## About this book

---

The *System Monitor Guide and Reference* describes how to collect different kinds of information about your database and the database manager.

It also explains how you can use the information you collected to understand database activity, improve performance, and determine the cause of problems.

# Chapter 1. Interfaces for database monitoring

There are two ways to monitor operations in your database. You can view information that shows the state of various aspects of the database at a specific point in time. Or, you can set up event monitors to capture historical information as specific types of database events take place.

You can monitor your database operations in real-time using monitoring table functions. For example, you can use a monitoring table function to examine the total amount of space used in a table space. These table functions let you examine *monitor elements* and metrics that report on virtually all aspects of database operations using SQL. The monitoring table functions use a lightweight, high-speed monitoring infrastructure.

In addition to the monitoring table functions, [snapshot monitoring](#) routines are also available. However, the snapshot monitoring facilities use an older monitoring infrastructure and are no longer being enhanced. So, where possible, use the monitoring table functions instead.

For information on how to move from snapshot monitoring to the latest monitoring interfaces, see [Db2 monitoring: Migrate from snapshot monitor interfaces to in-memory metrics monitor interfaces](#), on the Hybrid Data Management Community site.

**Note:** The new in-memory MON\_ table functions provide monitoring for only the connected database, unlike the deprecated SNAP\_GET\_ table functions. This behavior provides much better security separation and significantly reduces the impact on system resources during monitoring collection. Snapshot monitoring routines enable users to monitor other databases within the same instance. Consider this when planning your move from snapshot monitoring.

Event monitors capture information about database operations over time, as specific types of events occur. For example, you can create an event monitor to capture information about locks and deadlocks as they occur in the system. Or, you might create an event monitor to record when a threshold that you specify (for example, the total processor time used by an application or workload) is exceeded. Event monitors generate output in different formats, and can write this output to regular tables. Some event monitors have additional output options.

The IBM Db2® Data Management Console provides a browser-based interface that you can use to isolate and analyze typical database performance problems. You can also view a summary of the health of your databases and drill down. For more information, see the [Monitoring](#) section of the IBM Db2 Data Management Console documentation.

---

## Database monitoring

The term *database monitoring* refers to the tasks associated with examining the operational status of your database.

Database monitoring is a vital activity for the maintenance of the performance and health of your database management system. To facilitate monitoring, the database management system collects information from the database manager, its databases, and any connected applications. With this information you can perform the following types of tasks, and more:

- Forecast hardware requirements based on database usage patterns.
- Analyze the performance of individual applications or SQL queries.
- Track the usage of indexes and tables.
- Pinpoint the cause of poor system performance.
- Assess the impact of optimization activities (for example, altering database manager configuration parameters, adding indexes, or modifying SQL queries).

### Related information

[Technical article: Db2 monitoring enhancements for BLU Acceleration](#)

## Built-in administrative routines and views for monitoring

---

You can access monitor data by using built-in administrative routines and views. These routines and views are a light-weight alternative to the traditional system monitor that collect and query data for systems, activities, or data objects.

Data for monitored elements are continually accumulated in memory and available for querying. You can choose to receive data for a single object or for all objects. For example, choose service class A or table TABLE1 as single objects.

When using these built-in routines and views in partitioned database environments or Db2 pureScale® environments, you can choose to receive data for a single partition, all partitions, one member, or all members. If you choose to receive data for all partitions or all members, the table functions return one row for each partition. Using SQL, you can sum the values across partitions to obtain the value of a monitor element across partitions.

### Related information

[Technical article: Db2 monitoring: Migrate from snapshot monitor interfaces to in-memory metrics monitor interfaces](#)

## Monitoring request information using table functions

The request monitoring perspective encompasses the complete volume of work and effort expended by the data server to process application requests. From this perspective, you can determine what the data server is doing as a whole as well as for particular subsets of application requests.

Monitor elements for this perspective, referred to as request monitor elements, cover the entire range of data server operations associated with processing requests.

Request monitor elements are continually accumulated and aggregated in memory so they are immediately available for querying. Request monitor elements are aggregated across requests at various levels of the workload management (WLM) object hierarchy: by unit of work, by workload, by service class. They are also aggregated by connection.

Use the following table functions for accessing current request monitoring information:

- MON\_GET\_AGENT
- MON\_GET\_CONNECTION and MON\_GET\_CONNECTION\_DETAILS
- MON\_GET\_SERVICE\_SUBCLASS and MON\_GET\_SERVICE\_SUBCLASS\_DETAILS
- MON\_GET\_UNIT\_OF\_WORK and MON\_GET\_UNIT\_OF\_WORK\_DETAILS
- MON\_GET\_UTILITY
- MON\_GET\_WORKLOAD and MON\_GET\_WORKLOAD\_DETAILS

This set of table functions enables you to drill down or focus on request monitor elements at a particular level of aggregation. Table functions are provided in pairs: one for relational access to commonly used data and the other for XML access to the complete set of available monitor elements.

The request monitoring information is collected by these table functions by default for a database created in version 11.5. You can change default settings using one or both of the following methods:

- Setting the **mon\_req\_metrics** database configuration parameter to specify the minimum level of collection for all service classes.
- Issue the CREATE SERVICE CLASS or ALTER SERVICE CLASS statement with the COLLECT REQUEST METRICS clause to specify the level of collection for a service superclass. Use this setting to increase the level of collection for a given service class over the minimum level of collection set for all service classes.

If you specify NONE, request monitor elements are not collected. If you specify BASE, base level of data for all request monitor elements is collected for all service classes.

## Example

The following example shows how to collect request monitoring information for only a subset of service classes:

1. Set the database configuration parameter **mon\_req\_metrics** to NONE as follows:

```
UPDATE DB CFG FOR SAMPLE USING mon_req_metrics NONE
```

2. For each required service class, set the level of collection by issuing the ALTER SERVICE CLASS statement as follows:

```
ALTER SERVICE CLASS service-class-name COLLECT REQUEST METRICS BASE.
```

## Monitoring activities using table functions

The activity monitoring perspective focuses on the subset of data server processing related to executing activities. In the context of SQL statements, the term activity refers to the execution of the section for a SQL statement.

Monitor elements for this perspective, referred to as activity monitor elements, are a subset of the request monitor elements. Activity monitor elements measure aspects of work done for statement section execution. Activity monitoring includes other information such as SQL statement text for the activity.

For activities in progress, activity metrics are accumulated in memory. For activities that are SQL statements, activity metrics are also accumulated in the package cache. In the package cache activity metrics are aggregated over all executions of each SQL statement section.

Use the following table functions to access current data for activities:

- MON\_GET\_ACTIVITY
- MON\_GET\_ACTIVITY\_DETAILS
- MON\_GET\_PKG\_CACHE\_STMT
- MON\_GET\_PKG\_CACHE\_STMT\_DETAILS

Activity monitoring information is collected by default for a new database. You can change default settings using one or both of the following settings:

- The **mon\_act\_metrics** database configuration parameter specifies the minimum level of collection in all workloads.
- The COLLECT ACTIVITY METRICS clause of the CREATE/ALTER WORKLOAD statement specifies the level of collection for a given workload over the minimum level of collection set for all workloads.

The possible values for each setting are the following:

### None

No activity monitor elements are collected

### Base

All activity monitor elements are collected

For example, to collect activity monitor elements for only selected workloads, do the following:

1. Set the **mon\_act\_metrics** database configuration parameter to NONE.
2. Set the COLLECT ACTIVITY METRICS clause of the CREATE/ALTER WORKLOAD statement to BASE. By default, the values for other workloads is NONE.

## Monitoring data objects using table functions

The data object monitoring perspective provides information about operations performed on data objects, that is tables, indexes, buffer pools, table spaces, and containers.

A different set of monitor elements is available for each object type. Monitor elements for a data object are incremented each time a request involves processing that object. For example, when processing a request that involves reading rows from a particular table, the metric for rows read is incremented for that table.

Use the following table functions to access current details for data objects:

- MON\_GET\_BUFFERPOOL
- MON\_GET\_TABLESPACE
- MON\_GET\_CONTAINER
- MON\_GET\_TABLE
- MON\_GET\_INDEX

These table functions return data in a relational form.

You cannot access historical data for data objects.

Data object monitor elements are collected by default for new databases. You can use the **mon\_obj\_metrics** database configuration parameter to reduce the amount of data collected by the table functions.

The possible values for this configuration parameter are the following:

### None

No data object monitor elements are collected

### Base

Some data object monitor elements are collected

### Extended

All data object monitor elements are collected

To stop collecting data object monitor elements reported by the following table functions, set the **mon\_obj\_metrics** configuration parameter to NONE.

- MON\_GET\_BUFFERPOOL
- MON\_GET\_TABLESPACE
- MON\_GET\_CONTAINER

## Object usage

When SQL statements are executed, they use various database objects, such as tables and indexes. Knowing which database objects a statement accesses and how the statement affects them can help you identify targets for monitoring or performance tuning.

The following table shows the entities that you can use to explore the relationship between database objects and statements.

Table 1. Ways to identify object usage

Mechanism	Definition	Usage
Usage list	A usage list is a database object that records each DML statement section that references a particular table or index and captures statistics about that section as it executes.	Identify the statements that affected a table or index. If you notice an unusual value for a metric when monitoring a database object, use a usage list to determine whether a particular statement contributed to that metric. You can also view statistics for each statement that affected the object.
Section explain with actuals	A section explain is a set of information about the access plan that the optimizer chose for an SQL statement. You can capture section actuals as part of the explain. Section actuals are runtime statistics that are collected when a section executes.	Identify the tables or indexes that a statement affects. You can view statistics for each table or index and use these statistics to determine how the statement affects each object and where tuning might be required.

You can use the information in a usage list or section explain with actuals as baseline data for performance tuning. Collect information about object usage before tuning statements or database configuration parameters. After tuning, collect the information again to verify that tuning improved performance.

### ***Identifying the statements that affect a table***

Use usage lists to identify DML statement sections that affect a particular table when the statement sections execute. You can view statistics for each statement and use these statistics to determine where additional monitoring or tuning might be required.

### **Before you begin**

Do the following tasks:

- Identify a table for which you want to view object usage statistics. You can use the MON\_GET\_TABLE table function to view monitor metrics for one or more tables.
- To issue the required statements, ensure that the privileges that are held by the authorization ID of each statement include DBADM authority or SQLADM authority.
- Ensure that you have EXECUTE privilege on the MON\_GET\_TABLE\_USAGE\_LIST and MON\_GET\_USAGE\_LIST\_STATUS table functions.

### **About this task**

When you view the output of the MON\_GET\_TABLE table function, you might see an unusual value for a monitor element. You can use usage lists to determine whether any DML statements contributed to this value.

Usage lists contain statistics about factors like locks and buffer pool usage for each statement that affected a table during a particular time frame. If you determine that a statement affected a table negatively, use these statistics to determine where further monitoring might be required or how the statement can be tuned.

## Procedure

To identify the statements that affect a table:

1. Set the **mon\_obj\_metrics** configuration parameter to EXTENDED by issuing the following command:

```
DB2 UPDATE DATABASE CONFIGURATION USING MON_OBJ_METRICS EXTENDED
```

Setting this configuration parameter to EXTENDED ensures that statistics are collected for each entry in the usage list.

