online. New rows from the attached partition are added to existing nonpartitioned block indexes.

- When you detach a data partition from a data partitioned MDC table that is created at a level lower than Db2 V9.7 Fix Pack 1, the block indexes are nonpartitioned. The following restrictions apply:
  - Access to the newly detached table is not allowed in the same unit of work as the detach operation.
  - Block indexes on the target table, created as part of the detach operation, are rebuilt upon the first access to the table after the detach operation is committed. If the source table had any partitioned indexes before the detach operation, then the index object for the target table is marked invalid to allow for recreation of the block indexes. As a result, access time is increased while the block indexes and all other partitioned indexes are re-created.

  When you detach a partition from a partitioned MDC table created by using Db2 V9.7 Fix Pack 1 or later releases, the block indexes are partitioned, and the previous restrictions do not apply. Assuming that no other dependent objects such as dependent MQTs exist, access to the newly detached table is allowed in the same unit of work. All the partitioned indexes, including block indexes, become indexes on the target table without the need to be re-created.
- ***Considerations for implicitly hidden columns:*** A column that is defined as implicitly hidden can be explicitly referenced in an ALTER TABLE statement. For example, an implicitly hidden column can be altered or specified as part of a referential constraint, check constraint, or materialized query table definition.

  Altering a table to make some of its columns implicitly hidden can impact the behavior of data movement utilities that are working with the table. When a table contains implicitly hidden columns, utilities like IMPORT, INGEST, and LOAD require that you specify whether data for the hidden columns is included in the operation. For example, this might mean that a load operation that ran successfully before the table was altered, now fails (SQLCODE SQL2437N). Similarly, EXPORT requires that you specify whether data for the hidden columns is included in the operation.

  Data movement utilities must use the DB2_DMU_DEFAULT registry variable, or the **implicitlyhiddeninclude** or **implicitlyhiddenmissing** file type modifiers when working with tables that contain implicitly hidden columns.
- ***Row access control that is activated explicitly***: The ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for a table. When this happens, a default row permission is implicitly created and allows no access to any rows of the table, unless permitted by a row permission that is explicitly created by the security administrator. The default row permission is always enabled.

  When the table is referenced in a data manipulation statement, all enabled row permissions that have been created for the table, including the default row permission, are implicitly applied by the database manager to control which rows in the table are accessible. A row access control search

condition is derived by application of the logical 0R operator to the search condition in each enabled row permission. This derived search condition acts as a filter to the table before any user specified operations, such as predicates, grouping, ordering, are processed. This derived search condition permits the authorization IDs that are specified in the permission definitions to access certain rows in the table.

When the ACTIVATE ROW ACCESS CONTROL clause is used, all the packages and dynamically cached statements that reference the table are invalidated.

Row access control remains enforced until the DEACTIVATE ROW ACCESS CONTROL clause is used to stop enforcing it.

- ***Implicit object that is created when row access control is activated for a table***: When the ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for a table, the database manager implicitly creates a default row permission for the table. The default row permission prevents all access to the table. The implicitly created row permission resides in the same schema of the base table and has a name in the form of SYS_DEFAULT_ROW_PERMISSION__table-name ... up to 128 characters. Notice two underscores after "PERMISSION". If this name is not unique, the last 4 characters are reserved for a unique number *'nnnn'*, where *'nnnn'* is a four-alphanumeric-character string that start at '0000' and is incremented by one value each time until a unique name is found.

  The owner of the default row permission is SYSIBM. The default row permission is always enabled. The default row permission is dropped when row access control is deactivated or when the table is dropped.
- ***Activating column access control:*** The ACTIVATE COLUMN ACCESS CONTROL clause is used to activate column level access control for a table. The access to the table is not restricted but when the table is referenced in a data manipulation statement, all enabled column masks that were created for the table are applied to mask the column values referenced in the final result table.

  When column masks are used to mask the column values, they determine the values in the final result table. If a column has a column mask and the column (specifically a simple reference to a column name or a column that is embedded in an expression) appears in the outermost select list, the column mask is applied to the column to produce the values for the final result table. If the column does not appear in the outermost select list but it participates in the final result table, for example, it appears in a materialized table expression or view, the column mask is applied to the column in such a way that the masked value is included in the result table of the materialized table expression or view so that it can be used in the final result table.

  The application of column masks does not interfere with the operations of other clauses within the statement such as the WHERE, GROUP BY, HAVING, SELECT DISTINCT, and ORDER BY. The rows that are returned in the final result table remain the same, except that the values in the resulting rows might have been masked by the column masks. As such, if the masked column also appears in an ORDER BY *sort-key*, the order is based on the original column values and the masked values in the final result table might not reflect that order. Similarly, the masked values might not reflect the uniqueness that is enforced by SELECT DISTINCT.

  A column mask is applied in the following contexts:

  – The outermost SELECT clause or clauses of a SELECT or SELECT INTO statement, or if the column does not appear in the outermost select list but it participates in the final result table, one or more outermost SELECT clauses of the corresponding materialized table expression or view where the column appears.
  – The outermost SELECT clause or clauses of a SELECT FROM INSERT, SELECT FROM UPDATE, or SELECT FROM DELETE operation.
  – The outermost SELECT clause or clauses that are used to derive the new values for an INSERT, UPDATE, or MERGE statement, or a SET *transition-variable-name* assignment statement. The same masking applies to a scalar fullselect expression that appears in the outermost SELECT clause or clauses of the previously mentioned statements, the right side of a SET *host-variable* assignment statement, the VALUES INTO statement, or the VALUES statement.

  Column masks are not applied when the masked column appears in the following contexts:

  – WHERE clauses.

  - GROUP BY clauses.
  - HAVING clauses.
  - SELECT DISTINCT.
  - ORDER BY clauses.
- ***Row and column access control are not enforced when EXPLAIN tables are populated:*** Row and column access control can be enforced for EXPLAIN tables. However, the enabled row permissions and column masks are not applied when the database manager inserts rows into those tables.
- ***Row and column access control are not enforced when event monitor tables are populated:*** Row and column access control can be enforced for event monitor tables. However, the enabled row permissions and column masks are not applied when the database manager inserts rows into those tables.
- ***Row and column access control are not enforced when temporal history tables are populated:*** Row and column access control can be enforced for temporal history tables. However, the enabled row permissions and column masks are not applied when the database manager accesses those tables for operations on the system-period temporal tables.
- ***Stop enforcing row or column access control:*** The DEACTIVATE ROW ACCESS CONTROL clause is used to stop enforcing row access control for a table. The default row permission is dropped. Thereafter, when the table is referenced in a data manipulation statement, explicitly created row permissions are not applied.

  The DEACTIVATE COLUMN ACCESS CONTROL clause is used to stop enforcing column access control for a table. Thereafter, when the table is referenced in a data manipulation statement, the column masks are not applied.

  The explicitly created row permissions or column masks, if any, remain but have no effect.

  All the packages and dynamically cached statements that reference the table are invalidated when row or column access control is deactivated.
- ***Secure triggers for row and column access control:*** Triggers are used for database integrity, and as such, a balance between row and column access control (security) and database integrity is needed. Enabled row permissions and column masks are not applied to the initial values of transition variables and transition tables. Row and column access control enforced for the triggering table is also ignored for any transition variables or transition tables that are referenced in the trigger body. To ensure that no security concern exist for SQL statements in the trigger action to access sensitive data in transition variables and transition tables, the trigger must be created or altered with the SECURED option. If a trigger is not secure, row and column access control cannot be enforced for the triggering table (SQLSTATE 55019).
- ***Secure user-defined functions for row and column access control:*** If a row permission or column mask definition references a user-defined function, the function must be altered with the SECURED option because the sensitive data might be passed as arguments to the function. When a user-defined function is referenced in a data manipulation statement where a table that enforces row or column access control is referenced, and the function arguments reference the columns from such a table, if the function is not secure, this impacts the access plan selection and might yield poor performance. The database manager considers the SECURED option an assertion that declares the user has established a change control audit procedure for all changes to the user-defined function. It is assumed that such a control audit procedure is in place and that all subsequent ALTER FUNCTION statements or changes to external packages are being reviewed by this audit process.
- ***Database operations where row and column access control is not applicable:*** Row and column access control must not compromise database integrity. Columns that are involved in primary keys, unique keys, indexes, check constraints, and referential integrity must not be subject to row and column access control. Column masks can be defined for those columns but they are not applied during the process of key building or constraint or RI enforcement.
- ***Defining a system-period temporal table:*** A system-period temporal table definition includes the following aspects:
  - A system period named SYSTEM_TIME, which is defined by using a row-begin column and a row-end column. See the descriptions of AS ROW BEGIN, AS ROW END, and period-definition.

  - A transaction-start-ID column. See the description of AS TRANSACTION START ID.
  - A system-period data versioning definition that is specified on a subsequent ALTER TABLE statement by using the ADD VERSIONING action, which includes the name of the associated history table. See the description of the ADD VERSIONING clause under ALTER TABLE.

  To ensure that the history table cannot be implicitly dropped when a system-period temporal table is dropped, use the WITH RESTRICT ON DROP clause in the definition of the history table.
- ***Defining an application-period temporal table:*** An application-period temporal table definition includes an application period with the name BUSINESS_TIME. The application period is defined by using a begin column and an end column with both columns having the same data type that is either DATE or TIMESTAMP(**p**). See the description of period-definition.

  Data-change operations on an application-period temporal table can result in an automatic insert of one or two extra rows when a row is updated or deleted. When an update or delete of a row in an application-period temporal table is specified for a portion of the period represented by that row, the row is updated or deleted and one or two rows are automatically inserted to represent the portion of the row that is not changed. New values are generated for each generated column in an application-period temporal table for each row that is automatically inserted as a result of an update or delete operation on the table. If a generated column is defined as part of a unique or primary key, parent key in a referential constraint, or unique index, it is possible that an automatic insert violates a constraint or index in which case an error is returned.
- ***Considerations for transaction-start-ID columns:*** A transaction-start-ID column contains a null value if the column allows null values, and there is a row-begin column, and the value of the row-begin column is unique from values of row-begin columns that are generated for other transactions. Given that the column might contain null values, it is recommended that one of the following methods be used when you retrieve a value from the column:
  - COALESCE (transaction_start_id_col, row_begin_col)
  - CASE WHEN transaction_start_id_col IS NOT NULL THEN transaction_start_id_col ELSE row_begin_col END
- ***Considerations for system-period temporal tables and row and column access control:*** Row and column access control can be defined on both the system-period temporal table and the associated history table.
  - When a system-period temporal table is accessed, any row and column access rules that are defined on the system-period temporal table are applied to all of the rows that are returned from the system-period temporal table, regardless of whether the rows are stored in the system-period temporal table or the history table. The row and column access rules that are defined on the history table are not applied.
  - When the history table is accessed directly, the row and column access rules that are defined on the history table are applied.

  When a system-period temporal table is defined and row access control or column access control is activated for the system-period temporal table, the database manager automatically activates row access control on the history table and creates a default row permission for the history table.
- ***Considerations for column-organized tables:*** The following options can be specified to alter a column-organized table definition (underlined options are defaults):
  - ACTIVATE NOT LOGGED INITIALLY
  - ACTIVATE/DEACTIVATE COLUMN ACCESS CONTROL
  - ACTIVATE/DEACTIVATE ROW ACCESS CONTROL
  - ADD *{PRIMARY KEY | UNIQUE}* [ENFORCED | NOT ENFORCED]
  - ADD COLUMN, unless there is an outstanding asynchronous background process that is creating the table's column compression dictionary (SQL20054N)
  - ADD CONSTRAINT *<constraint-name>* CHECK NOT ENFORCED (when used with *{ENABLE | DISABLE}* QUERY OPTIMIZATION)

  - ADD CONSTRAINT *<constraint-name> {PRIMARY KEY | UNIQUE | FOREIGN KEY NOT ENFORCED}*
  - ADD MATERIALIZED QUERY
  - ADD PERIOD {SYSTEM_TIME | BUSINESS_TIME}
  - ADD RESTRICT ON DROP
  - ADD VERSIONING USE HISTORY TABLE
  - ALTER COLUMN *<column name>* SET DATA TYPE (increase VARCHAR/VARGRAPHIC column length only)
  - ALTER COLUMN <column-name> SET *{NOT HIDDEN | IMPLICITLY HIDDEN}*
  - DATA CAPTURE NONE
  - DROP *{PRIMARY KEY | UNIQUE | CONSTRAINT} <constraint-name>*
  - DROP DEFAULT
  - DROP GENERATED
  - DROP MATERIALIZED QUERY
  - DROP PERIOD {SYSTEM_TIME | BUSINESS_TIME}
  - DROP RESTRICT ON DROP
  - DROP VERSIONING
  - LOG INDEX BUILD *{NULL | OFF | ON}*
  - SET GENERATED [ALWAYS | BY DEFAULT]
  - SET DEFAULT
  - SET GENERATED AS ROW {BEGIN | END}
  - SET GENERATED AS TRANSACTION START ID

  Other options are not supported for column-organized tables.
- ***Considerations for random distribution tables***
  - Altering the table to make it a materialized query table is not supported
- ***Considerations for random distribution tables that use generate by random method***
  - The following options are not supported to alter a random distribution key column definition (in addition to those options, which are already not supported for a distribution key column in a non-random distribution table):
    - ALTER COLUMN *<column-name>* SET NOT HIDDEN
    - ALTER COLUMN *<column-name>* DROP NOT NULL
    - ALTER COLUMN *<column-name>* DROP GENERATED
    - ALTER COLUMN *<column-name>* COMPRESS *{OFF | SYSTEM DEFAULT}*
    - RENAME COLUMN *<column-name>*
  - Random distribution cannot be dropped with ALTER TABLE DROP DISTRIBUTION statement.
- ***Syntax alternatives***: The following alternatives are non-standard. They are supported for compatibility with earlier product versions or with other database products.
  - The ADD keyword is optional for:
    - Unnamed PRIMARY KEY constraints
    - Unnamed referential constraints
    - Referential constraints whose name follows the phrase FOREIGN KEY
  - The CONSTRAINT keyword can be omitted from a *column-definition* defining a references-clause
  - *constraint-name* can be specified following FOREIGN KEY (without the CONSTRAINT keyword)
  - SET SUMMARY AS can be specified in place of SET MATERIALIZED QUERY AS

- SET MATERIALIZED QUERY AS DEFINITION ONLY can be specified in place of DROP MATERIALIZED QUERY
- SET MATERIALIZED QUERY AS (fullselect) can be specified in place of ADD MATERIALIZED QUERY (fullselect)
- ADD PARTITIONING KEY can be specified in place of ADD DISTRIBUTE BY HASH; the optional USING HASHING clause can also still be specified in this case
- DROP PARTITIONING KEY can be specified in place of DROP DISTRIBUTION
- The LONG VARCHAR and LONG VARGRAPHIC data types continue to be supported but are deprecated and not recommended, especially for portable applications
- A comma can be used to separate multiple options in the *identity-alteration* clause
- PART can be specified in place of PARTITION
- VALUES can be specified in place of ENDING AT
- NOMINVALUE, NOMAXVALUE, NOCYCLE, NOCACHE, and NOORDER can be specified in place of NO MINVALUE, NO MAXVALUE, NO CYCLE, NO CACHE, and NO ORDER, respectively
- DROP EXPRESSION can be specified in place of DROP GENERATED to drop the generated expression attribute for a column.
- DROP IDENTITY can be specified in place of DROP GENERATED to drop the identity attribute for a column.
- When you specify the value of the datetime special register, NOW() can be specified in place of CURRENT_TIMESTAMP.

- When an ALTER TABLE statement invalidates an existing VIEW, the statistics profile for the invalidated VIEW is blanked.

Examples

1. Add a column named RATING, which is one character long, to the DEPARTMENT table.

```
ALTER TABLE DEPARTMENT
   ADD RATING CHAR(1)
```

2. Add a column named SITE_NOTES to the PROJECT table. Create SITE_NOTES as a varying-length column with a maximum length of 1000 bytes. The values of the column do not have an associated character set and therefore must not be converted.

```
ALTER TABLE PROJECT
   ADD SITE_NOTES  VARCHAR(1000) FOR BIT DATA
```

3. Assume a table that is called EQUIPMENT exists defined with the following columns:

```
Column Name        Data Type
EQUIP_NO           INT
EQUIP_DESC         VARCHAR(50)
LOCATION           VARCHAR(50)
EQUIP_OWNER        CHAR(3)
```

   Add a referential constraint to the EQUIPMENT table so that the owner (EQUIP_OWNER) must be a department number (DEPTNO) that is present in the DEPARTMENT table. DEPTNO is the primary key of the DEPARTMENT table. If a department is removed from the DEPARTMENT table, the owner (EQUIP_OWNER) values for all equipment that is owned by that department should become unassigned (or set to null). Give the constraint the name DEPTQUIP.

```
ALTER TABLE EQUIPMENT
     ADD CONSTRAINT DEPTQUIP
      FOREIGN KEY (EQUIP_OWNER)
        REFERENCES DEPARTMENT
           ON DELETE SET NULL
```

Also, an extra column is needed to allow the recording of the quantity that is associated with this equipment record. Unless otherwise specified, the EQUIP_QTY column should have a value of 1 and must never be null.

```
ALTER TABLE EQUIPMENT
  ADD COLUMN EQUIP_QTY
  SMALLINT NOT NULL DEFAULT 1
```

4. Alter table EMPLOYEE. Add the check constraint that is named REVENUE defined so that each employee must make a total of salary and commission greater than $30,000.

```
ALTER TABLE EMPLOYEE
  ADD CONSTRAINT REVENUE
  CHECK (SALARY + COMM > 30000)
```

5. Alter table EMPLOYEE. Drop the constraint REVENUE, which was previously defined.

```
ALTER TABLE EMPLOYEE
  DROP CONSTRAINT REVENUE
```

6. Alter a table to log SQL changes in the default format.

```
ALTER TABLE SALARY1
  DATA CAPTURE NONE
```

7. Alter a table to log SQL changes in an expanded format.

```
ALTER TABLE SALARY2
  DATA CAPTURE CHANGES
```

8. Alter the EMPLOYEE table to add four new columns with default values.

```
ALTER TABLE EMPLOYEE
   ADD COLUMN HEIGHT MEASURE   DEFAULT MEASURE(1)
   ADD COLUMN BIRTHDAY BIRTHDATE DEFAULT DATE('01-01-1850')
   ADD COLUMN FLAGS BLOB(1M)  DEFAULT BLOB(X'01')
   ADD COLUMN PHOTO PICTURE   DEFAULT BLOB(X'00')
```

The default values use various function names when specifying the default. Since MEASURE is a distinct type based on INTEGER, the MEASURE function is used. The HEIGHT column default could have been specified without the function since the source type of MEASURE is not BLOB or a datetime data type. Since BIRTHDATE is a distinct type based on DATE, the DATE function is used (BIRTHDATE cannot be used here). For the FLAGS and PHOTO columns the default is specified by using the BLOB function even though PHOTO is a distinct type. To specify a default for BIRTHDAY, FLAGS and PHOTO columns, a function must be used because the type is a BLOB or a distinct type that is sourced on a BLOB or datetime data type.

9. A table called CUSTOMERS is defined with the following columns:

```
Column Name         Data Type
BRANCH_NO           SMALLINT
CUSTOMER_NO         DECIMAL(7)
CUSTOMER_NAME       VARCHAR(50)
```

In this table, the primary key is made up of the BRANCH_NO and CUSTOMER_NO columns. To distribute the table, you need to create a distribution key for the table. The table must be defined in a table space on a single-node database partition group. The primary key must be a superset of the distribution key columns, and at least one of the columns of the primary key must be used as the distribution key. Make BRANCH_NO the distribution key as follows:

```
ALTER TABLE CUSTOMERS
  ADD DISTRIBUTE BY HASH (BRANCH_NO)
```

10. A remote table EMPLOYEE was created in a federated system by using transparent DDL. Alter the remote table EMPLOYEE to add the columns PHONE_NO and WORK_DEPT; also, add a primary key on the existing column EMP_NO and the new column WORK_DEPT.

```
ALTER TABLE EMPLOYEE
  ADD COLUMN PHONE_NO CHAR(4) NOT NULL
  ADD COLUMN WORK_DEPT CHAR(3)
  ADD PRIMARY KEY (EMP_NO, WORK_DEPT)
```

11. Alter the DEPARTMENT table to add a functional dependency FD1, then drop the functional dependency FD1 from the DEPARTMENT table.

```
ALTER TABLE DEPARTMENT
  ADD CONSTRAINT FD1
    CHECK ( DEPTNAME DETERMINED BY DEPTNO) NOT ENFORCED

ALTER TABLE DEPARTMENT
  DROP CHECK FD1
```

12. Change the default value for the WORKDEPT column in the EMPLOYEE table to 123.

```
ALTER TABLE EMPLOYEE
  ALTER COLUMN WORKDEPT
    SET DEFAULT '123'
```

13. Associate the security policy DATA_ACCESS with the table EMPLOYEE.

```
ALTER TABLE EMPLOYEE
  ADD SECURITY POLICY DATA_ACCESS
```

14. Alter the table EMPLOYEE to protect the SALARY column.

```
ALTER TABLE EMPLOYEE
  ALTER COLUMN SALARY
  SECURED WITH EMPLOYEESECLABEL
```

15. Assume that you have a table that is named SALARY_DATA that is defined with the following columns:

```
Column Name            Data Type
-----------            ---------
EMP_NAME               VARCHAR(50) NOT NULL
EMP_ID                 SMALLINT NOT NULL
EMP_POSITION           VARCHAR(100) NOT NULL
SALARY                 DECIMAL(5,2)
PROMOTION_DATE         DATE NOT NULL
```

Change this table to allow salaries to be stored in a DECIMAL(6,2) column, make PROMOTION_DATE an optional field that can be set to the null value, and remove the EMP_POSITION column.

```
ALTER TABLE SALARY_DATA
  ALTER COLUMN SALARY SET DATA TYPE DECIMAL(6,2)
  ALTER COLUMN PROMOTION_DATE DROP NOT NULL
  DROP COLUMN EMP_POSITION
```

16. Add a column named DATE_ADDED to the table BOOKS. The default value for this column is the current time stamp.

```
ALTER TABLE BOOKS
  ADD COLUMN DATE_ADDED TIMESTAMP
  WITH DEFAULT CURRENT TIMESTAMP
```

17. Alter table with label-based access control security attributes into a materialized query table. Base tables tt1 and tt2 exist and were created with the following SQL:

```
CREATE TABLE tt1
   (c1 INT SECURED WITH C, c2 DB2SECURITYLABEL) SECURITY POLICY P;
CREATE TABLE tt2
   (c3 INT SECURED WITH B, c4 DB2SECURITYLABEL) SECURITY POLICY P;
```

Table tt2 can be altered to be a materialized query table with the following SQL:

```
ALTER TABLE tt2 ADD (SELECT * FROM tt1 WHERE c1 > 10)
   DATA INITIALLY DEFERRED REFRESH DEFERRED;
```

Table tt2 becomes a materialized query table with the secure policy P. tt2.c3 has security label P.B. tt2.c4 has security label P.C and it is also DB2SECURITYLABEL.

ALTER TABLESPACE

The ALTER TABLESPACE statement is used to modify an existing table space.

You can modify a table space in the following ways:

- Add a container to, or drop a container from a DMS table space; that is, a table space created with the MANAGED BY DATABASE option.
- Modify the size of a container in a DMS table space.
- Lower the high water mark for a DMS table space through extent movement.
- Add a container to an SMS table space on a database partition that currently has no containers.
- Modify the PREFETCHSIZE setting for a table space.
- Modify the BUFFERPOOL used for tables in the table space.
- Modify the OVERHEAD setting for a table space.
- Modify the TRANSFERRATE setting for a table space.
- Modify the file system caching policy for a table space.
- Enable or disable auto-resize for a DMS or automatic storage table space.
- Rebalance a regular or large automatic storage table space.
- Modify the DATA TAG setting for a table space.
- Alter a DMS table space to an automatic storage table space.
- Modify the STOGROUP setting that is associated with a table space.

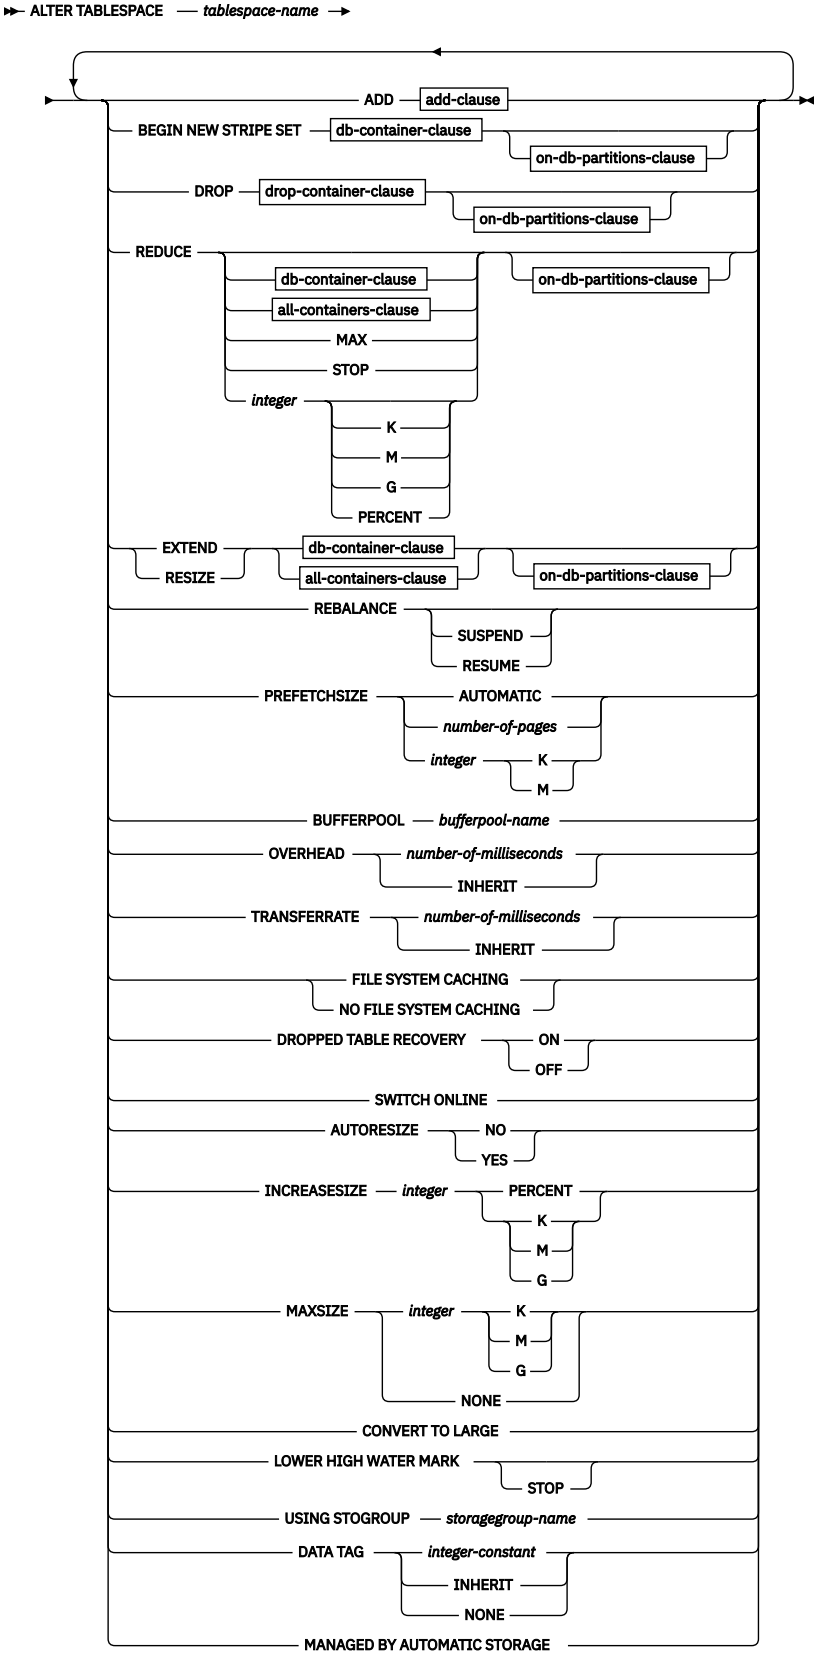
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

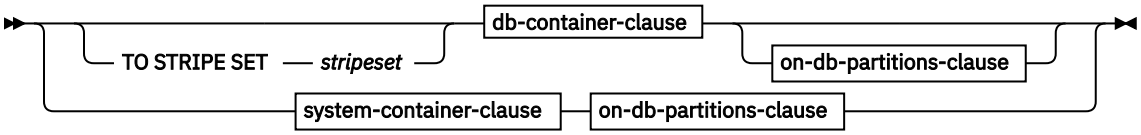
Authorization

The privileges that are held by the authorization ID of the statement must include SYSCTRL or SYSADM authority.

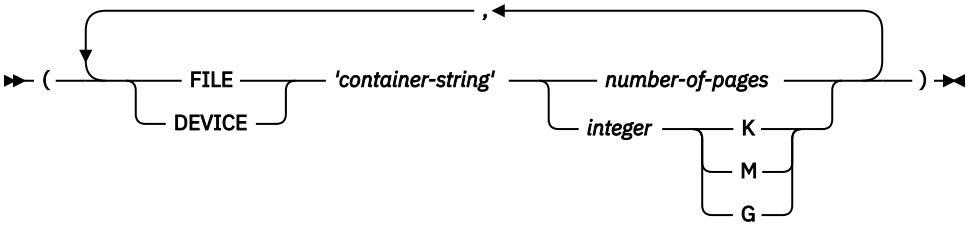
Syntax



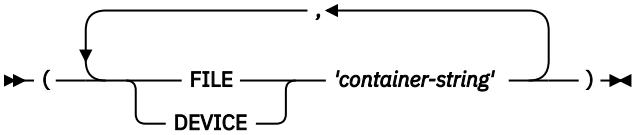
add-clause



db-container-clause

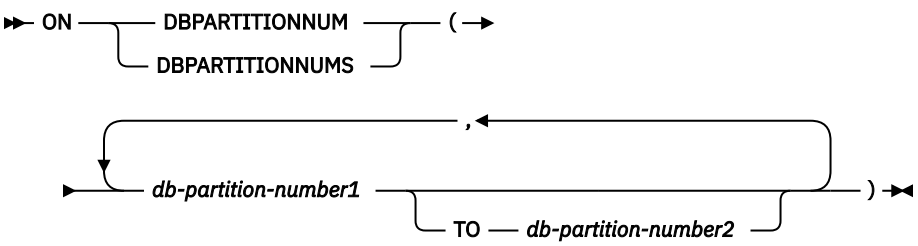


drop-container-clause

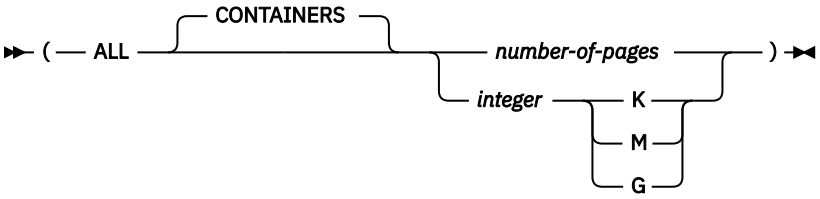


system-container-clause

on-db-partitions-clause



all-containers-clause



Description

tablespace-name
Names the table space. This is a one-part name. It is a long SQL identifier (either ordinary or delimited).

ADD
Specifies that one or more new containers are to be added to the table space.

TO STRIPE SET *stripeset*
Specifies that one or more new containers are added to the table space, and that they are placed into the provided stripe set.

BEGIN NEW STRIPE SET
Specifies that a new stripe set is to be created in the table space, and that one or more containers are to be added to this new stripe set. Subsequently, containers that are added by using the ADD option are added to this new stripe set unless TO STRIPE SET is specified.

DROP
Specifies that one or more containers are to be dropped from the table space.

REDUCE
For non-automatic storage table spaces, specifies that existing containers are to be reduced in size. The size that is specified is the size by which the existing container is decreased. If the *all-containers-clause* is specified, all containers in the table space decrease by this size. If the reduction in size results in a table space size that is smaller than the current high water mark, an attempt is made to reduce the high water mark before attempting to reduce the containers. For non-automatic storage table spaces, the REDUCE clause must be followed by a *db-container-clause* or an *all-containers-clause*.

For automatic storage table spaces, specifies that the current high water mark is to be reduced, if possible, and that the size of the table space is to be reduced to the new high water mark. For automatic storage table spaces, the REDUCE clause must not be followed by a *db-container-clause*, an *all-containers-clause*, or an *on-db-partitions-clause*.

Note: The REDUCE option with the MAX, numeric value, PERCENT, or STOP clauses, and the LOWER HIGH WATER MARK option with the STOP clause, are only available for database and automatic storage-managed table spaces with the reclaimable storage attribute. Moreover, these options must be specified and run without any other options, including each other.

The **MAX**, **STOP**, *integer* **[K | M | G]**, or *integer* **PERCENT** clause takes effect when the statement is processed and is not rolled back if the unit of work, in which the statement is executed, is rolled back.

db-container-clause
Adds one or more containers to a DMS table space. The table space must identify a DMS table space that already exists at the application server.

all-containers-clause
Extends, reduces, or resizes all of the containers in a DMS table space. The table space must identify a DMS table space that already exists at the application server.

MAX
For automatic storage table spaces with reclaimable storage, specifies that the maximum number of extents should be moved to the beginning of the table space to lower the high water mark. Additionally, the size of the table space is reduced to the new high water mark. This reduction does not apply to non-automatic storage table spaces.

STOP
For automatic storage table spaces with reclaimable storage, interrupts the extent movement operation if in progress. This option is not available for non-automatic storage table spaces.

***integer* [K | M | G] or *integer* PERCENT**
For automatic storage table spaces with reclaimable storage, specifies the numeric value by which the table space is to be reduced through extent movement. The value can be expressed in several ways:

- An integer that is specified without K, M, G, or PERCENT indicates that the numeric value is the number of pages by which the table space is to be reduced.
- An integer that is specified with K, M, or G indicates the reduction size in kilobytes, megabytes, or gigabytes. The value is first converted from bytes to number of pages based on the page size of the table space.
- An integer that is specified with PERCENT indicates the number of extents to move, as a percentage of the current size of the table space.

After extent movement is complete, the table space size is reduced to the new high water mark. This option is not available for non-automatic storage table spaces.

on-db-partitions-clause
Specifies one or more database partitions for the corresponding container operations.

EXTEND
Specifies that existing containers are to be increased in size. The size specified is the size by which the existing container is increased. If the *all-containers-clause* is specified, all containers in the table space increase by this size.

RESIZE
Specifies that the size of existing containers is to be changed. The size specified is the new size for the container. If the *all-containers-clause* is specified, all containers in the table space are changed to this size. If the operation affects more than one container, these containers must all either increase in size, or decrease in size. It is not possible to increase some while decreasing others (SQLSTATE 429BC).

db-container-clause
Adds one or more containers to a DMS table space. The table space must identify a DMS table space that already exists at the application server.

drop-container-clause
Drops one or more containers from a DMS table space. The table space must identify a DMS table space that already exists at the application server.

system-container-clause
Adds one or more containers to an SMS table space on the specified database partitions. The table space must identify an SMS table space that already exists at the application server. There must not be any containers on the specified database partitions for the table space (SQLSTATE 42921).

on-db-partitions-clause
Specifies one or more database partitions for the corresponding container operations.

all-containers-clause
Extends, reduces, or resizes all of the containers in a DMS table space. The table space must identify a DMS table space that already exists at the application server.

REBALANCE
For regular and large automatic storage table spaces, initiates the creation of containers on recently added storage paths, the drop of containers from storage paths that are in the "Drop Pending" state, or both. During the rebalance, data is moved into containers on new paths, and moved out of containers on dropped paths. The rebalance runs asynchronously in the background and does not affect the availability of data.

Note: The **SUSPEND** or **RESUME** clause takes effect when the statement is processed and is not rolled back if the unit of work, in which the statement is executed, is rolled back.

SUSPEND
Suspends the active rebalance operation on the specified table space. If no active rebalance operation exists, no action is taken and success is returned. The suspend state is persistent and if the database is deactivated while the rebalance is suspended, then upon database activation the rebalance operation is restarted from the suspended state. Suspending a rebalance operation when it is already suspended has no effect and success is returned.

RESUME
Resumes a previously suspended rebalance operation. If no active rebalance operation exists, no action is taken and success is returned. If the rebalance is PAUSED because of an online backup operation, then the table space rebalance is taken out of the suspended state but remains paused until the online backup is completed.

PREFETCHSIZE
Specifies to read in the data needed by a query before it is referenced by the query so that the query does not need to wait for I/O to be performed.

AUTOMATIC
Specifies that the prefetch size of a table space is to be updated automatically; that is, the prefetch size is managed by the database manager.

The database updates the prefetch size automatically whenever the number of containers in a table space changes (following successful execution of an ALTER TABLESPACE statement that adds or drops one or more containers). The prefetch size is also automatically updated at database startup.

Automatic updating of the prefetch size can be turned off by specifying a numeric value in the PREFETCHSIZE clause.

number-of-pages
Specifies the number of PAGESIZE pages that are read from the table space when data prefetching is being performed. The maximum value is 32767.

***integer* K | M**
Specifies the prefetch size value as an integer value followed by K (for kilobytes) or M (for megabytes). If specified in this way, the floor of the number of bytes divided by the page size is used to determine the number of pages value for prefetch size.

BUFFERPOOL *bufferpool-name*
The name of the buffer pool that is used for tables in this table space. The buffer pool must currently exist in the database (SQLSTATE 42704). The database partition group of the table space must be defined for the buffer pool (SQLSTATE 42735).

OVERHEAD *number-of-milliseconds* or OVERHEAD INHERIT
Specifies the I/O controller overhead and disk seek and latency time. This value is used to determine the cost of I/O during query optimization. For more information on tuning, refer to Table space impact on query optimization.

number-of-milliseconds
Any numeric literal (integer, decimal, or floating point) that specifies the I/O controller overhead and disk seek and latency time, in milliseconds. The number should be an average for all containers that belong to the table space, if not the same for all containers.

INHERIT
If INHERIT is specified, the table space must be defined using automatic storage and the OVERHEAD is dynamically inherited from the storage group. INHERIT cannot be specified if the table space is not defined using automatic storage (SQLSTATE 42858). If the OVERHEAD is set to undefined for the storage group and you set OVERHEAD to INHERIT, the database creation default is used.

version 10.1 For a database that was created in Db2 or later, the default I/O controller overhead and disk seek and latency time is 6.725 milliseconds.

For a database that was upgraded from a previous version of Db2 to Db2 version 10.1 or later, the default I/O controller overhead and disk seek and latency time is as follows:

- 7.5 milliseconds for a database that is created in Db2 version 9.7 or higher.

TRANSFERRATE *number-of-milliseconds* or TRANSFERRATE INHERIT
Specifies the time to read one page into memory. This value is used to determine the cost of I/O during query optimization. For more information on tuning, refer to Table space impact on query optimization.

number-of-milliseconds
Any numeric literal (integer, decimal, or floating point) that specifies the time to read one page (4 K or 8 K) into memory, in milliseconds. The number should be an average for all containers that belong to the table space, if not the same for all containers.

INHERIT
If INHERIT is specified, the table space must be defined using automatic storage and the TRANSFERRATE is dynamically inherited from the storage group. INHERIT cannot be specified if the table space is not defined using automatic storage (SQLSTATE 42858). If the DEVICE READ RATE of the storage group is set to undefined and the user sets TRANSFERRATE to INHERIT, the database creation default is used.

When an automatic storage table space inherits the TRANSFERRATE setting from the storage group it is using, the DEVICE READ RATE of the storage group, which is in megabytes per second, is converted into milliseconds per page read accounting for the table space's PAGESIZE setting of the table space. The conversion formula follows:

TRANSFERRATE = (1 / DEVICE READ RATE) * 1000 / 1024000 * PAGESIZE

For a database that was created in Db2 version 10.1 or later, the default time to read one page into memory for 4 KB PAGESIZE table space is 0.04 milliseconds.

For a database that was upgraded from a previous version of Db2 to Db2 version 10.1 or later, the default time to read one page into memory is as follows:

- 0.06 milliseconds for a database that is created in Db2 version 9.7 or higher

FILE SYSTEM CACHING or NO FILE SYSTEM CACHING
Specifies whether I/O operations are buffered or non-cached at the file system level. Changes to the I/O mode are not dynamic and will take effect on the next database activation. The default I/O mode is determined based on operating system, file system type, and in the case of SMS table spaces, data object type. For more information, see "file system caching configurations". After a non-default file system caching option is chosen, it is not possible to return to the default (unspecified) behavior. Instead, the file system caching mode must be selected explicitly.

FILE SYSTEM CACHING
All I/O operations in the target table space are cached at the file system level.

NO FILE SYSTEM CACHING
Specifies that all I/O operations are to bypass the file system-level cache. LOB and Long field data in SMS table spaces are excepted.

Note:

Db2 supports disk devices with physical sector sizes of 512 bytes or 4096 bytes.

Support for 4096 byte sector sizes is not enabled by default, and can be enabled using the **DB2_4K_DEVICE_SUPPORT** registry variable.

DROPPED TABLE RECOVERY
Specifies whether tables that have been dropped from *tablespace-name* can be recovered by using the **RECOVER DROPPED TABLE ON** option of the **ROLLFORWARD DATABASE** command. For partitioned tables, dropped table recovery is always on, even if dropped table recovery is turned off for non-partitioned tables in one or more table spaces.

ON
Specifies that dropped tables can be recovered.

OFF
Specifies that dropped tables cannot be recovered.

SWITCH ONLINE
Specifies that table spaces in OFFLINE state are to be brought online if their containers become accessible. If the containers are not accessible, an error is returned (SQLSTATE 57048).

AUTORESIZE
Specifies whether the auto-resize capability of a database-managed space (DMS) table space or an automatic storage table space is to be enabled. Auto-resizable table spaces automatically increase in size when they become full.

NO
Specifies that the auto-resize capability of a DMS table space or an automatic storage table space is to be disabled. If the auto-resize capability is disabled, any values that were previously specified for INCREASESIZE or MAXSIZE are not kept.

YES
Specifies that the auto-resize capability of a DMS table space or an automatic storage table space is to be enabled.

INCREASESIZE *integer* PERCENT or INCREASESIZE *integer* K | M | G
Specifies the amount, per database partition, by which a table space that is enabled for auto-resize is automatically increased, in the case that the table space is full and a request for space was made. The integer value must be followed by:

- PERCENT to specify the amount as a percentage of the table space size at the time that a request for space is made. When PERCENT is specified, the integer value must be in the range 0 - 100 (SQLSTATE 42615).
- K (for kilobytes), M (for megabytes), or G (for gigabytes) to specify the amount in bytes.

The actual value used might be slightly smaller or larger than what was specified, because the database manager strives to maintain consistent growth across containers in the table space.

MAXSIZE *integer* K | M | G or MAXSIZE NONE
Specifies the maximum size to which a table space that is enabled for auto-resize can automatically be increased.

integer
Specifies a hard limit on the size, per database partition, to which a DMS table space or an automatic storage table space can automatically be increased. The integer value must be followed by K (for kilobytes), M (for megabytes), or G (for gigabytes). The actual value used might be slightly smaller than what was specified, because the database manager strives to maintain consistent growth across containers in the table space.

NONE
Specifies that the table space is to be allowed to grow to file system capacity, or to the maximum table space size (described in "SQL and XML limits").

CONVERT TO LARGE
Modifies an existing regular DMS table space to be a large DMS table space. The table space and its contents are locked during conversion. This option can only be used on regular DMS table spaces. If an SMS table space, a temporary table space, or the system catalog table space is specified, an error is returned (SQLSTATE 560CF). You cannot convert a table space that contains a data partition of a partitioned table that has data partitions in another table space (SQLSTATE 560CF). Conversion cannot be reversed after being committed. If tables in the table space are defined with DATA CAPTURE CHANGES, consider the storage and capacity limits of the target table and table space.

LOWER HIGH WATER MARK
For both automatic storage and non-automatic storage table spaces with reclaimable storage, triggers the extent movement operation to move the maximum number of extents lower in the table space. Although the high water mark is lowered, the size of the table space is not reduced. This must be followed by an ALTER TABLESPACE REDUCE for automatic storage table spaces or ALTER TABLESPACE REDUCE with the *db-container-clause* or *all-containers-clause* for non-automatic storage table spaces.

Note: The LOWER HIGH WATER MARK option with the STOP clause, and the REDUCE option with the MAX, numeric value, PERCENT, or STOP clauses, are only available for database-managed and automatic storage-managed table spaces with the reclaimable storage attribute. Moreover, these options must be specified and run without any other options, including each other.

Note: This clause takes effect when the statement is processed and is not rolled back if the unit of work, in which the statement is executed, is rolled back.

STOP
For both automatic storage and non-automatic storage table spaces with reclaimable storage, interrupts the extent movement operation if in progress.

USING STOGROUP
Associates a table space with a different storage group. The data that is associated with the table space is moved from its current storage group to the specified storage group. This clause only applies to automatic storage table spaces unless specified with the MANAGED BY AUTOMATIC STORAGE clause (SQLSTATE 42858).

For automatic storage table spaces, an implicit REBALANCE is started at commit time. For a database-managed table space being converted to automatic storage-managed, an explicit REBALANCE statement is required.

In a partitioned database environment, to alter the storage group association of a table space, the table space must be defined by using automatic storage on all database partitions. If the table space on any database partition is not defined by using automatic storage, this command will fail unless specified with the MANAGED BY AUTOMATIC STORAGE clause (SQLSTATE 42858). However, it is not required that a table space has the same storage group association on all database partitions for this command to succeed in moving the table space on all database partitions.

storagegroup-name
Identifies the storage group in which table space data is stored. *storagegroup-name* must identify a storage group that exists at the current server (SQLSTATE 42704). This is a one-part name.

DATA TAG *integer-constant*, DATA TAG INHERIT or DATA TAG NONE
Specifies a tag for the data in the table space. This value can be used as part of a WLM configuration in a work class definition or referenced within a threshold definition. For more information, refer to the CREATE WORK CLASS SET, ALTER WORK CLASS SET, CREATE THRESHOLD, and ALTER THRESHOLD statements. This clause cannot be specified for USER or SYSTEM TEMPORARY table spaces or for the catalog table space (SQLSTATE 42858).

integer-constant
Valid values for *integer-constant* are integers in the range 1 - 9. If an *integer-constant* is specified and an associated storage group exists, the data tag that is specified for the table space overrides any data tag value that is specified for the associated storage group.

INHERIT
If INHERIT is specified, the table space must be defined using automatic storage and the DATA TAG is dynamically inherited from the storage group. INHERIT cannot be specified if the table space is not defined using automatic storage (SQLSTATE 42858).

NONE
If NONE is specified, there is no data tag.

MANAGED BY AUTOMATIC STORAGE
Enables automatic storage for a database-managed (DMS) table space. After automatic storage is enabled, no further container operations can be executed on the table space. The table space being converted cannot be using RAW (DEVICE) containers.

If the USING STOGROUP clause is not included when converting from a DMS table space to an automatic storage table space, then the default storage group is specified.

Rules

- The BEGIN NEW STRIPE SET clause cannot be specified in the same statement as ADD, DROP, EXTEND, REDUCE, and RESIZE, unless those clauses are being directed to different database partitions (SQLSTATE 429BC).
- The stripe set value that is specified with the TO STRIPE SET clause must be within the valid range for the table space being altered (SQLSTATE 42615).
- When adding or removing space from the table space, the following rules must be followed:
  - EXTEND and RESIZE can be used in the same statement if the size of each container is increasing (SQLSTATE 429BC).
  - REDUCE and RESIZE can be used in the same statement if the size of each container is decreasing (SQLSTATE 429BC).
  - EXTEND and REDUCE cannot be used in the same statement, unless they are being directed to different database partitions (SQLSTATE 429BC).
  - ADD cannot be used with REDUCE or DROP in the same statement, unless they are being directed to different database partitions (SQLSTATE 429BC).

  - DROP cannot be used with EXTEND or ADD in the same statement, unless they are being directed to different database partitions (SQLSTATE 429BC).
- The AUTORESIZE, INCREASESIZE, or MAXSIZE clause cannot be specified for system-managed space (SMS) table spaces, temporary table spaces that were created using automatic storage, or DMS table spaces that are defined to use raw device containers (SQLSTATE 42601).
- The INCREASESIZE or MAXSIZE clause cannot be specified if the table space is not auto-resizable (SQLSTATE 42601).
- When specifying a new maximum size for a table space, the value must be larger than the current size on each database partition (SQLSTATE 560B0).
- Container operations (ADD, EXTEND, RESIZE, DROP, or BEGIN NEW STRIPE SET) cannot be performed on automatic storage table spaces, because the database manager is controlling the space management of such table spaces (SQLSTATE 42858).
- Raw device containers cannot be added to an auto-resizable DMS table space (SQLSTATE 42601).
- The CONVERT TO LARGE clause cannot be specified in the same statement as any other clause (SQLSTATE 429BC).
- The REBALANCE clause cannot be specified with any other clause (SQLSTATE 429BC).
- The REBALANCE clause is only valid for regular and large automatic storage table spaces (SQLSTATE 42601). Temporary automatic storage table spaces should be dropped and re-created to take advantage of recently added storage paths or to have their containers removed from storage paths being dropped.
- Container operations and the REBALANCE clause cannot be specified if the table space is in the "DMS rebalancer is active" state (SQLSTATE 55041).
- The USING STOGROUP clause cannot be specified for temporary table spaces (SQLSTATE 42858).
- The following clauses are not supported in Db2 pureScale environments:
  - ADD *db-container-clause*
  - BEGIN NEW STRIPE SET *db-container-clause*
  - DROP *db-container-clause*
  - REBALANCE
  - RESIZE *db-container-clause*
  - USING STOGROUP
- The ADD, DROP, RESIZE, EXTEND, REDUCE, LOWER HIGH WATER MARK, and BEGIN_STRIPE_SET clauses cannot be used with the MANAGED BY AUTOMATIC STORAGE clause or the USING STOGROUP clause (SQLSTATE 429BC).
- The USING STOGROUP clause cannot be specified if the table space is in the "rebalancer is active "state (SQLSTATE 55041).
- ***Container size limit***: In DMS table spaces, a container must be at least two times the extent size pages in length (SQLSTATE 54039). The maximum size of a container is operating system dependent.
- ***Container definition length limit***: Each container definition requires 53 bytes plus the number of bytes necessary to store the container name. The combined length of all container definitions for the table space cannot exceed 208 kilobytes (SQLSTATE 54034).

Notes

- Default container operations are container operations that are specified in the ALTER TABLESPACE statement, but that are not explicitly directed to a specific database partition. These container operations are sent to any database partition that is not listed in the statement. If these default container operations are not sent to any database partition, because all database partitions are explicitly mentioned for a container operation, a warning is returned (SQLSTATE 01589).

- After space has been added or removed from a table space, and the transaction is committed, the contents of the table space can be rebalanced across the containers. Access to the table space is not restricted during rebalancing.
- If the table space is in OFFLINE state and the containers are accessible, the user can disconnect all applications and connect to the database again to bring the table space out of OFFLINE state. Alternatively, the SWITCH ONLINE option can bring the table space up (out of OFFLINE) while the rest of the database is still up and being used.
- If adding more than one container to a table space, it is recommended that they are added in the same statement so that the cost of rebalancing is incurred only once. An attempt to add containers to the same table space in separate ALTER TABLESPACE statements within a single transaction result in an error (SQLSTATE 55041).
- Any attempts to extend, reduce, resize, or drop containers that do not exist will raise an error (SQLSTATE 428B2).
- When extending, reducing, or resizing a container, the container type must match the type that was used when the container was created (SQLSTATE 428B2).
- An attempt to change container sizes in the same table space, using separate ALTER TABLESPACE statements but within a single transaction, will raise an error (SQLSTATE 55041).
- In a partitioned database, if more than one database partition exists on the same physical node, the same device or specific path cannot be specified for such database partitions (SQLSTATE 42730). For this environment, either specify a unique *container-string* for each database partition or use a relative path name.
- Although the table space definition is transactional and the changes to the table space definition are reflected in the catalog tables on commit, the buffer pool with the new definition cannot be used until the next time the database is started. The buffer pool that was in use when the ALTER TABLESPACE statement was issued will continue to be used in the interim.
- The REDUCE, RESIZE, or DROP option attempts to free unused extents, if necessary, for DMS table spaces, and the REDUCE option attempts to free unused extents for automatic storage table spaces. The removal of unused extents allows the table space high water mark to be reduced to a value that accurately represents the amount of space used, which, in turn, enables larger reductions in table space size.
- ***Conversion to large DMS table spaces***: After conversion, it is recommended that you issue the COMMIT statement and then increase the storage capacity of the table space.
  - If the table space is enabled for auto-resize, the MAXSIZE table space attribute should be increased, unless it is already set to NONE.
  - If the table space is not enabled for auto-resize, you have two choices:
    - Enable auto-resize by issuing the ALTER TABLESPACE statement with the AUTORESIZE YES option.
    - Add more storage by adding stripe sets, extending the size of existing containers, or both.

  Indexes for tables in a converted table space must be reorganized or rebuilt before they can support large record identifiers (RIDs).
  - The indexes can be rebuilt by using the **REORG INDEXES ALL** command with the REBUILD option. Specify the **ALLOW NO ACCESS** option for partitioned tables.
  - Alternatively, the tables can be reorganized (not INPLACE), which will rebuild all indexes and enable the tables to support more than 255 rows per page.

  To determine which tables do not yet support large RIDs, use the ADMIN_GET_TAB_INFO table function.
- The rebalance of an automatic storage table space that has containers on a storage path in the "Drop Pending" state will drop those containers. New containers might need to be created to hold the data that is being moved off the dropped containers. There must be sufficient free space on the other storage paths in the database to allow those containers to be created, otherwise an error is returned SQLSTATE 57011. The actual amount of free space that is required depends on many factors, including the location of the high-water mark extent and the stripe sets being altered. However, to ensure that the

operation is successful, there should be at least enough free space on the remaining storage paths as space is being consumed by the containers being dropped.

- If the REBALANCE clause is specified but the data server determines that there is no need to create new containers or drop existing ones, a rebalance does not occur and the statement succeeds with a warning (SQLSTATE 01690).
- In addition to adding containers on recently added paths, the REBALANCE operation can also be used to add containers on existing storage paths. Each stripe set in the table space is examined and storage paths that are not in use by a particular stripe set are identified. For each storage path identified, if sufficient free space on it exists, a new container is created. The container will have the same size as the other containers in the stripe set. This would be beneficial if a given storage path ran out of space, table spaces stopped using it (by creating stripe sets on the other paths), and more storage was given to the path. In this case, no new paths have been added, but the rebalance will attempt to include that storage path in stripe sets where it wasn't included before.
- Auto-resize can still occur while a rebalance of an automatic storage table space is in progress.
- When a DMS table space is enabled for automatic storage by the MANAGED BY AUTOMATIC STORAGE clause, that table space has one or more stripe sets of user-defined (non-automatic storage) containers and one or more stripe sets of automatic storage containers. Rebalancing the table space (by using the REBALANCE clause) removes all of the user-defined containers. The database manager might extend existing automatic storage containers or create new automatic storage containers to hold the data being moved from the user-defined containers.
- ***Syntax alternatives***: The following are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - NODE can be specified in place of DBPARTITIONNUM.
  - NODES can be specified in place of DBPARTITIONNUMS.
- For the Db2 Developer-C Edition:
  - Altering an auto-resize table space without specifying **MAXSIZE** will implicitly set **MAXSIZE** to the remaining capacity, up to the defined storage size.
  - An attempt to resize, add, or extend the container size of all table spaces larger than the defined storage size will result in a fail.
  - Altering a table space fails if there exists a subsequent ALTER TABLESPACE that hasn’t been committed.

Examples

- *Example 1:* Add a device to the PAYROLL table space.

```
ALTER TABLESPACE PAYROLL
  ADD (DEVICE '/dev/rhdisk9' 10000)
```

- *Example 2:* Change the prefetch size and I/O overhead for the ACCOUNTING table space.

```
ALTER TABLESPACE ACCOUNTING
  PREFETCHSIZE 64
  OVERHEAD 19.3
```

- *Example 3:* Create a table space TS1, then resize the containers so that all of the containers have 2000 pages. (Three different ALTER TABLESPACE statements that accomplish this resizing are shown.)

```
CREATE TABLESPACE TS1
  MANAGED BY DATABASE
  USING (FILE '/conts/cont0' 1000,
          DEVICE '/dev/rcont1' 500,
          FILE 'cont2' 700)
ALTER TABLESPACE TS1
  RESIZE (FILE '/conts/cont0' 2000,
           DEVICE '/dev/rcont1' 2000,
           FILE 'cont2' 2000)
```

OR

```
ALTER TABLESPACE TS1
  RESIZE (ALL 2000)
```

OR

```
ALTER TABLESPACE TS1
  EXTEND (FILE '/conts/cont0' 1000,
           DEVICE '/dev/rcont1' 1500,
           FILE 'cont2' 1300)
```

- *Example 4:* Extend all of the containers in the DATA_TS table space by 1000 pages.

```
ALTER TABLESPACE DATA_TS
  EXTEND (ALL 1000)
```

- *Example 5:* Resize all of the containers in the INDEX_TS table space to 100 megabytes (MB).

```
ALTER TABLESPACE INDEX_TS
  RESIZE (ALL 100 M)
```

- *Example 6:* Add three new containers. Extend the first container, and resize the second.

```
ALTER TABLESPACE TS0
  ADD (FILE 'cont2' 2000, FILE 'cont3' 2000)
  ADD (FILE 'cont4' 2000)
  EXTEND (FILE 'cont0' 100)
  RESIZE (FILE 'cont1' 3000)
```

- *Example 7:* Table space TSO exists on database partitions 0, 1 and 2. Add a new container to database partition 0. Extend all of the containers on database partition 1. Resize a container on all database partitions other than the ones that were explicitly specified (that is, database partitions 0 and 1).

```
ALTER TABLESPACE TS0
  ADD (FILE 'A' 200) ON DBPARTITIONNUM (0)
  EXTEND (ALL 200) ON DBPARTITIONNUM (1)
  RESIZE (FILE 'B' 500)
```

  The RESIZE clause is the default container clause in this example, and will be executed on database partition 2, because other operations are being explicitly sent to database partitions 0 and 1. However, if there had only been these two database partitions, the statement would have succeeded, but returned a warning (SQL1758W) that default containers had been specified but not used.

- *Example 8:* Enable the auto-resize option for table space DMS_TS1, and set its maximum size to 256 megabytes.

```
ALTER TABLESPACE DMS_TS1
  AUTORESIZE YES MAXSIZE 256 M
```

- *Example 9:* Enable the auto-resize option for table space AUTOSTORE1, and change its growth rate to 5%.

```
ALTER TABLESPACE AUTOSTORE1
  AUTORESIZE YES INCREASESIZE 5 PERCENT
```

- *Example 10:* Change the growth rate for an auto-resizable table space named MY_TS to 512 kilobytes, and set its maximum size to be as large as possible.

```
ALTER TABLESPACE MY_TS
  INCREASESIZE 512 K MAXSIZE NONE
```

- *Example 11:* Enable automatic storage for database-managed table space DMS_TS10 and have it use storage group sg_3.

```
ALTER TABLESPACE DMS_TS10
  MANAGED BY AUTOMATIC STORAGE
  USING STOGROUP sg_3
```

- *Example 12*: An ALTER DATABASE statement removed the paths `/db/filesystem1` and `/db/filesystem2` from the currently connected database. The table spaces named PRODTS1, PRODTS2, and PRODTS3 were the only table spaces using the removed paths. Rebalance these table spaces. Three ALTER TABLESPACE statements must be used.

```
ALTER TABLESPACE PRODTS1 REBALANCE
ALTER TABLESPACE PRODTS2 REBALANCE
ALTER TABLESPACE PRODTS3 REBALANCE
```

- *Example 13:* Enable automatic storage for database-managed table space DATA1 and remove all of the existing non-automatic storage containers from the table space. The first statement must be committed before the second statement can be run.

```
ALTER TABLESPACE DATA1 MANAGED BY AUTOMATIC STORAGE
ALTER TABLESPACE DATA1 REBALANCE
```

- *Example 14:* Trigger extent movement for an automatic storage table space with reclaimable storage attribute, in order to reduce the size of the containers by 10 MB.

```
ALTER TABLESPACE DMS_TS1 REDUCE 10 M
```

- *Example 15:* Trigger extent movement for a non-automatic storage table space with reclaimable storage attribute and then reduce the size of each container by 10 MB.

```
ALTER TABLESPACE TBSP1 LOWER HIGH WATER MARK
ALTER TABLESPACE TBSP1 REDUCE (ALL CONTAINERS 10 M)
```

ALTER THRESHOLD

The ALTER THRESHOLD statement alters the definition of a threshold.

Invocation

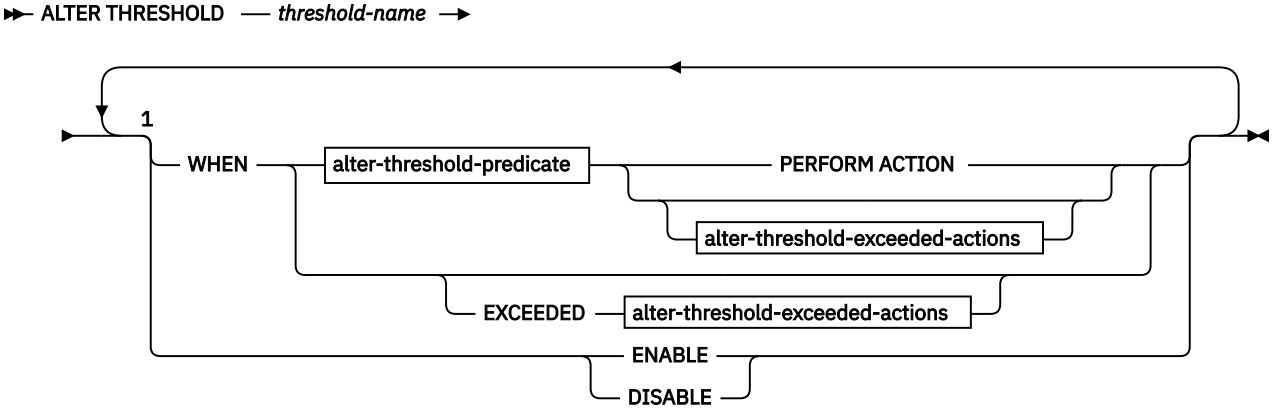
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

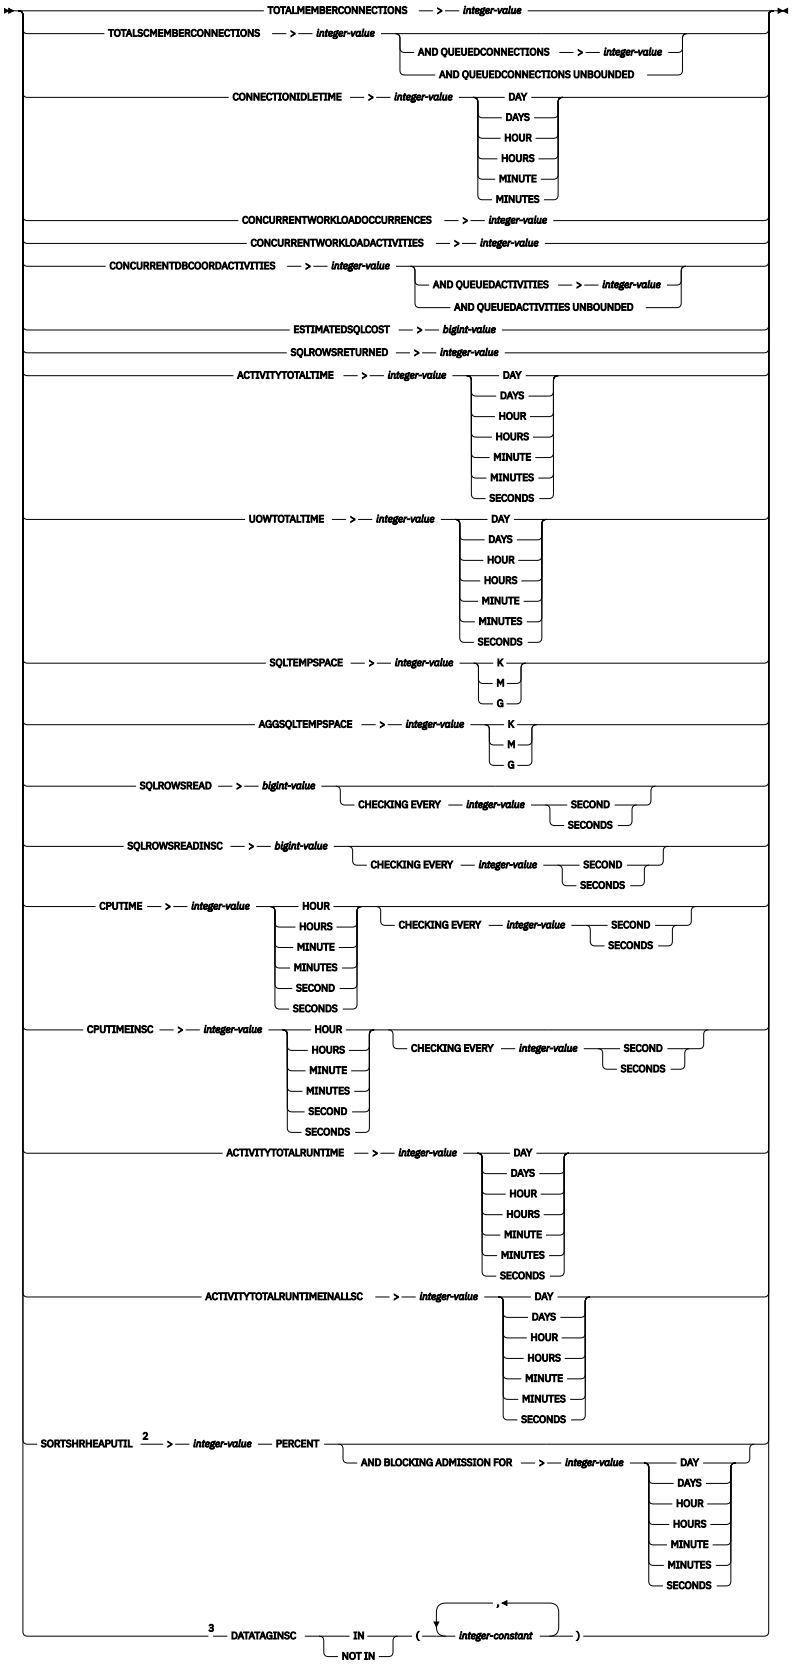
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- SQLADM authority, only if every alteration clause is a COLLECT clause
- WLMADM authority
- DBADM authority

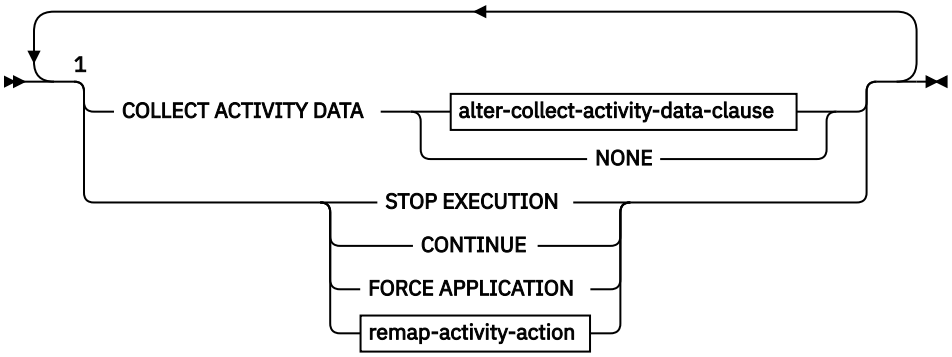
Syntax



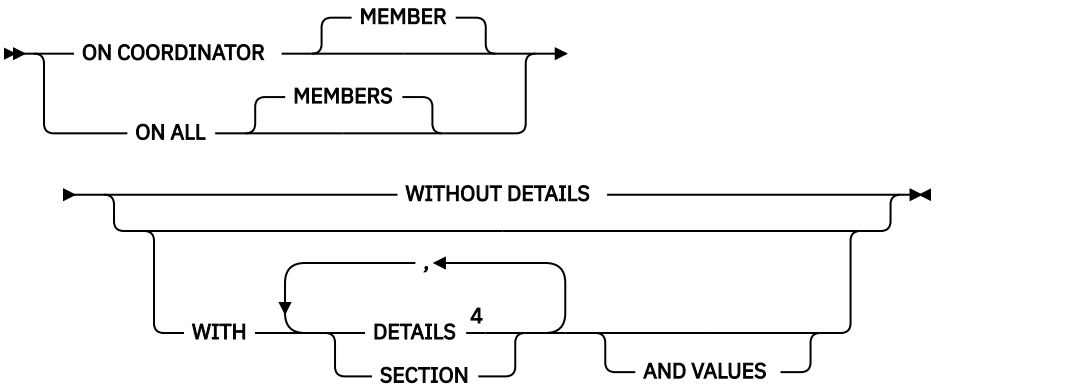
alter-threshold-predicate



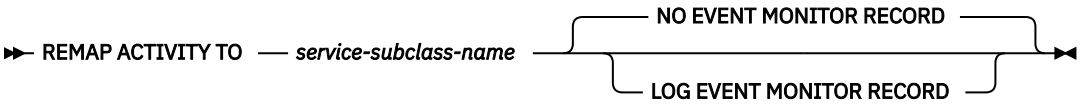
alter-threshold-exceeded-actions



alter-collect-activity-data-clause



remap-activity-action



Notes:

[1] The same clause must not be specified more than once.
[2] This feature is available in Db2 Version 11.5 Mod Pack 2 and later versions.
[3] Each data tag value can be specified only once.
[4] The DETAILS keyword is the minimum to be specified, followed by the option separated by a comma.

Description

threshold-name
Identifies the threshold to be altered. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The name must uniquely identify an existing threshold at the current server (SQLSTATE 42704).

WHEN *alter-threshold-predicate* or WHEN EXCEEDED
Replaces the existing upper bound value in the threshold predicate condition with a new upper bound value. The condition of the threshold cannot be changed to a different one.

PERFORM ACTION
When altering the value of the threshold predicate condition, specifies that the threshold exceeded action is not changed.

EXCEEDED
Specifies to keep the same threshold predicate that was specified originally for this altered threshold.

alter-threshold-predicate

TOTALMEMBERCONNECTIONS > *integer-value*
This condition defines an upper bound on the number of coordinator connections that can run concurrently on a member. This value can be zero or any positive integer (SQLSTATE 42820). A value of zero means that any new coordinator connection will be prevented from connecting. All currently running or queued connections will continue.

TOTALSCMEMBERCONNECTIONS > *integer-value*
This condition defines an upper bound on the number of coordinator connections that can run concurrently on a member in a specific service superclass. This value can be zero or any positive integer (SQLSTATE 42820). A value of zero means that any new connection will be prevented from joining the service class. All currently running or queued connections will continue.

AND QUEUEDCONNECTIONS > *integer-value* or AND QUEUEDCONNECTIONS UNBOUNDED
Specifies a queue size for when the maximum number of coordinator connections is exceeded. This value can be zero or any positive integer (SQLSTATE 42820). A value of zero means that no coordinator connections are queued. Specifying UNBOUNDED will queue every connection that exceeds the specified maximum number of coordinator connections, and the *threshold-exceeded-actions* will never be executed.

CONNECTIONIDLETIME > *integer-value* DAY | DAYS | HOUR | HOURS | MINUTE | MINUTES
This condition defines an upper bound for the amount of time the database manager will allow a connection to remain idle. This value can be any positive integer (not zero) (SQLSTATE 42820). Use a valid duration keyword to specify an appropriate unit of time for *integer-value*. This condition is enforced at the coordinator member.

If you specify the STOP EXECUTION action with CONNECTIONIDLETIME thresholds, the connection for the application is dropped when the threshold is exceeded. Any subsequent attempt by the application to access the data server will receive SQLSTATE 5U026 since the application is no longer connected to the data server.

The maximum value for this threshold is 2 147 483 640 seconds. Any value specified that has a seconds equivalent larger than 2 147 483 640 seconds will be set to this number of seconds.

CONCURRENTWORKLOADOCCURRENCES > *integer-value*
This condition defines an upper bound on the number of concurrent occurrences for the workload on each member. This value can be any positive integer (not zero) (SQLSTATE 42820).

CONCURRENTWORKLOADACTIVITIES > *integer-value*
This condition defines an upper bound on the number of concurrent coordinator activities and nested activities for the workload on each member. This value can be any positive integer (not zero) (SQLSTATE 42820).

Each nested activity must satisfy the following conditions:

- It must be a recognized coordinator activity. Any nested coordinator activity that does not fall within the recognized types of activities will not be counted. Similarly, nested subagent activities, such as remote node requests, are not counted.
- It must be directly invoked from user logic, such as a user-written procedure issuing SQL statements.

Internal SQL activities, such as those generated by the setting of a constraint or the refreshing of a materialized query table, are also not counted by this threshold, because they are initiated by the database manager and not directly invoked by user logic.

CONCURRENTDBCOORDACTIVITIES > *integer-value*
This condition defines an upper bound on the number of recognized database coordinator activities that can run concurrently on all members in the specified domain. This value can be zero or any positive integer (SQLSTATE 42820). A value of zero means that any new database coordinator activities will be prevented from executing. All currently running or queued database coordinator activities will continue. All activities are tracked by this condition, except for the following items:

- CALL statements are not controlled by this threshold, but all nested child activities started within the called routine are under this threshold's control. Anonymous blocks and autonomous routines are classified as CALL statements.
- User-defined functions are controlled by this threshold, but child activities nested in a user-defined function are not controlled. If an autonomous routine is called from within a user defined function, neither the autonomous routine nor any child activities of the autonomous routine are under threshold control.
- Trigger actions that invoke CALL statements and the child activities of these CALL statements are not controlled by this threshold. INSERT, UPDATE, or DELETE statements that can cause a trigger to activate continue to be under threshold control.

Important: Before using CONCURRENTDBCOORDACTIVITIES thresholds, be sure to become familiar with the effects that they can have on the database system.

For more information, refer to "CONCURRENTDBCOORDACTIVITIES threshold" in *Db2 Workload Management Guide and Reference*.

AND QUEUEDACTIVITIES > *integer-value* or AND QUEUEDACTIVITIES UNBOUNDED
Specifies a queue size for when the maximum number of database coordinator activities is exceeded. This value can be zero or any positive integer (SQLSTATE 42820). A value of zero means that no database coordinator activities are queued. Specifying UNBOUNDED will queue every database coordinator activity that exceeds the specified maximum number of database coordinator activities, and the *threshold-exceeded-actions* will never be executed.

Note: If a threshold action of CONTINUE is specified for a queuing threshold, it effectively makes the size of the queue unbounded, regardless of any hard value specified for the queue size.

ESTIMATEDSQLCOST > *bigint-value*
This condition defines an upper bound for the optimizer-assigned cost (in timerons) of an activity. This value can be any positive big integer (not zero) (SQLSTATE 42820). This condition is enforced at the coordinator member. Activities tracked by this condition are:

- Coordinator activities of type data manipulation language (DML).
- Nested DML activities that are invoked from user logic. Consequently, DML activities that can be initiated by the database manager through internal SQL are not tracked by this condition (unless their cost is included in the parent's estimate, in which case they are indirectly tracked).

SQLROWSRETURNED > *integer-value*
This condition defines an upper bound for the number of rows returned to a client application from the application server. This value can be any positive integer (not zero) (SQLSTATE 42820).This condition is enforced at the coordinator member. Activities tracked by this condition are:

- Coordinator activities of type DML.
- Nested DML activities that are derived from user logic. Activities that are initiated by the database manager through internal SQL are not affected by this condition.

Result sets returned from within a procedure are treated separately as individual activities. There is no aggregation of the rows that are returned by the procedure itself.

ACTIVITYTOTALTIME > *integer-value* DAY | DAYS | HOUR | HOURS | MINUTE | MINUTES | SECONDS
This condition defines an upper bound for the amount of time the database manager will allow an activity to execute, including the time the activity was queued. The definition domain for this condition must be DATABASE, work action (a threshold for a work action definition domain is created using a CREATE WORK ACTION SET or ALTER WORK ACTION SET statement, and the work action set must be applied to a workload or a database), SERVICE SUPERCLASS, SERVICE SUBCLASS, or WORKLOAD, and the enforcement scope must be DATABASE (SQLSTATE 5U037). This condition is logically enforced at the coordinator member.

The specified *integer-value* must be an integer that is greater than zero (SQLSTATE 42820). Use a valid duration keyword to specify an appropriate unit of time for *integer-value*. If the specified

time unit is SECONDS, the value must be a multiple of 10 (SQLSTATE 42615). The maximum value that can be specified for this threshold is 2 147 483 640 seconds. If any value (using the DAY, HOUR, MINUTE, or SECONDS time unit) has a seconds equivalent larger than the maximum value, an error is returned (SQLSTATE 42615).

UOWTOTALTIME > *integer-value* DAY | DAYS | HOUR | HOURS | MINUTE | MINUTES | SECONDS
This condition defines an upper bound for the amount of time the database manager will allow a unit of work to execute. This value can be any non-zero positive integer (SQLSTATE 42820). Use a valid duration keyword to specify an appropriate unit of time for *integer-value*. If the specified time unit is SECONDS, the value must be a multiple of 10 (SQLSTATE 42615). This condition is enforced at the coordinator member.

The maximum value that can be specified for this threshold is 2 147 483 640 seconds. If any value (using the DAY, HOUR, MINUTE, or SECONDS time unit) has a seconds equivalent larger than the maximum value, an error is returned (SQLSTATE 42615).

SQLTEMPSPACE > *integer-value* K | M | G
This condition defines the maximum amount of system temporary space that can be consumed by an SQL statement on a member. This value can be any positive integer (not zero) (SQLSTATE 42820).

If *integer-value K* (in either upper- or lowercase) is specified, the maximum size is 1024 times *integer-value*. If *integer-value M* is specified, the maximum size is 1 048 576 times *integer-value*. If *integer-value G* is specified, the maximum size is 1 073 741 824 times *integer-value*.

Activities tracked by this condition are:

- Coordinator activities of type DML and corresponding subagent work (subsection execution).
- Nested DML activities that are derived from user logic and their corresponding subagent work (subsection execution). Activities that are initiated by the database manager through an internal SQL are not affected by this condition.

AGGSQLTEMPSPACE > *integer-value* K | M | G

This condition defines the maximum amount of system temporary space that can be consumed by a set of statements in a service class on a member. This value can be any positive integer (not zero) (SQLSTATE 42820).

If *integer-value* K (in either upper- or lowercase) is specified, the maximum size is 1024 times *integer-value*. If *integer-value* M is specified, the maximum size is 1 048 576 times *integer-value*. If *integer-value* G is specified, the maximum size is 1 073 741 824 times *integer-value*.

Activities contributing to the aggregate that is tracked by this condition are:

- Coordinator activities of type DML and corresponding subagent work like subsection execution.
- Nested DML activities that are derived from user logic and their corresponding subagent work like subsection execution. Activities initiated by the database manager through an internal SQL statement are not affected by this condition.

SQLROWSREAD > *bigint-value*
This condition defines an upper bound on the number of rows that may be read by an activity during its lifetime on a particular member. This value can be any positive big integer (not zero) (SQLSTATE 42820). Note that the number of rows read is different from the number of rows returned, which is controlled by the SQLROWSRETURNED condition.

Activities tracked by this condition are:

- Coordinator activities of type DML and corresponding subagent work (like subsection execution).
- Internal SQL activities like those initiated by the setting of a constraint, or the refreshing of a materialized query table, are also not tracked by this threshold, because they are initiated by the database manager and not directly invoked by user logic.

CHECKING EVERY *integer-value* SECOND | SECONDS
Specifies how frequently the threshold condition is checked for an activity. The threshold is checked at the end of each request (like a fetch operation, for example) and on the interval defined by the CHECKING clause. The CHECKING clause defines an upper bound on how long a threshold violation may go undetected. The value can be any positive integer (not zero) with a maximum value of 86400 seconds (SQLSTATE 42820). Setting a low value may impact system performance negatively.

SQLROWSREADINSC > *bigint-value*
This condition defines an upper bound on the number of rows that may be read by an activity on a particular member while it is executing in a service subclass. Rows read before executing in the service subclass specified are not counted. This value can be any positive big integer (not zero) (SQLSTATE 42820). Note that the number of rows read is different from the number of rows returned, which is controlled by the SQLROWSRETURNED condition.

Activities tracked by this condition are:

- Coordinator activities of type DML and corresponding subagent work (like subsection execution).
- Internal SQL activities like those initiated by the setting of a constraint, or the refreshing of a materialized query table, are also not tracked by this threshold, because they are initiated by the database manager and not directly invoked by user logic.

CHECKING EVERY *integer-value* SECOND | SECONDS
Specifies how frequently the threshold condition is checked for an activity. The threshold is checked at the end of each request (like a fetch operation, for example) and on the interval defined by the CHECKING clause. The CHECKING clause defines an upper bound on how long a threshold violation may go undetected. The value can be any positive integer (not zero) with a maximum value of 86400 seconds (SQLSTATE 42820). Setting a low value may impact system performance negatively.

CPUTIME > *integer-value* DAY | DAYS | HOUR | HOURS | MINUTE | MINUTES | SECOND | SECONDS
This condition defines an upper bound for the amount of processor time that an activity may consume during its lifetime on a particular member. The processor time tracked by this threshold is measured from the time that the activity starts executing. This value can be any positive integer (not zero) (SQLSTATE 42820).

Activities tracked by this condition are:

- Coordinator activities of type DML and corresponding subagent work (like subsection execution).
- Internal SQL activities, like those initiated by the setting of a constraint or the refreshing of a materialized query table, are also not tracked by this threshold, because they are initiated by the database manager and not directly invoked by user logic.
- Activities of type CALL. For CALL activities, the processor time tracked for the procedure does not include the processor time used by any child activity or by any fenced mode processes. The threshold condition will be checked only upon return from user logic to the database engine. For example: During execution of a trusted routine, the threshold condition will be checked only when the routine issues a request to the database engine.

CHECKING EVERY *integer-value* SECOND | SECONDS
Specifies how frequently the threshold condition is checked for an activity. The granularity of the CPUTIME threshold is approximately this number multiplied by the degree of parallelism for the activity. For example: If the threshold is checked every 60 seconds and the degree of parallelism is 2, the activity might use an extra 2 minutes of processor time instead of 1 minute before the threshold violation is detected. The value can be any positive integer (not zero) with a maximum value of 86400 seconds (SQLSTATE 42820). Setting a low value may impact system performance negatively.

CPUTIMEINSC > *integer-value* DAY | DAYS | HOUR | HOURS | MINUTE | MINUTES | SECOND | SECONDS
This condition defines an upper bound for the amount of processor time that an activity may consume on a particular member while it is executing in a service subclass. The processor time

tracked by this threshold is measured from the time that the activity starts executing in the service subclass identified in the threshold domain. Any processor time used before that point is not counted toward the limit imposed by this threshold. This value can be any positive integer (not zero) (SQLSTATE 42820).

Activities tracked by this condition are:

- Coordinator activities of type DML and corresponding subagent work (like subsection execution).
- Internal SQL activities, like those initiated by the setting of a constraint or the refreshing of a materialized query table, are also not tracked by this threshold, because they are initiated by the database manager and not directly invoked by user logic.
- Activities of type CALL. For CALL activities, the processor time tracked for the procedure does not include the processor time used by any child activity or by any fenced mode processes. The threshold condition will be checked only upon return from user logic to the database engine. For example: During execution of a trusted routine, the threshold condition will be checked only when the routine issues a request to the database engine.

CHECKING EVERY *integer-value* SECOND | SECONDS
Specifies how frequently the threshold condition is checked for an activity. The granularity of the CPUTIMEINSC threshold is approximately this number multiplied by the degree of parallelism for the activity. For example: If the threshold is checked every 60 seconds and the degree of parallelism is 2, the activity might use an extra 2 minutes of processor time instead of 1 minute before the threshold violation is detected. The value can be any positive integer (not zero) with a maximum value of 86400 seconds (SQLSTATE 42820). Setting a low value may impact system performance negatively.

ACTIVITYTOTALRUNTIME > *integer-value* DAY | DAYS | HOUR | HOURS | MINUTE | MINUTES | SECONDS
This condition is used to define an upper bound for the amount of time the database manager allows an activity to run. The amount of time does not include the time that the activity was queued by a WLM concurrency threshold. The definition domain for this condition must be one of the following thresholds (SQLSTATE 5U037):

- Database
- Service superclass
- Service subclass
- Statement
- Workload
- Work action [1]

1. A threshold for a work action definition domain is created by using a CREATE WORK ACTION SET or ALTER WORK ACTION SET statement. The work action set must be applied to a workload or a database.

The enforcement scope must be DATABASE (SQLSTATE 5U037).

The specified *integer-value* must be an integer that is greater than zero (SQLSTATE 42820). Use a valid duration keyword to specify an appropriate unit of time for *integer-value*. If the specified time unit is SECONDS, the value must be a multiple of 10 (SQLSTATE 42615). The maximum value that can be specified for this threshold is 2 147 483 640 seconds. If any value for the DAY, HOUR, MINUTE, or SECONDS time unit has a seconds equivalent larger than the maximum value, an error is returned (SQLSTATE 42615).

ACTIVITYTOTALRUNTIMEINALLSC > *integer-value* DAY | DAYS | HOUR | HOURS | MINUTE | MINUTES | SECONDS
This condition is used to define an upper bound for the amount of time the database manager allows an activity to run. The amount of time does not include the time that the activity was queued by a WLM concurrency threshold. The execution time that is tracked by this threshold is measured from the time that the activity starts running.

The definition domain for this condition must be service subclass (SERVICE CLASS specifying the UNDER clause), and the enforcement scope must be DATABASE (SQLSTATE 5U037).

The specified *integer-value* must be an integer that is greater than zero (SQLSTATE 42820). Use a valid duration keyword to specify an appropriate unit of time for *integer-value*. If the specified time unit is SECONDS, the value must be a multiple of 10 (SQLSTATE 42615). The maximum value that can be specified for this threshold is 2 147 483 640 seconds. If any value for the DAY, HOUR, MINUTE, or SECONDS time unit has a seconds equivalent larger than the maximum value, an error is returned (SQLSTATE 42615).

SORTSHRHEAPUTIL > *integer-value* PERCENT

Attention: This feature is available in Db2 Version 11.5 Mod Pack 2 and later versions.

This condition defines the maximum shared sort memory that may be requested by a query as a percentage of the total database shared sort memory (sheapthres_shr). When the adaptive workload manager is enabled, the threshold considers both estimated and actual memory requirements for a query. Any positive integer between 1 to 100 can be specified as a percent value.

Activities tracked by this condition are:

- Coordinator activities of type data manipulation language (DML).
- Nested DML activities that are directly invoked from user logic.

AND BLOCKING ADMISSION FOR *integer-value*

Specifies that action will only be taken if the sort memory requirements are exceeded, work is currently queued behind the violating activity and WLM admission control has not admitted any requests for the specified amount of time. For work inside the WLM admission queue, this condition will only be evaluated once a request reaches the front of the admission queue. Every time a request is allowed by admission control, the queue time will be reset. If multiple requests violate this threshold a cascading effect will be observed until something that doesn't violate this threshold is found or the last request is reached (as in, no other requests behind).

The maximum value for this threshold is 2147483640 seconds. Any value specified that has a seconds equivalent larger than 2147483640 seconds will be set to this number of seconds. The time specified has a minimum accuracy of 10 seconds, so any value specified is subject to accuracy of this amount. A value of zero is equivalent to not specifying a BLOCKING ADMISSION FOR clause.

DATATAGINSC IN *(integer-constant, ...)*

This condition defines one or more data tag values specified on a table space that the activity touches. The data tag on a table space, or its underlying storage group (where applicable), can be either not be set or set to a value from 1 to 9. If the activity touches a table space that has no data tag set (either at the table space or storage group level), this threshold will not have any affect on that activity. The definition domain for this condition must be a service subclass (SERVICE CLASS specifying the UNDER clause), and the enforcement scope must be DATABASE PARTITION (SQLSTATE 5U037). This condition is enforced independently at each database partition.

Activities tracked by this condition are:

- Coordinator activities of type data manipulation language (DML).
- Nested DML activities that are directly invoked from user logic.

DML activities that can be initiated by the database manager through internal SQL are not tracked by this condition.

This threshold is only checked when a scan is opened on a table or when an insert is performed into a table. Fetching data from a table after a scan has been opened will not violate the threshold.

DATATAGINSC NOT IN *(integer-constant, ...)*

This condition defines one or more data tag values not specified on a table space that the activity touches. The data tag on a table space, or its underlying storage group (where applicable), can be

either not be set or set to a value from 1 to 9. If the activity touches a table space that has no data tag set (either at the table space or storage group level), this threshold will not have any affect on that activity. The definition domain for this condition must be a service subclass (SERVICE CLASS specifying the UNDER clause), and the enforcement scope must be DATABASE PARTITION (SQLSTATE 5U037). This condition is enforced independently at each database partition.

Activities tracked by this condition are:

- Coordinator activities of type data manipulation language (DML).
- Nested DML activities that are directly invoked from user logic.

DML activities that can be initiated by the database manager through internal SQL are not tracked by this condition.

This threshold is only checked when a scan is opened on a table or when an insert is performed into a table. Fetching data from a table after a scan has been opened will not violate the threshold.

alter-threshold-exceeded-actions

Specifies what action is to be taken when a condition is exceeded. Each time that a condition is exceeded, an event is recorded in all active threshold violations event monitors.

COLLECT ACTIVITY DATA

Specifies that data about each activity that exceeded the threshold is to be sent to any active activities event monitor when the activity completes. The COLLECT ACTIVITY DATA setting does not apply to non-activity thresholds, such as CONNECTIONIDLETIME, TOTALDBPARTITIONCONNECTIONS, TOTALSCPARTITIONCONNECTIONS, CONCURRENTWORKLOADOCCURRENCES, or UOWTOTALTIME.

alter-collect-activity-data-clause

ON COORDINATOR MEMBER

Specifies that the activity data is to be collected only at the coordinator member of the activity.

ON ALL MEMBERS

Specifies that the activity data is to be collected at all members on which the activity is processed. On remote members, a record for the activity may be captured multiple times as the activity comes and goes on those members. For predictive thresholds, activity information is collected at all members only if you also specify the CONTINUE action for exceeded thresholds. For reactive thresholds, the ON ALL MEMBERS clause has no effect and activity information is always collected only at the coordinator member. For both predictive and reactive thresholds, any input data values, section information, or values will be collected only at the coordinator member.

WITHOUT DETAILS

Specifies that data about each activity associated with the work class for which this work action is defined should be sent to any active activities event monitor, when the activity completes execution. Details about statement, compilation environment, and section environment data are not sent.

WITH

DETAILS

Specifies that statement and compilation environment data is to be sent to any active activities event monitor, for those activities that have them. Section environment data is not sent.

SECTION

Specifies that statement, compilation environment, section environment data, and section actuals are to be sent to any active activities event monitor for those activities that have them. DETAILS must be specified if SECTION is specified. For predictive thresholds, section actuals will be collected on any member where the activity data is collected. For reactive thresholds, section actuals will be collected only on the coordinator member.

AND VALUES
Specifies that input data values are to be sent to any active activities event monitor, for those activities that have them. This data does not include SQL statements that are compiled by using the REOPT ALWAYS bind option.

NONE
Specifies that activity data should not be collected for each activity that exceeds the threshold.

STOP EXECUTION
The execution of the activity is stopped and an error is returned (SQLSTATE 5U026). In the case of the UOWTOTALTIME threshold, the unit of work is rolled back.

CONTINUE
The execution of the activity is not stopped. When the condition also has a queue, this option causes queuing to extend beyond the size of the queue.

FORCE APPLICATION
The application is forced off the system (SQLSTATE 55032). This action can only be specified for the UOWTOTALTIME threshold.

remap-activity-action

REMAP ACTIVITY TO *service-subclass-name*
The activity is mapped to *service-subclass-name*. The execution of the activity is not stopped. This action is valid only for in-service-class and in-all-service-class thresholds like CPUTIMEINSC, SQLROWSREADINSC, DATATAGINSC IN and DATATAGINSC NOT IN and ACTIVITYTOTALRUNTIMEINALLSC thresholds (SQLSTATE 5U037). The service-subclass-name must identify an existing service subclass under the same superclass associated with the threshold (SQLSTATE 5U037). The service-subclass-name cannot be the same as the associated service subclass of the threshold (SQLSTATE 5U037).

NO EVENT MONITOR RECORD
Specifies that no threshold violation record will be written.

LOG EVENT MONITOR RECORD
Specifies that if a THRESHOLD VIOLATIONS event monitor exists and is active, a threshold violation record is written to it.

ENABLE or DISABLE
Specifies whether or not the threshold is enabled for use by the database manager.

ENABLE
The threshold is used by the database manager to restrict the execution of database activities. Currently running database activities will continue to execute without the restriction of this threshold.

DISABLE
The threshold is not used by the database manager to restrict the execution of database activities. New database activities will not be restricted by this threshold. Thresholds with a queue, for example TOTALSCMEMBERCONNECTIONS or CONCURRENTDBCOORDACTIVITIES, must be disabled before they can be dropped.

Notes

- Thresholds can be defined on different aspects of database behavior to monitor and control that behavior. When a threshold is defined on activities, unless otherwise specified, it will be enforced only during the actual execution of SQL statements, not including compilation time, and the load utility.
- The CONCURRENTWORKLOADOCCURRENCES threshold and the CONCURRENTWORKLOADACTIVITIES threshold differ in scope. CONCURRENTWORKLOADOCCURRENCES controls how many connections can map to a workload definition simultaneously, and CONCURRENTWORKLOADACTIVITIES controls how many activities each connection that is mapped to the workload definition can submit concurrently.
- Changes are written to the system catalog, but do not take effect until after a COMMIT statement, even for the connection that issues the statement.

- Only one uncommitted WLM-exclusive SQL statement at a time is allowed across all partitions. If an uncommitted WLM-exclusive SQL statement is executing, subsequent WLM-exclusive SQL statements will wait until the current WLM-exclusive SQL statement commits or rolls back.
- The new value for a threshold affects only database activities that start executing after the alter operation commits.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - DATABASE PARTITION can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - DATABASE PARTITIONS can be specified in place of MEMBERS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - TOTALDBPARTITIONCONNECTIONS can be specified in place of TOTALMEMBERCONNECTIONS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - TOTALSCPARTITIONCONNECTIONS can be specified in place of TOTALSCMEMBERCONNECTIONS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.

Example

Alter the threshold MAXBIGQUERIESCONCURRENCY to a maximum of three activities rather than two.

```
ALTER THRESHOLD MAXBIGQUERIESCONCURRENCY
  WHEN CONCURRENTDBCOORDACTIVITIES > 3
  STOP EXECUTION
```

Because this is a threshold with a queue, the threshold cannot be dropped unless it is disabled, as follows:

```
ALTER THRESHOLD MAXBIGQUERIESCONCURRENCY DISABLE
```

ALTER TRIGGER

The ALTER TRIGGER statement changes the description of a trigger at the current server.

Invocation

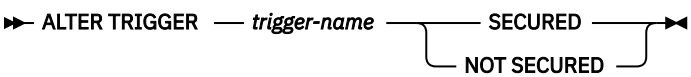
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following privileges:

- SECADM authority
- CREATE_SECURE_OBJECT authority

Syntax



Description

trigger-name
Identifies the trigger to be altered. The *trigger-name* must identify a trigger that exists at the current server (SQLSTATE 42704).

NOT SECURED or SECURED
Specifies whether the trigger is considered secure.

SECURED
Specifies the trigger is considered secure. SECURED must be specified for a trigger whose subject table is a table on which row level or column level access control has been activated (SQLSTATE 428H8). Similarly, SECURED must be specified for a trigger that is created on a view and one or more of the underlying tables in that view definition has row level or column level access control activated (SQLSTATE 428H8).

NOT SECURED
Specifies the trigger is considered not secure. Altering a trigger from secured to not secured fails if the trigger is defined on a table for which row or column level access control is activated (SQLSTATE 428H8). Similarly, altering a trigger from secured to not secured fails if the trigger is defined on a view and one or more of the underlying tables in that view definition has row or column level access control activated (SQLSTATE 428H8).

Examples

- *Example 1*: Alter trigger TRIGGER1 to SECURED.

```
ALTER TRIGGER TRIGGER1 SECURED
```

- *Example 2*: Alter trigger TRIGGER1 to NOT SECURED.

```
ALTER TRIGGER TRIGGER1 NOT SECURED
```

ALTER TRUSTED CONTEXT

The ALTER TRUSTED CONTEXT statement modifies the definition of a trusted context at the current server.

Important: The DATA_ENCRYPT authentication type is deprecated and might be removed in a future release. To encrypt data in-transit between clients and Db2 databases, we recommend that you use the Db2 database system support of Transport Layer Security (TLS). For more information, see Encryption of data in transit

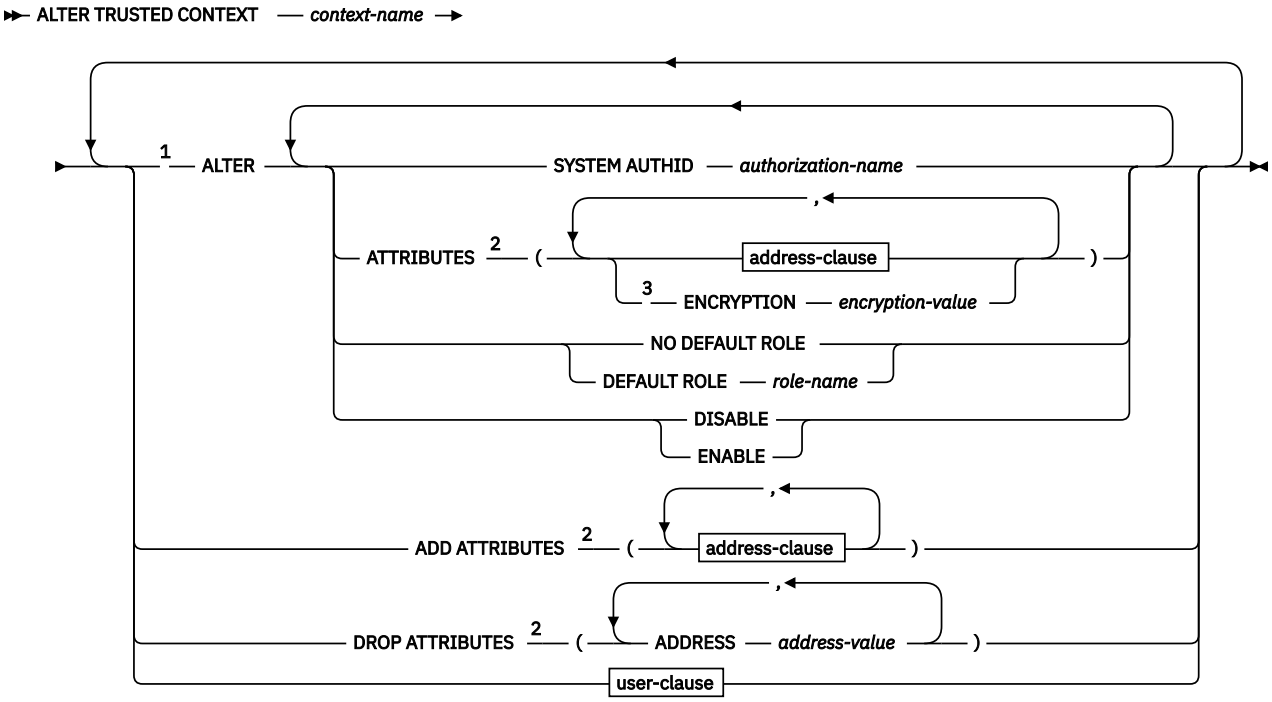
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

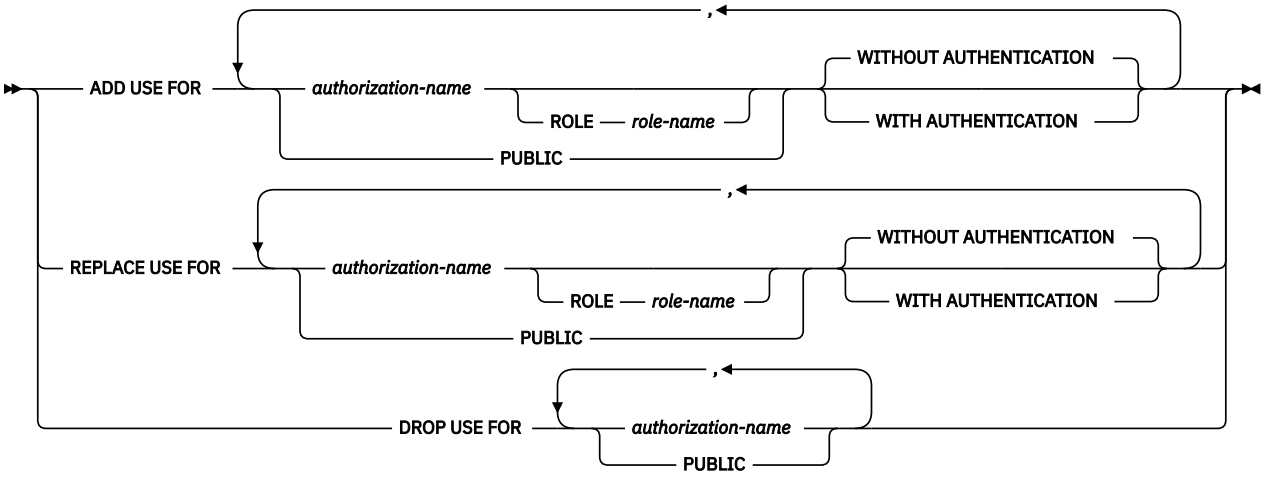
The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



address-clause

user-clause



Notes:

[1] Each of the ATTRIBUTES, DEFAULT ROLE, ENABLE, and WITH USE clauses can be specified at most once (SQLSTATE 42614).

[2] Each attribute name and corresponding value must be unique (SQLSTATE 4274D).

[3] ENCRYPTION cannot be specified more than once (SQLSTATE 42614); however, WITH ENCRYPTION can be specified for each ADDRESS that is specified.

Description

context-name
Identifies the trusted context that is to be altered. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *context-name* must identify a trusted context that exists at the current server (SQLSTATE 42704).

ALTER
Alters the options and attributes of a trusted context.

SYSTEM AUTHID *authorization-name*
Specifies that the context is a connection established by system authorization ID *authorization-name*, which must not be associated with an existing trusted context (SQLSTATE 428GL). It cannot be the authorization ID of the statement (SQLSTATE 42502).

ATTRIBUTES (...)
Specifies a list of one or more connection trust attributes, upon which the trusted context is defined, that are to be modified. Existing values for the specified attributes are replaced with the new values. If an attribute is not currently part of the trusted context definition, an error is returned (SQLSTATE 4274C). Attributes that are not specified retain their previous values.

ADDRESS *address-value*
Specifies the actual communication address used by the client to communicate with the database server. The only protocol supported is TCP/IP. Previous ADDRESS values for the specified trusted context are removed. The ADDRESS attribute can be specified multiple times, but each *address-value* pair must be unique for the set of attributes (SQLSTATE 4274D).

When establishing a trusted connection, if multiple values are defined for the ADDRESS attribute of a trusted context, a candidate connection is considered to match this attribute if the address used by the connection matches any of the defined values for the ADDRESS attribute of the trusted context.

address-value
Specifies a string constant that contains the value to be associated with the ADDRESS trust attribute. The *address-value* must be an IPv4 address, an IPv6 address, or a secure domain name.

- An IPv4 address must not contain leading spaces and is represented as a dotted decimal address. An example of an IPv4 address is 9.112.46.111. The value 'localhost' or its equivalent representation '127.0.0.1' will not result in a match; the real IPv4 address of the host must be specified instead.
- An IPv6 address must not contain leading spaces and is represented as a colon hexadecimal address. An example of an IPv6 address is 2001:0DB8:0000:0000:0008:0800:200C:417A. IPv4-mapped IPv6 addresses (for example, ::ffff:192.0.2.128) will not result in a match. Similarly, 'localhost' or its IPv6 short representation '::1' will not result in a match.
- A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is corona.torolab.ibm.com. When a domain name is converted to an IP address, the result of this conversion could be a set of one or more IP addresses. In this case, an incoming connection is said to match the ADDRESS attribute of a trusted context object if the IP address from which the connection originates matches any of the IP addresses to which the domain name was converted. When creating a trusted context object, it is advantageous to provide domain name values for the ADDRESS attribute instead of static IP addresses, particularly in Dynamic Host Configuration Protocol (DHCP) environments. With DHCP, a device can have a different IP address each time it connects to the network. So, if a static IP address is provided for the ADDRESS attribute of a trusted context object, some device might acquire a trusted connection unintentionally. Providing domain names for the ADDRESS attribute of a trusted context object avoids this problem in DHCP environments.

WITH ENCRYPTION *encryption-value*
Specifies the minimum level of encryption of the data stream or network encryption for this specific *address-value*. This *encryption-value* overrides the global ENCRYPTION attribute setting for this specific *address-value*.

encryption-value
Specifies a string constant that contains the value to be associated with the ENCRYPTION trust attribute for this specific *address-value*. The *encryption-value* must be one of the following values (SQLSTATE 42615):

- NONE, no specific level of encryption is required
- LOW, a minimum of light encryption is required; the authentication type on the database manager must be DATA_ENCRYPT if an incoming connection is to match the encryption setting for this specific address
- HIGH, Secure Sockets Layer (SSL) encryption, or equivalent, must be used for data communication between the database client and the database server if an incoming connection is to match the encryption setting for this specific address

ENCRYPTION *encryption-value*
Specifies the minimum level of encryption of the data stream or network encryption. The default is NONE.

encryption-value
Specifies a string constant that contains the value to be associated with the ENCRYPTION trust attribute for this specific *address-value*. The *encryption-value* must be one of the following values (SQLSTATE 42615):

- NONE, no specific level of encryption is required for an incoming connection to match the ENCRYPTION attribute of this trusted context object
- LOW, a minimum of light encryption is required; the authentication type on the database manager must be DATA_ENCRYPT if an incoming connection is to match the ENCRYPTION attribute of this trusted context object
- HIGH, Secure Sockets Layer (SSL) encryption, or equivalent, must be used for data communication between the database client and the database server if an incoming connection is to match the ENCRYPTION attribute of this trusted context object

For details about the ENCRYPTION trust attribute, see "CREATE TRUSTED CONTEXT".

NO DEFAULT ROLE or DEFAULT ROLE *role-name*
Specifies whether or not a default role is associated with a trusted connection that is based on this trusted context. If a trusted connection for this context is active, the change comes into effect on the next switch user request or a new connection request.

NO DEFAULT ROLE
Specifies that the trusted context does not have a default role.

DEFAULT ROLE *role-name*
Specifies that *role-name* is the default role for the trusted context. The *role-name* must identify a role that exists at the current server (SQLSTATE 42704). This role is used with the user in a trusted connection, based on this trusted context, when the user does not have a user-specific role defined as part of the definition of the trusted context.

ENABLE or DISABLE
Specifies whether the trusted context is enabled or disabled.

ENABLE
Specifies that the trusted context is enabled.

DISABLE
Specifies that the trusted context is disabled. A trusted context that is disabled is not considered when a trusted connection is established.

ADD ATTRIBUTES
Specifies a list of one or more additional trust attributes on which the trusted context is defined.

ADDRESS *address-value*

Specifies the actual communication address used by the client to communicate with the database server. The only protocol supported is TCP/IP. The ADDRESS attribute can be specified multiple times, but each *address-value* pair must be unique for the set of attributes (SQLSTATE 4274D).

When establishing a trusted connection, if multiple values are defined for the ADDRESS attribute of a trusted context, a candidate connection is considered to match this attribute if the address used by the connection matches any of the defined values for the ADDRESS attribute of the trusted context.

address-value

Specifies a string constant that contains the value to be associated with the ADDRESS trust attribute. The *address-value* must be an IPv4 address, an IPv6 address, or a secure domain name.

- An IPv4 address must not contain leading spaces and is represented as a dotted decimal address. An example of an IPv4 address is 9.112.46.111. The value 'localhost' or its equivalent representation '127.0.0.1' will not result in a match; the real IPv4 address of the host must be specified instead.
- An IPv6 address must not contain leading spaces and is represented as a colon hexadecimal address. An example of an IPv6 address is 2001:0DB8:0000:0000:0008:0800:200C:417A. IPv4-mapped IPv6 addresses (for example, ::ffff:192.0.2.128) will not result in a match. Similarly, 'localhost' or its IPv6 short representation '::1' will not result in a match.
- A domain name is converted to an IP address by the domain name server, where a resulting IPv4 or IPv6 address is determined. An example of a domain name is corona.torolab.ibm.com.

WITH ENCRYPTION *encryption-value*

Specifies the minimum level of encryption of the data stream or network encryption for this specific *address-value*. This *encryption-value* overrides the global ENCRYPTION attribute setting for this specific *address-value*.

encryption-value

Specifies a string constant that contains the value to be associated with the ENCRYPTION trust attribute for this specific *address-value*. The *encryption-value* must be one of the following values (SQLSTATE 42615):

- NONE, no specific level of encryption is required
- LOW, a minimum of light encryption is required; the authentication type on the database manager must be DATA_ENCRYPT if an incoming connection is to match the encryption setting for this specific address
- HIGH, Secure Sockets Layer (SSL) encryption, or equivalent, must be used for data communication between the database client and the database server if an incoming connection is to match the ENCRYPTION attribute of this trusted context object

DROP ATTRIBUTES

Specifies that one or more attributes are to be dropped from the definition of the trusted context. If the attribute and attribute value pair is not currently part of the trusted context definition, an error is returned (SQLSTATE 4274C).

ADDRESS *address-value*

Specifies that the identified communication address is to be removed from the definition of the trusted context. The *address-value* specifies a string constant that contains the value of an existing ADDRESS trust attribute.

ADD USE FOR

Specifies additional users who can use a trusted connection based on this trusted context. If the definition of a trusted context allows access by PUBLIC and a list of users, the specifications for a user override the specifications for PUBLIC.

authorization-name
Specifies that the trusted connection can be used by the specified *authorization-name*. The *authorization-name* must not identify an authorization ID that is already defined to use the trusted context, and must not be specified more than once in the ADD USE FOR clause (SQLSTATE 428GM). It must also not be the authorization ID of the statement (SQLSTATE 42502).

ROLE *role-name*
Specifies that *role-name* is the role to be used for the user. The *role-name* must identify a role that exists at the current server (SQLSTATE 42704). The role explicitly specified for the user overrides any default role associated with the trusted context.

PUBLIC
Specifies that a trusted connection that is based on this trusted context can be used by any user. PUBLIC must not already be defined to use the trusted context, and PUBLIC must not be specified more than once in the ADD USE FOR clause (SQLSTATE 428GM).

WITHOUT AUTHENTICATION or WITH AUTHENTICATION
Specifies whether or not switching the current user on a trusted connection based on this trusted context requires authentication.

WITHOUT AUTHENTICATION
Specifies that switching the current user on a trusted connection based on this trusted context to this user does not require authentication.

WITH AUTHENTICATION
Specifies that switching the current user on a trusted connection based on this trusted context to this user requires authentication.

REPLACE USE FOR
Specifies that the way in which a particular user or PUBLIC uses the trusted context is to change.

authorization-name
Specifies the *authorization-name* of the user whose use of the trusted connection is to change. The trusted context must already be defined to allow use by the *authorization-name* (SQLSTATE 428GN), and *authorization-name* must not be specified more than once in the REPLACE USE FOR clause (SQLSTATE 428GM). It must also not be the authorization ID of the statement (SQLSTATE 42502).

ROLE *role-name*
Specifies that *role-name* is the role for the user. The *role-name* must identify a role that exists at the current server (SQLSTATE 42704). The role explicitly specified for the user overrides any default role associated with the trusted context.

PUBLIC
Specifies that the attributes for use of the trusted connection by PUBLIC are to change. The trusted context must already be defined to allow use by PUBLIC (SQLSTATE 428GN), and PUBLIC must not be specified more than once in the REPLACE USE FOR clause (SQLSTATE 428GM).

WITHOUT AUTHENTICATION or WITH AUTHENTICATION
Specifies whether or not switching the current user on a trusted connection based on this trusted context requires authentication.

WITHOUT AUTHENTICATION
Specifies that switching the current user on a trusted connection based on this trusted context to this user does not require authentication.

WITH AUTHENTICATION
Specifies that switching the current user on a trusted connection based on this trusted context to this user requires authentication.

DROP USE FOR
Specifies who can no longer use the trusted context. The users who are removed from the definition of the trusted context are those users who are currently allowed to use the trusted context. If one or more, but not all, users can be removed from the definition of the trusted context, the specified

users are removed and a warning is returned (SQLSTATE 01682). If none of the specified users can be removed from the definition of the trusted context, an error is returned (SQLSTATE 428GN).

authorization-name
Removes the ability of the specified authorization ID to use this trusted context.

PUBLIC
Removes the ability of all users (except the system authorization ID and individual authorization IDs that have been explicitly enabled) to use this trusted context.

Rules

- A trusted context-exclusive SQL statement must be followed by a COMMIT or a ROLLBACK statement (SQLSTATE 5U021). Trusted context-exclusive SQL statements are:
  - CREATE TRUSTED CONTEXT, ALTER TRUSTED CONTEXT, or DROP (TRUSTED CONTEXT)
- A trusted context-exclusive SQL statement cannot be issued within a global transaction; for example, an XA transaction or a global transaction that is initiated as part of two-phase commit for federated transactions (SQLSTATE 51041).

Notes

- When providing an IP address as part of a trusted context definition, the address must be in the format that is in effect for the network. For example, providing an address in an IPv6 format when the network is IPv4 will not result in a match. In a mixed environment, it is advantageous to specify both the IPv4 and the IPv6 representations of the address, or better yet, to specify a secure domain name (for example, corona.torolab.ibm.com), which hides the address format details.
- Only one uncommitted trusted context-exclusive SQL statement is allowed at a time across all database partitions. If an uncommitted trusted context-exclusive SQL statement is executing, subsequent trusted context-exclusive SQL statements will wait until the current trusted context-exclusive SQL statement commits or rolls back.
- Changes are written to the system catalog but do not take effect until they are committed, even for the connection that issues the statement.
- ***Order of operations:*** The order of operations within an ALTER TRUSTED CONTEXT statement is:
  - DROP
  - ALTER
  - ADD ATTRIBUTES
  - ADD USE FOR
  - REPLACE USE FOR
- ***Effect of changes on existing trusted connections:*** If trusted connections exist for the trusted context being altered, the connections remain trusted with the definition in effect before the ALTER TRUSTED CONTEXT statement until the next switch user request or the connection terminates. If the trusted context is disabled while trusted connections for this context are active, the connections remain trusted until the next switch user request or the connection terminates. If trust attributes are changed with the ALTER TRUSTED CONTEXT statement, trusted connections that exist at the time of the ALTER TRUSTED CONTEXT statement that use the trusted context are allowed to continue.
- ***Role privileges:*** If there is no role associated with the user or the trusted context, only the privileges associated with the user are applicable. This is the same as not being in a trusted context.

Examples

- *Example 1:* Assume that trusted context APPSERVER exists and that it is enabled. Issue an ALTER TRUSTED CONTEXT statement to allow Bill to use the trusted context APPSERVER, but put the trusted context in the disabled state.

```
ALTER TRUSTED CONTEXT APPSERVER
  DISABLE
  ADD USE FOR BILL
```

- *Example 2:* Assume that trusted context SECUREROLE exists. Issue an ALTER TRUSTED CONTEXT statement to modify the existing user Joe to use the trusted context with authentication and to add everyone else to use the trusted context without authentication.

```
ALTER TRUSTED CONTEXT SECUREROLE
  REPLACE USE FOR JOE WITH AUTHENTICATION
  ADD USE FOR PUBLIC WITHOUT AUTHENTICATION
```

- *Example 3:* Assume that trusted context SECUREROLEENCRYPT exists with ADDRESS attribute values '9.13.55.100' and '9.12.30.112', and ENCRYPTION attribute value 'NONE'. Issue an ALTER statement to modify the ADDRESS attribute values and the encryption attribute to 'LOW'.

```
ALTER TRUSTED CONTEXT SECUREROLEENCRYPT
  ALTER ATTRIBUTES (ADDRESS '9.12.155.200',
    ENCRYPTION 'LOW')
```

ALTER TYPE (structured)

The ALTER TYPE statement is used to add or drop attributes or method specifications of a user-defined structured type. Properties of existing methods can also be altered.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

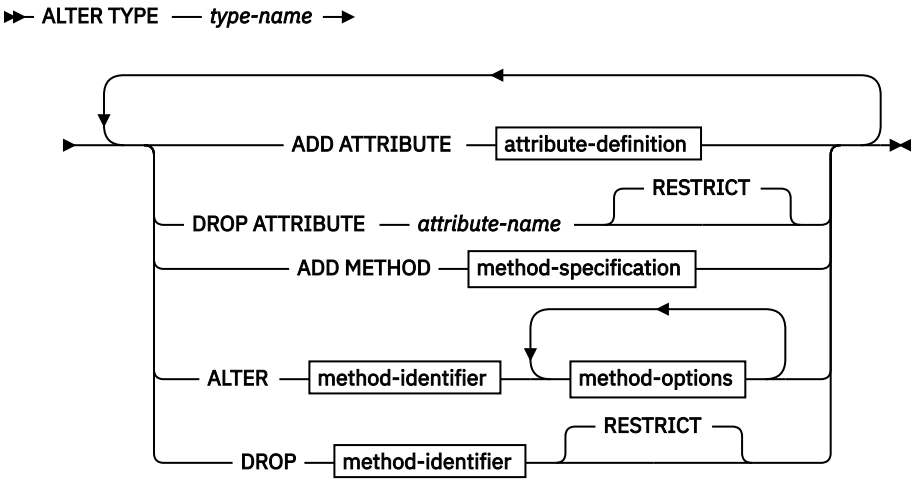
- ALTERIN privilege on the schema of the type
- Owner of the type, as recorded in the OWNER column of the SYSCAT.DATATYPES catalog view
- SCHEMAADM authority on the schema of the type
- DBADM authority

To alter a method to be not fenced, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

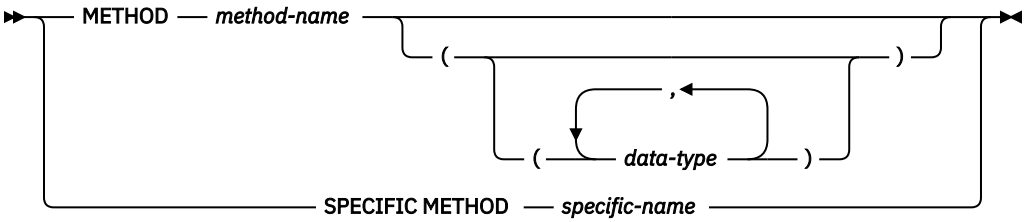
- CREATE_NOT_FENCED_ROUTINE authority on the database
- DBADM authority

To alter a method to be fenced, no additional authorities or privileges are required.

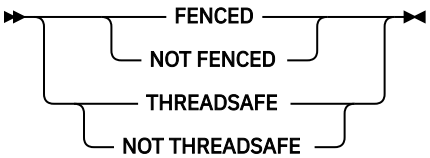
Syntax



method-identifier



method-options



Description

type-name

Identifies the structured type to be changed. It must be an existing type defined in the catalog (SQLSTATE 42704), and the type must be a structured type (SQLSTATE 428DP). In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names.

ADD ATTRIBUTE

Adds an attribute after the last attribute of the existing structured type.

attribute-definition

Defines the attributes of the structured type.

attribute-name

Specifies a name for the attribute. The name cannot be the same as any other attribute of this structured type (including inherited attributes) or any subtype of this structured type (SQLSTATE 42711).

A number of names used as keywords in predicates are reserved for system use, and may not be used as an *attribute-name* (SQLSTATE 42939). The names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH and the comparison operators.

data-type 1
Specifies the data type of the attribute. It is one of the data types listed under CREATE TABLE, other than XML (SQLSTATE 42601). The data type must identify an existing data type (SQLSTATE 42704). If *data-type* is specified without a schema name, the type is resolved by searching the schemas on the SQL path. The description of various data types is given in "CREATE TABLE". If the attribute data type is a reference type, the target type of the reference must be a structured type that exists (SQLSTATE 42704).

To prevent type definitions that, at run time, would permit an instance of the type to directly, or indirectly, contain another instance of the same type or one of its subtypes, there is a restriction that a type may not be defined such that one of its attribute types directly or indirectly uses itself (SQLSTATE 428EP).

Character and graphic string data types cannot specify string units of CODEUNITS32.

lob-options
Specifies the options associated with LOB types (or distinct types based on LOB types). For a detailed description of lob-options, see "CREATE TABLE".

DROP ATTRIBUTE
Drops an attribute of the existing structured type.

attribute-name
The name of the attribute. The attribute must exist as an attribute of the type (SQLSTATE 42703).

RESTRICT
Enforces the rule that no attribute can be dropped if *type-name* is used as the type of an existing table, view, column, attribute nested inside the type of a column, or an index extension.

ADD METHOD *method-specification*
Adds a method specification to the type identified by *type-name*. The method cannot be used until a separate CREATE METHOD statement is used to give the method a body. For more information about *method-specification*, see "CREATE TYPE (Structured)".

ALTER *method-identifier*
Uniquely identifies an instance of a method that is to be altered. The specified method may or may not have an existing method body. Methods declared as LANGUAGE SQL cannot be altered (SQLSTATE 42917).

method-identifier

METHOD *method-name*
Identifies a particular method, and is valid only if there is exactly one method instance with the name *method-name* for the type *type-name*. The identified method can have any number of parameters defined for it. If no method by this name exists for the type, an error (SQLSTATE 42704) is raised. If there is more than one instance of the method for the type, an error (SQLSTATE 42725) is raised.

METHOD *method-name (data-type,...)*
Provides the method signature, which uniquely identifies the method. The method resolution algorithm is not used.

method-name
Specifies the name of the method for the type *type-name*.

(data-type,...)
Values must match the data types that were specified (in the corresponding position) on the CREATE TYPE statement. The number of data types, and the logical concatenation of the data types, is used to identify the specific method instance.

If a data type is unqualified, the type name is resolved by searching the schemas on the SQL path. This also applies to data type names specified for a REFERENCE type.

It is not necessary to specify the length, precision, or scale for the parameterized data types. Instead, an empty set of parentheses can be coded to indicate that these attributes are to be ignored when looking for a data type match.

FLOAT() cannot be used (SQLSTATE 42601), because the parameter value indicates different data types (REAL or DOUBLE).

If length, precision, or scale is coded, the value must exactly match that specified in the CREATE TYPE statement.

A type of FLOAT(*n*) does not need to match the defined value for *n*, because 0 < *n* < 25 means REAL, and 24 < *n* < 54 means DOUBLE. Matching occurs on the basis of whether the type is REAL or DOUBLE.

If no method with the specified signature exists for the type in the named or implied schema, an error (SQLSTATE 42883) is raised.

SPECIFIC METHOD *specific-name*
Identifies a particular method, using the name that is specified or defaulted to at method creation time. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The *specific-name* must identify a specific method instance in the named or implied schema; otherwise, an error (SQLSTATE 42704) is raised.

method-options
Specifies the options that are to be altered for the method.

FENCED or NOT FENCED
Specifies whether the method is considered safe to run in the database manager operating environment's process or address space (NOT FENCED), or not (FENCED). Most methods have the option of running as FENCED or NOT FENCED.

If a method is altered to be FENCED, the database manager insulates its internal resources (for example, data buffers) from access by the method. In general, a method running as FENCED will not perform as well as a similar one running as NOT FENCED.

CAUTION: Use of NOT FENCED for methods that were not adequately coded, reviewed, and tested can compromise the integrity of a Db2 database. Db2 databases take some precautions against many of the common types of inadvertent failures that might occur, but cannot guarantee complete integrity when NOT FENCED methods are used.

A method declared as NOT THREADSAFE cannot be altered to be NOT FENCED (SQLSTATE 42613).

If a method has any parameters defined AS LOCATOR, and was defined with the NO SQL option, the method cannot be altered to be FENCED (SQLSTATE 42613).

This option cannot be altered for LANGUAGE OLE methods (SQLSTATE 42849).

THREADSAFE or NOT THREADSAFE
Specifies whether a method is considered safe to run in the same process as other routines (THREADSAFE), or not (NOT THREADSAFE).

If the method is defined with LANGUAGE other than OLE:

- If the method is defined as THREADSAFE, the database manager can invoke the method in the same process as other routines. In general, to be threadsafe, a method should not use any global or static data areas. Most programming references include a discussion of writing threadsafe routines. Both FENCED and NOT FENCED methods can be THREADSAFE. If the method is defined with LANGUAGE OLE, THREADSAFE may not be specified (SQLSTATE 42613).
- If the method is defined as NOT THREADSAFE, the database manager will never invoke the method in the same process as another routine. Only a fenced method can be NOT THREADSAFE (SQLSTATE 42613).

DROP *method-identifier*
Uniquely identifies an instance of a method that is to be dropped. The specified method must not have an existing method body (SQLSTATE 428ER). Use the DROP METHOD statement to drop the method

body before using ALTER TYPE DROP METHOD. Methods implicitly generated by the CREATE TYPE statement (such as mutators and observers) cannot be dropped (SQLSTATE 42917).

RESTRICT
Indicates that the specified method is restricted from having an existing method body. Use the DROP METHOD statement to drop the method body before using ALTER TYPE DROP METHOD.

Rules

- Adding or dropping an attribute is not allowed for type *type-name* (SQLSTATE 55043) if either:
  - The type or one of its subtypes is the type of an existing table or view.
  - There exists a column of a table whose type directly or indirectly uses *type-name*. The terms *directly uses* and *indirectly uses* are defined in "Structured types".
  - The type or one of its subtypes is used in an index extension.
- A type may not be altered by adding attributes so that the total number of attributes for the type, or any of its subtypes, exceeds 4082 (SQLSTATE 54050).
- ADD ATTRIBUTE option:
  - ADD ATTRIBUTE generates observer and mutator methods for the new attribute. These methods are similar to those generated when a structured type is created (see "CREATE TYPE (Structured)"). If these methods conflict with or override any existing methods or functions, the ALTER TYPE statement fails (SQLSTATE 42745).
  - If the INLINE LENGTH for the type (or any of its subtypes) was explicitly specified by the user with a value less than 292, and the attributes added cause the specified inline length to be less than the size of the result of the constructor function for the altered type (32 bytes plus 10 bytes per attribute), then an error results (SQLSTATE 42611).
- DROP ATTRIBUTE option:
  - An attribute that is inherited from an existing supertype cannot be dropped (SQLSTATE 428DJ).
  - DROP ATTRIBUTE drops the mutator and observer methods of the dropped attributes, and checks dependencies on those dropped methods.
- DROP METHOD option:
  - An original method that is overridden by other methods cannot be dropped (SQLSTATE 42893).

Notes

- It is not possible to alter a method that is in the SYSIBM, SYSFUN, or SYSPROC schema (SQLSTATE 42832).
- When a type is altered by adding or dropping an attribute, all packages are invalidated that depend on functions or methods that use this type or a subtype of this type as a parameter or a result.
- When an attribute is added to or dropped from a structured type:
  - If the INLINE LENGTH of the type was calculated by the system when the type was created, the INLINE LENGTH values are automatically modified for the altered type, and all of its subtypes to account for the change. The INLINE LENGTH values are also automatically (recursively) modified for all structured types where the INLINE LENGTH was calculated by the system and the type includes an attribute of any type with a changed INLINE LENGTH.
  - If the INLINE LENGTH of any type affected by adding or dropping attributes was explicitly specified by a user, then the INLINE LENGTH for that particular type is not changed. Special care must be taken for explicitly specified inline lengths. If it is likely that a type will have attributes added later on, then the inline length, for any uses of that type or one of its subtypes in a column definition, should be large enough to account for the possible increase in length of the instantiated object.
  - If new attributes are to be made visible to application programs, existing transform functions must be modified to match the new structure of the data type.

- In a partitioned database environment, the use of SQL in external user-defined functions or methods is not supported (SQLSTATE 42997).
- ***Privileges***: The EXECUTE privilege is not given for any methods explicitly specified in the ALTER TYPE statement until a method body is defined using the CREATE METHOD statement. The owner of the user-defined type has the ability to drop the method specification using the ALTER TYPE statement.

Examples

- *Example 1:* The ALTER TYPE statement can be used to permit a cycle of mutually referencing types and tables. Consider mutually referencing tables named EMPLOYEE and DEPARTMENT.

  The following sequence would allow the types and tables to be created.

```
CREATE TYPE DEPT ...
CREATE TYPE EMP ... (including attribute named DEPTREF of type REF(DEPT))
ALTER TYPE DEPT ADD ATTRIBUTE MANAGER REF(EMP)
CREATE TABLE DEPARTMENT OF DEPT ...
CREATE TABLE EMPLOYEE OF EMP (DEPTREF WITH OPTIONS SCOPE DEPARTMENT)
ALTER TABLE DEPARTMENT ALTER COLUMN MANAGER ADD SCOPE EMPLOYEE
```

  The following sequence would allow these tables and types to be dropped.

```
DROP TABLE EMPLOYEE   (the MANAGER column in DEPARTMENT becomes unscoped)
DROP TABLE DEPARTMENT
ALTER TYPE DEPT DROP ATTRIBUTE MANAGER
DROP TYPE EMP
DROP TYPE DEPT
```

- *Example 2:* The ALTER TYPE statement can be used to create a type with an attribute that references a subtype.

```
CREATE TYPE EMP ...
CREATE TYPE MGR UNDER EMP ...
ALTER TYPE EMP ADD ATTRIBUTE MANAGER REF(MGR)
```

- *Example 3:* The ALTER TYPE statement can be used to add an attribute. The following statement adds the SPECIAL attribute to the EMP type. Because the inline length was not specified on the original CREATE TYPE statement, the inline length is recalculated by adding 13 (10 bytes for the new attribute + attribute length + 2 bytes for a non-LOB attribute).

```
ALTER TYPE EMP ...
  ADD ATTRIBUTE SPECIAL CHAR(1)
```

- *Example 4:* The ALTER TYPE statement can be used to add a method associated with a type. The following statement adds a method called BONUS.

```
ALTER TYPE EMP ...
  ADD METHOD BONUS (RATE DOUBLE)
    RETURNS INTEGER
    LANGUAGE SQL
    CONTAINS SQL
    NO EXTERNAL ACTION
    DETERMINISTIC
```

  Note that the BONUS method cannot be used until a CREATE METHOD statement is issued to create the method body. If it is assumed that type EMP includes an attribute called SALARY, then the following example shows a method body definition.

```
CREATE METHOD BONUS(RATE DOUBLE) FOR EMP
  RETURN CAST(SELF.SALARY * RATE AS INTEGER)
```

ALTER USAGE LIST

The ALTER USAGE LIST statement alters the definition of a usage list.

Invocation

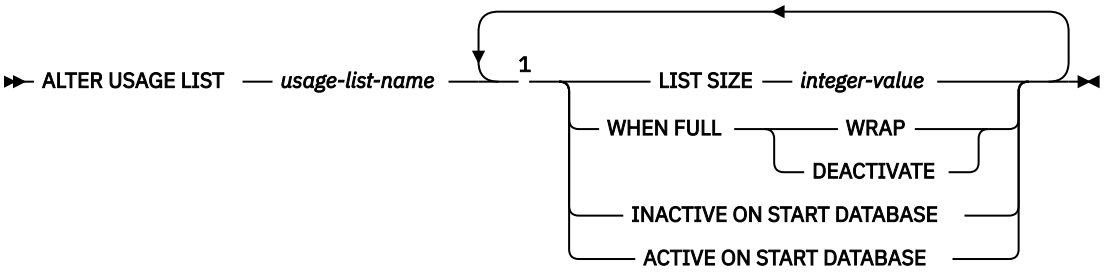
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include one of the following privileges:

- DBADM authority
- SQLADM authority

Syntax



Notes:

[1] The same clause cannot be specified more than once

Description

usage-list-name
Identifies the usage list to be altered. The *usage-list-name* must identify a usage list that exists at the current server (SQLSTATE 42704).

LIST SIZE *integer-value*
Specifies that the size of this list is *integer-value* entries. The minimum size that can be specified is 10 and the maximum is 5000 (SQLSTATE 428B7).

WHEN FULL
Specifies the action to perform when an active usage list becomes full.

WRAP
Specifies that the usage list wraps and replaces the oldest entries.

DEACTIVATE
Specifies that the usage list deactivates.

INACTIVE ON START DATABASE
Specifies that the usage list is not activated for monitoring whenever the database is activated. Collection must be explicitly started using the SET USAGE LIST statement.

ACTIVE ON START DATABASE
Specifies that the usage list is automatically activated for monitoring whenever the database is activated. In a partitioned database environment or Db2 pureScale environment, the collection is automatically started whenever the database member is activated.

Notes

- ***When changes take effect***: If the current state of a usage list is active, then the alterations do not take effect when the statement is processed or when the changes are committed. The changes to the usage list take effect the next time the state of usage list is set to active. In a partitioned database environment or Db2 pureScale environment, the alterations take effect the next time the usage list at a member is activated.

ALTER USER MAPPING

The ALTER USER MAPPING statement is used to change the authorization ID or password that is used at a data source for a specified federated server authorization ID.

Invocation

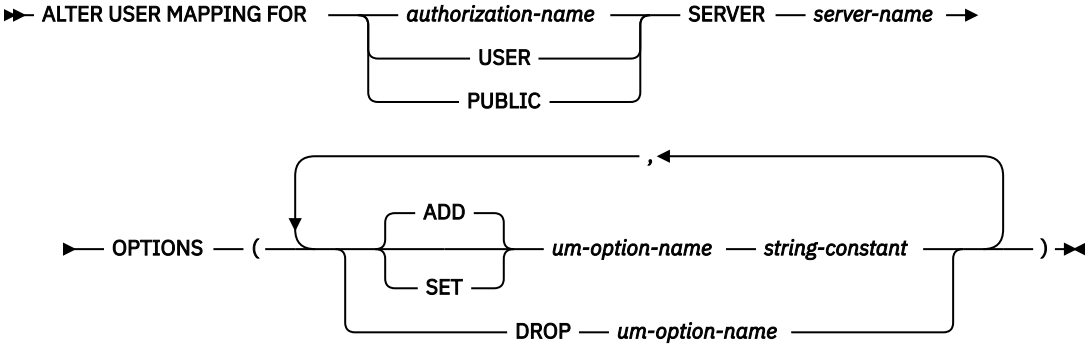
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

If the authorization ID of the statement is different from the authorization name that is mapped to the data source, the privileges held by the authorization ID of the statement must include DBADM authority. Otherwise, if the authorization ID and the authorization name match, no authorities or privileges are required.

When altering a public user mapping, the privileges held by the authorization ID of the statement must include DBADM authority.

Syntax



Description

authorization-name
Specifies the authorization name under which a user or application connects to a federated database.

USER
The value in the special register USER. When USER is specified, then the authorization ID of the ALTER USER MAPPING statement will be mapped to the data source authorization ID that is specified in the REMOTE_AUTHID user option.

PUBLIC
Specifies that any valid authorization ID for the local federated database will be mapped to the data source authorization ID that is specified in the REMOTE_AUTHID user option.

SERVER *server-name*
Identifies the data source accessible under the remote authorization ID that maps to the local authorization ID that's denoted by *authorization-name* or referenced by USER.

OPTIONS
Indicates what user options are to be enabled, reset, or dropped for the mapping that is being altered.

ADD
Enables a new user option.

SET
Changes the setting of a user option.

um-option-name
The user mapping option that is to be added or reset. Which options you can specify depends on the data source of the object for which a wrapper is being created. For a list of data sources and the user mapping options that apply to each, see Data source options.

string-constant
The user-mapping option setting as a character string constant enclosed in single quotation marks.

DROP *um-option-name*
Drops a user mapping option.

Notes

- A user option cannot be specified more than once in the same ALTER USER MAPPING statement (SQLSTATE 42853). When a user option is enabled, reset, or dropped, any other user options that are in use are not affected.
- An ALTER USER MAPPING statement within a given unit of work (UOW) cannot be processed (SQLSTATE 55007) if the UOW already includes one of the following items:
  - A SELECT statement that references a nickname for a table or view at the data source that is to be included in the mapping
  - An open cursor on a nickname for a table or view at the data source that is to be included in the mapping
  - Either an INSERT, DELETE, or UPDATE issued against a nickname for a table or view at the data source that is to be included in the mapping.
- Public user mappings and non-public user mappings cannot coexist on the same federated server. This means that if you have created public user mappings, you will not be able to create non-public user mappings on the same federated server. The reverse is also true, if you have created non-public user mappings, you will not be able to create public user mappings on the same federated server.

Examples

1. Jim uses a local database to connect to an Oracle data source called ORACLE1. He accesses the local database under the authorization ID KLEEWEIN; KLEEWEIN maps to CORONA, the authorization ID under which he accesses ORACLE1. Jim is going to start accessing ORACLE1 under a new ID, JIMK. So KLEEWEIN now needs to map to JIMK.

```
ALTER USER MAPPING FOR KLEEWEIN
  SERVER ORACLE1
  OPTIONS ( SET REMOTE_AUTHID 'JIMK'  )
```

2. Mary uses a federated database to connect to a Db2 for z/OS data source called DORADO. She uses one authorization ID to access Db2 and another to access DORADO, and she has created a mapping between these two IDs. She has been using the same password with both IDs, but now decides to use a separate password, ZNYQ, with the ID for DORADO. Accordingly, she needs to map her federated database password to ZNYQ.

```
ALTER USER MAPPING FOR MARY
  SERVER DORADO
  OPTIONS ( ADD REMOTE_PASSWORD 'ZNYQ'  )
```

ALTER VIEW

The ALTER VIEW statement modifies an existing view by altering a reference type column to add a scope. The ALTER VIEW statement also enables or disables a view for use in query optimization.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

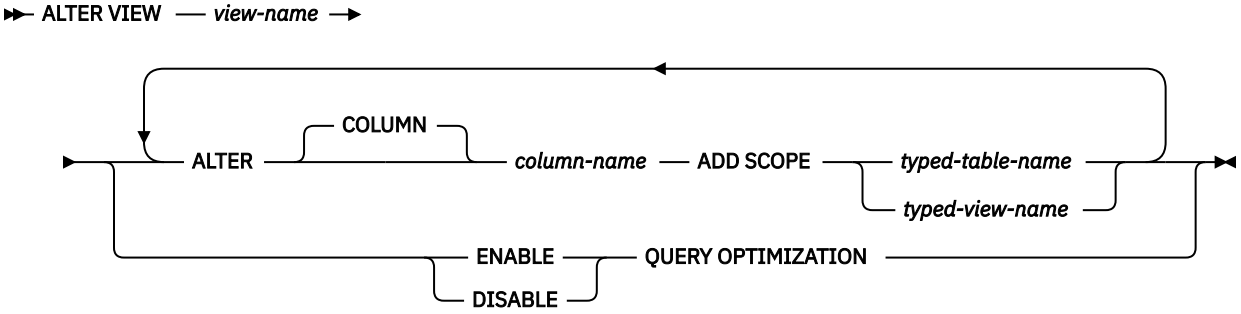
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- ALTERIN privilege on the schema of the view
- Owner of the view to be altered
- CONTROL privilege on the view to be altered
- SCHEMAADM authority on the schema of the view
- DBADM authority

To enable or disable a view for use in query optimization, the privileges held by the authorization ID of the statement must also include at least one of the following authorities for each of the tables or underlying tables of views that are referenced in the FROM clause of the view fullselect:

- ALTER privilege on the table
- ALTERIN privilege on the schema of the table
- SCHEMAADM authority on the schema of the table
- DBADM authority

Syntax



Description

view-name
Specifies the view that is to be changed. It must be a view that is described in the catalog.

ALTER COLUMN *column-name*
Specifies the name of the column that is to be altered. The *column-name* must identify an existing column of the view (SQLSTATE 42703). The name cannot be qualified.

ADD SCOPE
Adds a scope to an existing reference type column that does not already have a scope defined (SQLSTATE 428DK). The column must not be inherited from a superview (SQLSTATE 428DJ).

typed-table-name
Specifies the name of a typed table. The data type of *column-name* must be REF(*S*), where *S* is the type of *typed-table-name* (SQLSTATE 428DM). No checking is done of any existing values in *column-name* to ensure that the values actually reference existing rows in *typed-table-name*.

typed-view-name
Specifies the name of a typed view. The data type of *column-name* must be REF(*S*), where *S* is the type of *typed-view-name* (SQLSTATE 428DM). No checking is done of any existing values in *column-name* to ensure that the values actually reference existing rows in *typed-view-name*.

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION
Specifies whether or not the view and any associated statistics are to be used to improve the optimization of queries. DISABLE QUERY OPTIMIZATION is the default when a view is created.

ENABLE QUERY OPTIMIZATION
Specifies that the view includes statistics that can be used to improve the optimization of queries that involve this view or queries that include subqueries similar to the fullselect of this view.

DISABLE QUERY OPTIMIZATION
Specifies that the view and any associated statistics are not to be used to improve the optimization of queries.

Rules

- A view cannot be enabled for query optimization if:
  - The view directly or indirectly references a materialized query table (MQT). Note that an MQT or statistical view can reference a statistical view
  - The view directly or indirectly references a catalog table.
  - It is a typed view

Notes

- To be considered for optimizing a query, a view:
  - Cannot contain an aggregation or distinct operation
  - Cannot contain a union, except, or intersect operation
  - Cannot contain an OLAP specification
- If a view is altered to disable query optimization, cached query plans that used the view for query optimization are invalidated. If a view is altered to enable query optimization, cached query plans are invalidated if they reference the same tables as the newly enabled view references, either directly or indirectly through other views. The invalidation of these cached query plans results in implicit revalidation that takes the view's changed query optimization property into account.

  The query optimization property for a view has no impact on static embedded SQL statements.

ALTER WORK ACTION SET

The ALTER WORK ACTION SET statement alters a work action set by adding, altering, or dropping work actions within the work action set.

Invocation

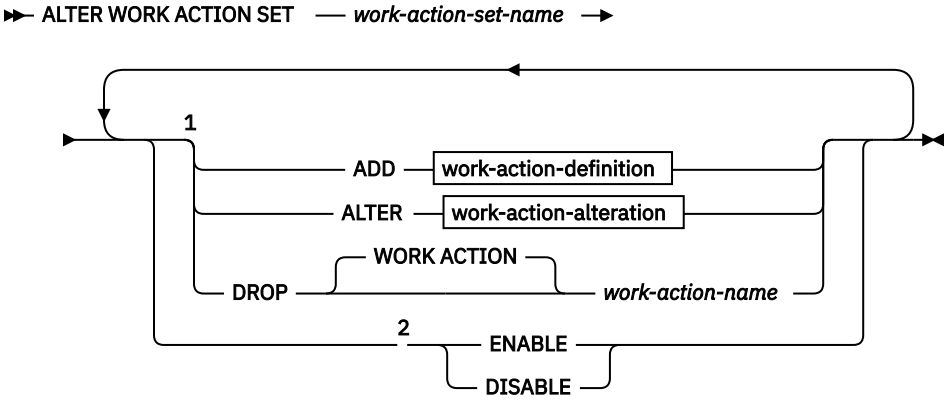
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

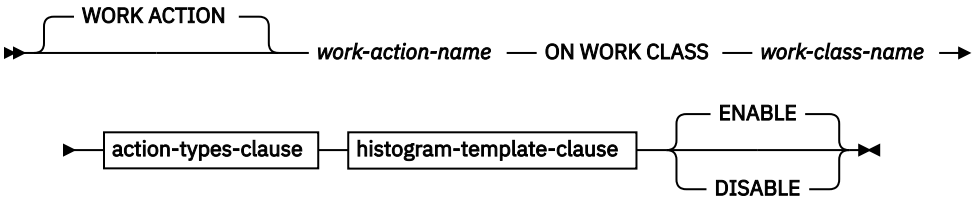
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- SQLADM authority, only if every alteration clause is a COLLECT clause
- WLMADM authority
- DBADM authority

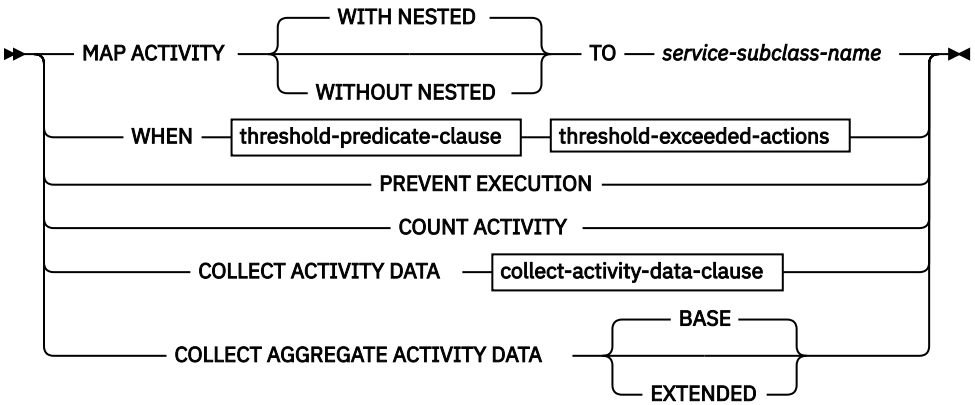
Syntax



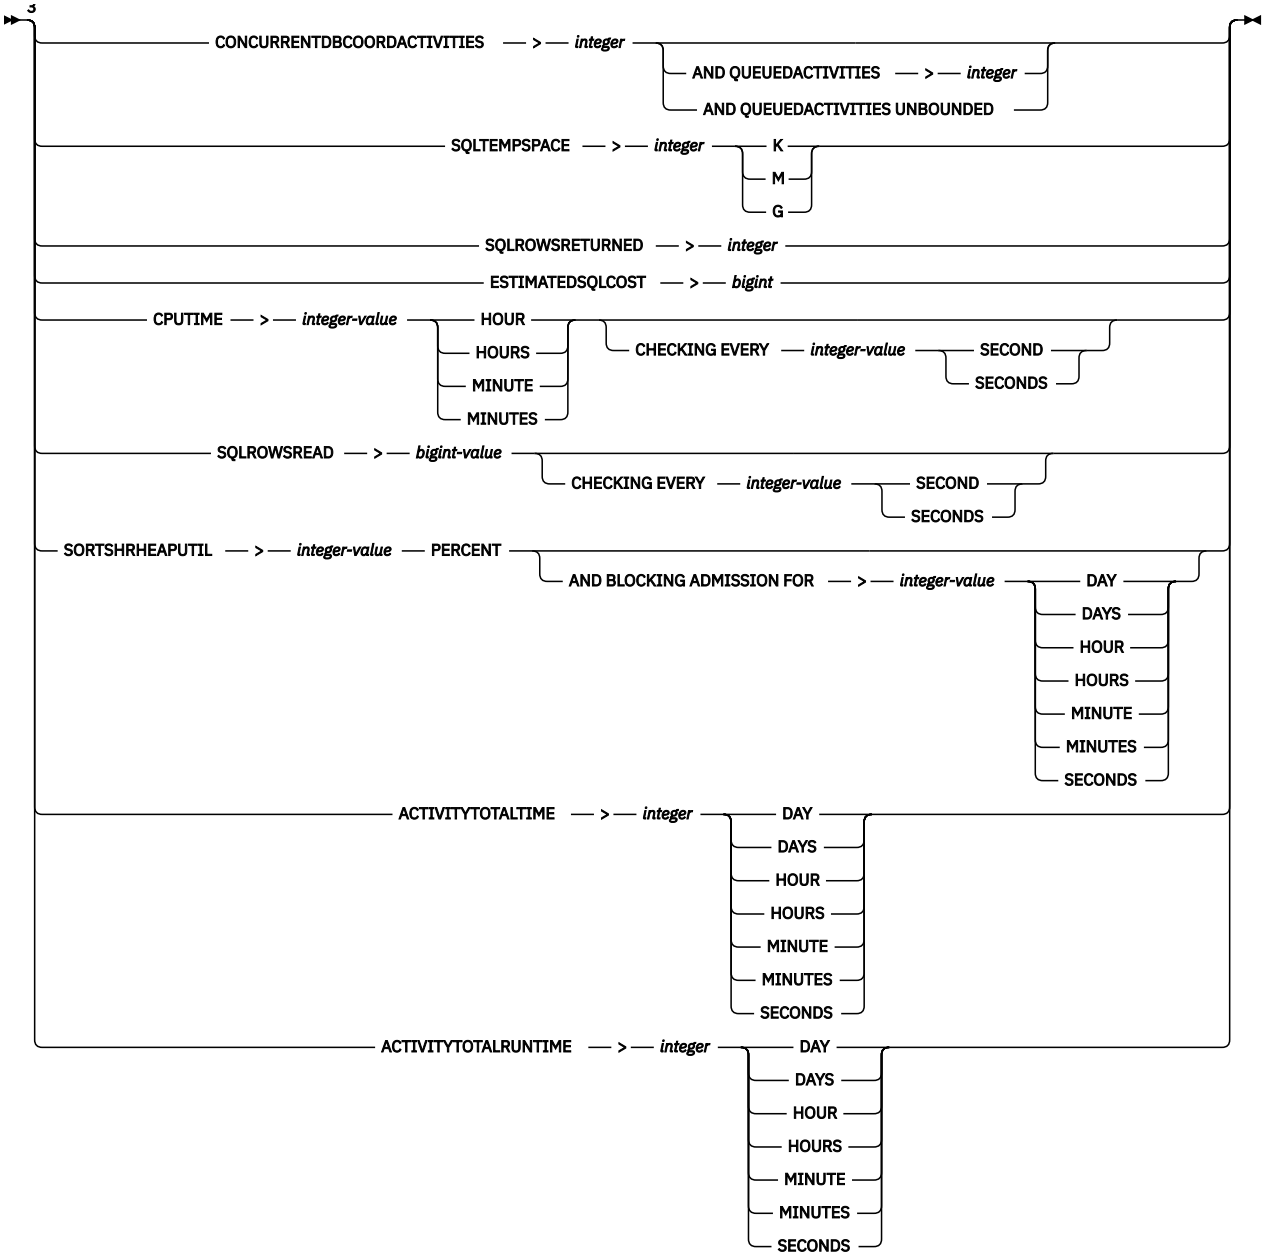
work-action-definition



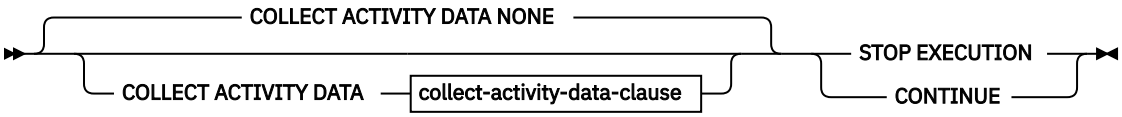
action-types-clause



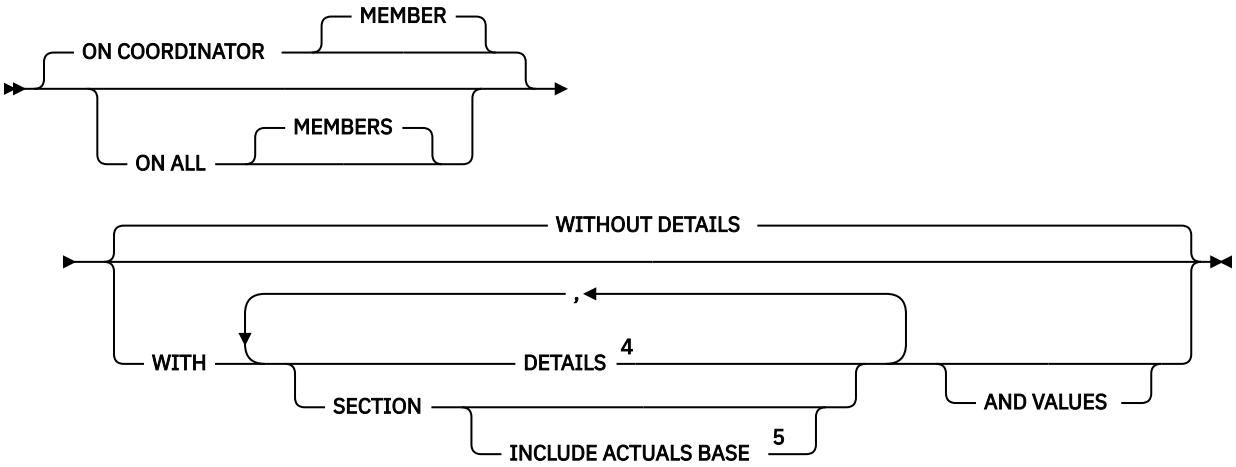
threshold-predicate-clause



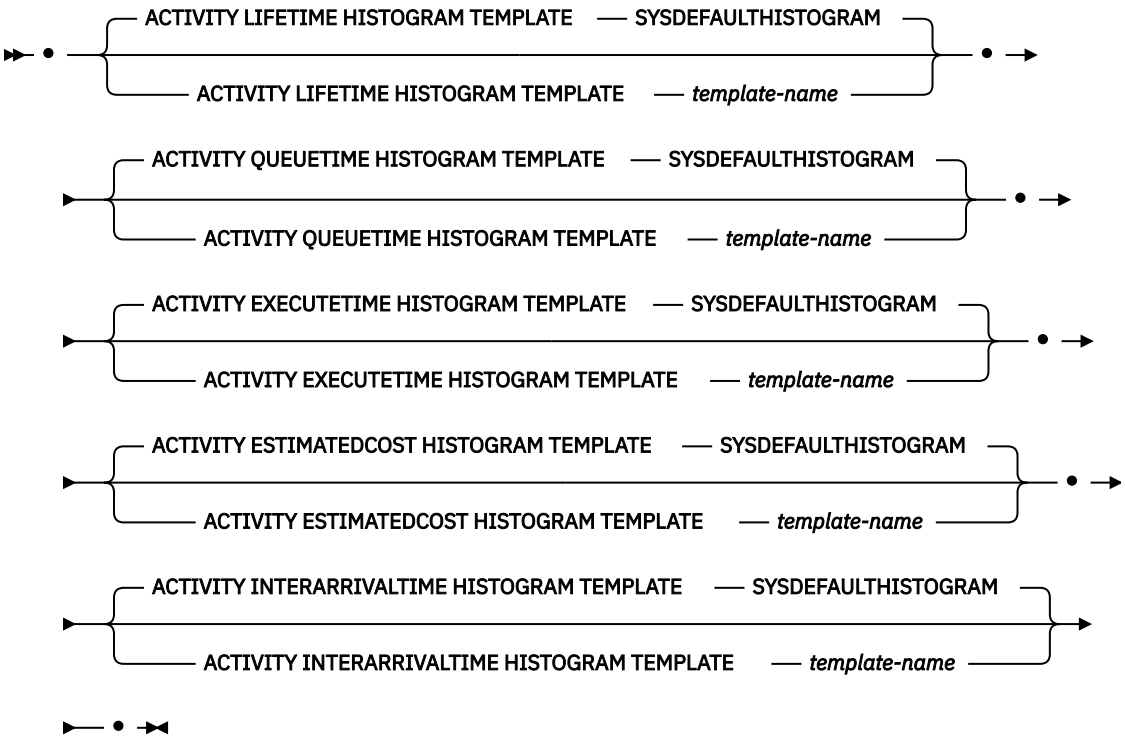
threshold-exceeded-actions



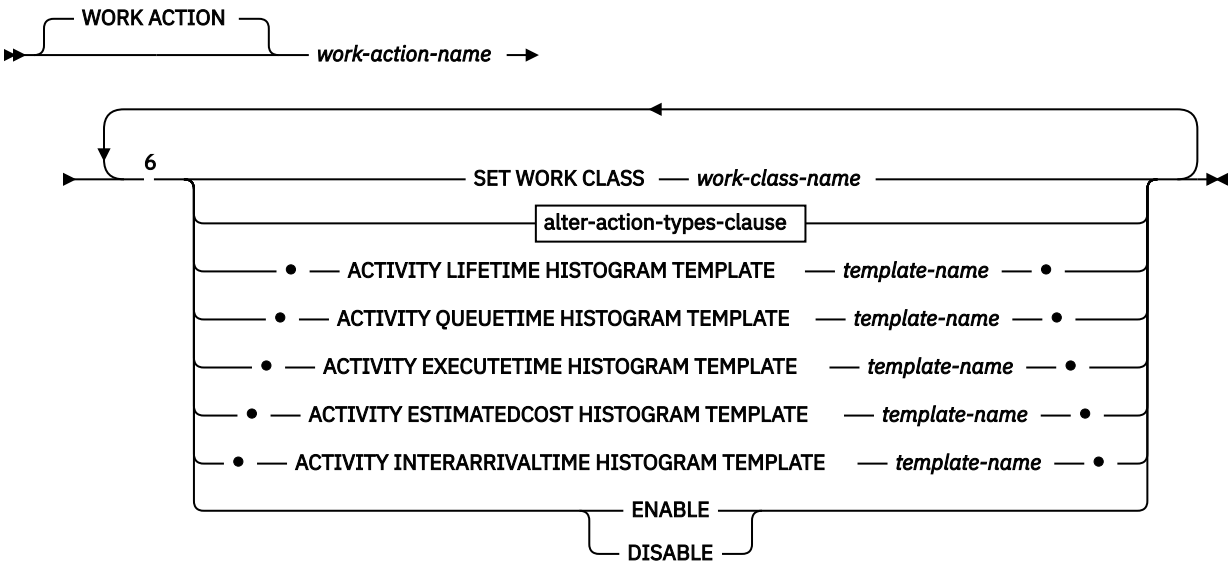
collect-activity-data-clause



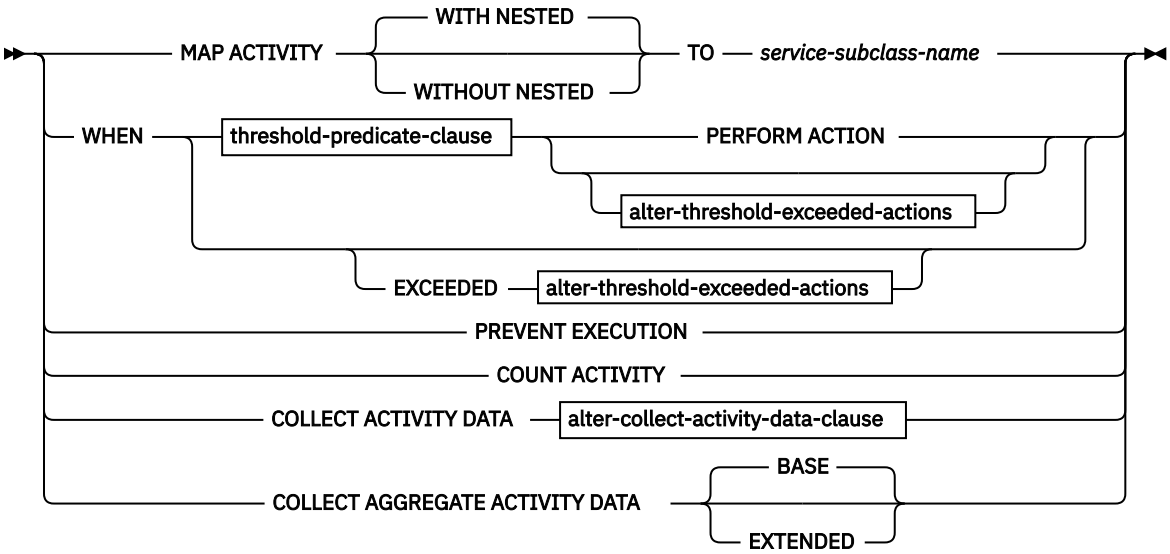
histogram-template-clause



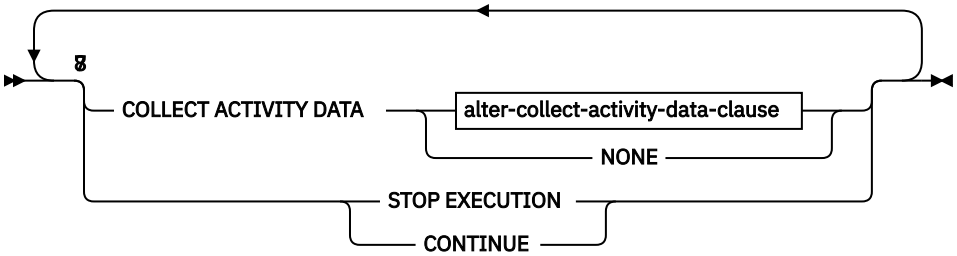
work-action-alteration



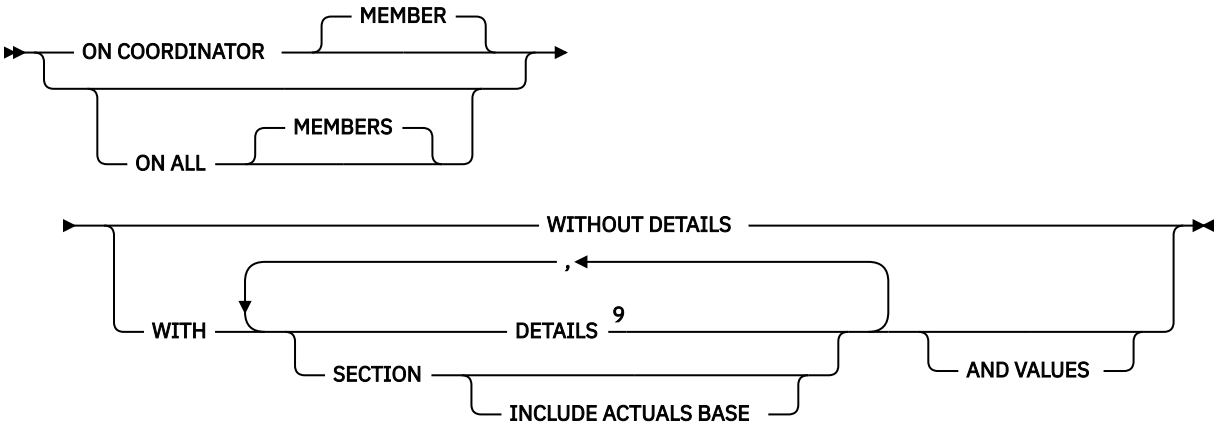
alter-action-types-clause



alter-threshold-exceeded-actions



alter-collect-activity-data-clause



Notes:

[1] The ADD, ALTER, and DROP clauses are processed in the order in which they are specified.

[2] The ENABLE or DISABLE clause can only be specified once in the same statement.

[3] Only one work action of the same threshold type can be applied to a single work class at a time. When altering a threshold work action, the threshold predicate cannot be changed.

[4] The DETAILS keyword is the minimum to be specified, followed by the option separated by a comma.

[5] This clause does not apply to thresholds.

[6] The same clause must not be specified more than once.

[7] The same clause must not be specified more than once.

[8] If an existing work action does not have a threshold-exceeded action defined for it and it is being altered to become a threshold work action, then either STOP EXECUTION or CONTINUE must be specified, and if COLLECT ACTIVITY DATA is not specified, then COLLECT ACTIVITY DATA NONE is the default.

[9] The DETAILS keyword is the minimum to be specified, followed by the option separated by a comma.

Description

work-action-set-name

Identifies the work action set that is to be altered. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *work-action-set-name* must identify a work action set that exists at the current server (SQLSTATE 42704).

ADD

Adds a work action to the work action set.

WORK ACTION *work-action-name*

Names the work action. The *work-action-name* must not identify a work action that already exists at the current server under this work action set (SQLSTATE 42710). The *work-action-name* cannot begin with 'SYS' (SQLSTATE 42939).

ON WORK CLASS *work-class-name*

Specifies the work class that identifies the database activities to which this work action will apply. The *work-class-name* must exist in the *work-class-set-name* at the current server (SQLSTATE 42704).

MAP ACTIVITY

Specifies a work action of mapping the activity. This action can only be specified if the object for which this work action set is defined is a service superclass (SQLSTATE 5U034).

WITH NESTED or WITHOUT NESTED

Specifies whether or not activities that are nested under this activity are mapped to the service subclass. The default is WITH NESTED.

WITH NESTED

All database activities that have a nesting level of zero that are classified under the work class, and all database activities nested under this activity, are mapped to the service

subclass; that is, activities with a nesting level greater than zero are run under the same service class as activities with a nesting level of zero.

WITHOUT NESTED
Only database activities that have a nesting level of zero that are classified under the work class are mapped to the service subclass. Database activities that are nested under this activity are handled according to their activity type.

TO *service-subclass-name*
Specifies the service subclass to which activities are to be mapped. The *service-subclass-name* must already exist in the *service-superclass-name* at the current server (SQLSTATE 42704). The *service-subclass-name* cannot be the default service subclass, SYSDEFAULTSUBCLASS (SQLSTATE 5U018).

WHEN
Specifies the threshold that will be applied to the database activity that is associated with the work class for which this work action is defined. A threshold can only be specified if the database manager object for which this work action set is defined is a database (SQLSTATE 5U034). None of these thresholds apply to internal database activities initiated by the database manager or to database activities generated by administrative SQL routines.

threshold-predicate-clause
For a description of valid threshold types, see the "CREATE THRESHOLD" statement.

threshold-exceeded-actions
For a description of valid threshold-exceeded actions, see the "CREATE THRESHOLD" statement.

PREVENT EXECUTION
Specifies that none of the database activities associated with the work class for which this work action is defined will be allowed to run (SQLSTATE 5U033).

COUNT ACTIVITY
Specifies that all of the database activities associated with the work class are to be run and that each time one is run, the counter for the work class will be incremented.

COLLECT ACTIVITY DATA
Specifies that data about each activity associated with the work class for which this work action is defined is to be sent to any active activities event monitor when the activity completes.

collect-activity-data-clause

ON COORDINATOR MEMBER
Specifies that the activity data is to be collected at only the coordinator member of the activity.

ON ALL MEMBERS
Specifies that the activity data is to be collected at all members on which the activity is processed. For predictive thresholds, activity information is collected at all members only if you also specify the CONTINUE action for exceeded thresholds. For reactive thresholds, the ON ALL MEMBERS clause has no effect and activity information is always collected only at the coordinator member. For both predictive and reactive thresholds, any input data values, section information, or values will be collected only at the coordinator member.

WITHOUT DETAILS
Specifies that data about each activity associated with the work class for which this work action is defined should be sent to any active activities event monitor, when the activity completes execution. Details about statement, compilation environment, and section environment data are not sent.

WITH

DETAILS
Specifies that statement and compilation environment data is to be sent to any active activities event monitor, for those activities that have them. Section environment data is not sent.

SECTION
Specifies that statement, compilation environment and section environment data is to be sent to any active activities event monitor for those activities that have them. DETAILS must be specified if SECTION is specified.

INCLUDE ACTUALS BASE
Specifies that section actuals should also be collected on any partition where the activity data is collected. For section actuals to be collected, either INCLUDE ACTUALS clause must be specified or the **section_actuals** database configuration parameter must be set.

The effective setting for the collection of section actuals is the combination of the INCLUDE ACTUALS clause, the **section_actuals** database configuration parameter, and the <collectsectionactuals> setting specified on the WLM_SET_CONN_ENV routine. For example, if INCLUDE ACTUALS BASE is specified, yet the **section_actuals** database configuration parameter value is NONE and <collectsectionactuals> is set to NONE, then the effective setting for the collection of section actuals is BASE.

BASE specifies that the following actuals should be enabled and collected during the activity's execution:

- Basic operator cardinality counts
- Statistics for each object referenced (DML statements only)

AND VALUES
Specifies that input data values are to be sent to any active activities event monitor, for those activities that have them.

NONE
Specifies that activity data should not be collected for each activity that is associated with the work class for which this work action is defined.

COLLECT AGGREGATE ACTIVITY DATA
Specifies that aggregate activity data is to be captured for activities that are associated with the work class for which this work action is defined and sent to the statistics event monitor, if one is active. This information is collected periodically on an interval that is specified by the **wlm_collect_int** database configuration parameter. The default is COLLECT AGGREGATE ACTIVITY DATA BASE. This clause cannot be specified for a work action defined in a work action set that is applied to a database.

BASE
Specifies that basic aggregate activity data should be captured for activities associated with the work class for which this work action is defined and sent to the statistics event monitor, if one is active. Basic aggregate activity data includes:

- Estimated activity cost high watermark
- Rows returned high watermark
- Temporary table space usage high watermark. Only activities that have an SQLTEMPSPACE threshold applied to them participate in this high watermark.
- Activity life time histogram
- Activity queue time histogram
- Activity execution time histogram

EXTENDED
Specifies that all aggregate activity data should be captured for activities associated with the work class for which this work action is defined and sent to the statistics event monitor, if one is active. This includes all basic aggregate activity data plus:

- Activity data manipulation language (DML) estimated cost histogram
- Activity DML inter-arrival time histogram

ENABLE or DISABLE
Specifies whether or not the work action is to be considered when database activities are submitted. The default is ENABLE.

ENABLE
Specifies that the work action is enabled and will be considered when database activities are submitted.

DISABLE
Specifies that the work action is disabled and will not be considered when database activities are submitted.

histogram-template-clause
Specifies histogram templates to use when collecting aggregate activity data for activities associated with the work class to which this work action is assigned. Aggregate activity data is only collected for the work class when the work action type is COLLECT AGGREGATE ACTIVITY DATA.

ACTIVITY LIFETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the duration, in milliseconds, of database activities running during a specific interval. The database activities are those associated with the work class to which this work action is assigned. This time includes both time queued and time executing. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY QUEUETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities are queued during a specific interval. The database activities are those associated with the work class to which this work action is assigned. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY EXECUTETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities are executing during a specific interval. The database activities are those associated with the work class to which this work action is assigned. This time does not include the time spent queued. Activity execution time is collected in this histogram at each member where the activity executes. On the activity's coordinator member, this is the end-to-end execution time (that is, the life time less the time spent queued). On non-coordinator members, this is the time that these members spend working on behalf of the activity. During the execution of a given activity, the database manager might present work to a non-coordinator member more than once, and each time the non-coordinator member will collect the execution time for that occurrence of the activity. Therefore, the counts in the execution time histogram might not represent the actual number of unique activities that executed on a member. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY ESTIMATEDCOST HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the estimated cost, in timerons, of DML activities associated with the work class to which this work action is assigned. The default is SYSDEFAULTHISTOGRAM. This information is

only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option.

ACTIVITY INTERARRIVALTIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, between the arrival of one DML activity and the arrival of the next DML activity, for any activity associated with the work class to which this work action is assigned. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option.

ALTER
Alters the definition of the work action. You can change the work class to which this work action applies, and the action that is to be applied to the database activity that falls within the work class.

WORK ACTION *work-action-name*
Identifies the work action. The *work-action-name* must identify a work action that exists at the current server under this work action set (SQLSTATE 42704).

SET WORK CLASS *work-class-name*
Specifies the work class that identifies the database activities to which this work action will apply. The *work-class-name* must exist in the *work-class-set-name* at the current server (SQLSTATE 42704).

MAP ACTIVITY
Specifies a work action of mapping the activity. This action can only be specified if the object for which this work action set is defined is a service superclass (SQLSTATE 5U034).

WITH NESTED or WITHOUT NESTED
Specifies whether or not activities that are nested under this activity are mapped to the service subclass. The default is WITH NESTED.

WITH NESTED
All database activities that have a nesting level of zero that are classified under the work class, and all database activities nested under this activity are mapped to the service subclass.

WITHOUT NESTED
Only database activities that have a nesting level of zero that are classified under the work class are mapped to the service subclass. Database activities that are nested under this activity are handled according to their activity type.

TO *service-subclass-name*
Specifies the service subclass to which activities are to be mapped. The *service-subclass-name* must already exist in the *service-superclass-name* at the current server (SQLSTATE 42704). The *service-subclass-name* cannot be the default service subclass, SYSDEFAULTSUBCLASS (SQLSTATE 5U018).

WHEN
Specifies the threshold to be altered for the database activity that is associated with the work class for which this work action is defined.

threshold-predicate-clause
For a description of valid threshold types, see the "CREATE THRESHOLD" statement.

PERFORM ACTION
When altering the value of the threshold predicate condition, specifies that the threshold exceeded action is not changed. The work action must be a threshold (SQLSTATE 42613).

alter-threshold-exceeded-actions
For a description of valid alter-threshold-exceeded-actions, see threshold-exceeded-actions in the "CREATE THRESHOLD" statement.

EXCEEDED
Specifies to keep the same threshold predicate that was specified originally for this altered threshold. The work action must be a threshold (SQLSTATE 42613).

PREVENT EXECUTION
Specifies that none of the database activities associated with the work class for which this work action is defined will be allowed to run (SQLSTATE 5U033).

COUNT ACTIVITY
Specifies that all of the database activities associated with the work class are to be run and that each time one is run, the counter for the work class will be incremented.

COLLECT ACTIVITY DATA
Specifies that data about each activity associated with the work class for which this work action is defined is to be sent to any active activities event monitor when the activity completes.

alter-collect-activity-data-clause

ON COORDINATOR MEMBER
Specifies that the activity data is to be collected only at the coordinator member of the activity.

ON ALL MEMBERS
Specifies that activity data is to be collected at all members where the activity is processed. On remote members, a record for the activity may be captured multiple times as the activity comes and goes on those members. If the AND VALUES clause is specified, activity input values will be collected only for the members of the coordinator.

WITHOUT DETAILS
Specifies that data about each activity that is associated with the work class for which this work action is defined should be sent to any active activities event monitor when the activity completes execution. Details about statement, compilation environment, and section environment data are not sent.

WITH

DETAILS
Specifies that statement and compilation environment data is to be sent to any active activities event monitor, for those activities that have them. Section environment data is not sent.

SECTION
Specifies that statement, compilation environment, section environment data, and section actuals are to be sent to any active activities event monitor for those activities that have them. DETAILS must be specified if SECTION is specified. Section actuals will be collected on any member where the activity data is collected.

INCLUDE ACTUALS BASE
Specifies that section actuals should also be collected on any partition where the activity data is collected. For section actuals to be collected, either INCLUDE ACTUALS clause must be specified or the **section_actuals** database configuration parameter must be set.

The effective setting for the collection of section actuals is the combination of the INCLUDE ACTUALS clause, the **section_actuals** database configuration parameter, and the <collectsectionactuals> setting specified on the WLM_SET_CONN_ENV routine. For example, if INCLUDE ACTUALS BASE is specified, yet the **section_actuals** database configuration parameter value is NONE and <collectsectionactuals> is set to NONE, then the effective setting for the collection of section actuals is BASE.

BASE specifies that the following actuals should be enabled and collected during the activity's execution:

- Basic operator cardinality counts
- Statistics for each object referenced (DML statements only)

AND VALUES
Specifies that input data values are to be sent to any active activities event monitor, for those activities that have them.

NONE
Specifies that activity data should not be collected for each activity that is associated with the work class for which this work action is defined.

COLLECT AGGREGATE ACTIVITY DATA
Specifies that aggregate activity data is to be captured for activities that are associated with the work class for which this work action is defined and sent to the statistics event monitor, if one is active. This information is collected periodically on an interval that is specified by the **wlm_collect_int** database configuration parameter. The default is COLLECT AGGREGATE ACTIVITY DATA BASE. This clause cannot be specified for a work action defined in a work action set that is applied to a database.

BASE
Specifies that basic aggregate activity data should be captured for activities associated with the work class for which this work action is defined and sent to the statistics event monitor, if one is active. Basic aggregate activity data includes:

- Estimated activity cost high watermark
- Rows returned high watermark
- Temporary table space usage high watermark
- Activity life time histogram
- Activity queue time histogram
- Activity execution time histogram

EXTENDED
Specifies that all aggregate activity data should be captured for activities associated with the work class for which this work action is defined and sent to the statistics event monitor, if one is active. This includes all basic aggregate activity data plus:

- Activity DML estimated cost histogram
- Activity DML inter-arrival time histogram

ACTIVITY LIFETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the duration, in milliseconds, of database activities running during a specific interval. This time includes both time queued and time executing. The database activities are those associated with the work class to which this work action is assigned. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY QUEUETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities are queued during a specific interval. The database activities are those associated with the work class to which this work action is assigned. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY EXECUTETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities are executing during a specific interval. The database activities are those associated with the work class to which this work action is assigned. This time does not include the time spent queued. Activity execution time is collected in this histogram at each member where the activity executes. On the activity's coordinator member, this is the end-to-end execution time (that is, the life time less the time spent queued). On non-coordinator members, this is the time that these members spend working on behalf of the activity. During the execution of a given activity, the database manager might present work to a non-coordinator member more than once, and each time the non-coordinator member will collect

the execution time for that occurrence of the activity. Therefore, the counts in the execution time histogram might not represent the actual number of unique activities that executed on a member. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY ESTIMATEDCOST HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the estimated cost, in timerons, of data manipulation language (DML) activities associated with the work class to which this work action is assigned. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option.

ACTIVITY INTERARRIVALTIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, between the arrival of one DML activity and the arrival of the next DML activity, for any activity associated with the work class to which this work action is assigned. The default is SYSDEFAULTHISTOGRAM. This information is only collected when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option.

ENABLE or DISABLE
Specifies whether or not the work action is to be considered when database activities are submitted.

ENABLE
Specifies that the work action is enabled and will be considered when database activities are submitted.

DISABLE
Specifies that the work action is disabled and will not be considered when database activities are submitted.

DROP *work-action-name*
Drops the work action from the work action set. The *work-action-name* must identify a work action that exists at the current server under this work action set (SQLSTATE 42704).

A threshold created as part of a work action set cannot be manipulated directly. You must first disable the work action in order to disable the threshold. You can then drop the work action once the threshold is not being used. For more information, see "Dropping a work action" in the *Db2 Workload Management Guide and Reference*.

ENABLE or DISABLE
Specifies whether or not the work action set is to be considered when database activities are submitted.

ENABLE
Specifies that the work action set is enabled and will be considered when database activities are submitted.

DISABLE
Specifies that the work action set is disabled and will not be considered when database activities are submitted.

Rules

- A workload management (WLM)-exclusive SQL statement must be followed by a COMMIT or a ROLLBACK statement (SQLSTATE 5U021). WLM-exclusive SQL statements are:
  - CREATE HISTOGRAM TEMPLATE, ALTER HISTOGRAM TEMPLATE, or DROP (histogram template)
  - CREATE SERVICE CLASS, ALTER SERVICE CLASS, or DROP (service class)
  - CREATE THRESHOLD, ALTER THRESHOLD, or DROP (threshold)
  - CREATE WORK ACTION SET, ALTER WORK ACTION SET, or DROP (work action set)
  - CREATE WORK CLASS SET, ALTER WORK CLASS SET, or DROP (work class set)

  - CREATE WORKLOAD, ALTER WORKLOAD, or DROP (workload)
  - GRANT (workload privileges) or REVOKE (workload privileges)
- A WLM-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.

Notes

- Changes are written to the system catalog, but do not take effect until they are committed, even for the connection that issues the statement.
- Thresholds with a queue, for example CONCURRENTDBCOORDACTIVITIES, must be disabled before they can be dropped.
- Only one uncommitted WLM-exclusive SQL statement at a time is allowed across all partitions. If an uncommitted WLM-exclusive SQL statement is executing, subsequent WLM-exclusive SQL statements will wait until the current WLM-exclusive SQL statement commits or rolls back.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - DATABASE PARTITION can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - DATABASE PARTITIONS can be specified in place of MEMBERS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.

Examples

- *Example 1:* Alter the DATABASE_ACTIONS work action set and add two work actions using the work class LARGE_SELECTS. For the work action ONE_CONCURRENT_SELECT, apply a concurrency threshold of 1 to control the number of activities that can run at one time, and allow a maximum of 3 to be queued. For work action BIG_ROWS_RETURNED, limit the number of rows that can be returned by database activities that fall within that class to 1 000 000.

```
ALTER WORK ACTION SET DATABASE_ACTIONS
  ADD WORK ACTION ONE_CONCURRENT_SELECT ON WORK CLASS LARGE_SELECTS
     WHEN CONCURRENTDBCOORDACTIVITIES > 1
        AND QUEUEDACTIVITIES > 3 STOP EXECUTION
  ADD WORK ACTION BIG_ROWS_RETURNED ON WORK CLASS LARGE_SELECTS
     WHEN SQLROWSRETURNED > 1000000 STOP EXECUTION
```

- *Example 2:* Alter the ADMIN_APPS_ACTIONS work action set to alter the MAP_SELECTS work action to map all activities that run in super service class ADMIN_APPS under the work class SELECT_CLASS to the service subclass ALL_SELECTS. Also add a new work action called MAP_UPDATES that maps all activities that would run in the work class UPDATE_CLASS to the service subclass ALL_SELECTS.

```
ALTER WORK ACTION SET ADMIN_APPS_ACTIONS
  ALTER WORK ACTION MAP_SELECTS MAP ACTIVITY TO ALL_SELECTS
  ADD WORK ACTION MAP_UPDATES ON WORK CLASS UPDATE_CLASS
    MAP ACTIVITY TO ALL_SELECTS
```

ALTER WORK CLASS SET

The ALTER WORK CLASS SET statement adds, alters, or drops work classes within a work class set.

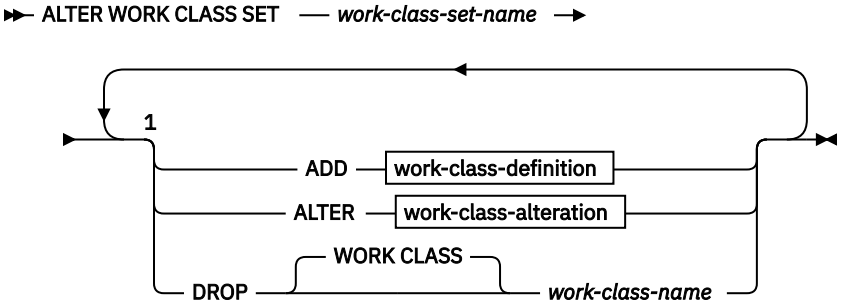
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

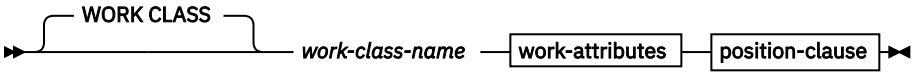
Authorization

The privileges held by the authorization ID of the statement must include WLMADM or DBADM authority.