2. Create a usage list for the table by using the CREATE USAGE LIST statement.  
For example, to create the INVENTORYUL usage list for the SALES.INVENTORY table, issue the following command:

```
CREATE USAGE LIST SALES.INVENTORYUL FOR TABLE SALES.INVENTORY
```

3. Activate the collection of object usage statistics by using the SET USAGE LIST STATE statement.  
For example, to activate collection for the INVENTORYUL usage list, issue the following command:

```
SET USAGE LIST SALES.INVENTORYUL STATE = ACTIVE
```

4. During the collection of object statistics, ensure that the usage list is active and that sufficient memory is allocated for the usage list by using the MON\_GET\_USAGE\_LIST\_STATUS table function.  
For example, to check the status of the INVENTORYUL usage list, issue the following command:

```
SELECT MEMBER,  
       STATE,  
       LIST_SIZE,  
       USED_ENTRIES,  
       WRAPPED  
FROM TABLE(MON_GET_USAGE_LIST_STATUS('SALES', 'INVENTORYUL', -2))
```

5. Run the statements for which you want to collect the object usage statistics.
6. When the time period for which you want to collect object usage statistics is elapsed, deactivate the collection of usage list data by using the SET USAGE LIST STATE statement.  
For example, to deactivate collection for the INVENTORYUL usage list, issue the following command:

```
SET USAGE LIST SALES.INVENTORYUL STATE = INACTIVE
```

7. View the information that you collected by using the MON\_GET\_TABLE\_USAGE\_LIST function.  
You can view statistics for a subset or for all of the statements that affected the table during the time period for which you collected statistics.

For example, to see only the 10 statements that read the most rows of the table, issue the following command:

```
SELECT MEMBER,  
       EXECUTABLE_ID,  
       NUM_REFERENCES,  
       NUM_REF_WITH_METRICS,  
       ROWS_READ,  
       ROWS_INSERTED,  
       ROWS_UPDATED,  
       ROWS_DELETED  
FROM TABLE(MON_GET_TABLE_USAGE_LIST('SALES', 'INVENTORYUL', -2))  
ORDER BY ROWS_READ DESC  
FETCH FIRST 10 ROWS ONLY
```

8. If you want to view the text of a statement that affected the table, use the value of the **executable\_id** element in the MON\_GET\_TABLE\_USAGE\_LIST output as input for the MON\_GET\_PKG\_CACHE\_STMT table function.

For example, issue the following command to view the text of a particular statement:

```
SELECT STMT_TEXT  
FROM TABLE  
(MON_GET_PKG_CACHE_STMT(NULL,  
x'01000000000000007C00000000000000000000000020020081126171720728997', NULL, -2))
```

9. Use the list of statements and the statistics that are provided for the statements to determine where additional monitoring or tuning, if any, is required.

For example, a statement that has a low value for the **pool\_writes** monitor element compared to the **direct\_writes** monitor element value might have buffer pool issues that require attention.

## What to do next

When you do not require the information in the usage list, free the memory that is associated with the usage list by using the SET USAGE LIST STATE statement. For example, to free the memory that is associated with the INVENTORYUL usage list, issue the following command:

```
SET USAGE LIST SALES.INVENTORYUL STATE = RELEASED
```

## Identifying how a statement affects database objects

Use a section explain that includes section actuals information to identify how a statement affects database objects. You can use statistics about how the statement section affected each table or index to determine whether additional monitoring or tuning is required.

## Before you begin

Do the following tasks:

- Identify a statement for which you want to view object usage statistics.
- Ensure that you migrated your explain tables to the database system.
- Ensure that automatic statistics profile generation is not enabled.
- Ensure that you have the privileges that are required to call the EXPLAIN\_FROM\_ACTIVITY procedure.

## About this task

After you identify a statement for which you want to view object usage statistics, you can get a section explain that includes section actuals information. Section actuals information indicates how the statement affected each table or index that the statement used when it executed.

Actuals information includes runtime statistics about factors like locks and buffer pool usage for each table or index. You can compare these statistics to baseline data and use them to determine where additional monitoring or tuning might be required.

## Procedure

To determine how database objects are affected by a statement:

1. Enable the collection of section actuals at the database level by issuing the following command:

```
DB2 UPDATE DATABASE CONFIGURATION USING SECTION_ACTUALS BASE
```

2. Create a workload to collect section actuals information for activities that are submitted by the application that issues the statement.  
For example, to create the ACTWORKLOAD workload for activities that are submitted by the TEST application and enable collection for those activities, issue the following command:

```
CREATE WORKLOAD ACTWORKLOAD APPLNAME ('TEST')  
COLLECT ACTIVITY DATA ON ALL WITH DETAILS,SECTION INCLUDE ACTUALS BASE
```

Enabling collection of section actuals can also be accomplished in the following ways:

- The CREATE SERVICE CLASS or ALTER SERVICE CLASS statement
- The CREATE WORK ACTION SET or ALTER WORK ACTION SET statement
- The WLM\_SET\_CONN\_ENV procedure
- The **section\_actuals** configuration parameter

3. Create an activity event monitor by using the CREATE EVENT MONITOR statement.  
For example, to create the ACTEVMON activity event monitor, issue the following command:

```
CREATE EVENT MONITOR ACTEVMON
FOR ACTIVITIES
WRITE TO TABLE
CONTROL (TABLE CONTROL_ACTEVMON ),
ACTIVITY (TABLE ACTIVITY_ACTEVMON ),
ACTIVITYSTMT (TABLE ACTIVITYSTMT_ACTEVMON ),
ACTIVITYVALS (TABLE ACTIVITYVALS_ACTEVMON ),
ACTIVITYMETRICS (TABLE ACTIVITYMETRICS_ACTEVMON )
```

4. Activate the activity event monitor that you created by using the SET EVENT MONITOR STATE statement.  
For example, to activate the ACTEVMON activity event monitor, issue the following command:

```
SET EVENT MONITOR ACTEVMON STATE 1
```

5. Run the application that issues the statement for which you want to view object statistics.
6. Find identifier information for the statement section by using the following command to query the activity event monitor tables:

```
SELECT APPL_ID,
       UOW_ID,
       ACTIVITY_ID,
       STMT_TEXT
FROM ACTIVITYSTMT_ACTEVMON
```

7. Obtain a section explain with actuals by using the activity identifier information as input for the EXPLAIN\_FROM\_ACTIVITY procedure.  
For example, to obtain a section explain for a section with an application ID of \*N2.DB2INST1.0B5A12222841, a unit of work ID of 16, and an activity ID of 4, issue the following command:

```
CALL EXPLAIN_FROM_ACTIVITY( '*N2.DB2INST1.0B5A12222841', 16, 4, 'ACTEVMON',
'MYSCHEMA', ?, ?, ?, ?, ? )
```

You get output that looks like the following sample output:

```
Value of output parameters
-----
Parameter Name : EXPLAIN_SCHEMA
Parameter Value : MYSCHEMA

Parameter Name : EXPLAIN_REQUESTER
Parameter Value : GSDBUSER3

Parameter Name : EXPLAIN_TIME
Parameter Value : 2010-11-23-10.51.09.631945

Parameter Name : SOURCE_NAME
Parameter Value : SQLC2J21

Parameter Name : SOURCE_SCHEMA
Parameter Value : NULLID

Parameter Name : SOURCE_VERSION
Parameter Value :

Return Status = 0
```

8. Format the explain data by using the **db2exfmt** command.  
Use the values of the **explain\_requester**, **explain\_time**, **source\_name**, **source\_schema**, and **source\_version** parameters in the output from the EXPLAIN\_FROM\_ACTIVITY procedure as input for the command.
9. View the explain output to determine how the section affected the database objects that it used when it executed.  
Statistics in the output might indicate that additional monitoring or tuning is required.

For example, if a table that the section uses has a high value for the **lock\_wait** monitor element, lock management might be required.

10. If you tune the statement, repeat steps [“5” on page 8](#) through [“9” on page 8](#) to verify that performance is improved.

## What to do next

Deactivate the activity event monitor by using the SET EVENT MONITOR STATE statement. For example, to deactivate the ACTEVMON activity event monitor, issue the following command:

```
SET EVENT MONITOR ACTEVMON STATE 0
```

## Monitoring locking using table functions

You can retrieve information about locks using table functions. Unlike request, activity or data object monitor elements, information about locks is always available from the database manager. You do not need to enable the collection of this information.

Use the following monitor table functions to access current information for locks in the system:

- MON\_GET\_LOCKS
- MON\_GET\_APPL\_LOCKWAIT

Both table functions return data in relational form.

## Monitoring the overall system by using table functions

You can retrieve information about overall system usage by using table functions.

### Monitoring a database by using table functions

You can retrieve information about the overall impact on a particular database by using table functions. You can retrieve database level-specific monitoring information such as activation status (**DB\_ACTIVATION\_STATE**) and activation time (**DB\_CONN\_TIME**). You can also see request and bufferpool monitor elements that are aggregated for the entire database.

Use the following monitor function to access current information about the database:

- MON\_GET\_DATABASE

### Monitoring system memory by using table functions

You can retrieve information about system memory usage by using table functions.

You can examine memory usage at the level of memory sets, which are allocations of memory from the operating system. You can also examine memory usage by specific memory pools within a particular memory set. Use the following monitor functions to access current information about memory usage:

- MON\_GET\_MEMORY\_SET
- MON\_GET\_MEMORY\_POOL

### Monitoring the database manager system by using table functions

You can retrieve information about the instance within a database by using table functions. You can find out when the instance was started (**DB2START\_TIME**). You can also obtain the counts of agents that are operating within and connections to the instance. You can also find out system level information about the processes and threads that make up an instance.

Use the following monitor function to access current information about the instance:

- MON\_GET\_INSTANCE

Use the following functions to access current system information about Db2 EDUs and Db2 member:

- ENV\_GET\_DB2\_EDU\_SYSTEM\_RESOURCES
- ENV\_GET\_DB2\_SYSTEM\_RESOURCES

### Monitoring information about a member's host by using table functions

You can retrieve information about a member's host by using table functions. You can examine operating system, CPU, memory, and other system information.

Use the following functions to access current system information about a Db2 member's host:

- ENV\_GET\_SYSTEM\_RESOURCES
- ENV\_GET\_NETWORK\_RESOURCES

### Monitoring routines using table functions

You can use table functions to retrieve information about routines.

Table functions can be used to monitor routines and provide the following information:

- Aggregated metrics that report the total cost of the routine. Metrics are aggregated across all invocations of the routine and include metrics for all child statements and requests that are executed by the routine.
- Lists of statements that are executed by routines that assist you in drilling down and problem determination
- Lists of routines that might be invoked by a statement that aid you in performing additional drill downs on routine-related details.

Use the following monitor functions to access information about routines:

- MON\_GET\_ROUTINE
- MON\_GET\_ROUTINE\_DETAILS
- MON\_GET\_ROUTINE\_EXEC\_LIST
- MON\_GET\_SECTION\_ROUTINE

### Example: Identifying the most expensive routines by CPU consumption

You can use routine monitoring to identify your most expensive routines.

#### Scenario

In this example, a database administrator (DBA) wants to identify the database routines that are consuming the most total CPU. The DBA issues the following query which displays all routines that have executed since database activation time:

```
SELECT ROUTINESHEMA, ROUTINEMODULENAME, ROUTINENAME,  
       SPECIFICNAME, SUM(TOTAL_CPU_TIME) AS TOTAL_CPU  
FROM TABLE(MON_GET_ROUTINE(NULL, NULL, NULL, NULL, -2)) AS T  
GROUP BY ROUTINESHEMA, ROUTINEMODULENAME, ROUTINENAME, SPECIFICNAME  
ORDER BY TOTAL_CPU DESC
```

The result is ordered by total routine CPU consumption.

ROUTINESHEMA	ROUTINEMODULENAME	ROUTINENAME	SPECIFICNAME
TOTAL_CPU			
-----			
SYSIBMINTERNAL	-	COMPILED_ANON_BLOCK_INVOKE	
SQL120801135416210		8942414	
DRICARD	-	PROC1	
PROC1		23444	
SYSIBMSUBROUTINE	-	PROC1_66613_101877843	

MON\_GET\_ROUTINE table function shows that the stored procedure is using a higher than expected amount of CPU resources. The DBA previously configured the database to track statement information by routine, using the MON\_RTN\_EXECLIST database configuration parameter. The DBA issues the following query to sum the CPU usage for each statement that is executed by the routine across all members:

```

WITH TOTAL_STMT_CPU (EXEC_ID, TOTAL_CPU, NUM_ROUTINES, MIN_MEMBER) AS
  (SELECT
    EXECUTABLE_ID,
    SUM(TOTAL_CPU_TIME),
    MAX(NUM_ROUTINES),
    MIN(MEMBER)
  FROM
    TABLE(MON_GET_ROUTINE_EXEC_LIST('P', 'TEST', NULL, 'PROC1', -2)) AS T
  GROUP BY
    EXECUTABLE_ID
  ),
TOTAL_RTN_CPU (TOTAL_RTN_CPU) AS
  (SELECT
    SUM(TOTAL_CPU_TIME)
  FROM
    TABLE(MON_GET_ROUTINE('P', 'TEST', NULL, 'PROC1', -2)) AS R
  )
SELECT
  B.EXEC_ID,
  100*B.TOTAL_CPU / A.TOTAL_RTN_CPU AS PERCENT_CPU,
  B.NUM_ROUTINES,
  C.STMT_TEXT
FROM
  TOTAL_RTN_CPU AS A,
  TOTAL_STMT_CPU AS B,
  TABLE(MON_GET_PKG_CACHE_STMT(NULL, NULL, NULL, -2)) AS C
WHERE
  B.EXEC_ID = C.EXECUTABLE_ID AND
  B.MIN_MEMBER = C.MEMBER AND
  A.TOTAL_RTN_CPU <> 0
ORDER BY
  TOTAL_CPU DESC

```

The result lists the statements executed by the stored procedure ranked by percentage CPU consumption relative to the total CPU used by the routine.

EXEC_ID STMT_TEXT	PERCENT_CPU	NUM_ROUTINES
x'010000000000000056010000000000002000000010020120801142628005514' (COL1, COL2STATS) AS AF	10	0 WITH GET_UPDATE_LIST
x'010000000000000056010000000000002000000010020120801142628005514' values(3, 'd', 'd', 'd')	1	0 insert into T1
x'010000000000000056010000000000001000000010020120801142628005514' SYSIBMSUBROUTINE.P1_66613_1157394573()	0	1 call

3 record(s) selected.

The CPU usage reported for each statement by the MON\_GET\_ROUTINE\_EXEC\_LIST table function does not include CPU consumed by any child statements. The report that is generated by MON\_GET\_ROUTINE\_EXEC\_LIST shows only the percentage of CPU consumed by statements invoked directly by the routine. The DBA can continue the investigation in the following ways:

- If a direct child statement is using most of the CPU, the MON\_GET\_ROUTINE\_EXEC\_LIST report identifies that candidate and the DBA can investigate that statement. For example, drilling down on the statement that has high CPU usage using the MON\_GET\_PKG\_CACHE\_STMT table function to list the full set of metrics for all executions of the statement:

```

SELECT * FROM TABLE(MON_GET_PKG_CACHE_STMT
(NULL, '<high_cpu_consuming_exec_id>', NULL, -2)) AS T

```

- If the output shows that none of the statements that are executed directly by the routine are using a high amount of CPU, the DBA can examine the **num\_routines** monitor element that is listed for each executed statement.
  - If **num\_routines** is 0 (zero) for each executed statement, then the high CPU consumption is due to processing in the routine itself.

- If **num\_routines** is not zero, then the DBA can use the MON\_GET\_SECTION\_ROUTINE table function to determine the routines that the statement invoked and investigate if those routines might be contributing to the overall CPU consumption of TEST.PROC1. For example:

```
SELECT
  ROUTINESHEMA, ROUTINEMODULENAME, ROUTINENAME, SPECIFICNAME
FROM TABLE(MON_GET_SECTION_ROUTINE('<exec_id>')) AS T
```

The returned result is:

ROUTINESHEMA	ROUTINEMODULENAME	ROUTINENAME	SPECIFICNAME
DRICARD	-	PROC1	PROC1
SYSIBMSUBROUTINE	-	PROC1_66613_101877843	-

2 record(s) selected

The DBA can investigate these routines for high CPU consumption, but must keep in mind that the routines might have been called from different contexts other than TEST.PROC1. This means that the metrics returned from MON\_GET\_SECTION\_ROUTINE for these routines might be larger than the metrics for TEST.PROC1.

### Example: Listing aggregate routine metrics for an anonymous block

You can use routine monitoring to list the aggregate metrics for statements that are executed by an anonymous block.

#### Scenario

In this example, a database administrator (DBA) wants to view the aggregate metrics for all statements that are executed by an anonymous block with the statement text 'BEGIN ... END'. The DBA issues the following query to find the **executable\_id** for the anonymous block in the package cache:

```
SELECT EXECUTABLE_ID
FROM TABLE(MON_GET_PKG_CACHE_STMT(NULL, NULL, NULL, -1)) AS T
WHERE STMT_TEXT = 'BEGIN BLAH BLAH END'
```

The returned result is:

```
EXECUTABLE_ID
-----
x'010000000000000007A0000000000000000000000000000020020120801153841789993'
```

1 record(s) selected.

Using the returned **executable\_id**, the DBA issues the following query to find the aggregate metrics for the anonymous block:

```
SELECT * FROM TABLE(MON_GET_ROUTINE('A', NULL, NULL, NULL, -2)) AS T
WHERE DYN_COMPOUND_EXEC_ID = x'010000000000000007A0000000000000000000000000000020020120801153841789993'
```

The returned result is:

ROUTINETYPE	ROUTINESHEMA	ROUTINEMODULENAME	ROUTINENAME	SPECIFICNAME
DYN_COMPOUND_EXEC_ID				
C	SYSIBMINTERNAL	-	COMPILED_ANON_BLOCK_INVOKE	SQL120801153841490

x'010000000000000007A0000000000000000000000000000020020120801153841789993'

000000000000000000000000

20020120801153841789993'

1 record(s) selected.

Alternatively, the DBA can look up the internal procedure and schema name corresponding to the anonymous block by using the MON\_GET\_SECTION\_ROUTINE table function and then pass those values

as inputs to the MON\_GET\_ROUTINE table function. This method would return only information for the anonymous block and so avoids filtering the output with a WHERE clause.

## Example: Retrieving statement text for a routine

You can use routine monitoring to retrieve the statements that are executed by a routine.

### Scenario

In this example, a database administrator (DBA) is manually investigating costly statements executed by a routine. As part of the investigation it can be useful to link a row in MON\_GET\_ROUTINE\_EXEC\_LIST to a specific statement or line of the routine. Getting statement text for short lived routines like anonymous blocks, dynamic SQL statements, or external routines is accomplished by retrieving the statement from the package cache. The following query links a row in MON\_GET\_ROUTINE\_EXEC\_LIST to a specific statement:

```
SELECT
  A.ROUTINETYPE, A.ROUTINESCHEMA, A.ROUTINENAME,
  A.SECTION_TYPE, A.SECTION_NUMBER, A.STMTNO,
  SUBSTR(B.STMT_TEXT,1,160)
FROM
  TABLE(MON_GET_ROUTINE_EXEC_LIST('P', 'DRICARD', NULL, 'PROC1', -1)) AS A,
  TABLE(MON_GET_PKG_CACHE_STMT(NULL, NULL, NULL, -1)) AS B
WHERE
  A.EXECUTABLE_ID=B.EXECUTABLE_ID
```

The returned result is as follows:

```
STMT_TEXT
-----
WITH GET_UPDATE_LIST (COL1, COL2STATS) AS AF
insert into T1 values(3,'d','d','d')
call SYSIBMSUBROUTINE.P1_66613_1157394573()

3 record(s) selected.
```

**Note:** If a dynamic SQL statement or external routine statement is returned by MON\_GET\_ROUTINE\_EXEC\_LIST and the associated **executable\_id** is no longer in the package cache, that statement text cannot be recovered unless an event monitor was used to log this information. The refresh cycle for InfoSphere® Optim™ Performance Manager product allows it to retrieve this information in most cases.

For compiled SQL statements and inlined routines, the statement text can be found by using the package and statement information that is returned by MON\_GET\_ROUTINE\_EXEC\_LIST. For example:

```
SELECT RS.ROUTINETYPE, RS.ROUTINESCHEMA, RS.ROUTINENAME,
  RS.SECTION_NUMBER, RS.STMTNO, SUBSTR(SS.TEXT,1,160)
FROM
  TABLE(MON_GET_ROUTINE_EXEC_LIST('F', 'DRICARD', '', 'MYFUNC', -1)) AS RS,
  SYSIBM.SYSSTMT SS
WHERE
  RS.SECTION_TYPE = 'S'
  AND SS.PLNAME = RS.PACKAGE_SCHEMA
  AND SS.PLCREATOR = RS.PACKAGE_NAME
  AND SS.STMTNO = RS.STMTNO
  AND SS.SECTNO = RS.SECTION_NUMBER
```

The returned result is as follows:

```
STMT_TEXT
-----
insert into MYTABLE values('1')

1 record(s) selected.
```

## Other monitoring table functions

Besides table functions that return information about the system, activities, locks, or data objects there are also table functions that return various types of miscellaneous information. These functions include ones that return information related to the fast communications manager (FCM), and about the status of table space extent movement.

Each of the table functions that follow can be used at any time. Unlike the table functions that return request metrics (the system monitoring perspective), activity metrics (the activity monitoring perspective) or metrics related to data objects (the data object monitoring perspective), it is not necessary to first enable the collection of the monitor elements returned by these functions.

- MON\_GET\_FCM
- MON\_GET\_FCM\_CONNECTION\_LIST
- MON\_GET\_EXTENT\_MOVEMENT\_STATUS

## Interfaces that return monitor data in XML documents

Some monitor data is reported as elements in XML documents.

Using XML to report monitor information provides improved extensibility and flexibility. New monitor elements can be added without having to add new columns to an output table. Also, XML documents can be processed in a number of ways, depending on your needs. For example:

- You can use XQuery to run queries against the XML document.
- You can use the XSLTRANSFORM scalar function to transform the document into other formats.
- You can view their contents as formatted text by using built-in MON\_FORMAT\_XML\_\* formatting functions, or the XMLTABLE table function.

XML documents that contain monitor elements are produced by several monitoring interfaces. The sections that follow describe how results are returned as XML documents.