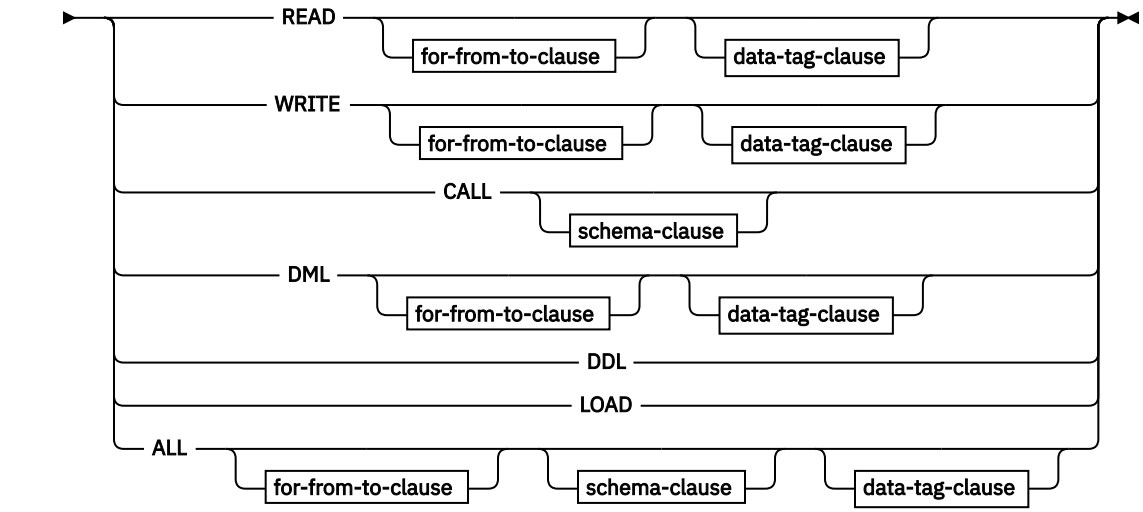
Syntax



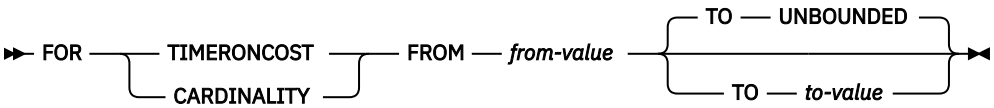
work-class-definition



work-attributes



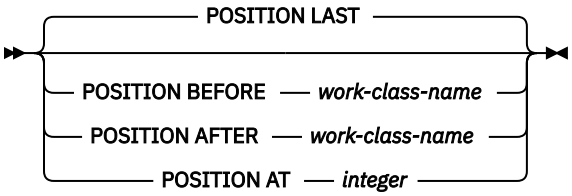
for-from-to-clause



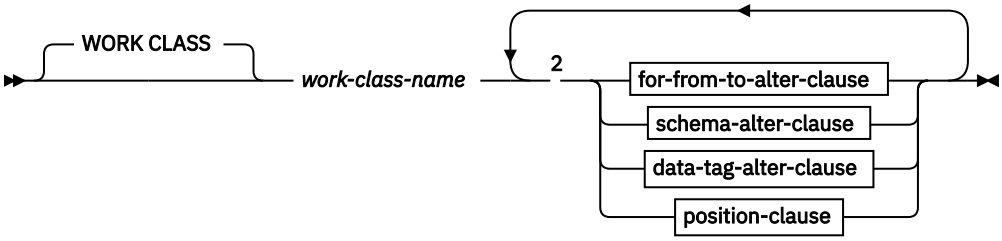
data-tag-clause

schema-clause

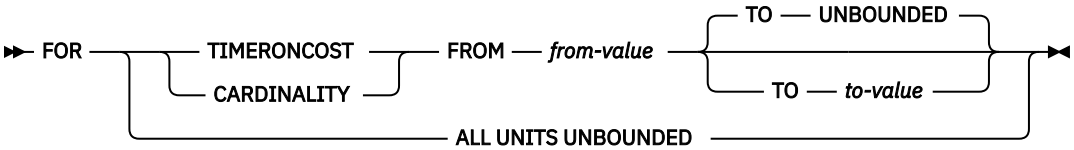
position-clause



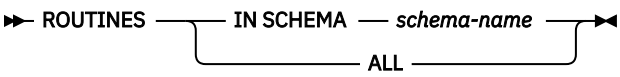
work-class-alteration



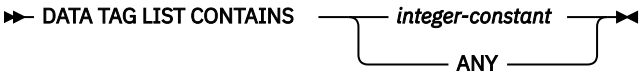
for-from-to-alter-clause



schema-alter-clause



data-tag-alter-clause



Notes:

[1] The ADD, ALTER, and DROP clauses are processed in the order in which they are specified.
[2] The same clause must not be specified more than once.

Description

work-class-set-name
Identifies the work class set that is to be altered. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *work-class-set-name* must identify a work class set that exists at the current server (SQLSTATE 42704).

ADD
Adds a work class to the work class set. For details, see "CREATE WORK CLASS SET".

ALTER
Alters the database activity attributes and the position of a specific work class within the work class set.

WORK CLASS *work-class-name*
Identifies the work class to be altered. The *work-class-name* must identify a work class that exists within the work class set at the current server (SQLSTATE 42704).

DROP
Drops the work class from the work class set.

WORK CLASS *work-class-name*
Identifies the work class to be dropped. The *work-class-name* must identify a work class that exists within the work class set at the current server (SQLSTATE 42704). A work class cannot be

dropped if there is a work action in any of the work action sets associated with this work class set that is dependent on it (SQLSTATE 42893).

for-to-from-alter-clause

FOR
Indicates the type of information that is being specified in the FROM *from-value* TO *to-value* clause. The FOR clause is only used for the following work types:

- ALL
- DML
- READ
- WRITE

TIMERONCOST
The estimated cost of the work, in timerons. This value is used to determine whether the work falls within the range specified in the FROM *from-value* TO *to-value* clause.

CARDINALITY
The estimated cardinality of the work. This value is used to determine whether the work falls within the range specified in the FROM *from-value* TO *to-value* clause.

FROM *from-value* TO UNBOUNDED or FROM *from-value* TO *to-value*
Specifies the range of either timeron value (for estimated cost) or cardinality within which the database activity must fall if it is to be part of this work class. The range is inclusive of *from-value* and *to-value*. This range is only used for the following work types:

- ALL
- DML
- READ
- WRITE

FROM *from-value* TO UNBOUNDED
The *from-value* must be zero or a positive DOUBLE value (SQLSTATE 5U019). The range has no upper bound.

FROM *from-value* TO *to-value*
The *from-value* must be zero or a positive DOUBLE value and the *to-value* must be a positive DOUBLE value. The *from-value* must be smaller than or equal to the *to-value* (SQLSTATE 5U019).

ALL UNITS UNBOUNDED
Indicates that no range is to be specified in the FROM *from-value* TO *to-value* clause, and that all work that falls within the specified work type is to be included.

schema-alter-clause

ROUTINES
This clause is only used if the work type is CALL or ALL and the database activity is a CALL statement.

IN SCHEMA *schema-name*
Specifies the schema name of the procedure that the CALL statement will be calling.

ALL
Specifies that all schemas are included.

data-tag-alter-clause

DATA TAG LIST CONTAINS *integer-constant*
Specifies the value of the tag given to any data which the database activity might touch if it is to be part of this work class. If the clause is not specified for the work class, all work that falls within the specified work type, regardless of what data it might touch, will be included (that is, the default is to ignore the data tag). This clause is used only if the work type is READ, WRITE,

DML, or ALL and the database activity is a DML statement. Valid values for *integer-constant* are integers from 1 to 9.

DATA TAG LIST CONTAINS ANY
Indicates that any data tag setting, including no data tag, is valid for the work class. All work that falls within the specified work type is to be included, regardless of the data tag.

position-clause

POSITION
Specifies where this work class is to be placed within the work class set, which determines the order in which work classes are evaluated. When performing work class assignment at run time, the database manager first determines the work class set that is associated with the object, either the database or a service superclass. The first matching work class within that work class set is then selected. If this keyword is not specified, the work class is placed in the last position.

LAST
Specifies that the work class is to be placed last in the ordered list of work classes within the work class set.

BEFORE *work-class-name*
Specifies that the work class is to be placed before work class *work-class-name* in the list. The *work-class-name* must identify a work class in the work class set that exists at the current server (SQLSTATE 42704).

AFTER *work-class-name*
Specifies that the work class is to be placed after work class *work-class-name* in the list. The *work-class-name* must identify a work class in the work class set that exists at the current server (SQLSTATE 42704).

AT *position*
Specifies the absolute position at which the work class is to be placed within the work class set in the ordered list of work classes. This value can be any positive integer (not zero) (SQLSTATE 42615). If *position* is greater than the number of existing work classes plus one, the work class is placed at the last position within the work class set.

Rules

- A workload management (WLM)-exclusive SQL statement must be followed by a COMMIT or a ROLLBACK statement (SQLSTATE 5U021). WLM-exclusive SQL statements are:
  - CREATE HISTOGRAM TEMPLATE, ALTER HISTOGRAM TEMPLATE, or DROP (HISTOGRAM TEMPLATE)
  - CREATE SERVICE CLASS, ALTER SERVICE CLASS, or DROP (SERVICE CLASS)
  - CREATE THRESHOLD, ALTER THRESHOLD, or DROP (THRESHOLD)
  - CREATE WORK ACTION SET, ALTER WORK ACTION SET, or DROP (WORK ACTION SET)
  - CREATE WORK CLASS SET, ALTER WORK CLASS SET, or DROP (WORK CLASS SET)
  - CREATE WORKLOAD, ALTER WORKLOAD, or DROP (WORKLOAD)
  - GRANT (Workload Privileges) or REVOKE (Workload Privileges)
- A WLM-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.

Notes

- Changes are written to the system catalog, but do not take effect until they are committed, even for the connection that issues the statement.
- Only one uncommitted WLM-exclusive SQL statement at a time is allowed across all partitions. If an uncommitted WLM-exclusive SQL statement is executing, subsequent WLM-exclusive SQL statements will wait until the current WLM-exclusive SQL statement commits or rolls back.

Examples

- *Example 1:* Alter work class set LARGE_QUERIES and set the two existing work classes to have each range starting at 100 000, keeping the range unbounded. Add a third work class for all SELECT statements that have an estimated timeron cost greater than or equal to 10 000, and position this work class to take priority over the existing two work classes.

```
ALTER WORK CLASS SET LARGE_QUERIES
  ALTER WORK CLASS LARGE_ESTIMATED_COST
   FOR TIMERONCOST FROM 100000 TO UNBOUNDED
  ALTER WORK CLASS LARGE_CARDINALITY
   FOR CARDINALITY FROM 100000 TO UNBOUNDED
  ADD WORK CLASS LARGE_SELECTS WORK TYPE READ
   FOR TIMERONCOST FROM 10000 TO UNBOUNDED POSITION AT 1
```

- *Example 2:* Alter a work class set named DML_STATEMENTS to add a work class that represents all DML SELECT statements that contain a DELETE, INSERT, MERGE, or UPDATE statement.

```
ALTER WORK CLASS SET DML_STATEMENTS
  ADD WORK CLASS UPDATE_CLASS WORK TYPE WRITE
```

ALTER WORKLOAD

The ALTER WORKLOAD statement alters a workload.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

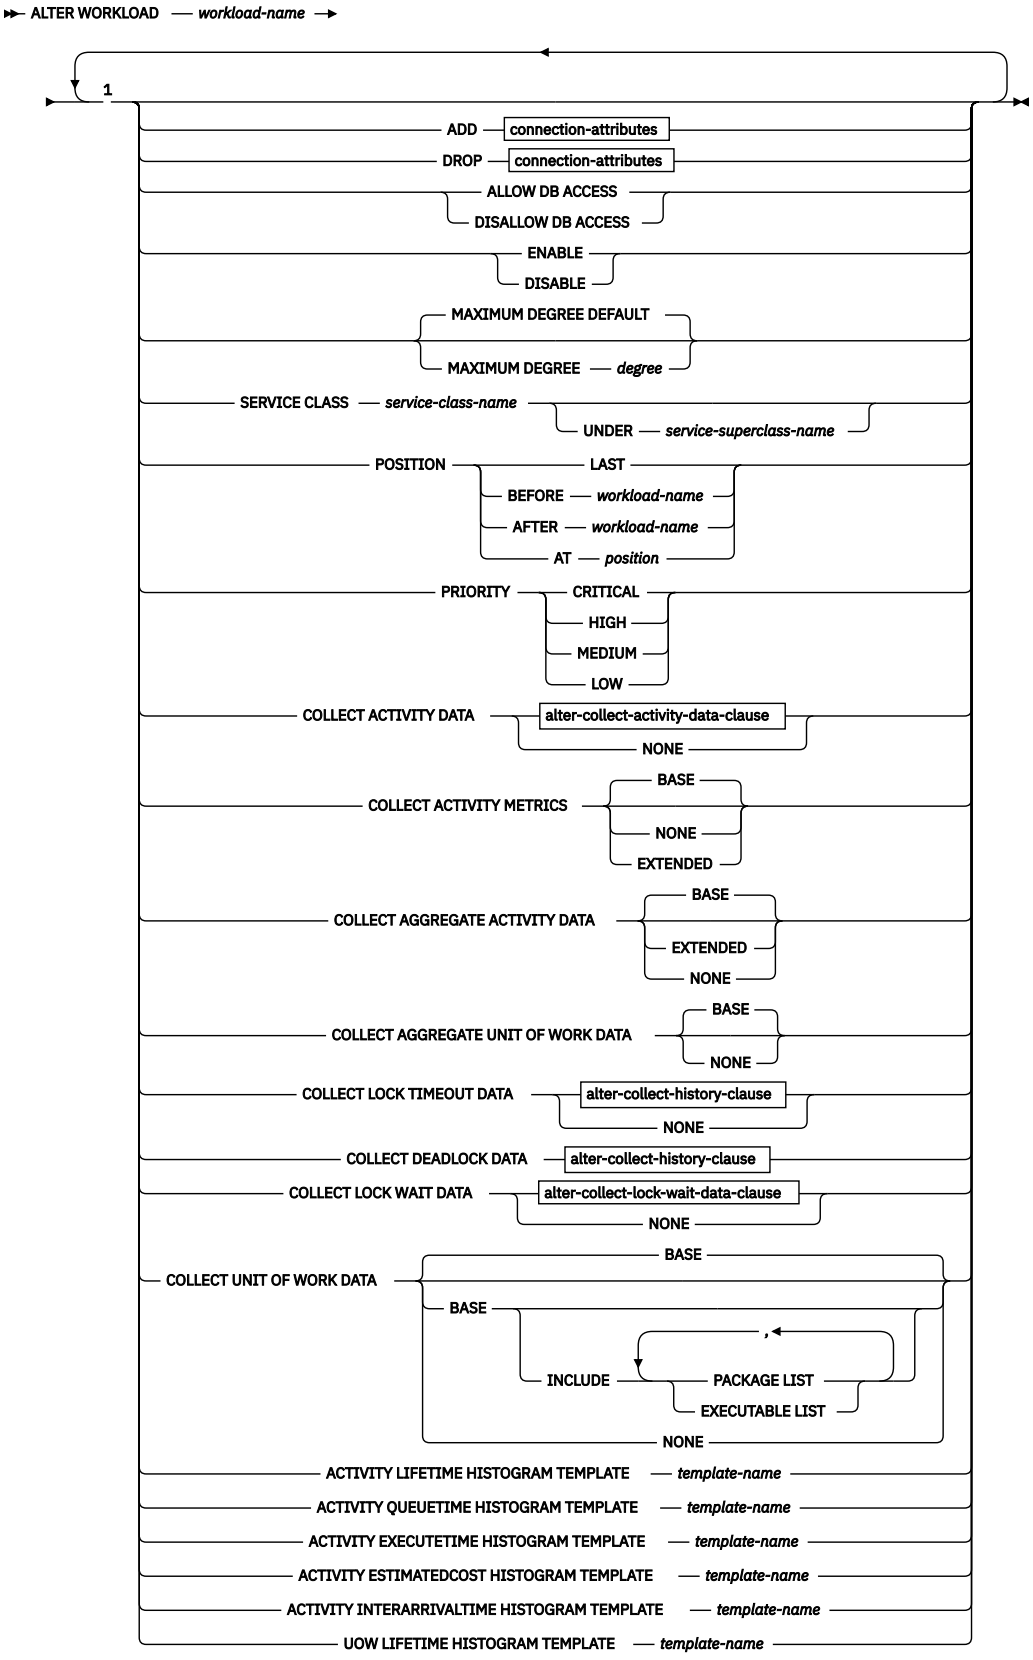
Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

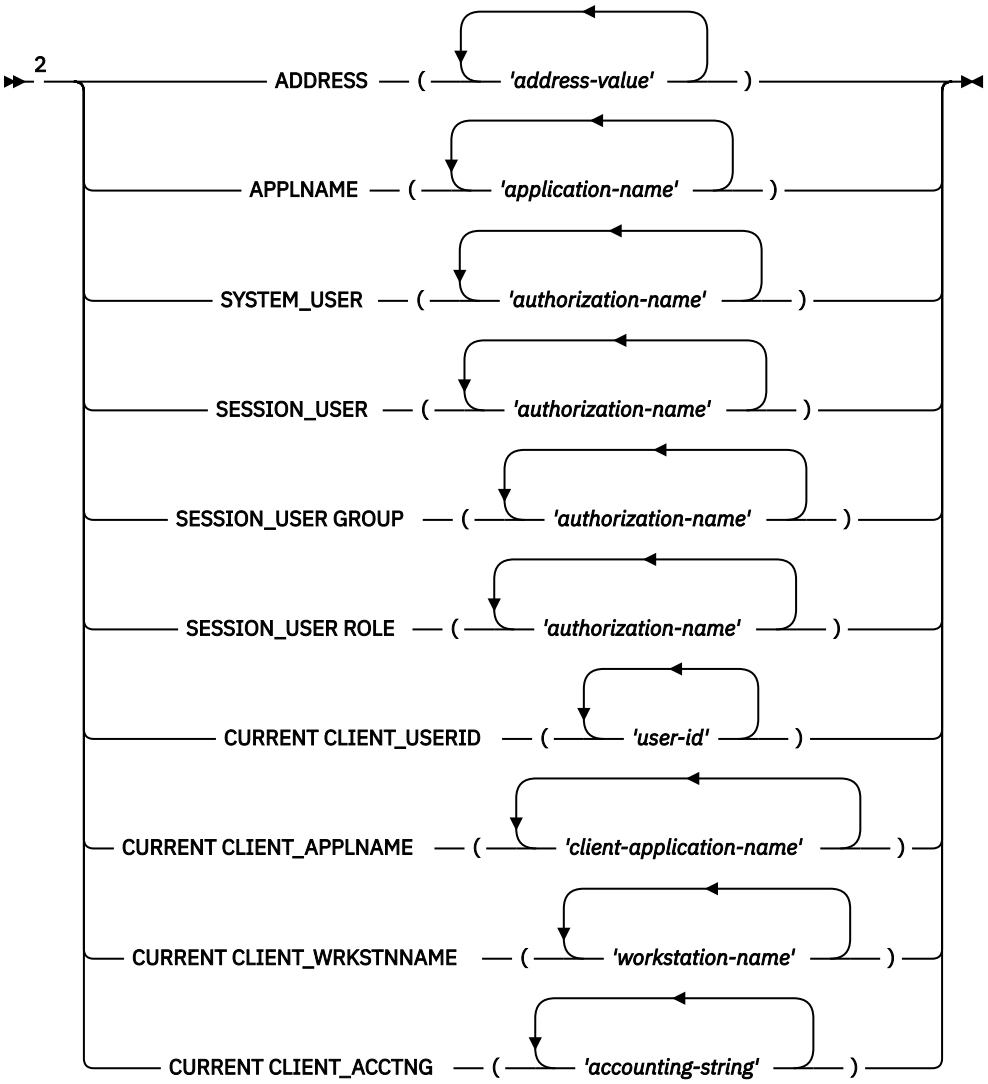
- SQLADM authority, only if every alteration clause is a COLLECT clause
- WLMADM authority
- DBADM authority

To specify any clause other than a COLLECT clause, the authorization ID of the statement must include DBADM or WLMADM authority.

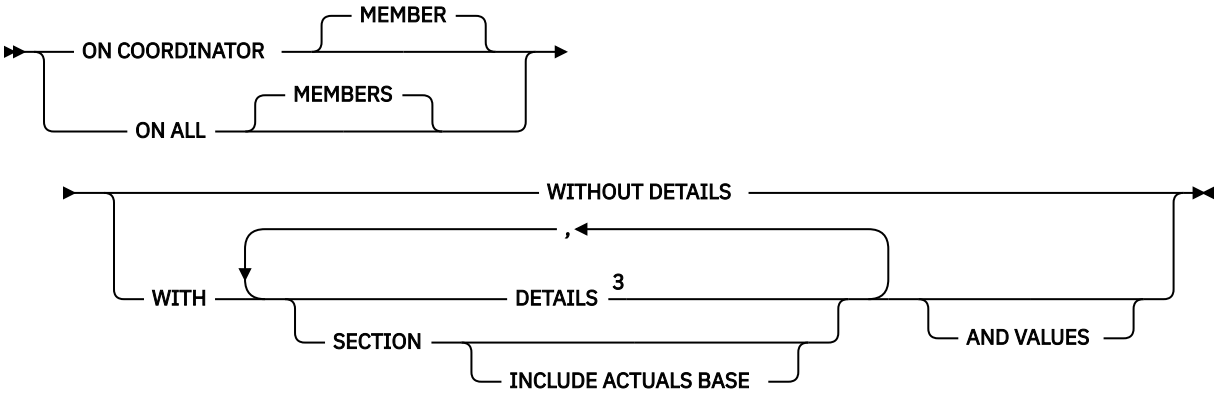
Syntax



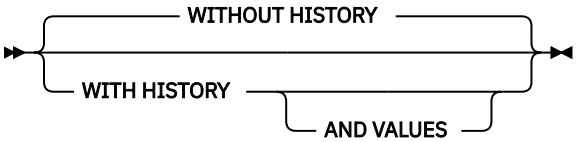
connection-attributes



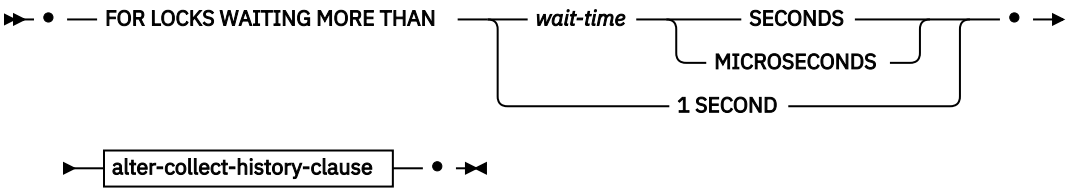
alter-collect-activity-data-clause



alter-collect-history-clause



alter-collect-lock-wait-data-clause



Notes:

[1] The same clause must not be specified more than once.

[2] Each connection attribute clause can only be specified once.

[3] The DETAILS keyword is the minimum to be specified, followed by the option separated by a comma.

Description

workload-name

Identifies the workload that is to be altered. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *workload-name* must identify a workload that exists at the current server (SQLSTATE 42704).

ADD *connection-attributes*

Adds one or more connection attribute values to the definition of the workload. Each specified connection attribute value must not already be defined for the workload (SQLSTATE 5U039). The ADD option cannot be specified if *workload-name* is 'SYSDEFAULTUSERWORKLOAD' or 'SYSDEFAULTADMWORKLOAD' (SQLSTATE 42832).

DROP *connection-attributes*

Drops one or more connection attribute values from the definition of the workload. Each specified connection attribute value must be defined for the workload (SQLSTATE 5U040). The DROP option cannot be specified if *workload-name* is 'SYSDEFAULTUSERWORKLOAD' or 'SYSDEFAULTADMWORKLOAD' (SQLSTATE 42832). There must be at least one defined connection attribute value. The last connection attribute value cannot be dropped (SQLSTATE 5U022).

connection-attributes

Specifies connection attribute values for the workload. All connection attributes are case sensitive, except for ADDRESS.

ADDRESS ('*address-value*', ...)

Specifies one or more IPv4 addresses, IPv6 addresses, or secure domain names for the ADDRESS connection attribute. An address value cannot appear more than once in the list (SQLSTATE 42713). The only supported protocol is TCP/IP. Each address value must be an IPv4 address, an IPv6 address, or a secure domain name.

An IPv4 address must not contain leading spaces and is represented as a dotted decimal address. An example of an IPv4 address is `9.112.46.111`. The value `localhost` or its equivalent representation `127.0.0.1` will not result in a match; the real IPv4 address of the host must be specified instead. An IPv6 address must not contain leading spaces and is represented as a colon hexadecimal address. An example of an IPv6 address is `2001:0DB8:0000:0000:0008:0800:200C:417A`. IPv4-mapped IPv6 addresses (`::ffff:192.0.2.128`, for example) will not result in a match. Similarly, `localhost` or its IPv6 short representation `::1` will not result in a match. A domain name is converted to an IP address by the domain name server where a resulting IPv4 or IPv6 address is determined. An example of a domain name is `corona.torolab.ibm.com`. When a domain name is converted to an IP address, the result of this conversion could be a set of one or more IP addresses. In this case, an incoming connection is said to match the ADDRESS attribute of a workload object if the IP address from which the connection originates matches any of the IP addresses to which the domain name was converted.

When creating a workload object, you should specify domain name values for the ADDRESS attribute instead of static IP addresses, particularly in Dynamic Host Configuration Protocol (DHCP) environments where a device can have a different IP address each time it connects to the network.

APPLNAME ('*application-name*', ...)
Specifies one or more applications for the APPLNAME connection attribute. An application name cannot appear more than once in the list (SQLSTATE 42713). If *application-name* does not contain a single asterisk character (*), is equivalent to the value shown in the "Application name" field in system monitor output and in output from the LIST APPLICATIONS command. If *application-name* does contain a single asterisk character (*), the value is used as an expression to represent a set of application names, where the asterisk (*) represents a string of zero or more characters. If the expression needs to include an asterisk character in the application name, use a sequence of two asterisk characters (**).

SYSTEM_USER ('*authorization-name*', ...)
Specifies one or more authorization IDs for the SYSTEM USER connection attribute. An authorization ID cannot appear more than once in the list (SQLSTATE 42713).

SESSION_USER ('*authorization-name*', ...)
Specifies one or more authorization IDs for the SESSION USER connection attribute. An authorization ID cannot appear more than once in the list (SQLSTATE 42713).

SESSION_USER GROUP ('*authorization-name*', ...)
Specifies one or more authorization IDs for the SESSION_USER GROUP connection attribute. An authorization ID cannot appear more than once in the list (SQLSTATE 42713).

SESSION_USER ROLE ('*authorization-name*', ...)
Specifies one or more authorization IDs for the SESSION_USER ROLE connection attribute. The roles of a session authorization ID in this context refer to all the roles that are available to the session authorization ID, regardless of how the roles were obtained. An authorization ID cannot appear more than once in the list (SQLSTATE 42713).

CURRENT CLIENT_USERID ('*user-id*', ...)
Specifies one or more client user IDs for the CURRENT CLIENT_USERID connection attribute. A client user ID cannot appear more than once in the list (SQLSTATE 42713). If *user-id* contains a single asterisk character (*), the value is used as an expression to represent a set of user IDs, where the asterisk (*) represents a string of zero or more characters. If the expression needs to include an asterisk character in the user ID, use a sequence of two asterisk characters (**).

CURRENT CLIENT_APPLNAME ('*client-application-name*', ...)
Specifies one or more applications for the CURRENT CLIENT_APPLNAME connection attribute. An application name cannot appear more than once in the list (SQLSTATE 42713). If *client-application-name* does not contain a single asterisk character (*), is equivalent to the value shown in the "TP Monitor client application name" field in system monitor output. If *client-application-name* does contain a single asterisk character (*), the value is used as an expression to represent a set of application names, where the asterisk (*) represents a string of zero or more characters. If the expression needs to include an asterisk character in the application name, use a sequence of two asterisk characters (**).

CURRENT CLIENT_WRKSTNNAME ('*workstation-name*', ...)
Specifies one or more client workstation names for the CURRENT CLIENT_WRKSTNNAME connection attribute. A client workstation name cannot appear more than once in the list (SQLSTATE 42713). If *workstation-name* contains a single asterisk character (*), the value is used as an expression to represent a set of workstation names, where the asterisk (*) represents a string of zero or more characters. If the expression needs to include an asterisk character in the workstation name, use a sequence of two asterisk characters (**).

CURRENT CLIENT_ACCTNG ('*accounting-string*', ...)
Specifies one or more client accounting strings for the CURRENT CLIENT_ACCTNG connection attribute. A client accounting string cannot appear more than once in the list (SQLSTATE 42713). If *accounting-string* contains a single asterisk character (*), the value is used as an expression to represent a set of accounting strings, where the asterisk (*) represents a string of zero or more characters. If the expression needs to include an asterisk character in the accounting string, use a sequence of two asterisk characters (**).

ALLOW DB ACCESS or DISALLOW DB ACCESS
Specifies whether or not a workload occurrence associated with this workload is allowed access to the database.

ALLOW DB ACCESS
Specifies that workload occurrences associated with this workload are allowed access to the database.

DISALLOW DB ACCESS
Specifies that workload occurrences associated with this workload are not allowed access to the database. The next unit of work associated with this workload will be rejected (SQLSTATE 5U020). Workload occurrences that are already running are allowed to complete. This option cannot be specified if *workload-name* is 'SYSDEFAULTADMWORKLOAD' (SQLSTATE 42832).

ENABLE or DISABLE
Specifies whether or not this workload will be considered when a workload is chosen.

ENABLE
Specifies that the workload is enabled and will be considered when a workload is chosen.

DISABLE
Specifies that the workload is disabled and will not be considered when a workload is chosen. This option cannot be specified if *workload-name* is SYSDEFAULTUSERWORKLOAD or SYSDEFAULTADMWORKLOAD (SQLSTATE 42832).

MAXIMUM DEGREE
Specifies the maximum runtime degree of parallelism for this workload. The MAXIMUM DEGREE attribute can not be altered if *workload-name* is SYSDEFAULTADMWORKLOAD.

DEFAULT
If `DB2_WORKLOAD=ANALYTICS`, this setting enables intrapartition parallelism for this workload. Otherwise, this setting specifies that this workload inherits the intrapartition parallelism setting from the database manager configuration parameter **intra_parallel**. When **intra_parallel** is set to `NO`, this workload runs with intrapartition parallelism disabled. When **intra_parallel** is set to YES, this workload runs with intrapartition parallelism enabled. This workload does not specify a maximum runtime degree for assigned applications. Therefore, the actual runtime degree is determined as the lower of the value of **max_querydegree** configuration parameter, the MAXIMUM DEGREE set on the query service class, the value set by SET RUNTIME DEGREE command, and the SQL statement compilation degree.

degree
Specifies the maximum degree of parallelism for this workload. Valid values are 1 to 32,767. With value 1, the associated requests run with intrapartition parallelism disabled. With value 2 to 32,767, the associated requests run with intrapartition parallelism enabled. The actual runtime degree is determined as the lower of this *degree*, the value of **max_querydegree** configuration parameter, the MAXIMUM DEGREE set on the query service class, the value set by SET RUNTIME DEGREE command and the SQL statement compilation degree.

SERVICE CLASS *service-class-name*
Specifies that requests associated with this workload are to be executed in the service class *service-class-name*. The *service-class-name* must identify a service class that exists at the current server (SQLSTATE 42704). The *service-class-name* cannot be 'SYSDEFAULTSUBCLASS', 'SYSDEFAULTSYSTEMCLASS', or 'SYSDEFAULTMAINTENANCECLASS' (SQLSTATE 5U032). This option cannot be specified if *workload-name* is 'SYSDEFAULTADMWORKLOAD' (SQLSTATE 42832).

UNDER *service-superclass-name*
This clause is used when specifying a service subclass. The *service-superclass-name* identifies the service superclass of *service-class-name*. The *service-superclass-name* must identify a service superclass that exists at the current server (SQLSTATE 42704). The *service-superclass-name* cannot be 'SYSDEFAULTSYSTEMCLASS' or 'SYSDEFAULTMAINTENANCECLASS' (SQLSTATE 5U032).

POSITION
Specifies where this workload is to be placed within the ordered list of workloads. At run time, this list is searched in order for the first workload that matches the required connection attributes. This option cannot be specified if *workload-name* is 'SYSDEFAULTUSERWORKLOAD' or 'SYSDEFAULTADMWORKLOAD' (SQLSTATE 42832).

LAST
Specifies that the workload is to be last in the list, before the default workloads SYSDEFAULTUSERWORKLOAD and SYSDEFAULTADMWORKLOAD.

BEFORE *relative-workload-name*
Specifies that the workload is to be placed before workload *relative-workload-name* in the list. The *relative-workload-name* must identify a workload that exists at the current server (SQLSTATE 42704). The BEFORE option cannot be specified if *relative-workload-name* is 'SYSDEFAULTUSERWORKLOAD' or 'SYSDEFAULTADMWORKLOAD' (SQLSTATE 42832).

AFTER *relative-workload-name*
Specifies that the workload is to be placed after workload *relative-workload-name* in the list. The *relative-workload-name* must identify a workload that exists at the current server (SQLSTATE 42704). The AFTER option cannot be specified if *relative-workload-name* is 'SYSDEFAULTUSERWORKLOAD' or 'SYSDEFAULTADMWORKLOAD' (SQLSTATE 42832).

AT *position*
Specifies the absolute position at which the workload is to be placed in the list. This value can be any positive integer (not zero) (SQLSTATE 42615). If *position* is greater than the number of existing workloads plus one, the workload is placed at the last position, just before SYSDEFAULTUSERWORKLOAD and SYSDEFAULTADMWORKLOAD.

PRIORITY
Specifies the priority of the work from this workload compared to that of the work in other workloads in the same service superclass. Within a service superclass priority is used to prioritize more important jobs over less important jobs. Work scheduling across superclasses does not use the priority for scheduling, but instead uses only resource-based scheduling.

COLLECT ACTIVITY DATA
Specifies that data about each activity associated with this workload is to be sent to any active activities event monitor when the activity completes.

alter-collect-activity-data-clause

ON COORDINATOR MEMBER
Specifies that activity data is to be collected only at the coordinator member of the activity.

ON ALL MEMBERS
Specifies that activity data is to be collected at all members where the activity is processed. On remote members, a record for the activity may be captured multiple times as the activity comes and goes on those members. If the AND VALUES clause is specified, activity input values will be collected only for the members of the coordinator.

WITHOUT DETAILS
Specifies that data about each activity that is associated with this workload is to be sent to any active activities event monitor, when the activity completes execution. Details about statement, compilation environment, and section environment data are not sent.

WITH

DETAILS
Specifies that statement and compilation environment data is to be sent to any active activities event monitor, for those activities that have them. Section environment data is not sent.

SECTION
Specifies that statement, compilation environment, section environment data, and section actuals are to be sent to any active activities event monitor for those activities that have them. DETAILS must be specified if SECTION is specified. Section actuals will be collected on any member where the activity data is collected.

INCLUDE ACTUALS BASE
Specifies that section actuals should also be collected on any partition where the activity data is collected. For section actuals to be collected, either INCLUDE ACTUALS clause must be specified or the **section_actuals** database configuration parameter must be set.

The effective setting for the collection of section actuals is the combination of the INCLUDE ACTUALS clause, the **section_actuals** database configuration parameter, and the <collectsectionactuals> setting specified on the WLM_SET_CONN_ENV routine. For example, if INCLUDE ACTUALS BASE is specified, yet the **section_actuals** database configuration parameter value is NONE and <collectsectionactuals> is set to NONE, then the effective setting for the collection of section actuals is BASE.

BASE specifies that the following actuals should be enabled and collected during the activity's execution:

- Basic operator cardinality counts
- Statistics for each object referenced (DML statements only)

AND VALUES
Specifies that input data values are to be sent to any active activities event monitor, for those activities that have them. This data does not include SQL statements that are compiled by using the REOPT ALWAYS bind option.

NONE
Specifies that activity data is not collected for each activity that is associated with this workload.

COLLECT ACTIVITY METRICS
Specifies that monitor metrics should be collected for an activity submitted by an occurrence of the workload. The default is COLLECT ACTIVITY METRICS NONE.

The effective activity metrics collection setting is the combination of the attribute specified by the COLLECT ACTIVITY METRICS clause on the workload submitting the activity, and the MON_ACT_METRICS database configuration parameter. If either the workload attribute or the configuration parameter has a value other than NONE, metrics will be collected for the activity.

NONE
Specifies that no metrics will be collected for any activity submitted by an occurrence of the workload.

BASE
Specifies that basic metrics will be collected for any activity submitted by an occurrence of the workload.

EXTENDED
Specifies that basic metrics will be collected for any activity submitted by an occurrence of the workload. In addition, specifies that the values for the following monitor elements should be determined with additional granularity:

- **total_section_time**
- **total_section_proc_time**
- **total_routine_user_code_time**
- **total_routine_user_code_proc_time**
- **total_routine_time**

COLLECT AGGREGATE ACTIVITY DATA
Specifies that aggregate activity data about the activities associated with this workload is to be sent to the statistics event monitor, if one is active. This information is collected periodically on an interval that is specified by the **wlm_collect_int** database configuration parameter. The default when COLLECT AGGREGATE ACTIVITY DATA is specified is COLLECT AGGREGATE ACTIVITY DATA BASE.

BASE
Specifies that basic aggregate activity data about the activities associated with this workload is to be sent to the statistics event monitor, if one is active. Basic aggregate activity data includes:

- Estimated activity cost high watermark
- Rows returned high watermark
- Temporary table space usage high watermark. Only activities that have an SQLTEMPSPACE threshold applied to them participate in this high watermark.
- Activity life time histogram
- Activity queue time histogram
- Activity execution time histogram

EXTENDED
Specifies that all aggregate activity data about the activities associated with this workload is to be sent to the statistics event monitor, if one is active. This includes all basic aggregate activity data plus:

- Activity data manipulation language (DML) estimated cost histogram
- Activity DML inter-arrival time histogram

NONE
Specifies that no aggregate activity data is to be collected for this workload.

COLLECT AGGREGATE UNIT OF WORK DATA
Specifies that aggregate unit of work data about the units of work associated with this workload is to be sent to the statistics event monitor, if one is active. This information is collected periodically on an interval that is specified by the **wlm_collect_int** database configuration parameter. The default, when COLLECT AGGREGATE UNIT OF WORK DATA is specified, is COLLECT AGGREGATE UNIT OF WORK DATA BASE.

BASE
Specifies that basic aggregate unit of work data about the units of work associated with this workload is to be sent to the statistics event monitor, if one is active. Basic aggregate unit of work data includes:

- Unit of work lifetime histogram

NONE
Specifies that no aggregate unit of work data is to be collected for this workload.

COLLECT LOCK TIMEOUT DATA
Specifies that data about lock timeout events that occur within this workload is sent to any active locking event monitor when the lock event occurs. The lock timeout data is collected on all members. This setting works in conjunction with the **MON_LOCKTIMEOUT** database configuration setting. The setting that produces the most detailed output is honored.

alter-collect-history-clause

WITHOUT HISTORY
Specifies that data about lock events that occur within this workload is sent to any active locking event monitor when the lock event occurs. Past activity history and input values are not sent to the event monitor.

WITH HISTORY
Specifies to collect past activity history in the current unit of work for all of this type of lock events. The activity history buffer will wrap after the maximum size limit is used.

The default limit on the number of past activities to be kept by any one application is 250. If the number of past activities is greater than the limit, only the newest activities are reported. This default value can be overridden using the registry variable DB2_MAX_INACT_STMTS to specify a different value. You can choose a different value for the limit to increase or reduce the amount of system monitor heap used for past activity information.

AND VALUES
Specifies that input data values are to be sent to any active locking event monitor for those activities that have them. These data values will not include LOB data, LONG VARCHAR data, LONG VARGRAPHIC data, structured type data, or XML data. For SQL statements compiled using the REOPT ALWAYS bind option, there will be no REOPT compilation or statement execution data values provided in the event information.

NONE
Specifies that lock timeout data for the workload is not collected at any member.

COLLECT DEADLOCK DATA
Specifies that data about deadlock events that occur within this workload is sent to any active locking event monitor when the lock event occurs. The deadlock data is collected on all members. This setting is only honored if the **MON_DEADLOCK** database configuration parameter is not set to NONE.

alter-collect-history-clause

WITHOUT HISTORY
Specifies that data about lock events that occur within this workload is sent to any active locking event monitor when the lock event occurs. Past activity history and input values are not sent to the event monitor.

WITH HISTORY
Specifies to collect past activity history in the current unit of work for all of these type of lock events. The activity history buffer will wrap after the maximum size limit is used.

The default limit on the number of past activities to be kept by any one application is 250. If the number of past activities is greater than the limit, only the newest activities are reported. This default value can be overridden using the registry variable DB2_MAX_INACT_STMTS to specify a different value. You can choose a different value for the limit to increase or reduce the amount of system monitor heap used for past activity information.

AND VALUES
Specifies that input data values are to be sent to any active locking event monitor for those activities that have them. These data values will not include LOB data, LONG VARCHAR data, LONG VARGRAPHIC data, structured type data, or XML data. For SQL statements compiled using the REOPT ALWAYS bind option, there will be no REOPT compilation or statement execution data values provided in the event information.

COLLECT LOCK WAIT DATA
Specifies that data about lock wait events that occur within this workload is sent to any active locking even monitor when the lock has not been acquired within *wait-time*. This setting works in conjunction with the **mon_lockwait** and **mon_lw_thresh** database configuration parameters. The setting that produces the most detailed output is honored.

alter-collect-lock-wait-data-clause

FOR LOCKS WAITING MORE THAN *wait-time* SECONDS | MICROSECONDS) | 1 SECOND
Specifies that data about lock wait events that occur within this workload is sent to the applicable event monitor when the lock has not been acquired within *wait-time*.

This value can be any non-negative integer. Use a valid duration keyword to specify an appropriate unit of time for *wait-time*. The minimum valid value for the *wait-time* parameter is 1000 microseconds.

WITH HISTORY
Specifies to collect past activity history in the current unit of work for all of this type of lock events. The activity history buffer will wrap after the maximum size limit is used.

The default limit on the number of past activities to be kept by any one application is 250. If the number of past activities is greater than the limit, only the newest activities are reported. This default value can be overridden using the registry variable DB2_MAX_INACT_STMTS to specify a different value. You can choose a different value for the limit to increase or reduce the amount of system monitor heap used for past activity information.

AND VALUES
Specifies that input data values are to be sent to any active locking event monitor for those activities that have them. These data values will not include LOB data, LONG VARCHAR data, LONG VARGRAPHIC data, structured type data, or XML data. For SQL statements compiled using the REOPT ALWAYS bind option, there will be no REOPT compilation or statement execution data values provided in the event information.

NONE
Specifies that the lock wait event for the workload is not collected at any member.

COLLECT UNIT OF WORK DATA
Specifies that data about each unit of work, also referred to as a transaction, associated with this workload is to be sent to the unit of work event monitors, if any have been created, when the unit of work ends. The default is COLLECT UNIT OF WORK BASE. If the **mon_uow_data** database configuration parameter is set to BASE, it takes precedence over the COLLECT UNIT OF WORK DATA parameter. A value of NONE for the **mon_uow_data** indicates that the COLLECT UNIT OF WORK DATA parameters of individual workloads is used.

BASE
Specifies that the base level of data for transactions, associated with this workload, is sent to the unit of work event monitors.

Some of the information reported in a unit of work event are system level request metrics. The collection of these metrics is controlled independently from the collection of the unit of work data. The request metrics are controlled with the COLLECT REQUEST METRICS clause on superclass, or using the **mon_req_metrics** database configuration parameter. The service super class which the workload is associated with, or the service super class of the service subclass which the workload is associated with, must have the collection of request metrics enabled in order for the request metrics to be present in the unit of work event. If the request metrics collection is not enabled, the value of the request metrics will be zero.

INCLUDE PACKAGE LIST
Specifies that base level of data and the package list for transactions associated with this workload are sent to the unit of work event monitor.

The size of the collected package list is determined by the value of the **mon_pkglist_sz** database configuration parameter. If this value is 0, then the package list is not collected even if the PACKAGE LIST option is specified.

In a partitioned database environment, the package list is only available on the coordinator member. The BASE level will be collected on remote members.

Some of the information reported in a unit of work event are system level request metrics. The collection of these metrics is controlled independently from the collection of the unit of work data. The request metrics are controlled with the COLLECT REQUEST METRICS clause on superclass, or using the **mon_req_metrics** database configuration parameter. The service super class which the workload is associated with, or the service super class of the service subclass which the workload is associated with, must have the collection of request metrics enabled in order for the request metrics to be present in the unit of work event. If the request metrics collection is not enabled, the value of the request metrics will be zero.

INCLUDE EXECUTABLE LIST
Specifies that executable ID list will be collected for a unit of work together with base level of data and sent to the unit of work event monitor.

NONE
Specifies that no unit of work data for transactions associated with this workload is sent to the unit of work event monitor.

ACTIVITY LIFETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the duration, in milliseconds, of database activities running in the workload during a specific interval. This time

includes both time queued and time executing. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY QUEUETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities running in the workload are queued during a specific interval. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY EXECUTETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities running in the workload are executing during a specific interval. This time does not include the time spent queued. Activity execution time is collected in this histogram at the coordinator member only. The time does not include idle time. Idle time is the time between the execution of requests belonging to the same activity when no work is being done. An example of idle time is the time between the end of opening a cursor and the start of fetching from that cursor. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY ESTIMATEDCOST HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the estimated cost, in timerons, of DML activities running in the workload. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option.

ACTIVITY INTERARRIVALTIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, between the arrival of one DML activity into this workload and the arrival of the next DML activity into this workload. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option.

UOW LIFETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the duration, in milliseconds, of units of work running in the workload during a specific interval. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE UNIT OF WORK DATA clause is specified with the BASE option.

Rules

- A workload management (WLM)-exclusive SQL statement must be followed by a COMMIT or a ROLLBACK statement (SQLSTATE 5U021). WLM-exclusive SQL statements are:
  - CREATE HISTOGRAM TEMPLATE, ALTER HISTOGRAM TEMPLATE, or DROP (HISTOGRAM TEMPLATE)
  - CREATE SERVICE CLASS, ALTER SERVICE CLASS, or DROP (SERVICE CLASS)
  - CREATE THRESHOLD, ALTER THRESHOLD, or DROP (THRESHOLD)
  - CREATE WORK ACTION SET, ALTER WORK ACTION SET, or DROP (WORK ACTION SET)
  - CREATE WORK CLASS SET, ALTER WORK CLASS SET, or DROP (WORK CLASS SET)
  - CREATE WORKLOAD, ALTER WORKLOAD, or DROP (WORKLOAD)
  - GRANT (Workload Privileges) or REVOKE (Workload Privileges)
- A WLM-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.

Notes

- Changes are written to the system catalog, but do not take effect until they are committed, even for the connection that issues the statement. For newly submitted workload occurrences, changes take effect after the ALTER WORKLOAD statement commits. For active workload occurrences, changes take effect at the beginning of the next unit of work.

- Only one uncommitted WLM-exclusive SQL statement at a time is allowed across all partitions. If an uncommitted WLM-exclusive SQL statement is executing, subsequent WLM-exclusive SQL statements will wait until the current WLM-exclusive SQL statement commits or rolls back.
- If the DISABLE option is specified, the workload is disabled after the statement commits. The workload is not considered the next time that a workload is chosen. If there is an active workload occurrence associated with this workload when the ALTER WORKLOAD statement commits, it continues to run until the end of the current unit of work. At the beginning of the next unit of work, a workload re-evaluation takes place, and the connection becomes associated with a different workload.
- ***Privileges***: The USAGE privilege is not granted to any user, group, or role when a workload is created. To enable use of a workload, grant USAGE privilege on that workload to a user, a group, or a role using the GRANT USAGE ON WORKLOAD statement.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - DATABASE PARTITION can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - DATABASE PARTITIONS can be specified in place of MEMBERS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - COLLECT UNIT OF WORK DATA PACKAGE LIST can be specified in place of COLLECT UNIT OF WORK DATA BASE INCLUDE PACKAGE LIST.

Examples

- *Example 1:* The workload PAYROLL is currently positioned such that the workload INVENTORY is considered first when the database manager chooses a workload at run time. Alter the evaluation order so that PAYROLL will be considered first.

```
ALTER WORKLOAD PAYROLL
  POSITION BEFORE INVENTORY
```

- *Example 2:* Alter the evaluation order so that the workload BENCHMARK is evaluated by the database manager before any other workload in the catalog.

```
ALTER WORKLOAD BENCHMARK
  POSITION AT 1
```

- *Example 3:* The workload REPORTS was created with APPLNAME set to appl1, appl2, and appl3, and SYSTEM_USER set to BOB and MARY. Alter the workload to add a new application, appl4 to the application name list, and remove appl2, because it should no longer be mapped to REPORTS.

```
ALTER WORKLOAD REPORTS
  ADD APPLNAME ('appl4')
  DROP APPLNAME ('appl2')
```

- *Example 4:* Assuming a lock event monitor called LOCK exists and is active, create lock event records with statement history for lock timeout events that occur within the workload APP.

```
ALTER WORKLOAD APP
  COLLECT LOCK TIMEOUT DATA WITH HISTORY
```

- *Example 5:* Assuming a lock event monitor called LOCK exists and is active, create lock event records for only deadlock and lock timeout events that occur within the workload PAYROLL on all partitions.

```
ALTER WORKLOAD PAYROLL
  COLLECT DEADLOCK DATA
  COLLECT LOCK TIMEOUT DATA WITHOUT HISTORY
```

- *Example 6:* Assuming a lock event monitor called LOCK exists and is active, create lock event records with statement history and values for deadlock events that occur within the workload INVOICE.

```
ALTER WORKLOAD INVOICE
  COLLECT DEADLOCK DATA WITH HISTORY AND VALUES
```

- *Example 7:* Assuming a lock event monitor called LOCK exists and is active, create lock event records with statement history and values for locks acquired after waiting for more than 150 milliseconds that occur within the workload INVOICE.

```
ALTER WORKLOAD INVOICE
  COLLECT LOCK WAIT DATA FOR LOCKS WAITING MORE THAN 150000
  MICROSECONDS WITH HISTORY AND VALUES
```

- *Example 8:* Alter the workload REPORTS to collect unit of work data and send it to the unit of work event monitor:

```
ALTER WORKLOAD REPORTS
  COLLECT UNIT OF WORK DATA BASE
```

ALTER WRAPPER

The ALTER WRAPPER statement is used to update the properties of a wrapper.

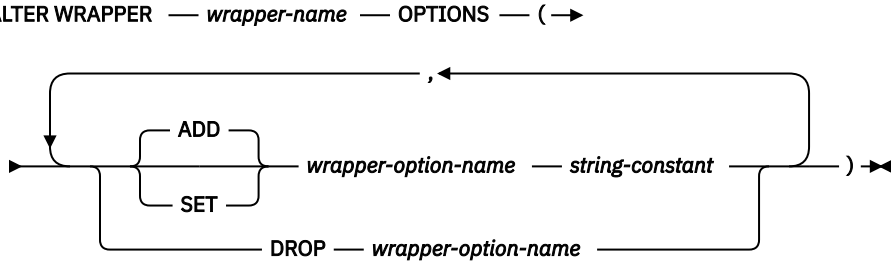
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include DBADM authority.

Syntax



Description

wrapper-name
Specifies the name of the wrapper.

OPTIONS
Indicates what wrapper options are to be enabled, reset, or dropped.

ADD
Enables a new wrapper option.

SET
Changes the setting of a wrapper option.

wrapper-option-name
The wrapper option that is to be added or reset. Which options you can specify depends on the data source of the object for which a wrapper is being created. For a list of data sources and the wrapper options that apply to each, see Data source options.

string-constant
The wrapper option setting as a character string constant enclosed in single quotation marks.

DROP *wrapper-option-name*
Drops a wrapper option.

Notes

- Execution of the ALTER WRAPPER statement does not include checking the validity of wrapper-specific options.
- An ALTER WRAPPER statement within a given unit of work (UOW) cannot be processed (SQLSTATE 55007) if the UOW already includes one of the following items:
  - A SELECT statement that references a nickname that belongs to the wrapper.
  - An open cursor on a nickname that belongs to the wrapper.
  - An INSERT, DELETE, or UPDATE statement issued against a nickname that belongs to the wrapper.

Example

Set the DB2_FENCED option on for wrapper NET8.

```
ALTER WRAPPER NET8 OPTIONS (SET DB2_FENCED 'Y')
```

ALTER XSROBJECT

This statement is used to either enable or disable the decomposition support for a specific XML schema. Annotated XML schemas can be used to decompose XML documents into relational tables, if decomposition has been enabled for those XML schemas.

Invocation

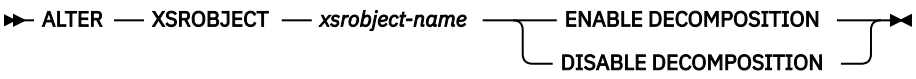
The ALTER XSROBJECT statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if the DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

One of the following authorities is required:

- DBADM
- ALTERIN on the SQL schema
- SCHEMAADM authority on the SQL schema
- Ownership of the XSR object to be altered

Syntax



Description

xsrobject-name
Identifies the XSR object to be altered. The *xsrobject-name*, including the implicit or explicit schema qualifier, must uniquely identify an existing XSR object at the current server. If no XSR object with this identifier exists, an error is returned (SQLSTATE 42704).

ENABLE DECOMPOSITION or DISABLE DECOMPOSITION
Enables or disables the use of the XSR object for decomposition. The identified XSR object must be an XML schema (SQLSTATE 42809). In order to enable decomposition, the XML schema needs to be annotated with decomposition rules (SQLSTATE 225DE) and the objects referenced by the decomposition rules must exist at the current server (SQLSTATE 42704).

Notes

- When decomposition for an XSR object is disabled, all related catalog entries are removed.
- Decomposition support for an XSR object will be disabled if any objects the XSR object depends on (such as tables) are dropped or altered to become incompatible with the XSR object.
- In a partitioned database environment, you can issue this statement by connecting to any partition.

ASSOCIATE LOCATORS

The ASSOCIATE LOCATORS statement gets the result set locator value for each result set returned by a procedure.

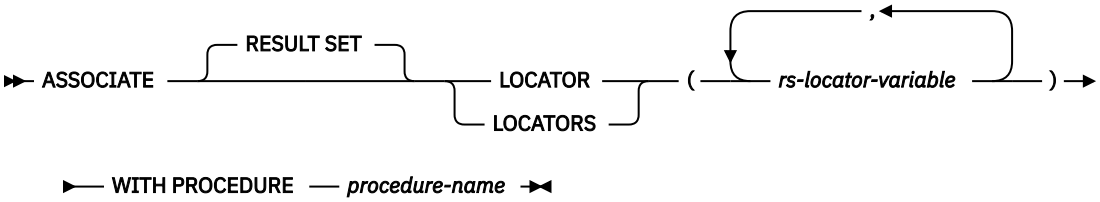
Invocation

This statement can only be embedded in an SQL procedure. It is not an executable statement and cannot be dynamically prepared.

Authorization

None required.

Syntax



Description

rs-locator-variable
Specifies a result set locator variable that has been declared in a compound SQL (Procedure) statement.

WITH PROCEDURE
Identifies the procedure that returns result set locators by the specified procedure name.

procedure-name
A procedure name is a qualified or unqualified name.

A fully qualified procedure name is a two-part name. The first part is an identifier that contains the schema name of the procedure. The last part is an identifier that contains the name of the procedure. A period must separate each of the parts. Any or all of the parts can be a delimited identifier.

If the procedure name is unqualified, it has only one name because the implicit schema name is not added as a qualifier to the procedure name. Successful execution of the ASSOCIATE LOCATOR statement only requires that the unqualified procedure name in the statement be the same as the procedure name in the most recently executed CALL statement that was specified with an unqualified procedure name. The implicit schema name for the unqualified name in the CALL statement is not considered in the match. The rules for how the procedure name must be specified are described in the following paragraph.

When the ASSOCIATE LOCATORS statement is executed, the procedure name or specification must identify a procedure that the requester has already invoked using the CALL statement. The procedure name in the ASSOCIATE LOCATORS statement must be specified the same way that it was specified on the CALL statement. For example, if a two-part name was specified on the CALL statement, you must use a two-part name in the ASSOCIATE LOCATORS statement.

Notes

- If the number of result set locator variables that are listed in the ASSOCIATE LOCATORS statement is less than the number of locators returned by the procedure, all variables in the statement are assigned a value, and a warning is issued.
- If the number of result set locator variables that are listed in the ASSOCIATE LOCATORS statement is greater than the number of locators returned by the procedure, the extra variables are assigned a value of 0.
- If a procedure is called more than once from the same caller, only the most recent result sets are accessible.
- Result set locator values are available for a procedure that is called using an EXECUTE statement executing the CALL statement that was previously prepared by the PREPARE statement. Result set locator values, however, are not available for a procedure that is called using an EXECUTE IMMEDIATE statement.
- Module-procedure names referenced in an ASSOCIATE LOCATORS statement can only be 1-part or 2-part qualified name references. A 3-part name reference is not allowed (SQLSTATE 42601). Any CALL statement that references a module-procedure that was referenced in an ASSOCIATE LOCATORS statement, must specify the module-procedure with the same 1-part or 2-part qualified name used in the ASSOCIATE LOCATORS statement.

Examples

The statements in the following examples are assumed to be embedded in SQL Procedures.

- *Example 1*: Use result set locator variables LOC1 and LOC2 to get the result set locator values for the two result sets returned by procedure P1. Assume that the procedure is called with a one-part name.

```
CALL P1;
ASSOCIATE RESULT SET LOCATORS (LOC1, LOC2)
  WITH PROCEDURE P1;
```

- *Example 2*: Repeat the scenario in Example 1, but use a two-part name to specify an explicit schema name for the procedure to ensure that procedure P1 in schema MYSCHEMA is used.

```
CALL MYSCHEMA.P1;
ASSOCIATE RESULT SET LOCATORS (LOC1, LOC2)
  WITH PROCEDURE MYSCHEMA.P1;
```

AUDIT

The AUDIT statement determines the audit policy that is to be used for a particular database or database object at the current server. Whenever the object is in use, it is audited according to that policy.

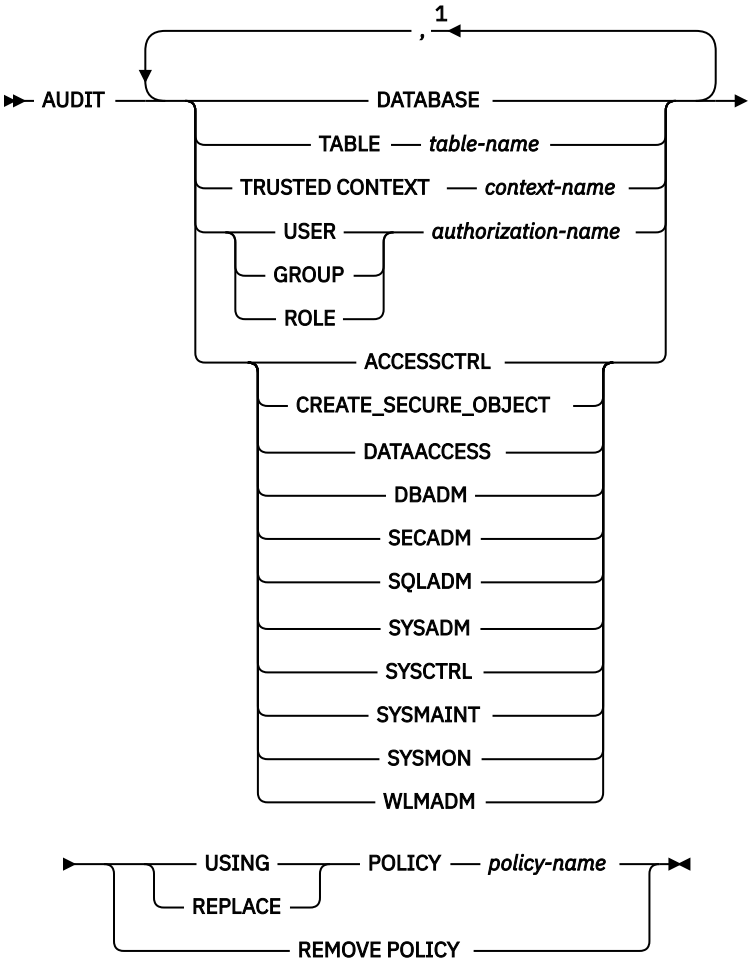
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Notes:

[1] Each clause (with the same object name, if applicable) can be specified at most once (SQLSTATE 42713).

Description

ACCESSCTRL, CREATE_SECURE_OBJECT, DATAACCESS, DBADM, SECADM, SQLADM, SYSADM, SYSCTRL, SYSMAINT, SYSMON, or WLMADM
Specifies that an audit policy is to be associated with or removed from the specified authority. All auditable events that are initiated by a user who holds the specified authority, even if that authority is not required for the event, will be audited according to the associated audit policy.

DATABASE
Specifies that an audit policy is to be associated with or removed from the database at the current server. All auditable events that occur within the database are audited according to the associated audit policy.

TABLE *table-name*
Specifies that an audit policy is to be associated with or removed from *table-name*. The *table-name* must identify a table, materialized query table (MQT), or nickname that exists at the current server (SQLSTATE 42704). It cannot be a view, a catalog table, a created temporary table, a declared temporary table (SQLSTATE 42995), or a typed table (SQLSTATE 42997). Only EXECUTE category audit events, with or without data, will be generated when the table is accessed, even if the policy indicates that other categories should be audited.

TRUSTED CONTEXT *context-name*
Specifies that an audit policy is to be associated with or removed from *context-name*. The *context-name* must identify a trusted context that exists at the current server (SQLSTATE 42704). All auditable events that happen within the trusted connection defined by the trusted context *context-name* will be audited according to the associated audit policy.

USER *authorization-name*
Specifies that an audit policy is to be associated with or removed from the user with authorization ID *authorization-name*. All auditable events that are initiated by *authorization-name* will be audited according to the associated audit policy.

GROUP *authorization-name*
Specifies that an audit policy is to be associated with or removed from the group with authorization ID *authorization-name*. All auditable events that are initiated by users who are members of *authorization-name* will be audited according to the associated audit policy. If user membership in a group cannot be determined, the policy will not apply to that user.

ROLE *authorization-name*
Specifies that an audit policy is to be associated with or removed from the role with authorization ID *authorization-name*. The *authorization-name* must identify a role that exists at the current server (SQLSTATE 42704). All auditable events that are initiated by users who are members of *authorization-name* will be audited according to the associated audit policy. Indirect role membership through other roles or groups is valid.

USING, REMOVE, or REPLACE
Specifies whether the audit policy should be used, removed, or replaced for the specified object.

USING
Specifies that the audit policy is to be used for the specified object. An existing audit policy must not already be defined for the object (SQLSTATE 5U041). If an audit policy already exists, it must be removed or replaced.

REMOVE
Specifies that the audit policy is to be removed from the specified object. Use of the object will no longer be audited according to the audit policy. The association is deleted from the catalog when the audit policy is removed from the object.

REPLACE
Specifies that the audit policy is to replace an existing audit policy for the specified object. This combines both REMOVE and USING options into one step to ensure that there is no period of time in which an audit policy does not apply to the specified object. If a policy was not in use for the specified object, REPLACE is equivalent to USING.

POLICY *policy-name*

Specifies the audit policy that is to be used to determine audit settings. The *policy-name* must identify an existing audit policy at the current server (SQLSTATE 42704).

Rules

- An AUDIT-exclusive SQL statement must be followed by a COMMIT or ROLLBACK statement (SQLSTATE 5U021). AUDIT-exclusive SQL statements are:
  - AUDIT
  - CREATE AUDIT POLICY, ALTER AUDIT POLICY, or DROP (AUDIT POLICY)
  - DROP (ROLE or TRUSTED CONTEXT if it is associated with an audit policy)
- An AUDIT-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.
- An object can be associated with no more than one policy (SQLSTATE 5U042).

Notes

- Packages that are dependent on the table that is being audited become invalid when an audit policy is added or removed from that table.
- Changes are written to the catalog, but do not take effect until after a COMMIT statement executes.
- Changes do not take effect until the next unit of work that references the object to which the audit policy applies. For example, if the audit policy is in use for the database, no current units of work will begin auditing according to the policy until after a COMMIT or a ROLLBACK statement completes.
- Views accessing a table that is associated with an audit policy are audited according to the underlying table's policy.
- The audit policy that applies to a table does not apply to a materialized query table (MQT) based on that table. It is recommended that if you associate an audit policy with a table, you also associate that policy with any MQT based on that table. The compiler might automatically use an MQT, even though an SQL statement references the base table; however, the audit policy in use for the base table will still be in effect.
- When a switch user operation is performed within a trusted context, all audit policies are re-evaluated according to the new user, and no policies from the old user are used for the current session. This applies specifically to audit policies associated directly with the user, the user's group or role memberships, and the user's authorities. For example, if the current session was audited because the previous user was a member of an audited role, and the switched-to user is not a member of that role, that policy no longer applies to the session.
- When a SET SESSION USER statement is executed, the audit policies associated with the original user (and that user's group and role memberships and authorities) are combined with the policies that are associated with the user specified in the SET SESSION USER statement. The audit policies associated with the original user are still in effect, as are the policies for the user specified in the SET SESSION USER statement. If multiple SET SESSION USER statements are issued within a session, only the audit policies associated with the original user and the current user are considered.
- If the object with which an audit policy is associated is dropped, the association to the audit policy is removed from the catalog and no longer exists. If that object is recreated at some later time, the object will not be audited according to the policy that was associated with it when the object was dropped.
- When multiple objects are specified, the policy applies to each of them individually. The policy applies to the individual objects within the statement, and not their intersection. It is not possible to combine policies with an "AND" type configuration.

Examples

- *Example 1:* Use the audit policy DBAUDPRF to determine the audit settings for the database at the current server.

```
AUDIT DATABASE USING POLICY DBAUDPRF
```

- *Example 2:* Remove the audit policy from the EMPLOYEE table.

```
AUDIT TABLE EMPLOYEE REMOVE POLICY
```

- *Example 3:* Use the audit policy POWERUSERS to determine the audit settings for the authorities SYSADM, DBADM, and SECADM, as well as the group DBAS.

```
AUDIT SYSADM, DBADM, SECADM, GROUP DBAS USING POLICY POWERUSERS
```

- *Example 4:* Replace the audit policy for the role TELLER with the new policy TELLERPRF.

```
AUDIT ROLE TELLER REPLACE POLICY TELLERPRF
```

- *Example 5:* Specifying multiple objects

```
AUDIT TABLE EMPLOYEE, ROLE TELLER USING POLICY TABLEAUDIT
```

The above statement is equivalent to these separate statements:

```
AUDIT TABLE EMPLOYEE USING POLICY TABLEAUDIT
AUDIT ROLE TELLER USING POLICY TABLEAUDIT
```

BEGIN DECLARE SECTION

The BEGIN DECLARE SECTION statement marks the beginning of a host variable declare section.

Invocation

This statement can only be embedded in an application program. It is not an executable statement. It must not be specified in REXX.

Authorization

None required.

Syntax

Description

The BEGIN DECLARE SECTION statement may be coded in the application program wherever variable declarations can appear in accordance with the rules of the host language. It is used to indicate the beginning of a host variable declaration section. A host variable section ends with an END DECLARE SECTION statement.

Rules

- The BEGIN DECLARE SECTION and the END DECLARE SECTION statements must be paired and may not be nested.
- SQL statements cannot be included within the declare section.
- Variables referenced in SQL statements must be declared in a declare section in all host languages other than REXX. Furthermore, the section must appear before the first reference to the variable.

Generally, host variables are not declared in REXX with the exception of LOB locators and file reference variables. In this case, they are not declared within a BEGIN DECLARE SECTION.

- Variables declared outside a declare section should not have the same name as variables declared within a declare section.
- LOB data types must have their data type and length preceded with the SQL TYPE IS keywords.

Examples

- *Example 1:* Define the host variables hv_smint (smallint), hv_vchar24 (varchar(24)), hv_double (double), hv_blob_50k (blob(51200)), hv_struct (of structured type "struct_type" as blob(10240)) in a C program.

```
EXEC SQL  BEGIN DECLARE SECTION;
  short  hv_smint;
  struct {
  short hv_vchar24_len;
  char  hv_vchar24_value[24];
 }                              hv_vchar24;
  double hv_double;
  SQL TYPE IS BLOB(50K) hv_blob_50k;
  SQL TYPE IS struct_type AS BLOB(10k) hv_struct;
EXEC SQL  END DECLARE SECTION;
```

- *Example 2:* Define the host variables HV-SMINT (smallint), HV-VCHAR24 (varchar(24)), HV-DEC72 (dec(7,2)), and HV-BLOB-50k (blob(51200)) in a COBOL program.

```
WORKING-STORAGE SECTION.
      EXEC SQL BEGIN DECLARE SECTION  END-EXEC.
01  HV-SMINT              PIC S9(4)       COMP-4.
01  HV-VCHAR24.
    49 HV-VCHAR24-LENGTH  PIC S9(4)       COMP-4.
    49 HV-VCHAR24-VALUE   PIC X(24).
01  HV-DEC72              PIC S9(5)V9(2)  COMP-3.
01 HV-BLOB-50K            USAGE SQL TYPE IS BLOB(50K).
      EXEC SQL END DECLARE SECTION  END-EXEC.
```

- *Example 3:* Define the host variables HVSMINT (smallint), HVVCHAR24 (char(24)), HVDOUBLE (double), and HVBLOB50k (blob(51200)) in a Fortran program.

```
EXEC SQL  BEGIN DECLARE SECTION
  INTEGER*2      HVSMINT
  CHARACTER*24   HVVCHAR24
  REAL*8         HVDOUBLE
  SQL TYPE IS BLOB(50K)  HVBLOB50K
EXEC SQL  END DECLARE SECTION
```

Note: In Fortran, if the expected value is greater than 254 bytes, then a CLOB host variable should be used.

- *Example 4:* Define the host variables HVSMINT (smallint), HVBLOB50K (blob(51200)), and HVCLOBLOC (a CLOB locator) in a REXX program.

```
DECLARE :HVCLOBLOC  LANGUAGE TYPE CLOB LOCATOR
call sqlexec 'FETCH c1 INTO :HVSMINT, :HVBLOB50K'
```

Note that the variables HVSMINT and HVBLOB50K were implicitly defined by using them in the FETCH statement.

CALL

The CALL statement calls a procedure or a foreign procedure.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

When invoked using the command line processor, there are some additional rules for specifying arguments of the procedure.

For more information, refer to "Using command line SQL statements and XQuery statements" in *Command Reference*.

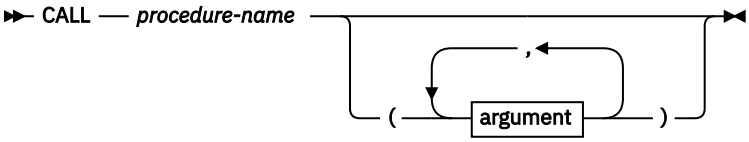
Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

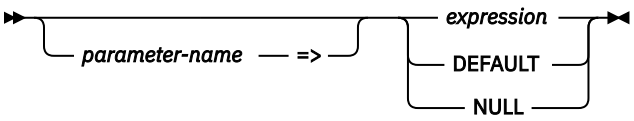
- EXECUTE privilege on the procedure
- EXECUTEIN privilege on the schema containing the procedure
- DATAACCESS authority on the schema containing the procedure
- DATAACCESS authority

If a matching procedure exists that the authorization ID of the statement is not authorized to execute, an error is returned (SQLSTATE 42501).

Syntax



argument



Description

procedure-name
Specifies the procedure that is to be called. It must be a procedure that is described in the catalog or that is declared in the scope of the compound SQL (compiled) statement that includes the CALL statement. The specific procedure to invoke is chosen using procedure resolution. (For more details, see the "Notes" section of this statement.)

argument

parameter-name
Name of the parameter to which the argument is assigned. When an argument is assigned to a parameter by name, then all the arguments that follow it must also be assigned by name (SQLSTATE 4274K).

A named argument must be specified only once (implicitly or explicitly) (SQLSTATE 4274K).

Named arguments are not supported on the call to an uncataloged procedure (SQLSTATE 4274K).

***expression* or DEFAULT or NULL**
Each specification of *expression*, the DEFAULT keyword, or the NULL keyword is an argument of the CALL. The *n*th unnamed argument of the CALL statement corresponds to the *n*th parameter defined in the CREATE PROCEDURE statement for the procedure.

Named arguments correspond to the same named parameter, regardless of the order in which they are specified.

If the DEFAULT keyword is specified, the default as defined in the CREATE PROCEDURE statement is used if it exists; otherwise the null value is used as the default.

If the NULL keyword is specified, the null value is passed as the parameter value.

Each argument of the CALL must be compatible with the corresponding parameter in the procedure definition as follows:

- IN parameter
  - The argument must be assignable to the parameter.
  - The assignment of a string argument uses the storage assignment rules.
- OUT parameter
  - The argument must be a single variable or parameter marker (SQLSTATE 42886).
  - The argument must be assignable to the parameter.
  - The assignment of a string argument uses the retrieval assignment rules.
- INOUT parameter
  - The argument must be a single variable or parameter marker (SQLSTATE 42886).
  - The argument must be assignable to the parameter.
  - The assignment of a string argument uses the storage assignment rules on invocation and the retrieval assignment rules on return.

Notes

- ***Parameter assignments:*** When the CALL statement is executed, the value of each of its arguments is assigned (using storage assignment) to the corresponding parameter of the procedure. A parameter value that is defined to have a default value can be omitted from the argument list when invoking the procedure.

  When the CALL statement is executed, control is passed to the procedure according to the calling conventions of the host language. When execution of the procedure is complete, the value of each parameter of the procedure is assigned (using storage assignment) to the corresponding argument of the CALL statement defined as OUT or INOUT. If an error is returned by the procedure, OUT arguments are undefined and INOUT arguments are unchanged. For details on the assignment rules, see "Assignments and comparisons".

  When the CALL statement is in an SQL procedure and is calling another SQL procedure, assignment of XML parameters is done by reference. When an XML argument is passed by reference, the input node trees, if any, are used directly from the XML argument, preserving all properties, including document order, the original node identities, and all parent properties.
- ***Procedure signatures:*** A procedure is identified by its schema, a procedure name, and the number of parameters. This is called a procedure signature, which must be unique within the database. There can be more than one procedure with the same name in a schema, provided that the number of parameters is different for each procedure.
- ***SQL path:*** A procedure can be invoked by referring to a qualified name (schema and procedure name), followed by an optional list of arguments enclosed by parentheses. A procedure can also be invoked without the schema name, resulting in a choice of possible procedures in different schemas with the same number of parameters. In this case, the SQL path is used to assist in procedure resolution. The SQL path is a list of schemas that is searched to identify a procedure with the same name and number of parameters. For static CALL statements, SQL path is specified using the FUNCPATH bind option. For dynamic CALL statements, SQL path is the value of the CURRENT PATH special register.
- ***Procedure resolution:*** Given a procedure invocation, the database manager must decide which of the possible procedures with the same name to execute.

  Local scope procedure resolution is used when a procedure is invoked from within a compound SQL (compiled) statement and either of the following criteria exist:

  - A procedure with the same name as the invoked procedure is declared in the same compound SQL (compiled) statement

– A procedure with the same name as the invoked procedure is declared in a compound SQL (compiled) statement within which the compound SQL (compiled) statement that invoked the procedure is nested

Local scope procedure resolution means that only declared procedures within the scope of the compound SQL (compiled) statement that invoked the procedure are considered during procedure resolution regardless of the existence of possible matching built-in procedures, schema procedures, or module procedures. *Global scope procedure resolution* is used in all other cases and considers candidates from schemas and modules depending on the context of the invocation and the qualification of the procedure name.

– Let *A* be the number of arguments in a procedure invocation.
– Let *P* be the number of parameters in a procedure signature.
– Let *N* be the number of parameters without a default.

Candidate procedures for resolution of a procedure invocation are selected based on the following criteria:

– Each candidate procedure has a matching name and an applicable number of parameters. An applicable number of parameters satisfies the condition $N \leq A \leq P$.
– Each candidate procedure has parameters such that for each named argument in the CALL statement there exists a parameter with a matching name that does not already correspond to a positional (or unnamed) argument.
– Each parameter of a candidate procedure that does not have a corresponding argument in the CALL statement, specified by either position or name, is defined with a default.
– Each candidate procedure from a set of one or more schemas has the EXECUTE privilege associated with the authorization ID of the statement invoking the function.
– Each candidate procedure from a schema has the EXECUTEIN privilege or DATAACCESS authority on the schema associated with the authorization ID of the statement invoking the function.

In addition, the set of candidate procedures depends on the environment where the procedure is invoked and how the procedure name is qualified.

– If the procedure name is unqualified, procedure resolution is done using the steps that follow:

  1. If the procedure is invoked from within a compound SQL (compiled) statement and a declared procedure with the same name exists in the nested scope, search the set of compound SQL (compiled) statements within which the CALL statement is nested for candidate procedures. If no candidate procedures are found, an error is returned (SQLSTATE 42884). If a single candidate procedure is found, resolution is complete. If there are multiple candidate procedures, determine the candidate procedure with the lowest number of parameters and eliminate candidate procedures with a higher number of parameters.
  2. If the procedure is invoked from within a module object, search within the module for candidate procedures. If one or more candidate procedures are found in the context module, then these candidate procedures are included with any candidate procedures from the schemas in the SQL path (see next item).
  3. Search all schema procedures with a schema in the SQL path for candidate procedures. If one or more candidate procedures are found in the schemas of the SQL path, then these candidate procedures are included with any candidate procedures from the context module (see previous item). If a single candidate procedure remains, resolution is complete. If there are multiple candidate procedures, choose the procedure from the context module if still a candidate and otherwise choose the procedure whose schema is earliest in the SQL path. If there are still multiple candidate procedures, determine the candidate procedure with the lowest number of parameters and eliminate candidate procedures with a higher number of parameters.

  If there are no candidate procedures remaining after step 3, an error is returned (SQLSTATE 42884).

– If the procedure name is qualified, procedure resolution is done using the steps that follow:

1. If the procedure is invoked from within a compound SQL (compiled) statement and a declared procedure with the same name exists where the qualifier matches the label of the compound SQL (compiled) statement from the set of compound SQL (compiled) statements within which the CALL statement is nested, search that compound SQL (compiled) statement with the matching label for candidate procedures. If no candidate procedures are found, an error is returned (SQLSTATE 42884). If a single candidate procedure is found, resolution is complete. If there are multiple candidate procedures, determine the candidate procedure with the lowest number of parameters and eliminate candidate procedures with a higher number of parameters.
2. If the procedure is invoked from within a module and the qualifier matches the name of the module from within which the procedure is invoked, search within the module for candidate procedures. If the qualifier is a single identifier, then the schema name of the module is ignored when matching the module name. If the qualifier is a two part identifier, then it is compared to the schema-qualified module name when determining a match. If a single candidate procedure exists, resolution is complete. If there are multiple candidate procedures, choose the candidate procedure with the least number of parameters. If the qualifier does not match or there are no candidate procedures, then continue with the next step.
3. Consider the qualifier as a schema name and search within that schema for candidate procedures. If a single candidate procedure exists, resolution is complete. If there are multiple candidate procedures, choose the candidate procedure with the least number of parameters and resolution is complete. If the schema does not exist or there are no authorized candidate procedures, and the qualifier matched the name of the module in the first step, then return an error. Otherwise, continue to the next step.
4. Consider the qualifier as a module name, without considering EXECUTE privilege on modules.
   - If the module name is qualified with a schema name, then search published procedures within this module for candidate procedures.
   - If the module name is not qualified with a schema name, then the schema for the module is the first schema in the SQL path that has a matching module name. If found, then search published procedures within this module for candidate procedures.
   - If the module is not found using the SQL path, check for a module public alias that matches the name of the procedure qualifier. If found, then search published procedures within this module for candidate procedures.

   If a matching module is not found or there are no candidate procedures in the matching module, then a procedure not found error is returned (SQLSTATE 42884). If there are multiple candidate procedures, choose the candidate procedure with the least number of parameters. Resolution is complete if the authorization ID of the CALL statement has EXECUTE privilege on the module, or EXECUTEIN privilege on the schema containing the module, of the remaining candidate procedure, otherwise an authorization error is returned (SQLSTATE 42501).

- ***Retrieving the DB2_RETURN_STATUS from an SQL procedure:*** If an SQL procedure successfully issues a RETURN statement with a status value, this value is returned in the first SQLERRD field of the SQLCA. If the CALL statement is issued in an SQL procedure, use the GET DIAGNOSTICS statement to retrieve the DB2_RETURN_STATUS value. The value is -1 if the SQLSTATE indicates an error. The values is 0 if no error is returned and the RETURN statement was not specified in the procedure.
- ***Returning result sets from procedures:*** If the calling program is written using CLI, JDBC, or SQLJ, or the caller is an SQL procedure, result sets can be returned directly to the caller. The procedure indicates that a result set is to be returned by declaring a cursor on that result set, opening a cursor on the result set, and leaving the cursor open when exiting the procedure.

  At the end of a procedure:

  – For every cursor that has been left open, a result set is returned to the caller or (for WITH RETURN TO CLIENT cursors) directly to the client.
  – Only unread rows are passed back. For example, if the result set of a cursor has 500 rows, and 150 of those rows have been read by the procedure at the time the procedure is terminated, rows 151 through 500 will be returned to the caller or application (as appropriate).

If the procedure was invoked from CLI or JDBC, and more than one cursor is left open, the result sets can only be processed in the order in which the cursors were opened.

- ***Improving performance:*** The values of all arguments are passed from the application to the procedure. To improve the performance of this operation, host variables that correspond to OUT parameters and have lengths of more than a few bytes should be set to the null value before the CALL statement is executed.
- ***Nesting CALL statements:*** Procedures can be called from routines as well as application programs. When a procedure is called from a routine, the call is considered to be nested.

  If a procedure returns any query result sets, the result sets are returned as follows:

  – RETURN TO CALLER result sets are visible only to the program that is at the previous nesting level.
  – RETURN TO CLIENT results sets are visible only if the procedure was invoked from a set of nested procedures. If a function or method occurs anywhere in the call chain, the result set is not visible. If the result set is visible, it is only visible to the client application that made the initial procedure call.

  Consider the following example:

```
Client program:
EXEC SQL CALL PROCA;

  PROCA:
  EXEC SQL CALL PROCB;

    PROCB:
    EXEC SQL DECLARE B1 CURSOR WITH RETURN TO CLIENT ...;
    EXEC SQL DECLARE B2 CURSOR WITH RETURN TO CALLER ...;
    EXEC SQL DECLARE B3 CURSOR FOR SELECT UDFA FROM T1;

      UDFA:
      EXEC SQL CALL PROCC;

        PROCC:
        EXEC SQL DECLARE C1 CURSOR WITH RETURN TO CLIENT ...;
        EXEC SQL DECLARE C2 CURSOR WITH RETURN TO CALLER ...;
```

  From procedure PROCB:

  – Cursor B1 is visible in the client application, but not visible in procedure PROCA.
  – Cursor B2 is visible in PROCA, but not visible to the client.

  From procedure PROCC:

  – Cursor C1 is visible to neither UDFA nor to the client application. (Because UDFA appears in the call chain between the client and PROCC, the result set is not returned to the client.)
  – Cursor C2 is visible in UDFA, but not visible to any of the higher procedures.
- ***Nesting procedures within triggers, compound statements, functions, or methods:*** When a procedure is called within a trigger, compound statement, function, or method:

  – The procedure must not issue a COMMIT or a ROLLBACK statement.
  – Result sets returned from the procedure cannot be accessed.
  – If the procedure is defined as READS SQL DATA or MODIFIES SQL DATA, no statement in the procedure can access a table that is being modified by the statement that invoked the procedure (SQLSTATE 57053). If the procedure is defined as MODIFIES SQL DATA, no statement in the procedure can modify a table that is being read or modified by the statement that invoked the procedure (SQLSTATE 57053).

    When a procedure is called within a function or method:

    - The procedure has the same table access restrictions as the invoking function or method.
    - Savepoints defined before the function or method was invoked will not be visible to the procedure, and savepoints defined inside the procedure will not be visible outside the function or method.
    - RETURN TO CLIENT result sets returned from the procedure cannot be accessed from the client.

- ***Compilation of CALL statements from Db2 for IBM i and Db2 for z/OS:*** The compilation of CALL statements from Db2 for IBM i and Db2 for z/OS implicitly behave as if CALL_RESOLUTION DEFERRED was specified. When CALL statements are compiled with CALL_RESOLUTION DEFERRED, all arguments must be provided via host variables, and expressions are not allowed.
- ***Syntax alternatives:*** There is an older form of the CALL statement that can be embedded in an application by precompiling the application with the CALL_RESOLUTION DEFERRED option. This option is not available for SQL procedures and federated procedures.

Examples

- *Example 1:* A Java procedure is defined in the database using the following statement:

```
CREATE PROCEDURE PARTS_ON_HAND (IN PARTNUM INTEGER,
                                OUT COST DECIMAL(7,2),
                                OUT QUANTITY INTEGER)
               EXTERNAL NAME 'parts!onhand'
               LANGUAGE JAVA
               PARAMETER STYLE DB2GENERAL;
```

  A Java application calls this procedure using the following code fragment:

```
...
CallableStatement stpCall;

String sql = "CALL PARTS_ON_HAND (?, ?, ?)";

stpCall = con.prepareCall(sql); /*con is the connection */

stpCall.setInt(1, hvPartnum);
stpCall.setBigDecimal(2, hvCost);
stpCall.setInt(3, hvQuantity);

stpCall.registerOutParameter(2, Types.DECIMAL, 2);
stpCall.registerOutParameter(3, Types.INTEGER);

stpCall.execute();

hvCost = stpCall.getBigDecimal(2);
hvQuantity = stpCall.getInt(3);
...
```

  This application code fragment will invoke the Java method onhand in class `parts`, because the procedure name specified on the CALL statement is found in the database and has the external name `parts!onhand`.

- *Example 2:* There are six FOO procedures, in four different schemas, registered as follows (note that not all required keywords appear):

```
CREATE PROCEDURE AUGUSTUS.FOO (INT) SPECIFIC FOO_1 ...
CREATE PROCEDURE AUGUSTUS.FOO (DOUBLE, DECIMAL(15, 3)) SPECIFIC FOO_2 ...
CREATE PROCEDURE JULIUS.FOO (INT) SPECIFIC FOO_3 ...
CREATE PROCEDURE JULIUS.FOO (INT, INT, INT) SPECIFIC FOO_4 ...
CREATE PROCEDURE CAESAR.FOO (INT, INT) SPECIFIC FOO_5 ...
CREATE PROCEDURE NERO.FOO (INT,INT) SPECIFIC FOO_6 ...
```

  The procedure reference is as follows (where I1 and I2 are INTEGER values):

```
CALL FOO(I1, I2)
```

  Assume that the application making this reference has an SQL path established as:

```
"JULIUS", "AUGUSTUS", "CAESAR"
```

  Following through the algorithm...

  The procedure with specific name FOO_6 is eliminated as a candidate, because the schema "NERO" is not included in the SQL path. FOO_1, FOO_3, and FOO_4 are eliminated as candidates, because they have the wrong number of parameters. The remaining candidates are considered in order, as determined by the SQL path. Note that the types of the arguments and parameters are ignored.

The parameters of FOO_5 exactly match the arguments in the CALL, but FOO_2 is chosen because "AUGUSTUS" appears before "CAESAR" in the SQL path.

- *Example 3:* Assume the following procedure exists.

```
CREATE PROCEDURE update_order(
                  IN IN_POID BIGINT,
                  IN IN_CUSTID BIGINT DEFAULT GLOBAL_CUST_ID,
                  IN NEW_STATUS VARCHAR(10) DEFAULT NULL,
                  IN NEW_ORDERDATE DATE DEFAULT NULL,
                  IN NEW_COMMENTS VARCHAR(1000)DEFAULT NULL)...
```

Also assume that the global variable GLOBAL_CUST_ID is set to the value 1002. Call the procedure to change the status of order 5000 for customer 1002 to 'Shipped'. Leave the rest of the order data as it is by allowing the rest of the arguments to default to the null value.

```
CALL update_order (5000, NEW_STATUS => 'Shipped')
```

The customer with ID 1001 has called and indicated that they received their shipment for purchase order 5002 and are satisfied. Update their order.

```
CALL update_order (5002,
          IN_CUSTID => 1001,
          NEW_STATUS => 'Received',
          NEW_COMMENTS => 'Customer satisfied with the order.')
```

- *Example 4:* The following example illustrates procedure resolution, given two procedures named *p1*:

```
CREATE PROCEDURE p1(i1 INT)...
CREATE PROCEDURE p1(i1 INT DEFAULT 0, i2 INT DEFAULT 0)...
CALL p1(i2=>1)
```

The argument names are taken into consideration during the candidate selection process. Therefore, only the second version of *p1* will be considered a candidate. Furthermore, it can be successfully called because *i1* in this version of *p1* is defined with a default, so only specifying *i2* on the call to *p1* is valid.

- *Example 5:* The following example is another illustration of procedure resolution, given two procedures named *p1*:

```
CREATE PROCEDURE p1(i1 INT, i2 INT DEFAULT 0)...
CREATE PROCEDURE p1(i1 INT DEFAULT 0, i2 INT DEFAULT 0, i3 INT DEFAULT 0)...
CALL p1(i2=>1)
```

One of the criteria for a procedure parameter which does not have a corresponding argument in the CALL statement (specified by either position or name) is that the parameter is defined with a default value. Therefore, the first version of *p1* is not considered a candidate.

CASE

The CASE statement selects an execution path based on multiple conditions. This statement should not be confused with the CASE expression, which allows an expression to be selected based on the evaluation of one or more conditions.

Invocation

This statement can be embedded in:

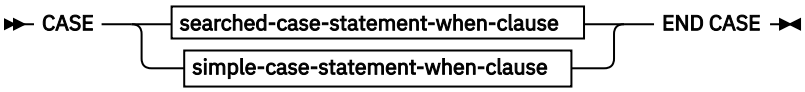
- An SQL procedure definition
- A compound SQL (compiled) statement
- A compound SQL (inlined) statement

The compound SQL statements can be embedded in an SQL procedure definition, SQL function definition, or SQL trigger definition. The CASE statement is not an executable statement and cannot be dynamically prepared.

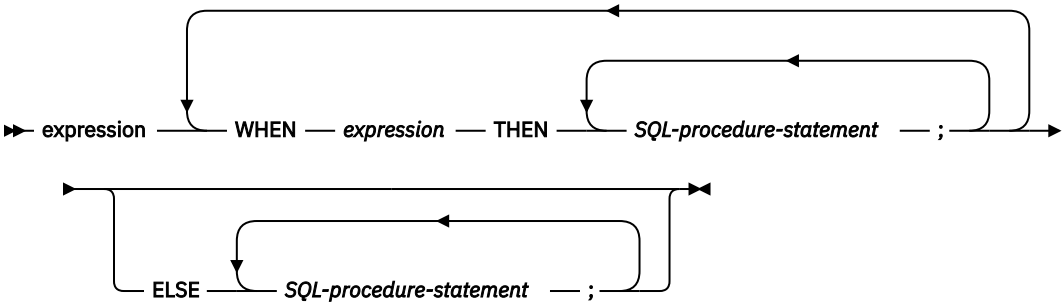
Authorization

No privileges are required to invoke the CASE statement. However, the privileges held by the authorization ID of the statement must include all necessary privileges to invoke the SQL statements and expressions that are embedded in the CASE statement.

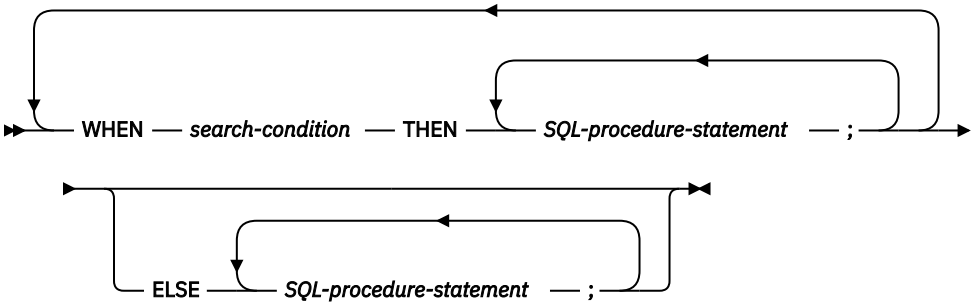
Syntax



simple-case-statement-when-clause



searched-case-statement-when-clause



Description

CASE
Begins a *case-statement*.

simple-case-statement-when-clause
The value of the *expression* before the first WHEN keyword is tested for equality with the value of each *expression* that follows the WHEN keyword. If the search condition is true, the THEN statement is executed. If the result is unknown or false, processing continues to the next search condition. If the result does not match any of the search conditions, and an ELSE clause is present, the statements in the ELSE clause are processed.

searched-case-statement-when-clause
The *search-condition* following the WHEN keyword is evaluated. If it evaluates to true, the statements in the associated THEN clause are processed. If it evaluates to false, or unknown, the next *search-condition* is evaluated. If no *search-condition* evaluates to true and an ELSE clause is present, the statements in the ELSE clause are processed.

SQL-procedure-statement
Specifies a statement that should be invoked. See *SQL-procedure-statement* in "Compound SQL (compiled)" statement.

END CASE
Ends a *case-statement*.

Notes

- If none of the conditions specified in the WHEN are true, and an ELSE clause is not specified, an error is issued at runtime, and the execution of the case statement is terminated (SQLSTATE 20000).
- Ensure that your CASE statement covers all possible execution conditions.

Examples

Depending on the value of SQL variable `v_workdept`, update column DEPTNAME in table DEPARTMENT with the appropriate name.

- *Example 1*: The following example shows how to do this using the syntax for a *simple-case-statement-when-clause*:

```
CASE v_workdept
  WHEN'A00'
    THEN UPDATE department
    SET deptname = 'DATA ACCESS 1';
  WHEN 'B01'
    THEN UPDATE department
    SET deptname = 'DATA ACCESS 2';
  ELSE UPDATE department
    SET deptname = 'DATA ACCESS 3';
END CASE
```

- *Example 2*: The following example shows how to do this using the syntax for a *searched-case-statement-when-clause*:

```
CASE
  WHEN v_workdept = 'A00'
    THEN UPDATE department
    SET deptname = 'DATA ACCESS 1';
  WHEN v_workdept = 'B01'
    THEN UPDATE department
    SET deptname = 'DATA ACCESS 2';
  ELSE UPDATE department
    SET deptname = 'DATA ACCESS 3';
END CASE
```

CLOSE

The CLOSE statement closes a cursor. If a result table was created when the cursor was opened, that table is destroyed.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that cannot be dynamically prepared. When invoked using the command line processor, some options cannot be specified. For more information, refer to "Using command line SQL statements and XQuery statements".

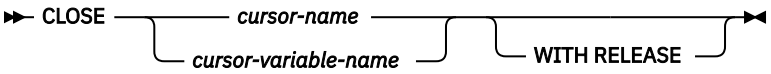
Authorization

If the *cursor-variable-name* references a global variable, then the privileges held by the authorization ID of the statement must include one of the following authorities:

- READ privilege on the global variable that is not defined in a module
- EXECUTE privilege on the module of the global variable that is defined in a module
- EXECUTEIN privilege on the schema containing the module of the global variable that is defined in a module
- DATAACCESS authority on the schema containing the module of the global variable that is defined in a module

For the authorization required to use a cursor, see "DECLARE CURSOR".

Syntax



Description

cursor-name
Identifies the cursor to be closed. The *cursor-name* must identify a declared cursor as explained in the DECLARE CURSOR statement. When the CLOSE statement is executed, the cursor must be in the open state.

cursor-variable-name
Identifies the cursor to be closed. The *cursor-variable-name* must identify a cursor variable. When the CLOSE statement is executed, the underlying cursor of *cursor-variable-name* must be in the open state (SQLSTATE 24501). A CLOSE statement using *cursor-variable-name* can only be used within a compound SQL (compiled) statement.

WITH RELEASE
The release of all locks that have been held for the cursor is attempted. Note that not all of the locks are necessarily released; these locks may be held for other operations or activities.

Notes

- At the end of a unit of work, all cursors that belong to an application process and that were declared without the WITH HOLD option are implicitly closed.
- An underlying cursor of a cursor variable is implicitly closed when it becomes an orphaned cursor. An underlying cursor becomes orphaned when it is no longer an underlying cursor of any cursor variable. For example, this could occur if all the cursor variables for an underlying cursor are in the same scope and all of them go out of scope at the same time.
- The WITH RELEASE clause has no effect when closing cursors defined in functions or methods. The clause also has no effect when closing cursors defined in procedures called from functions or methods.
- The WITH RELEASE clause has no effect for cursors that are operating under isolation levels CS or UR. When specified for cursors that are operating under isolation levels RS or RR, WITH RELEASE terminates some of the guarantees of those isolation levels. Specifically, if the cursor is opened again, an RS cursor may experience the 'nonrepeatable read' phenomenon and an RR cursor may experience either the 'nonrepeatable read' or 'phantom' phenomenon.

  If a cursor that was originally either RR or RS is reopened after being closed using the WITH RELEASE clause, new locks will be acquired.
- Special rules apply to cursors within a procedure that have not been closed before returning to the calling program.
- While a cursor is open (that is, it has not been closed yet), any changes to sequence values as a result of statements involving that cursor (for example, a FETCH or an UPDATE using the cursor that includes a NEXT VALUE expression for a sequence) will not result in an update to PREVIOUS VALUE for those sequences as seen by that cursor. The PREVIOUS VALUE values for these affected sequences are updated when the cursor is closed explicitly with the CLOSE statement. In a partitioned database environment, if a cursor is closed implicitly by a commit or a rollback, the PREVIOUS VALUE may not be updated with the most recently generated value for the sequence.

Example

A cursor is used to fetch one row at a time into the C program variables `dnum`, `dname`, and `mnum`. Finally, the cursor is closed. If the cursor is reopened, it is again located at the beginning of the rows to be fetched.

```
EXEC SQL DECLARE C1 CURSOR FOR
  SELECT DEPTNO, DEPTNAME, MGRNO
```

```
  FROM TDEPT
  WHERE ADMRDEPT = 'A00';

EXEC SQL OPEN C1;

while (SQLCODE==0) {                                                    .
  EXEC SQL FETCH C1 INTO :dnum, :dname, :mnum;
     .
     .
}
EXEC SQL CLOSE C1;
```

COMMENT

The COMMENT statement adds or replaces comments in the catalog descriptions of various objects.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

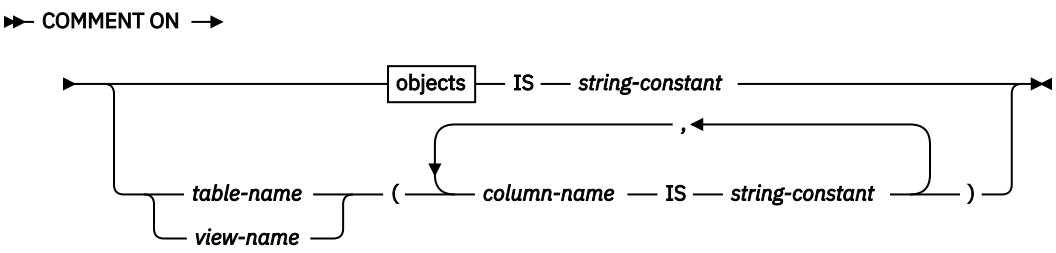
Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

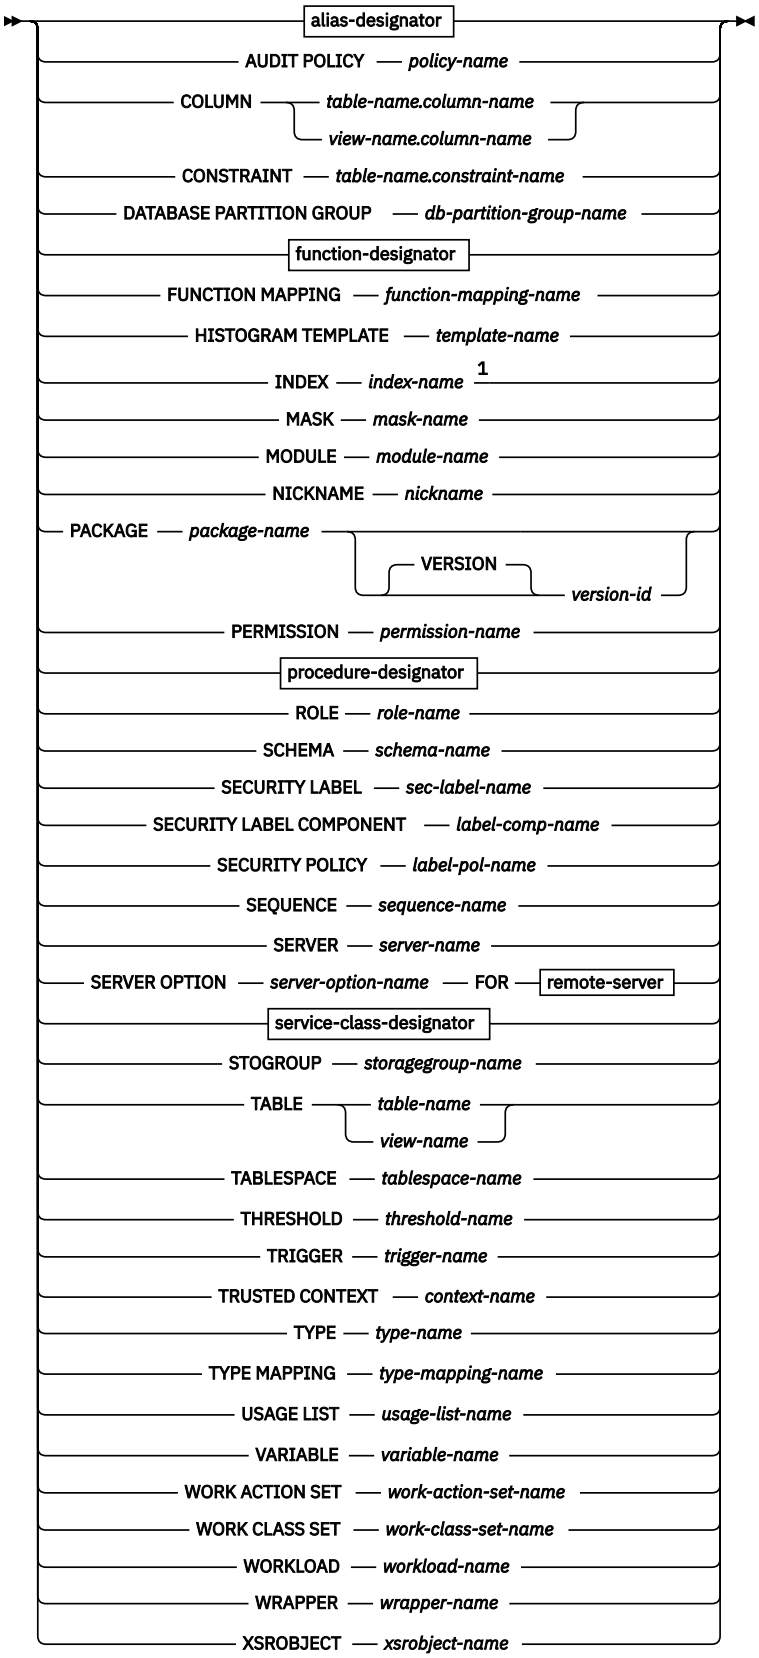
- Owner of the object (underlying table for column or constraint), as recorded in the OWNER column of the catalog view for the object
- ALTERIN privilege on the schema (applicable only to objects that allow more than one-part names)
- CONTROL privilege on the object (applicable only to index, package, table, or view objects)
- ALTER privilege on the object (applicable only to table objects)
- CREATE_SECURE_OBJECT authority (applicable only to secure functions or secure triggers)
- The WITH ADMIN OPTION (applicable only to roles)
- SCHEMAADM authority on the schema (applicable only to objects that allow more than one-part names)
- WLMADM authority (applicable only to workload manager objects)
- SECADM authority (applicable only to audit policy, column mask, role, row permission, secure function, secure trigger, security label, security label component, security policy, or trusted context objects; also applicable to tables for which row level access control or column level access control has been activated)
- DBADM authority (applicable to all objects except audit policy, role, security label, security label component, security policy, or trusted context objects)

Note that for table space, storage group, or database partition group, and bufferpools, the authorization ID must have SYSCTRL or SYSADM authority.

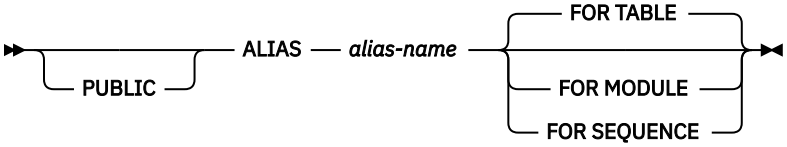
Syntax



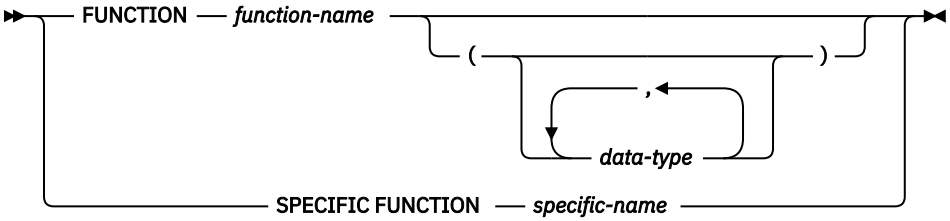
objects



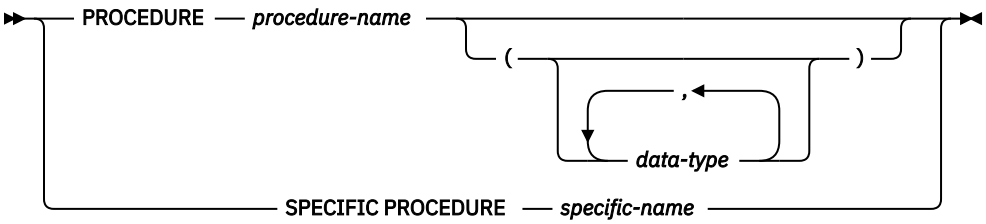
alias-designator



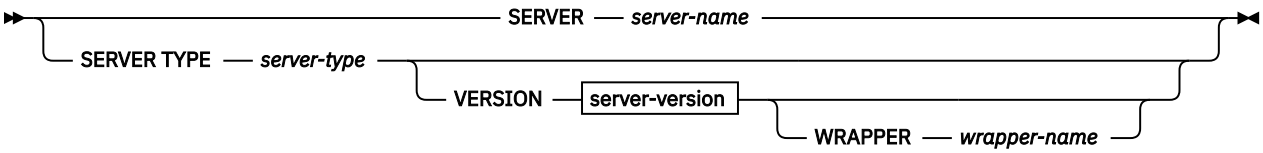
function-designator



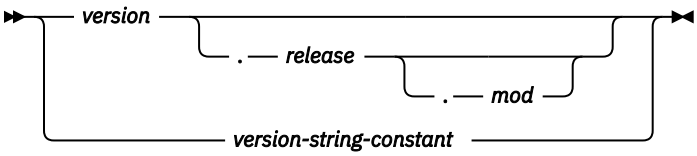
procedure-designator



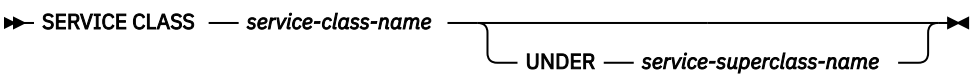
remote-server



server-version



service-class-designator



Notes:

[1] *Index-name* can be the name of either an index or an index specification.

Description

alias-designator

ALIAS *alias-name*

Indicates a comment will be added or replaced for an alias. The *alias-name* must identify an alias that exists at the current server (SQLSTATE 42704).

FOR TABLE, FOR MODULE, or FOR SEQUENCE

Specifies the object type for the alias.

FOR TABLE

The alias is for a table, view, or nickname. The comment replaces the value of the REMARKS column of the SYSCAT.TABLES catalog view for the row that describes the alias.

FOR MODULE
The alias is for a module. The comment replaces the value of the REMARKS column of the SYSCAT.MODULES catalog view for the row that describes the alias.

FOR SEQUENCE
The alias is for a sequence. The comment replaces the value of the REMARKS column of the SYSCAT.SEQUENCES catalog view for the row that describes the alias.

If PUBLIC is specified, the *alias-name* must identify a public alias that exists at the current server (SQLSTATE 42704).

AUDIT POLICY *policy-name*
Indicates a comment will be added or replaced for an audit policy. The *policy-name* must identify an audit policy that exists at the current server (SQLSTATE 42704). The comment replaces the value of the REMARKS column of the SYSCAT.AUDITPOLICIES catalog view for the row that describes the audit policy.

COLUMN *table-name.column-name* or *view-name.column-name*
Indicates that a comment for a column will be added or replaced. The *table-name.column-name* or *view-name.column-name* combination must identify a column and table combination that exists at the current server (SQLSTATE 42704), but must not identify a global temporary table (SQLSTATE 42995). The comment replaces the value of the REMARKS column of the SYSCAT.COLUMNS catalog view for the row that describes the column.

CONSTRAINT *table-name.constraint-name*
Indicates a comment will be added or replaced for a constraint. The *table-name.constraint-name* combination must identify a constraint and the table that it constrains; they must exist at the current server (SQLSTATE 42704). The comment replaces the value of the REMARKS column of the SYSCAT.TABCONST catalog view for the row that describes the constraint.

DATABASE PARTITION GROUP *db-partition-group-name*
Indicates a comment will be added or replaced for a database partition group. The *db-partition-group-name* must identify a distinct database partition group that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.DBPARTITIONGROUPS catalog view for the row that describes the database partition group.

function-designator
Indicates a comment will be added or replaced for a function. For more information, see "Function, method, and procedure designators" on page 745.

It is not possible to comment on a function that is in the SYSIBM, SYSIBMADM, SYSFUN, or SYSPROC schema (SQLSTATE 42832).

The comment replaces the value of the REMARKS column of the SYSCAT.ROUTINES catalog view for the row that describes the function.

FUNCTION MAPPING *function-mapping-name*
Indicates a comment will be added or replaced for a function mapping. The *function-mapping-name* must identify a function mapping that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.FUNCMAPPINGS catalog view for the row that describes the function mapping.

HISTOGRAM TEMPLATE *template-name*
Indicates a comment will be added or replaced for a histogram template. The *template-name* must identify a histogram template that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.HISTOGRAMTEMPLATES catalog view for the row that describes the histogram template.

INDEX *index-name*
Indicates a comment will be added or replaced for an index or index specification. The *index-name* must identify either a distinct index or an index specification that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.INDEXES catalog view for the row that describes the index or index specification.

MASK *mask-name*
Identifies the column mask to which the comment applies. *mask-name* must identify a column mask that exists at the current server (SQLSTATE 42704). The comment is placed in the REMARKS column of the SYSCAT.CONTROLS catalog table for the row that describes the mask.

MODULE *module-name*
Indicates a comment will be added or replaced for a module. The *module-name* must identify a module that exists at the current server (SQLSTATE 42704). The specified name must not be an alias for a module (SQLSTATE 560CT). The comment replaces the value for the REMARKS column of the SYSCAT.MODULES catalog view for the row that describes the module.

NICKNAME *nickname*
Indicates a comment will be added or replaced for a nickname. The *nickname* must be a nickname that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.TABLES catalog view for the row that describes the nickname.

PACKAGE *package-name*
Indicates that a comment will be added or replaced for a package. The package name must identify a package that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.PACKAGES catalog view for the row that describes the package.

VERSION *version-id*
Identifies which package version is to be commented on. If a value is not specified, the version defaults to the empty string. If multiple packages with the same package name but different versions exist, only one package version can be commented on in one invocation of the COMMENT statement. Delimit the version identifier with double quotation marks when it:

- Is generated by the VERSION(AUTO) precompiler option
- Begins with a digit
- Contains lowercase or mixed-case letters

If the statement is invoked from an operating system command prompt, precede each double quotation mark delimiter with a back slash character to ensure that the operating system does not strip the delimiters.

PERMISSION *permission-name*
Identifies the row permission to which the comment applies. *permission-name* must identify a row permission that exists at the current server (SQLSTATE 42704, SQLCODE -204). The comment is placed in the REMARKS column of the SYSCAT.CONTROLS catalog table for the row that describes the permission.

procedure-designator
Indicates a comment will be added or replaced for a procedure. For more information, see "Function, method, and procedure designators" on page 745.

It is not possible to comment on a procedure that is in the SYSIBM, SYSIBMADM, SYSFUN, or SYSPROC schema (SQLSTATE 42832).

The comment replaces the value of the REMARKS column of the SYSCAT.ROUTINES catalog view for the row that describes the procedure.

ROLE *role-name*
Indicates a comment will be added or replaced for a role. The *role-name* must identify a role that exists at the current server (SQLSTATE 42704). The comment replaces the value of the REMARKS column of the SYSCAT.ROLES catalog view for the row that describes the role.

SCHEMA *schema-name*
Indicates a comment will be added or replaced for a schema. The *schema-name* must identify a schema that exists at the current server (SQLSTATE 42704). The comment replaces the value of the REMARKS column of the SYSCAT.SCHEMATA catalog view for the row that describes the schema.

SECURITY LABEL *sec-label-name*
Indicates that a comment will be added or replaced for the security label named *sec-label-name*. The name must be qualified with a security policy and must identify a security label that exists at the

current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.SECURITYLABELS catalog view for the row that describes the security label.

SECURITY LABEL COMPONENT *label-comp-name*
Indicates that a comment will be added or replaced for the security label component named *label-comp-name*. The *label-comp-name* must identify a security label component that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.SECURITYLABELCOMPONENTS catalog view for the row that describes the security label component.

SECURITY POLICY *label-pol-name*
Indicates that a comment will be added or replaced for the security policy named *label-pol-name*. The *label-pol-name* must identify a security policy that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.SECURITYPOLICIES catalog view for the row that describes the security policy.

SEQUENCE *sequence-name*
Indicates a comment will be added or replaced for a sequence. The *sequence-name* must identify a sequence that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.SEQUENCES catalog view for the row that describes the sequence.

SERVER *server-name*
Indicates a comment will be added or replaced for a data source. The *server-name* must identify a data source that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.SERVERS catalog view for the row that describes the data source.

SERVER OPTION *server-option-name* FOR *remote-server*
Indicates a comment will be added or replaced for a server option.

server-option-name
Identifies a server option. This option must be one that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.SERVEROPTIONS catalog view for the row that describes the server option.

remote-server
Describes the data source to which the *server-option* applies.

SERVER *server-name*
Names the data source to which the *server-option* applies. The *server-name* must identify a data source that exists at the current server.

TYPE *server-type*
Specifies the type of data source (such as Db2 for z/OS or Oracle) to which the *server-option* applies. The *server-type* can be specified in either lower- or uppercase; it will be stored in uppercase in the catalog.

VERSION
Specifies the version of the data source identified by *server-name*.

version
Specifies the version number. *version* must be an integer.

release
Specifies the number of the release of the version denoted by *version*. *release* must be an integer.

mod
Specifies the number of the modification of the release denoted by *release*. *mod* must be an integer.

version-string-constant
Specifies the complete designation of the version. The *version-string-constant* can be a single value (for example, '8i'); or it can be the concatenated values of *version*, *release*, and, if applicable, *mod* (for example, '8.0.3').

WRAPPER *wrapper-name*
Identifies the wrapper that is used to access the data source referenced by *server-name.*

service-class-designator

SERVICE CLASS *service-class-name*
Indicates a comment will be added or replaced for a service class. The *service-class-name* must identify a service class that exists at the current server (SQLSTATE 42704). To add or replace a comment for a service subclass, the *service-superclass-name* must be specified using the UNDER clause. The comment replaces the value for the REMARKS column of the SYSCAT.SERVICECLASSES catalog view for the row that describes the service class.

UNDER *service-superclass-name*
Specifies the service superclass of the service subclass when adding or replacing a comment for a service subclass. The *service-superclass-name* must identify a service superclass that exists at the current server (SQLSTATE 42704).

STOGROUP *storagegroup-name*
Indicates a comment will be added or replaced for a storage group. The *storagegroup-name* must identify a distinct storage group that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.STOGROUPS catalog view for the row that describes the storage group.

TABLE *table-name* or *view-name*
Indicates a comment will be added or replaced for a table or view. The *table-name* or *view-name* must identify a table or view (not an alias or nickname) that exists at the current server (SQLSTATE 42704) and must not identify a declared temporary table (SQLSTATE 42995). The comment replaces the value for the REMARKS column of the SYSCAT.TABLES catalog view for the row that describes the table or view.

TABLESPACE *tablespace-name*
Indicates a comment will be added or replaced for a table space. The *tablespace-name* must identify a distinct table space that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.TABLESPACES catalog view for the row that describes the table space.

THRESHOLD *threshold-name*
Indicates a comment will be added or replaced for a threshold. The *threshold-name* must identify a threshold that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.THRESHOLDS catalog view for the row that describes the threshold.

TRIGGER *trigger-name*
Indicates a comment will be added or replaced for a trigger. The *trigger-name* must identify a distinct trigger that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.TRIGGERS catalog view for the row that describes the trigger.

TRUSTED CONTEXT *context-name*
Indicates a comment will be added or replaced for a trusted context. The *context-name* must identify a trusted context that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.CONTEXTS catalog view for the row that describes the trusted context.

TYPE *type-name*
Indicates a comment will be added or replaced for a user-defined type. The *type-name* must identify a user-defined type that exists at the current server (SQLSTATE 42704). The comment replaces the value of the REMARKS column of the SYSCAT.DATATYPES catalog view for the row that describes the user-defined type.

In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names.

TYPE MAPPING *type-mapping-name*
Indicates a comment will be added or replaced for a user-defined data type mapping. The *type-mapping-name* must identify a data type mapping that exists at the current server (SQLSTATE 42704).

The comment replaces the value for the REMARKS column of the SYSCAT.TYPEMAPPINGS catalog view for the row that describes the mapping.

USAGE LIST *usage-list-name*
Indicates a comment will be added or replaced for a usage list. The *usage-list-name* must identify a usage list that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.USAGELISTS catalog view for the row that describes the usage list.

VARIABLE *variable-name*
Indicates a comment will be added or replaced for a global variable. The *variable-name* must identify a global variable that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.VARIABLES catalog view for the row that describes the variable.

WORK ACTION SET *work-action-set-name*
Indicates a comment will be added or replaced for a work action set. The *work-action-set-name* must identify a work action set that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.WORKACTIONSETS catalog view for the row that describes the work action set.

WORK CLASS SET *work-class-set-name*
Indicates a comment will be added or replaced for a work class set. The *work-class-set-name* must identify a work class set that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.WORKCLASSSETS catalog view for the row that describes the work class set.

WORKLOAD *workload-name*
Indicates that a comment will be added or replaced for a workload. The *workload-name* must identify a workload that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.WORKLOADS catalog view for the row that describes the workload.

WRAPPER *wrapper-name*
Indicates a comment will be added or replaced for a wrapper. The *wrapper-name* must identify a wrapper that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.WRAPPERS catalog view for the row that describes the wrapper.

XSROBJECT *xsrobject-name*
Indicates a comment will be added or replaced for an XSR object. The *xsrobject-name* must identify an XSR object that exists at the current server (SQLSTATE 42704). The comment replaces the value for the REMARKS column of the SYSCAT.XSROBJECTS catalog view for the row that describes the XSR object.

IS *string-constant*
Specifies the comment to be added or replaced. The *string-constant* can be any character string constant of up to 254 bytes. (Carriage return and line feed each count as 1 byte.)

***table-name*|*view-name* ({ *column-name* IS *string-constant* } ...)**
This form of the COMMENT statement provides the ability to specify comments for multiple columns of a table or view. The column names must not be qualified, each name must identify a column of the specified table or view, and the table or view must exist at the current server. The *table-name* cannot be a declared temporary table (SQLSTATE 42995).

A comment cannot be made on a column of an inoperative view (SQLSTATE 51024).

Notes

- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - NODEGROUP can be specified in place of DATABASE PARTITION GROUP
  - DISTINCT TYPE *type-name* can be specified in place of TYPE *type-name*
  - DATA TYPE *type-name* can be specified in place of TYPE *type-name*

– SYNONYM can be specified in place of ALIAS

Examples

- *Example 1:* Add a comment for the EMPLOYEE table.

```
COMMENT ON TABLE EMPLOYEE
  IS 'Reflects first quarter reorganization'
```

- *Example 2:* Add a comment for the EMP_VIEW1 view.

```
COMMENT ON TABLE EMP_VIEW1
  IS 'View of the EMPLOYEE table without salary information'
```

- *Example 3:* Add a comment for the EDLEVEL column of the EMPLOYEE table.

```
COMMENT ON COLUMN EMPLOYEE.EDLEVEL
  IS 'highest grade level passed in school'
```

- *Example 4:* Add comments for two different columns of the EMPLOYEE table.

```
COMMENT ON EMPLOYEE
  (WORKDEPT IS 'see DEPARTMENT table for names',
  EDLEVEL IS 'highest grade level passed in school' )
```

- *Example 5:* Pellow wants to comment on the CENTER function, which he created in his PELLOW schema, using the signature to identify the specific function to be commented on.

```
COMMENT ON FUNCTION CENTER (INT,FLOAT)
  IS 'Frank''s CENTER fctn, uses Chebychev method'
```

- *Example 6:* McBride wants to comment on another CENTER function, which she created in the PELLOW schema, using the specific name to identify the function instance to be commented on:

```
COMMENT ON SPECIFIC FUNCTION PELLOW.FOCUS92 IS
  'Louise''s most triumphant CENTER function, uses the
       Brownian fuzzy-focus technique'
```

- *Example 7:* Comment on the function ATOMIC_WEIGHT in the CHEM schema, where it is known that there is only one function with that name:

```
COMMENT ON FUNCTION CHEM.ATOMIC_WEIGHT
  IS 'takes atomic nbr, gives atomic weight'
```

- *Example 8:* Eigler wants to comment on the SEARCH procedure, which he created in his EIGLER schema, using the signature to identify the specific procedure to be commented on.

```
COMMENT ON PROCEDURE SEARCH (CHAR,INT)
  IS 'Frank''s mass search and replace algorithm'
```

- *Example 9:* Macdonald wants to comment on another SEARCH function, which he created in the EIGLER schema, using the specific name to identify the procedure instance to be commented on:

```
COMMENT ON SPECIFIC PROCEDURE EIGLER.DESTROY IS
  'Patrick''s mass search and destroy algorithm'
```

- *Example 10:* Comment on the procedure OSMOSIS in the BIOLOGY schema, where it is known that there is only one procedure with that name:

```
COMMENT ON PROCEDURE BIOLOGY.OSMOSIS
  IS 'Calculations modelling osmosis'
```

- *Example 11:* Comment on an index specification named INDEXSPEC.

```
COMMENT ON INDEX INDEXSPEC
  IS 'An index specification that indicates to the optimizer
  that the table referenced by nickname NICK1 has an index.'
```

- *Example 12:* Comment on the wrapper whose default name is NET8.

```
COMMENT ON WRAPPER NET8
  IS 'The wrapper for data sources associated with
      Oracle's Net8 client software.'
```

- *Example 13:* Create a comment on the XML schema HR.EMPLOYEE.

```
COMMENT ON XSROBJECT HR.EMPLOYEE
  IS 'This is the base XML Schema for employee data.'
```

- *Example 14:* Create a comment for trusted context APPSERVER.

```
COMMENT ON TRUSTED CONTEXT APPSERVER
  IS 'WebSphere Server'
```

- *Example 15:* Create a comment for column mask M1.

```
COMMENT ON MASK M1 IS 'Column mask for column EMP.SALARY'
```

COMMIT

The COMMIT statement terminates a unit of work and commits the database changes that were made by that unit of work.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

None required.

Syntax

Description

The unit of work in which the COMMIT statement is executed is terminated and a new unit of work is initiated. All changes made by the following statements executed during the unit of work are committed: ALTER, COMMENT, CREATE, DROP, GRANT, LOCK TABLE, REVOKE, SET INTEGRITY, and the data change statements (INSERT, DELETE, MERGE, UPDATE), including those nested in a query.

The following statements, however, are not under transaction control and changes made by them are independent of the COMMIT statement:

- SET CONNECTION
- SET ENCRYPTION PASSWORD
- SET EVENT MONITOR STATE
- SET PASSTHRU

  Note: Although the SET PASSTHRU statement is not under transaction control, the passthru session initiated by the statement is under transaction control.
- SET SERVER OPTION
- SET variable
- Assignments to updatable special registers

All locks acquired by the unit of work subsequent to its initiation are released, except necessary locks for open cursors that are declared WITH HOLD. All open cursors not defined WITH HOLD are closed. Open cursors defined WITH HOLD remain open, and the cursor is positioned before the next logical row of the result table. (A FETCH must be performed before a positioned UPDATE or DELETE statement is issued.) All LOB locators are freed. Note that this is true even when the locators are associated with LOB values retrieved via a cursor that has the WITH HOLD property.

Dynamic SQL statements prepared in a package bound with the KEEPDYNAMIC YES option are kept in the SQL context after a COMMIT statement. This is the default behavior. The statement might be implicitly prepared again, as a result of DDL operations that are rolled back within the unit of work. Inactive dynamic SQL statements prepared in a package bound with KEEPDYNAMIC NO are removed from the SQL context after a COMMIT. The statement must be prepared again before it can be executed in a new transaction.

All savepoints set within the transaction are released.

The following statements behave differently than other data definition language (DDL) and data control language (DCL) statements. Changes made by these statements do not take effect until the statement is committed, even for the current connection that issues the statement. Only one of these statements can be issued by any application at a time, and only one of these statements is allowed within any one unit of work. Each statement must be followed by a COMMIT or a ROLLBACK statement before another one of these statements can be issued.

- CREATE SERVICE CLASS, ALTER SERVICE CLASS, or DROP (SERVICE CLASS)
- CREATE THRESHOLD, ALTER THRESHOLD, or DROP (THRESHOLD)
- CREATE WORK ACTION, ALTER WORK ACTION, or DROP (WORK ACTION)
- CREATE WORK CLASS, ALTER WORK CLASS, or DROP (WORK CLASS)
- CREATE WORKLOAD, ALTER WORKLOAD, or DROP (WORKLOAD)
- GRANT (Workload Privileges) or REVOKE (Workload Privileges)

Notes

- It is strongly recommended that each application process explicitly ends its unit of work before terminating. If the application program ends normally without a COMMIT or ROLLBACK statement then the database manager attempts a commit or rollback depending on the application environment.
- For information about the impact of COMMIT on cached dynamic SQL statements, see "EXECUTE".
- For information about potential impacts of COMMIT on created temporary tables, see "CREATE GLOBAL TEMPORARY TABLE".
- For information about potential impacts of COMMIT on declared temporary tables, see "DECLARE GLOBAL TEMPORARY TABLE".
- The following dynamic SQL statements may be active during COMMIT:
  - Open WITH HOLD cursor
  - COMMIT statement
  - CALL statements under which the COMMIT statement was executed

Example

Commit alterations to the database made since the last commit point.

```
COMMIT WORK
```

Compound SQL

A compound SQL statement is a sequence of individual SQL statements enclosed by BEGIN and END keywords.

There are three types of compound SQL statements:

- Inlined: A compound SQL (inlined) statement is a compound SQL statement that is inlined at run time within another SQL statement. Compound SQL (inlined) statements have the property of being atomically executed; if the execution of any of the statements raises an error, the full statement is rolled back.
- Embedded: Combines one or more other SQL statements (*sub-statements*) into an executable block.
- Compiled: A compound SQL (compiled) statement can contain SQL control statements and SQL statements. Compound SQL (compiled) statements can be used to implement procedural logic through a sequence of SQL statements with a local scope for variables, conditions, cursors, and handlers.

Compound SQL (inlined)

A compound SQL (inlined) statement is a compound SQL statement that is inlined at run time within another SQL statement. Compound SQL (inlined) statements have the property of being atomically executed; if the execution of any of the statements raises an error, the full statement is rolled back.

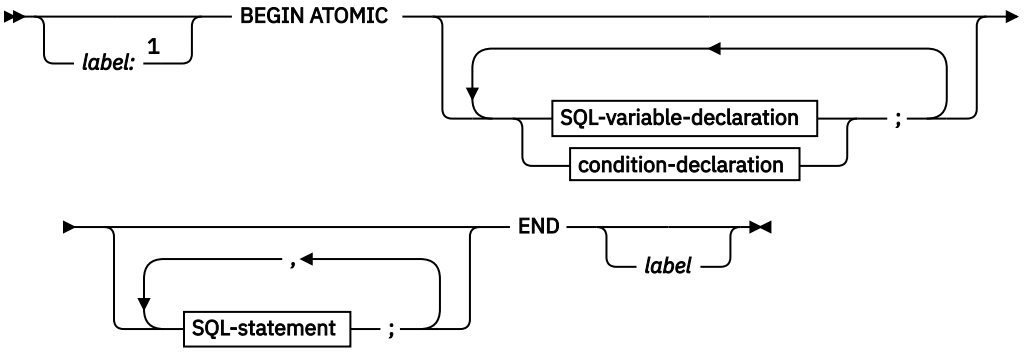
Invocation

This statement can be embedded in a trigger, SQL function, or SQL method, or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

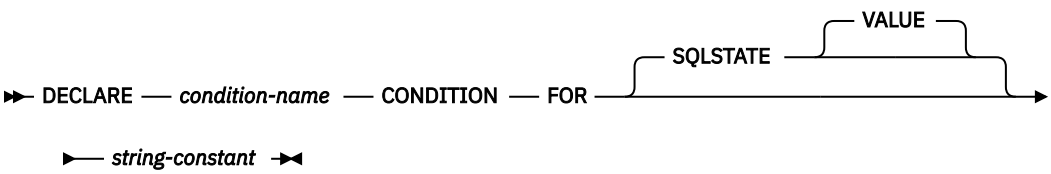
The privileges held by the authorization ID of the statement must also include all of the privileges necessary to invoke the SQL statements that are specified in the compound statement.

Syntax

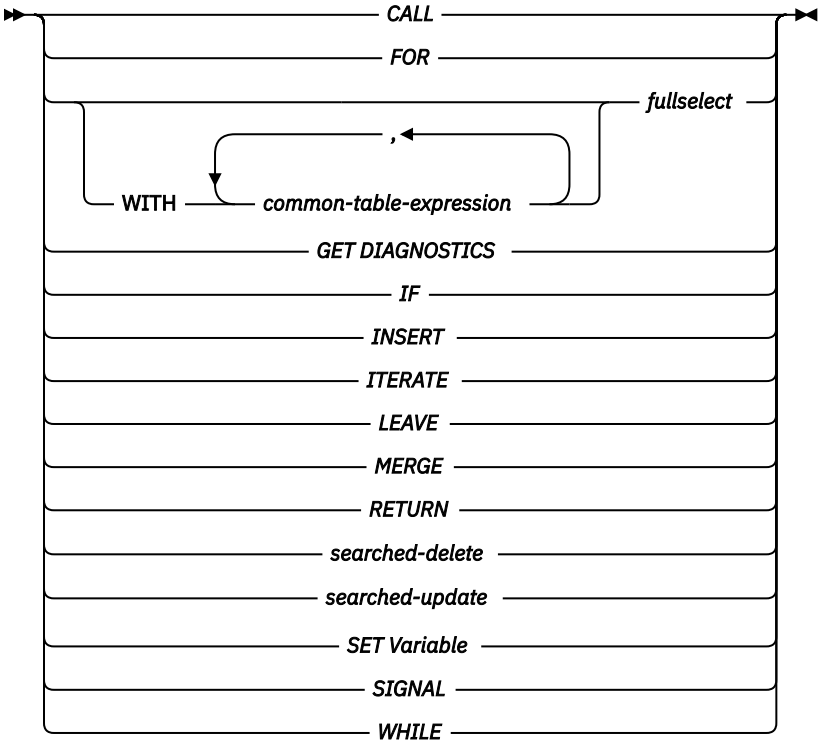


SQL-variable-declaration

condition-declaration



SQL-statement



Notes:

[1] A label can only be specified when the statement is in a function, method, or trigger definition.

Description

label
Defines the label for the code block. If the beginning label is specified, it can be used to qualify SQL variables declared in the compound SQL (inlined) statement and can also be specified on a LEAVE statement. If the ending label is specified, it must be the same as the beginning label.

ATOMIC
ATOMIC indicates that, if an error occurs in the compound statement, all SQL statements in the compound statement will be rolled back, and any remaining SQL statements in the compound statement are not processed.

If the ATOMIC keyword is specified in an SQL function in a module or an SQL procedure, the compound statement is processed as a compound SQL (compiled) statement.

SQL-statement
Specifies an SQL statement to be executed within the compound SQL (inlined) statement.

SQL-variable-declaration
Declares a variable that is local to the compound SQL (inlined) statement.

SQL-variable-name
Defines the name of a local variable. SQL variable names are converted to uppercase. The name cannot be the same as:

- Another SQL variable within the compound statement
- A parameter name

If an SQL statement contains an identifier with the same name as an SQL variable and a column reference, the identifier is interpreted as a column.

data-type
Specifies the data type of the variable. The XML data type is not supported in a compound SQL (inlined) statement used in a trigger, in a method, or as a stand-alone statement (SQLSTATE 429BB). The XML data type is supported when the compound SQL (inlined) statement is used in an SQL function body.

DEFAULT
Defines the default for the SQL variable. The variable is initialized when the compound SQL (inlined) statement is executed. The default value must be assignment-compatible with the data type of the variable. If a default value is not specified, the default for the SQL variable is initialized to the null value.

NULL
Specifies NULL as the default for the SQL variable.

constant
Specifies a constant as the default for the SQL variable.

condition-declaration
Declares a condition name and corresponding SQLSTATE value.

condition-name
Specifies the name of the condition. The condition name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement (SQLSTATE 42734). A condition name can only be referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement (SQLSTATE 42737).

FOR SQLSTATE *string-constant*
Specifies the SQLSTATE associated with the condition. The *string-constant* must be specified as five characters enclosed by single quotation marks, and the SQLSTATE class (the first two characters) must not be '00'.

Notes

- Compound SQL (inlined) statements are compiled as one single statement. This statement is effective for short scripts involving little control flow logic but significant data flow. For larger constructs with requirements for nested control flow or condition handling, a better choice is to use the compound SQL (compiled) statement or an SQL procedure.
- A procedure called within a compound statement must not issue a COMMIT or a ROLLBACK statement (SQLSTATE 42985).
- ***Table access restrictions:*** If a procedure is defined as READS SQL DATA or MODIFIES SQL DATA, no statement in the procedure can access a table that is being modified by the compound statement that invoked the procedure (SQLSTATE 57053). If the procedure is defined as MODIFIES SQL DATA, no statement in the procedure can modify a table that is being read or modified by the compound statement that invoked the procedure (SQLSTATE 57053).
- ***XML assignments:*** Assignment to parameters and variables of data type XML is done by reference in SQL function bodies.

  When XML values are passed by reference, any input node trees are used directly. This direct usage preserves all properties, including document order, the original node identities, and all parent properties.
- ***Isolation level:*** If a *select-statement*, *fullselect*, or *subselect* specifies an *isolation-clause*, the clause is ignored and a warning is returned.

Example

This example illustrates how inline SQL PL can be used in a data warehousing scenario for data cleansing.

The example introduces three tables. The TARGET table contains the cleansed data. The EXCEPT table stores rows that cannot be cleansed (exceptions) and the SOURCE table contains the raw data to be cleansed.

A simple SQL function called DISCRETIZE is used to classify and modify the data. It returns the null value for all bad data. The compound SQL (inlined) statement then cleanses the data. It walks all rows of the SOURCE table in a FOR-loop and decides whether the current row gets inserted into the TARGET or the EXCEPT table, depending on the result of the DISCRETIZE function. More elaborate mechanisms (multistage cleansing) are possible with this technique.

The same code can be written using an SQL Procedure or any other procedure or application in a host language. However, the compound SQL (inlined) statement offers a unique advantage in that the FOR-loop does not open a cursor and the single row inserts are not really single row inserts. In fact, the logic is effectively a multi-table insert from a shared select.

This is achieved by compilation of the compound SQL (inlined) statement as a single statement. Similar to a view whose body is integrated into the query that uses it and then is compiled and optimized as a whole within the query context, the database optimizer compiles and optimizes both the control and data flow together. The whole logic is therefore executed within the runtime environment of the database. No data is moved outside of the core database engine, as would be done for a procedure.

The first step is to create the required tables:

```
CREATE TABLE TARGET
  (PK INTEGER NOT NULL
  PRIMARY KEY, C1 INTEGER)
```

This creates a table called TARGET to contain the cleansed data.

```
CREATE TABLE EXCEPT
  (PK INTEGER NOT NULL
  PRIMARY KEY, C1 INTEGER)
```

This creates a table called EXCEPT to contain the exceptions.

```
CREATE TABLE SOURCE
  (PK INTEGER NOT NULL
  PRIMARY KEY, C1 INTEGER)
```

This creates a table called SOURCE to hold the data that is to be cleansed.

Next, a function named DISCRETIZE is created to cleanse the data by throwing out all values outside [0..1000] and aligning them to steps of 10.

```
CREATE FUNCTION DISCRETIZE(RAW INTEGER) RETURNS INTEGER
  RETURN CASE
    WHEN RAW < 0 THEN CAST(NULL AS INTEGER)
    WHEN RAW > 1000 THEN NULL
    ELSE ((RAW / 10) * 10) + 5
  END
```

Then the values are inserted:

```
INSERT INTO SOURCE (PK, C1)
  VALUES (1,   -5),
         (2, NULL),
         (3, 1200),
         (4,   23),
         (5,   10),
         (6,  876)
```

Invoke the function:

```
  BEGIN ATOMIC
    FOR ROW AS
      SELECT PK, C1, DISCRETIZE(C1) AS D FROM SOURCE
    DO
      IF ROW.D IS NULL THEN
```

```
        INSERT INTO EXCEPT VALUES(ROW.PK, ROW.C1);
      ELSE
        INSERT INTO TARGET VALUES(ROW.PK, ROW.D);
      END IF;
    END FOR;
  END
```

And test the results:

```
SELECT * FROM EXCEPT ORDER BY 1
PK          C1
----------- -----------
          1          -5
          2           -
          3        1200
  3 record(s) selected.

SELECT * FROM TARGET ORDER BY 1
PK          C1
----------- -----------
          4          25
          5          15
          6         875
  3 record(s) selected.
```

The final step is to clean up:

```
DROP FUNCTION DISCRETIZE
DROP TABLE SOURCE
DROP TABLE TARGET
DROP TABLE EXCEPT
```

Compound SQL (embedded)

Combines one or more other SQL statements (*sub-statements*) into an executable block.

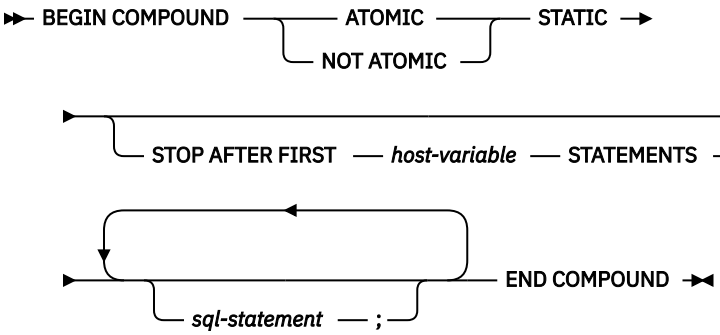
Invocation

This statement can only be embedded in an application program. The entire compound SQL (embedded) statement construct is an executable statement that cannot be dynamically prepared. The statement is not supported in REXX.

Authorization

No privileges are required to invoke an compound SQL (embedded). However, the privileges held by the authorization ID of the statement must include all necessary privileges to invoke the SQL statements that are embedded in the compound statement.

Syntax



Description

ATOMIC
Specifies that, if any of the sub-statements within the compound SQL (embedded) statement fail, then all changes made to the database by any of the sub-statements, including changes made by successful sub-statements, are undone.

NOT ATOMIC
Specifies that, regardless of the failure of any sub-statements, the compound SQL (embedded) statement will not undo any changes made to the database by the other sub-statements.

STATIC
Specifies that input variables for all sub-statements retain their original value. For example, if

```
SELECT ... INTO :abc ...
```

is followed by:

```
UPDATE T1 SET C1 = 5 WHERE C2 = :abc
```

the UPDATE statement will use the value that :abc had at the start of the execution of the compound SQL (embedded) statement, not the value that follows the SELECT INTO.

If the same variable is set by more than one sub-statement, the value of that variable following the compound SQL (embedded) statement is the value set by the last sub-statement.

Note: Non-static behavior is not supported. This means that the sub-statements should be viewed as executing non-sequentially and sub-statements should not have interdependencies.

STOP AFTER FIRST
Specifies that only a certain number of sub-statements will be executed.

host-variable
A small integer that specifies the number of sub-statements to be executed.

STATEMENTS
Completes the STOP AFTER FIRST *host-variable* clause.

sql-statement
All executable statements except the following can be contained within an embedded static compound SQL (embedded) statement:

```
CALL                FETCH
CLOSE               OPEN
CONNECT             PREPARE
Compound SQL        RELEASE (Connection)
DESCRIBE            ROLLBACK
DISCONNECT          SET CONNECTION
EXECUTE IMMEDIATE   SET variable
```

Note: INSERT, UPDATE, and DELETE are not supported in compound SQL for use with nicknames.

If a COMMIT statement is included, it must be the last sub-statement. If COMMIT is in this position, it will be issued even if the STOP AFTER FIRST *host-variable* STATEMENTS clause indicates that not all of the sub-statements are to executed. For example, suppose COMMIT is the last sub-statement in a compound SQL block of 100 sub-statements. If the STOP AFTER FIRST STATEMENTS clause indicates that only 50 sub-statements are to be executed, then COMMIT will be the 51st sub-statement.

An error will be returned if COMMIT is included when using CONNECT TYPE 2 or running in an XA distributed transaction processing environment (SQLSTATE 25000).

Rules

- Db2 Connect does not support SELECT statements selecting LOB columns in a compound SQL block.
- No host language code is allowed within a compound SQL (embedded) statement; that is, no host language code is allowed between the sub-statements that make up the compound SQL (embedded) statement.

- Only NOT ATOMIC compound SQL (embedded) statements will be accepted by Db2 Connect.
- Compound SQL (embedded) statements cannot be nested.
- A prepared COMMIT statement is not allowed in an ATOMIC compound SQL (embedded) statement

Notes

- One SQLCA is returned for the entire compound SQL (embedded) statement. Most of the information in that SQLCA reflects the values set by the application server when it processed the last sub-statement. For instance:
  - The SQLCODE and SQLSTATE are normally those for the last sub-statement (the exception is described in the next point).
  - If a "no data found" warning (SQLSTATE 02000) is returned, that warning is given precedence over any other warning so that a WHENEVER NOT FOUND exception can be acted upon. (This means that the SQLCODE, SQLERRML, SQLERRMC, and SQLERRP fields in the SQLCA that is eventually returned to the application are those from the sub-statement that triggered the "no data found" warning. If there is more than one "no data found" warning within the compound SQL (embedded) statement, the fields for the last sub-statement will be the fields that are returned.)
  - The SQLWARN indicators are an accumulation of the indicators set for all sub-statements.
- If one or more errors occurred during NOT ATOMIC compound SQL execution and none of these are of a serious nature, the SQLERRMC will contain information about these errors, up to a maximum of seven errors. The first token of the SQLERRMC will indicate the total number of errors that occurred. The remaining tokens will each contain the ordinal position and the SQLSTATE of the failing sub-statement within the compound SQL (embedded) statement. The format is a character string of the form:

  ```
  nnnXsssccccc
  ```

  with the substring starting with X repeating up to six more times and the string elements defined as follows.

  nnn
  The total number of statements that produced errors. (If the number would exceed 999, counting restarts at zero.) This field is left-aligned and padded with blanks.

  X
  The token separator X'FF'.

  sss
  The ordinal position of the statement that caused the error. (If the number would exceed 999, counting restarts at zero.) For example, if the first statement failed, this field would contain the number one left-aligned ("1").

  ccccc
  The SQLSTATE of the error.
- The second SQLERRD field contains the number of statements that failed (returned negative SQLCODEs).
- The third SQLERRD field in the SQLCA is an accumulation of the number of rows affected by all sub-statements.
- The fourth SQLERRD field in the SQLCA is a count of the number of successful sub-statements. If, for example, the third sub-statement in a compound SQL (embedded) statement failed, the fourth SQLERRD field would be set to 2, indicating that 2 sub-statements were successfully processed before the error was encountered.
- The fifth SQLERRD field in the SQLCA is an accumulation of the number of rows updated or deleted due to the enforcement of referential integrity constraints for all sub-statements that triggered such constraint activity.

Examples

- *Example 1:* In a C program, issue a compound SQL (embedded) statement that updates both the ACCOUNTS and TELLERS tables. If there is an error in any of the statements, undo the effect of all statements (ATOMIC). If there are no errors, commit the current unit of work.

```
EXEC SQL BEGIN COMPOUND ATOMIC STATIC
  UPDATE ACCOUNTS SET ABALANCE = ABALANCE + :delta
    WHERE AID = :aid;
  UPDATE TELLERS SET TBALANCE = TBALANCE + :delta
    WHERE TID = :tid;
  INSERT INTO TELLERS (TID, BID, TBALANCE) VALUES (:i, :branch_id, 0);
  COMMIT;
END COMPOUND;
```

- *Example 2:* In a C program, insert 10 rows of data into the database. Assume the host variable :nbr contains the value 10 and S1 is a prepared INSERT statement. Further, assume that all the inserts should be attempted regardless of errors (NOT ATOMIC).

```
EXEC SQL BEGIN COMPOUND NOT ATOMIC STATIC STOP AFTER FIRST :nbr STATEMENTS
  EXECUTE S1 USING DESCRIPTOR :*sqlda0;
  EXECUTE S1 USING DESCRIPTOR :*sqlda1;
  EXECUTE S1 USING DESCRIPTOR :*sqlda2;
  EXECUTE S1 USING DESCRIPTOR :*sqlda3;
  EXECUTE S1 USING DESCRIPTOR :*sqlda4;
  EXECUTE S1 USING DESCRIPTOR :*sqlda5;
  EXECUTE S1 USING DESCRIPTOR :*sqlda6;
  EXECUTE S1 USING DESCRIPTOR :*sqlda7;
  EXECUTE S1 USING DESCRIPTOR :*sqlda8;
  EXECUTE S1 USING DESCRIPTOR :*sqlda9;
END COMPOUND;
```

Compound SQL (compiled)

A compound SQL (compiled) statement can contain SQL control statements and SQL statements. Compound SQL (compiled) statements can be used to implement procedural logic through a sequence of SQL statements with a local scope for variables, conditions, cursors, and handlers.

Invocation

This statement can be embedded in a trigger, SQL function, or SQL procedure; or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared.

Authorization

For an *SQL-variable-declaration* that specifies a *cursor-value-constructor* that uses a *select-statement*, the privileges held by the authorization ID of the statement must include the privileges necessary to execute the *select-statement*. See the Authorization section in "SQL queries".

The privileges held by the authorization ID of the statement must also include all of the privileges necessary to invoke the SQL statements that are specified in the compound statement.

Only PUBLIC group privileges are considered for any SQL objects specified inside the body of compound statement.

Notes:

[1] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).
[2] If *data-type4* specifies a CURSOR built-in type or *cursor-type-name*, only NULL or *cursor-value-constructor* can be specified. Only DEFAULT NULL can be explicitly specified for *array-type-name* or *row-type-name* .
[3] Only DEFAULT NULL can be explicitly specified for *array-type-name*.
[4] Only DEFAULT NULL can be explicitly specified for *row-type-name*.
[5] *statement-name* cannot be specified if *cursor-parameter-declaration* is specified.

Description

label
Defines the label for the code block. If the beginning label is specified, it can be used to qualify SQL variables declared in the compound statement and can also be specified on a LEAVE statement. If the ending label is specified, it must be the same as the beginning label.

ATOMIC or NOT ATOMIC
ATOMIC indicates that if an unhandled exception condition occurs in the compound statement, all SQL statements in the compound statement will be rolled back.

NOT ATOMIC indicates that an unhandled exception condition within the compound statement does not cause the compound statement to be rolled back.

If the ATOMIC keyword is specified in a dynamically prepared compound statement or an SQL function that is not within a module, the compound statement is processed as a compound SQL (inlined) statement.

A compound statement that is used in the function body of a module table function can only be defined as NOT ATOMIC.

type-declaration
Declares a user-defined data type that is local to the compound statement.

type-name
Specifies the name of a local user-defined data type. The name cannot be the same as any other type declared within the current compound statement (SQLSTATE 42734). The unqualified *type-name* has the same restrictions as described in any CREATE TYPE statement (SQLSTATE 42939).

array-type-definition
Specifies the attributes of an array data type to associate with the *type-name*. See "CREATE TYPE (array)" for a description of the syntax elements. The *row-type-name* can refer to a declared row type that is previously declared and in the scope of the current compound SQL (compiled) statement. The *variable-name* specified in an anchored-data-type clause can refer to a local variable in the scope of the current compound SQL (compiled) statement.

distinct-type-definition
Specifies the source type and optional data type constraints of a weakly typed distinct type to associate with the *type-name*. See "CREATE TYPE (distinct)" for a complete description of the

syntax elements. The *variable-name* specified in anchored-non-row-data-type clause can refer to a local variable in the scope of the current compound SQL (compiled) statement. The data type of the anchor *variable-name* or *column-name* must be a built-in data type.

row-type-definition
Specifies the fields of a row data type to associate with the *type-name*. See "CREATE TYPE (row)" for a complete description of the syntax elements. The *variable-name* specified in anchored-non-row-data-type or anchored-row-data-type clauses can refer to a local variable in the scope of the current compound SQL (compiled) statement.

SQL-variable-declaration
Declares a variable that is local to the compound statement.

SQL-variable-name
Defines the name of a local variable. All SQL variable names are converted to uppercase. The name cannot be the same as another SQL variable within the same compound statement and cannot be the same as a parameter name. An SQL variable name must not be the same as a column name. If an SQL statement contains an identifier with the same name as an SQL variable and a column reference, the identifier is interpreted as a column. If the compound statement in which the variable is declared has a label, then references to the variable can be qualified with the label. For example, variable V declared in a compound statement with a label C can be referred to as C.V.

data-type4
Specifies the data type of the variable. A structured type or reference type cannot be specified (SQLSTATE 429BB).

built-in-type
Specifies a built-in data type. For a more complete description of each built-in data type except BOOLEAN and CURSOR, which cannot be specified for a table, see "CREATE TABLE". The XML data type cannot be specified in a compound SQL (compiled) statement used in a trigger, in a function, or as a stand-alone statement (SQLSTATE 429BB). The XML data type can be specified when the compound SQL (compiled) statement is used in an SQL procedure body.

BOOLEAN
For a Boolean.

CURSOR
For a cursor.

anchored-data-type
Identifies another object used to determine the data type of the SQL variable. The data type of the anchor object has the same limitations that apply to specifying the data type directly, or in the case of a row, to creating a row type.

ANCHOR DATA TYPE TO
Indicates an anchored data type is used to specify the data type.

variable-name
Identifies an SQL variable, SQL parameter, or global variable. The data type of the referenced variable is used as the data type for *SQL-variable-name*.

table-name.column-name
Identifies a column name of an existing table or view. The data type of the column is used as the data type for *SQL-variable-name*.

ROW OF *table-name* or *view-name*
Specifies a row of fields with names and data types that are based on the column names and column data types of the table identified by *table-name* or the view identified by *view-name*. The data type of *SQL-variable-name* is an unnamed row type.

ROW OF *cursor-variable-name*
Specifies a row of fields with names and data types that are based on the field names and field data types of the cursor variable identified by *cursor-variable-name*. The specified cursor variable must be one of the following elements (SQLSTATE 428HS):

- An SQL variable or global variable with a strongly typed cursor data type
- An SQL variable or global variable with a weakly typed cursor data type that was created or declared with a CONSTANT clause specifying a *select-statement* where all the result columns are named.

If the cursor type of the cursor variable is not strongly rtyped using a named row type, the data type of *SQL-variable-name* is an unnamed row type.

array-type-name
Specifies the name of a user-defined array type. The array data type can be a locally declared data type, a schema data type, or a module data type.

cursor-type-name
Specifies the name of a cursor type. The cursor data type can be a schema data type or a module data type.

distinct-type-name
Specifies the name of a distinct type. The distinct data type can be a schema data type or a module data type. The length, precision, and scale of the declared variable are, respectively, the length, precision, and scale of the source type of the distinct type.

row-type-name
Specifies the name of a user-defined row type. The row data type can be a locally declared data type, a schema data type or a module data type. The fields of the variable are the fields of the row type.

DEFAULT or CONSTANT
Specifies a value for the SQL variable when the compound SQL (compiled) statement is referenced. If neither is specified, the default for the SQL variable is the null value. Only DEFAULT NULL can be explicitly specified if *array-type-name* or *row-type-name* is specified.

DEFAULT
Defines the default for the SQL variable. The variable is initialized when the compound SQL (compiled) statement is referenced. The default value must be assignment-compatible with the data type of the variable.

CONSTANT
Specifies that the SQL variable has a fixed value that cannot be changed. An SQL variable that is defined using CONSTANT cannot be used as the target of any assignment operation. The fixed value must be assignment-compatible with the data type of the variable.

NULL
Specifies NULL as the default for the SQL variable.

constant
Specifies a constant as the default for the SQL variable. If *data-type4* specifies a CURSOR built-in type or *cursor-type-name*, *constant* cannot be specified (SQLSTATE 42601).

cursor-value-constructor
A *cursor-value-constructor* specifies the *select-statement* that is associated with the SQL variable. The assignment of a *cursor-value-constructor* to a cursor variable defines the underlying cursor of that cursor variable.

(cursor-parameter-declaration, ...)
Specifies the input parameters of the cursor, including the name and the data type of each parameter. Named input parameters can be specified only if *select-statement* is also specified in *cursor-value-constructor* (SQLSTATE 428HU).

parameter-name
Names the cursor parameter for use as an SQL variable within *select-statement*. The name cannot be the same as any other parameter name for the cursor. Names should also be chosen to avoid any column names that could be used in *select-statement*, since column names are resolved before parameter names.

data-type5
Specifies the data type of the cursor parameter used within *select-statement*. Structured types, and reference types cannot be specified (SQLSTATE 429BB).

built-in-type
Specifies a built-in data type. For a more complete description of each built-in data type, see "CREATE TABLE". The BOOLEAN and CURSOR built-in types cannot be specified (SQLSTATE 429BB).

anchored-non-row-data-type
Identifies another object used to determine the data type of the cursor parameter. The data type of the anchor object has the same limitations that apply to specifying the data type directly.

ANCHOR DATA TYPE TO
Indicates an anchored data type is used to specify the data type.

variable-name
Identifies a local SQL variable, an SQL parameter, or a global variable. The data type of the referenced variable is used as the data type for the cursor parameter.

table-name.column-name
Identifies a column name of an existing table or view. The data type of the column is used as the data type for the cursor parameter.

distinct-type-name
Specifies the name of a distinct type. If *distinct-type-name* is specified without a schema name, the distinct type is resolved by searching the schemas in the SQL path.

holdability
Specifies whether the cursor is prevented from being closed as a consequence of a commit operation. See "DECLARE CURSOR" for more information. The default is WITHOUT HOLD.

WITHOUT HOLD
Does not prevent the cursor from being closed as a consequence of a commit operation.

WITH HOLD
Maintains resources across multiple units of work. Prevents the cursor from being closed as a consequence of a commit operation.

select-statement
Specifies the SELECT statement of the cursor. See "select-statement" for more information. If *cursor-parameter-declaration* is included in *cursor-value-constructor*, then *select-statement* must not include any local SQL variables or routine SQL parameters (SQLSTATE 42704).

statement-name
Specifies the prepared *select-statement* of the cursor. See "PREPARE" for an explanation of prepared statements. The target cursor variable must not have a data type that is a strongly rtyped user-defined cursor type (SQLSTATE 428HU). Named input parameters must not be specified in *cursor-value-constructor* if *statement-name* is specified (SQLSTATE 428HU).

RESULT_SET_LOCATOR VARYING
Specifies the data type for a result set locator variable.

condition-declaration
Declares a condition name with an optional associated SQLSTATE value.

condition-name
Specifies the name of the condition. The condition name must be unique within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement (SQLSTATE 42734). A condition name can only be

referenced within the compound statement in which it is declared, including any compound statements that are nested within that compound statement (SQLSTATE 42737).

CONDITION FOR SQLSTATE VALUE*string-constant*
Specifies the SQLSTATE that is associated with the condition. The string constant must be specified as five characters enclosed in single quotation marks, and the SQLSTATE class (the first two characters) must not be '00'. If this clause is not specified, the condition has no associated SQLSTATE value.

statement-declaration
Declares a list of one or more names that are local to the compound statement. Each name in *statement-name* must not be the same as any other statement name declared in the same compound statement.

return-codes-declaration
Declares special variables called SQLSTATE and SQLCODE that are set automatically to the value returned after processing an SQL statement. Both the SQLSTATE and SQLCODE variables can only be declared in the outermost compound statement when there are nested compound SQL (compiled) statements; for example in an SQL procedure body. These variables may be declared only once per SQL procedure.

declare-cursor-statement
Declares a built-in cursor in the procedure body. Variables of user-defined cursor data types are declared using *SQL-variable-declaration* statements.

Each declared cursor must have a unique name within the compound statement in which it is declared, excluding any declarations in compound statements that are nested within that compound statement (SQLSTATE 42734). The cursor can be referenced only from within the compound statement in which it is declared, including any compound statements that are nested within that compound statement (SQLSTATE 34000).

Use an OPEN statement to open the cursor, and a FETCH statement to read rows using the cursor. To return result sets from the SQL procedure to the client application, the cursor must be declared using the WITH RETURN clause. The following example returns one result set to the client application:

```
CREATE PROCEDURE RESULT_SET()
  LANGUAGE SQL
  RESULT SETS 1
  BEGIN
    DECLARE C1 CURSOR WITH RETURN FOR
      SELECT id, name, dept, job
        FROM staff;
    OPEN C1;
END
```

Note: To process result sets, you must write your client application using one of the Db2 Call Level Interface (Db2 Call Level Interface), Open Database Connectivity (ODBC), Java Database Connectivity (JDBC), or embedded SQL for Java (SQLJ) application programming interfaces.

For more information about declaring a cursor, see "DECLARE CURSOR".

procedure-declaration
Declares a procedure that is local to the compound statement. The definition of a local procedure does not include the specification of any of the options possible in a "CREATE PROCEDURE (SQL)" statement. The options default as they would for a "CREATE PROCEDURE (SQL)" statement with the exception of MODIFIES SQL DATA. The data access level for the procedure is automatically determined to be the minimum level required to process the SQL procedure body.

procedure-name
Defines the names of a local procedure. The name must be specified without any qualification (SQLSTATE 42601). The procedure signature, consisting of the *procedure-name* and the number of declared parameters, must be unique within the current compound statement. Outer compound statements within which the current compound statement is nested cannot contain a procedure with the same name.

parameter-declaration
Specifies the parameters of the local procedure. See "CREATE PROCEDURE (SQL)" for a description of the syntax elements. The parameter data type can be a locally declared data type in the scope of the current compound statement.

SQL-procedure-body
Specifies the SQL statement that is the body of the SQL procedure. Names referenced in the *SQL-procedure-body* can refer to declared objects (such as declared variables, data types, and procedures) that are previously declared and in the scope of the compound statement in which the local procedure is declared.

handler-declaration
Specifies a *handler*, and a set of one or more *SQL-procedure-statements* to execute when an exception or completion condition occurs in the compound statement.*SQL-procedure-statement* is a statement that executes when the handler receives control.

A handler is said to be active for the duration of the execution of the set of *SQL-procedure-statements* that follow the set of *handler-declarations* within the compound statement in which the handler is declared, including any nested compound statements.

There are three types of condition handlers:

CONTINUE
After the handler is invoked successfully, control is returned to the SQL statement that follows the statement that raised the exception. If the error that raised the exception is a FOR, IF, CASE, WHILE, or REPEAT statement (but not an SQL-procedure-statement within one of these), then control returns to the statement that follows END FOR, END IF, END CASE, END WHILE, or END REPEAT.

EXIT
After the handler is invoked successfully, control is returned to the end of the compound statement that declared the handler.

UNDO
Before the handler is invoked, any SQL changes that were made in the compound statement are rolled back. After the handler is invoked successfully, control is returned to the end of the compound statement that declared the handler. If UNDO is specified, the compound statement where the handler is declared must be ATOMIC.

The conditions that cause the handler to be activated are defined in the handler-declaration as follows:

specific-condition-value
Specifies that the handler is a *specific condition handler*.

SQLSTATE VALUE*string-constant*
Specifies an SQLSTATE for which the handler is invoked. The first two characters of the SQLSTATE value must not be '00'.

condition-name
Specifies a condition name for which the handler is invoked. The condition name must be previously defined in a condition declaration or it must identify a condition that exists at the current server.

general-condition-value
Specifies that the handler is a *general condition handler*.

SQLEXCEPTION
Specifies that the handler is invoked when an exception condition occurs. An exception condition is represented by an SQLSTATE value whose first two characters are not '00', '01', or '02'.

SQLWARNING
Specifies that the handler is invoked when a warning condition occurs. A warning condition is represented by an SQLSTATE value whose first two characters are '01'.

NOT FOUND
Specifies that the handler is invoked when a NOT FOUND condition occurs. A NOT FOUND condition is represented by an SQLSTATE value whose first two characters are '02'.

SQL-procedure-statement
Specifies the SQL procedure statement.

label
Specifies a label for the SQL procedure statement. The label must be unique within a list of SQL procedure statements, including any compound statements nested within the list. Note that compound statements that are not nested can use the same label. A list of SQL procedure statements is possible in a number of SQL control statements.

SQL-statement
All executable SQL statements except for:

- ALTER
- CONNECT
- CREATE
- DESCRIBE
- DISCONNECT
- DROP
- FLUSH EVENT MONITOR
- FREE LOCATOR
- GRANT
- REFRESH TABLE
- RELEASE (connection only)
- RENAME TABLE
- RENAME TABLESPACE
- REVOKE
- SET CONNECTION
- SET INTEGRITY
- SET PASSTHRU
- SET SERVER OPTION
- TRANSFER OWNERSHIP

The following executable statements are not supported in stand-alone compound SQL (compiled) statements, but are supported in compound SQL (compiled) statements used within an SQL function, SQL procedure, or trigger:

- CREATE of an index, table, or view
- DECLARE GLOBAL TEMPORARY TABLE
- DROP of an index, table, or view
- GRANT
- ROLLBACK

The ROLLBACK statement is also not supported in any nested statement invoked within the stand-alone compound SQL (compiled) statement.

The following statements, which are not executable statements, are supported in compound SQL (compiled) statements:

- ALLOCATE CURSOR
- ASSOCIATE LOCATORS

Rules

- ATOMIC compound statements cannot be nested.
- The following rules apply to handler declarations:
  - A handler declaration cannot contain the same *condition-name* or SQLSTATE value more than once, and cannot contain an SQLSTATE value and a *condition-name* that represent the same SQLSTATE value.
  - Where two or more condition handlers are declared in a compound statement:
    - No two handler declarations may specify the same general condition category (SQLEXCEPTION, SQLWARNING, NOT FOUND).
    - No two handler declarations may specify the same specific condition, either as an SQLSTATE value or as a *condition-name* that represents the same value.
  - A handler is activated when it is the most appropriate handler for an exception or completion condition. The most appropriate handler is determined based on the following considerations:
    - The scope of a handler declaration *H* is the list of *SQL-procedure-statement* that follows the handler declarations contained within the compound statement in which *H* appears. This means that the scope of *H* does not include the statements contained in the body of the condition handler *H*, implying that a condition handler cannot handle conditions that arise inside its own body. Similarly, for any two handlers *H1* and *H2* declared in the same compound statement, *H1* will not handle conditions arising in the body of *H2*, and *H2* will not handle conditions arising in the body of *H1*.
    - A handler for a *specific-condition-value* or a *general-condition-value* C declared in an inner scope takes precedence over another handler for C declared in an enclosing scope.
    - When a specific handler for condition *C* and a general handler which would also handle *C* are declared in the same scope, the specific handler takes precedence over the general handler.
    - When a handler for a module condition that has no associated SQLSTATE value and a handler for SQLSTATE 45000 are declared in the same scope, the handler for the module condition takes precedence over the handler for SQLSTATE 45000.

    If an exception condition occurs for which there is no appropriate handler, the SQL procedure containing the failing statement is terminated with an unhandled exception condition. If a completion condition occurs for which there is no appropriate handler, execution continues with the next SQL statement.
- Referencing variables or parameters of data type XML in SQL procedures after a commit or rollback operation occurs, without first assigning new values to these variables, is not supported (SQLSTATE 560CE).
- ***Use of anchored data types:*** An anchored data type cannot refer to the following objects (SQLSTATE 428HS): a nickname, typed table, typed view, statistical view that is associated with an expression-based index, declared temporary table, row definition that is associated with a weakly typed cursor, object with a code page or collation that is different from the database code page or database collation.
- If named parameter markers are used in a compound SQL (compiled) statement that is dynamically prepared or executed, every parameter marker name must be unique (SQLSTATE 42997).

Notes

- ***XML assignments:*** Assignment to parameters and variables of data type XML is done by reference.

  Passing parameters of data type XML in a CALL statement to an SQL procedure is done by reference. When XML values are passed by reference, any input node trees are used directly from the XML argument. This direct usage preserves all properties, including document order, the original node identities, and all parent properties.

Examples

- *Example 1*: A simple stand-alone compound statement that outputs the word 'Hello':

```
SET SERVEROUTPUT ON;
BEGIN
    CALL DBMS_OUTPUT.PUT_LINE ( 'Hello' );
END
```

- *Example 2*: A simple stand-alone compound statement that counts the number of records in `staff` and outputs the result:

```
SET SERVEROUTPUT ON;
BEGIN
    DECLARE v_numRecords INTEGER DEFAULT 1;
 SELECT COUNT(*) INTO v_numRecords FROM staff;

 CALL DBMS_OUTPUT.PUT_LINE (v_numRecords);
END
```

- *Example 3*: Create a procedure with a compound SQL (compiled) statement that performs the following actions:

  1. Declares SQL variables
  2. Declares a cursor to return the salary of employees in a department determined by an IN parameter. In the SELECT statement, casts the data type of the *salary* column from a DECIMAL into a DOUBLE.
  3. Declares an EXIT handler for the condition NOT FOUND (end of file) which assigns the value '6666' to the OUT parameter `medianSalary`
  4. Select the number of employees in the given department into the SQL variable `numRecords`
  5. Fetch rows from the cursor in a WHILE loop until 50% + 1 of the employees have been retrieved
  6. Return the median salary

```
CREATE PROCEDURE DEPT_MEDIAN
  (IN deptNumber SMALLINT, OUT medianSalary DOUBLE)
  LANGUAGE SQL
  BEGIN
    DECLARE v_numRecords INTEGER DEFAULT 1;
    DECLARE v_counter INTEGER DEFAULT 0;
    DECLARE c1 CURSOR FOR
      SELECT CAST(salary AS DOUBLE) FROM staff
        WHERE DEPT = deptNumber
        ORDER BY salary;
    DECLARE EXIT HANDLER FOR NOT FOUND
      SET medianSalary = 6666;
-- initialize OUT parameter
      SET medianSalary = 0;
      SELECT COUNT(*) INTO v_numRecords FROM staff
        WHERE DEPT = deptNumber;
      OPEN c1;
      WHILE v_counter < (v_numRecords / 2 + 1) DO
        FETCH c1 INTO medianSalary;
        SET v_counter = v_counter + 1;
      END WHILE;
      CLOSE c1;
  END
```

- *Example 4*: The following example illustrates the flow of execution in a hypothetical case where an UNDO handler is activated from another condition as the result of RESIGNAL:

```
CREATE PROCEDURE A()
LANGUAGE SQL
CS1: BEGIN ATOMIC
  DECLARE C CONDITION FOR SQLSTATE '12345';
  DECLARE D CONDITION FOR SQLSTATE '23456';

  DECLARE UNDO HANDLER FOR C
  H1: BEGIN
    -- Perform rollback after error, perform final cleanup, and exit
    -- procedure A.

    -- ...
```

```
      -- When this handler completes, execution continues after
      -- compound statement CS1; procedure A will terminate.
    END;

    -- Perform some work here ...
    CS2: BEGIN
      DECLARE CONTINUE HANDLER FOR D
      H2: BEGIN
        -- Perform local recovery, then forward the error
        -- condition to the outer handler for additional
        -- processing.

        -- ...

        RESIGNAL C; -- will activate UNDO handler H1; execution
                    -- WILL NOT return here.  Any local cursors
                    -- declared in H2 and CS2 will be closed.
      END;

      -- Perform some more work here ...

      -- Simulate raising of condition D by some SQL statement
      -- in compound statement CS2:
      SIGNAL D; -- will activate H2
    END;
  END
```

CONNECT (type 1)

The CONNECT (Type 1) statement connects an application process to the identified application server according to the rules for remote unit of work.

An application process can only be connected to one application server at a time. This is called the *current server*. A default application server may be established when the application requester is initialized. If implicit connect is available and an application process is started, it is implicitly connected to the default application server. The application process can explicitly connect to a different application server by issuing a CONNECT statement. A connection lasts until a CONNECT RESET statement or a DISCONNECT statement is issued or until another CONNECT statement changes the application server.

Invocation

Although an interactive SQL facility might provide an interface that gives the appearance of interactive execution, this statement can only be embedded within an application program. It is an executable statement that cannot be dynamically prepared. When invoked using the command line processor, additional options can be specified.

For more information, refer to "Using command line SQL statements and XQuery statements" in *Command Reference*.

Authorization

CONNECT processing goes through two levels of access control. Both levels must be satisfied for the connection to be successful.

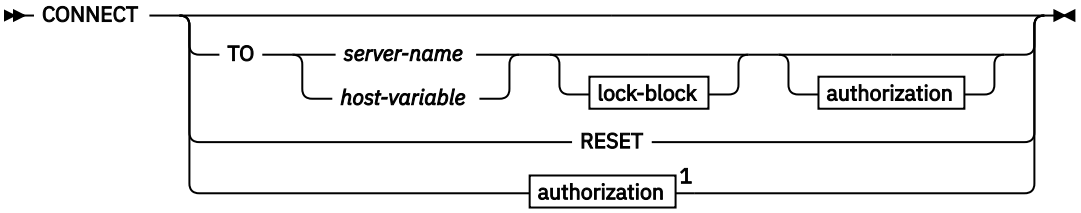
The first level of access control is authentication, where the user ID associated with the connection must be successfully authenticated according to the authentication method set up for the server. At successful authentication, a database authorization ID is derived from the connection user ID according to the authentication plug-in in effect for the server. This database authorization ID must then pass the second level of access control for the connection, that is, authorization. To do so, this authorization ID must hold at least one of the following authorities:

- CONNECT authority
- SECADM authority
- DBADM authority
- SYSADM authority

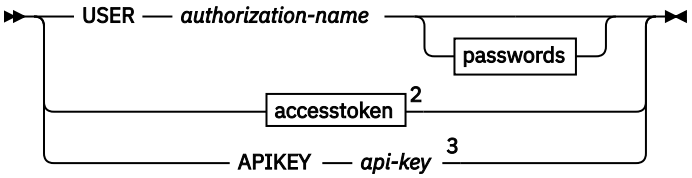
- SYSCTRL authority
- SYSMAINT authority
- SYSMON authority

Note: For a partitioned database, the user and group definitions must be identical across all database partitions.

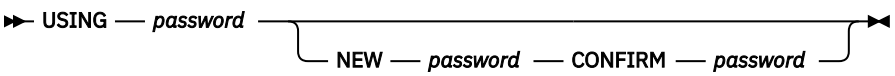
Syntax



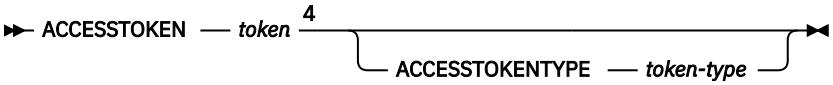
authorization



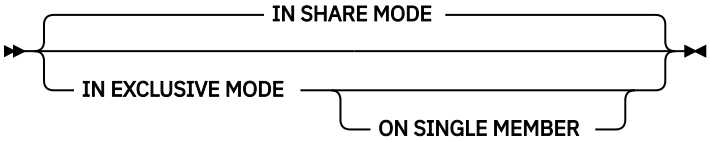
passwords



accesstoken



lock-block



Notes:

[1] This form is only valid if implicit connect is enabled.
[2] This feature is available starting from Db2 Version 11.5 Mod Pack 4.
[3] This feature is available starting from Db2 Version 11.5 Mod Pack 4.
[4] This feature is available starting from Db2 Version 11.5 Mod Pack 4.

Description

CONNECT (with no operand)

Returns information about the current server. The information is returned in the SQLERRP field of the SQLCA as described in "Successful Connection".

If a connection state exists, the authorization ID and database alias are placed in the SQLERRMC field of the SQLCA. If the authorization ID is longer than 8 bytes, it will be truncated to 8 bytes, and the truncation will be flagged in the SQLWARN0 and SQLWARN1 fields of the SQLCA, with 'W' and 'A', respectively.

If no connection exists and implicit connect is possible, then an attempt to make an implicit connection is made. If implicit connect is not available, this attempt results in an error (no existing connection). If no connection, then the SQLERRMC field is blank.

The territory code and code page of the application server are placed in the SQLERRMC field (as they are with a successful CONNECT statement).

This form of CONNECT:

- Does not require the application process to be in the connectable state.
- If connected, does not change the connection state.
- If unconnected and implicit connect is available, a connection to the default application server is made. In this case, the country or region code and code page of the application server are placed in the SQLERRMC field, like a successful CONNECT statement.
- If unconnected and implicit connect is not available, the application process remains unconnected.
- Does not close cursors.

TO *server-name* or *host-variable*

Identifies the application server by the specified *server-name* or a *host-variable* which contains the server-name.

If a *host-variable* is specified, it must be a character string variable with a length attribute that is not greater than 8, and it must not include an indicator variable. The *server-name* that is contained within the *host-variable* must be left-aligned and must not be delimited by quotation marks.

Note that the *server-name* is a database alias identifying the application server. It must be listed in the application requester's local directory.

When the CONNECT statement is executed, the application process must be in the connectable state.

Successful Connection

If the CONNECT statement is successful:

- All open cursors are closed, all prepared statements are destroyed, and all locks are released from the previous application server.
- The application process is disconnected from its previous application server, if any, and connected to the identified application server.
- The actual name of the application server (not an alias) is placed in the CURRENT SERVER special register.
- Information about the application server is placed in the SQLERRP field of the SQLCA. If the application server is an IBM product, the information has the form *pppvvrrm*, where:
  - *ppp* represents one of the following product identifiers:
    - DSN for Db2 for z/OS
    - ARI for Db2 Server for VSE & VM
    - QSQ for Db2 for IBM i
    - SQL for Db2
  - *vv* is a two-digit version identifier, such as '08'
  - *rr* is a two-digit release identifier, such as '01'
  - *m* is a one-character modification level identifier, such as '0'.

  For example, Version 9.5 of Db2 is identified as 'SQL09050'.
- The SQLERRMC field of the SQLCA is set to contain the following values (separated by X'FF')
  1. The country or region code of the application server (or blanks if using Db2 Connect),
  2. The code page of the application server (or CCSID if using Db2 Connect),
  3. The authorization ID (up to first 8 bytes only),

4. The database alias,
5. The platform type of the application server. Currently identified values are:

   Token
   Server

   QAS
   Db2 for IBM i

   QDB2
   Db2 for z/OS

   QDB2/6000
   Db2 Database for AIX

   QDB2/LINUX
   Db2 Database for Linux

   QDB2/NT
   Db2 Database for Windows

   QSQLDS/VM
   Db2 Server for VM

   QSQLDS/VSE
   Db2 Server for VSE
6. The agent ID. It identifies the agent executing within the database manager on behalf of the application. This field is the same as the **agent_id** element returned by the database monitor.
7. The agent index. It identifies the index of the agent and is used for service.
8. If the server instance operates in a Db2 pureScale environment, as indicated by SQLWARN0 and SQLWARN4 being set to 'W' and 'S' respectively, this value represents the member number. If, as indicated by token 10, the server instance operates in a partitioned environment, this token represents the member number. If the server instance operates in a non-partitioned environment and outside of a Db2 pureScale environment, this value is not applicable and is always 0.
9. The code page of the application client.
10. If this value is zero, the server instance operates in a non-partitioned environment and outside of a Db2 pureScale environment. Otherwise, this non-zero value represents the number of members in a Db2 pureScale instance, if SQLWARN0 and SQLWARN4 are set to 'W' and 'S' respectively. If this value is non-zero but neither SQLWARN0 nor SQLWARN4 is set, it represents the number of members in a partitioned environment.

- The SQLERRD(1) field of the SQLCA indicates the maximum expected difference in length of mixed character data (CHAR data types) when converted to the database code page from the application code page. A value of 0 or 1 indicates no expansion; a value greater than 1 indicates a possible expansion in length; a negative value indicates a possible contraction.
- The SQLERRD(2) field of the SQLCA indicates the maximum expected difference in length of mixed character data (CHAR data types) when converted to the application code page from the database code page. A value of 0 or 1 indicates no expansion; a value greater than 1 indicates a possible expansion in length; a negative value indicates a possible contraction.
- The SQLERRD(3) field of the SQLCA indicates whether or not the database on the connection is updatable. A database is initially updatable, but is changed to read-only if a unit of work determines the authorization ID cannot perform updates. The value is one of:
  - 1 - updatable
  - 2 - read-only
- The SQLERRD(4) field of the SQLCA returns certain characteristics of the connection. The value is one of:

0
N/A (only possible if running from a client which is not at the latest level, is one-phase commit, and is an updater).

1
one-phase commit.

2
one-phase commit; read-only (only applicable to connections to DRDA1 databases in a TP Monitor environment).

3
two-phase commit.

- The SQLERRD(5) field of the SQLCA returns the authentication type for the connection. The value is one of:

  0
  Authenticated on the server.

  1
  Authenticated on the client.

  2
  Authenticated using Db2 Connect.

  4
  Authenticated on the server with encryption.

  5
  Authenticated using Db2 Connect with encryption.

  7
  Authenticated using an external Kerberos security mechanism.

  9
  Authenticated using an external GSS API plug-in security mechanism.

  11
  Authenticated on the server, which accepts encrypted data.

  255
  Authentication not specified.
- The SQLERRD(6) field of the SQLCA returns the database partition number of the database partition to which the connection was made if in a partitioned database environment. Otherwise, a value of 0 is returned.
- The SQLWARN1 field in the SQLCA will be set to 'A' if the authorization ID of the successful connection is longer than 8 bytes. This indicates that truncation has occurred. The SQLWARN0 field in the SQLCA will be set to 'W' to indicate this warning.

Unsuccessful Connection

If the CONNECT statement is unsuccessful:

- The SQLERRP field of the SQLCA is set to the name of the module at the application requester that detected the error. The first three characters of the module name identify the product.
- If the CONNECT statement is unsuccessful because the application process is not in the connectable state, the connection state of the application process is unchanged.
- If the CONNECT statement is unsuccessful because the *server-name* is not listed in the local directory, an error message (SQLSTATE 08001) is issued and the connection state of the application process remains unchanged:
  - If the application requester was not connected to an application server then the application process remains unconnected.
  - If the application requester was already connected to an application server, the application process remains connected to that application server. Any further statements are executed at that application server.

- If the CONNECT statement is unsuccessful for any other reason, the application process is placed into the unconnected state.

IN SHARE MODE
Allows other concurrent connections to the database and prevents other users from connecting to the database in exclusive mode.

IN EXCLUSIVE MODE
Prevents concurrent application processes from executing any operations at the application server, unless they have the same authorization ID as the user holding the exclusive lock. This option is not supported by Db2 Connect.

ON SINGLE MEMBER
Specifies that the coordinator database member is connected in exclusive mode and all other members are connected in share mode.

If the database is neither in a partitioned environment nor a Db2 pureScale environment, this option can be specified, but it has no effect.

RESET
Disconnects the application process from the current server. A commit operation is performed. If implicit connect is available, the application process remains unconnected until an SQL statement is issued.

USER *authorization-name/host-variable*
Identifies the user ID trying to connect to the application server. If a host-variable is specified, it must be a character string variable that does not include an indicator variable. The user ID that is contained within the *host-variable* must be left-aligned and must not be delimited by quotation marks.

USING *password/host-variable*
Identifies the password of the user ID trying to connect to the application server. The maximum length of the password is determined by the data server you are connecting to. If a host variable is specified, it must be a character string variable and it must not include an indicator variable.

NEW *password/host-variable* CONFIRM *password*
Identifies the new password that should be assigned to the user ID identified by the USER option. The maximum length of the password is determined by the data server you are connecting to. If a host variable is specified, it must be a character string variable and it must not include an indicator variable. The system on which the password will be changed depends on how the user authentication has been set up. To support the changing passwords on Linux, the database instance must be configured to use the security plug-ins IBMOSchgpwdclient and IBMOSchgpwdserver.

Notes

- It is good practice for the first SQL statement executed by an application process to be the CONNECT statement.
- If a CONNECT statement is issued to the current application server with a different user ID and password then the conversation is deallocated and reallocated. All cursors are closed by the database manager (with the loss of the cursor position if the WITH HOLD option was used).
- If a CONNECT statement is issued to the current application server with the same user ID and password then the conversation is not deallocated and reallocated. Cursors, in this case, are not closed.
- To use a multiple-partition partitioned database environment, the user or application must connect to one of the database partitions listed in the `db2nodes.cfg` file. You should try to ensure that not all users use the same database partition as the coordinator partition.
- The *authorization-name* SYSTEM cannot be explicitly specified in the CONNECT statement. However, on Windows operating systems, local applications running under the Local System Account can implicitly connect to the database, such that the user ID is SYSTEM.
- When connecting to Windows Server explicitly, the *authorization-name* or user *host-variable* can be specified using the Microsoft Windows Security Account Manager (SAM)-compatible name.

- The database can be inaccessible if the database was not explicitly activated, a client application performs frequent reconnections, or the time interval between issuing the **DEACTIVATE DATABASE** and **ACTIVATE DATABASE** commands is very short. Activate the database by issuing the **ACTIVATE DATABASE** command and then attempt to connect to the database.
- ***Syntax alternatives***: The following are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - DBPARTITIONNUM or NODE can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.

Examples

- *Example 1:* In a C program, connect to the application server TOROLAB, using database alias TOROLAB, user ID FERMAT, and password THEOREM.

```
   EXEC SQL  CONNECT TO TOROLAB USER FERMAT USING THEOREM;
```

- *Example 2:* In a C program, connect to an application server whose database alias is stored in the host variable APP_SERVER (varchar(8)). Following a successful connection, copy the 3-character product identifier of the application server to the variable PRODUCT (char(3)).

```
   EXEC SQL  CONNECT TO :APP_SERVER;
   if (strncmp(SQLSTATE,'00000',5))
     strncpy(PRODUCT,sqlca.sqlerrp,3);
```

- *Example 3:* Connect to the SAMPLE database using a JWT access token.

```
connect to sample accesstoken <access_token> accesstokentype jwt

   Database Connection Information

 Database server        = DB2/LINUXX8664 11.5.4.0
 SQL authorization ID   = NEWTON
 Local database alias   = SAMPLE
```

CONNECT (type 2)

The CONNECT (Type 2) statement connects an application process to the identified application server and establishes the rules for application-directed distributed unit of work. This server is then the current server for the process.

Most aspects of a CONNECT (Type 1) statement also apply to a CONNECT (Type 2) statement. Rather than repeating that material here, this section describes only those elements of Type 2 that differ from Type 1.

Invocation

Although an interactive SQL facility might provide an interface that gives the appearance of interactive execution, this statement can only be embedded within an application program. It is an executable statement that cannot be dynamically prepared. When invoked using the command line processor, additional options can be specified.

For more information, refer to "Using command line SQL statements and XQuery statements" in *Command Reference*.

Authorization

CONNECT processing goes through two levels of access control. Both levels must be satisfied for the connection to be successful.

The first level of access control is authentication, where the user ID associated with the connection must be successfully authenticated according to the authentication method set up for the server. At successful authentication, a database authorization ID is derived from the connection user ID according to the authentication plug-in in effect for the server. This database authorization ID must then pass the second

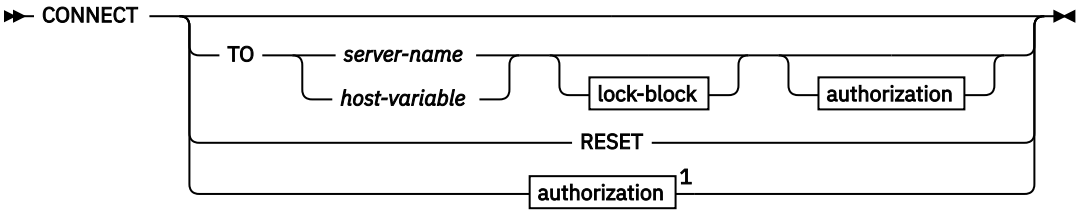
level of access control for the connection, that is, authorization. To do so, this authorization ID must hold at least one of the following authorities:

- CONNECT authority
- SECADM authority
- DBADM authority
- SYSADM authority
- SYSCTRL authority
- SYSMAINT authority
- SYSMON authority

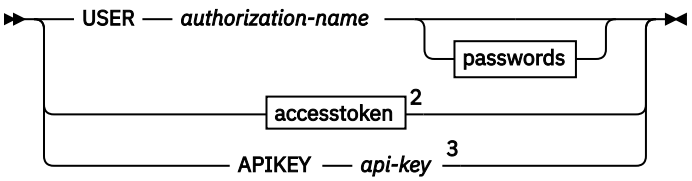
Note: For a partitioned database, the user and group definitions must be identical across all database partitions.

Syntax

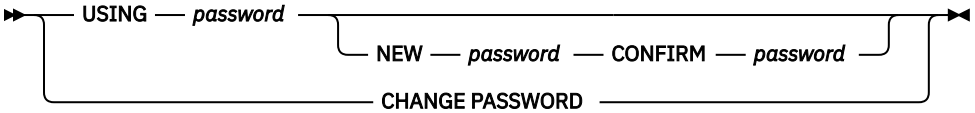
The selection between Type 1 and Type 2 is determined by precompiler options. For an overview of these options, see "Connecting to distributed relational databases".



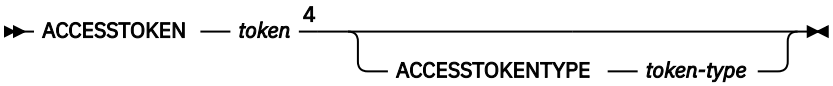
authorization



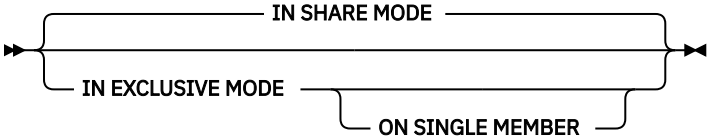
passwords



accesstoken



lock-block



Notes:

[1] This form is only valid if implicit connect is enabled.
[2] This feature is available starting from Db2 Version 11.5 Mod Pack 4.
[3] This feature is available starting from Db2 Version 11.5 Mod Pack 4.
[4] This feature is available starting from Db2 Version 11.5 Mod Pack 4.

Description

TO *server-name/host-variable*

The rules for coding the name of the server are the same as for Type 1.

If the SQLRULES(STD) option is in effect, the *server-name* must not identify an existing connection of the application process, otherwise an error (SQLSTATE 08002) is raised.

If the SQLRULES(DB2) option is in effect and the *server-name* identifies an existing connection of the application process, that connection is made current and the old connection is placed into the dormant state. That is, the effect of the CONNECT statement in this situation is the same as that of a SET CONNECTION statement.

For information about the specification of SQLRULES, see "Options that Govern Distributed Unit of Work Semantics".

Successful Connection

If the CONNECT statement is successful:

- A connection to the application server is either created (or made non-dormant) and placed into the current and held states.
- If the CONNECT TO is directed to a different server than the current server, then the current connection is placed into the dormant state.
- The CURRENT SERVER special register and the SQLCA are updated in the same way as for CONNECT (Type 1).

Unsuccessful Connection

If the CONNECT statement is unsuccessful:

- No matter what the reason for failure, the connection state of the application process and the states of its connections are unchanged.
- As with an unsuccessful Type 1 CONNECT, the SQLERRP field of the SQLCA is set to the name of the module at the application requester or server that detected the error.

CONNECT (with no operand), IN SHARE/EXCLUSIVE MODE, USER, and USING

If a connection exists, Type 2 behaves like a Type 1. The authorization ID and database alias are placed in the SQLERRMC field of the SQLCA. If a connection does not exist, no attempt to make an implicit connection is made and the SQLERRP and SQLERRMC fields return a blank. (Applications can check if a current connection exists by checking these fields.)

A CONNECT with no operand that includes USER and USING can still connect an application process to a database using the DB2DBDFT environment variable. This method is equivalent to a Type 2 CONNECT RESET, but permits the use of a user ID and password.

RESET

Equivalent to an explicit connect to the default database if it is available. If a default database is not available, the connection state of the application process and the states of its connections are unchanged.

Availability of a default database is determined by installation options, environment variables, and authentication settings.

Rules

- As outlined in "Options that Govern Distributed Unit of Work Semantics", a set of connection options governs the semantics of connection management. Default values are assigned to every preprocessed source file. An application can consist of multiple source files precompiled with different connection options.

  Unless a SET CLIENT command or API has been executed first, the connection options used when preprocessing the source file containing the first SQL statement executed at run time become the effective connection options.

If a CONNECT statement from a source file preprocessed with different connection options is subsequently executed without the execution of any intervening SET CLIENT command or API, an error (SQLSTATE 08001) is returned. Note that once a SET CLIENT command or API has been executed, the connection options used when preprocessing all source files in the application are ignored.

Example 1 in the "Examples" section of this statement illustrates these rules.

- Although the CONNECT statement can be used to establish or switch connections, CONNECT with the USER/USING clause will only be accepted when there is no current or dormant connection to the named server. The connection must be released before issuing a connection to the same server with the USER/USING clause, otherwise it will be rejected (SQLSTATE 51022). Release the connection by issuing a DISCONNECT statement or a RELEASE statement followed by a COMMIT statement.

Comparing Type 1 and Type 2 CONNECT Statements

The semantics of the CONNECT statement are determined by the CONNECT precompiler option or the SET CLIENT API (see "Options that Govern Distributed Unit of Work Semantics"). CONNECT Type 1 or CONNECT Type 2 can be specified and the CONNECT statements in those programs are known as Type 1 and Type 2 CONNECT statements, respectively. Their semantics are described in the following tables:

Use of **CONNECT**:

Type 1	Type 2
Each unit of work can only establish connection to one application server.	Each unit of work can establish connection to multiple application servers.
The current unit of work must be committed or rolled back before allowing a connection to another application server.	The current unit of work need not be committed or rolled back before connecting to another application server.
The CONNECT statement establishes the current connection. Subsequent SQL requests are forwarded to this connection until changed by another CONNECT.	Same as Type 1 CONNECT if establishing the first connection. If switching to a dormant connection and SQLRULES is set to STD, then the SET CONNECTION statement must be used instead.
Connecting to the current connection is valid and does not change the current connection.	Same as Type 1 CONNECT if the SQLRULES precompiler option is set to 'DB2'. If SQLRULES is set to STD, then the SET CONNECTION statement must be used instead.
Connecting to another application server disconnects the current connection. The new connection becomes the current connection. Only one connection is maintained in a unit of work.	Connecting to another application server puts the current connection into the *dormant state*. The new connection becomes the current connection. Multiple connections can be maintained in a unit of work. If the CONNECT is for an application server on a dormant connection, it becomes the current connection. Connecting to a dormant connection using CONNECT is only allowed if SQLRULES(DB2) was specified. If SQLRULES(STD) was specified, then the SET CONNECTION statement must be used instead.
SET CONNECTION statement is supported for Type 1 connections, but the only valid target is the current connection.	SET CONNECTION statement is supported for Type 2 connections to change the state of a connection from dormant to current.

Use of **CONNECT...USER...USING**:

Type 1	Type 2
Connecting with the USER...USING clauses disconnects the current connection and establishes a new connection with the given authorization name and password.	Connecting with the USER/USING clause will only be accepted when there is no current or dormant connection to the same named server.

Use of **Implicit CONNECT, CONNECT RESET**, and **Disconnecting**:

Type 1	Type 2
CONNECT RESET can be used to disconnect the current connection.	CONNECT RESET is equivalent to connecting to the default application server explicitly if one has been defined in the system. Connections can be disconnected by the application at a successful COMMIT. Prior to the commit, use the RELEASE statement to mark a connection as release-pending. All such connections will be disconnected at the next COMMIT. An alternative is to use the precompiler options DISCONNECT(EXPLICIT), DISCONNECT(CONDITIONAL), DISCONNECT(AUTOMATIC), or the DISCONNECT statement instead of the RELEASE statement.
After using CONNECT RESET to disconnect the current connection, if the next SQL statement is not a CONNECT statement, then it will perform an implicit connect to the default application server if one has been defined in the system.	CONNECT RESET is equivalent to an explicit connect to the default application server if one has been defined in the system.
It is an error to issue consecutive CONNECT RESETs.	It is an error to issue consecutive CONNECT RESETs ONLY if SQLRULES(STD) was specified because this option disallows the use of CONNECT to existing connection.
CONNECT RESET implicitly commits the current unit of work.	CONNECT RESET implicitly rolls back the current unit of work.
If an existing connection is disconnected by the system for whatever reasons, then subsequent non-CONNECT SQL statements to this database will receive an SQLSTATE of 08003.	If an existing connection is disconnected by the system, COMMIT, ROLLBACK, and SET CONNECTION statements are still permitted.
The unit of work will be implicitly committed when the application process terminates successfully.	Same as Type 1.
All connections (only one) are disconnected when the application process terminates.	All connections (current, dormant, and those marked for release pending) are disconnected when the application process terminates.

CONNECT Failures:

Type 1	Type 2
Regardless of whether there is a current connection when a CONNECT fails (with an error other than server-name not defined in the local directory), the application process is placed in the unconnected state. Subsequent non-CONNECT statements receive an SQLSTATE of 08003.	If there is a current connection when a CONNECT fails, the current connection is unaffected. If there was no current connection when the CONNECT fails, then the program is then in an unconnected state. Subsequent non-CONNECT statements receive an SQLSTATE of 08003.

Notes

- Implicit connect is supported for the first SQL statement in an application with Type 2 connections. In order to execute SQL statements on the default database, first the CONNECT RESET or the CONNECT USER/USING statement must be used to establish the connection. The CONNECT statement with no operands will display information about the current connection if there is one, but will not connect to the default database if there is no current connection.
- The *authorization-name* SYSTEM cannot be explicitly specified in the CONNECT statement. However, on Windows operating systems, local applications running under the Local System Account can implicitly connect to the database, such that the user ID is SYSTEM.
- When connecting to Windows Server explicitly, the *authorization-name* or user *host-variable* can be specified using the Microsoft Windows Security Account Manager (SAM)-compatible name.
- ***Termination of a connection***: When a connection is terminated and a transaction has not yet been committed or rolled back, see "Use of Implicit CONNECT, CONNECT RESET, and Disconnecting" section for details on what happens to such transactions. To ensure consistent behavior, code an explicit COMMIT statement or ROLLBACK statement instead of depending on the behavior of the CONNECT statement.
- ***Syntax alternatives***: The following are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - DBPARTITIONNUM or NODE can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.

Examples

- *Example 1:* This example illustrates the use of multiple source programs (shown in the boxes), some preprocessed with different connection options (shown in the statement preceding the code), and one of which contains a SET CLIENT API call.

  PGM1: CONNECT(2) SQLRULES(DB2) DISCONNECT(CONDITIONAL)

```
...
exec sql CONNECT TO OTTAWA;
exec sql SELECT col1 INTO :hv1
FROM tbl1;
...
```

  PGM2: CONNECT(2) SQLRULES(STD) DISCONNECT(AUTOMATIC)

```
...
exec sql CONNECT TO QUEBEC;
exec sql SELECT col1 INTO :hv1
FROM tbl2;
...
```

  PGM3: CONNECT(2) SQLRULES(STD) DISCONNECT(EXPLICIT)

```
...
SET CLIENT CONNECT 2  SQLRULES DB2  DISCONNECT EXPLICIT [1]
exec sql CONNECT TO LONDON;
exec sql SELECT col1 INTO :hv1
```

```
    FROM tbl3;
    ...
```

Note:

1. Not the actual syntax of the SET CLIENT API

PGM4: CONNECT(2) SQLRULES(DB2) DISCONNECT(CONDITIONAL)

```
    ...
    exec sql CONNECT TO REGINA;
    exec sql SELECT col1 INTO :hv1
    FROM tbl4;
    ...
```

If the application executes PGM1 then PGM2:

- connect to OTTAWA runs: connect=2, sqlrules=DB2, disconnect=CONDITIONAL
- connect to QUEBEC fails with SQLSTATE 08001 because both SQLRULES and DISCONNECT are different.

If the application executes PGM1 then PGM3:

- connect to OTTAWA runs: connect=2, sqlrules=DB2, disconnect=CONDITIONAL
- connect to LONDON runs: connect=2, sqlrules=DB2, disconnect=EXPLICIT

This is OK because the SET CLIENT API is run before the second CONNECT statement.

If the application executes PGM1 then PGM4:

- connect to OTTAWA runs: connect=2, sqlrules=DB2, disconnect=CONDITIONAL
- connect to REGINA runs: connect=2, sqlrules=DB2, disconnect=CONDITIONAL

This is OK because the preprocessor options for PGM1 are the same as those for PGM4.

- *Example 2:* This example shows the interrelationships of the CONNECT (Type 2), SET CONNECTION, RELEASE, and DISCONNECT statements. S0, S1, S2, and S3 represent four servers.

Sequence	Statement	Current Server	Dormant Connections	Release Pending
0	– No statement	– None	– None	– None
1	– SELECT * FROM TBLA	– S0 (default)	– None	– None
2	– CONNECT TO S1 – SELECT * FROM TBLB	– S1 – S1	– S0 – S0	– None – None
3	– CONNECT TO S2 – UPDATE TBLC SET ...	– S2 – S2	– S0, S1 – S0, S1	– None – None
4	– CONNECT TO S3 – SELECT * FROM TBLD	– S3 – S3	– S0, S1, S2 – S0, S1, S2	– None – None
5	– SET CONNECTION S2	– S2	– S0, S1, S3	– None
6	– RELEASE S3	– S2	– S0, S1	– S3
7	– COMMIT	– S2	– S0, S1	– None
8	– SELECT * FROM TBLE	– S2	– S0, S1	– None

Sequence	Statement	Current Server	Dormant Connections	Release Pending
9	– DISCONNECT S1	– S2	– S0	– None
	– SELECT * FROM TBLF	– S2	– S0	– None

- *Example 3:* Connect to the SAMPLE database using a JWT access token.

```
connect to sample accesstoken <access_token> accesstokentype jwt

   Database Connection Information

 Database server        = DB2/LINUXX8664 11.5.4.0
 SQL authorization ID   = NEWTON
 Local database alias   = SAMPLE
```

CREATE ALIAS

The CREATE ALIAS statement defines an alias for a module, nickname, sequence, table, view, or another alias. Aliases are also known as synonyms.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the alias does not exist
- SCHEMAADM authority on the schema if the schema name of the alias refers to an existing schema
- CREATEIN privilege on the schema, if the schema name of the alias refers to an existing schema, or CREATEIN privilege on SYSPUBLIC, if a public alias is being created
- DBADM authority

Privileges required to use the referenced object through its alias are identical to the privileges required to use the object directly.

To replace an existing alias, the authorization ID of the statement must be the owner of the existing alias (SQLSTATE 42501).

Syntax

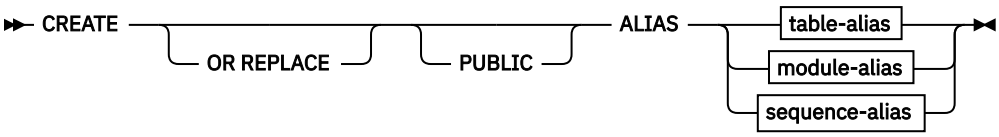


table-alias

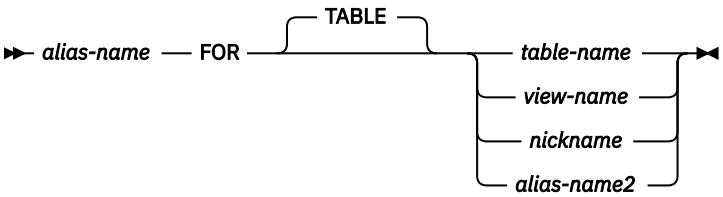
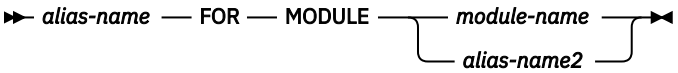


module-alias



sequence-alias

Description

OR REPLACE
Specifies to replace the definition for the alias if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog. This option is ignored if a definition for the alias does not exist at the current server. This option can be specified only by the owner of the object.

PUBLIC
Specifies that the alias is an object in the system schema SYSPUBLIC.

alias-name
Names the alias. For a table alias, the name must not identify a nickname, table, view, or table alias that exists at the current server. For a module alias, the name must not identify a module or module alias that exists at the current server. For a sequence alias, the name must not identify a sequence or sequence alias that exists at the current server.

If a two-part name is specified, the schema name cannot begin with 'SYS' (SQLSTATE 42939) except if PUBLIC is specified, then the schema name must be SYSPUBLIC (SQLSTATE 428EK).

FOR TABLE *table-name, view-name, nickname,* or *alias-name2*
Identifies the table, view, nickname, or table alias for which *alias-name* is defined. If another alias name is supplied (*alias-name2*), then it must not be the same as the new *alias-name* being defined (in its fully-qualified form). The *table-name* cannot be a declared temporary table (SQLSTATE 42995).

FOR MODULE *module-name*, or *alias-name2*
Identifies the module or module alias for which *alias-name* is defined. If another alias name is supplied (*alias-name2*), then it must not be the same as the new alias-name being defined (in its fully-qualified form).

FOR SEQUENCE *sequence-name*, or *alias-name2*
Identifies the sequence or sequence alias for which *alias-name* is defined. If another alias name is supplied (*alias-name2*), then it must not be the same as the new *alias-name* being defined (in its fully-qualified form). The *sequence-name* must not be a sequence generated by the system for an identity column (SQLSTATE 428FB).

Notes

- The keyword PUBLIC is used to create a public alias (also known as a public synonym). If the keyword PUBLIC is not used, the type of alias is a private alias (also known as a private synonym).
- Public aliases can be used only in SQL statements and with the LOAD utility.
- The definition of the newly created table alias is stored in SYSCAT.TABLES. The definition of the newly created module alias is stored in SYSCAT.MODULES. The definition of the newly created sequence alias is stored in SYSCAT.SEQUENCES.
- An alias can be defined for an object that does not exist at the time of the definition. If it does not exist, a warning is issued (SQLSTATE 01522). However, the referenced object must exist when a SQL statement containing the alias is compiled, otherwise an error is issued (SQLSTATE 52004).
- An alias can be defined to refer to another alias as part of an alias chain but this chain is subject to the same restrictions as a single alias when used in an SQL statement. An alias chain is resolved in the same way as a single alias. If an alias used in a statement in a package, an SQL routine, a trigger, the default

expression for a global variable, or a view definition points to an alias chain, then a dependency is recorded for the package, SQL routine, trigger, global variable, or view on each alias in the chain. An alias cannot refer to itself in an alias chain and such a cycle is detected at alias definition time (SQLSTATE 42916).

- **Resolving an unqualified alias name:** When resolving an unqualified name, private aliases are considered before public aliases.
- **Conservative binding for public aliases:** If a public alias is used in a statement in a package, an SQL routine, a trigger, the default expression for a global variable, or a view definition, the public alias will continue to be used by these objects regardless of what other object with the same name is created subsequently.
- Creating an alias with a schema name that does not already exist will result in the implicit creation of that schema provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products.
  - SYNONYM can be specified in place of ALIAS

Examples

- *Example 1:* HEDGES attempts to create an alias for a table T1 (both unqualified).

```
CREATE ALIAS A1 FOR T1
```

  The alias HEDGES.A1 is created for HEDGES.T1.

- *Example 2:* HEDGES attempts to create an alias for a table (both qualified).

```
CREATE ALIAS HEDGES.A1 FOR MCKNIGHT.T1
```

  The alias HEDGES.A1 is created for MCKNIGHT.T1.

- *Example 3:* HEDGES attempts to create an alias for a table (alias in a different schema; HEDGES is not a DBADM; HEDGES does not have CREATEIN on schema MCKNIGHT).

```
CREATE ALIAS  MCKNIGHT.A1 FOR MCKNIGHT.T1
```

  This example fails (SQLSTATE 42501).

- *Example 4:* HEDGES attempts to create an alias for an undefined table (both qualified; FUZZY.WUZZY does not exist).

```
CREATE ALIAS HEDGES.A1 FOR FUZZY.WUZZY
```

  This statement succeeds but with a warning (SQLSTATE 01522).

- *Example 5:* HEDGES attempts to create an alias for an alias (both qualified).

```
CREATE ALIAS HEDGES.A1 FOR MCKNIGHT.T1
CREATE ALIAS HEDGES.A2 FOR HEDGES.A1
```

  The first statement succeeds (as per example 2).

  The second statement succeeds and an alias chain is created, consisting of HEDGES.A2 which refers to HEDGES.A1 which refers to MCKNIGHT.T1. Note that it does not matter whether or not HEDGES has any privileges on MCKNIGHT.T1. The alias is created regardless of the table privileges.

- *Example 6:* Designate A1 as an alias for the nickname FUZZYBEAR.

```
CREATE ALIAS A1 FOR FUZZYBEAR
```

- *Example 7:* A large organization has a finance department numbered D108 and a personnel department numbered D577. D108 keeps certain information in a table that resides at a Db2 RDBMS. D577 keeps

certain records in a table that resides at an Oracle RDBMS. A DBA defines the two RDBMSs as data sources within a federated system, and gives the tables the nicknames of DEPTD108 and DEPTD577, respectively. A federated system user needs to create joins between these tables, but would like to reference them by names that are more meaningful than their alphanumeric nicknames. So the user defines FINANCE as an alias for DEPTD108 and PERSONNEL as an alias for DEPTD577.

```
CREATE ALIAS FINANCE FOR DEPTD108
CREATE ALIAS PERSONNEL FOR DEPTD577
```

- *Example 8:* Create a public alias called TABS for the catalog view SYSCAT.TABLES.

```
CREATE PUBLIC ALIAS TABS FOR SYSCAT.TABLES
```

CREATE AUDIT POLICY

The CREATE AUDIT POLICY statement defines an auditing policy at the current server. The policy determines what categories are to be audited; it can then be applied to other database objects to determine how the use of those objects is to be audited.

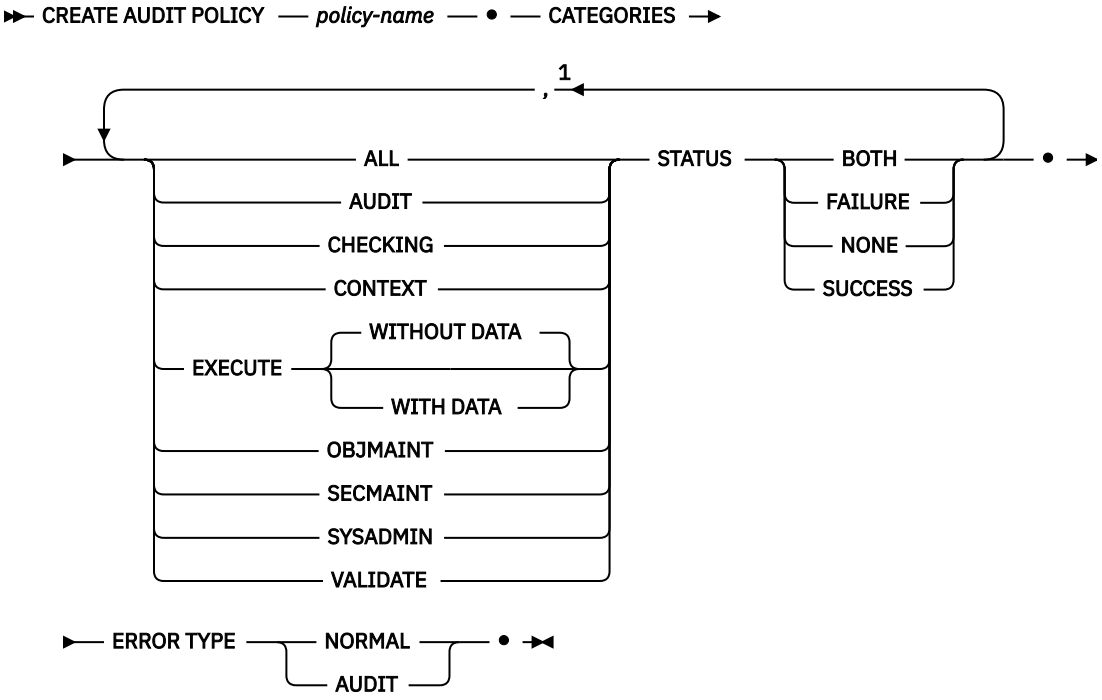
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Notes:

[1] Each category can be specified at most once (SQLSTATE 42614), and no other category can be specified if ALL is specified (SQLSTATE 42601).

Description

policy-name
Names the audit policy. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *policy-name* must not identify an audit policy already described in the catalog (SQLSTATE 42710). The name must not begin with the characters 'SYS' (SQLSTATE 42939).

CATEGORIES
A list of one or more audit categories for which a status is specified. If ALL is not specified, the STATUS of any category that is not explicitly specified is set to NONE.

ALL
Sets all categories to the same status. The EXECUTE category is WITHOUT DATA.

AUDIT
Generates records when audit settings are changed or when the audit log is accessed.

CHECKING
Generates records during authorization checking of attempts to access or manipulate database objects or functions.

CONTEXT
Generates records to show the operation context when a database operation is performed.

EXECUTE
Generates records to show the execution of SQL statements.

WITHOUT DATA or WITH DATA
Specifies whether or not input data values provided for any host variables and parameter markers should be logged as part of the EXECUTE category.

WITHOUT DATA
Input data values provided for any host variables and parameter markers are not logged as part of the EXECUTE category. WITHOUT DATA is the default.

WITH DATA
Input data values provided for any host variables and parameter markers are logged as part of the EXECUTE category. Not all input values are logged; specifically, LOB, LONG, XML, and structured type parameters appear as the null value. Date, time, and timestamp fields are logged in ISO format. The input data values are converted to the database code page before being logged. If code page conversion fails, no errors are returned and the unconverted data is logged.

OBJMAINT
Generates records when data objects are created or dropped.

SECMAINT
Generates records when object privileges, database privileges, or DBADM authority is granted or revoked. Records are also generated when the database manager security configuration parameters **sysadm_group**, **sysctrl_group**, or **sysmaint_group** are modified.

SYSADMIN
Generates records when operations requiring SYSADM, SYSMAINT, or SYSCTRL authority are performed.

VALIDATE
Generates records when users are authenticated or when system security information related to a user is retrieved.

STATUS
Specifies a status for the specified category.

BOTH
Successful and failing events will be audited.

FAILURE
Only failing events will be audited.

SUCCESS
Only successful events will be audited.

NONE
No events in this category will be audited.

ERROR TYPE
Specifies whether audit errors are to be returned or ignored.

NORMAL
Any errors generated by the audit are ignored and only the SQLCODEs for errors associated with the operation being performed are returned to the application.

AUDIT
All errors, including errors occurring within the audit facility itself, are returned to the application.

Rules

- An AUDIT-exclusive SQL statement must be followed by a COMMIT or ROLLBACK statement (SQLSTATE 5U021). AUDIT-exclusive SQL statements are:
  - AUDIT
  - CREATE AUDIT POLICY, ALTER AUDIT POLICY, or DROP (AUDIT POLICY)
  - DROP (ROLE or TRUSTED CONTEXT if it is associated with an audit policy)
- An AUDIT-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.

Notes

- Only one uncommitted AUDIT-exclusive SQL statement is allowed at a time across all database partitions. If an uncommitted AUDIT-exclusive SQL statement is executing, subsequent AUDIT-exclusive SQL statements wait until the current AUDIT-exclusive SQL statement commits or rolls back.
- Changes are written to the system catalog, but do not take effect until they are committed, even for the connection that issues the statement.

Example

Create an audit policy to audit successes and failures for the AUDIT and OBJMAINT categories; only failures for the SECMAINT, CHECKING, and VALIDATE categories, and no events for the other categories.

```
CREATE AUDIT POLICY DBAUDPRF
  CATEGORIES AUDIT    STATUS BOTH,
             SECMAINT STATUS FAILURE,
             OBJMAINT STATUS BOTH,
             CHECKING STATUS FAILURE,
             VALIDATE STATUS FAILURE
  ERROR TYPE NORMAL
```

CREATE BUFFERPOOL

The CREATE BUFFERPOOL statement defines a buffer pool at the current server. Buffer pools are defined on members which can access data partitions.

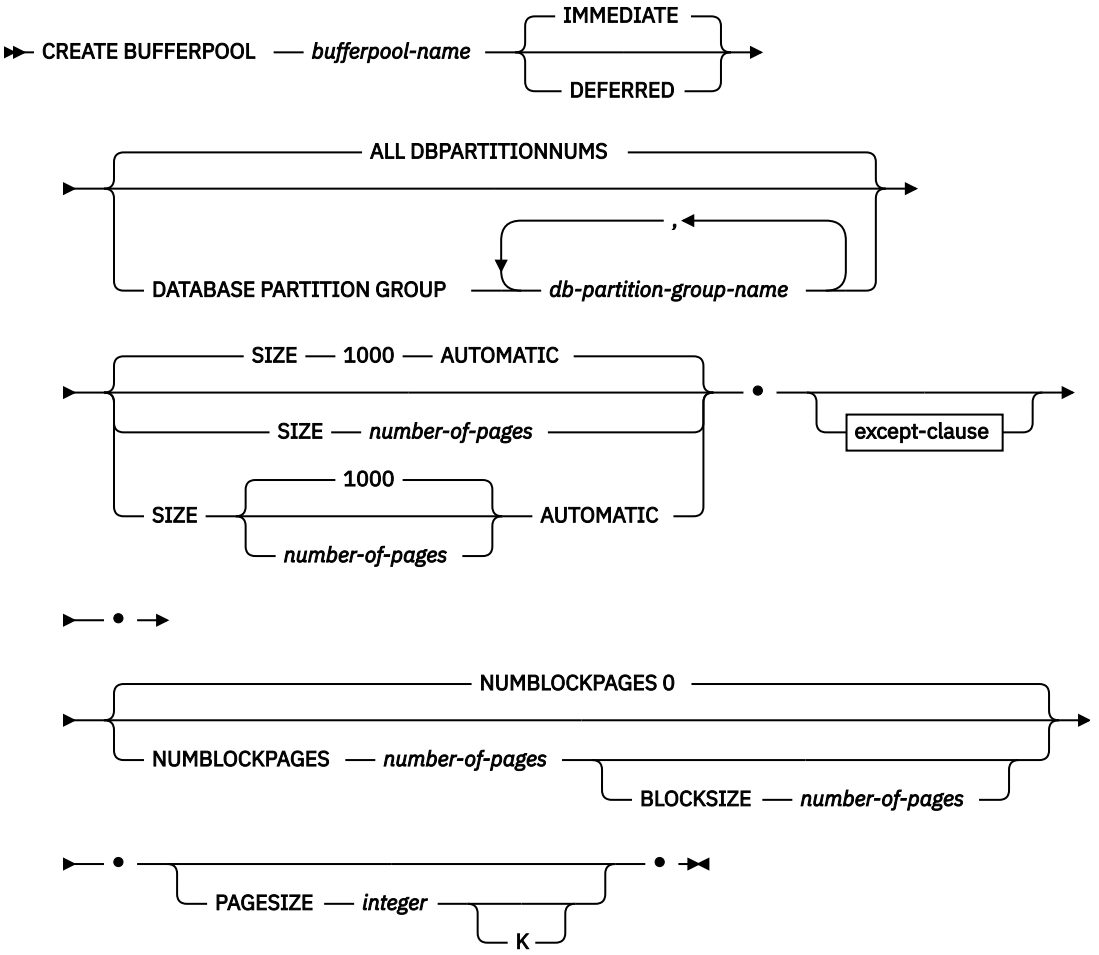
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

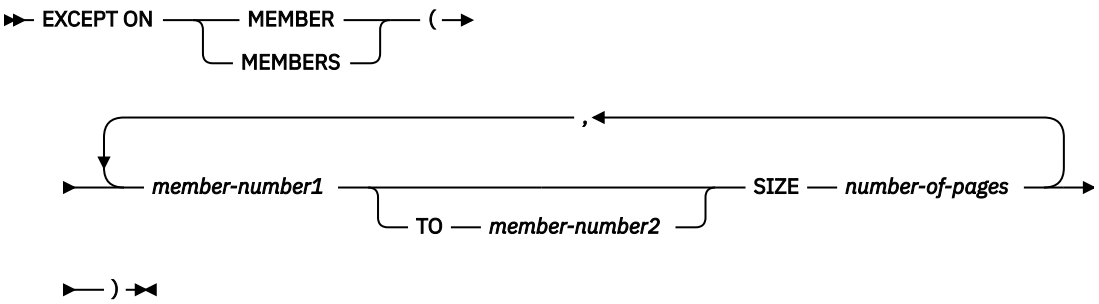
Authorization

The privileges held by the authorization ID of the statement must include SYSCTRL or SYSADM authority.

Syntax



except-clause



Description

bufferpool-name

Names the buffer pool. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *bufferpool-name* must not identify a buffer pool that already exists in the catalog (SQLSTATE 42710). The *bufferpool-name* must not begin with the characters 'SYS' (SQLSTATE 42939).

IMMEDIATE or DEFERRED

Indicates whether or not the buffer pool will be created immediately.

IMMEDIATE
The buffer pool will be created immediately after the CREATE BUFFERPOOL statement is committed. If there is not enough reserved space in the database shared memory to allocate the new buffer pool (SQLSTATE 01657) the statement is executed as DEFERRED.

DEFERRED
The buffer pool will be created when the database is deactivated (all applications need to be disconnected from the database). Reserved memory space is not needed; required memory will be allocated from the system.

ALL DBPARTITIONNUMS or DATABASE PARTITION GROUP
Identifies the members on which the buffer pool is to be defined. The default is ALL DBPARTITIONNUMS.

ALL DBPARTITIONNUMS
This buffer pool will be created on all members which can access all data partitions in the database.

DATABASE PARTITION GROUP ***db-partition-group-name, ...***
Identifies the database partition group or groups to which the buffer pool definition applies. The buffer pool will be created only on members in the specified database partition groups. Each database partition group must exist in the database (SQLSTATE 42704).

SIZE
Specifies the size of the buffer pool. This size will be the default size for all members on which the buffer pool exists. The default is 1000 pages.

number-of-pages
The number of pages for the new buffer pool. The minimum number of pages is 2 and the maximum is architecture-dependent (SQLSTATE 42615).

AUTOMATIC
Enables self tuning for this buffer pool. The database manager adjusts the size of the buffer pool in response to workload requirements. The implicit or explicit number of pages that are specified is used as the initial size of the buffer pool. On subsequent database activations, the buffer pool size is based on the last tuning value that is determined by the self-tuning memory manager (STMM). The STMM enforces a minimum size for automatic buffer pools, which is the minimum of the current size and 5000 pages. To determine the current size of buffer pools that are enabled for self tuning, use the MON_GET_BUFFERPOOL routine and examine the current size of the buffer pools. The size of the buffer pool is found in the **bp_cur_buffsz** monitor element.

NUMBLOCKPAGES ***number-of-pages***
Specifies the number of pages that should exist in the block-based area. The number of pages must not be greater than 98 percent of the number of pages for the buffer pool (SQLSTATE 54052). Specifying the value 0 disables block I/O. The actual value of NUMBLOCKPAGES used will be a multiple of BLOCKSIZE.

NUMBLOCKPAGES is not supported in a Db2 pureScale environment (SQLSTATE 56038).

BLOCKSIZE ***number-of-pages***
Specifies the number of pages in a block. The block size must be a value between 2 and 256 (SQLSTATE 54053). The default value is 32.

BLOCKSIZE is not supported in a Db2 pureScale environment (SQLSTATE 56038).

EXCEPT ON MEMBER or EXCEPT ON MEMBERS
Specifies the member or members for which the size of the buffer pool will be different than the default specified for the database partition group to which the member has access. If this clause is not specified, all members that can access the data partitions in the specified database partition group will have the same size as specified for this buffer pool.

member-number1
Specifies a member number for a member that has access to a data partition for which the buffer pool is created (SQLSTATE 42729).

TO *member-number2*
Specifies a range of member numbers. The value of *member-number2* must be greater than or equal to the value of *member-number1* (SQLSTATE 428A9). Each member identified by the member number range inclusive must have access to the data partition for which the buffer pool is created (SQLSTATE 428A9).

SIZE *number-of-pages*
The size of the buffer pool specified as the number of pages. The minimum number of pages is 2 and the maximum is architecture-dependent (SQLSTATE 42615).

PAGESIZE *integer* [K]
Defines the size of pages used for the buffer pool. The valid values for *integer* without the suffix K are 4096, 8192, 16384, or 32768. The valid values for *integer* with the suffix K are 4, 8, 16, or 32. Any number of spaces is allowed between *integer* and K, including no space. If the page size is not one of these values, an error is returned (SQLSTATE 428DE).

The default value is provided by the **pagesize** database configuration parameter, which is set when the database is created.

Notes

- If the buffer pool is created using the DEFERRED option, any table space created in this buffer pool will use a small system buffer pool of the same page size, until next database activation. The database has to be restarted for the buffer pool to become active and for table space assignments to the new buffer pool to take effect. The default option is IMMEDIATE.
- There should be enough real memory on the machine for the total of all the buffer pools, as well as for the rest of the database manager and application requirements. If the database is unable to obtain memory for the regular buffer pools, it will attempt to start with small system buffer pools, one for each page size (4K, 8K, 16K and 32K). In this situation, a warning will be returned to the user (SQLSTATE 01626), and the pages from all table spaces will use the system buffer pools.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - NODEGROUP can be specified in place of DATABASE PARTITION GROUP
  - DBPARTITIONNUM or NODE can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON
  - DBPARTITIONNUMS or NODES can be specified in place of MEMBERS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON

CREATE DATABASE PARTITION GROUP

The CREATE DATABASE PARTITION GROUP statement defines a new database partition group within the database, assigns database partitions to the database partition group, and records the database partition group definition in the system catalog.

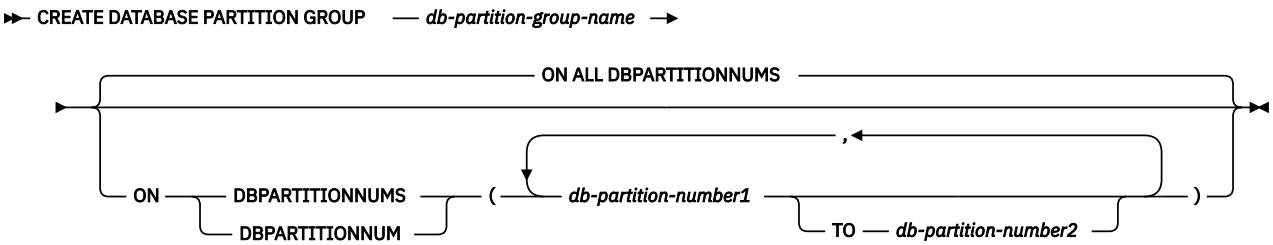
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SYSCTRL or SYSADM authority.

Syntax



Description

db-partition-group-name
Names the database partition group. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *db-partition-group-name* must not identify a database partition group that already exists in the catalog (SQLSTATE 42710). The *db-partition-group-name* must not begin with the characters 'SYS' or 'IBM' (SQLSTATE 42939).

ON ALL DBPARTITIONNUMS
Specifies that the database partition group is defined over all database partitions defined to the database (db2nodes.cfg file) at the time the database partition group is created.

If a database partition is added to the database system, the ALTER DATABASE PARTITION GROUP statement should be issued to include this new database partition in a database partition group (including IBMDEFAULTGROUP). Furthermore, the REDISTRIBUTE DATABASE PARTITION GROUP command must be issued to move data to the database partition.

ON DBPARTITIONNUMS
Specifies the database partitions that are in the database partition group. DBPARTITIONNUM is a synonym for DBPARTITIONNUMS.

db-partition-number1
Specify a database partition number. (A *node-name* of the form NODE*nnnnn* can be specified for compatibility with the previous version.)

TO *db-partition-number2*
Specify a range of database partition numbers. The value of *db-partition-number2* must be greater than or equal to the value of *db-partition-number1* (SQLSTATE 428A9). All database partitions between and including the specified database partition numbers are included in the database partition group.

Rules

- Each database partition specified by number must be defined in the db2nodes.cfg file (SQLSTATE 42729).
- Each *db-partition-number* listed in the ON DBPARTITIONNUMS clause can appear only once (SQLSTATE 42728).
- A valid *db-partition-number* is between 0 and 999 inclusive (SQLSTATE 42729).
- The CREATE DATABASE PARTITION GROUP statement might fail (SQLSTATE 55071) if an add database partition server request is either pending or in progress. This statement might also fail (SQLSTATE 55077) if a new database partition server is added online to the instance and not all applications are aware of the new database partition server.

Notes

- This statement creates a distribution map for the database partition group. A distribution map identifier (PMAP_ID) is generated for each distribution map. This information is recorded in the catalog and can be retrieved from SYSCAT.DBPARTITIONGROUPS and SYSCAT.PARTITIONMAPS. Each entry in the distribution map specifies the target database partition on which all rows that are hashed reside. For

a single-partition database partition group, the corresponding distribution map has only one entry. For a multiple partition database partition group, the corresponding distribution map has 32768 entries, where the database partition numbers are assigned to the map entries in a round-robin fashion, by default.

- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - NODE can be specified in place of DBPARTITIONNUM
  - NODES can be specified in place of DBPARTITIONNUMS
  - NODEGROUP can be specified in place of DATABASE PARTITION GROUP

Examples

The following examples are based on a partitioned database with six database partitions defined as 0, 1, 2, 5, 7, and 8.

- *Example 1*: Assume that you want to create a database partition group called MAXGROUP on all six database partitions. The statement is as follows:

```
CREATE DATABASE PARTITION GROUP MAXGROUP ON ALL DBPARTITIONNUMS
```

- *Example 2*: Assume that you want to create a database partition group called MEDGROUP on database partitions 0, 1, 2, 5, and 8. The statement is as follows:

```
CREATE DATABASE PARTITION GROUP MEDGROUP
  ON DBPARTITIONNUMS( 0 TO 2, 5, 8)
```

- *Example 3*: Assume that you want to create a single-partition database partition group MINGROUP on database partition 7. The statement is as follows:

```
CREATE DATABASE PARTITION GROUP MINGROUP
  ON DBPARTITIONNUM (7)
```

CREATE EVENT MONITOR

The CREATE EVENT MONITOR statement defines a monitor that records certain events that occur when you use the database. The definition of each event monitor also specifies where the database records the events.

Several different types of event monitors can be created by using this statement. Some of these types are described here, while the remaining types are described separately (see Related links). The types of event monitors that are described separately are as follows:

- Activities. The event monitor records activity events that occur by using the database. The definition of the activities event monitor also specifies where the database records the events.
- Change history. The event monitor records events for changes to configuration parameters, registry variables, and the execution of DDL statements and utilities. The event monitor also records initial configuration and registry values at event monitor startup time.
- Locking. The event monitor records lock-related events that occur by using the database. All records are collected in the unformatted event table.
- Package cache. The event monitor records events that are related to the package cache statement.
- Statistics. The event monitor records statistics events that occur by using the database. The definition of the statistics event monitor also specifies where the database records the events.
- Threshold violations. The event monitor records threshold violation events that occur by using the database. The definition of the threshold violations event monitor also specifies where the database records the events.

- Unit of work. The event monitor records events when a unit of work completes. All records are collected in the unformatted event table.

Invocation

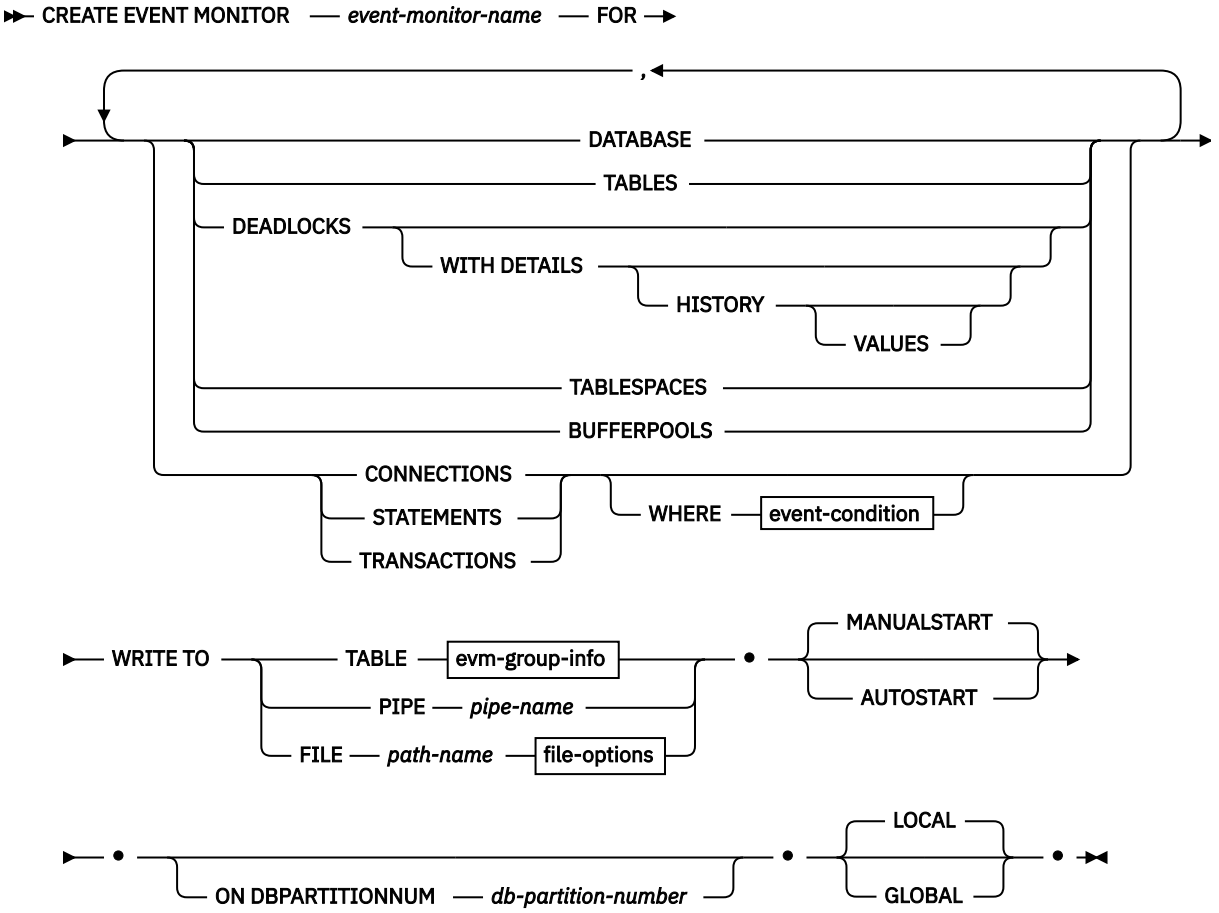
This statement can be embedded in an application program or entered interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

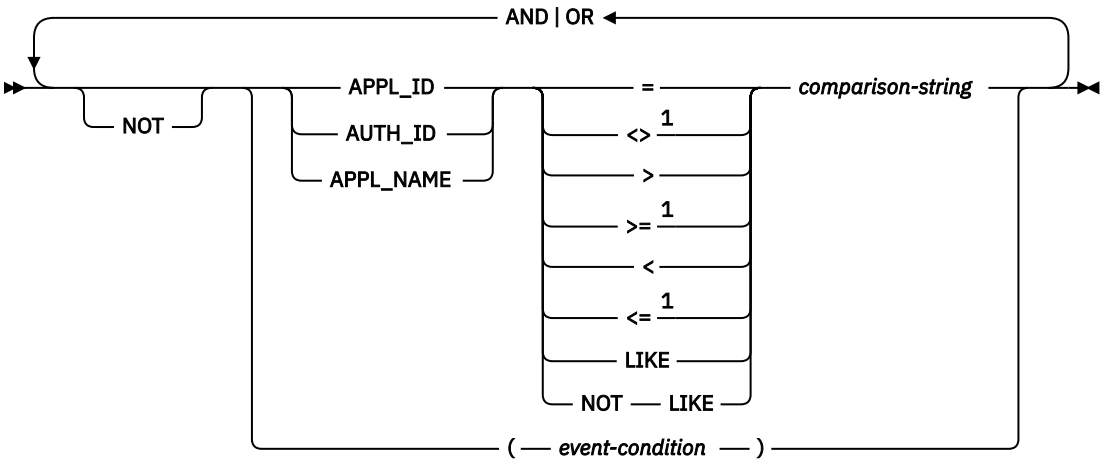
The privileges that are held by the authorization ID of the statement must include one of the following authorities:

- DBADM authority
- SQLADM authority

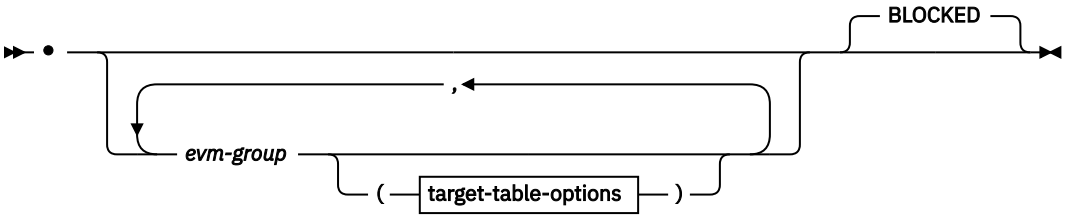
Syntax



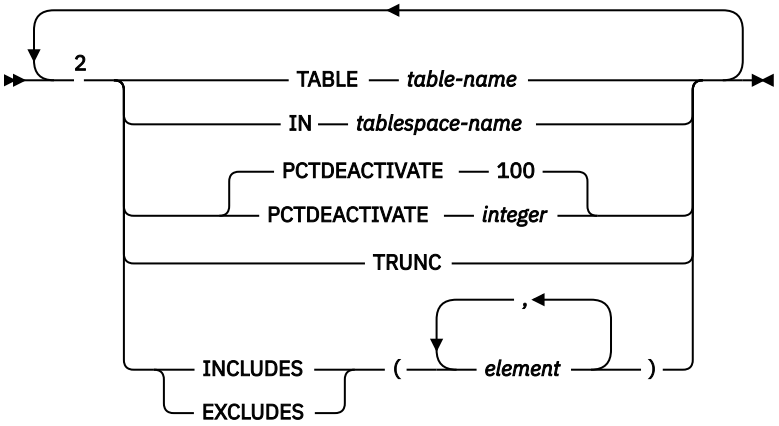
event-condition



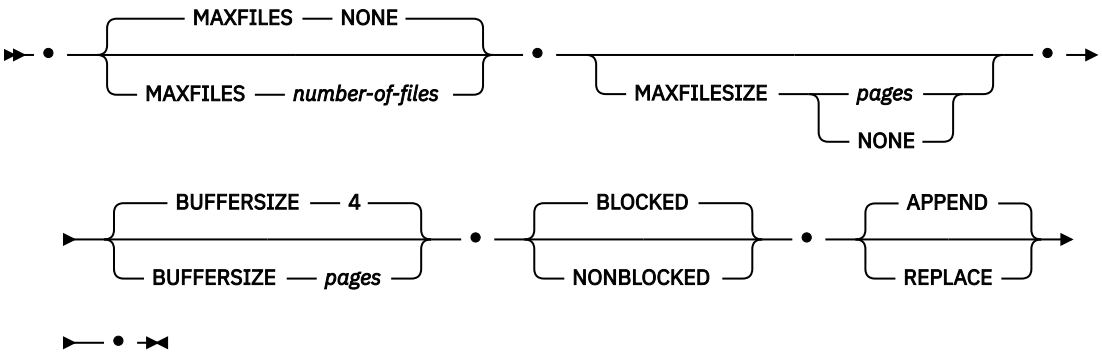
evm-group-info



target-table-options



file-options



Notes:

[1] Other forms of these operators are also supported.
[2] Each clause can be specified once.
[3] Clauses can be separated with a space or a comma.

Description

event-monitor-name
Name of the event monitor is a one-part name. It is an SQL identifier (either ordinary or delimited). The *event-monitor-name* must not identify an event monitor that exists in the catalog (SQLSTATE 42710).

FOR
Introduces the type of event to record.

DATABASE
Specifies that the event monitor records a database event when the last application disconnects from the database.

TABLES
Specifies that the event monitor records a table event for each active table when the last application disconnects from the database. For partitioned tables, a table event is recorded for each data partition of each active table. An active table is a table that changed since the first connection to the database.

DEADLOCKS

Note: This option was deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR FOR LOCKING statement to monitor lock-related events, such as lock timeouts, lock waits, and deadlocks.

Specifies that the event monitor records a deadlock event whenever a deadlock occurs.

WITH DETAILS
Specifies that the event monitor is to generate a more detailed deadlock connection event for each application that is involved in a deadlock. This additional detail includes:

- Information about the statement that the application was running when the deadlock occurred, such as the statement text.
- The locks that are held by the application when the deadlock occurred. In a partitioned database environment, includes only those locks that are held on the database partition on which the application was waiting for its lock when the deadlock occurred. For partitioned tables, includes the data partition identifier.

HISTORY
Specifies that the event monitor data also includes:

- The history of all statements in the current unit of work at the participating node (including WITH HOLD cursors that are opened in previous units of work). SELECT statements that are entered at the uncommitted read (UR) isolation level are not included in the statement history.
- The statement compilation environment for each SQL statement in binary format (if available)

VALUES
Specifies that the event monitor data also includes:

- The data values used as input variables for each SQL statement. These data values do not include LOB data, long data, structured type data, or XML data.

Only one of the following commands: DEADLOCKS, DEADLOCKS WITH DETAILS, DEADLOCKS WITH DETAILS HISTORY, or DEADLOCKS WITH DETAILS HISTORY VALUES can be specified in a single CREATE EVENT MONITOR statement (SQLSTATE 42613).

TABLESPACES
Specifies that the event monitor records a table space event for each table space when the last application disconnects from the database.

BUFFERPOOLS
Specifies that the event monitor records a buffer pool event when the last application disconnects from the database.

CONNECTIONS
Specifies that the event monitor records a connection event when an application disconnects from the database.

STATEMENTS
Specifies that the event monitor records a statement event whenever an SQL statement finishes running.

TRANSACTIONS

Note: This option was deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR FOR UNIT OF WORK statement to monitor transaction events.

Specifies that the event monitor records a transaction event whenever a transaction completes (that is, whenever there is a commit or rollback operation).

WHERE event-condition
Defines a filter that determines which connections cause a CONNECTION, STATEMENT, or TRANSACTION event to occur. If the result of the event condition is TRUE for a particular connection, then that connection generates the requested events.

This clause is a special form of the WHERE clause that should not be confused with a standard search condition.

To determine whether an application generates events for a particular event monitor, the WHERE clause is evaluated:

- For each active connection when an event monitor is first turned on,
- Then, for each new connection to the database at connect time

The WHERE clause is not evaluated for each event.

If no WHERE clause is specified, all events of the specified event type are monitored.

The event-condition must not exceed 32 678 bytes in the database code page (SQLSTATE 22001).

APPL_ID
Specifies that the application ID of each connection is compared with the *comparison-string* to determine whether the connection generates CONNECTION, STATEMENT, or TRANSACTION events (whichever was specified).

AUTH_ID
Specifies that the authorization ID of each connection is compared with the *comparison-string* to determine whether the connection generates CONNECTION, STATEMENT, or TRANSACTION events (whichever was specified).

APPL_NAME
Specifies that the application program name of each connection is compared with the *comparison-string* to determine whether the connection generates CONNECTION, STATEMENT, or TRANSACTION events (whichever was specified).

The application program name is the first 20 bytes of the application program file name after the last path separator.

comparison-string
A string to be compared with the APPL_ID, AUTH_ID, or APPL_NAME of each application that connects to the database. *comparison-string* must be a string constant (that is, you cannot use host variables and other string expressions).

WRITE TO
Introduces the target for the data.

TABLE
Indicates that the target for the event monitor data is a set of database tables. The event monitor separates the data stream into one or more logical data groups and inserts each group into a separate table. Data for groups with a target table is kept, whereas data for groups not having

a target table is discarded. Each monitor element that is contained within a group is mapped to a table column with the same name. Only elements that have a corresponding table column are inserted into the table. Other elements are discarded.

evm-group-info
Defines the target table for a logical data group. This clause must be specified for each grouping that is to be recorded. However, if no evm-group-info clauses are specified, all groups for the event monitor type are recorded.

For more information about logical data groups, see "Logical data groups and event monitor output tables" in *Database Monitoring Guide and Reference*.

evm-group
Identifies the logical data group for which a target table is being defined. The value depends upon the type of event monitor, as shown in the following table:

Table 130. Values for evm-group based on the type of event monitor

Type of Event Monitor	evm-group value
Database	• DB • CONTROL[1] • DBMEMUSE
Tables	• TABLE • CONTROL[1]
Deadlocks	• CONNHEADER • DEADLOCK • DLCONN • CONTROL[1]
Deadlocks with details	• CONNHEADER • DEADLOCK • DLCONN[2] • DLLOCK[3] • CONTROL[1]
Deadlocks with details history	• CONNHEADER • DEADLOCK • DLCONN[2] • DLLOCK[3] • STMTHIST • CONTROL[1]
Deadlocks with details history values	• CONNHEADER • DEADLOCK • DLCONN[2] • DLLOCK[3] • STMTHIST • STMTVALS • CONTROL[1]

Table 130. Values for evm-group based on the type of event monitor (continued)

Type of Event Monitor	evm-group value
Table spaces	• TABLESPACE • CONTROL[1]
Buffer pools	• BUFFERPOOL • CONTROL[1]
Connections	• CONNHEADER • CONN • CONTROL[1] • CONNMEMUSE
Statements	• CONNHEADER • STMT • SUBSECTION[4] • CONTROL[1]
Transactions	• CONNHEADER • XACT • CONTROL[1]
Activities	• ACTIVITY • ACTIVITYMETRICS • ACTIVITYSTMT • ACTIVITYVALS • CONTROL[1]
Statistics	• QSTATS • SCSTATS • SCMETRICS • WCSTATS • WLSTATS • WLMETRICS • HISTOGRAMBIN • CONTROL[1]
Threshold Violations	• THRESHOLDVIOLATIONS • CONTROL[1]
Locking[5]	• LOCK • LOCK_PARTICIPANTS • LOCK_PARTICIPANT_ACTIVITIES • LOCK_ACTIVITY_VALUES • CONTROL[1]

Table 130. Values for evm-group based on the type of event monitor (continued)

Type of Event Monitor	evm-group value
Package Cache[5]	• PKGCACHE • PKGCACHE_METRICS • CONTROL[1]
Unit of Work[5]	• UOW • UOW_METRICS • UOW_PACKGE_LIST • UOW_EXECUTABLE_LIST • CONTROL[1]
Change History	• CHANGESUMMARY • EVMONSTART • TXNCOMPLETION • DDLSTMTEXEC • DBDBMCFG • REGVAR • UTILSTART • UTILSTOP • UTILPHASE • UTILLOCATION • CONTROL[1]

[1] Logical data groups dbheader (conn_time element only), start, and overflow, are all written to the CONTROL group. The overflow group is written if the event monitor is non-blocked and events were discarded.

[2] Corresponds to the DETAILED_DLCONN event.

[3] Corresponds to the LOCK logical data groups that occur within each DETAILED_DLCONN event.

[4] Created only for partitioned database environments.

[5] Refers to the Formatted Event Table version of this event monitor type.

target-table-options

Identifies the target table for the group. If a value for *target-table-options* is not specified, CREATE EVENT MONITOR processing proceeds as follows:

- A derived table name is used (see description for TABLE *table-name*).
- A default table space is chosen (see description for IN *tablespace-name*).
- All elements are included.
- PCTDEACTIVATE and TRUNC are not specified.

TABLE *table-name*

Specifies the name of the target table. The target table must be a nonpartitioned row-organized table. If the name is unqualified, the table schema defaults to

the value in the CURRENT SCHEMA special register. If no name is provided, the unqualified name is derived from *evm-group* and *event-monitor-name* as follows:

```
substring(evm-group CONCAT '_'
  CONCAT event-monitor-name,1,128)
```

IN *tablespace-name*
Defines the table space in which the table is to be created. If no table space name is provided, the table space is chosen by using the same process as when a table is created without a table space name that uses CREATE TABLE.

PCTDEACTIVATE *integer*
If a table for the event monitor is being created in the automatic storage (non-temporary) or DMS table space, the PCTDEACTIVATE parameter specifies how full the table space must be before the event monitor automatically deactivates. The specified value, which represents a percentage, can range 0 - 100, where 100 means that the event monitor deactivates when the table space becomes full. The default value is 100 if PCTDEACTIVATE is not specified. This option is ignored for SMS table spaces.

Important: If the target table space has auto-resize enabled, set PCTDEACTIVATE to 100. Alternatively, omit this clause entirely to have the default of 100 apply. Otherwise, the event monitor might deactivate unexpectedly if the table space reaches the threshold that is specified by PCTDEACTIVTATE before the table space is automatically resized.

It is recommended that, when a target table space has auto-resize enabled, the PCTDEACTIVATE parameter be set to 100.

TRUNC
Specifies that the STMT_TEXT and STMT_VALUE_DATA columns are defined as VARCHAR(*n*), where *n* is the largest size that can fit into the table row. In this case, any data that is longer than *n* bytes is truncated. The following example illustrates how the value of *n* is calculated. Assume that:

- The table is created in a table space that uses 32K pages.
- The total length of all the other columns in the table equals 357 bytes.

In this case, the maximum row size for a table is 32677 bytes. Therefore, the element would be defined as VARCHAR(32316); that is, 32677 - 357 - 4. If TRUNC is not specified, the column is defined as CLOB(2M). STMT_TEXT is found in the STMT event group, the STMT_HISTORY event group, and the DLCONN event group (for deadlocks with details event monitors). STMT_VALUE_DATA is found in the DATA_VALUE event group.

INCLUDES
Specifies that the following elements are to be included in the table.

EXCLUDES
Specifies that the following elements are not to be included in the table.

element
Identifies a monitor element. Element information can be provided in one of the following forms:

- Specify no element information. In this case, all elements are included in the CREATE TABLE statement.
- Specify the elements to include in the form: INCLUDES (element1, element2, ..., element*n*). Only table columns are created for these elements.
- Specify the elements to exclude in the form: EXCLUDES (element1, element2, ..., element*n*). Only table columns are created for all elements except these.

Use the db2evtbl command to build a CREATE EVENT MONITOR statement that includes a complete list of elements for a group.

BLOCKED
Specifies that each agent that generates an event must wait for an event buffer to be written out to disk if the agent determines that both event buffers are full. Select BLOCKED to prevent event data loss. It is the default option.

PIPE
Specifies that the target for the event monitor data is a named pipe. The event monitor writes the data to the pipe in a single stream (that is, as if it were a single, infinitely long file). Writing the data to a pipe, an event monitor does not perform blocked writes. If the pipe buffer has no room, then the event monitor discards the data. It is the monitoring application's responsibility to read the data promptly if it wants to ensure no data loss.

pipe-name
The name of the pipe (FIFO on AIX) to which the event monitor writes the data.

The naming rules for pipes are platform-specific.

Operating system	Naming rules
AIX	Pipe names are treated like file names. As a result, relative pipe names are permitted, and are treated like relative path-names (see description for *path-name*).
Linux	Pipe names are treated like file names. As a result, relative pipe names are permitted, and are treated like relative path-names (see description for *path-name*).
Windows	There is special syntax for a pipe name and as a result, absolute pipe names are required.

The existence of the pipe is not checked at event monitor creation time. It is the responsibility of the monitoring application to create and open the pipe for reading at the time that the event monitor is activated. If the pipe is not available now, then the event monitor turns itself off and logs an error. (That is, if the event monitor was activated at database start time as a result of the AUTOSTART option, then the event monitor logs an error in the system error log). If the event monitor is activated by the SET EVENT MONITOR STATE SQL statement, then that statement fails (SQLSTATE 58030).

In a Db2 pureScale environment, the *pipe-name* must be on a shared file system whether the event monitor is LOCAL or GLOBAL. This requirement is to allow this event monitors to operate correctly if a member failover occurs. Failure to use a *pipe-name* on a shared file system results in an error (SQLSTATE 428A3) if the event monitor activates during a member failover.

FILE
Indicates that the target for the event monitor data is a file (or set of files). The event monitor writes out the stream of data as a series of eight character numbered files, with the extension "evt". (For example, `00000000.evt`, `00000001.evt`, and `00000002.evt`). The data should be considered to be one logical file even though the data is broken up into smaller pieces (that is, the start of the data stream is the first byte in the file`00000000.evt`; the end of the data stream is the last byte in the file `nnnnnnnn.evt`).

The maximum size of each file and the maximum number of files can be defined. An event monitor does not split a single event record across two files. However, an event monitor might write related records in two different files. It is the responsibility of the application that uses this data to track related information when it is processing the event files.

path-name
The name of the directory in which the event monitor writes the event files data. The path must be known at the server; however, the path itself might reside on another database partition (for example, an NFS-mounted file). A string constant must be used to specify the *path-name*.

The directory does not have to exist at CREATE EVENT MONITOR time. However, a check is made for the existence of the target path when the event monitor is activated. Then, if the target path does not exist, an error (SQLSTATE 428A3) is raised.

If an absolute path is specified, the specified path is the one used.

In environments other than Db2 pureScale, if a relative path (a path that does not start with the root) is specified, then the path relative to the DB2EVENT directory in the database directory is used. In a Db2 pureScale environment, if a relative path is specified, then the path relative to the directory owning the database in the database directory is used.

It is possible to specify two or more event monitors that have the same target path. However, when one of the event monitors is activated for the first time, and if the target directory is not empty, it is impossible to activate any of the other event monitors.

In a Db2 pureScale environment, the *path-name* must be on a shared file system whether this event monitor is LOCAL or GLOBAL. This requirement is to allow event monitors to operate correctly if a member failover occurs. Failure to use a *path-name* on a shared file system results in an error (SQLSTATE 428A3) if the event monitor activates during a member failover.

file-options
Specifies the options for the file format.

MAXFILES NONE
Specifies that the event monitor can create any number of event files. This is the default.

MAXFILES *number-of-files*
Specifies that the number of event monitor files that exist for a particular event monitor at any time is limited. Whenever an event monitor must create another file, it checks to make sure that the number of .evt files in the directory is less than *number-of-files*. If this limit is already reached, then the event monitor turns itself off.

If an application removes the event files from the directory after they are written, then the total number of files that an event monitor can produce can exceed *number-of-files*. This option is provided so that the event data does not use more than a specified amount of disk space.

MAXFILESIZE *pages*
Specifies that the size of each event monitor file has a limit. Whenever an event monitor writes a new event record to a file. It checks that the file does not grow to be greater than *pages* (in units of 4K pages). If the resulting file would be too large, then the event monitor switches to the next file. The default for this option is:

- Linux - 1000 4K pages
- UNIX - 1000 4K pages
- Windows - 200 4K pages

The number of pages must be greater than at least the size of the event buffer in pages. If this requirement is not met, then an error (SQLSTATE 428A4) is raised.

MAXFILESIZE NONE
Specifies that a file's size has no set limit. If MAXFILESIZE NONE is specified, then MAXFILES 1 must also be specified. This option means that one file contains all of the event data for a particular event monitor. In this case, the only event file is `00000000.evt`.

BUFFERSIZE *pages*
Specifies the size of the event monitor buffers (in units of 4K pages). All event monitor file I/O is buffered to improve the performance of the event monitors. The larger the buffers, the less I/O is performed by the event monitor. Highly active event monitors have larger buffers than relatively inactive event monitors. When the monitor is started, two buffers of the specified size are allocated. Event monitors use double buffering to permit asynchronous I/O.

The default size of each buffer is four pages (two 16K buffers are allocated). The minimum size is one page. The maximum size of the buffers is limited by the value of the MAXFILESIZE parameter and the size of the monitor heap because the buffers are allocated from that heap. If many event monitors are being used at the same time, increase the size of the **mon_heap_sz** database manager configuration parameter.

Event monitors that write their data to a pipe also have two internal (non-configurable) buffers that are each one page in size. These buffers are also allocated from the monitor heap (MON_HEAP). For each active event monitor that has a pipe target, increase the size of the database heap by two pages.

BLOCKED
Specifies that each agent that generates an event must wait for an event buffer to be written out to disk if the agent determines that both event buffers are full. BLOCKED must be selected to prevent event data loss. This is the default option.

NONBLOCKED
Specifies that each agent that generates an event must not wait for the event buffer to be written out to disk if the agent determines that both event buffers are full. NONBLOCKED event monitors do not slow down database operations to the extent of BLOCKED event monitors. However, NONBLOCKED event monitors are subject to data loss on highly active systems.

APPEND
Specifies that if event data files exist when the event monitor is turned on, then the event monitor appends the new event data to the existing stream of data files. When the event monitor is reactivated, it resumes writing to the event files from when it was turned off. APPEND is the default option.

The APPEND option does not apply at CREATE EVENT MONITOR time, if there exists event data in the directory where the newly created event monitor is to write its event data.

REPLACE
Specifies that if event data files exist when the event monitor is turned on, then the event monitor erases all of the event files and start writing data to file `00000000.evt`.

MANUALSTART
Specifies that the event monitor must be activated manually by using the SET EVENT MONITOR STATE statement. After a MANUALSTART event monitor is activated, it can be deactivated only by using the SET EVENT MONITOR STATE statement or by stopping the instance. This is the default.

AUTOSTART
Specifies that the event monitor is to be automatically activated whenever the database partition on which the event monitor runs is activated.

ON DBPARTITIONNUM *db-partition-number*
Specifies the database partition (in a partitioned database environment) or member (in a Db2 pureScale environment) on which a file or pipe event monitor is to run. When the monitoring scope is defined as LOCAL, data is collected only on the specified partition or member. When the monitoring scope is defined as GLOBAL, all database partitions or members collect data and report to the database partition or member with the specified number. The I/O component physically runs on the specified database partition or member, write records to the specified file or pipe.

When Db2 pureScale is enabled, -1 can be specified, which allows the I/O component to run from any active member. Additionally, if the I/O component is no longer able to run on member, the event monitor is restarted with the I/O component that is activated on another available active member.

This clause is not valid for table event monitors. In a partitioned database environment, write-to-table event monitors runs and writes events on all database partitions where table spaces for target tables are defined.

In a Db2 pureScale environment, write-to-table event monitors record events on all active members.

If this clause is not specified and Db2 pureScale is not enabled, the currently connected database partition number (for the application) is used.

If this clause is not specified and Db2 pureScale is enabled, the I/O component is able to run on any currently connected database partition number.

LOCAL
The event monitor reports only on the database partition that is running. It gives a partial trace of the database activity. This is the default.

This clause is valid for file or pipe monitors. It is not valid for table event monitors.

GLOBAL
The event monitor reports on all database partitions. For a partitioned database, only DEADLOCKS event monitors can be defined as GLOBAL.

This clause is valid for file or pipe monitors. It is not valid for table event monitors.

Rules

- Each of the event types (DATABASE, TABLES, DEADLOCKs, ...) can be specified only in a particular event monitor definition.

Notes

- Event monitor definitions are recorded in the SYSCAT.EVENTMONITORS catalog view. The events themselves are recorded in the SYSCAT.EVENTS catalog view. The names of target tables are recorded in the SYSCAT.EVENTTABLES catalog view.
- A performance impact occurs by using DEADLOCKS WITH DETAILS rather than DEADLOCKS. When a deadlock occurs, the database manager requires extra time to record the extra deadlock information.
- A CONNHEADER event is normally written whenever a connection is established. However, if an event monitor is created only for DEADLOCKS WITH DETAILS, a CONNHEADER event is written the first time that the connection participates in a deadlock.
- In a database with multiple database partitions, the ON DBPARTITIONNUM clause can be used with FILE and PIPE event monitors having a DEADLOCKS event type to indicate where the event monitor itself resides. Information from other database partitions, if relevant, is sent to that location for processing.
- In a database with multiple database partitions, a deadlock event monitor receives information about applications that have locks in the deadlock from all the database partitions on which those locks existed. If the database partition to which the application is connected (the application coordinator partition) is not one of the participating database partitions, no information about a deadlock event is received from that database partition.
- The BUFFERSIZE parameter restricts the size of STMT, STMT_HISTORY, DATA_VALUE, and DETAILED_DLCONN events. If an STMT or a STMT_HISTORY event cannot fit within a buffer, it is truncated by truncating statement text. If a DETAILED_DLCONN event cannot fit within a buffer, it is truncated by removing locks. If it still cannot fit, statement text is truncated. If a DATA_VAL event cannot fit within a buffer, the data value is truncated.

  Event monitors WITH DETAILS HISTORY VALUES (and to a lesser extent, WITH DETAILS HISTORY) use a significant amount of monitor heap space to track statements and their data values, as described in the **mon_heap_sz** configuration parameter.
- If the database partition on which the event monitor is to run is not active, event monitor activation occurs when that database partition next activates.
- After an event monitor is activated, it behaves like an autostart event monitor until that event monitor is explicitly deactivated or the instance is recycled. That is, if an event monitor is active when a database partition is deactivated, and that database partition is later reactivated, the event monitor is also explicitly reactivated.
- **Write to table event monitors** General notes:
  - All target tables are created when the CREATE EVENT MONITOR statement runs.

– If the creation of a table fails for any reason, an error is passed back to the application program, and the CREATE EVENT MONITOR statement fails.
– A target table can be used by one event monitor only. During CREATE EVENT MONITOR processing, if a target table is found to be defined for use by another event monitor, the CREATE EVENT MONITOR statement fails and an error is passed back to the application program. A table is defined for use by another event monitor if the table name matches a value found in the SYSCAT.EVENTTABLES catalog view.
– During CREATE EVENT MONITOR processing, if a table exists, but is not defined for use by another event monitor, no table is created, and processing continues. A warning is passed back to the application program.
– Any table spaces must exist before the CREATE EVENT MONITOR statement runs. The CREATE EVENT MONITOR statement does not create table spaces.
– If specified, the LOCAL and GLOBAL keywords are ignored. With WRITE TO TABLE event monitors, an event monitor output process or thread is started on each database partition in the instance, and each of these processes reports data only for the database partition on which it is running.
– The following event types from the flat monitor log file or pipe format are not recorded by writing to table event monitors:
  - LOG_STREAM_HEADER
  - LOG_HEADER
  - DB_HEADER (Elements db_name and db_path are not recorded. The element conn_time is recorded in CONTROL).
– In a partitioned database environment, data is only written to target tables on the database partitions where their table spaces exist. If a table space for a target table does not exist on some database partition, data for that target table is ignored. This behavior allows users to choose a subset of database partitions for monitoring, by creating a table space that exists only on certain database partitions.

  In a Db2 pureScale environment, data is written from every member.

  In a partitioned database environment, if some target tables do not reside on a database partition, but other target tables do reside on that database partition, only the data for the target tables that do reside on that database partition is recorded.
– Users must manually prune all target tables.

Table Columns:

– Column names in a table match an event monitor element identifier. Any event monitor element that does not have a corresponding target table column is ignored.
– Use the db2evtbl command to build a CREATE EVENT MONITOR command that includes a complete list of elements for a group.
– The types of columns that are used for monitor elements correlate to the following mapping:

```
SQLM_TYPE_STRING                    CHAR[n], VARCHAR[n] or CLOB(n)
                                    (If the data in the event monitor
                                    record exceeds n bytes,
                                    it is truncated.)
SQLM_TYPE_U8BIT and SQLM_TYPE_8BIT  SMALLINT, INTEGER or BIGINT
SQLM_TYPE_16BIT and SQLM_TYPE_U16BIT SMALLINT, INTEGER or BIGINT
SQLM_TYPE_32BIT and SQLM_TYPE_U32BIT INTEGER or BIGINT
SQLM_TYPE_U64BIT and SQLM_TYPE_64BIT BIGINT
sqlm_timestamp                      TIMESTAMP
sqlm_time(elapsed time)             BIGINT
sqlca:
  sqlerrmc                          VARCHAR[72]
  sqlstate                          CHAR[5]
  sqlwarn                           CHAR[11]
  other fields                      INTEGER or BIGINT
```

– Columns are defined to be NOT NULL.

– Because the performance of tables with CLOB columns is inferior to tables that have VARCHAR columns, consider using the TRUNC keyword to specify the STMT *evm-group* value (or the DLCONN *evm-group* value when using the DEADLOCKS WITH DETAILS event type).
– Unlike other target tables, the columns in the CONTROL table do not match monitor element identifiers. Columns are defined as follows:

Column Name	Data type	Nullable	Description
PARTITION_KEY	INTEGER	N	Distribution key (partitioned database only)
PARTITION_NUMBER	INTEGER	N	Database partition number (partitioned database only)
EVMONNAME	VARCHAR(128)	N	Name of the event monitor
MESSAGE	VARCHAR(128)	N	Describes the nature of the MESSAGE_TIME column. For more information, see "message - Control Table Message monitor element" in the *Database Monitoring Guide and Reference*.
MESSAGE_TIME	TIMESTAMP	N	Timestamp

– In a partitioned database environment, the first column of each table is named PARTITION_KEY, is NOT NULL, and is of type INTEGER. This column is used as the distribution key for the table. The value of this column is chosen so that each event monitor process inserts data into the database partition on which the process is running. That is, insert operations run locally on the database partition where the event monitor process is running. On any database partition, the **PARTITION_KEY** field contains the same value. This means that if a database partition is dropped and data is redistributed, all data on the dropped database partition goes to one other database partition instead of being evenly distributed. Therefore, before you remove a database partition, consider deleting all table rows on that database partition.
– In a partitioned database environment, a column that is named PARTITION_NUMBER can be defined for each table. This column is NOT NULL and is of type INTEGER. It contains the number of the database partition on which the data was inserted. Unlike the PARTITION_KEY column, the PARTITION_NUMBER column is not mandatory. The PARTITION_NUMBER column is not allowed in a nonpartitioned database environment.

Table Attributes:

– Default table attributes are used. Besides, distribution key (partitioned databases only), no extra options are specified when you create tables.
– Indexes on the table can be created.
– Extra table attributes (such as volatile, RI, triggers, constraints) can be added, but the event monitor process (or thread) ignores them.
– If "not logged initially" is added as a table attribute, it is turned off at the first COMMIT, and is not set back on.

Event Monitor Activation:

– When an event monitor activates, all target table names are retrieved from the SYSCAT.EVENTTABLES catalog view.

- In a partitioned database environment, activation processing occurs on every database partition of the instance. On a particular database partition, activation processing determines the table spaces and database partition groups for each target table. The event monitor activates on a database partition if at least one target table exists on that database partition. Moreover, if some target table is not found on a database partition, that target table is flagged so that data that is destined for that table is dropped during runtime processing.
- If a target table does not exist when the event monitor activates (or, in a partitioned database environment, if the table space does not reside on a database partition), activation continues, and data that would otherwise be inserted into this table is ignored.
- Activation processing validates each target table. If validation fails, activation of the event monitor fails, and messages are written to the administration log.
- During activation in a partitioned database environment, the CONTROL table rows for FIRST_CONNECT and EVMON_START are only inserted on the catalog database partition. The table space for the control table must exist on the catalog database partition. If it does not exist on the catalog database partition, these inserts are not inserted.
- In a partitioned database environment, if a partition is not yet active when a write to table event monitor is activated, the event monitor is activated the next time that partition is activated.

Run Time:

- An event monitor runs with DATAACCESS authority.
- While an event monitor is active, an insert operation into a target table fails:
  - Uncommitted changes are rolled back.
  - A message is written to the administration log.
  - The event monitor is deactivated.
- If an event monitor is active, a local COMMIT runs when it finishes processing an event monitor buffer.
- In a partitioned database environment, the actual statement text, which can be up to 2 MB, is only stored (in the STMT or DLCONN table) by the event monitor process on the application coordinator database partition. On other database partitions, this value has zero length.
- In an environment other than a partitioned database or a Db2 pureScale database, all write to table event monitors are deactivated when the last application exits (and the database was not activated explicitly). In a Db2 pureScale environment, write to table event monitors are deactivated on a given member when the database deactivates on that member and reactivates when the database activates on that member again. In a partitioned database environment, write to table event monitors are deactivated when the catalog partition deactivates.
- The DROP EVENT MONITOR statement does not drop target tables.
- Whenever a write-to-table event monitor activates, it acquires IN table locks on each target table to prevent them from being modified while the event monitor is active. Table locks are maintained on all tables while the event monitor is active. If exclusive access is required for any of the target tables (for example, when a utility is to be run), first deactivate the event monitor to release the table locks, and then attempting such access.

- **Syntax alternatives**: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - NODE can be specified in place of DBPARTITIONNUM
  - Commas can be used to separate multiple options in the *target-table-options* clause.

Examples

- *Example 1:* The following example creates an event monitor called SMITHPAY. This event monitor collects event data for the database and for the SQL statements that are run by the PAYROLL application that is owned by the JSMITH authorization ID. The data is appended to the absolute path /home/

jsmith/event/smithpay/. A maximum of 25 files are created. Each file is a maximum of 1 024 4K pages long. The file I/O is non-blocked.

```
CREATE EVENT MONITOR SMITHPAY
  FOR DATABASE, STATEMENTS
  WHERE APPL_NAME = 'PAYROLL' AND AUTH_ID = 'JSMITH'
  WRITE TO FILE '/home/jsmith/event/smithpay'
  MAXFILES 25
  MAXFILESIZE 1024
  NONBLOCKED
  APPEND
```

- *Example 2:* The following example creates an event monitor called DEADLOCKS_EVTS. This event monitor collects deadlock events and writes them to the relative path DLOCKS. One file is written, and the file size has no limit. Each time the event monitor is activated, it appends the event data to the file 00000000.evt if it exists. The event monitor is started each time that the database is started. The I/O is blocked by default.

```
CREATE EVENT MONITOR DEADLOCK_EVTS
  FOR DEADLOCKS
  WRITE TO FILE 'DLOCKS'
  MAXFILES 1
  MAXFILESIZE NONE
  AUTOSTART
```

- *Example 3:* This example creates an event monitor called DB_APPLS. This event monitor collects connection events, and writes the data to the named pipe /home/jsmith/applpipe.

```
CREATE EVENT MONITOR DB_APPLS
  FOR CONNECTIONS
  WRITE TO PIPE '/home/jsmith/applpipe'
```

- *Example 4:* This example, which assumes a partitioned database environment, creates an event monitor called FOO. This event monitor collects SQL statement events and writes them to SQL tables with the following derived names:
  - CONNHEADER_FOO
  - STMT_FOO
  - SUBSECTION_FOO
  - CONTROL_FOO

  Because no table space information is supplied, all tables are created in a table space selected by the system, based on the rules described under the IN *tablespace-name* clause. All tables include all elements for their group (that is, columns are defined whose names are equivalent to the element names.)

```
CREATE EVENT MONITOR FOO
  FOR STATEMENTS
  WRITE TO TABLE
```

- *Example 5:* This example, which assumes a partitioned database environment, creates an event monitor called BAR. This event monitor collects SQL statement and transaction events and writes them to tables as follows:
  - Any data from the STMT group is written to table MYDEPT.MYSTMTINFO. The table is created in table space MYTABLESPACE. Create columns only for the following elements: ROWS_READ, ROWS_WRITTEN, and STMT_TEXT. Any other elements of the group is discarded.
  - Any data from the SUBSECTION group is written to table MYDEPT.MYSUBSECTIONINFO. The table is created in table space MYTABLESPACE. The table includes all columns, except START_TIME, STOP_TIME, and PARTIAL_RECORD.
  - Any data from the XACT group is written to table XACT_BAR. Because no table space information is supplied, the table is created in a table space selected by the system, based on the rules described under the IN *tablespace-name* clause. This table includes all elements that are contained in the XACT group.

– No tables are created for connheader or control, and all data for these groups is discarded.

```
CREATE EVENT MONITOR BAR
  FOR STATEMENTS, TRANSACTIONS
  WRITE TO TABLE
  STMT(TABLE MYDEPT.MYSTMTINFO IN MYTABLESPACE
    INCLUDES(ROWS_READ, ROWS_WRITTEN, STMT_TEXT)),
  STMT(TABLE MYDEPT.MYSTMTINFO IN MYTABLESPACE
    EXCLUDES(START_TIME, STOP_TIME, PARTIAL_RECORD)),
  XACT
```

CREATE EVENT MONITOR (activities)

The CREATE EVENT MONITOR (activities) statement defines a monitor that will record activity events that occur when using the database. The definition of the activity event monitor also specifies where the database should record the events.

Invocation

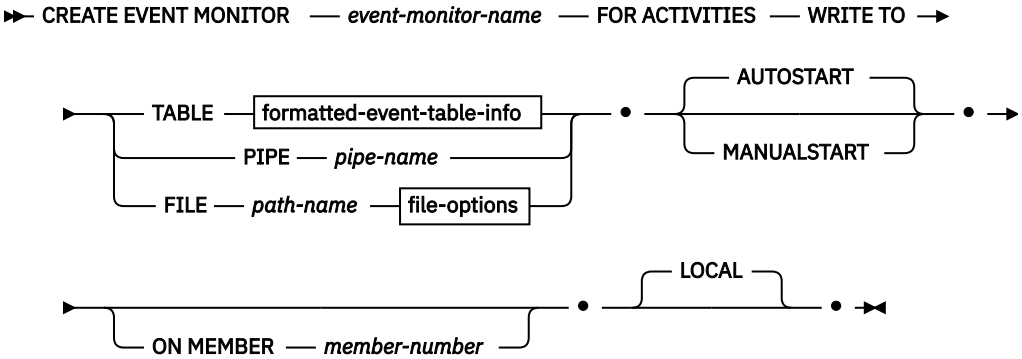
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

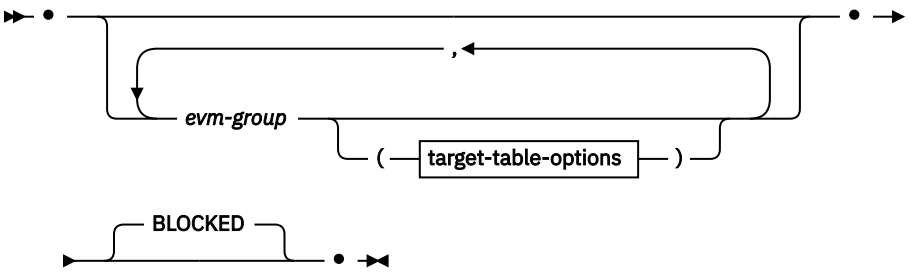
The privileges held by the authorization ID of the statement must include one of the following authorities:

- DBADM authority
- SQLADM authority

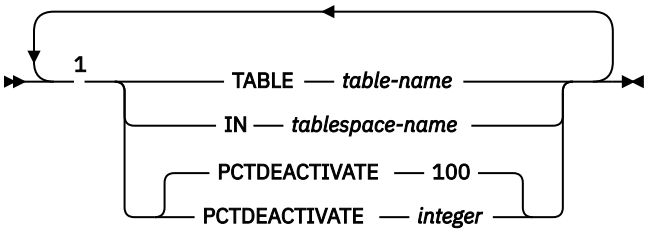
Syntax



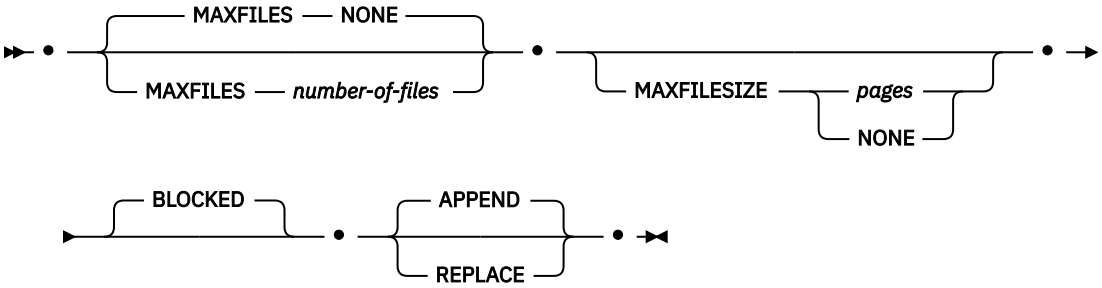
formatted-event-table-info



target-table-options



file-options



Notes:

[1] Each clause can be specified only once.
[2] Clauses can be separated with a space or a comma.

Description

event-monitor-name
Name of the event monitor. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *event-monitor-name* must not identify an event monitor that already exists in the catalog (SQLSTATE 42710).

FOR
Introduces the type of event to record.

ACTIVITIES
Specifies that the event monitor records an activity event when an activity finishes executing, or before the completion of execution if the event is triggered by the WLM_CAPTURE_ACTIVITY_IN_PROGRESS procedure. The activity must either:

- Belong to a service class or workload that has COLLECT ACTIVITY DATA set
- Belong to a work class whose associated work action is COLLECT ACTIVITY DATA
- Be identified as the activity that violated a threshold whose COLLECT ACTIVITY DATA clause was specified
- Have been identified in a call to the WLM_CAPTURE_ACTIVITY_IN_PROGRESS procedure before completing

WRITE TO
Introduces the target for the data.

TABLE
Indicates that the target for the event monitor data is a set of database tables. The event monitor separates the data stream into one or more logical data groups and inserts each group into a separate table. Data for groups having a target table is kept, whereas data for groups not having a target table is discarded. Each monitor element contained within a group is mapped to a table column with the same name. Only elements that have a corresponding table column are inserted into the table. Other elements are discarded.

formatted-event-table-info

Defines the target tables for an event monitor. This clause should be specified for each grouping that is to be recorded. However, if no evm-group-info clauses are specified, all groups for the event monitor type are recorded.

For more information about logical data groups, see "Logical data groups and event monitor output tables" in *Database Monitoring Guide and Reference*.

evm-group

Identifies the logical data group for which a target table is being defined. The value depends upon the type of event monitor, as shown in the following table:

Type of Event Monitor	evm-group Value
Activities	• ACTIVITY • ACTIVITYMETRICS • ACTIVITYSTMT • ACTIVITYVALS • CONTROL

target-table-options

Identifies the target table for the group.

TABLE *table-name*

Specifies the name of the target table. The target table must be a non-partitioned table. If the name is unqualified, the table schema defaults to the value in the CURRENT SCHEMA special register. If no name is provided, the unqualified name is derived from *evm-group* and *event-monitor-name* as follows:

```
substring(evm-group CONCAT '_'
  CONCAT event-monitor-name,1,128)
```

IN *tablespace-name*

Defines the table space in which the table is to be created. If no table space name is provided, the table space is chosen using the same process as when a table is created without a table space name using CREATE TABLE.

Since the page size affects the INLINE LOB lengths used, consider specifying a table space with as large a page size as possible in order to improve the INSERT performance of the event monitor.

PCTDEACTIVATE *integer*

If a table for the event monitor is being created in an automatic storage (non-temporary) or DMS table space, the PCTDEACTIVATE parameter specifies how full the table space must be before the event monitor automatically deactivates. The specified value, which represents a percentage, can range from 0 to 100, where 100 means that the event monitor deactivates when the table space becomes completely full. The default value assumed is 100 if PCTDEACTIVATE is not specified. This option is ignored for SMS table spaces.

Important: If the target table space has auto-resize enabled, set PCTDEACTIVATE parameter to 100. Alternatively, omit this clause entirely to have the default of 100 apply. Otherwise, the event monitor might deactivate unexpectedly if the table space reaches the threshold specified by PCTDEACTIVTATE before the table space is automatically resized.

If a value for *target-table-options* is not specified, CREATE EVENT MONITOR processing proceeds as follows:

- A derived table name is used.
- A default table space is chosen.

- The PCTDEACTIVATE parameter defaults to 100.

BLOCKED
Specifies that each agent that generates an event should wait for an event buffer to be written out to disk if the agent determines that both event buffers are full. BLOCKED should be selected to guarantee no event data loss. This is the default option.

PIPE
Specifies that the target for the event monitor data is a named pipe. The event monitor writes the data to the pipe in a single stream (that is, as if it were a single, infinitely long file). When writing the data to a pipe, an event monitor does not perform blocked writes. If there is no room in the pipe buffer, then the event monitor will discard the data. It is the monitoring application's responsibility to read the data promptly if it wishes to ensure no data loss.

pipe-name
The name of the pipe (FIFO on AIX) to which the event monitor will write the data.

The naming rules for pipes are platform specific.

Operating system	Naming rules
AIX	Pipe names are treated like file names. As a result, relative pipe names are permitted, and are treated like relative path-names (see description for *path-name*).
Linux	Pipe names are treated like file names. As a result, relative pipe names are permitted, and are treated like relative path-names (see description for *path-name*).
Windows	There is a special syntax for a pipe name and, as a result, absolute pipe names are required.

The existence of the pipe will not be checked at event monitor creation time. It is the responsibility of the monitoring application to have created and opened the pipe for reading at the time that the event monitor is activated. If the pipe is not available at this time, then the event monitor will turn itself off, and will log an error. (That is, if the event monitor was activated at database start time as a result of the AUTOSTART option, then the event monitor will log an error in the system error log.) If the event monitor is activated via the SET EVENT MONITOR STATE SQL statement, then that statement will fail (SQLSTATE 58030).

FILE
Indicates that the target for the event monitor data is a file (or set of files). The event monitor writes out the stream of data as a series of 8 character numbered files, with the extension "evt". (for example, `00000000.evt`, `00000001.evt`, and `00000002.evt`). The data should be considered to be one logical file even though the data is broken up into smaller pieces (that is, the start of the data stream is the first byte in the file `00000000.evt`; the end of the data stream is the last byte in the file *nnnnnnnn*`.evt`).

The maximum size of each file can be defined as well as the maximum number of files. An event monitor will never split a single event record across two files. However, an event monitor may write related records in two different files. It is the responsibility of the application that uses this data to keep track of such related information when processing the event files.

path-name
The name of the directory in which the event monitor should write the event files data. The path must be known at the server; however, the path itself could reside on another database partition (for example, an NFS mounted file). A string constant must be used when specifying the *path-name*.

The directory does not have to exist at CREATE EVENT MONITOR time. However, a check is made for the existence of the target path when the event monitor is activated. At that time, if the target path does not exist, an error (SQLSTATE 428A3) is raised.

If an absolute path is specified, the specified path will be the one used. In environments other than Db2 pureScale, if a relative path (a path that does not start with the root) is specified, then the path relative to the DB2EVENT directory in the database directory will be used. In a Db2 pureScale environment, if a relative path is specified, then the path relative to the database owning directory in the database directory will be used.

It is possible to specify two or more event monitors that have the same target path. However, once one of the event monitors has been activated for the first time, and as long as the target directory is not empty, it will be impossible to activate any of the other event monitors.

file-options
Specifies the options for the file format.

MAXFILES NONE
Specifies that there is no limit to the number of event files that the event monitor will create. This is the default.

MAXFILES *number-of-files*
Specifies that there is a limit on the number of event monitor files that will exist for a particular event monitor at any time. Whenever an event monitor has to create another file, it will check to make sure that the number of .evt files in the directory is less than *number-of-files*. If this limit has already been reached, then the event monitor will turn itself off.

If an application removes the event files from the directory after they have been written, then the total number of files that an event monitor can produce can exceed *number-of-files*. This option has been provided to allow a user to guarantee that the event data will not consume more than a specified amount of disk space.

MAXFILESIZE *pages*
Specifies that there is a limit to the size of each event monitor file. Whenever an event monitor writes a new event record to a file, it checks that the file will not grow to be greater than *pages* (in units of 4K pages). If the resulting file would be too large, then the event monitor switches to the next file. The default for this option is:

- Linux - 1000 4K pages
- UNIX - 1000 4K pages
- Windows - 200 4K pages

The number of pages must be greater than at least the size of the event buffer in pages. If this requirement is not met, then an error (SQLSTATE 428A4) is raised.

MAXFILESIZE NONE
Specifies that there is no set limit on a file's size. If MAXFILESIZE NONE is specified, then MAXFILES 1 must also be specified. This option means that one file will contain all of the event data for a particular event monitor. In this case the only event file will be 00000000.evt.

BLOCKED
Specifies that each agent that generates an event should wait for an event buffer to be written out to disk if the agent determines that both event buffers are full. BLOCKED should be selected to guarantee no event data loss. This is the default option.

APPEND
Specifies that if event data files already exist when the event monitor is turned on, then the event monitor will append the new event data to the existing stream of data files. When the event monitor is reactivated, it will resume writing to the event files as if it had never been turned off. APPEND is the default option.

The APPEND option does not apply at CREATE EVENT MONITOR time, if there is existing event data in the directory where the newly created event monitor is to write its event data.

REPLACE
Specifies that if event data files already exist when the event monitor is turned on, then the event monitor will erase all of the event files and start writing data to file `00000000.evt`.

MANUALSTART
Specifies that the event monitor must be activated manually using the SET EVENT MONITOR STATE statement. After a MANUALSTART event monitor has been activated, it can be deactivated only by using the SET EVENT MONITOR STATE statement or by stopping the instance.

AUTOSTART
Specifies that the event monitor is to be automatically activated whenever the database partition on which the event monitor runs is activated. This is the default behavior of the activities event monitor.

ON MEMBER *member-number*
Specifies the member on which a file or pipe event monitor is to run. When the monitoring scope is defined as LOCAL, data is collected only on the specified member. The I/O component will physically run on the specified member, writing records to the specified file or pipe.

When the Db2 pureScale feature is enabled, -1 is the default.

If a value of -1 is specified, it allows the I/O component to run from any active member. Additionally, in the event that the I/O component is no longer able to run on a given member, the event monitor will be restarted with the I/O component running on another available active member.

This clause is not valid for table event monitors. In a partitioned database environment, write-to-table event monitors will run and write events on all database partitions where table spaces for target tables are defined.

In a Db2 pureScale environment, write-to-table event monitors will record events on all active members.

If this clause is not specified and Db2 pureScale is not enabled, the currently connected member (for the application) is used.

If this clause is not specified and Db2 pureScale is enabled, the I/O component is able to run on any currently connected member.

LOCAL
The event monitor reports only on the member that is running. It gives a partial trace of the database activity. This is the default.

This clause is valid for file or pipe monitors. It is not valid for table event monitors.

GLOBAL is not a valid scope for this type of event monitor.

Rules

- The ACTIVITIES event type cannot be combined with any other event types in a particular event monitor definition.

Notes

- Event monitor definitions are recorded in the SYSCAT.EVENTMONITORS catalog view. The events themselves are recorded in the SYSCAT.EVENTS catalog view. The names of target tables are recorded in the SYSCAT.EVENTTABLES catalog view.
- If the member on which the event monitor is to run is not active, event monitor activation occurs when that member is reactivated.
- After an event monitor is activated, it behaves like an autostart event monitor until that event monitor is explicitly deactivated or the instance is recycled. That is, if an event monitor is active when a member

is deactivated, and that member is subsequently reactivated, the event monitor is also explicitly reactivated.

- The FLUSH EVENT MONITOR statement is not applicable to this event monitor and will have no effect when issued against it.
- ***Write to table event monitors***: General notes:
  - All target tables are created when the CREATE EVENT MONITOR statement executes.
  - If the creation of a table fails for any reason, an error is passed back to the application program, and the CREATE EVENT MONITOR statement fails.
  - A target table can only be used by one event monitor. During CREATE EVENT MONITOR processing, if a target table is found to have already been defined for use by another event monitor, the CREATE EVENT MONITOR statement fails, and an error is passed back to the application program. A table is defined for use by another event monitor if the table name matches a value found in the SYSCAT.EVENTTABLES catalog view.
  - During CREATE EVENT MONITOR processing, if a table already exists, but is *not* defined for use by another event monitor, no table is created, and processing continues. A warning is passed back to the application program.
  - Any table spaces must exist before the CREATE EVENT MONITOR statement is executed. The CREATE EVENT MONITOR statement does not create table spaces.
  - If specified, the LOCAL and GLOBAL keywords are ignored. With WRITE TO TABLE event monitors, an event monitor output process or thread is started on each member in the instance, and each of these processes reports data only for the member on which it is running.
  - The following event types from the flat monitor log file or pipe format are not recorded by write to table event monitors:
    - LOG_STREAM_HEADER
    - LOG_HEADER
    - DB_HEADER (Elements **db_name** and **db_path** are not recorded. The element **conn_time** is recorded in CONTROL.)
  - In a partitioned database environment, data is only written to target tables on the database partitions where their table spaces exist. If a table space for a target table does not exist on some database partition, data for that target table is ignored. This behavior allows users to choose a subset of database partitions for monitoring, by creating a table space that exists only on certain database partitions.

    In a Db2 pureScale environment, data will be written from every member.

    In a partitioned database environment, if some target tables do not reside on a database partition, but other target tables do reside on that same database partition, only the data for the target tables that do reside on that database partition is recorded.
  - Users must manually prune all target tables.

  Table Columns:

  - Column names in a table match an event monitor element identifier. Any event monitor element that does not have a corresponding target table column is ignored.
  - Use the **db2evtbl** command to build a CREATE EVENT MONITOR statement that includes a complete list of elements for a group.
  - The types of columns being used for monitor elements correlate to the following mapping:

```
SQLM_TYPE_STRING                     CHAR[n], VARCHAR[n] or CLOB(n)
                                     (If the data in the event monitor
                                     record exceeds n bytes,
                                     it is truncated.)
SQLM_TYPE_U8BIT and SQLM_TYPE_8BIT   SMALLINT, INTEGER or BIGINT
SQLM_TYPE_16BIT and SQLM_TYPE_U16BIT SMALLINT, INTEGER or BIGINT
SQLM_TYPE_32BIT and SQLM_TYPE_U32BIT INTEGER or BIGINT
SQLM_TYPE_U64BIT and SQLM_TYPE_64BIT BIGINT
sqlm_timestamp                       TIMESTAMP
```

```
sqlm_time(elapsed time)              BIGINT
sqlca:
  sqlerrmc                           VARCHAR[72]
  sqlstate                           CHAR[5]
  sqlwarn                            CHAR[11]
  other fields                       INTEGER or BIGINT
```

- Columns are defined to be NOT NULL.
- Unlike other target tables, the columns in the CONTROL table do not match monitor element identifiers. Columns are defined as follows:

Column Name	Data Type	Nullable	Description
PARTITION_KEY	INTEGER	N	Distribution key (partitioned database only)
PARTITION_NUMBER	INTEGER	N	Database partition number (partitioned database only)
EVMONNAME	VARCHAR(128)	N	Name of the event monitor
MESSAGE	VARCHAR(128)	N	Describes the nature of the MESSAGE_TIME column. For more details see, "message - Control Table Message monitor element" in the *Database Monitoring Guide and Reference*
MESSAGE_TIME	TIMESTAMP	N	Timestamp

- In a partitioned database environment, the first column of each table is named PARTITION_KEY, is NOT NULL, and is of type INTEGER. This column is used as the distribution key for the table. The value of this column is chosen so that each event monitor process inserts data into the member on which the process is running; that is, insert operations are performed locally on the member where the event monitor process is running. On any database partition, the PARTITION_KEY field will contain the same value. This means that if a database partition is dropped and data redistribution is performed, all data on the dropped database partition will go to one other database partition instead of being evenly distributed. Therefore, before removing a database partition, consider deleting all table rows on that database partition.
- In a partitioned database environment, a column named PARTITION_NUMBER can be defined for each table. This column is NOT NULL and is of type INTEGER. It contains the number of the database partition on which the data was inserted. Unlike the PARTITION_KEY column, the PARTITION_NUMBER column is not mandatory. The PARTITION_NUMBER column is not allowed in a non-partitioned database environment.

Table Attributes:

- Default table attributes are used. Besides distribution key (partitioned databases only), no extra options are specified when creating tables.
- Indexes on the table can be created.
- Extra table attributes (such as volatile, RI, triggers, constraints, and so on) can be added, but the event monitor process (or thread) will ignore them.
- If "not logged initially" is added as a table attribute, it is turned off at the first COMMIT, and is not set back on.

Event Monitor Activation:

- When an event monitor activates, all target table names are retrieved from the SYSCAT.EVENTTABLES catalog view.
- In a partitioned database environment, activation processing occurs on every member of the instance. On a particular member, activation processing determines the table spaces and database partition groups for each target table. The event monitor only activates on a database partition if at least one target table exists on that database partition. Moreover, if some target table is not found on a database partition, that target table is flagged so that data destined for that table is dropped during runtime processing.
- If a target table does not exist when the event monitor activates (or, in a partitioned database environment, if the table space does not reside on a database partition), activation continues, and data that would otherwise be inserted into this table is ignored.
- Activation processing validates each target table. If validation fails, activation of the event monitor fails, and messages are written to the administration log.
- During activation in a partitioned database environment, the CONTROL table rows for FIRST_CONNECT and EVMON_START are only inserted on the catalog database partition. This requires that the table space for the control table exist on the catalog database partition. If it does not exist on the catalog database partition, these inserts are not performed.
- In a partitioned database environment, if a member is not yet active when a write to table event monitor is activated, the event monitor will be activated the next time that member is activated.

Run Time:

- An event monitor runs with DATAACCESS authority.
- If, while an event monitor is active, an insert operation into a target table fails:
  - Uncommitted changes are rolled back.
  - A message is written to the administration log.
  - The event monitor is deactivated.
- If an event monitor is active, it performs a local COMMIT when it has finished processing an event monitor buffer.
- In an environment other than a partitioned database or a Db2 pureScale environment, all write to table event monitors are deactivated when the last application terminates (and the database has not been explicitly activated).

  In a Db2 pureScale environment, write to table event monitors are deactivated on a given member when the member stops and is reactivated when the member restarts.

  In a partitioned database environment, write to table event monitors are deactivated when the catalog partition deactivates.
- The DROP EVENT MONITOR statement does not drop target tables.
- Whenever a write-to-table event monitor activates, it will acquire IN table locks on each target table in order to prevent them from being modified while the event monitor is active. Table locks are maintained on all tables while the event monitor is active. If exclusive access is required on any of the target tables (for example, when a utility is to be run), first deactivate the event monitor to release the table locks before attempting such access.

- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - DBPARTITIONNUM or NODE can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - Commas can be used to separate multiple options in the *target-table-options* clause

Example

Define an activity event monitor named DBACTIVITIES

```
CREATE EVENT MONITOR DBACTIVITIES
    FOR ACTIVITIES
    WRITE TO TABLE
    ACTIVITY (TABLE ACTIVITY_DBACTIVITIES
              IN USERSPACE1
              PCTDEACTIVATE 100),
```

```
    ACTIVITYMETRICS (TABLE ACTIVITYMETRICS_DBACTIVITIES
                     IN USERSPACE1
                     PCTDEACTIVATE 100),
```

```
    ACTIVITYSTMT (TABLE ACTIVITYSTMT_DBACTIVITIES
                  IN USERSPACE1
                  PCTDEACTIVATE 100),
    ACTIVITYVALS (TABLE ACTIVITYVALS_DBACTIVITIES
                  IN USERSPACE1
                  PCTDEACTIVATE 100),
    CONTROL (TABLE CONTROL_DBACTIVITIES
             IN USERSPACE1
             PCTDEACTIVATE 100)
    AUTOSTART;
```

CREATE EVENT MONITOR (change history)

The CREATE EVENT MONITOR (change history) statement creates an event monitor that can record events for changes to configuration parameters, registry variables, and the execution of DDL statements and utilities.

The event monitor created by the CREATE EVENT MONITOR (change history) statement can also record initial configuration and registry values at event monitor startup time. The set of events recorded depends on the event controls specified in the CREATE EVENT MONITOR statement.

Invocation

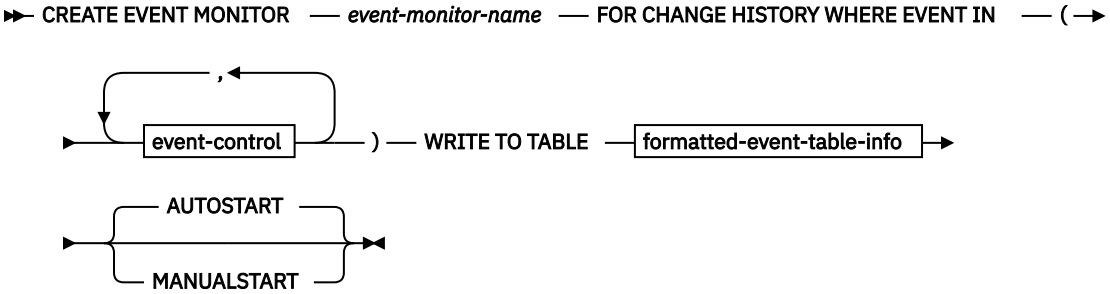
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

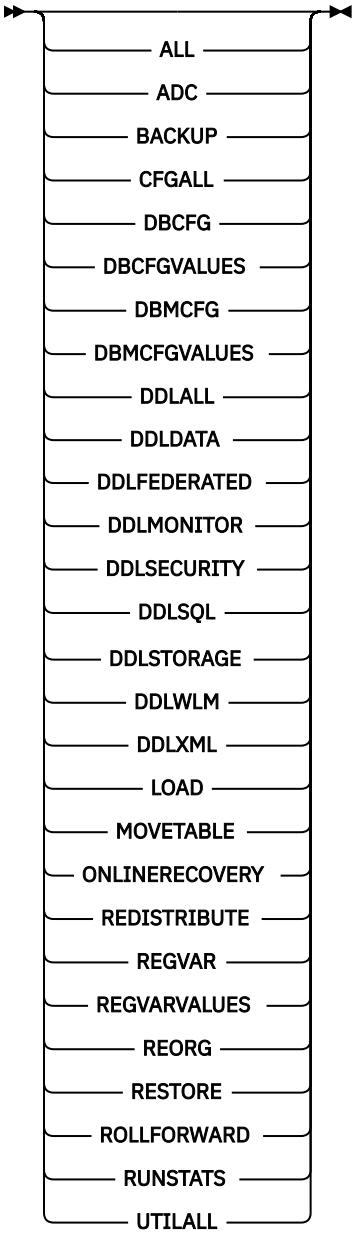
The privileges held by the authorization ID of the statement must include one of the following authorities:

- SQLADM authority
- DBADM authority

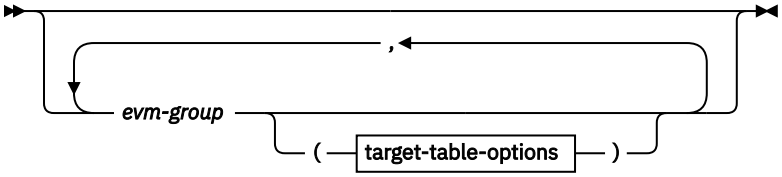
Syntax



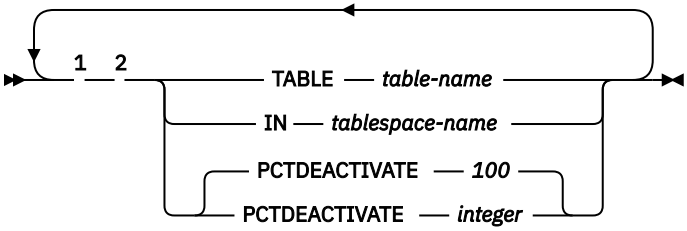
event-control



formatted-event-table-info



target-table-options



Notes:

[1] Each condition can be specified only once (SQLSTATE 42613).

[2] Clauses can be separated with a space or a comma.

Description

event-monitor-name

Name of the event monitor. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *event-monitor-name* must not identify an event monitor that exists in the catalog (SQLSTATE 42710).

FOR

Introduces the type of event to record.

CHANGE HISTORY

Specifies that this event monitor can record events for configuration changes, registry changes, and the execution of DDL statements and utilities. It can also record initial configuration and registry values at event monitor startup time. The set of events recorded depends on the event controls specified in the WHERE EVENT IN clause.

WHERE EVENT IN (event-control, ...)

Specifies one or more event controls used to identify which events are captured by the event monitor.

event-control

ALL

Capture all event types.

ADC

Capture execution of the automatic dictionary creation (ADC) utility.

BACKUP

Capture execution of the online backup utility.

CFGALL

Capture all configuration parameter and registry variable event types.

DBCFG

Capture database configuration parameter changes.

DBCFGVALUES

Record initial values for all database configuration parameters at event monitor startup time if any database configuration parameter update was not captured by the event monitor.

DBMCFG

Capture database manager configuration parameter changes.

DBMCFGVALUES

Record initial values for all database manager configuration parameters at event monitor startup time if any database manager configuration parameter update was not captured by the event monitor.

DDLALL

Capture execution for all types of DDL statements.

DDLDATA

Capture execution of index, sequence, table, and temporary table DDL.

DDLFEDERATED

Capture execution of nickname, server, type mapping, user mapping, and wrapper DDL.

DDLMONITOR

Capture execution of event monitor and usage list DDL.

DDLSECURITY

Capture execution of audit policy, grant, mask, permission role, revoke, security label, security label component, security policy, and trusted context DDL.

DDLSQL
Capture execution of alias, function, method, module, package, procedure, schema, synonym, transform, trigger, type, variable, and view DDL.

DDLSTORAGE
Capture execution of the ALTER DATABASE statement and buffer pool, partition group, storage group, and table space DDL.

DDLWLM
Capture execution of histogram, service class, threshold, work action set, work class set, and workload DDL.

DDLXML
Capture execution of XSROBJECT DDL.

LOAD
Capture execution of the load utility.

MOVETABLE
Capture execution of the table move utility (invocations of the ADMIN_MOVE_TABLE stored procedure).

ONLINERECOVERY
Capture execution of a crash recovery operation which utilized an asynchronous backward phase that allowed for database connectivity during the operation. (This includes the implicit crash recovery performed during an HADR TAKEOVER).

REDISTRIBUTE
Capture execution of the redistribute partition group utility.

REGVAR
Capture immediate registry variables changes.

REGVARVALUES
Record initial values for registry variables at event monitor startup time.

REORG
Capture execution of the reorg utility.

RESTORE
Capture execution of the online restore utility.

ROLLFORWARD
Capture execution of the online rollforward utility.

RUNSTATS
Capture execution of the runstats utility.

UTILALL
Capture execution of the load, move table, online backup, online restore, online rollforward, redistribute, reorg and runstats utilities.

WRITE TO
Introduces the target for the data.

TABLE
Indicates that the target for the event monitor data is a set of database tables. The event monitor separates the data stream into one or more logical data groups and inserts each group into a separate table. Each monitor element contained within a group is mapped to a table column with the same name. Only elements that have a corresponding table column are inserted into the table.

formatted-event-table-info
Defines the target table for a logical data group. Specify this clause for each grouping that is to be recorded. However, if no *evm-group* clauses are specified, the groups required for the event-control options specified are created along with the CONTROL, CHANGESUMMARY, and EVMONSTART logical groups.

evm-group
Identifies the logical data group for which a target table is being defined. The value depends upon the type of event monitor, as shown in the following table:

Type of event monitor	evm-group value
Change history	• CONTROL • CHANGESUMMARY • EVMONSTART • TXNCOMPLETION • DDLSTMTEXEC • DBDBMCFG • REGVAR • UTILSTART • UTILSTOP • UTILPHASE • UTILLOCATION

target-table-options
Identifies the target table for the group.

TABLE *table-name*
Specifies the name of the target table. The target table must be a non-partitioned table. If the name is unqualified, the table schema defaults to the value in the CURRENT SCHEMA special register. If no name is provided, the unqualified name is derived from *evm-group* and *event-monitor-name* as follows:

```
SUBSTRING(evm-group CONCAT '_'
   CONCAT event-monitor-name, 1, 128)
```

IN *tablespace-name*
Defines the table space in which the table is to be created. If no table space name is provided, the table space is chosen using the same process as when a table is created without a table space name using CREATE TABLE.

PCTDEACTIVATE *integer*
If a table for the event monitor is being created in an automatic storage (non-temporary) or DMS table space, the PCTDEACTIVATE parameter specifies how full the table space must be before the event monitor automatically deactivates. The specified value, which represents a percentage, can range from 0 to 100, where 100 means that the event monitor deactivates when the table space becomes full. The default value is 100 if PCTDEACTIVATE is not specified. This option is ignored for SMS table spaces.

Important: If the target table space has auto-resize enabled, set PCTDEACTIVATE parameter to 100. Alternatively, omit this clause entirely to have the default of 100 apply. Otherwise, the event monitor might deactivate unexpectedly if the table space reaches the threshold specified by PCTDEACTIVTATE before the table space is automatically resized.

If a value for target-table-info is not specified, CREATE EVENT MONITOR processing proceeds as follows:

- A derived table name is used.
- A default table space is chosen.
- The PCTDEACTIVATE parameter defaults to 100.

AUTOSTART
Specifies that the event monitor is to be automatically activated whenever the database partition on which the event monitor runs is activated. This is the default behavior.

MANUALSTART
Specifies that the event monitor must be activated manually using the SET EVENT MONITOR STATE statement. After a MANUALSTART event monitor is activated, it can be deactivated by using the SET EVENT MONITOR STATE statement or by stopping the instance.

Notes

- ***Creation of target event tables:*** The target event tables are created when the CREATE EVENT MONITOR FOR CHANGE HISTORY statement executes if the target tables do not exist.
- ***Previously created event tables:*** During CREATE EVENT MONITOR FOR CHANGE HISTORY processing, if an event table has already been defined for use by another event monitor, the CREATE EVENT MONITOR FOR CHANGE HISTORY statement fails, and an error is returned to the application program. An event table is defined for use by another event monitor if the event table name matches a value found in the SYSCAT.EVENTTABLES catalog view. If the event table exists and is not defined for use by another event monitor, then a table is not created, any other table options parameters are ignored, and processing continues. A warning is returned to the application program.
- ***Dropping event monitors:*** Dropping the event monitor does not drop the event tables. The associated event tables must be manually dropped after the event monitor is dropped.
- ***Pruning:*** The event tables must be manually pruned.
- ***Behavior in a partitioned environment:*** In a partitioned environment, if some target event tables do not exist on a partition, but other target event tables do exist on that same partition, only the data for the target event tables that do exist on that partition is recorded.
- ***FLUSH EVENT MONITOR:*** The FLUSH EVENT MONITOR statement is not applicable to this event monitor and has no effect when issued against it.
- ***Modifying event controls after monitor creation:*** After the change history event monitor is created, the event controls specified using the WHERE EVENT IN clause in the CREATE EVENT MONITOR statement cannot be changed or altered. To change the event controls, the event monitor must be deactivated, dropped, and then recreated specifying a new set of event controls using the WHERE EVENT IN clause.

Examples

- *Example 1*: This example creates a change history event monitor called CFG_WITH_OFFLINE that records configuration changes and initial values for configuration.

```
CREATE EVENT MONITOR CFG_WITH_OFFLINE
   FOR CHANGE HISTORY WHERE EVENT IN (CFGALL)
   WRITE TO TABLE
     CHANGESUMMARY (TABLE CHG_SUMMARY_HISTORY),
     DBDBMCFG (TABLE DB_DBM_HISTORY),
     REGVAR (TABLE REGVAR_HISTORY)
   AUTOSTART
```

  In this example the target tables are explicitly specified. The previous statement creates the following tables:

```
CHG_SUMMARY_HISTORY
DB_DBM_HISTORY
REGVAR_HISTORY
```

- *Example 2*: This example creates a change history event monitor called BKP_REST that collects events describing all online backup and restore utility executions.

```
CREATE EVENT MONITOR BKP_REST
   FOR CHANGE HISTORY WHERE EVENT IN (BACKUP, RESTORE)
   WRITE TO TABLE
```

  In this example the target tables are not explicitly specified. The CREATE EVENT MONITOR statement creates only the target tables that are needed based on the controls specified in the WHERE EVENT IN clause, along with tables for the CONTROL, CHANGESUMMARY, and EVMONSTART logical data groups. The BACKUP and RESTORE controls enable collection of utility events for online backup and

restore, and require the UTILSTART, UTILSTOP, UTILLOCATION, and UTILPHASE logical data groups. The previous statement creates the following tables:

```
CONTROL_BKP_REST
CHANGESUMMARY_BKP_REST
EVMONSTART_BKP_REST
UTILSTART_BKP_REST
UTILSTOP_BKP_REST
UTILLOCATION_BKP_REST
UTILPHASE_BKP_REST
```

CREATE EVENT MONITOR (locking)

The CREATE EVENT MONITOR (locking) statement creates an event monitor that will record lock-related events that occur when using the database.

Invocation

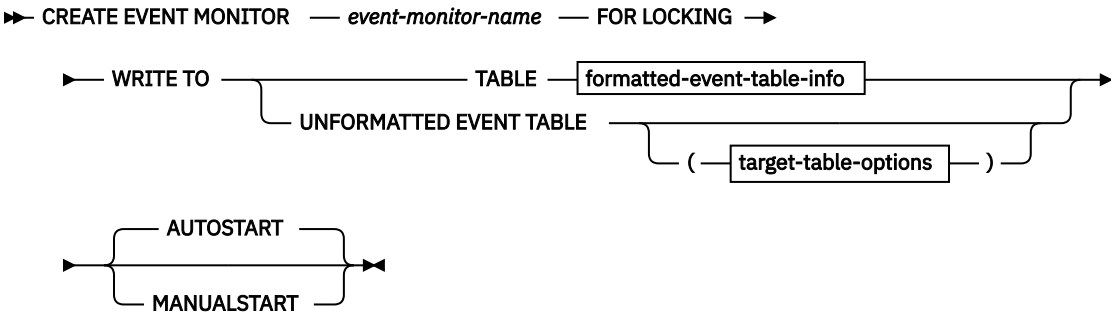
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

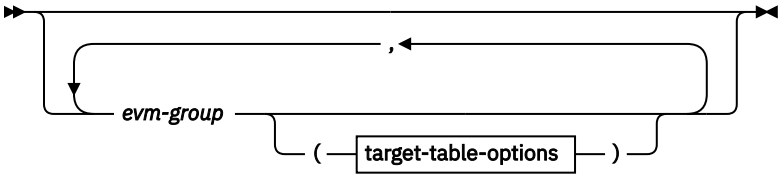
The privileges held by the authorization ID of the statement must include one of the following authorities:

- DBADM authority
- SQLADM authority

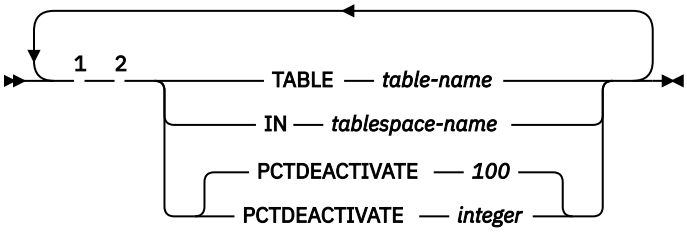
Syntax



formatted-event-table-info



target-table-options



Notes:

[1] Each table option can be specified a maximum of one time (SQLSTATE 42613).
[2] Clauses can be separated with a space or a comma.

Description

event-monitor-name
Name of the event monitor. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *event-monitor-name* must not identify an event monitor that already exists in the catalog (SQLSTATE 42710).

FOR
Introduces the type of event to record.

LOCKING
Specifies that this passive event monitor will record any lock event produced when the database manager encounters one or more of these conditions:

- LOCKTIMEOUT: the lock has timed-out.
- DEADLOCK: the lock was involved in a deadlock (victim and participant(s)).
- LOCKWAIT: locks that are not acquired in the specified duration.

The creation of the lock event monitor does not indicate that the locking data will be collected immediately. The actual locking event of interest is controlled at the workload level or database level.

WRITE TO
Specifies the target for the data.

TABLE
Indicates that the target for the event monitor data is a set of formatted event tables. The event monitor separates the data stream into one or more logical data groups and inserts each group into a separate table. Data for groups having a target table is kept, whereas data for groups not having a target table is discarded. Each monitor element contained within a group is mapped to a table column with the same name. Only elements that have a corresponding table column are inserted into the table. Other elements are discarded.

formatted-event-table-info
Defines the target formatted event tables for the event monitor. This clause should specify each grouping that is to be recorded. However, if no *evm-group* clauses are specified, all groups for the event monitor type are recorded.

For more information about logical data groups, see "Logical data groups and event monitor output tables" in *Database Monitoring Guide and Reference*.

evm-group
Identifies a logical data group for which a target table is being defined. The value depends upon the type of event monitor, as shown in the following table:

Type of Event Monitor	evm-group Value
Locking	• LOCK • LOCK_PARTICIPANTS • LOCK_PARTICIPANT_ACTIVITIES • LOCK_ACTIVITY_VALUES • CONTROL

UNFORMATTED EVENT TABLE
Specifies that the target for the event monitor is an unformatted event table. The unformatted event table is used to store collected locking event monitor data. Data is stored in an internal binary format within an inlined BLOB column. Each event can insert multiple records into this table and each inserted record can be of a different type with the associated BLOB content varying as

well. The data in the BLOB column is not in a readable format and requires conversion, through use of the **db2evmonfmt** Java-based tool, EVMON_FORMAT_UE_TO_XML table function, or EVMON_FORMAT_UE_TO_TABLES procedure, into a consumable format such as an XML document or a relational table.

target-table-options
Identifies options for the target table. If a value for **target-table-options** is not specified, CREATE EVENT MONITOR FOR LOCKING processing proceeds as follows:

- A derived table name is used (as explained in the description for TABLE *table-name*).
- A default table space is chosen using the same process as when a table is created without a table space name using CREATE TABLE.
- PCTDEACTIVATE is set to 100.

TABLE *table-name*
Specifies the name of the target table. The target table must be a non-partitioned table. If the name is unqualified, the table schema defaults to the value in the CURRENT SCHEMA special register. If a name is not provided for an unformatted event table, the unqualified name is equal to the *event-monitor-name*, that is, the unformatted event table will be named after the event monitor. If no name is provided for a formatted event table, the unqualified name is derived from *evm-group* and *event-monitorname* as follows:

```
substring(evm-group CONCAT '_'
  CONCAT event-monitor-name,1,128)
```

IN *tablespace-name*
Defines the table space in which the table is to be created. The CREATE EVENT MONITOR FOR LOCKING statement does not create table spaces.

If a table space name is not provided, the table space is chosen using the same process as when a table is created without a table space name using CREATE TABLE.

When specifying the table space name for a formatted event table, the table space's page size affects the INLINE LOB lengths used Consider specifying a table space with as large a page size as possible in order to improve the INSERT performance of the event monitor.

PCTDEACTIVATE *integer*
If a table for the event monitor is being created in an automatic storage (non-temporary) or DMS table space, the PCTDEACTIVATE parameter specifies how full the table space must be before the event monitor automatically deactivates. The specified value, which represents a percentage, can range from 0 to 100. The default value is 100, where 100 means the event monitor deactivates when the table space becomes completely full. The default value assumed is 100 if PCTDEACTIVATE is not specified. This option is ignored for SMS table spaces.

Important: If the target table space has auto-resize enabled, set PCTDEACTIVATE to 100. Alternatively, omit this clause entirely to have the default of 100 apply. Otherwise, the event monitor might deactivate unexpectedly if the table space reaches the threshold specified by PCTDEACTIVTATE before the table space is automatically resized.

AUTOSTART
Specifies that the event monitor is to be automatically activated whenever the database partition on which the event monitor runs is activated. This is the default behavior of the locking event monitor.

MANUALSTART
Specifies that the event monitor must be activated manually using the SET EVENT MONITOR STATE statement. After a MANUALSTART event monitor has been activated, it can be deactivated only by using the SET EVENT MONITOR STATE statement or by stopping the instance.

Notes

- The target table is created when the CREATE EVENT MONITOR FOR LOCKING statement executes, if it doesn't already exist.

- During CREATE EVENT MONITOR FOR LOCKING processing, if a table is found to have already been defined for use by another event monitor, the CREATE EVENT MONITOR FOR LOCKING statement fails, and an error is passed back to the application program. A table is defined for use by another event monitor if the table name matches a value found in the SYSCAT.EVENTTABLES catalog view. If the table exists and is not defined for use by another event monitor, then the event monitor will re-use the table.
- Dropping the event monitor will not drop any tables. Any associated tables must be manually dropped after the event monitor is dropped.
- Lock event data is not automatically pruned from either unformatted event tables or regular tables created by this event monitor. An option for pruning data from UE tables is available when using the EVMON_FORMAT_UE_TO_TABLES procedure. For event monitors that write to regular tables, event data must be pruned manually.
- The FLUSH EVENT MONITOR statement is not applicable to this event monitor and will have no effect when issued against it.
- For unformatted event tables event data is inserted into the table into an inlined BLOB data column. Normally, BLOB data is stored in a separate LOB table space and can experience additional performance overhead as a result. When inlined into the data page of the base table, the BLOB data does not experience this overhead. The database manager will automatically inline the BLOB data portion of an unformatted event table record if the size of the BLOB data is less than the table space page size minus the record prefix. Therefore to achieve high efficiency and application throughput, it is suggested that you create the event monitor in as large a table space as possible up to and including a 32KB table space and associated bufferpool.

  Example

  The lock event monitor currently has the following two record types:

  – Application Info Record

  – Application Activity Record

  Application Info Record = maximum size 3.5KB

  Application Activity Record = 3KB + SQL statement text size (where SQL statement text size is max 2MB)

  The Application Info Record is very small and should always be inlined as long as a 4KB page size is being used. The Application Activity Record will be inlined based on the following formula:

  ```
  Application Activity Record < inline length (Pagesize - overhead non-LOB
  columns (0.5KB))
     3KB + SQL statement text < inline length (Pagesize - overhead non-LOB
  columns (0.5KB))

           SQL statement text < Pagesize - nonLOB overhead (1K) - 3KB
           SQL statement text < 16KB - 1KB - 3KB
                             < 12KB
  ```

  Therefore, when using a 16KB pagesize, the lock event monitor records will only be inlined if the SQL statement being captured is less than 12KB in size.
- Create only one locking event monitor per database. Creating more than one locking event monitor uses additional processor cycles and storage, without providing any additional data.

  Important: For compatibility with older versions of the product, all databases are created with the DB2DETAILDEADLOCK event monitor enabled. The locking event monitor introduced in Db2 Version 9.7 is the preferred mechanism for collecting data related to locks; the DB2DETAILEDDEALOCK event monitor is deprecated and might be removed in a future release. When you create a locking event monitor, disable and drop the DB2DETAILEDDEADLOCK event monitor to prevent the collection of duplicate, unnecessary information.

  To remove the DB2DETAILDEADLOCK event monitor, issue the following SQL statements:

  ```
  SET EVENT MONITOR DB2DETAILDEADLOCK state 0
  DROP EVENT MONITOR DB2DETAILDEADLOCK
  ```

- In a partitioned database environment, data is written only to target tables on the database partitions where their table spaces exist. If a table space for a target table does not exist on some database partition, data for that target table is ignored. This behavior allows users to choose a subset of database partitions for monitoring to be chosen, by creating a table space that exists only on certain database partitions.
- In a partitioned database environment, if some target tables do not reside on a database partition, but other target tables do reside on that same database partition, only the data for the target unformatted event tables that do reside on that database partition is recorded.

Examples

- *Example 1:* This example creates a locking event monitor LOCKEVMON that will collect locking events that occur on the database of creation.

```
CREATE EVENT MONITOR LOCKEVMON
  FOR LOCKING
  WRITE TO TABLE
```

  This event monitor writes its output to the following tables:

  LOCK_LOCKEVMON
  LOCK_PARTICIPANTS_LOCKEVMON
  LOCK_PARTICIPANT_ACTIVITIES_LOCKEVMON
  LOCK_ACTIVITY_VALUES_LOCKEVMON
  CONTROL_LOCKEVMON

- *Example 2:* This example creates a locking event monitor LOCKEVMON that will collect locking events that occur on the database of creation and store it in the unformatted event table IMRAN.LOCKEVENTS.

```
CREATE EVENT MONITOR LOCKEVMON
  FOR LOCKING
  WRITE TO UNFORMATTED EVENT TABLE (TABLE IMRAN.LOCKEVENTS)
```

- *Example 3:* This example creates a locking event monitor LOCKEVMON that will collect locking events that occur on the database of creation and store it in the unformatted event table IMRAN.LOCKEVENTS in table space APPSPACE. The event monitor will deactivate when the table space becomes 85% full.

```
CREATE EVENT MONITOR LOCKEVMON
  FOR LOCKING
  WRITE TO UNFORMATTED EVENT TABLE
     (TABLE IMRAN.LOCKEVENTS IN APPSPACE PCTDEACTIVATE 85)
```

CREATE EVENT MONITOR (package cache) statement

The CREATE EVENT MONITOR (package cache) statement creates an event monitor that will record events when the cache entry for a section is flushed from the package cache.

Invocation

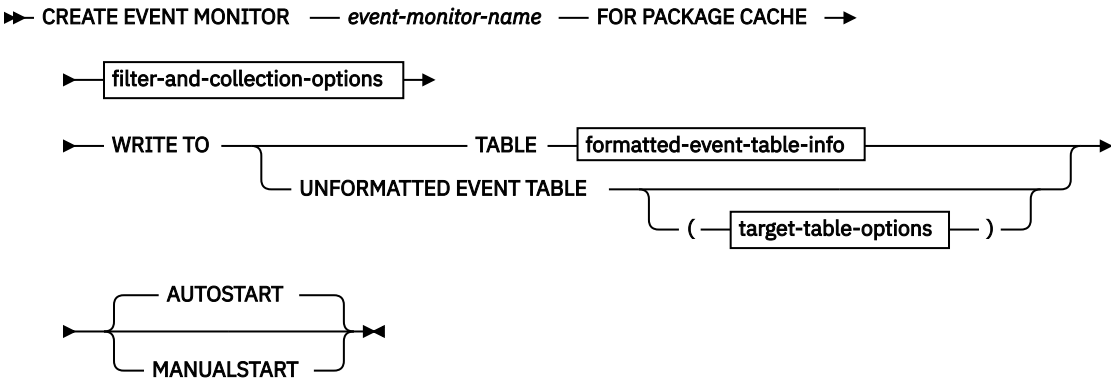
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

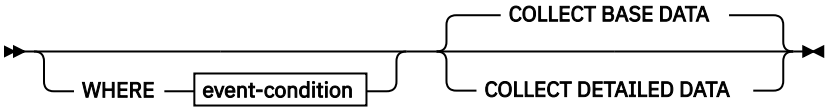
The privileges held by the authorization ID of the statement must include one of the following authorities:

- DBADM authority
- SQLADM authority

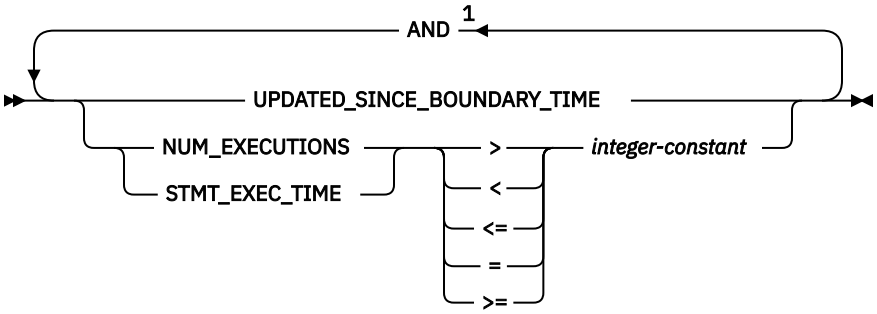
Syntax



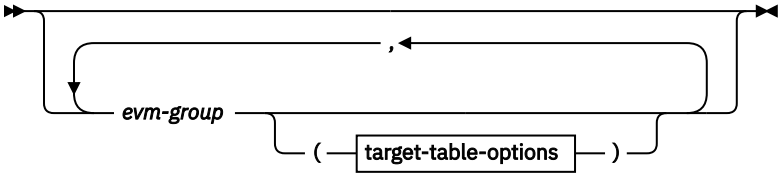
filter-and-collection-options



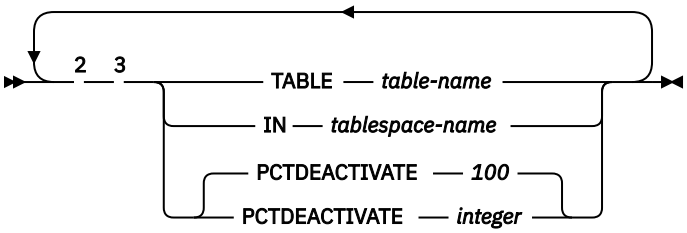
event-condition



formatted-event-table-info



target-table-options



Notes:

[1] Each condition can be specified only once (SQLSTATE 42613).
[2] Each table option can be specified a maximum of one time (SQLSTATE 42613).
[3] Clauses can be separated with a space or a comma.

Description

event-monitor-name
Name of the event monitor. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *event-monitor-name* must not identify an event monitor that already exists in the catalog (SQLSTATE 42710).

FOR
Introduces the type of event to record.

PACKAGE CACHE
Specifies that this event monitor will record an event when the cache entry for a static or dynamic SQL statement is flushed from the package cache. This event monitor is not passive and will start to record events once it is activated.

filter-and-collection-options
Specify a set of filter and collection options.

WHERE

event-condition
Defines a filter that determines whether entries that are flushed from the package cache should cause an event to occur. If the event condition is TRUE for a particular entry that is being flushed from the package cache, then that entry will be recorded as an event.

This clause is a special form of the WHERE clause that should not be confused with a standard search condition. This is a simple WHERE clause that includes the use of NOT, OR, and LIKE operators, unlike the WHERE clause specified for the CONNECTIONS, TRANSACTIONS, and STATEMENTS event monitors.

If the WHERE clause is not specified, all entries flushed from the package cache will be monitored.

UPDATED_SINCE_BOUNDARY_TIME
Specifies that evicted entries, whose metrics were updated after the boundary time, should be collected by this event monitor. The boundary time is set by calling the MON_GET_PKG_CACHE_STMT table function with the value of the input key "updated_boundary_time" set as the name of this event monitor.

The boundary time is initially set to the activation timestamp of the event monitor.

NUM_EXECUTIONS > | < | <= | = | >= *integer-constant*
Specifies that the monitor element **num_executions** should be compared with the *integer-constant* in order to determine whether to generate an event. NUM_EXECUTIONS is the number of times that the section of the evicted entry was executed.

Note: The **num_executions** monitor element counts all executions of a statement, whether or not the execution of the statement contributed to the activity metrics that are reported.

STMT_EXEC_TIME > | < | <= | = | >= *integer-constant*
Specifies that the monitor element **stmt_exec_time** should be compared with the *integer-constant* in order to determine whether to generate an event. STMT_EXEC_TIME is the total aggregated time spent executing the statement of the evicted entry. The unit of time for the *integer-constant* must be specified as milliseconds.

COLLECT BASE DATA
Specifies that the same level of information returned by the MON_GET_PKG_CACHE_STMT table function should be captured. This is the default collect option.

COLLECT DETAILED DATA
Specifies that the BASE level information should be collected as well as the runtime executable section of the flushed entry.

WRITE TO
Specifies the target for the data.

TABLE
Indicates that the target for the event monitor data is a set of database tables. The event monitor separates the data stream into one or more logical data groups and inserts each group into a separate table. Data for groups having a target table is kept, whereas data for groups not having a target table is discarded. Each monitor element contained within a group is mapped to a table column with the same name. Only elements that have a corresponding table column are inserted into the table. Other elements are discarded.

formatted-event-table-info
Defines the target formatted event tables for the event monitor. This clause should specify each grouping that is to be recorded. However, if no *evm-group* clauses are specified, all groups for the event monitor type are recorded.

For more information about logical data groups, see "Logical data groups and event monitor output tables" in *Database Monitoring Guide and Reference*.

evm-group
Identifies a logical data group for which a target table is being defined. The value depends upon the type of event monitor, as shown in the following table:

Type of Event Monitor	evm-group Value
Package Cache	• PKGCACHE • PKGCACHE_METRICS • PKGCACHE_STMT_ARGS • CONTROL

UNFORMATTED EVENT TABLE
Specifies that the target for the event monitor is an unformatted event table. The unformatted event table is used to store collected package cache event monitor data. Data is stored in its original binary format within an inlined BLOB column. The BLOB column can contain multiple binary records of different types. The data in the BLOB column is not in a readable format and requires conversion, through use of the **db2evmonfmt** Java-based tool, EVMON_FORMAT_UE_TO_XML table function, or EVMON_FORMAT_UE_TO_TABLES procedure, into a consumable format such as an XML document or a relational table.

target-table-options
Identifies options for the target table. If a value for **target-table-options** is not specified, CREATE EVENT MONITOR FOR PACKAGE CACHE processing proceeds as follows:

- A derived table name is used (as explained in the description for TABLE *table-name*).
- A default table space is chosen using the same process as when a table is created without a table space name using CREATE TABLE.
- PCTDEACTIVATE is set to 100.

TABLE *table-name*
Specifies the name of the target table. The target table must be a non-partitioned table. If the name is unqualified, the table schema defaults to the value in the CURRENT SCHEMA special register. If a name is not provided for an unformatted event table, the unqualified name is equal to the *event-monitor-name*, that is, the unformatted event table will be named after the event monitor. If no name is provided for a formatted event table, the unqualified name is derived from *evm-group* and *event-monitor-name* as follows:

```
substring(evm-group CONCAT '_'
  CONCAT event-monitor-name,1,128)
```

IN *tablespace-name*
Specifies the table space in which the table is to be created. The CREATE EVENT MONITOR FOR PACKAGE CACHE statement does not create table spaces.

If a table space name is not provided, the table space is chosen using the same process as when a table is created without a table space name using CREATE TABLE.

The table space's page size affects the INLINE LOB lengths used. Consider specifying a table space with as large a page size as possible in order to improve the INSERT performance of the event monitor.

PCTDEACTIVATE ***integer***
If a table for the event monitor is being created in an automatic storage (non-temporary) or DMS table space, the PCTDEACTIVATE parameter specifies how full the table space must be before the event monitor automatically deactivates. The specified value, which represents a percentage, can range from 0 to 100, where 100 means that the event monitor deactivates when the table space becomes completely full. The default value assumed is 100 if PCTDEACTIVATE is not specified. This option is ignored for SMS table spaces.

Important: If the target table space has auto-resize enabled, set PCTDEACTIVATE parameter to 100. Alternatively, omit this clause entirely to have the default of 100 apply. Otherwise, the event monitor might deactivate unexpectedly if the table space reaches the threshold specified by PCTDEACTIVTATE before the table space is automatically resized.

AUTOSTART
Specifies that the event monitor is to be automatically activated whenever the database partition on which the event monitor runs is activated. This is the default behavior of the package cache event monitor.

MANUALSTART
Specifies that the event monitor must be activated manually using the SET EVENT MONITOR STATE statement. After a MANUALSTART event monitor has been activated, it can be deactivated by using the SET EVENT MONITOR STATE statement or by stopping the instance.

Notes

- The target table is created when the CREATE EVENT MONITOR FOR PACKAGE CACHE statement executes, if it doesn't already exist.
- During CREATE EVENT MONITOR FOR PACKAGE CACHE processing, if a table is found to have already been defined for use by another event monitor, the CREATE EVENT MONITOR FOR PACKAGE CACHE statement fails, and an error is passed back to the application program. A table is defined for use by another event monitor if the table name matches a value found in the SYSCAT.EVENTTABLES catalog view. If the table exists and is not defined for use by another event monitor, then the event monitor will re-use the table.
- Dropping the event monitor will not drop any tables. Any associated tables must be manually dropped after the event monitor is dropped.
- Lock event data is not automatically pruned from either unformatted event tables or regular tables created by this event monitor. An option for pruning data from UE tables is available when using the EVMON_FORMAT_UE_TO_TABLES procedure. For event monitors that write to regular tables, event data must be pruned manually.
- In a partitioned database environment, data is written to target tables only on the members where their table spaces exist. If a table space for a target table does not exist on a member, the event data that would be written to that target table is not captured on that member. This behavior allows users to choose a subset of members for monitoring, by creating a table space that exists only on certain members.
- In a partitioned database environment, data is written to target tables only on the member where the entries are evicted from the database package cache.
- In a partitioned database environment, if some target tables do not reside on a member, but other target tables do reside on that same member, only the data for the target unformatted event tables that do reside on that member is recorded.
- The FLUSH EVENT MONITOR statement is not applicable to this event monitor and will have no effect when issued against it.

- After the package cache event monitor is created, the filter and control options cannot be changed or altered. To change the filter and control options, the event monitor must be deactivated, dropped, and then recreated with the new filter and control options.

Use large table space for high throughput
Event data is inserted into the unformatted event table into an inlined BLOB data column. Normally, BLOB data is stored in a separate LOB table space and can experience additional performance overhead as a result. When inlined into the data page of the base table, the BLOB data does not experience this overhead. The database manager will automatically inline the BLOB data portion of an unformatted event table record if the size of the BLOB data is less than the table space page size minus the record prefix. Therefore, to achieve high efficiency and application throughput, it is suggested that you create the event monitor in as large a table space as possible, up to and including a 32 KB table space, and associated bufferpool.

Inline of package cache records
For the package cache event monitor, the size of the **stmt_text**, **comp_env_desc**, and the **section_env** monitor elements will determine if the package cache record will be inlined or not. If the total of these fields exceeds the table space size, then the record will not be inlined.

Determine if EVENT_DATA is inlined
Use the ADMIN_IS_INLINED and ADMIN_EST_INLINE_LENGTH functions to determine whether the record is inlined and get an estimate of the inline length that is required.

Restrictions

- During database deactivation, evicted entries will not be collected by the package cache event monitor.

Examples

- *Example 1:* This example creates a package cache event monitor called CACHEEVMON that will collect data related to package cache section eviction events and write the data to tables.

```
CREATE EVENT MONITOR CACHEEVMON
  FOR PACKAGE CACHE
  WRITE TO TABLE
```

This event monitor writes its output to the following tables:

PKGCACHE_CACHEEVMON
PKGCACHE_METRICS_CACHEEVMON
PKGCACHE_STMT_ARGS
CONTROL_CACHEEVMON

- *Example 2:* This example creates a package cache event monitor called CACHESTMTEVMON that will collect data related to package cache section eviction events and store it in the unformatted event table ALAN.STMTEVENTS.

```
CREATE EVENT MONITOR CACHESTMTEVMON
  FOR PACKAGE CACHE
  WRITE TO UNFORMATTED EVENT TABLE (TABLE ALAN.STMTEVENTS)
```

- *Example 3:* This example creates a package cache event monitor called CACHESTMTEVMON that will collect data related to package cache section eviction events and store it in the unformatted event table ALAN.STMTEVENTS in table space APPSPACE. The event monitor will deactivate when the table space becomes 85% full.

```
CREATE EVENT MONITOR CACHESTMTEVMON
  FOR PACKAGE CACHE
  WRITE TO UNFORMATTED EVENT TABLE
     (TABLE ALAN.STMTEVENTS IN APPSPACE PCTDEACTIVATE 85)
```

CREATE EVENT MONITOR (statistics)

The CREATE EVENT MONITOR (statistics) statement defines a monitor that will record statistics events that occur when using the database. The definition of the statistics event monitor also specifies where the database should record the events.

Invocation

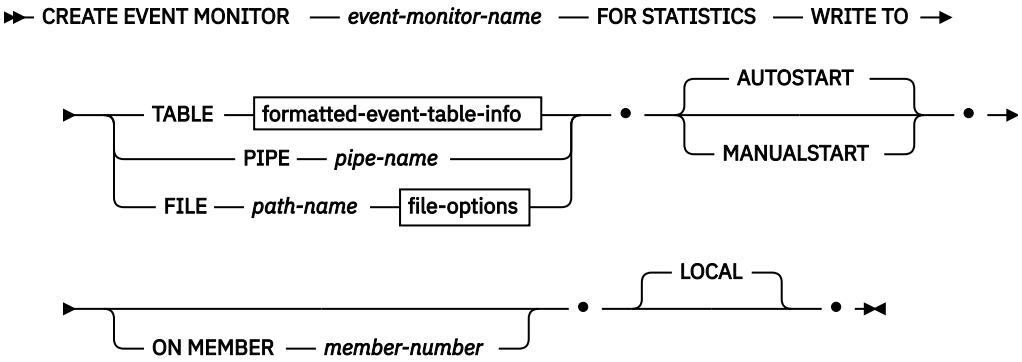
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

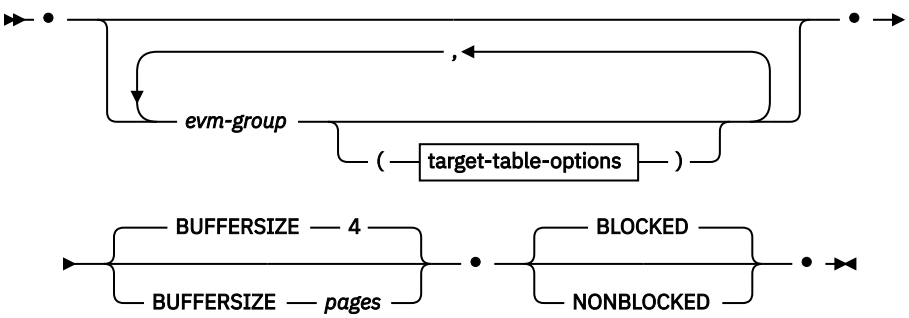
The privileges held by the authorization ID of the statement must include one of the following authorities:

- DBADM authority
- SQLADM authority

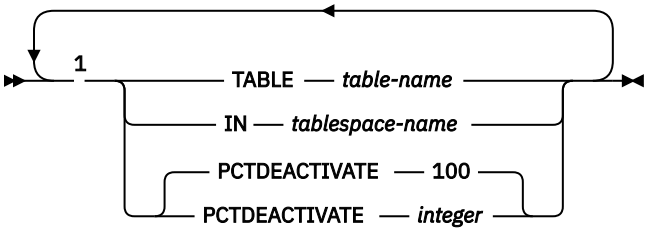
Syntax



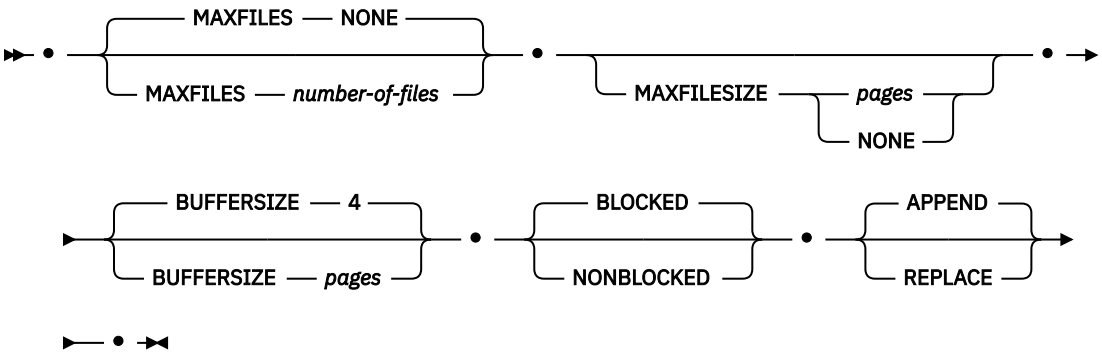
formatted-event-table-info



target-table-options



file-options



Notes:

[1] Each clause can be specified only once.
[2] Clauses can be separated with a space or a comma.

Description

event-monitor-name
Name of the event monitor. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *event-monitor-name* must not identify an event monitor that already exists in the catalog (SQLSTATE 42710).

FOR
Introduces the type of event to record.

STATISTICS
Specifies that the event monitor records a service class, workload, or work class event:

- Every *period* minutes, where *period* is the value of the **wlm_collect_int** database configuration parameter
- When the mon_collect_stats procedure is called

WRITE TO
Introduces the target for the data.

TABLE
Indicates that the target for the event monitor data is a set of database tables. The event monitor separates the data stream into one or more logical data groups and inserts each group into a separate table. Data for groups having a target table is kept, whereas data for groups not having a target table is discarded. Each monitor element contained within a group is mapped to a table column with the same name. Only elements that have a corresponding table column are inserted into the table. Other elements are discarded.

formatted-event-table-info
Defines the target tables for an event monitor. This clause should be specified for each grouping that is to be recorded. However, if no evm-group-info clauses are specified, all groups for the event monitor type are recorded.

For more information about logical data groups, see "Logical data groups and event monitor output tables" in *Database Monitoring Guide and Reference*.

evm-group
Identifies the logical data group for which a target table is being defined. The value depends upon the type of event monitor, as shown in the following table:

Type of Event Monitor	evm-group Value
Statistics	• CONTROL • HISTOGRAMBIN • OSMETRICS • QSTATS • SCMETRICS • SCSTATS • SUPERCLASSMETRICS • SUPERCLASSSTATS • WCSTATS • WLMETRICS • WLSTATS

target-table-options
Identifies the target table for the group.

TABLE *table-name*
Specifies the name of the target table. The target table must be a non-partitioned table. If the name is unqualified, the table schema defaults to the value in the CURRENT SCHEMA special register. If no name is provided, the unqualified name is derived from *evm-group* and *event-monitor-name* as follows:

```
substring(evm-group CONCAT '_'
  CONCAT event-monitor-name,1,128)
```

IN *tablespace-name*
Defines the table space in which the table is to be created. If no table space name is provided, the table space is chosen using the same process as when a table is created without a table space name using CREATE TABLE.

PCTDEACTIVATE *integer*
If a table for the event monitor is being created in an automatic storage (non-temporary) or DMS table space, the PCTDEACTIVATE parameter specifies how full the table space must be before the event monitor automatically deactivates. The specified value, which represents a percentage, can range from 0 to 100, where 100 means that the event monitor deactivates when the table space becomes completely full. The default value assumed is 100 if PCTDEACTIVATE is not specified. This option is ignored for SMS table spaces.

Important: If the target table space has auto-resize enabled, set PCTDEACTIVATE parameter to 100. Alternatively, omit this clause entirely to have the default of 100 apply. Otherwise, the event monitor might deactivate unexpectedly if the table space reaches the threshold specified by PCTDEACTIVTATE before the table space is automatically resized.

If a value for *target-table-options* is not specified, CREATE EVENT MONITOR processing proceeds as follows:

- A derived table name is used.
- A default table space is chosen.
- PCTDEACTIVATE defaults to 100.

BUFFERSIZE *pages*
Specifies the size of the event monitor buffers (in units of 4K pages). Table event monitors insert all data from a buffer, and issues a COMMIT once the buffer has been processed. The larger the buffers, the larger the commit scope used by the event monitor. Highly

active event monitors should have larger buffers than relatively inactive event monitors. When a monitor is started, two buffers of the specified size are allocated. Event monitors use double buffering to permit asynchronous I/O.

The default size of each buffer is 4 pages (two 16K buffers are allocated). The minimum size is 1 page. The maximum size of the buffers is limited by the size of the monitor heap, because the buffers are allocated from that heap. If many event monitors are being used at the same time, increase the size of the **mon_heap_sz** database manager configuration parameter.

Note: This keyword is not supported for statistics event monitors. The compiler accepts this keyword, but the keyword has no effect on the behavior of the event monitor.

BLOCKED
Specifies that each agent that generates an event should wait for an event buffer to be written out to disk if the agent determines that both event buffers are full. BLOCKED should be selected to guarantee no event data loss. This is the default option.

Note: This keyword is not supported for statistics event monitors. The compiler accepts this keyword, but the keyword has no effect for statistics event monitors. The event monitor is created as if the BLOCKED keyword was specified.

NONBLOCKED
Specifies that each agent that generates an event should not wait for the event buffer to be written out to disk if the agent determines that both event buffers are full. NONBLOCKED event monitors do not slow down database operations to the extent of BLOCKED event monitors. However, NONBLOCKED event monitors are subject to data loss on highly active systems.

PIPE
Specifies that the target for the event monitor data is a named pipe. The event monitor writes the data to the pipe in a single stream (that is, as if it were a single, infinitely long file). When writing the data to a pipe, an event monitor does not perform blocked writes. If there is no room in the pipe buffer, then the event monitor will discard the data. It is the monitoring application's responsibility to read the data promptly if it wishes to ensure no data loss.

pipe-name
The name of the pipe (FIFO on AIX) to which the event monitor will write the data.

The naming rules for pipes are platform specific.

Operating system	Naming rules
AIX	Pipe names are treated like file names. As a result, relative pipe names are permitted, and are treated like relative path-names (see description for *path-name*).
Linux	Pipe names are treated like file names. As a result, relative pipe names are permitted, and are treated like relative path-names (see description for *path-name*).
Windows	There is a special syntax for a pipe name and, as a result, absolute pipe names are required.

The existence of the pipe will not be checked at event monitor creation time. It is the responsibility of the monitoring application to have created and opened the pipe for reading at the time that the event monitor is activated. If the pipe is not available at this time, then the event monitor will turn itself off, and will log an error. (That is, if the event monitor was activated at database start time as a result of the AUTOSTART option, then the event monitor will log an error in the system error log.) If the event monitor is activated via the SET EVENT MONITOR STATE SQL statement, then that statement will fail (SQLSTATE 58030).

FILE

Indicates that the target for the event monitor data is a file (or set of files). The event monitor writes out the stream of data as a series of 8 character numbered files, with the extension "evt". (for example, 00000000.evt, 00000001.evt, and 00000002.evt). The data should be considered to be one logical file even though the data is broken up into smaller pieces (that is, the start of the data stream is the first byte in the file 00000000.evt; the end of the data stream is the last byte in the file nnnnnnnn.evt).

The maximum size of each file can be defined as well as the maximum number of files. An event monitor will never split a single event record across two files. However, an event monitor may write related records in two different files. It is the responsibility of the application that uses this data to keep track of such related information when processing the event files.

path-name

The name of the directory in which the event monitor should write the event files data. The path must be known at the server; however, the path itself could reside on another database partition (for example, an NFS mounted file). A string constant must be used when specifying the *path-name*.

The directory does not have to exist at CREATE EVENT MONITOR time. However, a check is made for the existence of the target path when the event monitor is activated. At that time, if the target path does not exist, an error (SQLSTATE 428A3) is raised.

If an absolute path is specified, the specified path will be the one used.

In a Db2 pureScale environment, if a relative path is specified, then the path relative to the database owning directory in the database directory will be used.

In environments other than Db2 pureScale, if a relative path (a path that does not start with the root) is specified, then the path relative to the DB2EVENT directory in the database directory will be used.

It is possible to specify two or more event monitors that have the same target path. However, once one of the event monitors has been activated for the first time, and as long as the target directory is not empty, it will be impossible to activate any of the other event monitors.

file-options

Specifies the options for the file format.

MAXFILES NONE

Specifies that there is no limit to the number of event files that the event monitor will create. This is the default.

MAXFILES *number-of-files*

Specifies that there is a limit on the number of event monitor files that will exist for a particular event monitor at any time. Whenever an event monitor has to create another file, it will check to make sure that the number of .evt files in the directory is less than *number-of-files*. If this limit has already been reached, then the event monitor will turn itself off.

If an application removes the event files from the directory after they have been written, then the total number of files that an event monitor can produce can exceed *number-of-files*. This option has been provided to allow a user to guarantee that the event data will not consume more than a specified amount of disk space.

MAXFILESIZE *pages*

Specifies that there is a limit to the size of each event monitor file. Whenever an event monitor writes a new event record to a file, it checks that the file will not grow to be greater than *pages* (in units of 4K pages). If the resulting file would be too large, then the event monitor switches to the next file. The default for this option is:

- Linux - 1000 4K pages
- UNIX - 1000 4K pages
- Windows - 200 4K pages

The number of pages must be greater than at least the size of the event buffer in pages. If this requirement is not met, then an error (SQLSTATE 428A4) is raised.

MAXFILESIZE NONE
Specifies that there is no set limit on a file's size. If MAXFILESIZE NONE is specified, then MAXFILES 1 must also be specified. This option means that one file will contain all of the event data for a particular event monitor. In this case the only event file will be 00000000.evt.

BUFFERSIZE *pages*
Specifies the size of the event monitor buffers (in units of 4K pages). All event monitor file I/O is buffered to improve the performance of the event monitors. The larger the buffers, the less I/O will be performed by the event monitor. Highly active event monitors should have larger buffers than relatively inactive event monitors. When the monitor is started, two buffers of the specified size are allocated. Event monitors use double buffering to permit asynchronous I/O.

The default size of each buffer is 4 pages (two 16K buffers are allocated). The minimum size is 1 page. The maximum size of the buffers is limited by the value of the MAXFILESIZE parameter, as well as the size of the monitor heap, because the buffers are allocated from that heap. If many event monitors are being used at the same time, increase the size of the **mon_heap_sz** database manager configuration parameter.

Event monitors that write their data to a pipe also have two internal (non-configurable) buffers that are each 1 page in size. These buffers are also allocated from the monitor heap (MON_HEAP). For each active event monitor that has a pipe target, increase the size of the database heap by 2 pages.

Note: This keyword is not supported for statistics event monitors. The compiler accepts this keyword, but the keyword has no effect on the behavior of the event monitor.

BLOCKED
Specifies that each agent that generates an event should wait for an event buffer to be written out to disk if the agent determines that both event buffers are full. BLOCKED should be selected to guarantee no event data loss. This is the default option.

NONBLOCKED
Specifies that each agent that generates an event should not wait for the event buffer to be written out to disk if the agent determines that both event buffers are full. NONBLOCKED event monitors do not slow down database operations to the extent of BLOCKED event monitors. However, NONBLOCKED event monitors are subject to data loss on highly active systems.

Note: This keyword is not supported for statistics event monitors. The compiler accepts this keyword, but the keyword has no effect for statistics event monitors. The event monitor is created as if the BLOCKED keyword was specified.

APPEND
Specifies that if event data files already exist when the event monitor is turned on, then the event monitor will append the new event data to the existing stream of data files. When the event monitor is reactivated, it will resume writing to the event files as if it had never been turned off. APPEND is the default option.

The APPEND option does not apply at CREATE EVENT MONITOR time, if there is existing event data in the directory where the newly created event monitor is to write its event data.

REPLACE
Specifies that if event data files already exist when the event monitor is turned on, then the event monitor will erase all of the event files and start writing data to file 00000000.evt.

MANUALSTART
Specifies that the event monitor must be activated manually using the SET EVENT MONITOR STATE statement. After a MANUALSTART event monitor has been activated, it can be deactivated only by using the SET EVENT MONITOR STATE statement or by stopping the instance.

AUTOSTART
Specifies that the event monitor is to be automatically activated whenever the member on which the event monitor runs is activated. This is the default behavior of the statistics event monitor.

ON MEMBER *member-number*
Specifies the member on which a file or pipe event monitor is to run. When the monitoring scope is defined as LOCAL, data is collected only on the specified member. The I/O component will physically run on the specified member, writing records to the specified file or pipe.

When Db2 pureScale feature is enabled, -1 is the default.

If -1 is specified, it allows the I/O component to run from any active member. Additionally, in the event that the I/O component is no longer able to run on a given member, the event monitor will be restarted with the I/O component running on another available active member.

This clause is not valid for table event monitors. In a partitioned database environment, write-to-table event monitors will run and write events on all database partitions where table spaces for target tables are defined.

In a Db2 pureScale environment, write-to-table event monitors will record events on all active members.

If this clause is not specified and the Db2 pureScale feature is not enabled, the currently connected database partition number (for the application) is used.

If this clause is not specified and Db2 pureScale is enabled, the I/O component is able to run on any currently connected member.

LOCAL
The event monitor reports only on the member that is running. It gives a partial trace of the database activity. This is the default.

This clause is valid for file or pipe monitors. It is not valid for table event monitors.

GLOBAL is not a valid scope for this type of event monitor.

Rules

- The STATISTICS event type cannot be combined with any other event types in a particular event monitor definition.

Notes

- Event monitor definitions are recorded in the SYSCAT.EVENTMONITORS catalog view. The events themselves are recorded in the SYSCAT.EVENTS catalog view. The names of target tables are recorded in the SYSCAT.EVENTTABLES catalog view.
- If the member on which the event monitor is to run is not active, event monitor activation occurs when that member next activates.
- After an event monitor is activated, it behaves like an autostart event monitor until that event monitor is explicitly deactivated or the instance is recycled. That is, if an event monitor is active when a member is deactivated, and that member is subsequently reactivated, the event monitor is also explicitly reactivated.
- If you create the event monitor such that the logical data groups event_scstats or event_wlstats are included in the event monitor output, metrics are reported in two XML documents contained in the event monitor output. The monitor elements reported in the `metrics` document show the change in value for the monitor elements since the last time statistics were collected. The elements reported in

details_xml are the same monitor elements, however, they show the values since the database was activated. That is, they continue to increase until the database is deactivated.

Important: The XML document details_xml is deprecated in the statistics event monitor, and might be removed in a future release. For more information, see "Reporting of metrics in details_xml by the statistics event monitor has been deprecated" at http://www.ibm.com/support/knowledgecenter/SSEPGG_10.1.0/com.ibm.db2.luw.wn.doc/doc/i0060390.html.

- ***Write to table event monitors***: General notes:
  - All target tables are created when the CREATE EVENT MONITOR statement executes.
  - If the creation of a table fails for any reason, an error is passed back to the application program, and the CREATE EVENT MONITOR statement fails.
  - A target table can only be used by one event monitor. During CREATE EVENT MONITOR processing, if a target table is found to have already been defined for use by another event monitor, the CREATE EVENT MONITOR statement fails, and an error is passed back to the application program. A table is defined for use by another event monitor if the table name matches a value found in the SYSCAT.EVENTTABLES catalog view.
  - During CREATE EVENT MONITOR processing, if a table already exists, but is *not* defined for use by another event monitor, no table is created, and processing continues. A warning is passed back to the application program.
  - Any table spaces must exist before the CREATE EVENT MONITOR statement is executed. The CREATE EVENT MONITOR statement does not create table spaces.
  - If specified, the LOCAL and GLOBAL keywords are ignored. With WRITE TO TABLE event monitors, an event monitor output process or thread is started on each member in the instance, and each of these processes reports data only for the member on which it is running.
  - The following event types from the flat monitor log file or pipe format are not recorded by write to table event monitors:
    - LOG_STREAM_HEADER
    - LOG_HEADER
    - DB_HEADER (Elements db_name and db_path are not recorded. The element conn_time is recorded in CONTROL.)
  - In a partitioned database environment, data is only written to target tables on the database partitions where their table spaces exist. If a table space for a target table does not exist on some database partition, data for that target table is ignored. This behavior allows users to choose a subset of member for monitoring, by creating a table space that exists only on certain member.

    In a Db2 pureScale environment, data will be written from every member.

    In a partitioned database environment, if some target tables do not reside on a database partition, but other target tables do reside on that same database partition, only the data for the target tables that do reside on that database partition is recorded.
  - Users must manually prune all target tables.

  Table Columns:

  - Column names in a table match an event monitor element identifier. Any event monitor element that does not have a corresponding target table column is ignored.
  - Use the db2evtbl command to build a CREATE EVENT MONITOR command that includes a complete list of elements for a group.
  - The types of columns being used for monitor elements correlate to the following mapping:

```
SQLM_TYPE_STRING                    CHAR[n], VARCHAR[n] or CLOB(n)
                                    (If the data in the event monitor
                                    record exceeds n bytes,
                                    it is truncated.)
SQLM_TYPE_U8BIT and SQLM_TYPE_8BIT   SMALLINT, INTEGER or BIGINT
SQLM_TYPE_16BIT and SQLM_TYPE_U16BIT SMALLINT, INTEGER or BIGINT
SQLM_TYPE_32BIT and SQLM_TYPE_U32BIT INTEGER or BIGINT
```

```
SQLM_TYPE_U64BIT and SQLM_TYPE_64BIT BIGINT
sqlm_timestamp                       TIMESTAMP
sqlm_time(elapsed time)              BIGINT
sqlca:
  sqlerrmc                           VARCHAR[72]
  sqlstate                           CHAR[5]
  sqlwarn                            CHAR[11]
  other fields                       INTEGER or BIGINT
```

- Columns are defined to be NOT NULL.
- Unlike other target tables, the columns in the CONTROL table do not match monitor element identifiers. Columns are defined as follows:

Column Name	Data Type	Nullable	Description
PARTITION_KEY	INTEGER	N	Distribution key (partitioned database only)
PARTITION_NUMBER	INTEGER	N	Database partition number (partitioned database only)
EVMONNAME	VARCHAR(128)	N	Name of the event monitor
MESSAGE	VARCHAR(128)	N	Describes the nature of the MESSAGE_TIME column. For more details see, "message - Control Table Message monitor element" in the *Database Monitoring Guide and Reference*
MESSAGE_TIME	TIMESTAMP	N	Timestamp

- In a partitioned database environment, the first column of each table is named PARTITION_KEY, is NOT NULL, and is of type INTEGER. This column is used as the distribution key for the table. The value of this column is chosen so that each event monitor process inserts data into the member on which the process is running; that is, insert operations are performed locally on the member where the event monitor process is running. On any database partition, the PARTITION_KEY field will contain the same value. This means that if a database partition is dropped and data redistribution is performed, all data on the dropped database partition will go to one other database partition instead of being evenly distributed. Therefore, before removing a database partition, consider deleting all table rows on that database partition.
- In a partitioned database environment, a column named PARTITION_NUMBER can be defined for each table. This column is NOT NULL and is of type INTEGER. It contains the number of the database partition on which the data was inserted. Unlike the PARTITION_KEY column, the PARTITION_NUMBER column is not mandatory. The PARTITION_NUMBER column is not allowed in a non-partitioned database environment.

Table Attributes:

- Default table attributes are used. Besides distribution key (partitioned databases only), no extra options are specified when creating tables.
- Indexes on the table can be created.
- Extra table attributes (such as volatile, RI, triggers, constraints, and so on) can be added, but the event monitor process (or thread) will ignore them.

– If "not logged initially" is added as a table attribute, it is turned off at the first COMMIT, and is not set back on.

Event Monitor Activation:

– When an event monitor activates, all target table names are retrieved from the SYSCAT.EVENTTABLES catalog view.
– In a partitioned database environment, activation processing occurs on every member of the instance. On a particular member, activation processing determines the table spaces and database partition groups for each target table. The event monitor only activates on a member if at least one target table exists on that database partition. Moreover, if some target table is not found on a database partition, that target table is flagged so that data destined for that table is dropped during runtime processing.
– If a target table does not exist when the event monitor activates (or, in a partitioned database environment, if the table space does not reside on a database partition), activation continues, and data that would otherwise be inserted into this table is ignored.
– Activation processing validates each target table. If validation fails, activation of the event monitor fails, and messages are written to the administration log.
– During activation in a partitioned database environment, the CONTROL table rows for FIRST_CONNECT and EVMON_START are only inserted on the catalog database partition. This requires that the table space for the control table exist on the catalog database partition. If it does not exist on the catalog database partition, these inserts are not performed.
– In a partitioned database environment, if a member is not yet active when a write to table event monitor is activated, the event monitor will be activated the next time that member is activated.

Run Time:

– An event monitor runs with DATAACCESS authority.
– If, while an event monitor is active, an insert operation into a target table fails:
  - Uncommitted changes are rolled back.
  - A message is written to the administration log.
  - The event monitor is deactivated.
– If an event monitor is active, it performs a local COMMIT when it has finished processing an event monitor buffer.
– In an environment other than a partitioned database or a Db2 pureScale environment, all write to table event monitors are deactivated when the last application terminates (and the database has not been explicitly activated).

  In a Db2 pureScale environment, write to table event monitors are deactivated on a given member when the member stops and is reactivated when the member restarts.

  In a partitioned database environment, write to table event monitors are deactivated when the catalog partition deactivates.
– The DROP EVENT MONITOR statement does not drop target tables.
– Whenever a write-to-table event monitor activates, it will acquire IN table locks on each target table in order to prevent them from being modified while the event monitor is active. Table locks are maintained on all tables while the event monitor is active. If exclusive access is required on any of the target tables (for example, when a utility is to be run), first deactivate the event monitor to release the table locks before attempting such access.

- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  – DBPARTITIONNUM or NODE can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  – Commas can be used to separate multiple options in the *target-table-options* clause

Example

Define a statistics event monitor named DBSTATISTICS

```
CREATE EVENT MONITOR DBSTATISTICS
    FOR STATISTICS
    WRITE TO TABLE
    SCSTATS (TABLE SCSTATS_DBSTATISTICS
             IN USERSPACE1
             PCTDEACTIVATE 100),
    SCMETRICS (TABLE SCMETRICS_DBSTATISTICS
             IN USERSPACE1
             PCTDEACTIVATE 100),
    SUPERCLASSSTATS (TABLE SUPERCLASSTATS_DBSTATISTICS
             IN USERSPACE1
             PCTDEACTIVATE 100),
    SUPERCLASSMETRICS (TABLE SUPERCLASSMETRICS_DBSTATISTICS
             IN USERSPACE1
             PCTDEACTIVATE 100),
    WCSTATS (TABLE WCSTATS_DBSTATISTICS
             IN USERSPACE1
             PCTDEACTIVATE 100),
    WLSTATS (TABLE WLSTATS_DBSTATISTICS
             IN USERSPACE1
             PCTDEACTIVATE 100),
    QSTATS (TABLE QSTATS_DBSTATISTICS
             IN USERSPACE1
             PCTDEACTIVATE 100),
    HISTOGRAMBIN (TABLE HISTOGRAMBIN_DBSTATISTICS
             IN USERSPACE1
             PCTDEACTIVATE 100),
    OSMETRICS (TABLE OSMETRICS_DBSTATISTICS
             IN USERSPACE1
             PCTDEACTIVATE 100),
    CONTROL (TABLE CONTROL_DBSTATISTICS
             IN USERSPACE1
             PCTDEACTIVATE 100)
    AUTOSTART;
```

CREATE EVENT MONITOR (threshold violations)

The CREATE EVENT MONITOR (threshold violations) statement defines a monitor that will record threshold violation events that occur when using the database. The definition of the threshold violations event monitor also specifies where the database should record the events.

Invocation

The threshold violations event monitor can collect more information about the application that violated the threshold. The addition of these monitor elements does not affect existing threshold violations event monitors, but in order to collect the additional application information existing monitors must dropped and recreated.

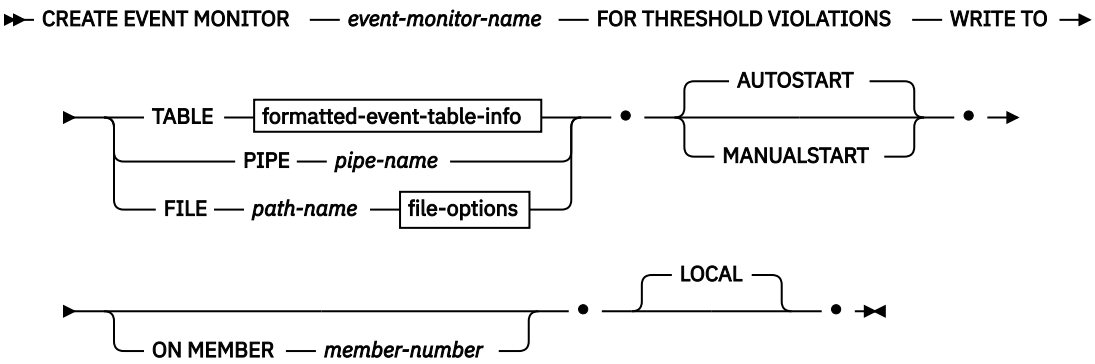
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

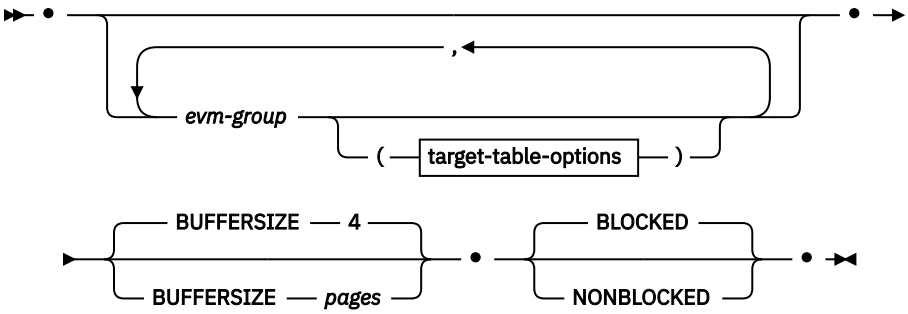
The privileges held by the authorization ID of the statement must include one of the following authorities:

- DBADM authority
- SQLADM authority

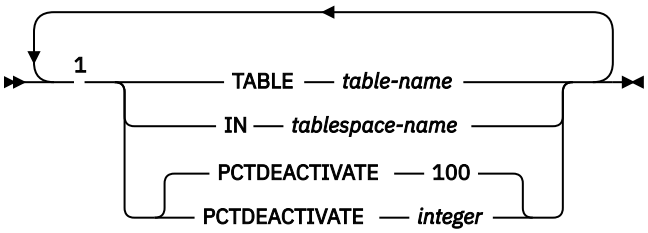
Syntax



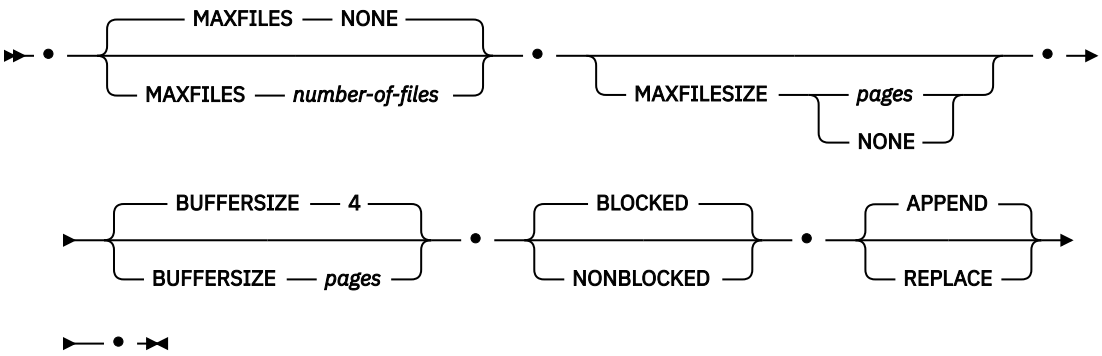
formatted-event-table-info



target-table-options



file-options



Notes:

[1] Each clause can be specified only once.
[2] Clauses can be separated with a space or a comma.

Description

event-monitor-name
Name of the event monitor. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *event-monitor-name* must not identify an event monitor that already exists in the catalog (SQLSTATE 42710).

FOR
Introduces the type of event to record.

THRESHOLD VIOLATIONS
Specifies that the event monitor records a threshold violation event when a threshold is violated. Such events can be recorded at any point in the life of an activity, not just at completion.

WRITE TO
Introduces the target for the data.

TABLE
Indicates that the target for the event monitor data is a set of database tables. The event monitor separates the data stream into one or more logical data groups and inserts each group into a separate table. Data for groups having a target table is kept, whereas data for groups not having a target table is discarded. Each monitor element contained within a group is mapped to a table column with the same name. Only elements that have a corresponding table column are inserted into the table. Other elements are discarded.

formatted-event-table-info
Defines the target tables for an event monitor. This clause should be specified for each grouping that is to be recorded. However, if no evm-group-info clauses are specified, all groups for the event monitor type are recorded.

For more information about logical data groups, see "Logical data groups and event monitor output tables" in *Database Monitoring Guide and Reference*.

evm-group
Identifies the logical data group for which a target table is being defined. The value depends upon the type of event monitor, as shown in the following table:

Type of Event Monitor	evm-group Value
Threshold violations	• THRESHOLDVIOLATIONS • CONTROL

target-table-options
Identifies the target table for the group.

TABLE *table-name*
Specifies the name of the target table. The target table must be a non-partitioned table. If the name is unqualified, the table schema defaults to the value in the CURRENT SCHEMA special register. If no name is provided, the unqualified name is derived from *evm-group* and *event-monitor-name* as follows:

```
substring(evm-group CONCAT '_'
  CONCAT event-monitor-name,1,128)
```

IN *tablespace-name*
Defines the table space in which the table is to be created. If no table space name is provided, the table space is chosen using the same process as when a table is created without a table space name using CREATE TABLE.

PCTDEACTIVATE *integer*
If a table for the event monitor is being created in an automatic storage (non-temporary) or DMS table space, the PCTDEACTIVATE parameter specifies how full the table space must be before the event monitor automatically deactivates. The specified value, which represents a percentage, can range from 0 to 100, where

100 means that the event monitor deactivates when the table space becomes completely full. The default value assumed is 100 if PCTDEACTIVATE is not specified. This option is ignored for SMS table spaces.

Important: If the target table space has auto-resize enabled, set PCTDEACTIVATE parameter to 100. Alternatively, omit this clause entirely to have the default of 100 apply. Otherwise, the event monitor might deactivate unexpectedly if the table space reaches the threshold specified by PCTDEACTIVTATE before the table space is automatically resized.

If a value for *target-table-options* is not specified, CREATE EVENT MONITOR processing proceeds as follows:

- A derived table name is used.
- A default table space is chosen.
- The PCTDEACTIVATE parameter defaults to 100.

BUFFERSIZE ***pages***
Specifies the size of the event monitor buffers (in units of 4K pages). Table event monitors insert all data from a buffer, and issues a COMMIT once the buffer has been processed. The larger the buffers, the larger the commit scope used by the event monitor. Highly active event monitors should have larger buffers than relatively inactive event monitors. When a monitor is started, two buffers of the specified size are allocated. Event monitors use double buffering to permit asynchronous I/O.

The default size of each buffer is 4 pages (two 16K buffers are allocated). The minimum size is 1 page. The maximum size of the buffers is limited by the size of the monitor heap, because the buffers are allocated from that heap. If many event monitors are being used at the same time, increase the size of the **mon_heap_sz** database manager configuration parameter.

Note: This keyword is not supported for threshold violation event monitors. The compiler accepts this keyword, but the keyword has no effect on the behavior of the event monitor.

BLOCKED
Specifies that each agent that generates an event should wait for an event buffer to be written out to disk if the agent determines that both event buffers are full. BLOCKED should be selected to guarantee no event data loss. This is the default option.

NONBLOCKED
Specifies that each agent that generates an event should not wait for the event buffer to be written out to disk if the agent determines that both event buffers are full. NONBLOCKED event monitors do not slow down database operations to the extent of BLOCKED event monitors. However, NONBLOCKED event monitors are subject to data loss on highly active systems.

Note: This keyword is not supported for threshold violation event monitors. The compiler accepts this keyword, but the keyword has no effect for threshold violation event monitors. The event monitor is created as if the BLOCKED keyword was specified.

PIPE
Specifies that the target for the event monitor data is a named pipe. The event monitor writes the data to the pipe in a single stream (that is, as if it were a single, infinitely long file). When writing the data to a pipe, an event monitor does not perform blocked writes. If there is no room in the pipe buffer, then the event monitor will discard the data. It is the monitoring application's responsibility to read the data promptly if it wishes to ensure no data loss.

pipe-name
The name of the pipe (FIFO on AIX) to which the event monitor will write the data.

The naming rules for pipes are platform specific.

Operating system	Naming rules
AIX	Pipe names are treated like file names. As a result, relative pipe names are permitted, and are treated like relative path-names (see description for *path-name*).
Linux	Pipe names are treated like file names. As a result, relative pipe names are permitted, and are treated like relative path-names (see description for *path-name*).
Windows	There is a special syntax for a pipe name and, as a result, absolute pipe names are required.

The existence of the pipe will not be checked at event monitor creation time. It is the responsibility of the monitoring application to have created and opened the pipe for reading at the time that the event monitor is activated. If the pipe is not available at this time, then the event monitor will turn itself off, and will log an error. (That is, if the event monitor was activated at database start time as a result of the AUTOSTART option, then the event monitor will log an error in the system error log.) If the event monitor is activated via the SET EVENT MONITOR STATE SQL statement, then that statement will fail (SQLSTATE 58030).

FILE

Indicates that the target for the event monitor data is a file (or set of files). The event monitor writes out the stream of data as a series of 8 character numbered files, with the extension "evt". (for example, 00000000.evt, 00000001.evt, and 00000002.evt). The data should be considered to be one logical file even though the data is broken up into smaller pieces (that is, the start of the data stream is the first byte in the file 00000000.evt; the end of the data stream is the last byte in the file nnnnnnnn.evt).

The maximum size of each file can be defined as well as the maximum number of files. An event monitor will never split a single event record across two files. However, an event monitor may write related records in two different files. It is the responsibility of the application that uses this data to keep track of such related information when processing the event files.

path-name

The name of the directory in which the event monitor should write the event files data. The path must be known at the server; however, the path itself could reside on another database partition (for example, an NFS mounted file). A string constant must be used when specifying the *path-name*.

The directory does not have to exist at CREATE EVENT MONITOR time. However, a check is made for the existence of the target path when the event monitor is activated. At that time, if the target path does not exist, an error (SQLSTATE 428A3) is raised.

If an absolute path is specified, the specified path will be the one used.

In environments other than Db2 pureScale, if a relative path (a path that does not start with the root) is specified, then the path relative to the DB2EVENT directory in the database directory will be used.

In a Db2 pureScale environment, if a relative path is specified, then the path relative to the database owning directory in the database directory will be used.

It is possible to specify two or more event monitors that have the same target path. However, once one of the event monitors has been activated for the first time, and as long as the target directory is not empty, it will be impossible to activate any of the other event monitors.

file-options

Specifies the options for the file format.

MAXFILES NONE
Specifies that there is no limit to the number of event files that the event monitor will create. This is the default.

MAXFILES *number-of-files*
Specifies that there is a limit on the number of event monitor files that will exist for a particular event monitor at any time. Whenever an event monitor has to create another file, it will check to make sure that the number of .evt files in the directory is less than *number-of-files*. If this limit has already been reached, then the event monitor will turn itself off.

If an application removes the event files from the directory after they have been written, then the total number of files that an event monitor can produce can exceed *number-of-files*. This option has been provided to allow a user to guarantee that the event data will not consume more than a specified amount of disk space.

MAXFILESIZE *pages*
Specifies that there is a limit to the size of each event monitor file. Whenever an event monitor writes a new event record to a file, it checks that the file will not grow to be greater than *pages* (in units of 4K pages). If the resulting file would be too large, then the event monitor switches to the next file. The default for this option is:

- Linux - 1000 4K pages
- UNIX - 1000 4K pages
- Windows - 200 4K pages

The number of pages must be greater than at least the size of the event buffer in pages. If this requirement is not met, then an error (SQLSTATE 428A4) is raised.

MAXFILESIZE NONE
Specifies that there is no set limit on a file's size. If MAXFILESIZE NONE is specified, then MAXFILES 1 must also be specified. This option means that one file will contain all of the event data for a particular event monitor. In this case the only event file will be 00000000.evt.