- [“Monitor table functions with names that end with \\_DETAILS” on page 15](#)
- [“XML data returned by event monitors” on page 16.](#)

### Monitor table functions with names that end with "\_DETAILS"

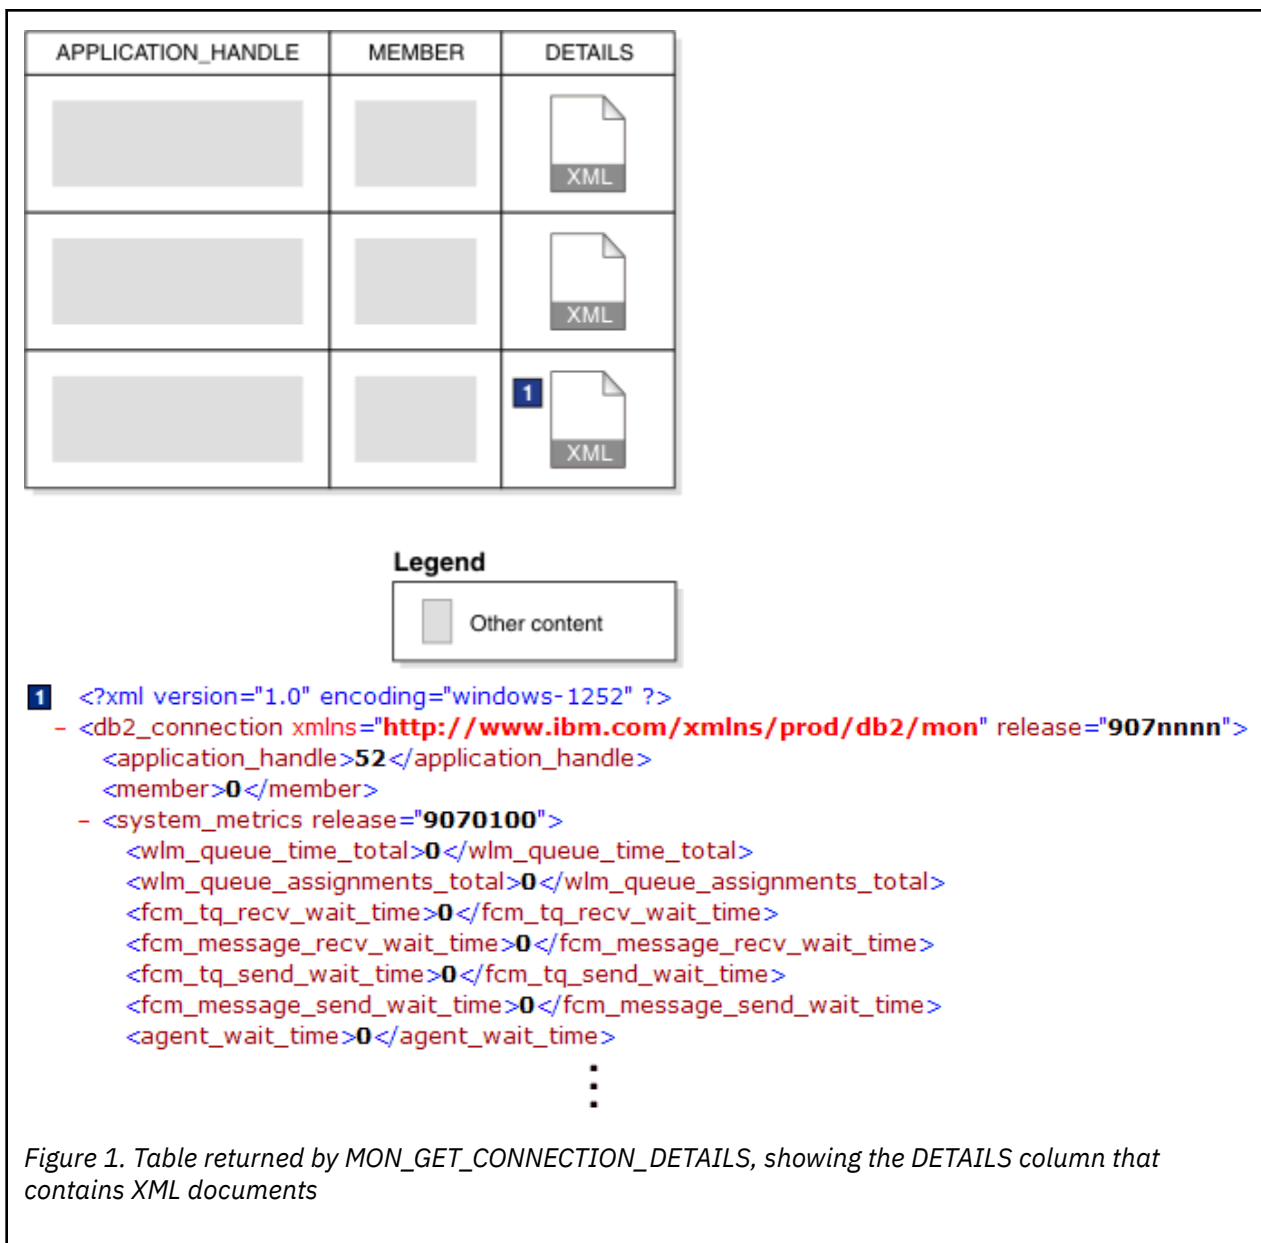

Examples of these table functions include:

- MON\_GET\_PKG\_CACHE\_STMT\_DETAILS
- MON\_GET\_WORKLOAD\_DETAILS
- MON\_GET\_CONNECTION\_DETAILS
- MON\_GET\_SERVICE\_SUBCLASS\_DETAILS
- MON\_GET\_ACTIVITY\_DETAILS
- MON\_GET\_UNIT\_OF\_WORK\_DETAILS

These table functions return monitor elements from the system and the activity monitoring perspectives. Most of the monitor elements returned by these functions are contained in an XML document. For example, the MON\_GET\_CONNECTION\_DETAILS table function returns the following columns:

- APPLICATION\_HANDLE
- MEMBER
- DETAILS

The DETAILS column of each row contains an XML document that contains monitor element data. This XML document is composed of several document elements that correspond to monitor elements. [Figure 1 on page 16](#) illustrates the DETAILS column that contains the XML documents. In addition, it shows monitor elements returned in the XML documents in the DETAILS column.

In the preceding example, the `<agent_wait_time>` XML document element corresponds to **agent\_wait\_time** monitor element.

The schema for the XML document that is returned in the DETAILS column is available in the file `sql1lib/misc/DB2MonRoutines.xsd`. Further details can be found in the file `sql1lib/misc/DB2MonCommon.xsd`.

Some of the monitor elements contained in the document in the DETAILS column might be grouped into higher-level document elements. For example, monitor elements that report on activity-related metrics are part of the **activity\_metrics** element. Similarly, system-level metrics are part of the **system\_metrics** element.

### XML data returned by event monitors

Several event monitors return data in XML format. They are summarized in [Table 2 on page 17](#). Details about the XML documents returned by the various event monitor are described in the sections that follow.

Table 2. XML documents returned by various event monitors

Event monitor	Event monitor output format	XML document returned <sup>1</sup>
<a href="#">“Statistics event monitor” on page 17</a>	Relational table File Named pipe	<b>metrics</b> The metrics reported in this document reflect the change in value for each metric since the last time statistics were collected. <b>details_xml</b> The metrics reported in this document accumulate until the database is deactivated.
<a href="#">“Activity event monitor” on page 18</a>	Relational table File Named pipe	details_xml
<a href="#">“Package cache event monitor” on page 19</a>	Unformatted event (UE) table	metrics This document can be viewed only after the UE table is transformed to either XML or relational tables.
<a href="#">“Unit of work event monitor” on page 19</a>	Unformatted event (UE) table	metrics This document can be viewed only after the UE table is transformed to either XML or relational tables.

### Statistics event monitor

The statistics event monitor records metrics in XML format when either of the two following logical data groups are included in the event monitor output:

- EVENT\_SCSTATS
- EVENT\_SUPERCLASSTATS
- EVENT\_WLSTATS

When you create a statistics event monitor to report on monitor elements in either of these groups, some system metrics are collected as part of two XML documents. One for each of the **details\_xml** and **metrics** monitor elements. Both XML documents contain the same set of monitor elements. In the **metrics** document, the values of the elements reflect the change in value for each element since the last time statistics were collected. The values of the elements contained in **details\_xml** are not reset at each interval; they are reset only when the database is reactivated. If the data is written to a file or named pipe, these elements are part of the self-describing data stream. If the event monitor data is written to a table, the **metrics** document is stored in a column called METRICS; **details\_xml** is stored in a column called DETAILS\_XML. [Figure 2 on page 18](#) shows the XML documents in the METRICS and DETAILS\_XML columns as they appear in the SCSTATS table produced by the statistics event monitor:

<sup>1</sup> Note: In these topics, when details\_xml appears in lowercase letters, it refers to the XML document details\_xml. DETAILS\_XML, in uppercase letters, refers to a column in a relational table called DETAILS\_XML that contains the details\_xml documents.

...	CONCURRENT_WLO_ACT_TOP	...	DETAILS_XML	LAST_WLM_RESET	...	METRICS	PARTITION_NUMBER	...
			<b>1</b>			<b>1</b>		

**Legend**  
 Other content

*Figure 2. Output of statistics event monitor (when written to a table), showing the DETAILS\_XML and METRICS columns.*

Each of the documents contained in these columns contains **system\_metrics** as the top-level element, which, in turn, contains a number of monitor elements that report on system-related metrics.

```

1 <?xml version="1.0" encoding="windows-1252" ?>
  - <db2_connection xmlns="http://www.ibm.com/xmlns/prod/db2/mon" release="907nnnn">
    <application_handle>52</application_handle>
    <member>0</member>
  - <system_metrics release="9070100">
    <wlm_queue_time_total>0</wlm_queue_time_total>
    <wlm_queue_assignments_total>0</wlm_queue_assignments_total>
    <fcm_tq_rcv_wait_time>0</fcm_tq_rcv_wait_time>
    <fcm_message_rcv_wait_time>0</fcm_message_rcv_wait_time>
    <fcm_tq_send_wait_time>0</fcm_tq_send_wait_time>
    <fcm_message_send_wait_time>0</fcm_message_send_wait_time>
    <agent_wait_time>0</agent_wait_time>
    :
  -

```

In addition to viewing system metrics from the XML document in the **metrics** monitor element, you can view the individual metrics directly from the output associated with the EVENT\_SCMETRICS, EVENT\_SUPERCLASSMETRICS and EVENT\_WLMETRICS logical data groups.

**Notes:**

- The **system\_metrics** element that is reported in the details\_xml document contained in the DETAILS\_XML column produced by the statistics event monitor is also a part of the XML document contained in the DETAILS column returned by the MON\_GET\_SERVICE\_SUBCLASS\_DETAILS and MON\_GET\_WORKLOAD\_DETAILS table functions. Like the metrics reported in the details\_xml document, the values for the metrics reported in the document contained in the DETAILS column accumulate until the database is deactivated.
- See “[Information written to XML for system\\_metrics and activity\\_metrics monitor elements](#)” on page 267 for the schema for the XML output from a statistics event monitor.

**Activity event monitor**

When you create an activity event monitor to report on monitor elements in the event\_activity logical data group (see “[event\\_activity logical data group](#)” on page 44), one of the columns produced is DETAILS\_XML. If the event monitor is written to a table, DETAILS\_XML is a column. If it is written to a

file or named pipe, DETAILS\_XML is part of the self-describing data stream. Either way, the document contains the **activity\_metrics** monitor element, which, in turn, contains a number of monitor elements that report on metrics related to activities. See [“ Information written to XML for system\\_metrics and activity\\_metrics monitor elements ” on page 267](#) for the schema for the XML output from an activity event monitor.

**Note:** activity\_metrics as reported in the XML document in the DETAILS\_XML column produced by the activity event monitor is also a part of the XML document contained in the DETAILS column returned by the MON\_GET\_ACTIVITY\_DETAILS table function.