BUFFERSIZE *pages*
Specifies the size of the event monitor buffers (in units of 4K pages). All event monitor file I/O is buffered to improve the performance of the event monitors. The larger the buffers, the less I/O will be performed by the event monitor. Highly active event monitors should have larger buffers than relatively inactive event monitors. When the monitor is started, two buffers of the specified size are allocated. Event monitors use double buffering to permit asynchronous I/O.

The default size of each buffer is 4 pages (two 16K buffers are allocated). The minimum size is 1 page. The maximum size of the buffers is limited by the value of the MAXFILESIZE parameter, as well as the size of the monitor heap, because the buffers are allocated from that heap. If many event monitors are being used at the same time, increase the size of the **mon_heap_sz** database manager configuration parameter.

Event monitors that write their data to a pipe also have two internal (non-configurable) buffers that are each 1 page in size. These buffers are also allocated from the monitor heap (MON_HEAP). For each active event monitor that has a pipe target, increase the size of the database heap by 2 pages.

Note: This keyword is not supported for threshold violation event monitors. The compiler accepts this keyword, but the keyword has no effect on the behavior of the event monitor.

BLOCKED
Specifies that each agent that generates an event should wait for an event buffer to be written out to disk if the agent determines that both event buffers are full. BLOCKED should be selected to guarantee no event data loss. This is the default option.

NONBLOCKED
Specifies that each agent that generates an event should not wait for the event buffer to be written out to disk if the agent determines that both event buffers are full. NONBLOCKED event monitors do not slow down database operations to the extent of BLOCKED event monitors. However, NONBLOCKED event monitors are subject to data loss on highly active systems.

Note: This keyword is not supported for threshold violation event monitors. The compiler accepts this keyword, but the keyword has no effect for threshold violation event monitors. The event monitor is created as if the BLOCKED keyword was specified.

APPEND
Specifies that if event data files already exist when the event monitor is turned on, then the event monitor will append the new event data to the existing stream of data files. When the event monitor is reactivated, it will resume writing to the event files as if it had never been turned off. APPEND is the default option.

The APPEND option does not apply at CREATE EVENT MONITOR time, if there is existing event data in the directory where the newly created event monitor is to write its event data.

REPLACE
Specifies that if event data files already exist when the event monitor is turned on, then the event monitor will erase all of the event files and start writing data to file 00000000.evt.

MANUALSTART
Specifies that the event monitor must be activated manually using the SET EVENT MONITOR STATE statement. After a MANUALSTART event monitor has been activated, it can be deactivated only by using the SET EVENT MONITOR STATE statement or by stopping the instance.

AUTOSTART
Specifies that the event monitor is to be automatically activated whenever the database partition on which the event monitor runs is activated. This is the default behavior of the threshold violations event monitor.

ON MEMBER *member-number*
Specifies the member on which a file or pipe event monitor is to run. When the monitoring scope is defined as LOCAL, data is collected only on the member. The I/O component will physically run on the specified member, writing records to the specified file or pipe.

When the Db2 pureScale is enabled, -1 is the default.

If the value is -1, it allows the I/O component to run from any active member. Additionally, in the event that the I/O component is no longer able to run on a given member, the event monitor will be restarted with the I/O component running on another available active member.

This clause is not valid for table event monitors. In a partitioned database environment, write-to-table event monitors will run and write events on all database partitions where table spaces for target tables are defined.

In a Db2 pureScale environment, write-to-table event monitors will record events on all active members.

If this clause is not specified and Db2 pureScale is not enabled, the currently connected member is used.

If this clause is not specified and Db2 pureScale is enabled, the I/O component is able to run on any currently connected member.

LOCAL
The event monitor reports only on the member that is running. It gives a partial trace of the database activity. This is the default.

This clause is valid for file or pipe monitors. It is not valid for table event monitors.

GLOBAL is not a valid scope for this type of event monitor.

Rules

- The THRESHOLD VIOLATIONS event type cannot be combined with any other event types in a particular event monitor definition.

Notes

- Event monitor definitions are recorded in the SYSCAT.EVENTMONITORS catalog view. The events themselves are recorded in the SYSCAT.EVENTS catalog view. The names of target tables are recorded in the SYSCAT.EVENTTABLES catalog view.
- If the member on which the event monitor is to run is not active, event monitor activation occurs when that member next activates.
- After an event monitor is activated, it behaves like an autostart event monitor until that event monitor is explicitly deactivated or the instance is recycled. That is, if an event monitor is active when a member is deactivated, and that member is subsequently reactivated, the event monitor is also explicitly reactivated.
- ***Write to table event monitors***: General notes:
  - All target tables are created when the CREATE EVENT MONITOR statement executes.
  - If the creation of a table fails for any reason, an error is passed back to the application program, and the CREATE EVENT MONITOR statement fails.
  - A target table can only be used by one event monitor. During CREATE EVENT MONITOR processing, if a target table is found to have already been defined for use by another event monitor, the CREATE EVENT MONITOR statement fails, and an error is passed back to the application program. A table is defined for use by another event monitor if the table name matches a value found in the SYSCAT.EVENTTABLES catalog view.
  - During CREATE EVENT MONITOR processing, if a table already exists, but is *not* defined for use by another event monitor, no table is created, and processing continues. A warning is passed back to the application program.
  - Any table spaces must exist before the CREATE EVENT MONITOR statement is executed. The CREATE EVENT MONITOR statement does not create table spaces.
  - If specified, the LOCAL and GLOBAL keywords are ignored. With WRITE TO TABLE event monitors, an event monitor output process or thread is started on each member in the instance, and each of these processes reports data only for the member on which it is running.
  - The following event types from the flat monitor log file or pipe format are not recorded by write to table event monitors:
    - LOG_STREAM_HEADER
    - LOG_HEADER
    - DB_HEADER (Elements db_name and db_path are not recorded. The element conn_time is recorded in CONTROL.)
  - In a partitioned database environment, data is only written to target tables on the database partitions where their table spaces exist. If a table space for a target table does not exist on some database partition, data for that target table is ignored. This behavior allows users to choose a subset of database partitions for monitoring, by creating a table space that exists only on certain database partitions.

    In a Db2 pureScale environment, data will be written from every member.

    In a partitioned database environment, if some target tables do not reside on a database partition, but other target tables do reside on that same database partition, only the data for the target tables that do reside on that database partition is recorded.
  - Users must manually prune all target tables.

Table Columns:

- Column names in a table match an event monitor element identifier. Any event monitor element that does not have a corresponding target table column is ignored.
- Use the db2evtbl command to build a CREATE EVENT MONITOR command that includes a complete list of elements for a group.
- The types of columns being used for monitor elements correlate to the following mapping:

```
SQLM_TYPE_STRING                    CHAR[n], VARCHAR[n] or CLOB(n)
                                    (If the data in the event monitor
                                    record exceeds n bytes,
                                    it is truncated.)
SQLM_TYPE_U8BIT and SQLM_TYPE_8BIT  SMALLINT, INTEGER or BIGINT
SQLM_TYPE_16BIT and SQLM_TYPE_U16BIT SMALLINT, INTEGER or BIGINT
SQLM_TYPE_32BIT and SQLM_TYPE_U32BIT INTEGER or BIGINT
SQLM_TYPE_U64BIT and SQLM_TYPE_64BIT BIGINT
sqlm_timestamp                      TIMESTAMP
sqlm_time(elapsed time)             BIGINT
sqlca:
  sqlerrmc                          VARCHAR[72]
  sqlstate                          CHAR[5]
  sqlwarn                           CHAR[11]
  other fields                      INTEGER or BIGINT
```

- Columns are defined to be NOT NULL.
- Unlike other target tables, the columns in the CONTROL table do not match monitor element identifiers. Columns are defined as follows:

Column Name	Data Type	Nullable	Description
PARTITION_KEY	INTEGER	N	Distribution key (partitioned database only)
PARTITION_NUMBER	INTEGER	N	Database partition number (partitioned database only)
EVMONNAME	VARCHAR(128)	N	Name of the event monitor
MESSAGE	VARCHAR(128)	N	Describes the nature of the MESSAGE_TIME column. For more details see, "message - Control Table Message monitor element" in the *Database Monitoring Guide and Reference*
MESSAGE_TIME	TIMESTAMP	N	Timestamp

- In a partitioned database environment, the first column of each table is named PARTITION_KEY, is NOT NULL, and is of type INTEGER. This column is used as the distribution key for the table. The value of this column is chosen so that each event monitor process inserts data into the database partition on which the process is running; that is, insert operations are performed locally on the database partition where the event monitor process is running. On any database partition, the PARTITION_KEY field will contain the same value. This means that if a database partition is dropped and data redistribution is performed, all data on the dropped database partition will go to one other database partition instead of being evenly distributed. Therefore, before removing a database partition, consider deleting all table rows on that database partition.

– In a partitioned database environment, a column named PARTITION_NUMBER can be defined for each table. This column is NOT NULL and is of type INTEGER. It contains the number of the database partition on which the data was inserted. Unlike the PARTITION_KEY column, the PARTITION_NUMBER column is not mandatory. The PARTITION_NUMBER column is not allowed in a non-partitioned database environment.

Table Attributes:

– Default table attributes are used. Besides distribution key (partitioned databases only), no extra options are specified when creating tables.
– Indexes on the table can be created.
– Extra table attributes (such as volatile, RI, triggers, constraints, and so on) can be added, but the event monitor process (or thread) will ignore them.
– If "not logged initially" is added as a table attribute, it is turned off at the first COMMIT, and is not set back on.

Event Monitor Activation:

– When an event monitor activates, all target table names are retrieved from the SYSCAT.EVENTTABLES catalog view.
– In a partitioned database environment, activation processing occurs on every database partition of the instance. On a particular database partition, activation processing determines the table spaces and database partition groups for each target table. The event monitor only activates on a database partition if at least one target table exists on that database partition. Moreover, if some target table is not found on a database partition, that target table is flagged so that data destined for that table is dropped during runtime processing.
– If a target table does not exist when the event monitor activates (or, in a partitioned database environment, if the table space does not reside on a database partition), activation continues, and data that would otherwise be inserted into this table is ignored.
– Activation processing validates each target table. If validation fails, activation of the event monitor fails, and messages are written to the administration log.
– During activation in a partitioned database environment, the CONTROL table rows for FIRST_CONNECT and EVMON_START are only inserted on the catalog database partition. This requires that the table space for the control table exist on the catalog database partition. If it does not exist on the catalog database partition, these inserts are not performed.
– In a partitioned database environment, if a partition is not yet active when a write to table event monitor is activated, the event monitor will be activated the next time that partition is activated.

Run Time:

– An event monitor runs with DATAACCESS authority.
– If, while an event monitor is active, an insert operation into a target table fails:
  - Uncommitted changes are rolled back.
  - A message is written to the administration log.
  - The event monitor is deactivated.
– If an event monitor is active, it performs a local COMMIT when it has finished processing an event monitor buffer.
– In an environment other than a partitioned database or a Db2 pureScale environment, all write to table event monitors are deactivated when the last application terminates (and the database has not been explicitly activated).

  In a Db2 pureScale environment, write to table event monitors are deactivated on a given member when the member stops and is reactivated when the member restarts.

  In a partitioned database environment, write to table event monitors are deactivated when the catalog partition deactivates.

  - The DROP EVENT MONITOR statement does not drop target tables.
  - Whenever a write-to-table event monitor activates, it will acquire IN table locks on each target table in order to prevent them from being modified while the event monitor is active. Table locks are maintained on all tables while the event monitor is active. If exclusive access is required on any of the target tables (for example, when a utility is to be run), first deactivate the event monitor to release the table locks before attempting such access.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - DBPARTITIONNUM or NODE can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - Commas can be used to separate multiple options in the *target-table-options* clause

Example

Define a threshold violation event monitor named DBTHRESHOLDVIOLATIONS

```
CREATE EVENT MONITOR DBTHRESHOLDVIOLATIONS
    FOR THRESHOLD VIOLATIONS
    WRITE TO TABLE
    THRESHOLDVIOLATIONS (TABLE THRESHOLDVIOLATIONS_DBTHRESHOLDVIOLATIONS
                         IN USERSPACE1
                         PCTDEACTIVATE 100),
    CONTROL (TABLE CONTROL_DBTHRESHOLDVIOLATIONS
             IN USERSPACE1
             PCTDEACTIVATE 100)
    AUTOSTART;
```

CREATE EVENT MONITOR (unit of work)

The CREATE EVENT MONITOR (unit of work) statement creates an event monitor that will record events when a unit of work completes.

Invocation

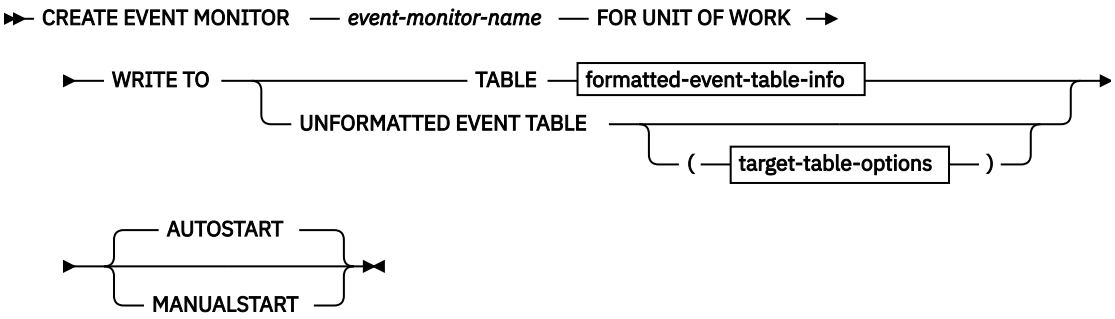
This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

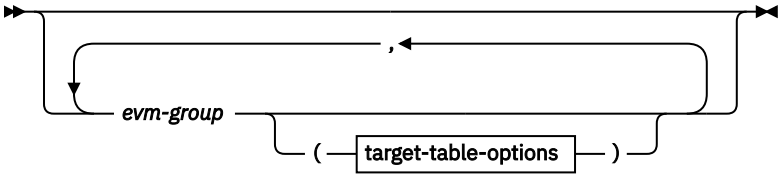
The privileges held by the authorization ID of the statement must include one of the following authorities:

- DBADM authority
- SQLADM authority

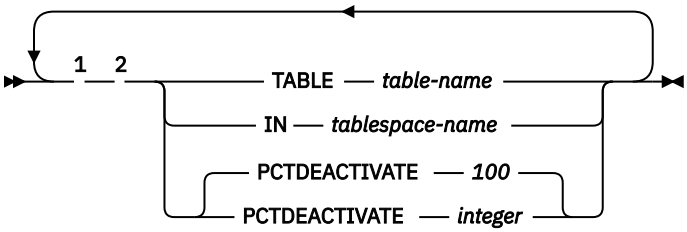
Syntax



formatted-event-table-info



target-table-options



Notes:

[1] Each table option can be specified a maximum of one time (SQLSTATE 42613).
[2] Clauses can be separated with a space or a comma.

Description

event-monitor-name
Name of the event monitor. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *event-monitor-name* must not identify an event monitor that already exists in the catalog (SQLSTATE 42710).

FOR
Introduces the type of event to record.

UNIT OF WORK
Specifies that this passive event monitor will record an event whenever a unit of work is completed (that is, whenever there is a commit or rollback).

The creation of the unit of work event monitor does not indicate that the unit of work data will be collected immediately. The actual unit of work event of interest is controlled at the workload level.

WRITE TO
Specifies the target for the data.

TABLE
Indicates that the target for the event monitor data is a set of database tables. The event monitor separates the data stream into one or more logical data groups and inserts each group into a separate table. Data for groups having a target table is kept, whereas data for groups not having a target table is discarded. Each monitor element contained within a group is mapped to a table column with the same name. Only elements that have a corresponding table column are inserted into the table. Other elements are discarded.

formatted-event-table-info
Defines the target formatted event tables for the event monitor. This clause should specify each grouping that is to be recorded. However, if no *evm-group* clauses are specified, all groups for the event monitor type are recorded.

For more information about logical data groups, see "Logical data groups and event monitor output tables" in *Database Monitoring Guide and Reference*.

evm-group
Identifies a logical data group for which a target table is being defined. The value depends upon the type of event monitor, as shown in the following table:

Type of Event Monitor	evm-group Value
Unit of work	• UOW • UOW_METRICS • UOW_PACKAGE_LIST • UOW_EXECUTABLE_LIST • CONTROL

UNFORMATTED EVENT TABLE
Specifies that the target for the event monitor is an unformatted event table. The unformatted event table is used to store collected unit of work event monitor data. Data is stored in its original binary format within an inlined BLOB column. The BLOB column can contain multiple binary records of different types. The data in the BLOB column is not in a readable format and requires conversion, through use of the **db2evmonfmt** Java-based tool, EVMON_FORMAT_UE_TO_XML table function, or EVMON_FORMAT_UE_TO_TABLES procedure, into a consumable format such as an XML document or a relational table.

target-table-options
Identifies options for the target table. If a value for **target-table-options** is not specified, CREATE EVENT MONITOR processing proceeds as follows:

- A derived table name is used (as explained in the description for TABLE *table-name*).
- A default table space is chosen using the same process as when a table is created without a table space name using CREATE TABLE.
- PCTDEACTIVATE is set to 100.

TABLE *table-name*
Specifies the name of the target table. The target table must be a non-partitioned table. If the name is unqualified, the table schema defaults to the value in the CURRENT SCHEMA special register. For an unformatted event table if a name is not provided, the unqualified name is equal to the *event-monitor-name*, that is, the unformatted event table will be named after the event monitor. For a formatted event table if no name is provided, the unqualified name is derived from *evm-group* and *event-monitor-name* as follows:

```
substring(evm-group CONCAT '_'
  CONCAT event-monitor-name,1,128)
```

IN *tablespace-name*
Specifies the table space in which the table is to be created. The CREATE EVENT MONITOR FOR UNIT OR WORK statement does not create table spaces.

If a table space name is not provided, the table space is chosen using the same process as when a table is created without a table space name using CREATE TABLE.

Since the page size affects the INLINE LOB lengths used, consider specifying a table space with as large a page size as possible in order to improve the INSERT performance of the event monitor.

PCTDEACTIVATE *integer*
If a table for the event monitor is being created in an automatic storage (non-temporary) or DMS table space, the PCTDEACTIVATE parameter specifies how full the table space must be before the event monitor automatically deactivates. The specified value, which represents a percentage, can range from 0 to 100, where 100 means that the event monitor deactivates when the table space becomes completely full. The default value assumed is 100 if PCTDEACTIVATE is not specified. This option is ignored for SMS table spaces.

Important: If the target table space has auto-resize enabled, set PCTDEACTIVATE parameter to 100. Alternatively, omit this clause entirely to have the default of 100 apply. Otherwise,

the event monitor might deactivate unexpectedly if the table space reaches the threshold specified by PCTDEACTIVTATE before the table space is automatically resized.

AUTOSTART
Specifies that the event monitor is to be automatically activated whenever the database partition on which the event monitor runs is activated. This is the default behavior of the unit of work event monitor.

MANUALSTART
Specifies that the event monitor must be activated manually using the SET EVENT MONITOR STATE statement. After a MANUALSTART event monitor has been activated, it can be deactivated only by using the SET EVENT MONITOR STATE statement or by stopping the instance.

Notes

- The table is created when the CREATE EVENT MONITOR FOR UNIT OF WORK statement executes, if it doesn't already exist.
- During CREATE EVENT MONITOR FOR UNIT OF WORK processing, if a table is found to have already been defined for use by another event monitor, the CREATE EVENT MONITOR FOR UNIT OF WORK statement fails, and an error is passed back to the application program. A table is defined for use by another event monitor if the table name matches a value found in the SYSCAT.EVENTTABLES catalog view. If the table exists and is not defined for use by another event monitor, then no table is created, any other table **target-table-options** parameters are ignored, and processing continues. A warning is passed back to the application program.
- Dropping the event monitor will not drop any tables. Any associated tables must be manually dropped after the event monitor is dropped.
- Lock event data is not automatically pruned from either unformatted event tables or regular tables created by this event monitor. An option for pruning data from UE tables is available when using the EVMON_FORMAT_UE_TO_TABLES procedure. For event monitors that write to regular tables, event data must be pruned manually.
- For unformatted event tables event data is inserted into the table into an inlined BLOB data column. Normally, BLOB data is stored in a separate LOB table space and can experience additional performance overhead as a result. When inlined into the data page of the base table, the BLOB data does not experience this overhead. The database manager will automatically inline the BLOB data portion of an unformatted event table record if the size of the BLOB data is less than the table space page size minus the record prefix. Therefore to achieve high efficiency and application throughput, it is suggested that you create the event monitor in as large a table space as possible up to and including a 32 KB table space and associated bufferpool.
- Create only one unit of work event monitor per database and not create multiple unit of work event monitors on the same database.
- In a partitioned database environment, data is written only to target tables on the database partitions where their table spaces exist. If a table space for a target unformatted event table does not exist on some database partition, data for that target table is ignored. This behavior allows users to choose a subset of database partitions for monitoring to be chosen, by creating a table space that exists only on certain database partitions.
- In a multi-member environment, data is only written to target tables on the member where work occurs within the unit of work.
- In a partitioned database environment, if some target tables do not reside on a database partition, but other target tables do reside on that same database partition, only the data for the target tables that do reside on that database partition is recorded.
- The unit of work event monitor is not affected by the unit or work event monitor switch. The unit of work event monitor switch is not changed when a unit or work event monitor is created, and the contents of the unit or work event monitor are not affected by changes to the unit of work event monitor switch.
- The FLUSH EVENT MONITOR statement is not applicable to this event monitor and will have no effect when issued against it.

- Creation of the unit of work event monitor does not cause events to be written to the event monitor. The unit of work event monitor must be activated with SET EVENT MONITOR STATE, and the unit of work data must be collected by either altering the appropriate workload to specify COLLECT UNIT OF WORK DATA or setting the **mon_uow_data** database configuration parameter to a value other than NONE.
- When using unformatted event tables, create the unit of work event monitor in a table space with at least 8 KB page size to ensure that the event data is contained within the inlined BLOB column of the unformatted event table. If the BLOB column is not inlined, then the performance of writing and reading the events to the unformatted event table might not be efficient.

Examples

- *Example 1:* This example creates a unit of work event monitor UOWEVMON that collects data for unit of work events that occur on the database of creation, and writes data tables using default table names:

```
CREATE EVENT MONITOR UOWEVMON
  FOR UNIT OF WORK
  WRITE TO TABLE
```

  This event monitor writes its output to the following tables:

  UOW_UOWEVMON
  UOW_METRICS_UOWEVMON
  UOW_PACKAGE_LIST_UOWEVMON
  UOW_EXECUTABLE_LIST_UOWEVMON
  UOW_CONTROL_UOWEVMON

  Note: Whether the tables for package list and executable list information are populated with data is dependent on whether you specify that that data is to be collected. You control the collection of this data is using the mon_uow_pkglist or mon_uow_execlist configuration parameters, or with the appropriate COLLECT UNIT OF WORK DATA clause on the CREATE or ALTER WORKLOAD statements.
- *Example 2:* This example creates a unit of work event monitor UOWEVMON that will collect unit of work events that occur on the database of creation and store it in the unformatted event table GREG.UOWEVENTS.

```
CREATE EVENT MONITOR UOWEVMON
  FOR UNIT OF WORK
  WRITE TO UNFORMATTED EVENT TABLE (TABLE GREG.UOWEVENTS)
```

- *Example 3:* This example creates a unit of work event monitor UOWEVMON that will collect unit of work events that occur on the database of creation and store it in the unformatted event table GREG.UOWEVENTS in table space APPSPACE. The event monitor will deactivate when the table space becomes 85% full.

```
CREATE EVENT MONITOR UOWEVMON
  FOR UNIT OF WORK
  WRITE TO UNFORMATTED EVENT TABLE
     (TABLE GREG.UOWEVENTS IN APPSPACE PCTDEACTIVATE 85)
```

CREATE EXTERNAL TABLE

While tables typically reside in a database, an external table resides in a text-based, delimited file, or in a fixed-length-format file outside of a database.

Use an external table to:

- Store data outside the database while retaining the ability to query that data. To unload data from the database into an external file, specify the external table as the target table in one of the following SQL statements:
  - INSERT SQL
  - SELECT INTO SQL

  - CREATE EXTERNAL TABLE AS SELECT SQL
- Load data from an external file into a table in the database. You can perform operations such as casts, joins, and dropping columns to manipulate data during loading. To load data into the database from an external table, use a FROM clause in a SELECT SQL statement as you would for any other table.
- Transfer data to another application.

An advantage of using external tables for Extraction-Transformation-Loading (ETL) processes is that they can be carried out using plain SQL. Because an SQL-based ETL process can be initiated from any SQL client, it eliminates the need for special ETL tools.

An external table is of one of the following types:

Named
The external table has a name and catalog entry similar to a normal table.

Transient
The external table has a system-generated name of the form SYSTET<number> and does not have a catalog entry. For example, the system might create a transient external table to hold the result of a query. The lifetime of such a table is the duration of the query.

Invocation

This statement can be embedded in an application program or issued using dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges that are held by the authorization ID of the statement must have either DBADM authority or the following privileges or authorities:

- CREATETAB authority
- One of the following privileges or authorities:
  - USE privilege on the table space
  - SYSADM authority
  - SYSCTRL authority
- One of the following privileges or authorities:
  - IMPLICIT_SCHEMA authority on the database (if the implicit or explicit schema name of the table does not exist)
  - CREATEIN privilege on the schema (if the schema name of the table refers to an existing schema)
  - SCHEMAADM authority on the schema (if the schema name of the table refers to an existing schema)

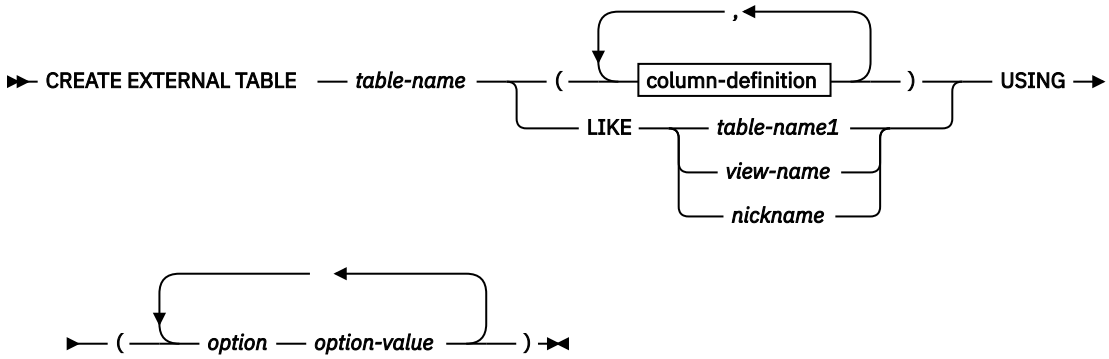
If a subtable is being defined, one of the following conditions must be met:

- The authorization ID must be the same as the owner of the root table of the table hierarchy.
- The privileges that are held by the authorization ID must include SCHEMAADM authority on the schema that contains the root table of the table hierarchy.
- The privileges that are held by the authorization ID must include DBADM authority.

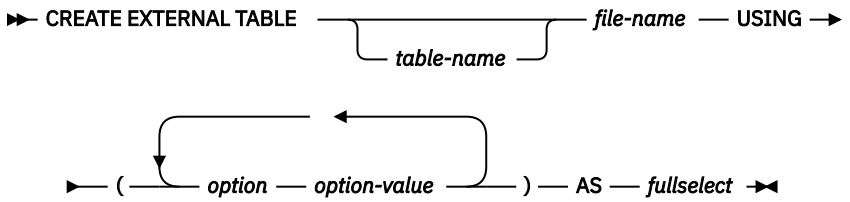
Syntax

The syntax of this statement depends on the nature of the external table that is to be created:

- Use the following syntax to create, in the catalog, a table definition for a new external table. Specifying a table name is mandatory, so the resulting external table is a named table. A DATAOBJECT or FILE_NAME option must be specified to identify the target file.



- Use the following syntax to use an existing table as a template for a new external table and to populate it with the contents of the source table. If this statement specifies a table name explicitly, the resulting external table is a named table; otherwise, the resulting external table is a transient table. The file name must be specified by either the `file-name` parameter or a DATAOBJECT or FILE_NAME option.



If you specify one or more column definitions, the following additional parameters apply:

Description

table-name
The names of the external table. The name, including the implicit or explicit qualifier, must not identify a table, view, nickname, or alias that is already described in the catalog. The schema name cannot be SYSIBM, SYSCAT, SYSFUN, or SYSSTAT (SQLSTATE 42939).

file-name
The fully-qualified name of the file (or any medium that can be treated as a file) that is to contain the external table to be created. If this parameter is specified, the DATAOBJECT or FILE_NAME option cannot be specified.

If the input data file is `gzip` compressed, this will be detected and the data is uncompressed by the Db2 server. The `COMPRESS GZIP` option can be used, but it is not mandatory for loading `gzip` compressed files.

If the input data file is `lz4` compressed, the `COMPRESS LZ4` option must be specified.

When both the REMOTESOURCE option is set to LOCAL (this is its default value) and the **`extbl_strict_io`** configuration parameter is set to NO, the path to the external table file is an absolute path and must be one of the paths specified by the **`extbl_location`** configuration parameter. Otherwise, the path to the external table file is relative to the path that is specified by the **`extbl_location`** configuration parameter followed by the authorization ID of the table definer. For example, if **`extbl_location`** is set to `/home/xyz` and the authorization ID of the table definer is `user1`, the path to the external table file is relative to `/home/xyz/user1/`.

The file name must be a valid UTF-8 string.
For a load operation, the following conditions apply:

- The file must already exist.
- Required permissions:
  - If the external table is a named external table, the owner must have read permission for the file and write permission for the LOGDIR directory.
  - If the external table is a transient external table, the authorization ID of the statement must have read permission for the file and write permission for the LOGDIR directory.

For an unload operation, the following conditions apply:

- If the file exists, it is overwritten.
- Required permissions:
  - If the external table is a named external table, the owner must have read and write permission for the directory of this file.
  - If the external table is transient, the authorization ID of the statement must have read and write permission for the directory of this file.

column-definition
Defines the attributes of a column.

column-name
Names a column of the table. The name cannot be qualified, and the same name cannot be used for more than one column of the table (SQLSTATE 42711).

built-in-type
One of the following built-in data types:

SMALLINT
A small integer.

[INTEGER | INT]
A large integer.

BIGINT
A big integer.

[DECIMAL | DEC | NUMERIC | NUM](*precision-integer, scale-integer*)
A decimal number.

- The precision integer specifies the total number of digits. It must be in the range 1 - 31. The default is 5.
- The scale integer specifies the number of digits to the right of the decimal point. It cannot be negative and cannot exceed the precision. The default is 0.

FLOAT(*integer*)
A single or double-precision floating-point number. If the specified length is in the range:

- 1 - 24, the number uses single precision
- 25 - 53, the number uses double-precision

Instead of FLOAT, you can specify:

REAL
For single precision floating-point.

DOUBLE
For double-precision floating-point.

DOUBLE PRECISION
For double-precision floating-point.

FLOAT
For double-precision floating-point.

DECFLOAT*(precision-integer)*
A decimal floating-point number. The precision integer specifies the total number of digits, which can be either 16 or 34. The default is 34.

[CHARACTER | CHAR](*integer* [OCTETS | CODEUNITS32])
A fixed-length character string of the specified number of code units. This number can range from 1 - 255 OCTETS or from 1 - 63 CODEUNITS32. The default is 1.

[VARCHAR | CHARACTER VARYING | CHAR VARYING](*integer* [OCTETS | CODEUNITS32])
A varying-length character string with a maximum length of the specified number of code units. This number can range from 1 - 32672 OCTETS or from 1 - 8168 CODEUNITS32.

FOR BIT DATA
Specifies that the contents of the column are to be treated as bit (binary) data. During data exchange with other systems, code page conversions are not performed. Comparisons are done in binary, irrespective of the database collating sequence.

The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

[CLOB | CHARACTER LARGE OBJECT | CHAR LARGE OBJECT](*integer* [K] [OCTETS | CODEUNITS32])
A character large object string with a maximum length of the specified number of code units. The default maximum length is 65,535 bytes.

If you want to multiply the length integer by 1024, specify a K (kilo) multiplier.

- Regardless of whether you use a K multiplier, the resulting length is limited by the maximum length of a CLOB column in an external table, which is 65,535 OCTETS, 32,767 CODEUNITS16, or 16,383 CODEUNITS32. Note that 64K OCTETS and 16K CODEUNITS32 each exceed the maximum length by one, and so are not allowed.
- Any number of spaces (including zero spaces) are allowed between the data type and the length specification or between the length integer and the K multiplier. For example, the following specifications are all equivalent and valid:

```
CLOB(50K)
CLOB(50 K)
CLOB (50   K)
```

- The K multiplier can be specified in either uppercase or lowercase.

In a Unicode database, the default string units for a character string data type are determined by the value of the NLS_STRING_UNITS global variable or *string_units* database configuration parameter. In a non-Unicode database, the default string units for character string data types are OCTETS.

OCTETS
Specifies that the units of the length attribute are bytes.

CODEUNITS32
Specifies that the units of the length attribute are Unicode UTF-32 code units, which approximates counting in characters. This does not affect the underlying code page of the data type. The actual length of a data value is determined by counting the UTF-32 code units as if the data were converted to UTF-32. CODEUNITS32 can be specified only in a Unicode database (SQLSTATE 560AA).

GRAPHIC(*integer* [CODEUNITS16 | CODEUNITS32])
A fixed-length graphic string of the specified length, which can range from 1 - 127 double bytes, 1 - 127 CODEUNITS16, or 1 - 63 CODEUNITS32. The default length is 1.

VARGRAPHIC(*integer* [CODEUNITS16 | CODEUNITS32])
A varying-length graphic string of the specified maximum length, which can range from 1 - 16336 double bytes, 1 - 16336 CODEUNITS16, or 1 - 8168 CODEUNITS32.

DBCLOB(*integer* [K] [CODEUNITS16 | CODEUNITS32])
A character large object string of the specified maximum length in double bytes, Unicode UTF-16 code units, or Unicode UTF-32 code units. The default maximum length is 32,767 double bytes.

If you want to multiply the length integer by 1024, specify a K (kilo) multiplier.

- Regardless of whether you use a K multiplier, the resulting length is limited by the maximum length of a DBCLOB column in an external table, which is 32,767 CODEUNITS16 or 16,383 CODEUNITS32. Note that 32K CODEUNITS16 and 16K CODEUNITS32 each exceed the maximum length by one, and so are not allowed.
- Any number of spaces (including zero spaces) are allowed between the data type and the length specification or between the length integer and the K multiplier. For example, the following specifications are all equivalent and valid:

```
DBCLOB(50K)
DBCLOB(50 K)
DBCLOB (50   K)
```

- The K multiplier can be specified in either uppercase or lowercase.

In a Unicode database, the default string units for a character string data type are determined by the value of the NLS_STRING_UNITS global variable or *string_units* database configuration parameter. In a non-Unicode database, the default string units for character string data types is CODEUNITS16.

CODEUNITS16
Specifies that the units of the length attribute are Unicode UTF-16 code units, which is the same as counting in double bytes. CODEUNITS16 can be specified only in a Unicode database (SQLSTATE 560AA).

CODEUNITS32
Specifies that the units of the length attribute are Unicode UTF-32 code units. This does not affect the underlying code page of the data type. The actual length of a data value is determined by counting the UTF-32 code units as if the data were converted to UTF-32. CODEUNITS32 can be specified only in a Unicode database (SQLSTATE 560AA).

[NATIONAL CHARACTER | NATIONAL CHAR | NCHAR](*integer*)
A fixed-length string of the specified length. The default length is 1.

The NATIONAL CHARACTER type maps to either a fixed-length character or a fixed-length graphic string, depending on the value of the *nchar_mapping* database configuration parameter, which also defines the string units.

[NATIONAL CHARACTER VARYING | NATIONAL CHAR VARYING | NCHAR VARYING | NVARCHAR](*integer*)
A varying-length string of the specified maximum length.

The NATIONAL CHARACTER VARYING type maps to either a varying-length character or a varying-length graphic string, depending on the value of the *nchar_mapping* database configuration parameter, which also defines the string units.

[NATIONAL CHARACTER LARGE OBJECT | NCHAR LARGE OBJECT | NCLOB](*integer* [K])
A large object string of the specified maximum length. The default maximum length is 16,383 double bytes.

This data type maps to either a character large object (CLOB) or a double-byte character large object (DBCLOB), depending on the current value of the *nchar_mapping* database configuration parameter, which also defines the string units. See the description of the CLOB or DBCLOB parameter (whichever applies) for information about possible values for the length integer and how to use a K (kilo) multiplier.

BINARY(*integer*)
A fixed-length binary string of the specified length, which must be in the range 1 - 255 bytes. The default length is 1.

[VARBINARY | BINARY VARYING](*integer*)
A varying-length binary string of the specified maximum length, which must be in the range 1 - 32672 bytes.

[BLOB | BINARY LARGE OBJECT](*integer* [K])
A binary large object string with a maximum length of the specified number of code units. The default maximum length is 65,535 bytes.

If you want to multiply the length integer by 1024, specify a K (kilo) multiplier.

- Regardless of whether you use a K multiplier, the resulting length is limited by the maximum length of a BLOB column in an external table, which is 65,535 bytes. Note that 64K exceeds the maximum length by one, and so is not allowed.
- Any number of spaces (including zero spaces) are allowed between the data type and the length specification or between the length integer and the K multiplier. For example, the following specifications are all equivalent and valid:

```
BLOB(50K)
BLOB(50 K)
BLOB (50   K)
```

- The K multiplier can be specified in either uppercase or lowercase.

DATE
A date.

TIME
A time.

TIMESTAMP(*integer*) or TIMESTAMP
A timestamp. The integer specifies the number of decimal places for fractions of seconds, from 0 (seconds) to 12 (picoseconds). The default is 6 (microseconds).

BOOLEAN
A Boolean value.

LIKE *table-name1* or *view-name* or *nickname*
Specifies that the columns of the table have the same name and description as the columns of the specified table (*table-name1*), view (*view-name*), or nickname (*nickname*). The specified table, view,

or nickname must either exist in the catalog or must be a declared temporary table. A typed table or typed view cannot be specified (SQLSTATE 428EC).

The use of LIKE is an implicit definition of *n* columns, where *n* is the number of columns in the identified table (including implicitly hidden columns), view, or nickname. A column of the new table that corresponds to an implicitly hidden column in the existing table will also be defined as implicitly hidden. The implicit definition depends on what is specified after LIKE:

- If a table is specified, then the implicit definition includes the column name, data type, hidden attribute, and nullability characteristic of each of the columns of that table. If EXCLUDING COLUMN DEFAULTS is not specified, then the column default is also included.
- If a view is specified, then the implicit definition includes the column name, data type, and nullability characteristic of each of the result columns of the fullselect defined in that view. The data types of the view columns must be data types that are valid for columns of a table.
- If a nickname is specified, then the implicit definition includes the column name, data type, and nullability characteristic of each column of that nickname.
- If a protected table is specified, the new table inherits the same security policy and protected columns as the identified table.
- If a table is specified and if that table contains a row-begin column, row-end column, or transaction-start-ID column, the corresponding column of the new table inherits only the data type of the source column. The new column is not considered a generated column.
- If a table that includes a period is specified, the new table does not inherit the period definition.
- If a system-period temporal table is specified, the new table is not a system-period temporal table.
- If a random distribution table that uses the **random by generation** method is specified, and if the new table that is being created does not share the same table distribution, the **RANDOM_DISTRIBUTION_KEY** column that is used to generate the random distribution values is not included.

Column default attributes can be included or excluded, based on the copy-attributes clauses. The implicit definition does not include any other attributes of the specified table, view, or nickname. Consequently, the new table does not have any primary key, unique constraints, foreign key constraints, referential integrity constraints, triggers, indexes, ORGANIZE BY specification, or PARTITIONING KEY specification.

When a table is identified in the LIKE clause and that table contains a ROW CHANGE TIMESTAMP column, the corresponding column of the new table inherits only the data type of the ROW CHANGE TIMESTAMP column. The new column is not considered to be a generated column.

If a table is specified, and if row or column level access control is activated for that table, it is not inherited by the new table.

option

The following options control the loading of data to or retrieval of data from an external-table file. The value of each option is a text string and is not case-sensitive.

BOOLSTYLE or BOOLEAN_STYLE

During a load operation, all Boolean values must use the same style. This option specifies the Boolean style that is to be used:

- 1_0 (this is the default)
- T_F
- Y_N
- YES_NO
- TRUE_FALSE

CARDINALITY

Non-zero positive integer value to override the estimation of the expected number of returned rows.

CCSID
The coded character set identifier (CCSID) of the input data file. The value can be any valid integer value from the CCSID specification. There is no default value. The CCSID and ENCODING options are mutually exclusive when the value of the ENCODING option is UTF8, LATIN9, or INTERNAL.

Which styles are used for dates and times depends on whether a CCSID is specified:

- When a CCSID is specified, and when DATESTYLE, TIMESTYLE, DATEDELIM, or TIMEDELIM are not specified, the values or defaults for DATE_FORMAT, TIME_FORMAT, and TIMESTAMP_FORMAT are used.
- When a CCSID is not specified, and when TIMESTAMP_FORMAT, DATE_FORMAT or TIME_FORMAT are not specified, the values or defaults for DATESTYLE, TIMESTYLE, DATEDELIM, and TIMEDELIM are used.

COMPRESS
For a load operation or an unload operation, whether the data file data is compressed:

GZIP
The data file data is compressed by using the GZIP compression algorithm.

NO
The data file data is not compressed. This is the default.

LZ4
The data file data is compressed by using the LZ4 compression algorithm.

The COMPRESS option cannot be specified if the value of the REMOTESOURCE option is GZIP or LZ4.

CRINSTRING
How to interpret an unescaped carriage-return (CR) or carriage-return line-feed (CRLF) character:

TRUE or ON
An unescaped CR character is interpreted as data, not as a record delimiter.

FALSE or OFF
An unescaped CR is interpreted as a record delimiter. This is the default.

Use fixed-length format for **CRINSTRING** only if the value of the **CtrlChars** option is set to OFF.

CTRLCHARS
Whether to allow an ASCII value 1 - 31 in a CHAR or VARCHAR field. Any NULL, CR, or LF characters must be escaped. Allowed values are:

TRUE or ON
An ASCII value 1 - 31 in a CHAR or VARCHAR field is allowed.

If fixed-length format is enabled, all unescaped characters are allowed.

FALSE or OFF
An ASCII value 1 - 31 in a CHAR or VARCHAR field is not allowed. This is the default.

If fixed-length format is enabled, unescaped characters cause an error.

Exceptions for fixed-length format:

- \t, \n
- \r if the CRinString option is set to ON

DATAOBJECT or FILE_NAME
The fully-qualified name of the file (or any medium that can be treated as a file) that is to contain the external table to be created. This option is mandatory when the name of the file is not specified immediately after the table name; otherwise, it is not allowed.

When both the REMOTESOURCE option is set to LOCAL (this is its default value) and the **extbl_strict_io** configuration parameter is set to NO, the path to the external table file is an absolute path and must be one of the paths specified by the **extbl_location** configuration parameter. Otherwise, the path to the external table file is relative to the path that is specified

by the **extbl_location** configuration parameter followed by the authorization ID of the table definer. For example, if **extbl_location** is set to `/home/xyz` and the authorization ID of the table definer is `user1`, the path to the external table file is relative to `/home/xyz/user1/`.

The file name must be a valid UTF-8 string.
For a load operation, the following conditions apply:

- The file must already exist.
- Required permissions:
  - If the external table is a named external table, the owner must have read permission for the file and write permission for the LOGDIR directory.
  - If the external table is a transient external table, the authorization ID of the statement must have read permission for the file and write permission for the LOGDIR directory.

For an unload operation, the following conditions apply:

- If the file exists, it is overwritten.
- Required permissions:
  - If the external table is a named external table, the owner must have read and write permission for the directory of this file.
  - If the external table is transient, the authorization ID of the statement must have read and write permission for the directory of this file.

DATEDELIM
The delimiter character that separates the components of a date, according to the format specified by the DATESTYLE option. If you specify an empty string, there is no delimiter between the date components, and days and months must be specified as two-digit numbers. When DATESTYLE is set to MONDY or MONDY2, the default DATEDELIM value is a space. The TIMESTAMP_FORMAT and DATEDELIM options are mutually exclusive.

DATESTYLE
How to interpret the date format. For days or months in the range 1 - 9, use 1 digit, 2 digits, or a space followed by a single digit. When the DATEDELIM option is a space, you can specify a comma after the day. An error occurs if you:

- Specify zero for a day, month, or year
- Specify a nonexistent date (for example, 32 August or 30 February)

The DATESTYLE option and the DATE_FORMAT or TIMESTAMP_FORMAT option are mutually exclusive.

Table 131. Possible values for the DateStyle option. The example shows how the date 21 March 2014 would be represented when DATEDELIM is set to '-'.

Value	Description	Example
YMD	4-digit year, 2-digit month, 2-digit day. This is the default.	2014-03-21
DMY	2-digit day, 2-digit month, 4-digit year.	21-03-2014
MDY	2-digit month, 2-digit day, 4-digit year.	03-21-2014
MONDY	3-character month, 2-digit day, 4-digit year.	Mar 21 2014
DMONY	2-digit day, 3-character month, 4-digit year.	21-Mar-2014
Y2MD	2-digit year, 2-digit month, 2-digit day. Not supported for unloads.	14-03-21
DMY2	2-digit day, 2-digit month, 2-digit year. Not supported for unloads.	21-03-14

Table 131. Possible values for the DateStyle option. The example shows how the date 21 March 2014 would be represented when DATEDELIM is set to '-'. *(continued)*

Value	Description	Example
MDY2	2-digit month, 2-digit day, 2-digit year. Not supported for unloads.	03-21-14
MONDY2	3-character month, 2-digit day, 2-digit year. Not supported for unloads.	Mar 21 14
DMONY2	2-digit day, 3-character month, 2-digit year. Not supported for unloads.	21-Mar-14

DATETIMEDELIM
A single-byte character that separates the date component and time component of the timestamp data type.

The default delimiter is a space (' ').

Between the date component and the time component, a delimiter is not required. For example, both of the following values are valid:

```
2010-10-10 10:10:10
2010-10-1010:10:10
```

DATE_FORMAT
The format of the date field in the data file. The value can be any of the date format strings that are accepted by the "TIMESTAMP_FORMAT " on page 527. The default is YYYY-MM-DD. The DATE_FORMAT option and the DATEDELIM or DATESTYLE option are mutually exclusive.

DECIMALDELIM or DECIMAL_CHARACTER
The decimal delimiter for the data types FLOAT, DOUBLE, TIME, and TIMESTAMP. Allowed values are ' , ' and ' . '.

DECPLUSBLANK
Specifies how the positive decimal value is represented during the unload operation.

You can specify one of the following values for this option:

NONE
This is the default.

This value represents a positive decimal value without a sign.

PLUS
Specifies that a positive decimal value is represented by a '+' sign.

BLANK
Specifies that a positive decimal value is represented by a blank sign instead of a '+' sign.

If you specify the DECPLUSBLANK option for the load operation, the output is not affected.

Examples for a table test with ddl (decimal (6,2)) and all the available values for the DECPLUSBLANK option:

```
1234
-4563
```

- Create external table '/tmp/unload.txt' using (DECPLUSBLANK NONE) as select * from test:

```
unload.txt
1234.00
-4563.00
```

- Create external table '/tmp/unload.txt' using (DECPLUSBLANK PLUS) as select * from test:

```
unload.txt
+1234.00
-4563.00
```

- Create external table '/tmp/unload.txt' using (DECPLUSBLANK BLANK) as select * from test:

```
unload.txt
 1234.00
-4563.00
```

DELIMITER or COLUMN_DELIMITER
The character that is used to delimit the fields of an input or output record. The default is a vertical bar (`'|'`).

You can specify a character in the 7-bit ASCII range (decimal 1 - 127) in any of the following ways:

- As a single character (for example `DELIMITER ';'`)
- By specifying its corresponding ASCII decimal value (for example, `DELIMITER 59` or `DELIMITER '59'`)
- By specifying its corresponding ASCII hex value (for example, `DELIMITER x'3B'`)

The decimal range 128 - 255 is supported only with the ISO character set input file by specifying its corresponding ASCII decimal value or hex value. If the input file is in the UTF8 character set, this delimiter value range is not supported.

ENCODING
The type of data in the file:

UTF8
The file uses UTF8 encoding for all character data.

LATIN9
The file uses LATIN9 encoding for all character data.

INTERNAL
This is the default option.

The file uses a mixture of both UTF8 and LATIN9 encoding.

Files are encoded in Netezza internal format and therefore should be used only for files that are extracted from Netezza by using ENCODING (INTERNAL).

When the target column is CODEUINTS32 (NCHAR/VARCHAR), the input data is validated to be valid UTF-8 characters.

This option is supported only in a Unicode database.

DBCS_GRAPHIC
This value is allowed only for a load operation, not an unload operation. If this value is specified, the CCSID option must also be specified. During the load operation, fields of type GRAPHIC or VARGRAPHIC are encoded using the double-byte character set of the specified CCSID; fields of all other types are encoded using the mixed-byte character set of the specified CCSID.

Note: ENCODING cannot be set to DBCS_GRAPHIC for a DEL file that was created by the EXPORT utility, because such DEL files are encoded using a single character set.

The CCSID and ENCODING options are mutually exclusive when the value of the ENCODING option is UTF8, LATIN9, or INTERNAL.

ESCAPECHAR or ESCAPE_CHARACTER
Which character is to be regarded as an escape character. An escape character indicates that the character that follows it, which would otherwise be treated as a field-delimiter character or end-of-row sequence character, is instead treated as part of the value in the field. The escape character is ignored for graphic-string data. There is no default.

FILLRECORD
For a load operation, the field of a record are loaded into the columns of a target table from left to right. This option specifies whether an input record can contain fewer fields than there are columns defined for the target table:

TRUE or ON
An input line can contain fewer fields, provided that all columns for which a value is missing are nullable. Missing values are set to NULL. If one or more columns for which a value is missing is not nullable, the record is rejected.

FALSE or OFF
An input line that contains fewer columns is rejected. This is the default.

FORMAT or FILE_FORMAT
The data format of the source file:

TEXT
The data to be loaded or unloaded is in text-delimited format. This is the default.

INTERNAL
The data is in an internal format used by Netezza Platform Software (NPS). This value is valid only when loading data from a file to the database, not when unloading data to a file. If this value is specified for the FORMAT option, the following options, and only these options, must also be specified:

- DATAOBJECT or FILE_NAME.
- REMOTESOURCE, SWIFT or S3. If the REMOTESOURCE option is specified, it must have the value LOCAL or YES.

  Attention: In the container-only release of Db2 Version 11.5 Mod Pack 1 or later releases, AZURE is compatible, in addition to SWIFT and S3.
- COMPRESS. This must be set to GZIP.

BINARY
The data is in an internal format that is used by Db2.

FIXED
The data is in fixed-length format.

Fixed-length format is supported only for load operations.

Files in fixed-length format use ordinal positions, which are offsets, to identify where fields are within the record.

Note:

- The following external table options are not supported for the fixed-length format:
  - Delimiter
  - Encoding
  - EscapeChar
  - FillRecord
  - IgnoreZero
  - IncludeZeroSeconds
  - Lfinstring
  - QuotedValue
  - RequireQuotes
  - TimeExtraZeros
  - TruncString
- There are no field delimiters.

- An end-of-record delimiter is required even for the last record.
- Usually, data in fixed-length format files does not have decimal delimiters or time delimiters because delimiters are not necessary and use space.
- The locations of delimiters are fixed and specified in the layout definition because the fields are fixed in size. This definition comes with the fixed-length format data file.
- To load fixed-format data into the database, you must define the target data type for the fields and the locations within the record.
- You do not have to load all fields in a fixed-length format file. You can skip them by using the *filler* specification.
- The order of fields in the data file must match the order in the target table. Alternatively, you must create an external table definition that specifies the order of the fields as database columns.
- You can change the field order by using an external table definition in combination with an insert-select statement.
- Typically, unknown values or null values are represented by known data patterns that are classified as representing null.

The following parameters apply when the FORMAT option of the external table is set to FIXED:

LAYOUT

Mandatory.

A layout is an ordered collection of zone or field definitions. It defines the location of the fields of the input record.

Specify comma-separated zone definitions within braces { }.

Each zone definition is made up of mutually exclusive, non-overlapping clauses.

No default value.

The clauses must be in the following order, even if some of them are optional and can be empty:

USE TYPE

Optional.

Indicates whether a zone is a normal data zone, a reference zone, or a filler zone.

For data zones, this value is omitted.

A reference zone is specified as **REF**. This specification implies that the zone is referred by another zone for zone length or null values.

A filler zone is specified as **FILLER**. Filler zones specify that the bytes or characters are treated as fillers in a data file.

NAME

Optional.

The name of the zone.

Currently, this definition is not used. Typically, it is provided to identify the field.

TYPE

Optional.

Defines the type of the zone.

If you do not specify the type, it gets the default value of the corresponding type of a table column.

Valid values are as follows:

- CHAR
- VARCHAR
- NCHAR

- NVARCHAR
- SMALLINT
- BIGINT
- BINARY
- VARBINARY
- GRAPHIC
- VARGRAPHIC
- FLOAT
- DOUBLE
- DEC, NUM, or NUMERIC
- DECFLOAT
- BOOLEAN
- DATE
- TIME
- TIMESTAMP

STYLE

Optional.

Defines the zone representation.

The default representation is based on zone type and format option.

All other styles are valid only for their corresponding non-textual zone types.

Valid values are as follows:

- INTERNAL

  Valid only for textual zones, that is, char, varchar, nchar, and nvarchar.
- DECIMAL

  Valid for integer and numeric zone types.
- DECIMALDELIM <'decimal-delim'>

  Valid for numeric, float, double, and time style (time and timestamp) zone types.
- FLOATING

  Valid for float or double zone types.
- EXPONENTIAL

  Valid for float or double zone types.
- YMD <'date-delim'>

  Valid for date zones, including other date styles that are supported for the DateStyle and DateDelim external table options.
- 12Hour <'time-delim'>

  Valid for time zones, including other time styles that are supported for the TimeStyle and TimeDelim external table options.
- 24Hour <'time-delim'>

  Valid for time zones, including other time styles that are supported for the TimeStyle and TimeDelim external table options.
- YMD <'date-delim'> 24Hour <'time-delim'>

Valid for timestamp zones, including other combinations of date and time styles that are supported for the DateStyle, DateDelim, TimeStyle, and TimeDelim external table options.

- TRUE_FALSE, Y_N, 1_0

  Valid for boolean zones, including other boolean styles that are supported for the BoolStyle external table option. The style must be in accordance with the format.

LENGTH

Optional.

Specified as bytes or characters followed by the number or the internal reference to the reference zone.

Number of bytes or characters as provided or as referenced by the reference zone.

For reference zones or filler zones, you cannot use internal references. For reference zones, the number of bytes specifies how the data is read from the data file to get the referred value.

You can use plus signs and minus signs as follows:

```
BYTES @2 + 10
BYTES @2 - 10
```

NULLIF

Optional.

Definition of the zone NULLESS attribute.

Specifies a known data pattern within the field that, when it is present, signifies that the field is null.

The length is equal to or less than the column width. The maximum length is 39 bytes.

You can use the following types of references:

@

Internal reference to numeric zones.

Exact match of the numeric value.

&

External reference.

Exact match of the specified value.

&&

Isolated reference.

Leading spaces and trailing spaces are to be skipped with the exact string match.

Nulls are detailed in the following examples:

Table 132. Layout example

Use type	Name	Type	Style	Length	Nullif
NA	f1	int4	DECIMAL	Bytes 10	Nullif & = 0
NA	f2	date	YMD	Bytes 10	Nullif &= '2000-10-10'
NA	f3	char(20)	INTERNAL	Chars 10	Nullif &&='ab'
Filler	f4	char(10)	NA	Bytes 10	NA

Remember:

- The referred zone in a length clause must be of type integer.

- You must not specify the NULLIF option for reference zones or filler zones.
- Reference zones and filler zones cannot have variable lengths.
- Variable length zones cannot refer themselves.
- Define the referred zone in a length clause as REF.
- Length-clause references can use only the INTERNAL (@) reference. External or isolated references are not supported.
- Between the referred zone of a length clause and the zone itself, reference zones are not allowed.
- If the reference type is INTERNAL (@), the NULLIF clause cannot refer to itself.
- If the column is non-nullable, it may not have the NULLIF clause.
- Variable length is allowed only for the string type of zones.
- The NULLIF clause can refer only to REF zones or the zones themselves.
- Between the zone that is referred by the NULLIF clause and the zone itself, other referred zones are not allowed, except for the zone that is referred in the length clause.
- The record length can point to zone 1 only for reference.
- A REF must have a zone that refers it.
- The NULLIF clause can have external references only if the REF zone is non-integer.

Recordlength
Specifies the length of the entire record, where null-indicator bytes are included if they exist, and the record delimiter is excluded if it exists.

The value is a constant integer.

The value can also be an internal reference to the reference zone in the layout definition.

There is no default value.

You can use plus signs and minus signs for an internal reference as follows:

```
RECORDLENGTH @1 + 10
RECORDLENGTH @1 - 10
```

IGNOREZERO or TRIM_NULLS
Specifies whether the binary value zero in CHAR fields and VARCHAR fields is to be discarded.

TRUE or ON
The byte value zero is ignored.

FALSE or OFF
The byte value zero is not ignored. This is the default.

KEEP
The binary value zero is accepted and allowed as part of the input field.

INCLUDEHEADER or COLUMN_NAMES
For an unload operation, whether the table column names are to be included as headers in the external-table file:

TRUE or ON
The table column names are to be included as headers.

FALSE or OFF
The table column names are not to be included as headers. This is the default.

INCLUDEZEROSECONDS
For an unload operation, whether to specify **00** as the value for seconds when no value for seconds is available:

TRUE or ON
Specify **00** as the value for seconds.

FALSE or OFF
Do not specify a value for seconds. This is the default.

INCLUDEHIDDEN
For a load operation, specify whether hidden column values are present in a data file.

The `INCLUDEHIDDEN` option works when you are creating an external table by using the LIKE or SAMEAS clause, and base table has hidden columns.

TRUE
A data file contains values against hidden column.

FALSE
A data file does not contain values against hidden column. This is the default. You can change the default value by using the registry variable `DB2_EXTBL_INCLUDE_HIDDEN_COLS`.

LFINSTRING
Specifies how to interpret an unescaped line-feed (sometimes called an LF or newline) character within string data:

TRUE or ON
An unescaped LF character is interpreted as a record delimiter only if it is in the last field of a record; otherwise, it is treated as data. To cause an LF character that is in the last field of a record to be treated as data, enclose the value of that field in single or double quotation marks.

FALSE or OFF
An unescaped LF character is interpreted as a record delimiter regardless of its position. This is the default.

This option is not supported for unload operations.

Attention: This SQL compatibility enhancement is only available in Db2 Version 11.5 Mod Pack 2 and later versions.

LOGDIR or ERROR_LOG
The directory to which the following files are written:

<database>.<schema>.<external-table-name>.<file-name>.<application-handle>.<id>.bad
A file containing rejected records (that is, records that could not be processed).

<database>.<schema>.<external-table-name>.<file-name>.<application-handle>.<id>.log
A log file.

The default is the directory to which the external-table file is written. If the length of the name that is constructed for a .bad or .log file would exceed the allowed maximum, the name of the file that contains the external table (indicated by `<file-name>`) is truncated so that the maximum is not exceeded.

If a .log or .bad file is generated while carrying out an operation on a partition, the name of the generated file is suffixed with a period followed by the 3-digit partition number.

MAXERRORS or MAX_ERRORS
For a load operation, the threshold for the number of rejected records at which the system stops processing and immediately rolls back the load. The default is 1 (that is, a single rejected record results in a rollback).

For fixed-length format, the following conditions apply:

- The parser reports errors for each field or zone rather than one error for the row.
- Multiple errors can be reported for the same row.
- When the parser detects an error in a field or zone, it recovers by using the field length or zone length. It then continues from the next field or zone until the end of record is reached, or an unrecoverable error occurs, or the MaxErrors limit is reached.
- Unrecoverable errors include the following errors:
  - RecordLength mismatch.

- RecordDelimiter is not found.
- The RecordLength value is not valid, that is, the value is a negative value or zero.
- The zone length is not valid, that is, the value is a negative value.
- The UTF-8 initial byte is not valid.
- The UTF-8 continuation bytes are not valid.

MULTIPARTSIZEMB

When the DB2_ENABLE_COS_SDK registry variable is set to ON, Db2 remote storage communication with cloud object storage is facilitated through an embedded vendor COS SDK which allows Db2 to stream objects/files to cloud object storage in multiple parts (aka 'multipart upload'). This parameter specifies the part size for multipart upload, in megabytes (MB), for the file being unloaded, and overrides the value specified in the MULTIPARTSIZEMB dbm config parameter. This option is available starting in Version 11.5 Modification Pack 7, in Linux (x86) environments only.

MAXROWS or MAX_ROWS

If set to a positive integer, this specifies the maximum number of records (rows) in the external table that are to be processed. If set to 0 (the default), there is no limit and all rows are processed. During a load operation, if MAXROWS is set to a positive value, after that number of rows are processed, regardless of whether some of the rows were rejected or skipped, the system ends the load operation and commits all inserted records.

MERIDIANDELIM

A single-byte character that separates the seconds component from the AM token or PM token in the 12-hour delimited and undelimited formats of a time value.

The default delimiter is a space (`' '`).

Between the seconds component and the AM token or PM token, a delimiter is not required. For example, both of the following values are valid:

```
1:02:46.12345 AM
1:02:46.12345AM
```

NOLOG

Specifies whether the `.log` file for the external table is created.

This option does not apply to `.bad` files.

Possible values are:

TRUE
No `.log` file is created.

FALSE
The `.log` file is created.

This is the default.

NULLVALUE or NULL_VALUE

The UTF-8 string of at most 4 bytes that is to be used to indicate a null value. The default is `'NULL'`.

PARTITION

If the Database Partitioning Feature (DPF) is enabled for the database, an external table can be partitioned into several files. The name of each of the data files that comprise an external table are suffixed with a period followed by a 3-digit number from 000 to 999 that indicates the number of the partition. For example, if an external table with the name **dataFile.txt** is divided into three partitions, the files that comprise it have the names **dataFile.txt.000**, **dataFile.txt.001**, and **dataFile.txt.002**. These files must be accessible from all members.

For a partitioned external table, the PARTITION option specifies to which partition or partitions the statement applies:

PARTITION ALL
The statement applies to all of the partitions that comprise the external table. For an unload operation, this is the only value that is allowed.

PARTITION (*n* TO *n*)
The statement applies to all of the partitions in the specified range, for example, **PARTITION (54 TO 62)**.

PARTITION (*n*,*n*,...)
The statement applies only to the specified partition or partitions, for example, **PARTITION (53)** or **PARTITION (51,57,58)**. If more than one partition number is specified, they must be in ascending order (sqlcode SQL0263N with SQLSTATE=42615) and there can be no duplicates (sqlcode SQL0265N with SQLSTATE=42615).

If a .log or .bad file is generated while carrying out an operation on a partitioned external table, the name of the generated file is suffixed with a period followed by the 3-digit partition number.

If the DPF is enabled and the PARTITION option is not specified, the external table is treated as single-partitioned table on the coordinator member. The names of the external table file and the .log and .bad files are not suffixed with a partition number.

If the DPF is not enabled, the PARTITION option can be specified, but only with the value ALL, (0 to 0), or (0) (SQL0644N). It will have no effect.

The REMOTESOURCE and PARTITION options are mutually exclusive.

QUOTEDNULL
For a load operation, how to interpret a value that is enclosed in single or double quotation marks and that matches the null value specified by the NULLVALUE or NULL_VALUE option (for example, "NULL" or 'NULL'):

TRUE or ON
The value is interpreted as a null value. This is the default.

FALSE or OFF
The value is interpreted as a character string.

QUOTEDVALUE or STRING_DELIMITER
Whether data values are enclosed in quotation marks:

SINGLE or YES
Data values are enclosed in single quotation marks (').

DOUBLE
Data values are enclosed in double quotation marks (").

NO
Data values are not enclosed in quotation marks. This is the default.

RECORDDELIM or RECORD_DELIMITER
The string literal that is to be interpreted as a row (record) delimiter. The default is `'\n'`.

When CRINSTRING is set to TRUE, RECORDDELIM cannot contain a CR ('\r') character - with the sole exception of a CRLF ('\r\n') delimiter allowed with CRINSTRING for text format only.

REMOTESOURCE
Where the external-table file resides and, if it resides on a remote system, whether the file data is to be compressed:

LOCAL
The file resides on the local server, that is, the system that hosts the database. This is the default.

YES
The file resides on a system other than the local server. For example, specify YES if a client system is connected to the database and the file resides on that system. File data is not compressed before it is transferred.

GZIP
Similar to YES, except that the file data is compressed using the GZIP compression algorithm before the data is transferred, and is decompressed after it is received. This improves overall performance when a large amount of compressible data is being transferred.

LZ4
Similar to YES, except that the file data is compressed using the LZ4 compression algorithm before the data is transferred, and is decompressed after it is received. This improves overall performance when a large amount of compressible data is being transferred.

The REMOTESOURCE, SWIFT, and S3 options are mutually exclusive.

Attention: In the container-only release of Db2 Version 11.5 Mod Pack 1 or later versions, AZURE is compatible and its options are mutually exclusive with REMOTESOURCE, SWIFT, and S3.

The REMOTESOURCE and PARTITION options are mutually exclusive. The COMPRESS option cannot be specified if the value of the REMOTESOURCE option is GZIP or LZ4.

REQUIREQUOTES
Whether quotation marks are mandatory:

TRUE or ON
Quotation marks are mandatory. The QUOTEDVALUE option must be set to YES, SINGLE, or DOUBLE.

FALSE or OFF
Quotation marks are not mandatory. This is the default.

SKIPROWS or SKIP_ROWS
For a load operation, the number of rows to skip before beginning to load the data. The default is 0. Because skipped rows are processed before they are skipped, a skipped row is still capable of causing a processing error.

SOCKETBUFSIZE
The size, in bytes, of the chunks of data that are read from the source file. Valid values range from 64 KB - 800 MB. If you specify a value outside this range, the value is set to the nearest valid value. The default is 8 MB.

STRICTNUMERIC
For a load operation, how to treat a value that is to be inserted into a DECIMAL field when its scale exceeds that defined for the field:

TRUE or ON
The row containing the value to be inserted is rejected. For example, if any of the following values were to be loaded into a DECIMAL(5,3) field, the row containing that value would be rejected:

```
12.666666666
-98.34496862785
0.00089
```

FALSE or OFF
The row containing the value to be inserted is accepted, and the portion of the decimal fraction that exceeds the scale defined for the field is truncated. This is the default. For example, the values in the previous example would be converted to:

```
12.666
-98.344
0.000
```

SWIFT
Specifies that the source data file is located in a Swift object store. The REMOTESOURCE, SWIFT, and S3 options are mutually exclusive. Use the DATAOBJECT option to specify the file name.

Attention: In the container-only release of Db2 Version 11.5 Mod Pack 1 or later versions, AZURE is compatible and its options are mutually exclusive with REMOTESOURCE, SWIFT, and S3.

Syntax:

```
SWIFT (endpoint, authKey1, authKey2, bucket)
```

where:

endpoint
A character string that specifies the URL of the SWIFT web service.

authKey1
A character string that specifies the access ID or username of the Swift open stack account used to validate the user.

authKey2
A character string that specifies the password of the Swift open stack account used to validate the user.

bucket
The name of the Swift open stack container (bucket) in which the file resides.

Example:

```
CREATE EXTERNAL TABLE exttab1(a int) using
  (dataobject 'datafile1.dat'
   swift('https://dal05.objectstorage.softlayer.net/auth/v1.0/',
    'XXXOS123456-2:xxx123456',
    'b207c6e974020737d92174esdf6d5be9382aa4c335945a14eaa9172c70f8df16',
    'my_dev'
   )
  )
```

S3

Specifies that the source data file is located in an S3 compatible object store. The REMOTESOURCE, SWIFT, and S3 options are mutually exclusive. Use the DATAOBJECT option to specify the file name.

Attention: In the container-only release of Db2 Version 11.5 Mod Pack 1 or later versions, AZURE is compatible and its options are mutually exclusive with REMOTESOURCE, SWIFT, and S3.

Syntax:

```
S3 (endpoint, authKey1, authKey2, bucket)
```

where:

endpoint
A character string that specifies the URL of the S3 compatible web service.

authKey1
A character string that specifies the S3 access key ID of the access keys used to validate the user and all user actions. For IBM Cloud Object Storage, this is the access key ID from the HMAC credentials.

authKey2
A character string that specifies the S3 secret key of the access keys that are used to validate the user and all user actions. For IBM Cloud Object Storage, this is the secret access key from the HMAC credentials.

bucket
The name of the S3 bucket in which the file resides.

Note: For IBM Cloud Object Storage, to create HMAC credentials, when creating new service credentials, specify `{"HMAC:true}` in the **Add Inline Configuration Parameters** field.

Example using AWS S3:

```
CREATE EXTERNAL TABLE exttab2(a int) using
  (dataobject 'datafile2.dat'
   s3('s3.amazonaws.com',
    'XXXOS123456-2:xxx123456',
    'bs07c6e974040737d92174e5e96d5be9382aa4c33xxx5a14eaa9172c70f8df16',
    'my_dev'
   )
  )
```

Example using IBM Cloud Object Storage:

```
CREATE EXTERNAL TABLE exttab2(a int) using
  (dataobject 'datafile2.dat'
   s3('s3-api.us-geo.objectstorage.softlayer.net',
    '1a2bkXXXsaddntLo0xX0',
    'XXxxiEPjJ7T7WBUz74E6abcdABCDE8Q7RgU4gYY9',
    'my_dev'
   )
  )
```

AZURE

Attention: This feature is available in the container-only release of Db2 Version 11.5 Mod Pack 1 or later versions.

Specifies that the source data file is located in Microsoft Azure Blob Storage. The REMOTESOURCE, SWIFT, S3, and AZURE options are mutually exclusive. Use the DATAOBJECT option to specify the file name. Syntax:

Syntax:

```
AZURE (endpoint, authKey1, authKey2, bucket)
```

where:

endpoint
A character string that specifies the URL of the AZURE web service.

authKey1
A character string that specifies the access ID or username of the Azure Blob Storage account used to validate the user.

authKey2
A character string that specifies the access key of the Azure Blob Storage account used to validate the user.

bucket
The name of the Azure Blob Storage container (bucket) in which the file resides.

Example:

```
CREATE EXTERNAL TABLE exttab1(a int) using
  (dataobject 'datafile1.dat'
   azure('https://my_account.blob.core.windows.net',
    'my_account',
    'lW+oHjmZecPS++IKgThAHlMUOaFUA5C6Z2RlFmc9JPpK34RO/ZIOywzILxJnzGPHz6d/
yDrcQDAwH5wySbOZMQ==',
    'my_bucket'
   )
  )
```

Example using IBM Cloud Object Storage:

```
CREATE EXTERNAL TABLE exttab2(a int) using
  (dataobject 'datafile2.dat'
   s3('s3-api.us-geo.objectstorage.softlayer.net',
    '1a2bkXXXsaddntLo0xX0',
    'XXxxiEPjJ7T7WBUz74E6abcdABCDE8Q7RgU4gYY9',
    'my_dev'
```

```
    )
  )
```

TIMEDELIM
The single-byte character that is to separate time components (hours, minutes, and seconds). The default is ' : '. If TIMEDELIM is set to an empty string, hours, minutes, and seconds must all be specified as two-digit numbers. The TIMESTAMP_FORMAT and TIMEDELIM options are mutually exclusive.

TIMEROUNDNANOS or TIMEEXTRAZEROS

Note: This option applies only to TIMESTAMP columns.

Specifies whether records that contain time values whose non-zero precision exceeds six decimal places are to be accepted (and rounded to the nearest microsecond) or rejected:

TRUE
All records are accepted. Their time values are rounded to the nearest microsecond.

FALSE
Only those records that can be stored without a loss of precision (for example, '08.15.32.123' or '08.15.32.12345600000', but not '08.15.32.1234567') are accepted. All other records are rejected. This is the default.

TIMESTYLE
The time format that is to be used in the data file:

24HOUR
24-hour format, for example 23:55. This is the default.

12HOUR
12-hour format, for example 11:55 PM. An AM or PM token can be preceded by a single space and is not case-sensitive.

The TIMESTYLE option and the TIME_FORMAT or TIMESTAMP_FORMAT option are mutually exclusive.

TIMESTAMP_FORMAT
The format of the timestamp field in the data file. The value can be any of the format strings that are accepted by the “TIMESTAMP_FORMAT ” on page 527. The default is **'YYYY-MM-DD HH.MI.SS'**. The TIMESTAMP_FORMAT option and the TIMEDELIM, DATEDELIM, TIMESTYLE, or DATESTYLE option are mutually exclusive.

TIME_FORMAT
The format of the time field in the data file. The value can be any of the time format strings that are accepted by the “TIMESTAMP_FORMAT ” on page 527. The default is **HH.MI.SS**. The TIME_FORMAT option and a TIMEDELIM or TIMESTYLE option are mutually exclusive.

TRIMBLANKS
How an external table is to treat leading or trailing blanks (that is, leading or trailing space characters) in a string:

LEADING
All leading blanks (that is, blanks that precede the first non-blank character) are removed.

TRAILING
All trailing blanks (that is, blanks that follow the last non-blank character) are removed.

BOTH
All leading and trailing blanks are removed.

NONE
No blanks are removed. This is the default.

When reading data from a file and loading it into an external table:

- If QUOTEDVALUE or STRING_DELIMITER is specified with the values SINGLE, YES, or DOUBLE, leading and trailing blanks within quotation marks are not removed.

- For CHAR and NCHAR data, the values TRAILING or BOTH will not have any effect on trailing blanks, because the string will automatically be re-padded with trailing blanks.

TRUNCSTRING or TRUNCATE_STRING
How the system processes a CHAR or VARCHAR string that exceeds its declared storage size:

TRUE
The system truncates a string value that exceeds its declared storage size.

FALSE
The system returns an error when a string value exceeds its declared storage size. This is the default.

Y2BASE
The year that is the beginning of the 100-year range. Years that are specified as 2 digits are counted from this year. The default is 2000. This option must be specified when DATESTYLE is set to Y2MD, MDY2, DMY2, MONDY2 or DMONY2.

Table 133. Options

Option	Default	Applies to Load	Applies to Unload
Azure **Attention:** This option only applies to the container-only release of Db2 Version 11.5 Mod Pack 1 or later versions.	(no default)	Y	Y
BOOLSTYLE or BOOLEAN_STYLE	1_0	Y	Y
CARDINALITY	(no default)	Y	Y
CCSID	(no default)	Y	Y
COMPRESS	NO	Y	Y
CRINSTRING	FALSE	Y	Y
CTRLCHARS	FALSE	Y	N
DATAOBJECT or FILE_NAME	(no default)	Y	Y
DATEDELIM	'-'	Y	Y
DATETIMEDELIM	A space (' ')	Y	Y
DATESTYLE	YMD	Y	Y
DATE_FORMAT	YYYY-MM-DD	Y	Y
DECIMALDELIM or DECIMAL_CHARACTER	'.'	Y	Y
DELIMITER	'|'	Y	Y
ENCODING	INTERNAL	Y	Y[1]
ESCAPECHAR or ESCAPE_CHARACTER	(no default)	Y	Y
FILLRECORD	FALSE	Y	N
FORMAT or FILE_FORMAT	TEXT	Y	Y
IGNOREZERO or TRIM_NULLS	FALSE	Y	N
INCLUDEHEADER or COLUMN_NAMES	FALSE	N	Y

Table 133. Options (continued)

Option	Default	Applies to Load	Applies to Unload
INCLUDEZEROSECONDS	FALSE	Y	Y
INCLUDEHIDDEN	FALSE	Y	N
LFINSTRING	FALSE	Y	N
LOGDIR or ERROR_LOG	target directory of external-table file	Y	N
MULTIPARTSIZEMB	value specified by the MULTIPARTSIZEMB dbm config parameter.	Y	N
MAXERRORS or MAX_ERRORS	1	Y	N
MAXROWS or MAX_ROWS	0	Y	N
MERIDIANDELIM	A space (' ')	Y	Y
NOLOG	FALSE	Y	Y
NULLVALUE or NULL_VALUE	'NULL'	Y	Y
PARTITION	(no default)	Y	Y
QUOTEDNULL	TRUE	Y	N
QUOTEDVALUE	NO	Y	N
RECORDDELIM or RECORD_DELIMITER	'\n'	Y	N
REMOTESOURCE	LOCAL	Y	Y
REQUIREQUOTES	FALSE	Y	N
SKIPROWS or SKIP_ROWS	0	Y	N
SOCKETBUFSIZE	8 MB	Y	Y
STRICTNUMERIC	FALSE	Y	N
SWIFT	(no default)	Y	Y
S3	(no default)	Y	Y
TIMEDELIM	':'	Y	Y
TIMEROUNDNANOS or TIMEEXTRAZEROS	FALSE	Y	N
TIMESTAMP_FORMAT	'YYYY-MM-DD HH.MI.SS'	Y	Y
TIMESTYLE	24HOUR	Y	Y
TIME_FORMAT	HH.MI.SS	Y	Y
TRIMBLANKS	NONE	Y	Y
TRUNCSTRING or TRUNCATE_STRING	FALSE	Y	N
Y2BASE	2000	Y	N

[1] Only for the values INTERNAL, UTF8, and LATIN9.

AS SELECT STATEMENT
Specifies that, for each column in the derived result table of the fullselect, a corresponding column is to be defined for the table and populated with the results of the query. Each defined column adopts the following attributes from its corresponding column of the result table (if applicable to the data type):

- Column name
- Column description
- Data type, length, precision, and scale
- Nullability

Notes

- Records that cannot be processed (if any) are written to a file with a name of the form:

```
<database>.<schema>.<external-table-name>.<file-name>.<application-handle>.<id>.bad
```

  Errors are logged in a file with a name of the form:

```
<database>.<schema>.<external-table-name>.<file-name>.<application-handle>.<id>.log
```

  These files are located in the directory specified by the LOGDIR or ERROR_LOG option.

  For an operation on a partition, the name of the generated .bad or .log file is suffixed with a period followed by the 3-digit partition number.
- To create, insert into, or drop a named external table, issue a CREATE, INSERT, or DROP statement. You cannot insert into or drop a transient external table.
- Dropping an external table deletes the table definition but does not delete the data file that is associated with the table.

Restrictions

- Remote external table restrictions:
  - It is not allowed within routines
  - It is not allowed with the use of LOAD CURSOR
  - For remote external tables (that is, for external tables are not located in a Swift or S3 object store and for which the REMOTESOURCE option is set to a value other than LOCAL):

    Attention: In the container-only release of Db2 Version 11.5 Mod Pack 1 or later versions, AZURE is compatible, with the same remote external table restriction.

    Note: A single query or subquery cannot select from more than one external table at a time, and cannot reference the same external table more than once. If necessary, combine data from several external tables into a single table and use that table in the query.

    In addition, a union operation cannot involve more than one external table.
- External tables can be queried only by a user ID defined within the operating system.
- External tables cannot be used by a Db2 instance running on a Windows system.
- Data being loaded must be properly formatted.
- You cannot delete, truncate, or update an external table.

Syntax alternatives

The following alternatives are non-standard. They are supported for compatibility with earlier product versions or with other database products.

- SAMEAS can be used in place of LIKE.

- For the REMOTESOURCE option, the values ODBC, JDBC, or OLE-DB can be specified in place of YES.
- If the FORMAT option is set to INTERNAL, the value YES can be specified in place of GZIP for the COMPRESS option.

Examples

- Unload data to an external table:

```
CREATE EXTERNAL TABLE 'order.tbl' USING (DELIMITER '|') AS SELECT * from orders;
```

```
CREATE EXTERNAL TABLE 'export.csv' USING (DELIMITER ',') AS SELECT foo.x, bar.y, bar.dt FROM
foo, bar WHERE foo.x = bar.x;
```

- Load data from an external table:

```
INSERT INTO target SELECT * FROM EXTERNAL 'data.txt' USING (DELIMITER '|');
```

```
INSERT INTO orders SELECT * FROM EXTERNAL 'order.tbl'( order_num INT, order_dt TIMESTAMP)
USING (DELIMITER '|');
```

- Select data from an external table:

```
SELECT * FROM EXTERNAL 'order.tbl' (order_num INT, order_dt TIMESTAMP) USING (DELIMITER '|');
```

```
SELECT * FROM EXTERNAL 'test.txt' LIKE test_table USING (DELIMITER ',');
```

```
SELECT x, y AS dt FROM EXTERNAL 'test.txt' ( x integer, y decimal(18,4) ) USING (DELIMITER
',');
```

CREATE FUNCTION

The CREATE FUNCTION statement is used to register or define a user-defined function or function template at the current server.

There are five different types of functions that can be created using this statement. Each of these is described separately.

- External Scalar. The function is written in a programming language and returns a scalar value. The external executable is registered in the database, along with various attributes of the function.
- External Table. The function is written in a programming language and returns a complete table. The external executable is registered in the database along with various attributes of the function.
- OLE DB External Table. A user-defined OLE DB external table function is registered in the database to access data from an OLE DB provider.
- Sourced or Template. A source function is implemented by invoking another function (either built-in, external, SQL, or source) that is already registered in the database.

  It is possible to create a partial function, called a *function template*, which defines what types of values are to be returned, but which contains no executable code. The user maps it to a data source function within a federated system, so that the data source function can be invoked from a federated database. A function template can be registered only with an application server that is designated as a federated server.
- SQL Scalar, Table or Row. The function body is written in SQL and defined together with the registration in the database. It returns a scalar value, a table, or a single row.
- Aggregate interface. A aggregate interface function is implemented by invoking several external procedures and an external function which are referred to as component routines.

The CREATE FUNCTION statement can be submitted in obfuscated form. In an obfuscated statement, only the function name and its parameters are readable. The rest of the statement is encoded in such

a way that is not readable but can be decoded by the database server. Obfuscated statements can be produced by calling the DBMS_DDL.WRAP function.

CREATE FUNCTION (aggregate interface)

The CREATE FUNCTION (aggregate interface) statement is used to register a user-defined aggregate function at the current server.

An aggregate function returns a single value that is the result of an evaluation of a set of like values, such as those in a column within a set of rows.

Invocation

This statement can be embedded in an application program or issued in dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges that are held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the schema name of the function does not refer to an existing schema
- CREATEIN privilege on the schema, if the schema name of the function refers to an existing schema
- DBADM authority

The privileges that are held by the authorization ID of the statement must also include EXECUTE privilege on the following routines, if the authorization ID of the statement does not have DATAACCESS authority:

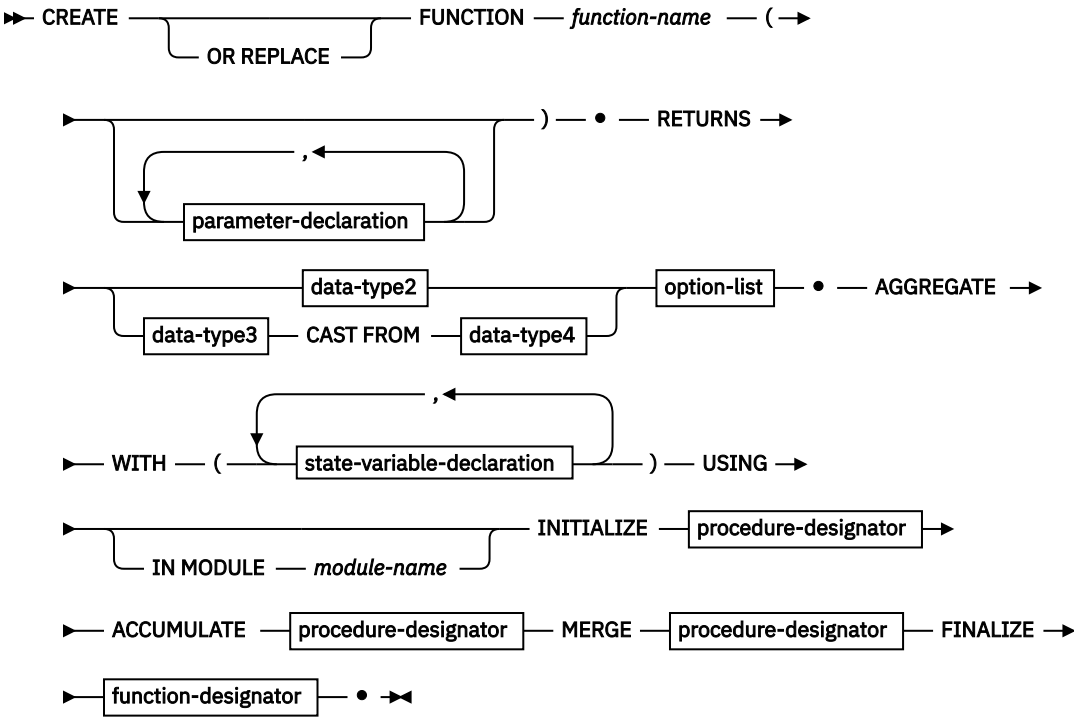
- INITIATE
- ACCUMULATE
- MERGE
- FINALIZE

Group privileges, except for PUBLIC, are not considered on any dependent object specified in the CREATE FUNCTION statement.

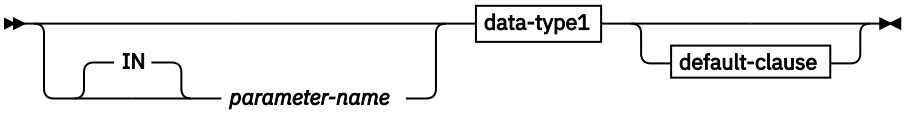
To replace an existing function, the authorization ID of the statement must be the owner of the existing function (SQLSTATE 42501).

If the SECURED option is specified, the authorization ID of the statement must include SECADM or CREATE_SECURE_OBJECT authority (SQLSTATE 42501).

Syntax

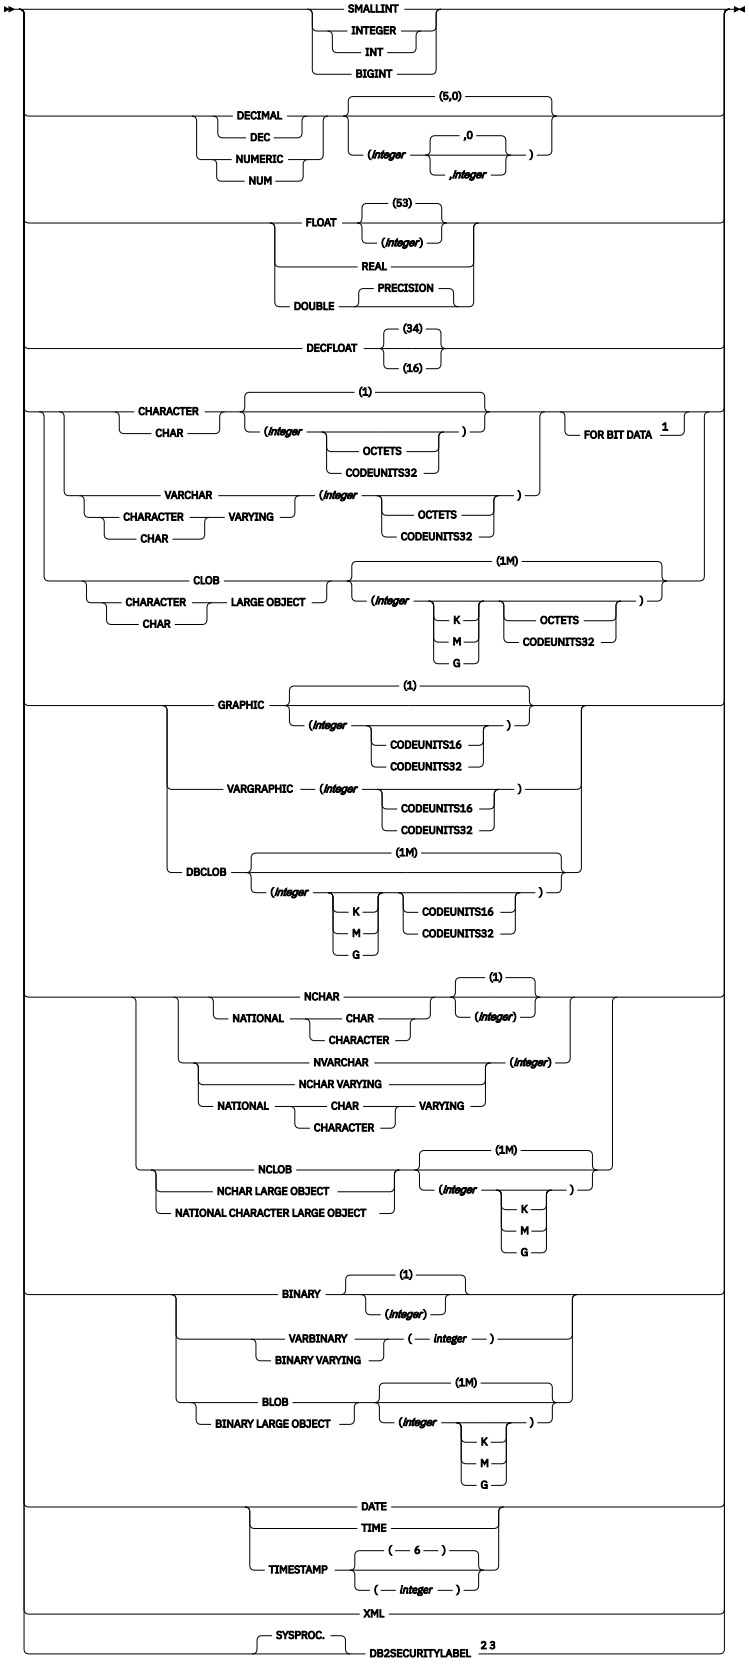


parameter-declaration

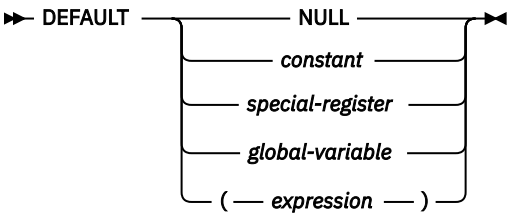


data-type1, data-type2, data-type3, data-type4, data-type5

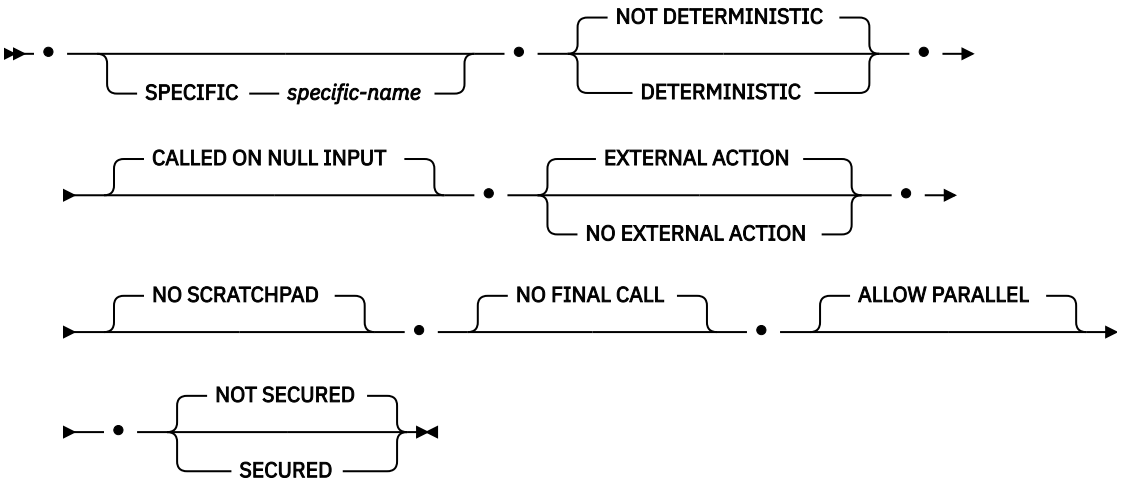
built-in-type



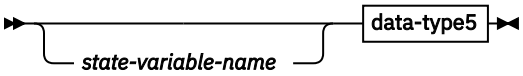
default-clause



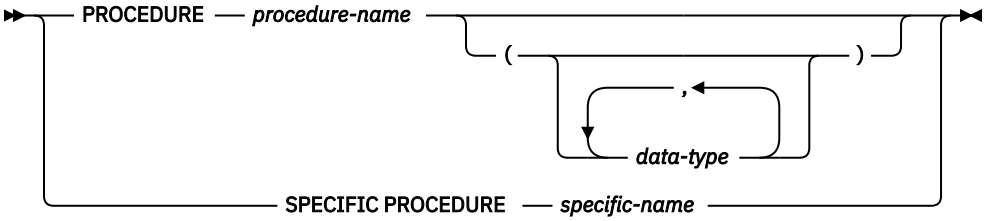
option-list



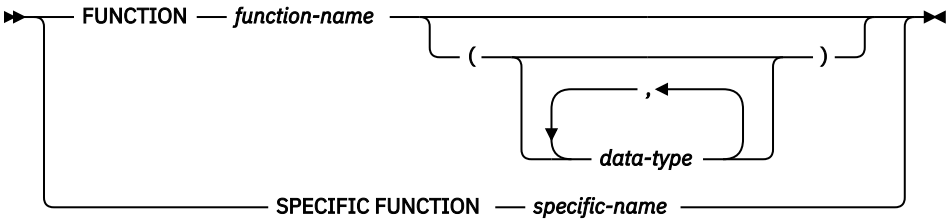
state-variable-declaration



procedure-designator



function-designator



Notes:

[1] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

[2] DB2SECURITYLABEL is the built-in distinct type that must be used to define the row security label column of a protected table.

[3] For a column of type DB2SECURITYLABEL, NOT NULL WITH DEFAULT is implicit and cannot be explicitly specified (SQLSTATE 42842). The default value for a column of type DB2SECURITYLABEL is the session authorization ID's security label for write access.

Description

OR REPLACE

Specifies to replace the definition for the function if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that privileges that were granted on the function are not affected. This option can be specified only by the owner of the object. This option is ignored if a definition for the function does not exist at the current server. An existing function can be replaced if either of the following conditions apply:

- The specific name and function name of the new definition must be the same as the specific name and function name of the old definition
- The signature of the new definition must match the signature of the old definition

Otherwise, a new function is created.

If the function is referenced in the definition of a row permission or a column mask, the function cannot be replaced (SQLSTATE 42893).

function-name

Names the function that is being defined. It is a qualified or unqualified name that designates a function. The unqualified form of *function-name* is an SQL identifier. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The qualified form is a *schema-name* followed by a period and an SQL identifier. The qualified name must not be the same as the data type of the first parameter, if that first parameter is a structured type.

The function signature must not identify a function or method described in the catalog (SQLSTATE 42723). When the name is being assessed, the number of parameters and the data type of each parameter (without regard for any length, precision or scale attributes of the data type) is considered. The unqualified name, together with the number and data types of the parameters, must be unique within its schema. However, the name does not need to be unique across schemas.

If a two-part name is specified, the *schema-name* cannot begin with "SYS" (SQLSTATE 42939).

A number of names that are used as keywords in predicates are reserved for system use, and cannot be used as a *function-name* (SQLSTATE 42939). The names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators.

In general, the same name can be used for more than one function if the function signatures are different.

Although it is not prohibited, do not give an aggregate interface function the same name as a built-in function, unless it is an intentional override. Examples of such functions are MAX, MIN, and AVG. Creating a user-defined function that has different behavior, yet the same name, and consistent arguments as a built-in scalar or aggregate function, can lead to problems. Examples include:

- Problems in dynamic SQL statements
- Static SQL applications can fail when they are rebound
- Applications might appear to run successfully but provide a different result

(*parameter-declaration*,...)

Identifies the number of input parameters of the function, and specifies the mode, name, data type, and optional default value of each parameter. One entry in the list must be specified for each parameter that the function expects to receive. Up to 90 parameters can be specified (SQLSTATE 54023).

You can register a function that has no parameters; the parentheses must still be coded, with no intervening data types. For example:

```
CREATE FUNCTION WOOFER() ...
```

Two functions with identical names in the same schema cannot have the same type for all corresponding parameters. Lengths, precisions, and scales are not considered in this type comparison. Therefore, CHAR(8) and CHAR(35) are considered to be the same type, as are DECIMAL(11,2) and DECIMAL (4,3). A weakly typed distinct type that is specified for a parameter is considered to be the same data type as the source type of the distinct type. For a Unicode database, CHAR(13) and GRAPHIC(8) are considered to be the same type. Further bundling of types causes them to be treated as the same type for this purpose, such as DECIMAL and NUMERIC. A duplicate signature returns an error (SQLSTATE 42723).

IN
Identifies the parameter as an input parameter to the function. Any changes that are made to the parameter within the function are not available to the invoking context when control is returned.

parameter-name
Specifies an optional name for the parameter. The name cannot be the same as any other *parameter-name* in the parameter list (SQLSTATE 42734).

data-type1
Specifies the data type of the parameter. The data type can be a built-in data type. For a complete description of each built-in data type, see "CREATE TABLE " on page 1351. The data type must not be XML, CLOB, DBCLOB, or BLOB. (SQLSTATE 42815). The data type must not be a distinct type (SQLSTATE 42611).

DEFAULT
Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The special registers that can be specified as the default are the same as those special registers that can be specified for a column default (see *default-clause* in the "CREATE TABLE " on page 1351). Other special registers can be specified as the default by using an expression.

The expression can be any expression of the type described in "Expressions" on page 132. If a default value is not specified, the parameter has no default and the corresponding argument cannot be omitted on invocation of the procedure. The maximum size of the expression is 64 KB.

The default expression must not modify SQL data (SQLSTATE 428FL or SQLSTATE 429BL). The expression must be assignment compatible to the parameter data type (SQLSTATE 42821).

RETURNS
This mandatory clause identifies the output of the function.

data-type2
Specifies the data type of the output.

In this case, the same considerations apply as described in *data-type1* for function parameters.

The data type must not be a distinct type (SQLSTATE 42611).

data-type3* CAST FROM *data-type4
Specifies the data type of the output.

This form of the RETURNS clause returns a different data type to the invoking statement than the data type that was returned by the function code of the FINALIZE function. Example:

```
CREATE FUNCTION GET_HIRE_DATE(CHAR(6))
  RETURNS DATE CAST FROM CHAR(10)
  ...
```

In the preceding code, the function code returns a CHAR(10) value to the database manager. The database manager then converts it to a DATE and passes that value to the invoking statement. The *data-type4* must be castable to the *data-type3* parameter. If it is not castable, an error (SQLSTATE 42880) is returned.

The length, precision, or scale for *data-type3* can be inferred from *data-type4*. Although you can specify the length, precision, or scale for parameterized types for *data-type3*, it is not necessary. Instead, empty parentheses can be used. For example, VARCHAR() can be used).

FLOAT() cannot be used (SQLSTATE 42601) since parameter value indicates different data types (REAL or DOUBLE).

Distinct types are not valid as the type specified in *data-type3* or *data-type4* (SQLSTATE 42815).

The cast operation is also subject to runtime checks that might result in conversion errors.

built-in-type
See "CREATE TABLE " on page 1351 for the description of built-in data types.

option-list

SPECIFIC *specific-name*
Provides a unique name for the instance of the function that is being defined. This specific name can be used when sourcing on this function, dropping the function, or commenting on the function. It can never be used to invoke the function. The unqualified form of *specific-name* is an SQL identifier. The qualified form is a *schema-name* followed by a period and an SQL identifier. The name, including the implicit or explicit qualifier, must not identify another function instance or method specification that exists at the application server; otherwise, an error (SQLSTATE 42710) is returned.

The *specific-name* can be the same as an existing *function-name*.

If no qualifier is specified, the qualifier that was used for *function-name* is used. If a qualifier is specified, it must be the same as the explicit or implicit qualifier of *function-name* or an error (SQLSTATE 42882) is returned.

If *specific-name* is not specified, a unique name is generated by the database manager. The unique name is SQL followed by a character timestamp, SQLyymmddhhmmssxxx.

DETERMINISTIC or NOT DETERMINISTIC
This optional clause specifies whether the function always returns the same results for given argument values (DETERMINISTIC) or whether the function depends on some state values that affect the results (NOT DETERMINISTIC). That is, a DETERMINISTIC function must always return the same result from successive invocations with identical inputs. Optimizations taking advantage of the fact that identical inputs always produce the same results are prevented by specifying NOT DETERMINISTIC. An example of a NOT DETERMINISTIC function would be a random-number generator. An example of a DETERMINISTIC function would be a function that determines the square root of the input. If DETERMINISTIC is specified, then the INITIALIZE, ACCUMULATE, MERGE, and FINALIZE routines that are identified must also be DETERMINISTIC (SQLSTATE 428IA).

CALLED ON NULL INPUT
CALLED ON NULL INPUT always applies to aggregate interface functions. In other words, the function is called regardless of whether any argument's set of values are all null. The INITIALIZE, ACCUMULATE, and MERGE procedures that are identified are also always CALLED ON NULL INPUT since they are procedures. The FINALIZE function that is identified must also be CALLED ON NULL INPUT (SQLSTATE 428IA). Any parameter of the component routines can return a null value or a normal (non-null) value. Responsibility for testing for null argument values lies with the component routine.

EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the function has actions that change the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a file. The default is EXTERNAL ACTION.

EXTERNAL ACTION
Specifies that the function has actions that change the state of an object that the database manager does not manage.

A function with external actions might return incorrect results if the function is executed by parallel tasks. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function.

NO EXTERNAL ACTION
Specifies that the function does not have actions that change the state of an object that the database manager does not manage. The database manager uses this information during optimization of SQL statements. If NO EXTERNAL ACTION is specified, then the INITIALIZE, ACCUMULATE, MERGE, and FINALIZE routines that are identified must also be NO EXTERNAL ACTION (SQLSTATE 428IA).

NO SCRATCHPAD
This optional clause can be used to specify whether a scratchpad is to be provided for an external function. NO SCRATCHPAD is allowed for an aggregate interface function. The INITIALIZE, ACCUMULATE, and MERGE procedures identified always have NO SCRATCHPAD since they are procedures. The FINALIZE function that is identified must also be NO SCRATCHPAD (SQLSTATE 428IA).

NO FINAL CALL
This optional clause specifies whether a final call is to be made to an external function. NO FINAL CALL is allowed for an aggregate interface function. The INITIALIZE, ACCUMULATE, and MERGE procedures that are identified always are NO FINAL CALL since they are procedures. The FINALIZE function that is identified must also be NO FINAL CALL (SQLSTATE 428IA).

ALLOW PARALLEL
This optional clause specifies whether, for a single reference to the function, the invocation of the function can be parallelized. For aggregate interface functions, only ALLOW PARALLEL is supported.

NOT SECURED or SECURED
Specifies whether the function is considered secure for row and column access control. The default is NOT SECURED.

NOT SECURED
Indicates that the function is not considered secure. When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled and column level access control is activated for its table (SQLSTATE 428HA). This rule applies to the non-secure user-defined functions that are invoked anywhere in the statement.

SECURED
Indicates that the function is considered secure.

AGGREGATE
This mandatory clause indicates that the CREATE FUNCTION statement is being used to register a user-defined aggregate function.

WITH
This clause is used to specify the state variables that are available between the stages of aggregate function processing. There must be at least one state variable defined.

state-variable-name
Specifies an optional name for the state variable. The name cannot be the same as any other *state-variable-name* in the list of state variables for this function definition (SQLSTATE 42734).

data-type5
Specifies the data type of a state variable.

The considerations that apply for the parameters of functions (as described in *data-type1*) also apply for function parameters. However, XML, CLOB, DBCLOB, and BLOB data types are not allowed as state variable data types (SQLSTATE 42611). The data type for *data-type5* must not be a distinct type (SQLSTATE 42611).

The total byte count of the state variables cannot be bigger than 32677 using the table row size approach to counting bytes (SQLSTATE 42611).

USING
This mandatory clause specifies how the aggregate function processing is implemented. The USING clause specifies a set of user-defined procedures and a user-defined scalar function that implement the phases of aggregate function processing.

IN MODULE *module-name*
This optional clause specifies that the three procedures and one function that are specified in the INITIALIZE, ACCUMULATE, MERGE, and FINALIZE clauses are in module *module-name*. If this clause is specified, the *procedure-name*, *function-name*, or *specific-name* specified in *procedure-designator* and *function-designator* must be unqualified names (SQLSTATE 42601).

INITIALIZE *procedure-designator*
Uniquely identifies a single procedure that implements the initialization phase of the aggregation.

The procedure that is selected must have output parameters only. The number of output parameters must be the same as the number of state variables specified in the AGGREGATE WITH clause (SQLSTATE 428IA). The data type of each output parameter in the procedure that is selected must have the exact same type as the corresponding data type specified in the AGGREGATE WITH clause (SQLSTATE 428IA).

Specify the following combinations of options for the selected procedure (SQLSTATE 428IA):

- LANGUAGE C and NO SQL
- LANGUAGE JAVA and NO SQL
- LANGUAGE SQL and CONTAINS SQL

The procedure must exist when this statement is run, unless the AUTO_REVAL database configuration parameter is set to DEFERRED_FORCE.

ACCUMULATE *procedure-designator*
Uniquely identifies a single procedure that implements the accumulate phase of the aggregation.

The procedure that is selected must meet the following criteria (SQLSTATE 428IA):

- The procedure that is selected must first have the same number of input-only parameters as the number of the parameters specified in the aggregation function.
- The procedure that is selected must then have the same number of INOUT parameters as the number of the state variables specified in the AGGREGATE WITH clause.

The data type of each input-only parameter in the procedure that is selected must have the exact same type as the corresponding data type specified in *parameter-declaration* (SQLSTATE 428IA). The data type of each INOUT parameter in the procedure that is selected must have the exact same type as the corresponding data type specified in the AGGREGATE WITH clause (SQLSTATE 428IA).

Specify the following combinations of options for the selected procedure (SQLSTATE 428IA):

- LANGUAGE C and NO SQL
- LANGUAGE JAVA and NO SQL
- LANGUAGE SQL and CONTAINS SQL

The procedure must exist when this statement is run, unless the AUTO_REVAL database configuration parameter is set to DEFERRED_FORCE.

MERGE *procedure-designator*
Uniquely identifies a single procedure that implements the merge phase of the aggregation.

The procedure that is selected must meet the following criteria (SQLSTATE 428IA):

- The procedure that is selected must first have the same number of input-only parameters as the number of the state variables specified in the AGGREGATE WITH clause.
- The procedure that is selected must then have the same number of INOUT parameters as the number of the state variables specified in the AGGREGATE WITH clause.

The data type of each input-only parameter in the procedure that is selected must have the exact same data type as the corresponding data type specified in the AGGREGATE WITH clause (SQLSTATE 428IA). The data type of each INOUT parameter in the procedure that is selected must have the exact same type as the corresponding data type specified in the AGGREGATE WITH clause (SQLSTATE 428IA).

Specify the following combinations of options for the selected procedure (SQLSTATE 428IA):

- LANGUAGE C and NO SQL
- LANGUAGE JAVA and NO SQL
- LANGUAGE SQL and CONTAINS SQL

The procedure must exist when this statement is run, unless the AUTO_REVAL database configuration parameter is set to DEFERRED_FORCE.

FINALIZE *function-designator*
Uniquely identifies a single user-defined scalar function that implements the final result phase of the aggregation.

The function that is selected must have the same number of input-only parameters as the number of the state variables specified in the AGGREGATE WITH clause (SQLSTATE 428IA). The data type of each input-only parameter in the function that is selected must have the exact same data type as the corresponding data type specified in the AGGREGATE WITH clause (SQLSTATE 428IA). The output data type of the function that is selected must have the exact same type as the output data type specified in the RETURNS clause (SQLSTATE 428IA).

Specify the following combinations of options for the selected procedure (SQLSTATE 428IA):

- LANGUAGE C and NO SQL
- LANGUAGE JAVA and NO SQL
- LANGUAGE SQL and CONTAINS SQL

The function must exist when this statement is run, unless the AUTO_REVAL database configuration parameter is set to DEFERRED_FORCE.

In the descriptions for the INITIALIZE, ACCUMULATE, MERGE, and FINALIZE routines, exact same data type means that lengths, precisions, scales, string units, and CCSIDs are considered in this type comparison. Therefore, the following data types are considered different:

- CHAR(8) and CHAR(35)
- VARCHAR(10 OCTETS) and VARCHAR(10 CODEUNIT32)
- DECIMAL(11,2) and DECIMAL (4,3)

A weakly typed distinct type is considered to be a different data type as the source type of the distinct type. CHAR(13) and GRAPHIC(13) are considered to be different types, even in a Unicode database.

procedure-designator

PROCEDURE *procedure-name*
Identifies a particular procedure, and is valid only if exactly one procedure instance with the name *procedure-name* exists in the schema. The identified procedure can have any number of parameters defined for it. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. If no procedure by this name exists in the named or implied schema, an error (SQLSTATE 42704) is returned. If there is more than one instance of the procedure in the named or implied schema, an error (SQLSTATE 42725) is returned. If a procedure by this name exists and the authorization ID of the statement does not have EXECUTE privilege on this procedure, an error (SQLSTATE 42501) is returned.

PROCEDURE *procedure-name (data-type,...)*
Provides the procedure signature, which uniquely identifies the procedure. The procedure resolution algorithm is not used.

procedure-name
Specifies the name of the procedure. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names.

(data-type,...)

Values must match the data types that were specified (in the corresponding position) on the CREATE PROCEDURE statement. The number of data types, and the logical concatenation of the data types, is used to identify the specific procedure instance.

If a data type is unqualified, the type name is resolved by searching the schemas on the SQL path.

It is not necessary to specify the length, precision, or scale for the parameterized data types. Instead, an empty set of parentheses can be coded to indicate that these attributes are to be ignored when looking for a data type match.

FLOAT() cannot be used (SQLSTATE 42601) because the parameter value indicates different data types (REAL or DOUBLE).

If length, precision, or scale is coded, the value must exactly match that specified in the CREATE PROCEDURE statement. When length is specified for character and graphic string data types, the string unit of the length attribute must exactly match that specified in the CREATE PROCEDURE statement.

A type of FLOAT(*n*) does not need to match the defined value for *n* because $0 < n < 25$ means REAL, and $24 < n < 54$ means DOUBLE. Matching occurs based on whether the type is REAL or DOUBLE.

If no procedure with the specified signature exists in the named or implied schema, an error (SQLSTATE 42883) is returned.

If a procedure by this procedure signature exists and the authorization ID of the statement does not have EXECUTE privilege on this procedure, an error (SQLSTATE 42501) is returned.

SPECIFIC PROCEDURE *specific-name*

Identifies a particular procedure, by using the name that is specified or defaulted to at procedure creation time. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The *specific-name* must identify a specific procedure instance in the named or implied schema; otherwise, an error (SQLSTATE 42704) is returned. If a procedure by this specific-name exists, and the authorization ID of the statement does not have EXECUTE privilege on this procedure, an error (SQLSTATE 42501) is returned.

FUNCTION *function-name*

Identifies a particular function, and is valid only if exactly one function instance with the name *function-name* exists in the schema. The identified function can have any number of parameters defined for it. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. If no function by this name exists in the named or implied schema, an error (SQLSTATE 42704) is returned. If there is more than one instance of the function in the named or implied schema, an error (SQLSTATE 42725) is returned. If a function by this name exists and the authorization ID of the statement does not have EXECUTE privilege on this function, an error (SQLSTATE 42501) is returned.

function-designator

FUNCTION *function-name (data-type,...)*

Provides the function signature, which uniquely identifies the function. The function resolution algorithm is not used.

function-name

Specifies the name of the function. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names.

(data-type,...)
Values must match the data types that were specified (in the corresponding position) on the CREATE FUNCTION statement. The number of data types, and the logical concatenation of the data types, is used to identify the specific function instance.

If a data type is unqualified, the type name is resolved by searching the schemas on the SQL path.

It is not necessary to specify the length, precision, or scale for the parameterized data types. Instead, an empty set of parentheses can be coded to indicate that these attributes are to be ignored when looking for a data type match.

FLOAT() cannot be used (SQLSTATE 42601) because the parameter value indicates different data types (REAL or DOUBLE).

If length, precision, or scale is coded, the value must exactly match that specified in the CREATE FUNCTION statement. When length is specified for character and graphic string data types, the string unit of the length attribute must exactly match that specified in the CREATE FUNCTION statement.

A type of FLOAT(*n*) does not need to match the defined value for *n* because 0 < *n* < 25 means REAL, and 24 < *n* < 54 means DOUBLE. Matching occurs based on whether the type is REAL or DOUBLE.

If no function with the specified signature exists in the named or implied schema, an error (SQLSTATE 42883) is returned.

If a function by this function signature exists and the authorization ID of the statement does not have EXECUTE privilege on this function, an error (SQLSTATE 42501) is returned.

SPECIFIC FUNCTION *specific-name*
Identifies a particular user-defined function, by using the name that is specified or defaulted to at function creation time. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The *specific-name* must identify a specific function instance in the named or implied schema; otherwise, an error (SQLSTATE 42704) is returned. If a function by this *specific-name* exists, and the authorization ID of the statement does not have EXECUTE privilege on this function, an error (SQLSTATE 42501) is returned.

Notes

- ***Privileges:*** The definer of a function always receives the EXECUTE privilege on the function. The definer of a function also receives the right to drop the function. The definer of the function is also given the WITH GRANT OPTION if the definer of the function has EXECUTE WITH GRANT OPTION on all of the component routines.

Examples

1. Define an aggregate function that returns the average of a set of numeric values, by using Java routines.

```
CREATE OR REPLACE PROCEDURE myavg_initialize(OUT sum DOUBLE, OUT count INT)
   LANGUAGE JAVA PARAMETER STYLE JAVA
   FENCED NO SQL
   EXTERNAL NAME 'myclass!myavg_initialize';

CREATE OR REPLACE PROCEDURE myavg_accumulate(IN input DOUBLE, INOUT sum DOUBLE, INOUT count
INT)
   LANGUAGE JAVA PARAMETER STYLE JAVA
   FENCED NO SQL
   EXTERNAL NAME 'myclass!myavg_accumulate';

CREATE OR REPLACE PROCEDURE myavg_merge(IN sum DOUBLE, IN count INT,
      INOUT mergesum DOUBLE, INOUT mergecount INT)
   LANGUAGE JAVA PARAMETER STYLE JAVA
```

```
   FENCED NO SQL
   EXTERNAL NAME 'myclass!myavg_merge';

CREATE OR REPLACE FUNCTION myavg_finalize(sum DOUBLE, count INT)
   RETURNS DECFLOAT(34)
   LANGUAGE JAVA PARAMETER STYLE JAVA
   FENCED NO SQL
   EXTERNAL NAME 'myclass!myavg_finalize';

CREATE OR REPLACE FUNCTION myavg(DOUBLE)
   RETURNS DECFLOAT(34)
   AGGREGATE WITH (sum DOUBLE, count INT)
   USING
   INITIALIZE PROCEDURE myavg_initialize
   ACCUMULATE PROCEDURE myavg_accumulate
   MERGE PROCEDURE myavg_merge
   FINALIZE FUNCTION myavg_finalize;
```

2. Define an aggregate function with procedure and function names that are unqualified. Define the aggregate function under the schema FOO. Invoke the aggregate function under schema BAR.

```
SET SCHEMA FOO;

CREATE OR REPLACE FUNCTION myavg(DOUBLE)
   RETURNS DOUBLE
   AGGREGATE WITH (sum DOUBLE, count INT)
   USING
   INITIALIZE PROCEDURE myavg_initialize
   ACCUMULATE PROCEDURE myavg_accumulate
   MERGE PROCEDURE myavg_merge
   FINALIZE FUNCTION myavg_finalize;

SET SCHEMA BAR;

SELECT FOO.myavg(c1) FROM t1;
```

   The database manager looks for procedures with the names of *FOO.myavg_initialize*, *FOO.myavg_accumulate*, *FOO.myavg_merge*, and function with the name of *FOO.myavg_finalize* for the invocation of *FOO.myavg*.

3. Define an aggregate function with specific procedure and function names that are unqualified. Define the aggregate function under the schema FOO. Invoke the aggregate function under schema BAR.

```
SET SCHEMA FOO;

CREATE OR REPLACE FUNCTION myavg(DOUBLE)
   RETURNS DOUBLE
   AGGREGATE WITH (sum DOUBLE, count INT)
   USING
   INITIALIZE SPECIFIC PROCEDURE myavg_initialize1
   ACCUMULATE SPECIFIC PROCEDURE myavg_accumulate1
   MERGE SPECIFIC PROCEDURE myavg_merge1
   FINALIZE SPECIFIC FUNCTION myavg_finalize1;

SET SCHEMA BAR;

SELECT FOO.myavg(c1) FROM t1;
```

   The database manager looks for procedures with the specific names of *FOO.myavg_initialize1*, *FOO.myavg_accumulate1*, *FOO.myavg_merge1*, and function with the specific name of *FOO.myavg_finalize1* for the invocation of *FOO.myavg*.

4. Define an aggregate function without some of the component routines. The aggregate function will be created as invalid and revalidation will be invoked in the next access.

```
UPDATE DB CFG USING AUTO_REVAL DEFERRED_FORCE;

CREATE OR REPLACE PROCEDURE myavg_initialize(OUT sum DOUBLE, OUT count INT)
   LANGUAGE JAVA PARAMETER STYLE JAVA
   FENCED NO SQL
   EXTERNAL NAME 'myclass!myavg_initialize';

CREATE OR REPLACE PROCEDURE myavg_accumulate(IN input DOUBLE, INOUT sum DOUBLE, INOUT count
INT)
   LANGUAGE JAVA PARAMETER STYLE JAVA
   FENCED NO SQL
```

```
   EXTERNAL NAME 'myclass!myavg_accumulate';

-- component routine merge and finalize are missing, the creation is successful and myavg is
invalid:
CREATE OR REPLACE FUNCTION myavg(DOUBLE)
   RETURNS DOUBLE
   AGGREGATE WITH (sum DOUBLE, count INT)
   USING
   INITIALIZE  PROCEDURE myavg_initialize
   ACCUMULATE PROCEDURE myavg_accumulate
   MERGE PROCEDURE myavg_merge
   FINALIZE FUNCTION myavg_finalize;

CREATE OR REPLACE PROCEDURE myavg_merge(IN sum DOUBLE, IN count INT,
      INOUT mergesum DOUBLE, INOUT mergecount INT)
   LANGUAGE JAVA PARAMETER STYLE JAVA
   FENCED NO SQL
   EXTERNAL NAME 'myclass!myavg_merge';

CREATE OR REPLACE FUNCTION myavg_finalize(sum DOUBLE, count INT)
   RETURNS DOUBLE
   LANGUAGE JAVA PARAMETER STYLE JAVA
   FENCED NO SQL
   EXTERNAL NAME 'myclass!myavg_finalize';

-- revalidation of myavg will be invoked and it will be successful
SELECT myavg(c1) FROM t1;
```

5. Define an aggregate function by using a global variable as a default for its parameter. Dropping the global variable invalidates the function.

```
CREATE VARIABLE gv1 DOUBLE;

-- create all 4 component routines (myavg_initialize, myavg_accumulate, myavg_merge,
myavg_finalize) like Example 1
...
...
...

CREATE OR REPLACE FUNCTION myavg(p1 DOUBLE DEFAULT gv1)
   RETURNS DOUBLE
   AGGREGATE WITH (sum DOUBLE, count INT)
   USING
   INITIALIZE SPECIFIC PROCEDURE myavg_initialize
   ACCUMULATE SPECIFIC PROCEDURE myavg_accumulate
   MERGE SPECIFIC PROCEDURE myavg_merge
   FINALIZE SPECIFIC FUNCTION myavg_finalize;

-- the following statement invalidates the function 'myavg'
DROP VARIABLE gv1;
```

6. Define an aggregate function whose component routines use a global variable as a default for its parameter. Dropping the global variable invalidates both the component routine and the aggregate function.

```
CREATE VARIABLE gv1 INT;

CREATE OR REPLACE PROCEDURE myavg_initialize(OUT sum DOUBLE, OUT count INT DEFAULT gv1)
   LANGUAGE JAVA PARAMETER STYLE JAVA
   FENCED NO SQL
   EXTERNAL NAME 'myclass!myavg_initialize';

-- create the remaining 3 component routines (myavg_accumulate, myavg_merge, myavg_finalize)
like Example 1
...
...
...

CREATE OR REPLACE FUNCTION myavg(DOUBLE)
   RETURNS DOUBLE
   AGGREGATE WITH (sum DOUBLE, count INT)
   USING
   INITIALIZE SPECIFIC PROCEDURE myavg_initialize
   ACCUMULATE SPECIFIC PROCEDURE myavg_accumulate
   MERGE SPECIFIC PROCEDURE myavg_merge
   FINALIZE SPECIFIC FUNCTION myavg_finalize;

-- the following statement invalidates both the routine 'myavg_initialize' and the function
```

```
'myavg'
DROP VARIABLE gv1;
```

7. Define an aggregation function, then create a procedure that calls the aggregation function. Next, drop or replace one of the component routines. Either action invalidates both the aggregation function and the procedure that calls it.

```
CREATE OR REPLACE PROCEDURE myavg_initialize(OUT sum DOUBLE, OUT count INT)
   LANGUAGE JAVA PARAMETER STYLE JAVA
   FENCED NO SQL
   EXTERNAL NAME 'myclass!myavg_initialize';

-- create the remaining 3 component routines (myavg_accumulate, myavg_merge, myavg_finalize)
like Example 1
...
...
...

CREATE OR REPLACE FUNCTION myavg(DOUBLE)
   RETURNS DOUBLE
   AGGREGATE WITH (sum DOUBLE, count INT)
   USING
   INITIALIZE SPECIFIC PROCEDURE myavg_initialize
   ACCUMULATE SPECIFIC PROCEDURE myavg_accumulate
   MERGE SPECIFIC PROCEDURE myavg_merge
   FINALIZE SPECIFIC FUNCTION myavg_finalize;

CREATE OR REPLACE PROCEDURE myproc (OUT p1 DOUBLE)
BEGIN
   SET p1 = (SELECT myavg(c1) FROM t1);
END;

-- drop the component routine
-- this action invalidates both the 'myavg' aggregation function and the 'myproc' procedure
that calls it:
DROP PROCEDURE myavg_initialize;

-- re-create the component routine
-- like the DROP statement, this action invalidates both the 'myavg' aggregation function
and the 'myproc' procedure that calls it:
CREATE OR REPLACE PROCEDURE myavg_initialize(OUT sum DOUBLE, OUT count INT)
   LANGUAGE C PARAMETER STYLE C
   FENCED NO SQL
   EXTERNAL NAME 'myclass!myavg_initialize_C_version';

-- revaliation is invoked the next time 'myproc' is accessed
-- both the 'myavg' aggregation function and the 'myproc' procedure are revalidated
CALL myproc(?);
```

8. Use the AUTO_REVAL database configuration parameter to control the invalidation and revalidation semantics.

```
UPDATE DB CFG USING AUTO_REVAL DEFERRED_FORCE;

-- global variable 'gv1' does not exist; the 'myavg_initialize' procedure can be created,
but it is invalid
CREATE OR REPLACE PROCEDURE myavg_initialize(OUT sum DOUBLE, OUT count INT default gv1)
   LANGUAGE JAVA PARAMETER STYLE JAVA
   FENCED NO SQL
   EXTERNAL NAME 'myclass!myavg_initialize';

-- create the remaining 3 component routines (myavg_accumulate, myavg_merge, myavg_finalize)
like Example 1
...
...
...

-- the 'myavg' function can be created, but it is invalid
CREATE OR REPLACE FUNCTION myavg(DOUBLE)
   RETURNS mydouble
   AGGREGATE WITH (sum DOUBLE, count INT)
   USING
   INITIALIZE SPECIFIC PROCEDURE myavg_initialize
   ACCUMULATE SPECIFIC PROCEDURE myavg_accumulate
   MERGE SPECIFIC PROCEDURE myavg_merge
   FINALIZE SPECIFIC FUNCTION myavg_finalize;

-- create the global variable 'gv1'
CREATE VARIABLE gv1 DOUBLE;
```

```
-- revalidation of 'myavg' function and 'myavg_initialize' procedure is invoked;
revalidation is successful
SELECT myavg(c1) FROM t1;

-- change the setting of the AUTO_REVAL database configuration parameter to IMMEDAITE
UPDATE DB CFG USING AUTO_REVAL IMMEDIATE;

-- the CREATE OR REPLACE VARIABLE statement invokes the revalidation for both 'myavg'
function and 'myavg_initialize' procedure
CREATE OR REPLACE VARIABLE gv1 DOUBLE DEFAULT 1.0;
```

9. Create an aggregate function that uses SQL routines to calculate and return the average of a set of numeric values.

```
CREATE OR REPLACE PROCEDURE myavg_initialize(OUT sum DECFLOAT, OUT count INT)
LANGUAGE SQL
CONTAINS SQL
BEGIN

  SET sum = 0;
  SET count = 0;

END @

CREATE OR REPLACE PROCEDURE myavg_accumulate(IN input DECFLOAT, INOUT sum DECFLOAT, INOUT
count INT)
LANGUAGE SQL
CONTAINS SQL
BEGIN

  SET sum = sum + input;
  SET count = count + 1;

END @

CREATE OR REPLACE PROCEDURE myavg_merge(IN sum DECFLOAT, IN count INT,
INOUT mergesum DECFLOAT, INOUT mergecount INT)
LANGUAGE SQL
CONTAINS SQL
BEGIN

  SET mergesum = sum + mergesum;
  SET mergecount = count + mergecount;

END @

CREATE OR REPLACE FUNCTION myavg_finalize(sum DECFLOAT, count INT)
LANGUAGE SQL
CONTAINS SQL
RETURNS DECFLOAT(34)
BEGIN

  RETURN (sum /  count);

END @

CREATE OR REPLACE FUNCTION myavg(DECFLOAT)
RETURNS DECFLOAT(34)
AGGREGATE WITH (sum DECFLOAT, count INT)
USING
INITIALIZE PROCEDURE myavg_initialize
ACCUMULATE PROCEDURE myavg_accumulate
MERGE PROCEDURE myavg_merge
FINALIZE FUNCTION myavg_finalize
@
```

CREATE FUNCTION (external scalar)

The CREATE FUNCTION (External Scalar) statement is used to register a user-defined external scalar function at the current server. A *scalar function* returns a single value each time it is invoked, and is in general valid wherever an SQL expression is valid.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CREATE_EXTERNAL_ROUTINE authority on the database and at least one of the following authorities:
  - IMPLICIT_SCHEMA authority on the database, if the schema name of the function does not refer to an existing schema
  - CREATEIN privilege on the schema, if the schema name of the function refers to an existing schema
  - SCHEMAADM authority on the schema, if the schema name of the function refers to an existing schema
- DBADM authority

Group privileges are not considered for any table or view specified in the CREATE FUNCTION statement.

To create a not-fenced function, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

- CREATE_NOT_FENCED_ROUTINE authority on the database
- DBADM authority

To create a fenced function, no additional authorities or privileges are required.

To replace an existing function, the authorization ID of the statement must be the owner of the existing function (SQLSTATE 42501).

If the SECURED option is specified, the authorization ID of the statement must include SECADM or CREATE_SECURE_OBJECT authority (SQLSTATE 42501).

Syntax

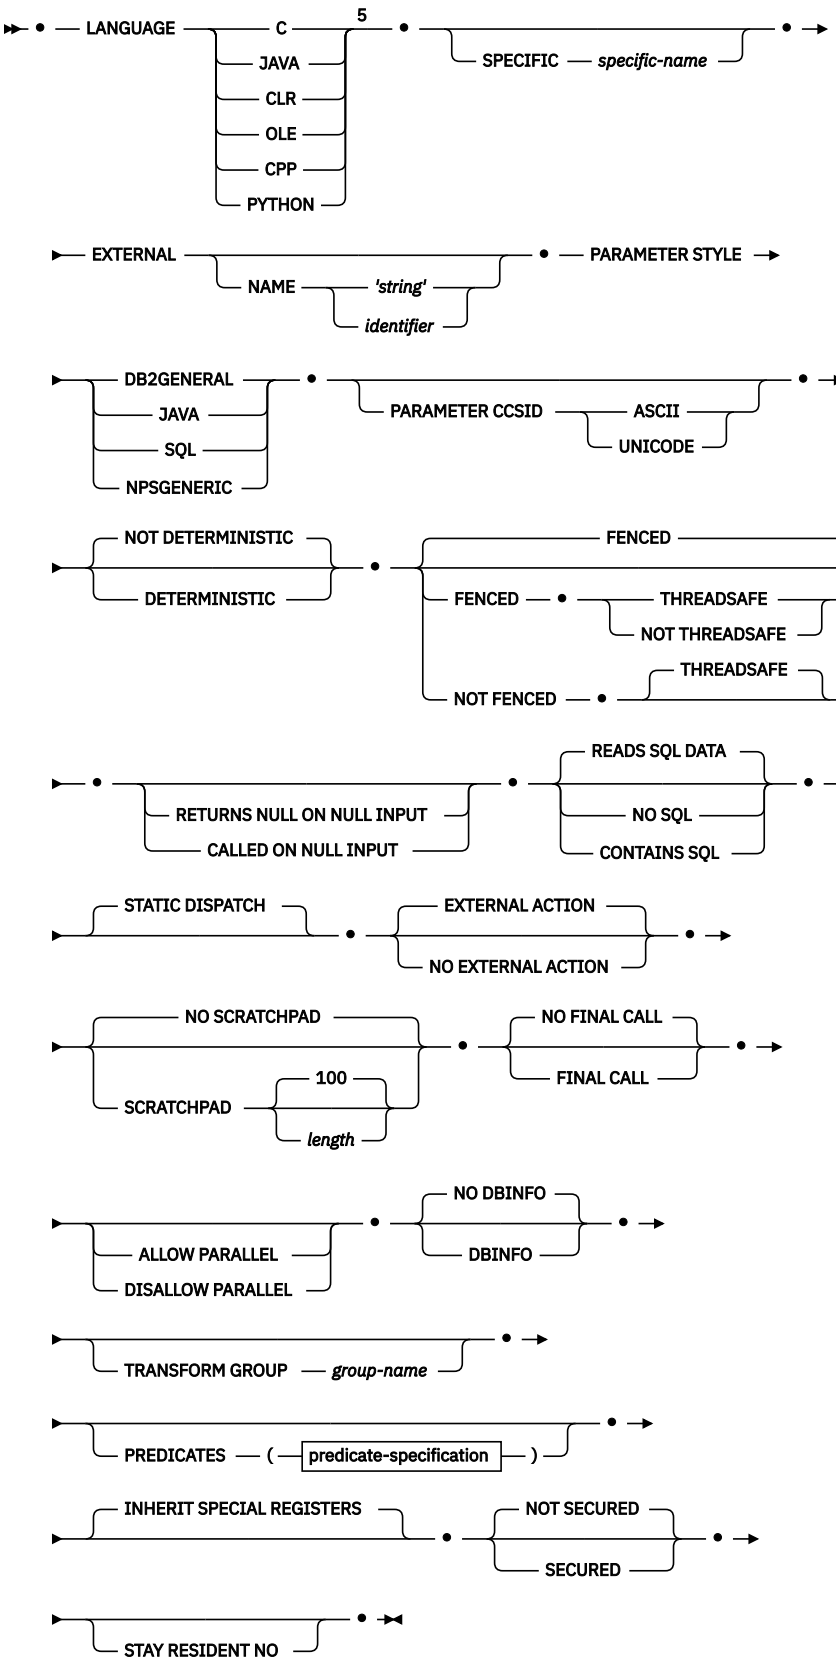
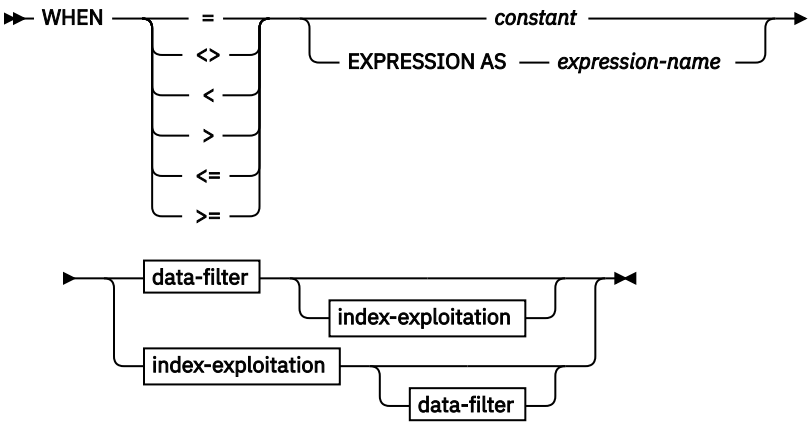
)

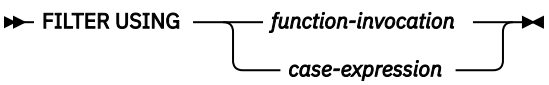
option-list



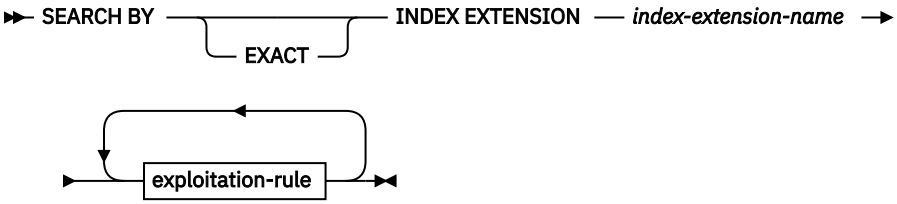
predicate-specification



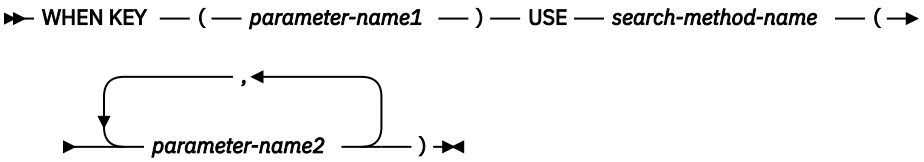
data-filter



index-exploitation



exploitation-rule



Notes:

[1] OUT and INOUT are valid only if the function has LANGUAGE C.

[2] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

[3] DB2SECURITYLABEL is the built-in distinct type that must be used to define the row security label column of a protected table.

[4] For a column of type DB2SECURITYLABEL, NOT NULL WITH DEFAULT is implicit and cannot be explicitly specified (SQLSTATE 42842). The default value for a column of type DB2SECURITYLABEL is the session authorization ID's security label for write access.

[5] LANGUAGE SQL is also supported.

Description

OR REPLACE

Specifies to replace the definition for the function if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that privileges that were granted on the function are not affected. This option can be specified only by the owner of the object. This option is ignored if a definition for the function does not exist at the current server. To replace an existing function, the specific name and function name of the new definition must be the same as the specific name and function name of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new function is created.

If the function is referenced in the definition of a row permission or a column mask, the function cannot be replaced (SQLSTATE 42893).

function-name
Names the function being defined. It is a qualified or unqualified name that designates a function. The unqualified form of *function-name* is an SQL identifier. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The qualified form is a *schema-name* followed by a period and an SQL identifier. The qualified name must not be the same as the data type of the first parameter, if that first parameter is a structured type.

The name, including the implicit or explicit qualifiers, together with the number of parameters and the data type of each parameter (without regard for any length, precision or scale attributes of the data type) must not identify a function or method described in the catalog (SQLSTATE 42723). The unqualified name, together with the number and data types of the parameters, while of course unique within its schema, need not be unique across schemas.

If a two-part name is specified, the *schema-name* cannot begin with "SYS";. Otherwise, an error (SQLSTATE 42939) is raised.

A number of names used as keywords in predicates are reserved for system use, and cannot be used as a *function-name*. The names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators. Failure to observe this rule will lead to an error (SQLSTATE 42939).

In general, the same name can be used for more than one function if there is some difference in the signature of the functions.

Although there is no prohibition against it, an external user-defined function should not be given the same name as a built-in function, unless it is an intentional override. To give a function having a different meaning the same name (for example, LENGTH, VALUE, MAX), with consistent arguments, as a built-in scalar or aggregate function, is to invite trouble for dynamic SQL statements, or when static SQL applications are rebound; the application may fail, or perhaps worse, may appear to run successfully while providing a different result.

(parameter-declaration,...)
Identifies the number of input parameters of the function, and specifies the mode, name, data type, and optional default value of each parameter. One entry in the list must be specified for each parameter that the function expects to receive. Up to 90 parameters can be specified (SQLSTATE 54023).

You can register a function that has no parameters; the parentheses must still be coded, with no intervening data types. For example:

```
CREATE FUNCTION WOOFER() ...
```

No two identically-named functions within a schema are permitted to have exactly the same type for all corresponding parameters. Lengths, precisions, and scales are not considered in this type comparison. Therefore, CHAR(8) and CHAR(35) are considered to be the same type, as are DECIMAL(11,2) and DECIMAL (4,3). A weakly typed distinct type specified for a parameter is considered to be the same data type as the source type of the distinct type. For a Unicode database, CHAR(13) and GRAPHIC(8) are considered to be the same type. There is some further bundling of types that causes them to be treated as the same type for this purpose, such as DECIMAL and NUMERIC. A duplicate signature returns an error (SQLSTATE 42723).

IN | OUT | INOUT
Specifies the mode of the parameter. If an error is returned by the function, OUT parameters are undefined and INOUT parameters are unchanged. The default is IN.

IN
Identifies the parameter as an input parameter to the function. Any changes made to the parameter within the function are not available to the invoking context when control is returned.

OUT
Identifies the parameter as an output parameter for the function.

The function must be defined with LANGUAGE C (SQLSTATE 42613).

The function can be referenced only on the right side of an assignment statement that is in a compound SQL (compiled) statement, and the function reference cannot be part of an expression (SQLSTATE 42887).

INOUT
Identifies the parameter as both an input and output parameter for the function.

The function must be defined with LANGUAGE C (SQLSTATE 42613).

The function can be referenced only on the right side of an assignment statement that is in a compound SQL (compiled) statement, and the function reference cannot be part of an expression (SQLSTATE 42887).

parameter-name
Specifies an optional name for the parameter. Parameter names are required to reference the parameters of a function in the *index-exploitation* clause of a predicate specification. The name cannot be the same as any other *parameter-name* in the parameter list (SQLSTATE 42734).

data-type1
Specifies the data type of the parameter. The data type can be a built-in data type, a distinct type, a structured type, or a reference type. For a more complete description of each built-in data type, see "CREATE TABLE". Some data types are not supported in all languages. For details on the mapping between SQL data types and host language data types, see "Data types that map to SQL data types in embedded SQL applications".

- A datetime type parameter is passed as a character data type, and the data is passed in the ISO format.
- DECIMAL (and NUMERIC) are invalid with LANGUAGE C and OLE (SQLSTATE 42815).
- DECFLOAT is invalid with LANGUAGE C, COBOL, CLR, JAVA, and OLE (SQLSTATE 42815).
- XML is invalid with LANGUAGE OLE.
- Because the XML value that is seen inside a function is a serialized version of the XML value that is passed as a parameter in the function call, parameters of type XML must be declared using the syntax `XML AS CLOB(`*n*`)`.
- CLR does not support DECIMAL scale greater than 28 (SQLSTATE 42613).
- Array types cannot be specified (SQLSTATE 42815).
- BINARY and VARBINARY data types are invalid with LANGUAGE CLR and OLE (SQLSTATE 42815).

For a user-defined distinct type, the length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). A distinct type parameter is passed as the source type of the distinct type. If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

For a user-defined structured type, the appropriate transform functions must exist in the associated transform group.

For a reference type, the parameter can be specified as REF(*type-name*) if the parameter is unscoped.

DEFAULT
Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The special registers that can be specified as

the default are that same as those that can be specified for a column default (see *default-clause* in the CREATE TABLE statement). Other special registers can be specified as the default by using an expression.

The expression can be any expression of the type described in "Expressions". If a default value is not specified, the parameter has no default and the corresponding argument cannot be omitted on invocation of the procedure. The maximum size of the *expression* is 64K bytes.

The default expression must not modify SQL data (SQLSTATE 428FL or SQLSTATE 429BL). The expression must be assignment compatible to the parameter data type (SQLSTATE 42821).

A default cannot be specified in the following situations:

- For INOUT or OUT parameters (SQLSTATE 42601)
- For a parameter of type ARRAY, ROW, or CURSOR (SQLSTATE 429BB)
- For a parameter to a function definition that also specified a PREDICATES clause (SQLSTATE 42613)

AS LOCATOR
Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type based on a LOB data type (SQLSTATE 42601). Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

If the function is FENCED and has the NO SQL option, the AS LOCATOR clause cannot be specified (SQLSTATE 42613).

RETURNS
This mandatory clause identifies the output of the function.

data-type2
Specifies the data type of the output.

In this case, exactly the same considerations apply as for the parameters of external functions described previously in *data-type1* for function parameters.

AS LOCATOR
For LOB types or distinct types which are based on LOB types, the AS LOCATOR clause can be added. This indicates that a LOB locator is to be passed from the UDF instead of the actual value.

data-type3* CAST FROM *data-type4
Specifies the data type of the output.

This form of the RETURNS clause is used to return a different data type to the invoking statement from the data type that was returned by the function code. For example, in

```
CREATE FUNCTION GET_HIRE_DATE(CHAR(6))
  RETURNS DATE CAST FROM CHAR(10)
  ...
```

the function code returns a CHAR(10) value to the database manager, which, in turn, converts it to a DATE and passes that value to the invoking statement. The *data-type4* must be castable to the *data-type3* parameter. If it is not castable, an error (SQLSTATE 42880) is raised.

Since the length, precision or scale for *data-type3* can be inferred from *data-type4,* it not necessary (but still permitted) to specify the length, precision, or scale for parameterized types specified for *data-type3*. Instead empty parentheses may be used (for example VARCHAR() may be used). FLOAT() cannot be used (SQLSTATE 42601) since parameter value indicates different data types (REAL or DOUBLE).

Distinct types, array types, and structured types are not valid as the type specified in *data-type4* (SQLSTATE 42815).

The cast operation is also subject to runtime checks that might result in conversion errors being raised.

AS LOCATOR
For *data-type4* specifications that are LOB types or distinct types which are based on LOB types, the AS LOCATOR clause can be added. This indicates that a LOB locator is to be passed back from the UDF instead of the actual value.

built-in-type
See "CREATE TABLE" for the description of built-in data types.

SPECIFIC *specific-name*
Provides a unique name for the instance of the function that is being defined. This specific name can be used when sourcing on this function, dropping the function, or commenting on the function. It can never be used to invoke the function. The unqualified form of *specific-name* is an SQL identifier. The qualified form is a *schema-name* followed by a period and an SQL identifier. The name, including the implicit or explicit qualifier, must not identify another function instance or method specification that exists at the application server; otherwise an error (SQLSTATE 42710) is raised.

The *specific-name* may be the same as an existing *function-name*.

If no qualifier is specified, the qualifier that was used for *function-name* is used. If a qualifier is specified, it must be the same as the explicit or implicit qualifier of *function-name* or an error (SQLSTATE 42882) is raised.

If *specific-name* is not specified, a unique name is generated by the database manager. The unique name is SQL followed by a character timestamp, SQLyymmddhhmmssxxx.

EXTERNAL
This clause indicates that the CREATE FUNCTION statement is being used to register a new function based on code written in an external programming language and adhering to the documented linkage conventions and interface.

If NAME clause is not specified "NAME *function-name*" is assumed.

NAME *'string'*
This clause identifies the name of the user-written code which implements the function being defined.

The *'string'* option is a string constant with a maximum of 254 bytes. The format used for the string is dependent on the LANGUAGE specified.

- For LANGUAGE C:

  The *string* specified is the library name and function within the library, which the database manager invokes to execute the user-defined function being created. The library (and the function within the library) do not need to exist when the CREATE FUNCTION statement is executed. However, when the function is used in an SQL statement, the library and function within the library must exist and be accessible from the database server machine; otherwise, an error is returned (SQLSTATE 42724).

  The *string* can be specified as follows:

  Extraneous blanks are not permitted within the single quotation marks.

  library_id
  Identifies the library name containing the function. The database manager will look for the library as follows:

Operating system	Library name location
Linux AIX	If `myfunc` was given as the *library_id*, and the database manager is being run from `/u/production`, the database manager will look for the function in library `/u/production/sqllib/function/myfunc`
Windows	The database manager will look for the function in a directory path that is specified by the LIBPATH or PATH environment variable

absolute_path_id
Identifies the full path name of the file containing the function. The format depends on the operating system, as illustrated in the following table:

Operating system	Full path name example
Linux AIX	A value of '/u/jchui/mylib/myfunc' would cause the database manager to look in `/u/jchui/mylib` for the `myfunc` shared library.
Windows	A value of 'd:\mylib\myfunc.dll' would cause the database manager to load the dynamic link library, `myfunc.dll`, from the `d:\mylib` directory. If an absolute path ID is being used to identify the routine body, be sure to append the `.dll` extension.

! func_id
Identifies the entry point name of the function to be invoked. The ! serves as a delimiter between the library ID and the function ID. The format depends on the operating system, as illustrated in the following table:

Operating system	Entry point name of the function
Linux AIX	A value of 'mymod!func8' would direct the database manager to look for the library `$inst_home_dir/sqllib/function/mymod` and to use entry point `func8` within that library.
Windows	A value of 'mymod!func8' would direct the database manager to load the `mymod.dll` file and to call the `func8()` function in the dynamic link library (DLL).

If the string is not properly formed, an error is returned (SQLSTATE 42878).

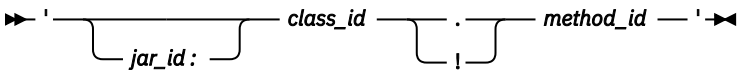
The body of every external function should be in a directory that is available on every database partition.

- For LANGUAGE JAVA:

  The *string* specified contains the optional jar file identifier, class identifier and method identifier, which the database manager invokes to execute the user-defined function being created. The class identifier and method identifier do not need to exist when the CREATE FUNCTION statement is executed. If a *jar_id* is specified, it must exist when the CREATE FUNCTION

statement is executed. However, when the function is used in an SQL statement, the method identifier must exist and be accessible from the database server machine; otherwise, an error is returned (SQLSTATE 42724).

The *string* can be specified as follows:



Extraneous blanks are not permitted within the single quotation marks.

jar_id
Identifies the jar identifier given to the jar collection when it was installed in the database. It can be either a simple identifier, or a schema qualified identifier. Examples are 'myJar' and 'mySchema.myJar'.

class_id
Identifies the class identifier of the Java object. If the class is part of a package, the class identifier part must include the complete package prefix, for example, 'myPacks.UserFuncs'. The directory the Java virtual machine will look in for the classes depends on the operating system, as illustrated in the following table:

Operating system	**Directory the Java virtual machine will look in for the classes**
Linux AIX	`'.../myPacks/UserFuncs/'`
Windows	`'...\myPacks\UserFuncs\'`

method_id
Identifies the method name of the Java object to be invoked.

- For LANGUAGE CLR:

The *string* specified represents the .NET assembly (library or executable), the class within that assembly, and the method within the class that the database manager invokes to execute the function being created. The module, class, and method do not need to exist when the CREATE FUNCTION statement is executed. However, when the function is used in an SQL statement, the module, class, and method must exist and be accessible from the database server machine; otherwise, an error is returned (SQLSTATE 42724).

C++ routines that are compiled with the '/clr' compiler option to indicate that they include managed code extensions must be cataloged as 'LANGUAGE CLR' and not 'LANGUAGE C'. The database server needs to know that the .NET infrastructure is being utilized in a user-defined function in order to make necessary runtime decisions. All user-defined functions using the .NET infrastructure must be cataloged as 'LANGUAGE CLR'.

The *string* can be specified as follows:

The name must be enclosed by single quotation marks. Extraneous blanks are not permitted.

assembly
Identifies the DLL or other assembly file in which the class resides. Any file extensions (such as .dll) must be specified. If the full path name is not given, the file must reside in the function directory of the database product's installation path

For example, `c:\sqllib\function`.

If the file resides in a subdirectory of the installation function directory, the subdirectory can be given before the file name rather than specifying the full path.

For example, if your install directory is `c:\sqllib` and your assembly file is `c:\sqllib\function\myprocs\mydotnet.dll`, it is only necessary to specify 'myprocs\mydotnet.dll' for the assembly.

The case sensitivity of this parameter is the same as the case sensitivity of the file system.

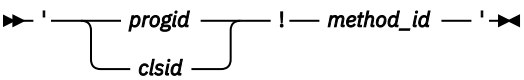
class_id
Specifies the name of the class within the given assembly in which the method that is to be invoked resides. If the class resides within a namespace, the full namespace must be given in addition to the class. For example, if the class EmployeeClass is in namespace MyCompany.ProcedureClasses, then MyCompany.ProcedureClasses.EmployeeClass must be specified for the class. Note that the compilers for some .NET languages will add the project name as a namespace for the class, and the behavior may differ depending on whether the command line compiler or the GUI compiler is used. This parameter is case sensitive.

method_id
Specifies the method within the given class that is to be invoked. This parameter is case sensitive.

- For LANGUAGE OLE:

The *string* specified is the OLE programmatic identifier (progid) or class identifier (clsid), and method identifier, which the database manager invokes to execute the user-defined function being created. The programmatic identifier or class identifier, and method identifier do not need to exist when the CREATE FUNCTION statement is executed. However, when the function is used in an SQL statement, the method identifier must exist and be accessible from the database server machine; otherwise, an error is returned (SQLSTATE 42724).

The *string* can be specified as follows:



Extraneous blanks are not permitted within the single quotation marks.

progid
Identifies the programmatic identifier of the OLE object.

progid is not interpreted by the database manager but only forwarded to the OLE APIs at run time. The specified OLE object must be creatable and support late binding (also called IDispatch-based binding).

clsid
Identifies the class identifier of the OLE object to create. It can be used as an alternative for specifying a *progid* in the case that an OLE object is not registered with a progid. The *clsid* has the form:

```
{nnnnnnnn-nnnn-nnnn-nnnn-nnnnnnnnnnnn}
```

where 'n' is an alphanumeric character. *clsid* is not interpreted by the database manager but only forwarded to the OLE APIs at run time.

method_id
Identifies the method name of the OLE object to be invoked.

- For LANGUAGE CPP:

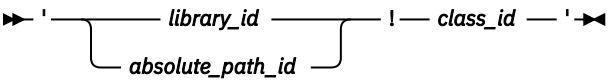
The *string* specified is the library identifier and class identifier within the library, which contains the evaluate method the database manager invokes to execute the user-defined function that is being created. If the string is not properly formed, an error is returned (SQLSTATE 42878).

It is not necessary that the library (or the class within the library) exist when the CREATE FUNCTION statement is executed. However, when the function is used in an SQL statement,

the library and class within the library must exist and be accessible from the database server machine; otherwise, an error is returned (SQLSTATE 42724).

The body of every external function should be in a directory that is available on every database partition.

The *string* can be specified as follows:



Extraneous blanks are not permitted within the single quotation marks.

library_id
The name of the library that contains the function:

- On a UNIX system, if the specified library ID is `myfunc`, and if the database manager is being run from `/u/production`, the database manager looks for the function in the following library:

```
/u/production/sqllib/function/myfunc
```

- On a Windows operating system, the database manager looks for the function in the directory path specified by the LIBPATH or PATH environment variable.

absolute_path_id
The full path of the file that contains the function. For example:

- On a UNIX system, the following specification causes the database manager to look in `/u/jchui/mylib` for the myfunc shared library:

```
'/u/jchui/mylib/myfunc'
```

- On a Windows operating system, the following specification causes the database manager to load the dynamic link library myfunc.dll from the `d:\mylib` directory:

```
'd:\mylib\myfunc.dll'
```

  If an absolute path ID is being used to identify the routine body, be sure to append the .dll extension.

class_id
The name of the class that contains the methods that are to be invoked.

For example, if you specify `'mymod!myclass'`:

- On a UNIX system, the database manager looks for the library `$inst_home_dir/sqllib/function/mymod` and invokes the evaluate method of the myclass class in that library.
- On a Windows operating system, the database manager loads the mymod.dll file and calls the evaluate method of the myclass class in the dynamic link library (DLL).

NAME *identifier*
This *identifier* specified is an SQL identifier. The SQL identifier is used as the *library-id* in the string. Unless it is a delimited identifier, the identifier is folded to upper case. If the identifier is qualified with a schema name, the schema name portion is ignored. This form of NAME can only be used with LANGUAGE C.

LANGUAGE
This mandatory clause specifies the language interface convention to which the body of the user-defined function is written.

C
The database manager calls the user-defined function as if it were a C function. The user-defined function must conform to the C language calling and linkage convention as defined by the standard ANSI C prototype.

JAVA
The database manager calls the user-defined function as a method in a Java class.

CLR
The database manager calls the user-defined function as a method in a .NET class. LANGUAGE CLR is supported only for user-defined functions running on Windows operating systems. NOT FENCED cannot be specified for a CLR routine (SQLSTATE 42601).

OLE
The database manager calls the user-defined function as if it were a method exposed by an OLE automation object. The user-defined function must conform with the OLE automation data types and invocation mechanism, as described in the *OLE Automation Programmer's Reference*.

LANGUAGE OLE is supported for user-defined functions for this database product only in Windows operating systems. THREADSAFE may not be specified for UDFs defined with LANGUAGE OLE (SQLSTATE 42613).

CPP
The database manager calls the user-defined function by invoking the evaluate method of a C++ class.

PYTHON
The database manager calls the user-defined function as a method in a Python class.

PARAMETER STYLE
This clause is used to specify the conventions used for passing parameters to and returning the value from functions.

DB2GENERAL
Used to specify the conventions for passing parameters to and returning the value from external functions that are defined as a method in a Java class. This can only specified when LANGUAGE JAVA is used.

The value DB2GENRL may be used as a synonym for DB2GENERAL.

JAVA
This means that the function will use a parameter passing convention that conforms to the Java language and SQLJ Routines specification. This can only be specified when LANGUAGE JAVA is used, no structured data types are specified as parameters, and no CLOB, BLOB, or DBCLOB data types are specified as return types (SQLSTATE 429B8). PARAMETER STYLE JAVA functions do not support the FINAL CALL, SCRATCHPAD, or DBINFO clause.

SQL
Used to specify the conventions for passing parameters to and returning the value from external functions that conform to C language calling and linkage conventions, methods exposed by OLE automation objects, or public static methods of a .NET object. This must be specified when LANGUAGE C, LANGUAGE CLR, or LANGUAGE OLE is used.

NPSGENERIC

Used to specify the conventions for passing parameters to and returning the value from external functions that are defined as a method in a C++ class. This can specified only when the LANGUAGE option is set to CPP or PYTHON.

When NPSGENERIC is specified as the parameter style, the UDF is written in C++ as a derived class of the nz.udx_ver2.Udf class. The class must implement the following two methods in addition to its constructor and destructor:

static Udf* Udf::instantiate(UdxInit *pInit)
Static member method instantiate(), which must instantiate a new instance of the UDF derived class and return a pointer to the new instance as a class Udf pointer. The engine uses this method to create an instance of a UDF object.

virtual ReturnValue Udf::evaluate()
Member method evaluate(), which is called by the engine to evaluate the user function and return a value to the caller.

PARAMETER CCSID

Specifies the encoding scheme to use for all string data passed into and out of the function. If the PARAMETER CCSID clause is not specified, the default is PARAMETER CCSID UNICODE for Unicode databases, and PARAMETER CCSID ASCII for all other databases.

ASCII

Specifies that string data is encoded in the database code page. If the database is a Unicode database, PARAMETER CCSID ASCII cannot be specified (SQLSTATE 56031). When the function is invoked, the application code page for the function is the database code page.

UNICODE

Specifies that string data is encoded in Unicode. If the database is a Unicode database, character data is in UTF-8, and graphic data is in UCS-2. If the database is not a Unicode database, character data is in UTF-8. In either case, when the function is invoked, the application code page for the function is 1208.

If the database is not a Unicode database, and a function with PARAMETER CCSID UNICODE is created, the function cannot have any graphic types, the XML type, or user-defined types (SQLSTATE 560C1).

If the database is not a Unicode database, and the alternate collating sequence has been specified in the database configuration, functions can be created with either PARAMETER CCSID ASCII or PARAMETER CCSID UNICODE. All string data passed into and out of the function will be converted to the appropriate code page.

This clause cannot be specified with LANGUAGE CPP, LANGUAGE OLE, LANGUAGE JAVA, or LANGUAGE CLR (SQLSTATE 42613).

DETERMINISTIC or NOT DETERMINISTIC

This optional clause specifies whether the function always returns the same results for given argument values (DETERMINISTIC) or whether the function depends on some state values that affect the results (NOT DETERMINISTIC). That is, a DETERMINISTIC function must always return the same result from successive invocations with identical inputs. Optimizations taking advantage of the fact that identical inputs always produce the same results are prevented by specifying NOT DETERMINISTIC. An example of a NOT DETERMINISTIC function would be a random-number generator. An example of a DETERMINISTIC function would be a function that determines the square root of the input.

FENCED or NOT FENCED

This clause specifies whether or not the function is considered "safe" to run in the database manager operating environment's process or address space.

If a function is registered as FENCED, the database manager protects its internal resources (for example, data buffers) from access by the function. Most functions will have the option of running as FENCED or NOT FENCED. In general, a function running as FENCED will not perform as well as a similar one running as NOT FENCED.

CAUTION: Use of NOT FENCED for functions not adequately coded, reviewed, and tested can compromise the integrity of your database. This database product safeguards against many of the common types of inadvertent failures that might occur, but cannot guarantee complete integrity when NOT FENCED user-defined functions are used.

Only FENCED can be specified for a function with LANGUAGE OLE or NOT THREADSAFE (SQLSTATE 42613).

If the function is FENCED and has the NO SQL option, the AS LOCATOR clause cannot be specified (SQLSTATE 42613).

Either SYSADM authority, DBADM authority, or a special authority (CREATE_NOT_FENCED_ROUTINE) is required to register a user-defined function as NOT FENCED.

LANGUAGE CLR user-defined functions cannot be created when specifying the NOT FENCED clause (SQLSTATE 42601).

THREADSAFE or NOT THREADSAFE

Specifies whether the function is considered safe to run in the same process as other routines (THREADSAFE), or not (NOT THREADSAFE).

If the function is defined with LANGUAGE other than OLE:

- If the function is defined as THREADSAFE, the database manager can invoke the function in the same process as other routines. In general, to be threadsafe, a function should not use any global or static data areas. Most programming references include a discussion of writing threadsafe routines. Both FENCED and NOT FENCED functions can be THREADSAFE.
- If the function is defined as NOT THREADSAFE, the database manager will never simultaneously invoke the function in the same process as another routine.

For FENCED functions, THREADSAFE is the default if the LANGUAGE is JAVA or CLR. For all other languages, NOT THREADSAFE is the default. If the function is defined with LANGUAGE OLE, THREADSAFE may not be specified (SQLSTATE 42613).

For NOT FENCED functions, THREADSAFE is the default. NOT THREADSAFE cannot be specified (SQLSTATE 42613).

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT

This optional clause can be used to avoid a call to the external function if any of the arguments is null. If the user-defined function is defined to have no parameters, then this null argument condition cannot arise, and it does not matter how this specification is coded. If this clause is not specified, the default is RETURNS NULL ON NULL INPUT, except when PARAMETER STYLE JAVA is specified, in which case the default is CALLED ON NULL INPUT.

If RETURNS NULL ON NULL INPUT is specified, and if, at execution time, any one of the function's arguments is null, then the user-defined function is not called and the result is the null value.

If CALLED ON NULL INPUT is specified, then regardless of whether any arguments are null, the user-defined function is called. It can return a null value or a normal (non-null) value. But responsibility for testing for null argument values lies with the UDF.

The value NULL CALL may be used as a synonym for CALLED ON NULL INPUT for backwards and family compatibility. Similarly, NOT NULL CALL may be used as a synonym for RETURNS NULL ON NULL INPUT.

READS SQL DATA, NO SQL, or CONTAINS SQL

Specifies the classification of SQL statements that the function can run. The database manager verifies that the SQL statements that the function issues are consistent with this specification.

For the classification of each statement, see "SQL statements that can be executed in routines and triggers" in Developing User-defined Routines (SQL and External).

The default is READS SQL DATA.

READS SQL DATA

Specifies that the function can run statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL (SQLSTATE 38002 or 42985). The function cannot run SQL statements that modify data. (SQLSTATE 38003 or 42985).

NO SQL

Specifies that the function can run only SQL statements with a data access classification of NO SQL (SQLSTATE 38001).

CONTAINS SQL

Specifies that the function can run only SQL statements with a data access classification of CONTAINS SQL or NO SQL (SQLSTATE 38004 or 42985). The function cannot run any SQL statements that read or modify data (SQLSTATE 38003 or 42985).

STATIC DISPATCH

This optional clause indicates that at function resolution time, a function is chosen by the database server based on the static types (declared types) of the parameters of the function.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a file. The default is EXTERNAL ACTION.

EXTERNAL ACTION

Specifies that the function takes an action that changes the state of an object that the database manager does not manage.

A function with external actions might return incorrect results if the function is executed by parallel tasks. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

NO EXTERNAL ACTION

Specifies that the function does not take any action that changes the state of an object that the database manager does not manage. The database manager uses this information during optimization of SQL statements.

NO SCRATCHPAD or SCRATCHPAD *length*

This optional clause may be used to specify whether a scratchpad is to be provided for an external function. (It is strongly recommended that user-defined functions be re-entrant, so a scratchpad provides a means for the function to "save state" from one call to the next.)

- If SCRATCHPAD is specified, then at first invocation of the user-defined function, memory is allocated for a scratchpad to be used by the external function. On each invocation of the user-defined function, an additional argument is passed to the external function which addresses the scratchpad. This scratchpad has the following characteristics:
  - *length*, if specified, sets the size of the scratchpad in bytes; this value must be between 1 and 32 767 (SQLSTATE 42820). The default size is 100 bytes.
  - It is initialized to all X'00''s.
  - Its scope is the SQL statement. There is one scratchpad per reference to the external function in the SQL statement. So if the UDFX function in the following statement is defined with the SCRATCHPAD keyword, three scratchpads would be assigned.

    ```
    SELECT A, UDFX(A) FROM TABLEB
      WHERE UDFX(A) > 103 OR UDFX(A) < 19
    ```

    If ALLOW PARALLEL is specified or defaulted to, then the scope is different from the one shown previously. If the function is executed in multiple database partitions, a scratchpad would be assigned in each database partition where the function is processed, for each reference to the function in the SQL statement. Similarly, if the query is executed with intrapartition parallelism enabled, more than three scratchpads may be assigned.
  - It is persistent. Its content is preserved from one external function call to the next. Any changes made to the scratchpad by the external function on one call will be there on the next call. The database manager initializes scratchpads at the beginning of execution of each SQL statement. The database manager may reset scratchpads at the beginning of execution of each subquery. The system issues a final call before resetting a scratchpad if the FINAL CALL option is specified.
  - It can be used as a central point for system resources (for example, memory) which the external function might acquire. The function could acquire the memory on the first call, keep its address in the scratchpad, and refer to it in subsequent calls.

    (In such a case where system resource is acquired, the FINAL CALL keyword should also be specified; this causes a special call to be made at end-of-statement to allow the external function to free any system resources acquired.)
- If NO SCRATCHPAD is specified then no scratchpad is allocated or passed to the external function.

SCRATCHPAD cannot be specified in combination with a PARAMETER STYLE JAVA function.

FINAL CALL or NO FINAL CALL

This optional clause specifies whether a final call is to be made to an external function. The purpose of such a final call is to enable the external function to free any system resources it has acquired. It can be useful in conjunction with the SCRATCHPAD keyword in situations where the external function acquires system resources such as memory and anchors them in the scratchpad.

- If FINAL CALL is specified, then at execution time an additional argument is passed to the external function which specifies the type of call. The types of calls are:

  Normal call
  SQL arguments are passed and a result is expected to be returned.

  First call
  The first call to the external function for this reference to the user-defined function in this SQL statement. The first call is a normal call.

  Final call
  A final call to the external function to enable the function to free up resources. The final call is not a normal call. This final call occurs at the following times:

  End-of-statement
  This case occurs when the cursor is closed for cursor-oriented statements, or when the statement is through executing otherwise.

  End-of-parallel-task
  This case occurs when the function is executed by parallel tasks.

  End-of-transaction or interrupt
  This case occurs when the normal end-of-statement does not occur. For example, the logic of an application may for some reason bypass the close of the cursor. During this type of final call, no SQL statements may be issued except for CLOSE cursor (SQLSTATE 38505). This type of final call is indicated with a special value in the "call type" argument.

  If a commit operation occurs while a cursor defined as WITH HOLD is open, a final call is made at the subsequent close of the cursor or at the end of the application.
- If NO FINAL CALL is specified, no "call type" argument is passed to the external function, and no final call is made.

FINAL CALL cannot be specified in combination with the following parameter settings:

- PARAMETER STYLE JAVA
- LANGUAGE CPP

ALLOW PARALLEL or DISALLOW PARALLEL

This optional clause specifies whether, for a single reference to the function, the invocation of the function can be parallelized. In general, the invocations of most scalar functions should be parallelizable, but there may be functions (such as those depending on a single copy of a scratchpad) that cannot. If either ALLOW PARALLEL or DISALLOW PARALLEL are specified for a scalar function, then this specification is accepted. The following questions should be considered in determining which keyword is appropriate for the function.

- Are all the UDF invocations completely independent of each other? If YES, then specify ALLOW PARALLEL.
- Does each UDF invocation update the scratchpad, providing value(s) that are of interest to the next invocation? (For example, the incrementing of a counter.) If YES, then specify DISALLOW PARALLEL or accept the default.
- Is there some external action performed by the UDF which should happen only on one database partition? If YES, then specify DISALLOW PARALLEL or accept the default.
- Is the scratchpad used, but only so that some expensive initialization processing can be performed a minimal number of times? If YES, then specify ALLOW PARALLEL.
- Is the function going to be invoked in a query that accesses a column-organized table? If YES, then specifying ALLOW PARALLEL might improve performance.

In any case, the body of every external function should be in a directory that is available on every database partition.

The default value is ALLOW PARALLEL, except if one or more of the following options is specified in the statement.

- NOT DETERMINISTIC
- EXTERNAL ACTION
- SCRATCHPAD
- FINAL CALL

If any of these options is specified or implied, the default value is DISALLOW PARALLEL.

INHERIT SPECIAL REGISTERS
This optional clause specifies that updatable special registers in the function will inherit their initial values from the environment of the invoking statement. For a function invoked in the select-statement of a cursor, the initial values are inherited from the environment when the cursor is opened. For a routine invoked in a nested object (for example a trigger or view), the initial values are inherited from the runtime environment (not inherited from the object definition).

No changes to the special registers are passed back to the invoker of the function.

Non-updatable special registers, such as the datetime special registers, reflect a property of the statement currently executing, and are therefore set to their default values.

NO DBINFO or DBINFO
This optional clause specifies whether certain specific information known by the database server will be passed to the UDF as an additional invocation-time argument (DBINFO) or not (NO DBINFO). NO DBINFO is the default. DBINFO is not supported for the following clauses (SQLSTATE 42613):

- LANGUAGE OLE
- PARAMETER STYLE JAVA

If DBINFO is specified, then a structure is passed to the UDF which contains the following information:

- Data base name - the name of the currently connected database.
- Application ID - unique application ID which is established for each connection to the database.
- Application Authorization ID - the application runtime authorization ID, regardless of the nested UDFs in between this UDF and the application.
- Code page - identifies the database code page.
- Schema name - under the exact same conditions as for Table name, contains the name of the schema; otherwise blank.
- Table name - if and only if the UDF reference is either the right side of a SET clause in an UPDATE statement or an item in the VALUES list of an INSERT statement, contains the unqualified name of the table being updated or inserted; otherwise blank.
- Column name - under the exact same conditions as for Table name, contains the name of the column being updated or inserted; otherwise blank.
- Database version/release - identifies the version, release and modification level of the database server invoking the UDF.
- Platform - contains the server's platform type.
- Table function result column numbers - not applicable to external scalar functions.

TRANSFORM GROUP *group-name*
Indicates the transform group to be used for user-defined structured type transformations when invoking the function. A transform is required if the function definition includes a user-defined structured type as either a parameter or returns data type. If this clause is not specified, the default group name DB2_FUNCTION is used. If the specified (or default) *group-name* is not defined for a referenced structured type, an error is raised (SQLSTATE 42741). If a required FROM SQL or TO SQL

transform function is not defined for the given group-name and structured type, an error is raised (SQLSTATE 42744).

The transform functions, both FROM SQL and TO SQL, whether designated or implied, must be SQL functions which properly transform between the structured type and its built in type attributes.

PREDICATES

Defines the filtering or index extension exploitation performed when this function is used in a predicate. A predicate-specification allows the optional SELECTIVITY clause of a search-condition to be specified. If the PREDICATES clause is specified, the function must be defined as DETERMINISTIC with NO EXTERNAL ACTION (SQLSTATE 42613). If the PREDICATES clause is specified, and the database is not a Unicode database, PARAMETER CCSID UNICODE must not be specified (SQLSTATE 42613).

WHEN *comparison-operator*

Introduces a specific use of the function in a predicate with a comparison operator ("=", "<", ">", ">=", "<=", "<>").

constant

Specifies a constant value with a data type comparable to the RETURNS type of the function (SQLSTATE 42818). When a predicate uses this function with the same comparison operator and this constant, the specified filtering and index exploitation will be considered by the optimizer.

EXPRESSION AS *expression-name*

Provides a name for an expression. When a predicate uses this function with the same comparison operator and an expression, filtering and index exploitation may be used. The expression is assigned an expression name so that it can be used as a search function argument. The *expression-name* cannot be the same as any *parameter-name* of the function being created (SQLSTATE 42711). When an expression is specified, the type of the expression is identified.

FILTER USING

Allows specification of an external function or a case expression to be used for additional filtering of the result table.

function-invocation

Specifies a filter function that can be used to perform additional filtering of the result table. This is a version of the defined function (used in the predicate) that reduces the number of rows on which the user-defined predicate must be executed, to determine if rows qualify. If the results produced by the index are close to the results expected for the user-defined predicate, applying the filtering function may be redundant. If not specified, data filtering is not performed.

This function can use any *parameter-name*, the *expression-name*, or constants as arguments (SQLSTATE 42703), and returns an integer (SQLSTATE 428E4). A return value of 1 means the row is kept, otherwise it is discarded.

This function must also:

- Not be defined with LANGUAGE SQL (SQLSTATE 429B4)
- Not be defined with NOT DETERMINISTIC or EXTERNAL ACTION (SQLSTATE 42845)
- Not have a structured data type as the data type of any of the parameters (SQLSTATE 428E3)
- Not include a subquery (SQLSTATE 428E4)
- Not include an XMLQUERY or XMLEXISTS expression (SQLSTATE 428E4)

If an argument invokes another function or method, these rules are also enforced for this nested function or method. However, system-generated observer methods are allowed as arguments to the filter function (or any function or method used as an argument), as long as the argument evaluates to a built-in data type.

The definer of the function must have EXECUTE privilege on the specified filter function.

The *function-invocation* clause must not exceed 65 536 bytes in length in the database code page (SQLSTATE 22001).

case-expression
Specifies a case expression for additional filtering of the result table. The *searched-when-clause* and *simple-when-clause* can use *parameter-name*, *expression-name*, or a constant (SQLSTATE 42703). An external function with the rules specified in FILTER USING *function-invocation* may be used as a result-expression. Any function or method referenced in the *case-expression* must also conform to the four rules listed under *function-invocation*.

Subqueries and XMLQUERY or XMLEXISTS expressions cannot be used anywhere in the *case-expression* (SQLSTATE 428E4).

The case expression must return an integer (SQLSTATE 428E4). A return value of 1 in the result-expression means that the row is kept; otherwise it is discarded.

The *case-invocation* clause must not exceed 65 536 bytes in length in the database code page (SQLSTATE 22001).

index-exploitation
Defines a set of rules in terms of the search method of an index extension that can be used to exploit the index.

SEARCH BY INDEX EXTENSION *index-extension-name*
Identifies the index extension. The *index-extension-name* must identify an existing index extension.

EXACT
Indicates that the index lookup is exact in terms of the predicate evaluation. Use EXACT indicate that neither the original user-defined predicate function or the filter need to be applied after the index lookup. The EXACT predicate is useful when the index lookup returns the same results as the predicate.

If EXACT is not specified, then the original user-defined predicate is applied after index lookup. If the index is expected to provide only an approximation of the predicate, do not specify the EXACT option.

If the index lookup is not used, then the filter function and the original predicate have to be applied.

exploitation-rule
Describes the search targets and search arguments and how they can be used to perform the index search through a search method defined in the index extension.

WHEN KEY (*parameter-name1*)
This defines the search target. Only one search target can be specified for a key. The *parameter-name1* value identifies parameter names of the defined function (SQLSTATE 42703 or 428E8).

The data type of *parameter-name1* must match that of the source key specified in the index extension (SQLSTATE 428EY). The match must be exact for built-in and distinct data types and within the same structured type hierarchy for structured types.

This clause is true when the values of the named parameter are columns that are covered by an index based on the index extension specified.

USE *search-method-name*(*parameter-name2,...*)
This defines the search argument. It identifies which search method to use from those defined in the index extension. The *search-method-name* must match a search method defined in the index extension (SQLSTATE 42743). The *parameter-name2* values identify parameter names of the defined function or the *expression-name* in the EXPRESSION AS clause (SQLSTATE 42703). It must be different from any parameter name specified in the search target (SQLSTATE 428E9). The number of parameters and the data type of each *parameter-name2* must match the parameters defined for the search method in the index extension (SQLSTATE

42816). The match must be exact for built-in and distinct data types and within the same structured type hierarchy for structured types.

NOT SECURED or SECURED
Specifies whether the function is considered secure for row and column access control. The default is NOT SECURED.

NOT SECURED
Indicates that the function is not considered secure. When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled and column level access control is activated for its table (SQLSTATE 428HA). This rule applies to the non secure user-defined functions that are invoked anywhere in the statement.

SECURED
Indicates that the function is considered secure. The function must be secure when it is referenced in a row permission or a column mask (SQLSTATE 428H8).

STAY RESIDENT NO
Specifies that the library that is loaded for the function is not to remain resident in memory after the function ends. This clause is ignored when:

- The NOT FENCED clause is specified.
- The LANGUAGE option is set to JAVA or CLR.

Notes

- Determining whether one data type is castable to another data type does not consider length or precision and scale for parameterized data types such as CHAR and DECIMAL. Therefore, errors may occur when using a function as a result of attempting to cast a value of the source data type to a value of the target data type. For example, VARCHAR is castable to DATE but if the source type is actually defined as VARCHAR(5), an error will occur when using the function.
- When choosing the data types for the parameters of a user-defined function, consider the rules for promotion that will affect its input values (see "Promotion of data types"). For example, a constant which may be used as an input value could have a built-in data type different from the one expected and, more significantly, may not be promoted to the data type expected. Based on the rules for promotion, it is generally recommended to use the following data types for parameters:
  - INTEGER instead of SMALLINT
  - DOUBLE instead of REAL
  - VARCHAR instead of CHAR
  - VARGRAPHIC instead of GRAPHIC
- For portability of UDFs across platforms the following data types should not be used:
  - FLOAT- use DOUBLE or REAL instead.
  - NUMERIC- use DECIMAL instead.
  - LONG VARCHAR- use CLOB (or BLOB) instead.
- A function and a method may not be in an overriding relationship (SQLSTATE 42745). For more information about overriding, see "CREATE TYPE (Structured)".
- A function may not have the same signature as a method (comparing the first *parameter-type* of the function with the *subject-type* of the method) (SQLSTATE 42723).
- Creating a function with a schema name that does not already exist will result in the implicit creation of that schema provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- In a partitioned database environment, the use of SQL in external user-defined functions or methods is not supported (SQLSTATE 42997).
- Only routines defined as NO SQL can be used to define an index extension (SQLSTATE 428F8).

- If the function allows SQL, the external program must not attempt to access any federated objects (SQLSTATE 55047).
- A Java routine defined as NOT FENCED will be invoked as if it had been defined as FENCED THREADSAFE.
- XML parameters are only supported in LANGUAGE JAVA external functions when the PARAMETER STYLE DB2GENERAL clause is specified.
- ***Table access restrictions***

  If a function is defined as READS SQL DATA, no statement in the function can access a table that is being modified by the statement which invoked the function (SQLSTATE 57053). For example, suppose the user-defined function BONUS() is defined as READS SQL DATA. If the statement UPDATE EMPLOYEE SET SALARY = SALARY + BONUS(EMPNO) is invoked, no SQL statement in the BONUS function can read from the EMPLOYEE table.
- ***Setting of the default value***: Parameters of a function that are defined with a default value are set to their default value when the functions is invoked, but only if a value is not supplied for the corresponding argument, or is specified as DEFAULT, when the function is invoked.
- ***Privileges***: The definer of a function always receives the EXECUTE privilege WITH GRANT OPTION on the function, as well as the right to drop the function.

  When the function is used in an SQL statement, the function definer must have the EXECUTE privilege on any packages used by the function or EXECUTEIN privilege or DATAACCESS authority on the schema containing the packages.
- ***EXTERNAL ACTION functions***: If an EXTERNAL ACTION function is invoked in other than the outermost select list, the results are unpredictable since the number of times the function is invoked will vary depending on the access plan used.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of this database product and with other database products. These alternatives are non-standard and should not be used.
  - PARAMETER STYLE DB2SQL can be specified in place of PARAMETER STYLE SQL
  - NOT VARIANT can be specified in place of DETERMINISTIC, and VARIANT can be specified in place of NOT DETERMINISTIC
  - NULL CALL can be specified in place of CALLED ON NULL INPUT, and NOT NULL CALL can be specified in place of RETURNS NULL ON NULL INPUT

  The following syntax is accepted as the default behavior:
  - ASUTIME NO LIMIT
  - NO COLLID
  - PROGRAM TYPE SUB
  - STAY RESIDENT NO
  - CCSID UNICODE in a Unicode database
  - CCSID ASCII in a non-Unicode database if PARAMETER CCSID UNICODE is not specified
- ***Creating a secure function***: Normally users with SECADM authority do not have privileges to create database objects such as triggers and functions. Typically; they will examine the data accessed by the function, ensure it is secure, then grant the CREATE_SECURE_OBJECT authority to someone who currently has required privileges to create a secure user-defined function. After the function is created, they will revoke the CREATE_SECURE_OBJECT authority from the function owner.

  The SECURED attribute is considered to be an assertion that declares the user has established a change control audit procedure for all changes to the user-defined function. The database manager assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages.
- ***Invoking other user-defined functions in a secure function***: If a secure user-defined function invokes other user-defined functions, the database manager does not validate whether those nested user-

defined functions have the SECURED attribute. If those nested functions can access sensitive data, the user with SECADM authority needs to ensure those functions are allowed to access those data and a change control audit procedure has been established for all changes to those functions.

- ***Replacing an existing function such that the secure attribute is changed (from SECURED to NOT SECURED and vice versa)***: Packages and dynamically cached SQL statements that depend on the function may be invalidated because the secure attribute affects the access path selection for statements involving tables for which row or column level access control is activated.

Examples

1. Pellow is registering the CENTER function in his PELLOW schema. Let those keywords that will default do so, and let the system provide a function specific name:

```
CREATE FUNCTION CENTER (INT,FLOAT)
  RETURNS FLOAT
  EXTERNAL NAME 'mod!middle'
  LANGUAGE C
  PARAMETER STYLE SQL
  DETERMINISTIC
  NO SQL
  NO EXTERNAL ACTION
```

2. Now, McBride (who has DBADM authority) is registering another CENTER function in the PELLOW schema, giving it an explicit specific name for subsequent data definition language use, and explicitly providing all keyword values. Note also that this function uses a scratchpad and presumably is accumulating data there that affects subsequent results. Since DISALLOW PARALLEL is specified, any reference to the function is not parallelized and therefore a single scratchpad is used to perform some one-time only initialization and save the results.

```
CREATE FUNCTION PELLOW.CENTER (FLOAT, FLOAT, FLOAT)
  RETURNS DECIMAL(8,4) CAST FROM FLOAT
  SPECIFIC FOCUS92
  EXTERNAL NAME 'effects!focalpt'
  LANGUAGE C   PARAMETER STYLE SQL
  DETERMINISTIC   FENCED   NOT NULL CALL   NO SQL   NO EXTERNAL ACTION
  SCRATCHPAD   NO FINAL CALL
  DISALLOW PARALLEL
```

3. The following example is the C language user-defined function program written to implement the rule `output = 2 * input - 4` returning NULL if and only if the input is null. It could be written even more simply (that is, without null checking), if the CREATE FUNCTION statement had used NOT NULL CALL. The CREATE FUNCTION statement:

```
CREATE FUNCTION ntest1 (SMALLINT)
  RETURNS SMALLINT
  EXTERNAL NAME 'ntest1!nudft1'
  LANGUAGE C    PARAMETER STYLE SQL
  DETERMINISTIC   NOT FENCED   NULL CALL
  NO SQL   NO EXTERNAL ACTION
```

   The program code:

```
#include "sqlsystm.h"
/* NUDFT1 IS A USER_DEFINED SCALAR FUNCTION */
/* udft1 accepts smallint input
and produces smallint output
implementing the rule:
if (input is null)
set output = null;
else
set output = 2 * input - 4;
*/
void SQL_API_FN nudft1
(short *input,      /* ptr to input arg */
short *output,     /* ptr to where result goes */
short *input_ind,  /* ptr to input indicator var */
short *output_ind, /* ptr to output indicator var */
char sqlstate[6],  /* sqlstate, allows for null-term */
char fname[28],    /* fully qual func name, nul-term */
char finst[19],    /* func specific name,  null-term */
```

```
char msgtext[71])  /* msg text buffer,     null-term */
{
/* first test for null input */
if (*input_ind == -1)
{
/* input is null, likewise output */
*output_ind = -1;
}
else
{
/* input is not null.  set output to 2*input-4 */
*output = 2 * (*input) - 4;
/* and set out null indicator to zero */
*output_ind = 0;
}
/* signal successful completion by leaving sqlstate as is */
/* and exit */
return;
}
/* end of UDF: NUDFT1 */
```

4. The following example registers a Java UDF which returns the position of the first vowel in a string. The UDF is written in Java, is to be run fenced, and is the findvwl method of class javaUDFs.

```
CREATE FUNCTION findv ( CLOB(100K))
  RETURNS INTEGER
  FENCED
  LANGUAGE JAVA
  PARAMETER STYLE JAVA
  EXTERNAL NAME 'javaUDFs.findvwl'
  NO EXTERNAL ACTION
  CALLED ON NULL INPUT
  DETERMINISTIC
  NO SQL
```

5. This example outlines a user-defined predicate WITHIN that takes two parameters, g1 and g2, of type SHAPE as input:

```
CREATE FUNCTION within (g1 SHAPE, g2 SHAPE)
RETURNS INTEGER
LANGUAGE C
PARAMETER STYLE SQL
DETERMINISTIC
NOT FENCED
NO SQL
NO EXTERNAL ACTION
EXTERNAL NAME 'db2sefn!SDESpatilRelations'
PREDICATES
WHEN = 1
FILTER USING mbrOverlap(g1..xmin, g1..ymin, g1..xmax, g1..max,
g2..xmin, g2..ymin, g2..xmax, g2..ymax)
SEARCH BY INDEX EXTENSION gridIndex
WHEN KEY(g1) USE withinExplRule(g2)
WHEN KEY(g2) USE withinExplRule(g1)
```

The description of the WITHIN function is similar to that of any user-defined function, but the following additions indicate that this function can be used in a user-defined predicate.

- **PREDICATES WHEN = 1** indicates that when this function appears as

  ```
  within(g1, g2) = 1
  ```

  in the WHERE clause of a DML statement, the predicate is to be treated as a user-defined predicate and the index defined by the index extension *gridIndex* should be used to retrieve rows that satisfy this predicate. If a constant is specified, the constant specified during the DML statement has to match exactly the constant specified in the create index statement. This condition is provided mainly to cover Boolean expression where the result type is either a 1 or a 0. For other cases, the EXPRESSION clause is a better choice.
- **FILTER USING mbrOverlap** refers to a filtering function mbrOverlap, which is a cheaper version of the WITHIN predicate. In this example, the mbrOverlap function takes the minimum bounding rectangles as input and quickly determines if they overlap or not. If the minimum bounding

rectangles of the two input shapes do not overlap, then g1 will not be contained with g2. Therefore the tuple can be safely discarded, avoiding the application of the expensive WITHIN predicate.

- The **SEARCH BY INDEX EXTENSION** clause indicates that combinations of index extension and search target can be used for this user-defined predicate.