## Package cache event monitor

The package cache event monitor writes its output to an unformatted event (UE) table. If you convert the data in this table with the EVMON\_FORMAT\_UE\_TO\_TABLES table function, one of the tables produced is PKGCACHE\_EVENT. This table contains a METRICS column. In each row, this column contains an XML document with elements associated with package cache event monitor elements.

**Note:** The EVMON\_FORMAT\_UE\_TO\_TABLES table function also creates a separate table for the metrics collected by this event monitor called PKGCACHE\_METRICS. This table contains the same information reported in the METRICS column of the PKGCACHE\_EVENT table. So, you can retrieve metrics from the columns of the PKGCACHE\_METRICS table, or you can use the XML document contained in the METRICS column of the PKGCACHE\_EVENT table. See [“ Information written to relational tables by EVMON\\_FORMAT\\_UE\\_TO\\_TABLES for a package cache event monitor ” on page 223](#) for details.

The EVMON\_FORMAT\_UE\_TO\_XML function also produces an XML document with elements associated with package cache event monitor elements. For example, the XML document element <num\_executions> corresponds to the **num\_executions** monitor element. See [“ Information written to XML for a package cache event monitor ” on page 237](#) for the schema for the XML output from a package cache event monitor.

## Unit of work event monitor

The unit of work event monitor writes its output to an unformatted event (UE) table. If you convert the data in this table with the EVMON\_FORMAT\_UE\_TO\_TABLES table function, one of the tables produced is UOW\_EVENT. This table contains a METRICS column, which contains an XML document with elements associated with unit of work event monitor elements.

**Note:** The EVMON\_FORMAT\_UE\_TO\_TABLES table function also creates a separate table for the metrics collected by this event monitor called UOW\_METRICS. This table contains the same information reported in the METRICS column of the UOW\_EVENT table. So, you can retrieve metrics from the columns of the UOW\_METRICS table, or you can use the XML document contained in the METRICS column of the UOW\_EVENT table. See [“ Information written to relational tables by EVMON\\_FORMAT\\_UE\\_TO\\_TABLES for a unit of work event monitor ” on page 177](#) for details.

The EVMON\_FORMAT\_UE\_TO\_XML function also produces an XML document with elements associated with unit of work event monitor elements. For example, the XML document element <workload\_name> corresponds to the **workload\_name** monitor element. See [“ Information written to XML by EVMON\\_FORMAT\\_UE\\_TO\\_XML for a unit of work event monitor ” on page 194](#) for the schema for the XML output from a unit of work event monitor.

## Interfaces for viewing XML monitor information as formatted text

You can view the data contained in the XML documents produced by monitor interfaces in several ways, depending on how you want to view or use the data. You can use XQuery to query and manipulate the XML documents returned by monitoring interfaces. You can also use table functions to format the XML documents for easier reading.

XQuery provides a powerful and flexible interface for querying and manipulating XML data. However, there are times where you might want to view element data in a text-based format. Depending on your needs, you can view monitor elements contained in an XML document in column- or row-oriented format. The former is useful if you know which monitor elements you want to see. The latter is useful if you do not know ahead of time which monitor elements you want to examine, such as when you want to see the

top five types of wait times. The sections that follow describe two ways that you can view monitor data contained in XML documents as formatted text.

- [“Viewing monitor elements in column-oriented format” on page 20](#)
- [“Viewing monitor elements in row-oriented format” on page 21](#)

## Viewing monitor elements in column-oriented format

The XMLTABLE table function takes an XML document as input and converts it into a relational table such that each of the selected XML document elements appears as a column. This approach is useful if you know which monitor elements you want to display. For example, assume that you have created a statistics event monitor called DBSTATS to collect information from the event\_scstats logical data group. This event monitor is defined to write its output to a table, and the output table name is by default SCSTATS\_DBSTATS. (See [“event\\_scstats logical data group” on page 69](#) for more information about the monitor elements associated with this logical data group.) The monitor elements in this logical group include **details\_xml**, which is actually an XML document that itself contains the metrics that comprise the **system\_metrics** monitor element. (See [“system\\_metrics” on page 268](#) for more information about the monitor elements associated with the system\_metrics monitor element.) To view specific **system\_metrics** monitor elements contained in details\_xml, such as rows\_returned, total\_section\_time, or total\_cpu\_time, you can use the XMLTABLE table function to format selected monitor elements from the details\_xml documents returned by the statistics event monitor. The example that follows illustrates this. (For presentation purposes, the SQL returns results only for a specific service class.)

```
SELECT partition_number,
       service_class_id,
       statistics_timestamp,
       event.rows_returned,
       event.total_section_time,
       event.total_cpu_time
FROM   SCSTATS_DBSTATS as DBSTATS,
XMLTABLE( XMLNAMESPACES( DEFAULT 'http://www.ibm.com/xmlns/prod/db2/mon' ),
          '$metrics/system_metrics' PASSING XMLPARSE( DOCUMENT DBSTATS.METRICS ) as "metrics"
          COLUMNS
          rows_returned          BIGINT          PATH 'rows_returned',
          total_section_time     BIGINT          PATH 'total_section_time',
          total_cpu_time         BIGINT          PATH 'total_cpu_time'
          ) AS EVENT
WHERE  service_class_id = 12;
```

The following output shows the results for this query:

PARTITION_NUMBER	SERVICE_CLASS_ID	STATISTICS_TIMESTAMP	ROWS_RETURNED	TOTAL_SECTION_TIME	TOTAL_CPU_TIME
990	0	1531250	12	2010-01-05-12.14.37.001717	402
990	0	1531250	12	2010-01-05-12.15.00.035409	402
1064	0	1609375	12	2010-01-05-12.20.00.021884	412
1075	0	1687500	12	2010-01-05-12.25.00.039175	422

<sup>2</sup> Note: In these topics, when details\_xml appears in lowercase letters, it refers to the XML document details\_xml. DETAILS\_XML, in uppercase letters, refers to a column in a relational table called DETAILS\_XML that contains the details\_xml documents.

10 record(s) selected.

In this case, the first three columns are displayed directly from the table SCSTATS\_DBSTATS table produced by the statistics event monitor. The last three columns are metrics monitor elements extracted from the XML document in the DETAILS\_XML column of the table.

For more information about using XMLTABLE, refer to the documentation for that function. You can also see examples of using XMLTABLE to view monitor elements in the documentation for the various MON\_GET\_\*\_DETAILS functions.

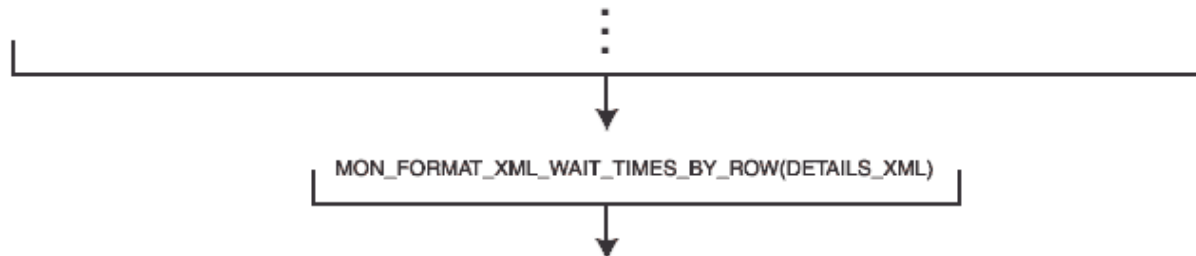

### Viewing monitor elements in row-oriented format

The table functions with names of the form MON\_FORMAT\_XML\_\*\_BY\_ROW provide a quick way to display the metrics monitor elements contained in an XML document. They report metrics in a row-based format, with each monitor element appearing in a row by itself. The following functions are included in this group:

- MON\_FORMAT\_XML\_COMPONENT\_TIMES\_BY\_ROW
- MON\_FORMAT\_XML\_TIMES\_BY\_ROW
- MON\_FORMAT\_XML\_WAIT\_TIMES\_BY\_ROW
- MON\_FORMAT\_XML\_METRICS\_BY\_ROW

For example, the XML document returned by the statistics event monitor, DETAILS\_XML, might look something like the one shown in the first part of Figure 3 on page 21. If you use the MON\_FORMAT\_XML\_WAIT\_TIMES\_BY\_ROW function to format the content of DETAILS\_XML, the output would look like the table at the bottom of the diagram.

```
<?xml version="1.0" encoding="windows-1252" ?>
- <system_metrics xmlns="http://www.ibm.com/xmlns/prod/db2/mon" release="907nnnn">
  <wlm_queue_time_total>0</wlm_queue_time_total>
  <wlm_queue_assignments_total>0</wlm_queue_assignments_total>
  <fcm_tq_recv_wait_time>0</fcm_tq_recv_wait_time>
  <fcm_message_recv_wait_time>0</fcm_message_recv_wait_time>
  <fcm_tq_send_wait_time>0</fcm_tq_send_wait_time>
  <fcm_message_send_wait_time>0</fcm_message_send_wait_time>
  <agent_wait_time>0</agent_wait_time>
  <agent_waits_total>0</agent_waits_total>
  <lock_wait_time>0</lock_wait_time>
```

METRIC_NAME	TOTAL_TIME_VALUE	COUNT	PARENT_METRIC_NAME
WLM_QUEUE_TIME_TOTAL	0	0	TOTAL_WAIT_TIME
FCM_TQ_REC_V_WAIT_TIME	0	0	FCM_REC_V_WAIT_TIME
FCM_MESSAGE_REC_V_WAIT_TIME	0	0	FCM_REC_V_WAIT_TIME
FCM_TQ_SEND_WAIT_TIME	0	0	FCM_SEND_WAIT_TIME
FCM_MESSAGE_SEND_WAIT_TIME	0	0	FCM_SEND_WAIT_TIME
AGENT_WAIT_TIME	0	0	TOTAL_WAIT_TIME
LOCK_WAIT_TIME	0	0	TOTAL_WAIT_TIME
DIRECT_READ_TIME	0	0	TOTAL_WAIT_TIME
DIRECT_WRITE_TIME	0	0	TOTAL_WAIT_TIME
LOG_BUFFER_WAIT_TIME	0	0	TOTAL_WAIT_TIME
LOG_DISK_WAIT_TIME	0	0	TOTAL_WAIT_TIME
⋮			

Figure 3. An XML file containing monitoring data, processed by one of the MON\_FORMAT\_XML\_\* functions

The number of columns returned varies by the specific function that you use. For example `MON_FORMAT_XML_METRICS_BY_ROW` returns two columns, one for the metric name, and one for its corresponding value:

METRIC_NAME	VALUE
WLM_QUEUE_TIME_TOTAL	0
WLM_QUEUE_ASSIGNMENTS_TOT	0
FCM_TO_RECV_WAIT_TIME	0
FCM_MESSAGE_RECV_WAIT_TIM	0
FCM_TO_SEND_WAIT_TIME	0
⋮	⋮

By comparison, `MON_FORMAT_XML_TIMES_BY_ROW` returns four columns:

METRIC_NAME	TOTAL_TIME_VALUE	COUNT	PARENT_METRIC_NAME
WLM_QUEUE_TIME_TOTAL	0	0	TOTAL_WAIT_TIME
FCM_TO_RECV_WAIT_TIME	0	0	FCM_RECV_WAIT_TIME
FCM_MESSAGE_RECV_WAIT_TIME	0	0	FCM_RECV_WAIT_TIME
FCM_TO_SEND_WAIT_TIME	0	0	FCM_SEND_WAIT_TIME
FCM_MESSAGE_SEND_WAIT_TIME	0	0	FCM_SEND_WAIT_TIME
⋮	⋮	⋮	⋮

The `MON_FORMAT_XML*_BY_ROW` functions are useful when you do not know which elements you want to view. For example, you might want to see the top 10 wait-time monitor elements for the workload named `CLPWORKLOAD`. To collect this information, you can create a statistics event monitor called `DBSTATS` (event `wlstats` logical data group). Assuming you set up this event monitor to write to a table, it records metrics in a column called `DETAILS_XML` in the table called `WLSTATS_DBSTATS` by default. Once the output table from the event monitor is populated with monitor data, you can construct a query that uses the `MON_FORMAT_XML_WAIT_TIMES_BY_ROW` function to extract the monitor elements you want to see:

```
SELECT SUBSTR(STATS.WORKLOAD_NAME,1,15) AS WORKLOAD_NAME,
       SUBSTR(METRICS.METRIC_NAME,1,30) AS METRIC_NAME,
       SUM(METRICS.TOTAL_TIME_VALUE) AS TOTAL_TIME_VALUE
FROM   WLSTATS_DBSTATS AS STATS,
       TABLE(MON_FORMAT_XML_WAIT_TIMES_BY_ROW(STATS.DETAILS_XML)) AS METRICS
WHERE  WORKLOAD_NAME='CLPWORKLOAD' AND (PARENT_METRIC_NAME='TOTAL_WAIT_TIME')
GROUP BY WORKLOAD_NAME,METRIC_NAME
ORDER BY TOTAL_TIME_VALUE DESC
FETCH FIRST 10 ROWS ONLY
```

**Remember:** Time spent monitor elements are organized into hierarchies. In this example, to avoid double-counting wait times, only the monitor elements that roll-up to **total\_wait\_time** are included (see the `WHERE` clause in the preceding SQL statement). Otherwise, **total\_wait\_time** itself would be included in the results, which includes several individual wait times.

The output that follows shows what the results of the preceding query might look like:

WORKLOAD_NAME	METRIC_NAME	TOTAL_TIME_VALUE
CLPWORKLOAD	LOCK_WAIT_TIME	15138541
CLPWORKLOAD	DIRECT_READ_TIME	6116231
CLPWORKLOAD	POOL_READ_TIME	6079458
CLPWORKLOAD	DIRECT_WRITE_TIME	452627
CLPWORKLOAD	POOL_WRITE_TIME	386208
CLPWORKLOAD	IPC_SEND_WAIT_TIME	283172
CLPWORKLOAD	LOG_DISK_WAIT_TIME	103888
CLPWORKLOAD	DIAGLOG_WRITE_WAIT_TIME	78198
CLPWORKLOAD	IPC_RECV_WAIT_TIME	15612
CLPWORKLOAD	TCPIP_SEND_WAIT_TIME	3291

10 record(s) selected.

**Note:** The `MON_FORMAT_XML*_BY_ROW` functions return only monitor elements that track measurements or *metrics*. These include monitor elements that track wait and component times, as well as counters. They do not return non-metrics monitor elements contained in the XML document, such as `uow_id`, or `activity_id`.

You can use the XMLTABLE function to view *any* of the elements (including non-metrics elements) contained in the XML document. However, the most frequently used, non-metrics monitor elements are returned as columns by the monitor functions that begin with MON\_GET\_\*, such as MON\_GET\_UNIT\_OF\_WORK, or MON\_GET\_CONNECTION. If you are not familiar with XML, you might find it faster and easier to create queries using these functions than using the XMLTABLE function to extract monitor elements from an XML document.

To summarize: if you are interested in viewing non-metrics monitor elements, the MON\_GET\_\* series of table functions might be a good alternative to the XMLTABLE function. If you are interested in viewing metrics monitor elements, the MON\_FORMAT\_XML\_\*\_BY\_ROW table functions might suit your needs.

### ***Viewing metrics monitor elements from XML documents as rows in a table***

One way to view metrics-related information contained in an XML document returned from an event monitor is to convert it into a format where each monitor element appears in a row by itself. This format is useful if you want to view the information in a text-based format, but do not know specifically which monitor elements you want to examine.

### **About this task**

To view metrics information in row-based format from the XML documents returned by various monitoring interfaces, use the MON\_FORMAT\_XML\_\*\_BY\_ROW table functions.

### **Procedure**

The example shown in this task uses the MON\_FORMAT\_XML\_TIMES\_BY\_ROW table function to view component times for a statement as tracked by the package cache event monitor. It assumes that a package cache event monitor called PKGCACHEEVENTS has been created and activated. The package cache event monitor writes its output to an unformatted event (UE) table. Before it can be used, the data in the UE table must be converted to either relational tables using the EVMON\_FORMAT\_UE\_TO\_TABLES stored procedure, or to XML using the EVMON\_FORMAT\_UE\_TO\_XML table function. This task shows the first of these two approaches.

1. First, convert the unformatted event (UE) table that the package cache event monitor writes to into relational tables using the EVMON\_FORMAT\_UE\_TO\_TABLES procedure

```
call EVMON_FORMAT_UE_TO_TABLES ('PkgCache', NULL, NULL, NULL, NULL, NULL,
    NULL, 0, 'SELECT * FROM PKGCACHEEVENTS')
```

This procedure creates two tables:

- One is called PKGCACHE\_EVENT, which contains a column called METRICS. This column, in turn, contains XML documents with metrics monitor elements.
- The other is called PKGCACHE\_METRICS.

**Note:** You could view the metrics directly from the columns in PKGCACHE\_METRICS, rather than extract metrics from the METRICS column of the PKGCACHE\_EVENT table. However, when you examine PKGCACHE\_METRICS, the metrics appear in columns, rather than rows; it is not as easy to get a ranking of, say, the metrics with the highest values.

2. Query the two tables produced in the preceding step to determine which statement is the most expensive in terms of execution times:

```
SELECT EVENTS.EXECUTABLE_ID,
       SUM(METRICS.STMT_EXEC_TIME) AS TOTAL_STMT_EXEC_TIME
FROM   PKGCACHE_EVENT AS EVENTS,
       PKGCACHE_METRICS AS METRICS
WHERE  EVENTS.XMLID = METRICS.XMLID
GROUP BY EVENTS.EXECUTABLE_ID
ORDER BY TOTAL_STMT_EXEC_TIME DESC
FETCH FIRST 5 ROWS ONLY
```

In the preceding query, the two tables produced in step “1” on page 23 are joined so that the statement IDs from the PKGCACHE\_EVENT table can be associated with their execution times in the PKGCACHE\_METRICS table:

```
EXECUTABLE_ID
TOTAL_STMT_EXEC_TIME
-----
-----
x'01000000000000001A0300000000000000000000000020020091215115933859000'
 250
x'0100000000000000015030000000000000000000000020020091215115850328000'
 191
x'0100000000000000021020000000000000000000000020020091215115818343001'
 129
x'01000000000000000C402000000000000000000000020020091215115838578000'
 41
x'01000000000000000B002000000000000000000000020020091215115838203000'
 38

5 record(s) selected.
```

The first item in the results represents the statement with the largest overall execution time.

3. Optional: If you like, you can display the text for the statement using the following SQL:

```
SELECT SUBSTR(STMT_TEXT,1,60) AS STMT_TEXT
FROM PKGCACHE_EVENT
WHERE EXECUTABLE_ID =
x'010000000000000001A03000000000000000000000020020091215115933859000'
```

Results:

```
STMT_TEXT
-----
DROP XSROBJECT MYSHEMA.EVMON_PKGCACHE_SCHEMA_SQL09070

1 record(s) selected.
```

4. Use the MON\_FORMAT\_XML\_TIMES\_BY\_ROW table function to view a listing of the time-spent monitor elements for the statement you identified in step “2” on page 23:

```
SELECT SUBSTR(XMLMETRICS.METRIC_NAME,1,30) AS METRIC_NAME,
       XMLMETRICS.TOTAL_TIME_VALUE,
       SUBSTR(XMLMETRICS.PARENT_METRIC_NAME,1,30) AS PARENT_METRIC_NAME
FROM PKGCACHE_EVENT AS EVENTS,
     TABLE(MON_FORMAT_XML_TIMES_BY_ROW(EVENTS.METRICS)) AS XMLMETRICS
WHERE EVENTS.EXECUTABLE_ID=
x'010000000000000001A03000000000000000000000020020091215115933859000'
AND PARENT_METRIC_NAME='STMT_EXEC_TIME'
ORDER BY XMLMETRICS.TOTAL_TIME_VALUE DESC
```

Notes:

- Remember that time-spent monitor elements are organized into hierarchies. To eliminate double-counting, only those metrics that roll-up to **stmt\_exec\_time** are included in the results. Otherwise, **stmt\_exec\_time** itself would be included in the results, which includes several individual component times.
- **PARENT\_METRIC\_NAME**, one of the columns returned by **MON\_FORMAT\_XML\_TIMES\_BY\_ROW** is included for illustrative purposes.

When run, the following results are returned by this query:

METRIC_NAME	TOTAL_TIME_VALUE	PARENT_METRIC_NAME
TOTAL_ACT_WAIT_TIME	234	STMT_EXEC_TIME
TOTAL_SECTION_PROC_TIME	15	STMT_EXEC_TIME

Here, you can see that the total processing time adds up to 249 ms. Compare this time to the total time of 250 shown in step “2” on page 23; the extra millisecond is accounted for by other times (for example, waits) not included in **stmt\_exec\_time**.

## Results

In the results from the preceding example, you can see the arrangement of the metrics: they appear in row-oriented format, one metric per row. The advantage of using this approach is that you do not need to know ahead of time which metrics or monitor elements you want to see. If you want to see which of the time-spent metrics have the five highest values, or which metrics fall within a specific range of values, you can easily create a query to return the results you are interested in. By contrast, if you use the XMLTABLE function to display the monitor elements as columns, you need to specify which monitor elements to display (or display them all).

## Example

### Viewing the contents of the DETAILS column produced by a MON\_GET\_\*\_DETAILS table function

You can also use the MON\_FORMAT\_XML\_\*\_BY\_ROW functions to view the contents of the DETAILS column returned by any of the MON\_GET\_\*\_DETAILS functions. For example, MON\_GET\_CONNECTION\_DETAILS returns a DETAILS column that contains an XML document with metrics that pertain to a database connection.

For example, to view the non-zero component times for each connection across all members, you could use the following query:

```
SELECT CONDETAILS.APPLICATION_HANDLE,
       SUBSTR(XMLMETRICS.METRIC_NAME,1,30) AS METRIC_NAME,
       SUM(XMLMETRICS.TOTAL_TIME_VALUE) AS TOTAL_TIME_VALUE,
       SUBSTR(XMLMETRICS.PARENT_METRIC_NAME,1,30) AS PARENT_METRIC_NAME
FROM TABLE(MON_GET_CONNECTION_DETAILS(NULL,-1)) AS CONDETAILS,
     TABLE(MON_FORMAT_XML_COMPONENT_TIMES_BY_ROW(CONDETAILS.DETAILS)) AS
XMLMETRICS
WHERE TOTAL_TIME_VALUE > 0 AND XMLMETRICS.PARENT_METRIC_NAME='TOTAL_RQST_TIME'
GROUP BY CONDETAILS.APPLICATION_HANDLE,
         XMLMETRICS.PARENT_METRIC_NAME,
         XMLMETRICS.METRIC_NAME
ORDER BY CONDETAILS.APPLICATION_HANDLE ASC, TOTAL_TIME_VALUE DESC
```

### Notes:

- To eliminate double-counting, only those metrics that roll-up to **total\_rqst\_time** are included in the results (WHERE . . . XMLMETRICS.PARENT\_METRIC\_NAME='TOTAL\_RQST\_TIME'). Otherwise, total\_rqst\_time itself would be included in the results, which includes several individual component times.
- PARENT\_METRIC\_NAME, one of the columns returned by MON\_FORMAT\_XML\_COMPONENT\_TIMES\_BY\_ROW is included for illustrative purposes.