6. This example outlines a user-defined predicate DISTANCE that takes two parameters, P1 and P2, of type POINT as input:

```
CREATE FUNCTION distance (P1 POINT, P2 POINT)
  RETURNS INTEGER
  LANGUAGE C
  PARAMETER STYLE SQL
  DETERMINISTIC
  NOT FENCED
  NO SQL
  NO EXTERNAL ACTION
  EXTERNAL NAME 'db2sefn!SDEDistances'
  PREDICATES
  WHEN > EXPRESSION AS distExpr
  SEARCH BY INDEX EXTENSION gridIndex
  WHEN KEY(P1) USE distanceGrRule(P2, distExpr)
  WHEN KEY(P2) USE distanceGrRule(P1, distExpr)
```

The description of the DISTANCE function is similar to that of any user-defined function, but the following additions indicate that when this function is used in a predicate, that predicate is a user-defined predicate.

- **PREDICATES WHEN > EXPRESSION AS distExpr** is another valid predicate specification. When an expression is specified in the WHEN clause, the result type of that expression is used for determining if the predicate is a user-defined predicate in the DML statement. For example:

```
SELECT T1.C1
  FROM T1, T2
  WHERE distance (T1.P1, T2.P1) > T2.C2
```

The predicate specification distance takes two parameters as input and compares the results with T2.C2, which is of type INTEGER. Since only the data type of the right side expression matters, (as opposed to using a specific constant), it is better to choose the EXPRESSION clause in the CREATE FUNCTION DDL for specifying a wildcard as the comparison value.

Alternatively, the following statement is also a valid user-defined predicate:

```
SELECT T1.C1
  FROM T1, T2
  WHERE distance(T1.P1, T2.P1) > distance (T1.P2, T2.P2)
```

There is currently a restriction that only the right side is treated as the expression; the term on the left side is the user-defined function for the user-defined predicate.

- The **SEARCH BY INDEX EXTENSION** clause indicates that combinations of index extension and search target can be used for this user-defined-predicate. In the case of the distance function, the expression identified as distExpr is also one of the search arguments that is passed to the range-producer function (defined as part of the index extension). The expression identifier is used to define a name for the expression so that it is passed to the range-producer function as an argument.

CREATE FUNCTION (external table)

The CREATE FUNCTION (External Table) statement is used to register a user-defined external table function at the current server.

A *table function* can be used in the FROM clause of a SELECT, and returns a table to the SELECT by returning one row at a time.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CREATE_EXTERNAL_ROUTINE authority on the database and at least one of the following authorities:
  - IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the function does not exist
  - CREATEIN privilege on the schema, if the schema name of the function exists
  - SCHEMAADM authority on the schema, if the schema name of the function exists
- DBADM authority

Group privileges are not considered for any table or view specified in the CREATE FUNCTION statement.

To create a not-fenced function, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

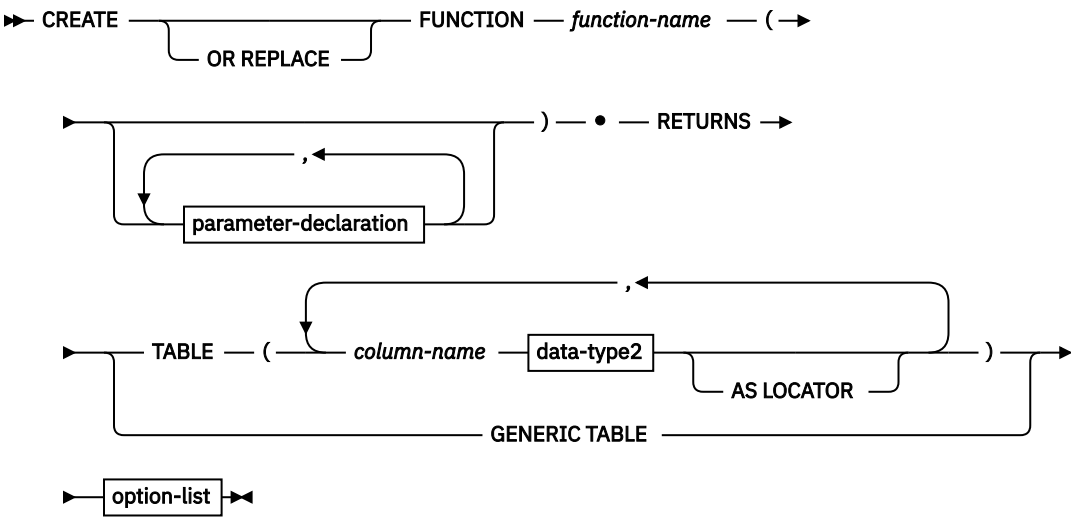
- CREATE_NOT_FENCED_ROUTINE authority on the database
- DBADM authority

To create a fenced function, no additional authorities or privileges are required.

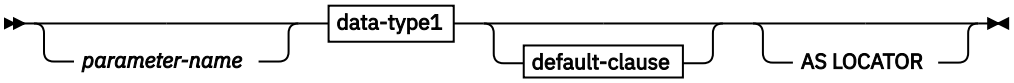
To replace an existing function, the authorization ID of the statement must be the owner of the existing function (SQLSTATE 42501).

If the SECURED option is specified, the authorization ID of the statement must include SECADM or CREATE_SECURE_OBJECT authority (SQLSTATE 42501).

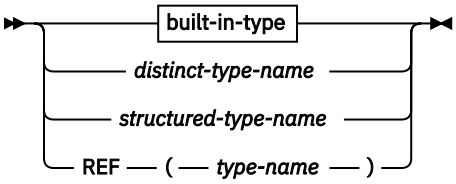
Syntax



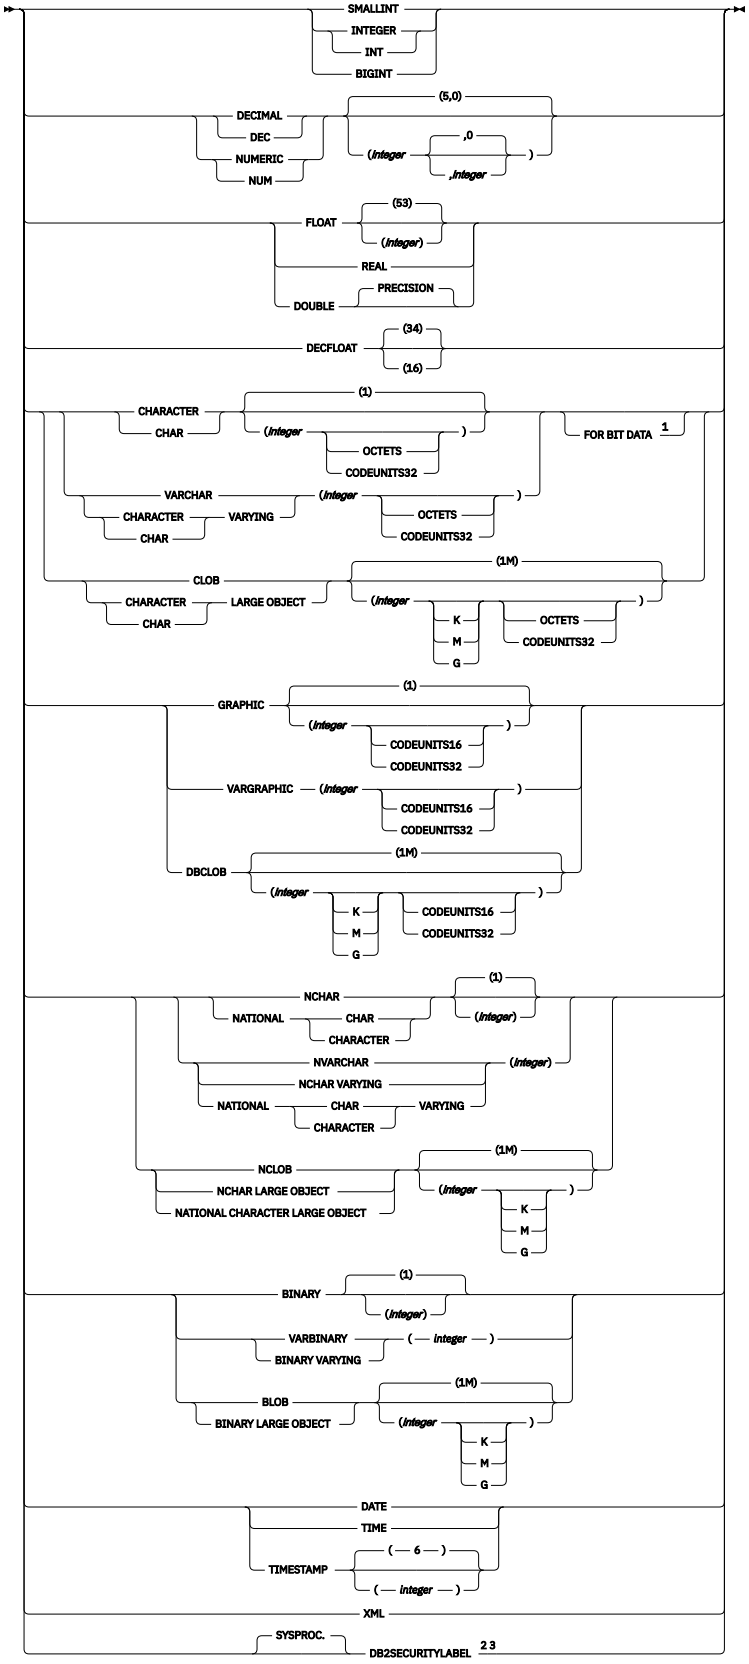
parameter-declaration



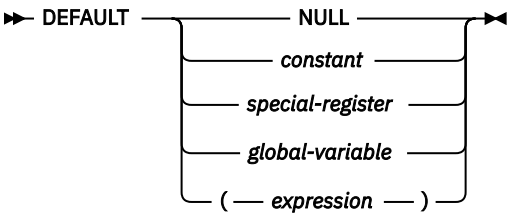
data-type1, data-type2



built-in-type

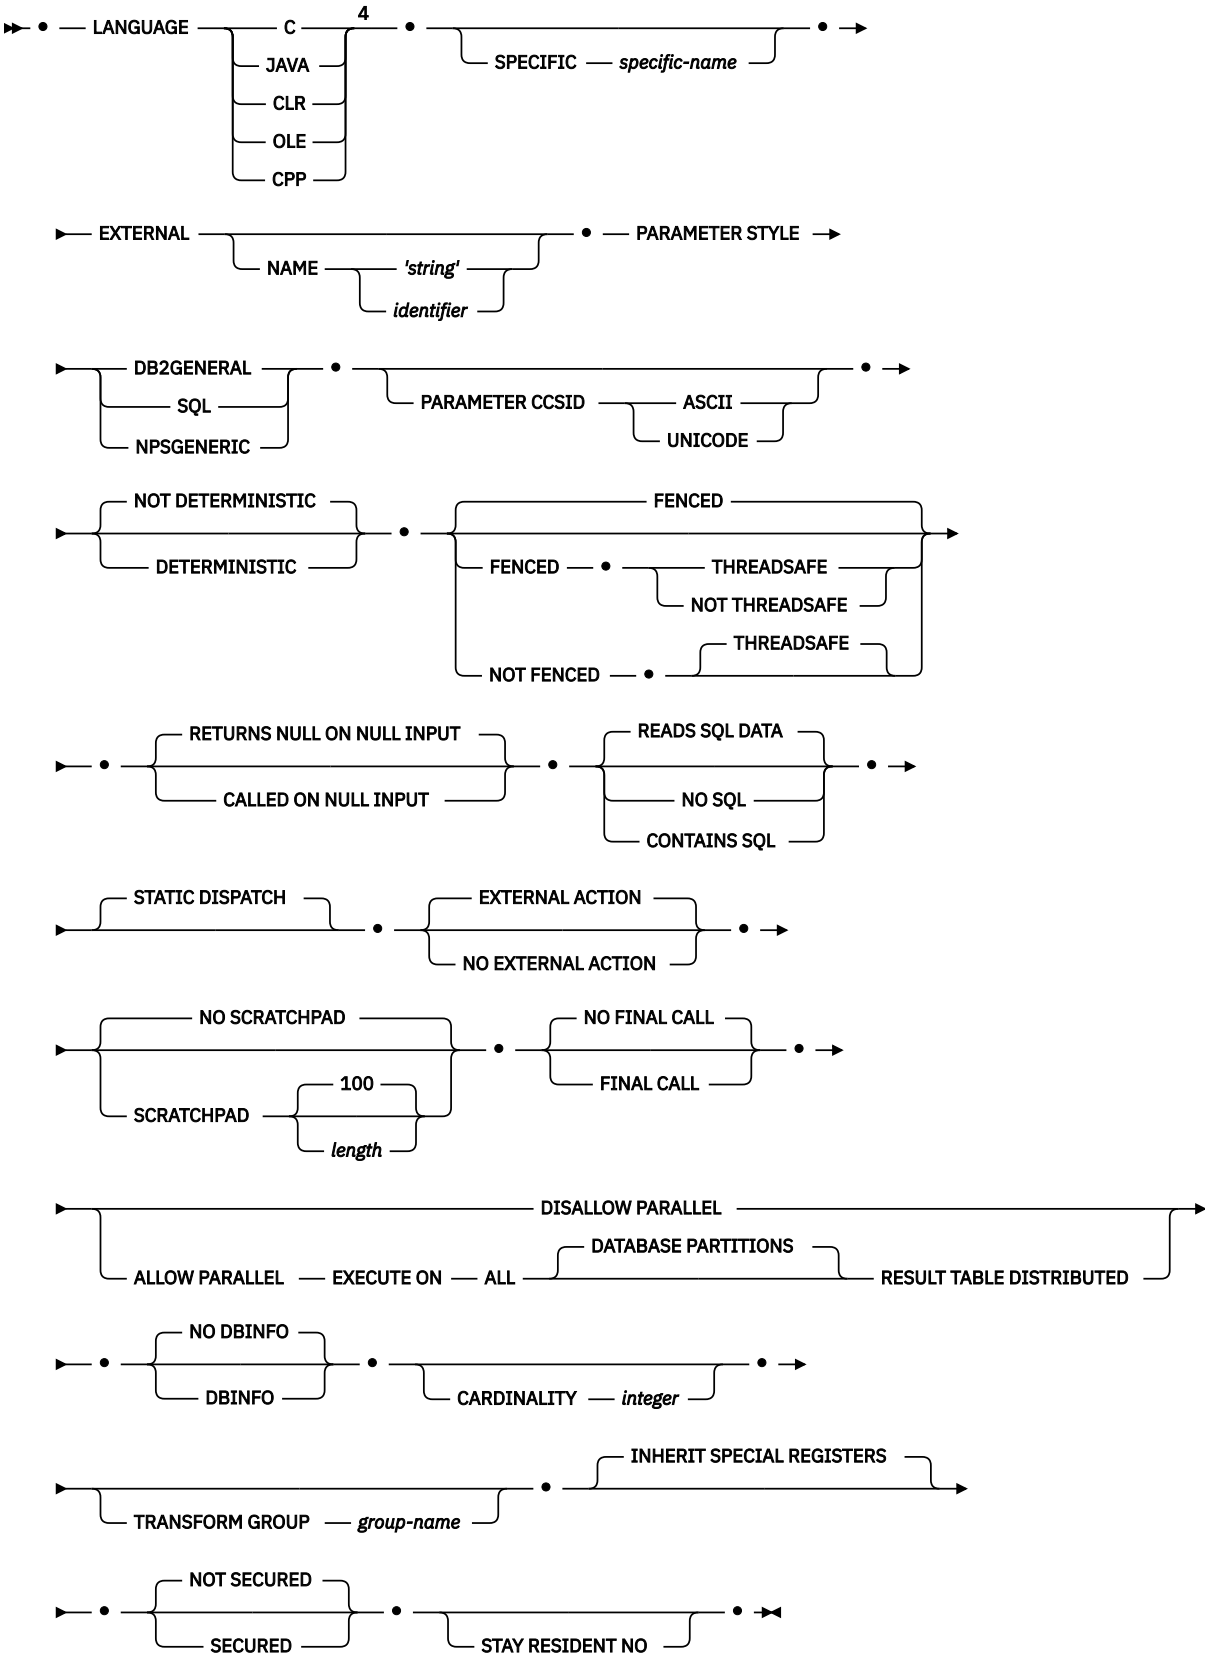


default-clause



DEFAULT
NULL
constant
special-register
global-variable
(
expression
)

option-list



Notes:

[1] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

[2] DB2SECURITYLABEL is the built-in distinct type that must be used to define the row security label column of a protected table.

[3] For a column of type DB2SECURITYLABEL, NOT NULL WITH DEFAULT is implicit and cannot be explicitly specified (SQLSTATE 42842). The default value for a column of type DB2SECURITYLABEL is the session authorization ID's security label for write access.

[4] For information about creating LANGUAGE OLE DB external table functions, see "CREATE FUNCTION (OLE DB External Table)". For information about creating LANGUAGE SQL table functions, see "CREATE FUNCTION (SQL Scalar, Table, or Row)".

Description

OR REPLACE

Specifies to replace the definition for the function if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that privileges that were granted on the function are not affected. This option can be specified only by the owner of the object. This option is ignored if a definition for the function does not exist at the current server. To replace an existing function, the specific name and function name of the new definition must be the same as the specific name and function name of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new function is created.

If the function is referenced in the definition of a row permission or a column mask, the function cannot be replaced (SQLSTATE 42893).

function-name

Names the function being defined. It is a qualified or unqualified name that designates a function. The unqualified form of *function-name* is an SQL identifier. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The qualified form is a *schema-name* followed by a period and an SQL identifier. The qualified name must not be the same as the data type of the first parameter, if that first parameter is a structured type.

The name, including the implicit or explicit qualifiers, together with the number of parameters and the data type of each parameter (without regard for any length, precision or scale attributes of the data type) must not identify a function described in the catalog (SQLSTATE 42723). The unqualified name, together with the number and data types of the parameters, while of course unique within its schema, need not be unique across schemas.

If a two-part name is specified, the *schema-name* cannot begin with "SYS" (SQLSTATE 42939).

A number of names used as keywords in predicates are reserved for system use, and cannot be used as a *function-name* (SQLSTATE 42939). The names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators.

The same name can be used for more than one function if there is some difference in the signature of the functions. Although there is no prohibition against it, an external user-defined table function should not be given the same name as a built-in function.

(*parameter-declaration*,...)

Identifies the number of input parameters of the function, and specifies the data type and optional default value of each parameter. One entry in the list must be specified for each parameter that the function will expect to receive. No more than 90 parameters are allowed (SQLSTATE 54023).

It is possible to register a function that has no parameters. In this case, the parentheses must still be coded, with no intervening data types. For example:

```
CREATE FUNCTION WOOFER() ...
```

No two identically-named functions within a schema are permitted to have exactly the same type for all corresponding parameters. Lengths, precisions, and scales are not considered in this type comparison. Therefore, CHAR(8) and CHAR(35) are considered to be the same type, as are

DECIMAL(11,2) and DECIMAL (4,3). A weakly typed distinct type specified for a parameter is considered to be the same data type as the source type of the distinct type. For a Unicode database, CHAR(13) and GRAPHIC(8) are considered to be the same type. There is some further bundling of types that causes them to be treated as the same type for this purpose, such as DECIMAL and NUMERIC. A duplicate signature returns an error (SQLSTATE 42723).

parameter-name
Specifies an optional name for the input parameter. The name cannot be the same as any other *parameter-name* in the parameter list (SQLSTATE 42734).

data-type1
Specifies the data type of the input parameter. The data type can be a built-in data type, a distinct type, a structured type, or a reference type. For a more complete description of each built-in data type, see "CREATE TABLE". Some data types are not supported in all languages. For details on the mapping between SQL data types and host language data types, see "Data types that map to SQL data types in embedded SQL applications".

- A datetime type parameter is passed as a character data type, and the data is passed in the ISO format.
- DECIMAL (and NUMERIC) are invalid with LANGUAGE C and OLE (SQLSTATE 42815).
- XML is invalid with LANGUAGE OLE.
- Because the XML value that is seen inside a function is a serialized version of the XML value that is passed as a parameter in the function call, parameters of type XML must be declared using the syntax `XML AS CLOB(`*n*`)`.
- CLR does not support DECIMAL scale greater than 28 (SQLSTATE 42613).
- Array types cannot be specified (SQLSTATE 42815).
- BINARY and VARBINARY data types are invalid with LANGUAGE CLR and OLE (SQLSTATE 42815).

For a user-defined distinct type, the length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). A distinct type parameter is passed as the source type of the distinct type. If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

For a user-defined structured type, the appropriate transform functions must exist in the associated transform group.

For a reference type, the parameter can be specified as REF(*type-name*) if the parameter is unscoped.

DEFAULT
Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The special registers that can be specified as the default are that same as those that can be specified for a column default (see *default-clause* in the CREATE TABLE statement). Other special registers can be specified as the default by using an expression.

The expression can be any expression of the type described in "Expressions". If a default value is not specified, the parameter has no default and the corresponding argument cannot be omitted on invocation of the procedure. The maximum size of the *expression* is 64K bytes.

The default expression must not modify SQL data (SQLSTATE 428FL or SQLSTATE 429BL). The expression must be assignment compatible to the parameter data type (SQLSTATE 42821).

A default cannot be specified for a parameter of type ARRAY, ROW, or CURSOR (SQLSTATE 429BB).

AS LOCATOR
Specifies that a locator to the value of the parameter is passed to the function instead of the actual value. Specify AS LOCATOR only for parameters with a LOB data type or a distinct type

based on a LOB data type (SQLSTATE 42601). Passing locators instead of values can result in fewer bytes being passed to the function, especially when the value of the parameter is very large.

The AS LOCATOR clause has no effect on determining whether data types can be promoted, nor does it affect the function signature, which is used in function resolution.

If the function is FENCED and has the NO SQL option, the AS LOCATOR clause cannot be specified (SQLSTATE 42613).

RETURNS
Specifies the output of the function.

TABLE
Specifies that the output of the function is a table. The parentheses that follow this keyword delimit a list of the names and types of the columns of the table. The list style resembles the style of a simple CREATE TABLE statement which has no additional specifications (constraints, for example). No more than 255 columns are allowed (SQLSTATE 54011).

column-name
Specifies the name of this column. The name cannot be qualified and the same name cannot be used for more than one column of the table.

data-type2
Specifies the data type of the column, and can be any data type supported for a parameter of a UDF written in the particular language, except for structured types (SQLSTATE 42997).

AS LOCATOR
When *data-type2* is a LOB type or distinct type based on a LOB type, the use of this option indicates that the function is returning a locator for the LOB value that is instantiated in the result table.

The valid types for use with this clause are discussed in the "CREATE FUNCTION (external scalar)" statement topic.

GENERIC TABLE
Specifies that the output of the function is a generic table. This clause is allowed only if you specify the LANGUAGE JAVA clause and the PARAMETER STYLE DB2GENERAL clause (SQLSTATE 42613).

built-in-type
See "CREATE TABLE" for the description of built-in data types.

SPECIFIC *specific-name*
Provides a unique name for the instance of the function that is being defined. This specific name can be used when sourcing on this function, dropping the function, or commenting on the function. It can never be used to invoke the function. The unqualified form of *specific-name* is an SQL identifier. The qualified form is a *schema-name* followed by a period and an SQL identifier. The name, including the implicit or explicit qualifier, must not identify another function instance that exists at the application server; otherwise an error (SQLSTATE 42710) is raised.

The *specific-name* may be the same as an existing *function-name*.

If no qualifier is specified, the qualifier that was used for *function-name* is used. If a qualifier is specified, it must be the same as the explicit or implicit qualifier of *function-name* or an error (SQLSTATE 42882) is raised.

If *specific-name* is not specified, a unique name is generated by the database manager. The unique name is SQL followed by a character timestamp, SQLyymmddhhmmssxxx.

EXTERNAL
This clause indicates that the CREATE FUNCTION statement is being used to register a new function based on code written in an external programming language and adhering to the documented linkage conventions and interface.

If NAME clause is not specified "NAME *function-name*" is assumed.

NAME *'string'*

This clause identifies the user-written code that implements the function being defined.

The *'string'* option is a string constant with a maximum of 254 bytes. The format used for the string is dependent on the LANGUAGE specified.

- For LANGUAGE C:

  The *string* specified is the library name and function within the library, which the database manager invokes to execute the user-defined function being created. The library (and the function within the library) do not need to exist when the CREATE FUNCTION statement is executed. However, when the function is used in an SQL statement, the library and function within the library must exist and be accessible from the database server machine.

  The *string* can be specified as follows:

  Extraneous blanks are not permitted within the single quotation marks.

  library_id

  Identifies the library name containing the function. The database manager will look for the library as follows:

Operating system	Library name location
Linux AIX	If `myfunc` was given as the *library_id*, and the database manager is being run from `/u/production`, the database manager will look for the function in library `/u/production/sqllib/function/myfunc`
Windows	The database manager will look for the function in a directory path that is specified by the LIBPATH or PATH environment variable

  absolute_path_id

  Identifies the full path name of the file containing the function. The format depends on the operating system, as illustrated in the following table:

Operating system	Full path name example
Linux AIX	A value of '/u/jchui/mylib/myfunc' would cause the database manager to look in `/u/jchui/mylib` for the `myfunc` shared library.
Windows	A value of 'd:\mylib\myfunc.dll' would cause the database manager to load the dynamic link library, `myfunc.dll`, from the `d:\mylib` directory. If an absolute path ID is being used to identify the routine body, be sure to append the `.dll` extension.

  ! func_id

  Identifies the entry point name of the function to be invoked. The ! serves as a delimiter between the library ID and the function ID. The format depends on the operating system, as illustrated in the following table:

Operating system	Entry point name of the function
Linux AIX	A value of 'mymod!func8' would direct the database manager to look for the library `$inst_home_dir/sqllib/function/mymod` and to use entry point `func8` within that library.
Windows	A value of 'mymod!func8' would direct the database manager to load the `mymod.dll` file and to call the `func8()` function in the dynamic link library (DLL).

If the string is not properly formed, an error is returned (SQLSTATE 42878).

In any case, the body of every external function should be in a directory that is available on every database partition.

- For LANGUAGE JAVA:

  The *string* specified contains the optional jar file identifier, class identifier and method identifier, which the database manager invokes to execute the user-defined function being created. The class identifier and method identifier do not need to exist when the CREATE FUNCTION statement is executed. If a *jar_id* is specified, it must exist when the CREATE FUNCTION statement is executed. However, when the function is used in an SQL statement, the method identifier must exist and be accessible from the database server machine.

  The *string* can be specified as follows:

  Extraneous blanks are not permitted within the single quotation marks.

  jar_id
  Identifies the jar identifier given to the jar collection when it was installed in the database. It can be either a simple identifier, or a schema qualified identifier. Examples are 'myJar' and 'mySchema.myJar'

  class_id
  Identifies the class identifier of the Java object. If the class is part of a package, the class identifier part must include the complete package prefix, for example, 'myPacks.UserFuncs'. The directory the Java virtual machine will look in for the classes depends on the operating system, as illustrated in the following table:

Operating system	Directory the Java virtual machine will look in for the classes
Linux AIX	`'.../myPacks/UserFuncs/'`
Windows	`'...\myPacks\UserFuncs\'`

  method_id
  Identifies the method name of the Java object to be invoked.

- For LANGUAGE CLR:

  The *string* specified represents the .NET assembly (library or executable), the class within that assembly, and the method within the class that the database manager invokes to execute the

function being created. The module, class, and method do not need to exist when the CREATE FUNCTION statement is executed. However, when the function is used in an SQL statement, the module, class, and method must exist and be accessible from the database server machine; otherwise, an error is returned (SQLSTATE 42724).

C++ routines that are compiled with the '/clr' compiler option to indicate that they include managed code extensions must be cataloged as 'LANGUAGE CLR' and not 'LANGUAGE C'. The database server needs to know that the .NET infrastructure is being utilized in a user-defined function in order to make necessary runtime decisions. All user-defined functions using the .NET infrastructure must be cataloged as 'LANGUAGE CLR'.

The *string* can be specified as follows:

The name must be enclosed by single quotation marks. Extraneous blanks are not permitted.

assembly
Identifies the DLL or other assembly file in which the class resides. Any file extensions (such as `.dll`) must be specified. If the full path name is not given, the file must reside in the function directory of the database product's installation path

For example, `c:\sqllib\function`.

If the file resides in a subdirectory of the install function directory, the subdirectory can be given before the file name rather than specifying the full path.

For example, if your install directory is `c:\sqllib` and your assembly file is `c:\sqllib\function\myprocs\mydotnet.dll`, it is only necessary to specify 'myprocs\mydotnet.dll' for the assembly.

The case sensitivity of this parameter is the same as the case sensitivity of the file system.

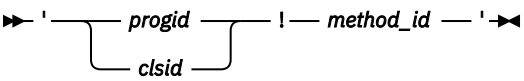
class_id
Specifies the name of the class within the given assembly in which the method that is to be invoked resides. If the class resides within a namespace, the full namespace must be given in addition to the class. For example, if the class EmployeeClass is in namespace MyCompany.ProcedureClasses, then MyCompany.ProcedureClasses.EmployeeClass must be specified for the class. Note that the compilers for some .NET languages will add the project name as a namespace for the class, and the behavior may differ depending on whether the command line compiler or the GUI compiler is used. This parameter is case sensitive.

method_id
Specifies the method within the given class that is to be invoked. This parameter is case sensitive.

- For LANGUAGE OLE:

The *string* specified is the OLE programmatic identifier (progid) or class identifier (clsid), and method identifier, which the database manager invokes to execute the user-defined function being created. The programmatic identifier or class identifier, and method identifier do not need to exist when the CREATE FUNCTION statement is executed. However, when the function is used in an SQL statement, the method identifier must exist and be accessible from the database server machine; otherwise, an error is returned (SQLSTATE 42724).

The *string* can be specified as follows:



Extraneous blanks are not permitted within the single quotation marks.

progid
Identifies the programmatic identifier of the OLE object.

progid is not interpreted by the database manager but only forwarded to the OLE APIs at run time. The specified OLE object must be creatable and support late binding (also called IDispatch-based binding).

clsid
Identifies the class identifier of the OLE object to create. It can be used as an alternative for specifying a *progid* in the case that an OLE object is not registered with a progid. The *clsid* has the form:

{nnnnnnnn-nnnn-nnnn-nnnn-nnnnnnnnnnnn}

where 'n' is an alphanumeric character. *clsid* is not interpreted by the database manager but only forwarded to the OLE APIs at run time.

method_id
Identifies the method name of the OLE object to be invoked.

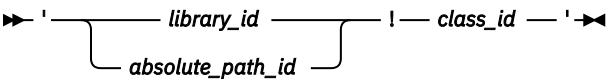
- For LANGUAGE CPP:

The *string* specified is the library identifier and class identifier within the library, which contains the evaluate method the database manager invokes to execute the user-defined function that is being created. If the string is not properly formed, an error is returned (SQLSTATE 42878).

It is not necessary that the library (or the class within the library) exist when the CREATE FUNCTION statement is executed. However, when the function is used in an SQL statement, the library and class within the library must exist and be accessible from the database server machine; otherwise, an error is returned (SQLSTATE 42724).

The body of every external function should be in a directory that is available on every database partition.

The *string* can be specified as follows:



Extraneous blanks are not permitted within the single quotation marks.

library_id
The name of the library that contains the function:

– On a UNIX system, if the specified library ID is `myfunc`, and if the database manager is being run from `/u/production`, the database manager looks for the function in the following library:

```
/u/production/sqllib/function/myfunc
```

– On a Windows operating system, the database manager looks for the function in the directory path specified by the LIBPATH or PATH environment variable.

absolute_path_id
The full path of the file that contains the function. For example:

– On a UNIX system, the following specification causes the database manager to look in `/u/jchui/mylib` for the myfunc shared library:

```
'/u/jchui/mylib/myfunc'
```

– On a Windows operating system, the following specification causes the database manager to load the dynamic link library myfunc.dll from the `d:\mylib` directory:

```
'd:\mylib\myfunc.dll'
```

If an absolute path ID is being used to identify the routine body, be sure to append the .dll extension.

class_id
The name of the class that contains the methods that are to be invoked.

For example, if you specify `'mymod!myclass'`:

- On a UNIX system, the database manager looks for the library `$inst_home_dir/sqllib/function/mymod` and invokes the evaluate method of the myclass class in that library.
- On a Windows operating system, the database manager loads the mymod.dll file and calls the evaluate method of the myclass class in the dynamic link library (DLL).

NAME *identifier*
This clause identifies the name of the user-written code which implements the function being defined. The *identifier* specified is an SQL identifier. The SQL identifier is used as the *library-id* in the string. Unless it is a delimited identifier, the identifier is folded to upper case. If the identifier is qualified with a schema name, the schema name portion is ignored. This form of NAME can only be used with LANGUAGE C.

LANGUAGE
This mandatory clause is used to specify the language interface convention to which the user-defined function body is written.

C
This means the database manager will call the user-defined function as if it were a C function. The user-defined function must conform to the C language calling and linkage convention as defined by the standard ANSI C prototype.

JAVA
This means the database manager will call the user-defined function as a method in a Java class.

CLR
The database manager calls the user-defined function as a method in a .NET class. LANGUAGE CLR is supported only for user-defined functions running on Windows operating systems. NOT FENCED cannot be specified for a CLR routine (SQLSTATE 42601).

OLE
The database manager calls the user-defined function as if it were a method exposed by an OLE automation object. The user-defined function must conform with the OLE automation data types and invocation mechanism, as described in the *OLE Automation Programmer's Reference*.

LANGUAGE OLE is supported for user-defined functions for this database product only in Windows 32-bit operating systems.

For information about creating LANGUAGE OLE DB external table functions, see "CREATE FUNCTION (OLE DB External Table)".

CPP
The database manager calls the user-defined function by invoking the evaluate method of a C++ class.

PARAMETER STYLE
This clause is used to specify the conventions used for passing parameters to and returning the value from functions.

DB2GENERAL
Used to specify the conventions for passing parameters to and returning the value from external functions that are defined as a method in a Java class. This can only be specified when LANGUAGE JAVA is used.

SQL
Used to specify the conventions for passing parameters to and returning the value from external functions that conform to C language calling and linkage conventions, methods exposed by OLE automation objects, or public static methods of a .NET object. This must be specified when LANGUAGE C, LANGUAGE CLR, or LANGUAGE OLE is used.

NPSGENERIC

Used to specify the conventions for passing parameters to and returning the value from external functions that are defined as a method in a C++ class. This can specified only when the LANGUAGE option is set to CPP.

When NPSGENERIC is specified as the parameter style, the UDF is written in C++ as a derived class of the nz.udx_ver2.Udf class. The class must implement the following two methods in addition to its constructor and destructor:

static Udf* Udf::instantiate(UdxInit *pInit)
Static member method instantiate(), which must instantiate a new instance of the UDF derived class and return a pointer to the new instance as a class Udf pointer. The engine uses this method to create an instance of a UDF object.

virtual ReturnValue Udf::evaluate()
Member method evaluate(), which is called by the engine to evaluate the user function and return a value to the caller.

PARAMETER CCSID

Specifies the encoding scheme to use for all string data passed into and out of the function. If the PARAMETER CCSID clause is not specified, the default is PARAMETER CCSID UNICODE for Unicode databases, and PARAMETER CCSID ASCII for all other databases.

ASCII
Specifies that string data is encoded in the database code page. If the database is a Unicode database, PARAMETER CCSID ASCII cannot be specified (SQLSTATE 56031). When the function is invoked, the application code page for the function is the database code page.

UNICODE
Specifies that string data is encoded in Unicode. If the database is a Unicode database, character data is in UTF-8, and graphic data is in UCS-2. If the database is not a Unicode database, character data is in UTF-8. In either case, when the function is invoked, the application code page for the function is 1208.

If the database is not a Unicode database, and a function with PARAMETER CCSID UNICODE is created, the function cannot have any graphic types or user-defined types (SQLSTATE 560C1).

If the database is not a Unicode database, table functions can be created with PARAMETER CCSID UNICODE, but the following rules apply:

- The alternate collating sequence must be specified in the database configuration before creating the table function (SQLSTATE 56031). PARAMETER CCSID UNICODE table functions collate with the alternate collating sequence specified in the database configuration.
- Tables or table functions created with CCSID ASCII, and tables or table functions created with CCSID UNICODE, cannot both be used in a single SQL statement (SQLSTATE 53090). This applies to tables and table functions referenced directly in the statement, as well as to tables and table functions referenced indirectly (such as, for example, through referential integrity constraints, triggers, materialized query tables, and tables in the body of views).
- Table functions created with PARAMETER CCSID UNICODE cannot be referenced in SQL functions or SQL methods (SQLSTATE 560C0).
- An SQL statement that references a table function created with PARAMETER CCSID UNICODE cannot invoke an SQL function or SQL method (SQLSTATE 53090).
- Graphic types, the XML type, and user-defined types cannot be used as parameters to PARAMETER CCSID UNICODE table functions (SQLSTATE 560C1).
- SQL statements are always interpreted in the database code page. In particular, this means that every character in literals, hex literals, and delimited identifiers must have a representation in the database code page; otherwise, the character will be replaced with the substitution character.

If the database is not a Unicode database, and the alternate collating sequence has been specified in the database configuration, functions can be created with either PARAMETER CCSID ASCII or

PARAMETER CCSID UNICODE. All string data passed into and out of the function will be converted to the appropriate code page.

This clause cannot be specified with LANGUAGE CPP, LANGUAGE OLE, LANGUAGE JAVA, or LANGUAGE CLR (SQLSTATE 42613).

DETERMINISTIC or NOT DETERMINISTIC

This optional clause specifies whether the function always returns the same results for given argument values (DETERMINISTIC) or whether the function depends on some state values that affect the results (NOT DETERMINISTIC). That is, a DETERMINISTIC function must always return the same table from successive invocations with identical inputs. Optimizations taking advantage of the fact that identical inputs always produce the same results are prevented by specifying NOT DETERMINISTIC. An example of a table function that is non-deterministic is one that references special registers, global variables, non-deterministic functions, or sequences in a way that affects the table function result table.

FENCED or NOT FENCED

This clause specifies whether the function is considered "safe" to run in the database manager operating environment's process or address space (NOT FENCED), or not (FENCED).

If a function is registered as FENCED, the database manager protects its internal resources (for example, data buffers) from access by the function. Most functions will have the option of running as FENCED or NOT FENCED. In general, a function running as FENCED will not perform as well as a similar one running as NOT FENCED.

CAUTION: Use of NOT FENCED for functions not adequately coded, reviewed and tested can compromise the integrity of your database. This database product safeguards against many of the common types of inadvertent failures that might occur, but cannot guarantee complete integrity when NOT FENCED user defined functions are used.

Only FENCED can be specified for a function with LANGUAGE OLE or NOT THREADSAFE (SQLSTATE 42613).

If the function is FENCED and has the NO SQL option, the AS LOCATOR clause cannot be specified (SQLSTATE 42613).

Either SYSADM authority, DBADM authority, or a special authority (CREATE_NOT_FENCED_ROUTINE) is required to register a user-defined function as NOT FENCED.

LANGUAGE CLR user-defined functions cannot be created when specifying the NOT FENCED clause (SQLSTATE 42601).

THREADSAFE or NOT THREADSAFE

Specifies whether the function is considered safe to run in the same process as other routines (THREADSAFE), or not (NOT THREADSAFE).

If the function is defined with LANGUAGE other than OLE:

- If the function is defined as THREADSAFE, the database manager can invoke the function in the same process as other routines. In general, to be threadsafe, a function should not use any global or static data areas. Most programming references include a discussion of writing threadsafe routines. Both FENCED and NOT FENCED functions can be THREADSAFE.
- If the function is defined as NOT THREADSAFE, the database manager will never simultaneously invoke the function in the same process as another routine.

For FENCED functions, THREADSAFE is the default if the LANGUAGE is JAVA or CLR. For all other languages, NOT THREADSAFE is the default. If the function is defined with LANGUAGE OLE, THREADSAFE may not be specified (SQLSTATE 42613).

For NOT FENCED functions, THREADSAFE is the default. NOT THREADSAFE cannot be specified (SQLSTATE 42613).

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT

This optional clause may be used to avoid a call to the external function if any of the arguments is null. If the user-defined function is defined to have no parameters, then of course this null argument condition cannot arise, and it does not matter how this specification is coded.

If RETURNS NULL ON NULL INPUT is specified, and if, at table function OPEN time, any of the function's arguments are null, then the user-defined function is not called. The result of the attempted table function scan is the empty table (a table with no rows).

If CALLED ON NULL INPUT is specified, then regardless of whether any arguments are null, the user-defined function is called. It can return a null value or a normal (non-null) value. But responsibility for testing for null argument values lies with the UDF.

The value NULL CALL may be used as a synonym for CALLED ON NULL INPUT for backwards and family compatibility. Similarly, NOT NULL CALL may be used as a synonym for RETURNS NULL ON NULL INPUT.

READS SQL DATA, NO SQL, CONTAINS SQL

Specifies the classification of SQL statements that the function can run. The database manager verifies that the SQL statements that the function issues are consistent with this specification.

For the classification of each statement, see "SQL statements that can be executed in routines and triggers" in Developing User-defined Routines (SQL and External).

The default is READS SQL DATA.

READS SQL DATA

Specifies that the function can run statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL (SQLSTATE 38002 or 42985). The function cannot run SQL statements that modify data (SQLSTATE 38003 or 42985).

NO SQL

Specifies that the function can run only SQL statements with a data access classification of NO SQL. If the ALLOW PARALLEL, EXECUTE ON ALL DATABASE PARTITIONS, and RESULT TABLE DISTRIBUTED clauses are all specified, NO SQL is the only option allowed.

CONTAINS SQL

Specifies that the function can run only SQL statements with a data access classification of CONTAINS SQL or NO SQL (SQLSTATE 38004 or 42985). The function cannot run any SQL statements that read or modify data (SQLSTATE 38003 or 42985).

STATIC DISPATCH

This optional clause indicates that at function resolution time, a function is chosen by the database server based on the static types (declared types) of the parameters of the function.

EXTERNAL ACTION or NO EXTERNAL ACTION

Specifies whether the function takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a file. The default is EXTERNAL ACTION.

EXTERNAL ACTION

Specifies that the function takes an action that changes the state of an object that the database manager does not manage.

A function with external actions might return incorrect results if the function is executed by parallel tasks. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function. Specify the DISALLOW PARALLEL clause for functions that do not work correctly with parallelism.

NO EXTERNAL ACTION

Specifies that the function does not take any action that changes the state of an object that the database manager does not manage. The database manager uses this information during optimization of SQL statements.

NO SCRATCHPAD or SCRATCHPAD *length*

This optional clause may be used to specify whether a scratchpad is to be provided for an external function. (It is strongly recommended that user-defined functions be re-entrant, so a scratchpad provides a means for the function to "save state" from one call to the next.)

- If SCRATCHPAD is specified, then at first invocation of the user-defined function, memory is allocated for a scratchpad to be used by the external function. On each invocation of the user-defined function, an additional argument is passed to the external function which addresses the scratchpad. The scratchpad has the following characteristics:
  - *length*, if specified, sets the size of the scratchpad in bytes and must be between 1 and 32,767 (SQLSTATE 42820). The default value is 100.
  - It is initialized to all X'00''s.
  - Its scope is the SQL statement. There is one scratchpad per reference to the external function in the SQL statement. So if the UDFX function in the following statement is defined with the SCRATCHPAD keyword, two scratchpads would be assigned.

    ```
    SELECT A.C1, B.C2
      FROM TABLE (UDFX(:hv1)) AS A,
           TABLE (UDFX(:hv1)) AS B
        WHERE ...
    ```

  - It is persistent. It is initialized at the beginning of the execution of the statement, and can be used by the external table function to preserve the state of the scratchpad from one call to the next. If the FINAL CALL keyword is also specified for the UDF, then the scratchpad is NEVER altered, and any resources anchored in the scratchpad should be released when the special FINAL call is made.

    If NO FINAL CALL is specified or defaulted, then the external table function should clean up any such resources on the CLOSE call, as the database server will re-initialize the scratchpad on each OPEN call. This determination of FINAL CALL or NO FINAL CALL and the associated behavior of the scratchpad could be an important consideration, particularly if the table function will be used in a subquery or join, since that is when multiple OPEN calls can occur during the execution of a statement.
  - It can be used as a central point for system resources (for example, memory) which the external function might acquire. The function could acquire the memory on the first call, keep its address in the scratchpad, and refer to it in subsequent calls.

    (As previously outlined, the FINAL CALL/NO FINAL CALL keyword is used to control the re-initialization of the scratchpad, and also dictates when the external table function should release resources anchored in the scratchpad.)
- If NO SCRATCHPAD is specified then no scratchpad is allocated or passed to the external function.

FINAL CALL or NO FINAL CALL

This optional clause specifies whether a final call (and a separate first call) is to be made to an external function. It also controls when the scratchpad is re-initialized. If NO FINAL CALL is specified, then the database server can only make three types of calls to the table function: open, fetch and close. However, if FINAL CALL is specified, then in addition to open, fetch and close, a first call and a final call can be made to the table function.

For external table functions, the call-type argument is ALWAYS present, regardless of which option is chosen.

If the final call is being made because of an interrupt or end-of-transaction, the UDF may not issue any SQL statements except for CLOSE cursor (SQLSTATE 38505). A special value is passed in the "call type" argument for these special final call situations.

FINAL CALL cannot be specified in combination with LANGUAGE CPP.

DISALLOW PARALLEL or ALLOW PARALLEL EXECUTE ON ALL DATABASE PARTITIONS RESULT TABLE DISTRIBUTED

Specifies whether or not, for a single reference to the function, the invocation of the function is to be parallelized.

DISALLOW PARALLEL

Specifies that on each invocation of the function, the function is invoked on a single database partition.

ALLOW PARALLEL EXECUTE ON ALL DATABASE PARTITIONS RESULT TABLE DISTRIBUTED

Specifies that on each invocation of the function, the function is invoked on all database partitions. The union of the result sets obtained on each database partition is returned. The function cannot execute SQL statements (the NO SQL clause must also be specified).

NO DBINFO or DBINFO

This optional clause specifies whether certain specific information known to the database server is to be passed to the function as an additional invocation-time argument (DBINFO) or not (NO DBINFO). NO DBINFO is the default. DBINFO is not supported for LANGUAGE OLE or PARAMETER TYLE NPSGENERIC (SQLSTATE 42613).

If DBINFO is specified, a structure containing the following information is passed to the function:

- Database name - the name of the currently connected database
- Application ID - the unique application ID that is established for each connection to the database
- Application authorization ID - the application runtime authorization ID, regardless of any nested functions between this function and the application
- Code page - the database code page
- Schema name - not applicable to external table functions
- Table name - not applicable to external table functions
- Column name - not applicable to external table functions
- Database version or release - the version, release, and modification level of the database server that is invoking the function
- Platform - the server's platform type
- Table function result column numbers - an array of result column numbers that is used by the statement referencing the function; this information enables the function to return only required column values instead of all column values
- Database partition number - the number of the database partition on which the external table function is invoked; in a single database partition environment, this value is 0

CARDINALITY *integer*

This optional clause provides an estimate of the expected number of rows to be returned by the function for optimization purposes. Valid values range from 0 to 9,223,372,036,854,775,807.

If the CARDINALITY clause is not specified for a table function, assume a finite value is assumed as a default; the same value assumed for tables for which the RUNSTATS utility has not gathered statistics.

Warning: If a function has infinite cardinality (that is, if it returns a row every time it is called to do so, and never returns the "end-of-table" condition), then queries that require the end-of-table condition to correctly function will never terminate and will have to be interrupted. Examples of such queries are those that contain a GROUP BY or an ORDER BY clause. For that reason, writing UDFs that have infinite cardinality is not recommended.

TRANSFORM GROUP *group-name*

Indicates the transform group to be used for user-defined structured type transformations when invoking the function. A transform is required if the function definition includes a user-defined structured type as a parameter data type. If this clause is not specified, the default group name DB2_FUNCTION is used. If the specified (or default) *group-name* is not defined for a referenced structured type, an error results (SQLSTATE 42741). If a required FROM SQL transform function is not defined for the given group-name and structured type, an error results (SQLSTATE 42744).

INHERIT SPECIAL REGISTERS
This optional clause specifies that updatable special registers in the function will inherit their initial values from the environment of the invoking statement. For a function invoked in the select-statement of a cursor, the initial values are inherited from the environment when the cursor is opened. For a routine invoked in a nested object (for example a trigger or view), the initial values are inherited from the runtime environment (not inherited from the object definition).

No changes to the special registers are passed back to the invoker of the function.

Non-updatable special registers, such as the datetime special registers, reflect a property of the statement currently executing, and are therefore set to their default values.

NOT SECURED or SECURED
Specifies whether the function is considered secure for row and column access control. The default is NOT SECURED.

NOT SECURED
Indicates that the function is not considered secure. When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled and column level access control is activated for its table (SQLSTATE 428HA). This rule applies to the non secure user-defined functions that are invoked anywhere in the statement.

SECURED
Indicates that the function is considered secure. The function must be secure when it is referenced in a row permission or a column mask (SQLSTATE 428H8, SQLCODE -20470).

STAY RESIDENT NO
Specifies that the library that is loaded for the function is not to remain resident in memory after the function ends. This clause is ignored when:

- The NOT FENCED clause is specified.
- The LANGUAGE option is set to JAVA or CLR.

Rules

- In a partitioned database environment, the use of SQL in external user-defined functions or methods is not supported (SQLSTATE 42997).
- Only routines defined as NO SQL can be used to define an index extension (SQLSTATE 428F8).
- If the function allows SQL, the external program must not attempt to access any federated objects (SQLSTATE 55047).
- ***Table access restrictions*** If a function is defined as READS SQL DATA, no statement in the function can access a table that is being modified by the statement which invoked the function (SQLSTATE 57053). For example, suppose the user-defined function BONUS() is defined as READS SQL DATA. If the statement UPDATE EMPLOYEE SET SALARY = SALARY + BONUS(EMPNO) is invoked, no SQL statement in the BONUS function can read from the EMPLOYEE table.

Notes

- When choosing the data types for the parameters of a user-defined function, consider the rules for promotion that will affect its input values. For example, a constant which may be used as an input value could have a built-in data type that is different from the one expected and, more significantly, may not be promoted to the data type expected. Based on the rules for promotion, it is generally recommended to use the following data types for parameters:
  - INTEGER instead of SMALLINT
  - DOUBLE instead of REAL
  - VARCHAR instead of CHAR
  - VARGRAPHIC instead of GRAPHIC
- For portability of UDFs across platforms, it is recommended to use the following data types:

  - DOUBLE or REAL instead of FLOAT
  - DECIMAL instead of NUMERIC
  - CLOB (or BLOB) instead of LONG VARCHAR
- Creating a function with a schema name that does not already exist will result in the implicit creation of that schema provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- A Java routine defined as NOT FENCED will be invoked as if it had been defined as FENCED THREADSAFE.
- ***Privileges***: The definer of a function always receives the EXECUTE privilege WITH GRANT OPTION on the function, as well as the right to drop the function. When the function is used in an SQL statement, the function definer must have the EXECUTE privilege on any packages used by the function or EXECUTEIN privilege or DATAACCESS authority on the schema containing the packages. .
- ***Setting of the default value***: Parameters of a function that are defined with a default value are set to their default value when the functions is invoked, but only if a value is not supplied for the corresponding argument, or is specified as DEFAULT, when the function is invoked.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of this database product and with other database products. These alternatives are non-standard and should not be used.
  - PARAMETER STYLE DB2SQL can be specified in place of PARAMETER STYLE SQL
  - NOT VARIANT can be specified in place of DETERMINISTIC
  - VARIANT can be specified in place of NOT DETERMINISTIC
  - NULL CALL can be specified in place of CALLED ON NULL INPUT
  - NOT NULL CALL can be specified in place of RETURNS NULL ON NULL INPUT
  - DB2GENRL can be specified in place of DB2GENERAL

  The following syntax is accepted as the default behavior:
  - ASUTIME NO LIMIT
  - NO COLLID
  - PROGRAM TYPE SUB
  - STAY RESIDENT NO
  - CCSID UNICODE in a Unicode database
  - CCSID ASCII in a non-Unicode database if PARAMETER CCSID UNICODE is not specified
- ***Creating a secure function***: Normally users with SECADM authority do not have privileges to create database objects such as triggers and functions. Typically they will examine the data accessed by the function, ensure it is secure, then grant the CREATE_SECURE_OBJECT authority to someone who currently has required privileges to create a secure user-defined function. After the function is created, they will revoke the CREATE_SECURE_OBJECT authority from the function owner.

  The SECURED attribute is considered to be an assertion that declares the user has established a change control audit procedure for all changes to the user-defined function. The database manager assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages.
- ***Invoking other user-defined functions in a secure function***: If a secure user-defined function invokes other user-defined functions, the database manager does not validate whether those nested user-defined functions have the SECURED attribute. If those nested functions can access sensitive data, the user with SECADM authority needs to ensure those functions are allowed to access those data and a change control audit procedure has been established for all changes to those functions.
- ***Replacing an existing function such that the secure attribute is changed (from SECURED to NOT SECURED and vice versa)***: Packages and dynamically cached SQL statements that depend on the function may be invalidated because the secure attribute affects the access path selection for statements involving tables for which row or column level access control is activated.

- ***EXTERNAL ACTION functions***: If an EXTERNAL ACTION function is invoked in other than the outermost select list, the results are unpredictable since the number of times the function is invoked will vary depending on the access plan used.

Examples

- *Example 1:* The following example registers a table function written to return a row consisting of a single document identifier column for each known document in a text management system. The first parameter matches a given subject area and the second parameter contains a given string.

  Within the context of a single session, the UDF will always return the same table, and therefore it is defined as DETERMINISTIC. Note the RETURNS clause which defines the output from DOCMATCH. FINAL CALL must be specified for each table function. In addition, the DISALLOW PARALLEL keyword is added as table functions cannot operate in parallel. Although the size of the output for DOCMATCH is highly variable, CARDINALITY 20 is a representative value, and is specified to help the database optimizer.

```
CREATE FUNCTION DOCMATCH (VARCHAR(30), VARCHAR(255))
  RETURNS TABLE (DOC_ID CHAR(16))
  EXTERNAL NAME '/common/docfuncs/rajiv/udfmatch'
  LANGUAGE C
  PARAMETER STYLE SQL
  NO SQL
  DETERMINISTIC
  NO EXTERNAL ACTION
  NOT FENCED
  SCRATCHPAD
  FINAL CALL
  DISALLOW PARALLEL
  CARDINALITY 20
```

- *Example 2:* The following example registers an OLE table function that is used to retrieve message header information and the partial message text of messages in Microsoft Exchange.

```
CREATE FUNCTION MAIL()
  RETURNS TABLE (TIMERECEIVED DATE,
                 SUBJECT VARCHAR(15),
                 SIZE INTEGER,
                 TEXT VARCHAR(30))
  EXTERNAL NAME 'tfmail.header!list'
  LANGUAGE OLE
  PARAMETER STYLE SQL
  NOT DETERMINISTIC
  FENCED
  CALLED ON NULL INPUT
  SCRATCHPAD
  FINAL CALL
  NO SQL
  EXTERNAL ACTION
  DISALLOW PARALLEL
```

CREATE FUNCTION (OLE DB external table)

The CREATE FUNCTION (OLE DB External Table) statement is used to register a user-defined OLE DB external table function to access data from an OLE DB provider.

A *table function* can be used in the FROM clause of a SELECT.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

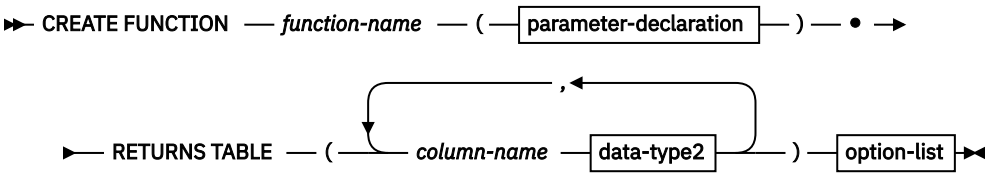
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CREATE_EXTERNAL_ROUTINE authority on the database and at least one of the following authorities:
  - IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the function does not exist
  - CREATEIN privilege on the schema, if the schema name of the function exists
  - SCHEMAADM authority on the schema, if the schema name of the function exists
- DBADM authority

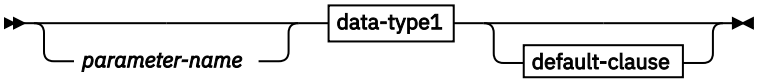
Group privileges are not considered for any table or view specified in the CREATE FUNCTION statement.

If the SECURED option is specified, the authorization ID of the statement must include SECADM authority or CREATE_SECURE_OBJECT authority (SQLSTATE 42501).

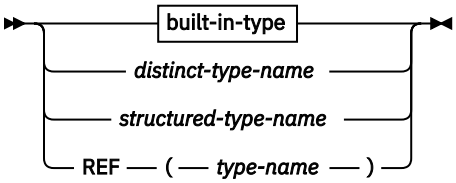
Syntax



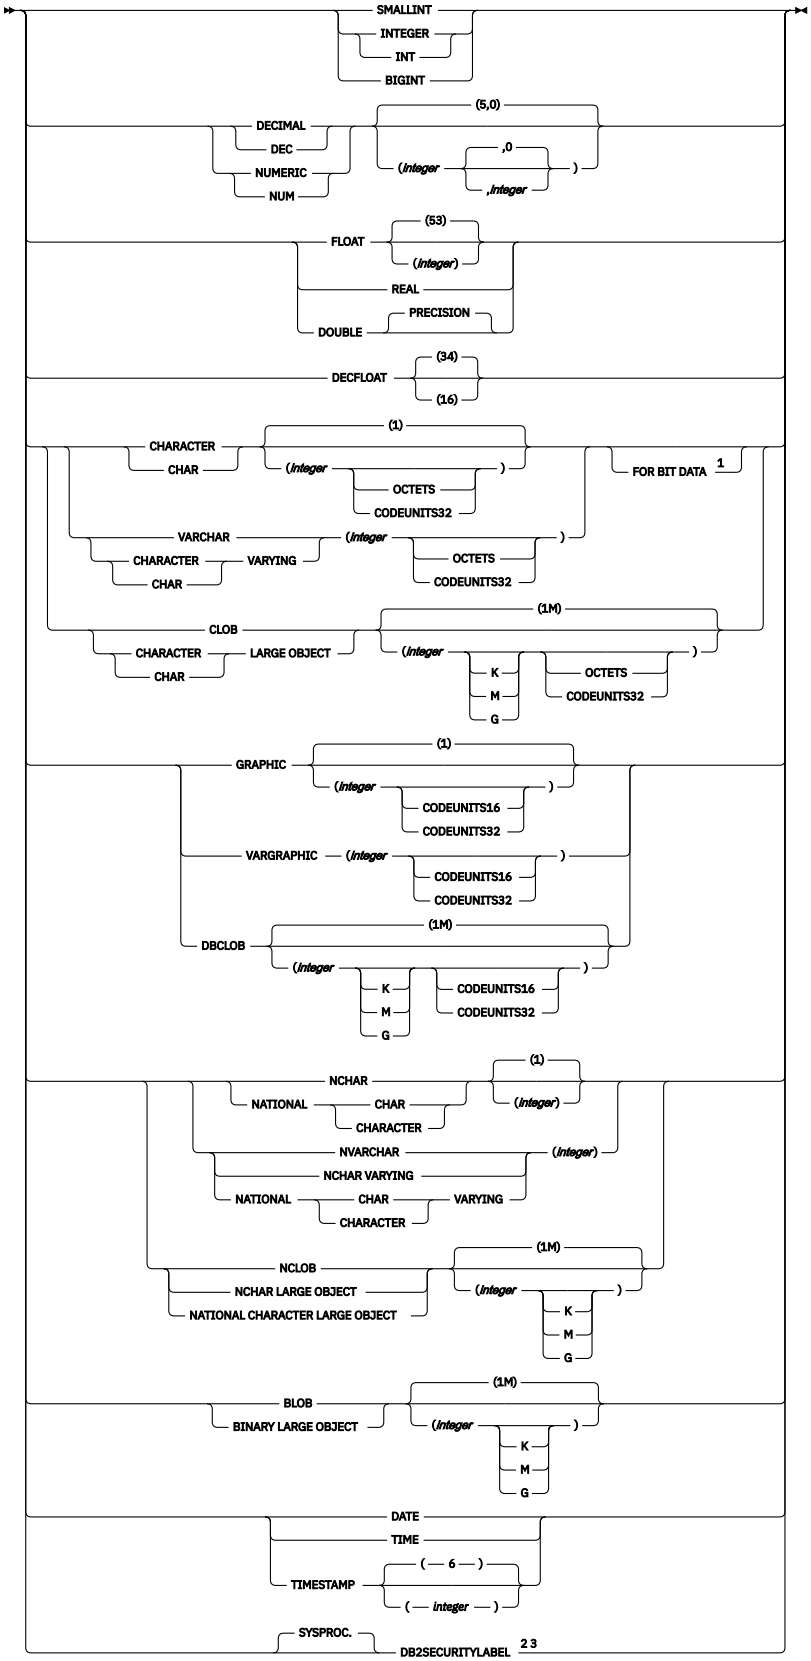
parameter-declaration



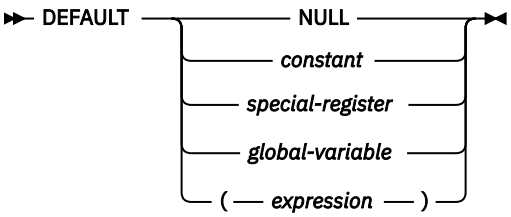
data-type1, data-type2



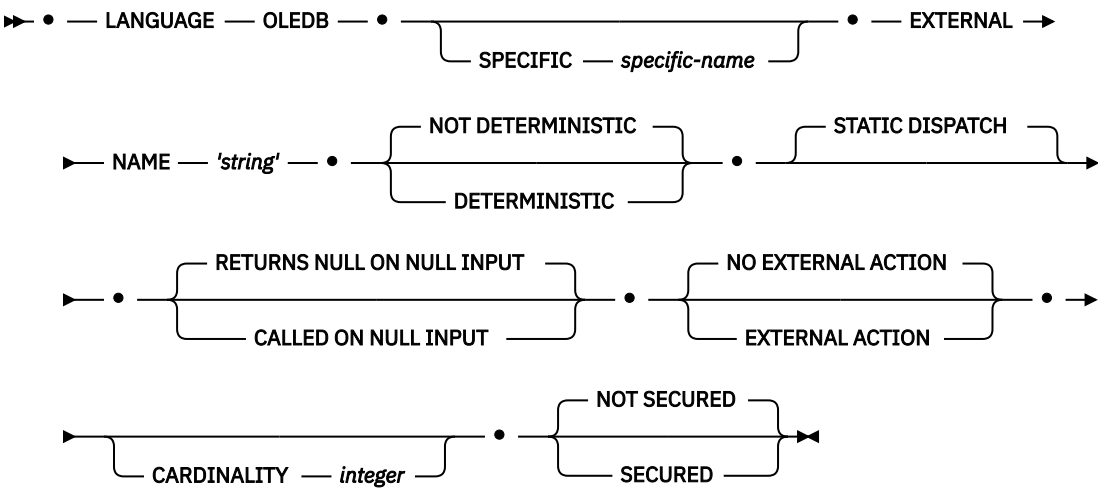
built-in-type



default-clause



option-list



Notes:

[1] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

[2] DB2SECURITYLABEL is the built-in distinct type that must be used to define the row security label column of a protected table.

[3] For a column of type DB2SECURITYLABEL, NOT NULL WITH DEFAULT is implicit and cannot be explicitly specified (SQLSTATE 42842). The default value for a column of type DB2SECURITYLABEL is the session authorization ID's security label for write access.

Description

function-name

Names the function being defined. It is a qualified or unqualified name that designates a function. The unqualified form of *function-name* is an SQL identifier. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The qualified form is a *schema-name* followed by a period and an SQL identifier.

The name, including the implicit or explicit qualifiers, together with the number of parameters and the data type of each parameter (without regard for any length, precision or scale attributes of the data type) must not identify a function described in the catalog (SQLSTATE 42723). The unqualified name, together with the number and data types of the parameters, while of course unique within its schema, need not be unique across schemas.

If a two-part name is specified, the *schema-name* cannot begin with 'SYS' (SQLSTATE 42939).

A number of names used as keywords in predicates are reserved for system use, and cannot be used as a *function-name* (SQLSTATE 42939). The names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators.

The same name can be used for more than one function if there is some difference in the signature of the functions. Although there is no prohibition against it, an external user-defined table function should not be given the same name as a built-in function.

(*parameter-declaration*,...)

Identifies the number of input parameters of the function, and specifies the data type and optional default value of each parameter. If no input parameter is specified, data is retrieved from the external source possibly subsetted through query optimization. The input parameter passes command text to an OLE DB provider.

It is possible to register a function that has no parameters. In this case, the parentheses must still be coded, with no intervening data types. For example:

```
CREATE FUNCTION WOOFER() ...
```

No two identically-named functions within a schema are permitted to have exactly the same type for all corresponding parameters. Lengths, precisions, and scales are not considered in this type comparison. Therefore, CHAR(8) and CHAR(35) are considered to be the same type. A weakly typed distinct type specified for a parameter is considered to be the same data type as the source type of the distinct type. For a Unicode database, CHAR(13) and GRAPHIC(8) are considered to be the same type. A duplicate signature returns an error (SQLSTATE 42723).

parameter-name

Specifies an optional name for the input parameter.

data-type1

Specifies the data type of the input parameter. The data type can be any character or graphic string data type or a distinct type based on a character or graphic string data type. Parameters of type BINARY, VARBINARY, and XML are not supported (SQLSTATE 42815).

For a more complete description of each built-in data type, see "CREATE TABLE".

For a user-defined distinct type, the length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). A distinct type parameter is passed as the source type of the distinct type. If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

DEFAULT

Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The special registers that can be specified as the default are that same as those that can be specified for a column default (see *default-clause* in the CREATE TABLE statement). Other special registers can be specified as the default by using an expression.

The expression can be any expression of the type described in "Expressions". If a default value is not specified, the parameter has no default and the corresponding argument cannot be omitted on invocation of the procedure. The maximum size of the *expression* is 64K bytes.

The default expression must not modify SQL data (SQLSTATE 428FL or SQLSTATE 429BL). The expression must be assignment compatible to the parameter data type (SQLSTATE 42821).

A default cannot be specified for a parameter of type ARRAY, ROW, or CURSOR (SQLSTATE 429BB).

RETURNS TABLE

Specifies that the output of the function is a table. The parentheses that follow this keyword delimit a list of the names and types of the columns of the table, resembling the style of a simple CREATE TABLE statement which has no additional specifications (constraints, for example).

column-name

Specifies the name of the column which must be the same as the corresponding rowset column name. The name cannot be qualified and the same name cannot be used for more than one column of the table.

data-type2

Specifies the data type of the column. BINARY, VARBINARY, and XML are not supported (SQLSTATE 42815).

built-in-type
See "CREATE TABLE" for the description of built-in data types.

SPECIFIC *specific-name*
Provides a unique name for the instance of the function that is being defined. This specific name can be used when sourcing on this function, dropping the function, or commenting on the function. It can never be used to invoke the function. The unqualified form of *specific-name* is an SQL identifier. The qualified form is a *schema-name* followed by a period and an SQL identifier. The name, including the implicit or explicit qualifier, must not identify another function instance that exists at the application server; otherwise an error (SQLSTATE 42710) is raised.

The *specific-name* may be the same as an existing *function-name*.

If no qualifier is specified, the qualifier that was used for *function-name* is used. If a qualifier is specified, it must be the same as the explicit or implicit qualifier of *function-name* or an error (SQLSTATE 42882) is raised.

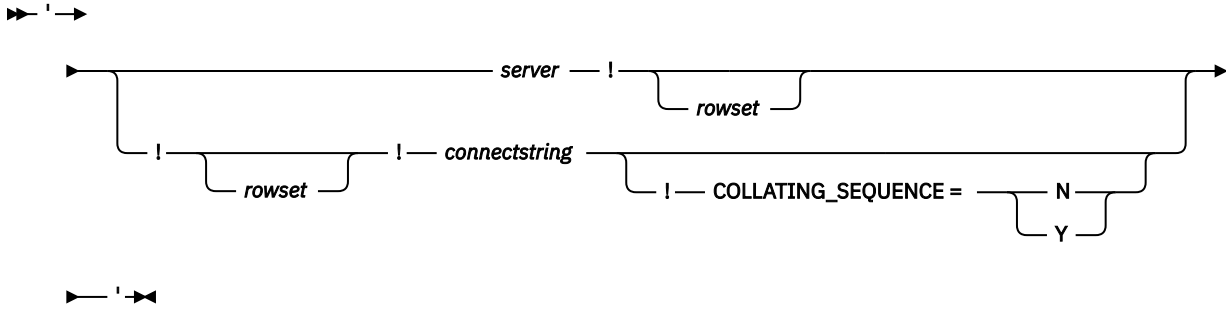
If *specific-name* is not specified, a unique name is generated by the database manager. The unique name is SQL followed by a character timestamp, SQLyymmddhhmmssxxx.

EXTERNAL NAME *'string'*
This clause identifies the external table and an OLE DB provider.

The 'string' option is a string constant with a maximum of 254 bytes.

The string specified is used to establish a connection and session with an OLE DB provider, and retrieve data from a rowset. The OLE DB provider and data source do not need to exist when the CREATE FUNCTION statement is executed.

The *string* can be specified as follows:



server
Identifies the local name of a data source as defined by "CREATE SERVER".

rowset
Identifies the rowset (table) exposed by the OLE DB provider. Fully qualified table names must be provided for OLE DB providers that support catalog or schema names.

connectstring
String version of the initialization properties needed to connect to a data source. The basic format of a connection string is based on the ODBC connection string. The string contains a series of keyword/value pairs separated by semicolons. The equal sign (=) separates each keyword and its value. Keywords are the descriptions of the OLE DB initialization properties (property set DBPROPSET_DBINIT) or provider-specific keywords.

COLLATING_SEQUENCE
Specifies whether the data source uses the same collating sequence as Db2. For details, see "CREATE SERVER". Valid values are as follows:

- Y = Same collating sequence
- N = Different collating sequence

If COLLATING_SEQUENCE is not specified, the data source is assumed to have a different collating sequence than Db2.

If *server* is provided, *connectstring* or COLLATING_SEQUENCE are not allowed in the external name. They are defined as server options CONNECTSTRING and COLLATING_SEQUENCE. If no *server* is provided, a *connectstring* must be provided. If *rowset* is not provided, the table function must have an input parameter to pass through command text to the OLE DB provider.

LANGUAGE OLEDB
This means the database manager will deploy a built-in generic OLE DB consumer to retrieve data from the OLE DB provider. No table function implementation is required by the developer.

LANGUAGE OLEDB table functions can be created on any platform, but only executed on platforms supported by Microsoft OLE DB.

DETERMINISTIC or NOT DETERMINISTIC
This optional clause specifies whether the function always returns the same results for given argument values (DETERMINISTIC) or whether the function depends on some state values that affect the results (NOT DETERMINISTIC). That is, a DETERMINISTIC function must always return the same table from successive invocations with identical inputs. Optimizations taking advantage of the fact that identical inputs always produce the same results are prevented by specifying NOT DETERMINISTIC.

STATIC DISPATCH
This optional clause indicates that at function resolution time, the database manager chooses a function based on the static types (declared types) of the parameters of the function.

RETURNS NULL ON NULL INPUT or CALLED ON NULL INPUT
This optional clause may be used to avoid a call to the external function if any of the arguments is null. If the user-defined function is defined to have no parameters, then of course this null argument condition cannot arise.

If RETURNS NULL ON NULL INPUT is specified and if at execution time any one of the function's arguments is null, the user-defined function is not called and the result is the empty table; that is, a table with no rows.

If CALLED ON NULL INPUT is specified, then at execution time regardless of whether any arguments are null, the user-defined function is called. It can return an empty table or not, depending on its logic. But responsibility for testing for null argument values lies with the UDF.

The value NULL CALL may be used as a synonym for CALLED ON NULL INPUT for backwards and family compatibility. Similarly, NOT NULL CALL may be used as a synonym for RETURNS NULL ON NULL INPUT.

NO EXTERNAL ACTION or EXTERNAL ACTION
Specifies whether the function takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a file. The default is NO EXTERNAL ACTION.

NO EXTERNAL ACTION
Specifies that the function does not take any action that changes the state of an object that the database manager does not manage. The database manager uses this information during optimization of SQL statements.

EXTERNAL ACTION
Specifies that the function takes an action that changes the state of an object that the database manager does not manage.

CARDINALITY *integer*
This optional clause provides an estimate of the expected number of rows to be returned by the function for optimization purposes. Valid values for *integer* range from 0 to 2 147 483 647 inclusive.

If the CARDINALITY clause is not specified for a table function, a finite value is assumed as the default. The finite value is the same value that is assumed for tables for which the RUNSTATS utility has not gathered statistics.

Warning: If a function does, in fact, have infinite cardinality - that is, it returns a row every time it is called to do so, and never returns the "end-of-table" condition - then queries that require the

end-of-table condition to correctly function will be infinite, and will have to be interrupted. Examples of such queries are those that contain a GROUP BY or an ORDER BY clause. Writing such UDFs is not recommended.

NOT SECURED or SECURED
Specifies whether the function is considered secure for row and column access control. The default is NOT SECURED.

NOT SECURED
Indicates that the function is not considered secure. When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled and column level access control is activated for its table (SQLSTATE 428HA). This rule applies to the non secure user-defined functions that are invoked anywhere in the statement.

SECURED
Indicates that the function is considered secure. The function must be secure when it is referenced in a row permission or a column mask (SQLSTATE 428H8).

Notes

- FENCED, FINAL CALL, SCRATCHPAD, PARAMETER STYLE SQL, DISALLOW PARALLEL, NO DBINFO, NOT THREADSAFE, and NO SQL are implicit in the statement and can be specified.
- When choosing the data types for the parameters of a user-defined function, consider the rules for promotion that will affect its input values. For example, a constant which may be used as an input value could have a built-in data type that is different from the one expected and, more significantly, may not be promoted to the data type expected. Based on the rules for promotion, it is generally recommended to use the following data types for parameters:
  - VARCHAR instead of CHAR
  - VARGRAPHIC instead of GRAPHIC
- For portability of UDFs across platforms, it is recommended to use the following data types:
  - DOUBLE or REAL instead of FLOAT
  - DECIMAL instead of NUMERIC
  - CLOB (or BLOB) instead of LONG VARCHAR
- Creating a function with a schema name that does not already exist will result in the implicit creation of that schema provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- ***Privileges***: The definer of a function always receives the EXECUTE privilege WITH GRANT OPTION on the function, as well as the right to drop the function.
- ***Setting of the default value***: Parameters of a function that are defined with a default value are set to their default value when the functions is invoked, but only if a value is not supplied for the corresponding argument, or is specified as DEFAULT, when the function is invoked.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - NOT VARIANT can be specified in place of DETERMINISTIC
  - VARIANT can be specified in place of NOT DETERMINISTIC
  - NULL CALL can be specified in place of CALLED ON NULL INPUT
  - NOT NULL CALL can be specified in place of RETURNS NULL ON NULL INPUT
- ***Creating a secure function***: Normally users with SECADM authority do not have privileges to create database objects such as triggers or functions. Typically they will examine the data accessed by the function, ensure it is secure, then grant the CREATE_SECURE_OBJECT authority to someone who currently has required privileges to create a secure user-defined function. After the function is created, they will revoke the CREATE_SECURE_OBJECT authority from the function owner.

The SECURED attribute is considered to be an assertion that declares the user has established a change control audit procedure for all changes to the user-defined function. The database manager assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages.

- ***Invoking other user-defined functions in a secure function***: If a secure user-defined function invokes other user-defined functions, the database manager does not validate whether those nested user-defined functions have the SECURED attribute. If those nested functions can access sensitive data, the user with SECADM authority needs to ensure those functions are allowed to access those data and a change control audit procedure has been established for all changes to those functions.
- ***EXTERNAL ACTION functions***: If an EXTERNAL ACTION function is invoked in other than the outermost select list, the results are unpredictable since the number of times the function is invoked will vary depending on the access plan used.

Examples

1. Register an OLE DB table function, which retrieves order information from a Microsoft Access database. The connection string is defined in the external name.

```
CREATE FUNCTION orders ()
  RETURNS TABLE (orderid INTEGER,
                 customerid CHAR(5),
                 employeeid INTEGER,
                 orderdate TIMESTAMP,
                 requireddate TIMESTAMP,
                 shippeddate TIMESTAMP,
                 shipvia INTEGER,
                 freight dec(19,4))
  LANGUAGE OLEDB
  EXTERNAL NAME '!orders!Provider=Microsoft.Jet.OLEDB.3.51;
                       Data Source=c:\sqllib\samples\oledb\nwind.mdb
  !COLLATING_SEQUENCE=Y';
```

2. Register an OLE DB table function, which retrieves customer information from an Oracle database. The connection string is provided through a server definition. The table name is fully qualified in the external name. The local user john is mapped to the remote user dave. Other users will use the guest user ID in the connection string.

```
CREATE SERVER spirit
  WRAPPER OLEDB
  OPTIONS (CONNECTSTRING 'Provider=MSDAORA;Persist Security Info=False;
                          User ID=guest;password=pwd;Locale Identifier=1033;
                          OLE DB Services=CLIENTCURSOR;Data Source=spirit');

CREATE USER MAPPING FOR john
  SERVER spirit
  OPTIONS (REMOTE_AUTHID 'dave', REMOTE_PASSWORD 'mypwd');

CREATE FUNCTION customers ()
  RETURNS TABLE (customer_id INTEGER,
                 name  VARCHAR(20),
                 address VARCHAR(20),
                 city VARCHAR(20),
                 state VARCHAR(5),
                 zip_code INTEGER)
  LANGUAGE OLEDB
  EXTERNAL NAME 'spirit!demo.customer';
```

3. Register an OLE DB table function, which retrieves information about stores from a MS SQL Server 7.0 database. The connection string is provided in the external name. The table function has an input parameter to pass through command text to the OLE DB provider. The rowset name does not need to be specified in the external name. The query example passes in SQL statement text to retrieve the top three stores.

```
CREATE FUNCTION favorites (varchar(600))
  RETURNS TABLE (store_id CHAR (4),
                 name  VARCHAR (41),
                 sales INTEGER)
  SPECIFIC favorites
  LANGUAGE OLEDB
```

```
    EXTERNAL NAME '!!Provider=SQLOLEDB.1;Persist Security Info=False;
                   User ID=sa;Initial Catalog=pubs;Data Source=WALTZ;
                   Locale Identifier=1033;Use Procedure for Prepare=1;
                   Auto Translate=False;Packet Size=4096;Workstation ID=WALTZ;
                   OLE DB Services=CLIENTCURSOR;';

  SELECT *
    FROM TABLE (favorites
               (' select top 3 sales.stor_id as store_id, ' CONCAT
                    ' stores.stor_name as name, ' CONCAT
                    ' sum(sales. qty) as sales ' CONCAT
                ' from sales, stores ' CONCAT
                ' where sales.stor_id = stores.stor_id ' CONCAT
                ' group by sales.stor_id, stores.stor_name ' CONCAT
                ' order by sum(sales.qty) desc ')) as f;
```

CREATE FUNCTION (sourced or template)

The CREATE FUNCTION (Sourced or Template) statement is used to register a function or function template with a server.

This statement can register the following objects:

- A user-defined function, based on another existing scalar or aggregate function, at the current server.
- A function template with an application server that is designated as a federated server. A *function template* is a partial function that contains no executable code. The user creates it for the purpose of mapping it to a data source function. After the mapping is created, the user can specify the function template in queries submitted to the federated server. When such a query is processed, the federated server will invoke the data source function to which the template is mapped, and return values whose data types correspond to those in the RETURNS portion of the template's definition.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

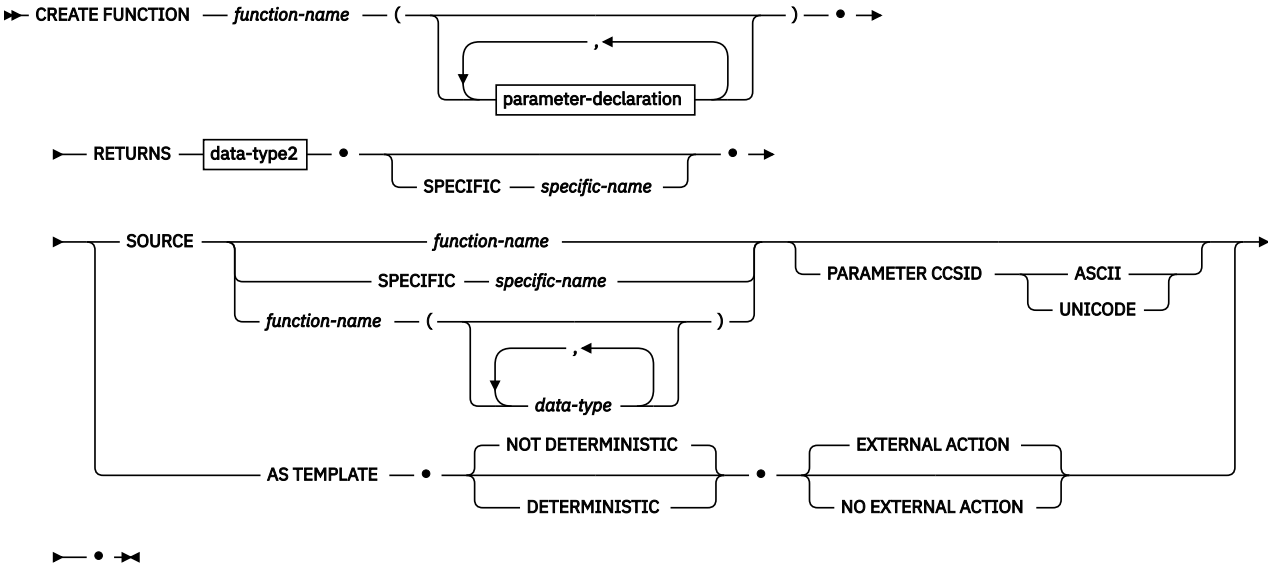
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the function does not exist
- CREATEIN privilege on the schema, if the schema name of the function exists
- SCHEMAADM authority on the schema, if the schema name of the function exists
- DBADM authority

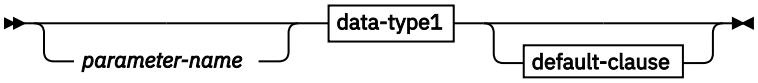
The privileges held by the authorization ID of the statement must also include EXECUTE privilege on the source function or EXECUTEIN privilege on the schema containing the source function if the authorization ID of the statement does not have DATAACCESS authority on the database or DATAACCESS authority on the schema containing the source function and the SOURCE clause is specified.

Group privileges are not considered for any table or view specified in the CREATE FUNCTION statement.

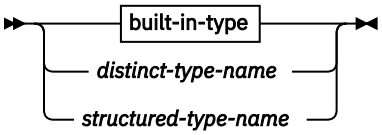
Syntax



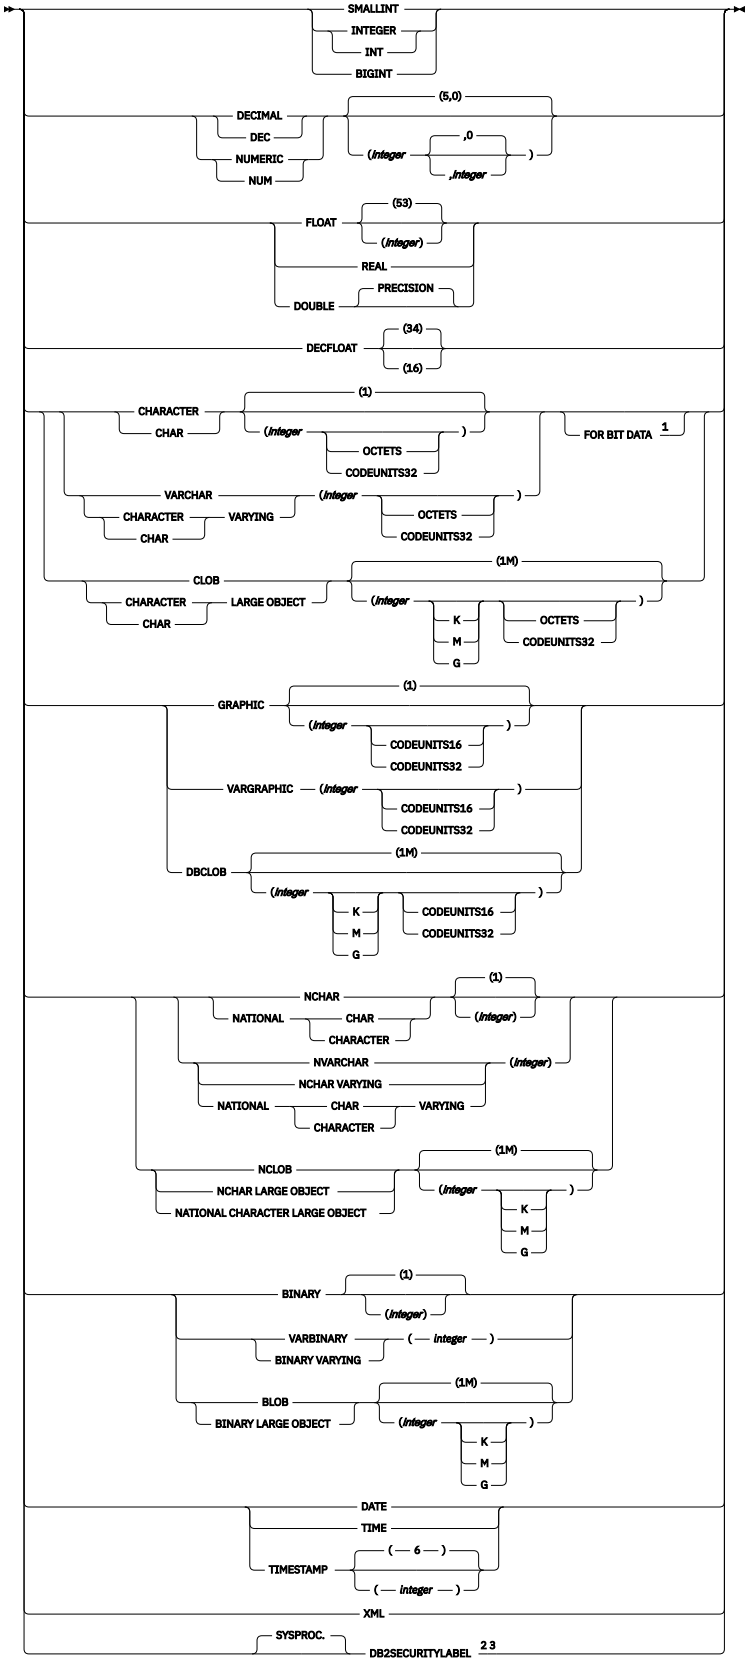
parameter-declaration



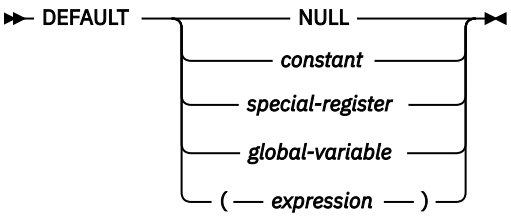
data-type1, data-type2



built-in-type



default-clause



Notes:

[1] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).
[2] DB2SECURITYLABEL is the built-in distinct type that must be used to define the row security label column of a protected table.
[3] For a column of type DB2SECURITYLABEL, NOT NULL WITH DEFAULT is implicit and cannot be explicitly specified (SQLSTATE 42842). The default value for a column of type DB2SECURITYLABEL is the session authorization ID's security label for write access.

Description

function-name
Names the function or function template being defined. It is a qualified or unqualified name that designates a function. The unqualified form of *function-name* is an SQL identifier. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The qualified form is a *schema-name* followed by a period and an SQL identifier.

The name, including the implicit or explicit qualifiers, together with the number of parameters and the data type of each parameter (without regard for any length, precision or scale attributes of the data type) must not identify a function or function template described in the catalog (SQLSTATE 42723). The unqualified name, together with the number and data types of the parameters, while of course unique within its schema, need not be unique across schemas.

If a two-part name is specified, the *schema-name* cannot begin with 'SYS' (SQLSTATE 42939).

A number of names used as keywords in predicates are reserved for system use, and cannot be used as a *function-name* (SQLSTATE 42939). The names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators.

When naming a user-defined function that is sourced on an existing function with the purpose of supporting the same function with a user-defined distinct type, the same name as the sourced function may be used. This allows users to use the same function with a user-defined distinct type without realizing that an additional definition was required. In general, the same name can be used for more than one function if there is some difference in the signature of the functions.

(parameter-declaration,...)
Identifies the number of input parameters of the function or function template, and specifies the data type and optional default value of each parameter. One entry in the list must be specified for each parameter that the function or function template will expect to receive. No more than 90 parameters are allowed (SQLSTATE 54023).

It is possible to register a function that has no parameters. In this case, the parentheses must still be coded, with no intervening data types. For example:

```
CREATE FUNCTION WOOFER() ...
```

No two identically-named functions within a schema are permitted to have exactly the same type for all corresponding parameters. This restriction also applies to a function and function template with the same name within the same schema. Lengths, precisions, and scales are not considered in this type comparison. Therefore, CHAR(8) and CHAR(35) are considered to be the same type, as

are DECIMAL(11,2) and DECIMAL (4,3). A weakly typed distinct type specified for a parameter is considered to be the same data type as the source type of the distinct type. For a Unicode database, CHAR(13) and GRAPHIC(8) are considered to be the same type. There is some further bundling of types that causes them to be treated as the same type for this purpose, such as DECIMAL and NUMERIC. A duplicate signature returns an error (SQLSTATE 42723).

parameter-name
Specifies an optional name for the input parameter. The name cannot be the same as any other *parameter-name* in the parameter list (SQLSTATE 42734).

data-type1
Specifies the data type of the input parameter. The data type can be a built-in data type, a distinct type, or a structured type.

Any valid SQL data type can be used if it is castable to the type of the corresponding parameter of the function identified in the SOURCE clause (for information, see "Casting between data types"). However, this checking does not guarantee that an error will not occur when the function is invoked.

For a more complete description of each built-in data type, see "CREATE TABLE".

- A datetime type parameter is passed as a character data type, and the data is passed in the ISO format.
- Array types cannot be specified (SQLSTATE 42879).
- A reference type specified as REF(*type-name*) cannot be specified (SQLSTATE 42879).

For a user-defined distinct type, the length, precision, or scale attributes for the parameter are those of the source type of the distinct type (those specified on CREATE TYPE). A distinct type parameter is passed as the source type of the distinct type. If the name of the distinct type is unqualified, the database manager resolves the schema name by searching the schemas in the SQL path.

For a user-defined structured type, the appropriate transform functions must exist in the associated transform group.

Because the function is sourced, it is not necessary (but still permitted) to specify length, precision, or scale for the parameterized data types. Empty parentheses can be used instead; for example, CHAR(). A *parameterized data type* is any one of the data types that can be defined with a specific length, scale, or precision. The parameterized data types are the string data types, the decimal data types, and the TIMESTAMP data type.

With a function template, empty parentheses can also be used instead of specifying length, precision, or scale for the parameterized data types. It is recommended to use empty parentheses for the parameterized data types. If you use empty parentheses, the length, precision, or scale is the same as that of the remote function, which is determined when the function template is mapped to a remote function by creating a function mapping. If you omit parentheses altogether, the default length for the data type is used (see "CREATE TABLE").

DEFAULT
Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The special registers that can be specified as the default are that same as those that can be specified for a column default (see *default-clause* in the CREATE TABLE statement). Other special registers can be specified as the default by using an expression.

The expression can be any expression of the type described in "Expressions". If a default value is not specified, the parameter has no default and the corresponding argument cannot be omitted on invocation of the procedure. The maximum size of the *expression* is 64K bytes.

The default expression must not modify SQL data (SQLSTATE 428FL or SQLSTATE 429BL). The expression must be assignment compatible to the parameter data type (SQLSTATE 42821).

A default cannot be specified for a parameter of type ARRAY, ROW, or CURSOR (SQLSTATE 429BB).

RETURNS

This mandatory clause identifies the output of the function or function template.

data-type2

Specifies the data type of the output.

With a sourced scalar function, any valid SQL data type is acceptable, as is a distinct type, provided it is castable from the result type of the source function. An array type cannot be specified as the data type of a parameter (SQLSTATE 42879).

The parameter of a parameterized type need not be specified for parameters of a sourced function. Instead, empty parentheses can be used; for example, VARCHAR().

For additional considerations and rules that apply to the specification of the data type in the RETURNS clause when the function is sourced on another, see the "Rules" section of this statement.

With a function template, empty parentheses are not allowed (SQLSTATE 42611). Length, precision, or scale must be specified for the parameterized data types. It is recommended to specify the same length, precision, or scale as that of the remote function.

built-in-type

See "CREATE TABLE" for the description of built-in data types.

SPECIFIC *specific-name*

Provides a unique name for the instance of the function that is being defined. This specific name can be used when sourcing on this function, dropping the function, or commenting on the function. It can never be used to invoke the function. The unqualified form of *specific-name* is an SQL identifier. The qualified form is a *schema-name* followed by a period and an SQL identifier. The name, including the implicit or explicit qualifier, must not identify another function instance that exists at the application server; otherwise an error (SQLSTATE 42710) is returned.

The *specific-name* may be the same as an existing *function-name*.

If no qualifier is specified, the qualifier that was used for *function-name* is used. If a qualifier is specified, it must be the same as the explicit or implicit qualifier of *function-name* or an error (SQLSTATE 42882) is returned.

If *specific-name* is not specified, a unique name is generated by the database manager. The unique name is SQL followed by a character timestamp, SQLyymmddhhmmssxxx.

SOURCE

Specifies that the new function is being defined as a sourced function. A *sourced function* is implemented by another function (the *source function*). The function must be a scalar or aggregate function that exists at the current server, and it must be one of the following types of functions:

- A function that was defined with a CREATE FUNCTION statement
- A cast function that was generated by a CREATE TYPE statement
- A built-in function

If the source function is not a built-in function, the particular function can be identified by its name, function signature, or specific name.

If the source function is a built-in function, the SOURCE clause must include a function signature for the built-in function. The source function must not be any of the following built-in functions (If a particular syntax is indicated, only the indicated form cannot be specified.):

- CARDINALITY
- CHAR when more than one parameter is specified and the first parameter is a datetime data type
- CHARACTER_LENGTH with the string units parameter
- COALESCE
- CONTAINS
- CURSOR_ROWCOUNT

- DATAPARTITIONNUM
- DBPARTITIONNUM
- DEREF
- EXTRACT
- GRAPHIC when more than one parameter is specified and the first parameter is a datetime data type
- GREATEST
- HASHEDVALUE
- INSERT with the string units parameter
- INSTR with the string units parameter
- LCASE with the string units parameter
- LEAST
- LEFT with the string units parameter
- LENGTH with the string units parameter
- LOCATE with the string units parameter
- LOCATE_IN_STRING with the string units parameter
- LOWER with the string units parameter
- MAX
- MAX_CARDINALITY
- MIN
- NODENUMBER
- NULLIF
- NVL
- OVERLAY with the string units parameter
- PARAMETER
- POSITION with the string units parameter
- RAISE_ERROR
- REC2XML
- RID
- RID_BIT
- RIGHT with the string units parameter
- SCORE
- STRIP
- SUBSTRING with the string units parameter
- TRIM
- TRIM_ARRAY
- TYPE_ID
- TYPE_NAME
- TYPE_SCHEMA
- UCASE with the string units parameter
- UPPER with the string units parameter
- VALUE
- VARCHAR when more than one parameter is specified and the first parameter is a datetime data type

- VARGRAPHIC when more than one parameter is specified and the first parameter is a datetime data type
- XMLATTRIBUTES
- XMLCOMMENT
- XMLCONCAT
- XMLDOCUMENT
- XMLELEMENT
- XMLFOREST
- XMLNAMESPACES
- XMLPARSE
- XMLPI
- XMLQUERY
- XMLROW
- XMLSERIALIZE
- XMLTEXT
- XMLVALIDATE
- XMLXSROBJECTID
- XSLTRANSFORM

function-name

Identifies the function to use as the source. Valid only if this name is unique within the schema and the authorization ID has DATAACCESS authority on the schema, EXECUTEIN privilege on the schema, or EXECUTE privilege on the function. This syntax variant is not valid for a source function that is a built-in function.

If you provide an unqualified name, the SQL path will be used to locate the function. This is the value of the CURRENT PATH special register. The first schema in the SQL path that has this function name and whose authorization ID has DATAACCESS authority on the schema, EXECUTEIN privilege on the schema, or EXECUTE privilege on the function is selected.

The database will return error SQLSTATE 42704 for each of the following cases:

- no function by this name exists in the named schema
- the name is not valid
- there is no function with this name in the SQL path

The database will return error SQLSTATE 42725 if there is more than one authorized instance of the function in the named or located schema.

The database will return error SQLSTATE 42501 if a function with this name exists but the authorization ID of the statement does not have EXECUTE privilege, or EXECUTEIN privilege, or DATAACCESS authority on the schema of the function.

SPECIFIC *specific-name*

Identifies the particular user-defined function that is to be used as the source, by the *specific-name* either specified or defaulted to at function creation time. This syntax variant is not valid for a source function that is a built-in function.

If an unqualified name is provided, the current SQL path is used to locate the function. The first schema in the SQL path that has a function with this specific name for which the authorization ID of the statement has EXECUTE privilege or EXECUTEIN privilege or DATAACCESS authority on the schema is selected.

If no function by this *specific-name* exists in the named schema or if the name is not qualified and there is no function with this *specific-name* in the SQL path, an error (SQLSTATE 42704) is returned. If a function by this *specific-name* exists, and the authorization ID of the statement does

not have EXECUTE privilege on this function or EXECUTEIN privilege or DATAACCESS authority on the schema, an error (SQLSTATE 42501) is returned.

function-name (data-type,...)
Provides the function signature, which uniquely identifies the source function. This is the only valid syntax variant for a source function that is a built-in function.

The rules for function resolution are applied to select one function from the functions with the same function name, given the data types specified in the SOURCE clause. However, the data type of each parameter in the function selected must have the exact same type as the corresponding data type specified in the source function.

function-name
Gives the function name of the source function. If an unqualified name is provided, then the schemas of the user's SQL path are considered.

data-type
Must match the data type that was specified on the CREATE FUNCTION statement in the corresponding position (comma separated).

It is not necessary to specify the length, precision or scale for the parameterized data types. Instead an empty set of parentheses may be coded to indicate that these attributes are to be ignored when looking for a data type match. For example, DECIMAL() will match a parameter whose data type was defined as DECIMAL(7,2)).

FLOAT() cannot be used (SQLSTATE 42601), because the parameter value indicates different data types (REAL or DOUBLE).

However, if length, precision, or scale is coded, the value must exactly match that specified in the CREATE FUNCTION statement. This can be useful in assuring that the intended function will be used. Note also that synonyms for data types will be considered a match (for example DEC and NUMERIC will match).

A type of FLOAT(n) does not need to match the defined value for n, because 0<n<25 means REAL and 24<n<54 means DOUBLE. Matching occurs based on whether the type is REAL or DOUBLE.

If no function with the specified signature exists in the named or implied schema, an error (SQLSTATE 42883) is returned.

PARAMETER CCSID
Specifies the encoding scheme to use for all string data passed into and out of the function. If the PARAMETER CCSID clause is not specified, the default is PARAMETER CCSID UNICODE for Unicode databases, and PARAMETER CCSID ASCII for all other databases.

ASCII
Specifies that string data is encoded in the database code page. If the database is a Unicode database, PARAMETER CCSID ASCII cannot be specified (SQLSTATE 56031). When the function is invoked, the application code page for the function is the database code page.

UNICODE
Specifies that string data is encoded in Unicode. If the database is a Unicode database, character data is in UTF-8, and graphic data is in UCS-2. If the database is not a Unicode database, character data is in UTF-8. In either case, when the function is invoked, the application code page for the function is 1208.

The PARAMETER CCSID clause must specify the same encoding scheme as the source function (SQLSTATE 53090).

AS TEMPLATE
Indicates that this statement will be used to create a function template, not a function with executable code.

NOT DETERMINISTIC or DETERMINISTIC
Specifies whether the function returns the same results for identical input arguments. The default is NOT DETERMINISTIC.

NOT DETERMINISTIC
Specifies that the function might not return the same result each time that the function is invoked with the same input arguments. The function depends on some state values that affect the results. The database manager uses this information during optimization of SQL statements. An example of a function that is not deterministic is one that generates random numbers.

A function that is not deterministic might receive incorrect results if it is executed by parallel tasks.

DETERMINISTIC
Specifies that the function always returns the same result each time that the function is invoked with the same input arguments. The database manager uses this information during optimization of SQL statements. An example of a function that is deterministic is one that calculates the square root of the input argument.

EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the function takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a file. The default is EXTERNAL ACTION.

EXTERNAL ACTION
Specifies that the function takes an action that changes the state of an object that the database manager does not manage. EXTERNAL ACTION must be implicitly or explicitly specified if the SQL routine body invokes a function that is defined with EXTERNAL ACTION (SQLSTATE 428C2).

A function with external actions might return incorrect results if the function is executed by parallel tasks. For example, if the function sends a note for each initial call to it, one note is sent for each parallel task instead of once for the function.

NO EXTERNAL ACTION
Specifies that the function does not take any action that changes the state of an object that the database manager does not manage. The database manager uses this information during optimization of SQL statements.

Rules

- For convenience, in this section the function being created will be called CF and the function identified in the SOURCE clause will be called SF, no matter which of the three allowable syntaxes was used to identify SF.
  - The unqualified name of CF and the unqualified name of SF can be different.
  - A function named as the source of another function can, itself, use another function as its source. Extreme care should be exercised when exploiting this facility, because it could be very difficult to debug an application if an indirectly invoked function returns an error.
  - The following clauses are invalid if specified in conjunction with the SOURCE clause (because CF will inherit these attributes from SF):
    - CAST FROM ...,
    - EXTERNAL ...,
    - LANGUAGE ...,
    - PARAMETER STYLE ...,
    - DETERMINISTIC / NOT DETERMINISTIC,
    - FENCED / NOT FENCED,
    - RETURNS NULL ON NULL INPUT / CALLED ON NULL INPUT
    - EXTERNAL ACTION / NO EXTERNAL ACTION
    - NO SQL / CONTAINS SQL / READS SQL DATA

- SCRATCHPAD / NO SCRATCHPAD
- FINAL CALL / NO FINAL CALL
- RETURNS TABLE (...)
- CARDINALITY ...
- ALLOW PARALLEL / DISALLOW PARALLEL
- DBINFO / NO DBINFO
- THREADSAFE / NOT THREADSAFE
- INHERIT SPECIAL REGISTERS

An error (SQLSTATE 42613) will result from violation of these rules.

- The number of input parameters in CF must be the same as those in SF; otherwise an error (SQLSTATE 42624) is returned.
- It is not necessary for CF to specify length, precision, or scale for a parameterized data type in the case of:
  - The function's input parameters,
  - Its RETURNS parameter

  Instead, empty parentheses may be specified as part of the data type (for example: VARCHAR()) in order to indicate that the length/precision/scale will be the same as those of the source function, or determined by the casting.

  However, if length, precision, or scale is specified then the value in CF is checked against the corresponding value in SF as outlined in the remaining rules for input parameters and returns value.
- The specification of the input parameters of CF are checked against those of SF. The data type of each parameter of CF must either be the same as or be *castable* to the data type of the corresponding parameter of SF. If any parameter is not the same type or castable, an error (SQLSTATE 42879) is returned.

  Note that this rule provides no guarantee against an error occurring when CF is used. An argument that matches the data type and length or precision attributes of a CF parameter may not be assignable if the corresponding SF parameter has a shorter length or less precision. In general, parameters of CF should not have length or precision attributes that are greater than the attributes of the corresponding SF parameters.
- The specifications for the RETURNS data type of CF are checked against that of SF. The final RETURNS data type of SF, after any casting, must either be the same as or castable to the RETURNS data type of CF. Otherwise an error (SQLSTATE 42866) is returned.

  Note that this rule provides no guarantee against an error occurring when CF is used. A result value that matches the data type and length or precision attributes of the SF RETURNS data type may not be assignable if the CF RETURNS data type has a shorter length or less precision. Caution should be used when choosing to specify the RETURNS data type of CF as having length or precision attributes that are less than the attributes of the SF RETURNS data type.
- Revalidation of CF that does not have a parameter with a default expression is not supported (SQLSTATE 42997).

Notes

- Determining whether one data type is castable to another data type does not consider length or precision and scale for parameterized data types such as CHAR and DECIMAL. Therefore, errors may occur when using a function as a result of attempting to cast a value of the source data type to a value of the target data type. For example, VARCHAR is castable to DATE but if the source type is actually defined as VARCHAR(5), an error will occur when using the function.
- When choosing the data types for the parameters of a user-defined function, consider the rules for promotion that will affect its input values (see "Promotion of data types"). For example, a constant which may be used as an input value could have a built-in data type different from the one expected

and, more significantly, may not be promoted to the data type expected. Based on the rules for promotion, it is generally recommended to use the following data types for parameters:

  - INTEGER instead of SMALLINT
  - DOUBLE instead of REAL
  - VARCHAR instead of CHAR
  - VARGRAPHIC instead of GRAPHIC
- Creating a function with a schema name that does not already exist will result in the implicit creation of that schema provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- For a federated server to recognize a data source function, the function must map to a counterpart at the federated database. If the database contains no counterpart, the user must create the counterpart and then the mapping.

  The counterpart can be a function (scalar or source) or a function template. If the user creates a function and the required mapping, then, each time a query that specifies the function is processed, the database manager (1) compares strategies for invoking it with strategies for invoking the data source function, and (2) invokes the function that is expected to require less overhead.

  If the user creates a function template and the mapping, then each time a query that specifies the template is processed, the database manager invokes the data source function that it maps to, provided that an access plan for invoking this function exists.
- ***Privileges***: The definer of a function always receives the EXECUTE privilege on the function, as well as the right to drop the function. The definer of the function is also given the WITH GRANT OPTION if any of the following conditions apply:
  - The source function is a built-in function.
  - The definer of the function has EXECUTE WITH GRANT OPTION on the source function.
  - The definer of the function has EXECUTEIN WITH GRANT OPTION on the schema containing the source function.
  - The function is a template.
- ***EXTERNAL ACTION functions***: If an EXTERNAL ACTION function is invoked in other than the outermost select list, the results are unpredictable since the number of times the function is invoked will vary depending on the access plan used.
- ***Setting of the default value***: Parameters of a function that are defined with a default value are set to their default value when the functions is invoked, but only if a value is not supplied for the corresponding argument, or is specified as DEFAULT, when the function is invoked.
- **Create function mapping to table or row functions:** A create function mapping to remote functions that returns a table or a row is not supported in a federated database.
- **Inheriting SECURED or NOT SECURED attributes from the source function:** The sourced user-defined function inherits the SECURED or NOT SECURED attribute from the source function in which only the topmost user-defined function is considered. If the topmost user-defined function is secure, any nested user-defined functions are considered secure. The database manager does not validate whether those nested user-defined functions are secure. If those nested functions can access sensitive data, the user with SECADM authority needs to ensure those functions are allowed to access those data and that a change control audit procedure has been established for all changes to those functions.

Examples

- *Example 1:* Some time after the creation of Pellow's original CENTER external scalar function, another user wants to create a function based on it, except this function is intended to accept only integer arguments.

```
CREATE FUNCTION MYCENTER (INTEGER, INTEGER)
  RETURNS FLOAT
  SOURCE PELLOW.CENTER (INTEGER, FLOAT)
```

- *Example 2:* A distinct type, HATSIZE, has been created based on the built-in INTEGER data type. It would be useful to have an AVG function to compute the average hat size of different departments. This is easily done as follows:

```
CREATE FUNCTION AVG (HATSIZE) RETURNS HATSIZE
  SOURCE SYSIBM.AVG (INTEGER)
```

  The creation of the distinct type has generated the required cast function, allowing the cast from HATSIZE to INTEGER for the argument and from INTEGER to HATSIZE for the result of the function.
- *Example 3:* In a federated system, a user wants to invoke an Oracle UDF that returns table statistics in the form of values with double-precision floating points. The federated server can recognize this function only if there is a mapping between the function and a federated database counterpart. But no such counterpart exists. The user decides to provide one in the form of a function template, and to assign this template to a schema called NOVA. The user uses the following code to register the template with the federated server.

```
CREATE FUNCTION NOVA.STATS (DOUBLE, DOUBLE)
  RETURNS DOUBLE
  AS TEMPLATE DETERMINISTIC NO EXTERNAL ACTION
```

- *Example 4:* In a federated system, a user wants to invoke an Oracle UDF that returns the dollar amounts that employees of a particular organization earn as bonuses. The federated server can recognize this function only if there is a mapping between the function and a federated database counterpart. No such counterpart exists; thus, the user creates one in the form of a function template. The user uses the following code to register this template with the federated server.

```
CREATE FUNCTION BONUS ()
  RETURNS DECIMAL (8,2)
  AS TEMPLATE DETERMINISTIC NO EXTERNAL ACTION
```

CREATE FUNCTION (SQL scalar, table, or row)

The CREATE FUNCTION (SQL scalar, table, or row) statement is used to define a user-defined SQL scalar, table, or row function.

A *scalar function* returns a single value each time it is invoked, and is generally valid wherever an SQL expression is valid. A *table function* can be used in a FROM clause and returns a table. A *row function* can be used as a transform function and returns a row.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the function does not exist
- CREATEIN privilege on the schema, if the schema name of the function refers to an existing schema
- SCHEMAADM authority on the schema, if the schema name of the function exists
- DBADM authority

and at least one of the following authorities on each table, view, or nickname identified in any fullselect:

- CONTROL privilege on that table, view, or nickname
- SELECT privilege on that table, view, or nickname

- SELECTIN privilege on the schema containing the table, view, or nickname
- DATAACCESS authority on the schema containing the table, view, or nickname
- DATAACCESS authority on the database

Group privileges other than PUBLIC are not considered for any table or view specified in the CREATE FUNCTION statement.

Authorization requirements of the data source for the table or view referenced by the nickname are applied when the function is invoked. The authorization ID of the connection can be mapped to a different remote authorization ID.

The privileges held by the authorization ID of the statement must also include all of the privileges necessary to invoke the SQL statements that are specified in the function body.

To replace an existing function, the authorization ID of the statement must be the owner of the existing function (SQLSTATE 42501).

If the SECURED option is specified, the authorization ID of the statement must include SECADM or CREATE_SECURE_OBJECT authority (SQLSTATE 42501).

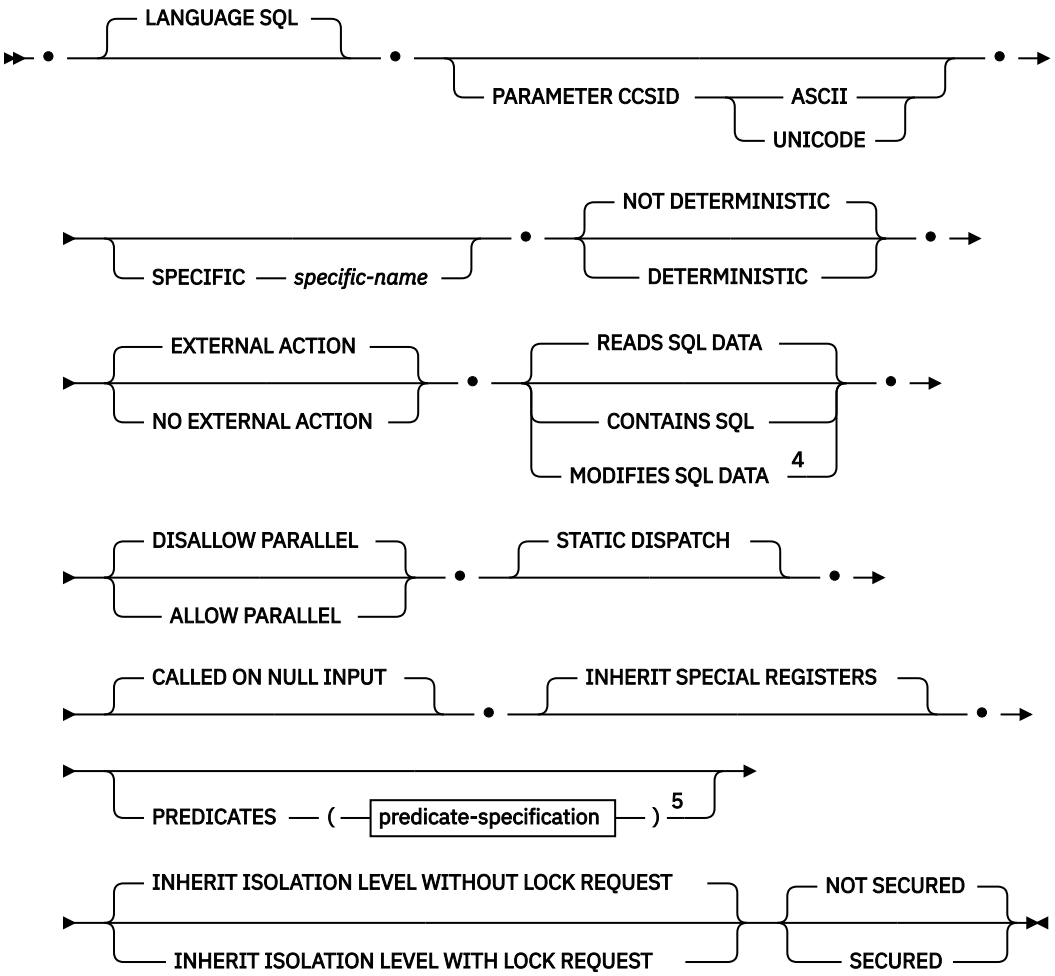
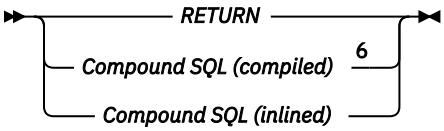
option-list



SQL-function-body



Notes:

[1] OUT and INOUT are valid only if RETURNS specifies a scalar result and the SQL-function-body is a compound SQL (compiled) statement.

[2] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

[3] DB2SECURITYLABEL is the built-in distinct type that must be used to define the row security label column of a protected table.

[4] Valid only for compiled scalar function definition and an inlined table function definition. A compiled scalar function defined as MODIFIES SQL DATA can only be used as the only element on the right side of an assignment statement that is within a compound SQL (compiled) statement.

[5] Valid only if RETURNS specifies a scalar result (*data-type2*)

[6] The following apply to the specification of a compound SQL (compiled) statement: a) Must be used if the parameter data types or returned data types include a row type, array type, or cursor type; b) Must be used if the RETURNS TABLE clause specifies any syntax other than a column-list; c) Not supported if RETURNS ROW is specified; d) Not supported when defining a table function in a partitioned database environment.

Description

OR REPLACE

Specifies to replace the definition for the function if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that privileges that were granted on the function are not affected. This option can be specified only by the owner of the object. This option is ignored if a definition for the function does not exist at the current server. To replace an existing function, the specific name and function name of the new definition must be the same as the specific name and function name of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new function is created.

If the function is referenced in the definition of a row permission or a column mask, the function cannot be replaced (SQLSTATE 42893).

function-name

Names the function being defined. It is a qualified or unqualified name that designates a function. The unqualified form of *function-name* is an SQL identifier. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The qualified form is a *schema-name* followed by a period and an SQL identifier.

The name, including the implicit or explicit qualifiers, together with the number of parameters and the data type of each parameter (without regard for any length, precision or scale attributes of the data type) must not identify a function described in the catalog (SQLSTATE 42723). The unqualified name, together with the number and data types of the parameters, while of course unique within its schema, need not be unique across schemas.

If a two-part name is specified, the *schema-name* cannot begin with 'SYS' (SQLSTATE 42939).

A number of names used as keywords in predicates are reserved for system use, and cannot be used as a *function-name* (SQLSTATE 42939). The names are SOME, ANY, ALL, NOT, AND, OR, BETWEEN, NULL, LIKE, EXISTS, IN, UNIQUE, OVERLAPS, SIMILAR, MATCH, and the comparison operators.

The same name can be used for more than one function if there is some difference in the signature of the functions. Although there is no prohibition against it, an external user-defined table function should not be given the same name as a built-in function.

(*parameter-declaration*, ...)

Identifies the number of input parameters of the function, and specifies the mode, name, data type, and optional default value of each parameter. One entry in the list must be specified for each parameter that the function will expect to receive. No more than 90 parameters are allowed (SQLSTATE 54023).

It is possible to register a function that has no parameters. In this case, the parentheses must still be coded, with no intervening data types. For example:

```
CREATE FUNCTION WOOFER() ...
```

No two identically-named functions within a schema are permitted to have exactly the same type for all corresponding parameters. Lengths, precisions, and scales are not considered in this type comparison. Therefore, CHAR(8) and CHAR(35) are considered to be the same type, as are DECIMAL(11,2) and DECIMAL (4,3), as well as DECFLOAT(16) and DECFLOAT(34). A weakly typed distinct type specified for a parameter is considered to be the same data type as the source type of the distinct type. For a Unicode database, CHAR(13) and GRAPHIC(8) are considered to be the same type. There is some further bundling of types that causes them to be treated as the same type for this purpose, such as DECIMAL and NUMERIC. A duplicate signature returns an error (SQLSTATE 42723).

If the data type for a parameter is a Boolean data type, array type, cursor type, or row type, the SQL function body can only reference the parameter within a compound SQL (compiled) statement (SQLSTATE 428H2).

IN | OUT | INOUT
Specifies the mode of the parameter. If an error is returned by the function, OUT parameters are undefined and INOUT parameters are unchanged. The default is IN.

IN
Identifies the parameter as an input parameter to the function. Any changes made to the parameter within the function are not available to the invoking context when control is returned.

OUT
Identifies the parameter as an output parameter for the function.

The function must be a scalar function that is defined with a compound SQL (compiled) statement (SQLSTATE 42613).

The function can be referenced only on the right side of an assignment statement that is in a compound SQL (compiled) statement, and the function reference cannot be part of an expression (SQLSTATE 42887).

INOUT
Identifies the parameter as both an input and output parameter for the function.

The function must be a scalar function that is defined with a compound SQL (compiled) statement (SQLSTATE 42613).

The function can be referenced only on the right side of an assignment statement that is in a compound SQL (compiled) statement, and the function reference cannot be part of an expression (SQLSTATE 42887).

parameter-name
Specifies a name for the parameter. The name cannot be the same as any other *parameter-name* in the parameter list (SQLSTATE 42734).

data-type1
Specifies the data type of the parameter.

built-in-type
Specifies a built-in data type. For a more complete description of each built-in data type except BOOLEAN and CURSOR, which cannot be specified for a table, see "CREATE TABLE".

BOOLEAN
For a Boolean.

CURSOR
For a reference to an underlying cursor.

anchored-data-type
Identifies another object used to define the parameter data type. The data type of the anchor object can be any of the data types explicitly allowed as *data-type1*. The data type of the anchor object has the same limitations that apply to specifying the data type directly, or in the case of a row, to creating a row type.

ANCHOR DATA TYPE TO
Indicates an anchored data type is used to specify the data type.

variable-name1
Identifies a global variable. The data type of the global variable is used as the data type for *parameter-name*.

table-name.column-name
Identifies a column name of an existing table or view. The data type of the column is used as the data type for *parameter-name*.

ROW OF *table-name* or *view-name*
Specifies a row of fields with names and data types that are based on the column names and column data types of the table identified by *table-name* or the view identified by *view-name*. The data type of *parameter-name* is an unnamed row type.

ROW OF *cursor-variable-name*
Specifies a row of fields with names and data types that are based on the field names and field data types of the cursor variable identified by *cursor-variable-name*. The specified cursor variable must be one of the following elements (SQLSTATE 428HS):

- A global variable with a strongly typed cursor data type
- A global variable with a weakly typed cursor data type that was created or declared with a CONSTANT clause specifying a *select-statement* where all the result columns are named.

If the cursor type of the cursor variable is not strongly typed using a named row type, the data type of *parameter-name* is an unnamed row type.

array-type-name
Specifies the name of a user-defined array type. If *array-type-name* is specified without a schema name, the array type is resolved by searching the schemas in the SQL path.

cursor-type-name
Specifies the name of a cursor type. If *cursor-type-name* is specified without a schema name, the cursor type is resolved by searching the schemas in the SQL path.

distinct-type-name
Specifies the name of a distinct type. The length, precision, and scale of the parameter are, respectively, the length, precision, and scale of the source type of the distinct type. A distinct type parameter is passed as the source type of the distinct type. If *distinct-type-name* is specified without a schema name, the distinct type is resolved by searching the schemas in the SQL path.

REF (*type-name*)
Specifies a reference type without a scope. The specified *type-name* must identify a user-defined structured type (SQLSTATE 428DP). The system does not attempt to infer the scope of the parameter or result. Inside the body of the function, a reference type can be used in a dereference operation only by first casting it to have a scope. Similarly, a reference returned by an SQL function can be used in a dereference operation only by first casting it to have a scope. If a type name is specified without a schema name, the *type-name* is resolved by searching the schemas in the SQL path.

row-type-name
Specifies the name of a user-defined row type. The fields of the parameter are the fields of the row type. If *row-type-name* is specified without a schema name, the row type is resolved by searching the schemas in the SQL path.

structured-type-name
Specifies the name of a user-defined structured type. If *structured-type-name* is specified without a schema name, the structured type is resolved by searching the schemas in the SQL path.

DEFAULT
Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression, or the keyword NULL. The special registers that can be specified as the default are that same as those that can be specified for a column default (see *default-clause* in the CREATE TABLE statement). Other special registers can be specified as the default by using an expression.

The expression can be any expression of the type described in "Expressions". If a default value is not specified, the parameter has no default and the corresponding argument cannot be omitted on invocation of the procedure. The maximum size of the *expression* is 64K bytes.

The default expression must not modify SQL data (SQLSTATE 428FL or SQLSTATE 429BL). The expression must be assignment compatible to the parameter data type (SQLSTATE 42821).

A default cannot be specified in the following situations:

- For INOUT or OUT parameters (SQLSTATE 42601)

- For a parameter of type ARRAY, ROW, or CURSOR (SQLSTATE 429BB)
- For a parameter to a function definition that also specified RETURNS ROW or a PREDICATES clause (SQLSTATE 42613)

RETURNS

This mandatory clause identifies the type of output of the function.

If the data type of the output of the function is a Boolean data type, array type, cursor type, or row type, the SQL function body must be a compound SQL (compiled) statement (SQLSTATE 428H2).

data-type2

Specifies the data type of the output.

In this statement, exactly the same considerations apply as for the parameters of SQL functions described previously in *data-type1* for function parameters.

ROW

Specifies that the output of the function is a single row. If the function returns more than one row, an error is returned (SQLSTATE 21505).

This form of a row function can be used only as a transform function for a structured type (having one structured type as its parameter and returning only built-in data types).

column-list

The list of column names and data types returned for a ROW function. The *column-list* must include at least two columns (SQLSTATE 428F0).

column-name

Specifies the name of this column. The name cannot be qualified and the same name cannot be used for more than one column in the list.

data-type3

Specifies the data type of the column, and can be any data type supported by a parameter of the SQL function.

The same considerations apply as for the parameters of SQL functions described previously in *data-type1* for function parameters. However, *data-type3* does not support *anchored-data-type*, *array-type-name*, *cursor-type-name*, and *row-type-name*.

TABLE

Specifies that the output of the function is a table.

column-list

The list of column names and data types returned for a TABLE function

column-name

Specifies the name of this column. The name cannot be qualified and the same name cannot be used for more than one column in the list.

data-type3

Specifies the data type of the column, and can be any data type supported by a parameter of the SQL function.

The same considerations apply as for the parameters of SQL functions described previously in *data-type1* for function parameters. However, *data-type3* does not support *anchored-data-type*, *array-type-name*, *cursor-type-name*, and *row-type-name*.

row-type-name

Specifies a row type from which the fields are used to derive the column list. The field names of the row type are used as the column names.

anchored-row-data-type

Identifies row information from another object to use as the columns of the returned table.

ANCHOR DATA TYPE TO

Indicates an anchored data type is used to specify the data type.

variable-name
Identifies a global variable. The data type of the referenced variable must be a row type.

ROW OF *table-name* or *view-name*
Specifies a row of fields with names and data types that are based on the column names and column data types of the table identified by *table-name* or the view identified by *view-name*. The data types of the anchor object columns have the same limitations that apply to *data-type3*.

ROW OF *cursor-variable-name*
Specifies a row of fields with names and data types that are based on the field names and field data types of the cursor variable identified by *cursor-variable-name*. The specified cursor variable must be one of the following objects (SQLSTATE 428HS):

- A global variable with a strongly typed cursor data type.
- A global variable with a weakly typed cursor data type that was created or declared with a CONSTANT clause specifying a select-statement where all the result columns are named.

ELEMENT OF *array-type-name*
Specifies an array type from which the element data type is used to derive the column list. If *array-type-name* identifies an array type with elements that are a row type, the field names of the row type are used as the column names. If the *array-type-name* identifies an array type with elements that are not row types, the single result column name is COLUMN_VALUE.

built-in-type
See "CREATE TABLE" for the description of built-in data types.

SPECIFIC *specific-name*
Provides a unique name for the instance of the function that is being defined. This specific name can be used when sourcing on this function, dropping the function, or commenting on the function. It can never be used to invoke the function. The unqualified form of *specific-name* is an SQL identifier. The qualified form is a *schema-name* followed by a period and an SQL identifier. The name, including the implicit or explicit qualifier, must not identify another function instance that exists at the application server; otherwise an error is raised (SQLSTATE 42710).

The *specific-name* may be the same as an existing *function-name*.

If no qualifier is specified, the qualifier that was used for *function-name* is used. If a qualifier is specified, it must be the same as the explicit or implicit qualifier of *function-name* or an error is raised (SQLSTATE 42882).

If *specific-name* is not specified, a unique name is generated by the database manager. The unique name is SQL followed by a character timestamp, SQLyymmddhhmmssxxx.

LANGUAGE SQL
Specifies that the function is written using SQL.

PARAMETER CCSID
Specifies the encoding scheme to use for all string data passed into and out of the function. If the PARAMETER CCSID clause is not specified, the default is PARAMETER CCSID UNICODE for Unicode databases, and PARAMETER CCSID ASCII for all other databases.

ASCII
Specifies that string data is encoded in the database code page. If the database is a Unicode database, PARAMETER CCSID ASCII cannot be specified (SQLSTATE 56031).

UNICODE
Specifies that character data is in UTF-8, and that graphic data is in UCS-2. If the database is not a Unicode database, PARAMETER CCSID UNICODE cannot be specified (SQLSTATE 56031).

DETERMINISTIC or NOT DETERMINISTIC
This optional clause specifies whether the function always returns the same results for given argument values (DETERMINISTIC) or whether the function depends on some state values that affect the results (NOT DETERMINISTIC). That is, a DETERMINISTIC function must always return

the same table from successive invocations with identical inputs. Optimizations taking advantage of the fact that identical inputs always produce the same results are prevented by specifying NOT DETERMINISTIC.

EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the function takes an action that changes the state of an object that the database manager does not manage. An example of an external action is sending a message or writing a record to a file. The default is EXTERNAL ACTION.

EXTERNAL ACTION
Specifies that the function takes an action that changes the state of an object that the database manager does not manage.

NO EXTERNAL ACTION
Specifies that the function does not take any action that changes the state of an object that the database manager does not manage. The database manager uses this information during optimization of SQL statements.

READS SQL DATA, CONTAINS SQL, or MODIFIES SQL DATA
Specifies the classification of SQL statements that the function can run. The database manager verifies that the SQL statements that the function issues are consistent with this specification.

For the classification of each statement, see "SQL statements that can be executed in routines and triggers" in Developing User-defined Routines (SQL and External).

READS SQL DATA
Specifies that the function can run statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL. The function cannot run SQL statements that modify data (SQLSTATE 42985). This is the default.

CONTAINS SQL
Specifies that the function can run only SQL statements with a data access classification of **CONTAINS SQL**. The function cannot run any SQL statements that read or modify data (SQLSTATE 42985).

MODIFIES SQL DATA
Specifies that the function can run any SQL statement except those statements that are not supported in any function.

ALLOW PARALLEL or DISALLOW PARALLEL
This clause specifies whether a UDF can be parallelized, that is, whether a single invocation of the UDF can cause several instances of the UDF (usually one instance per partition) to run in parallel. Parallelization usually improves overall performance, but is allowed only when all the following conditions are met:

- The **CONTAINS SQL** clause is specified.
- All invocations of the UDF are completely independent of each other.

DISALLOW PARALLEL is the default.

STATIC DISPATCH
This optional clause indicates that at function resolution time, a function is chosen based on the static types (declared types) of the parameters of the function.

CALLED ON NULL INPUT
This clause indicates that the function is called regardless of whether any of its arguments are null. It can return a null value or a non-null value. Responsibility for testing null argument values lies with the user-defined function.

The phrase NULL CALL may be used in place of CALLED ON NULL INPUT.

INHERIT SPECIAL REGISTERS
This optional clause indicates that updatable special registers in the function will inherit their initial values from the environment of the invoking statement. For a function that is invoked in the select-statement of a cursor, the initial values are inherited from the environment when the cursor is opened.

For a routine that is invoked in a nested object (for example, a trigger or a view), the initial values are inherited from the runtime environment (not the object definition).

No changes to the special registers are passed back to the caller of the function.

Some special registers, such as the datetime special registers, reflect a property of the statement currently executing, and are therefore never inherited from the caller.

PREDICATES

For predicates using this function, this clause identifies those that can exploit the index extensions, and can use the optional SELECTIVITY clause for the predicate's search condition. If the PREDICATES clause is specified, the function must be defined as DETERMINISTIC with NO EXTERNAL ACTION (SQLSTATE 42613). If the PREDICATES clause is specified, and the database is not a Unicode database, PARAMETER CCSID UNICODE must not be specified (SQLSTATE 42613). PREDICATES cannot be specified if SQL-function-body is a compound SQL (compiled) statement (SQLSTATE 42613).

predicate-specification

For details on predicate specification, see "CREATE FUNCTION (External Scalar)".

INHERIT ISOLATION LEVEL WITHOUT LOCK REQUEST or INHERIT ISOLATION LEVEL WITH LOCK REQUEST

Specifies whether or not a lock request can be associated with the isolation-clause of the statement when the function inherits the isolation level of the statement that invokes the function. The default is INHERIT ISOLATION LEVEL WITHOUT LOCK REQUEST.

INHERIT ISOLATION LEVEL WITHOUT LOCK REQUEST

Specifies that, as the function inherits the isolation level of the invoking statement, it cannot be invoked in the context of an SQL statement which includes a lock-request-clause as part of a specified isolation-clause (SQLSTATE 42601).

INHERIT ISOLATION LEVEL WITH LOCK REQUEST

Specifies that, as the function inherits the isolation level of the invoking statement, it also inherits the specified lock-request-clause.

SQL-function-body

Specifies the body of the function. Parameter names can be referenced in the SQL-function-body. Parameter names may be qualified with the function name to avoid ambiguous references.

For RETURN statement, see: RETURN statement.

For *Compound SQL (compiled)*, see: Compound SQL (compiled) statement.

For *Compound SQL (inlined)*, see: Compound SQL (inlined) statement.

NOT SECURED or SECURED

Specifies whether the function is considered secure for row and column access control. The default is NOT SECURED.

NOT SECURED

Indicates that the function is not considered secure. When the function is invoked, the arguments of the function must not reference a column for which a column mask is enabled and column level access control is activated for its table (SQLSTATE 428HA). This rule applies to the non secure user-defined functions that are invoked anywhere in the statement.

SECURED

Indicates that the function is considered secure. The function must be secure when it is referenced in a row permission or a column mask (SQLSTATE 428H8).

Rules

- ***Use of anchored data types:*** An anchored data type cannot refer to the following objects (SQLSTATE 428HS): a nickname, typed table, typed view, statistical view that is associated with an expression-based index, declared temporary table, row definition that is associated with a weakly typed cursor, object with a code page or collation that is different from the database code page or database collation.

- ***Use of cursor and row types:*** A function that uses a cursor type or row type for a parameter or returns a cursor type or row type can only be invoked from within a compound SQL (compiled) statement (SQLSTATE 428H2).
- ***Table access restrictions***: If a function is defined as READS SQL DATA, no statement in the function can access a table that is being modified by the statement that invoked the function (SQLSTATE 57053). For example, suppose the user-defined function BONUS() is defined as READS SQL DATA. If the statement UPDATE EMPLOYEE SET SALARY = SALARY + BONUS(EMPNO) is invoked, no SQL statement in the BONUS function can read from the EMPLOYEE table.

  If a function defined with MODIFIES SQL DATA contains nested CALL statements, read access to the tables being modified by the function (by either the function definition or the statement that invoked the function) is not allowed (SQLSTATE 57053).
- ***Use in a partitioned database environment***:
  - In a partitioned database environment, a scalar function defined using a compound SQL (compiled) statement defined as MODIFIES SQL can be referenced only on the right side of an assignment statement and the function reference cannot be part of an expression. Such an assignment statement cannot be in a Compound SQL (inlined) statement.
  - In a partitioned database environment, a scalar function defined using a compound SQL (compiled) statement which is defined as CONTAINS SQL is subject to additional restrictions: no explicit statement execution and all procedural logic must be supported without the need for executing a SQL statement.
  - In a partitioned database environment, a scalar function defined using a compound SQL (compiled) statement which is defined as READS SQL is always forced to run in the coordinator agent. It can also not be used in context of an UPDATE or DELETE statement.

Notes

- Resolution of function calls inside the function body is done according to the SQL path that is effective for the CREATE FUNCTION statement and does not change after the function is created.
- If an SQL function contains multiple references to any of the date or time special registers, all references return the same value, and it will be the same value returned by the register invocation in the statement that called the function.
- The body of an SQL function cannot contain a recursive call to itself or to another function or method that calls it, since such a function could not exist to be called.
- If an object referenced in the SQL function body does not exist or is marked invalid, or the definer temporarily doesn't have privileges to access the object, and if the database configuration parameter **auto_reval** is not set to DISABLED, then the SQL function will still be created successfully. The SQL function will be marked invalid and will be revalidated the next time it is invoked.
- The following rules are enforced by all statements that create functions or methods:
  - A function may not have the same signature as a method (comparing the first *parameter-type* of the function with the *subject-type* of the method).
  - A function and a method may not be in an overriding relationship. That is, if the function were a method with its first parameter as subject, it must not override, or be overridden by, another method. For more information about overriding methods, see the "CREATE TYPE (Structured)" statement.
  - Because overriding does not apply to functions, it is permissible for two functions to exist such that, if they were methods, one would override the other.

  For the purpose of comparing parameter-types in the preceding rules:
  - Parameter-names, lengths, AS LOCATOR, and FOR BIT DATA are ignored.
  - A subtype is considered to be different from its supertype.
- ***Privileges***: The definer of a function always receives the EXECUTE privilege on the function, as well as the right to drop the function. The definer of a function is also given the WITH GRANT OPTION on the

function if the definer has WITH GRANT OPTION on all privileges required to define the function, or if the definer has SYSADM or DBADM authority.

The definer of a function only acquires privileges if the privileges from which they are derived exist at the time the function is created. The definer must have these privileges either directly, or because PUBLIC has the privileges. Privileges held by groups of which the function definer is a member are not considered. When using the function, the connected user's authorization ID must have the valid privileges on the table or view that the nickname references at the data source.

- ***Setting of the default value***: Parameters of a function that are defined with a default value are set to their default value when the functions is invoked, but only if a value is not supplied for the corresponding argument, or is specified as DEFAULT, when the function is invoked.
- ***EXTERNAL ACTION functions***: If an EXTERNAL ACTION function is invoked in other than the outermost select list, the results are unpredictable since the number of times the function is invoked will vary depending on the access plan used.
- ***Creating a secure function***: Normally users with SECADM authority do not have privileges to create database objects such as triggers or functions. Typically they will examine the data accessed by the function, ensure it is secure, then grant the CREATE_SECURE_OBJECT authority to someone who currently has required privileges to create a secure user-defined function. After the function is created, they will revoke the CREATE_SECURE_OBJECT authority from the function owner.

  The SECURED attribute is considered to be an assertion that declares the user has established a change control audit procedure for all changes to the user-defined function. The database manager assumes that such a control audit procedure is in place for all subsequent ALTER FUNCTION statements or changes to external packages.
- ***Invoking other user-defined functions in a secure function***: If a secure user-defined function invokes other user-defined functions, the database manager does not validate whether those nested user-defined functions have the SECURED attribute. If those nested functions can access sensitive data, the user with SECADM authority needs to ensure those functions are allowed to access those data and a change control audit procedure has been established for all changes to those functions.
- ***Replacing an existing function such that the secure attribute is changed (from SECURED to NOT SECURED and vice versa)***: Packages and dynamically cached SQL statements that depend on the function may be invalidated because the secure attribute affects the access path selection for statements involving tables for which row or column level access control is activated.
- ***Rebinding dependent packages***: Every compiled SQL function has a dependent package. The package can be rebound at any time by using the REBIND_ROUTINE_PACKAGE procedure. Explicitly rebinding the dependent package does not revalidate an invalid function. Revalidate an invalid function with automatic revalidation or explicitly by using the ADMIN_REVALIDATE_DB_OBJECTS procedure. Function revalidation automatically rebinds the dependent package.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used:

  – NULL CALL can be specified in place of CALLED ON NULL INPUT

  The following syntax is accepted as the default behavior:

  – CCSID UNICODE in a Unicode database

  – CCSID ASCII in a non-Unicode database

Examples

- *Example 1:* Define a scalar function that returns the tangent of a value using the existing sine and cosine functions.

```
CREATE FUNCTION TAN (X DOUBLE)
  RETURNS DOUBLE
  LANGUAGE SQL
  CONTAINS SQL
  NO EXTERNAL ACTION
```

```
  DETERMINISTIC
  RETURN SIN(X)/COS(X)
```

- *Example 2:* Define a transform function for the structured type PERSON.

```
CREATE FUNCTION FROMPERSON (P PERSON)
  RETURNS ROW (NAME VARCHAR(10), FIRSTNAME VARCHAR(10))
  LANGUAGE SQL
  CONTAINS SQL
  NO EXTERNAL ACTION
  DETERMINISTIC
  RETURN VALUES (P..NAME, P..FIRSTNAME)
```

- *Example 3:* Define a table function that returns the employees in a specified department number.

```
CREATE FUNCTION DEPTEMPLOYEES (DEPTNO CHAR(3))
  RETURNS TABLE (EMPNO CHAR(6),
                 LASTNAME VARCHAR(15),
                 FIRSTNAME VARCHAR(12))
  LANGUAGE SQL
  READS SQL DATA
  NO EXTERNAL ACTION
  DETERMINISTIC
  RETURN
    SELECT EMPNO, LASTNAME, FIRSTNME
      FROM EMPLOYEE
      WHERE EMPLOYEE.WORKDEPT = DEPTEMPLOYEES.DEPTNO
```

- *Example 4:* Define the table function from Example 3 with auditing.

```
CREATE FUNCTION DEPTEMPLOYEES (DEPTNO CHAR(3))
  RETURNS TABLE (EMPNO CHAR(6),
                 LASTNAME VARCHAR(15),
                 FIRSTNAME VARCHAR(12))
  LANGUAGE SQL
  MODIFIES SQL DATA
  NO EXTERNAL ACTION
  DETERMINISTIC
  BEGIN ATOMIC
    INSERT INTO AUDIT
    VALUES (USER,
            'Table: EMPLOYEE Prd: DEPTNO = ' CONCAT DEPTNO);
    RETURN
      SELECT EMPNO, LASTNAME, FIRSTNME
        FROM EMPLOYEE
        WHERE EMPLOYEE.WORKDEPT = DEPTEMPLOYEES.DEPTNO
  END
```

- *Example 5:* Define a scalar function that reverses a string.

```
CREATE FUNCTION REVERSE(INSTR VARCHAR(4000))
  RETURNS VARCHAR(4000)
  DETERMINISTIC NO EXTERNAL ACTION CONTAINS SQL
  BEGIN ATOMIC
  DECLARE REVSTR, RESTSTR VARCHAR(4000) DEFAULT '';
  DECLARE LEN INT;
  IF INSTR IS NULL THEN
  RETURN NULL;
  END IF;
  SET (RESTSTR, LEN) = (INSTR, LENGTH(INSTR));
  WHILE LEN > 0 DO
  SET (REVSTR, RESTSTR, LEN)
    = (SUBSTR(RESTSTR, 1, 1) CONCAT REVSTR,
    SUBSTR(RESTSTR, 2, LEN - 1),
    LEN - 1);
  END WHILE;
  RETURN REVSTR;
END
```

- *Example 6:* Create a function that increments a variable passed as an INOUT parameter and return any error as the return code.

```
CREATE FUNCTION increment(INOUT result INTEGER, IN delta INTEGER)
  RETURNS INTEGER
  BEGIN
```

```
    DECLARE code INTEGER DEFAULT 0;
    DECLARE SQLCODE INTEGER;
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN
    SET code = SQLCODE;
    RETURN code;
  END;
  SET result = result + delta;
  RETURN code;
END@
```

- *Example 7:* Create a compiled SQL function that takes an XML document as input and returns the customer name.

```
CREATE FUNCTION get_customer_name_compiled(doc XML)
  RETURNS VARCHAR(25)
  BEGIN
    RETURN XMLCAST(XMLQUERY
       ('$d/customerinfo/name' PASSING doc AS "d")AS VARCHAR(25));
  END
```

- *Example 8:* Create a compiled SQL function that takes a phone number and a region number passed as IN parameters and returns the complete number in an OUT XML parameter.

```
CREATE FUNCTION construct_xml_phone
  (IN  phoneNo VARCHAR(20),
   IN  regionNo VARCHAR(8),
   OUT full_phone_xml XML)
  RETURNS VARCHAR(28)
  LANGUAGE SQL
  NO EXTERNAL ACTION
  BEGIN
    SET full_phone_xml = XMLELEMENT (NAME "phone", regionNo || phoneNo);
    RETURN regionNo || phoneNo;
  END
```

CREATE FUNCTION MAPPING

The CREATE FUNCTION MAPPING statement can define a mapping between a federated database function or function template and a data source function, or disable a default mapping between a federated database function and a data source function.

When defining a mapping, the CREATE FUNCTION MAPPING statement can associate the federated database function or template with a function at the following sources:

- A specified data source
- A range of data sources; for example, all data sources of a particular type and version

If multiple function mappings are applicable to a function, the most recent one is applied.

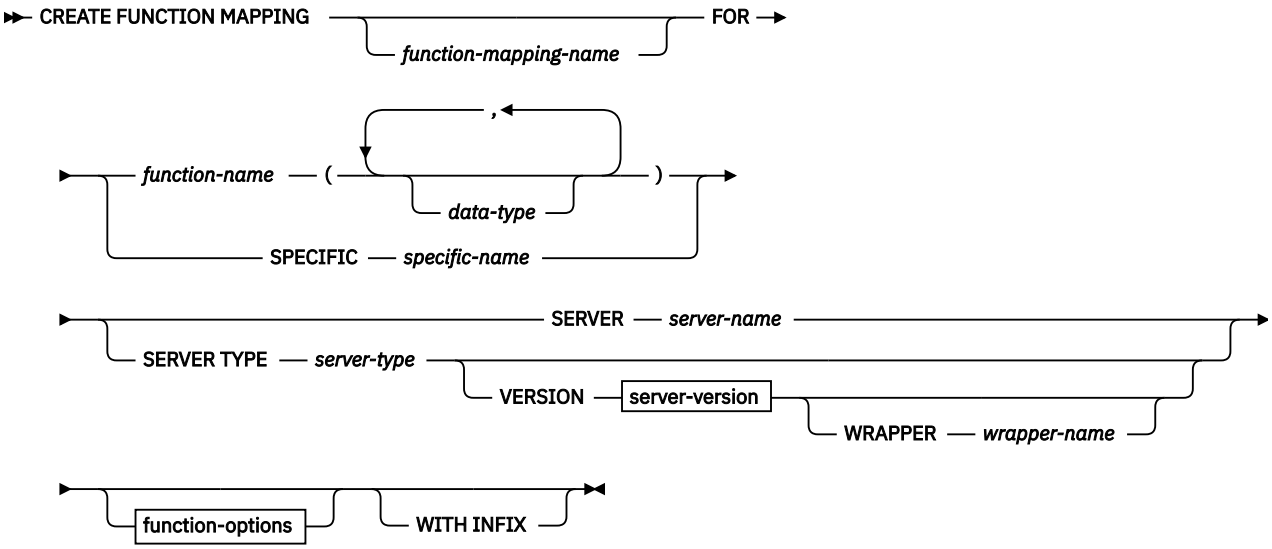
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

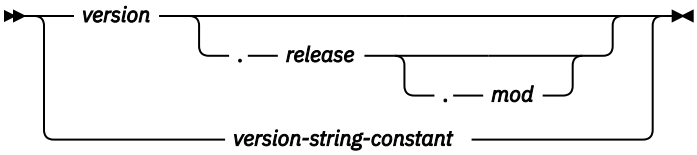
Authorization

The privileges held by the authorization ID of the statement must include DBADM authority.

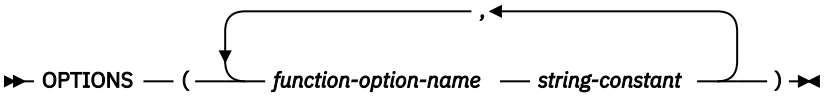
Syntax



server-version



function-options



Description

function-mapping-name
Names the function mapping. The name must not identify a function mapping that is already described in the catalog (SQLSTATE 42710).

If the *function-mapping-name* is omitted, a system-generated unique name is assigned.

function-name
Specifies the qualified or unqualified name of the federated database function or federated database function template from which to map.

data-type
For a function or function template that has input parameters, *data-type* specifies the data type of each parameter. The *data type* cannot be an XML or a user-defined type.

Empty parentheses can be used instead of specifying length, precision, or scale for the parameterized data types. It is recommended to use empty parentheses for the parameterized data types; for example, CHAR(). A parameterized data type is any one of the data types that can be defined with a specific length, scale, or precision. The parameterized data types are the string data types and the decimal data types. If you specify length, precision, or scale, it must be the same as that of the function template. If you omit parentheses altogether, the default length for the data type is used (see the description of the CREATE TABLE statement).

SPECIFIC *specific-name*
Identifies the function or function template from which to map. Specify *specific-name* to create a convenient function name.

SERVER *server-name*
Names the data source containing the function that is being mapped.

SERVER TYPE *server-type*
Identifies the type of data source containing the function that is being mapped.

VERSION
Identifies the version of the data source denoted by *server-type*.

version
Specifies the version number. The value must be an integer.

release
Specifies the number of the release of the version denoted by *version*. The value must be an integer.

mod
Specifies the number of the modification of the release denoted by *release*. The value must be an integer.

version-string-constant
Specifies the complete designation of the version. The *version-string-constant* can be a single value (for example, '8i'); or it can be the concatenated values of *version*, *release* and, if applicable, *mod* (for example, '8.0.3').

WRAPPER *wrapper-name*
Specifies the name of the wrapper that the federated server uses to interact with data sources of the type and version denoted by *server-type* and *server-version*.

OPTIONS
Specify configuration options for the function mapping to be created. Which options you can specify depends on the data source of the object for which a function mapping is being created. For a list of data sources and the function mapping options that apply to each, see Data source options. Each option value is a character string constant that must be enclosed in single quotation marks.

WITH INFIX
Specifies that the data source function be generated in infix format. The federated database system converts prefix notation to the infix notation that is used by the remote data source.

Notes

- A federated database function or function template can map to a data source function if:
  - The federated database function or template has the same number of input parameters as the data source function.
  - The data types that are defined for the federated function or template are compatible with the corresponding data types defined for the data source function.
- If a distributed request references a built-in database function that maps to a data source function, the optimizer develops strategies for invoking either function when the request is processed. The built-in database function is invoked if doing so requires less overhead than invoking the data source function. Otherwise, if invoking the built-in database function requires more overhead, the data source function is invoked.
- If a distributed request references a built-in database function template that maps to a data source function, only the data source function can be invoked when the request is processed. The template cannot be invoked because it has no executable code.
- Default function mappings can be rendered inoperable by disabling them (they cannot be dropped). To disable a default function mapping, code the CREATE FUNCTION MAPPING statement so that it specifies the name of the built-in database function within the mapping and sets the DISABLE option to 'Y'.
- Functions in the SYSIBM schema do not have a specific name. To override the default function mapping for a function in the SYSIBM schema, specify *function-name* using the explicit qualifier SYSIBM; for example, SYSIBM.LENGTH().

- A CREATE FUNCTION MAPPING statement within a given unit of work (UOW) cannot be processed (SQLSTATE 55007) under either of the following conditions:
  - The statement references a single data source, and the UOW already includes one of the following:
    - A SELECT statement that references a nickname for a table or view within this data source
    - An open cursor on a nickname for a table or view within this data source
    - Either an INSERT, DELETE, or UPDATE statement issued against a nickname for a table or view within this data source
  - The statement references a category of data sources (for example, all data sources of a specific type and version), and the UOW already includes one of the following:
    - A SELECT statement that references a nickname for a table or view within one of these data sources
    - An open cursor on a nickname for a table or view within one of these data sources
    - Either an INSERT, DELETE, or UPDATE statement issued against a nickname for a table or view within one of these data sources
- **Create function mapping to table or row functions:** A create function mapping to remote functions that returns a table or a row is not supported in a federated database.
- **Syntax alternatives:** The following syntax is supported for compatibility with previous versions of Db2:
  - ADD can be specified before *function-option-name string-constant*.

Examples

- *Example 1:* Map a function template to a UDF that all Oracle data sources can access. The template is called STATS and belongs to a schema called NOVA. The Oracle UDF is called STATISTICS and belongs to a schema called STAR.

```
CREATE FUNCTION MAPPING MY_ORACLE_FUN1
  FOR NOVA.STATS (DOUBLE, DOUBLE)
  SERVER TYPE ORACLE
  OPTIONS (REMOTE_NAME 'STAR.STATISTICS')
```

- *Example 2:* Map a function template called BONUS to a UDF, also called BONUS, that is used at an Oracle data source called ORACLE1.

```
CREATE FUNCTION MAPPING MY_ORACLE_FUN2
  FOR BONUS()
  SERVER ORACLE1
  OPTIONS (REMOTE_NAME 'BONUS')
```

- *Example 3:* Assume that there is a default function mapping between the WEEK system function that is defined to the federated database and a similar function that is defined to Oracle data sources. When a query that requests Oracle data and that references WEEK is processed, either WEEK or its Oracle counterpart will be invoked, depending on which one is estimated by the optimizer to require less overhead. The DBA wants to find out how performance would be affected if only WEEK were invoked for such queries. To ensure that WEEK is invoked each time, the DBA must disable the mapping.

```
CREATE FUNCTION MAPPING
  FOR SYSFUN.WEEK(INT)
  SERVER TYPE ORACLE
  OPTIONS (DISABLE 'Y')
```

- *Example 4:* Map the federated function UCASE(CHAR) to a UDF that is used at an Oracle data source called ORACLE2. Include the estimated number of instructions per invocation of the Oracle UDF.

```
CREATE FUNCTION MAPPING MY_ORACLE_FUN4
  FOR SYSFUN.UCASE(CHAR)
  SERVER ORACLE2
  OPTIONS
    (REMOTE_NAME 'UPPERCASE',
    INSTS_PER_INVOC '1000')
```

CREATE GLOBAL TEMPORARY TABLE

The CREATE GLOBAL TEMPORARY TABLE statement creates a description of a temporary table at the current server. Each session that selects from a created temporary table retrieves only rows that the same session has inserted. When the session terminates, the rows of the table associated with the session are deleted.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

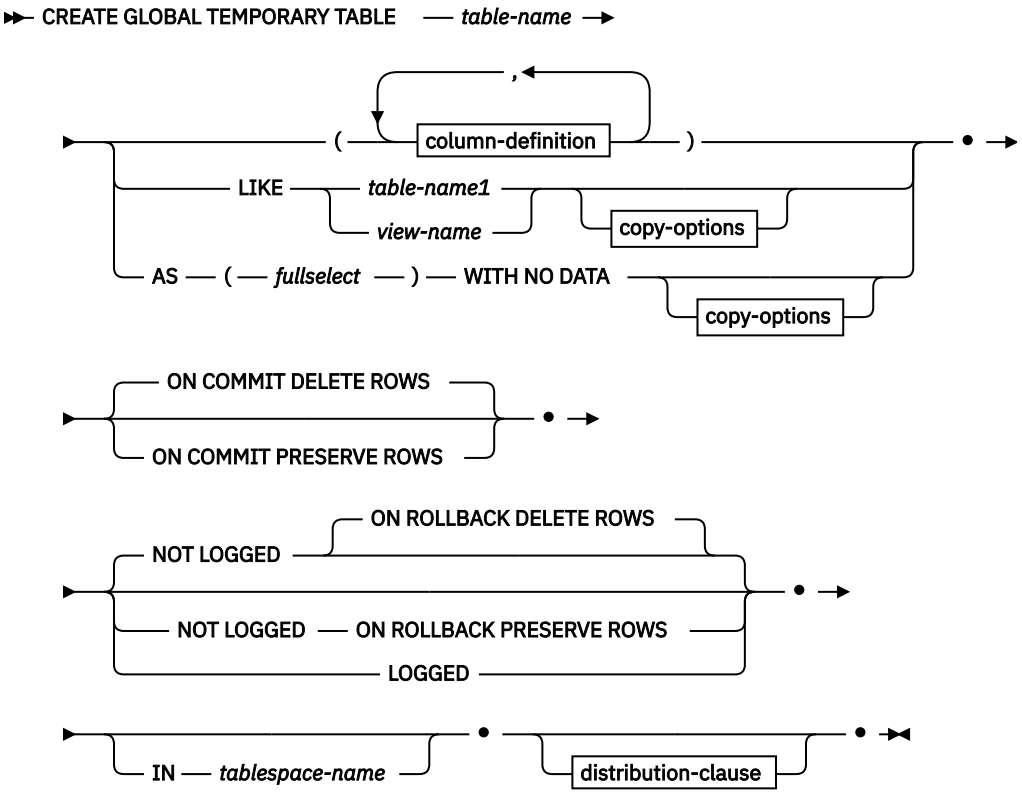
The privileges held by the authorization ID of the statement must include either DBADM authority, or CREATETAB authority in combination with further authorization, as described here:

- One of the following privileges and authorities:
  - USE privilege on the table space
  - SYSADM
  - SYSCTRL
- Plus one of these privileges and authorities:
  - IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the table does not exist
  - CREATEIN privilege on the schema, if the schema name of the table refers to an existing schema
  - SCHEMAADM authority on the schema, if the schema name of the table refers to an existing schema

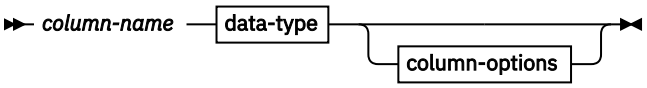
When defining a table using LIKE or a fullselect, the privileges held by the authorization ID of the statement must also include at least one of the following on each identified table or view:

- SELECT privilege on the table or view
- CONTROL privilege on the table or view
- SELECTIN privilege on the schema containing the table or view
- DATAACCESS authority on the schema containing the table or view
- DATAACCESS authority

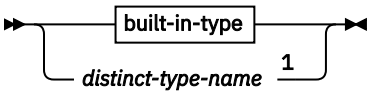
Syntax



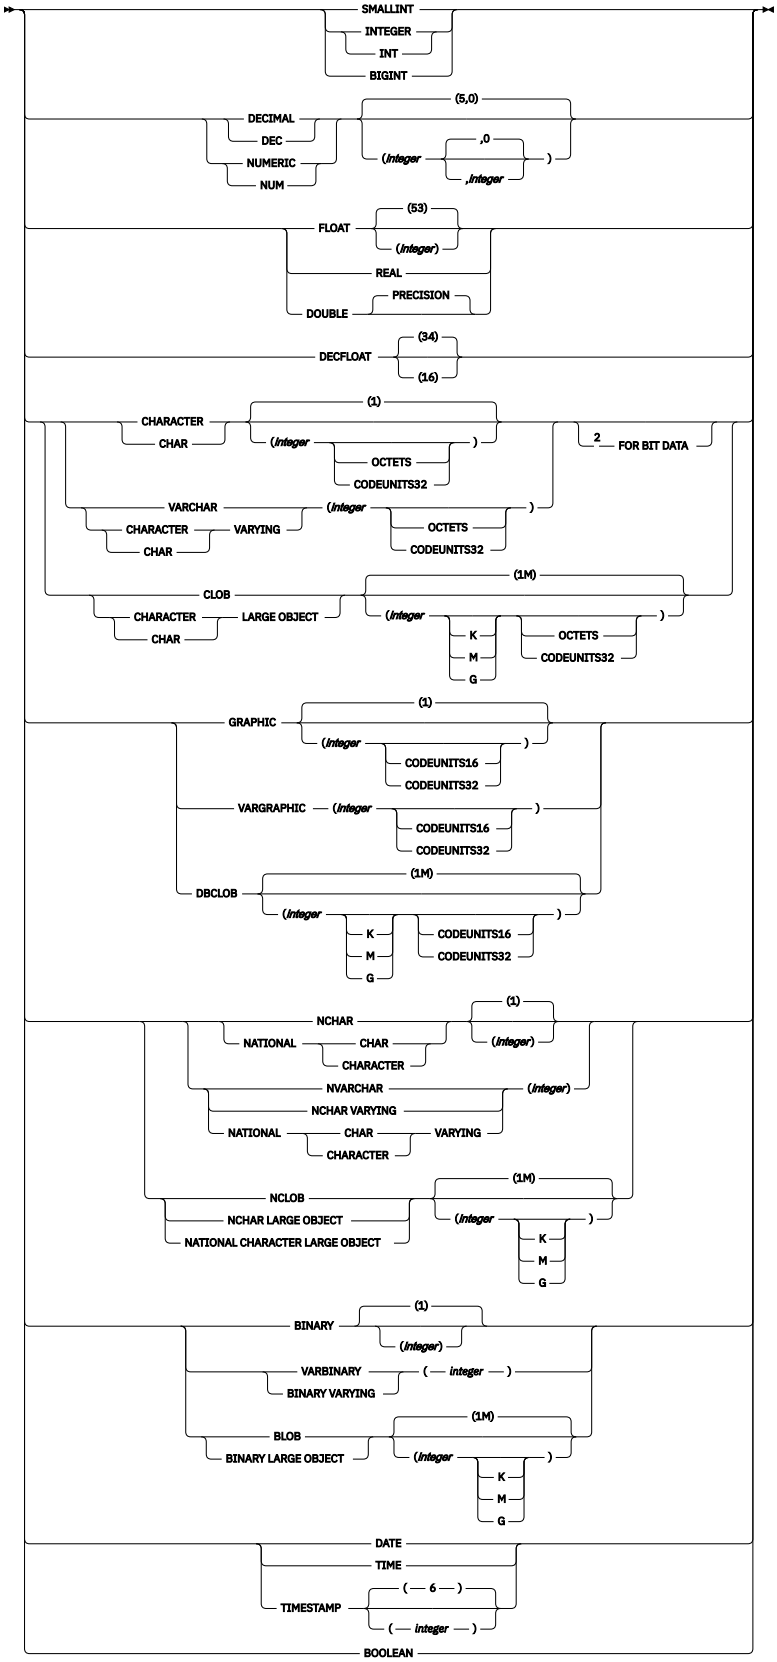
column-definition



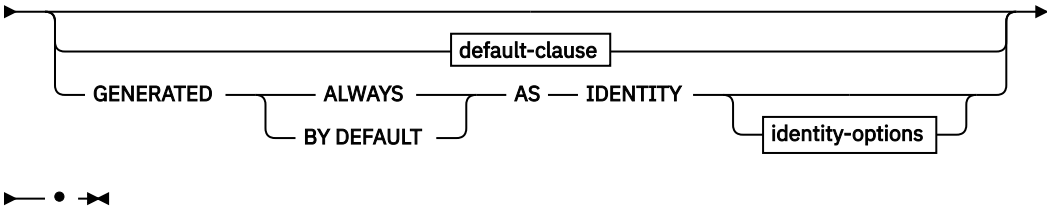
data-type



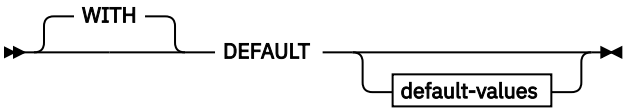
built-in-type



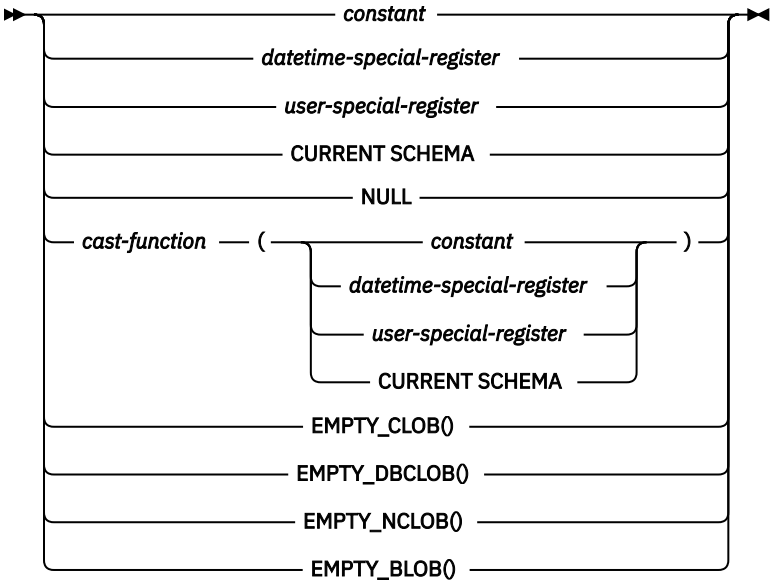
column-options



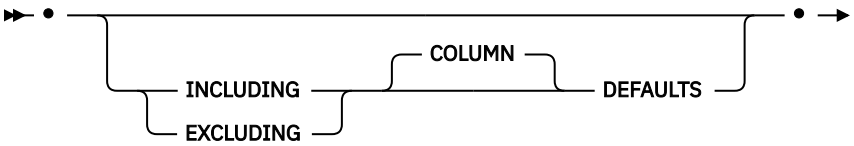
default-clause

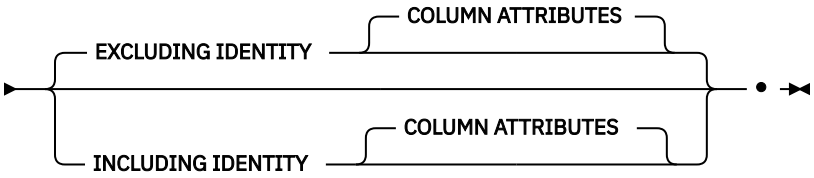


default-values

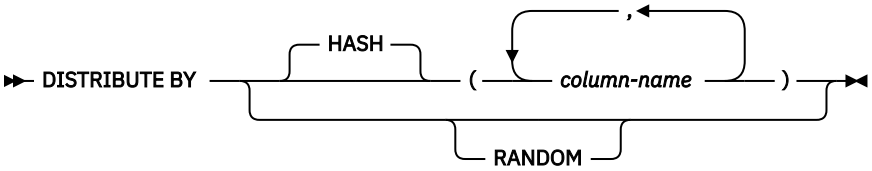


copy-options





distribution-clause



Notes:

[1] The specified distinct type cannot have any data type constraints and the source type cannot be an anchored data type.
[2] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

Description

table-name
Names the table. The name, including the implicit or explicit qualifier, must not identify a table, view, nickname, or alias described in the catalog. If a two-part name is specified, the schema name cannot begin with 'SYS' (SQLSTATE 42939).

column-definition
Defines the attributes of a column of the temporary table.

column-name
Names a column of the table. The name cannot be qualified, and the same name cannot be used for more than one column of the table (SQLSTATE 42711).

A table can have the following:

- A 4K page size with a maximum of 500 columns, where the byte counts of the columns must not be greater than 4 005.
- An 8K page size with a maximum of 1 012 columns, where the byte counts of the columns must not be greater than 8 101.
- A 16K page size with a maximum of 1 012 columns, where the byte counts of the columns must not be greater than 16 293.
- A 32K page size with a maximum of 1 012 columns, where the byte counts of the columns must not be greater than 32 677.

A created temporary table cannot have a row-begin column, row-end column, or a transaction-start-ID column.

For more details, see "Row Size" in “CREATE TABLE ” on page 1351.

data-type
Specifies the data type of the column

built-in-type
Specifies a built-in data type. See "CREATE TABLE" for a description of *built-in-type*.

An XML and SYSPROC.DB2SECURITYLABEL data type cannot be specified for a created temporary table.

distinct-type-name
For a user-defined type that is a distinct type. If a distinct type name is specified without a schema name, the distinct type name is resolved by searching the schemas on the SQL path (defined by the FUNCPATH preprocessing option for static SQL and by the CURRENT PATH register for dynamic SQL).

If a column is defined using a distinct type, then the data type of the column is the distinct type. The length and the scale of the column are respectively the length and the scale of the source type of the distinct type. The distinct type for a column cannot have any data type constraints and the source type cannot be an anchored data type (SQLSTATE 428H2).

column-options
Defines additional options related to the columns of the table.

NOT NULL
Prevents the column from containing null values. For specification of null values, see NOT NULL in "CREATE TABLE".

default-clause
Specifies a default value for the column.

WITH
An optional keyword.

DEFAULT
Provides a default value in the event a value is not supplied on INSERT or is specified as DEFAULT on INSERT or UPDATE. If a default value is not specified following the DEFAULT keyword, the default value depends on the data type of the column as shown in "ALTER TABLE".

If the column is based on a column of a typed table, a specific default value must be specified when defining a default. A default value cannot be specified for the object identifier column of a typed table (SQLSTATE 42997).

If a column is defined using a distinct type, then the default value of the column is the default value of the source data type cast to the distinct type.

If a column is defined using a structured type, the *default-clause* cannot be specified (SQLSTATE 42842).

Omission of DEFAULT from a *column-definition* results in the use of the null value as the default for the column. If such a column is defined NOT NULL, then the column does not have a valid default.

default-values
Specific types of default values that can be specified are as follows.

constant
Specifies the constant as the default value for the column. The specified constant must:

- represent a value that could be assigned to the column in accordance with the rules of assignment
- not be a floating-point constant unless the column is defined with a floating-point data type
- be a numeric constant or a decimal floating-point special value if the data type of the column is a decimal floating-point. Floating-point constants are first interpreted as DOUBLE and then converted to decimal floating-point if the target column is DECFLOAT. For DECFLOAT(16) columns, decimal constants having precision greater than 16 digits will be rounded using the rounding modes specified by the CURRENT DECFLOAT ROUNDING MODE special register.
- not have nonzero digits beyond the scale of the column data type if the constant is a decimal constant (for example, 1.234 cannot be the default for a DECIMAL(5,2) column)
- be expressed with no more than 254 bytes including the quote characters, any introducer character such as the X for a hexadecimal constant, and characters from the fully qualified function name and parentheses when the constant is the argument of a *cast-function*

datetime-special-register
Specifies the value of the datetime special register (CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP) at the time of INSERT, UPDATE, or LOAD as the default for the column. The data type of the column must be the data type that corresponds to the special register specified (for example, data type must be DATE when CURRENT DATE is specified).

user-special-register
Specifies the value of the user special register (CURRENT USER, SESSION_USER, SYSTEM_USER) at the time of INSERT, UPDATE, or LOAD as the default for the column. The data type of the column must be a character string with a length not less than the length attribute of a user special register. Note that USER can be specified in place of SESSION_USER and CURRENT_USER can be specified in place of CURRENT USER.

CURRENT SCHEMA
Specifies the value of the CURRENT SCHEMA special register at the time of INSERT, UPDATE, or LOAD as the default for the column. If CURRENT SCHEMA is specified, the data type of the column must be a character string with a length greater than or equal to the length attribute of the CURRENT SCHEMA special register.

NULL
Specifies NULL as the default for the column. If NOT NULL was specified, DEFAULT NULL may be specified within the same column definition but will result in an error on any attempt to set the column to the default value.

cast-function
This form of a default value can only be used with columns defined as a distinct type, BLOB or datetime (DATE, TIME or TIMESTAMP) data type. For distinct type, with the exception of distinct types based on BLOB or datetime types, the name of the function must match the name of the distinct type for the column. If qualified with a schema name, it must be the same as the schema name for the distinct type. If not qualified, the schema name from function resolution must be the same as the schema name for the distinct type. For a distinct type based on a datetime type, where the default value is a constant, a function must be used and the name of the function must match the name of the source type of the distinct type with an implicit or explicit schema name of SYSIBM. For other datetime columns, the corresponding datetime function may also be used. For a BLOB or a distinct type based on BLOB, a function must be used and the name of the function must be BLOB with an implicit or explicit schema name of SYSIBM.

constant
Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type or for the data type if not a distinct type. If the *cast-function* is BLOB, the constant must be a string constant.

datetime-special-register
Specifies CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP. The source type of the distinct type of the column must be the data type that corresponds to the specified special register.

user-special-register
Specifies CURRENT USER, SESSION_USER, or SYSTEM_USER. The data type of the source type of the distinct type of the column must be a string data type with a length of at least 8 bytes. If the *cast-function* is BLOB, the length attribute must be at least 8 bytes.

CURRENT SCHEMA
Specifies the value of the CURRENT SCHEMA special register. The data type of the source type of the distinct type of the column must be a character string with a length greater than or equal to the length attribute of the CURRENT SCHEMA special register. If the cast-function is BLOB, the length attribute must be at least 8 bytes.

EMPTY_CLOB(), EMPTY_DBCLOB(), or EMPTY_BLOB()
Specifies a zero-length string as the default for the column. The column must have the data type that corresponds to the result data type of the function.

If the value specified is not valid, an error is returned (SQLSTATE 42894).

IDENTITY and *identity-options*
For specification of identity columns, see IDENTITY and *identity-options* in "CREATE TABLE".

LIKE *table-name1* or *view-name* or *nickname*
Specifies that the columns of the table have exactly the same name and description as the columns of the identified table (*table-name1*), view (*view-name*), or nickname (*nickname*). The name specified after LIKE must identify a table, view, or nickname that exists in the catalog, or a declared temporary table. A typed table or typed view cannot be specified (SQLSTATE 428EC). A protected table cannot be specified (SQLSTATE 42962). A table that has a column defined as IMPLICITLY HIDDEN cannot be specified (SQLSTATE 560AE).

The use of LIKE is an implicit definition of *n* columns, where *n* is the number of columns in the identified table (including implicitly hidden columns), view, or nickname. The implicit definition depends on what is identified after LIKE.

- If a table is identified, then the implicit definition includes the column name, data type and nullability characteristic of each of the columns of *table-name1*. If EXCLUDING COLUMN DEFAULTS is not specified, then the column default is also included.
- If a view is identified, then the implicit definition includes the column name, data type, and nullability characteristic of each of the result columns of the fullselect defined in *view-name*. The data types of the view columns must be data types that are valid for columns of a table.
- If a nickname is identified, then the implicit definition includes the column name, data type, and nullability characteristic of each column of *nickname*.
- If a random distribution table using the random by generation method is identified, then the **RANDOM_DISTRIBUTION_KEY** column used for generation of random distribution values is not included. Unless the new table being created shares the same table distribution.

Column default and identity column attributes may be included or excluded, based on the *copy-attributes* clauses. The implicit definition does not include any other attributes of the identified table, view, or nickname. Thus the new table does not have any unique constraints, foreign key constraints, triggers, indexes, table partitioning keys, or distribution keys. The table is created in the table space implicitly or explicitly specified by the IN clause, and the table has any other optional clause only if the optional clause is specified.

When a table is identified in the LIKE clause and that table contains a ROW CHANGE TIMESTAMP column, the corresponding column of the new table inherits only the data type of the ROW CHANGE TIMESTAMP column. The new column is not considered to be a generated column.

If row or column level access control (RCAC) is enforced for *table-name1*, RCAC is not inherited by the new table.

AS (*fullselect*) WITH NO DATA
Specifies that the columns of the table have the same name and description as the columns that would appear in the derived result table of the fullselect if the fullselect were to be executed. The use of AS (*fullselect*) is an implicit definition of *n* columns for the created temporary table, where *n* is the number of columns that would result from the fullselect.

The implicit definition includes the following attributes of the *n* columns (if applicable to the data type):

- Column name
- Data type, length, precision, and scale
- Nullability

The following attributes are not included (the default value and identity attributes can be included by using the *copy-options*):

- Default value
- Identity attributes
- Hidden attribute
- ROW CHANGE TIMESTAMP

The implicit definition does not include any other optional attributes of the tables or views referenced in the fullselect.

Every select list element must have a unique name (SQLSTATE 42711). The AS clause can be used in the select clause to provide unique names. The fullselect must not refer to host variables or include parameter markers. The data types of the result columns of the fullselect must be data types that are valid for columns of a table.

If row or column level access control (RCAC) is enforced for any table that is specified in *fullselect*, RCAC is not cascaded to the new table.

copy-options

These options specify whether to copy additional attributes of the source result table definition (table, view, or fullselect).

INCLUDING COLUMN DEFAULTS

Column defaults for each updatable column of the source result table definition are copied. Columns that are not updatable will not have a default defined in the corresponding column of the created table.

If LIKE *table-name1* is specified, and *table-name1* identifies a base table, created temporary table, or declared temporary table, then INCLUDING COLUMN DEFAULTS is the default.

EXCLUDING COLUMN DEFAULTS

Column defaults are not copied from the source result table definition.

This clause is the default, except when LIKE *table-name* is specified and *table-name* identifies a base table, created temporary table, or declared temporary table.

INCLUDING IDENTITY COLUMN ATTRIBUTES

If available, identity column attributes (START WITH, INCREMENT BY, and CACHE values) are copied from the source's result table definition. It is possible to copy these attributes if the element of the corresponding column in the table, view, or fullselect is the name of a column of a table, or the name of a column of a view which directly or indirectly maps to the column name of a base table or created temporary table with the identity property. In all other cases, the columns of the new temporary table will not get the identity property. For example:

- The select list of the fullselect includes multiple instances of the name of an identity column (that is, selecting the same column more than once)
- The select list of the fullselect includes multiple identity columns (that is, it involves a join)
- The identity column is included in an expression in the select list
- The fullselect includes a set operation (union, except, or intersect).

EXCLUDING IDENTITY COLUMN ATTRIBUTES

Identity column attributes are not copied from the source result table definition.

ON COMMIT

Specifies the action taken on the created temporary table when a COMMIT operation is performed. The default is DELETE ROWS.

DELETE ROWS

All rows of the table will be deleted if no WITH HOLD cursor is open on the table.

PRESERVE ROWS

Rows of the table will be preserved.

LOGGED or NOT LOGGED

Specifies whether operations for the table are logged. The default is NOT LOGGED ON ROLLBACK DELETE ROWS.

NOT LOGGED

Specifies that insert, update, or delete operations against the table are not to be logged, but that the creation or dropping of the table is to be logged. During a ROLLBACK (or ROLLBACK TO SAVEPOINT) operation:

- If the table had been created within a unit of work (or savepoint), the table is dropped
- If the table had been dropped within a unit of work (or savepoint), the table is recreated, but without any data

ON ROLLBACK

Specifies the action that is to be taken on the not logged created temporary table when a ROLLBACK (or ROLLBACK TO SAVEPOINT) operation is performed. The default is DELETE ROWS.

DELETE ROWS

If the table data has been changed, all the rows will be deleted.

PRESERVE ROWS
Rows of the table will be preserved.

LOGGED
Specifies that insert, update, or delete operations against the table as well as the creation or dropping of the table are to be logged.

IN *tablespace-name*
Identifies the table space in which the created temporary table will be instantiated. The table space must exist and be a USER TEMPORARY table space (SQLSTATE 42838), over which the authorization ID of the statement has USE privilege (SQLSTATE 42501). If this clause is not specified, a table space for the table is determined by choosing the USER TEMPORARY table space with the smallest sufficient page size over which the authorization ID of the statement has USE privilege. When more than one table space qualifies, preference is given according to who was granted the USE privilege:

1. The authorization ID
2. A group to which the authorization ID belongs
3. PUBLIC

If more than one table space still qualifies, the final choice is made by the database manager. When no USER TEMPORARY table space qualifies, an error is raised (SQLSTATE 42727).

Determination of the table space can change when:

- Table spaces are dropped or created
- USE privileges are granted or revoked

The sufficient page size of a table is determined by either the byte count of the row or the number of columns. For more details, see "Row Size" in “CREATE TABLE ” on page 1351.

distribution-clause
Specifies the database partitioning or the way the data is distributed across multiple database partitions.

DISTRIBUTE BY HASH (*column-name*, ...)
Specifies the use of the default hashing function on the specified columns, called a *distribution key*, as the distribution method across database partitions. The *column-name* must be an unqualified name that identifies a column of the table (SQLSTATE 42703). The same column must not be identified more than once (SQLSTATE 42709). No column whose data type is BLOB, CLOB, DBCLOB, XML, distinct type based on any of these types, or structured type can be used as part of a distribution key (SQLSTATE 42962).

If this clause is not specified, and the table resides in a multiple partition database partition group with multiple database partitions, a default distribution key is automatically defined.

If none of the columns satisfies the requirements for a default distribution key, the table is created without one. Such tables are allowed only in table spaces that are defined on single-partition database partition groups.

For tables in table spaces that are defined on single-partition database partition groups, any collection of columns with data types that are valid for a distribution key can be used to define the distribution key. If this clause is not specified, no distribution key is created.

DISTRIBUTE BY RANDOM
Specifies that the database manager will select a distribution key to spread data evenly across all database partitions of the database partitioning group. Data distribution is accomplished by using a *random by generation* method. In this method, the database manager will include a column in the table to generate and store a generated value to use in the hashing function. The column will be created with the **IMPLICITLY HIDDEN** clause so that it does not appear in queries unless explicitly included. The value of the column will be automatically generated as new rows are added to the table. By default, the column name is **RANDOM_DISTRIBUTION_KEY**. If it collides with the existing column, a non-conflicting name will be generated by the database manager.

Notes

- A user temporary table space must exist before a created temporary table can be created (SQLSTATE 42727).
- Data row compression is enabled for a created temporary table. When the database manager determines that there is a performance gain, table row data with XML documents stored inline in the base table object is compressed. However, data compression of the XML storage object of a created temporary table is not supported.
- Index compression is enabled by default for indexes that are created on created temporary tables. Compression will be shown as on, but indexes will not be compressed if the correct license (IBM Db2 Storage Optimization Feature) is not applied.
- ***Instantiation and termination***: For the explanations that follow, P denotes a session and T is a created temporary table in the session P:
  - An empty instance of T is created as a result of the first reference to T that is executed in P.
  - Any SQL statement in P can make reference to T and any reference to T in P is a reference to that same instance of T.
  - Assuming that the ON COMMIT DELETE ROWS clause was specified implicitly or explicitly, then when a commit operation terminates a unit of work in P, and there is no open WITH HOLD cursor in P that is dependent on T, the commit includes the operation DELETE FROM T.
  - When a rollback operation terminates a unit of work or a savepoint in P, and that unit of work or savepoint includes a modification to T:
    - If NOT LOGGED was specified, all rows from T are deleted unless ON ROLLBACK PRESERVE ROWS was also specified
    - If NOT LOGGED was not specified, the changes to T are undone
  - If NOT LOGGED was specified and an INSERT, UPDATE or DELETE statement fails during execution (as opposed to a compilation error), all rows from T are deleted.
  - When a rollback operation terminates a unit of work or a savepoint in P, and that unit of work or savepoint includes the creation of T, then the rollback includes the operation DROP TABLE T.
  - If a rollback operation terminates a unit of work or a savepoint in P, and that unit of work or savepoint includes the drop of a created temporary table T, then the rollback will undo the drop of the table. If NOT LOGGED was specified, then the table will also have been emptied.
  - When the application process that referenced T terminates or disconnects from the database, the private instance of T is dropped and its instantiated rows are destroyed.
  - When the connection to the server at which T was referenced terminates, the private instance of T is dropped and its instantiated rows are destroyed.
- ***Restrictions on the use of created temporary tables***: Created temporary tables cannot:
  - Be specified in an ALTER, LOCK, or RENAME statement (SQLSTATE 42995)
  - Be specified in referential constraints (SQLSTATE 42995)
- ***Syntax alternatives***: The following alternatives are non-standard. They are supported for compatibility with earlier product versions or with other database products.
  - DEFINITION ONLY can be specified in place of WITH NO DATA
  - The PARTITIONING KEY clause or DISTRIBUTE ON clause can be specified in place of the DISTRIBUTE BY clause.
  - When specifying the value of the datetime special register, NOW() can be specified in place of CURRENT_TIMESTAMP.
  - In a CHAR or VARCHAR column definition, you do not need to specify the CCSID explicitly; the correct CCSID will be used automatically. However, if you do specify the CCSID explicitly, it must correspond to the type of database being used:
    - `CCSID ASCII` for a non-unicode database

- CCSID UNICODE for a unicode database

Examples

- *Example 1*: Create a temporary table, CURRENTMAP. Name two columns, CODE and MEANING, both of which cannot contain nulls. CODE contains numeric data and MEANING has character data.

```
CREATE GLOBAL TEMPORARY TABLE CURRENTMAP
   (CODE        INTEGER      NOT NULL,
    MEANING     VARCHAR(254) NOT NULL)
```

- *Example 2*: Create a temporary table, TMPDEPT.

```
CREATE GLOBAL TEMPORARY TABLE TMPDEPT
   (TMPDEPTNO   CHAR(3)      NOT NULL,
    TMPDEPTNAME VARCHAR(36)  NOT NULL,
    TMPMGRNO    CHAR(6),
    TMPLOCATION CHAR(16) )
```

CREATE HISTOGRAM TEMPLATE

The CREATE HISTOGRAM TEMPLATE statement defines a template describing the type of histogram that can be used to override one or more of the default histograms of a service class or a work class.

Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include WLMADM or DBADM authority.

Syntax

Description

template-name
Names the histogram template. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The name must not identify an existing histogram template at the current server (SQLSTATE 42710). The name must not begin with the characters 'SYS' (SQLSTATE 42939).

HIGH BIN VALUE *bigint-constant*
Specifies the top value of the second to last bin (the last bin has an unbounded top value). The units depend on how the histogram is used. The maximum value is 268 435 456.

Rules

- A workload management (WLM)-exclusive SQL statement must be followed by a COMMIT or a ROLLBACK statement (SQLSTATE 5U021). WLM-exclusive SQL statements are:
  - CREATE HISTOGRAM TEMPLATE, ALTER HISTOGRAM TEMPLATE, or DROP (HISTOGRAM TEMPLATE)
  - CREATE SERVICE CLASS, ALTER SERVICE CLASS, or DROP (SERVICE CLASS)
  - CREATE THRESHOLD, ALTER THRESHOLD, or DROP (THRESHOLD)
  - CREATE WORK ACTION SET, ALTER WORK ACTION SET, or DROP (WORK ACTION SET)
  - CREATE WORK CLASS SET, ALTER WORK CLASS SET, or DROP (WORK CLASS SET)

  - CREATE WORKLOAD, ALTER WORKLOAD, or DROP (WORKLOAD)
  - GRANT (Workload Privileges) or REVOKE (Workload Privileges)
- A WLM-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.

Notes

- Only one uncommitted WLM-exclusive SQL statement at a time is allowed across all partitions. If an uncommitted WLM-exclusive SQL statement is executing, subsequent WLM-exclusive SQL statements will wait until the current WLM-exclusive SQL statement commits or rolls back.
- Changes are written to the system catalog, but do not take effect until they are committed, even for the connection that issues the statement.

Example

Create a histogram template named LIFETIMETEMP on service class PAYROLL in service superclass ADMIN that will override the default activity lifetime histogram template with a new high bin value of 90 000, which represents 90 000 milliseconds. This will produce a histogram with exponentially increasing bin ranges, ending with a bin whose range is 90 000 to infinity.

```
CREATE HISTOGRAM TEMPLATE LIFETIMETEMP
  HIGH BIN VALUE 90000

CREATE SERVICE CLASS PAYROLL
  UNDER ADMIN ACTIVITY LIFETIME HISTOGRAM TEMPLATE LIFETIMETEMP
```

CREATE INDEX

The CREATE INDEX statement is used to define an index on a database table.

An index can be defined on XML data, or on relational data. The CREATE INDEX statement is also used to create an index specification (metadata that indicates to the optimizer that a data source table has an index).