The preceding query returns the following results:

APPLICATION_HANDLE	METRIC_NAME	TOTAL_TIME_VALUE	PARENT_METRIC_NAME
52	TOTAL_SECTION_TIME	3936	TOTAL_RQST_TIME
52	TOTAL_COMPILE_TIME	482	TOTAL_RQST_TIME
52	TOTAL_COMMIT_TIME	15	TOTAL_RQST_TIME
52	TOTAL_ROLLBACK_TIME	1	TOTAL_RQST_TIME
496	TOTAL_COMPILE_TIME	251	TOTAL_RQST_TIME
496	TOTAL_SECTION_TIME	46	TOTAL_RQST_TIME
496	TOTAL_IMPLICIT_COMPILE_TIME	5	TOTAL_RQST_TIME

7 record(s) selected.

As this example shows, only metrics that comprise **total\_rqst\_time** are included. Had the WHERE . . . XMLMETRICS.PARENT\_METRIC\_NAME='TOTAL\_RQST\_TIME' clause not been included in the query, the results would look like those that follow:

APPLICATION_HANDLE	METRIC_NAME	TOTAL_TIME_VALUE	PARENT_METRIC_NAME
	<b>52 TOTAL_RQST_TIME</b>	<b>4603</b>	-
52	TOTAL_SECTION_TIME	3942	TOTAL_RQST_TIME
52	TOTAL_COMPILE_TIME	537	TOTAL_RQST_TIME
52	TOTAL_SECTION_SORT_TIME	299	TOTAL_SECTION_TIME
52	TOTAL_COMMIT_TIME	15	TOTAL_RQST_TIME
52	TOTAL_ROLLBACK_TIME	1	TOTAL_RQST_TIME
	<b>496 TOTAL_RQST_TIME</b>	<b>341</b>	-
496	TOTAL_COMPILE_TIME	251	TOTAL_RQST_TIME
496	TOTAL_SECTION_TIME	46	TOTAL_RQST_TIME
496	TOTAL_IMPLICIT_COMPILE_TIME	5	TOTAL_RQST_TIME
496	TOTAL_SECTION_SORT_TIME	2	TOTAL_SECTION_TIME

11 record(s) selected.

In this case, the values for **total\_rqst\_time** for each connection are included in the results, which includes the values for all other elements for which it is the parent. Similarly, the values for items in *italics* roll up to the **total\_section\_time**. Had they not been excluded in the WHERE clause, they would have been triple-counted in the results, as **total\_section\_time** itself rolls up to **total\_rqst\_time**.

## Monitoring scenarios

### Scenario: Identifying costly applications using built-in administrative views

Recent increases in the workload on the ShopMart database have started hindering overall database performance. Jessie, the ShopMart DBA, is trying to identify the larger resource consumers in the daily workload using the following administrative views:

#### MON\_CONNECTION\_SUMMARY

This view helps Jessie identify applications that might be performing large table scans:

```
CONNECT TO SHOPMART;
SELECT APPLICATION_HANDLE, ROWS_READ_PER_ROWS_RETURNED
FROM SYSIBMADM.MON_CONNECTION_SUMMARY;
```

The value of ROWS\_READ\_PER\_ROWS\_RETURNED shows her the average number of rows accessed from the base tables per rows returned to the application. If this value is a high number, the application might be performing a table scan that could be avoided with the creation of an index. Jessie uses this view to identify potentially troublesome queries, and then she can investigate further by looking at the SQL to see whether there are any ways to reduce the number of rows that are read in the execution of the query.

#### MON\_CURRENT\_SQL

Jessie uses the MON\_CURRENT\_SQL administrative view to identify the longest running queries that are currently being executed:

```
CONNECT TO SHOPMART;
SELECT ELAPSED_TIME_SEC, ACTIVITY_STATE, ACTIVITY_TYPE, APPLICATION_HANDLE
FROM SYSIBMADM.MON_CURRENT_SQL
ORDER BY ELAPSED_TIME_SEC DESC
FETCH FIRST 5 ROWS ONLY;
```

Using this view, she can determine the length of time these queries have been running, and the status of these queries. If a query has been executing for a long time and is waiting on a lock, she can issue a query on the MON\_LOCKWAITS administrative view specifying an agent id to investigate further.

The MON\_CURRENT\_SQL view can also tell her the statement that is being executed, allowing her to identify potentially problematic SQL.

## MON\_PKG\_CACHE\_SUMMARY

Jessie uses the MON\_PKG\_CACHE\_SUMMARY to troubleshoot queries that have been identified as problematic. This view can tell her how frequently a query is run as well as the average execution time for each of these queries:

```
CONNECT TO SHOPMART;
SELECT SECTION_TYPE, EXECUTABLE_ID, NUM_COORD_EXEC,
       NUM_COORD_EXEC_WITH_METRICS, AVG_STMT_EXEC_TIME, PREP_TIME
FROM SYSIBMADM.MON_PKG_CACHE_SUMMARY
ORDER BY NUM_COORD_EXEC DESC;
```

The value of PREP\_TIME tells Jessie what amount of time was spent compiling the queries compared to its execution time. If the time it takes to compile and optimize a query is almost as long as it takes for the query to execute, Jessie might want to advise the owner of the query to change the optimization class used for the query. Lowering the optimization class might make the query complete optimization more rapidly and therefore return a result sooner. However, if a query takes a significant amount of time to prepare but is executed thousands of times (without being prepared again) then changing the optimization class might not benefit query performance.

Jessie also uses the MON\_PKG\_CACHE\_SUMMARY view to identify the most frequently executed and the longest-running SQL statements. Having this information will allow Jessie to focus her SQL tuning efforts on the queries that represent some of the biggest resource consumers

To identify the most frequently run SQL statements, Jessie issues the following statements:

```
CONNECT TO SHOPMART;
SELECT SECTION_TYPE, NUM_COORD_EXEC, NUM_COORD_EXEC_WITH_METRICS,
       AVG_STMT_EXEC_TIME, PREP_TIME, SUBSTR(STMT_TEXT, 1, 100) AS STMT_TEXT
FROM SYSIBMADM.MON_PKG_CACHE_SUMMARY
ORDER BY NUM_COORD_EXEC DESC
FETCH FIRST 5 ROWS ONLY;
```

The output shows all of the details regarding the execution time and the statement text for the five most frequent SQL statements.

To identify the SQL statements with the longest execution times, Jessie examines the queries with the top five values for AVG\_STMT\_EXEC\_TIME:

```
CONNECT TO SHOPMART;
SELECT SECTION_TYPE, NUM_COORD_EXEC, NUM_COORD_EXEC_WITH_METRICS,
       AVG_STMT_EXEC_TIME, SUBSTR(STMT_TEXT, 1, 100) AS STMT_TEXT
FROM SYSIBMADM.MON_PKG_CACHE_SUMMARY
ORDER BY AVG_STMT_EXEC_TIME DESC
FETCH FIRST 5 ROWS ONLY;
```

## Scenario: Monitoring buffer pool efficiency using built-in administrative views

**Note:** The information that follows discusses buffer pools in environments other than Db2 pureScale environments. Buffer pools work differently in Db2 pureScale environments. For more information, see "[Buffer pool monitoring in a Db2 pureScale environment](#)", in the *Database Monitoring Guide and Reference*.

John, a DBA, suspects that poor application performance in the SALES database is a result of buffer pools that function inefficiently. To investigate, he takes a look at the buffer pool hit ratio using the MON\_BP\_UTILIZATION administrative view:

```
CONNECT TO SALES;
SELECT BP_NAME, DATA_HIT_RATIO_PERCENT, INDEX_HIT_RATIO_PERCENT,
       XDA_HIT_RATIO_PERCENT, COL_HIT_RATIO_PERCENT
FROM SYSIBMADM.MON_BP_UTILIZATION;
```

John sees that the hit ratio for one of the buffer pools is very low, which means that too many pages are being read from disk instead of being read from the buffer pool.

He then decides to use the MON\_BP\_UTILIZATION administrative view to see whether the prefetchers require tuning:

```
CONNECT TO SALES;  
SELECT BP_NAME, PREFETCH_RATIO_PERCENT FROM SYSIBMADM.MON_BP_UTILIZATION;
```

The value of PREFETCH\_RATIO\_PERCENT tells him the percentage of pages read asynchronously with prefetching. A low value indicates that a high percentage of data is being read directly from disk, and might indicate that more prefetchers are required.

Since the value for PREFETCH\_RATIO\_PERCENT seems within the acceptable range, John uses the MON\_BP\_UTILIZATION administrative view to investigate how well the page cleaners are working to clear space for incoming data pages:

```
CONNECT TO SALES;  
SELECT BP_NAME, AVG_WRITE_TIME, SYNC_WRITES_PERCENT,  
       AVG_SYNC_WRITE_TIME, AVG_ASYNC_WRITE_TIME  
FROM SYSIBMADM.MON_BP_UTILIZATION;
```

The value of SYNC\_WRITES\_PERCENT tells John what percentage of physical write requests that were performed synchronously. If this number is low, it might mean that the page cleaners are working well to clear space in the buffer pool ahead of incoming requests for new data pages. If this number is high, then a higher number of physical writes are being performed by database agents while an application waits for data a data page to be read into the buffer pool.

John sees that the value of SYNC\_WRITES\_PERCENT is 75 percent, so he decides to configure more page cleaners for the SALES database to increase the rate of asynchronous writes. After increasing the number of page cleaners, he can use the buffer pool administrative views again to see the effects of his tuning.

## Event monitors

---

Monitoring table functions and snapshot routines return the values of monitor elements at the specific point in time the routine is run, which is useful when you want to check the current state of your system. However, you might not always want to monitor points in time. There are many times when you need to capture information about the state of your system at exactly the time that a specific event occurs. Event monitors serve this purpose.

Event monitors can be created to capture point-in-time information related to different kinds of *events* that take place in your system. For example, you can create an event monitor to capture information when a specific threshold that you define is exceeded. The information captured includes such things as the ID of the application that was running when the threshold was exceeded. Or, you might create an event monitor to determine what statement was running when a lock event occurred.

### Types of events for which event monitors capture data

You can use event monitors to capture information related to many different kinds of events that take place on your system.

The following table lists the types of events that occur in the system that you can monitor with an event monitor. It also describes the type of data collected for different events, as well as when the monitoring data is collected. The names of the event monitors shown in column two correspond to the keywords used to create that type of event monitor using the CREATE EVENT MONITOR statement.