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

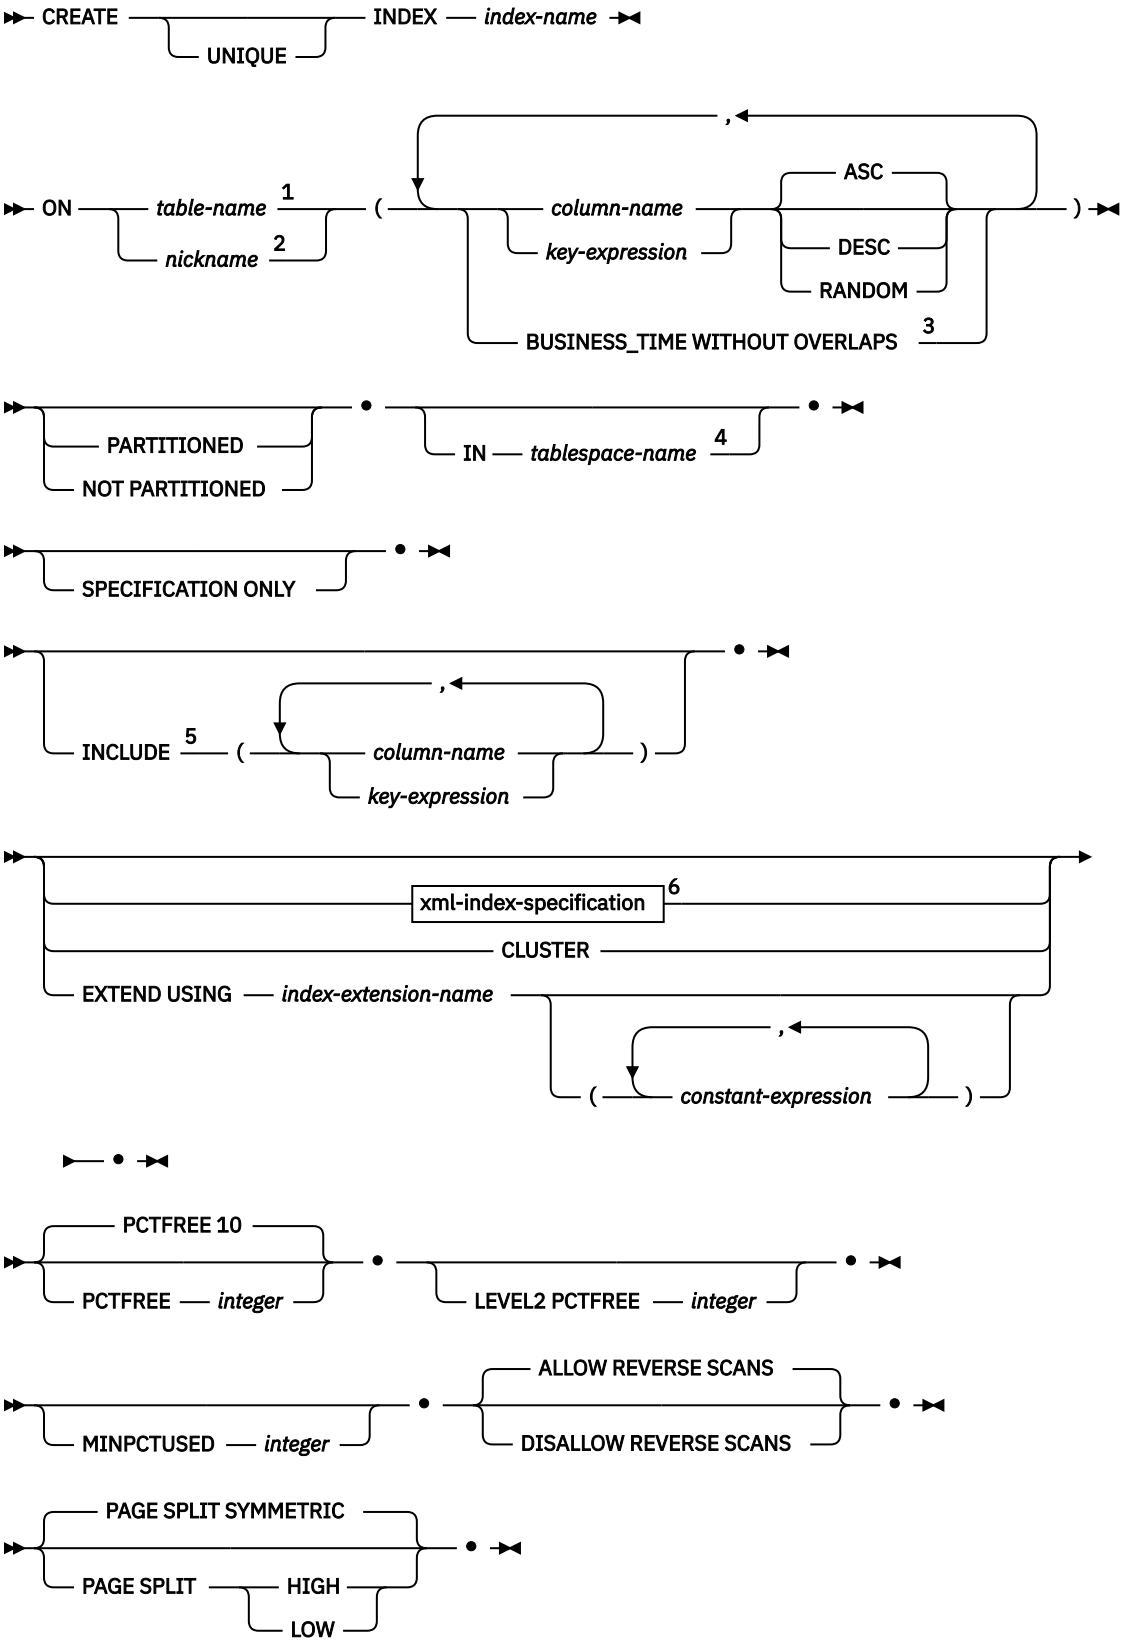
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

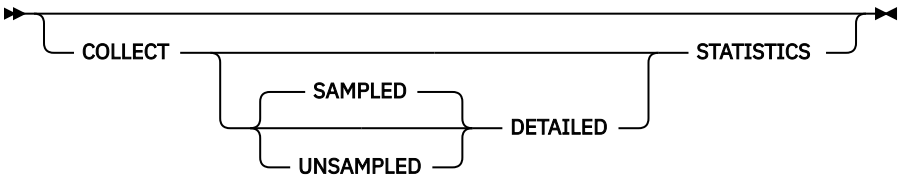
- One of:
  - CONTROL privilege on the table or nickname on which the index is defined
  - INDEX privilege on the table or nickname on which the index is defined
  - SCHEMAADM authority on the schema containing the table or nickname on which the index is defined

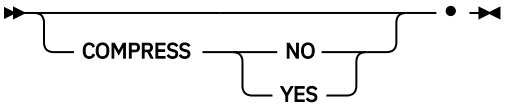
  and one of:
  - IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the index does not exist
  - CREATEIN privilege on the schema, if the schema name of the index refers to an existing schema
  - SCHEMAADM authority on the schema, if the schema name of the index refers to an existing schema
- DBADM authority

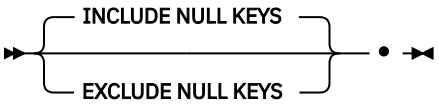
No explicit privilege is required to create an index on a declared temporary table.

Syntax









Notes:

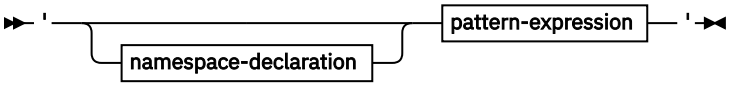
[1] In a federated system, *table-name* must identify a table in the federated database. It cannot identify a data source table.
[2] If *nickname* is specified, the CREATE INDEX statement creates an index specification. In this case, INCLUDE, *xml-index-specification*, CLUSTER, EXTEND USING, PCTFREE, MINPCTUSED, DISALLOW REVERSE SCANS, ALLOW REVERSE SCANS, PAGE SPLIT, or COLLECT STATISTICS cannot be specified.
[3] The BUSINESS_TIME WITHOUT OVERLAPS clause can be specified only if UNIQUE is specified.
[4] The IN *tablespace-name* clause can be specified only for a nonpartitioned index on a partitioned table.
[5] The INCLUDE clause can be specified only if UNIQUE is specified.
[6] If *xml-index-specification* is specified, *column-name* DESC, INCLUDE, or CLUSTER cannot be specified.

xml-index-specification

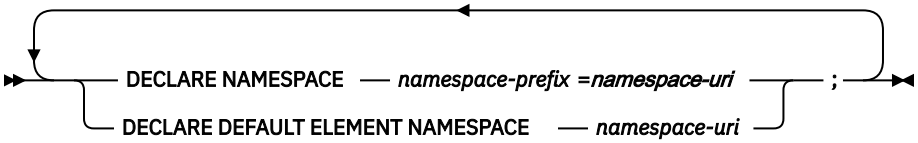
Notes:

[1] The alternative syntax GENERATE KEYS USING XMLPATTERN can be used.

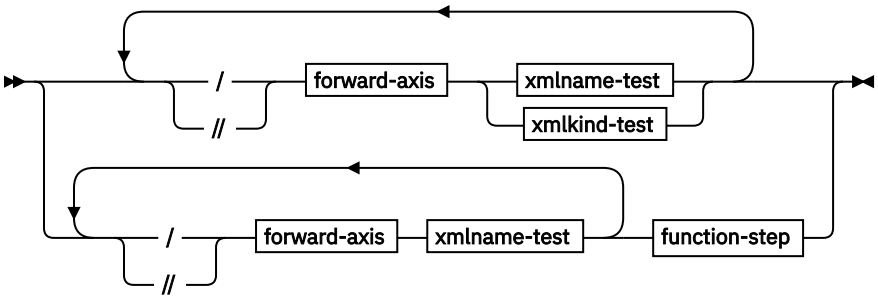
xmlpattern-clause



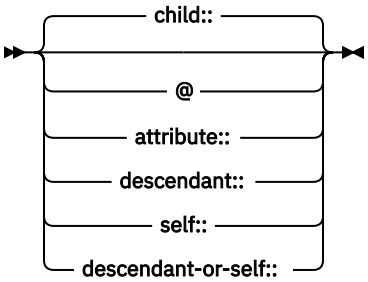
namespace-declaration



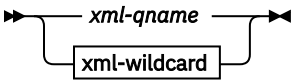
pattern-expression



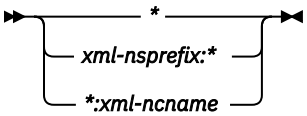
forward-axis



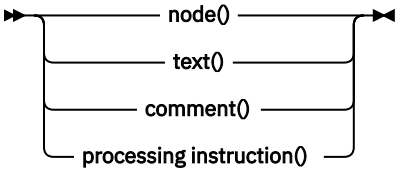
xmlname-test



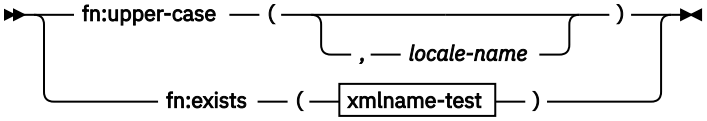
xml-wildcard



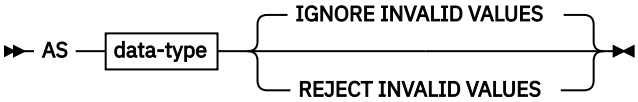
xmlkind-test



function-step

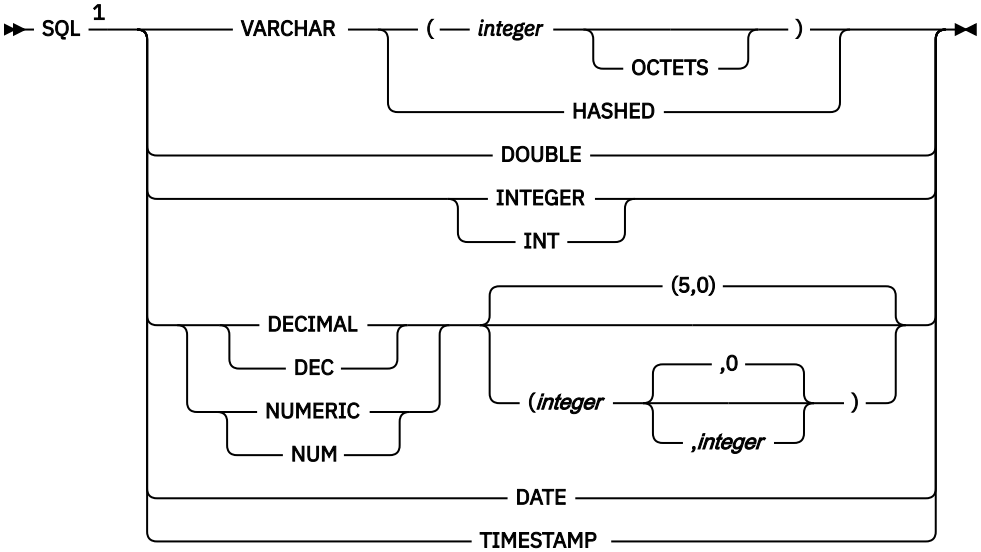


xmltype-clause



data-type

sql-data-type



Notes:

[1] If you specify a function name, such as fn:upper-case, at the end of the XML pattern, the supported index data types might be a subset of the index data types shown here. You can check for valid index data types in the description for xmlpattern-clause.

Description

UNIQUE

If ON *table-name* is specified, UNIQUE prevents the table from containing two or more rows with the same value of the index key. The uniqueness is enforced at the end of the SQL statement that updates rows or inserts new rows.

The uniqueness is also checked during the execution of the CREATE INDEX statement. If the table already contains rows with duplicate key values, the index is not created.

If the index is on an XML column (the index is an index over XML data), the uniqueness applies to values with the specified *pattern-expression* for all rows of the table. Uniqueness is enforced on each value after the value has been converted to the specified *sql-data-type*. Because converting to the specified *sql-data-type* might result in a loss of precision or range, or different values might be hashed to the same key value, multiple values that appear to be unique in the XML document might result in duplicate key errors. The uniqueness of character strings depends on XQuery semantics where trailing blanks are significant. Therefore, values that would be duplicates in SQL but differ in trailing blanks are considered unique values in an index over XML data.

When UNIQUE is used, null values are treated as any other values. For example, if the key is a single column that may contain null values, that column may contain no more than one null value.

If the UNIQUE option is specified, and the table has a distribution key, the columns in the index key must be a superset of the distribution key. That is, the columns specified for a unique index key must include all the columns of the distribution key (SQLSTATE 42997).

Primary or unique keys cannot be subsets of dimensions (SQLSTATE 429BE).

If ON *nickname* is specified, UNIQUE should be specified only if the data for the index key contains unique values for every row of the data source table. The uniqueness will not be checked.

For an index over XML data, UNIQUE can be included only if the context step of the *pattern-expression* specifies a single complete path and does not contain a descendant or descendant-or-self axis, "//", an *xml-wildcard*, *node()*, or *processing-instruction()* (SQLSTATE 429BS).

In a partitioned database environment, the following rules apply to a table with one or more XML columns:

- A distributed table cannot have a unique index over XML data.
- A unique index over XML data is supported only on a table that does not have a distribution key and that is on a single node multi-partition database.
- If a unique index over XML data exists on a table, the table cannot be altered to add a distribution key.

INDEX *index-name*

Names the index or index specification. The name, including the implicit or explicit qualifier, must not identify an index or index specification that is described in the catalog, or an existing index on a declared temporary table (SQLSTATE 42704). The qualifier must not be SYSIBM, SYSCAT, SYSFUN, or SYSSTAT (SQLSTATE 42939).

The implicit or explicit qualifier for indexes on declared temporary tables must be SESSION (SQLSTATE 428EK).

ON *table-name* or *nickname*

The *table-name* identifies a table on which an index is to be created. The table must be a base table (not a view), a created temporary table, a declared temporary table, a materialized query table that exists at the current server, or a declared temporary table. The name of a declared temporary table must be qualified with SESSION.

The *table-name* must not identify a catalog table (SQLSTATE 42832).

If UNIQUE is specified and *table-name* is a typed table, it must not be a subtable (SQLSTATE 429B3).

nickname is the nickname on which an index specification is to be created. The *nickname* references either a data source table whose index is described by the index specification, or a data source view that is based on such a table. The *nickname* must be listed in the catalog.

If the index key contains at least one *key-expression*, the *table-name* cannot be any of the following objects:

- A materialized query table (MQT) (SQLSTATE 429BX)
- A staging table (SQLSTATE 429BX)
- A typed table (SQLSTATE 429BX)
- A declared or created user temporary table (SQLSTATE 42995)
- A column-organized table (SQLSTATE 42858)
- A table that is an event monitor target (SQLSTATE 429BX)
- A nickname (SQLSTATE 42601)

column-name

For an index, *column-name* identifies a column that is to be part of the index key. For an index specification, *column-name* is the name by which the federated server references a column of a data source table.

The number of columns plus twice the number of identified periods cannot exceed 64 (SQLSTATE 54008). If *table-name* is a typed table, the number of columns cannot exceed 63 (SQLSTATE 54008). If *table-name* is a subtable, at least one *column-name* must be introduced in the subtable; that is, not inherited from a supertable (SQLSTATE 428DS). No *column-name* can be repeated (SQLSTATE 42711). The maximum number of columns in an index with random ordering is reduced by one for each column that is specified with random ordering

The sum of the stored lengths of the specified columns must not be greater than the index key length limit for the page size. For key length limits, see "SQL limits". If *table-name* is a typed table, the index key length limit is further reduced by 4 bytes. If the index has random ordering, the index key length is further reduced by 2 bytes.

Note that this length can be reduced by system overhead, which varies according to the data type of the column and whether it is nullable. For more information on overhead affecting this limit, see "Byte Counts" in "CREATE TABLE".

No LOB column or distinct type column based on a LOB can be used as part of an index, even if the length attribute of the column is small enough to fit within the index key length limit for the page size (SQLSTATE 54008). A structured type column can only be specified if the EXTEND USING clause is also specified (SQLSTATE 42962). If the EXTEND USING clause is specified, only one column can be specified, and the type of the column must be a structured type or a distinct type that is not based on a LOB (SQLSTATE 42997).

If an index has only one column, and that column has the XML data type, and the GENERATE KEY USING XMLPATTERN clause is also specified, the index is an index over XML data. A column with the XML data type can be specified only if the GENERATE KEY USING XMLPATTERN clause is also specified (SQLSTATE 42962). If the GENERATE KEY USING XMLPATTERN clause is specified, only one column can be specified, and the type of the column must be XML.

key-expression
Specifies an expression that must evaluate to a scalar value with the following restrictions:

- The expression must return a scalar value which can be indexed (no LOBs, XMLs, LONG VARCHAR or LONG VARGRAPHIC) (SQLSTATE 429BX)
- The following data types are not supported as input to the expression-based index key:
  - LONG VARCHAR and LONG VARGRAPHIC (deprecated data types)
  - XML
  - User defined distinct types on any of the types listed previously
  - User-defined weakly typed distinct types that include a data type constraint
  - User-defined structured types and reference types
  - Array, cursor, and row types
- The expression must contain at least one column reference (SQLSTATE 429BX)
- The expression cannot contain any of the following (SQLSTATE 429BX):
  - Subqueries
  - Aggregate functions
  - Non-deterministic functions
  - Functions with external actions
  - User-defined functions
  - Text search functions, such as SCORE, CONTAINS
  - Partitioning scalar functions, such as HASHEDVALUE
  - Dynamic data type scalar functions, such TYPE_ID, TYPE_NAME, TYPE_SCHEMA
  - Host Variables
  - Parameter markers
  - Sequence references
  - Special registers and built-in functions that depend on the value of a special register
  - Global variables and built-in functions that depend on the value of a global variable
  - A TYPE predicate
  - Regular expression functions or the REGEXP_LIKE predicate
  - A LIKE predicate
  - String scalar functions INSTR, INSTRB, LOCATE, LOCATE_IN_STRING, POSITION or POSSTR
  - OLAP specifications
  - Dereference operations or DEREF functions where the scoped reference argument is other than the object identifier (OID) column
  - CAST specifications with a SCOPE clause
  - Error tolerant nested-table-expressions

If an index key includes at least one *key-expression*, the index key is referred to as an expression-based index key.

ASC
Specifies that index entries are to be kept in ascending order of the column values; this is the default setting. ASC cannot be specified for indexes that are defined with EXTEND USING (SQLSTATE 42601).

DESC
Specifies that index entries are to be kept in descending order of the column values. DESC cannot be specified for indexes that are defined with EXTEND USING, or if the index is an index over XML data (SQLSTATE 42601).

RANDOM
Specifies that index entries are to be kept in random order of the column values. RANDOM cannot be specified in the following cases:

- With the EXTENDED USING clause (SQLSTATE 42613).
- With the SPECIFICATION ONLY clause (SQLSTATE 42613).
- For an index that is created on a declared or created globally temporary table (DGTT or CGTT) (SQLSTATE 42995).
- For an index that is created on a column-organized table (SQLSTATE 42858).
- If the CLUSTER option is specified (SQLSTATE 42613).
- On an indexed column that is of type CHAR or VARCHAR with ICU collations, except when the columns are declared as FOR BIT DATA (SQLSTATE 42997).
- On an indexed column that is of type GRAPHIC or VARGRAPHIC with ICU collations (SQLSTATE 42997).
- On an indexed column that is of type XML (SQLSTATE 42613).
- On an index which includes a *key-expression* (SQLSTATE 42997).

BUSINESS_TIME WITHOUT OVERLAPS
BUSINESS_TIME WITHOUT OVERLAPS can only be specified for an index defined as UNIQUE (SQLSTATE 428HW) to indicate that for the rest of the specified keys, the values are unique with respect to any period of time. BUSINESS_TIME WITHOUT OVERLAPS can only be specified as the last item in the list. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the end column and begin column of the period BUSINESS_TIME are automatically added to the index key in ascending order and enforce that there are no overlaps in time. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as key columns, as columns in the partitioning key, or as columns in the distribution key (SQLSTATE 428HW).

PARTITIONED
Indicates that a partitioned index should be created. The *table-name* must identify a table defined with data partitions (SQLSTATE 42601).

If the table is partitioned and neither PARTITIONED nor NOT PARTITIONED is specified, the index is created as partitioned (with a few exceptions). A nonpartitioned index is created instead of a partitioned index if any of the following situations apply:

- UNIQUE is specified and the index key does not include all the table partitioning key columns.
- A spatial index is created.

A partitioned index with a definition that duplicates the definition of a nonpartitioned index is not considered to be a duplicate index. For more details, see the "Rules" on page 1257 section in this topic.

The PARTITIONED keyword cannot be specified for the following indexes:

- An index on a nonpartitioned table (SQLSTATE 42601)
- A unique index where the index key does not explicitly include all the table partitioning key columns (SQLSTATE 42990)
- A spatial index (SQLSTATE 42997)

A partitioned index cannot be created on a partitioned table that has detached dependent tables, for example, MQTs (SQLSTATE 55019).

The table space placement for an index partition of the partitioned index is determined by the following rules:

- If the table being indexed was created using the *partition-tablespace-options* INDEX IN clause of the CREATE TABLE statement, the index partition is created in the table space specified in that INDEX IN clause.
- If the CREATE TABLE statement for the table being indexed did not specify the *partition-tablespace-options* INDEX IN clause, the index partition partitioned index is created in the same table space as the corresponding data partition that it indexes.

The IN clause of the CREATE INDEX statement is not supported for partitioned indexes (SQLSTATE 42601). The *tablespace-clauses* INDEX IN clause of the CREATE TABLE statement is ignored for partitioned indexes. If BUSINESS_TIME WITHOUT OVERLAPS is specified for the index key, the partitioning key columns must not include the begin or end column of the BUSINESS_TIME period (SQLSTATE 428HW).

NOT PARTITIONED
Indicates that a nonpartitioned index should be created that spans all of the data partitions defined for the table. The *table-name* must identify a table defined with data partitions (SQLSTATE 42601).

A nonpartitioned index with a definition that duplicates the definition of a partitioned index is not considered to be a duplicate index. For more details, see the "Rules" on page 1257 section in this topic.

The table space placement for a the nonpartitioned index is determined by the following rules:

- If you specify the IN clause of the CREATE INDEX statement, the nonpartitioned index is placed in the table space specified in that IN clause.
- If you do not specify the IN clause of the CREATE INDEX statement, the following rules determine the table space placement of the nonpartitioned index:
  - If the table being indexed was created using the *tablespace-clauses* INDEX IN clause of the CREATE TABLE statement, the nonpartitioned index is placed in the table space specified in that INDEX IN clause.
  - If the table being indexed was created without using the *tablespace-clauses* INDEX IN clause of the CREATE TABLE statement, the nonpartitioned index is created in the table space of the first visible or attached data partition of the table. The first visible or attached data partition of the table is the first partition in the list of data partitions that are sorted on the basis of range specifications. Also, the authorization ID of the statement is not required to have the USE privilege on the default table space.

IN *tablespace-name*
Specifies the table space in which the nonpartitioned index on a partitioned table is created. This clause cannot be specified for a partitioned index or an index on a nonpartitioned table (SQLSTATE 42601). The specification of a table space specifically for the index overrides a specification made using the INDEX IN clause when the table was created.

The table space specified by *tablespace-name* must be in the same database partition group as the data table spaces for the table and manage space in the same way as the other table spaces of the partitioned table (SQLSTATE 42838); it must be a table space on which the authorization ID of the statement holds the USE privilege.

If the IN clause is not specified, the index is created in the table space that was specified by the INDEX IN clause on the CREATE TABLE statement. If no INDEX IN clause was specified, the table space of the first visible or attached data partition of the table is used. This is the first partition in the list of data partitions that are sorted on the basis of range specifications. If the IN clause is not specified, the authorization ID of the statement is not required to have the USE privilege on the default table space.

SPECIFICATION ONLY
Indicates that this statement will be used to create an index specification that applies to the data source table referenced by *nickname*. SPECIFICATION ONLY must be specified if *nickname* is specified (SQLSTATE 42601). It cannot be specified if *table-name* is specified (SQLSTATE 42601).

If the index specification applies to an index that is unique, the database manager does not verify that the column values in the remote table are unique. If the remote column values are not unique, queries against the nickname that include the index column might return incorrect data or errors.

This clause cannot be used when creating an index on a created temporary table or declared temporary table (SQLSTATE 42995).

INCLUDE
This keyword introduces a clause that specifies additional columns to be appended to the set of index key columns. Any columns included with this clause are not used to enforce uniqueness. These included columns might improve the performance of some queries through index only access. The columns must be distinct from the columns used to enforce uniqueness (SQLSTATE 42711). UNIQUE must be specified when INCLUDE is specified (SQLSTATE 42613). The limits for the number of columns and sum of the length attributes apply to all of the columns in the unique key and in the index.

This clause cannot be used with created temporary tables or declared temporary tables (SQLSTATE 42995).

This clause cannot be used with column-organized tables (SQLSTATE 42858).

column-name
Identifies a column that is included in the index but not part of the unique index key. The same rules apply as defined for columns of the unique index key. The keywords ASC, DESC, or RANDOM can be specified following *column-name* but have no effect on the order.

key-expression
Specifies an expression that is included in the index but not part of the unique index key. The same rules apply as defined for expressions of the unique index key. The keywords ASC, DESC, or RANDOM can be specified after *key-expression* but have no effect on the order.

INCLUDE cannot be specified for indexes that are defined with EXTEND USING, if *nickname* is specified, or if the index is defined on an XML column (SQLSTATE 42601).

xml-index-specification
Specifies how index keys are generated from XML documents that are stored in an XML column. *xml-index-specification* cannot be specified if there is more than one index column, or if the column does not have the XML data type.

This clause only applies to XML columns (SQLSTATE 429BS).

GENERATE KEY USING XMLPATTERN *xmlpattern-clause*
Specifies the parts of an XML document that are to be indexed. XML pattern values are the indexed values generated by the *xmlpattern-clause*. List data type nodes are not supported in the index. If a node is qualified by the *xmlpattern-clause* and an XML schema exists that specifies that the node is a list data type, then the list data type node cannot be indexed (SQLSTATE 23526 for CREATE INDEX statements, or SQLSTATE 23525 for INSERT and UPDATE statements).

xmlpattern-clause
Contains a pattern expression that identifies the nodes that are to be indexed. It consists of an optional *namespace-declaration* and a required *pattern-expression*.

namespace-declaration
If the pattern expression contains qualified names, a *namespace-declaration* must be specified to define namespace prefixes. A default namespace can be defined for unqualified names.

DECLARE NAMESPACE *namespace-prefix=namespace-uri*
Maps *namespace-prefix*, which is an NCName, to *namespace-uri*, which is a string literal. The *namespace-declaration* can contain multiple *namespace-prefix*-to-

namespace-uri mappings. The *namespace-prefix* must be unique within the list of *namespace-declaration* (SQLSTATE 10503).

DECLARE DEFAULT ELEMENT NAMESPACE *namespace-uri*
Declares the default namespace URI for unqualified element names or types. If no default namespace is declared, unqualified names of elements and types are in no namespace. Only one default namespace can be declared (SQLSTATE 10502).

pattern-expression
Specifies the nodes in an XML document that are indexed. The *pattern-expression* can contain pattern-matching characters (*). It is similar to a path expression in XQuery, but represents a subset of the XQuery language that this database supports.

/ (forward slash)
Separates path expression steps.

// (double forward slash)
This is the abbreviated syntax for /descendant-or-self::node()/. You cannot use *// (double forward slash)* if you also specify UNIQUE.

forward-axis

child::
Specifies children of the context node. This is the default, if no other forward axis is specified.

@
Specifies attributes of the context node. This is the abbreviated syntax for attribute::.

attribute::
Specifies attributes of the context node.

descendant::
Specifies the descendants of the context node. You cannot use *descendant::* if you also specify UNIQUE.

self::
Specifies just the context node itself.

descendant-or-self::
Specifies the context node and the descendants of the context node. You cannot use descendant-or-self:: if you also specify UNIQUE.

xmlname-test
Specifies the node name for the step in the path using a qualified XML name (xml-qname) or a wildcard (xml-wildcard).

xml-ncname
An XML name as defined by XML 1.0. It cannot include a colon character.

xml-qname
Specifies a qualified XML name (also known as a QName) that can have two possible forms:

- xml-nsprefix:xml-ncname, where the xml-nsprefix is an xml-ncname that identifies an in-scope namespace
- xml-ncname, which indicates that the default namespace should be applied as the implicit xml-nsprefix

xml-wildcard
Specifies an xml-qname as a wildcard that can have three possible forms:

- * (a single asterisk character) indicates any xml-qname
- *xml-nsprefix*:* indicates any xml-ncname within the specified namespace
- *:*xml-ncname* indicates a specific XML name in any in-scope namespace

You cannot use *xml-wildcard* in the context step of a pattern expression if you also specify UNIQUE.

xmlkind-test

Use these options to specify what types of nodes you pattern match. The following options are available to you:

node()

Matches any node. You cannot use *node()* if you also specify UNIQUE.

text()

Matches any text node.

comment()

Matches any comment node.

processing-instruction()

Matches any processing instruction node. You cannot use processing-instruction() if you also specify UNIQUE.

function-step

Use these function calls to specify indexes with special properties, such as case insensitivity. Only one function step is allowed per XMLPATTERN clause. Function steps can be applied only on elements or attributes. No *xmlkind-test* option can be placed immediately before the function step. The function cannot be used in the middle of the XMLPATTERN, and must appear only in the final step. Currently, only the fn:upper-case and fn:exists functions are supported.

Note that instead of specifying the prefix fn: for the function name, you can specify another valid namespace, or you can omit fn: entirely.

fn:upper-case

Force the index values to be stored in the uppercase form. The first parameter of fn:upper-case is mandatory, and must be a context item expression (' . '); the second parameter is optional, and is the locale. If fn:upper-case appears in the pattern, VARCHAR and VARCHAR HASHED are the only index types supported.

fn:exists

Check for the existence of an element or attribute item in the XML document. If the item exists, this predicate returns true. The parameter of fn:exists is mandatory, and must be an element or attribute. If this function is used in the index path, the index type must be defined as VARCHAR(1).

xmltype-clause

AS *data-type*

Specifies the data type to which indexed values are converted before they are stored. Values are converted to the index XML data type that corresponds to the specified index SQL data type.

Table 134. Corresponding index data types

Index XML data type	**Index SQL data type**
xs:string	VARCHAR(*integer*), VARCHAR HASHED
xs:double	DOUBLE
xs:int	INTEGER
xs:decimal	DECIMAL
xs:date	DATE
xs:dateTime	TIMESTAMP

For VARCHAR(*integer*) and VARCHAR HASHED, the value is converted to an xs:string value using the XQuery function fn:string. The length attribute of VARCHAR(*integer*) is applied as a constraint to the resulting xs:string value. An index SQL data type of VARCHAR HASHED applies a hash algorithm to the resulting xs:string value to generate a hash code that is inserted into the index.

For indexes using the data types DOUBLE, DATE, INTEGER, DECIMAL, and TIMESTAMP, the value is converted to the index XML data type using the XQuery cast expression.

If the index is unique, the uniqueness of the value is enforced after the value is converted to the indexed type.

data-type
The following data type is supported:

sql-data-type
Supported SQL data types are:

VARCHAR(*integer*[OCTETS])
If this form of VARCHAR is specified, *integer* is used as a constraint. If document nodes that are to be indexed have values that are longer than *integer*, the documents are not inserted into the table if the index already exists. If the index does not exist, the index is not created. *integer* is a value between 1 and a page size-dependent maximum. Table 135 on page 1252 shows the maximum value for each page size.

Table 135. Maximum length of document nodes by page size

Page size	Maximum length of document node (bytes)
4KB	817
8KB	1841
16KB	3889
32KB	7985

XQuery semantics are used for string comparisons, where trailing blanks are significant. This differs from SQL semantics, where trailing blanks are insignificant during comparisons.

OCTETS
Specifies that the units of the length attribute is bytes.

When no string units are specified for a character string data type in a Unicode database, the string units are implicit and determined by the value of the NLS_STRING_UNITS global variable or *string_units* database configuration parameter. When the implicit string units are CODEUNITS32, the OCTETS keyword must be specified (SQLSTATE 42601).

In a non-Unicode database, the string units for character string data types are OCTETS.

VARCHAR HASHED
Specify VARCHAR HASHED to handle indexing of arbitrary length character strings. The length of an indexed string has no limit. An eight-byte hash code is generated over the entire string. Indexes that use these hashed character strings can be used only for equality lookups. XQuery semantics are used for string equality comparisons, where trailing blanks are significant. This differs from SQL semantics, where trailing blanks are insignificant during comparisons. The hash on the string preserves XQuery semantics for equality and not SQL semantics.

DOUBLE
Specifies that the data type DOUBLE is used for indexing numeric values. Unbounded decimal types and 64 bit integers may lose precision when they are stored as a DOUBLE value. The values for DOUBLE may include the special numeric values *NaN*, *INF*, *-INF*, *+0*, and *-0*, even though the SQL data type DOUBLE itself does not support these values.

INTEGER
Specifies that the data type INTEGER is used for indexing XML values. Note that the XML schema data type xs:integer allows a greater range of values than does the integer SQL data type. If an out-of-range value is encountered, an error is returned. If a value conforms to the lexical format of xs:double but does not conform to the lexical format of xs:int, such as 3.5, 3.0, or 3E1, an error is also returned.

DECIMAL(*integer*, *integer*)
Specifies that the data type DECIMAL is used for indexing XML values. The DECIMAL type takes two parameters, *precision* and *scale*. The first parameter, *precision*, is an integer constant with a value in the range of 1 to 31 that specifies the total number of digits. The second parameter, *scale*, is an integer constant that is greater than or equal to zero, and less than or equal to precision. The *scale* specifies the number of digits to the right of the decimal point.

Digits are not truncated from the end of a decimal number. An error is returned if the number of digits to the right of the decimal separator character is greater than the scale. Also, an error is returned if the number of significant digits to the left of the decimal character (the whole part of the number) is greater than precision.

DATE
Specifies that the data type DATE is used for indexing XML values. Note that the XML schema data type for xs:date allows greater range of values than the pureXML® xs:date data type that corresponds to the SQL data type. If an out-of-range value is encountered, an error is returned.

TIMESTAMP
Specifies that the data type TIMESTAMP is used for indexing XML values. Note that the XML schema data type for xs:dateTime allows greater range of values and fractional seconds precision than the pureXML xs:dateTime data type that corresponds to the SQL data type. If an out-of range value is encountered, an error is returned.

IGNORE INVALID VALUES
Specifies that XML pattern values that are invalid lexical forms for the target index XML data type are ignored and that the corresponding values in the stored XML documents are not indexed by the CREATE INDEX statement. By default, invalid values are ignored. During insert and update operations, the invalid XML pattern values are not indexed, but XML documents are still inserted into the table. No error or warning is raised, because specifying these data types is not a constraint on the XML pattern values (XQuery expressions that search for the specific XML index data type will not consider these values).

The rules for what XML pattern values can be ignored are determined by the specified SQL data type.

- If the SQL data type is VARCHAR(*integer*) or VARCHAR HASHED, XML pattern values are never ignored since any sequence of characters is valid.
- If the SQL data type is DOUBLE, DECIMAL, or INTEGER, any XML pattern value that does not conform to the lexical format of the XML data type xs:double is ignored. If the SQL data type is DECIMAL or INTEGER and the XML pattern value conforms to the lexical format of the XML data type xs:double but not to the lexical format of xs:decimal or

xs:int, respectively, an error is returned. For example, if the SQL data type is INTEGER, the XML pattern values of 3.5, 3.0, and 3e0 conform to the lexical format of xs:double but return an error (SQLSTATE 23525) because they do not conform to the lexical format of xs:int. XML pattern values such as 'A123' or 'hello' are ignored for the same index.

- If the SQL data type is a datetime data type, any XML pattern value that does not conform to the lexical format of the corresponding XML data type (xs:date or xs:dateTime) is ignored.

If an XML pattern value does conform to the appropriate lexical format, an error is returned if the value is outside the value space for the data type or exceeds the maximum length or precision and scale of the specified SQL data type. If the index does not exist, the index is not created (SQLSTATE 23526).

REJECT INVALID VALUES
All XML pattern values must be valid in the context of the lexical definition of the index XML data type. In addition the value must be in the range of the value space of the index XML data type. See the Related reference section, later, for links to details on the lexical definition and value space for each data type. For example, when you specify the REJECT INVALID VALUES clause, if you create an index of INTEGER type, XML pattern values such as 3.5, 3.0, 3e0, 'A123' and 'hello' will return an error (SQLSTATE 23525). XML data is not inserted or updated in the table if the index already exists (SQLSTATE 23525). If the index does not exist, the index is not created (SQLSTATE 23526).

CLUSTER
Specifies that the index is the clustering index of the table. The cluster factor of a clustering index is maintained or improved dynamically as data is inserted into the associated table, by attempting to insert new rows physically close to the rows for which the key values of this index are in the same range. Only one clustering index may exist for a table so CLUSTER may not be specified if it was used in the definition of any existing index on the table (SQLSTATE 55012). A clustering index may not be created on a table that is defined to use append mode (SQLSTATE 428D8).

CLUSTER is disallowed if *nickname* is specified, or if the index is an index over XML data (SQLSTATE 42601).

This clause cannot be used with the following types of tables:

- Created temporary tables or declared temporary tables (SQLSTATE 42995)
- Range-clustered tables (SQLSTATE 429BG)
- Column-organized tables (SQLSTATE 42858)

EXTEND USING *index-extension-name*
Names the *index-extension* used to manage this index. If this clause is specified, then there must be only one *column-name* specified and that column must be a structured type or a distinct type (SQLSTATE 42997). The *index-extension-name* must name an index extension described in the catalog (SQLSTATE 42704). For a distinct type, the column must exactly match the type of the corresponding source key parameter in the index extension. For a structured type column, the type of the corresponding source key parameter must be the same type or a supertype of the column type (SQLSTATE 428E0).

This clause cannot be used with created temporary tables or declared temporary tables (SQLSTATE 42995).

This clause cannot be used with column-organized tables (SQLSTATE 42858).

Starting with IBM Db2 10.5, this clause is also supported in Db2 pureScale environments. For version 10.5 Fix Pack 3 and earlier fix pack releases, this clause is not supported in Db2 pureScale environments (SQLSTATE 56038).

This clause cannot be used if the index key contains at least one *key-expression* (SQLSTATE 42601).

constant-expression
Identifies values for any required arguments for the index extension. Each expression must be a constant value with a data type that exactly matches the defined data type of the corresponding

index extension parameters, including length or precision, and scale (SQLSTATE 428E0). This clause must not exceed 32 768 bytes in length in the database code page (SQLSTATE 22001).

PCTFREE *integer*
Specifies what percentage of each index page to leave as free space when building the index. The first entry in a page is added without restriction. When additional entries are placed in an index page at least *integer* percent of free space is left on each page. The value of *integer* can range from 0 to 99. If a value greater than 10 is specified, only 10 percent free space will be left in non-leaf pages.

If an explicit value for PCTFREE is not provided, and if **DB2_INDEX_PCTFREE_DEFAULT** is not set, then PCTFREE will have a default value of 10.

PCTFREE is disallowed if *nickname* is specified (SQLSTATE 42601). This clause cannot be used with created temporary tables or declared temporary tables (SQLSTATE 42995).

LEVEL2 PCTFREE *integer*
Specifies what percentage of each index level 2 page to leave as free space when building the index. The value of *integer* can range from 0 to 99. If LEVEL2 PCTFREE is not set, a minimum of 10 or PCTFREE percent of free space is left on all non-leaf pages. If LEVEL2 PCTFREE is set, *integer* percent of free space is left on level 2 intermediate pages, and a minimum of 10 or *integer* percent of free space is left on level 3 and higher intermediate pages.

LEVEL2 PCTFREE is disallowed if *nickname* is specified (SQLSTATE 42601). This clause cannot be used with created temporary tables or declared temporary tables (SQLSTATE 42995).

MINPCTUSED *integer*
Indicates whether index leaf pages are merged online, and the threshold for the minimum percentage of space used on an index leaf page. If, after a key is removed from an index leaf page, the percentage of space used on the page is at or below *integer* percent, an attempt is made to merge the remaining keys on this page with those of a neighboring page. If there is sufficient space on one of these pages, the merge is performed and one of the pages is deleted. The value of *integer* can be from 0 to 99. A value of 50 or below is recommended for performance reasons. Specifying this option will have an impact on update and delete performance. Merging is only done during update and delete operations when an exclusive table lock is held. If an exclusive table lock does not exist, keys are marked as pseudo deleted during update and delete operations, and no merging is done. Consider using the CLEANUP ONLY ALL option of REORG INDEXES to merge leaf pages instead of using the MINPCTUSED option of CREATE INDEX.

MINPCTUSED is disallowed if *nickname* is specified (SQLSTATE 42601). This clause cannot be used with created temporary tables or declared temporary tables (SQLSTATE 42995).

DISALLOW REVERSE SCANS
Specifies that an index only supports forward scans or scanning of the index in the order that was defined at index creation time.

DISALLOW REVERSE SCANS cannot be specified together with *nickname* (SQLSTATE 42601).

ALLOW REVERSE SCANS
Specifies that an index can support both forward and reverse scans; that is, scanning of the index in the order that was defined at index creation time, and scanning in the opposite order.

ALLOW REVERSE SCANS cannot be specified together with *nickname* (SQLSTATE 42601).

PAGE SPLIT
Specifies the page split behavior when values are inserted into an index. The default is SYMMETRIC.

SYMMETRIC
Specifies that pages are to be split roughly in the middle. Use this option in the following situations:

- When the insertion into an index is random
- When the insertion into an index does not follow the patterns that are addressed by the PAGE SPLIT HIGH and PAGE SPLIT LOW options

HIGH
Specifies an index page split behavior that uses the space on index pages efficiently when there are ever-increasing values in the index. Increasing values in the index might occur when the following conditions are met:

- There is an index with multiple key parts and there are multiple index pages of values where all except the last key part has the same value.
- All insert operations into the table consist of a new value, which has the same value as existing keys for all but the last key part.
- The last key part of the inserted value is larger than the values of the existing keys.

For example, assume that an index has the following key values:

```
(1,1),(1,2),(1,3), ... (1,n),
(2,1),(2,2),(2,3), ... (2,n),
...
(m,1),(m,2),(m,3), ... (m,n)
```

The next key to be inserted would have the value `(x,y)` where `1 <= x <= m` and `y > n`.

In such cases, use the PAGE SPLIT HIGH clause so that page splits do not result in many pages that are 50 percent empty.

LOW
Specifies an index page split behavior that uses the space on index pages efficiently when there are ever-decreasing values in the index. Decreasing values in the index might occur when the following conditions are met:

- There is an index with multiple key parts and there are multiple index pages of values where all except the last key part has the same value.
- All insert operations into the table consist of a new value, which has the same value as existing keys for all but the last key part.
- The last key part of the inserted value is smaller than the values of the existing keys.

In such cases, use the PAGE SPLIT LOW clause so that page splits do not result in many pages that are 50 percent empty.

COLLECT STATISTICS
Specifies that basic index statistics are to be collected during index creation.

SAMPLED
Specifies that a sampling technique is to be used when processing index entries to collect extended index statistics. This option is used to balance performance considerations with the need for accuracy of the statistics. This option is the default when DETAILED is specified immediately following the keyword COLLECT.

UNSAMPLED
Specifies that sampling is not to be used when processing index entries to collect extended index statistics. Instead, each index entry is examined individually. This option can significantly increase CPU and memory consumption.

DETAILED
Specifies that extended index statistics (CLUSTERFACTOR and PAGE_FETCH_PAIRS) are also to be collected during index creation.

COMPRESS
Specifies whether index compression is enabled. By default, index compression will be enabled if data row compression is enabled or if the table is a declared global temporary table (DGTT) or created global temporary table (CGTT); index compression will be disabled if data row compression is disabled. This option can be used to override the default behavior. COMPRESS is disallowed if *nickname* is specified (SQLSTATE 42601).

YES
Specifies that index compression is enabled. Insert and update operations on the index will be subject to compression.

NO
Specifies that index compression is disabled.

INCLUDE NULL KEYS
Specifies that an index entry is created when all parts of the index key contain the null value. This is the default setting.

EXCLUDE NULL KEYS
Specifies that an index entry is not created when all parts of the index key contain the null value. When any part of the index key is not a null value, an index entry is created. You cannot specify **EXCLUDE NULL KEYS** with the following syntax elements:

- A nickname
- The **GENERATE KEY USING XMLPATTERN** clause
- The **EXTEND USING** clause.

If an index is defined as unique, rows with null keys are not considered when enforcing uniqueness.

This clause cannot be used with column-organized tables (SQLSTATE 42858).

Rules

- The CREATE INDEX statement fails (SQLSTATE 01550) when attempting to create an index that matches an existing index.

  A number of factors are used to determine if two indexes match. These factors are combined in various different ways into the rules that determine if two indexes match. The following factors are used to determine if two indexes match:

  1. The sets of index columns and key expressions, including any INCLUDE columns and key expressions, are the same in both indexes.
  2. The ordering of index key columns and key expressions, including any INCLUDE columns, is the same in both indexes.
  3. The key columns and key expressions of the new index are the same or a superset of the key columns and key expressions in the existing index.
  4. The ordering attributes of the columns and key expressions are the same in both indexes.
  5. The existing index is unique.
  6. Both indexes are non-unique.

  The following combinations of these factors form the rules that determine when two indexes are considered duplicates:

  – "1" on page 1257 + "2" on page 1257 + "4" on page 1257 + "5" on page 1257
  – "1" on page 1257 + "2" on page 1257 + "4" on page 1257 + "6" on page 1257
  – "1" on page 1257 + "2" on page 1257 + "3" on page 1257 + "5" on page 1257

  Exceptions:

  – If one of the compared indexes is partitioned and the other of the compared indexes is nonpartitioned, the indexes are not considered duplicates if the indexes have different names, even if other matching index conditions are met.
  – For indexes over XML data, the index descriptions are not considered duplicates if the index names are different, even if the indexed XML column, the XML patterns, and the data type, including its options, are identical.
- Unique indexes on system-maintained MQTs are not supported (SQLSTATE 42809).
- The COLLECT STATISTICS options are not supported if a nickname is specified (SQLSTATE 42601).

- The creation of an index with an expression-based key in a partitioned database environment is supported only from the catalog database partition (SQLSTATE 42997).
- **Restrictions for indexes on column-organized tables:**
  - The following clauses are not supported when creating an index on a column-organized table (SQLSTATE 42858):
    - RANDOM
    - CLUSTER
    - EXTEND USING
    - INCLUDE
    - EXCLUDE NULL KEYS
    - *key-expression*
- **Indexes cannot be created on column-organized temporary tables.**

Notes

- Concurrent read/write access during index creation, and default index creation behavior differs for indexes on nonpartitioned tables, nonpartitioned indexes, partitioned indexes, and indexes in a Db2 pureScale environment:
  - For nonpartitioned indexes, concurrent read/write access to the table is permitted while an index is being created, except when the EXTEND USING clause is specified. Once the index has been built, changes that were made to the table during index creation time are forward-fitted to the new index. Write access to the table is then blocked while index creation completes, after which the new index becomes available.
  - For partitioned indexes, concurrent read/write access to the table is permitted while an index is being created, except when the EXTEND USING clause is specified. Once the index partition has been built, changes that were made to the partition during creation time of that index partition are forward-fitted to the new index partition. Write access to the data partition is then blocked while index creation completes on the remaining data partitions. After the index partition for the last data partition is built and the transaction is committed, all data partitions are available for read and write.
  - Prior to Version 11.5, in a Db2 pureScale environment, concurrent read access during index creation is the default behavior. You can enable concurrent write access by setting the registry variable *DB2_INDEX_CREATE_ALLOW_WRITE* to ON. For more information, see **DB2_INDEX_CREATE_ALLOW_WRITE**. Starting in Version 11.5, in a Db2 pureScale environment, concurrent write access is enabled by default.

  CREATE INDEX tries to forward-fit the concurrent changes before blocking writers. However, if there is a lot of concurrent database activity such that CREATE INDEX is not able to keep up with the changes coming in, it will block new writers sooner so it can complete the forward-fit. CREATE INDEX does as much of the create completion work as it can before writers are blocked, to keep the period of unavailability as short as possible. The size of the index and the amount of current activity impact this period of time.

  To circumvent this default behavior, use the LOCK TABLE statement to explicitly lock the table before issuing a CREATE INDEX statement. (The table can be locked in either SHARE or EXCLUSIVE mode, depending on whether read access is to be allowed.)
- If the named table already contains data, CREATE INDEX creates the index entries for it. If the table does not yet contain data, CREATE INDEX creates a description of the index; the index entries are created when data is inserted into the table.
- Once the index is created and data is loaded into the table, it is advisable to issue the RUNSTATS command. The RUNSTATS command updates statistics collected on the database tables, columns, and indexes. These statistics are used to determine the optimal access path to the tables. By issuing the RUNSTATS command, the database manager can determine the characteristics of the new index. If data has been loaded before the CREATE INDEX statement is issued, it is recommended that the COLLECT

STATISTICS option on the CREATE INDEX statement be used as an alternative to the RUNSTATS command.

- If you collect statistics during index creation, the resulting statistics might be inconsistent. If the table has been modified since you last collected statistics on the table and its existing indexes, you should subsequently run the RUNSTATS command to provide a set of consistent statistics across the table and all of its indexes.
- Creating an index with a schema name that does not already exist will result in the implicit creation of that schema provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- The optimizer can recommend indexes before creating the actual index.
- If an index specification is being defined for a data source table that has an index, the name of the index specification does not have to match the name of the index.
- The explain facility, the Design Advisor, or the EXPLAIN option in Data Server Manager can be used to recommend indexes before creating the actual index. However, none of these methods will recommend indexes containing expression-based keys.
- ***Collecting index statistics***: The UNSAMPLED DETAILED option is available to change the way index statistics are collected. However, it should be used only in cases where it is clear that DETAILED does not yield accurate statistics.
- ***Generated Objects***: If an index is created with expression-based keys, a system-generated statistical view and a system-generated package will also be created and associated with the index.
- ***Syntax alternatives***: The following syntax is tolerated and ignored:
  - CLOSE
  - DEFINE
  - FREEPAGE
  - GBPCACHE
  - PIECESIZE
  - TYPE 2
  - using-block

  The following syntax is accepted as the default behavior:
  - COPY NO
  - DEFER NO

Examples

- *Example 1:* Create an index named UNIQUE_NAM on the PROJECT table. The purpose of the index is to ensure that there are not two entries in the table with the same value for project name (PROJNAME). The index entries are to be in ascending order.

```
CREATE UNIQUE INDEX UNIQUE_NAM
   ON PROJECT(PROJNAME)
```

- *Example 2:* Create an index named JOB_BY_DPT on the EMPLOYEE table. Arrange the index entries in ascending order by job title (JOB) within each department (WORKDEPT).

```
CREATE INDEX JOB_BY_DPT
   ON EMPLOYEE (WORKDEPT, JOB)
```

- *Example 3:* The nickname EMPLOYEE references a data source table called CURRENT_EMP. After this nickname was created, an index was defined on CURRENT_EMP. The columns chosen for the index key were WORKDEBT and JOB. Create an index specification that describes this index. Through this

specification, the optimizer will know that the index exists and what its key is. With this information, the optimizer can improve its strategy to access the table.

```
CREATE UNIQUE INDEX JOB_BY_DEPT
  ON EMPLOYEE (WORKDEPT, JOB)
  SPECIFICATION ONLY
```

- *Example 4:* Create an extended index type named SPATIAL_INDEX on a structured type column location. The description in index extension GRID_EXTENSION is used to maintain SPATIAL_INDEX. The literal is given to GRID_EXTENSION to create the index grid size.

```
CREATE INDEX SPATIAL_INDEX ON CUSTOMER (LOCATION)
  EXTEND USING (GRID_EXTENSION (x'000100100010001000400010'))
```

- *Example 5:* Create an index named IDX1 on a table named TAB1, and collect basic index statistics on index IDX1.

```
CREATE INDEX IDX1 ON TAB1 (col1) COLLECT STATISTICS
```

- *Example 6:* Create an index named IDX2 on a table named TAB1, and collect detailed index statistics on index IDX2.

```
CREATE INDEX IDX2 ON TAB1 (col2) COLLECT DETAILED STATISTICS
```

- *Example 7:* Create an index named IDX3 on a table named TAB1, and collect detailed index statistics on index IDX3 using sampling.

```
CREATE INDEX IDX3 ON TAB1 (col3) COLLECT SAMPLED DETAILED STATISTICS
```

- *Example 8:* Create a unique index named A_IDX on a partitioned table named MYNUMBERDATA in table space IDX_TBSP.

```
CREATE UNIQUE INDEX A_IDX ON MYNUMBERDATA (A) IN IDX_TBSP
```

- *Example 9:* Create a non-unique index named B_IDX on a partitioned table named MYNUMBERDATA in table space IDX_TBSP.

```
CREATE INDEX B_IDX ON MYNUMBERDATA (B)
  NOT PARTITIONED IN IDX_TBSP
```

- *Example 10:* Create an index over XML data on a table named COMPANYINFO, which contains an XML column named COMPANYDOCS. The XML column COMPANYDOCS contains a large number of XML documents similar to the one below:

```
<company name="Company1">
  <emp id="31201" salary="60000" gender="Female">
    <name>
      <first>Laura</first>
      <last>Brown</last>
    </name>
    <dept id="M25">
      Finance
    </dept>
  </emp>
</company>
```

Users of the COMPANYINFO table often need to retrieve employee information using the employee ID. An index like the following one can make that retrieval more efficient.

```
CREATE INDEX EMPINDEX ON COMPANYINFO(COMPANYDOCS)
  GENERATE KEY USING XMLPATTERN '/company/emp/@id'
    AS SQL DOUBLE
```

- *Example 11:* The following index is logically equivalent to the index created in the previous example, except that it uses unabbreviated syntax.

```
CREATE INDEX EMPINDEX ON COMPANYINFO(COMPANYDOCS)
  GENERATE KEY USING XMLPATTERN '/child::company/child::emp/attribute::id'
    AS SQL DOUBLE
```

- *Example 12:* Create an index on a column named DOC, indexing only the book title as a VARCHAR(100). Because the book title should be unique across all books, the index must be unique.

```
CREATE UNIQUE INDEX MYDOCSIDX ON MYDOCS(DOC)
  GENERATE KEY USING XMLPATTERN '/book/title'
    AS SQL VARCHAR(100)
```

- *Example 13:* Create an index on a column named DOC, indexing the chapter number as a DOUBLE. This example includes namespace declarations.

```
CREATE INDEX MYDOCSIDX ON MYDOCS(DOC)
  GENERATE KEY USING XMLPATTERN
    'declare namespace b="http://www.example.com/book/";
     declare namespace c="http://acme.org/chapters";
       /b:book/c:chapter/@number'
    AS SQL DOUBLE
```

- *Example 14:* Create a unique index named IDXPROJEST on table PROJECT and include column PRSTAFF to allow index-only access of the estimated mean staffing information.

```
CREATE UNIQUE INDEX IDXPROJEST ON PROJECT (PROJNO) INCLUDE (PRSTAFF)
```

- *Example 15:* Create a unique index on a column named USER_ID and exclude null keys from that index.

```
CREATE UNIQUE INDEX IDXUSERID ON CUSTOMER (USER_ID) EXCLUDE NULL KEYS
```

- *Example 16:* Create an index with an expression-based key using upper case of employee's name and ID:

```
CREATE INDEX EMP_UPPERNAME ON EMPLOYEE (UPPER(NAME), ID)
```

CREATE INDEX EXTENSION

The CREATE INDEX EXTENSION statement defines an extension object for use with indexes on tables that have structured type or distinct type columns.

Invocation

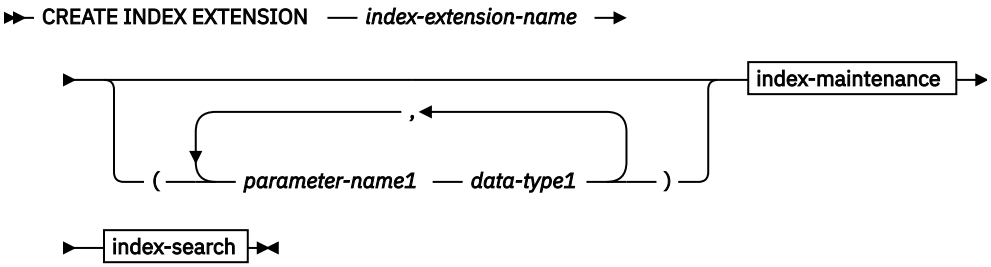
This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

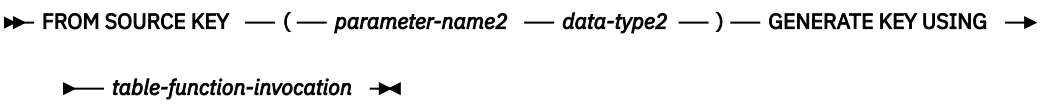
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the schema name of the index extension does not refer to an existing schema
- CREATEIN privilege on the schema, if the schema name of the index extension refers to an existing schema
- SCHEMAADM authority on the schema, if the schema name of the index extension refers to an existing schema
- DBADM authority

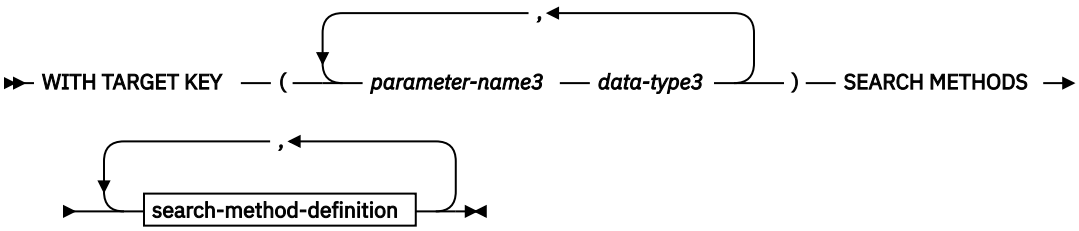
Syntax



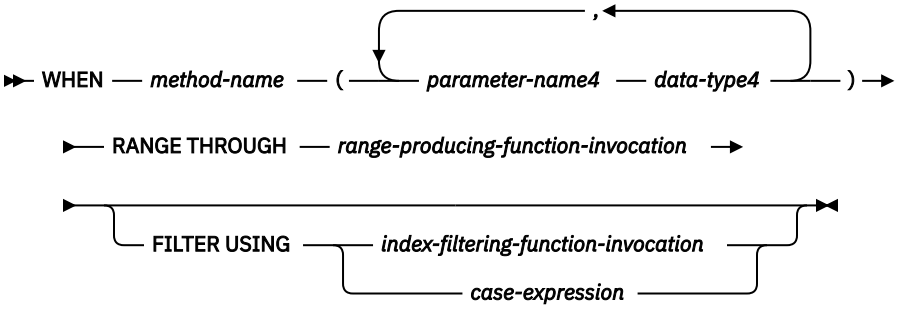
index-maintenance



index-search



search-method-definition



Description

index-extension-name

Names the index extension. The name, including the implicit or explicit qualifier, must not identify an index extension described in the catalog. If a two-part *index-extension-name* is specified, the schema name cannot begin with 'SYS'; otherwise, an error is returned (SQLSTATE 42939).

parameter-name1

Identifies a parameter that is passed to the index extension at CREATE INDEX time to define the actual behavior of this index extension. The parameter that is passed to the index extension is called an *instance parameter*, because that value defines a new instance of an index extension.

parameter-name1 must be unique within the definition of the index extension. No more than 90 parameters are allowed. If this limit is exceeded, an error (SQLSTATE 54023) is returned.

data-type1

Specifies the data type of each parameter. One entry in the list must be specified for each parameter that the index extension will expect to receive. The only SQL data types that can be specified are those that can be used as constants, such as VARCHAR, INTEGER, DECIMAL, DOUBLE, or VARGRAPHIC (SQLSTATE 429B5). The decimal floating-point data type cannot be specified (SQLSTATE 429B5). The parameter value that is received by the index extension at

CREATE INDEX must match *data-type1* exactly, including length, precision, and scale (SQLSTATE 428E0).

Character and graphic string data types cannot specify string units of CODEUNITS32.

index-maintenance
Specifies how the index keys of a structured or distinct type column are maintained. Index maintenance is the process of transforming the source column to a target key. The transformation process is defined using a table function that has previously been defined in the database.

FROM SOURCE KEY (*parameter-name2 data-type2*)
Specifies a structured data type or distinct type for the source key column that is supported by this index extension.

parameter-name2
Identifies the parameter that is associated with the source key column. A source key column is the index key column (defined in the CREATE INDEX statement) with the same data type as *data-type2*.

data-type2
Specifies the data type for *parameter-name2*; *data-type2* must be a user-defined structured type or a distinct type that is not sourced on LOB, XML, or DECFLOAT (SQLSTATE 42997). When the index extension is associated with the index at CREATE INDEX time, the data type of the index key column must:

- Exactly match *data-type2* if it is a distinct type; or
- Be the same type or a subtype of *data-type2* if it is a structured type

Otherwise, an error is returned (SQLSTATE 428E0).

GENERATE KEY USING *table-function-invocation*
Specifies how the index key is generated using a user-defined table function. Multiple index entries may be generated for a single source key data value. An index entry cannot be duplicated from a single source key data value (SQLSTATE 22526). The function can use *parameter-name1*, *parameter-name2*, or a constant as arguments. If the data type of *parameter-name2* is a structured data type, only the observer methods of that structured type can be used in its arguments (SQLSTATE 428E3). The output of the GENERATE KEY function must be specified in the TARGET KEY specification. The output of the function can also be used as input for the index filtering function specified on the FILTER USING clause.

The function used in *table-function-invocation* must:

- Resolve to a table function (SQLSTATE 428E4)
- Not be defined with PARAMETER CCSID UNICODE if this database is not a Unicode database (SQLSTATE 428E4)
- Not be defined with LANGUAGE SQL (SQLSTATE 428E4)
- Not be defined with NOT DETERMINISTIC (SQLSTATE 428E4) or EXTERNAL ACTION (SQLSTATE 428E4)
- Be defined with NO SQL (SQLSTATE 428E4)
- Not have a structured data type, LOB or XML (SQLSTATE 428E3) in the data type of the parameters, with the exception of system-generated observer methods
- Not include a subquery (SQLSTATE 428E3)
- Not include an XMLQUERY or XMLEXISTS expression (SQLSTATE 428E3)
- Return columns with data types that follow the restrictions for data types of columns of an index defined without the EXTEND USING clause

If an argument invokes another operation or routine, it must be an observer method (SQLSTATE 428E3).

The definer of the index extension must have EXECUTE privilege on the function, EXECUTEIN privilege on the schema containing this function, or DATAACCESS authority on the schema containing this function.

index-search
Specifies how searching is performed by providing a mapping of the search arguments to search ranges.

WITH TARGET KEY
Specifies the target key parameters that are the output of the key generation function specified on the GENERATE KEY USING clause.

parameter-name3
Identifies the parameter associated with a given target key. *parameter-name3* corresponds to the columns of the RETURNS table as specified in the table function of the GENERATE KEY USING clause. The number of parameters specified must match the number of columns returned by that table function (SQLSTATE 428E2).

data-type3
Specifies the data type for each corresponding *parameter-name3*. *data-type3* must exactly match the data type of each corresponding output column of the RETURNS table, as specified in the table function of the GENERATE KEY USING clause (SQLSTATE 428E2), including the length, precision, and type.

SEARCH METHODS
Introduces the search methods that are defined for the index.

search-method-definition
Specifies the method details of the index search. It consists of a method name, the search arguments, a range producing function, and an optional index filter function.

WHEN *method-name*
The name of a search method. This is an SQL identifier that relates to the method name specified in the index exploitation rule (found in the PREDICATES clause of a user-defined function). A *search-method-name* can be referenced by only one WHEN clause in the search method definition (SQLSTATE 42713).

parameter-name4
Identifies the parameter of a search argument. These names are for use in the RANGE THROUGH and FILTER USING clauses.

data-type4
The data type associated with a search parameter.

RANGE THROUGH *range-producing-function-invocation*
Specifies an external table function that produces search ranges. This function uses *parameter-name1*, *parameter-name4*, or a constant as arguments and returns a set of search ranges.

The table function used in *range-producing-function-invocation* must:

- Resolve to a table function (SQLSTATE 428E4)
- Not include a subquery (SQLSTATE 428E3) or SQL function (SQLSTATE 428E4) in its arguments
- Not include an XMLQUERY or XMLEXISTS expression in its arguments (SQLSTATE 428E3)
- Not be defined with PARAMETER CCSID UNICODE if this database is not a Unicode database (SQLSTATE 428E4)
- Not be defined with LANGUAGE SQL (SQLSTATE 428E4)
- Not be defined with NOT DETERMINISTIC or EXTERNAL ACTION (SQLSTATE 428E4)
- Be defined with NO SQL (SQLSTATE 428E4)

The number and types of this function's results must relate to the results of the table function specified in the GENERATE KEY USING clause (SQLSTATE 428E1) by:

- Returning up to twice as many columns as returned by the key transformation function

- Having an even number of columns, in which the first half of the return columns defines the start of the range (start key values), and the second half of the return columns defines the end of the range (stop key values)
- Having each start key column with the same type as the corresponding stop key column
- Having the type of each start key column be the same as the corresponding key transformation function column

More precisely, let $a_1:t_1$, ..., $a_n:t_n$ be the function result columns and data types of the key transformation function. The function result columns of the *range-producing-function-invocation* must be $b_1:t_1$, ..., $b_m:t_m$, $c_1:t_1$, ..., $c_m:t_m$, where m <= n and the "b" columns are the start key columns and the "c" columns are the stop key columns.

When the *range-producing-function-invocation* returns a null value as the start or stop key value, the semantics are undefined.

The definer of the index extension must have EXECUTE privilege on the function, EXECUTEIN privilege on the schema containing this function, or DATAACCESS authority on the schema containing this function.

FILTER USING

Allows specification of an external function or a case expression to be used for filtering index entries that were returned after applying the range-producing function.

index-filtering-function-invocation

Specifies an external function to be used for filtering index entries. This function uses the *parameter-name1*, *parameter-name3*, *parameter-name4*, or a constant as arguments (SQLSTATE 42703) and returns an integer (SQLSTATE 428E4). If the value returned is 1, the row corresponding to the index entry is retrieved from the table. Otherwise, the index entry is not considered for further processing.

If not specified, index filtering is not performed.

The function used in the *index-filtering-function-invocation* must:

- Not be defined with PARAMETER CCSID UNICODE if this database is not a Unicode database (SQLSTATE 428E4)
- Not be defined with LANGUAGE SQL (SQLSTATE 429B4)
- Not be defined with NOT DETERMINISTIC or EXTERNAL ACTION (SQLSTATE 42845)
- Be defined with NO SQL (SQLSTATE 428E4)
- Not have a structured data type in the data type of any of the parameters (SQLSTATE 428E3)
- Not include a subquery (SQLSTATE 428E3)
- Not include an XMLQUERY or XMLEXISTS expression (SQLSTATE 428E3)

If an argument invokes another function or method, these rules are also enforced for this nested function or method. However, system-generated observer methods are allowed as arguments to the filter function (or any function or method used as an argument), as long as the argument results in a built-in data type.

The definer of the index extension must have EXECUTE privilege on the function, EXECUTEIN privilege on the schema containing this function, or DATAACCESS authority on the schema containing this function..

case-expression

Specifies a case expression for filtering index entries. Either *parameter-name1*, *parameter-name3*, *parameter-name4*, or a constant (SQLSTATE 42703) can be used in the *searched-when-clause* and *simple-when-clause*. An external function with the rules specified in FILTER USING *index-filtering-function-invocation* may be used in *result-expression*. Any function referenced in the *case-expression* must also conform to the rules listed under *index-filtering-function-invocation*. In addition, subqueries and XMLQUERY or XMLEXISTS expressions cannot be used anywhere else in the *case-expression* (SQLSTATE 428E4). The case expression must return an integer (SQLSTATE

428E4). A return value of 1 in the *result-expression* means that the index entry is kept; otherwise, the index entry is discarded.

Notes

- Creating an index extension with a schema name that does not already exist will result in the implicit creation of that schema, provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.

Example

The following example creates an index extension called *grid_extension* that uses a structured type SHAPE column in a table function called *gridEntry* to generate seven index target keys. This index extension also provides two index search methods to produce search ranges when given a search argument.

```
CREATE INDEX EXTENSION GRID_EXTENSION (LEVELS VARCHAR(20) FOR BIT DATA)
  FROM SOURCE KEY (SHAPECOL SHAPE)
  GENERATE KEY USING GRIDENTRY(SHAPECOL..MBR..XMIN,
                               SHAPECOL..MBR..YMIN,
                               SHAPECOL..MBR..XMAX,
                               SHAPECOL..MBR..YMAX,
                               LEVELS)
  WITH TARGET KEY (LEVEL INT, GX INT, GY INT,
                   XMIN INT, YMIN INT, XMAX INT, YMAX INT)
  SEARCH METHODS
  WHEN SEARCHFIRSTBYSECOND (SEARCHARG SHAPE)
  RANGE THROUGH GRIDRANGE(SEARCHARG..MBR..XMIN,
                               SEARCHARG..MBR..YMIN,
                               SEARCHARG..MBR..XMAX,
                               SEARCHARG..MBR..YMAX,
                               LEVELS)
  FILTER USING
    CASE WHEN (SEARCHARG..MBR..YMIN > YMAX) OR
       SEARCHARG..MBR..YMAX < YMIN) THEN 0
    ELSE CHECKDUPLICATE(LEVEL, GX, GY,
                              XMIN, YMIN, XMAX, YMAX,
                              SEARCHARG..MBR..XMIN,
                              SEARCHARG..MBR..YMIN,
                              SEARCHARG..MBR..XMAX,
                              SEARCHARG..MBR..YMAX,
                              LEVELS)
    END
  WHEN SEARCHSECONDBYFIRST (SEARCHARG SHAPE)
  RANGE THROUGH GRIDRANGE(SEARCHARG..MBR..XMIN,
                               SEARCHARG..MBR..YMIN,
                               SEARCHARG..MBR..XMAX,
                               SEARCHARG..MBR..YMAX,
                               LEVELS)
  FILTER USING
    CASE WHEN (SEARCHARG..MBR..YMIN > YMAX) OR
       SEARCHARG..MBR..YMAX < YMIN) THEN 0
    ELSE MBROVERLAP(XMIN, YMIN, XMAX, YMAX,
                               SEARCHARG..MBR..XMIN,
                               SEARCHARG..MBR..YMIN,
                               SEARCHARG..MBR..XMAX,
                               SEARCHARG..MBR..YMAX)
    END
```

CREATE MASK

The CREATE MASK statement creates a column mask at the current server. A column mask specifies the value to be returned for a specified column.

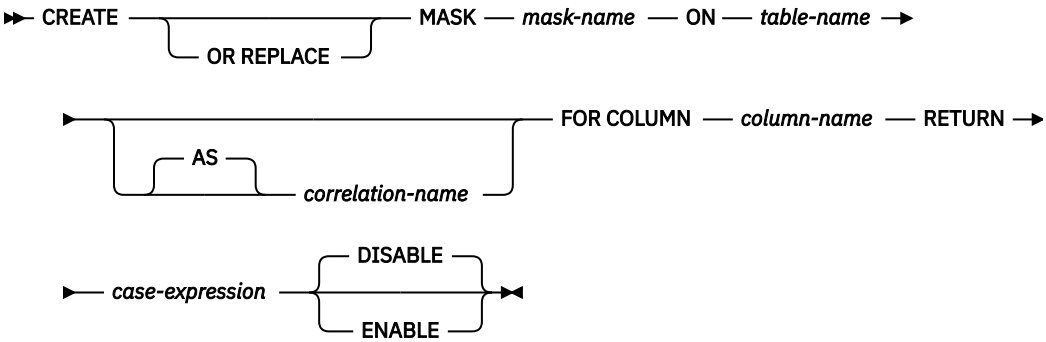
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority. SECADM authority can create a column mask in any schema. Additional privileges are not needed to reference other objects in the mask definition. For example, the SELECT privilege is not needed to retrieve from a table, and the EXECUTE privilege is not needed to call a user-defined function.

Syntax



Description

OR REPLACE
Specifies to replace the definition for the column mask if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog.

mask-name
Names the column mask. The name, including the implicit or explicit qualifier, must not identify a column mask or a row permission that already exists at the current server (SQLSTATE 42710).

table-name
Identifies the table on which the column mask is created. The name must identify a table that exists at the current server (SQLSTATE 42704). It must not identify a nickname, created or declared temporary table, view, synonym, typed table, alias (SQLSTATE 42809), shadow table or base table of a shadow table (SQLSTATE 428HZ), external table (SQLSTATE 42858), or catalog table (SQLSTATE 42832).

correlation-name
Specifies a correlation name that can be used within *case-expression* to designate the table.

FOR COLUMN *column-name*
Identifies the column to which the mask applies. *column-name* must be an unqualified name that identifies a column of the table (SQLSTATE 42703). A mask must not already exist for the column (SQLSTATE 428HC). The column must not be any of the following columns:

- A LOB column or a distinct type column that is based on a LOB (SQLSTATE 42962).
- An XML column (SQLSTATE 42962).
- A column referenced in an expression that defines a generated column (SQLSTATE 428HB).

RETURN *case-expression*
Specifies a CASE expression to be evaluated to determine the value to return for the column (SQLSTATE 42601). The result of the CASE expression is returned in place of the column value in a row. The result data type, null attribute, and length attribute of the CASE expression must be identical or promotable to those of *column-name* (SQLSTATE 428HB). If the data type of *column-name* is a user-defined data type, the result data type of the CASE expression must be the same user-defined data type. The CASE expression must not reference any of the following objects or elements (SQLSTATE 428HB):

- A created global temporary table or a declared global temporary table.
- A shadow table.

- An external table.
- A nickname.
- A table function.
- A method.
- A parameter marker (SQLSTATE 42601).
- A user-defined function that is defined as not secure.
- A function or expression (such as row change expression, sequence expression) that is non-deterministic or has an external action.
- An XMLQUERY scalar function.
- An XMLEXISTS predicate.
- An OLAP specification.
- A * or `name.*` in a SELECT clause.
- A pseudo-column.
- An aggregate function without specifying the SELECT clause.
- A view that includes any of the previously listed restrictions in its definition.

If the CASE expression references tables for which row or column access control is currently activated, access control from those tables are not cascaded. See the Notes section for details.

ENABLE or DISABLE

Specifies that the column mask is to be enabled or disabled for column access control. The default is DISABLE.

DISABLE

Specifies that the column mask is to be disabled for column access control. If column access control is not currently activated for the table, the column mask will remain ineffective when column access control is activated for the table.

ENABLE

Specifies that the column mask is to be enabled for column access control. If column access control is not currently activated for the table, the column mask will become effective when column access control is activated for the table. If column access control is currently activated for the table, the column mask becomes effective immediately and all packages and dynamic cached statements that reference the table are invalidated.

The application of enabled column masks does not interfere with the operations of other clauses within the statement such as the WHERE, GROUP BY, HAVING, SELECT DISTINCT, and ORDER BY. The rows returned in the final result table remain the same, except that the values in the resulting rows might be masked by the column masks. As such, if the masked column also appears in an ORDER BY *sort-key*, the order is based on the original column values and the masked values in the final result table might not reflect that order. Similarly, the masked values might not reflect the uniqueness enforced by SELECT DISTINCT. If the masked column is embedded in an expression, the result of the expression might become different because the column mask is applied on the column before the expression evaluation can take place. For example, applying a column mask on column SSN might change the result of aggregate function COUNT(DISTINCT SSN) because the DISTINCT operation is performed on the masked values. On the other hand, if the expression in the query is the same as the expression used to mask the column value in the column mask definition, the result of the expression might remain unchanged. For example, the expression in the query is 'XXX-XX-' || SUBSTR(SSN, 8, 4) and the same expression appears in the column mask definition. In this particular example, you can replace the expression in the query with column SSN to avoid the same expression getting evaluated twice.

A column mask is created as a stand alone object without knowing all of the contexts in which it might be used. To mask a column value in the final result table, the column mask definition is merged into a query by the database manager. When the column mask definition is brought into the context of the statement, it might conflict with certain SQL semantics in the statement. Therefore, in some situations, the combination of the statement and the application of the column mask might

return an error (SQLSTATE 428HD). When this happens, either the statement needs to be modified or the column mask must be dropped or recreated with a different definition. See the ALTER TABLE statement description for those situations where a bind time error might be issued for the statement.

If the column is not nullable, its column mask definition will not consider a null value for the column. After column access control is activated for the target table, if the target table is the null-padded table in an outer join operation, the column value in the final result table might be a null. To ensure the column mask has the ability to mask a null value, when the database manager merges the column mask definition into the query, if the target table is the null-padded table in an outer join operation, "WHEN *target-column* IS NULL THEN NULL" will be added as the first WHEN clause to the column mask definition. This forces a null value to be always masked to a null. For a nullable column, this takes away the ability to mask a null value to something else but it is an acceptable restriction from security and usability standpoints.

When a column is used to derive the new value for an INSERT, UPDATE, MERGE, or a SET *transition-variable* assignment statement, the original column value, not the masked value, is used to derive the new value. If the column has a column mask, that column mask is applied to ensure the evaluation of the access control rules at run time masks the column to itself, not to a constant or an expression. This is to ensure the masked values are the same as the original column values. If a column mask does not mask the column to itself, the existing row is not updated or the new row is not inserted and an error is returned at run time (SQLSTATE 428HD). If there is a requirement for masked data to be inserted into a table, the default behavior can be changed by setting the registry variable DB2_ALLOW_WRITE_OF_MASKED_DATA=YES. The rules that are used to apply column masks in order to derive the new values follow the same rules described previously for the final result table of a query.

See the ALTER TABLE statement with the ACTIVATE COLUMN ACCESS CONTROL clause for information about how to activate column access control for the table and how a column mask is applied.

Notes

- **Column masks that are created before column access control is activated for a table:** The CREATE MASK statement is an independent statement that can be used to create a column access control mask before column access control is activated for a table. The only requirement is that the table and the columns exist before the mask is created. Multiple column masks can be created for a table but a column can have one mask only.

  The definition of a mask is stored in the database catalog. Dependency on the table for which the mask is being created and dependencies on other objects referenced in the definition are recorded. No package or dynamic cached statement is invalidated. A column mask can be created as enabled or disabled for column access control. An enabled column mask does not take effect until the ALTER TABLE statement with the ACTIVATE COLUMN ACCESS CONTROL clause is used to activate column access control for the table. SECADM authority is required to issue such an ALTER TABLE statement. A disabled column mask remains ineffective even when column access control is activated for the table. The ALTER MASK statement can be used to alter between ENABLE and DISABLE.

  After column access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled column masks that have been created for the table are implicitly applied by the database manager to mask the values returned for the columns referenced in the final result table of the queries or to determine the new values used in the data change statements.

  Creating column masks before activating column access control for a table is the recommended sequence to avoid multiple invalidations of packages and dynamic cached statements that reference the table.
- **Column masks that are created after column access control is activated for a table:** The enabled column masks become effective as soon as they are committed. All the packages and dynamic cached statements that reference the table are invalidated. Thereafter, when the table is referenced in a data manipulation statement, all enabled column masks are implicitly applied by the database manager to

the statement. Any disabled column masks remain ineffective even when column access control is activated for the table.

- **No cascaded effect when column or row access control enforced tables are referenced in column mask definitions:** A column mask definition can reference tables and columns that are currently enforced by row or column access control. Access control from those tables and columns are ignored when the table for which the column mask is being created is referenced in a data manipulation statement.
- **Consideration for database limits:** If the data manipulation statement already approaches some database limits in the statement, the more enabled column masks and enabled row permissions are created, the more likely they might affect some limits. This is because the enabled column mask and enabled row permission definitions are implicitly merged into the statement when the table is referenced in a data manipulation statement.
- **Column masks that are enabled but in the invalid state:** If a column mask is enabled for column access control but its state is set to invalid, access to the table on which the column mask is defined is blocked until this situation is resolved (SQLSTATE 560D0).
- **Column masks that return data which is not assignable to the column the mask is defined on:** A column mask can be defined so it can return data which is not assignable to the data type of the column the mask is defined on. When this occurs, the CREATE MASK statement is successful but a cast error will be reported when the mask is applied in a user query.

Examples

- *Example 1*: After column access control is activated for table EMPLOYEE, Paul from the payroll department can see the social security number of the employee whose employee number is 123456. Mary who is a manager can see only the last four characters of the social security number. Peter who is neither role cannot see the social security number.

```
CREATE MASK SSN_MASK ON EMPLOYEE
  FOR COLUMN SSN RETURN
    CASE WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER,'PAYROLL') = 1)
                                THEN SSN
         WHEN (VERIFY_GROUP_FOR_USER(SESSION_USER,'MGR') = 1)
                                THEN 'XXX-XX-' || SUBSTR(SSN,8,4)
         ELSE NULL
    END
  ENABLE;
ALTER TABLE EMPLOYEE ACTIVATE COLUMN ACCESS CONTROL;
SELECT SSN FROM EMPLOYEE WHERE EMPNO = 123456;
```

- *Example 2*: In the SELECT statement, column SSN is embedded in an expression that is the same as the expression used in the column mask SSN_MASK. After column access control is activated for table EMPLOYEE, the column mask SSN_MASK is applied to column SSN in the SELECT statement. For this particular expression, the SELECT statement produces the same result as before column access control is activated for all users. The user can replace the expression in the SELECT statement with column SSN to avoid the same expression getting evaluated twice.

```
CREATE MASK SSN_MASK ON EMPLOYEE
  FOR COLUMN SSN RETURN
    CASE WHEN (1 = 1) THEN 'XXX-XX-' || SUBSTR(SSN,8,4)
         ELSE NULL
    END
  ENABLE;
ALTER TABLE EMPLOYEE ACTIVATE COLUMN ACCESS CONTROL;
SELECT 'XXX-XX-' || SUBSTR(SSN,8,4) FROM EMPLOYEE WHERE EMPNO = 123456;
```

- *Example 3*: The California state government conducted a survey for the library usage of the households in each city. Fifty households in each city were sampled in the survey. Each household was given an option, opt-in or opt-out, to show whether their usage in any reports generated from the result of the survey.

  A SELECT statement is used to generate a report to show the average hours used by households in each city. Column mask CITY_MASK is created to mask the city name based on the opt-in or opt-out information chosen by the sampled households. However, after column access control is activated for

table LIBRARY_USAGE, the SELECT statement receives a bind time error. This is because column mask CITY_MASK references another column LIBRARY_OPT and LIBRARY_OPT does not identify a grouping column.

```
CREATE MASK CITY_MASK ON LIBRARY_USAGE
  FOR COLUMN CITY RETURN
    CASE WHEN (LIBRARY_OPT = 'OPT-IN') THEN CITY
         ELSE ' '
    END
  ENABLE;
ALTER TABLE LIBRARY_USAGE ACTIVATE COLUMN ACCESS CONTROL;
SELECT CITY, AVG(LIBRARY_TIME) FROM LIBRARY_USAGE GROUP BY CITY;
```

- *Example 4*: Employee with EMPNO 123456 earns bonus $8000 and salary $80000 in May. When the manager retrieves his salary, the manager receives his salary, not the null value. This is because of no cascaded effect when column mask SALARY_MASK references column BONUS for which column mask BONUS_MASK is defined.

```
CREATE MASK SALARY_MASK ON EMPLOYEE
  FOR COLUMN SALARY RETURN
    CASE WHEN (BONUS < 10000) THEN SALARY
         ELSE NULL
    END
  ENABLE;
CREATE MASK BONUS_MASK ON EMPLOYEE
  FOR COLUMN BONUS RETURN
    CASE WHEN (BONUS > 5000) THEN NULL
         ELSE BONUS
    END
  ENABLE;
ALTER TABLE EMPLOYEE ACTIVATE COLUMN ACCESS CONTROL;
SELECT SALARY FROM EMPLOYEE WHERE EMPNO = 123456;
```

CREATE METHOD

The CREATE METHOD statement is used to associate a method body with a method specification that is already part of the definition of a user-defined structured type.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CREATEIN privilege on the schema of the structured type referred to in the CREATE METHOD statement
- The owner of the structured type referred to in the CREATE METHOD statement
- SCHEMAADM authority on the schema of the structured type referred to in the CREATE METHOD statement
- DBADM authority

To associate an external method body with its method specification, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

- CREATE_EXTERNAL_ROUTINE authority on the database
- DBADM authority

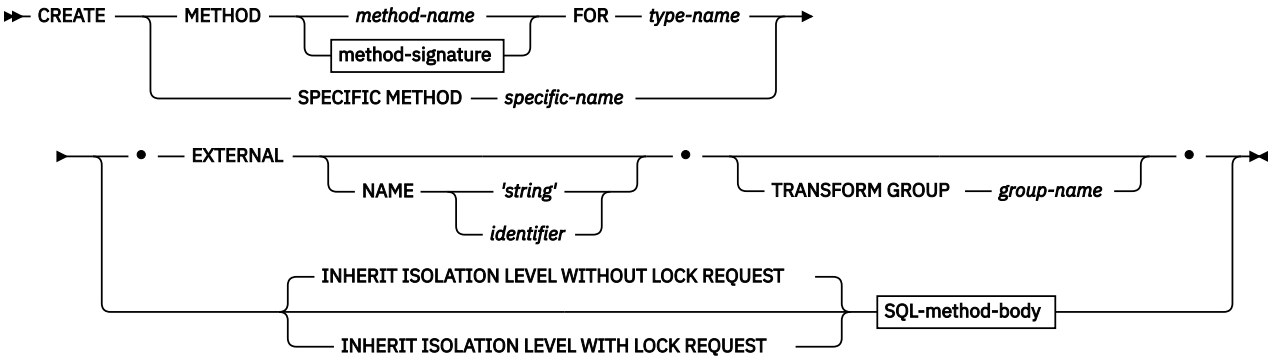
When creating an SQL method, the privileges held by the authorization ID of the statement must also include at least one of the following authorities for each table, view, or nickname identified in any fullselect:

- CONTROL privilege on that table, view, or nickname
- SELECT privilege on that table, view, or nickname
- SELECTIN privilege on the schema containing the table, view, or nickname
- DATAACCESS authority on the schema containing the table, view, or nickname
- DATAACCESS authority on the database

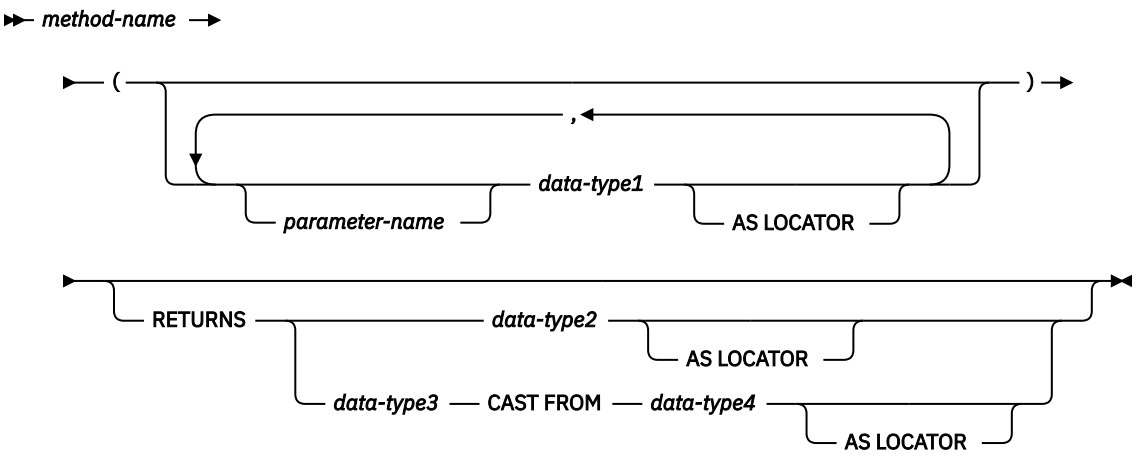
Group privileges other than PUBLIC are not considered for any table or view specified in the CREATE METHOD statement.

Authorization requirements of the data source for the table or view referenced by the nickname are applied when the method is invoked. The authorization ID of the connection can be mapped to a different remote authorization ID.

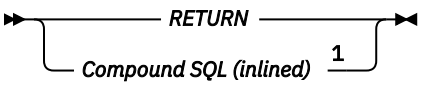
Syntax



method-signature



SQL-method-body



Notes:

[1] The compound SQL (inlined) statement is only supported for an SQL-method-body in an SQL method definition in a non-partitioned database.

Description

METHOD

Identifies an existing method specification that is associated with a user-defined structured type. The method-specification can be identified through one of the following means:

method-name
Names the method specification for which a method body is being defined. The implicit schema is the schema of the subject type (*type-name*). There must be only one method specification for *type-name* that has this *method-name* (SQLSTATE 42725).

method-signature
Provides the method signature which uniquely identifies the method to be defined. The method signature must match the method specification that was provided on the CREATE TYPE or ALTER TYPE statement (SQLSTATE 42883).

method-name
Names the method specification for which a method body is being defined. The implicit schema is the schema of the subject type (*type-name*).

parameter-name
Identifies the parameter name. If parameter names are provided in the method signature, they must be exactly the same as the corresponding parts of the matching method specification. Parameter names are supported in this statement solely for documentation purposes.

data-type1
Specifies the data type of each parameter. Array types are not supported (SQLSTATE 42815).

For a more complete description of each built-in data type, see "CREATE TABLE".

Character and graphic string data types cannot specify string units of CODEUNITS32.

AS LOCATOR
For the LOB types or distinct types which are based on a LOB type, the AS LOCATOR clause can be added.

RETURNS
This clause identifies the output of the method. If a RETURNS clause is provided in the method signature, it must be exactly the same as the corresponding part of the matching method specification on CREATE TYPE. The RETURNS clause is supported in this statement solely for documentation purposes.

data-type2
Specifies the data type of the output. Array types are not supported (SQLSTATE 42815).

AS LOCATOR
For LOB types or distinct types which are based on LOB types, the AS LOCATOR clause can be added. This indicates that a LOB locator is to be returned by the method instead of the actual value.

data-type3* CAST FROM *data-type4
This form of the RETURNS clause is used to return a different data type to the invoking statement from the data type that was returned by the function code.

AS LOCATOR
For LOB types or distinct types which are based on LOB types, the AS LOCATOR clause can be used to indicate that a LOB locator is to be returned from the method instead of the actual value.

FOR *type-name*
Names the type for which the specified method is to be associated. The name must identify a type already described in the catalog (SQLSTATE 42704). In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names.

SPECIFIC METHOD *specific-name*
Identifies the particular method, using the specific name either specified or defaulted to at CREATE TYPE time. The specific-name must identify a method specification in the named or implicit schema; otherwise, an error is raised (SQLSTATE 42704).

EXTERNAL
This clause indicates that the CREATE METHOD statement is being used to register a method, based on code written in an external programming language, and adhering to the documented linkage conventions and interface. The matching method-specification in CREATE TYPE must specify a LANGUAGE other than SQL. When the method is invoked, the subject of the method is passed to the implementation as an implicit first parameter.

If the NAME clause is not specified, "NAME *method-name*" is assumed.

NAME
This clause identifies the name of the user-written code which implements the method being defined.

'*string*'
The *string* option is a string constant with a maximum of 254 bytes. The format used for the string is dependent on the LANGUAGE specified. For more information about the specific language conventions, see "CREATE FUNCTION (External Scalar) statement".

identifier
This identifier specified is an SQL identifier. The SQL identifier is used as the library-id in the string. Unless it is a delimited identifier, the identifier is folded to upper case. If the identifier is qualified with a schema name, the schema name portion is ignored. This form of NAME can only be used with LANGUAGE C (as defined in the method-specification on CREATE TYPE).

TRANSFORM GROUP *group-name*
Indicates the transform group that is used for user-defined structured type transformations when invoking the method. A transform is required since the method definition includes a user-defined structured type.

It is strongly recommended that a transform group name be specified; if this clause is not specified, the default group-name used is DB2_FUNCTION. If the specified (or default) group-name is not defined for a referenced structured type, an error results (SQLSTATE 42741). Likewise, if a required FROM SQL or TO SQL transform function is not defined for the given group-name and structured type, an error results (SQLSTATE 42744).

INHERIT ISOLATION LEVEL WITHOUT LOCK REQUEST or INHERIT ISOLATION LEVEL WITH LOCK REQUEST
Specifies whether or not a lock request can be associated with the isolation-clause of the statement when the method inherits the isolation level of the statement that invokes the method. The default is INHERIT ISOLATION LEVEL WITHOUT LOCK REQUEST.

INHERIT ISOLATION LEVEL WITHOUT LOCK REQUEST
Specifies that, as the method inherits the isolation level of the invoking statement, it cannot be invoked in the context of an SQL statement which includes a lock-request-clause as part of a specified isolation-clause (SQLSTATE 42601).

INHERIT ISOLATION LEVEL WITH LOCK REQUEST
Specifies that, as the method inherits the isolation level of the invoking statement, it also inherits the specified lock-request-clause.

SQL-method-body
The SQL-method-body defines how the method is implemented if the method specification in CREATE TYPE is LANGUAGE SQL.

The SQL-method-body must comply with the following parts of method specification:

- DETERMINISTIC or NOT DETERMINISTIC (SQLSTATE 428C2)
- EXTERNAL ACTION or NO EXTERNAL ACTION (SQLSTATE 428C2)
- CONTAINS SQL or READS SQL DATA (SQLSTATE 42985)

Parameter names can be referenced in the SQL-method-body. The subject of the method is passed to the method implementation as an implicit first parameter named SELF.

For additional details, see "Compound SQL (inlined) statement" and "RETURN statement".

Rules

- The method specification must be previously defined using the CREATE TYPE or ALTER TYPE statement before CREATE METHOD can be used (SQLSTATE 42723).
- If the method being created is an overriding method, those packages that are dependent on the following methods are invalidated:
  - The original method
  - Other overriding methods that have as their subject a supertype of the method being created
- The XML data type cannot be used in a method.

Notes

- If the method allows SQL, the external program must not attempt to access any federated objects (SQLSTATE 55047).
- ***Privileges***: The definer of a method always receives the EXECUTE privilege on the method, as well as the right to drop the method.

  If an EXTERNAL method is created, the definer of the method always receives the EXECUTE privilege WITH GRANT OPTION.

  If an SQL method is created, the definer of the method will only be given the EXECUTE privilege WITH GRANT OPTION on the method when the definer has WITH GRANT OPTION on all privileges required to define the method, or if the definer has SYSADM or DBADM authority. The definer of an SQL method only acquires privileges if the privileges from which they are derived exist at the time the method is created. The definer must have these privileges either directly, or because PUBLIC has the privileges. Privileges held by groups of which the method definer is a member are not considered. When using the method, the connected user's authorization ID must have the valid privileges on the table or view that the nickname references at the data source.
- ***Table access restrictions***: If a method is defined as READS SQL DATA, no statement in the method can access a table that is being modified by the statement which invoked the method (SQLSTATE 57053).

Examples

- *Example 1:*

```
CREATE METHOD BONUS (RATE DOUBLE)
  FOR EMP
  RETURN SELF..SALARY * RATE
```

- *Example 2:*

```
CREATE METHOD SAMEZIP (addr address_t)
  RETURNS INTEGER
  FOR address_t
  RETURN
    (CASE
      WHEN (self..zip = addr..zip)
        THEN 1
      ELSE 0
    END)
```

- *Example 3:*

```
CREATE METHOD DISTANCE (address_t)
  FOR address_t
  EXTERNAL NAME 'addresslib!distance'
  TRANSFORM GROUP func_group
```

CREATE MODULE

The CREATE MODULE statement creates a module at the application server.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

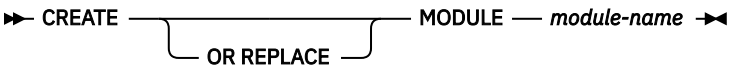
Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the module does not exist.
- CREATEIN privilege on the schema, if the schema name of the module refers to an existing schema.
- SCHEMAADM authority on the schema, if the schema name of the module refers to an existing schema.
- DBADM authority

To replace an existing module, the authorization ID of the statement must be the owner of the existing module (SQLSTATE 42501).

Syntax



Description

OR REPLACE
Specifies replacing the definition for the module if one exists at the current server. The existing module definition is effectively dropped, including all the objects in the module, before the new definition is replaced in the catalog, with the exception that privileges that were granted on the module are not affected. This option is ignored if a definition for the module does not exist at the current server. This option can be specified only by the owner of the object.

module-name
Names the module. The name, including the implicit or explicit qualifier, must not identify an existing module at the current server. The module name and the schema name must not begin with the characters 'SYS' (SQLSTATE 42939) and use of SESSION is not recommended.

Notes

- A module is intended to be a collection of other database objects. Once a module is created, objects in the module are managed using the ALTER MODULE statement. A module can include functions, procedures, types, global variables and conditions. The objects in a module can be published to make them available for reference from outside the module. If an object is not published, it can only be referenced from within the module. A module can be considered to consist of 2 parts:
  - The module specification consists of all the published objects excluding the bodies of any routines.
  - The module body which consists of all objects that are not published and the bodies of any published routines.

  The module management actions include
  - ADD to add an object to the module without publishing it or to replace a routine prototype with the implemented routine definition.

– PUBLISH to add an object to the module and publish it.
– COMMENT on objects in the module.
– DROP to drop an object within the module or drop the module body.

At least one published object should exist in a module in order to have some way to reference the module.

Example

Create a module named *salesModule*

```
CREATE MODULE salesModule
```

CREATE NICKNAME

The CREATE NICKNAME statement defines a nickname for a data source object.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

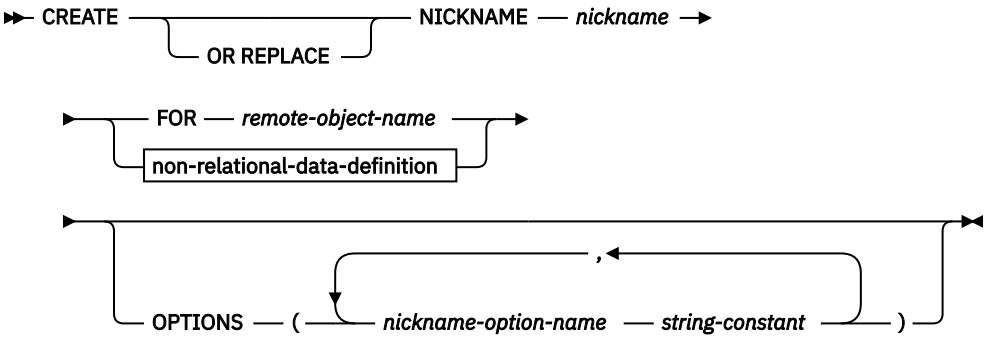
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CREATETAB authority on the federated database, as well as one of:
  – IMPLICIT_SCHEMA authority on the federated database, if the implicit or explicit schema name of the nickname does not exist
  – CREATEIN privilege on the schema, if the schema name of the nickname refers to an existing schema
  – SCHEMAADM authority on the schema, if the schema name of the nickname refers to an existing schema
- DBADM authority

For data sources that require a user mapping, the privileges held by the authorization ID at the data source must include the privilege to select data from the object that the nickname represents.

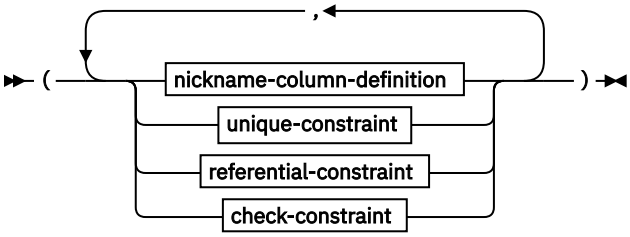
To replace an existing nickname, the authorization ID of the statement must be the owner of the existing nickname (SQLSTATE 42501).

Syntax



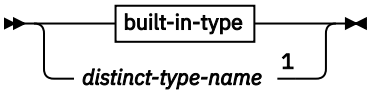
non-relational-data-definition

nickname-column-list

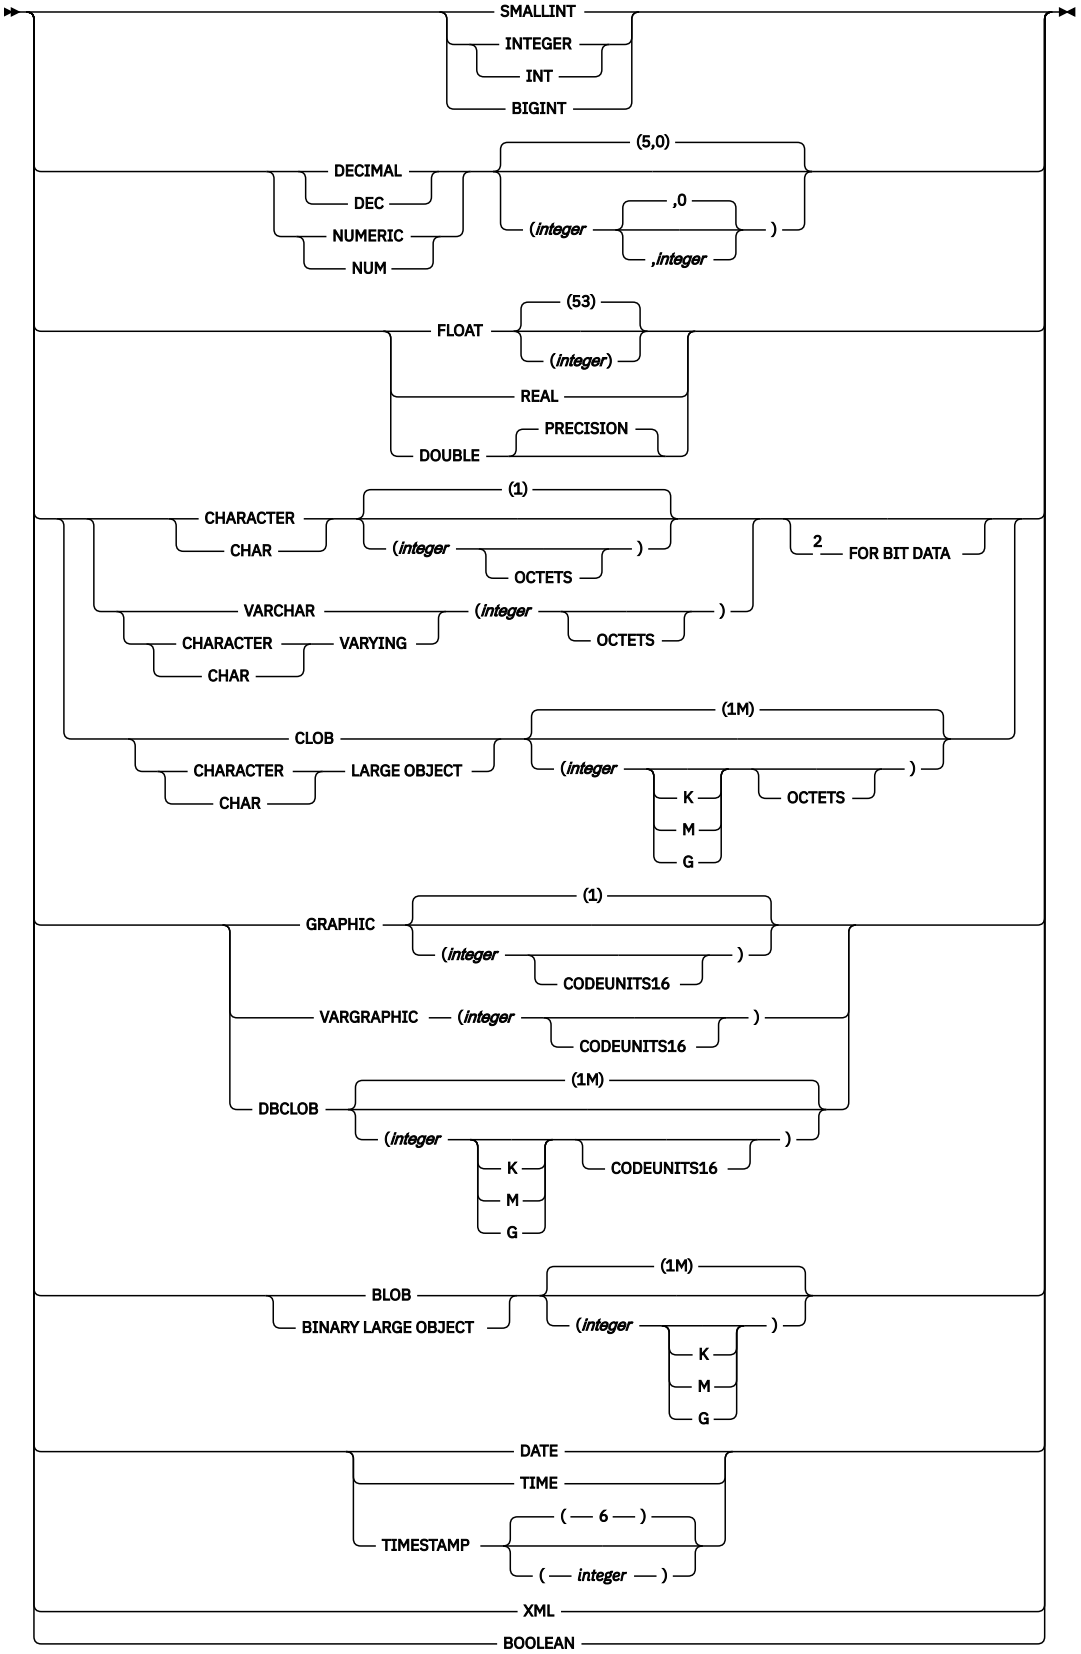


nickname-column-definition

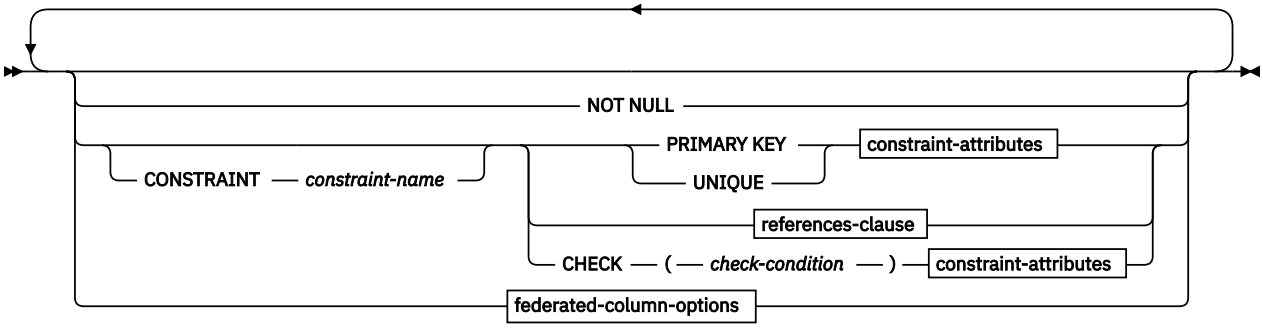
local-data-type



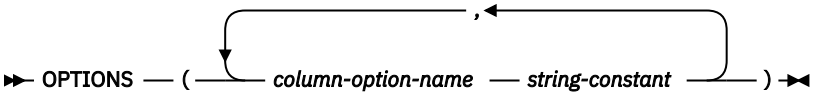
built-in-type



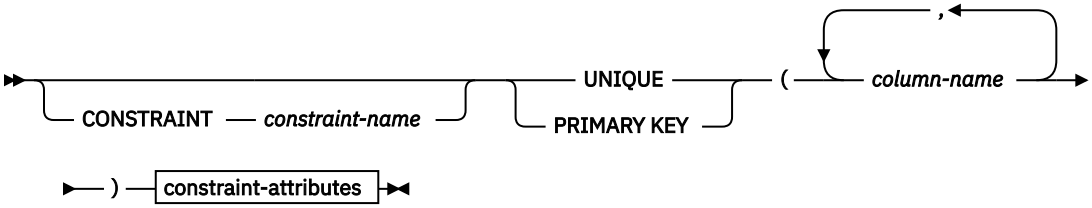
nickname-column-options



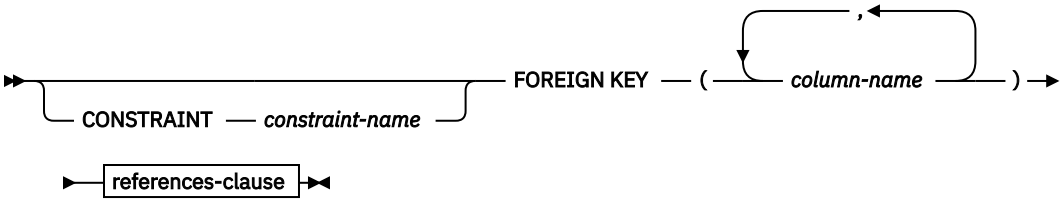
federated-column-options



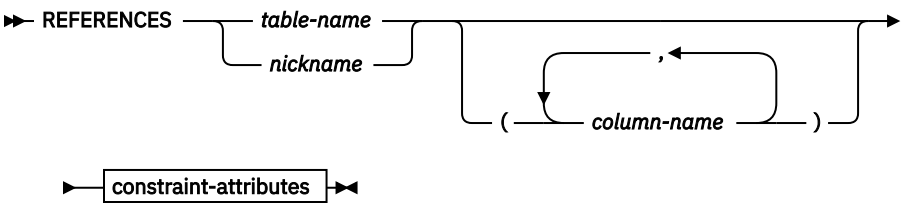
unique-constraint



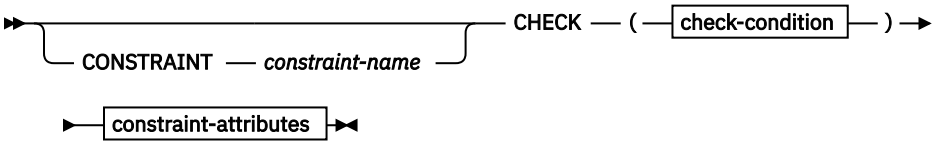
referential-constraint



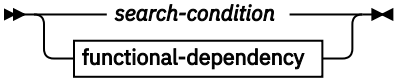
references-clause



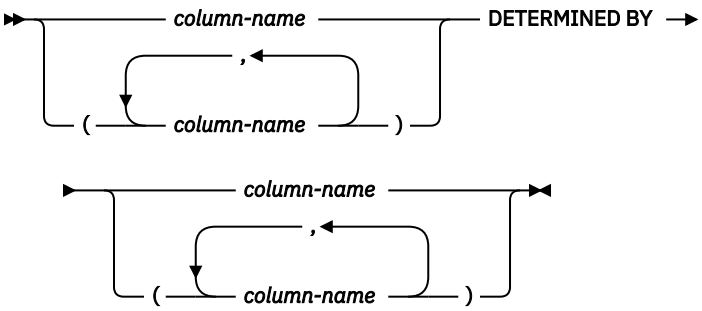
check-constraint



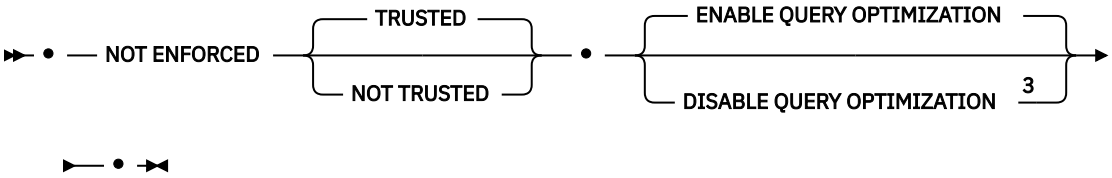
check-condition



functional-dependency



constraint-attributes



Notes:

[1] The specified distinct type cannot have any data type constraints and the source type cannot be an anchored data type (SQLSTATE 428H2).

[2] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow.

[3] DISABLE QUERY OPTIMIZATION is not supported for a unique or primary key constraint.

Description

OR REPLACE
Specifies to replace the definition for the nickname if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that privileges that were granted on the nickname are not affected. This option is ignored if a definition for the nickname does not exist at the current server. This option can be specified only by the owner of the object.

nickname
Specifies a nickname, the identifier used by the federated server for the data source object. The nickname, including the implicit or explicit qualifier, must not identify a table, view, nickname, or alias described in the catalog. The schema name must not begin with 'SYS' (SQLSTATE 42939).

FOR *remote-object-name*
Specifies an identifier. For data sources that support schema names, this is a three-part identifier with the format *data-source-name.remote-schema-name.remote-table-name*. For data sources that do not support schema names, this is a two-part identifier with the format *data-source-name.remote-table-name*.

data-source-name
Names the data source that contains the table or view for which the nickname is being created. The *data-source-name* is the same name that was assigned to the *server-name* in the CREATE SERVER statement.

remote-schema-name
Names the schema to which the table or view belongs. If the remote schema name contains any special or lowercase characters, it must be enclosed by double quotation marks.

remote-table-name
Names the specific data source object (such as a table, alias of a table, or view) for which the nickname is being created. The table cannot be a declared temporary table (SQLSTATE 42995). If the remote table name contains any special or lowercase characters, it must be enclosed by double quotation marks.

For Db2 you can also specify the alias of a table, view, or nickname. For Db2 for z/OS or Db2 for IBM i, you can specify the alias of a table or view.

non-relational-data-definition
Defines the data that is to be accessed through a nonrelational wrapper.

nickname-column-definition
Defines the local attributes of the column for the nickname. Some wrappers require these attributes to be specified, while other wrappers allow the attributes to be determined from the data source.

column-name
Specifies the local name for the column. The name might be different than the corresponding column of the *remote-object-name*.

local-data-type
Specifies the local data type for the column. Some wrappers only support a subset of the SQL data types. For descriptions of specific data types, see "CREATE TABLE" .

built-in-type
See "CREATE TABLE" for the description of built-in data types.

nickname-column-options
Specifies additional options related to columns of the nickname.

NOT NULL
Specifies that the column does not allow null values.

CONSTRAINT *constraint-name*
Names the constraint. A *constraint-name* must not identify a constraint that was already specified within the same CREATE NICKNAME statement (SQLSTATE 42710).

If this clause is omitted, an 18 byte long identifier that is unique among the identifiers of existing constraints defined on the nickname is generated by the system. (The identifier consists of 'SQL' followed by a sequence of 15 numeric characters generated by a timestamp-based function.)

When used with a PRIMARY KEY or UNIQUE constraint, the *constraint-name* can be used as the name of an index specification that is created to support the constraint.

PRIMARY KEY
This provides a shorthand method of defining a primary key composed of a single column. Thus, if PRIMARY KEY is specified in the definition of column C, the effect is the same as if the PRIMARY KEY(C) clause is specified as a separate clause.

See PRIMARY KEY within the description of *unique-constraint*.

UNIQUE
This provides a shorthand method of defining a unique key composed of a single column. Thus, if UNIQUE is specified in the definition of column C, the effect is the same as if the UNIQUE(C) clause is specified as a separate clause.

See UNIQUE within the description of *unique-constraint*.

references-clause
This provides a shorthand method of defining a foreign key composed of a single column. Thus, if a references-clause is specified in the definition of column C, the effect is the same as if that references-clause were specified as part of a FOREIGN KEY clause in which C is the only identified column.

See *references-clause* within the description of *referential-constraint*.

CHECK (*check-condition*)
This provides a shorthand method of defining a check constraint that applies to a single column. See description for CHECK (*check-condition*).

OPTIONS
Indicates the column options that are added when the nickname is created. Some wrappers require that certain column options be specified.

column-option-name
Specifies the name of the option.

string-constant
Specifies the setting for *column-option-name* as a character string constant.

unique-constraint
Defines a unique or primary key constraint.

CONSTRAINT *constraint-name*
Names the primary key or unique constraint.

UNIQUE (*column-name*,...)
Defines a unique key composed of the identified columns. The identified columns must be defined as NOT NULL. Each *column-name* must identify a column of the nickname and the same column must not be identified more than once.

The number of identified columns must not exceed 64, and the sum of their stored lengths must not exceed the index key length limit for the page size. For column stored lengths, see "Byte Counts" in "CREATE TABLE". For key length limits, see "SQL and XQuery limits". No LOB column, distinct type column based on a LOB, or structured type column can be used as part of a unique key, even if the length attribute of the column is small enough to fit within the index key length limit for the page size (SQLSTATE 54008).

The set of columns in the unique key cannot be the same as the set of columns in the primary key or another unique key (SQLSTATE 01543). (If LANGLEVEL is SQL92E or MIA, an error is returned, SQLSTATE 42891.)

The description of the nickname as recorded in the catalog includes the unique key and its index specification. An index specification will automatically be created for the columns in the sequence specified with ascending order for each column. The name of the index specification will be the same as the *constraint-name* if this does not conflict with an existing index or index specification in the schema where the nickname is created. If the name of the index specification conflicts, the name will be 'SQL' followed by a character timestamp (*yymmddhhmmssxxx*), with SYSIBM as the schema name.

PRIMARY KEY (*column-name*,...)
Defines a primary key composed of the identified columns. The clause must not be specified more than once, and the identified columns must be defined as NOT NULL. Each *column-name* must identify a column of the nickname, and the same column must not be identified more than once.

The number of identified columns must not exceed 64, and the sum of their stored lengths must not exceed the index key length limit for the page size. For column stored lengths, see "Byte Counts" in "CREATE TABLE". For key length limits, see "SQL and XQuery limits". No LOB column, distinct type column based on a LOB, or structured type column can be used as part of a primary key, even if the length attribute of the column is small enough to fit within the index key length limit for the page size (SQLSTATE 54008).

The set of columns in the primary key cannot be the same as the set of columns in a unique key (SQLSTATE 01543). (If LANGLEVEL is SQL92E or MIA, an error is returned, SQLSTATE 42891.)

Only one primary key can be defined on a nickname.

The description of the nickname as recorded in the catalog includes the primary key and its index specification. An index specification will automatically be created for the columns in the sequence specified with ascending order for each column. The name of the index specification will be the same as the *constraint-name* if this does not conflict with an existing index or index specification in the schema where the nickname is created. If the name of the index specification conflicts, the name will be 'SQL', followed by a character timestamp (*yymmddhhmmssxxx*), with SYSIBM as the schema name.

referential-constraint
Defines a referential constraint.

CONSTRAINT *constraint-name*
Names the referential constraint.

FOREIGN KEY (*column-name*,...)
Defines a referential constraint with the specified *constraint-name*.

Let N1 denote the object nickname of the statement. The foreign key of the referential constraint is composed of the identified columns. Each name in the list of column names must identify a column of N1, and the same column must not be identified more than once.

The number of identified columns must not exceed 64, and the sum of their stored lengths must not exceed the index key length limit for the page size. For column stored lengths, see "Byte Counts" in "CREATE TABLE". For key length limits, see "SQL and XQuery limits". Foreign keys can be defined on variable length columns whose length is greater than 255 bytes. No LOB column, distinct type column based on a LOB, or structured type column can be used as part of a foreign key (SQLSTATE 42962). There must be the same number of foreign key columns as there are in the parent key, and the data types of the corresponding columns must be compatible (SQLSTATE 42830). Two column descriptions are compatible if they have compatible data types (both columns are numeric, character string, graphic, datetime, or have the same distinct type).

references-clause
Specifies the parent table or the parent nickname, and the parent key for the referential constraint.

REFERENCES *table-name* or *nickname*
The table or nickname specified in a REFERENCES clause must identify a base table or a nickname that is described in the catalog, but must not identify a catalog table.

A referential constraint is a duplicate if its foreign key, parent key, and parent table or parent nickname are the same as the foreign key, parent key, and parent table or parent nickname of a previously specified referential constraint. Duplicate referential constraints are ignored, and a warning is returned (SQLSTATE 01543).

In the following discussion, let N2 denote the identified parent table or parent nickname, and let N1 denote the nickname being created (or altered). N1 and N2 may be the same nickname.

The specified foreign key must have the same number of columns as the parent key of N2, and the description of the *n*th column of the foreign key must be comparable to the description of the *n*th column of that parent key. Datetime columns are not considered to be comparable to string columns for the purposes of this rule.

The referential constraint specified by a FOREIGN KEY clause defines a relationship in which N2 is the parent and N1 is the dependent.

(*column-name*,...)
The parent key of a referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of N2. The same column must not be identified more than once.

The list of column names must match the set of columns (in any order) of the primary key or a unique constraint that exists on N2 (SQLSTATE 42890). If a column name list is not specified, N2 must have a primary key (SQLSTATE 42888). Omission of the column name list is an implicit specification of the columns of that primary key in the sequence originally specified.

constraint-attributes
Defines attributes associated with referential integrity or check constraints.

NOT ENFORCED
The constraint is not enforced by the database manager during normal operations, such as insert, update, or delete.

TRUSTED
The data can be trusted to conform to the constraint. TRUSTED must be used only if the data in the table is independently known to conform to the constraint. Query results might be unpredictable if the data does not actually conform to the constraint. This is the default option.

NOT TRUSTED
The data cannot be trusted to conform to the constraint. NOT TRUSTED is intended for cases where the data conforms to the constraint for most rows, but it is not independently known that all the rows or future additions will conform to the constraint. If a constraint is NOT TRUSTED and enabled for query optimization, then it will not be used to perform optimizations that depend on the data conforming completely to the constraint. NOT TRUSTED can be specified only for referential integrity constraints (SQLSTATE 42613).

ENABLE QUERY OPTIMIZATION
The constraint is assumed to be true and can be used for query optimization under appropriate circumstances.

DISABLE QUERY OPTIMIZATION
The constraint cannot be used for query optimization.

check-constraint
Defines a check constraint. A *check-constraint* is a *search-condition* that must evaluate to not false or that defines a functional dependency between columns.

CONSTRAINT *constraint-name*
Names the check constraint.

CHECK (*check-condition*)
Defines a check constraint. The *check-condition* must be true or unknown for every row of the nickname.

search-condition
The *search-condition* has the following restrictions:

- A column reference must be to a column of the nickname being created.
- The *search-condition* cannot contain a TYPE predicate.
- It cannot contain any of the following elements (SQLSTATE 42621):
  - Subqueries
  - Dereference operations or DEREF functions where the scoped reference argument is other than the object identifier (OID) column
  - CAST specifications with a SCOPE clause
  - Column functions
  - Functions that are not deterministic
  - Functions defined to have an external action
  - User-defined functions defined with either CONTAINS SQL or READS SQL DATA
  - Host variables
  - Parameter markers
  - Special registers and built-in functions that depend on the value of a special register
  - Global variables
  - References to generated columns other than the identity column

functional-dependency
Defines a functional dependency between columns.

The parent set of columns contains the identified columns that immediately precede the DETERMINED BY clause. The child set of columns contains the identified columns that immediately follow the DETERMINED BY clause. All of the restrictions on the *search-condition*

apply to parent set and child set columns, and only simple column references are allowed in the set of columns (SQLSTATE 42621). The same column must not be identified more than once in the functional dependency (SQLSTATE 42709). The data type of the column must not be a LOB data type, a distinct type based on a LOB data type, or a structured type (SQLSTATE 42962). No column in the child set of columns can be a nullable column (SQLSTATE 42621).

If a check constraint is specified as part of a *column-definition*, a column reference can only be made to the same column. Check constraints specified as part of a nickname definition can have column references identifying columns previously defined in the CREATE NICKNAME statement. Check constraints are not checked for inconsistencies, duplicate conditions, or equivalent conditions. Therefore, contradictory or redundant check constraints can be defined, resulting in possible errors at execution time.

FOR SERVER *server-name*

Specifies a server that was registered using the CREATE SERVER statement. This server will be used to access the data for the nickname.

OPTIONS

Specify configuration options for the nickname to be created. Which options you can specify depends on the data source of the object for which a nickname is being created. For a list of data sources and the nickname options that apply to each, see Data source options. Each option value is a character string constant that must be enclosed in single quotation marks.

Notes

- Examples of relational data source objects are: tables and views. Examples of nonrelational data source objects are: Documentum objects or registered tables, text files (.txt), and Microsoft Excel files (.xls).
- The data source object that the nickname references must already exist at the data source denoted by the first qualifier in *remote-object-name*.
- The list of supported data source data types varies from wrapper to wrapper. XML and REF data source data types are not supported by any of the wrappers. DECFLOAT data source data type is supported only by the Db2 wrapper for IBM Db2 Version 9.5 or later. When the CREATE NICKNAME statement specifies a *remote-object-name* that has columns with unsupported data types, an error is returned.

  LONG VARCHAR and LONG VARGRAPHIC data source data types are mapped to CLOB and DBCLOB data types, respectively. LONG VARCHAR FOR BIT DATA is mapped to BLOB.
- The maximum allowable length for index names is 128 bytes. If a nickname is being created for a relational table that has an index whose name exceeds this length, the entire name is not cataloged. Rather, it is truncated to 128 bytes. If the string formed by these characters is not unique within the schema to which the index belongs, an attempt is made to make it unique by replacing the last character with 0. If the result is still not unique, the last character is changed to 1. This process is repeated with numbers 2 through 9 and, if necessary, with numbers 0 through 9 for the name's 127th character, 126th character, and so on, until a unique name is generated. To illustrate: The 130-byte name of an index on a data source table is AREALLY...REALLYLONGNAME. The names AREALLY...REALLYLONGNA and AREALLY...REALLYLONGN0 already exist in the schema to which this index belongs. The new name is over 128 bytes; therefore, it is truncated to AREALLY...REALLYLONGNA. Because this name already exists in the schema, the truncated version is changed to AREALLY...REALLYLONGN0. Because this name also exists, the truncated version is changed to AREALLY...REALLYLONGN1. This name does not already exist in the schema, so it is accepted as a new name.
- When a nickname is created for a data source object, the names of the nickname columns are stored in the catalog. When the data source object is a table or a view, the nickname column names are created to be the same as the table or view column names. If a name exceeds the maximum allowable length for a database column name, the name is truncated to this length. If the truncated version is not unique among the other column names in the table or view, it is made unique by following the procedure described in the preceding paragraph.
- If the data source object has indexes defined, index specifications for each index are created when the nickname is created. Index specifications are not created at the data source for indexes that have:

  - Duplicate column names
  - More than 64 columns
  - More than 1024 bytes in the sum of the length of the index key parts
- If the definition of a remote data source object is changed (for example, a column is deleted or a data type is changed), the nickname should be dropped and recreated; otherwise, errors might occur when the nickname is used in an SQL statement.
- ***Caching and protected objects:*** When a nickname is created, if the data source object is not protected, `ALLOW CACHING` is in effect for the nickname. If the federated server can detect that the data source object is protected, `DISALLOW CACHING` is in effect for the nickname. The `DISALLOW CACHING` option ensures that each time the nickname is used, data for the appropriate authorization ID is returned from the data source at query execution time. This is done by restricting the nickname from being used in the definition of a materialized query table at the federated server, which might be being used to cache the nickname data. The ALTER NICKNAME statement can be used to change between `ALLOW CACHING` and `DISALLOW CACHING`.
- BINARY and VARBINARY types are not supported in a Federated system.
- If the remote data source is Hive, Spark, or Impala, and if the remote data source object contains a column with a large-value character type such as STRING or VARCHAR(65535), the remote column is mapped to local column of type VARCHAR(32672), and any data in excess of 32672 bytes is truncated.
- **Syntax alternatives:** The following syntax is supported for compatibility with previous versions of Db2:
  - ADD can be specified before *nickname-option-name string-constant*.
  - ADD can be specified before *column-option-name string-constant*.

Examples

1. Create a nickname for a view, DEPARTMENT, that is in a schema called HEDGES. This view is stored in a Db2 for z/OS data source called OS390A.

```
CREATE NICKNAME DEPT
  FOR OS390A.HEDGES.DEPARTMENT
```

2. Select all records from the view for which a nickname was created in Example 1. The view must be referenced by its nickname. The remote view can be referenced using the name by which it is known at the data source only in pass-through sessions.

   The following statement is valid after nickname DEPT is created:

```
SELECT * FROM DEPT
```

   The following statement is invalid:

```
SELECT * FROM OS390A.HEDGES.DEPARTMENT
```

3. Create a nickname for the remote table JAPAN that is in a schema called salesdata. Because the schema name and table name on the data source are stored in lowercase, specify the remote schema name and table name with double quotation marks:

```
CREATE NICKNAME JPSALES
  FOR asia."salesdata"."japan"
```

4. Create a nickname for the table-structured file DRUGDATA1.TXT. Include the FILE_PATH, COLUMN DELIMITER, KEY_COLUMN, and VALIDATE_DATA_FILE nickname options in the statement.

```
CREATE NICKNAME DRUGDATA1
  (Dcode         INTEGER,
  DRUG           CHAR(20),
  MANUFACTURER   CHAR(20))
  FOR SERVER biochem_lab
  OPTIONS
    (FILE_PATH '/usr/pat/DRUGDATA1.TXT',
     COLUMN_DELIMITER ',',
```

```
        KEY_COLUMN 'DCODE',
        SORTED 'Y',
        VALIDATE_DATA_FILE 'Y')
```

5. Create the parent nickname CUSTOMERS over multiple XML files under the specified directory path / home/dbuser. Include the following options:
   - Column options:
     - XPATH column option for the VARCHAR(5) column named ID, indicating the element or attribute in the XML file(s) from which the column data is extracted
     - XPATH column option for the VARCHAR(16) column named NAME, indicating the element or attribute in the XML file(s) from which the column data is extracted
     - XPATH column option for the VARCHAR(30) column named ADDRESS, indicating the element or attribute in the XML file(s) from which the column data is extracted
     - PRIMARY_KEY column option for the VARCHAR(16) column named CID, which identifies the customers nickname as a parent nickname in a hierarchy of nicknames
   - Nickname options:
     - DIRECTORY_PATH nickname option to indicate the location of the XML files that provide the data
     - XPATH nickname option to indicate the element in the XML files where the data begins
     - STREAMING nickname option to indicate that the XML source data is separated and processed element by element. In this example, the element is a customer record.

```
CREATE NICKNAME customers
  (id      VARCHAR(5)   OPTIONS(XPATH './@id'),
   name    VARCHAR(16)  OPTIONS(XPATH './/name'),
   address VARCHAR(30)  OPTIONS(XPATH './/address/@street'),
   cid     VARCHAR(16)  OPTIONS(PRIMARY_KEY 'YES'))
   FOR SERVER xml_server
   OPTIONS
     (DIRECTORY_PATH '/home/dbuser',
      XPATH '//customer',
      STREAMING 'YES')
```

6. A Hive table with the name STR_TAB contains a column with the name COL5. COL5 has the type STRING and a column length of 2 GB. When you create a nickname for STR_TAB, the column length of COL5 is reduced to 32672 bytes.

```
CREATE NICKNAME "STRING_NCK" FOR "SERVER10"."STR_TAB"
SQL1812W  Remote column COL5 with length 2147483647 was reduced to 32672. SQLSTATE=0169E
```

CREATE PERMISSION

The CREATE PERMISSION statement creates a row permission at the current server.

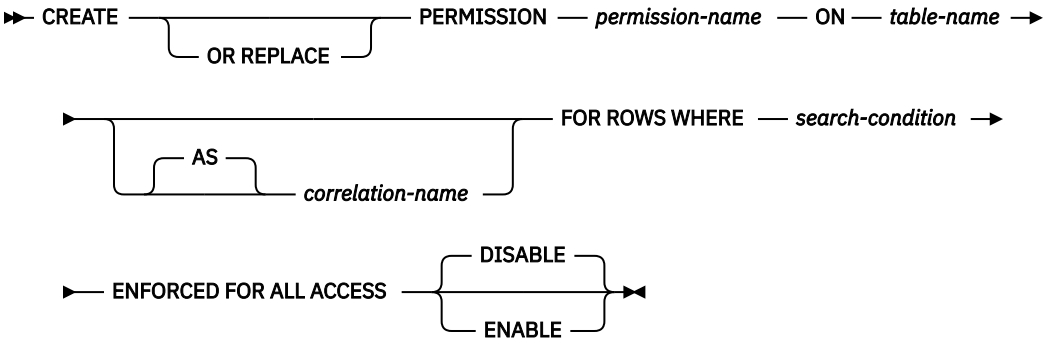
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is implicitly or explicitly specified.

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority. SECADM authority can create a row permission in any schema. Additional privileges are not needed to reference other objects in the permission definition. For example, the SELECT privilege is not needed to retrieve from a table, and the EXECUTE privilege is not needed to call a user-defined function.

Syntax



Description

OR REPLACE
Specifies to replace the definition for the row permission if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog.

permission-name
Names the row permission. The name, including the implicit or explicit qualifier, must not identify a row permission or a column mask that already exists at the current server (SQLSTATE 42710).

table-name
Identifies the table on which the row permission is created. The name must identify a table that exists at the current server (SQLSTATE 42704). It must not identify a nickname, created or declared temporary table, view, synonym, typed table, external table (SQLSTATE 42858), or alias (SQLSTATE 42809). It must not identify a shadow table or a base table of a shadow table (SQLSTATE 428HZ). In releases before Db2 10.5.0.5, *table-name* must not identify a catalog table (SQLSTATE 42832).

correlation-name
Specifies a correlation name that can be used within *search-condition* to designate the table.

FOR ROWS WHERE
Indicates that a row permission is created. A row permission specifies a search condition under which rows of the table can be accessed.

search-condition
Specifies a condition that can be true or false for a row of the table. This follows the same rules used by the search condition in a WHERE clause of a subselect query. In addition, the search condition must not reference any of the following objects or elements (SQLSTATE 428HB):

- A created global temporary table or a declared global temporary table.
- A shadow table.
- An external table.
- A nickname.
- A table function.
- A method.
- A parameter marker (SQLSTATE 42601).
- A user-defined function that is defined as not secure.
- A function or expression (such as row change expression, sequence expression) that is non deterministic or has an external action
- An XMLQUERY scalar function.
- An XMLEXISTS predicate.
- An OLAP specification.
- A `*` or `name.*` in a SELECT clause.

- A pseudocolumn.
- An aggregate function without specifying the SELECT clause.
- A view that includes any of the previously listed restrictions in its definition.

If *search-condition* references tables with currently activated row or column access control, access control from those tables are not cascaded. See "Notes" for details.

ENFORCED FOR ALL ACCESS
Specifies that the row permission applies to all references of the table. If row access control is activated for the table, when the table is referenced in a data manipulation statement, the database manager implicitly applies the row permission to control the access of the table. If the reference of the table is for a fetch operation such as SELECT, the application of the row permission determines what set of rows can be retrieved by the user who requested the fetch operation. If the reference of the table is for a data change operation such as INSERT, the application of the row permission determines whether all rows to be changed can be inserted or updated by the user who requested the data change operation.

ENABLE or DISABLE
Specifies that the row permission is to be enabled or disabled. The default is DISABLE.

DISABLE
Specifies that the row permission is to be disabled. If row access control is not currently activated for the table, the row permission will remain ineffective when row access control is activated for the table.

ENABLE
Specifies that the row permission is to be enabled for row access control. If row access control is not currently activated for the table, the row permission will become effective when row access control is activated for the table. If row access control is currently activated for the table, the row permission becomes effective immediately and all packages and dynamically cached statements that reference the table are invalidated.

See the ACTIVATE ROW ACCESS CONTROL clause in the ALTER TABLE statement for more information about how to activate row access control and how row permissions are applied.

Notes

- **Row permissions that are created before row access control is activated for a table:** The CREATE PERMISSION statement is an independent statement that can be used to create a row permission before row access control is activated for a table. The only requirement is that the table and the columns exist before the permission is created. Multiple row permissions can be created for a table.

  The definition of the row permission is stored in the database catalog. Dependency on the table for which the permission is being created and dependencies on other objects referenced in the definition are recorded. No package or dynamic cached statement is invalidated. A row permission can be created as enabled or disabled for row access control. An enabled row permission does not take effect until the ALTER TABLE statement with the ACTIVATE ROW ACCESS CONTROL clause is used to activate row access control for the table. A disabled row permission remains ineffective even when row access control is activated for the table. The ALTER PERMISSION statement can be used to alter between ENABLE and DISABLE.

  After row access control is activated for a table, when the table is referenced in a data manipulation statement, all enabled row permissions that are defined for the table are implicitly applied by the database manager to control access to the table.

  Creating row permissions before activating row access control for a table is the recommended sequence to avoid multiple invalidations of packages and dynamic cached statements that reference the table.
- **Row permissions that are created after row access control is activated for a table:** An enabled row permission becomes effective as soon as it is committed. All the packages and dynamic cached statements that reference the table are invalidated. Thereafter, when the table is referenced in a data manipulation statement, all enabled row permissions are implicitly applied to the statement. Any disabled row permissions remain ineffective even when row access control is activated for the table.

- **No cascaded effect when row or column access control enforced tables are referenced in row permission definitions:** A row permission definition might reference tables and columns that are currently enforced by row or column access control. Access control from those tables are ignored when the table for which the row permission is being created is referenced in a data manipulation statement.
- **Consideration for database limits:** If the data manipulation statement already approaches some database limits in the statement, the more enabled row permissions and enabled column masks are created, the more likely they might affect some limits. This is because the enabled column mask and enabled row permission definitions are implicitly merged into the statement when the table is referenced in a data manipulation statement. See "SQL and XML Limits" for the limits of a statement.
- **Permissions that are enabled but in the invalid state:** If a permission is enabled for row access control but its state is set to invalid, access to the table on which the permission is defined is blocked until this situation is resolved (SQLSTATE 560D0).

Example

The tellers in a bank can only access customers from their own branch. All tellers are members in role TELLER. The customer service representatives are allowed to access all customers of the bank. All customer service representatives are members in role CSR. A row permission is created accordingly for each group of personnel in the bank by a user with SECADM authority. After row level access control is activated for table CUSTOMER, in the SELECT statement the search conditions of both row permissions are merged into the statement and they are combined with the logical OR operator to control the set of rows accessible by each group.

```
CREATE PERMISSION TELLER_ROW_ACCESS ON CUSTOMER
 FOR ROWS WHERE VERIFY_ROLE_FOR_USER
 (SESSION_USER,'TELLER') = 1 AND
        BRANCH = (SELECT HOME_BRANCH FROM INTERNAL_INFO
             WHERE EMP_ID = SESSION_USER)
ENFORCED FOR ALL ACCESS
ENABLE;

CREATE PERMISSION CSR_ROW_ACCESS ON CUSTOMER
 FOR ROWS WHERE VERIFY_ROLE_FOR_USER(SESSION_USER,'CSR') = 1
 ENFORCED FOR ALL ACCESS
 ENABLE;
```

CREATE PROCEDURE

The CREATE PROCEDURE statement defines a procedure at the current server.

Three different types of procedures can be created using this statement. Each of these types is described separately.

- External. The procedure body is written in a programming language. The external executable is referenced by a procedure defined at the current server, along with various attributes of the procedure.
- Sourced. The procedure body is part of the source procedure, which is referenced by the sourced procedure that is defined at the current server, along with various attributes of the procedure. A sourced procedure whose source procedure is at a data source is also called a *federated procedure*.
- SQL. The procedure body is written in SQL and defined at the current server, along with various attributes of the procedure.

The CREATE PROCEDURE statement can be submitted in obfuscated form. In an obfuscated statement, only the procedure name and its parameters are readable. The rest of the statement is encoded in such a way that is not readable but can be decoded by the database server. Obfuscated statements can be produced by calling the DBMS_DDL.WRAP function.

CREATE PROCEDURE (external)

The CREATE PROCEDURE (external) statement defines an external procedure at the current server.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- CREATE_EXTERNAL_ROUTINE authority on the database and at least one of the following authorities:
  - IMPLICIT_SCHEMA authority on the database, if the schema name of the procedure does not refer to an existing schema
  - CREATEIN privilege on the schema, if the schema name of the procedure refers to an existing schema
  - SCHEMAADM authority on the schema, if the schema name of the procedure refers to an existing schema
- DBADM authority

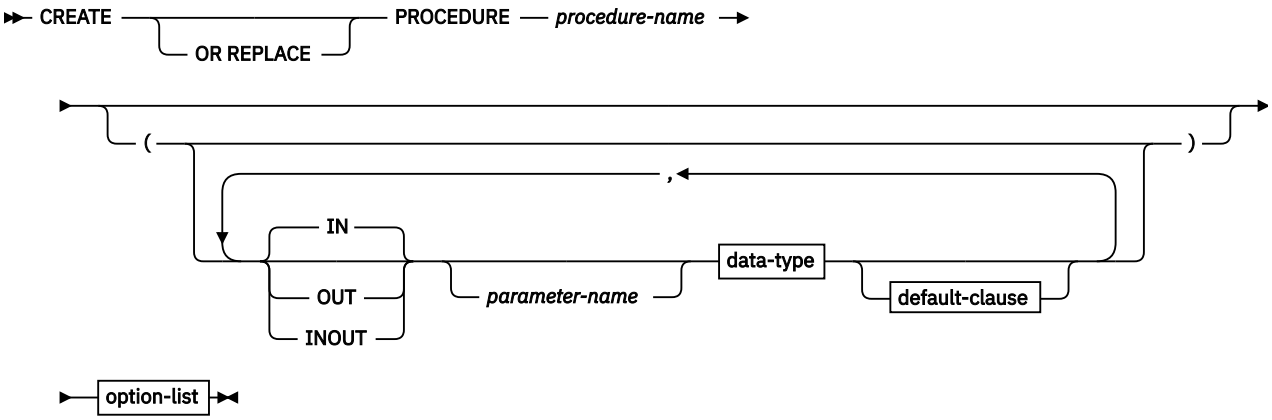
To create a not-fenced procedure, the privileges held by the authorization ID of the statement must also include at least one of the following authorities:

- CREATE_NOT_FENCED_ROUTINE authority on the database
- DBADM authority

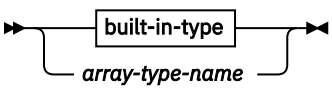
To create a fenced procedure, no additional authorities or privileges are required.

To replace an existing procedure, the authorization ID of the statement must be the owner of the existing procedure (SQLSTATE 42501).

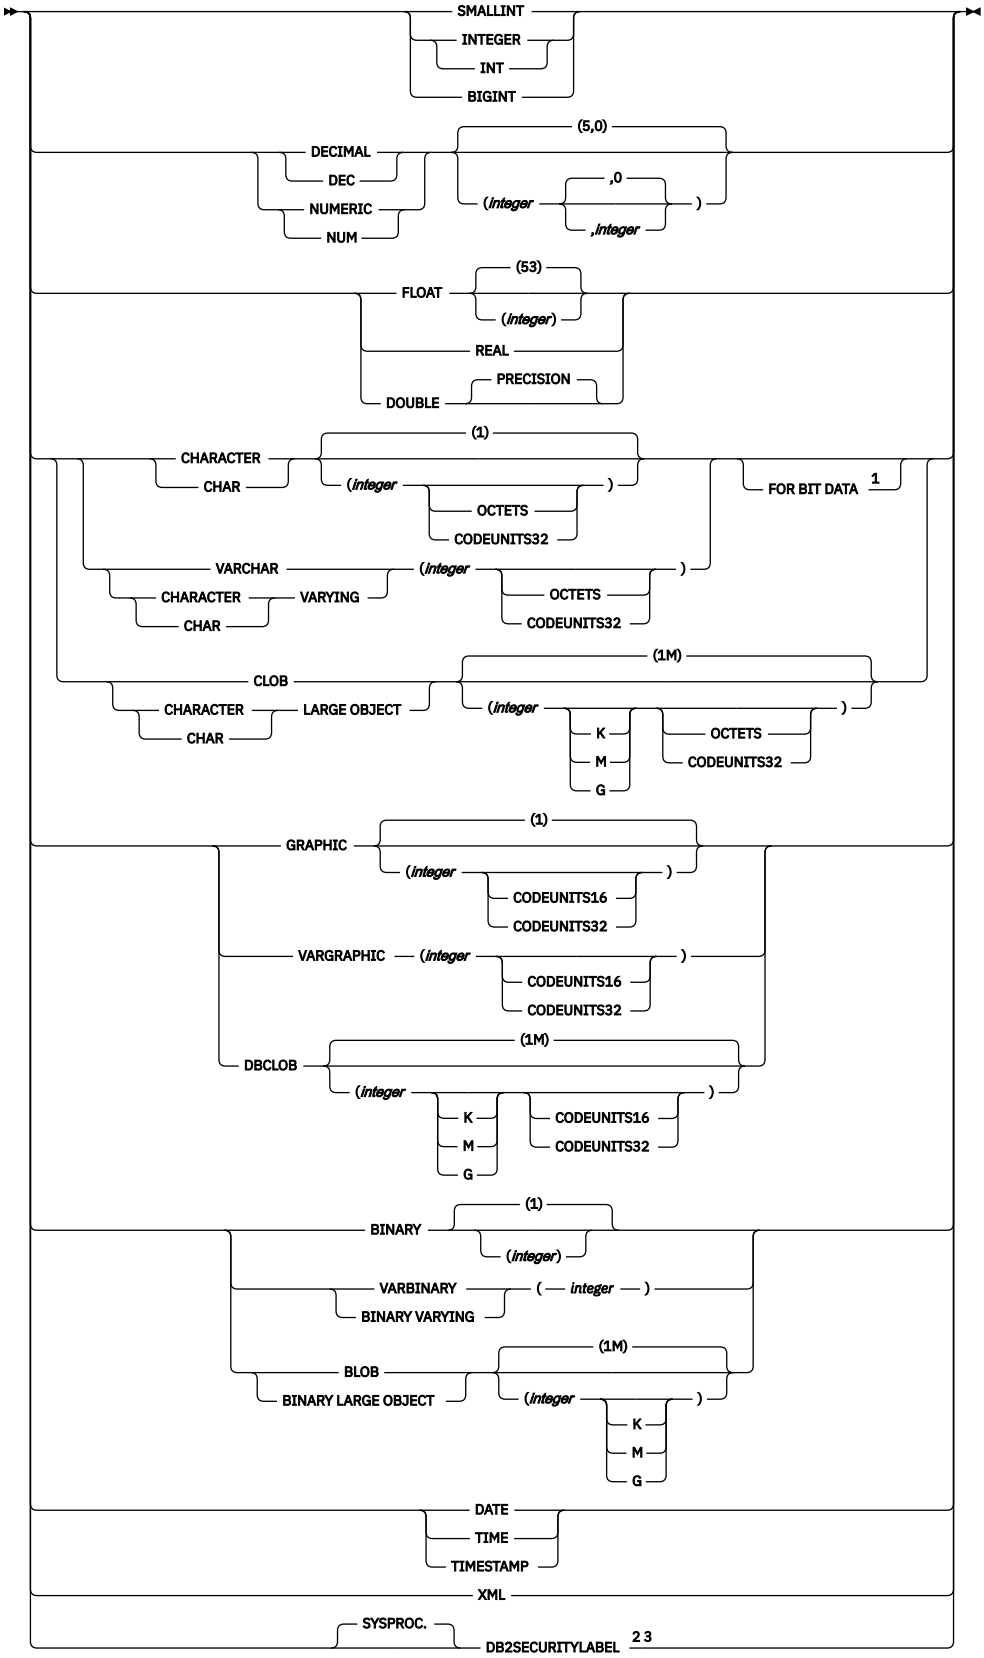
Syntax



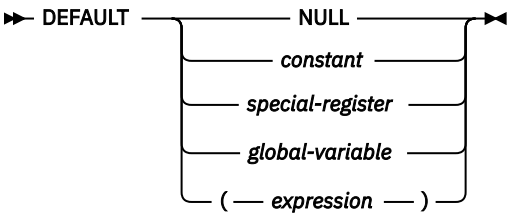
data-type



built-in-type

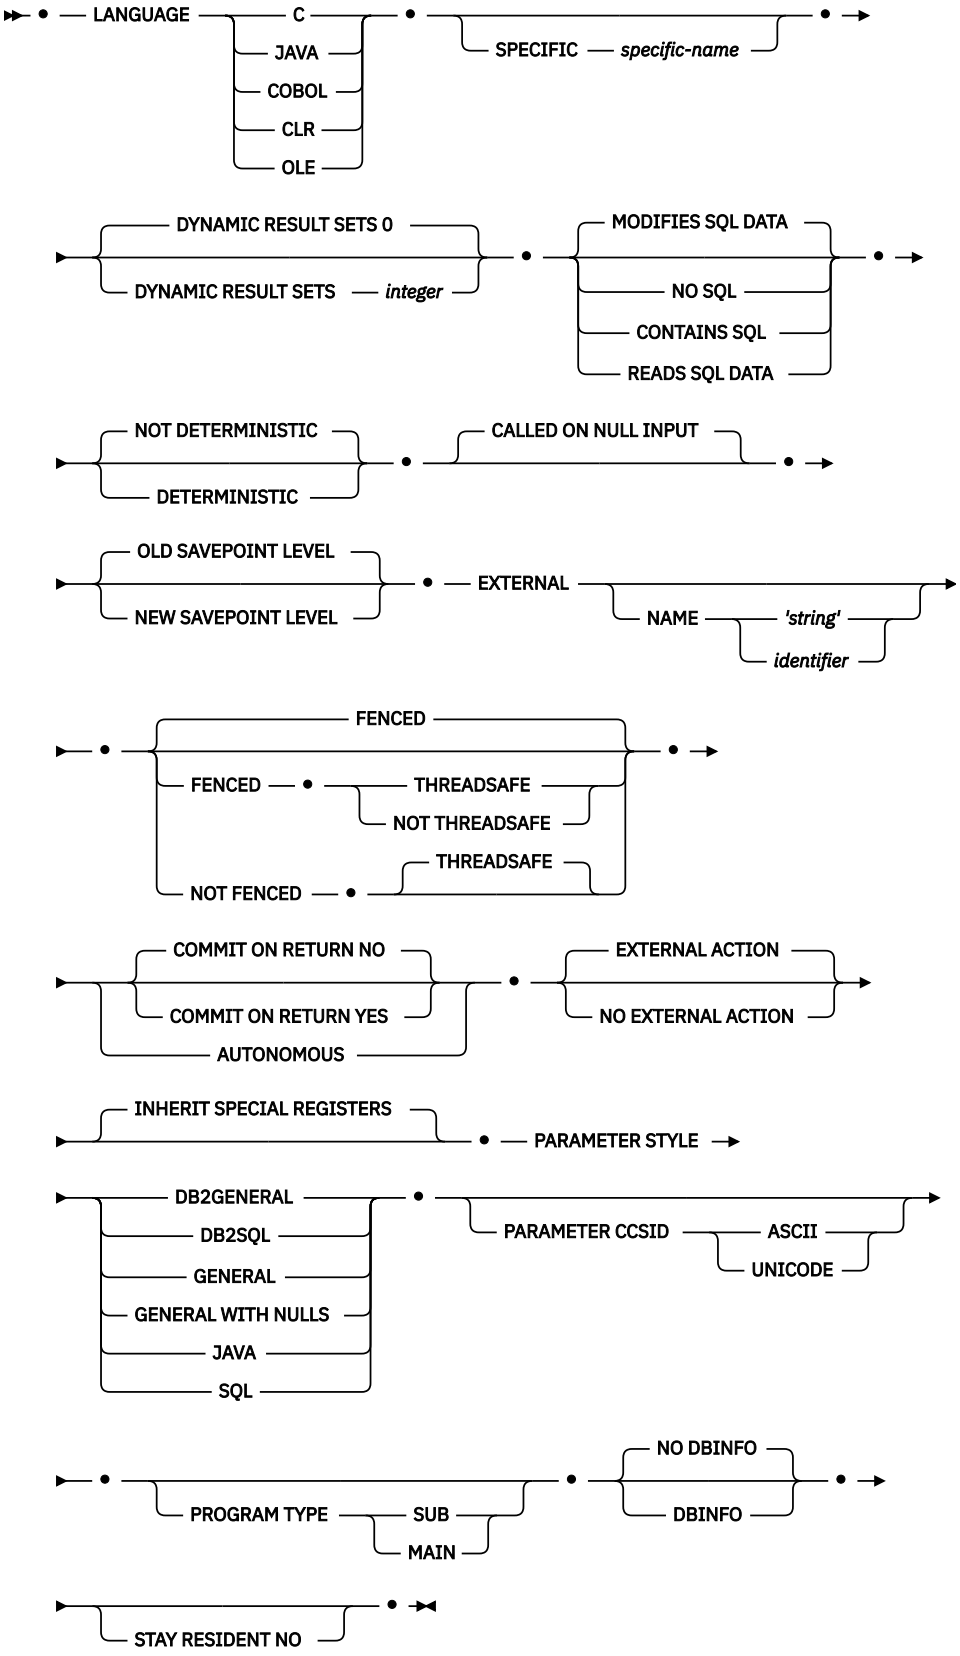


default-clause



DEFAULT
NULL
constant
special-register
global-variable
(
expression
)

option-list



Notes:

[1] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

[2] DB2SECURITYLABEL is the built-in distinct type that must be used to define the row security label column of a protected table.

[3] For a column of type DB2SECURITYLABEL, NOT NULL WITH DEFAULT is implicit and cannot be explicitly specified (SQLSTATE 42842). The default value for a column of type DB2SECURITYLABEL is the session authorization ID's security label for write access.

Description

OR REPLACE

Specifies to replace the definition for the procedure if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that privileges that were granted on the procedure are not affected. This option can be specified only by the owner of the object. This option is ignored if a definition for the procedure does not exist at the current server. To replace an existing procedure, the specific name and procedure name of the new definition must be the same as the specific name and procedure name of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new procedure is created.

procedure-name

Names the procedure being defined. It is a qualified or unqualified name that designates a procedure. The unqualified form of *procedure-name* is an SQL identifier. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The qualified form is a *schema-name* followed by a period and an SQL identifier.

The name, including the implicit or explicit qualifiers, together with the number of parameters must not identify a procedure described in the catalog (SQLSTATE 42723). The unqualified name, together with the number of the parameters, need not be unique across schemas.

If a two-part name is specified, the *schema-name* cannot begin with 'SYS' (SQLSTATE 42939).

(*IN | OUT | INOUT *parameter-name data-type default-clause,...)

Identifies the parameters of the procedure, and specifies the mode, optional parameter name, data type, and optional default value of each parameter. One entry in the list must be specified for each parameter that the procedure will expect.

No two identically-named procedures within a schema are permitted to have exactly the same number of parameters. A duplicate signature returns an SQL error (SQLSTATE 42723).

For example, given the statements:

```
CREATE PROCEDURE PART (IN NUMBER INT, OUT PART_NAME CHAR(35)) ...
CREATE PROCEDURE PART (IN COST DECIMAL(5,3), OUT COUNT INT) ...
```

the second statement will fail, because the number of parameters in the procedure is the same, even if the data types are not.

If an error is returned by the procedure, OUT parameters are undefined and INOUT parameters are unchanged.

IN

Identifies the parameter as an input parameter to the procedure. Any changes made to the parameter within the procedure are not available to the calling SQL application when control is returned. The default is IN.

OUT

Identifies the parameter as an output parameter for the procedure.

INOUT

Identifies the parameter as both an input and output parameter for the procedure.

parameter-name

Optionally specifies the name of the parameter. The parameter name must be unique for the procedure (SQLSTATE 42734).

data-type
Specifies the data type of the parameter. A structured type cannot be specified (SQLSTATE 429BB).

built-in-type
Specifies a built-in data type. For a more complete description of each built-in data type, see "CREATE TABLE". Only built-in data types that have a correspondence in the language that is being used to write the procedure may be specified.

- A datetime type parameter is passed as a character data type, and the data is passed in the ISO format.
- XML is invalid with LANGUAGE OLE.
- Because the XML value that is seen inside a procedure is a serialized version of the XML value that is passed as a parameter in the procedure call, parameters of type XML must be declared using the syntax `XML AS CLOB(`*n*`)`.
- CLR does not support DECIMAL scale greater than 28 (SQLSTATE 42613).
- Decimal floating-point is not supported with languages C, Java COBOL, CLR, and OLE (SQLSTATE 42613).
- BINARY and VARBINARY data types are invalid with LANGUAGE CLR and OLE (SQLSTATE 42815).

array-type-name
Specifies the name of a user-defined array type. If *array-type-name* is specified without a schema name, the array type is resolved by searching the schemas in the SQL path. The array must be an ordinary array and the procedure must be a Java procedure defined with the PARAMETER STYLE JAVA clause (SQLSTATE 428H2).

DEFAULT
Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression or the keyword NULL. The special registers that can be specified as the default are that same as those that can be specified for a column default (see "*default-clause*" in the "CREATE TABLE" statement). Other special registers can be specified as the default by using an expression.

The *expression* can be any expression of the type described in "Expressions". If a default value is not specified, the parameter has no default and the corresponding argument cannot be omitted on invocation of the procedure. The maximum size of the *expression* is 64K bytes.

The default expression must not modify SQL data (SQLSTATE 428FL or SQLSTATE 429BL). The expression must be assignment compatible to the parameter data type (SQLSTATE 42821).

A default cannot be specified in the following situations:

- For INOUT or OUT parameters (SQLSTATE 42601)
- For a parameter of type ARRAY, ROW, or CURSOR (SQLSTATE 429BB)

SPECIFIC *specific-name*
Provides a unique name for the instance of the procedure that is being defined. This specific name can be used when altering, dropping, or commenting on the procedure. It can never be used to invoke the procedure. The unqualified form of *specific-name* is an SQL identifier. The qualified form is a *schema-name* followed by a period and an SQL identifier. The name, including the implicit or explicit qualifier, must not identify another routine instance that exists at the application server; otherwise an error (SQLSTATE 42710) is raised.

The *specific-name* may be the same as an existing *procedure-name*.

If no qualifier is specified, the qualifier that was used for *procedure-name* is used. If a qualifier is specified, it must be the same as the explicit or implicit qualifier of *procedure-name* or an error (SQLSTATE 42882) is raised.

If *specific-name* is not specified, a unique name is generated by the database manager. The unique name is 'SQL' followed by a character timestamp: 'SQL*yymmddhhmmssxxx*'.

DYNAMIC RESULT SETS *integer*
Indicates the estimated upper bound of returned result sets for the procedure.

MODIFIES SQL DATA, NO SQL, CONTAINS SQL, READS SQL DATA
Specifies the classification of SQL statements that can be run by this procedure, or any routine that is called by this procedure. The database manager verifies that the SQL statements issued by the procedure and all routines that are called by the procedure are consistent with this specification.

For the classification of each statement, see "SQL statements that can be executed in routines and triggers" in Developing User-defined Routines (SQL and External).

The default is MODIFIES SQL DATA.

MODIFIES SQL DATA
Specifies that the procedure can run any SQL statement except statements that are not supported in procedures (SQLSTATE 38003).

NO SQL
Specifies that the procedure can run only SQL statements with a data access classification of NO SQL (SQLSTATE 38001).

CONTAINS SQL
Specifies that the procedure can run only statements with a data access classification of CONTAINS SQL or NO SQL (SQLSTATE 38003 or 38004).

READS SQL DATA
Specifies that the procedure can run statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL (SQLSTATE 38002 or 38003 or 42985).

DETERMINISTIC or NOT DETERMINISTIC
This clause specifies whether the procedure always returns the same results for given argument values (DETERMINISTIC) or whether the procedure depends on some state values that affect the results (NOT DETERMINISTIC). That is, a DETERMINISTIC procedure must always return the same result from successive invocations with identical inputs.

This clause currently does not impact processing of the procedure.

CALLED ON NULL INPUT
CALLED ON NULL INPUT always applies to procedures. This means that the procedure is called regardless of whether any arguments are null. Any OUT or INOUT parameter can return a null value or a normal (non-null) value. Responsibility for testing for null argument values lies with the procedure.

OLD SAVEPOINT LEVEL or NEW SAVEPOINT LEVEL
Specifies whether or not this procedure establishes a new savepoint level for savepoint names and effects. OLD SAVEPOINT LEVEL is the default behavior. For more information about savepoint levels, see the "Rules" section in the description of the SAVEPOINT statement.

LANGUAGE
This mandatory clause is used to specify the language interface convention to which the procedure body is written.

C
This means the database manager will call the procedure as if it were a C procedure. The procedure must conform to the C language calling and linkage convention as defined by the standard ANSI C prototype.

JAVA
This means the database manager will call the procedure as a method in a Java class.

COBOL
This means the database manager will call the procedure as if it were a COBOL procedure.

For Micro Focus COBOL, NOT THREADSAFE should be specified for procedures defined

CLR
This means the database manager will call the procedure as a method in a .NET class. At this time, LANGUAGE CLR is only supported for procedures running on Windows operating systems. NOT FENCED cannot be specified for a CLR routine (SQLSTATE 42601).

OLE
This means the database manager will call the procedure as if it were a method exposed by an OLE automation object. The stored-procedure must conform with the OLE automation data types and invocation mechanism. Also, the OLE automation object needs to be implemented as an in-process server (DLL). These restrictions are outlined in the *OLE Automation Programmer's Reference*.

LANGUAGE OLE is only supported for procedures stored in databases running on Windows operating systems. THREADSAFE may not be specified for procedures defined with LANGUAGE OLE (SQLSTATE 42613).

EXTERNAL
This clause indicates that the CREATE PROCEDURE statement is being used to register a new procedure based on code written in an external programming language and adhering to the documented linkage conventions and interface.

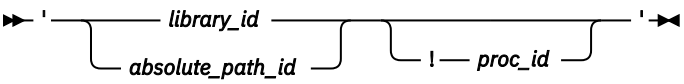
If the NAME clause is not specified, "NAME *procedure-name*" is assumed. If the NAME clause is not formatted correctly, an error is returned (SQLSTATE 42878).

NAME *'string'*
This clause identifies the name of the user-written code which implements the procedure being defined.

The 'string' option is a string constant with a maximum of 254 bytes. The format used for the string is dependent on the LANGUAGE specified.

- For LANGUAGE C:

  The *string* specified is the library name and procedure within the library, which the database manager invokes to execute the procedure being CREATEd. The library (and the procedure within the library) do not need to exist when the CREATE PROCEDURE statement is performed. However, when the procedure is called, the library and procedure within the library must exist and be accessible from the database server machine.



The name must be enclosed by single quotation marks. Extraneous blanks are not permitted.

library_id
Identifies the library name containing the procedure. The database manager will look for the library as follows:

Operating system	Library name location
Linux AIX	If 'myfunc' was given as the *library_id*, and the database manager is being run from `/u/production`, the database manager will look for the procedure in library `/u/production/sqllib/function/myproc` if FENCED is specified, or `/u/production/sqllib/function/unfenced/myproc` if NOT FENCED is specified.
Windows	The database manager will look for the function in a directory path that is specified by the LIBPATH or PATH environment variable.

Stored procedures located in any of these directories do not use any of the registered attributes.

absolute_path_id
Identifies the full path name of the procedure. The format depends on the operating system, as illustrated in the following table:

Operating system	Full path name example
Linux AIX	A value of '/u/jchui/mylib/myproc' would cause the database manager to look in `/u/jchui/mylib` for the `myproc` procedure.
Windows	A value of 'd:\mylib\myproc.dll' would cause the database manager to load the file `myproc.dll` from the `d:\mylib` directory. If an absolute path ID is being used to identify the routine body, be sure to append the `.dll` extension.

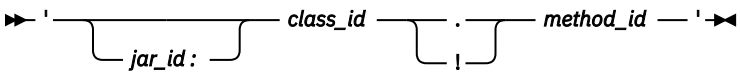
! proc_id
Identifies the entry point name of the procedure to be invoked. The exclamation point (!) serves as a delimiter between the library ID and the procedure ID. '!proc8' would direct the database manager to look for the library in the location specified by *absolute_path_id*, and to use entry point proc8 within that library.

If the string is not properly formed, an error is returned (SQLSTATE 42878).

The body of every procedure should be in a directory that is mounted and available on every database partition.

- For LANGUAGE JAVA:

  The *string* specified contains the optional jar file identifier, class identifier and method identifier, which the database manager invokes to execute the procedure being created. The class identifier and method identifier do not need to exist when the CREATE PROCEDURE statement is performed. If a *jar_id* is specified, it must exist when the CREATE PROCEDURE statement is performed. However, when the procedure is called, the class identifier and the method identifier must exist and be accessible from the database server machine, otherwise an error is returned (SQLSTATE 42884).



The name must be enclosed by single quotation marks. Extraneous blanks are not permitted.

jar_id
Identifies the jar identifier given to the jar collection when it was installed in the database. It can be either a simple identifier or a schema qualified identifier. Examples are 'myJar' and 'mySchema.myJar'.

class_id
Identifies the class identifier of the Java object. If the class is part of a package, the class identifier part must include the complete package prefix, for example, 'myPacks.StoredProcs'. The directory the Java virtual machine will look in for the classes depends on the operating system, as illustrated in the following table:

Operating system	Directory the Java virtual machine will look in for the classes
Linux AIX	`'.../myPacks/UserProcs/'`
Windows	`'...\myPacks\UserProcs\'`

method_id
Identifies the method name with the Java class to be invoked.

- For LANGUAGE CLR:

The *string* specified represents the .NET assembly (library or executable), the class within that assembly, and the method within the class that the database manager invokes to execute the procedure being created. The module, class, and method do not need to exist when the CREATE PROCEDURE statement is executed. However, when the procedure is called, the module, class, and method must exist and be accessible from the database server machine, otherwise an error is returned (SQLSTATE 42284).

C++ routines that are compiled with the '/clr' compiler option to indicate that they include managed code extensions must be cataloged as 'LANGUAGE CLR' and not 'LANGUAGE C'. The database manager needs to know that the .NET infrastructure is being utilized in a procedure in order to make necessary runtime decisions. All procedures using the .NET infrastructure must be cataloged as 'LANGUAGE CLR'.

The name must be enclosed by single quotation marks. Extraneous blanks are not permitted.

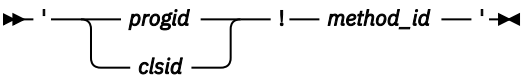
assembly
Identifies the DLL or other assembly file in which the class is located. Any file extensions (such as .dll) must be specified. If the full path name is not given, the file must be in the function directory of the database instance path (for example, `C:\Program Data\IBM\Db2\Copy Name`). If the file is in a subdirectory of the instance function directory, the subdirectory can be given before the file name rather than specifying the full path. For example, if your instance directory is `C:\Program Data\IBM\Db2\Copy Name` and your assembly file is `C:\Program Data\IBM\Db2\Copy Name\function\myprocs\mydotnet.dll`, it is only necessary to specify `'myprocs\mydotnet.dll'` for the assembly. The case sensitivity of this parameter is the same as the case sensitivity of the file system.

class_id
Specifies the name of the class within the given assembly in which the method that is to be invoked resides. If the class resides within a namespace, the full namespace must be given in addition to the class. For example, if the class EmployeeClass is in namespace MyCompany.ProcedureClasses, then MyCompany.ProcedureClasses.EmployeeClass must be specified for the class. Note that the compilers for some .NET languages will add the project name as a namespace for the class, and the behavior may differ depending on whether the command line compiler or the GUI compiler is used. This parameter is case sensitive.

method_id
Specifies the method within the given class that is to be invoked. This parameter is case sensitive.

- For LANGUAGE OLE:

The string specified is the OLE programmatic identifier (*progid*) or class identifier (*clsid*), and method identifier (*method_id*), which the database manager invokes to execute the procedure being created by the statement. The programmatic identifier or class identifier, and the method identifier do not need to exist when the CREATE PROCEDURE statement is executed. However, when the procedure is used in the CALL statement, the method identifier must exist and be accessible from the database server machine, otherwise an error results (SQLSTATE 42724).



The name must be enclosed by single quotation marks. Extraneous blanks are not permitted.

progid
Identifies the programmatic identifier of the OLE object.

A *progid* is not interpreted by the database manager, but only forwarded to the OLE automation controller at run time. The specified OLE object must be creatable and support late binding (also known as IDispatch-based binding). By convention, progids have the following format:

```
<program_name>.<component_name>.<version>
```

Because this is only a convention, and not a rule, *progids* may in fact have a different format.

clsid
Identifies the class identifier of the OLE object to create. It can be used as an alternative for specifying a progid in the case that an OLE object is not registered with a progid. The *clsid* has the form:

```
{nnnnnnnn-nnnn-nnnn-nnnn-nnnnnnnnnnnn}
```

where 'n' is an alphanumeric character. A *clsid* is not interpreted by the database manager, but only forwarded to the OLE APIs at run time.

method_id
Identifies the method name of the OLE object to be invoked.

NAME *identifier*
This *identifier* specified is an SQL identifier. The SQL identifier is used as the *library-id* in the string. Unless it is a delimited identifier, the identifier is folded to upper case. If the identifier is qualified with a schema name, the schema name portion is ignored. This form of NAME can only be used with LANGUAGE C.

FENCED or NOT FENCED
This clause specifies whether the procedure is considered "safe" to run in the database manager operating environment's process or address space (NOT FENCED), or not (FENCED).

If a procedure is registered as FENCED, the database manager protects its internal resources (for example, data buffers) from access by the procedure. All procedures have the option of running as FENCED or NOT FENCED. In general, a procedure running as FENCED will not perform as well as a similar one running as NOT FENCED.

CAUTION: Use of NOT FENCED for procedures that were not adequately coded, reviewed, and tested can compromise the integrity of a Db2 database. Db2 databases take some precautions against many of the common types of inadvertent failures that might occur, but cannot guarantee complete integrity when NOT FENCED stored procedures are used.

Either SYSADM authority, DBADM authority, or a special authority (CREATE_NOT_FENCED) is required to register a procedure as NOT FENCED. Only FENCED can be specified for a procedure with LANGUAGE OLE or NOT THREADSAFE.

LANGUAGE CLR procedures cannot be created when specifying the NOT FENCED clause (SQLSTATE 42601).

THREADSAFE or NOT THREADSAFE
Specifies whether the procedure is considered safe to run in the same process as other routines (THREADSAFE), or not (NOT THREADSAFE).

If the procedure is defined with LANGUAGE other than OLE:

- If the procedure is defined as THREADSAFE, the database manager can invoke the procedure in the same process as other routines. In general, to be threadsafe, a procedure should not use any global or static data areas. Most programming references include a discussion of writing threadsafe routines. Both FENCED and NOT FENCED procedures can be THREADSAFE.
- If the procedure is defined as NOT THREADSAFE, the database manager will never invoke the procedure in the same process as another routine.

For FENCED procedures, THREADSAFE is the default if the LANGUAGE is JAVA or CLR. For all other languages, NOT THREADSAFE is the default. If the procedure is defined with LANGUAGE OLE, THREADSAFE may not be specified (SQLSTATE 42613).

For NOT FENCED procedures, THREADSAFE is the default. NOT THREADSAFE cannot be specified (SQLSTATE 42613).

COMMIT ON RETURN
Indicates whether a commit is to be issued on return from the procedure. The default is NO.

NO
A commit is not issued when the procedure returns.

YES
A commit is issued when the procedure returns if a positive SQLCODE is returned by the CALL statement

The commit operation includes the work that is performed by the calling application process and the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

AUTONOMOUS
Indicates the procedure should execute in its own autonomous transaction scope.

EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the procedure takes some action that changes the state of an object not managed by the database manager (EXTERNAL ACTION), or not (NO EXTERNAL ACTION). The default is EXTERNAL ACTION. If NO EXTERNAL ACTION is specified, the system can use certain optimizations that assume the procedure has no external impact.

INHERIT SPECIAL REGISTERS
This optional clause specifies that updatable special registers in the procedure will inherit their initial values from the environment of the invoking statement.

No changes to the special registers are passed back to the caller of the procedure.

Non-updatable special registers, such as the datetime special registers, reflect a property of the statement currently executing, and are therefore set to their default values.

PARAMETER STYLE
This clause is used to specify the conventions used for passing parameters to and returning the value from procedures.

DB2GENERAL
This means that the procedure will use a parameter passing convention that is defined for use with Java methods. This can only be specified when LANGUAGE JAVA is used.

DB2SQL
In addition to the parameters on the CALL statement, the following arguments are passed to the procedure:

- A vector containing a null indicator for each parameter on the CALL statement
- The SQLSTATE to be returned to the database manager
- The qualified name of the procedure
- The specific name of the procedure
- The SQL diagnostic string to be returned to the database manager

This can only be specified when LANGUAGE C, COBOL, CLR, or OLE is used.

GENERAL
This means that the procedure will use a parameter passing mechanism by which the procedure receives the parameters specified on the CALL. The parameters are passed directly, as expected by the language; the SQLDA structure is not used. This can only be specified when LANGUAGE C, COBOL, or CLR is used.

Null indicators are *not* directly passed to the program.

GENERAL WITH NULLS
In addition to the parameters on the CALL statement specified under GENERAL, another argument is passed to the procedure. This additional argument is a vector of null indicators, one for each of the parameters on the CALL statement. In C, this would be an array of short integers. This can only be specified when LANGUAGE C, COBOL, or CLR is used.

JAVA
This means that the procedure will use a parameter passing convention that conforms to the Java language and SQLJ Routines specification. IN/OUT and OUT parameters will be passed as single entry arrays to facilitate returning values. This can only be specified when LANGUAGE JAVA is used.

PARAMETER STYLE JAVA procedures do not support the DBINFO or PROGRAM TYPE clauses.

SQL
In addition to the parameters on the CALL statement, the following arguments are passed to the procedure:

- A null indicator for each parameter on the CALL statement
- The SQLSTATE to be returned to the database manager
- The qualified name of the procedure
- The specific name of the procedure
- The SQL diagnostic string to be returned to the database manager

This can only be specified when LANGUAGE C, COBOL, CLR, or OLE is used.

PARAMETER CCSID
Specifies the encoding scheme to use for all string data passed into and out of the procedure. If the PARAMETER CCSID clause is not specified, the default is PARAMETER CCSID UNICODE for Unicode databases, and PARAMETER CCSID ASCII for all other databases.

ASCII
Specifies that string data is encoded in the database code page. If the database is a Unicode database, PARAMETER CCSID ASCII cannot be specified (SQLSTATE 56031). When the procedure is invoked, the application code page for the procedure is the database code page.

UNICODE
Specifies that string data is encoded in Unicode. If the database is a Unicode database, character data is in UTF-8, and graphic data is in UCS-2. If the database is not a Unicode database, character data is in UTF-8. In either case, when the procedure is invoked, the application code page for the procedure is 1208.

If the database is not a Unicode database, and a procedure with PARAMETER CCSID UNICODE is created, the procedure cannot have any graphic types, the XML type, or user-defined types (SQLSTATE 560C1).

If the database is not a Unicode database, and the alternate collating sequence has been specified in the database configuration, procedures can be created with either PARAMETER CCSID ASCII or PARAMETER CCSID UNICODE. All data passed into and out of the procedure will be converted to the appropriate code page.

This clause cannot be specified with LANGUAGE OLE, LANGUAGE JAVA, or LANGUAGE CLR (SQLSTATE 42613).

PROGRAM TYPE
Specifies whether the procedure expects parameters in the style of a main routine or a subroutine. The default is SUB.

SUB
The procedure expects the parameters to be passed as separate arguments.

MAIN
The procedure expects the parameters to be passed as an argument counter, and a vector of arguments (argc, argv). The name of the procedure to be invoked must also be "main". Stored procedures of this type must still be built in the same fashion as a shared library, rather than a stand-alone executable. PROGRAM TYPE MAIN is only valid when the LANGUAGE clause specifies one of: C, COBOL, or CLR.

DBINFO or NO DBINFO
Specifies whether specific information known by the database manager is passed to the procedure when it is invoked as an additional invocation-time argument (DBINFO) or not (NO DBINFO). NO DBINFO is the default. DBINFO is not supported for LANGUAGE OLE (SQLSTATE 42613). It is also not supported for PARAMETER STYLE JAVA or DB2GENERAL.

If DBINFO is specified, a structure containing the following information is passed to the procedure:

- Data base name - the name of the currently connected database.
- Application ID - unique application ID which is established for each connection to the database.
- Application Authorization ID - the authorization ID of the user that connected to the database (the SYSTEM_USER special register).
- Code page - identifies the database code page.
- Database version/release - identifies the version, release and modification level of the database server invoking the procedure.
- Platform - contains the server's platform type.

The DBINFO structure is common for all external routines and contains additional fields that are not relevant to procedures.

If you change session authorization ID (the SESSION_USER special register) using the SET SESSION AUTHORIZATION statement, the Application Authorization ID still returns the value of the SYSTEM_USER special register.

STAY RESIDENT NO
Specifies that the library that is loaded for the function is not to remain resident in memory after the function ends. This clause is ignored when:

- The NOT FENCED clause is specified.
- The LANGUAGE option is set to JAVA or CLR.

Rules

- ***Autonomous routine restrictions:*** Autonomous routines cannot return result sets and do not support the following parameter data types (SQLSTATE 428H2):
  - Cursor types
  - Structured types
  - XML

  Global variables of cursor types cannot be referenced within the autonomous scope.

Notes

- Creating a procedure with a schema name that does not already exist results in the implicit creation of that schema, provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- A Java routine defined as NOT FENCED will be invoked as if it had been defined as FENCED THREADSAFE.
- A procedure that is called from within a compound SQL (inlined) statement will execute as if it were created specifying NEW SAVEPOINT LEVEL, even if OLD SAVEPOINT LEVEL was specified or defaulted to when the procedure was created.

- XML parameters are only supported in LANGUAGE JAVA external procedures when the PARAMETER STYLE DB2GENERAL clause is specified.
- ***Setting of the default value:*** Parameters of a procedure that are defined with a default value are set to their default value when the procedure is invoked, but only if a value is not supplied for the corresponding argument, or is specified as DEFAULT, when the procedure is invoked.
- ***Privileges:*** The definer of a procedure always receives the EXECUTE privilege WITH GRANT OPTION on the procedure, as well as the right to drop the procedure. When the procedure is used in an SQL statement, the procedure definer must have the EXECUTE privilege on any packages used by the procedure or EXECUTEIN privilege on the schema containing the packages used by the procedure.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - RESULT SETS can be specified in place of DYNAMIC RESULT SETS.
  - NULL CALL can be specified in place of CALLED ON NULL INPUT.
  - DB2GENRL can be specified in place of DB2GENERAL.
  - SIMPLE CALL can be specified in place of GENERAL.
  - SIMPLE CALL WITH NULLS can be specified in place of GENERAL WITH NULLS.
  - PARAMETER STYLE DB2DARI is supported.

  The following syntax is accepted as the default behavior:

  - ASUTIME NO LIMIT
  - NO COLLID
  - STAY RESIDENT NO
  - CCSID UNICODE in a Unicode database
  - CCSID ASCII in a non-Unicode database if PARAMETER CCSID UNICODE is not specified

Examples

- *Example 1:* Create the procedure definition for a procedure, written in Java, that is passed a part number and that returns the cost of the part and the quantity that is currently available.

```
CREATE PROCEDURE PARTS_ON_HAND (IN PARTNUM INTEGER,
    OUT COST DECIMAL(7,2),
    OUT QUANTITY INTEGER)
EXTERNAL NAME 'parts.onhand'
LANGUAGE JAVA PARAMETER STYLE JAVA
```

- *Example 2:* Create the procedure definition for a procedure, written in C, that is passed an assembly number and returns the number of parts that make up the assembly, total part cost, and a result set that lists the part numbers, quantity, and unit cost of each part.

```
CREATE PROCEDURE ASSEMBLY_PARTS (IN ASSEMBLY_NUM INTEGER,
    OUT NUM_PARTS INTEGER,
    OUT COST DOUBLE)
  EXTERNAL NAME 'parts!assembly'
  DYNAMIC RESULT SETS 1 NOT FENCED
  LANGUAGE C PARAMETER STYLE GENERAL
```

CREATE PROCEDURE (sourced)

The CREATE PROCEDURE (sourced) statement defines a procedure (the *sourced procedure*) that is based on another procedure (the *source procedure*). In a federated system, a *federated procedure* is a sourced procedure whose source procedure is at a supported data source.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

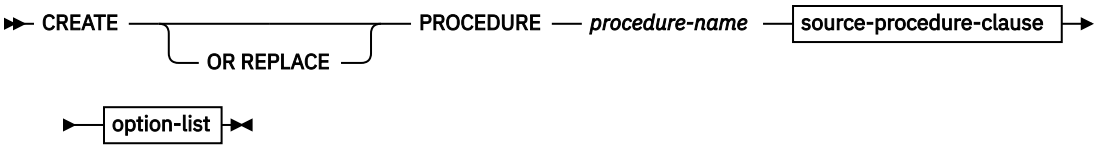
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the schema name of the procedure does not refer to an existing schema
- CREATEIN privilege on the schema, if the schema name of the procedure refers to an existing schema
- SCHEMAADM authority on the schema, if the schema name of the procedure refers to an existing schema
- DBADM authority

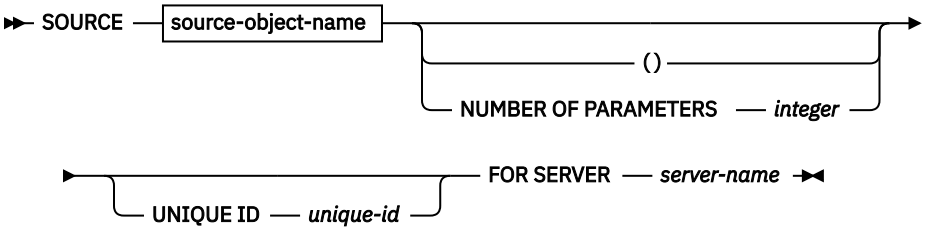
For data sources that require a user mapping, the privileges held at the data source by the authorization ID of the statement must include the privilege to select the procedure's description from the remote catalog tables.

To replace an existing procedure, the authorization ID of the statement must be the owner of the existing procedure (SQLSTATE 42501).

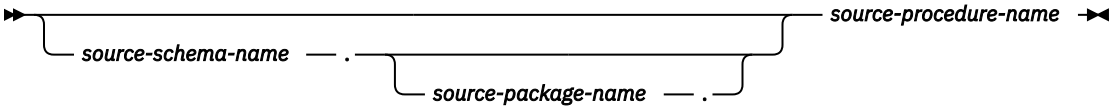
Syntax



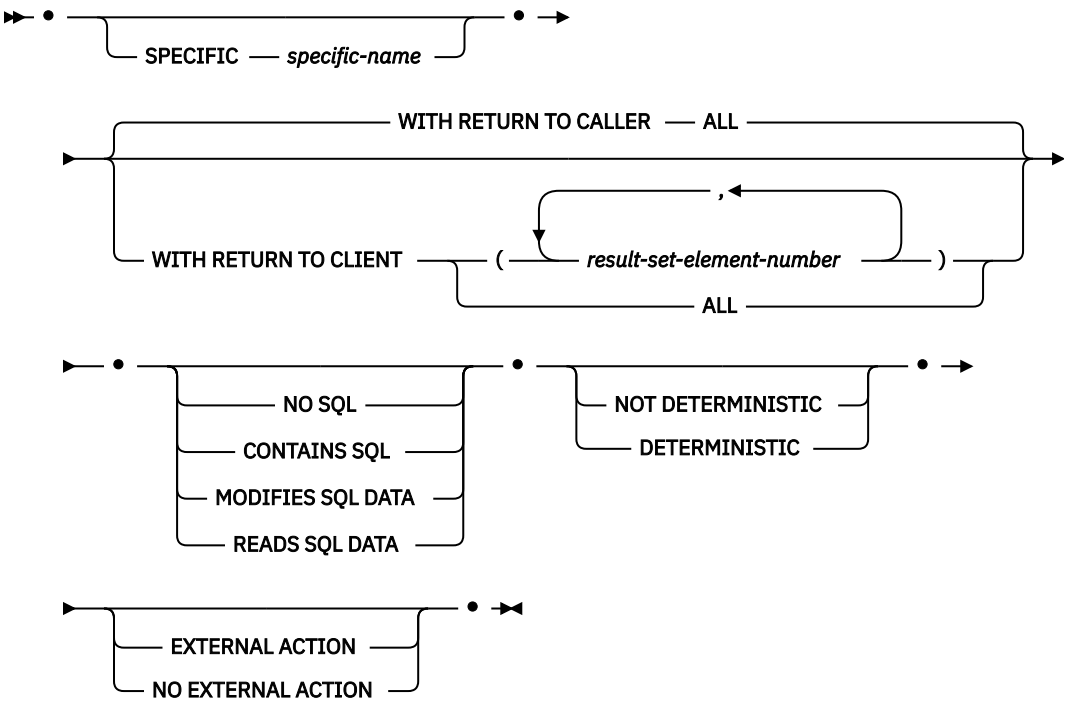
source-procedure-clause



source-object-name



option-list



Description

OR REPLACE
Specifies to replace the definition for the procedure if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that privileges that were granted on the procedure are not affected. This option can be specified only by the owner of the object. This option is ignored if a definition for the procedure does not exist at the current server. To replace an existing procedure, the specific name and procedure name of the new definition must be the same as the specific name and procedure name of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new procedure is created.

procedure-name
Names the sourced procedure being defined. It is a qualified or unqualified name that designates a procedure. The unqualified form of *procedure-name* is an SQL identifier. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile or bind option implicitly specifies the qualifier for unqualified object names. The qualified form is a *schema-name* followed by a period and an SQL identifier.

The name, including the implicit or explicit qualifiers, together with the number of parameters, must not identify a procedure that is described in the catalog (SQLSTATE 42723). The unqualified name, together with the number of parameters, need not be unique across schemas.

If a two-part name is specified, the *schema-name* cannot begin with 'SYS' (SQLSTATE 42939).

In a federated system, *procedure-name* is the name of the procedure on the federated server.

SOURCE *source-object-name*
Specifies the source procedure that is used by the procedure being defined. In a federated system, the source procedure is a procedure that is located at a supported data source.

source-schema-name
Identifies the schema name of the source procedure. If a schema name is used to identify the source procedure, the *source-schema-name* must be specified in the CREATE PROCEDURE (Sourced) statement. If the *source-schema-name* contains any special or lowercase characters, it must be enclosed by double quotation marks.

source-package-name
Identifies the package name of the source procedure. The *source-package-name* applies only to Oracle data sources. If a package name is used to identify the source procedure, the *source-package-name* must be specified in the CREATE PROCEDURE (Sourced) statement. If the *source-package-name* contains any special or lowercase characters, it must be enclosed by double quotation marks.

source-procedure-name
Identifies the procedure name of the source procedure. If the *source-procedure-name* contains any special or lowercase characters, it must be enclosed by double quotation marks.

( )
Indicates that the number of parameters is zero.

NUMBER OF PARAMETERS *integer*
Specifies the number of parameters for the source procedure. The minimum value for *integer* is 0, and the maximum value is 32 767.

UNIQUE ID *string-constant*
Provides a way to uniquely identify the source procedure when there are multiple procedures at the data source with the identical name, schema, and number of parameters. The *string-constant* value, which has a maximum length of 128, is interpreted uniquely by each data source.

FOR SERVER *server-name*
Specifies a server definition that was registered using the CREATE SERVER statement.

SPECIFIC *specific-name*
Provides a unique name for the instance of the sourced procedure that is being defined. This specific name can be used when altering, dropping, or commenting on the sourced procedure. This name can never be used to invoke the sourced procedure. The unqualified form of *specific-name* is an SQL identifier. The qualified form of *specific-name* is a *schema-name* followed by a period and an SQL identifier. The *specific-name* value, including the implicit or explicit qualifier, must not identify another procedure instance that exists at the application server; otherwise an error is returned (SQLSTATE 42710).

The *specific-name* can be the same as an existing *procedure-name*.

If no qualifier is specified, the qualifier that was used for *procedure-name* is used. If a qualifier is specified, it must be the same as the explicit or implicit qualifier for *procedure-name*, or an error is returned (SQLSTATE 42882).

If *specific-name* is not specified, a unique name is generated by the database manager. The unique name is 'SQL' followed by a character timestamp: 'SQL*yymmddhhmmssxxx*'.

WITH RETURN TO CALLER or WITH RETURN TO CLIENT
Indicates where the result sets from the source procedure are handled. If the source procedure is not from an Oracle data source, the only one result set is returned to the caller or client; and if the source procedure is coded to return more than one result set, only the first result set is returned to the caller or client. The default is WITH RETURN TO CALLER.

WITH RETURN TO CALLER ALL
Specifies that all result sets from the source procedure are returned to the caller.

WITH RETURN TO CLIENT
Indicates which result sets from the source procedure are returned directly to the client application. The dynamic result set value at the data source must be greater than 0 for a result set to be returned.

(result-set-element-number, ...)
Specifies a non-empty list of result sets to return to the client application (SQLSTATE 42601). A *result-set-element-number* identifies a result set based on the order the result sets are returned, where 1 identifies the first result set, 2 the second result set, and so on. A *result-set-element-number* greater than the total number of result sets returned is ignored. Each *result-set-element-number* must be an integer value greater than zero (SQLSTATE 42815), and must not exceed the value of a small integer constant (SQLSTATE 42820). The list of result

sets to return to the client application must not contain duplicate values and must be specified in ascending order (SQLSTATE 42815). Result sets are always processed in the order they are returned from the source procedure.

Result sets that are not identified in the list to return to client application are returned to the caller.

Note: This list of result sets to return to the client application must only be used with source procedures that are known to consistently return result sets that are intended for the client in the same position in the list of result sets each time they are executed. It is possible for a source procedure to return different sets of result sets each time it is executed, depending on the internal logic of the procedure. If this is the case, then specify either WITH RETURN TO CALLER ALL or WITH RETURN TO CLIENT ALL instead, and code the application to handle this case.

ALL
Specifies all result sets from the source procedure are returned to the client.

NO SQL, CONTAINS SQL, MODIFIES SQL DATA, READS SQL DATA
Specifies the classification of SQL statements that can be run by this procedure, or any routine that is called by this procedure. The database manager verifies that the SQL statements issued by the procedure and all routines that are called by the procedure are consistent with this specification.

For the classification of each statement, see "SQL statements that can be executed in routines and triggers" in Developing User-defined Routines (SQL and External).

Because the source procedure for the sourced procedure is not on the federated server, the specified level is not enforced during execution of the source procedure at the data source. If there is discrepancy between what is specified for the sourced procedure and what the source procedure actually does at the data source, data inconsistency might occur.

If this option is not explicitly specified, the value for the source procedure is used.

If this option is explicitly specified but does not match the value for the source procedure, an error is returned (SQLSTATE 428GS).

If this option is not available at the data source, the default is MODIFIES SQL DATA.

NO SQL
Specifies that the procedure can run only SQL statements with a data access classification of NO SQL. (SQLSTATE 38001).

CONTAINS SQL
Specifies that the procedure can run only statements with a data access classification of CONTAINS SQL or NO SQL (SQLSTATE 38003 or 38004).

MODIFIES SQL DATA
Specifies that the procedure can run any SQL statement except statements that are not supported in procedures (SQLSTATE 38003).

READS SQL DATA
Specifies that the procedure can run statements with a data access classification of READS SQL DATA, CONTAINS SQL, or NO SQL (SQLSTATE 38002 or 38003 or 42985).

DETERMINISTIC or NOT DETERMINISTIC
Specifies whether the sourced procedure always returns the same results for given argument values (DETERMINISTIC), or whether the sourced procedure depends on some stated values that affect the results (NOT DETERMINISTIC). A DETERMINISTIC sourced procedure must always return the same result from successive invocations with identical inputs. This clause currently does not impact the processing of the procedure. If this option is not explicitly specified, the value for the source procedure is used. If this option is not available at the data source, the default is NOT DETERMINISTIC. If this option is explicitly specified, but does not match the value for the source procedure, an error is returned (SQLSTATE 428GS).

EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the sourced procedure takes some action that changes the state of an object that is not managed by the database manager (EXTERNAL ACTION), or does not (NO EXTERNAL ACTION). If the NO EXTERNAL ACTION clause is specified, the federated database uses optimization that assumes that the sourced procedure has no external impact. If this option is not explicitly specified, the value for the source procedure is used. If this option is not available at the data source, the default is EXTERNAL ACTION. If this option is explicitly specified but does not match the value for the source procedure, an error is returned (SQLSTATE 428GS).

Rules

- If the *source-object-name*, along with the NUMBER OF PARAMETERS and UNIQUE ID clauses do not identify a procedure at the data source, an error is returned (SQLSTATE 42883); if more than one procedure is identified, an error is returned (SQLSTATE 42725).
- If the UNIQUE ID clause is specified and the data source does not support unique IDs, an error is returned (SQLSTATE 42883).

Notes

- Before a federated procedure can be registered for a data source, the federated server must be configured to access that data source. This configuration includes: registering the wrapper for the data source, creating the server definition for the data source, and creating the user mappings between the federated server and the data source server for the data sources that require user mapping.
- ***Creating procedures that are initially invalid:*** If an object referenced in the procedure body does not exist or is marked invalid, or the definer temporarily doesn't have privileges to access the object, and if the database configuration parameter **auto_reval** is not set to DISABLED, then the procedure will still be created successfully. The procedure will be marked invalid and will be revalidated the next time it is invoked.
- Unlike SQL and external procedures defined at the federated server, federated procedures do not inherit the special registers of the caller, even those whose *remote-object-name* refers to a procedure on a Db2 data source.
- If the definition of the source procedure is changed (for example, a parameter data type is changed), the federated procedure should be dropped and recreated; otherwise, errors might occur when the federated procedure is invoked.
- If the length of the source procedure parameter is longer than 128, the parameter name of the federated procedure is truncated to 128 bytes.
- ***Compatibilities***: The DataJoiner syntax for Create Stored Procedure Nickname is not supported. Parameter type mapping is handled similarly to nicknames: A catalog look-up determines the remote data type. The local parameter type is determined through forward type mapping.

Examples

- *Example 1:* Create a federated procedure named FEDEMPLOYEE for an Oracle procedure named EMPLOYEE, using the remote schema name USER1, the remote package name P1 at the federated server S1, and returning the result set to the client.

```
CREATE PROCEDURE FEDEMPLOYEE SOURCE USER1.P1.EMPLOYEE
  FOR SERVER S1 WITH RETURN TO CLIENT ALL
```

- *Example 2:* Create a federated procedure named FEDSALARYSTAT for an Oracle procedure named SALARYSTAT, using the remote schema name USER1, the remote package name P1 at the federated server S1, and returning the first and the third result set to the client, and remaining result sets to the caller.

```
CREATE OR REPLACE PROCEDURE FEDSALARYSTAT SOURCE USER1.P1.SALARYSTAT
FOR SERVER S1 WITH RETURN TO CLIENT(1,3)
```

CREATE PROCEDURE (SQL)

The CREATE PROCEDURE (SQL) statement defines an SQL procedure at the current server.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include at least one of the following authorities:

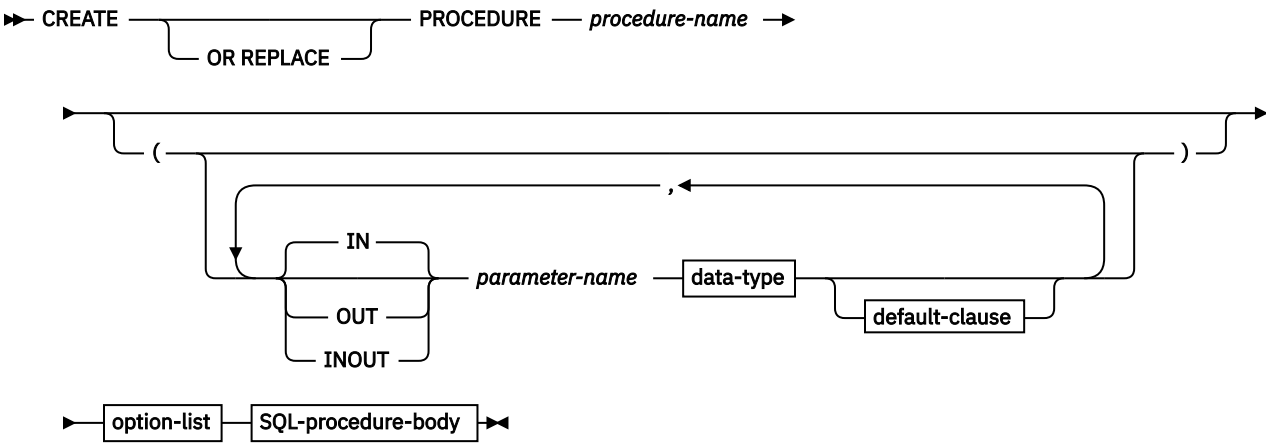
- If the implicit or explicit schema name of the procedure does not exist, IMPLICIT_SCHEMA authority on the database.
- If the schema name of the procedure refers to an existing schema, CREATEIN privilege on the schema.
- If the schema name of the procedure refers to an existing schema, SCHEMAADM authority on the schema.
- DBADM authority

The privileges held by the authorization ID of the statement must also include all of the privileges necessary to invoke the SQL statements that are specified in the procedure body.

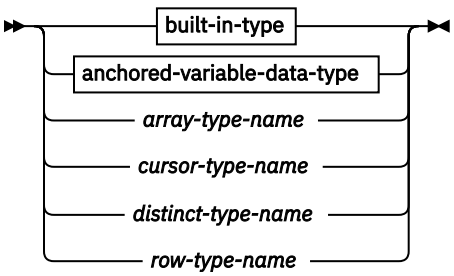
To replace an existing procedure, the authorization ID of the statement must be the owner of the existing procedure (SQLSTATE 42501).

Group privileges are not considered for any table or view specified in the CREATE PROCEDURE (SQL) statement.

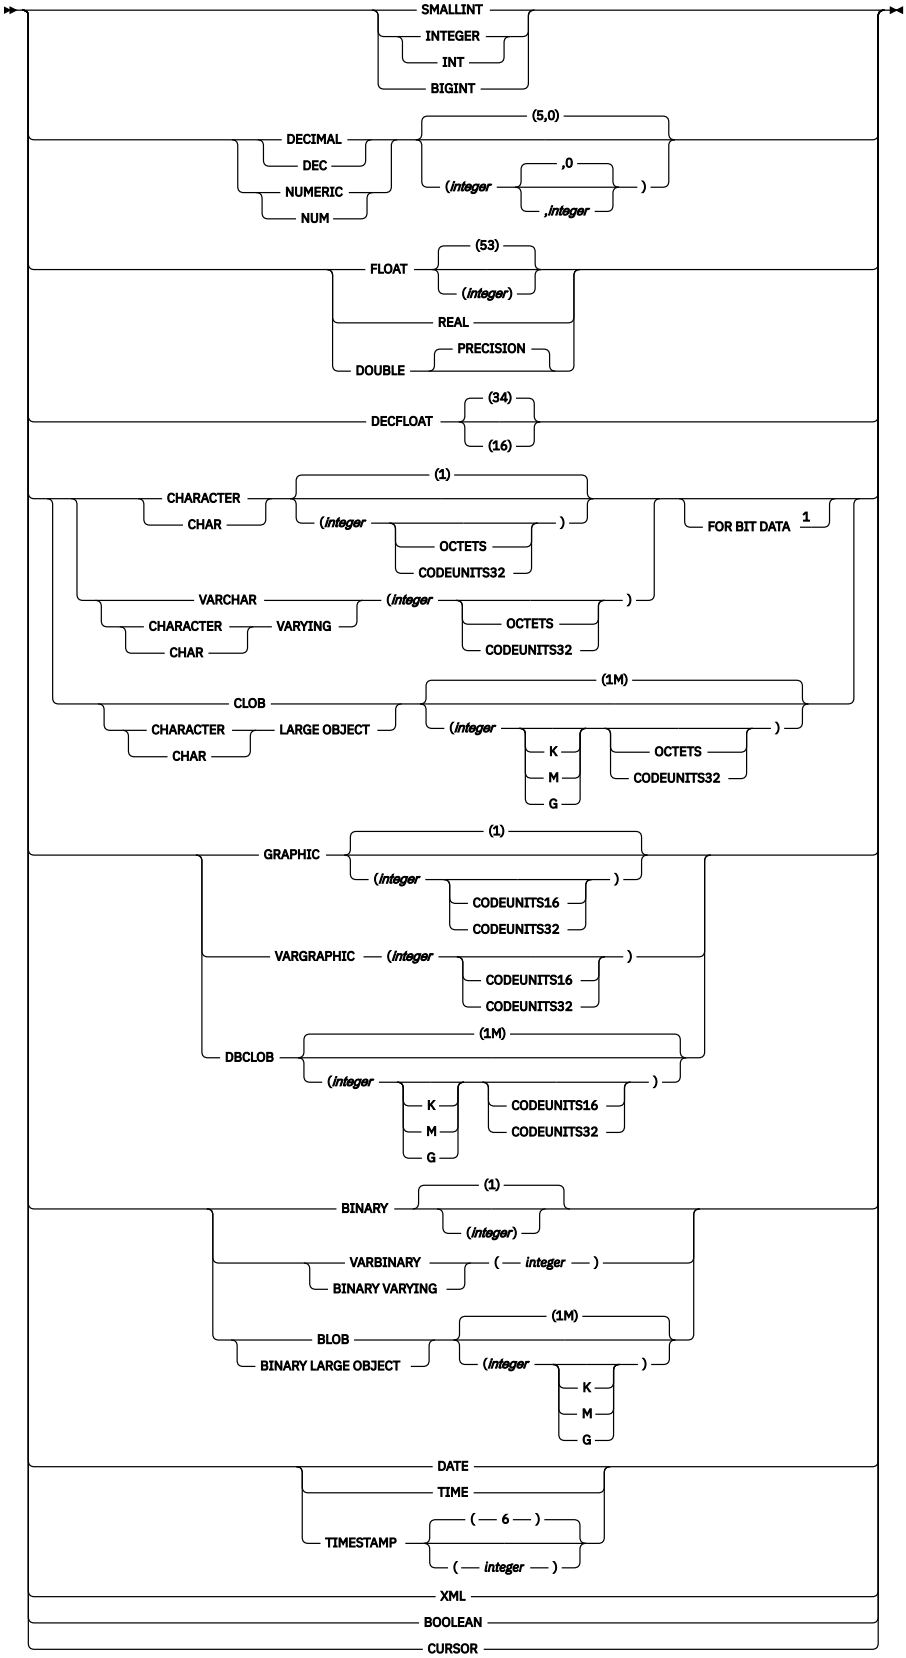
Syntax



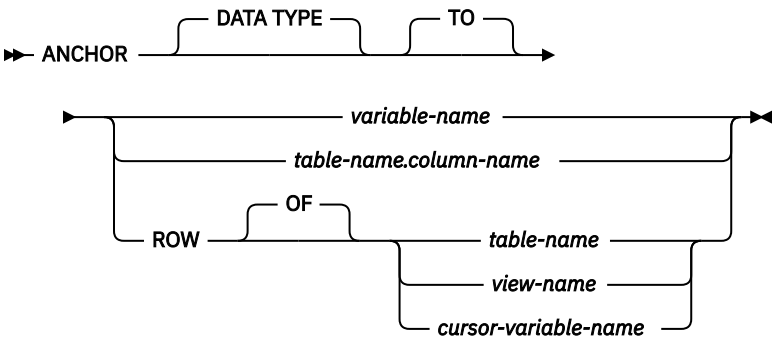
data-type



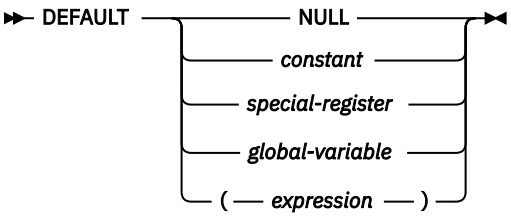
built-in-type



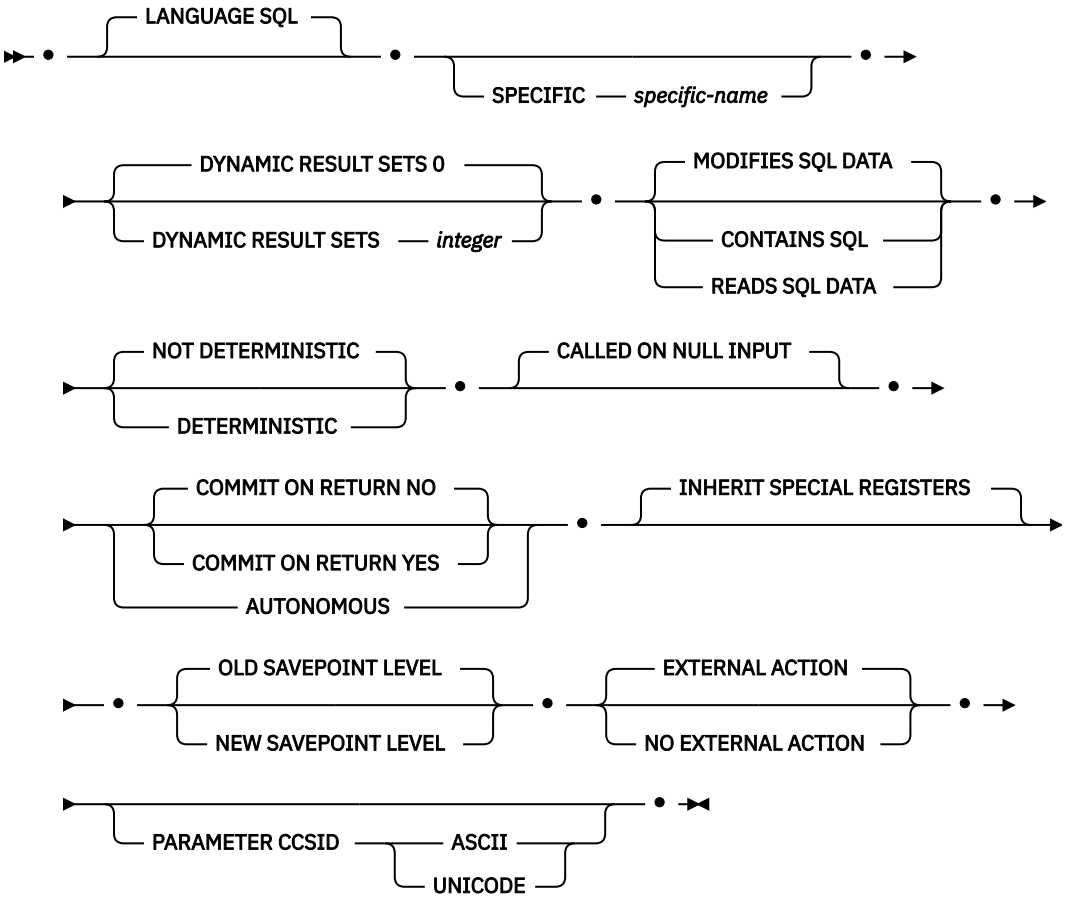
anchored-data-type



default-clause



option-list



SQL-procedure-body

Notes:

[1] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).

Description

OR REPLACE
Specifies to replace the definition for the procedure if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that privileges that were granted on the procedure are not affected. This option can be specified only by the owner of the object. This option is ignored if a definition for the procedure does not exist at the current server. To replace an existing procedure, the specific name and procedure name of the new definition must be the same as the specific name and procedure name of the old definition, or the signature of the new definition must match the signature of the old definition. Otherwise, a new procedure is created.

procedure-name
Names the procedure being defined. It is a qualified or unqualified name that designates a procedure. The unqualified form of *procedure-name* is an SQL identifier. In dynamic SQL statements, the CURRENT SCHEMA special register is used as a qualifier for an unqualified object name. In static SQL statements, the QUALIFIER precompile/bind option implicitly specifies the qualifier for unqualified object names. The qualified form is a *schema-name* followed by a period and an SQL identifier.

The name, including the implicit or explicit qualifiers, together with the number of parameters, must not identify a procedure described in the catalog (SQLSTATE 42723). The unqualified name, together with the number of parameters, is unique within its schema, but does not need to be unique across schemas.

If a two-part name is specified, the *schema-name* cannot begin with 'SYS'; otherwise, an error is returned (SQLSTATE 42939).

(*IN | OUT | INOUT *parameter-name data-type default-clause,...)
Identifies the parameters of the procedure, and specifies the mode, name, data type, and optional default value of each parameter. One entry in the list must be specified for each parameter that the procedure will expect.

It is possible to register a procedure that has no parameters. In this case, the parentheses must still be coded, with no intervening data types. For example:

```
CREATE PROCEDURE SUBWOOFER() ...
```

No two identically-named procedures within a schema are permitted to have exactly the same number of parameters. A duplicate signature raises an SQL error (SQLSTATE 42723).

For example, given the statements:

```
CREATE PROCEDURE PART (IN NUMBER INT, OUT PART_NAME CHAR(35)) ...
CREATE PROCEDURE PART (IN COST DECIMAL(5,3), OUT COUNT INT) ...
```

the second statement will fail because the number of parameters in the procedure is the same, even if the data types are not.

IN | OUT | INOUT
Specifies the mode of the parameter.

If an error is returned by the procedure, OUT parameters are undefined and INOUT parameters are unchanged.

IN
Identifies the parameter as an input parameter to the procedure. Any changes made to the parameter within the procedure are not available to the calling SQL application when control is returned. The default is IN.

OUT
Identifies the parameter as an output parameter for the procedure.

INOUT
Identifies the parameter as both an input and output parameter for the procedure.

parameter-name
Specifies the name of the parameter. The parameter name must be unique for the procedure (SQLSTATE 42734).

data-type
Specifies the data type of the parameter. A structured type or reference type cannot be specified (SQLSTATE 429BB).

built-in-type
Specifies a built-in data type. For a more complete description of each built-in data type except BOOLEAN and CURSOR, which cannot be specified for a table, see "CREATE TABLE".

BOOLEAN
For a Boolean.

CURSOR
For a reference to an underlying cursor.

anchored-data-type
Identifies another object used to define the data type. The data type of the anchor object has the same limitations that apply to specifying the data type directly, or in the case of a row, to creating a row type.

ANCHOR DATA TYPE TO
Indicates an anchored data type is used to specify the data type.

variable-name
Identifies a global variable. The data type of the global variable is used as the data type for *parameter-name*.

table-name.column-name
Identifies a column name of an existing table or view. The data type of the column is used as the data type for *parameter-name*.

ROW OF *table-name* or *view-name*
Specifies a row of fields with names and data types that are based on the column names and column data types of the table identified by *table-name* or the view identified by *view-name*. The data type of *parameter-name* is an unnamed row type.

ROW OF *cursor-variable-name*
Specifies a row of fields with names and data types that are based on the field names and field data types of the cursor variable identified by *cursor-variable-name*. The specified cursor variable must be one of the following elements (SQLSTATE 428HS):

- A global variable with a strongly typed cursor data type
- A global variable with a weakly typed cursor data type that was created or declared with a CONSTANT clause specifying a *select-statement* where all the result columns are named.

If the cursor type of the cursor variable is not strongly-typed using a named row type, the data type of *parameter-name* is an unnamed row type.

array-type-name
Specifies the name of a user-defined array type. If *array-type-name* is specified without a schema name, the array type is resolved by searching the schemas in the SQL path.

cursor-type-name
Specifies the name of a cursor type. If *cursor-type-name* is specified without a schema name, the cursor type is resolved by searching the schemas in the SQL path.

distinct-type-name
Specifies the name of a distinct type. The length, precision, and scale of the parameter are, respectively, the length, precision, and scale of the source type of the distinct type. A distinct type parameter is passed as the source type of the distinct type. If *distinct-type-name* is specified without a schema name, the distinct type is resolved by searching the schemas in the SQL path.

row-type-name
Specifies the name of a user-defined row type. The fields of the parameter are the fields of the row type. If *row-type-name* is specified without a schema name, the row type is resolved by searching the schemas in the SQL path.

DEFAULT
Specifies a default value for the parameter. The default can be a constant, a special register, a global variable, an expression or the keyword NULL. The special registers that can be specified as the default are that same as those that can be specified for a column default (see *default-clause* in the CREATE TABLE statement). Other special registers can be specified as the default by using an expression.

The *expression* can be any expression of the type described in "Expressions". If a default value is not specified, the parameter has no default and the corresponding argument cannot be omitted on invocation of the procedure. The maximum size of the *expression* is 64K bytes.

The default expression must not modify SQL data (SQLSTATE 428FL or SQLSTATE 429BL). The expression must be assignment compatible to the parameter data type (SQLSTATE 42821).

A default cannot be specified in the following situations:

- For INOUT or OUT parameters (SQLSTATE 42601)
- For a parameter of type ARRAY, ROW, or CURSOR (SQLSTATE 429BB)

SPECIFIC *specific-name*
Provides a unique name for the instance of the procedure that is being defined. This specific name can be used when altering, dropping, or commenting on the procedure. It can never be used to invoke the procedure. The unqualified form of *specific-name* is an SQL identifier. The qualified form is a *schema-name* followed by a period and an SQL identifier. The name, including the implicit or explicit qualifier, must not identify another procedure instance that exists at the application server; otherwise an error (SQLSTATE 42710) is raised.

The *specific-name* can be the same as an existing *procedure-name*.

If no qualifier is specified, the qualifier that was used for *procedure-name* is used. If a qualifier is specified, it must be the same as the explicit or implicit qualifier for *procedure-name*, or an error (SQLSTATE 42882) is raised.

If *specific-name* is not specified, a unique name is generated by the database manager. The unique name is 'SQL' followed by a character timestamp: 'SQL*yymmddhhmmssxxx*'.

If you intend to archive the procedure by using the **GET ROUTINE** command, ensure the specific-name has a maximum length of 18 characters.

DYNAMIC RESULT SETS *integer*
Indicates the estimated upper bound of returned result sets for the procedure.

MODIFIES SQL DATA, CONTAINS SQL, READS SQL DATA
Specifies the classification of SQL statements that can be run by this procedure or any routine that is called by this procedure. The database manager verifies that the SQL statements issued by the procedure and all routines that are called by the procedure are consistent with this specification.

For the classification of each statement, see "SQL statements that can be executed in routines and triggers" in Developing User-defined Routines (SQL and External).

The default is MODIFIES SQL DATA.

MODIFIES SQL DATA
Specifies that the procedure can run any SQL statement except statements that are not supported in procedures (SQLSTATE 38003 or 42985).

CONTAINS SQL
Specifies that the procedure can run only statements with a data access classification of CONTAINS SQL (SQLSTATE 38003 or 38004 or 42985).

READS SQL DATA
Specifies that the procedure can run statements with a data access classification of READS SQL DATA or CONTAINS SQL (SQLSTATE 38002 or 38003 or 42985).

If the BEGIN ATOMIC clause is used in a compound SQL procedure, the procedure can be created only if it is defined as MODIFIES SQL DATA.

DETERMINISTIC or NOT DETERMINISTIC
This clause specifies whether the procedure always returns the same results for given argument values (DETERMINISTIC) or whether the procedure depends on some state values that affect the results (NOT DETERMINISTIC). That is, a DETERMINISTIC procedure must always return the same result from successive invocations with identical inputs.

This clause currently does not impact processing of the procedure.

CALLED ON NULL INPUT
CALLED ON NULL INPUT always applies to procedures. This means that the procedure is called regardless of whether any arguments are null. Any OUT or INOUT parameter can return a null value or a normal (non-null) value. Responsibility for testing for null argument values lies with the procedure.

COMMIT ON RETURN
Indicates whether a commit is to be issued on return from the procedure. The default is NO.

NO
A commit is not issued when the procedure returns.

YES
A commit is issued when the procedure returns if a positive SQLCODE is returned by the CALL statement

The commit operation includes the work that is performed by the calling application process and the procedure.

If the procedure returns result sets, the cursors that are associated with the result sets must have been defined as WITH HOLD to be usable after the commit.

AUTONOMOUS
Indicates the procedure should execute in its own autonomous transaction scope.

INHERIT SPECIAL REGISTERS
This optional clause specifies that updatable special registers in the procedure will inherit their initial values from the environment of the invoking statement. For a routine invoked in a nested object (for example a trigger or view), the initial values are inherited from the runtime environment (not inherited from the object definition).

No changes to the special registers are passed back to the caller of the procedure.

Non-updatable special registers, such as the datetime special registers, reflect a property of the statement currently executing, and are therefore set to their default values.

OLD SAVEPOINT LEVEL or NEW SAVEPOINT LEVEL
Specifies whether or not this procedure establishes a new savepoint level for savepoint names and effects. OLD SAVEPOINT LEVEL is the default behavior. For more information about savepoint levels, see "Rules" in "SAVEPOINT".

LANGUAGE SQL
This clause is used to specify that the procedure body is written in the SQL language.

EXTERNAL ACTION or NO EXTERNAL ACTION
Specifies whether the procedure takes some action that changes the state of an object not managed by the database manager (EXTERNAL ACTION), or not (NO EXTERNAL ACTION). The default is EXTERNAL ACTION. If NO EXTERNAL ACTION is specified, the system can use certain optimizations that assume the procedure has no external impact.

PARAMETER CCSID
Specifies the encoding scheme to use for all string data passed into and out of the procedure. If the PARAMETER CCSID clause is not specified, the default is PARAMETER CCSID UNICODE for Unicode databases, and PARAMETER CCSID ASCII for all other databases.

ASCII
Specifies that string data is encoded in the database code page. If the database is a Unicode database, PARAMETER CCSID ASCII cannot be specified (SQLSTATE 56031).

UNICODE
Specifies that character data is in UTF-8, and that graphic data is in UCS-2. If the database is not a Unicode database, PARAMETER CCSID UNICODE cannot be specified (SQLSTATE 56031).

SQL-procedure-body
Specifies the SQL statement that is the body of the SQL procedure.

See *SQL-procedure-statement* in "Compound SQL (Compiled)" statement.

Rules

- ***Autonomous routine restrictions:*** Autonomous routines cannot return result sets and do not support the following data types (SQLSTATE 428H2):
  - User-defined cursor types
  - User-defined structured types
  - XML as IN, OUT, and INOUT parameters

  Session variables of cursor types cannot be referenced within the autonomous scope.
- ***Use of anchored data types:*** An anchored data type cannot refer to the following objects (SQLSTATE 428HS): a nickname, typed table, typed view, statistical view that is associated with an expression-based index, declared temporary table, row definition that is associated with a weakly typed cursor, object with a code page or collation that is different from the database code page or database collation.
- ***Use of cursor and row types:*** A procedure that uses a cursor type or row type for a parameter can be invoked only from within a compound SQL (compiled) statement (SQLSTATE 428H2), except for Java applications using JDBC, which can invoke a procedure with OUT parameters that have a cursor type. Invocation from Java external procedures is not supported.

Notes

- Creating a procedure with a schema name that does not already exist will result in the implicit creation of that schema, provided that the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- A procedure that is called from within a compound SQL (inlined) statement will execute as if it were created specifying NEW SAVEPOINT LEVEL, even if OLD SAVEPOINT LEVEL was specified or defaulted to when the procedure was created.
- ***Creating procedures that are initially invalid:*** If an object referenced in the procedure body does not exist or is marked invalid, or the definer temporarily doesn't have privileges to access the object, and if the database configuration parameter **auto_reval** is not set to DISABLED, then the procedure will still be created successfully. The procedure will be marked invalid and will be revalidated the next time it is invoked.
- ***Setting of the default value:*** Parameters of a procedure that are defined with a default value are set to their default value when the procedure is invoked, but only if a value is not supplied for the corresponding argument, or is specified as DEFAULT, when the procedure is invoked.
- ***Privileges:*** The definer of a procedure always receives the EXECUTE privilege WITH GRANT OPTION on the procedure, as well as the right to drop the procedure.
- ***Rebinding dependent packages:*** Every SQL procedure has a dependent package. The package can be rebound at any time by running the REBIND_ROUTINE_PACKAGE procedure. Explicitly rebinding the dependent package does not revalidate an invalid procedure. An invalid procedure should be

revalidated with automatic revalidation or by explicitly running the ADMIN_REVALIDATE_DB_OBJECTS procedure. Procedure revalidation automatically rebinds the dependent package.

- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - RESULT SETS can be specified in place of DYNAMIC RESULT SETS.
  - NULL CALL can be specified in place of CALLED ON NULL INPUT.

  The following syntax is accepted as the default behavior:
  - ASUTIME NO LIMIT
  - NO COLLID
  - STAY RESIDENT NO

Example

Create an SQL procedure that returns the median staff salary. Return a result set containing the name, position, and salary of all employees who earn more than the median salary.

```
CREATE PROCEDURE MEDIAN_RESULT_SET (OUT medianSalary DOUBLE)
  RESULT SETS 1
  LANGUAGE SQL
BEGIN
  DECLARE v_numRecords INT DEFAULT 1;
  DECLARE v_counter INT DEFAULT 0;

  DECLARE c1 CURSOR FOR
    SELECT CAST(salary AS DOUBLE)
      FROM staff
      ORDER BY salary;
  DECLARE c2 CURSOR WITH RETURN FOR
    SELECT name, job, CAST(salary AS INTEGER)
      FROM staff
      WHERE salary > medianSalary
      ORDER BY salary;

  DECLARE EXIT HANDLER FOR NOT FOUND
    SET medianSalary = 6666;

  SET medianSalary = 0;
  SELECT COUNT(*) INTO v_numRecords
    FROM STAFF;
  OPEN c1;
  WHILE v_counter < (v_numRecords / 2 + 1)
  DO
    FETCH c1 INTO medianSalary;
    SET v_counter = v_counter + 1;
  END WHILE;
  CLOSE c1;
  OPEN c2;
END
```

CREATE ROLE

The CREATE ROLE statement defines a role at the current server.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax

Description

role-name

Names the role. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The name must not identify an existing role at the current server (SQLSTATE 42710). The name must not begin with the characters 'SYS' and must not be 'ACCESSCTRL', 'DATAACCESS', 'DBADM', 'NONE', 'NULL', 'PUBLIC', 'SECADM', 'SQLADM', 'SCHEMAADM', or 'WLMADM' (SQLSTATE 42939).

Example

Create a role named DOCTOR.

```
CREATE ROLE DOCTOR
```

CREATE SCHEMA

The CREATE SCHEMA statement defines a schema. It is also possible to create some objects and grant privileges on objects within the statement.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

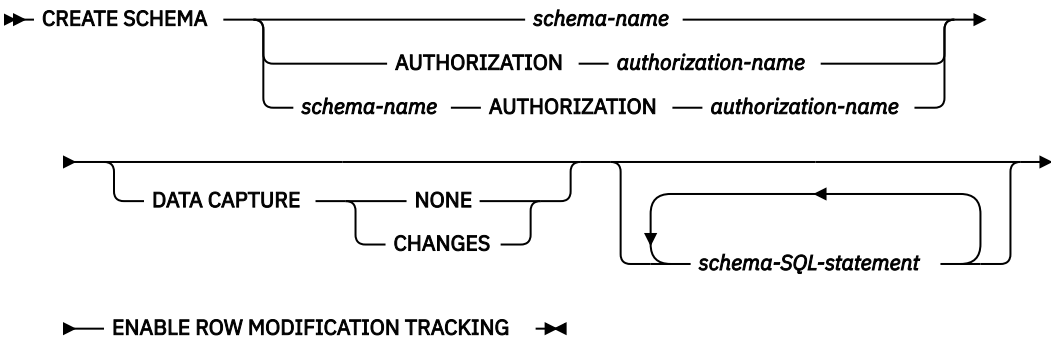
An authorization ID that holds DBADM authority can create a schema with any valid *schema-name* or *authorization-name*.

An authorization ID that does not hold DBADM authority can only create a schema with a *schema-name* or *authorization-name* that matches the authorization ID of the statement.

If the statement includes a *schema-SQL-statement*, the privileges held by the *authorization-name* (which, if not specified, defaults to the authorization ID of the statement) must include at least one of the following authorities:

- The privileges required to perform each *schema-SQL-statement*
- DBADM authority

Syntax



Description

schema-name
An identifier that names the schema. The name must not identify a schema already described in the catalog (SQLSTATE 42710). The name cannot begin with 'SYS' (SQLSTATE 42939). The owner of the schema is the authorization ID that issued the statement.

AUTHORIZATION *authorization-name*
Identifies the user who is the owner of the schema. The value of *authorization-name* is also used to name the schema. The *authorization-name* must not identify a schema already described in the catalog (SQLSTATE 42710).

schema-name* AUTHORIZATION *authorization-name
Identifies a schema called *schema-name*, whose owner is *authorization-name*. The *schema-name* must not identify a schema already described in the catalog (SQLSTATE 42710). The *schema-name* cannot begin with 'SYS' (SQLSTATE 42939).

DATA CAPTURE
Indicates whether extra information for data replication is to be written to the log. The default is determined based on the value of database configuration parameter **dft_schemas_dcc**. If the value is "Yes" the default is CHANGES, otherwise the default is NONE.

NONE
Indicates that no extra information for data replication will be logged.

CHANGES
Indicates that extra information regarding SQL changes to this schema will be written to the log. This option is required if this schema will be replicated and a replication capture program is used to capture changes for this schema from the log.

schema-SQL-statement
SQL statements that can be included as part of the CREATE SCHEMA statement are:

- CREATE TABLE statement, excluding typed tables and materialized query tables
- CREATE VIEW statement, excluding typed views
- CREATE INDEX statement
- COMMENT statement
- GRANT statement

ENABLE ROW MODIFICATION TRACKING
Indicates tables created in the schema are to be enabled for logical backup. Applies only to columnar organized tables. For a list of restrictions, see Schema enabled for row modification tracking.

Notes

- The owner of the schema is determined as follows:
  - If an AUTHORIZATION clause is specified, the specified *authorization-name* is the schema owner
  - If an AUTHORIZATION clause is not specified, the authorization ID that issued the CREATE SCHEMA statement is the schema owner.
- The schema owner is assumed to be a user (not a group).
- When the schema is explicitly created with the CREATE SCHEMA statement, the schema owner is granted CREATEIN, DROPIN, and ALTERIN privileges on the schema with the ability to grant these privileges to other users.
- The definer of any object created as part of the CREATE SCHEMA statement is the schema owner. The schema owner is also the grantor for any privileges granted as part of the CREATE SCHEMA statement.
- Unqualified object names in any SQL statement within the CREATE SCHEMA statement are implicitly qualified by the name of the created schema.
- Schema names that are shorter than 8-bytes are padded with blanks and stored in the catalog as 8-byte names.

- If the CREATE statement contains a qualified name for the object being created, the schema name specified in the qualified name must be the same as the name of the schema being created (SQLSTATE 42875). Any other objects referenced within the statements may be qualified with any valid schema name.
- It is recommended not to use "SESSION" as a schema name. Since declared temporary tables must be qualified by "SESSION", it is possible to have an application declare a temporary table with a name identical to that of a persistent table. An SQL statement that references a table with the schema name "SESSION" will resolve (at statement compile time) to the declared temporary table rather than a persistent table with the same name. Since an SQL statement is compiled at different times for static embedded and dynamic embedded SQL statements, the results depend on when the declared temporary table is defined. If persistent tables, views or aliases are not defined with a schema name of "SESSION", these issues do not require consideration.
- Setting the DATA CAPTURE attribute at the schema level causes newly created tables to inherit the DATA CAPTURE attribute from the schema if one is not specified at the table level.

Examples

- *Example 1:* As a user with DBADM authority, create a schema called RICK with the user RICK as the owner.

```
CREATE SCHEMA RICK AUTHORIZATION RICK
```

- *Example 2:* Create a schema that has an inventory part table and an index over the part number. Give authority on the table to user JONES.

```
CREATE SCHEMA INVENTRY

  CREATE TABLE PART (PARTNO   SMALLINT NOT NULL,
                     DESCR    VARCHAR(24),
                     QUANTITY INTEGER)

  CREATE INDEX PARTIND ON PART (PARTNO)

  GRANT ALL ON PART TO JONES
```

- *Example 3:* Create a schema called PERS with two tables that each have a foreign key that references the other table. This is an example of a feature of the CREATE SCHEMA statement that allows such a pair of tables to be created without the use of the ALTER TABLE statement.

```
CREATE SCHEMA PERS

  CREATE TABLE ORG (DEPTNUMB  SMALLINT NOT NULL,
                    DEPTNAME VARCHAR(14),
                    MANAGER  SMALLINT,
                    DIVISION VARCHAR(10),
                    LOCATION VARCHAR(13),
                    CONSTRAINT PKEYDNO
                      PRIMARY KEY (DEPTNUMB),
                    CONSTRAINT FKEYMGR
                      FOREIGN KEY (MANAGER)
                      REFERENCES STAFF (ID) )

  CREATE TABLE STAFF (ID        SMALLINT NOT NULL,
                      NAME     VARCHAR(9),
                      DEPT     SMALLINT,
                      JOB      VARCHAR(5),
                      YEARS    SMALLINT,
                      SALARY   DECIMAL(7,2),
                      COMM     DECIMAL(7,2),
                      CONSTRAINT PKEYID
                        PRIMARY KEY (ID),
                      CONSTRAINT FKEYDNO
                        FOREIGN KEY (DEPT)
                        REFERENCES ORG (DEPTNUMB) )
```

Schema enabled for row modification tracking

CREATE SECURITY LABEL COMPONENT

The CREATE SECURITY LABEL COMPONENT statement defines a component that is to be used as part of a security policy.

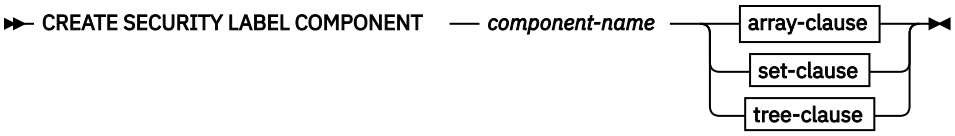
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

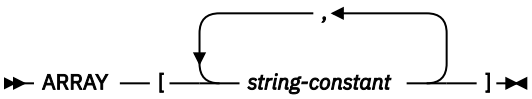
Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

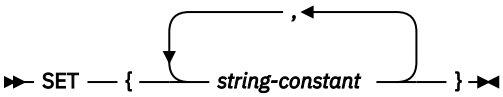
Syntax



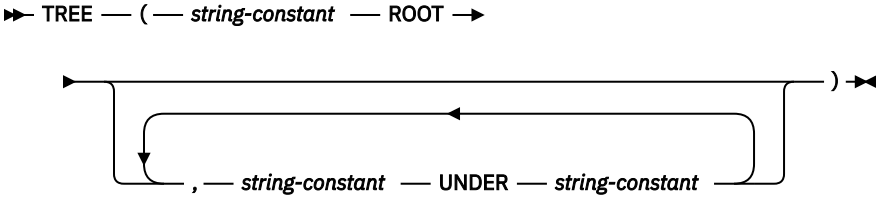
array-clause



set-clause



tree-clause



Description

component-name
Names the security label component. This is a one-part name. The name must not identify an existing security label component at the current server (SQLSTATE 42710).

ARRAY
Specifies an ordered set of elements.

***string-constant*,...**
One or more string constant values that make up the set of valid values for this security label component. The order in which the array elements appear is important. The first element ranks higher than the second element. The second element ranks higher than the third element and so on.

SET
Specifies an unordered set of elements.

***string-constant*,...**
One or more string constant values that make up the set of valid values for this security label component. The order of the elements is not important.

TREE
Specifies a tree structure of node elements.

string-constant
One or more string constant values that make up the set of valid values for this security label component.

ROOT
Specifies that the *string-constant* that follows the keyword is the root node element of the tree.

UNDER
Specifies that the *string-constant* before the UNDER keyword is a child of the *string-constant* that follows the UNDER keyword. An element must be defined as either being the root element or as being the child of another element before it can be used as a parent, otherwise an error (SQLSTATE 42704) is returned.

Rules

These rules apply to all three types of component (ARRAY, SET, and TREE):

- Element names cannot contain any of these characters:
  - Opening parenthesis - (
  - Closing parenthesis -)
  - Comma - ,
  - Colon - :
- An element name can have no more than 32 bytes (SQLSTATE 42622).
- If a security label component is a set or a tree, no more than 64 elements can be part of that component.
- A CREATE SECURITY LABEL COMPONENT statement can specify at most 65 535 elements for a security label component of type array.
- No element name can be used more than once in the same component (SQLSTATE 42713).

Examples

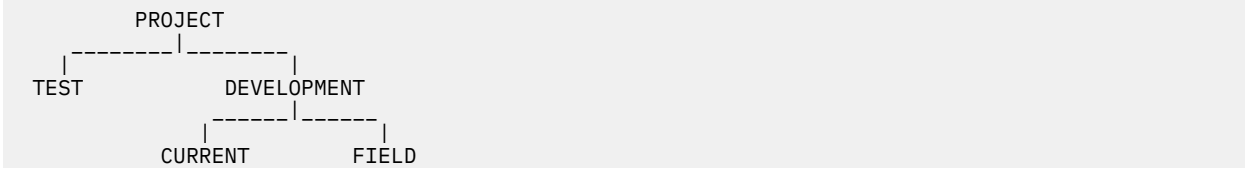
- *Example 1:* Create an ARRAY type security label component named LEVEL. The component has the following four elements, listed in order of decreasing rank: Top Secret, Secret, Classified, and Unclassified.

```
CREATE SECURITY LABEL COMPONENT LEVEL
  ARRAY ['Top Secret', 'Secret', 'Classified', 'Unclassified']
```

- *Example 2:* Create a SET type security label component named COMPARTMENTS. The component has the following three elements: Research, Analysis, and Collection.

```
CREATE SECURITY LABEL COMPONENT COMPARTMENTS
  SET {'Collection', 'Research', 'Analysis'}
```

- *Example 3:* Create a TREE type security label component named GROUPS. GROUPS has five elements: PROJECT, TEST, DEVELOPMENT, CURRENT, AND FIELD. The following diagram shows the relationship of these elements to one another:



```
CREATE SECURITY LABEL COMPONENT GROUPS
  TREE (
    'PROJECT' ROOT,
    'TEST' UNDER 'PROJECT',
    'DEVELOPMENT' UNDER 'PROJECT',
    'CURRENT' UNDER 'DEVELOPMENT',
    'FIELD' UNDER 'DEVELOPMENT'
  )
```

CREATE SECURITY LABEL

The CREATE SECURITY LABEL statement defines a security label.

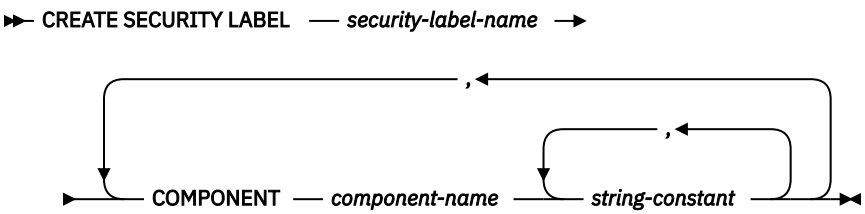
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Description

security-label-name
Names the security label. The name must be qualified with a security policy (SQLSTATE 42704), and must not identify an existing security label for this security policy (SQLSTATE 42710).

COMPONENT *component-name*
Specifies the name of a security label component. If the component is not part of the security policy *security-policy-name*, an error is returned (SQLSTATE 4274G). If a component is specified twice in the same statement, an error is returned (SQLSTATE 42713).

***string-constant*,...**
Specifies a valid element for the security component. A valid element is one that was specified when the security component was created. If the element is invalid, an error is returned (SQLSTATE 4274F).

Examples

- *Example 1:* Create a security label named EMPLOYEESECLABEL that is part of the DATA_ACCESS security policy, and that has the element Top Secret for the LEVEL component and the elements Research and Analysis for the COMPARTMENTS component.

```
CREATE SECURITY LABEL DATA_ACCESS.EMPLOYEESECLABEL
  COMPONENT LEVEL 'Top Secret',
  COMPONENT COMPARTMENTS 'Research', 'Analysis'
```

- *Example 2:* Create a security label named EMPLOYEESECLABELREAD that has the element Top Secret for the LEVEL component and the element Research for the COMPARTMENTS component.

```
CREATE SECURITY LABEL DATA_ACCESS.EMPLOYEESECLABELREAD
  COMPONENT LEVEL 'Top Secret',
  COMPONENT COMPARTMENTS 'Research'
```

- *Example 3:* Create a security label named EMPLOYEESECLABELWRITE that has the element Analysis for the COMPARTMENTS component and a null value for the LEVEL component. Assume that the security policy named DATA_ACCESS is the same security policy that is used in examples 1 and 2.

```
CREATE SECURITY LABEL DATA_ACCESS.EMPLOYEESECLABELWRITE
  COMPONENT COMPARTMENTS 'Analysis'
```

- *Example 4:* Create a security label named BEGINNER that is part of an existing CLASSPOLICY security policy, and that has the element Trainee for the TRUST component and the element Morning for the SECTIONS component.

```
CREATE SECURITY LABEL CLASSPOLICY.BEGINNER
  COMPONENT TRUST 'Trainee',
  COMPONENT SECTIONS 'Morning'
```

CREATE SECURITY POLICY

The CREATE SECURITY POLICY statement defines a security policy.

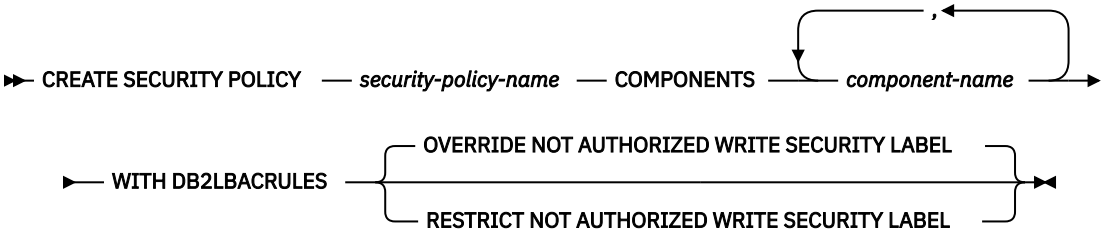
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges held by the authorization ID of the statement must include SECADM authority.

Syntax



Description

security-policy-name
Names the security policy. This is a one-part name. The name must not identify an existing security policy at the current server (SQLSTATE 42710).

COMPONENTS *component-name,...*
Identifies a security label component. The name must identify a security label component that already exists at the current server (SQLSTATE 42704). The same security component must not be specified more than once for the security policy (SQLSTATE 42713). No more than 16 security label components can be specified for a security policy (SQLSTATE 54062).

WITH DB2LBACRULES
Indicates what rule set that will be used when comparing security labels that are part of this security policy. There is currently only one rule set: DB2LBACRULES.

OVERRIDE NOT AUTHORIZED WRITE SECURITY LABEL or RESTRICT NOT AUTHORIZED WRITE SECURITY LABEL

Specifies the action that is to be taken when a user is not authorized to write the explicitly specified security label that is provided in the INSERT or UPDATE statement issued against a table that is protected with this security policy. A user's security label and exemption credentials determine the user's authorization to write an explicitly provided security label. The default is OVERRIDE NOT AUTHORIZED WRITE SECURITY LABEL.

OVERRIDE NOT AUTHORIZED WRITE SECURITY LABEL

Indicates that the value of the user's security label, rather than the explicitly specified security label, is to be used for write access during an insert or update operation.

RESTRICT NOT AUTHORIZED WRITE SECURITY LABEL

Indicates that the insert or update operation will fail if the user is not authorized to write the explicitly specified security label that is provided in the INSERT or UPDATE statement (SQLSTATE 42519).

Notes

- ***DB2LBACRULES rule set:*** DB2LBACRULES is a predefined set of rules that includes the following rules: DB2LBACREADARRAY, DB2LBACREADSET, DB2LBACREADTREE, DB2LBACWRITEARRAY, DB2LBACWRITESET, DB2LBACWRITETREE.
- Group and role authorizations are not considered by default when a security policy is created. Use the ALTER SECURITY POLICY statement to change this behavior and have them considered.

Examples

- *Example 1:* Create a security policy named DATA_ACCESS that uses the DB2LBACRULES rule set and has two components: LEVEL and COMPARTMENTS, in that order. Assume that both components already exist.

```
CREATE SECURITY POLICY DATA_ACCESS
  COMPONENTS LEVEL, COMPARTMENTS
  WITH DB2LBACRULES
```

- *Example 2:* Create a security policy named CONTRIBUTIONS that has the components MEMBER and BADGE, which are assumed to already exist.

```
CREATE SECURITY POLICY CONTRIBUTIONS
  COMPONENTS MEMBER, BADGE
  WITH DB2LBACRULES
```

CREATE SEQUENCE

The CREATE SEQUENCE statement defines a sequence at the application server.

Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

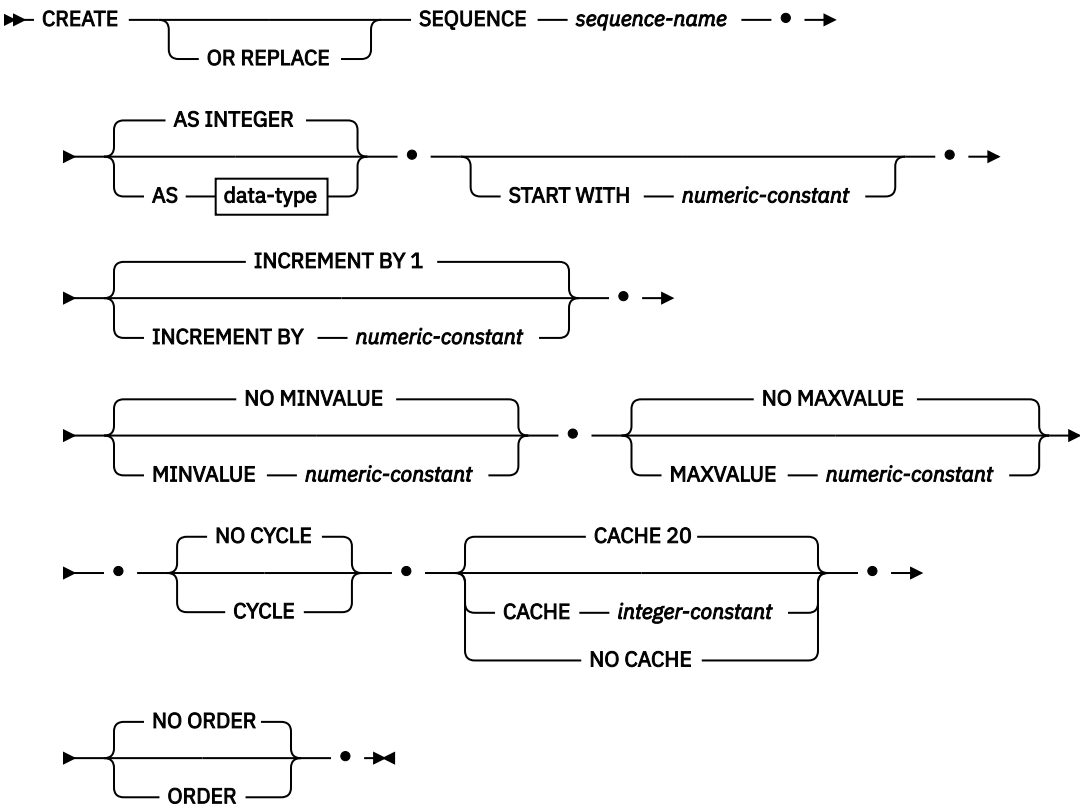
The privileges held by the authorization ID of the statement must include at least one of the following authorities:

- IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the sequence does not exist
- CREATEIN privilege on the schema, if the schema name of the sequence refers to an existing schema

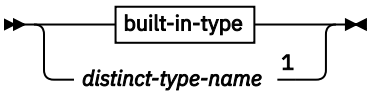
- SCHEMAADM authority on the schema, if the schema name of the sequence refers to an existing schema
- DBADM authority

To replace an existing sequence, the authorization ID of the statement must be the owner of the existing sequence (SQLSTATE 42501).

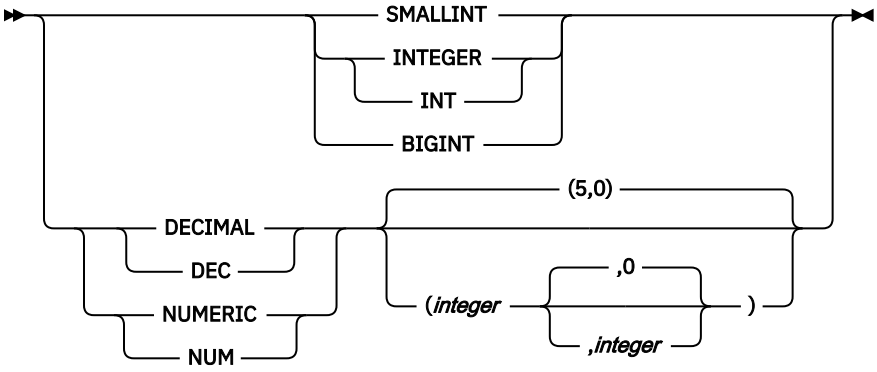
Syntax



data-type



built-in type



Notes:

[1] The specified distinct type cannot have any data type constraints and the source type cannot be an anchored data type.

Description

OR REPLACE
Specifies to replace the definition for the sequence if one exists at the current server. The existing definition is effectively dropped before the new definition is replaced in the catalog, with the exception that privileges that were granted on the sequence are not affected. This option is ignored if a definition for the sequence does not exist at the current server. This option can be specified only by the owner of the object.

sequence-name
Names the sequence. The combination of name, and the implicit or explicit schema name must not identify an existing sequence at the current server (SQLSTATE 42710).

The unqualified form of sequence-name is an SQL identifier. The qualified form is a qualifier followed by a period and an SQL identifier. The qualifier is a schema name.

If the sequence name is explicitly qualified with a schema name, the schema name cannot begin with 'SYS' or an error (SQLSTATE 42939) is raised.

AS *data-type*
Specifies the data type to be used for the sequence value. The data type can be any exact numeric type (SMALLINT, INTEGER, BIGINT or DECIMAL) with a scale of zero, or a user-defined distinct type or reference type for which the source type is an exact numeric type with a scale of zero (SQLSTATE 42815). The specified distinct type cannot have any data type constraints and the source type cannot be an anchored data type (SQLSTATE 428H2). The default is INTEGER.

START WITH *numeric-constant*
Specifies the first value for the sequence. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence (SQLSTATE 42815), without nonzero digits existing to the right of the decimal point (SQLSTATE 428FA). The default is MINVALUE for ascending sequences and MAXVALUE for descending sequences.

This value is not necessarily the value that a sequence would cycle to after reaching the maximum or minimum value of the sequence. The START WITH clause can be used to start a sequence outside the range that is used for cycles. The range used for cycles is defined by MINVALUE and MAXVALUE.

INCREMENT BY *numeric-constant*
Specifies the interval between consecutive values of the sequence. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence (SQLSTATE 42815). The value must not exceed the value of a large integer constant (SQLSTATE 42820) and must not contain nonzero digits to the right of the decimal point (SQLSTATE 428FA).

If this value is negative, this is a descending sequence. If this value is 0 or positive, this is an ascending sequence. The default is 1.

MINVALUE or NO MINVALUE
Specifies the minimum value at which a descending sequence either cycles or stops generating values, or an ascending sequence cycles to after reaching the maximum value.

MINVALUE *numeric-constant*
Specifies the numeric constant that is the minimum value. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence (SQLSTATE 42815), without nonzero digits existing to the right of the decimal point (SQLSTATE 428FA), but the value must be less than or equal to the maximum value (SQLSTATE 42815).

NO MINVALUE
For an ascending sequence, the value is the START WITH value, or 1 if START WITH is not specified. For a descending sequence, the value is the minimum value of the data type associated with the sequence. This is the default.

MAXVALUE or NO MAXVALUE
Specifies the maximum value at which an ascending sequence either cycles or stops generating values, or a descending sequence cycles to after reaching the minimum value.

MAXVALUE *numeric-constant*
Specifies the numeric constant that is the maximum value. This value can be any positive or negative value that could be assigned to a column of the data type associated with the sequence (SQLSTATE 42815), without nonzero digits existing to the right of the decimal point (SQLSTATE 428FA), but the value must be greater than or equal to the minimum value (SQLSTATE 42815).

NO MAXVALUE
For an ascending sequence, the value is the maximum value of the data type associated with the sequence. For a descending sequence, the value is the START WITH value, or -1 if START WITH is not specified.

CYCLE or NO CYCLE
Specifies whether the sequence should continue to generate values after reaching either its maximum or minimum value. The boundary of the sequence can be reached either with the next value landing exactly on the boundary condition, or by overshooting it.

CYCLE
Specifies that values continue to be generated for this sequence after the maximum or minimum value has been reached. If this option is used, after an ascending sequence reaches its maximum value it generates its minimum value; after a descending sequence reaches its minimum value it generates its maximum value. The maximum and minimum values for the sequence determine the range that is used for cycling.

When CYCLE is in effect, then duplicate values can be generated for the sequence.

NO CYCLE
Specifies that values will not be generated for the sequence once the maximum or minimum value for the sequence has been reached. This is the default.

CACHE or NO CACHE
Specifies whether to keep some preallocated values in memory for faster access. This is a performance and tuning option.

CACHE *integer-constant*
Specifies the maximum number of sequence values that are preallocated and kept in memory. Preallocating and storing values in the cache reduces synchronous I/O to the log when values are generated for the sequence.

In the event of a system failure, all cached sequence values that have not been used in committed statements are lost (that is, they will never be used). The value specified for the CACHE option is the maximum number of sequence values that could be lost in case of system failure.

The minimum value is 2 (SQLSTATE 42815). The default value is CACHE 20.

Use the CACHE and NO ORDER options to allow multiple caches of sequence values simultaneously. In a multi-partition or Db2 pureScale environment, multiple members can cache them.

In a Db2 pureScale environment, if both CACHE and ORDER are specified, the specification of ORDER overrides the specification of CACHE and instead NO CACHE will be in effect.

NO CACHE
Specifies that values of the sequence are not to be preallocated. It ensures that there is not a loss of values in the case of a system failure, shutdown or database deactivation. When this option is specified, the values of the sequence are not stored in the cache. In this case, every request for a new value for the sequence results in synchronous I/O to the log.

NO ORDER or ORDER
Specifies whether the sequence numbers must be generated in order of request.

ORDER
Specifies that the sequence numbers are generated in order of request.

NO ORDER
Specifies that the sequence numbers do not need to be generated in order of request. This is the default.

Notes

- It is possible to define a constant sequence, that is, one that would always return a constant value. This could be done by specifying an INCREMENT value of zero and a START WITH value that does not exceed MAXVALUE, or by specifying the same value for START WITH, MINVALUE and MAXVALUE. For a constant sequence, each time NEXT VALUE is invoked for the sequence, the same value is returned. A constant sequence can be used as a numeric global variable. ALTER SEQUENCE can be used to adjust the values that will be generated for a constant sequence.
- A sequence can be cycled manually by using the ALTER SEQUENCE statement. If NO CYCLE is implicitly or explicitly specified, the sequence can be restarted or extended using the ALTER SEQUENCE statement to cause values to continue to be generated once the maximum or minimum value for the sequence has been reached.
- A sequence can be explicitly defined to cycle by specifying the CYCLE keyword. Use the CYCLE option when defining a sequence to indicate that the generated values should cycle once the boundary is reached. When a sequence is defined to automatically cycle (that is, CYCLE was explicitly specified), the maximum or minimum value generated for a sequence might not be the actual MAXVALUE or MINVALUE specified, if the increment is a value other than 1 or -1. For example, the sequence defined with START `WITH=1, INCREMENT=2, MAXVALUE=10` will generate a maximum value of 9, and will not generate the value 10. When defining a sequence with CYCLE, carefully consider the impact of the values for MINVALUE, MAXVALUE and START WITH.
- Caching sequence numbers implies that a range of sequence numbers can be kept in memory for fast access. When an application accesses a sequence that can allocate the next sequence number from the cache, the sequence number allocation can happen quickly. However, if an application accesses a sequence that cannot allocate the next sequence number from the cache, the sequence number allocation may require having to wait for I/O operations to persistent storage. The choice of the value for CACHE should be done keeping in mind the performance and application requirements tradeoffs.
- ***Gaps in a sequence:*** Consecutive values in a sequence differ by the constant INCREMENT BY value specified for the sequence. However, gaps can occur in the values that are assigned to a sequence object by Db2.

  The following situations are some examples of how gaps can be introduced in the sequence values:

  – A transaction has advanced the sequence and then rolls back.
  – The SQL statement leading to the generation of the next value fails after the value was generated.
  – The NEXT VALUE expression is used in the SELECT statement of a cursor in a DRDA environment where the client uses block-fetch and not all retrieved rows are fetched by the application.
  – The sequence is altered and then the alteration is rolled back.
  – The sequence (or an identity column table) is dropped and then the drop is rolled back.
  – The SYSIBM.SYSSEQ table space is stopped or closed for any reason (including when DSMAX is reached).
  – The Db2 subsystem is stopped or goes down.

  Values of such gaps are not available for the current cycle, unless the sequence is altered and restarted in a specific way to make them available.

  A sequence is incremented independently of a transaction. Thus, a given transaction increments the sequence two times might see a gap in the two numbers that it receives if other transactions concurrently increment the same sequence. Most applications can tolerate these instances as these are not really gaps.
- The definer of a sequences is granted ALTER and USAGE privileges with the grant option. The owner of the sequence can drop the sequence.
- ***Syntax alternatives***: The following syntax alternatives are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.

  – A comma can be used to separate multiple sequence options

  - NOMINVALUE, NOMAXVALUE, NOCYCLE, NOCACHE, and NOORDER can be specified in place of NO MINVALUE, NO MAXVALUE, NO CYCLE, NO CACHE, and NO ORDER, respectively
- ***Considerations for a multi-partition or Db2 pureScale environment***:
  - If the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously. This can happen at each member in a multi-partition or Db2 pureScale environment. The requests for next value assignments from different members might not result in the assignment of values in strict numeric order. Assume, for example, in a multi-partition or Db2 pureScale environment, that members DB1A and DB1B are using the same sequence, and DB1A gets the cache values 1 to 20 and DB1B gets the cache values 21 to 40. In this scenario, if DB1A requested the next value first, then DB1B requested, and then DB1A requested again, the actual order of values assigned would be 1,21,2. Therefore, to guarantee that sequence numbers are generated in strict numeric order among multiple members using the same sequence concurrently, specify the ORDER option.
  - In a Db2 pureScale environment, using the ORDER or NO CACHE option ensures that the values assigned to a sequence which is shared by applications across multiple members are in strict numeric order. If ORDER is specified, then NO CACHE is implied even if CACHE *n* is specified.

Example

Create a sequence called ORG_SEQ that starts at 1, increments by 1, does not cycle, and caches 24 values at a time:

```
CREATE SEQUENCE ORG_SEQ
  START WITH 1
  INCREMENT BY 1
  NO MAXVALUE
  NO CYCLE
  CACHE 24
```

CREATE SERVICE CLASS

The CREATE SERVICE CLASS statement defines a service class.

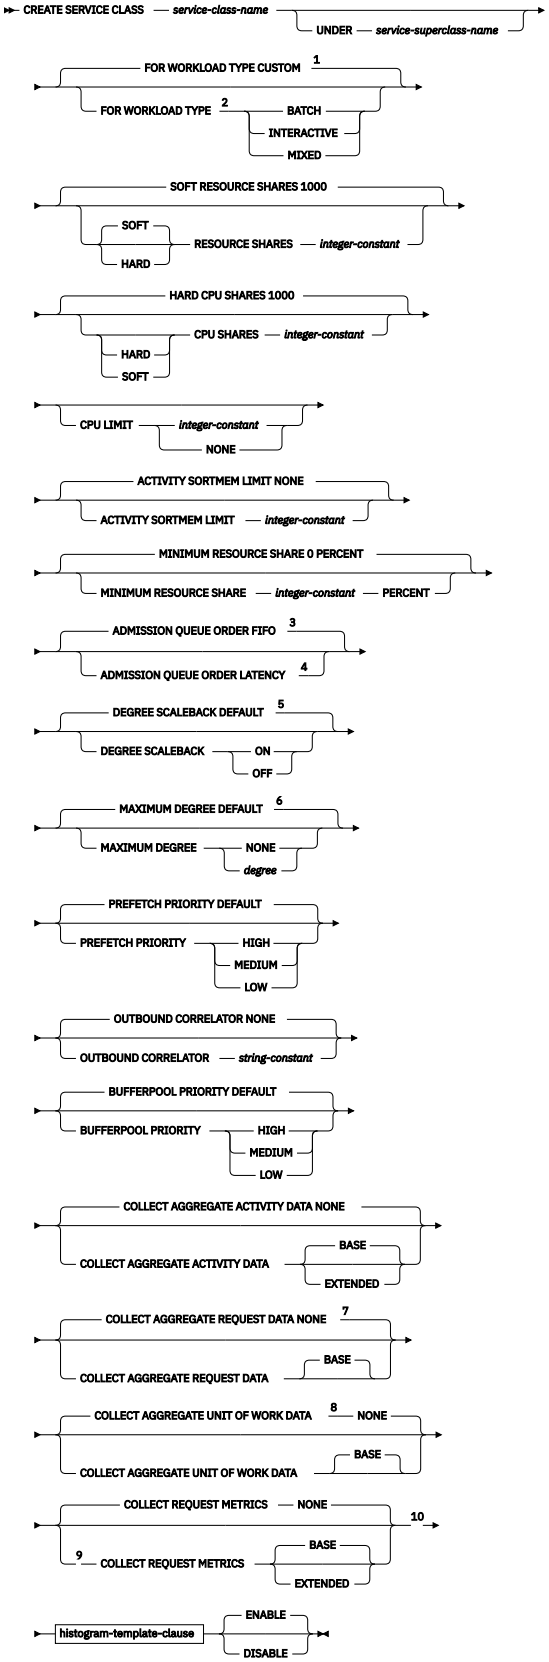
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

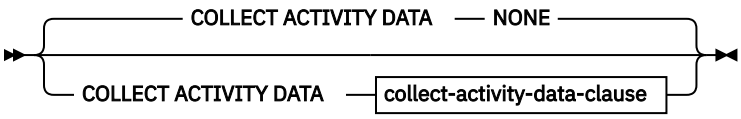
Authorization

The privileges held by the authorization ID of the statement must include WLMADM or DBADM authority.

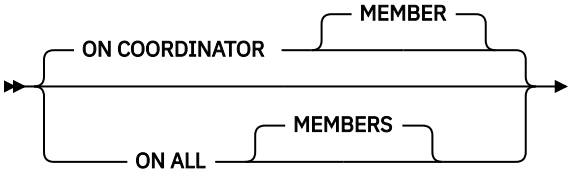
Syntax

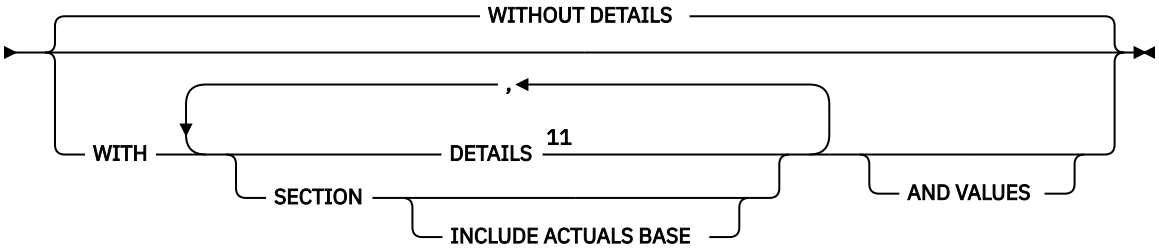


collect-activity-clause

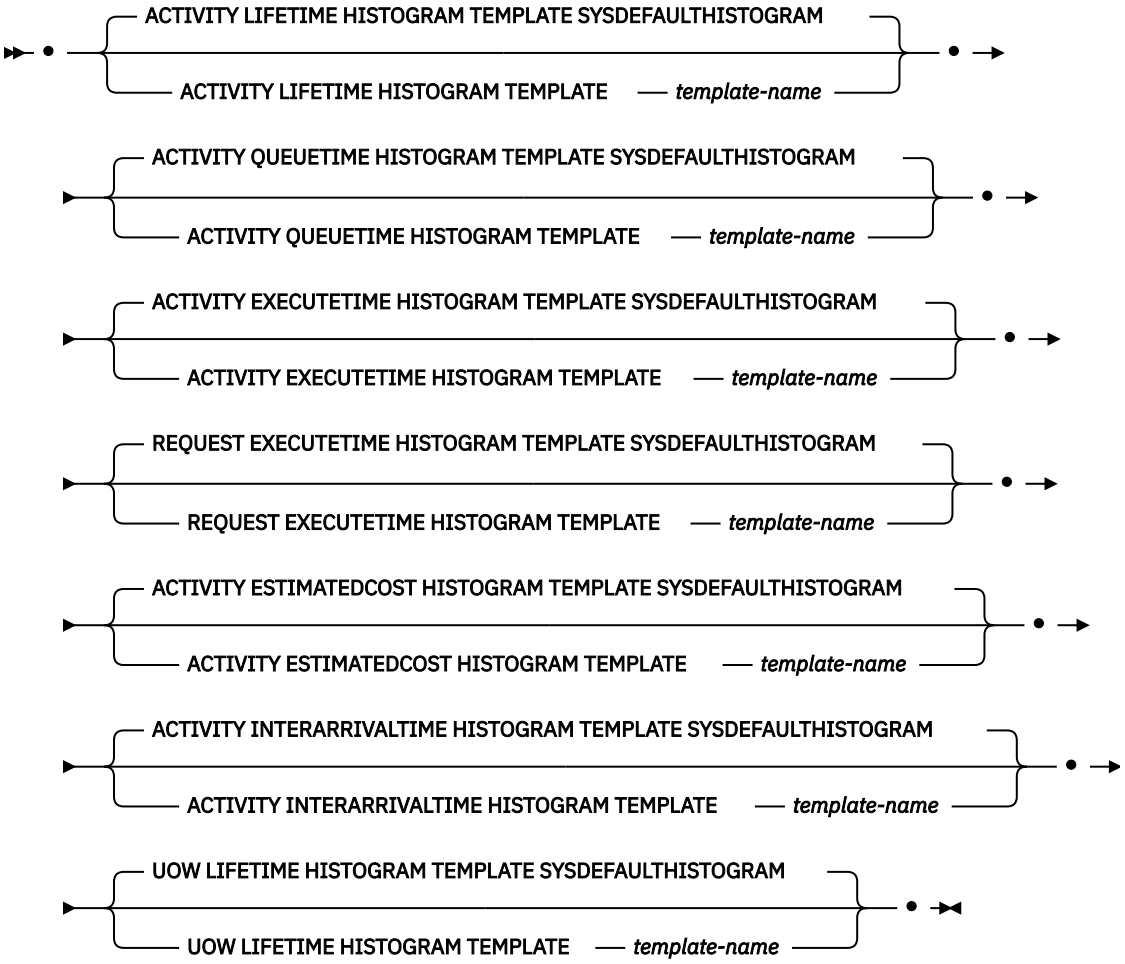


collect-activity-data-clause





histogram-template-clause



Notes:

[1] The FOR WORKLOAD TYPE clause is valid only for a service superclass (SQLSTATE 5U044).
[2] The FOR WORKLOAD TYPE clause is valid only for a service superclass (SQLSTATE 5U044).
[3] The ADMISSION QUEUE ORDER clause is valid only for a service subclass (SQLSTATE 5U043).

[4] The ADMISSION QUEUE ORDER clause is valid only for a service subclass (SQLSTATE 5U043).
[5] The DEGREE SCALEBACK DEFAULT option is valid only for a service subclass (SQLSTATE 5U043).
[6] The MAXIMUM DEGREE DEFAULT option is valid only for a service subclass (SQLSTATE 5U043).
[7] The COLLECT AGGREGATE REQUEST DATA clause is valid only for service subclasses.
[8] The COLLECT AGGREGATE UNIT OF WORK DATA clause is valid only for service subclasses.
[9] The COLLECT REQUEST METRICS clause is valid only for a service superclass.
[10] The REQUEST EXECUTETIME AND UOW LIFETIME HISTOGRAM TEMPLATE clauses are valid only for a service subclass.
[11] The DETAILS keyword is the minimum to be specified, followed by the option separated by a comma.

Description

service-class-name
Name of the service class to be created. This is a one-part name that is also an SQL identifier (either ordinary or delimited). The following restrictions apply:

- If the service class is a service superclass, the service class name must not identify a service superclass that already exists in the catalog (SQLSTATE 42710).
- If the service class is a service subclass, the service class name must not be the same as its service superclass, and must not identify a service subclass that already exists under the service superclass (SQLSTATE 42710).
- The name must not begin with the characters 'SYS' (SQLSTATE 42939).

UNDER *service-superclass-name*
Specifies that the service class is a subclass of service superclass *service-superclass-name*. If UNDER is not specified, the service class is a service superclass. The *service-superclass-name* must identify a service superclass that exists for the database (SQLSTATE 42704). The service superclass cannot be a default service class (SQLSTATE 5U029).

FOR WORKLOAD TYPE
Specifies the type of workload that is expected to run in the service superclass. This dictates how the service superclass is configured.

CUSTOM
The service superclass attributes are set to their default values. This is the default.

BATCH
The service superclass is configured to optimize it for large, batch-oriented activities.

INTERACTIVE
The service superclass is configured to optimize its response time for short activities.

MIXED
The service superclass is configured to handle a mixed set of activities of varying types and complexity.

RESOURCE SHARES
Specifies the number of shares of resources to which this service class is entitled, and whether the service class is allowed to exceed this number when other service classes in the same scope are not using their full entitlements. This value affects the amount of work the workload manager (WLM) adaptive admission control allows into the system.

HARD
The service class is not allowed to exceed its resource share entitlement.

SOFT
The service class is allowed to exceed its resource share entitlement when other service classes are not using their full entitlements.

Valid values are integers `1` - `65535`. The default is `SOFT RESOURCE SHARES 1000`.

Note: To use resource shares with WLM, you must enable the **wlm_admission_ctrl** configuration parameter.

CPU SHARES
Specifies the number of CPU shares that the workload manager (WLM) dispatcher allocates to this service class when work is executing within this service class, and whether the service class is allowed to exceed this number when other service classes in the same scope are not using their full entitlement.

HARD
The service class is not allowed to exceed its CPU share entitlement.

SOFT
The service class is allowed to exceed its CPU share entitlement when other service classes are not using their full entitlements.

Valid values are integers 1 - 65535. The default is `HARD CPU SHARES 1000`.

Note: To use CPU shares with WLM dispatcher, you must enable the **wlm_disp_cpu_shares** database manager configuration parameter.

CPU LIMIT
Specifies the maximum percentage of the CPU resources that the WLM dispatcher can assign to this service class. Valid values for the *integer-constant* are integers between 1 and 100. You can also specify **CPU LIMIT NONE** to indicate that there is no CPU limit.

ACTIVITY SORTMEM LIMIT

Specifies the maximum percentage of the configured shared sort memory (**SHEAPTHRES_SHR**) that individual queries executing in the service class are allowed to consume. Queries requiring more memory than the configured limit will have their individual per-operator **SORTHEAP** values reduced at runtime and memory requests will be throttled if they exceed the limit. Valid values for the integer-constant are integers between 10 and 100. You can also specify NONE to indicate there is no activity sort memory limit. The default is NONE.

The effective sort memory limit for a query will be the most restrictive of the limit defined at the subclass, superclass and database via the **ACT_SORTMEM_LIMIT** database configuration parameter. The sort memory limit applied to an activity is determined when the activity is first admitted for execution. The applied sort memory limit will not change if a query is remapped at runtime to a different service subclass.

The activity sort memory limit will only be enforced for queries that are managed by the adaptive workload manager. If the adaptive workload manager is disabled (**WLM_ADMISSION_CTRL** database config parameter is set to NO) or a query bypasses the adaptive workload manager, no sort memory limit will be applied to the query regardless of the service class it runs in.

Note: Setting an activity sort memory limit too low may result in reduced performance for queries.

MINIMUM RESOURCE SHARE *integer-constant* PERCENT
Specifies the percentage of entitled resources used by WLM adaptive admission control that is to be held in reserve for the service class when other service classes exceed their admission resource entitlement. Valid values for *integer-constant* are integers 0 - 100. The default is 0.

ADMISSION QUEUE ORDER
Specifies the queue order for activities queued by WLM adaptive admission control.

FIFO
Requests are queued in a first-in first-out order. This is the default.

LATENCY
The position of a request in the queue is based on its estimated execution time (that is, its latency) relative to the amount of time that has elapsed since it joined the queue.

DEGREE SCALEBACK
Specifies whether work running in this service class may have its degree scaled back. Queries set to DEGREE ANY may have their actual runtime degree scaled back by the database manager based on current CPU loads.

Scaling back the degree for service classes running simple queries may result in less contention and improved throughput. Disabling degree scale back for service classes with complex queries can help ensure more consistent and predictable response times. A setting of DEFAULT means a service subclass inherits its DEGREE SCALEBACK setting from the parent superclass. The DEFAULT setting is only applicable to service subclasses. The default setting for a service superclass is ON. The default value for a service subclass is DEFAULT.

MAXIMUM DEGREE
Specifies the maximum runtime degree of parallelism for activities that are running in this service class.

DEFAULT
This service subclass inherits its maximum degree value from its parent superclass. This value is the default for a service subclass. This setting is applicable only to service subclasses.

NONE
This service class does not specify a maximum runtime degree for assigned applications. The actual runtime degree is determined as the lower of the value of max_querydegree configuration parameter, the value set by SET RUNTIME DEGREE command, the SQL statement compilation degree and the MAXIMUM DEGREE value set on the Workload. This is the default for a service superclass.

degree
Specifies the maximum degree of parallelism for this service class. Valid values are 1 to 32767. The actual runtime degree is determined as the lower of this degree, the value of max_querydegree configuration parameter, the value set by SET RUNTIME DEGREE command, the SQL statement compilation degree and the MAXIMUM DEGREE set on the Workload.

PREFETCH PRIORITY
This parameter controls the priority with which agents in the service class can submit their prefetch requests. Valid values are HIGH, MEDIUM, LOW, or DEFAULT (SQLSTATE 42615). HIGH, MEDIUM, and LOW mean that prefetch requests will be submitted to the high, medium, and low priority queues. Prefetchers empty the priority queue in order from high to low. Agents in the service class submit their prefetch requests at the prefetch priority level when the next activity begins. If the prefetch priority is altered after a prefetch request is submitted, the request priority does not change. The default value is DEFAULT, which is internally mapped to MEDIUM for service superclasses. If DEFAULT is specified for a service subclass, it inherits the prefetch priority of its parent superclass.

The prefetch priority cannot be altered for a default subclass (SQLSTATE 5U032).

OUTBOUND CORRELATOR
Specifies whether or not to associate threads from this service class to an external workload manager service class.

If OUTBOUND CORRELATOR is set to a *string-constant* for the service superclass and OUTBOUND CORRELATOR NONE is set for a service subclass, the service subclass inherits the OUTBOUND CORRELATOR of its parent.

OUTBOUND CORRELATOR NONE
For a service superclass, specifies that there is no external workload manager service class association with this service class, and for a service subclass, specifies that the external workload manager service class association is the same as its parent. This is the default.

OUTBOUND CORRELATOR *string-constant*
Specifies the *string-constant* that is to be used as a correlator to associate threads from this service class to an external workload manager service class. The external workload manager must be active (SQLSTATE 5U030). The external workload manager should be set up to recognize the value of the specified string constant.

BUFFERPOOL PRIORITY
This parameter controls the bufferpool priority of pages fetched by activities in this service class. Valid values are HIGH, MEDIUM, LOW or DEFAULT (SQLSTATE 42615). Pages fetched by activities in a service class with higher bufferpool priority are less likely to be swapped out than pages fetched by activities in a service class with lower bufferpool priority. The default value is DEFAULT, which is internally mapped to LOW for service superclasses. If DEFAULT is specified for a service subclass, it inherits the bufferpool priority from its parent superclass.

The bufferpool priority cannot be altered for a default subclass (SQLSTATE 5U032).

COLLECT ACTIVITY DATA
Specifies that information about each activity that executes in this service class is to be sent to any active activities event monitor when the activity completes.

NONE
Specifies that activity data should not be collected for each activity that executes in this service class. This is the default.

ON COORDINATOR MEMBER
Specifies that activity data is to be collected only at the coordinator member of the activity.

ON ALL MEMBERS
Specifies that activity data is to be collected at all members where the activity is processed. On remote members, a record for the activity may be captured multiple times as the activity comes and goes on those members. If the AND VALUES clause is specified, activity input values will be collected only for the members of the coordinator.

WITHOUT DETAILS
Specifies that data about each activity that executes in the service class is to be sent to any active activities event monitor, when the activity completes execution. Details about statement, compilation environment, and section environment data are not sent.

WITH DETAILS
Specifies that statement and compilation environment data is to be sent to any active activities event monitor, for those activities that have them. Section environment data is not sent.

SECTION
Specifies that statement, compilation environment, section environment data, and section actuals are to be sent to any active activities event monitor for those activities that have them. DETAILS must be specified if SECTION is specified. Section actuals will be collected on any member where the activity data is collected.

INCLUDE ACTUALS BASE
Specifies that section actuals should also be collected on any partition where the activity data is collected. For section actuals to be collected, either INCLUDE ACTUALS clause must be specified or the **section_actuals** database configuration parameter must be set.

The effective setting for the collection of section actuals is the combination of the INCLUDE ACTUALS clause, the **section_actuals** database configuration parameter, and the <collectsectionactuals> setting specified on the WLM_SET_CONN_ENV routine. For example, if INCLUDE ACTUALS BASE is specified, yet the **section_actuals** database configuration parameter value is NONE and <collectsectionactuals> is set to NONE, then the effective setting for the collection of section actuals is BASE.

BASE specifies that the following should be enabled and collected during the activity's execution:

- Basic operator cardinality counts
- Statistics for each object referenced (DML statements only)

AND VALUES
Specifies that input data values are to be sent to any active activities event monitor, for those activities that have them. This data does not include SQL statements that are compiled by using the REOPT ALWAYS bind option.

COLLECT AGGREGATE ACTIVITY DATA
Specifies that aggregate activity data should be captured for this service class and sent to the statistics event monitor, if one is active. This information is collected periodically on an interval that is specified by the **wlm_collect_int** database configuration parameter.

BASE
Specifies that basic aggregate activity data should be captured for this service class and sent to the statistics event monitor, if one is active. Basic aggregate activity data includes:

- Estimated activity cost high watermark
- Rows returned high watermark
- Temporary table space usage high watermark

  Note: Only activities that have an SQLTEMPSPACE threshold applied to them participate in this high watermark.
- Activity life time histogram
- Activity queue time histogram
- Activity execution time histogram

This is the default when COLLECT AGGREGATE ACTIVITY DATA is specified, but without a value.

EXTENDED
Specifies that all aggregate activity data should be captured for this service class and sent to the statistics event monitor, if one is active. This includes all basic aggregate activity data plus:

- Activity data manipulation language (DML) estimated cost histogram
- Activity DML inter-arrival time histogram

NONE
Specifies that no aggregate activity data should be captured for this service class. This is the default when COLLECT AGGREGATE ACTIVITY DATA is not specified.

COLLECT AGGREGATE REQUEST DATA
Specifies that aggregate request data should be captured for this service class and sent to the statistics event monitor, if one is active. This information is collected periodically on an interval specified by the **wlm_collect_int** database configuration parameter. The COLLECT AGGREGATE REQUEST DATA clause is valid only for a service subclass.

BASE
Specifies that basic aggregate request data should be captured for this service class and sent to the statistics event monitor, if one is active.

NONE
Specifies that no aggregate request data should be captured for this service class. This is the default.

COLLECT AGGREGATE UNIT OF WORK DATA
Specifies that aggregate unit of work data is to be captured for this service class and sent to the statistics event monitor, if one is active. This information is collected periodically on an interval specified by the **wlm_collect_int** database configuration parameter. The COLLECT AGGREGATE UNIT OF WORK DATA clause is valid only for a service subclass.

BASE
Specifies that basic aggregate unit of work data is to be captured for this service class and sent to the statistics event monitor, if one is active. Basic aggregate unit of work includes:

- Unit of work lifetime histogram

NONE
Specifies that no aggregate unit of work data is to be collected for this service class. This is the default.

COLLECT REQUEST METRICS
Specifies that monitor metrics should be collected for any request submitted by a connection that is associated with the specified service superclass and sent to the statistics and unit of work event monitors, if active. The COLLECT REQUEST METRICS clause is valid only for a service superclass (SQLSTATE 50U44).

Note: The effective request metrics collection setting is the combination of the attribute specified by the COLLECT REQUEST METRICS clause on the service superclass associated with the connection submitting the request, and the **mon_req_metrics** database configuration parameter. If either the service superclass attribute or the configuration parameter has a value other than NONE, metrics will be collected for the request.

NONE
Specifies that no metrics will be collected for any request submitted by a connection associated with the service superclass. This is the default.

BASE
Specifies that basic metrics will be collected for any request submitted by a connection associated with the service superclass.

EXTENDED
Specifies that basic aggregate request data should be captured for this service class and sent to the statistics event monitor, if one is active. In addition, specifies that the values for the following monitor elements should be determined with additional granularity:

- **total_section_time**
- **total_section_proc_time**
- **total_routine_user_code_time**
- **total_routine_user_code_proc_time**
- **total_routine_time**

histogram-template-clause
Specifies the histogram templates to use when collecting aggregate activity data for activities executing in the service class.

ACTIVITY LIFETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the duration, in milliseconds, of database activities running in the service class during a specific interval. This time includes both time queued and time executing. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY QUEUETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities running in the service class are queued during a specific interval. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified, with either the BASE or EXTENDED option.

ACTIVITY EXECUTETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database activities running in the service class are executing during a specific interval. This time does not include the time spent queued. Activity execution time is collected in this histogram at the coordinator member only. The time does not include idle time. Idle time is the time between the execution of requests belonging to the same activity when no work is being done. An example of idle time is the time between the end of opening a cursor and the start of fetching from that cursor. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified,

with either the BASE or EXTENDED option. Only activities at nesting level 0 are considered for inclusion in the histogram.

REQUEST EXECUTETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, that database requests running in the service class are executing during a specific interval. This time does not include the time spent queued. Request execution time is collected in this histogram on each member where the request executes. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE REQUEST DATA clause is specified with the BASE option.

ACTIVITY ESTIMATEDCOST HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the estimated cost, in timerons, of DML activities running in the service class. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option. Only activities at nesting level 0 are considered for inclusion in the histogram.

ACTIVITY INTERARRIVALTIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the length of time, in milliseconds, between the arrival of one DML activity and the arrival of the next DML activity. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE ACTIVITY DATA clause is specified with the EXTENDED option.

UOW LIFETIME HISTOGRAM TEMPLATE *template-name*
Specifies the template that describes the histogram used to collect statistical data about the duration, in milliseconds, of units of work running in the service class during a specific interval. The default is SYSDEFAULTHISTOGRAM. This information is collected only when the COLLECT AGGREGATE UNIT OF WORK DATA clause is specified with the BASE option.

ENABLE or DISABLE
Specifies whether or not connections and activities can be mapped to the service class.

ENABLE
Connections and activities can be mapped to the service class. This is the default.

DISABLE
Connections and activities cannot be mapped to the service class. New connections or activities that are mapped to a disabled service class will be rejected (SQLSTATE 5U028). When a service superclass is disabled, its service subclasses are also disabled. When the service superclass is re-enabled, its service subclasses return to states that are defined in the system catalog. A default service class cannot be disabled (SQLSTATE 5U032).

Rules

- The maximum number of service subclasses that can be created under a service superclass is 61 (SQLSTATE 5U027).
- The maximum number of service superclasses that can be created for a database is 64 (SQLSTATE 5U027).
- A workload management (WLM)-exclusive SQL statement must be followed by a COMMIT or a ROLLBACK statement (SQLSTATE 5U027). WLM-exclusive SQL statements are:
  - CREATE HISTOGRAM TEMPLATE, ALTER HISTOGRAM TEMPLATE, or DROP (histogram template)
  - CREATE SERVICE CLASS, ALTER SERVICE CLASS, or DROP (service class)
  - CREATE THRESHOLD, ALTER THRESHOLD, or DROP (threshold)
  - CREATE WORK ACTION SET, ALTER WORK ACTION SET, or DROP (work action set)
  - CREATE WORK CLASS SET, ALTER WORK CLASS SET, or DROP (work class set)
  - CREATE WORKLOAD, ALTER WORKLOAD, or DROP (workload)
  - GRANT (workload privileges) or REVOKE (workload privileges)

- A WLM-exclusive SQL statement cannot be issued within a global transaction (SQLSTATE 51041) such as, for example, an XA transaction.

Notes

- A default subclass, SYSDEFAULTSUBCLASS, is automatically created for every service superclass.
- Only one uncommitted WLM-exclusive SQL statement at a time is allowed across all members. If an uncommitted WLM-exclusive SQL statement is executing, subsequent WLM-exclusive SQL statements will wait until the current WLM-exclusive SQL statement commits or rolls back.
- Changes are written to the system catalog, but do not take effect until after a COMMIT statement, even for the connection that issues the statement.
- ***Syntax alternatives***: The following are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - DATABASE PARTITION can be specified in place of MEMBER, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.
  - DATABASE PARTITIONS can be specified in place of MEMBERS, except when the DB2_ENFORCE_MEMBER_SYNTAX registry variable is set to ON.

Examples

- *Example 1:* Create a service superclass named PETSALES. The default subclass for PETSALES is automatically created.

```
CREATE SERVICE CLASS PETSALES
```

- *Example 2:* Create a service subclass named DOGSALES under service superclass PETSALES. Set service class DOGSALES as disabled.

```
CREATE SERVICE CLASS DOGSALES UNDER PETSALES DISABLE
```

- *Example 3:* Create a service superclass named BARNSALES with a prefetcher priority of LOW. The default subclass for BARNSALES is automatically created. Prefetch requests submitted by agents in the BARNSALES service class will go to the low priority prefetch queue.

```
CREATE SERVICE CLASS BARNSALES PREFETCH PRIORITY LOW
```

CREATE SERVER

The CREATE SERVER statement defines a data source to a federated database.

In this statement, the term SERVER and the parameter names that start with *server-* refer only to data sources in a federated system. They do not refer to the federated server in such a system, or to DRDA application servers.

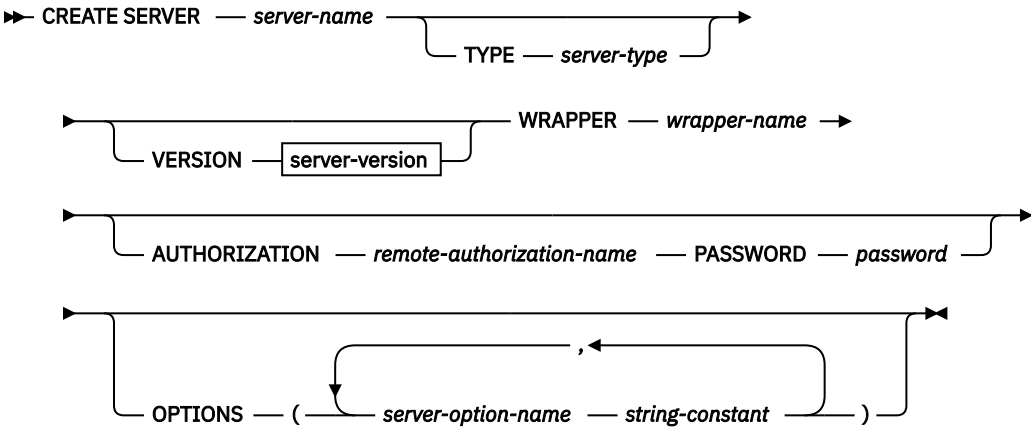
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

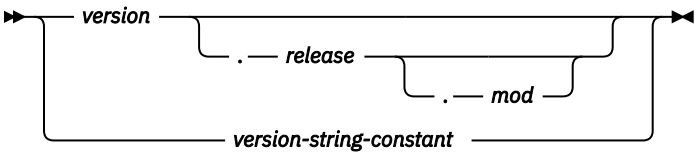
Authorization

The privileges held by the authorization ID of the statement must include DBADM authority.

Syntax



server-version



Description

server-name

Specifies the name of the data source that is being defined to the federated database. The name must not identify a data source that is described in the catalog. The server name must not be the same as the name of any of the table spaces in the federated database.

A server definition for relational data sources usually represents a remote database. Some relational database management systems, such as Oracle, do not allow multiple databases within each instance. Instead, each instance represents a server within a federated system.

For non-relational data sources, the purpose of a server definition varies from data source to data source. Some server definitions map to a search type and daemon, a website, or a web server. For other non-relational data sources, a server definition is created because the hierarchy of federated objects requires that data source files (identified by nicknames) are associated with a specific server object.

TYPE *server-type*

Specifies the type of the data source that is being defined to the federated database, and determines the default wrapper that is used.

Table 136. Server types and default wrappers

Data source	Type	Default Wrapper
Amazon Redshift	REDSHIFT	ODBC
Apache Hive	HIVE	ODBC
Apache Spark	SPARK	JDBC
Apache Spark SQL	SPARK_ODBC	ODBC
Cloudera Impala	IMPALA	ODBC
CouchDB	COUCHDB	NoSQL
database.com	DATABASE.COM	ODBC

Table 136. Server types and default wrappers (continued)		
Data source	**Type**	**Default Wrapper**
force.com	FORCE.COM	ODBC
HDFS parquet	HDFSPARQUET	NoSQL
IBM BigInsights	BIGSQL	DRDA
IBM Db2 Warehouse on Cloud	DASHDB	DRDA
IBM Db2 on Cloud	DASHDB	DRDA
IBM Db2 Warehouse	DASHDB	DRDA
IBM Db2	DB2/LUW	DRDA
Db2 for z/OS	DB2/ZOS	DRDA
Db2 for IBM i	DB2/ISERIES	DRDA
IBM Db2 Hosted	DB2/LUW	DRDA
IBM Db2 Server for VSE and VM	DB2/VM	DRDA
IBM PureData System for Analytics (formerly Netezza)	PDA (the type NETEZZA can also be used but is deprecated)	ODBC
IBM PureData System for Operational Analytics	DB2/LUW	DRDA
IBM PureData System for Transactions	DB2/LUW	DRDA
Informix® (with INFORMIX wrapper)	INFORMIX	INFORMIX
Informix (with ODBC wrapper)	INFORMIX_ODBC	ODBC
JDBC	JDBC	JDBC
MariaDB	MARIADB	ODBC
Microsoft Azure	AZURE	ODBC
Microsoft SQL Server (with MSSQLODBC3 wrapper)	MSSQLSERVER	MSSQLODBC3
Microsoft SQL Server (with ODBC wrapper)	MSSQL_ODBC	ODBC
MongoDB	MONGODBREST[1], MONGODRIVER[2], RESTHEART[3]	NoSQL
ODBC	ODBC	ODBC
Oracle (with NET8 wrapper)	ORACLE	NET8
Oracle (with ODBC wrapper)	ORACLE_ODBC	ODBC
Oracle Cloud	ORACLE_CLOUD	ODBC
Oracle MySQL	MYSQL	ODBC
Pivotal Greenplum	GREENPLUM	ODBC
Pivotal HAWQ	HAWQ	ODBC
PostgreSQL	POSTGRESQL	ODBC

Table 136. Server types and default wrappers (continued)		
Data source	**Type**	**Default Wrapper**
Progress OpenEdge	OPENEDGE	ODBC
Salesforce	SALESFORCE	ODBC
SAP HANA	HANA	ODBC
SAP Sybase	SYBASE	CTLIB
SAP Sybase IQ	SYBASEIQ	ODBC
SAP Sybase ASE	SYBASE_ODBC	ODBC
Teradata (with TERADATA wrapper)	TERADATA	TERADATA
Teradata (with ODBC wrapper)	TERADATA_ODBC	ODBC

This parameter is required by some wrappers. For example, it is required by an ODBC wrapper that is operating in DSN-less connection mode.

[1] Server type MONGODBREST uses RESTAPI to connect to MongoDB. The MONGODBREST option depends on an HTTP interface being configured correctly and running on MongoDB version 3.4, and earlier versions have a built-in HTTP interface.

[2] Server type MONGODRIVER uses the native MongoDB driver to connect to MongoDB. This approach has less dependency compared to other approaches and provides more performance advantages because this method leverages MongoDB full native API.

[3] Server type RESTHEART uses RESTAPI to get data. However, RestHeart is a third-party tool that must be installed separately. RestHeart supports more features than the MongoDB HTTP interface, and provides better performance than using MONGODBREST server type because it supports more filter functionality.

VERSION
Specifies the version of the data source denoted by *server-name*. This parameter is required by some wrappers.

version
Specifies the version number. The value must be an integer.

release
Specifies the number of the release of the version denoted by *version*. The value must be an integer.

mod
Specifies the number of the modification of the release denoted by *release*. The value must be an integer.

version-string-constant
Specifies the complete designation of the version. The *version-string-constant* can be a single value (for example, '8i'); or it can be the concatenated values of *version*, *release* and, if applicable, *mod* (for example, '8.0.3').

WRAPPER *wrapper-name*
Specifies the name of the wrapper that the federated server is to use to interact with the newly created server object. The default depends on the type of the remote server (see Table 136 on page 1344.

If the default wrapper does not already exist, it is created with the SET DB2_FENCED 'Y' option. A default wrapper is created only once. For example, if a wrapper with the name DRDA does not already exist, and if you issue two CREATE SERVER statements (one to create a BIGSQL server and another to create a DB2/ZOS server), and if you do not specify a wrapper name for either server explicitly, the first statement causes a default wrapper with the name DRDA to be created and both new servers use that wrapper.

Note: If a wrapper with the same name as a not-yet-created default wrapper already exists (for example, because it was created by a CREATE WRAPPER statement), that wrapper is not used as a default for a CREATE SERVER statement. In this situation, no default is available and the CREATE SERVER statement must specify a wrapper name explicitly.

AUTHORIZATION ***remote-authorization-name***
Required only for Db2 family data sources. Specifies the authorization ID under which any necessary actions are performed at the data source when the CREATE SERVER statement is processed. This authorization ID is not used when establishing subsequent connections to the server.

This ID must hold the authority (BINDADD or its equivalent) that the necessary actions require. If the *remote-authorization-name* is specified in mixed or lowercase characters (and the remote data source has case sensitive authorization names), the *remote-authorization-name* should be enclosed by double quotation marks.

PASSWORD ***password***
Required only for Db2 family data sources. Specifies the password associated with the authorization ID represented by *remote-authorization-name*. If the *password* is specified in mixed or lowercase characters (and the remote data source has case sensitive passwords), the *password* should be enclosed by double quotation marks.

OPTIONS
Specify configuration options for the for the server to be created. Which options you can specify depends on the data source of the object for which a server is being created. For a list of data sources and the server options that apply to each, see Data source options. Each option value is a character string constant that must be enclosed in single quotation marks.

Notes

- The *password* should be specified when the data source requires a password. If any letters in *password* must be in lowercase, enclose *password* in quotation marks.
- If the CREATE SERVER statement is used to define a Db2 family instance as a data source, Db2 may need to bind certain packages to that instance. If binding is required, the *remote-authorization-name* in the statement must have BIND authority. The time required for the bind operation to complete is dependent on data source speed and network connection speed.
- No verification occurs to ensure that the specified server version matches the remote server version. Specifying an incorrect server version can result in SQL errors when you access nicknames that belong to the database server definition. This is most likely when you specify a server version that is later than the remote server version. In that case, when you access nicknames that belong to the server definition, the database server might send SQL that the remote server does not recognize.
- The **AUTHORIZATION** keyword and **PASSWORD** keyword in the **CREATE SERVER** statement become optional if following conditions are true:
  - Db2 family data source.
  - Native wrapper or Db2 JDBC wrapper.
  - Server option **SSO_AUTH** value set to 'Y'.
- **Syntax alternatives:** The following syntax is supported for compatibility with previous product versions:
  - ADD can be specified before *server-option-name string-constant*.
- The TYPE server-type is optional for DSN connection mode but mandatory for DSN-less connection mode.

Examples

1. Register a server definition to access a Db2 for z/OS and OS/390®, Version 7.1 data source. CRANDALL is the name assigned to the Db2 for z/OS and OS/390 server definition. DRDA is the name of the wrapper used to access this data source. In addition, specify that:

- GERALD and drowssap are the authorization ID and password under which packages are bound at CRANDALL when this statement is processed.
- The alias for the Db2 for z/OS and OS/390 database that was specified with the CATALOG DATABASE statement is CLIENTS390.
- The authorization IDs and passwords under which CRANDALL can be accessed are to be sent to CRANDALL in uppercase.
- CLIENTS390 and the federated database use the same collating sequence.

```
CREATE SERVER CRANDALL
  TYPE DB2/ZOS
  VERSION 7.1
  WRAPPER DRDA
  AUTHORIZATION "GERALD"
  PASSWORD drowssap
  OPTIONS
      (DBNAME 'CLIENTS390',
      FOLD_ID 'U',
      FOLD_PW 'U',
      COLLATING_SEQUENCE 'Y')
```

2. Register a server definition to access an Oracle 9 data source. CUSTOMERS is the name assigned to the Oracle server definition. NET8 is the name of the wrapper used to access this data source. In addition, specify that:
   - ABC is the name of the node where the Oracle database server resides.
   - The CPU for the federated server runs twice as fast as the CPU that supports CUSTOMERS.
   - The I/O devices at the federated server process data one and a half times as fast as the I/O devices at CUSTOMERS.

```
CREATE SERVER CUSTOMERS
  TYPE ORACLE
  VERSION 9
  WRAPPER NET8
  OPTIONS
      (NODE 'ABC',
      CPU_RATIO '2.0',
      IO_RATIO '1.5')
```

3. Register a server definition for the Excel wrapper. The server definition is required to preserve the hierarchy of federated objects. BIOCHEM_LAB is the name assigned to the Excel server definition. EXCEL_2000_WRAPPER is the name of the wrapper used to access this data source.

```
CREATE SERVER BIOCHEM_DATA
  WRAPPER EXCEL_2000_WRAPPER
```

4. Register a server definition for the ODBC wrapper. To access Apache Hive within DSN-less mode, the server type must be specified. HOST is the Hive server address. PORT is the connection port number that is used to access this data source. PORT is an optional parameter. If PORT is not defined, the default number is 10000.

```
CREATE SERVER HIVE_SERV TYPE HIVE
      WRAPPER ODBC AUTHORIZATION ‘root’ PASSWORD ‘hadoop’
       OPTIONS (HOST ‘hives.cn.ibm.com’, PORT ‘10000’,
               DBNAME ‘default’, PASSWORD ‘Y’, PUSHDOWN ‘Y’)
```

5. Register a server definition to access to the Db2 data source, which uses the default DRDA wrapper. The server option **SSO_AUTH** indicates that remote data sources uses a single sign-on (SSO) authentication mechanism, so the **AUTHORIZATION** keyword and **PASSWORD** keyword can be removed.

```
CREATE SERVER server1 TYPE DB2/LUW VERSION 11 OPTIONS(HOST, PORT 50000, DBNAME sample,
SSO_AUTH 'Y')
```

CREATE STOGROUP

The CREATE STOGROUP statement defines a new storage group within the database, assigns storage paths to the storage group, and records the storage group definition and attributes in the catalog.

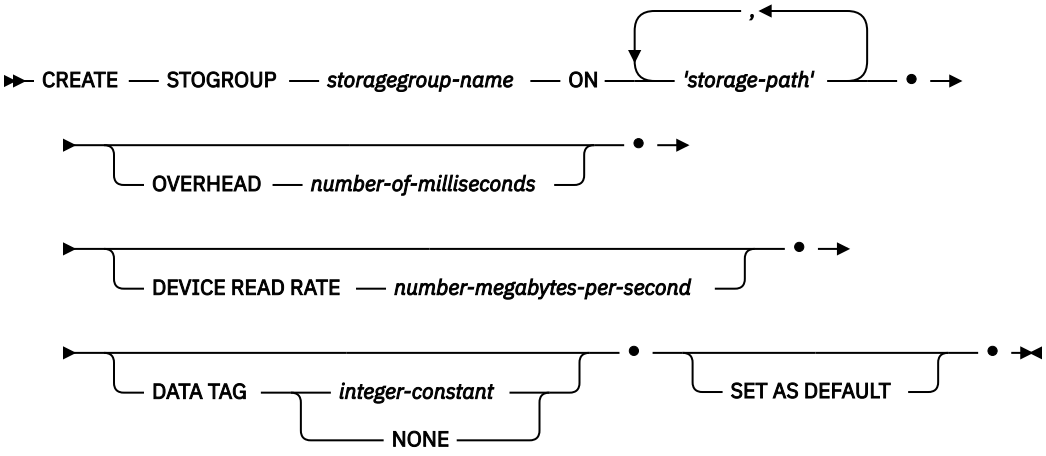
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The privileges that are held by the authorization ID of the statement must include SYSCTRL or SYSADM authority.

Syntax



Description

storagegroup-name

Names the storage group. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *storagegroup-name* must not identify a storage group that exists at the current server (SQLSTATE 42710). The *storagegroup-name* must not begin with the characters 'SYS' (SQLSTATE 42939).

ON

Specifies storage paths to be added for the named storage group. For partitioned database environments, the same storage paths are defined on all database partitions unless database partition expressions are used.

storage-path

A string constant that specifies containers the location where automatic storage table spaces are to be created. The format of the string depends on the operating system, as illustrated in the following table:

Operating system	Format of storage path string
Linux AIX	An absolute path
Windows	The letter name of a drive

The string can include database partition expressions to specify database partition number information in the storage path.

The maximum length of a path is 175 characters (SQLSTATE 54036).

A storage path that is added must be valid according to the naming rules for paths, and must be accessible (SQLSTATE 57019). Similarly, in a partitioned database environment, the storage path must exist and be accessible on every database partition (SQLSTATE 57019).

OVERHEAD *number-of-milliseconds*
Specifies the I/O controller usage and disk seek and latency time. This value is used to determine the cost of I/O during query optimization. The value of *number-of-milliseconds* is any numeric literal (integer, decimal, or floating point). If this value is not the same for all storage paths, set the value to a numeric literal that represents the average for all storage paths that belong to the storage group.

If the OVERHEAD clause is not specified, the OVERHEAD is set to 6.725 milliseconds.

DEVICE READ RATE *number-megabytes-per-second*
Specifies the device specification for the read transfer rate in megabytes per second. This value is used to determine the cost of I/O during query optimization. The value of *number-megabytes-per-second* is any numeric literal (integer, decimal, or floating point). If this value is not the same for all storage paths, set the value to a numeric literal that represents the average for all storage paths that belong to the storage group.

If the DEVICE READ RATE clause is not specified, the DEVICE READ RATE is set to the built-in default of 100 megabytes per second.

DATA TAG *integer-constant* or DATA TAG NONE
Specifies a tag for the data for table spaces that use this storage group unless explicitly overridden by the table space definition. This value can be used as part of a WLM configuration in a work class definition or referenced within a threshold definition. For more information, see the CREATE WORK CLASS SET and CREATE THRESHOLD statements.

integer-constant
Valid values for *integer-constant* are integers 1 - 9.

NONE
If NONE is specified, there is no data tag.

SET AS DEFAULT
Specifies the storage group that is created is designated as the default storage group. If no default storage group exists, the first one created is designated the default even if this clause is not specified. Since there can only be one storage group that is designated as the default storage group, specifying this clause removes the default attribute from the existing default storage group. Specifying a new default storage group has no effect to the storage group used by existing table spaces.

Rules

- The CREATE STOGROUP statement cannot be run while a database partition server is being added (SQLSTATE 55071).
- A storage group can have up to 128 defined storage paths (SQLSTATE 5U009).
- A database instance can have up to 256 defined storage groups (SQLSTATE 54035).

Notes

- ***Calculation of free space:*** When free space is calculated for a storage path on a database partition, the database manager checks for the existence of the following directories or mount points within the storage path. The database manager uses the first one that is found.

```
<storage path>/<instance name>/NODE####/<database name>
<storage path>/<instance name>/NODE####
<storage path>/<instance name>
<storage path>
```

Where:

– `<storage path>` is a storage path that is associated with the database.

  - <instance name> is the instance under which the database resides.
  - NODE#### corresponds to the database partition number (for example, NODE0000 or NODE0001).
  - <database name> is the name of the database.
- ***Isolating multiple database partitions under one storage path:*** The file systems can be mounted at a point beneath the storage path, and the database manager recognizes that the actual amount of free space available for table space containers might not be the same amount that is associated with the storage path directory itself.

  Consider an example in which two logical database partitions exist on one physical computer, and a single storage path exists (/dbdata). Each database partition uses this storage path, but you might want to isolate the data from each partition within its own file system. In this case, a separate file system can be created for each partition and it can be mounted at /dbdata/<instance>/NODE####. When creating containers on the storage path and determining free space, the database manager does not retrieve free space information for /dbdata, but instead retrieves it for the corresponding /dbdata/<instance>/NODE#### directory.
- ***Multiple storage paths:*** A storage path can be added to different storage groups, or to the same storage group multiple times.
- ***Similar media characteristics:*** Ensure that the storage paths added to a storage group share similar media characteristics. If the media characteristics are dissimilar, specify a value that represents an average for OVERHEAD and DEVICE READ RATE.

Examples

1. Create a storage group that is named HIGHEND with two paths under the /db directory (/db/filesystem1 and /db/filesystem2) which are attached to Solid State Disks.

```
CREATE STOGROUP HIGHEND ON '/db/filesystem1', '/db/filesystem2'
   OVERHEAD 0.75 DEVICE READ RATE 500
```

2. Create a storage group that is named MIDRANGE with two drives D and E and designate it as the default storage group.

```
CREATE STOGROUP MIDRANGE ON 'D:\', 'E:\' SET AS DEFAULT
```

3. Create a storage group that is named MIDRANGE with two paths under the /db directory, and designate it as the default storage group.

```
CREATE STOGROUP MIDRANGE ON '/db/filesystem1', '/db/filesystem2' SET AS DEFAULT
```

CREATE SYNONYM

The CREATE SYNONYM statement defines a synonym for a module, nickname, sequence, table, view, or another synonym.

Description

SYNONYM is a synonym for ALIAS.

CREATE TABLE

The CREATE TABLE statement defines a table. The definition must include its name and the names and attributes of its columns. The definition can include other attributes of the table, such as its primary key or check constraints.

To create a created temporary table, use the CREATE GLOBAL TEMPORARY TABLE statement. To declare a declared temporary table, use the DECLARE GLOBAL TEMPORARY TABLE statement.

Invocation

This statement can be embedded in an application program or issued by using dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

Authorization

The authorization ID of the statement must have either DBADM authority, or must have CREATETAB authority in combination with the following additional authorization:

- One of the following privileges or authorities:
  - USE privilege on the table space
  - SYSADM authority
  - SYSCTRL authority
- Plus one of these privileges or authorities:
  - IMPLICIT_SCHEMA authority on the database, if the implicit or explicit schema name of the table does not exist.
  - CREATEIN privilege on the schema, if the schema name of the table refers to an existing schema.
  - SCHEMAADM authority on the schema, if the schema name of the table refers to an existing schema.

If a subtable is being defined, at least one of the following conditions must be met:

- The authorization ID must be the same as the owner of the root table of the table hierarchy.
- The privileges that are held by the authorization ID must include SCHEMAADM authority on the schema that contains the root table of the table hierarchy.
- The privileges that are held by the authorization ID must include DBADM authority.

To define a foreign key, the authorization ID of the statement must have one of the following privileges for the parent table:

- REFERENCES privilege on the table
- REFERENCES privilege on each column of the specified parent key
- CONTROL privilege on the table
- SCHEMAADM authority on the schema, if the schema name of the parent table refers to an existing schema.
- DBADM authority

To define a materialized query table, the following conditions must be met:

- The authorization ID of the statement must have at least one of the following privileges on each table or view that is identified in the fullselect (privileges that are held through groups are not considered):
  - SELECT privilege on the table or view
  - CONTROL privilege on the table or view
  - SELECTIN privilege on the schema that contains the table or view
  - DATAACCESS authority on the schema that contains the table or view
  - DATAACCESS authority
- The authorization ID of the statement must have at least one of the following privileges on each table that is identified in the fullselect (this is required for altering the base table to associate it with the materialized query table):
  - ALTER privilege on the table or view
  - CONTROL privilege on the table or view
  - SCHEMAADM authority on the schema that contains the table or view

  - DBADM authority

To define a staging table that is associated with a materialized query table, the authorization ID of the statement must hold the following privileges:

- At least one of the following privileges for the materialized query table:
  - ALTER privilege on the materialized query table
  - CONTROL privilege on the materialized query table
  - SCHEMAADM authority on the schema that contains the materialized query table
  - DBADM authority
- At least one of the following privileges for each table or view that is identified in the fullselect of the materialized query table:
  - SELECT privilege on the table or view
  - CONTROL privilege on the table or view
  - SELECTIN privilege on the schema that contains the table or view
  - DATAACCESS authority on the schema that contains the table or view
  - DATAACCESS authority on the database

  In addition, at least one of the following privileges for each table or view identified in the fullselect of the materialized query table:
  - ALTER privilege on the table or view
  - CONTROL privilege on the table or view
  - SCHEMAADM authority on the schema that contains the table or view
  - DBADM authority

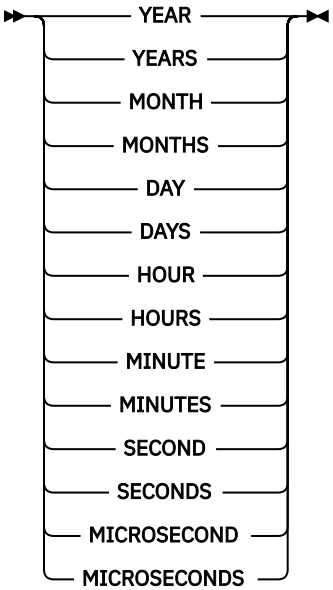
Duration-label



Notes:

[1] If you specify a dimensions clause, key sequence, or insert time, specifying ROW USING is optional unless the default table organization for the database is COLUMN, in which case specifying ROW USING is mandatory.

[2] If the first column-option chosen is a generated-clause with a generation-expression, then the data-type can be omitted. It will be determined from the resulting data-type of the generation-expression.
[3] The specified distinct type cannot have any data type constraints and the source type cannot be an anchored data type.
[4] The FOR BIT DATA clause can be specified in any order with the other column constraints that follow. The FOR BIT DATA clause cannot be specified with string units CODEUNITS32 (SQLSTATE 42613).
[5] DB2SECURITYLABEL is the built-in distinct type that must be used to define the row security label column of a protected table.
[6] A column of type DB2SECURITYLABEL, NOT NULL WITH DEFAULT is implicit and cannot be explicitly specified (SQLSTATE 42842). The default value for a column of type DB2SECURITYLABEL is the session authorization ID's security label for write access.
[7] The lob-options clause only applies to large object types (BLOB, CLOB, and DBCLOB) and distinct types based on large object types.
[8] The SCOPE clause only applies to the REF type.
[9] The default-clause and generated-clause cannot both be specified for the same column definition (SQLSTATE 42614).
[10] INLINE LENGTH applies only to columns defined as structured, XML, or LOB types.
[11] The same clause must not be specified more than once.
[12] Data type is optional for a row change timestamp column if the first column-option specified is a generated-clause. The data type default is TIMESTAMP(6).
[13] Data type is optional for row-begin and row-end timestamp columns if the first column-option specified is a generated-clause. The data type default is TIMESTAMP(12).
[14] Data type is optional for a transaction-start-ID timestamp columns if the first column-option specified is a generated-clause. The data type default is TIMESTAMP(12).
[15] Specifying which table space contains a table's indexes can be done when the table is created. If the table is a partitioned table, the index table space for a nonpartitioned index can be specified with the IN clause of the CREATE INDEX statement.
[16] This syntax for a partition-element is valid if only one partition-expression exists with a numeric or datetime data type.
[17] The first partition-element must include a starting-clause and the last partition-element must include an ending-clause.

Description

System-maintained, user-maintained, federated_tool-maintained, and replication-maintained materialized query tables (shadow tables) are referred to by the common term *materialized query table*, unless a need exists to identify each one separately.

IF NOT EXISTS

Specifies that no error message is shown when the table cannot be created because a table with the specified name already exists in the current database and schema. Typically, you use this option for scripted applications that are running SQL commands. When you suppress the `Table not found` error message, the scripted application is not impacted or halted.

The following conditions apply when you use this option:

- You cannot use the IF NOT EXISTS option with the AS SELECT clause. Using the IF NOT EXISTS option with the AS SELECT clause causes a syntax error.
- Unless other errors prevent the creation of the table, a CREATE TABLE message is returned although no table is created. The reason is that the failure is ignored if a table with the specified name already exists.
- The existing table and the specified table in the command are not compared, that is, the tables might have different sizes. The exisiting table remains as is with its current size. The content of the rows is not changed. The application must ensure that the target table and rows are as expected.

table-name
Names the table. The name, including the implicit or explicit qualifier, must not identify a table, view, nickname, or alias described in the catalog. The schema name must not be SYSIBM, SYSCAT, SYSFUN, or SYSSTAT (SQLSTATE 42939).

element-list
Defines the elements of a table, including the definition of columns and constraints on the table.

column-definition
Defines the attributes of a column.

column-name
Names a column of the table. The name cannot be qualified, and the same name cannot be used for more than one column of the table (SQLSTATE 42711).

A row-organized table can have the following:

- A 4K page size with a maximum of 500 columns, where the row size must not be greater than 4005.
- An 8K page size with a maximum of 1012 columns, where the row size must not be greater than 8101.
- A 16K page size with a maximum of 1012 columns, where the row size must not be greater than 16,293.
- A 32K page size with a maximum of 1012 columns, where the row size must not be greater than 32,677.

A column-organized table can have a maximum of 1012 columns, regardless of page size, where the byte counts of the columns must not be greater than 32,677. Extended row size support does not apply to column-organized tables.

For more information, see Row Size Limit.

data-type
Specifies the data type of the column.

built-in-type
One of the following built-in data types:

SMALLINT
A small integer.

[INTEGER | INT]
A large integer.

BIGINT
A big integer.

[DECIMAL | DEC | NUMERIC | NUM](*precision-integer, scale-integer*)
A decimal number.

- The precision integer specifies the total number of digits. It must be in the range 1 - 31. The default is 5.
- The scale integer specifies the number of digits to the right of the decimal point. It cannot be negative and cannot exceed the precision. The default is 0.

FLOAT(*integer*)
A single or double-precision floating-point number. If the specified length is in the range:

- 1 - 24, the number uses single precision.
- 25 - 53, the number uses double-precision.

Instead of FLOAT, you can specify:

REAL
For single precision floating-point.

DOUBLE
For double-precision floating-point.

DOUBLE PRECISION
For double-precision floating-point.

FLOAT
For double-precision floating-point.

DECFLOAT*(precision-integer)*
A decimal floating-point number. The precision integer specifies the total number of digits, which can be either 16 or 34. The default is 34.

[CHARACTER | CHAR](*integer* [OCTETS | CODEUNITS32])
A fixed-length character string of the specified number of code units. This number can range from 1 - 255 OCTETS or from 1 - 63 CODEUNITS32. The default is 1.

[VARCHAR | CHARACTER VARYING | CHAR VARYING](*integer* [OCTETS | CODEUNITS32])
A varying-length character string with a maximum length of the specified number of code units. This number can range from 1 - 32672 OCTETS or from 1 - 8168 CODEUNITS32.

FOR BIT DATA
Specifies that the contents of the column are to be treated as bit (binary) data. During data exchange with other systems, code page conversions are not performed. Comparisons are done in binary, irrespective of the database collating sequence.

CCSID
Specifies the encoding scheme for string data that is stored in the column. If the CCSID clause is not specified, the default is the CCSID of the table.

ASCII
Specifies that string data is encoded in the database code page. If the table is a Unicode table, CCSID ASCII cannot be specified (SQLSTATE 56031).

UNICODE, 1208, 1200
Specifies that string data is encoded in Unicode. Character data is in UTF-8; graphic data is in UTF-16 BE. CCSID 1208 and 1200 are synonyms for CCSID UNICODE. CCSID UNICODE cannot be specified for an SBCS database (SQLSTATE 560AA).

If the table is not a Unicode table, columns can be created with CCSID UNICODE, but the following rules apply:

- The alternative collating sequence must be specified in the database configuration before creating the table (SQLSTATE 56031). CCSID UNICODE columns collate with the alternative collating sequence that is specified in the database configuration.

  The only supported alternative collating sequence is IDENTITY_16BIT.
- The column cannot be a graphic data type.
- Anchored data types cannot anchor to a column that is created with CCSID UNICODE (SQLSTATE 428HS).
- Tables cannot have both the CCSID UNICODE clause and the DATA CAPTURE CHANGES clause specified (SQLSTATE 42613).
- Created temporary tables and declared temporary tables cannot have columns declared with CCSID UNICODE (SQLSTATE 56031).
- CCSID UNICODE columns cannot be specified in a CREATE SCHEMA statement (SQLSTATE 53090).
- A column of the exception table for a load operation must have the same CCSID as the corresponding target table column for the operation (SQLSTATE 428A5).
- A column of the exception table for a SET INTEGRITY statement must have the same CCSID as the corresponding target table column for the statement (SQLSTATE 53090).

- Columns of the target table for event monitor data must not be declared as CCSID UNICODE (SQLSTATE 55049).

[CLOB | CHARACTER LARGE OBJECT | CHAR LARGE OBJECT](*integer* [K | M | G] [OCTETS | CODEUNITS32])

A character large object string with a maximum length of the specified number of code units. The default is 1,048,576 (1M) code units.

If you want to multiply the length integer by 1024 (kilo), 1,048,576 (mega), or 1,073,741,824 (giga), specify a K (kilo), M (mega), or G (giga) multiplier.

- Regardless of which multiplier, if any, you use, the resulting length is limited by the maximum length of a CLOB column, which is 2,147,483,646 (for OCTETS) or 536,870,911 (for CODEUNITS32). If a multiple of K, M, or G slightly exceeds this maximum length (for example, 2G = 2,147,483,648), the maximum length is used instead.
- Any number of spaces (including zero spaces) is allowed between data type and the length specification or between the length integer and the K, M, or G multiplier. For example, the following specifications are all equivalent and valid:

```
CLOB(50K)
CLOB(50 K)
CLOB (50   K)
```

- The K, M, or G multiplier can be specified in either uppercase or lowercase.

In a Unicode database, the default string units for a character string data type are determined by the value of the NLS_STRING_UNITS global variable or *string_units* database configuration parameter. In a non-Unicode database, the default string units for character string data types are OCTETS.

OCTETS
Specifies that the units of the length attribute are bytes.

CODEUNITS32
Specifies that the units of the length attribute are Unicode UTF-32 code units, which approximate counting in characters. This does not affect the underlying code page of the data type. The actual length of a data value is determined by counting the UTF-32 code units as if the data were converted to UTF-32. CODEUNITS32 can be specified only in a Unicode database (SQLSTATE 560AA).

GRAPHIC(*integer* [CODEUNITS16 | CODEUNITS32])

A fixed-length graphic string of the specified length, which can range from 1 - 127 double bytes, 1 - 127 CODEUNITS16, or 1 - 63 CODEUNITS32. The default length is 1.

VARGRAPHIC(*integer* [CODEUNITS16 | CODEUNITS32])

A varying-length graphic string of the specified maximum length, which can range from 1 - 16336 double bytes, 1 - 16336 CODEUNITS16, or 1 - 8168 CODEUNITS32.

DBCLOB(*integer* [K | M | G] [CODEUNITS16 | CODEUNITS32])

A character large object string of the specified maximum length in double bytes, Unicode UTF-16 code units, or Unicode UTF-32 code units. The default is 1,048,576 (1M) code units.

If you want to multiply the length integer by 1024 (kilo), 1,048,576 (mega), or 1,073,741,824 (giga), specify a K (kilo), M (mega), or G (giga) multiplier.

- Regardless of which multiplier, if any, you use, the resulting length is limited by the maximum length of a DBCLOB column, which is which is 1,073,741,823 (for double bytes or CODEUNITS16) or 536,870,911 (for CODEUNITS32). If a multiple of K, M, or G slightly exceeds this maximum length (for example, 1G = 1,073,741,824), the maximum length is used instead.

- Any number of spaces (including zero spaces) is allowed between data type and the length specification or between the length integer and the K, M, or G multiplier. For example, the following specifications are all equivalent and valid:

```
DBCLOB(50K)
DBCLOB(50 K)
DBCLOB (50   K)
```

- The K, M, or G multiplier can be specified in either uppercase or lowercase.

In a Unicode database, the default string units for a character string data type are determined by the value of the NLS_STRING_UNITS global variable or *string_units* database configuration parameter. In a non-Unicode database, the default string units for character string data types is CODEUNITS16.

CODEUNITS16
Specifies that the units of the length attribute are Unicode UTF-16 code units, which are the same as counting in double bytes. CODEUNITS16 can be specified only in a Unicode database (SQLSTATE 560AA).

CODEUNITS32
Specifies that the units of the length attribute are Unicode UTF-32 code units. This does not affect the underlying code page of the data type. The actual length of a data value is determined by counting the UTF-32 code units as if the data were converted to UTF-32. CODEUNITS32 can be specified only in a Unicode database (SQLSTATE 560AA).

[NATIONAL CHARACTER | NATIONAL CHAR | NCHAR](*integer*)
A fixed-length string of the specified length. The default length is 1.

The NATIONAL CHARACTER type maps to either a fixed-length character or a fixed-length graphic string, depending on the value of the *nchar_mapping* database configuration parameter, which also defines the string units.

[NATIONAL CHARACTER VARYING | NATIONAL CHAR VARYING | NCHAR VARYING | NVARCHAR](*integer*)
A varying-length string of the specified maximum length.

The NATIONAL CHARACTER VARYING type maps to either a varying-length character or a varying-length graphic string, depending on the value of the *nchar_mapping* database configuration parameter, which also defines the string units.

[NATIONAL CHARACTER LARGE OBJECT | NCHAR LARGE OBJECT | NCLOB](*integer* [K | M | G])
A large object string of the specified maximum length.

This data type maps to either a character large object (CLOB) or a double-byte character large object (DBCLOB), depending on the current value of the *nchar_mapping* database configuration parameter, which also defines the string units. See the description of the CLOB or DBCLOB parameter (whichever applies) for information about possible values for the length integer and how to use a K (kilo), M (mega), or G (giga) multiplier.

BINARY(*integer*)
A fixed-length binary string of the specified length, which must be in the range 1 - 255 bytes. The default length is 1.

[VARBINARY | BINARY VARYING](*integer*)
A varying-length binary string of the specified maximum length, which must be in the range 1 - 32672 bytes.

[BLOB | BINARY LARGE OBJECT](*integer* [K | M | G])
A binary large object string of the specified maximum length. The default is 1,048,576 (1M) bytes.

If you want to multiply the length integer by 1024 (kilo), 1,048,576 (mega), or 1,073,741,824 (giga), specify a K (kilo), M (mega), or G (giga) multiplier.

- Regardless of which multiplier, if any, you use, the resulting length is limited by the maximum length of a BLOB column, which is 2,147,483,647 bytes. If a multiple of K, M, or G slightly exceeds this maximum length (for example, 2G = 2,147,483,648), the maximum length is used instead.
- Any number of spaces (including zero spaces) is allowed between data type and the length specification or between the length integer and the K, M, or G multiplier. For example, the following specifications are all equivalent and valid:

```
BLOB(50K)
BLOB(50 K)
BLOB (50   K)
```

- The K, M, or G multiplier can be specified in either uppercase or lowercase.

DATE
A date.

TIME
A time.

TIMESTAMP(*integer*) or TIMESTAMP
A time stamp. The integer specifies the precision of fractional seconds from 0 (seconds) to 12 (picoseconds). The default is 6 (microseconds).

XML
An XML document. Only well-formed XML documents can be inserted into an XML column.

An XML column has the following restrictions:

- The column cannot be part of any index except an index over XML data. Therefore, it cannot be included as a column of a primary key or unique constraint (SQLSTATE 42962).
- The column cannot be a foreign key of a referential constraint (SQLSTATE 42962).
- A default value (WITH DEFAULT) cannot be specified for the column (SQLSTATE 42613). If the column is nullable, the default for the column is the null value.
- The column cannot be used as the distribution key (SQLSTATE 42997).
- The column cannot be used as a data partitioning key (SQLSTATE 42962).
- The column cannot be used to organize a multidimensional clustering (MDC) table (SQLSTATE 42962).
- The column cannot be used in a range-clustered table (SQLSTATE 429BG).
- The column cannot be referenced in a check constraint except in a VALIDATED predicate (SQLSTATE 42621).

When a column of type XML is created, an XML path index is created on that column. A table-level XML region index is also created when the first column of type XML is created. The name of these indexes is "SQL" followed by a character time stamp (*yymmddhhmmssxxx*). The schema name is SYSIBM.

BOOLEAN
A Boolean value.

SYSPROC.DB2SECURITYLABEL
A built-in distinct type that must be used to define the row security label column of a protected table. The underlying data type of a column of the built-in distinct type DB2SECURITYLABEL is VARCHAR(128) FOR BIT DATA. A table can have at most one column of type DB2SECURITYLABEL (SQLSTATE 428C1).

distinct-type-name
For a user-defined type that is a distinct type. If a distinct type name is specified without a schema name, the distinct type name is resolved by searching the schemas on the SQL path (defined by the FUNCPATH preprocessing option for static SQL and by the CURRENT PATH register for dynamic SQL).

If a column is defined by using a distinct type, then the data type of the column is the distinct type. The length and the scale of the column are the length and the scale of the source type of the distinct type. The specified distinct type cannot have any data type constraints and the source type cannot be an anchored data type (SQLSTATE 428H2).

If a column defined by using a distinct type is a foreign key of a referential constraint, then the data type of the corresponding column of the primary key must have the same distinct type.

structured-type-name
For a user-defined type that is a structured type. If a structured type name is specified without a schema name, the structured type name is resolved by searching the schemas on the SQL path (defined by the FUNCPATH preprocessing option for static SQL, and by the CURRENT PATH register for dynamic SQL).

If a column is defined by using a structured type, then the static data type of the column is the structured type. The column can include values with a dynamic type that is a subtype of *structured-type-name*.

A column that is defined by using a structured type cannot be used in a primary key, unique constraint, foreign key, index key, or distribution key (SQLSTATE 42962).

If a column is defined by using a structured type, and contains a reference-type attribute at any level of nesting, that reference-type attribute is unscoped. To use such an attribute in a dereference operation, it is necessary to specify a SCOPE explicitly, using a CAST specification.

REF (*type-name2*)
For a reference to a typed table. If *type-name2* is specified without a schema name, the type name is resolved by searching the schemas on the SQL path (defined by the FUNCPATH preprocessing option for static SQL and by the CURRENT PATH register for dynamic SQL). The underlying data type of the column is based on the representation data type specified in the REF USING clause of the CREATE TYPE statement for *type-name2* or the root type of the data type hierarchy that includes *type-name2*.

column-options
Defines additional options that are related to columns of the table.

NOT NULL
Prevents the column from containing null values.

If NOT NULL is not specified, the column can contain null values, and its default value is either the null value or the value that is provided by the WITH DEFAULT clause.

NOT HIDDEN or IMPLICITLY HIDDEN
Specifies whether the column is to be defined as hidden. The hidden attribute determines whether the column is included in an implicit reference to the table, or whether it can be explicitly referenced in SQL statements. The default is NOT HIDDEN.

NOT HIDDEN
Specifies that the column is included in implicit references to the table, and that the column can be explicitly referenced.

IMPLICITLY HIDDEN
Specifies that the column is not visible in SQL statements unless the column is explicitly referenced by name. For example, assuming that a table includes a column that is defined with the IMPLICITLY HIDDEN clause, the result of a SELECT * does not include the implicitly hidden column. However, the result of a SELECT that explicitly refers to the name of an implicitly hidden column includes that column in the result table.

IMPLICITLY HIDDEN must not be specified for all columns of the table (SQLSTATE 428GU).

lob-options
Specifies options for LOB data types.

LOGGED
Specifies that changes that are made to the column are to be written to the log. The data in such columns is then recoverable with database utilities (such as RESTORE DATABASE). LOGGED is the default.

NOT LOGGED
Specifies that changes that are made to the column are not to be logged. This only applies to LOB data that is not inlined.

NOT LOGGED has no effect on a commit or rollback operation; that is, the database's consistency is maintained even if a transaction is rolled back, regardless of whether the LOB value is logged. The implication of not logging is that during a rollforward operation, after a backup or load operation, the LOB data will be replaced by zeros for those LOB values that would have had log records replayed during the rollforward. During crash recovery, all committed changes and changes rolled back reflect the expected results.

COMPACT
Specifies that the values in the LOB column should take up minimal disk space (free any extra disk pages in the last group that is used by the LOB value), rather than leave any leftover space at the end of the LOB storage area that might facilitate subsequent append operations. Storing data in this way might reduce the performance of append (length-increasing) operations on the column.

NOT COMPACT
Specifies some space for insertions to assist in future changes to the LOB values in the column. This is the default.

SCOPE
Identifies the scope of the reference type column.

A scope must be specified for any column that is intended to be used as the left operand of a dereference operator or as the argument of the DEREF function. Specifying the scope for a reference type column can be deferred to a subsequent ALTER TABLE statement to allow the target table to be defined, usually when mutually referencing tables.

typed-table-name
The name of a typed table. The table must already exist or be the same as the name of the table that is being created (SQLSTATE 42704). The data type of *column-name* must be REF(*S*), where *S* is the type of *typed-table-name* (SQLSTATE 428DM). No checking is done of values that are assigned to *column-name* to ensure that the values actually reference existing rows in *typed-table-name*.

typed-view-name
The name of a typed view. The view must already exist or be the same as the name of the view being created (SQLSTATE 42704). The data type of *column-name* must be REF(*S*), where *S* is the type of *typed-view-name* (SQLSTATE 428DM). No checking is done of values that are assigned to *column-name* to ensure that the values actually reference existing rows in *typed-view-name*.

CONSTRAINT *constraint-name*
Names the constraint. A *constraint-name* must not identify a constraint that was already specified within the same CREATE TABLE statement. (SQLSTATE 42710).

If this clause is omitted, an 18 byte long identifier that is unique among the identifiers of existing constraints defined on the table is generated by the system. (The identifier consists of "SQL" followed by a sequence of 15 numeric characters that are generated by a timestamp-based function).

When used with a PRIMARY KEY or UNIQUE constraint, the *constraint-name* can be used as the name of an index that is created to support the constraint.

PRIMARY KEY
This provides a shorthand method of defining a primary key that is composed of a single column. Thus, if PRIMARY KEY is specified in the definition of column C, the effect is the same as if the PRIMARY KEY(C) clause is specified as a separate clause.

A primary key cannot be specified if the table is a subtable (SQLSTATE 429B3) because the primary key is inherited from the supertable.

A ROW CHANGE TIMESTAMP column cannot be used as part of a primary key (SQLSTATE 429BV).

Row-begin, row-end, and transaction-start-ID columns cannot be used as part of a primary key (SQLSTATE 429BV).

See PRIMARY KEY within the *unique-constraint* description.

UNIQUE
This provides a shorthand method of defining a unique key that is composed of a single column. Thus, if UNIQUE is specified in the definition of column C, the effect is the same as if the UNIQUE(C) clause is specified as a separate clause.

A unique constraint cannot be specified if the table is a subtable (SQLSTATE 429B3) since unique constraints are inherited from the supertable.

See UNIQUE within the *unique-constraint* description.

references-clause
This provides a shorthand method of defining a foreign key that is composed of a single column. Thus, if a references-clause is specified in the definition of column C, the effect is the same as if that references-clause were specified as part of a FOREIGN KEY clause in which C is the only identified column.

See *references-clause* under *referential-constraint* description.

CHECK (*check-condition*)
This provides a shorthand method of defining a check constraint that applies to a single column. See description for CHECK (*check-condition*).

default-clause
Specifies a default value for the column.

WITH
An optional keyword.

DEFAULT

Provides a default value if a value is not supplied on insert or is specified as DEFAULT on INSERT or UPDATE. If a default value is not specified following the DEFAULT keyword, the default value depends on the data type of the column as shown in "ALTER TABLE". This clause must not be specified with generated-clause in a column definition (SQLSTATE 42614).

If a column is defined as XML, a default value cannot be specified (SQLSTATE 42613). The only possible default is NULL.

If the column is based on a column of a typed table, a specific default value must be specified when defining a default. A default value cannot be specified for the object identifier column of a typed table (SQLSTATE 42997).

If a column is defined by using a distinct type, then the default value of the column is the default value of the source data type cast to the distinct type.

If a column is defined by using a structured type, the *default-clause* cannot be specified (SQLSTATE 42842).

Omission of DEFAULT from a *column-definition* results in the use of the null value as the default for the column. If such a column is defined NOT NULL, then the column does not have a valid default.

default-values
Specific types of default values that can be specified are as follows.

constant
Specifies the constant as the default value for the column. The specified constant must:

- Represent a value that might be assigned to the column in accordance with the rules of assignment.
- Not be a floating-point constant unless the column is defined with a floating-point data type.
- Be a numeric constant or a decimal floating-point special value if the data type of the column is a decimal floating-point. Floating-point constants are first interpreted as DOUBLE and then converted to decimal floating-point if the target column is DECFLOAT. For DECFLOAT(16) columns, decimal constants having precision greater than 16 digits are rounded by using the rounding modes specified by the CURRENT DECFLOAT ROUNDING MODE special register.
- Not have nonzero digits beyond the scale of the column data type if the constant is a decimal constant (for example, 1.234 cannot be the default for a DECIMAL(5,2) column).
- Be expressed with no more than 254 bytes including the quotation mark characters, any introducer character such as the X for a hexadecimal constant, and characters from the fully qualified function name and parentheses when the constant is the argument of a *cast-function*

datetime-special-register
Specifies the value of the datetime special register (CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP) at the time of INSERT, UPDATE, or LOAD as the default for the column. The data type of the column must be the data type that corresponds to the special register specified (for example, data type must be DATE when CURRENT DATE is specified).

user-special-register
Specifies the value of the user special register (CURRENT USER, SESSION_USER, SYSTEM_USER) at the time of INSERT, UPDATE, or LOAD as the default for the column. The data type of the column must be a character string with a length not less than the length attribute of a user special register. USER can be specified in place of SESSION_USER and CURRENT_USER can be specified in place of CURRENT USER.

CURRENT SCHEMA
Specifies the value of the CURRENT SCHEMA special register at the time of INSERT, UPDATE, or LOAD as the default for the column. If CURRENT SCHEMA is specified, the data type of the column must be a character string with a length greater than or equal to the length attribute of the CURRENT SCHEMA special register.

CURRENT MEMBER
Specifies the value of the CURRENT MEMBER special register at the time of INSERT, UPDATE, or LOAD as the default for the column. If CURRENT MEMBER is specified, the data type of the column must allow assignment from an integer.

NULL
Specifies NULL as the default for the column. If NOT NULL was specified, DEFAULT NULL can be specified within the same column definition but results in an error on any attempt to set the column to the default value.

cast-function
This form of a default value can only be used with columns defined as a distinct type, BLOB, or datetime (DATE, TIME, or TIMESTAMP) data type. For distinct type, except

for distinct types based on BLOB or datetime types, the name of the function must match the name of the distinct type for the column. If qualified with a schema name, it must be the same as the schema name for the distinct type. If not qualified, the schema name from function resolution must be the same as the schema name for the distinct type. For a distinct type based on a datetime type, where the default value is a constant, a function must be used and the name of the function must match the name of the source type of the distinct type with an implicit or explicit schema name of SYSIBM. For other datetime columns, the corresponding datetime function can also be used. For a BLOB or a distinct type based on BLOB, a function must be used and the name of the function must be BLOB with an implicit or explicit schema name of SYSIBM.

constant
Specifies a constant as the argument. The constant must conform to the rules of a constant for the source type of the distinct type or for the data type if not a distinct type. If the *cast-function* is BLOB, the constant must be a string constant.

datetime-special-register
Specifies CURRENT DATE, CURRENT TIME, or CURRENT TIMESTAMP. The source type of the distinct type of the column must be the data type that corresponds to the specified special register.

user-special-register
Specifies CURRENT USER, SESSION_USER, or SYSTEM_USER. The data type of the source type of the distinct type of the column must be a string data type with a length of at least 8 bytes. If the *cast-function* is BLOB, the length attribute must be at least 8 bytes.

CURRENT SCHEMA
Specifies the value of the CURRENT SCHEMA special register. The data type of the source type of the distinct type of the column must be a character string with a length greater than or equal to the length attribute of the CURRENT SCHEMA special register. If the cast-function is BLOB, the length attribute must be at least 8 bytes.

EMPTY_CLOB(), EMPTY_DBCLOB(), or EMPTY_BLOB()
Specifies a zero-length string as the default for the column. The column must have the data type that corresponds to the result data type of the function.

If the value specified is not valid, an error is returned (SQLSTATE 42894).

generated-clause
Specifies a generated value for the column.

GENERATED

Specifies that the database generates values for the column. GENERATED must be specified if the column is to be considered an identity column or a row change time stamp column, row-begin column, row-end column, transaction-start-ID column, or generated expression column. A default clause must not be specified for a column that is defined as GENERATED (SQLSTATE 42623).

ALWAYS
Specifies that a value is always generated for the column when a row is inserted into the table, or whenever the result value of the *generation-expression* changes. The result of the expression is stored in the table. GENERATED ALWAYS is the recommended value unless data propagation or unload and reload operations are being done. GENERATED ALWAYS is the required value for generated columns.

BY DEFAULT
Specifies that the database generates a value for the column when a row is inserted, or updated specifying the DEFAULT clause, unless an explicit value is specified. BY DEFAULT is the recommended value when using data propagation or performing an unload and reload operation.

Although not explicitly required, to ensure uniqueness of the values, define a unique single-column index on generated IDENTITY columns.

AS IDENTITY
Specifies that the column is to be the identity column for this table. A table can only have a single identity column (SQLSTATE 428C1). The IDENTITY keyword can only be specified if the data type associated with the column is an exact numeric type with a scale of zero, or a user-defined distinct type for which the source type is an exact numeric type with a scale of zero (SQLSTATE 42815). SMALLINT, INTEGER, BIGINT, or DECIMAL with a scale of zero, or a distinct type based on one of these types, are considered exact numeric types. By contrast, single- and double-precision floating points are considered approximate numeric data types. Reference types, even if represented by an exact numeric type, cannot be defined as identity columns.

An identity column is implicitly NOT NULL. An identity column cannot have a DEFAULT clause (SQLSTATE 42623).

START WITH *numeric-constant*
Specifies the first value for the identity column. This value can be any positive or negative value that might be assigned to this column (SQLSTATE 42815), without nonzero digits existing to the right of the decimal point (SQLSTATE 428FA). The default is MINVALUE for ascending sequences, and MAXVALUE for descending sequences. This value is not necessarily the value that would be cycled to after reaching the maximum or minimum value for the identity column. The START WITH clause can be used to start the generation of values outside the range that is used for cycles. The range that is used for cycles is defined by MINVALUE and MAXVALUE.

INCREMENT BY *numeric-constant*
Specifies the interval between consecutive values of the identity column. This value can be any positive or negative value that might be assigned to this column (SQLSTATE 42815), and does not exceed the value of a large integer constant (SQLSTATE 42820), without nonzero digits existing to the right of the decimal point (SQLSTATE 428FA).

If this value is negative, this is a descending sequence. If this value is 0, or positive, this is an ascending sequence. The default is 1.

NO MINVALUE or MINVALUE
Specifies the minimum value at which a descending identity column either cycles or stops generating values, or an ascending identity column cycles to after reaching the maximum value.

NO MINVALUE
For an ascending sequence, the value is the START WITH value, or 1 if START WITH was not specified. For a descending sequence, the value is the minimum value of the data type of the column. This is the default.

MINVALUE *numeric-constant*
Specifies the numeric constant that is the minimum value. This value can be any positive or negative value that might be assigned to this column (SQLSTATE 42815), without nonzero digits existing to the right of the decimal point (SQLSTATE 428FA), but the value must be less than or equal to the maximum value (SQLSTATE 42815).

NO MAXVALUE or MAXVALUE
Specifies the maximum value at which an ascending identity column either cycles or stops generating values, or a descending identity column cycles to after reaching the minimum value.

NO MAXVALUE
For an ascending sequence, the value is the maximum value of the data type of the column. For a descending sequence, the value is the START WITH value, or -1 if START WITH was not specified. This is the default.

MAXVALUE *numeric-constant*
Specifies the numeric constant that is the maximum value. This value can be any positive or negative value that might be assigned to this column (SQLSTATE 42815), without nonzero digits existing to the right of the decimal point (SQLSTATE 428FA), but the value must be greater than or equal to the minimum value (SQLSTATE 42815).

NO CYCLE or CYCLE
Specifies whether this identity column should continue to generate values after generating either its maximum or minimum value.

NO CYCLE
Specifies that values are not generated for the identity column after the maximum or minimum value is reached. This is the default.

CYCLE
Specifies that values continue to be generated for this column after the maximum or minimum value is reached. If this option is used, after an ascending identity column reaches the maximum value, it generates its minimum value; or after a descending sequence reaches the minimum value, it generates its maximum value. The maximum and minimum values for the identity column determine the range that is used for cycling.

When CYCLE is in effect, duplicate values might be generated for an identity column. Although not explicitly required, a unique, single-column index should be defined on the generated column to ensure uniqueness of the values, if unique values are required. If a unique index exists on such an identity column and a non-unique value is generated, an error occurs (SQLSTATE 23505).

NO CACHE or CACHE
Specifies whether to keep some pre-allocated values in memory for faster access. If a new value is needed for the identity column, and none is available in the cache, then the end of the new cache block must be logged. However, when a new value is needed for the identity column, and an unused value exists in the cache, then the allocation of that identity value is faster, because no logging is necessary. This is a performance and tuning option.

NO CACHE
Specifies that values for the identity column are not to be pre-allocated.

When this option is specified, the values of the identity column are not stored in the cache. In this case, every request for a new identity value results in synchronous I/O to the log.

CACHE *integer-constant*
Specifies how many values of the identity sequence are to be pre-allocated and kept in memory. When values are generated for the identity column, pre-allocating and storing values in the cache reduces synchronous I/O to the log.

If a new value is needed for the identity column and no unused values are available in the cache, the allocation of the value involves waiting for I/O to the log. However, when a new value is needed for the identity column and an unused value exists in the cache, the allocation of that identity value can happen more quickly by avoiding the I/O to the log.

The minimum value is 2 (SQLSTATE 42815). The default value is CACHE 20.

Use the CACHE and NO ORDER options to allow multiple caches of identity values simultaneously. In a multi-partition or Db2 pureScale environment, multiple members can cache them.

In a Db2 pureScale environment, if both CACHE and ORDER are specified, the specification of ORDER overrides the specification of CACHE and instead NO CACHE will be in effect.

NO ORDER or ORDER
Specifies whether the identity values must be generated in order of request.

NO ORDER
Specifies that the values do not need to be generated in order of request. This is the default.

ORDER
Specifies that the values must be generated in order of request.

FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP
Specifies that the column is a time stamp column for the table. A value is generated for the column in each row that is inserted, and for any row in which any column is updated. The value that is generated for a ROW CHANGE TIMESTAMP column is a time stamp that corresponds to the insert or update time for that row. If multiple rows are inserted or updated with a single statement, the value of the ROW CHANGE TIMESTAMP column might be different for each row.

A table can only have one ROW CHANGE TIMESTAMP column (SQLSTATE 428C1). If *data-type* is specified, it must be TIMESTAMP or TIMESTAMP(6) (SQLSTATE 42842). A ROW CHANGE TIMESTAMP column cannot have a DEFAULT clause (SQLSTATE 42623). NOT NULL must be specified for a ROW CHANGE TIMESTAMP column (SQLSTATE 42831).

AS (*generation-expression*)
Specifies that the definition of the column is based on an expression. (If the expression for a GENERATED ALWAYS column includes a user-defined external function, changing the executable for the function (such that the results change for given arguments) can result in inconsistent data. This can be avoided by using the SET INTEGRITY statement to force the generation of new values). The *generation-expression* cannot contain any of the following (SQLSTATE 42621):

- Subqueries
- XMLQUERY or XMLEXISTS expressions
- Column functions
- Dereference operations or DEREF functions
- User-defined or built-in functions that are non-deterministic
- User-defined functions that use the EXTERNAL ACTION option
- User-defined functions that are not defined with NO SQL
- Host variables or parameter markers
- Special registers and built-in functions that depend on the value of a special register
- Global variables
- References to columns defined later in the column list
- References to other generated columns
- References to columns of type XML

The data type for the column is based on the result data type of the *generation-expression*. A CAST specification can be used to force a particular data type and to provide a scope (for a reference type only). If *data-type* is specified, values are assigned to the column according to the appropriate assignment rules. A generated column is considered to be nullable unless the NOT NULL column option is specified. The data type of a generated column and the result data type of the *generation-expression* must have equality defined (see "Assignments and comparisons"). This excludes columns and generation expressions of type LOB data types, XML, structured types, and distinct types based on any of these types (SQLSTATE 42962).

AS ROW BEGIN

Specifies that the generated value is assigned by the database manager whenever a row is inserted into the table or any column in the row is updated. The value is generated by using a reading from the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to the row-begin column or transaction-start-ID column in the table, or a row in a system-period temporal table is deleted.

For a system-period temporal table, the database manager ensures uniqueness of the generated values for a row-begin column across transactions. The time stamp value might be adjusted to ensure that rows that are inserted into an associated history table have the end time stamp value greater than the begin time stamp value. This can happen when a conflicting transaction is updating the same row in the system-period temporal table. The database configuration parameter **systime_period_adj** must be set to Yes for this adjustment to the time stamp value to occur. If multiple rows are inserted or updated within a single SQL transaction and an adjustment is not needed, the values for the row-begin column are the same for all the rows and are unique from the values that are generated for the column for another transaction. A row-begin column is required as the begin column of a SYSTEM_TIME period, which is the intended use for this type of generated column.

A table can have only one row-begin column (SQLSTATE 428C1). If *data-type* is not specified the column is defined as a TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12) (SQLSTATE 42842). The column cannot have a DEFAULT clause (SQLSTATE 42623), and must be defined as NOT NULL (SQLSTATE 42831). A row-begin column is not updatable.

AS ROW END

Specifies that a value for the data type of the column is assigned by the database manager whenever a row is inserted or any column in the row is updated. The assigned value is TIMESTAMP "9999-12-30-00.00.00.000000000000".

A row-end column is required as the second column of a SYSTEM_TIME period, which is the intended use for this type of generated column.

A table can have only one row-end column (SQLSTATE 428C1). If *data-type* is not specified, the column is defined as TIMESTAMP(12). If *data-type* is specified, it must be TIMESTAMP(12) (SQLSTATE 42842). The column cannot have a DEFAULT clause (SQLSTATE 42623), and must be defined as NOT NULL (SQLSTATE 42831). A row-end column is not updatable.

AS TRANSACTION START ID

Specifies that the value is assigned by the database manager whenever a row is inserted into the table or any column in the row is updated. The database manager assigns a unique time stamp value per transaction or the null value. The null value is assigned to the transaction-start-ID column if the column is nullable and if there is a row-begin column in the table for which the value did not need to be adjusted. Otherwise, the value is generated by using a reading of the time-of-day clock during execution of the first data change statement in the transaction that requires a value to be assigned to a row-begin column or transaction-start-ID column in the table, or a row in a system-period temporal table is deleted. If multiple rows are inserted or updated within a single SQL transaction, the values for the transaction-start-ID column are the same for all the rows and are unique from the values that are generated for the column for another transaction.

A transaction-start-ID column is required for a system-period temporal table, which is the intended use for this type of generated column.

A table can have only one transaction-start-ID column (SQLSTATE 428C1). If *data-type* is not specified, the column is defined as TIMESTAMP(12). If *data-type* is specified, it

must be TIMESTAMP(12). A transaction-start-ID column cannot have a DEFAULT clause (SQLSTATE 42623). A transaction-start-ID column is not updatable.

INLINE LENGTH *integer*

This option is valid only for a column that is defined using a structured type, XML, or LOB data type (SQLSTATE 42842).

For a column of data type XML or LOB, *integer* indicates the maximum byte size of the internal representation of an XML document or LOB data to store in the base table row. XML documents that have a larger internal representation are stored separately from the base table row in an auxiliary storage object. This takes place automatically. There is no default inline length for XML type columns. If the XML document or LOB data is stored inlined in the base table row, there is an additional overhead. For LOB data, the overhead is 4 bytes.

For a column of data type LOB, the default inline length is set to be the maximum size of the LOB descriptor if the clause is not specified. Any explicit INLINE LENGTH must be at least the maximum LOB descriptor size. The following table summarizes the LOB descriptor sizes.

Table 137. Sizes of the LOB descriptor for various LOB lengths.

Maximum LOB length in bytes	Minimum explicit INLINE LENGTH
1,024	68
8,192	92
65,536	116
524,000	140
4,190,000	164
134,000,000	196
536,000,000	220
1,070,000,000	252
1,470,000,000	276
2,147,483,647	312

For a structured type column, *integer* indicates the maximum size in bytes of an instance of a structured type to store inline with the rest of the values in the row. Instances of structured types that cannot be stored inline are stored separately from the base table row, similar to the way that LOB values are stored. This takes place automatically. The default INLINE LENGTH for a structured-type column is the inline length of its type (specified explicitly or by default in the CREATE TYPE statement). If INLINE LENGTH of the structured type is less than 292, the value 292 is used for the INLINE LENGTH of the column.

Note: The inline lengths of subtypes are not counted in the default inline length, meaning that instances of subtypes might not fit inline unless an explicit INLINE LENGTH is specified at CREATE TABLE time to account for existing and future subtypes.

The explicit INLINE LENGTH value cannot exceed 32 673. For a structured type or XML data type, it must be at least 292 (SQLSTATE 54010).

COMPRESS SYSTEM DEFAULT

Specifies that system default values are to be stored using minimal space. If the VALUE COMPRESSION clause is not specified, a warning is returned (SQLSTATE 01648), and system default values are not stored using minimal space.

Allowing system default values to be stored in this manner causes a slight performance penalty during insert and update operations on the column because of extra checking that is done.

The base data type must not be a DATE, TIME, TIMESTAMP, XML, or structured data type (SQLSTATE 42842). If the base data type is a varying-length string, this clause is ignored. String values of length 0 are automatically compressed if a table has been set with VALUE COMPRESSION.

COLUMN SECURED WITH *security-label-name*
Identifies a security label that exists for the security policy that is associated with the table. The name must not be qualified (SQLSTATE 42601). The table must have a security policy associated with it (SQLSTATE 55064). The table must not be a system-period temporal table.

Generally, you are not allowed to protect data in such a way that your current LBAC credentials do not allow you to write to that data. To protect a column with a particular security label, you must have LBAC credentials that allow you to write to data protected by that security label. You do not have to have SECADM authority.

period-definition

PERIOD
Defines a period for the table.

SYSTEM_TIME (*begin-column-name*, *end-column-name*)

Defines a system period with the name SYSTEM_TIME. There must not be a column in the table with the name SYSTEM_TIME (SQLSTATE 42711). A table can have only one SYSTEM_TIME period (SQLSTATE 42711). *begin-column-name* must be defined as ROW BEGIN and *end-column-name* must be defined as ROW END (SQLSTATE 428HN).

BUSINESS_TIME (*begin-column-name*, *end-column-name*)

Defines an application period with the name BUSINESS_TIME. There must not be a column in the table with the name BUSINESS_TIME (SQLSTATE 42711). A table can have only one BUSINESS_TIME period (SQLSTATE 42711). *begin-column-name* and *end-column-name* must both be defined as DATE or TIMESTAMP(*p*) where *p* is in the range 0 - 12 (SQLSTATE 42842), and the columns must be defined as NOT NULL (SQLSTATE 42831). *begin-column-name* and *end-column-name* must not identify a column that is defined with a GENERATED clause (SQLSTATE 428HZ).

An implicit check constraint is generated to ensure that the value of *end-column-name* is greater than the value of *begin-column-name*. The name of the implicitly created check constraint is DB2_GENERATED_CHECK_CONSTRAINT_FOR_BUSINESS_TIME and must not be the name of any other check constraint that is specified in the statement (SQLSTATE 42710).

unique-constraint
Defines a unique or primary key constraint. If the table has a distribution key, any unique or primary key must be a superset of the distribution key. A unique or primary key constraint cannot be specified for a table that is a subtable (SQLSTATE 429B3). Primary or unique keys cannot be subsets of dimensions (SQLSTATE 429BE). If the table is a root table, the constraint applies to the table and all its subtables.

CONSTRAINT *constraint-name*
Names the primary key or unique constraint.

UNIQUE (*column-name*, ...)
Defines a unique key that is composed of the identified columns. The identified columns must be defined as NOT NULL. Each *column-name* must identify a column of the table and the same column must not be identified more than once.

If the table has a BUSINESS_TIME period defined, BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in the key expression list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list must include at least one *column-name*. WITHOUT OVERLAPS means that for the other specified keys, the values are unique with respect to time for the BUSINESS_TIME period. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint (SQLSTATE 428HW).

The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following attributes to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The begin column of the BUSINESS_TIME period in ascending order

The number of identified columns must not exceed 64, and the sum of their stored lengths must not exceed the index key length limit for the page size. For column stored lengths, see Byte Counts. For key length limits, see "SQL limits". No LOB, XML, distinct type based on one of these types, or structured type can be used as part of a unique key, even if the length attribute of the column is small enough to fit within the index key length limit for the page size (SQLSTATE 54008).

The set of columns in the unique key cannot be the same as the set of columns in the primary key or another unique key (SQLSTATE 01543). (If LANGLEVEL is SQL92E or MIA, an error is returned, SQLSTATE 42891).

A unique constraint cannot be specified if the table is a subtable (SQLSTATE 429B3)because unique constraints are inherited from the supertable.

The description of the table as recorded in the catalog includes the unique key and, if enforced, its unique index. If enforced, a unique bidirectional index, which allows forward and reverse scans, is automatically created for the columns in the sequence that are specified with ascending order for each column. The name of the index is the same as the *constraint-name* if this does not conflict with an existing index in the schema where the table is created. If the index name conflicts, the name is SQL, followed by a character time stamp (*yymmddhhmmssxxx*), with SYSIBM as the schema name.

PRIMARY KEY (*column-name,...*)

Defines a primary key that is composed of the identified columns. The clause must not be specified more than once, and the identified columns must be defined as NOT NULL. Each *column-name* must identify a column of the table, and the same column must not be identified more than once.

If the table has a BUSINESS_TIME period defined, BUSINESS_TIME WITHOUT OVERLAPS can be specified as the last item in the key expression list. If BUSINESS_TIME WITHOUT OVERLAPS is specified, the list must include at least one *column-name*. WITHOUT OVERLAPS means that for the rest of the specified keys, the values are unique with respect to time for the BUSINESS_TIME period. When BUSINESS_TIME WITHOUT OVERLAPS is specified, the columns of the BUSINESS_TIME period must not be specified as part of the constraint (SQLSTATE 428HW). The specification of BUSINESS_TIME WITHOUT OVERLAPS adds the following attributes to the constraint:

- The end column of the BUSINESS_TIME period in ascending order
- The begin column of the BUSINESS_TIME period in ascending order

The number of identified columns must not exceed 64, and the sum of their stored lengths must not exceed the index key length limit for the page size. For column stored lengths, see Byte Counts. For key length limits, see "SQL limits". No LOB, XML, distinct type based on one of these types, or structured type can be used as part of a primary key, even if the length attribute of the column is small enough to fit within the index key length limit for the page size (SQLSTATE 54008).

The set of columns in the primary key cannot be the same as the set of columns in a unique key (SQLSTATE 01543). (If LANGLEVEL is SQL92E or MIA, an error is returned, SQLSTATE 42891).

Only one primary key can be defined on a table.

A primary key cannot be specified if the table is a subtable (SQLSTATE 429B3) because the primary key is inherited from the supertable.

The description of the table as recorded in the catalog includes the primary key and, if enforced, its primary index. If enforced, a unique bidirectional index, which allows forward and reverse scans, will automatically be created for the columns in the sequence specified with ascending order for each column. The name of the index is the same as the *constraint-name* if this does

not conflict with an existing index in the schema where the table is created. If the index name conflicts, the name is SQL, followed by a character time stamp (*yymmddhhmmssxxx*), with SYSIBM as the schema name.

When explicitly defining distribution keys using the **DISTRIBUTE BY HASH** clause, the columns of a *unique-constraint* must be a superset of the distribution key columns; column order is unimportant. When distribution keys are implicitly defined, they are selected based on the definition of the unique constraint. Implicit selection of distribution keys occurs in the following cases:

- Omit **DISTRIBUTE BY HASH** clause and the table is defined in a database partition group with multiple partitions.
- **DISTRIBUTE BY RANDOM** clause is used.

referential-constraint
Defines a referential constraint.

CONSTRAINT *constraint-name*
Names the referential constraint.

FOREIGN KEY (*column-name*,...)
Defines a referential constraint with the specified *constraint-name*.

Let T1 denote the object table of the statement. The foreign key of the referential constraint is composed of the identified columns. Each name in the list of column names must identify a column of T1 and the same column must not be identified more than once.

The number of identified columns must not exceed 64, and the sum of their stored lengths must not exceed the index key length limit for the page size. For column stored lengths, see Byte Counts. For key length limits, see "SQL limits". No LOB, XML, distinct type based on one of these types, or structured type column can be used as part of a foreign key (SQLSTATE 42962). There must be the same number of foreign key columns as there are in the parent key and the data types of the corresponding columns must be compatible (SQLSTATE 42830). Two-column descriptions are compatible if they have compatible data types (both columns are numeric, character strings, graphic, date/time, or have the same distinct type).

references-clause
Specifies the parent table or the parent nickname, and the parent key for the referential constraint.

REFERENCES *table-name* or *nickname*
The table or nickname that is specified in a REFERENCES clause must identify a base table or nickname that is described in the catalog, but must not identify a catalog table.

A referential constraint is a duplicate if its foreign key, parent key, and parent table or parent nickname are the same as the foreign key, parent key, and parent table or parent nickname of a previously specified referential constraint. Duplicate referential constraints are ignored, and a warning is returned (SQLSTATE 01543).

In the following discussion, let T2 denote the identified parent table, and let T1 denote the table that is being created (or altered). (T1 and T2 can be the same table).

The specified foreign key must have the same number of columns as the parent key of T2 and the description of the *n*th column of the foreign key must be comparable to the description of the *n*th column of that parent key. Datetime columns are not considered to be comparable to string columns for the purposes of this rule.

(*column-name*,...)
The parent key of a referential constraint is composed of the identified columns. Each *column-name* must be an unqualified name that identifies a column of T2. The same column must not be identified more than once.

The list of column names must match the set of columns (in any order) of the primary key or a unique constraint that exists on T2 (SQLSTATE 42890). If a column name list is not specified, then T2 must have a primary key (SQLSTATE 42888). Omission of the column

name list is an implicit specification of the columns of that primary key in the sequence originally specified.

The referential constraint that is specified by a FOREIGN KEY clause defines a relationship in which T2 is the parent and T1 is the dependent.

rule-clause

Specifies what action to take on dependent tables.

ON DELETE

Specifies what action is to take place on the dependent tables when a row of the parent table is deleted. There are four possible actions:

- NO ACTION (default)
- RESTRICT
- CASCADE
- SET NULL

The delete rule applies when a row of T2 is the object of a DELETE or propagated delete operation and that row has dependents in T1. Let *p* denote such a row of T2.

- If RESTRICT or NO ACTION is specified, an error occurs and no rows are deleted.
- If CASCADE is specified, the delete operation is propagated to the dependents of *p* in T1.
- If SET NULL is specified, each nullable column of the foreign key of each dependent of *p* in T1 is set to null.

SET NULL must not be specified unless some column of the foreign key allows null values. Omission of the clause is an implicit specification of ON DELETE NO ACTION.

If T1 is delete-connected to T2 through multiple paths, defining two SET NULL rules with overlapping foreign key definitions is not allowed. For example: T1 (i1, i2, i3). Rule1 with foreign key (i1, i2) and Rule2 with foreign key (i2, i3) is not allowed.

The firing order of the rules is:

1. RESTRICT
2. SET NULL OR CASCADE
3. NO ACTION

If any row in T1 is affected by two different rules, error occurs and no rows are deleted.

A referential constraint cannot be defined if it would cause a table to be delete-connected to itself by a cycle involving two or more tables, and where one of the delete rules is RESTRICT or SET NULL (SQLSTATE 42915).

A referential constraint that would cause a table to be delete-connected to either itself or another table by multiple paths can be defined, except in the following cases (SQLSTATE 42915):

- A table must not be both a dependent table in a CASCADE relationship (self-referencing, or referencing another table), and have a self-referencing relationship in which the delete rule is RESTRICT or SET NULL.
- A key overlaps another key when at least one column in one key is the same as a column in the other key. When a table is delete-connected to another table through multiple relationships with overlapping foreign keys, those relationships must have the same delete rule, and none of the delete rules can be SET NULL.
- When a table is delete-connected to another table through multiple relationships, and at least one of those relationships is specified with a delete rule of SET NULL, the foreign key definitions of these relationships must not contain any distribution key or multidimensional clustering (MDC) key column.

- When two tables are delete-connected to the same table through CASCADE relationships, the two tables must not be delete-connected to each other if the delete rule of the last relationship in each delete-connected path is RESTRICT or SET NULL.

If any row in T1 is affected by different delete rules, the result would be the effect of all the actions that are specified by these rules. AFTER triggers and CHECK constraints on T1 will also see the effect of all the actions. An example of this is a row that is targeted to be set null through one delete-connected path to an ancestor table, and targeted to be deleted by a second delete-connected path to the same ancestor table. The result would be the deletion of the row. AFTER DELETE triggers on this descendant table would be activated, but AFTER UPDATE triggers would not.

In applying the previously mentioned rules to referential constraints, in which either the parent table or the dependent table is a member of a typed table hierarchy, all the referential constraints that apply to any table in the respective hierarchies are considered.

ON UPDATE
Specifies what action is to take place on the dependent tables when a row of the parent table is updated. The clause is optional. ON UPDATE NO ACTION is the default and ON UPDATE RESTRICT is the only alternative.

The difference between NO ACTION and RESTRICT is described in the "Notes" section.

check-constraint
Defines a check constraint. A *check-constraint* is a *search-condition* that must evaluate to not false or a functional dependency that is defined between columns.

CONSTRAINT *constraint-name*
Names the check constraint.

CHECK (*check-condition*)
Defines a check constraint. The *search-condition* must be true or unknown for every row of the table.

search-condition
The *search-condition* has the following restrictions:

- A column reference must be to a column of the table that is being created.
- The *search-condition* cannot contain a TYPE predicate.
- The *search-condition* cannot contain any of the following (SQLSTATE 42621):
  - Subqueries
  - XMLQUERY or XMLEXISTS expressions
  - Dereference operations or DEREF functions where the scoped reference argument is other than the object identifier (OID) column
  - CAST specifications with a SCOPE clause
  - Column functions
  - Functions that are not deterministic
  - Functions that are defined to have an external action
  - User-defined functions that are defined with either MODIFIES SQL or READS SQL DATA
  - Host variables
  - Parameter markers
  - *sequence-references*
  - OLAP specifications
  - Special registers and built-in functions that depend on the value of a special register
  - Global variables
  - References to generated columns other than the identity column

- References to columns of type XML (except in a VALIDATED predicate)
- An error tolerant *nested-table-expression*

functional-dependency
Defines a functional dependency between columns.

***column-name* DETERMINED BY *column-name* or (*column-name*,...) DETERMINED BY (*column-name*,...)**
The parent set of columns contains the identified columns that immediately precede the DETERMINED BY clause. The child set of columns contains the identified columns that immediately follow the DETERMINED BY clause. All of the restrictions on the *search-condition* apply to parent set and child set columns, and only simple column references are allowed in the set of columns (SQLSTATE 42621). The same column must not be identified more than once in the functional dependency (SQLSTATE 42709). The data type of the column must not be a LOB data type, a distinct type based on a LOB data type, an XML data type, or a structured type (SQLSTATE 42962). A ROW CHANGE TIMESTAMP column cannot be used as part of a primary key (SQLSTATE 429BV). No column in the child set of columns can be a nullable column (SQLSTATE 42621).

If a check constraint is specified as part of a *column-definition*, a column reference can only be made to the same column. Check constraints that are specified as part of a table definition can have column references identifying columns that are previously defined in the CREATE TABLE statement. Check constraints are not checked for inconsistencies, duplicate conditions, or equivalent conditions. Therefore, contradictory or redundant check constraints can be defined, resulting in possible errors at execution time.

The *search-condition* "IS NOT NULL" can be specified; however, it is recommended that nullability is enforced directly, by using the NOT NULL attribute of a column. For example, `CHECK (salary + bonus > 30000)` is accepted if salary is set to NULL, because CHECK constraints must be either satisfied or unknown, and in this case, salary is unknown. However, `CHECK (salary IS NOT NULL)` would be considered false and a violation of the constraint if salary is set to NULL.

Check constraints with *search-condition* are enforced when rows in the table are inserted or updated. A check constraint that is defined on a table automatically applies to all subtables of that table.

A functional dependency is not enforced by the database manager during normal operations such as insert, update, delete, or set integrity. The functional dependency might be used during query rewrite to optimize queries. Incorrect results might be returned if the integrity of a functional dependency is not maintained.

constraint-attributes
Defines attributes that are associated with primary key, unique, referential integrity, or check constraints.

ENFORCED or NOT ENFORCED
Specifies whether the constraint is enforced by the database manager during normal operations such as insert, update, or delete. The default is determined by the setting of the **ddl_constraint_def** configuration parameter. You can override the default behavior by specifying either ENFORCED or NOT ENFORCED explicitly.

ENFORCED
The constraint is enforced by the database manager. ENFORCED cannot be specified in the following situations:

- For a functional dependency (SQLSTATE 42621)
- When a referential constraint refers to a nickname (SQLSTATE 428G7)

NOT ENFORCED
The constraint is not enforced by the database manager. A primary key constraint or unique constraint cannot be NOT ENFORCED if a dependent ENFORCED referential constraint exists.

TRUSTED
The data can be trusted to conform to the constraint. TRUSTED must be used only if the data in the table is independently known to conform to the constraint. Query results might be unpredictable if the data does not conform to the constraint. This is the default option.

Informational constraints must not be violated at any time. Informational constraints are used in query optimization, as well as the incremental processing of REFRESH IMMEDIATE MQT and staging tables. These processes might produce unpredictable results or incorrect MQT and staging table content if the constraints are violated. For example, the order in which parent-child tables are maintained is important. When you want to add rows to a parent-child table, you must insert rows into the parent table first. To remove rows from a parent-child table, you must delete rows from the child table first. This ensures that no orphan rows exist in the child table at any time. If informational constraints are violated, the incremental maintenance of dependent MQT data and staging table data might be optimized based on the violated informational constraints, producing incorrect data.

NOT TRUSTED
The data cannot be trusted to conform to the constraint. NOT TRUSTED is intended for cases where the data conforms to the constraint for most rows, but it is not independently known that all the rows or future additions will conform to the constraint. If a constraint is NOT TRUSTED and enabled for query optimization, then it will not be used to perform optimizations that depend on the data conforming completely to the constraint. NOT TRUSTED can be specified only for referential integrity constraints (SQLSTATE 42613).

ENABLE QUERY OPTIMIZATION or DISABLE QUERY OPTIMIZATION
Specifies whether the constraint or functional dependency can be used for query optimization under appropriate circumstances. The default is ENABLE QUERY OPTIMIZATION.

ENABLE QUERY OPTIMIZATION
The constraint is assumed to be true and can be used for query optimization.

DISABLE QUERY OPTIMIZATION
The constraint cannot be used for query optimization. DISABLE QUERY OPTIMIZATION cannot be specified for primary key and unique constraints (SQLSTATE 42613).

OF *type-name1*
Specifies that the columns of the table are based on the attributes of the structured type that is identified by *type-name1*. If *type-name1* is specified without a schema name, the type name is resolved by searching the schemas on the SQL path (defined by the FUNCPATH preprocessing option for static SQL and by the CURRENT PATH register for dynamic SQL). The type name must be the name of an existing user-defined type (SQLSTATE 42704) and it must be an instantiable structured type (SQLSTATE 428DP) with at least one attribute (SQLSTATE 42997).

If UNDER is not specified, an object identifier column must be specified (refer to the *OID-column-definition*). This object identifier column is the first column of the table. The object ID column is followed by columns based on the attributes of *type-name1*.

HIERARCHY *hierarchy-name*
Names the hierarchy table that is associated with the table hierarchy. It is created at the same time as the root table of the hierarchy. The data for all subtables in the typed table hierarchy is stored in the hierarchy table. A hierarchy table cannot be directly referenced in SQL statements. A *hierarchy-name* is a *table-name*. The *hierarchy-name*, including the implicit or explicit schema name, must not identify a table, nickname, view, or alias described in the catalog. If the schema name is specified, it must be the same as the schema name of the table that is being created (SQLSTATE 428DQ). If this clause is omitted when defining the root table, a name is generated by the system. This name consists of the name of the table that is being created, followed by a unique suffix, such that the identifier is unique among the identifiers of existing tables, views, and nicknames.

UNDER *supertable-name*
Indicates that the table is a subtable of *supertable-name*. The supertable must be an existing table (SQLSTATE 42704) and the table must be defined by using a structured type that is the immediate supertype of *type-name1* (SQLSTATE 428DB). The schema name of *table-name* and *supertable-name*

must be the same (SQLSTATE 428DQ). The table that is identified by *supertable-name* must not have any existing subtable already defined that uses *type-name1* (SQLSTATE 42742).

The columns of the table include the object identifier column of the supertable with its type modified to be REF(*type-name1*), followed by columns based on the attributes of *type-name1* (remember that the type includes the attributes of its supertype). The attribute names cannot be the same as the OID column name (SQLSTATE 42711).

Other table options, including table space, data capture, not logged initially, and distribution key options cannot be specified. These options are inherited from the supertable (SQLSTATE 42613).

INHERIT SELECT PRIVILEGES
Any user or group holding a SELECT privilege on the supertable is granted an equivalent privilege on the newly created subtable. The subtable definer is considered to be the grantor of this privilege.

typed-element-list
Defines the additional elements of a typed table. This includes the additional options for the columns, the addition of an object identifier column (root table only), and constraints on the table.

OID-column-definition
Defines the object identifier column for the typed table.

REF IS *OID-column-name* USER GENERATED
Specifies that an object identifier (OID) column is defined in the table as the first column. An OID is required for the root table of a table hierarchy (SQLSTATE 428DX). The table must be a typed table (the OF clause must be present) that is not a subtable (SQLSTATE 42613). The name for the column is defined as *OID-column-name* and cannot be the same as the name of any attribute of the structured type *type-name1* (SQLSTATE 42711). The column is defined with type REF(*type-name1*), NOT NULL, and a system required unique index (with a default index name) is generated. This column is referred to as the *object identifier column* or *OID column*. The keywords USER GENERATED indicate that the initial value for the OID column must be provided by the user when inserting a row. Once a row is inserted, the OID column cannot be updated (SQLSTATE 42808).

with-options
Defines additional options that apply to columns of a typed table.

column-name
Specifies the name of the column for which additional options are specified. The *column-name* must correspond to the name of a column of the table that is not also a column of a supertable (SQLSTATE 428DJ). A column name can only appear in one WITH OPTIONS clause in the statement (SQLSTATE 42613).

If an option is already specified as part of the type definition (in CREATE TYPE), the options specified here override the options in CREATE TYPE.

WITH OPTIONS *column-options*
Defines options for the specified column. See *column-options* described earlier. If the table is a subtable, primary key or unique constraints cannot be specified (SQLSTATE 429B3).

LIKE *table-name1* or *view-name* or *nickname*
Specifies that the columns of the table have the same name and description as the columns of the specified table (*table-name1*), view (*view-name*), or nickname (*nickname*). The specified table, view, or nickname must either exist in the catalog or must be a declared temporary table. A typed table or typed view cannot be specified (SQLSTATE 428EC).

The use of LIKE is an implicit definition of *n* columns, where *n* is the number of columns in the identified table (including implicitly hidden columns), view, or nickname. A column of the new table that corresponds to an implicitly hidden column in the existing table will also be defined as implicitly hidden. The implicit definition depends on what is specified after LIKE:

- If a table is specified, then the implicit definition includes the column name, data type, hidden attribute, and nullability characteristic of each of the columns of that table. If EXCLUDING COLUMN DEFAULTS is not specified, then the column default is also included.

- If a view is specified, then the implicit definition includes the column name, data type, and nullability characteristic of each of the result columns of the fullselect defined in that view. The data types of the view columns must be data types that are valid for columns of a table.
- If a nickname is specified, then the implicit definition includes the column name, data type, and nullability characteristic of each column of that nickname.
- If a protected table is specified, the new table inherits the same security policy and protected columns as the identified table.
- If a table is specified and if that table contains a row-begin column, row-end column, or transaction-start-ID column, the corresponding column of the new table inherits only the data type of the source column. The new column is not considered a generated column.
- If a table that includes a period is specified, the new table does not inherit the period definition.
- If a system-period temporal table is specified, the new table is not a system-period temporal table.
- If a random distribution table that uses the **random by generation** method is specified, and if the new table that is being created does not share the same table distribution, the **RANDOM_DISTRIBUTION_KEY** column that is used to generate the random distribution values is not included.

Column default and identity column attributes can be included or excluded, based on the copy-attributes clauses. The implicit definition does not include any other attributes of the identified table, view, or nickname. Consequently, the new table does not have any primary key, unique constraints, foreign key constraints, referential integrity constraints, triggers, indexes, ORGANIZE BY specification, or PARTITIONING KEY specification. The table is created in the table space implicitly or explicitly specified by the IN clause, and the table has any other optional clause only if the optional clause is specified.

When a table is identified in the LIKE clause and that table contains a ROW CHANGE TIMESTAMP column, the corresponding column of the new table inherits only the data type of the ROW CHANGE TIMESTAMP column. The new column is not considered to be a generated column.

If a table is specified, and if row or column level access control is activated for that table, it is not inherited by the new table.

copy-options

These options specify whether to copy additional attributes of the source result table definition (table, view, or fullselect).

INCLUDING COLUMN DEFAULTS

Column defaults for each updatable column of the source result table definition are copied. Columns that are not updatable will not have a default defined in the corresponding column of the created table.

If LIKE *table-name* is specified and *table-name* identifies a base table, created temporary table, or declared temporary table, then INCLUDING COLUMN DEFAULTS is the default. If LIKE *table-name* is specified and *table-name* identifies a nickname, then INCLUDING COLUMN DEFAULTS has no effect and column defaults are not copied.

EXCLUDING COLUMN DEFAULTS

Columns defaults are not copied from the source result table definition.

This clause is the default, except when LIKE *table-name* is specified and *table-name* identifies a base table, created temporary table, or declared temporary table.

INCLUDING IDENTITY COLUMN ATTRIBUTES

Identity column attributes are copied from the source result table definition, if possible. It is possible to copy the identity column attributes, if the element of the corresponding column in the table, view, or fullselect is the name of a table column, or the name of a view column that directly or indirectly maps to the name of a base table column with the identity property. In all other cases, the columns of the new table will not get the identity property. For example:

- The select list of the fullselect includes multiple instances of the name of an identity column (that is, selecting the same column more than once).

- The select list of the fullselect includes multiple identity columns (that is, it involves a join).
- The identity column is included in an expression in the select list
- The fullselect includes a set operation (union, except, or intersect).

EXCLUDING IDENTITY COLUMN ATTRIBUTES
Identity column attributes are not copied from the source result table definition.

as-result-table

column-name
Names the columns in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the *fullselect*. Each *column-name* must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the result table of the *fullselect*.

A list of column names must be specified if the result table of the fullselect has duplicate column names of an unnamed column (SQLSTATE 42908). An unnamed column is a column that is derived from a constant, function, expression, or set operation that is not named using the AS clause of the select list.

AS (*fullselect*)
Specifies that, for each column in the derived result table of the *fullselect*, a corresponding column is to be defined for the table. Each defined column adopts the following attributes from its corresponding column of the result table (if applicable to the data type):

- Column name
- Column description
- Data type, length, precision, and scale
- Nullability

The following attributes are not included (although the default value and identity attributes can be included by using the *copy-options*):

- Default value
- Identity attributes
- Hidden attribute
- ROW CHANGE TIMESTAMP
- Any other optional attributes of the tables or views that are referenced in the fullselect

The following restrictions apply:

- Every select list element must have a unique name (SQLSTATE 42711). The AS clause can be used in the select clause to provide unique names.
- The *fullselect* cannot refer to host variables or include parameter markers.
- The data types of the result columns of the *fullselect* must be data types that are valid for columns of a table.
- If row or column level access control (RCAC) is activated for any table that is specified in the *fullselect*, RCAC is not cascaded to the new table.
- The *fullselect* cannot include a *data-change-table-reference* clause (SQLSTATE 428FL).
- Any valid *fullselect* that does not reference a typed table or a typed view can be specified.

WITH NO DATA | WITH DATA
Determines whether to fill the columns of the table with data:

WITH NO DATA
Do not run the *fullselect*. It is used only to define the table, which is not populated with the results of the query.

WITH DATA
Run the *fullselect* and populate the table with the results of the query.

materialized-query-definition

column-name
Names the columns in the table. If a list of column names is specified, it must consist of as many names as there are columns in the result table of the fullselect. Each *column-name* must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the result table of the fullselect.

A list of column names must be specified if the result table of the *fullselect* has duplicate column names of an unnamed column (SQLSTATE 42908). An unnamed column is a column that is derived from a constant, function, expression, or set operation that is not named using the AS clause of the select list.

If MAINTAINED BY REPLICATION is specified, the column names in the column list must match the names of the columns from the table that is specified in the *fullselect*.

AS
Introduces the query that is used for the definition of the table and that determines the data to be included in the table.

fullselect
Defines the query on which the table is based. The resulting column definitions are the same as those for a view that is defined with the same query. A column of the new table that corresponds to an implicitly hidden column of a base table that is referenced in the fullselect is not considered hidden in the new table.

Every select list element must have a name (use the AS clause for expressions). The *materialized-query-definition* defines attributes of the materialized query table. The option that is chosen also defines the contents of the fullselect as follows:

The fullselect cannot include a *data-change-table-reference* clause (SQLSTATE 428FL), the fetch-clause, or the ORDER BY clause (SQLSTATE 428FJ).

When REFRESH DEFERRED or REFRESH IMMEDIATE is specified, the fullselect cannot include (SQLSTATE 428EC):

- References to a materialized query table, created temporary table, declared temporary table, or typed table in any FROM clause
- References to a view where the fullselect of the view violates any of the listed restrictions on the fullselect of the materialized query table
- Expressions that are a reference type (or distinct type based on this type)
- Functions that have any of the following attributes:
  - EXTERNAL ACTION
  - LANGUAGE SQL
  - CONTAINS SQL
  - READS SQL DATA
  - MODIFIES SQL DATA
- NOT SECURED functions if the functions reference a materialized query table, which then references a table that has row or column access control activated.
- Functions that depend on physical characteristics (for example, DBPARTITIONNUM, HASHEDVALUE, RID_BIT, RID)
- A ROW CHANGE expression or reference to a ROW CHANGE TIMESTAMP column of the row
- Table or view references to system objects (Explain tables also should not be specified)
- Expressions that are a structured type, LOB type (or a distinct type based on a LOB type), or XML type
- References to a protected table or protected nickname

When DISTRIBUTE BY REPLICATION is specified, the following restrictions apply:

- The GROUP BY clause is not allowed.
- The materialized query table must only reference a single table; that is, it cannot include a join.

When MAINTAINED BY REPLICATION is specified, the following restrictions apply:

- The query must be a subselect consisting of only a SELECT clause and a FROM clause.
- The FROM clause must reference a single table that is organized by row and that is not specified in an existing shadow table definition.
- The referenced table cannot be a range-partitioned table, a multidimensional clustering table, a range-clustered table, a temporal table, or a table that contains a LONG VARCHAR or LONG VARGRAPHIC column.
- The referenced table cannot be protected by row and column access control (RCAC) or label-based access control (LBAC).
- The select list can include only direct references to the columns of the table whose data types are supported in a column-organized table. No expressions can be used.
- The columns that are specified in the select list cannot be renamed by using the column name list or the AS clause in the select list.
- The referenced table must have at least one enforced primary key constraint or unique constraint, and the columns that are specified in the select list must include all the key columns from at least one of these constraints.

When REFRESH IMMEDIATE is specified:

- The query must be a subselect, with the exception that UNION ALL is supported in the input table expression of a GROUP BY.
- The query cannot be recursive.
- The query cannot include:
  - References to a nickname
  - Functions that are not deterministic
  - Scalar fullselects
  - Predicates with fullselects
  - Special registers and built-in functions that depend on the value of a special register
  - Global variables
  - SELECT DISTINCT
  - An error tolerant *nested-table-expression*
- If the FROM clause references more than one table or view, it can only define an inner join without using the explicit INNER JOIN syntax.
- When a GROUP BY clause is specified, the following considerations apply:
  - The supported column functions are SUM, COUNT, COUNT_BIG, and GROUPING (without DISTINCT). The select list must contain a COUNT(*) or COUNT_BIG(*) column. If the materialized query table select list contains SUM(X), where X is a nullable argument, the materialized query table must also have COUNT(X) in its select list. These column functions cannot be part of any expressions.
  - A HAVING clause is not allowed.
  - If in a multiple partition database partition group, the distribution key must be a subset of the GROUP BY items.
- The materialized query table must not contain duplicate rows, and the following restrictions specific to this uniqueness requirement apply, depending upon whether a GROUP BY clause is specified.
  - When a GROUP BY clause is specified, the following uniqueness-related restrictions apply:
    - All GROUP BY items must be included in the select list.

- When the GROUP BY contains GROUPING SETS, CUBE, or ROLLUP, the GROUP BY items and associated GROUPING column functions in the select list must form a unique key of the result set. Thus, the following restrictions must be satisfied:
  - No grouping sets can be repeated. For example, `ROLLUP(X,Y),X` is not allowed, because it is equivalent to `GROUPING SETS((X,Y),(X),(X))`.
  - If X is a nullable GROUP BY item that appears within GROUPING SETS, CUBE, or ROLLUP, then GROUPING(X) must appear in the select list.

– When a GROUP BY clause is not specified, the following uniqueness-related restrictions apply:
  - The materialized query table's uniqueness requirement is achieved by deriving a unique key for the materialized view from one of the unique key constraints defined in each of the underlying tables. Therefore, the underlying tables must have at least one unique key constraint that is defined on them, and the columns of these keys must appear in the select list of the materialized query table definition.

When REFRESH DEFERRED is specified:

- If the materialized query table is created with the intention of providing it with an associated staging table in a later statement, the fullselect of the materialized query table must follow the same restrictions and rules as a fullselect used to create a materialized query table with the REFRESH IMMEDIATE option.
- If the query is recursive, the materialized query table is not used to optimize the processing of queries.
- The materialized query table is not used to optimize the processing of static queries.

A materialized query table whose fullselect contains a GROUP BY clause is summarizing data from the tables that are referenced in the fullselect. Such a materialized query table is also known as a *summary table*. A summary table is a specialized type of materialized query table.

If the *fullselect* references a table or a view that depends on a table for which row or column level access control has been activated, those row or column level access controls are ignored when populating the materialized query table. The materialized query table is automatically created with row level access control activated. Direct access by users to this table does not see any content unless appropriate permissions are created or a user with SECADM authority chooses to deactivate row level access control on this materialized query table. Row and column level access control on the materialized query table does not affect internal routing by the SQL compiler to the materialized query table.

refreshable-table-options

Define the refreshable options of the materialized query table attributes.

DATA INITIALLY DEFERRED

Data is not inserted into the table as part of the CREATE TABLE statement. A REFRESH TABLE statement specifying the *table-name* is used to insert data into the table.

REFRESH

Indicates how the data in the table is maintained.

DEFERRED

The data in the table can be refreshed at any time by using the REFRESH TABLE statement. The data in the table only reflects the result of the query as a snapshot at the time the REFRESH TABLE statement is processed. System-maintained materialized query tables that are defined with this attribute do not allow INSERT, UPDATE, or DELETE statements (SQLSTATE 42807). User-maintained materialized query tables that are defined with this attribute do allow INSERT, UPDATE, or DELETE statements.

IMMEDIATE

The changes that are made to the underlying tables as part of a DELETE, INSERT, or UPDATE are cascaded to the materialized query table. In this case, the content of the table, at any point-in-time, is the same as if the specified *subselect* is processed.

Materialized query tables (MQTs) defined with this attribute do not allow INSERT, UPDATE, or DELETE statements (SQLSTATE 42807). Column-organized MQTs using the REFRESH IMMEDIATE option are not supported when the MAINTAINED BY SYSTEM clause is specified (SQL20058N).

ENABLE QUERY OPTIMIZATION
The materialized query table can be used for query optimization under appropriate circumstances.

DISABLE QUERY OPTIMIZATION
The materialized query table will not be used for query optimization. The table can still be queried directly.

MAINTAINED BY
Specifies whether the data in the materialized query table is maintained by the system, user, or replication tool. The default is SYSTEM.

SYSTEM
Specifies that the data in the materialized query table is maintained by the system. A system-maintained materialized query table that is defined as ORGANIZE BY COLUMN must use the REFRESH DEFERRED and DISTRIBUTE BY REPLICATION options.

USER
Specifies that the data in the materialized query table is maintained by the user. The user is allowed to perform update, delete, or insert operations against user-maintained materialized query tables. The REFRESH TABLE statement, which is used for system-maintained materialized query tables, cannot be invoked against user-maintained materialized query tables. Only a REFRESH DEFERRED materialized query table can be defined as MAINTAINED BY USER.

REPLICATION
Specifies that the data in the materialized query table is maintained by an external replication technology. MAINTAINED BY REPLICATION cannot be specified in a partitioned database environment or in a Db2 pureScale environment (SQLSTATE 56038). The REFRESH TABLE statement, which is used for system-maintained materialized query tables, cannot be issued against replication-maintained materialized query tables, which are referred to as *shadow tables*. Only a REFRESH DEFERRED materialized query table can be defined as MAINTAINED BY REPLICATION, and the definition must include ORGANIZE BY COLUMN.

FEDERATED_TOOL
Specifies that the data in the materialized query table is maintained by a federated replication tool. The REFRESH TABLE statement, which is used for system-maintained materialized query tables, cannot be invoked against federated_tool-maintained materialized query tables. Only a REFRESH DEFERRED materialized query table can be defined as MAINTAINED BY FEDERATED_TOOL.

When specifying this option, the select clause in the CREATE TABLE statement cannot contain a reference to a base table (SQLSTATE 428EC).

staging-table-definition
Defines the query that is supported by the staging table indirectly through an associated materialized query table. The underlying tables of the materialized query table are also the underlying tables for its associated staging table. The staging table collects changes that need to be applied to the materialized query table to synchronize it with the contents of the underlying tables.

If the *fullselect* references a table or a view that depends on a table for which row or column level access control has been activated, those row or column level access controls are ignored when populating the staging table. However, the staging table is automatically created with row level access control activated. Direct access by users to this staging table does not see any content unless appropriate permissions are created or a user with SECADM authority chooses to deactivate row level access control on this staging table. Row and column level access control on the staging table does not affect the internal process of applying the changes that are captured by the staging table to the associated materialized query table.

staging-column-name
Names the columns in the staging table. If a list of column names is specified, it must consist of *two* more names than exist columns in the materialized query table for which the staging table is defined. If the materialized query table is a replicated materialized query table, or the query defining the materialized query table does not contain a GROUP BY clause, the list of column names must consist of *three* more names than there are columns in the materialized query table for which the staging table is defined. Each column name must be unique and unqualified. If a list of column names is not specified, the columns of the table inherit the names of the columns of the associated materialized query table. The additional columns are named GLOBALTRANSID and GLOBALTRANSTIME, and if a third column is necessary, it is named OPERATIONTYPE.

Table 138. Extra Columns Appended in Staging Tables

Column Name	Data Type	Column Description
GLOBALTRANSID	CHAR(8) FOR BIT DATA	The global transaction ID for each propagated row
GLOBALTRANSTIME	CHAR(13) FOR BIT DATA	The time stamp of the transaction
OPERATIONTYPE	INTEGER	Operation for the propagated row, either insert, update, or delete.

A list of column names must be specified if any of the columns of the associated materialized query table duplicate any of the generated column names (SQLSTATE 42711).

FOR *table-name2*
Specifies the materialized query table that is used for the definition of the staging table. The name, including the implicit or explicit schema, must identify a materialized query table that exists at the current server defined with REFRESH DEFERRED. The fullselect of the associated materialized query table must follow the same restrictions and rules as a fullselect used to create a materialized query table with the REFRESH IMMEDIATE option.

The contents of the staging table can be used to refresh the materialized query table, by invoking the REFRESH TABLE statement, if the contents of the staging table are consistent with the associated materialized query table and the underlying source tables.

PROPAGATE IMMEDIATE
The changes that are made to the underlying tables as part of a delete, insert, or update operation are cascaded to the staging table in the same delete, insert, or update operation. If the staging table is not marked inconsistent, its content, at any point-in-time, is the delta changes to the underlying table since the last refresh materialized query table.

ORGANIZE BY
Specifies how the data is organized in the data pages of the table.

The following restrictions apply to a column-organized MQT:

- MQTs other than shadow tables must reference tables with the same organization as the MQT.
- The ORGANIZE BY COLUMN clause must be specified when creating a column-organized MQT, even if the **dft_table_org** database configuration parameter is set to COLUMN.
- For a column-organized MQT, the following types of tables can be used:
  - Shadow tables
  - User-maintained MQTs
  - System-maintained MQTs that are defined with the `REFRESH DEFERRED` and `DISTRIBUTE BY REPLICATION` clauses.

The default organization is determined by the value of the dft_table_org database configuration parameter. If **dft_table_org** is not specified, the default is ROW.

ROW
The data is stored by row in the data pages of the table. A given data page stores the data for one or more rows of the table.

COLUMN
The data is stored by column in the data pages of the table. Each data page stores data for one column of the table.

ROW USING
The data is stored by row in the data pages of the table and is further organized by using a dimensions clause, key sequence, or insert time. If you specify a dimensions clause, key sequence, or insert time, specifying ROW USING is optional unless the default table organization for the database is COLUMN, in which case specifying ROW USING is mandatory.

DIMENSIONS (*column-name*,...)
Specifies a dimension for each column or group of columns used to cluster the table data. A table whose definition specifies this clause is known as a multidimensional clustering (MDC) table. Use parentheses within the dimension list to specify that a group of columns is to be treated as a single dimension. The DIMENSIONS keyword is optional.

A clustering block index is automatically maintained for each specified dimension, and a block index, consisting of all columns used in the clause, is maintained if none of the clustering block indexes include them all. The set of columns that are used in the ORGANIZE BY clause must follow the rules for the CREATE INDEX statement that specifies CLUSTER.

Each column name that is specified in the ORGANIZE BY clause must be defined for the table (SQLSTATE 42703). A dimension cannot occur more than once in the dimension list (SQLSTATE 42709). The dimensions cannot contain a ROW CHANGE TIMESTAMP column, row-begin column, row-end column, transaction-start-ID column (SQLSTATE 429BV), or an XML column (SQLSTATE 42962). If the table uses extended row size, each dimension column with a data type of VARCHAR or VARGRAPHIC cannot have a length attribute that is greater than 24 bytes (SQLSTATE 54010).

Pages of the table are arranged in blocks of equal size, which is the extent size of the table space, and all rows of each block contain the same combination of dimension values.

A table can be both a multidimensional clustering (MDC) table and a partitioned table. Columns in such a table can be used in both the *range-partition-spec* and in the MDC key. Table partitioning is multi-column, not multidimensional.

For a partitioned MDC table created by Db2 Version 9.7 Fix Pack 1 or later releases, the block indexes are partitioned. The partitioned block index placement follows the general partitioned index storage placement rule. All index partitions for a given data partition, including MDC block indexes, share a single index object. By default, the index partitions for each specific data partition reside in the same table space as the data partition. This can be overridden with the partition level INDEX IN clause.

For MDC tables that were created using Db2 V9.7 or earlier, the block indexes are nonpartitioned and remain nonpartitioned if they are rebuilt. MDC tables with partitioned block indexes can co-exist in the same database as MDC tables with nonpartitioned block indexes. To change nonpartitioned block indexes to partitioned block indexes, use an online table move to migrate the MDC table.

KEY SEQUENCE *sequence-key-spec*
Specifies that the table is organized in ascending key sequence with a fixed size based on the specified range of key sequence values. A table that is organized in this way is referred to as a *range-clustered table*. Each possible key value in the defined range has a predetermined location in the physical table. The storage that is required for a range-clustered table must be available when the table is created, and must be sufficient to contain the number of rows in the specified range multiplied by the row size (for details on determining the space requirement, see Row Size Limit and Byte Counts).

column-name
Specifies a column of the table that is included in the unique key that determines the sequence of the range-clustered table. The data type of the column must be SMALLINT, INTEGER, or BIGINT (SQLSTATE 42611), and the columns must be defined as NOT NULL (SQLSTATE 42831). The same column must not be identified more than once in the sequence key. The number of identified columns must not exceed 64 (SQLSTATE 54008).

A unique index entry will automatically be created in the catalog for the columns in the key sequence specified with ascending order for each column. The name of the index will be SQL, followed by a character time stamp (*yymmddhhmmssxxx*), with SYSIBM as the schema name. An actual index object is not created in storage because the table organization is ordered by this key. If a primary key or a unique constraint is defined on the same columns as the range-clustered table sequence key, this same index entry is used for the constraint.

For the key sequence specification, a check constraint exists to reflect the column constraints. If the DISALLOW OVERFLOW clause is specified, the name of the check constraint is RCT, and the check constraint is enforced. If the ALLOW OVERFLOW clause is specified, the name of the check constraint is RCT_OFLOW, and the check constraint is not enforced.

STARTING FROM *constant*
Specifies the constant value at the low end of the range for *column-name*. Values less than the specified constant are only allowed if the ALLOW OVERFLOW option is specified. If *column-name* is a SMALLINT or INTEGER column, the constant must be an INTEGER constant. If *column-name* is a BIGINT column, the constant must be an INTEGER or BIGINT constant (SQLSTATE 42821). If a starting constant is not specified, the default value is 1.

ENDING AT *constant*
Specifies the constant value at the high end of the range for *column-name*. Values greater than the specified constant are only allowed if the ALLOW OVERFLOW option is specified. The value of the ending constant must be greater than the starting constant. If *column-name* is a SMALLINT or INTEGER column, the constant must be an INTEGER constant. If *column-name* is a BIGINT column, the constant must be an INTEGER or BIGINT constant (SQLSTATE 42821).

ALLOW OVERFLOW
Specifies that the range-clustered table allows rows with key values that are outside of the defined range of values. When a range-clustered table is created to allow overflows, the rows with key values outside of the range are placed at the end of the defined range without any predetermined order. Operations involving these overflow rows are less efficient than operations on rows having key values within the defined range.

DISALLOW OVERFLOW
Specifies that the range-clustered table does not allow rows with key values that are not within the defined range of values (SQLSTATE 23513). Range-clustered tables that disallow overflows will always maintain all rows in ascending key sequence.

The DISALLOW OVERFLOW clause cannot be specified if the table is a range-clustered materialized query table (SQLSTATE 429BG).

PCTFREE *integer*
Specifies the percentage of each page that is to be left as free space. The first row on each page is added without restriction. When additional rows are added to a page, at least *integer* percent of the page is left as free space. The value of *integer* can range from 0 to 99. A PCTFREE value of -1 in the system catalog (SYSCAT.TABLES) is interpreted as the default value. The default PCTFREE value for a table page is 0.

INSERT TIME
Specifies that rows are clustered in the table relative to the time they are inserted. Rows are inserted at the logical end of the table object instead of searching for available space.

A table that is organized by insert time is known as an insert time clustering (ITC) table. This type of table can use REORG TABLE RECLAIM EXTENTS to reclaim free extents for immediate use by other objects in the table space.

Data is clustered by using an implicitly created virtual dimension. A clustering block index is automatically maintained for this virtual dimension. The virtual dimension cannot be manipulated and it uses no space for each row that exists in the table. Pages of the table are arranged in blocks of equal size, which is the extent size of the table space.

The ORGANIZE BY INSERT TIME clause cannot be specified if the table is a typed table (SQLSTATE 428DH).

DATA CAPTURE
Indicates whether extra information for inter-database data replication is to be written to the log. This clause cannot be specified when creating a subtable (SQLSTATE 428DR).

If the clause is not specified and that table is not a typed table, then the default is determined by the DATA CAPTURE setting of the schema at the time the table is created.

NONE
Indicates that no extra information will be logged.

CHANGES
Indicates that extra information regarding SQL changes to this table will be written to the log. This option is required if this table will be replicated and the Capture program is used to capture changes for this table from the log.

If the table is a typed table that is not a subtable, then this option is not supported (SQLSTATE 428DH).

IN *tablespace-name*,...
Identifies the table spaces in which the table will be created. The table spaces must exist, they must be in the same database partition group, and they must be all regular DMS or all large DMS or all SMS table spaces (SQLSTATE 42838) on which the authorization ID of the statement holds the USE privilege.

A maximum of one IN clause is allowed at the table level. All data table spaces that are used by a table must have the same page size and extent size.

If only one table space is specified, all table parts are stored in this table space. This clause cannot be specified when creating a subtable (SQLSTATE 42613) because the table space is inherited from the root table of the table hierarchy.

If this clause is not specified, the database manager chooses a table space (from the set of existing table spaces in the database) with the smallest sufficient page size and where the row size is within the row size limit of the page size on which the authorization ID of the statement has USE privilege.

If more than one table space qualifies, choose the table space in the following order of preference, depending how the authorization ID of the statement was granted USE privilege on the table space:

1. The authorization ID
2. A role to which the authorization ID is granted
3. A group to which the authorization ID belongs
4. A role to which a group the authorization ID belongs is granted
5. PUBLIC
6. A role to which PUBLIC is granted

If more than one table space still qualifies, the final choice is made by the database manager.

Table space determination can change if:

- Table spaces are dropped or created
- USE privileges are granted or revoked

Partitioned tables can have their data partitions spread across multiple table spaces. When multiple table spaces are specified, all of the table spaces must exist, and they must all be either SMS or regular DMS or large DMS table spaces (SQLSTATE 42838). The authorization ID of the statement must hold the USE privilege on all of the specified table spaces.

The sufficient page size of a table is determined by either the byte count of the row or the number of columns. For more information, see Row Size Limits.

When a table is placed in a large table space:

- The table can be larger than a table in a regular table space. For more information on table and table space limits, see "SQL limits".
- The table can support more than 255 rows per data page, which can improve space usage on data pages.
- Indexes that are defined on the table will require an extra 2 bytes per row entry, compared to indexes defined on a table that resides in a regular table space.

CYCLE or NO CYCLE
Specifies whether the number of data partitions with no explicit table space can exceed the number of specified table spaces.

CYCLE
Specifies that if the number of data partitions with no explicit table space exceeds the number of specified table spaces, the table spaces are assigned to data partitions in a round-robin fashion.

NO CYCLE
Specifies that the number of data partitions with no explicit table space must not exceed the number of specified tables spaces (SQLSTATE 428G1). This option prevents the round-robin assignment of table spaces to data partitions.

tablespace-options
Specifies the table space in which indexes or long column values are to be stored. For details on types of table spaces, see "CREATE TABLESPACE".

INDEX IN *tablespace-name*
Identifies the table space in which any indexes on a nonpartitioned table or nonpartitioned indexes on a partitioned table are to be created. The specified table space must exist; it must be a DMS table space if the table has data in DMS table spaces, or an SMS table space if the partitioned table has data in SMS table spaces; it must be a table space on which the authorization ID of the statement holds the USE privilege; and it must be in the same database partition group as *tablespace-name* (SQLSTATE 42838).

Specifying which table space will contain indexes can be done when a table is created, or in the case of partitioned tables, it can be done by specifying the IN clause of the CREATE INDEX statement for a nonpartitioned index. Checking for the USE privilege on the table space is done at table creation time, not when an index is created later.

For a nonpartitioned index on a partitioned table, storage of the index is as follows:

- The table space by the IN clause of the CREATE INDEX statement
- The table-level table space that is specified for the INDEX IN clause of the CREATE TABLE statement
- If neither of the preceding are specified, the index is stored in the table space of the first attached or visible data partition

For more information about partitioned indexes on partitioned tables, see the description of the partition-element INDEX IN clause.

LONG IN *tablespace-name*
Identifies the table spaces in which the values of any long columns are to be stored. Long columns include those with LOB data types, XML type, distinct types with any of these as source types, or any columns that are defined with user-defined structured types whose

values cannot be stored inline. This option is allowed only if the IN clause identifies a DMS table space.

Note: An automatic storage table space is also a DMS table space.

The specified table space must exist. It can be a regular table space if it is the same table space in which the data is stored; otherwise, it must be a large DMS table space on which the authorization ID of the statement holds the USE privilege. It must also be in the same database partition group as *tablespace-name* (SQLSTATE 42838).

Specifying which table space will contain long, LOB, or XML columns can only be done when a table is created. Checking for the USE privilege is done at table creation time, not when a long or LOB column is added later.

For rules governing the use of the LONG IN clause with partitioned tables, see "Large object behavior in partitioned tables".

distribution-clause

Specifies the database partitioning or the way the data is distributed across multiple database partitions.

DISTRIBUTE BY HASH (*column-name*,...)

Specifies the use of the default hashing function on the specified columns as the distribution method across database partitions. The specified columns are called a *distribution key*.

- Each column name must be an unqualified name that identifies a column of the table (SQLSTATE 42703).
- The same column must not be identified more than once (SQLSTATE 42709).
- A column cannot be used as part of a distribution key if its data type is BLOB, CLOB, DBCLOB, XML, a distinct type based on any of these types, or a structured type (SQLSTATE 42962).
- The distribution key cannot contain a ROW CHANGE TIMESTAMP column (SQLSTATE 429BV).
- A distribution key cannot be specified for a table that is a subtable, because the distribution key is inherited from the root table in the table hierarchy (SQLSTATE 42613).
- A distribution key cannot contain row begin, row end, or transaction start ID columns.
- If a DISTRIBUTE BY HASH clause is not specified, and if the table resides in a multiple partition database partition group with multiple database partitions, a default distribution key is automatically defined.
- The columns of the distribution key must be a subset of the columns that make up any enforced unique constraints.

If none of the columns satisfy the requirements for a default distribution key, the table is created without one. Such tables are allowed only in table spaces that are defined on single-partition database partition groups.

For tables in table spaces that are defined on single-partition database partition groups, any collection of columns with data types that are valid for a distribution key can be used to define the distribution key. If you do not specify this clause, no distribution key is created.

For restrictions related to the distribution key, see Rules.

DISTRIBUTE BY RANDOM

Specifies that the database manager will select a distribution key to spread data evenly across all database partitions of the database partitioning group. There are two methods that the database manager uses to achieve this:

- **Random by unique**: If the table includes a unique or primary key, it uses the unique characteristics of the key columns to create a random spread of the data. The columns of the unique or primary key are used as the distribution keys.
- **Random by generation**: If the table does not have a unique or primary key, the database manager will include a column in the table to generate and store a generated value to use in the hashing function. The column will be created with the **IMPLICITLY HIDDEN** clause

so that it does not appear in queries unless explicitly included. The value of the column is automatically generated as new rows are added to the table. By default, the column name is **RANDOM_DISTRIBUTION_KEY**. If it collides with the existing column, a non-conflicting name is generated by the database manager.

DISTRIBUTE BY REPLICATION
Specifies that the data that is stored in the table is physically replicated on each database partition of the database partition group for the table spaces in which the table is defined. This means that a copy of all of the data in the table exists on each database partition. This option can only be specified for a materialized query table (SQLSTATE 42997).

partitioning-clause
Specifies how the data is partitioned within a database partition.

PARTITION BY RANGE *range-partition-spec*
Specifies the table partitioning scheme for the table.

partition-expression
Specifies the key data over which the range is defined to determine the target data partition of the data.

column-name
Identifies a column of the table-partitioning key. The *column-name* must be an unqualified name that identifies a column of the table (SQLSTATE 42703). The same column must not be identified more than once (SQLSTATE 42709). No column with a data type that is a BLOB, CLOB, DBCLOB, XML, distinct type based on any of these types, or structured type can be used as part of a table-partitioning key (SQLSTATE 42962).

The numeric literals that are used in the range specification are governed by the rules for numeric literals. All of the numeric literals (except the decimal floating-point special values) used in ranges corresponding to numeric columns are interpreted as integer, floating-point or decimal constants, in accordance with the rules specified for numeric constants. As a result, for decimal floating-point columns, the minimum and maximum numeric constant value that can be used in the range specification of a data partition is the smallest DOUBLE value and the largest DOUBLE value, respectively. Decimal floating-point special values can be used in the range specification. All decimal floating-point special values are interpreted as greater than MINVALUE and less than MAXVALUE.

The table partitioning columns cannot contain a ROW CHANGE TIMESTAMP column (SQLSTATE 429BV). The number of identified columns must not exceed 16 (SQLSTATE 54008).

NULLS LAST or NULLS FIRST
Indicates the partition placement of rows that have null values in the table partitioning key columns. These clauses do not affect the order of rows that are returned in an ORDER BY clause.

NULLS LAST
Indicates that null values are compared as the highest possible value, and are placed in a range ending at MAXVALUE.

NULLS FIRST
Indicates that null values are compared as the lowest possible value, and are placed in a range starting at MINVALUE.

partition-element
Specifies ranges for a data partitioning key and the table space where rows of the table in the range will be stored.

PARTITION *partition-name*
Names the data partition. The name must not be the same as any other data partition for the table (SQLSTATE 42710). If this clause is not specified, the name will be "PART" followed by the character form of an integer value to make the name unique for the table.

boundary-spec
Specifies the boundaries of a data partition. The lowest data partition must include a starting-clause, and the highest data partition must include an ending-clause (SQLSTATE 56016). Data partitions between the lowest and the highest can include either a starting-clause, ending-clause, or both clauses. If only the ending-clause is specified, the previous data partition must also have included an ending-clause (SQLSTATE 56016).

starting-clause
Specifies the low end of the range for a data partition. There must be at least one starting value specified and no more values than the number of columns in the data partitioning key (SQLSTATE 53038). If fewer values are specified than the number of columns, the remaining values are implicitly MINVALUE.

STARTING FROM
Introduces the *starting-clause*.

constant
Specifies a constant value with a data type that is assignable to the data type of the *column-name* to which it corresponds (SQLSTATE 53045). The value must not be in the range of any other boundary-spec for the table (SQLSTATE 56016).

MINVALUE
Specifies a value that is lower than the lowest possible value for the data type of the *column-name* to which it corresponds.

MAXVALUE
Specifies a value that is greater than the greatest possible value for the data type of the *column-name* to which it corresponds.

INCLUSIVE
Indicates that the specified range values are to be included in the data partition.

EXCLUSIVE
Indicates that the specified *constant* values are to be excluded from the data partition. This specification is ignored when MINVALUE or MAXVALUE is specified.

ending-clause
Specifies the high end of the range for a data partition. There must be at least one starting value specified and no more values than the number of columns in the data partitioning key (SQLSTATE 53038). If fewer values are specified than the number of columns, the remaining values are implicitly MAXVALUE.

ENDING AT
Introduces the *ending-clause*.

constant
Specifies a constant value with a data type that is assignable to the data type of the *column-name* to which it corresponds (SQLSTATE 53045). The value must not be in the range of any other boundary-spec for the table (SQLSTATE 56016).

MINVALUE
Specifies a value that is lower than the lowest possible value for the data type of the *column-name* to which it corresponds.

MAXVALUE
Specifies a value that is greater than the greatest possible value for the data type of the *column-name* to which it corresponds.

INCLUSIVE
Indicates that the specified range values are to be included in the data partition.

EXCLUSIVE
Indicates that the specified *constant* values are to be excluded from the data partition. This specification is ignored when MINVALUE or MAXVALUE is specified.

IN *tablespace-name*
Specifies the table space where the data partition is to be stored. The named table space must have the same page size, be in the same database partition group, and manage space in the same way as the other table spaces of the partitioned table (SQLSTATE 42838); it must be a table space on which the authorization ID of the statement holds the USE privilege. If this clause is not specified, a table space is assigned by default in a round-robin fashion from the list of table spaces that are specified for the table. If a table space was not specified for large objects by using the LONG IN clause, large objects are placed in the same table space as are the rest of the rows for the data partition. For partitioned tables, the LONG IN clause can be used to provide a list of table spaces. This list is used in round robin-fashion to place large objects for each data partition. For rules governing the use of the LONG IN clause with partitioned tables, see "Large object behavior in partitioned tables".

If the INDEX IN clause is not specified on the CREATE TABLE or the CREATE INDEX statement, the index is placed in the same table space as the first visible or attached partition of the table.

INDEX IN *tablespace-name*
Specifies the table space where the partitioned index on the partitioned table is to be stored.

The partition-element level INDEX IN clause only affects the storage of partitioned indexes. Storage of the index is as follows:

- If the INDEX IN clause is specified at the partition level when the table is created, the partitioned index is stored in the specified table space.
- If the INDEX IN clause is not specified at the partition level when the table is created, the partitioned index is stored in the table space of the corresponding data partition.

The INDEX IN clause can only be specified if the data table spaces are DMS table spaces and the table space specified by the INDEX IN clause is a DMS table space. If the data table space is an SMS table space, an error is returned (SQLSTATE 42839).

LONG IN *tablespace-name*
Identifies the table spaces in which the values of any long columns are to be stored. Long columns include those with LOB data types, XML type, distinct types with any of these as source types, or any columns defined with user-defined structured types whose values cannot be stored inline. This option is allowed only if the IN clause identifies a DMS table space.

Note: An automatic storage table space is also a DMS table space.

The specified table space must exist. It can be a regular table space if it is the same table space in which the data is stored; otherwise, it must be a large DMS table space on which the authorization ID of the statement holds the USE privilege. It must also be in the same database partition group as *tablespace-name* (SQLSTATE 42838).

Specifying which table space will contain long, LOB, or XML columns can only be done when a table is created. Checking for the USE privilege is done at table creation time, not when a long or LOB column is added later.

For rules governing the use of the LONG IN clause with partitioned tables, see "Large object behavior in partitioned tables".

EVERY (*constant*)
Specifies the width of each data partition range when using the automatically generated form of the syntax. Data partitions will be created starting at the STARTING FROM value and containing this number of values in the range. This form of the syntax is only supported for tables that are partitioned by a single numeric or datetime column (SQLSTATE 53038).

If the partitioning key column is a numeric type, the starting value of the first partition is the value that is specified in the starting-clause. The ending value for the first and all other partitions is calculated by adding the starting value of the partition to the increment value specified as *constant* in the EVERY clause. The starting value for all other partitions is calculated by taking the starting value for the previous partition and adding the increment value that is specified as *constant* in the EVERY clause.

If the partitioning key column is a DATE or a TIMESTAMP, the starting value of the first partition is the value that is specified in the starting-clause. The ending value for the first and all other partitions is calculated by adding the starting value of the partition to the increment value specified as a labeled duration in the EVERY clause. The starting value for all other partitions is calculated by taking the starting value for the previous partition and adding the increment value that is specified as a labeled duration in the EVERY clause.

For a numeric column, the EVERY value must be a positive numeric constant, and for a datetime column, the EVERY value must be a labeled duration (SQLSTATE 53045).

COMPRESS

Specifies whether row compression is to be used for the table.The **ddl_compression_def** configuration parameter determines the default value of the COMPRESS keyword.

NO

Row compression is disabled.

YES

Row compression is enabled. Insert and update operations on the table use row compression. Any XML storage objects that exist are also compressed. For both adaptive and classic row compression, a table-level compression dictionary is automatically created after the table is sufficiently populated with data. This also applies to the data in the XML storage object; if there is sufficient data in the XML storage object, a compression dictionary is automatically created and XML documents are subject to compression.

Note: The compression that is applied to the XML storage object is the same, regardless of whether you use adaptive or classic row compression.

For adaptive row compression, page-level compression dictionaries are created or updated as soon as data is inserted or changed in the table.

ADAPTIVE

Enables adaptive compression, and records are subject to being compressed with a table-level and a page-level compression dictionary. The functionality of COMPRESS YES ADAPTIVE is a superset of the functionality of COMPRESS YES STATIC. This is the default when COMPRESS YES is explicitly specified.

STATIC

Enables classic row compression using a table-level compression dictionary. This is the same row compression functionality that existed in previous Db2 versions. This is the default when row compression is used by default but COMPRESS YES is not explicitly specified.

VALUE COMPRESSION

This determines the row format that is to be used. Each data type has a different byte count depending on the row format that is used. For more information, see Byte Counts. If the table is a typed table, this option is only supported on the root table of the typed table hierarchy (SQLSTATE 428DR).

The null value is stored using 3 bytes. This is the same or less space than when VALUE COMPRESSION is not active for columns of all data types, except for CHAR(1). Whether a column is defined as nullable has no effect on the row size calculation. The zero-length data values for columns whose data type is VARCHAR, VARGRAPHIC, LONG VARCHAR, LONG VARGRAPHIC, CLOB, DBCLOB, VARBINARY, BLOB, or XML are to be stored using 2 bytes only, which is less than the storage required when VALUE COMPRESSION is not active. When a column is defined using the COMPRESS SYSTEM DEFAULT option, this also allows the system default value for the column to be stored using 3 bytes of total storage. The row format that is used to support this determines the byte counts for each data type,

and tends to cause data fragmentation when updating to or from the null value, a zero-length value, or the system default value.

WITH RESTRICT ON DROP
Indicates that the table cannot be dropped, and that the table space that contains the table cannot be dropped.

NOT LOGGED INITIALLY
Any changes that are made to the table by an Insert, Delete, Update, Create Index, Drop Index, or Alter Table operation in the same unit of work in which the table is created are not logged. For other considerations when using this option, see the "Notes" section of this statement.

All catalog changes and storage-related information are logged, as are all operations that are done on the table in subsequent units of work.

Note: If non-logged activity occurs against a table that has the NOT LOGGED INITIALLY attribute activated, and if a statement fails (causing a rollback), or a ROLLBACK TO SAVEPOINT is executed, the entire unit of work is rolled back (SQL1476N). Furthermore, the table for which the NOT LOGGED INITIALLY attribute was activated is marked inaccessible after the rollback has occurred, and can only be dropped. Therefore, the opportunity for errors within the unit of work in which the NOT LOGGED INITIALLY attribute is activated should be minimized.

CCSID
Specifies the encoding scheme for string data that is stored in the table. If the CCSID clause is not specified, the default is CCSID UNICODE for Unicode databases, and CCSID ASCII for all other databases.

ASCII
Specifies that string data is encoded in the database code page. If the database is a Unicode database, CCSID ASCII cannot be specified (SQLSTATE 56031).

UNICODE
Specifies that string data is encoded in Unicode. Character data is in UTF-8. Graphic data is not allowed.

If the database is not a Unicode database, tables can be created with CCSID UNICODE, but the following rules apply:

- The alternative collating sequence must be specified in the database configuration before creating the table (SQLSTATE 56031). CCSID UNICODE tables collate with the alternative collating sequence that is specified in the database configuration.

  The only supported alternative collating sequence is IDENTITY_16BIT.
- Graphic types, the XML type, and user-defined types cannot be used in CCSID UNICODE tables (SQLSTATE 560C1).
- Anchored data types cannot anchor to columns of a table that is created with CCSID UNICODE (SQLSTATE 428HS).
- Tables cannot have both the CCSID UNICODE clause and the DATA CAPTURE CHANGES clause specified (SQLSTATE 42613).
- The Explain tables cannot be created with CCSID UNICODE (SQLSTATE 55002).
- Created temporary tables and declared temporary tables cannot be created with CCSID UNICODE (SQLSTATE 56031).
- CCSID UNICODE tables cannot be created in a CREATE SCHEMA statement (SQLSTATE 53090).
- The exception table for a load operation must have the same CCSID as the target table for the operation (SQLSTATE 428A5).
- The exception table for a SET INTEGRITY statement must have the same CCSID as the target table for the statement (SQLSTATE 53090).
- The target table for event monitor data must not be declared as CCSID UNICODE (SQLSTATE 55049).

- SQL statements are always interpreted in the database code page. In particular, this means that every character in literals, hex literals, and delimited identifiers must have a representation in the database code page; otherwise, the character will be replaced with the substitution character.

Host variables in the application are always in the application code page, regardless of the CCSID of any tables in the SQL statements that are invoked. The database manager will perform code page conversions as necessary to convert data between the application code page and the section code page. The registry variable DB2CODEPAGE can be set at the client to change the application code page.

SECURITY POLICY
Names the security policy to be associated with the table.

policy-name
Identifies a security policy that already exists at the current server (SQLSTATE 42704).

OPTIONS (*table-option-name string-constant*, ...)
Table options are used to identify the remote base table. The *table-option-name* is the name of the option. The *string-constant* specifies the setting for the table option. The *string-constant* must be enclosed in single quotation marks.

The remote server (the server name that was specified in the CREATE SERVER statement) must be specified in the OPTIONS clause. The OPTIONS clause can also be used to override the schema or the unqualified name of the remote base table that is being created.

It is recommended that a schema name is specified. If a remote schema name is not specified, the qualifier for the table name is used. If the table name has no qualifier, the authorization ID of the statement is used.

If an unqualified name for the remote base table is not specified, *table-name* is used.

Rules

- The sum of the byte counts of the columns, including the inline lengths of all structured or XML type columns, must not be greater than the row size limit that is based on the page size of the table space (SQLSTATE 54010). For more information, see Byte Counts. For typed tables, the byte count is applied to the columns of the root table of the table hierarchy, and every additional column introduced by every subtable in the table hierarchy (extra subtable columns must be considered nullable for byte count purposes, even if defined as not nullable). There is also an additional 4 bytes of overhead to identify the subtable to which each row belongs.
- The number of columns in a table cannot exceed 1,012 (SQLSTATE 54011). For typed tables, the total number of attributes of the types of all of the subtables in the table hierarchy cannot exceed 1010. For random distribution tables using the random by generation method, the number of columns cannot exceed 1,011 because of the inclusion of the **RANDOM_DISTRIBUTION_KEY** column.
- An object identifier column of a typed table cannot be updated (SQLSTATE 42808).
- Any enforced unique or primary key constraint that is defined on the table must be a superset of the distribution key (SQLSTATE 42997).
- The following rules only apply to multiple database partition databases.
  - Tables that are composed only of columns with types LOB, XML, a distinct type based on one of these types, or a structured type can only be created in table spaces that are defined on single-partition database partition groups.
  - The distribution key definition of a table in a table space that is defined on a multiple partition database partition group cannot be altered.
  - The distribution key column of a typed table must be the OID column.
  - Partitioned staging tables are not supported.
- For databases running in a Db2 pureScale environment, the ORGANIZE BY clause cannot be specified (SQLSTATE 42997).

- The following restrictions apply to range-clustered tables:
  - A range-clustered table cannot be specified in a Db2 pureScale environment (SQLSTATE 42997).
  - A clustering index cannot be created.
  - Altering the table to add a column is not supported.
  - Altering the table to change the data type of a column is not supported.
  - Altering the table to change PCTFREE is not supported.
  - Altering the table to set APPEND ON is not supported.
  - DETAILED statistics are not available.
  - The load utility cannot be used to populate the table.
  - Columns cannot be of type XML.
  - Cannot be created as a random distribution table.
- The following restrictions apply to random distribution tables:
  - Cannot be defined as a typed table
  - Cannot be defined as a range-clustered table
  - Cannot be defined as a materialized-query-table
  - Cannot be defined as a staging table
  - For random distribution tables that use the "random by" generation method (this happens when a random distribution table is created without a unique or primary key), the following additional restrictions apply:
    - Cannot be used as exception tables when constraints are checked in bulk, such as during load operations or during execution of the SET INTEGRITY statement
    - Cannot be used as an explain table
- A table is not protected unless it has a security policy associated with it and it includes either a column of type DB2SECURITYLABEL or a column defined with the SECURED WITH clause. The former indicates that the table is a protected table with **row level granularity** and the latter indicates that the table a protected table with **column level granularity**.
- Declaring a column of type DB2SECURITYLABEL fails if the table does not have a security policy associated with it (SQLSTATE 55064).
- A security policy cannot be added to a typed table (SQLSTATE 428DH), materialized query table, or staging table (SQLSTATE 428FG).
- An error tolerant *nested-table-expression* cannot be specified in the fullselect of a *materialized-query-definition* (SQLSTATE 428GG).
- When creating a materialized query table and any of the base tables it depends upon are protected with label-based access control, the following rules apply:
  - Row level security
    - Only one table in the materialized query table's fullselect can have a column type of DB2SECURITYLABEL (SQLSTATE 428FG).
    - The row security label column must be selected and referenced as a stand-alone column in the outermost SELECT list in the materialized query table definition (SQLSTATE 428FG). The corresponding column in the materialized query table will be marked as the row security label column.
  - Column level security
    - If a table involved in the materialized query table definition has a column that is protected with a security label, and that column appears in the materialized query table definition, that column's security label is inherited by the corresponding column in the materialized query table. See the examples in this topic for more details.

  - When creating a materialized query table that depends on one or more tables that are protected by label-based access control, all base tables must have the same security policy object (SQLSTATE, 428FG). The materialized query table is automatically protected with that security policy object.
  - The security label that is associated with a materialized query table column is computed as the aggregate of one or more security labels. This aggregate consists of the security labels that are associated with the base tables' columns that participate in the definition of that materialized query table column. The aggregate also consists of the security labels that are associated with any base table columns that appear in other parts of the materialized query table definition, such as the `WHERE`, `ORDER BY`, and `HAVING` clauses. The **ALTER SECURITY POLICY** has a description of how two security labels are aggregated. See the examples in this topic for more details.
  - When a staging table is created for a materialized query table that is protected with label-based access control, that staging table carries automatic protection like the materialized query table. See the examples in this topic for more details.
  - Label-based access control is enforced for direct access to a materialized query table just as it is enforced for a regular table. There are no differences from this perspective. When the SQL compiler services a query through a materialized query table, the label-based access control defined on the materialized query table itself does not need to be enforced. The SQL compiler uses the materialized query table which factors in the label-based access control rules from the appropriate base tables.
- The *isolation-clause* cannot be specified in the *full-select* of the *materialized-query-definition* (SQLSTATE 42601).
- Subselect statements that contain a *lock-request-clause* are not eligible for MQT routing.
- National character data types can be specified only in an MBCS database (SQLSTATE 560AA).
- The following restrictions apply to insert time clustering (ITC) tables:
  - ITC tables are not supported in an SMS table space (SQLSTATE 42838).
  - Indexes that are defined on ITC tables are not supported in an SMS table space (SQLSTATE 42838).

Notes

- Creating a table with a schema name that does not already exist will result in the implicit creation of that schema provided the authorization ID of the statement has IMPLICIT_SCHEMA authority. The schema owner is SYSIBM. The CREATEIN privilege on the schema is granted to PUBLIC.
- If a foreign key is specified:
  - All packages with a delete usage on the parent table are invalidated.
  - All packages with an update usage on at least one column in the parent key are invalidated.
- Creating a subtable causes invalidation of all packages that depend on any table in table hierarchy.
- VARCHAR and VARGRAPHIC columns that are greater than 4,000 and 2,000 respectively should not be used as input parameters in functions in SYSFUN schema. Errors will occur when the function is invoked with an argument value that exceeds these lengths (SQLSTATE 22001).
- The use of NO ACTION or RESTRICT as delete or update rules for referential constraints determines when the constraint is enforced:

  RESTRICT
  The delete or update rule is enforced *before* all other constraints, including those referential constraints with modifying rules such as CASCADE or SET NULL.

  NO ACTION
  The delete or update rule is enforced *after* other referential constraints.

  One example where different behavior is evident involves the deletion of rows from a view that is defined as a UNION ALL of related tables.

```
Table T1 is a parent of table T3; delete rule as noted below.
Table T2 is a parent of table T3; delete rule CASCADE.

CREATE VIEW V1 AS SELECT * FROM T1 UNION ALL SELECT * FROM T2
```

```
DELETE FROM V1
```

If table T1 is a parent of table T3:

- With a delete rule of RESTRICT, a restrict violation (SQLSTATE 23001) is raised if t3 contains any child rows for parent keys of T1.
- With a delete rule of NO ACTION, the child rows might be deleted by the delete rule of CASCADE when deleting rows from T2 before the NO ACTION delete rule is enforced for the deletions from T1. If deletions from T2 did not result in the deletion of all child rows for parent keys of T1 in T3, then a constraint violation is raised (SQLSTATE 23504).

Note that the SQLSTATE returned is different depending on whether the delete or update rule is RESTRICT or NO ACTION.

- For tables in table spaces that are defined on multiple partition database partition groups, consider table collocation when choosing the distribution keys:
  - The tables must be in the same database partition group for collocation. The table spaces can be different, but must be defined in the same database partition group.
  - The distribution keys of the tables must have the same number of columns, and the corresponding key columns must be database partition-compatible for collocation.
  - The choice of distribution key also has an impact on performance of joins. If a table is frequently joined with another table, consider the joining columns as a distribution key for both tables.
- The NOT LOGGED INITIALLY option is useful for situations where a large result set needs to be created with data from an alternative source (another table or a file) and recovery of the table is not necessary. Using this option will save the overhead of logging the data. The following considerations apply when this option is specified:
  - When the unit of work is committed, all changes that were made to the table during the unit of work are flushed to disk.
  - When you run the rollforward utility and it encounters a log record that indicates that a table in the database was either populated by the Load utility or created with the NOT LOGGED INITIALLY option, the table will be marked as unavailable. The table will be dropped by the rollforward utility if it later encounters a DROP TABLE log. Otherwise, after the database is recovered, an error will be issued if any attempt is made to access the table (SQLSTATE 55019). The only operation that is permitted is to drop the table.
  - Once such a table is backed up as part of a database or table space backup, recovery of the table becomes possible.
- ***Use of materialized query tables to optimize query processing:*** The various types of materialized query tables use different controls to optimize the processing of queries.
  - A REFRESH DEFERRED materialized query table that is defined with ENABLE QUERY OPTIMIZATION can be used to optimize the processing of queries if each of the following conditions is true:
    - CURRENT REFRESH AGE is set to ANY.
    - CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION is set such that it includes the materialized query table type.
    - CURRENT QUERY OPTIMIZATION is set to 2 or a value greater than or equal to 5.

    Note: CURRENT REFRESH AGE does not affect query routing to MAINTAINED BY FEDERATED_TOOL materialized query tables.
  - A shadow table that is defined with ENABLE QUERY OPTIMIZATION can be used to optimize the processing of queries based on a replication latency threshold if each of the following conditions is true:
    - CURRENT REFRESH AGE is set to a duration other than zero or ANY.
    - CURRENT MAINTAINED TABLE TYPES FOR OPTIMIZATION is set to contain only REPLICATION or ALL.

- CURRENT QUERY OPTIMIZATION is set to 2 or a value greater than or equal to 5.

For a description of the nonzero duration values that can be specified, see "SET CURRENT REFRESH AGE statement".

– A REFRESH IMMEDIATE materialized query table that is defined with ENABLE QUERY OPTIMIZATION is always considered for optimization if CURRENT QUERY OPTIMIZATION is set to 2 or a value greater than or equal to 5.

– For this optimization to be able to use a REFRESH DEFERRED materialized query table that is not maintained by replication or a REFRESH IMMEDIATE materialized query table, the fullselect must conform to certain rules in addition to those already described:

- The fullselect must not include any special registers or built-in functions that depend on the value of a special register.
- The fullselect must not include any global variables.
- The fullselect must not include functions that are not deterministic.

If the query that is specified when creating a materialized query table does not conform to these rules, a warning is returned (SQLSTATE 01633).

- If a materialized query table is defined with REFRESH IMMEDIATE, or a staging table is defined with PROPAGATE IMMEDIATE, it is possible for an error to occur when attempting to apply the change resulting from an insert, update, or delete operation on an underlying table. The error will cause the failure of the insert, update, or delete operation on the underlying table.
- Materialized query tables or staging tables cannot be used as exception tables when constraints are checked in bulk, such as during load operations or during execution of the SET INTEGRITY statement.
- Certain operations cannot be performed on a table that is referenced by a materialized query table that is defined with REFRESH IMMEDIATE, or defined with REFRESH DEFERRED with an associated staging table:
  – IMPORT REPLACE cannot be used.
  – ALTER TABLE NOT LOGGED INITIALLY WITH EMPTY TABLE cannot be done.
- In a federated system, nicknames for relational data sources or local tables can be used as the underlying tables to create a materialized query table. Nicknames for non-relational data sources are not supported. When a nickname is one of the underlying tables, the REFRESH DEFERRED option must be used. System-maintained materialized query tables that reference nicknames are not supported in a partitioned database environment.
- ***Considerations for transaction-start-ID columns:*** A transaction-start-ID column contains a null value if the column allows null values, and there is a row-begin column and the value of the column is unique from values for row-begin columns that are generated for other transactions. Because the column might contain null values, it is recommended that you use one of the following methods when retrieving a value from the column:

```
COALESCE ( transaction_start_id_col,  row_begin_col)

CASE WHEN transaction_start_id_col IS NOT NULL
          THEN transaction_start_id_col
     ELSE row_begin_col END
```

- ***Defining a system-period temporal table:*** A system-period temporal table definition includes the following:
  – A system period that is named SYSTEM_TIME, which is defined by using a row-begin column and a row-end column. See the descriptions of AS ROW BEGIN, AS ROW END, and period-definition.
  – A transaction-start-ID column. See the description of AS TRANSACTION START ID.
  – A system-period data versioning definition that is specified on a subsequent ALTER TABLE statement that specifies the ADD VERSIONING action, which includes the name of the associated history table. See the description of the ADD VERSIONING clause under ALTER TABLE.

To ensure that the history table cannot be implicitly dropped when a system-period temporal table is dropped, use the WITH RESTRICT ON DROP clause in the definition of the history table. A history table can manually be dropped only when the RESTRICT ON DROP attribute is removed by an ALTER TABLE statement.

- ***Defining an application-period temporal table:*** An application-period temporal table definition includes an application period named BUSINESS_TIME. The application period is defined using a begin time stamp column and an end column. See the description of period-definition.

  Data change operations on an application-period temporal table might result in an automatic insert of one or two extra rows when a row is updated or deleted. When an update or delete of a row in an application-period temporal table is specified for a portion of the period represented by that row, the row is updated or deleted and one or two rows are automatically inserted to represent the portion of the row that is not changed. New values are generated for each generated column in an application-period temporal table for each row that is automatically inserted as a result of an update or delete operation on the table. If a generated column is defined as part of a unique or primary key, parent key in a referential constraint, or unique index, it is possible that an automatic insert will violate a constraint or index in which case an error is returned.

- ***Considerations for implicitly hidden columns:*** Creating a table with implicitly hidden columns can impact the behavior of data movement utilities that are working with the table. When a table contains implicitly hidden columns, utilities like IMPORT, INGEST, and LOAD require that you specify whether data for the hidden columns is included in the operation. For example, this might mean that a load operation runs successfully against a table without any hidden columns, but fails when run against a table that contains implicitly hidden columns (SQLCODE SQL2437N). Similarly, EXPORT requires that you specify whether data for the hidden columns is included in the operation.

  Data movement utilities must use the DB2_DMU_DEFAULT registry variable, or the **implicitlyhiddeninclude** or **implicitlyhiddenmissing** file type modifiers when working with tables that contain implicitly hidden columns.

- ***Transparent DDL:*** In a federated system, a remote base table can be created, altered, or dropped using Db2 SQL. This capability is known as *transparent DDL*. Before a remote base table can be created on a data source, the federated server must be configured to access that data source. This configuration includes creating the wrapper for the data source, supplying the server definition for the server where the remote base table will be located, and creating the user mappings between the federated server and the data source.

  Transparent DDL does impose some limitations on what can be included in the CREATE TABLE statement:

  – Only columns and a primary key can be created on the remote base table.
  – Specific clauses that are supported by transparent DDL include:
    - *column-definition* and *unique-constraint* in the *element-list* clause
    - NOT NULL and PRIMARY KEY in the *column-options* clause
    - OPTIONS
  – The remote data source must support:
    - The remote column data types to which the database column data types are mapped
    - The primary key option in the CREATE TABLE statement

    Depending on how the data source responds to requests it does not support, an error might be returned or the request might be ignored.

  When a remote base table is created using transparent DDL, a nickname is automatically created for that remote base table.

- A referential constraint can be defined in such a way that either the parent table or the dependent table is a part of a table hierarchy. In such a situation, the effect of the referential constraint depends on the type of statement:

1. For an INSERT, UPDATE, or DELETE statement, the constraint ensures that, for each row of the dependent table (or any of its subtables) that has a non-null foreign key, a row exists in the parent table (or one of its subtables) with a matching parent key. This rule is enforced against any action that affects a row of either table, regardless of how that action is initiated.
2. For a DROP TABLE statement:
   - If the dropped table is the parent table or dependent table, the constraint is dropped.
   - If a supertable of the dropped table is the parent table, the rows of the dropped table are considered to be deleted from the supertable. The referential constraint is checked and its delete rule is invoked for each of the deleted rows.
   - If a supertable of the dropped table is the dependent table, the constraint is not checked. Deletion of a row from a dependent table cannot result in violation of a referential constraint.

- ***Privileges:*** When any table is created, the definer of the table is granted CONTROL privilege. When a subtable is created, the SELECT privilege that each user or group has on the immediate supertable is automatically granted on the subtable with the table definer as the grantor.
- ***Row size limit:*** The maximum number of bytes allowed in the row of a row-organized table is dependent on the page size of the table space in which the table is created (*tablspace-name1*). The following table shows the row size limit and number of columns limit associated with each table space page size.

Table 139. Limits for Number of Columns and Row Size in Each Table Space Page Size (row-organized tables)

Page Size	Row Size Limit	Column Count Limit
4K	4005	500
8K	8101	1012
16K	16,293	1012
32K	32,677	1012

The actual number of columns for a row-organized table can be further limited by the following formula:

```
Total Columns * 8 + Number of LOB Columns * 12 <=
  Row Size Limit for Page Size
```

A column-organized table can have a maximum of 1012 columns, regardless of page size, where the byte counts of the columns must not be greater than 32,677.

- ***Byte counts:*** The following table contains the byte counts of columns by data type. This is used to calculate the row size. The byte counts depend on whether VALUE COMPRESSION is active. When VALUE COMPRESSION is not active, the byte counts also depend on whether the column is nullable. The byte counts shown apply when row compression is not enabled. If row compression is active, the total number of bytes used by a row will generally be smaller than for an uncompressed version of the row; it will never be larger.

  If a table is based on a structured type, an additional 4 bytes of overhead is reserved to identify rows of subtables, regardless of whether subtables are defined. Additional subtable columns must be considered nullable for byte count purposes, even if defined as not nullable.

Table 140. Byte Counts of Columns by Data Type

Data type	VALUE COMPRESSION is active[1]	VALUE COMPRESSION is not active	
		Column is nullable	Column is not nullable
SMALLINT	4	3	2
INTEGER	6	5	4
BIGINT	10	9	8

Table 140. Byte Counts of Columns by Data Type (continued)

Data type	VALUE COMPRESSION is active[1]	VALUE COMPRESSION is not active	
		Column is nullable	Column is not nullable
REAL	6	5	4
DOUBLE	10	9	8
DECIMAL	The integral part of (*p*/2)+3, where *p* is the precision	The integral part of (*p*/2)+2, where *p* is the precision	The integral part of (*p*/2)+1, where *p* is the precision
DECFLOAT(16)	10	9	8
DECFLOAT(34)	18	17	16
CHAR(*n*)	*n*+2	*n*+1	*n*
VARCHAR(*n*)	*n*+2	*n*+5 (within a table)	*n*+4 (within a table)
LONG VARCHAR[2]	22	25	24
BINARY	*n*+2	*n*+1	*n*
VARBINARY	*n*+2	*n*+5 (within a table)	*n*+4 (within a table)
GRAPHIC(*n*)	*n**2+2	*n**2+1	*n**2
VARGRAPHIC(*n*)	*n**2+2	*n**2+5 (within a table)	*n**2+4 (within a table)
LONG VARGRAPHIC[2]	22	25	24
DATE	6	5	4
TIME	5	4	3

BOOLEAN	3	2	1
XML (without INLINE LENGTH specified)	82	85	84
XML (with INLINE LENGTH specified)	INLINE LENGTH +2	INLINE LENGTH +4	INLINE LENGTH +3
Maximum LOB[3] length 1024 (without INLINE LENGTH specified)	70	73	72
Maximum LOB length 8192 (without INLINE LENGTH specified)	94	97	96
Maximum LOB length 65,536 (without INLINE LENGTH specified)	118	121	120
Maximum LOB length 524,000 (without INLINE LENGTH specified)	142	145	144

Table 140. Byte Counts of Columns by Data Type (continued)

Data type	VALUE COMPRESSION is active[1]	VALUE COMPRESSION is not active	
		Column is nullable	Column is not nullable
Maximum LOB length 4,190,000 (without INLINE LENGTH specified)	166	169	168
Maximum LOB length 134,000,000 (without INLINE LENGTH specified)	198	201	200
Maximum LOB length 536,000,000 (without INLINE LENGTH specified)	222	225	224
Maximum LOB length 1,070,000,000 (without INLINE LENGTH specified)	254	257	256
Maximum LOB length 1,470,000,000 (without INLINE LENGTH specified)	278	281	280
Maximum LOB length 2,147,483,647 (without INLINE LENGTH specified)	314	317	316
LOB with INLINE LENGTH specified	INLINE LENGTH + 2	INLINE LENGTH + 5	INLINE LENGTH + 4

[1] There is an additional 2 bytes of storage used by each row when VALUE COMPRESSION is active for that row.

[2]The LONG VARCHAR and LONG VARGRAPHIC data types are deprecated and might be removed in a future release.

[3] Each LOB value has a *LOB descriptor* in the base record that points to the location of the actual value. The size of the descriptor varies according to the maximum length defined for the column. When INLINE LENGTH is not specified for a LOB column, the size of the descriptor is used as the default inline length value.

When determining the byte counts for LOB columns, there are extra bytes to consider when a LOB column is part of a system temporary table that might get generated for insensitive cursors, scrollable cursors, and other queries that require temporary space or sorting of data. The number of extra bytes required might go as high as 70 bytes, depending on the specific query. If the base table is close to the maximum row length for the pagesize, an error might be returned when processing a query if the system temporary table cannot fit in the largest available system temporary table space. If an existing system temporary table space is available that has a 32K page size, then extended row size support is used where possible.

For a *distinct type*, the byte count is equivalent to the length of the source type of the distinct type. For a *reference type*, the byte count is equivalent to the length of the built-in data type on which the reference type is based. For a *structured type*, the byte count is equivalent to the INLINE LENGTH + 4. The INLINE LENGTH is the value specified (or implicitly calculated) for the column in the *column-options* clause.

The row sizes for the following sample tables assume that VALUE COMPRESSION is not specified:

```
DEPARTMENT 63 (0 + 3 + 33 + 7 +  3 + 17)
ORG        57 (0 + 3 + 19 + 2 + 15 + 18)
```

If VALUE COMPRESSION were to be specified, the row sizes would change to:

```
DEPARTMENT 69 (2 + 5 + 31 + 8 +  5 + 18)
ORG        53 (2 + 4 + 16 + 4 + 12 + 15)
```

Minimum page size requirements for a table with extended row size : When a data row is inserted or updated in a table with extended row size support and the physical data row length exceeds the maximum record length for the table space, a subset of the varying length string columns (VARCHAR or VARGRAPHIC) is stored as large object (LOB) data outside of the data row. The table column in the base row is replaced by a descriptor that is 24 bytes in size. In order to accommodate the extreme case where all VARCHAR or VARGRAPHIC data is stored outside of the data row, the database manager computes the minimum row size using the following method:

– Handles every VARCHAR(n) column where n > 24 as if it were VARCHAR(24)

– Handles every VARGRAPHIC(m) column where m > 12 as if it were VARGRAPHIC(12

The value is computed using the *Byte Counts of Columns by Data Type* table. The computed result is then used to find the lower bound of the page size where the table with extended row size can be created.

- ***Storage byte counts:*** The following tables describe the storage byte counts of columns by data type for data values.

  The first table defines the sets of attributes. Those attributes are referenced in the second table, which contains the details for the byte counts for each data type.

  The byte counts depend on whether VALUE COMPRESSION is active. When VALUE COMPRESSION is not active, the byte counts also depend on whether the column is nullable. The values in the table represent the amount of storage (in bytes) that is used to store the value. The byte counts shown apply when row compression is not enabled. If row compression is active, the total number of bytes used by a row will generally be smaller than for an uncompressed version of the row; it will never be larger.

Table 141. Definitions of the criteria referenced in the related table

Case	Data value	VALUE COMPRESSION	Column nullability
A	NULL	Not active	Nullable
B	NULL	Active [2]	Nullable
C	Zero-length	Active [2]	Not applicable
D	System default[1]	Active [2]	Not applicable
E	All other data values	Not active	Nullable
F	All other data values	Not active	Not nullable
G	All other data values	Active [2]	Not applicable

[1] When COMPRESS SYSTEM DEFAULT is specified for the column.

[2] There is an additional 2 bytes of storage used by each row when VALUE COMPRESSION is active for that row.

Table 142. Storage Byte Counts Based on Row Format, Data Type, and Data Value

Maximum LOB length 2,147,483,647	5	3	2	2	(60 to 312)+5	(60 to 312)+4	(60 to 312)+2

Table 142. Storage Byte Counts Based on Row Format, Data Type, and Data Value (continued)

Data type	Case A	Case B	Case C	Case D	Case E	Case F	Case G
XML	5	3	-	-	85	84	82

1 When COMPRESS SYSTEM DEFAULT is specified for the column.

2 The LONG VARCHAR and LONG VARGRAPHIC data types are deprecated and might be removed in a future release.

- ***Dimension columns:*** Because each distinct value of a dimension column is assigned to a different block of the table, clustering on an expression might be desirable, such as "INTEGER(ORDER_DATE)/100". In this case, a generated column can be defined for the table, and this generated column can then be used in the ORGANIZE BY DIMENSIONS clause. If the expression is monotonic with respect to a column of the table, the database might use the dimension index to satisfy range predicates on that column. For example, if the expression is simply *column-name* + *some-positive-constant*, it is monotonic increasing. User-defined functions, certain built-in functions, and using more than one column in an expression, prevent monotonicity or its detection.

  Dimensions involving generated columns whose expressions are non-monotonic, or whose monotonicity cannot be determined, can still be created, but range queries along slice or cell boundaries of these dimensions are not supported. Equality and IN predicates *can* be processed by slices or cells.

  A generated column is monotonic if the following is true with respect to the generating function, fn:

  – Monotonic increasing.

    For every possible pair of values x1 and x2, if x2>x1, then fn(x2)>fn(x1). For example:

    ```
    SALARY - 10000
    ```

  – Monotonic decreasing.

    For every possible pair of values x1 and x2, if x2>x1, then fn(x2)<fn(x1). For example:

    ```
    -SALARY
    ```

  – Monotonic non-decreasing.

    For every possible pair of values x1 and x2, if x2>x1, then fn(x2)>=fn(x1). For example:

    ```
    SALARY/1000
    ```

  – Monotonic non-increasing.

    For every possible pair of values x1 and x2, if x2>x1, then fn(x2)<=fn(x1). For example:

    ```
    -SALARY/1000
    ```

  The expression "PRICE*DISCOUNT" is not monotonic, because it involves more than one column of the table.

- ***Range-clustered tables:*** Organizing a table by key sequence is effective for certain types of tables. The table should have an integer key that is tightly clustered (dense) over the range of possible values. The columns of this integer key must not be nullable, and the key should logically be the primary key of the table. The organization of a range-clustered table precludes the need for a separate unique index object, providing direct access to the row for a specified key value, or a range of rows for a specified range of key values. The allocation of all the space for the complete set of rows in the defined key sequence range is done during table creation, and must be considered when defining a range-clustered table. The storage space is not available for any other use, even though the rows are initially marked deleted. If the full key sequence range will be populated with data only over a long period of time, this table organization might not be appropriate.
- A table can have at most one security policy.
- Referential integrity constraints that are defined on protected tables are enforced. Constraints violations in this case can be difficult to debug, because the database manager will not allow you

to see what row has caused a violation if you do not have the appropriate security label or exemptions credentials.

- When defining the order of columns in a table, frequently updated columns should be placed at the end of the definition to minimize the amount of data logged for updates. This includes ROW CHANGE TIMESTAMP columns. ROW CHANGE TIMESTAMP columns are guaranteed to be updated on each row update.
- ***Security and replication:*** Replication can cause data rows from a protected table to be replicated outside of the database. Care must be taken when setting up replication for a protected table, because data that is outside of the database cannot be protected.
- ***Considerations for a multi-partition or Db2 pureScale environment***:
  - If the CACHE and NO ORDER options are in effect, multiple caches can be active simultaneously. This can happen at each member in a multi-partition or Db2 pureScale environment. The requests for next value assignments from different members might not result in the assignment of values in strict numeric order. Assume, for example, in a multi-partition or Db2 pureScale environment, that members DB1A and DB1B are using the same sequence, and DB1A gets the cache values in the range 1 - 20 and DB1B gets the cache values in the range 21 - 40. In this scenario, if DB1A requested the next value first, then DB1B requested, and then DB1A requested again, the actual order of values assigned would be 1,21,2. Therefore, to guarantee that sequence numbers are generated in strict numeric order among multiple members using the same sequence concurrently, specify the ORDER option.
  - In a Db2 pureScale environment, using the ORDER or NO CACHE option ensures that the values assigned to a sequence which is shared by applications across multiple members are in strict numeric order. In a Db2 pureScale environment, if ORDER is specified, then NO CACHE is implied even if CACHE *n* is specified
- ***Considerations for row and column access control (RCAC)***: The ACTIVATE ROW ACCESS CONTROL, ACTIVATE COLUMN ACCESS CONTROL, DEACTIVATE ROW ACCESS CONTROL, and DEACTIVATE COLUMN ACCESS CONTROL clauses are not supported. Use the ALTER TABLE statement to activate or deactivate row or column level access control on a table.
- ***Considerations for column-organized tables:*** Create column-organized tables in automatic storage table spaces only.

  The following options are not supported for column-organized tables (underlined options are defaults). They can, however, be specified for row-organized tables that will be used in the same database and workloads as column-organized tables.

  - ORGANIZE BY {DIMENSIONS | KEY SEQUENCE | INSERT TIME}
  - DATA CAPTURE CHANGES
  - VALUE COMPRESSION
  - COMPRESS YES [ADAPTIVE | STATIC]
  - COMPRESS NO
  - PARTITION BY RANGE
  - FOR EACH ROW ON UPDATE AS ROW CHANGE TIMESTAMP
  - CREATE TABLE OF <type-name1> (to create a typed table)
  - PROPAGATE IMMEDIATE
  - CHECK
  - DETERMINED BY

  Structured type columns are not supported.

  The columns of a column-organized table must have one of the following data types:

  - SMALLINT
  - INTEGER
  - BIGINT

  - DECIMAL
  - REAL
  - DOUBLE
  - DECFLOAT
  - CHAR (including FOR BIT DATA)
  - VARCHAR (including FOR BIT DATA)
  - BINARY
  - VARBINARY
  - GRAPHIC
  - VARGRAPHIC
  - DATE
  - TIME
  - TIMESTAMP (*n*)
  - BOOLEAN
  - CLOB
  - BLOB
  - DBCLOB
  - NCLOB
  - Distinct types of a supported data type

Syntax alternatives

The following alternatives are non-standard. They are supported for compatibility with earlier product versions or with other database products.

- The following syntax is accepted as the default behavior:
  - IN database-name.tablespace-name
  - IN DATABASE database-name
  - FOR MIXED DATA
  - FOR SBCS DATA
- PART can be specified in place of PARTITION.
- PARTITION *partition-number* can be specified instead of PARTITION *partition-name*. A *partition-number* must not identify a partition that was previously specified in the CREATE TABLE statement. If a *partition-number* is not specified, a unique partition number is generated by the database manager.
- VALUES can be specified in place of ENDING AT.
- The CONSTRAINT keyword can be omitted from a *column-definition* defining a references-clause.
- *constraint-name* can be specified following FOREIGN KEY (without the CONSTRAINT keyword).
- SUMMARY can optionally be specified after CREATE.
- DEFINITION ONLY can be specified in place of WITH NO DATA.
- PARTITIONING KEY can be specified in place of DISTRIBUTE BY.
- DISTRIBUTE ON can be specified in place of DISTRIBUTE BY when it is followed by the HASH option, but not when it is followed by the REPLICATION option.
- REPLICATED can be specified in place of DISTRIBUTE BY REPLICATION
- A comma can be used to separate multiple options in the *identity-options* clause.
- NOMINVALUE, NOMAXVALUE, NOCYCLE, NOCACHE, and NOORDER can be specified in place of NO MINVALUE, NO MAXVALUE, NO CYCLE, NO CACHE, and NO ORDER, respectively.

- ADD can be specified before *table-option-name string-constant*.
- When specifying the value of the datetime special register, NOW() can be specified in place of CURRENT_TIMESTAMP.

Examples

1. Create table TDEPT in the DEPARTX table space. DEPTNO, DEPTNAME, MGRNO, and ADMRDEPT are column names. CHAR means the column will contain character data. NOT NULL means that the column cannot contain a null value. VARCHAR means the column will contain varying-length character data. The primary key consists of the column DEPTNO.

```
CREATE TABLE TDEPT
  (DEPTNO   CHAR(3)     NOT NULL,
   DEPTNAME VARCHAR(36) NOT NULL,
   MGRNO    CHAR(6),
   ADMRDEPT CHAR(3)     NOT NULL,
   PRIMARY KEY(DEPTNO))
IN DEPARTX
```

2. Create table PROJ in the SCHED table space. PROJNO, PROJNAME, DEPTNO, RESPEMP, PRSTAFF, PRSTDATE, PRENDATE, and MAJPROJ are column names. CHAR means the column will contain character data. DECIMAL means the column will contain packed decimal data. 5,2 means the following: 5 indicates the number of decimal digits, and 2 indicates the number of digits to the right of the decimal point. NOT NULL means that the column cannot contain a null value. VARCHAR means the column will contain varying-length character data. DATE means the column will contain date information in a three-part format (year, month, and day).

```
CREATE TABLE PROJ
  (PROJNO   CHAR(6)      NOT NULL,
   PROJNAME VARCHAR(24)  NOT NULL,
   DEPTNO   CHAR(3)      NOT NULL,
   RESPEMP  CHAR(6)      NOT NULL,
   PRSTAFF  DECIMAL(5,2)         ,
   PRSTDATE DATE                 ,
   PRENDATE DATE                 ,
   MAJPROJ  CHAR(6)      NOT NULL)
IN SCHED
```

3. Create a table called EMPLOYEE_SALARY where any unknown salary is considered 0. No table space is specified, so that the table will be created in a table space selected by the system based on the rules described for the *IN tablespace-name* clause.

```
CREATE TABLE EMPLOYEE_SALARY
  (DEPTNO   CHAR(3)      NOT NULL,
   DEPTNAME VARCHAR(36)  NOT NULL,
   EMPNO    CHAR(6)      NOT NULL,
   SALARY   DECIMAL(9,2) NOT NULL WITH DEFAULT)
```

4. Create distinct types for total salary and miles and use them for columns of a table created in the default table space. In a dynamic SQL statement assume the CURRENT SCHEMA special register is JOHNDOE and the CURRENT PATH is the default ("SYSIBM", "SYSFUN", "JOHNDOE").

   If a value for SALARY is not specified it must be set to 0 and if a value for LIVING_DIST is not specified it must to set to 1 mile.

```
CREATE TYPE JOHNDOE.T_SALARY AS INTEGER

CREATE TYPE JOHNDOE.MILES  AS FLOAT

CREATE TABLE EMPLOYEE
  (ID          INTEGER NOT NULL,
   NAME        CHAR (30),
   SALARY      T_SALARY NOT NULL WITH DEFAULT,
   LIVING_DIST MILES    DEFAULT MILES(1) )
```

5. Create distinct types for image and audio and use them for columns of a table. No table space is specified, so that the table will be created in a table space selected by the system based on the rules described for the IN *tablespace-name* clause. Assume the CURRENT PATH is the default.

```
CREATE TYPE IMAGE AS BLOB (10M)

CREATE TYPE AUDIO AS BLOB (1G)

CREATE TABLE PERSON
  (SSN    INTEGER NOT NULL,
   NAME   CHAR (30),
   VOICE  AUDIO,
   PHOTO  IMAGE)
```

6. Create table EMPLOYEE in the HUMRES table space. The constraints defined on the table are the following:
   - The values of department number must lie in the range 10 to 100.
   - The job of an employee can only be either "Sales", "Mgr", or "Clerk".
   - Every employee that has been with the company since 1986 must make more than $40,500.

   Note: If the columns included in the check constraints are nullable they could also be NULL.

```
CREATE TABLE EMPLOYEE
  (ID          SMALLINT NOT NULL,
   NAME        VARCHAR(9),
   DEPT        SMALLINT CHECK (DEPT BETWEEN 10 AND 100),
   JOB         CHAR(5) CHECK (JOB IN ('Sales','Mgr','Clerk')),
   HIREDATE    DATE,
   SALARY      DECIMAL(7,2),
   COMM        DECIMAL(7,2),
   PRIMARY KEY (ID),
   CONSTRAINT  YEARSAL CHECK (YEAR(HIREDATE) > 1986
     OR SALARY > 40500)
  )
  IN HUMRES
```

7. Create a table that is wholly contained in the PAYROLL table space.

```
CREATE TABLE EMPLOYEE .....
  IN PAYROLL
```

8. Create a table with its data part in ACCOUNTING and its index part in ACCOUNT_IDX.

```
CREATE TABLE SALARY.....
  IN ACCOUNTING INDEX IN ACCOUNT_IDX
```

9. Create a table and log SQL changes in the default format.

```
CREATE TABLE SALARY1 .....
```

   or

```
CREATE TABLE SALARY1 .....
  DATA CAPTURE NONE
```

10. Create a table and log SQL changes in an expanded format.

```
CREATE TABLE SALARY2 .....
  DATA CAPTURE CHANGES
```

11. Create a table EMP_ACT in the SCHED table space. EMPNO, PROJNO, ACTNO, EMPTIME, EMSTDATE, and EMENDATE are column names. Constraints defined on the table are:
    - The value for the set of columns, EMPNO, PROJNO, and ACTNO, in any row must be unique.

- The value of PROJNO must match an existing value for the PROJNO column in the PROJECT table and if the project is deleted all rows referring to the project in EMP_ACT should also be deleted.

```
CREATE TABLE EMP_ACT
  (EMPNO       CHAR(6) NOT NULL,
   PROJNO      CHAR(6) NOT NULL,
   ACTNO       SMALLINT NOT NULL,
   EMPTIME     DECIMAL(5,2),
   EMSTDATE    DATE,
   EMENDATE    DATE,
   CONSTRAINT EMP_ACT_UNIQ UNIQUE (EMPNO,PROJNO,ACTNO),
   CONSTRAINT FK_ACT_PROJ FOREIGN KEY (PROJNO)
                          REFERENCES PROJECT (PROJNO) ON DELETE CASCADE
  )
  IN SCHED
```

A unique index called EMP_ACT_UNIQ is automatically created in the same schema to enforce the unique constraint.

12. Create a table that is to hold information about famous goals for the ice hockey hall of fame. The table will list information about the player who scored the goal, the goaltender against who it was scored, the date, and a description. The description column is nullable.

```
CREATE TABLE HOCKEY_GOALS
  ( BY_PLAYER      VARCHAR(30)   NOT NULL,
    BY_TEAM        VARCHAR(30)   NOT NULL,
    AGAINST_PLAYER VARCHAR(30)   NOT NULL,
    AGAINST_TEAM   VARCHAR(30)   NOT NULL,
    DATE_OF_GOAL   DATE          NOT NULL,
    DESCRIPTION    CLOB(5000) )
```

13. Suppose an exception table is needed for the EMPLOYEE table. One can be created using the following statement.

```
CREATE TABLE EXCEPTION_EMPLOYEE AS
  (SELECT EMPLOYEE.*,
    CURRENT TIMESTAMP AS TIMESTAMP,
    CAST ('' AS CLOB(32K)) AS MSG
  FROM EMPLOYEE
  ) WITH NO DATA
```

14. Given the following table spaces with the indicated attributes:

```
TBSPACE            PAGESIZE    USER   USERAUTH
------------------ ----------- ------ --------
DEPT4K                    4096 BOBBY  Y
PUBLIC4K                  4096 PUBLIC Y
DEPT8K                    8192 BOBBY  Y
DEPT8K                    8192 RICK   Y
PUBLIC8K                  8192 PUBLIC Y
```

- If RICK creates the following table, it is placed in table space PUBLIC4K since the byte count is less than 4005; but if BOBBY creates the same table, it is placed in table space DEPT4K, since BOBBY has USE privilege because of an explicit grant:

```
CREATE TABLE DOCUMENTS
  (SUMMARY    VARCHAR(1000),
   REPORT     VARCHAR(2000))
```

- If BOBBY creates the following table, it is placed in table space DEPT8K since the byte count is greater than 4005, and BOBBY has USE privilege because of an explicit grant. However, if DUNCAN creates the same table, it is placed in table space PUBLIC8K, since DUNCAN has no specific privileges:

```
CREATE TABLE CURRICULUM
  (SUMMARY    VARCHAR(1000),
   REPORT     VARCHAR(2000),
   EXERCISES  VARCHAR(1500))
```

15. Create a table with a LEAD column defined with the structured type EMP. Specify an INLINE LENGTH of 300 bytes for the LEAD column, indicating that any instances of LEAD that cannot fit within the 300

bytes are stored outside the table (separately from the base table row, similar to the way LOB values are handled).

```
CREATE TABLE PROJECTS (PID INTEGER,
  LEAD EMP INLINE LENGTH 300,
  STARTDATE DATE,
            ...)
```

16. Create a table DEPT with five columns named DEPTNO, DEPTNAME, MGRNO, ADMRDEPT, and LOCATION. Column DEPT is to be defined as an IDENTITY column so that a value will always be generated for it. The values for the DEPT column should begin with 500 and increment by 1.

```
CREATE TABLE DEPT
  (DEPTNO     SMALLINT      NOT NULL
                 GENERATED ALWAYS AS IDENTITY
                   (START WITH 500, INCREMENT BY 1),
   DEPTNAME   VARCHAR(36)   NOT NULL,
   MGRNO      CHAR(6),
   ADMRDEPT   SMALLINT      NOT NULL,
   LOCATION   CHAR(30))
```

17. Create a SALES table that is distributed on the YEAR column, and that has dimensions on the REGION and YEAR columns. Data will be distributed across database partitions according to hashed values of the YEAR column. On each database partition, data will be organized into extents based on unique combinations of values of the REGION and YEAR columns on those database partitions.

```
CREATE TABLE SALES
  (CUSTOMER   VARCHAR(80),
   REGION     CHAR(5),
   YEAR       INTEGER)
DISTRIBUTE BY HASH (YEAR)
ORGANIZE BY DIMENSIONS (REGION, YEAR)
```

18. Create a SALES table with a PURCHASEYEARMONTH column that is generated from the PURCHASEDATE column. Use an expression to create a column that is monotonic with respect to the original PURCHASEDATE column, and is therefore suitable for use as a dimension. The table is distributed on the REGION column, and organized within each database partition into extents according to the PURCHASEYEARMONTH column; that is, different regions will be on different database partitions, and different purchase months will belong to different cells (or sets of extents) within those database partitions.

```
CREATE TABLE SALES
  (CUSTOMER            VARCHAR(80),
   REGION              CHAR(5),
   PURCHASEDATE        DATE,
   PURCHASEYEARMONTH   INTEGER
                          GENERATED ALWAYS AS (INTEGER(PURCHASEDATE)/100))
DISTRIBUTE BY HASH (REGION)
ORGANIZE BY DIMENSIONS (PURCHASEYEARMONTH)
```

19. Create a CUSTOMER table with a CUSTOMERNUMDIM column that is generated from the CUSTOMERNUM column. Use an expression to create a column that is monotonic with respect to the original CUSTOMERNUM column, and is therefore suitable for use as a dimension. The table is organized into cells according to the CUSTOMERNUMDIM column, so that there is a different cell in the table for every 50 customers. If a unique index were created on CUSTOMERNUM, customer numbers would be clustered in such a way that each set of 50 values would be found in a particular set of extents in the table.

```
CREATE TABLE CUSTOMER
  (CUSTOMERNUM      INTEGER,
   CUSTOMERNAME     VARCHAR(80),
   ADDRESS          VARCHAR(200),
   CITY             VARCHAR(50),
   COUNTRY          VARCHAR(50),
   CODE             VARCHAR(15),
   CUSTOMERNUMDIM   INTEGER
                       GENERATED ALWAYS AS (CUSTOMERNUM/50))
ORGANIZE BY DIMENSIONS (CUSTOMERNUMDIM)
```

20. Create a remote base table called EMPLOYEE on the Oracle server, ORASERVER. A nickname, named EMPLOYEE, which refers to this newly created remote base table, will also automatically be created.

```
CREATE TABLE EMPLOYEE
  (EMP_NO       CHAR(6)       NOT NULL,
   FIRST_NAME   VARCHAR(12)   NOT NULL,
   MID_INT      CHAR(1)       NOT NULL,
   LAST_NAME    VARCHAR(15)   NOT NULL,
   HIRE_DATE    DATE,
   JOB          CHAR(8),
   SALARY       DECIMAL(9,2),
   PRIMARY KEY (EMP_NO))
OPTIONS
  (REMOTE_SERVER 'ORASERVER',
   REMOTE_SCHEMA 'J15USER1',
   REMOTE_TABNAME 'EMPLOYEE')
```

The following CREATE TABLE statements show how to specify the table name, or the table name and the explicit remote base table name, to get the required case. The lowercase identifier, employee, is used to illustrate the implicit folding of identifiers.

Create a remote base table called EMPLOYEE (uppercase characters) on an Informix server, and create a nickname named EMPLOYEE (uppercase characters) on that table:

```
CREATE TABLE employee
  (EMP_NO CHAR(6) NOT NULL,
   ...)
OPTIONS
  (REMOTE_SERVER 'INFX_SERVER')
```

If the REMOTE_TABNAME option is not specified, and *table-name* is not delimited, the remote base table name will be in uppercase characters, even if the remote data source normally stores names in lowercase characters.

Create a remote base table called employee (lowercase characters) on an Informix server, and create a nickname named EMPLOYEE (uppercase characters) on that table:

```
CREATE TABLE employee
  (EMP_NO CHAR(6) NOT NULL,
   ...)
OPTIONS
  (REMOTE_SERVER 'INFX_SERVER',
   REMOTE_TABNAME 'employee')
```

When creating a table at a remote data source that supports delimited identifiers, use the REMOTE_TABNAME option and a character string constant that specifies the table name in the required case.

Create a remote base table called employee (lowercase characters) on an Informix server, and create a nickname named employee (lowercase characters) on that table:

```
CREATE TABLE "employee"
  (EMP_NO CHAR(6) NOT NULL,
   ...)
OPTIONS
  (REMOTE_SERVER 'INFX_SERVER')
```

If the REMOTE_TABNAME option is not specified, and *table-name* is delimited, the remote base table name will be identical to *table-name*.

21. Create a range-clustered table that can be used to locate a student using a student ID. For each student record, include the school ID, program ID, student number, student ID, student first name, student last name, and student grade point average (GPA).

```
CREATE TABLE STUDENTS
  (SCHOOL_ID     INTEGER   NOT NULL,
   PROGRAM_ID    INTEGER   NOT NULL,
   STUDENT_NUM   INTEGER   NOT NULL,
   STUDENT_ID    INTEGER   NOT NULL,
   FIRST_NAME    CHAR(30),
   LAST_NAME     CHAR(30),
```

```
    GPA           DOUBLE)
  ORGANIZE BY KEY SEQUENCE
    (STUDENT_ID
      STARTING FROM 1
      ENDING AT 1000000)
    DISALLOW OVERFLOW
```

The size of each record is the sum of the columns, plus alignment, plus the range-clustered table row header. In this case, the row size is 98 bytes: 4 + 4 + 4 + 4 + 30 + 30 + 8 + 3 (for nullable columns) + 1 (for alignment) + 10 (for the header). With a 4-KB page size (or 4096 bytes), after accounting for page overhead, there are 4038 bytes available, enough room for 41 records per page. Allowing for 1 million student records, there is a need for (1 million divided by 41 records per page) 24,391 pages. With two additional pages for table overhead, the final number of 4-KB pages that are allocated when the table is created is 24,393.

22. Create a table named DEPARTMENT with a functional dependency that has no specified constraint name.

```
CREATE TABLE DEPARTMENT
  (DEPTNO     SMALLINT      NOT NULL,
   DEPTNAME   VARCHAR(36)   NOT NULL,
   MGRNO      CHAR(6),
   ADMRDEPT   SMALLINT      NOT NULL,
   LOCATION   CHAR(30),
  CHECK (DEPTNAME DETERMINED BY DEPTNO) NOT ENFORCED)
```

23. Create a table with protected rows.

```
CREATE TABLE TOASTMASTERS
  (PERFORMANCE DB2SECURITYLABEL,
   POINTS      INTEGER,
   NAME        VARCHAR(50))
  SECURITY POLICY CONTRIBUTIONS
```

24. Create a table with protected columns.

```
CREATE TABLE TOASTMASTERS
  (PERFORMANCE CHAR(8),
   POINTS      INTEGER COLUMN SECURED WITH CLUBPOSITION,
   NAME        VARCHAR(50))
  SECURITY POLICY CONTRIBUTIONS
```

25. Create a table with protected rows and columns.

```
CREATE TABLE TOASTMASTERS
  (PERFORMANCE DB2SECURITYLABEL,
   POINTS      INTEGER COLUMN SECURED WITH CLUBPOSITION,
   NAME        VARCHAR(50))
  SECURITY POLICY CONTRIBUTIONS
```

26. Large objects for a partitioned table reside, by default, in the same table space as the data. This default behavior can be overridden by using the LONG IN clause to specify one or more table spaces for the large objects. Create a table named DOCUMENTS whose large object data is to be stored (in a round-robin fashion for each data partition) in table spaces TBSP1 and TBSP2.

```
CREATE TABLE DOCUMENTS
  (ID INTEGER,
   CONTENTS CLOB)
  LONG IN TBSP1, TBSP2
  PARTITION BY RANGE (ID)
    (STARTING 1 ENDING 1000
     EVERY 100)
```

Alternatively, use the long form of the syntax to explicitly identify a large table space for each data partition. In this example, the CLOB data for the first data partition is placed in LARGE_TBSP3, and the CLOB data for the remaining data partitions is spread across LARGE_TBSP1 and LARGE_TBSP2 in a round-robin fashion.

```
CREATE TABLE DOCUMENTS
  (ID INTEGER,
   CONTENTS CLOB)
```

```
     LONG IN LARGE_TBSP1, LARGE_TBSP2
     PARTITION BY RANGE (ID)
       (STARTING 1 ENDING 100
        IN TBSP1 LONG IN LARGE_TBSP3,
        STARTING 101 ENDING 1000
        EVERY 100)
```

27. Create a partitioned table named ACCESSNUMBERS having two data partitions. The row (10, NULL) is to be placed in the first partition, and the row (NULL, 100) is to be placed in the second (last) data partition.

```
   CREATE TABLE ACCESSNUMBERS
     (AREA INTEGER,
      EXCHANGE INTEGER)
     PARTITION BY RANGE (AREA NULLS LAST, EXCHANGE NULLS FIRST)
       (STARTING (1,1) ENDING (10,100),
        STARTING (11,1) ENDING (MAXVALUE,MAXVALUE))
```

Because null values in the second column are sorted first, the row (11, NULL) would sort below the low boundary of the last data partition (11, 1); attempting to insert this row returns an error. The row (12, NULL) would fall within the last data partition.

28. Create a table named RATIO having a single data partition and partitioning column PERCENT.

```
   CREATE TABLE RATIO
     (PERCENT INTEGER)
     PARTITION BY RANGE (PERCENT)
       (STARTING (MINVALUE) ENDING (MAXVALUE))
```

This table definition allows any integer value for column PERCENT to be inserted. The following definition for the RATIO table allows any integer value between 1 and 100 inclusive to be inserted into column PERCENT.

```
   CREATE TABLE RATIO
     (PERCENT INTEGER)
     PARTITION BY RANGE (PERCENT)
       (STARTING 0 EXCLUSIVE ENDING 100 INCLUSIVE)
```

29. Create a table named MYDOCS with two columns: one is an identifier, and the other stores XML documents.

```
   CREATE TABLE MYDOCS
     (ID INTEGER,
      DOC XML)
   IN HLTBSPACE
```

30. Create a table named NOTES with four columns, including one for storing XML-based notes.

```
   CREATE TABLE NOTES
     (ID          INTEGER,
      DESCRIPTION VARCHAR(255),
      CREATED     TIMESTAMP,
      NOTE        XML)
```

31. Create a table, EMP_INFO, that contains a phone number and address for each employee. Include a ROW CHANGE TIMESTAMP column in the table to track the modification of employee information.

```
CREATE TABLE EMP_INFO
     (EMPNO           CHAR(6) NOT NULL,
      EMP_INFOCHANGE  TIMESTAMP NOT NULL GENERATED ALWAYS
       FOR EACH ROW ON UPDATE
       AS ROW CHANGE TIMESTAMP,
      EMP_ADDRESS     VARCHAR(300),
      EMP_PHONENO     CHAR(4),
      PRIMARY KEY (EMPNO) )
```

32. Create a partitioned table named DOCUMENTS having two data partitions:

- The data object in the first partition resides in table space TBSP11. The partitioned index partition on the partition resides in table space TBSP21. The XML data object resides in table space TBSP31.

- The data object in the second partition resides in table space TBSP12. The partitioned index partition on the partition resides in table space TBSP22. The XML data object resides in table space TBSP32.

The table level INDEX IN clause has no impact on table space selection for partitioned indexes.

```
CREATE TABLE DOCUMENTS
(ID        INTEGER,
 CONTENTS  XML)  INDEX IN TBSPX
PARTITION BY (ID NULLS LAST)
(STARTING FROM 1 INCLUSIVE ENDING AT 100 INCLUSIVE
 IN TBSP11 INDEX IN TBSP21 LONG IN TBSP31,
 STARTING FROM 101 INCLUSIVE ENDING AT 200 INCLUSIVE
 IN TBSP21 INDEX IN TBSP22 LONG IN TBSP32)
```

33. Create a partitioned table named SALES having two data partitions:

- The data object in the first partition resides in table space TBSP11. The partitioned index partition on the partition resides in table space TBSP21.
- The data object in the second partition resides in table space TBSP12. The partitioned index object resides in table space TBSP22.

The table level INDEX IN clause has no impact on table space selection for partitioned indexes.

```
CREATE TABLE SALES
(SID     INTEGER,
 AMOUNT  INTEGER)  INDEX IN TBSPX
PARTITION BY RANGE (SID NULLS LAST)
(STARTING FROM 1 INCLUSIVE ENDING AT 100 INCLUSIVE
 IN TBSP11 INDEX IN TBSP21,
 STARTING FROM 101 INCLUSIVE ENDING AT 200 INCLUSIVE
 IN TBSP12 INDEX IN TBSP22)
```

34. Create a table named BOOKS with four columns, including one named DATE_ADDED, which inserts the current TIMESTAMP by default.

```
CREATE TABLE BOOKS
  (ISBN_NUM   INTEGER,
   TITLE      VARCHAR(255),
   AUTHOR     VARCHAR(255),
   DATE_ADDED TIMESTAMP WITH DEFAULT CURRENT TIMESTAMP)
```

35. Create a Unicode table called STUDENTS in a non-Unicode database. Assume that the database was created using code set 1252 and territory CA and the ALT_COLLATE database configuration parameter was updated to IDENTITY_16BIT.

```
CREATE TABLE STUDENTS (
            STUDENTID INT NOT NULL,
           FAMILY_NAME VARCHAR(36) NOT NULL,
           GIVEN_NAME VARCHAR(36) NOT NULL,
           PRIMARY KEY(STUDENTID))
      CCSID UNICODE
```

36. Create a table called TDEPT_TEMP, based on the TDEPT table that is created in Example 1.

```
CREATE TABLE TDEPT_TEMP LIKE TDEPT
```

The TDEPT_TEMP table will have the same definition as TDEPT except that the primary key will not be defined and a default table space will be implicitly chosen.

37. Create a column-organized user-maintained materialized query table on column-organized table CDE.TDEPT.

```
CREATE TABLE mqt_tdept AS
   (SELECT *
     FROM cde.tdept
     WHERE deptno BETWEEN 10 AND 20)
   DATA INITIALLY DEFERRED
   REFRESH DEFERRED
   MAINTAINED BY USER
   ORGANIZE BY COLUMN
```

38. Column security labels inherited by a materialized query table.

```
CREATE SECURITY LABEL COMPONENT level_array ARRAY ['A', 'B', 'C']

CREATE SECURITY POLICY P COMPONENTS level_array WITH DB2LBACRULES

CREATE SECURITY LABEL P.A COMPONENT level_array 'A'

CREATE SECURITY LABEL P.B COMPONENT level_array 'B'

CREATE SECURITY LABEL P.C COMPONENT level_array 'C'

CREATE TABLE t1 (c1 INT, c2 INT SECURED WITH B, c3 REAL SECURED WITH A)
   SECURITY POLICY P

CREATE TABLE t2 (c4 REAL, c5 INT SECURED WITH C, c6 DB2SECURITYLABEL)
   SECURITY POLICY P
```

Generate a materialized query table

```
CREATE TABLE m1 AS
   (SELECT  c1, c3, c5, c6 FROM  t1,t2 WHERE c2 !=100)
   DATA INITALLY DEFERRED REFRESH DEFERRED
```

The security label of t1.c2 is used to compute security labels of all columns of m1 because it appears in the predicates of the query. The label-based access control properties of the materialized query table m1 are:

- Security policy = P
- Security label of column m1.c1 = P.B
- Security label of column m1.c3 = P.A
- Security label of column m1.c5 = P.B
- Security label of column m1.c6 = P.B and it is also DB2SECURITYLABEL.

A staging table for a materialized query table is protected with label-based access control. Staging table st1 is defined as:

```
CREATE TABLE st1 FOR m1 PROPAGATE IMMEDIATE
```

The label-based access control properties of the staging table st1 are:

- Security policy = P
- Security label of column st1.c1 = P.B
- Security label of column st1.c3 = P.A
- Security label of column st1.c5 = P.B
- Security label of column st1.c6 = P.B and it is also DB2SECURITYLABEL.

39. The following example shows you how to create a shadow table called T1_SHADOW that is based on the row-organized table T1.

    a. Create the base table and define a primary key. The primary key on the base table must be included in the select list of the shadow table. The primary key on the shadow table is required to provide a one-to-one mapping for each row in the base table to the corresponding row in the shadow table. The primary key also facilitates maintenance of the shadow table.

    ```
    CREATE TABLE t1 (
      c1 INTEGER NOT NULL,
      c2 INTEGER
    ) ORGANIZE BY ROW;

    ALTER TABLE t1
      ADD CONSTRAINT t1_pk PRIMARY KEY(c1);
    ```

    b. Create the shadow table:

    ```
    CREATE TABLE t1_shadow AS
        (SELECT c1, c2 FROM t1)
    ```

```
  DATA INITIALLY DEFERRED
  REFRESH DEFERRED
  MAINTAINED BY REPLICATION
  ORGANIZE BY COLUMN;

SET INTEGRITY FOR t1_shadow ALL IMMEDIATE UNCHECKED;

ALTER TABLE t1_shadow
  ADD CONSTRAINT t1_shadow_pk PRIMARY KEY (c1);
```

40. Create a table that is named STRING_UNITS, which demonstrates each possible string unit specification.

```
CREATE TABLE string_units
   (c1 VARCHAR(10),
    c2 VARCHAR(10 OCTETS),
    c3 VARCHAR(10 CODEUNITS32),
    c4 VARGRAPHIC(10),
    c5 VARGRAPHIC(10 CODEUNITS16),
    c6 VARGRAPHIC(10 CODEUNITS32))
```

    The columns have the following string units:

    - c1 = OCTETS, if the environment string units is SYSTEM; CODEUNITS32 if the environment string units is CODEUNITS32
    - c2 = OCTETS
    - c3 = CODEUNITS32
    - c4 = CODEUNITS16, if the environment string units is SYSTEM; CODEUNITS32 if the environment string units is CODEUNITS32
    - c5 = CODEUNITS16
    - c6 = CODEUNITS32

    Environment string units can be set with the NLS_STRING_UNITS session level global variable. If the NLS_STRING_UNITS session level global variable is not set or is null, the environment string units are determined by the value of the **string_units** database configuration parameter.

41. Create a random distribution table using the random by unique method. The distribution keys are automatically set to both keys of the index: **ID** and **NAME**.

```
CREATE TABLE RAND_BY_UNIQUE (ID BIGINT NOT NULL,
                             NAME CHAR(25) NOT NULL,
                             DESCRIPTION VARCHAR(1000),
                             PRIMARY KEY(ID, NAME)) DISTRIBUTE BY RANDOM
```

42. Create a random distribution table using the random by generation method. The distribution key is set to an internal column **RANDOM_DISTRIBUTION_KEY**, which is hidden from SQL unless explicitly specified.

```
CREATE TABLE RAND_BY_GENERATION (C1 BIGINT) DISTRIBUTE BY RANDOM
```

CREATE TABLESPACE

The CREATE TABLESPACE statement defines a new table space within the database, assigns containers to the table space, and records the table space definition and attributes in the catalog.

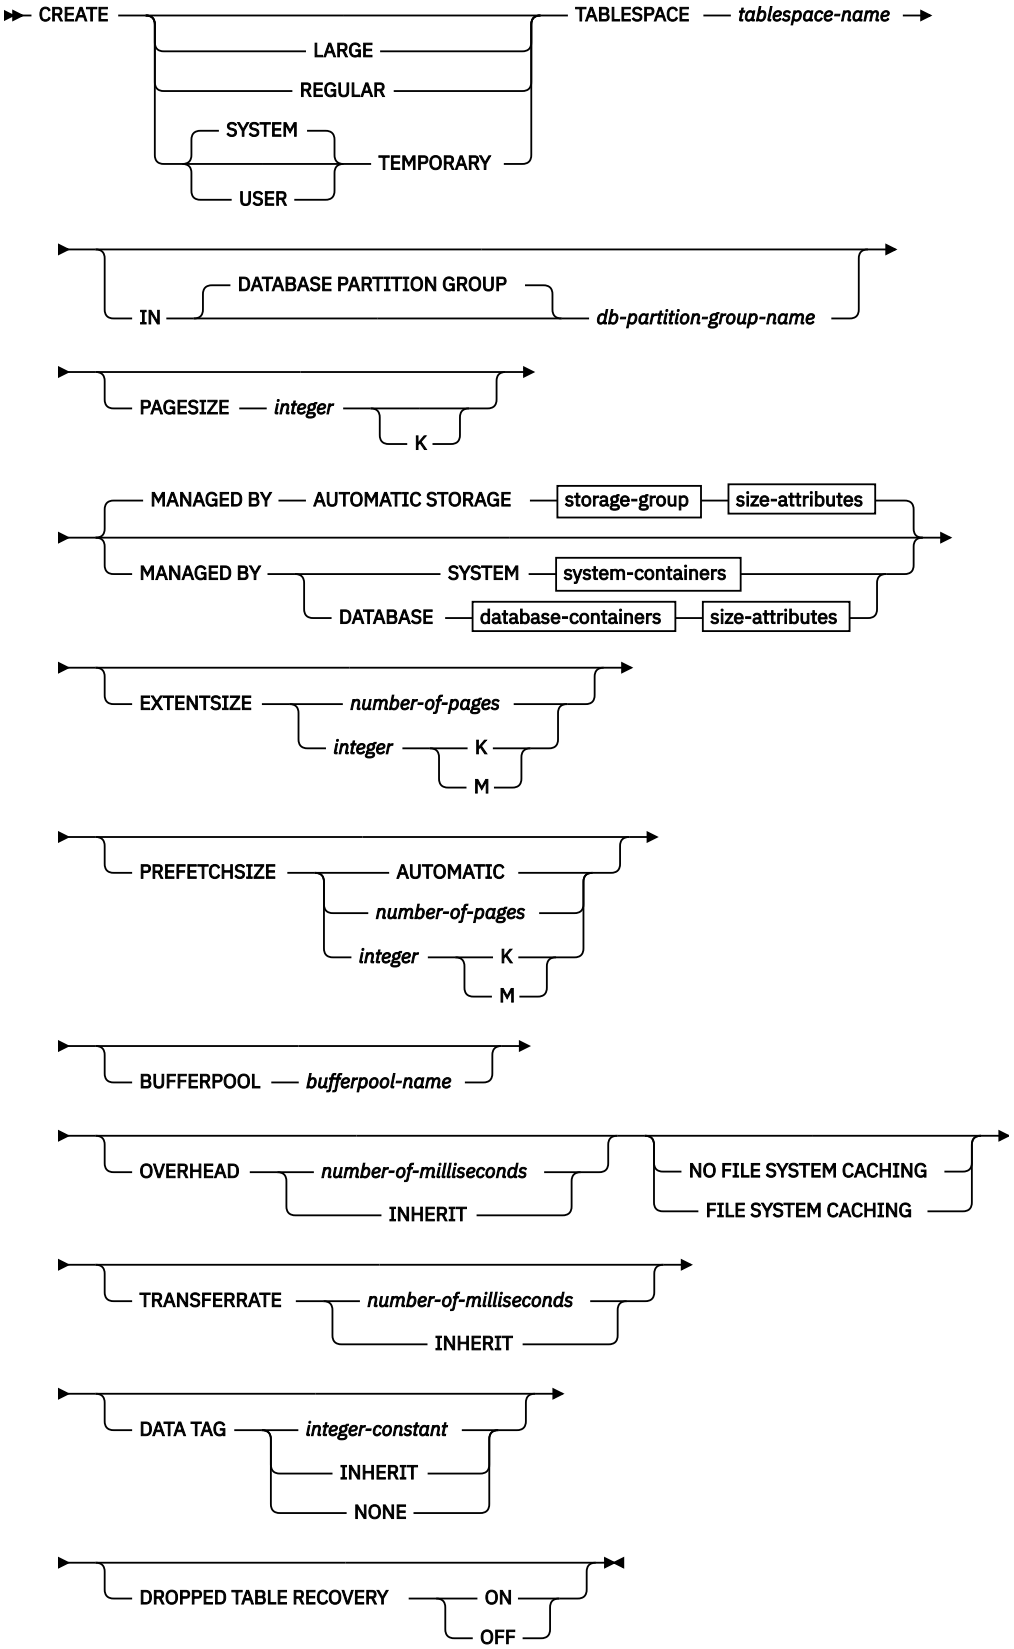
Invocation

This statement can be embedded in an application program or issued interactively. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

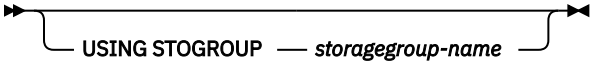
Authorization

The privileges that are held by the authorization ID of the statement must include SYSCTRL or SYSADM authority.

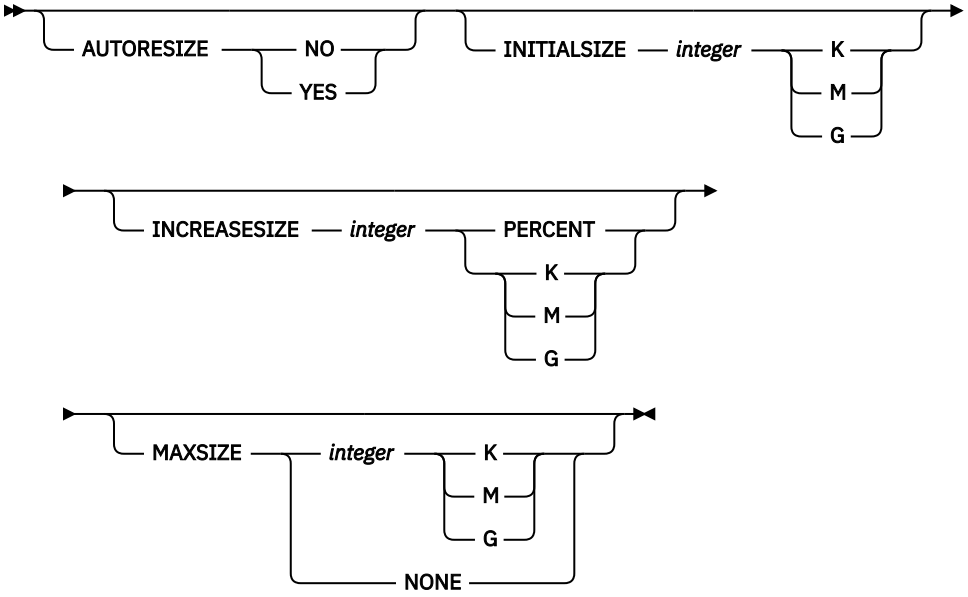
Syntax



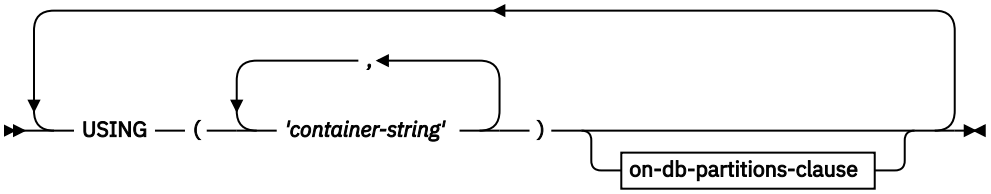
Storage-group



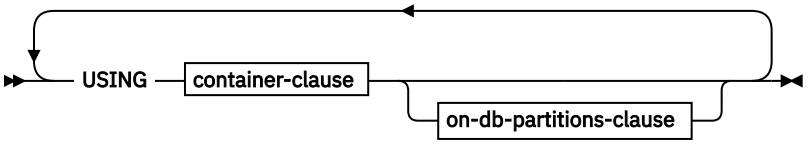
Size-attributes



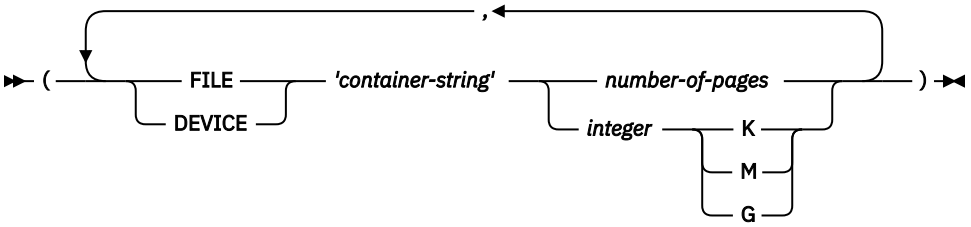
System-containers



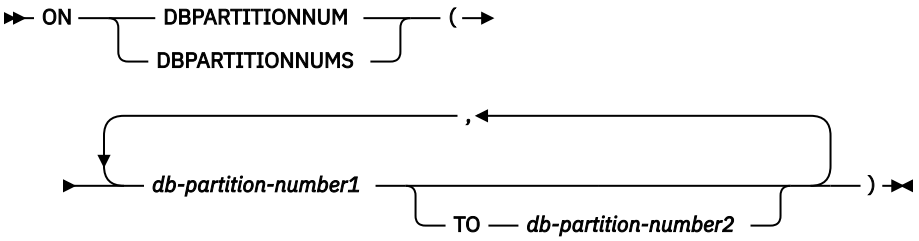
Database-containers



Container-clause



On-db-partitions-clause



Description

LARGE, REGULAR, SYSTEM TEMPORARY, or USER TEMPORARY
Specifies the type of table space that is to be created. If no type is specified, the default is determined by the MANAGED BY clause.

LARGE
Stores all permanent data. This type is only allowed on database-managed space (DMS) table spaces. It is also the default type for DMS table spaces when no type is specified. When a table is placed in a large table space:

- The table can be larger than a table in a regular table space. For more information on table and table space limits, see SQL and XML limits.
- The table can support more than 255 rows per data page, which can improve space utilization on data pages.
- Indexes that are defined on the table will require an extra 2 bytes per row entry, compared to indexes defined on a table that resides in a regular table space.

REGULAR
Stores all permanent data. This type applies to both DMS and SMS table spaces. This is the only type that is allowed for SMS table spaces, and it is also the default type for SMS table spaces when no type is specified.

SYSTEM TEMPORARY
Stores temporary tables, work areas that are used by the database manager to perform operations such as sorts or joins. A database must always have at least one SYSTEM TEMPORARY table space, because temporary tables can only be stored in such a table space. A temporary table space is created automatically when a database is created.

USER TEMPORARY
Stores created temporary tables and declared temporary tables. No user temporary table spaces exist when a database is created. To allow the definition of created temporary tables or declared temporary tables, at least one user temporary table space should be created with appropriate USE privileges.

tablespace-name
Names the table space. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *tablespace-name* must not identify a table space that already exists in the catalog (SQLSTATE 42710). The *tablespace-name* must not begin with the characters 'SYS' (SQLSTATE 42939).

IN DATABASE PARTITION GROUP *db-partition-group-name*
Specifies the database partition group for the table space. The database partition group must exist. The only database partition group that can be specified when creating a SYSTEM TEMPORARY table space is IBMTEMPGROUP. The DATABASE PARTITION GROUP keywords are optional.

If the database partition group is not specified, the default database partition group (IBMDEFAULTGROUP) is used for REGULAR, LARGE, and USER TEMPORARY table spaces. For SYSTEM TEMPORARY table spaces, the default database partition group IBMTEMPGROUP is used.

PAGESIZE *integer* [K]
Defines the size of pages that are used for the table space. The valid values for *integer* without the suffix K are 4096, 8192, 16384, or 32768. The valid values for *integer* with the suffix K are 4, 8, 16, or 32. Any number of spaces is allowed between *integer* and K, including no space. An error occurs if the page size is not one of these values (SQLSTATE 428DE), or if the page size is not the same as the page size of the buffer pool that is associated with the table space (SQLSTATE 428CB).

The default value is provided by the **pagesize** database configuration parameter, which is set when the database is created.

MANAGED BY AUTOMATIC STORAGE
Specifies that the table space is to be an automatic storage table space. If no storage groups are defined, an error is returned (SQLSTATE 55060).

The database manager automatically decides how the automatic storage table space is initially created. Temporary table spaces are initialized as system-managed space (SMS) table space and permanent table spaces are initialized as database-managed space (DMS) table space. When creating a permanent table space and the type of table space is not specified, the default behavior is to create a large table space. With an automatic storage table space, the database manager determines which containers are to be assigned to the table space, based on the storage paths that are associated with the storage group the table space uses.

storage-group
Specify the storage group for an automatic storage table space.

USING STOGROUP
For an automatic storage table space, identifies the storage group for the table space in which the table space data will be stored. If a *storagegroup-name* is not specified, then the currently designated default storage group is used. This clause only applies to automatic storage table spaces (SQLSTATE 42613).

storagegroup-name
Identifies the storage group in which table space data will be stored. *storagegroup-name* must identify a storage group that exists at the current server (SQLSTATE 42704). This is a one-part name.

size-attributes
Specify the size attributes for an automatic storage table space or a DMS table space that is not an automatic storage table space. SMS table spaces are not auto-resizable.

AUTORESIZE
Specifies whether the auto-resize capability of a DMS table space or an automatic storage table space is to be enabled. Auto-resizable table spaces automatically increase in size when they become full. The default is NO for DMS table spaces and YES for automatic storage table spaces.

NO
Specifies that the auto-resize capability of a DMS table space or an automatic storage table space is to be disabled.

YES
Specifies that the auto-resize capability of a DMS table space or an automatic storage table space is to be enabled.

INITIALSIZE *integer* K | M | G
Specifies the initial size, per database partition, of an automatic storage table space. This option is only valid for automatic storage table spaces. The integer value must be followed by K (for kilobytes), M (for megabytes), or G (for gigabytes). The actual value that is used might be slightly smaller than what was specified, because the database manager strives to maintain a consistent size across containers in the table space. Moreover, if the table space is auto-resizable and the initial size is not large enough to contain metadata that must be added to the new table space, the database manager will continue to extend the table space by the value of INCREASESIZE until enough space exists. If the INITIALSIZE clause is not specified, the database manager determines an appropriate value. The value for *integer* must be at least 48 K.

INCREASESIZE *integer* PERCENT or INCREASESIZE *integer* K | M | G
Specifies the amount, per database partition, by which a table space that is enabled for auto-resize will automatically be increased when the table space is full, and a request for space has been made. The integer value must be followed by:

- PERCENT to specify the amount as a percentage of the table space size at the time that a request for space is made. When PERCENT is specified, the integer value must be between `0` and `100` (SQLSTATE 42615).
- K (for kilobytes), M (for megabytes), or G (for gigabytes) to specify the amount in bytes.

The actual value that is used might be slightly smaller or larger than what was specified, because the database manager strives to maintain consistent growth across containers in the table space. If the table space is auto-resizable, but the INCREASESIZE clause is not specified, the database manager determines an appropriate value.

MAXSIZE *integer* K | M | G or MAXSIZE NONE
Specifies the maximum size to which a table space that is enabled for auto-resize can automatically be increased. If the table space is auto-resizable, but the MAXSIZE clause is not specified, the default is NONE.

integer
Specifies a hard limit on the size, per database partition, to which a DMS table space or an automatic storage table space can automatically be increased. The integer value must be followed by K (for kilobytes), M (for megabytes), or G (for gigabytes). The actual value that is used might be slightly smaller than what was specified, because the database manager strives to maintain consistent growth across containers in the table space.

NONE
Specifies that the table space is to be allowed to grow to file system capacity, or to the maximum table space size (described in "SQL and XML limits").

MANAGED BY SYSTEM
Specifies that the table space is to be an SMS table space.

MANAGED BY SYSTEM cannot be specified in a Db2 pureScale environment (SQLSTATE 42997).

Important: The SMS table space type is deprecated for user-defined permanent table spaces and might be removed in a future release. The SMS table space type is not deprecated for catalog and temporary table spaces. For more information, see "SMS permanent table spaces have been deprecated" at http://www.ibm.com/support/knowledgecenter/SSEPGG_10.1.0/com.ibm.db2.luw.wn.doc/doc/i0058748.html.

system-containers
Specify the containers for an SMS table space.

USING *('container-string', ...)*
For an SMS table space, identifies one or more containers that will belong to the table space and in which the table space data will be stored. The *container-string* cannot exceed 240 bytes in length.

Each *container-string* can be an absolute or relative directory name.

The directory name, if not absolute, is relative to the database directory, and can be a path name alias (or symbolic link) to storage that is not physically associated with the database directory. For example, *dbdir*`/work/c1` might be a symbolic link to a separate file system.

If any component of the directory name does not exist, it is created by the database manager. When a table space is dropped, all components created by the database manager are deleted. If the directory identified by *container-string* exists, it must not contain any files or subdirectories (SQLSTATE 428B2).

The format of *container-string* depends on the operating system.

Operating system	Format of absolute path name
Linux AIX	An absolute path name begins with a forward slash (/)
Windows	An absolute directory path name begins with a drive letter and a colon (:)

A relative path name on any platform does not begin with an operating system-dependent character.

For file-level protocols, such as NAS and CIFS, remote resources (such as LAN-redirected drives or NFS-mounted file systems) are currently supported only when the following technologies are used:

- Network Appliance Filers
- IBM Network Attached Storage

- NEC iStorage S2100, S2200, or S4100
- NEC Storage NS Series with a database server on Windows

  Note: NEC Storage NS Series is supported only with the use of an uninterrupted power supply (UPS); continuous UPS (rather than standby) is recommended.

An NFS-mounted file system on AIX must be mounted in uninterruptible mode using the **-o nointr** option.

Block-level protocols, such as iSCSI and FCP, are supported by any backend storage that has non-volatile RAM or battery backup. The storage technology must guarantee that successful writes are not lost in the event of failure, such as a power outage.

on-db-partitions-clause
Specifies the database partition or partitions on which the containers are created in a partitioned database. If this clause is not specified, then the containers are created on the database partitions in the database partition group that are not explicitly specified in any other *on-db-partitions-clauses*. For a SYSTEM TEMPORARY table space defined on database partition group IBMTEMPGROUP, when the *on-db-partitions-clause* is not specified, the containers will also be created on all new database partitions added to the database.

MANAGED BY DATABASE
Specifies that the table space is to be a DMS table space. When the type of table space is not specified, the default behavior is to create a large table space.

MANAGED BY DATABASE cannot be specified in a Db2 pureScale environment (SQLSTATE 42997).

Important: The DMS table space type is deprecated for user-defined permanent table spaces and might be removed in a future release. The DMS table space type is not deprecated for catalog and temporary table spaces. For more information, see "DMS permanent table spaces have been deprecated" at http://www.ibm.com/support/knowledgecenter/SSEPGG_10.1.0/com.ibm.db2.luw.wn.doc/doc/i0060577.html.

database-containers
Specify the containers for a DMS table space.

USING
Introduces a container-clause.

container-clause
Specifies the containers for a DMS table space.

(FILE|DEVICE *'container-string' number-of-pages, ...*)
For a DMS table space, identifies one or more containers that will belong to the table space and in which the table space data will be stored. The type of the container (either FILE or DEVICE) and its size (in PAGESIZE pages) are specified. The size can also be specified as an integer value followed by K (for kilobytes), M (for megabytes), or G (for gigabytes). If specified in this way, the floor of the number of bytes divided by the pagesize is used to determine the number of pages for the container. A mixture of FILE and DEVICE containers can be specified. The *container-string* cannot exceed 254 bytes in length.

For a FILE container, *container-string* must be an absolute or relative file name. The file name, if not absolute, is relative to the database directory. If any component of the directory name does not exist, it is created by the database manager. If the file does not exist, it will be created and initialized to the specified size by the database manager. When a table space is dropped, all components that are created by the database manager are deleted.

Note: If the file exists, it is overwritten, and if it is smaller than specified, it is extended. The file will not be truncated if it is larger than specified.

For a DEVICE container, *container-string* must be a device name. The device must already exist.

All containers must be unique across all databases. A container can belong to only one table space. The size of the containers can differ; however, optimal performance is achieved when

all containers are the same size. The exact format of *container-string* depends on the operating system.

For file-level protocols, such as NAS and CIFS, remote resources (such as LAN-redirected drives or NFS-mounted file systems) are currently supported only when the following technologies are used:

- Network Appliance Filers
- IBM Network Attached Storage
- NEC iStorage S2100, S2200, or S4100
- NEC Storage NS Series with a database server on Windows

Note: NEC Storage NS Series is supported only with the use of an uninterrupted power supply (UPS); continuous UPS (rather than standby) is recommended.

Block-level protocols, such as iSCSI and FCP, are supported by any backend storage that has non-volatile RAM or battery backup. The storage technology must guarantee that successful writes are not lost in the event of failure, such as a power outage.

on-db-partitions-clause
Specifies the database partition or partitions on which the containers are created in a partitioned database. If this clause is not specified, then the containers are created on the database partitions in the database partition group that are not explicitly specified in any other *on-db-partitions-clause*. For a SYSTEM TEMPORARY table space defined on database partition group IBMTEMPGROUP, when the *on-db-partitions-clause* is not specified, the containers will also be created on all new database partitions added to the database.

on-db-partitions-clause
Specifies the database partitions on which containers are created in a partitioned database.

ON DBPARTITIONNUMS
Keywords indicating that individual database partitions are specified. DBPARTITIONNUM is a synonym for DBPARTITIONNUMS.

db-partition-number1
Specify a database partition number.

TO *db-partition-number2*
Specify a range of database partition numbers. The value of *db-partition-number2* must be greater than or equal to the value of *db-partition-number1* (SQLSTATE 428A9). Containers are to be created on each database partition between and including the specified values. A specified database partition must be in the database partition group for the table space.

The database partition specified by number, and every database partition within the specified range of database partitions must exist in the database partition group for the table space (SQLSTATE 42729). A database partition number can only appear explicitly or within a range in exactly one *on-db-partitions-clause* for the statement (SQLSTATE 42613).

EXTENTSIZE *number-of-pages*
Specifies the number of PAGESIZE pages that will be written to a container before skipping to the next container. The extent size value can also be specified as an integer value followed by K (for kilobytes) or M (for megabytes). If specified in this way, the floor of the number of bytes divided by the page size is used to determine the value for the extent size. The database manager cycles repeatedly through the containers as data is stored.

In a Db2 pureScale environment, you should use an extent size of at least 32 pages. This minimum extent size reduces the amount of internal message traffic within the Db2 pureScale environment when extents are added for a table or index.

The default value is provided by the **dft_extent_sz** database configuration parameter, which has a valid range of 2-256 pages.

PREFETCHSIZE
Specifies to read in data that is needed by a query before it is referenced by the query, so that the query does not need to wait for I/O to be performed.

The default value is provided by the **dft_prefetch_sz** database configuration parameter.

AUTOMATIC
Specifies that the prefetch size of a table space is to be updated automatically; that is, the prefetch size will be managed by the database manager.

The prefetch size will be updated automatically whenever the number of containers in a table space changes (following successful execution of an ALTER TABLESPACE statement that adds or drops one or more containers). The prefetch size is also automatically updated at database startup.

number-of-pages
Specifies the number of PAGESIZE pages that will be read from the table space when data prefetching is being performed. The maximum value is 32767.

***integer* K | M**
Specifies the prefetch size value as an integer value followed by K (for kilobytes) or M (for megabytes). If specified in this way, the floor of the number of bytes divided by the page size is used to determine the number of pages value for prefetch size.

BUFFERPOOL *bufferpool-name*
The name of the buffer pool that is used for tables in this table space. The buffer pool must exist (SQLSTATE 42704). Furthermore, it must exist prior to the start of the transaction containing the CREATE TABLESPACE statement. If the buffer pool is created in the same UOW as the table space, it is not available to use. Instead, the table space will use the small system buffer pool with the matching page size. If not specified, the default buffer pool (IBMDEFAULTBP) is used. The page size of the buffer pool must match the page size specified (or defaulted) for the table space (SQLSTATE 428CB). The database partition group of the table space must be defined for the buffer pool (SQLSTATE 42735).

OVERHEAD *number-of-milliseconds* or OVERHEAD INHERIT
Specifies the I/O controller overhead and disk seek and latency time. This value is used to determine the cost of I/O during query optimization. If OVERHEAD is not specified for a non-automatic storage table space, the value defaults to the database creation default described later in the description for this keyword. If OVERHEAD is not specified for an automatic storage table space, the default is to INHERIT the value from the storage group it is using. If the OVERHEAD value at the storage group is undefined, the OVERHEAD defaults to the database creation default. For more information on tuning, refer to Table space impact on query optimization.

number-of-milliseconds
The value of *number-of-milliseconds* is any numeric literal (integer, decimal, or floating point). If this value is not the same for all containers, the number should be the average for all containers that belong to the table space.

INHERIT
If INHERIT is specified, the table space must be defined by using automatic storage and the OVERHEAD is dynamically inherited from the storage group. INHERIT cannot be specified if the table space is not defined by using automatic storage (SQLSTATE 42613).

For a database that was created in Db2 version 10.1 or later, the default I/O controller overhead and disk seek and latency time for 4 KB PAGESIZE table space is 6.725 milliseconds.

For a database that was upgraded from a previous version of Db2 to Db2 version 10.1 or later, the default I/O controller overhead and disk seek and latency time is as follows:

- 7.5 milliseconds for a database that is created in Db2 version 9.7 or higher

FILE SYSTEM CACHING or NO FILE SYSTEM CACHING
Specifies whether I/O operations are to be cached at the file system level or non-cached by using direct I/O. If neither option is specified, the I/O mode is determined based on operating system, file system, and in the case of SMS table spaces, data object type. For more information, see File

system caching configurations. Note that once a non-default file system caching option is chosen, it is not possible to return to the default (unspecified) behavior. Instead, the file system caching mode must be selected explicitly.

FILE SYSTEM CACHING
Specifies that all I/O operations in the target table space are to be cached at the file system level.

NO FILE SYSTEM CACHING
Specifies that all I/O operations are to bypass the file system-level cache. LOB and Long field data in SMS table spaces are excepted.

Note:

Db2 supports disk devices with physical sector sizes of 512 bytes or 4096 bytes.

Support for 4096 byte sector sizes is not enabled by default, and can be enabled using the **DB2_4K_DEVICE_SUPPORT** registry variable.

TRANSFERRATE *number-of-milliseconds* or TRANSFERRATE INHERIT
Specifies the time to read one page into memory. If TRANSFERRATE is not specified for a non-automatic storage table space, the value defaults to the database creation default described later in the description for this keyword. If TRANSFERRATE is not specified for an automatic storage table space, the default is to INHERIT the value from the storage group it is using. If the DEVICE READ RATE value at the storage group is undefined, the TRANSFERRATE defaults to the database creation default. For more information on tuning, refer to Table space impact on query optimization.

number-of-milliseconds
This value is used to determine the cost of I/O during query optimization. The value of *number-of-milliseconds* is any numeric literal (integer, decimal, or floating point). If this value is not the same for all containers, the number should be the average for all containers that belong to the table space.

INHERIT
If INHERIT is specified, the table space must be defined by using automatic storage and the TRANSFERRATE is dynamically inherited from the DEVICE READ RATE of the storage group. INHERIT cannot be specified if the table space is not defined by using automatic storage (SQLSTATE 42613).

When an automatic storage table space inherits the TRANSFERRATE setting from the storage group it is using, the DEVICE READ RATE of the storage group, which is in megabytes per second, is converted into milliseconds per page read accounting for the PAGESIZE setting of the table space. The conversion formula follows:

TRANSFERRATE = (1 / DEVICE READ RATE) * 1000 / 1024000 * PAGESIZE

For a database that was created in Db2 version 10.1 or later, the default time to read one page into memory for 4 KB PAGESIZE table space is 0.04 milliseconds.

For a database that was upgraded from a previous version of Db2 to Db2version 10.1 or later, the default time to read one page into memory is as follows:

- 0.06 milliseconds for a database that is created in Db2 version 9.7 or higher

DATA TAG *integer-constant*, DATA TAG INHERIT or DATA TAG NONE
Specifies a tag for the data in the table space. If the DATA TAG is not specified, the default for automatic storage table spaces is to INHERIT from the storage group it is using and for non-automatic table spaces it will be set to NONE. This value can be used as part of a WLM configuration in a work class definition (see “CREATE WORK CLASS SET ” on page 1560) or referenced within a threshold definition (see “CREATE THRESHOLD ” on page 1443). This clause cannot be specified if TEMPORARY is also specified (SQLSTATE 42613).

integer-constant
Valid values for *integer-constant* are integers in the range 1 - 9. If an *integer-constant* is specified and an associated storage group exists, the data tag that is specified for the table space will override any data tag value that is specified for the associated storage group.

INHERIT
If INHERIT is specified, the table space must be defined by using automatic storage and the data tag is dynamically inherited from the storage group. INHERIT cannot be specified if the table space is not defined by using automatic storage (SQLSTATE 42613).

NONE
If NONE is specified, there is no data tag.

DROPPED TABLE RECOVERY
Indicates whether dropped tables in the specified table space can be recovered by using the **RECOVER DROPPED TABLE** option of the **ROLLFORWARD DATABASE** command. This clause can only be specified for a regular or large table space (SQLSTATE 42613).

ON
Specifies that dropped tables can be recovered. This is the default.

OFF
Specifies that dropped tables cannot be recovered.

Rules

- If automatic storage is not defined for the database, an error is returned (SQLSTATE 55060).
- The INITIALSIZE clause cannot be specified with the MANAGED BY SYSTEM or MANAGED BY DATABASE clause (SQLSTATE 42601).
- The AUTORESIZE, INCREASESIZE, or MAXSIZE clause cannot be specified with the MANAGED BY SYSTEM clause (SQLSTATE 42601).
- The AUTORESIZE, INITIALSIZE, INCREASESIZE, or MAXSIZE clause cannot be specified for the creation of a temporary automatic storage table space (SQLSTATE 42601).
- The INCREASESIZE or MAXSIZE clause cannot be specified if the tables space is not auto-resizable (SQLSTATE 42601).
- AUTORESIZE cannot be enabled for DMS table spaces that are defined to use raw device containers (SQLSTATE 42601).
- A table space must initially be large enough to hold five extents (SQLSTATE 57011).
- The maximum size of a table space must be larger than its initial size (SQLSTATE 560B0).
- Container operations (ADD, EXTEND, RESIZE, DROP, or BEGIN NEW STRIPE SET) cannot be performed on automatic storage table spaces because the database manager is controlling the space management of such table spaces (SQLSTATE 42858).
- Each container definition requires 53 bytes plus the number of bytes necessary to store the container name. The combined length of all container definitions for the table space cannot exceed 208 kilobytes (SQLSTATE 54034).
- For a partitioned database, if more than one database partition resides on the same physical node, the same device or path cannot be specified for more than one database partition (SQLSTATE 42730). In this environment, either specify a unique *container-string* for each database partition, or use a relative path name.
- Only automatic storage table spaces can be created in a Db2 pureScale environment(SQLSTATE 42997).
- ***Container size limits:*** In DMS table spaces, a container must be at least two times the extent size pages in length (SQLSTATE 54039). The maximum size of a container is operating system dependent.

Notes

- Choosing between a database-managed space or a system-managed space for a table space is a fundamental choice involving tradeoffs.

- When more than one TEMPORARY table space exists in the database, they are used in round-robin fashion to balance their usage.
- The owner of the table space is granted USE privilege with the WITH GRANT OPTION on the table space when it is created.
- An automatic storage table space is created as either an SMS table space or a DMS table space. DMS is chosen for large and regular table spaces, and SMS is chosen for temporary table spaces. This behavior cannot be depended upon because it might change in a future release. When DMS is chosen and the type of table space is not specified, the default behavior is to create a large table space.
- The creation of an automatic storage table space does not include container definitions. The database manager automatically determines the location and size, if applicable, of the containers based on the storage paths that are associated with the specified storage group or the default storage group. The database manager will attempt to grow large and regular table spaces, as necessary, if the maximum size has not been reached. This might involve extending existing containers or adding containers to a new stripe set. Every time that the database is activated, the database manager automatically reconfigures the number and location of the containers for temporary table spaces that are not in an abnormal state.
- A large or regular automatic storage table space will not use new storage paths (see the description of the ALTER STOGROUP statement) until there is no more space in one of the existing storage paths that the table space is using. Temporary automatic storage table spaces can only use the new storage paths once the database has been deactivated and then reactivated.
- ***Media attributes*:** The following table shows how the media attributes of newly created table spaces are treated in upgraded and newly created Db2 version 10.1 databases.

Table 143. Media attributes across different versions of Db2

Media attributes	Upgraded Database	Newly Created Database
New automatic storage table spaces / storage group DEVICE READ RATE set to *undefined*	Defaults based on version database was created (no change)	Not applicable
New automatic storage table spaces / storage group OVERHEAD set to *undefined*	Defaults based on version database was created (no change)	Not applicable
New automatic storage table spaces / storage group DEVICE READ RATE is set	Inherit from storage group factoring in PAGESIZE	Inherit from storage group factoring in PAGESIZE
New automatic storage table spaces / storage group OVERHEAD is set	Inherit from storage group	Inherit from storage group
New non-automatic storage table spaces	Defaults based on version database was created (no change)	Db2 version 10.1 media defaults taking PAGESIZE into account

- ***Default TRANSFERRATE***: The following table shows how the default TRANSFERRATE value differs for newly created table spaces.

Table 144. Default TRANSFERRATE

PAGESIZE	TRANSFERRATE
4 KB	0.04 ms per page read
8 KB	0.08 ms per page read
16 KB	0.16 ms per page read
32 KB	0.32 ms per page read

- ***Syntax alternatives***: The following are supported for compatibility with previous versions of Db2 and with other database products. These alternatives are non-standard and should not be used.
  - NODE can be specified in place of DBPARTITIONNUM.
  - NODES can be specified in place of DBPARTITIONNUMS.
  - NODEGROUP can be specified in place of DATABASE PARTITION GROUP.
  - LONG can be specified in place of LARGE.
- For the Db2 Developer-C Edition:
  - Altering an auto-resize table space without specifying **MAXSIZE** will implicitly set **MAXSIZE** to the remaining capacity, up to the defined storage size.
  - An attempt to resize, add, or extend the container size of all table spaces larger than the defined storage size results in a fail.
  - Altering a table space fails if there exists a subsequent CREATE TABLESPACE that hasn't been committed.

Examples

1. Create a large DMS table space on a Linux system using three devices of 10 000 4K pages each. Specify their I/O characteristics.

```
CREATE TABLESPACE PAYROLL
  MANAGED BY DATABASE
  USING (DEVICE'/dev/rhdisk6' 10000,
    DEVICE '/dev/rhdisk7' 10000,
    DEVICE '/dev/rhdisk8' 10000)
  OVERHEAD 12.67
  TRANSFERRATE 0.18
```

2. Create a regular SMS table space on Windows using three directories on three separate drives, with a 64-page extent size, and a 32-page prefetch size.

```
CREATE TABLESPACE ACCOUNTING
  MANAGED BY SYSTEM
  USING ('/tbsp/acc1', '/tbsp/acc2', '/tbsp/acc3')
  EXTENTSIZE 64
  PREFETCHSIZE 32
```

3. Create a system temporary DMS table space on a Linux system by using two files of 50 000 pages each, and a 256-page extent size.

```
CREATE TEMPORARY TABLESPACE TEMPSPACE2
  MANAGED BY DATABASE
  USING (FILE 'dbtmp/tempspace2.f1' 50000,
    FILE 'dbtmp/tempspace2.f2' 50000)
  EXTENTSIZE 256
```

4. Create a large DMS table space in database partition group ODDNODEGROUP (database partitions 1, 3, and 5) on a Linux system. Use the device `/dev/rhdisk0` for 10 000 4K pages on each database partition. Specify a database partition-specific device with 40 000 4K pages for each database partition.

```
CREATE TABLESPACE PLANS
  MANAGED BY DATABASE
  USING (DEVICE '/dev/rhdisk0' 10000, DEVICE '/dev/rn1hd01' 40000)
  ON DBPARTITIONNUM (1)
  USING (DEVICE '/dev/rhdisk0' 10000, DEVICE '/dev/rn3hd03' 40000)
  ON DBPARTITIONNUM (3)
  USING (DEVICE '/dev/rhdisk0' 10000, DEVICE '/dev/rn5hd05' 40000)
  ON DBPARTITIONNUM (5)
```

5. Create a large automatic storage table space that is named DATATS, allowing the system to make all decisions concerning table space size and growth.

```
CREATE TABLESPACE DATATS
```

or

```
CREATE TABLESPACE DATATS
  MANAGED BY AUTOMATIC STORAGE
```

6. Create a system temporary automatic storage table space named TEMPDATA.

```
CREATE TEMPORARY TABLESPACE TEMPDATA
```

or

```
CREATE TEMPORARY TABLESPACE TEMPDATA
  MANAGED BY AUTOMATIC STORAGE
```

7. Create a large automatic storage table space that is named USERSPACE3 with an initial size of 100 megabytes and a maximum size of 1 gigabyte.

```
CREATE TABLESPACE USERSPACE3
  INITIALSIZE 100 M
  MAXSIZE 1 G
```

8. Create a large automatic storage table space that is named LARGEDATA with a growth rate of 10 percent (that is, its total size increases by 10 percent each time that it is automatically resized) and a maximum size of 512 megabytes. Instead of specifying the INITIALSIZE clause, let the database manager determine an appropriate initial size for the table space.

```
CREATE LARGE TABLESPACE LARGEDATA
  INCREASESIZE 10 PERCENT
  MAXSIZE 512 M
```

9. Create a large DMS table space that is named USERSPACE4 with two file containers (each container being 1 megabyte in size), a growth rate of 2 megabytes, and a maximum size of 100 megabytes.

```
CREATE TABLESPACE USERSPACE4
  MANAGED BY DATABASE USING (FILE '/db/file1' 1 M, FILE '/db/file2' 1 M)
  AUTORESIZE YES
  INCREASESIZE 2 M
  MAXSIZE 100 M
```

10. Create large DMS table spaces, using RAW devices on a Windows operating system.
    - To specify entire physical drives, use the \\.*physical-drive* format:

      ```
      CREATE TABLESPACE TS1
        MANAGED BY DATABASE USING (DEVICE '\\.\PhysicalDrive5' 10000,
          DEVICE '\\.\PhysicalDrive6' 10000)
      ```

    - To specify logical partitions by using drive letters:

      ```
      CREATE TABLESPACE TS2
        MANAGED BY DATABASE USING (DEVICE '\\.\G:' 10000,
          DEVICE '\\.\H:' 10000)
      ```

    - To specify logical partitions by using volume global unique identifiers (GUIDs), use the **db2listvolumes** utility to retrieve the volume GUID for each local partition, then copy the GUID for the logical partition that you want into the table space container clause:

      ```
      CREATE TABLESPACE TS3
        MANAGED BY DATABASE USING (
          DEVICE '\\?\Volume{2ca6a0c1-8542-11d8-9734-00096b5322d2}\' 20000M)
      ```

      You might prefer to use volume GUIDs over the drive letter format if you have more partitions than available drive letters on the machine.
    - To specify logical partitions by using junction points (or volume mount points), mount the RAW partition to another NTFS-formatted volume as a junction point, then specify the path to the junction point on the NTFS volume as the container path. For example:

```
CREATE TABLESPACE TS4
  MANAGED BY DATABASE USING (DEVICE 'C:\JUNCTION\DISK_1' 10000,
    DEVICE 'C:\JUNCTION\DISK_2' 10000)
```

The partition is queried first to see whether there is a file system on it; if yes, the partition is not treated as a RAW device, and normal file system I/O operations are performed on the partition.

Related information

Best practices: Database storage

CREATE THRESHOLD

The CREATE THRESHOLD statement defines a threshold.

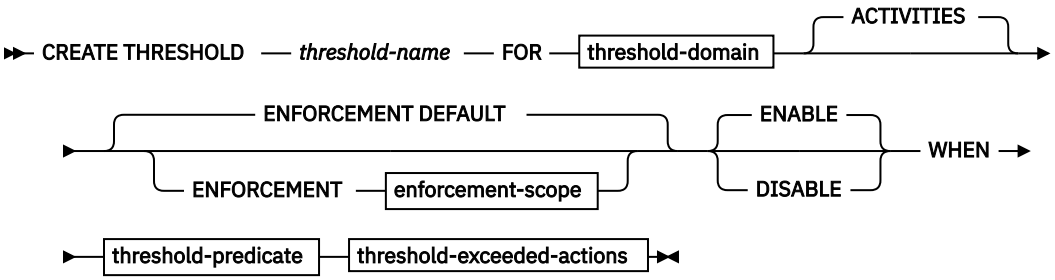
Invocation

This statement can be embedded in an application program or issued through the use of dynamic SQL statements. It is an executable statement that can be dynamically prepared only if DYNAMICRULES run behavior is in effect for the package (SQLSTATE 42509).

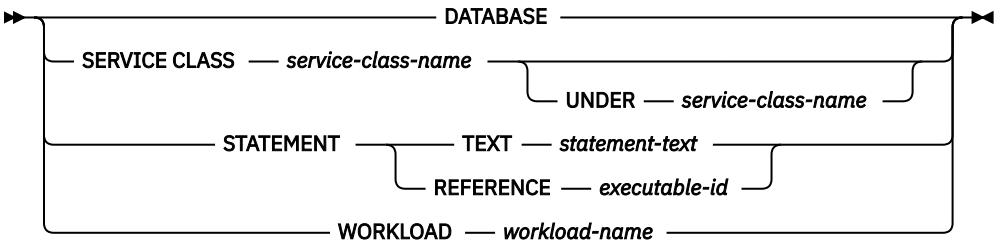
Authorization

The privileges held by the authorization ID of the statement must include WLMADM or DBADM authority.

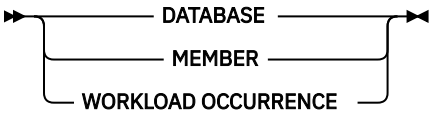
Syntax



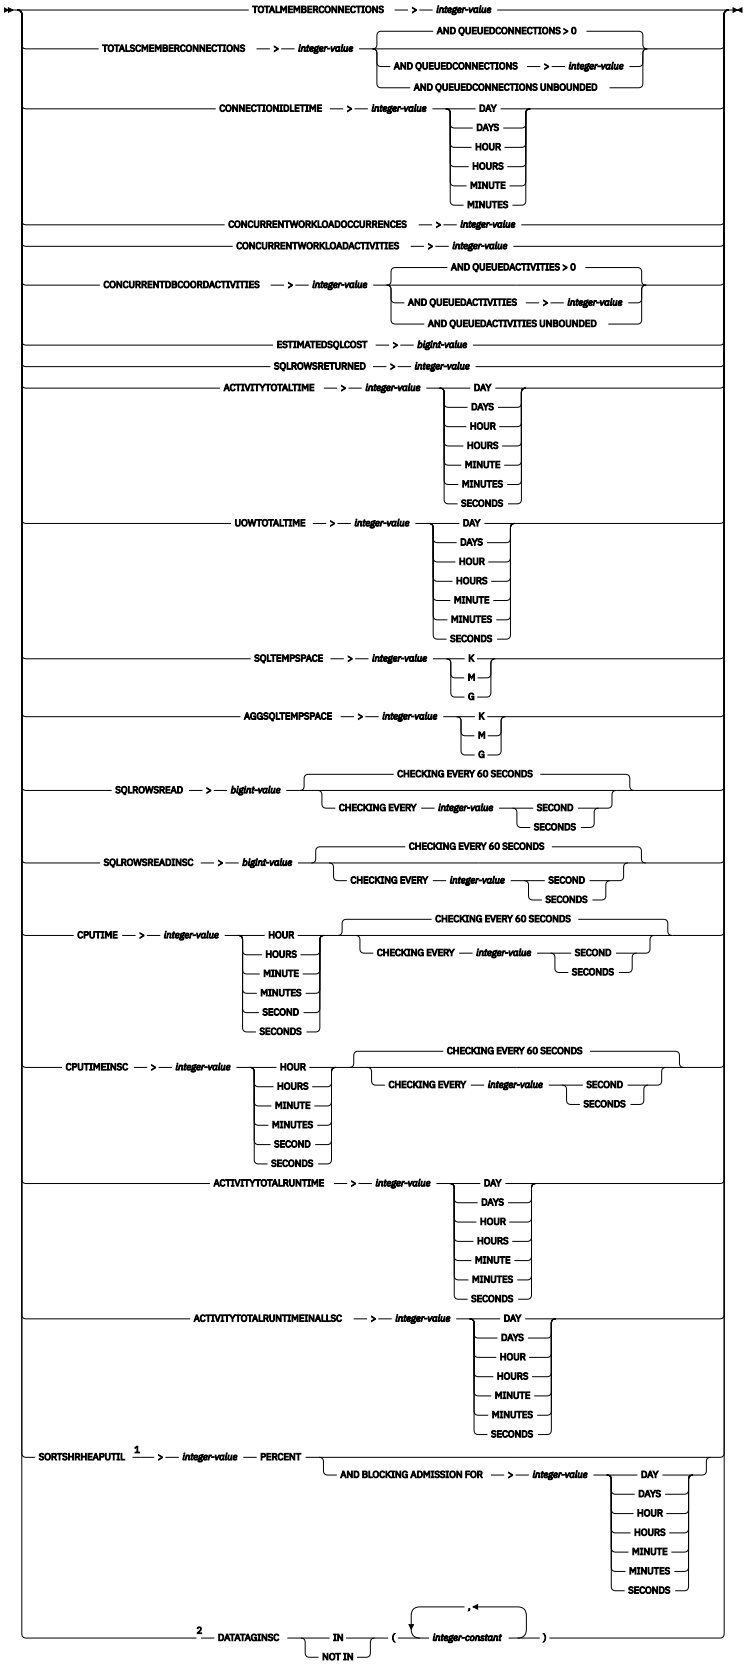
threshold-domain



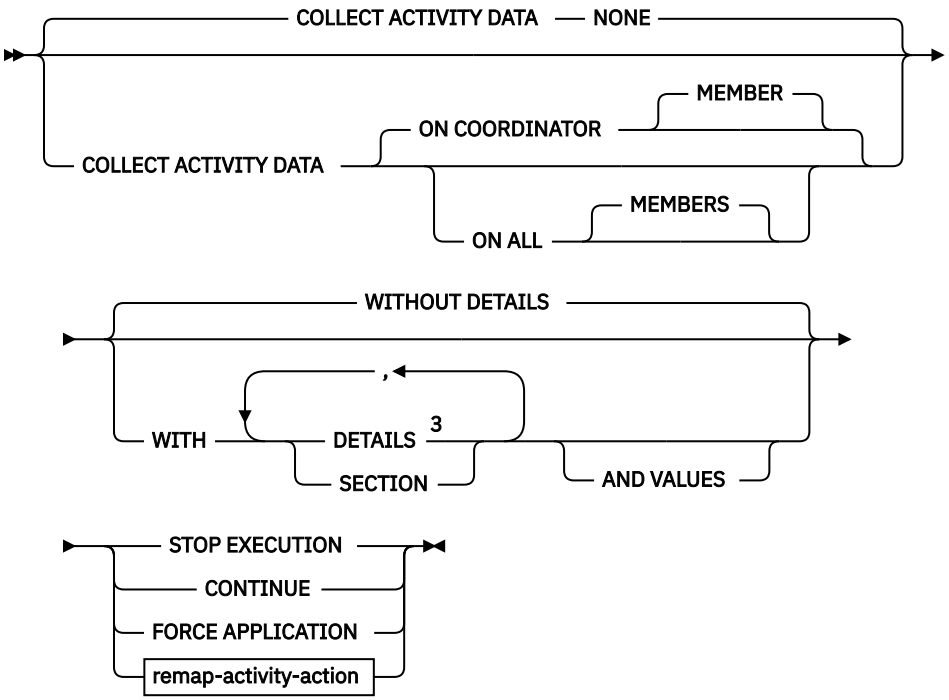
enforcement-scope



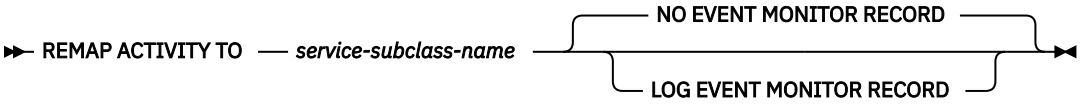
threshold-predicate



threshold-exceeded-actions



remap-activity-action



Notes:

[1] This feature is available in Db2 Version 11.5 Mod Pack 2 and later versions.

[2] Each data tag value can be specified only once.

[3] The DETAILS keyword is the minimum to be specified, followed by the option separated by a comma.

Description

threshold-name

Names the threshold. This is a one-part name. It is an SQL identifier (either ordinary or delimited). The *threshold-name* must not identify a threshold that already exists at the current server (SQLSTATE 42710). The name must not begin with the characters 'SYS' (SQLSTATE 42939).

FOR *threshold-domain* ACTIVITIES

Specifies the definition domain of the threshold.

DATABASE

This threshold applies to any activity in the database.

SERVICE CLASS *service-class-name*

This threshold applies to activities executing in service class *service-class-name*. If UNDER is not specified, *service-class-name* must identify an existing service superclass (SQLSTATE 42704). If UNDER is specified, *service-class-name* must identify an existing service subclass of the service superclass specified after the UNDER keyword (SQLSTATE 42704). The *service-class-name* cannot be the SYSDEFAULTSYSTEMCLASS service class or the SYSDEFAULTMAINTENANCECLASS service class (SQLSTATE 5U032).

UNDER *service-class-name*

Specifies a service superclass. The *service-class-name* must identify an existing service superclass (SQLSTATE 42704).

STATEMENT
This threshold applies to activities for a specific SQL statement. You identify the statement to use for the threshold by specifying the statement text or the statement's executable ID .

TEXT *statement-text*
This threshold applies to statements matching the text specified in *statement-text*. Both static and dynamic SQL statements are considered when the condition for the threshold is evaluated. At run time, the text specified for *statement-text* must be an exact match of the text of a statement in the package cache for the threshold to be violated. Differences in letter case or use of white space prevent a match from occurring between *statement-text* and any running SQL statement. The text for *statement-text* must be specified as a string constant. As such, the maximum length for the text of a statement for a statement threshold is 32 672 bytes, and not the usual 2 MB upper limit for statements.

Access plan differences do not affect statement matching. It is possible for multiple cached statements with same text but different access plans to match the threshold text defined by *statement-text*.

If a statement that otherwise matches the statement supplied for *statement-text* is altered or transformed during compilation in such a way that it differs from *statement-text*, the statements will not match. For example, if the statement concentrator is enabled, literal values might be replaced by parameter markers. No such transformation is applied to text supplied for the *statement-text* in the CREATE THRESHOLD statement. The text supplied to CREATE THRESHOLD must match exactly the transformed text of any statement of interest. You can determine the exact text of statements as they are executed using monitoring table functions such as **MON_GET_PKG_CACHE_STMT** and **MON_GET_ACTIVITY_DETAILS**.

The following predicates can be used with a statement threshold:

- **ACTIVITYTOTALRUNTIME**
- **ACTIVITYTOTALTIME**
- **CPUTIME**
- **ESTIMATEDSQLCOST**
- **SQLROWSREAD**
- **SQLROWSRETURNED**
- **SQLTEMPSPACE**

REFERENCE *executable-id*
This threshold applies to statements with text that matches the text of the statement with the specified executable ID. The database manager uses the executable ID to locate text of the statement from its section in the package cache. The text of the statement that is used for the threshold is that which was cached for the section at the time the threshold was created. For dynamic SQL, the statement referenced by the executable ID must be in the package cache. For static SQL, if the statement is not in the cache, the database manager retrieves it from the system catalogs.

Once the statement text is retrieved from the package cache, there is no direct relationship between the threshold and the specified executable ID; the cached section can even be evicted from the cache without impact on any threshold that was derived from it. Once the text associated with the executable ID is determined, the threshold created by this clause behaves in exactly the same way as one created by the STATEMENT TEXT clause.

WORKLOAD *workload-name*
This threshold applies to the specified workload. The *workload-name* must identify an existing workload (SQLSTATE 42704).

ENFORCEMENT *enforcement-scope*
The enforcement scope of the threshold.

DEFAULT
The default enforcement scope of the threshold will be used.

DATABASE
The threshold is enforced across all members within the definition domain; that is, all members of the database, and all members of the service class.

MEMBER
The threshold is enforced on a per member basis. There is no coordination across all members to enforce the threshold.

WORKLOAD OCCURRENCE
The threshold is enforced only within a workload occurrence. Two workload occurrences running concurrently on the same member will each have their own running count for this threshold.

ENABLE or DISABLE
Specifies whether or not the threshold is enabled for use by the database manager.

ENABLE
The threshold is used by the database manager to restrict the execution of database activities.

DISABLE
The threshold is not used by the database manager to restrict the execution of database activities.

WHEN *threshold-predicate*
Specifies the condition of the threshold.

TOTALMEMBERCONNECTIONS > *integer-value*
This condition defines an upper bound on the number of coordinator connections that can run concurrently on a member. This value can be zero or any positive integer (SQLSTATE 42820). A value of zero means that any new coordinator connection will be prevented from connecting. All currently running or queued connections will continue. The definition domain for this condition must be DATABASE, and the enforcement scope must be MEMBER (SQLSTATE 5U037). This threshold is not enforced for users with DBADM or WLMADM authority.

TOTALSCMEMBERCONNECTIONS > *integer-value*
This condition defines an upper bound on the number of coordinator connections that can run concurrently on a member in a specific service superclass. This value can be zero or any positive integer (SQLSTATE 42820). A value of zero means that any new connection will be prevented from joining the service class. All currently running or queued connections will continue. The definition domain for this condition must be SERVICE SUPERCLASS, and the enforcement scope must be MEMBER (SQLSTATE 5U037).

AND QUEUEDCONNECTIONS > *integer-value* or AND QUEUEDCONNECTIONS UNBOUNDED
Specifies a queue size for when the maximum number of coordinator connections is exceeded. This value can be any positive integer, including zero (SQLSTATE 42820). A value of zero means that no coordinator connections are queued. Specifying UNBOUNDED will queue every connection that exceeds the specified maximum number of coordinator connections, and the *threshold-exceeded-actions* will never be executed. The default is zero.

CONNECTIONIDLETIME > *integer-value* DAY | DAYS | HOUR | HOURS | MINUTE | MINUTES
This condition defines an upper bound for the amount of time the database manager will allow a connection to remain idle. This value can be any positive integer (not zero) (SQLSTATE 42820). Use a valid duration keyword to specify an appropriate unit of time for *integer-value*. The definition domain for this condition must be DATABASE or SERVICE SUPERCLASS, and the enforcement scope must be DATABASE (SQLSTATE 5U037). This condition is enforced at the coordinator member.

If you specify the STOP EXECUTION action with CONNECTIONIDLETIME thresholds, the connection for the application is dropped when the threshold is exceeded. Any subsequent attempt by the application to access the data server will receive SQLSTATE 5U026.

The maximum value for this threshold is 2 147 483 640 seconds. Any value specified that has a seconds equivalent larger than 2 147 483 640 seconds will be set to this number of seconds.

CONCURRENTWORKLOADOCCURRENCES > *integer-value*
This condition defines an upper bound on the number of concurrent occurrences for the workload on each member. This value can be any positive integer (not zero) (SQLSTATE 42820). The

definition domain for this condition must be WORKLOAD and the enforcement scope must be MEMBER (SQLSTATE 5U037).

CONCURRENTWORKLOADACTIVITIES > *integer-value*
This condition defines an upper bound on the number of concurrent coordinator activities and nested activities for the workload on each member. This value can be any positive integer (not zero) (SQLSTATE 42820). The definition domain for this condition must be WORKLOAD and the enforcement scope for this condition must be WORKLOAD OCCURRENCE (SQLSTATE 5U037).

Each nested activity must satisfy the following conditions:

- It must be a recognized coordinator activity. Any nested coordinator activity that does not fall within the recognized types of activities will not be counted. Similarly, nested subagent activities, such as remote node requests, are not counted.
- It must be directly invoked from user logic, such as a user-written procedure issuing SQL statements.

Internal SQL activities, such as those initiated by the setting of a constraint or the refreshing of a materialized query table, are also not counted by this threshold, because they are initiated by the database manager and not directly invoked by user logic.

CONCURRENTDBCOORDACTIVITIES > *integer-value*
This condition defines an upper bound on the number of recognized database coordinator activities that can run concurrently on all members in the specified domain. This value can be zero or any positive integer (SQLSTATE 42820). A value of zero means that any new database coordinator activities will be prevented from executing. All currently running or queued database coordinator activities will continue. The definition domain for this condition must be DATABASE, work action (a threshold for a work action definition domain is created using a CREATE WORK ACTION SET or ALTER WORK ACTION SET statement, and the work action set must be applied to a workload or a database), SERVICE SUPERCLASS, or SERVICE SUBCLASS. Also, the enforcement scope must be DATABASE (SQLSTATE 5U037) in environments other than Db2 pureScale, where the condition is enforced across the entire database, and MEMBER (SQLSTATE 5U037) in Db2 pureScale where the condition is enforced at each coordinator member. All activities are tracked by this condition, except for the following items:

- CALL statements are not controlled by this threshold, but all nested child activities started within the called routine are under this threshold's control. Anonymous blocks and autonomous routines are classified as CALL statements.
- User-defined functions are controlled by this threshold, but child activities nested in a user-defined function are not controlled. If an autonomous routine is called from within a user defined function, neither the autonomous routine nor any child activities of the autonomous routine are under threshold control.
- Trigger actions that invoke CALL statements and the child activities of these CALL statements are not controlled by this threshold. INSERT, UPDATE, or DELETE statements that can cause a trigger to activate continue to be under threshold control.
- To manage concurrency with a CALL statement, you may be able to use the TOTALSCPARTITIONCONNECTIONS threshold. The TOTALSCPARTITIONCONNECTIONS threshold is effective for controlling concurrency of CALL statements when your workload consists of transient connections. Transient connections are connections that are established only during the procedure invocation. The TOTALSCPARTITIONCONNECTIONS threshold is not appropriate if your workload consists of long-lived connections.

When a threshold is defined as part of a work action set, the enforcement scope is determined automatically based on the current environment (MEMBER, if the current environment is Db2 pureScale; DATABASE, if it is otherwise).

Important: Before using CONCURRENTDBCOORDACTIVITIES thresholds, be sure to become familiar with the effects that they can have on the database system.

For more information, refer to "CONCURRENTDBCOORDACTIVITIES threshold" in *Db2 Workload Management Guide and Reference*.

AND QUEUEDACTIVITIES > *integer-value* or AND QUEUEDACTIVITIES UNBOUNDED
Specifies a queue size for when the maximum number of database coordinator activities is exceeded. This value can be zero or any positive integer (SQLSTATE 42820). A value of zero means that no database coordinator activities are queued. Specifying UNBOUNDED will queue every database coordinator activity that exceeds the specified maximum number of database coordinator activities, and the *threshold-exceeded-actions* will never be executed. The default is zero.

Note: If a threshold action of CONTINUE is specified for a queuing threshold, it effectively makes the size of the queue unbounded, regardless of any hard value specified for the queue size.

ESTIMATEDSQLCOST > *bigint-value*
This condition defines an upper bound for the optimizer-assigned cost (in timerons) of an activity. This value can be any positive big integer (not zero) (SQLSTATE 42820). The definition domain for this condition must be DATABASE, work action (a threshold for a work action definition domain is created using a CREATE WORK ACTION SET or ALTER WORK ACTION SET statement, and the work action set must be applied to a workload or a database), SERVICE SUPERCLASS, SERVICE SUBCLASS, or WORKLOAD, and the enforcement scope must be DATABASE (SQLSTATE 5U037). This condition is enforced at the coordinator member. Activities tracked by this condition are:

- Coordinator activities of type data manipulation language (DML).
- Nested DML activities that are invoked from user logic. Consequently, DML activities that can be initiated by the database manager through internal SQL are not tracked by this condition (unless their cost is included in the parent's estimate, in which case they are indirectly tracked).

SQLROWSRETURNED > *integer-value*
This condition defines an upper bound for the number of rows returned to a client application from the application server. This value can be any positive integer (not zero) (SQLSTATE 42820). The definition domain for this condition must be DATABASE, work action (a threshold for a work action definition domain is created using a CREATE WORK ACTION SET or ALTER WORK ACTION SET statement, and the work action set must be applied to a workload or a database), SERVICE SUPERCLASS, SERVICE SUBCLASS, or WORKLOAD, and the enforcement scope must be DATABASE (SQLSTATE 5U037). This condition is enforced at the coordinator member. Activities tracked by this condition are:

- Coordinator activities of type DML.
- Nested DML activities that are derived from user logic. Activities that are initiated by the database manager through internal SQL are not affected by this condition.

Result sets returned from within a procedure are treated separately as individual activities. There is no aggregation of the rows that are returned by the procedure itself.

ACTIVITYTOTALTIME > *integer-value* DAY | DAYS | HOUR | HOURS | MINUTE | MINUTES | SECONDS
This condition defines an upper bound for the amount of time the database manager will allow an activity to execute, including the time the activity was queued. The definition domain for this condition must be DATABASE, work action (a threshold for a work action definition domain is created using a CREATE WORK ACTION SET or ALTER WORK ACTION SET statement, and the work action set must be applied to a workload or a database), SERVICE SUPERCLASS, SERVICE SUBCLASS, or WORKLOAD, and the enforcement scope must be DATABASE (SQLSTATE 5U037). This condition is logically enforced at the coordinator member.

The specified *integer-value* must be an integer that is greater than zero (SQLSTATE 42820). Use a valid duration keyword to specify an appropriate unit of time for *integer-value*. If the specified time unit is SECONDS, the value must be a multiple of 10 (SQLSTATE 42615). The maximum value that can be specified for this threshold is 2 147 483 640 seconds. If any value (using the DAY, HOUR, MINUTE, or SECONDS time unit) has a seconds equivalent larger than the maximum value, an error is returned (SQLSTATE 42615).

UOWTOTALTIME > *integer-value* DAY | DAYS | HOUR | HOURS | MINUTE | MINUTES | SECONDS

This condition defines an upper bound for the amount of time the database manager will allow a unit of work to execute. This value can be any non-zero positive integer (SQLSTATE 42820). Use a valid duration keyword to specify an appropriate unit of time for *integer-value*. If the specified time unit is SECONDS, the value must be a multiple of 10 (SQLSTATE 42615). The definition domain for this condition must be DATABASE, SERVICE SUPERCLASS, or WORKLOAD, and the enforcement scope must be DATABASE (SQLSTATE 5U037). This condition is enforced at the coordinator member.

The maximum value that can be specified for this threshold is 2 147 483 640 seconds. If any value (using the DAY, HOUR, MINUTE, or SECONDS time unit) has a seconds equivalent larger than the maximum value, an error is returned (SQLSTATE 42615).

SQLTEMPSPACE > *integer-value* K | M | G

This condition defines the maximum amount of system temporary space that can be consumed by an SQL statement on a member. This value can be any positive integer (not zero) (SQLSTATE 42820).

If *integer-value K* (in either upper- or lowercase) is specified, the maximum size is 1024 times *integer-value*. If *integer-value M* is specified, the maximum size is 1 048 576 times *integer-value*. If *integer-value G* is specified, the maximum size is 1 073 741 824 times *integer-value*.

The definition domain for this condition must be DATABASE, work action (a threshold for a work action definition domain is created using a CREATE WORK ACTION SET or ALTER WORK ACTION SET statement, and the work action set must be applied to a workload or a database), SERVICE SUPERCLASS, SERVICE SUBCLASS, or WORKLOAD, and the enforcement scope must be MEMBER (SQLSTATE 5U037). Activities tracked by this condition are:

- Coordinator activities of type DML and corresponding subagent work (subsection execution).
- Nested DML activities that are derived from user logic and their corresponding subagent work (subsection execution). Activities that are initiated by the database manager through an internal SQL are not affected by this condition.

AGGSQLTEMPSPACE > *integer-value* K | M | G

This condition defines the maximum amount of system temporary space that can be consumed by a set of statements in a service class on a member. This value can be any positive integer (not zero) (SQLSTATE 42820).

If *integer-value* K (in either upper- or lowercase) is specified, the maximum size is 1024 times *integer-value*. If *integer-value* M is specified, the maximum size is 1 048 576 times *integer-value*. If *integer-value* G is specified, the maximum size is 1 073 741 824 times *integer-value*.

The definition domain for this condition must be SERVICE SUBCLASS and the enforcement scope must be MEMBER (SQLSTATE 5U037).

Activities contributing to the aggregate that is tracked by this condition are:

- Coordinator activities of type DML and corresponding subagent work like subsection execution.
- Nested DML activities that are derived from user logic and their corresponding subagent work like subsection execution. Activities initiated by the database manager through an internal SQL statement are not affected by this condition.

SQLROWSREAD > *bigint-value*

This condition defines an upper bound on the number of rows that may be read by an activity during its lifetime on a particular member. This value can be any positive big integer (not zero) (SQLSTATE 42820). Note that the number of rows read is different from the number of rows returned, which is controlled by the SQLROWSRETURNED condition.

The definition domain for this condition must be DATABASE, SERVICE CLASS, a service subclass (SERVICE CLASS specifying the UNDER clause), WORKLOAD or a work action (a threshold for a work action definition domain is created using a CREATE WORK ACTION SET or ALTER WORK ACTION SET statement, and the work action set must be applied to a workload or a database),

and the enforcement scope must be MEMBER (SQLSTATE 5U037). This condition is enforced independently at each member.

Activities tracked by this condition are:

- Coordinator activities of type DML and corresponding subagent work (like subsection execution).
- Internal SQL activities like those initiated by the setting of a constraint, or the refreshing of a materialized query table, are also not tracked by this threshold, because they are initiated by the database manager and not directly invoked by user logic.

CHECKING EVERY *integer-value* SECOND | SECONDS
Specifies how frequently the threshold condition is checked for an activity. The threshold is checked at the end of each request (like a fetch operation, for example) and on the interval defined by the CHECKING clause. The CHECKING clause defines an upper bound on how long a threshold violation may go undetected. The default is 60 seconds. The value can be any positive integer (not zero) with a maximum value of 86400 seconds (SQLSTATE 42820). Setting a low value may impact system performance negatively.

SQLROWSREADINSC > *bigint-value*
This condition defines an upper bound on the number of rows that may be read by an activity on a particular member while it is executing in a service subclass. Rows read before executing in the service subclass specified are not counted. This value can be any positive big integer (not zero) (SQLSTATE 42820). Note that the number of rows read is different from the number of rows returned, which is controlled by the SQLROWSRETURNED condition.

The definition domain for this condition must be a service subclass (SERVICE CLASS specifying the UNDER clause) and the enforcement scope must be MEMBER (SQLSTATE 5U037). This condition is enforced independently at each member.

Activities tracked by this condition are:

- Coordinator activities of type DML and corresponding subagent work (like subsection execution).
- Internal SQL activities like those initiated by the setting of a constraint, or the refreshing of a materialized query table, are also not tracked by this threshold, because they are initiated by the database manager and not directly invoked by user logic.

CHECKING EVERY *integer-value* SECOND | SECONDS
Specifies how frequently the threshold condition is checked for an activity. The threshold is checked at the end of each request (like a fetch operation, for example) and on the interval defined by the CHECKING clause. The CHECKING clause defines an upper bound on how long a threshold violation may go undetected. The default is 60 seconds. The value can be any positive integer (not zero) with a maximum value of 86400 seconds (SQLSTATE 42820).Setting a low value may impact system performance negatively.

CPUTIME > *integer-value* HOUR | HOURS | MINUTE | MINUTES | SECOND | SECONDS
This condition defines an upper bound for the amount of processor time that an activity may consume during its lifetime on a particular member. The processor time tracked by this threshold is measured from the time that the activity starts executing. This value can be any positive integer (not zero) (SQLSTATE 42820).

The definition domain for this condition must be DATABASE, a service superclass (SERVICE CLASS), a service subclass (SERVICE CLASS specifying the UNDER clause), WORKLOAD or work action (a threshold for a work action definition domain is created using a CREATE WORK ACTION SET or ALTER WORK ACTION SET statement, and the work action set must be applied to a workload or a database), and the enforcement scope must be MEMBER (SQLSTATE 5U037). This condition is enforced independently at each member.

Activities tracked by this condition are:

- Coordinator activities of type DML and corresponding subagent work (like subsection execution).
- Internal SQL activities, like those initiated by the setting of a constraint or the refreshing of a materialized query table, are also not tracked by this threshold, because they are initiated by the database manager and not directly invoked by user logic.

- Activities of type CALL. For CALL activities, the processor time tracked for the procedure does not include the processor time used by any child activities or by any fenced mode processes. The threshold condition will be checked only upon return from user logic to the database engine. For example: During the execution of a trusted routine, the threshold condition will be checked only when the routine issues a request to the database engine).

CHECKING EVERY *integer-value* SECOND | SECONDS
Specifies how frequently the threshold condition is checked for an activity. The granularity of the CPUTIME threshold is approximately this number multiplied by the degree of parallelism for the activity. For example: If the threshold is checked every 60 seconds and the degree of parallelism is 2, the activity might use an extra 2 minutes of processor time instead of 1 minute before the threshold violation is detected. The default is 60 seconds. The value can be any positive integer (not zero) with a maximum value of 86400 seconds (SQLSTATE 42820). Setting a low value may impact system performance negatively.

CPUTIMEINSC > *integer-value* HOUR | HOURS | MINUTE | MINUTES | SECOND | SECONDS
This condition defines an upper bound for the amount of processor time that an activity may consume on a particular member while it is executing in a particular service subclass. The processor time tracked by this threshold is measured from the time that the activity starts executing in the service subclass identified in the threshold domain. Any processor time used before that point is not counted toward the limit imposed by this threshold. This value can be any positive integer (not zero) (SQLSTATE 42820).

The definition domain for this condition must be a service subclass (SERVICE CLASS specifying the UNDER clause), and the enforcement scope must be MEMBER (SQLSTATE 5U037). This condition is enforced independently at each member.

Activities tracked by this condition are:

- Coordinator activities of type DML and corresponding subagent work (like subsection execution).
- Internal SQL activities, like those initiated by the setting of a constraint or the refreshing of a materialized query table, are also not tracked by this threshold, because they are initiated by the database manager and not directly invoked by user logic.
- Activities of type CALL. For CALL activities, the processor time tracked for the procedure does not include the processor time used by any child activities or by any fenced mode processes. The threshold condition will be checked only upon return from user logic to the database engine. For example: During the execution of a trusted routine, the threshold condition will be checked only when the routine issues a request to the database engine).

CHECKING EVERY *integer-value* SECOND | SECONDS
Specifies how frequently the threshold condition is checked for an activity. The granularity of the CPUTIMEINSC threshold is approximately this number multiplied by the degree of parallelism for the activity. For example: If the threshold is checked every 60 seconds and the degree of parallelism is 2, the activity might use an extra 2 minutes of processor time instead of 1 minute before the threshold violation is detected. The default is 60 seconds. The value can be any positive integer (not zero) with a maximum value of 86400 seconds (SQLSTATE 42820). Setting a low value may impact system performance negatively.

ACTIVITYTOTALRUNTIME > *integer-value* DAY | DAYS | HOUR | HOURS | MINUTE | MINUTES | SECONDS
This condition is used to define an upper bound for the amount of time the database manager allows an activity to run. The amount of time does not include the time that the activity was queued by a WLM concurrency threshold. The definition domain for this condition must be one of the following thresholds (SQLSTATE 5U037):

- Database
- Service superclass
- Service subclass
- Statement
- Workload

- Work action [1]

1. A threshold for a work action definition domain is created by using a CREATE WORK ACTION SET or ALTER WORK ACTION SET statement. The work action set must be applied to a workload or a database.

The enforcement scope must be DATABASE (SQLSTATE 5U037).

The specified *integer-value* must be an integer that is greater than zero (SQLSTATE 42820). Use a valid duration keyword to specify an appropriate unit of time for *integer-value*. If the specified time unit is SECONDS, the value must be a multiple of 10 (SQLSTATE 42615). The maximum value that can be specified for this threshold is 2 147 483 640 seconds. If any value for the DAY, HOUR, MINUTE, or SECONDS time unit has a seconds equivalent larger than the maximum value, an error is returned (SQLSTATE 42615).

ACTIVITYTOTALRUNTIMEINALLSC > *integer-value* DAY | DAYS | HOUR | HOURS | MINUTE | MINUTES | SECONDS

This condition is used to define an upper bound for the amount of time the database manager allows an activity to run. The amount of time does not include the time that the activity was queued by a WLM concurrency threshold. The execution time that is tracked by this threshold is measured from the time that the activity starts running.

The definition domain for this condition must be service subclass (SERVICE CLASS specifying the UNDER clause), and the enforcement scope must be DATABASE (SQLSTATE 5U037).

The specified *integer-value* must be an integer that is greater than zero (SQLSTATE 42820). Use a valid duration keyword to specify an appropriate unit of time for *integer-value*. If the specified time unit is SECONDS, the value must be a multiple of 10 (SQLSTATE 42615). The maximum value that can be specified for this threshold is 2 147 483 640 seconds. If any value for the DAY, HOUR, MINUTE, or SECONDS time unit has a seconds equivalent larger than the maximum value, an error is returned (SQLSTATE 42615).

SORTSHRHEAPUTIL > *integer-value* PERCENT

Attention: This feature is available in Db2 Version 11.5 Mod Pack 2 and later versions.

This condition defines the maximum shared sort memory that may be requested by a query as a percentage of the total database shared sort memory (sheapthres_shr). When the adaptive workload manager is enabled, the threshold considers both estimated and actual memory requirements for a query. Any positive integer between 1 to 100 can be specified as a percent value. The execution time that is tracked by this threshold is measured from the time that the activity starts running.

The definition domain for this condition must be DATABASE, work action (a threshold for a work action definition domain is created using a CREATE WORK ACTION SET or ALTER WORK ACTION SET statement, and the work action set must be applied to a workload or a database), SERVICE SUPERCLASS, SERVICE SUBCLASS, STATEMENT or WORKLOAD, and the enforcement scope must be MEMBER (SQLSTATE 5U037).

Activities tracked by this condition are:

- Coordinator activities of type data manipulation language (DML).
- Nested DML activities that are directly invoked from user logic.

AND BLOCKING ADMISSION FOR *integer-value*

Specifies that action will only be taken if the sort memory requirements are exceeded, work is currently queued behind the violating activity, the queued work is blocking on sort memory and WLM admission control has not admitted any requests for the specified amount of time. For work inside the WLM admission queue, this condition will only be evaluated once a request reaches the front of the admission queue. Every time a request is allowed by admission control, the queue time will be resset. If multiple requests violate this threshold a cascading effect will be observed until something that doesn't violate this threshold is found or the last request is reached (as in, no other requests behind).

The maximum value for this threshold is 2147483640 seconds. Any value specified that has a seconds equivalent larger than 2147483640 seconds will be set to this number of seconds. The time specified has a minimum accuracy of 10 seconds, so any value specified is subject to accuracy of this amount. A value of zero is equivalent to not specifying a BLOCKING ADMISSION FOR clause.

DATATAGINSC IN *(integer-constant, ...)*

This condition defines one or more data tag values specified on a table space that the activity touches. The data tag on a table space, or its underlying storage group (where applicable), can be either not be set or set to a value from 1 to 9. If the activity touches a table space that has no data tag set (at either the table space or the storage group level), this threshold will not have any affect on that activity. The definition domain for this condition must be a service subclass (SERVICE CLASS specifying the UNDER clause), and the enforcement scope must be DATABASE PARTITION (SQLSTATE 5U037). This condition is enforced independently at each database partition.

Activities tracked by this condition are:

- Coordinator activities of type data manipulation language (DML).
- Nested DML activities that are directly invoked from user logic.

DML activities that can be initiated by the database manager through internal SQL are not tracked by this condition.

This threshold is checked only when a scan is opened on a table or when an insert is performed into a table. Fetching data from a table after a scan has been opened will not violate the threshold.

DATATAGINSC NOT IN *(integer-constant, ...)*

This condition defines one or more data tag values not specified on a table space that the activity touches. The data tag on a table space, or its underlying storage group (where applicable), can be either not be set or set to a value from 1 to 9. If the activity touches a table space that has no data tag set (either at the table space or the storage group level), this threshold will not have any affect on that activity. The definition domain for this condition must be a service subclass (SERVICE CLASS specifying the UNDER clause) and the enforcement scope must be DATABASE PARTITION (SQLSTATE 5U037). This condition is enforced independently at each database partition.

Activities tracked by this condition are:

- Coordinator activities of type data manipulation language (DML).
- Nested DML activities that are directly invoked from user logic.

DML activities that can be initiated by the database manager through internal SQL are not tracked by this condition.

This threshold is checked only when a scan is opened on a table or when an insert is performed into a table. Fetching data from a table after a scan has been opened will not violate the threshold.

threshold-exceeded-actions

Specifies what action is to be taken when a condition is exceeded. Each time that a condition is exceeded, an event is recorded in the threshold violations event monitor, if one is active.

COLLECT ACTIVITY DATA

Specifies that data about each activity that exceeded the threshold is to be sent to any active activities event monitor, when the activity completes. The default is COLLECT ACTIVITY DATA NONE. If COLLECT ACTIVITY DATA is specified, the default is WITHOUT DETAILS. The COLLECT ACTIVITY DATA setting does not apply to non-activity thresholds, such as the following: CONNECTIONIDLETIME, TOTALDBPARTITIONCONNECTIONS, TOTALSCPARTITIONCONNECTIONS, CONCURRENTWORKLOADOCCURRENCES, UOWTOTALTIME.

NONE

Specifies that activity data should not be collected for each activity that exceeds the threshold.

ON COORDINATOR MEMBER

Specifies that the activity data is to be collected only at the coordinator member of the activity.

ON ALL MEMBERS
Specifies that the activity data is to be collected at all members on which the activity is processed. On remote members, a record for the activity may be captured multiple times as the activity comes and goes on those members. For predictive thresholds, activity information is collected at all members only if you also specify the CONTINUE action for exceeded thresholds. For reactive thresholds, the ON ALL MEMBERS clause has no effect and activity information is always collected only at the coordinator member. For both predictive and reactive thresholds, any activity details, section information, or values will be collected only at the coordinator member.

WITHOUT DETAILS
Specifies that data about each activity associated with the work class for which this work action is defined is to be sent to any active activities event monitor, when the activity completes execution. Details about statement, compilation environment, and section environment data are not sent.

WITH

DETAILS
Specifies that statement and compilation environment data is to be sent to any active activities event monitor, for those activities that have them. Section environment data is not sent.

SECTION
Specifies that statement, compilation environment, section environment data, and section actuals are to be sent to any active activities event monitor for those activities that have them. DETAILS must be specified if SECTION is specified. For predictive thresholds, section actuals will be collected on any member where the activity data is collected. For reactive thresholds, section actuals will be collected only on the coordinator member.

AND VALUES
Specifies that input data values are to be sent to any active activities event monitor, for those activities that have them. This data does not include SQL statements that are compiled by using the REOPT ALWAYS bind option.

STOP EXECUTION