Table 3. Event Types

Type of event to monitor	Event monitor name	Event monitor properties	Details
Locks and deadlocks	LOCKING	<i>Uses of this event monitor</i>	To determine when locks or deadlocks occur, and the applications that are involved. The advantages of using the LOCKING event monitor instead of the deprecated DEADLOCKS event monitor include consolidated reporting of both lock and deadlock events, as well as the inclusion of information about lock waits and lock time-outs.
		<i>Data collected</i>	Comprehensive information regarding applications involved, including the identification of participating statements (and statement text) and a list of locks being held.
		<i>When the event data is generated<sup>1</sup></i>	<p>Upon detection of any of the following event types, depending on how you configure the event monitor:</p> <ul style="list-style-type: none"> <li>lock timeout</li> <li>deadlock</li> <li>lock wait beyond a specified duration</li> </ul>
Execution of a SQL statements or other operation that spawns a database activity.	ACTIVITIES	<i>Uses of this event monitor</i>	To track the execution of individual statements and other activities to understand what activities are running in the system. Also to capture activities for diagnostic reasons, and to study the resource consumption of SQL.
		<i>Data collected</i>	<p>Activity level data, generally for activities involving workload management objects.</p> <ul style="list-style-type: none"> <li>If WITH DETAILS was specified as part of COLLECT ACTIVITY DATA clause on the CREATE or ALTER statements for a workload management object, then information collected includes statement and compilation environment information for those activities that have it. If WITH SECTION is also specified, then statement, compilation environment, section environment data, and section actuals are also captured.</li> <li>If AND VALUES was also specified on the CREATE OR ALTER statement for the workload management object, the information collected will also include input data values for those activities that have it.</li> </ul>
		<i>When event data is generated<sup>1</sup></i>	<ul style="list-style-type: none"> <li>Upon completion of an activity that executed in a service class, workload or work class that had its COLLECT ACTIVITY DATA option turned on.</li> <li>When an activity violates a threshold that has the COLLECT ACTIVITY DATA option enabled.</li> <li>At the instant the WLM_CAPTURE_ACTIVITY_IN_PROGRESS stored procedure is executed.</li> <li>When an activity is executed by a connection for which activity collection has been enabled using the WLM_SET_CONN_ENV stored procedure.</li> </ul>

Table 3. Event Types (continued)

Type of event to monitor	Event monitor name	Event monitor properties	Details
Execution of an SQL statement	STATEMENTS	<i>Uses of this event monitor</i>	To see what requests are being made to the database as a result of the execution of SQL statements.
		<i>Data collected</i>	Statement start or stop time, CPU used, text of dynamic SQL, SQLCA (return code of SQL statement), and other metrics such as fetch count. For partitioned databases: CPU used, execution time, table and table queue information.  <b>Notes:</b> <ul style="list-style-type: none"> <li>When monitoring the execution of SQL procedures using statement event monitors, data manipulation language (DML) statements, such as INSERT, SELECT, DELETE, and UPDATE, generate events. Procedural statements, such as variable assignments and control structures (for example, WHILE or IF), do not generate events in a deterministic fashion.</li> <li>Statement start or stop time is unavailable when the Timestamp switch is off.</li> </ul>
		<i>When event data is generated</i>	End of SQL statement <sup>2</sup> ; for partitioned databases, End of subsection <sup>2</sup>
Completion of a unit of work (transaction)	UNIT OF WORK	<i>Uses of this event monitor</i>	To gather resource usage information and performance metrics for units of work that run on the system. This information can be used for purposes ranging from generating reports for billing or charge-back purposes of system resources used by an application, to troubleshooting performance problems caused by slow-running routines.  Recommended over the TRANSACTIONS event monitor.
		<i>Data collected</i>	Information about units of work (transactions), such as start and stop time, the workload and service class under which they ran. Option to include information about packages or executable IDs for statements run as part of the unit of work, as well as request metrics.
		<i>When event data is generated</i> <sup>1</sup>	Upon completion of a unit of work
Eviction of sections from the package cache	PACKAGE CACHE	<i>Uses of this event monitor</i>	To capture a history of statements (and related metrics) that are no longer in the package cache. This information can be used if you need to examine performance metrics for statements that are no longer available in memory.
		<i>Data collected</i>	Includes statement text and metrics aggregated over all executions of the section.
		<i>When event data is generated</i> <sup>1</sup>	As entries are evicted from the package cache.
Connections to the database by applications	CONNECTIONS	<i>Uses of this event monitor</i>	To capture metrics and other monitor elements for each connection to the database by an application.
		<i>Data collected</i>	All application-level counters. For example, the time that the application connected to or disconnected from the database, or number of lock escalations that the application was involved with.
		<i>When event data is generated</i>	End of connection <sup>2</sup>

Table 3. Event Types (continued)

Type of event to monitor	Event monitor name	Event monitor properties	Details
Deactivation of database	DATABASE	<i>Uses of this event monitor</i>	To capture metrics and other monitor elements that reflect information about the database as whole, since activation.
		<i>Data collected</i>	All database level counters. For example, the number of connections made to a database, time spent waiting on locks, or rows of data inserted since its activation.
		<i>When event data is generated</i>	Database deactivation <sup>2</sup>
	BUFFERPOOLS TABLESPACES	<i>Uses of this event monitor</i>	To capture metrics related to buffer pools and table spaces.
		<i>Data collected</i>	Counters for buffer pools, prefetchers, page cleaners and direct I/O for each buffer pool.
		<i>When event data is generated</i>	Database deactivation <sup>2</sup>
	TABLES	<i>Uses of this event monitor</i>	To capture metrics related to tables that have changed since database activation.
		<i>Data collected</i>	Table level counters, such as rows read or written, or disk pages used by data,LOB or index objects.
		<i>When event data is generated</i>	Database deactivation <sup>2</sup>
Statistics and metrics on workload management objects	STATISTICS	<i>Uses of this event monitor</i>	To capture processing metrics related to workload management objects (for example service superclasses, or workloads) in the database. For example, you could use a statistics event monitor to check on CPU utilization over time for a given workload.
		<i>Data collected</i>	Statistics computed from the activities that executed within each service class, workload, or work class that exists on the system.
		<i>When event data is generated</i>	Statistics can be collected automatically at regular intervals. This interval is defined with the <b>wlm_collect_int</b> database configuration parameter.  Data can also collected manually, using the WLM_COLLECT_STATS stored procedure.  <b>Note:</b> With either collection mechanism, the values of statistics monitor elements are reset to 0 after collection has taken place.
Exceeding a workload manager threshold	THRESHOLD VIOLATIONS	<i>Uses of this event monitor</i>	To determine when specific thresholds that you set are exceeded during database operations. Thresholds can be set for a variety of things, ranging from CPU time to the number of database connections, to the execution of specific statements. Data collected can be used for a variety of purposes, including monitoring for potential problems (such as approaching limits on temporary table space).
		<i>Data collected</i>	Threshold violation information.
		<i>When event data is generated</i>	Upon detection of a threshold violation. Thresholds are defined using the CREATE THRESHOLD statement.

Table 3. Event Types (continued)

Type of event to monitor	Event monitor name	Event monitor properties	Details
Changes to database or database manager configuration	CHANGE HISTORY	<i>Uses of this event monitor</i>	To captures change to database and database manager configuration and registry settings, execution of DDL statements, and execution of utilities
		<i>Data collected</i>	Database and database manager configuration parameter changes, registry variable changes, execution of DDL statements, execution of certain database utilities and commands, and change history event monitor startup.  <b>Note:</b> Generally, information related to events that occur while the change history event monitor is inactive or the database is offline are not captured. However, changes to registry variables and configuration parameters are recorded.
		<i>When event data is generated<sup>1</sup></i>	Upon monitor startup, when a parameter or variable changes, or when a command, DDL, or utility completes.
<p><b>Notes:</b></p> <ol style="list-style-type: none"> <li>1. If a database is deactivated while an activity event monitor is active, backlogged activity records in the queue are discarded. To ensure that you obtain all activities event monitor records and that none are discarded, deactivate the activities event monitor before deactivating the database. When an activities event monitor is explicitly deactivated, all backlogged activity records in the queue are processed before the event monitor deactivates.</li> <li>2. In addition to the defined times where data collection automatically occurs, you can use the FLUSH EVENT MONITOR SQL statement to generate events. The events generated by this method are written with the current database monitor values for all the monitor types (except for DEADLOCKS and DEADLOCKS WITH DETAILS) associated with the flushed event monitor.</li> </ol>			

Table 4. Event Types For Deprecated Event Monitors

Type of event to monitor	Event monitor name	Event monitor properties	Details
Deadlocks	DEADLOCKS <sup>2</sup>	<i>Uses of this event monitor</i>	To determine when deadlocks occur, and the applications that are involved.
		<i>Data collected</i>	Applications involved, and locks in contention.
		<i>When event data is generated</i>	Detection of a deadlock
	DEADLOCKS WITH DETAILS <sup>2</sup>	<i>Uses of this event monitor</i>	To determine when deadlocks occur, and the applications that are involved.
		<i>Data collected</i>	Comprehensive information regarding applications involved, including the identification of participating statements (and statement text) and a list of locks being held. Using a DEADLOCKS WITH DETAILS event monitor instead of a DEADLOCKS event monitor will incur a performance cost when deadlocks occur, due to the extra information that is collected.
		<i>When event data is generated</i>	Detection of a deadlock
	DEADLOCKS WITH DETAILS HISTORY <sup>2</sup>	<i>Uses of this event monitor</i>	To determine when deadlocks occur, and the applications that are involved.
		<i>Data collected</i>	All information reported in a DEADLOCKS WITH DETAILS event monitor, along with the statement history for the current unit of work of each application owning a lock participating in a deadlock scenario for the database partition where that lock is held. Using a DEADLOCKS WITH DETAILS HISTORY event monitor will incur a minor performance cost when activated due to statement history tracking.
		<i>When event data is generated</i>	Detection of a deadlock
	DEADLOCKS WITH DETAILS HISTORY VALUES <sup>2</sup>	<i>Uses of this event monitor</i>	
		<i>Data collected</i>	All information reported in a deadlock with details and history, along with the values provided for any parameter markers at the time of execution of a statement. Using a DEADLOCKS WITH DETAILS HISTORY VALUES event monitor will incur a more significant performance cost when activated due to extra copying of data values.
		<i>When event data is generated</i>	Detection of a deadlock
Completion of a unit of work (transaction)	TRANSACTIONS <sup>3</sup>	<i>Uses of this event monitor</i>	
		<i>Data collected</i>	UOW work start or stop time, previous UOW time, CPU consumed, locking and logging metrics. Transaction records are not generated if running with XA.
		<i>When event data is generated</i>	Upon completion of a unit of work <sup>1</sup>

**Notes:**

1. In addition to the defined times where data collection automatically occurs, you can use the FLUSH EVENT MONITOR SQL statement to generate events. The events generated by this method are written with the current database monitor values for all the monitor types (except for DEADLOCKS and DEADLOCKS WITH DETAILS) associated with the flushed event monitor.
2. This event monitor has been deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR FOR LOCKING statement to monitor lock-related events, such as lock timeouts, lock waits, and deadlocks.
3. This event monitor has been deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR FOR UNIT OF WORK statement to monitor transaction events.

**Note:** A detailed deadlock event monitor is created for each newly created database. This event monitor, named DB2DETAILDEADLOCK, starts when the database is activated and will write to files in the database directory. You can avoid the additional processor time this event monitor requires by dropping it. The

DB2DETAILDEADLOCK event monitor is deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR FOR LOCKING statement to monitor lock-related events, such as lock timeouts, lock waits, and deadlocks.

## Working with event monitors

Generally, the process of creating and using event monitors to capture information about the system when certain events occur is similar for all event monitor types. First you create the event monitor, then you enable data collection, and finally, you access the data gathered.

### About this task

This topic provides an outline of the general steps to follow when working with event monitors.

### Procedure

To use an event monitor to capture event information:

1. Create the event monitor.

To create an event monitor, use the appropriate version of the CREATE EVENT MONITOR statement. When you create an event monitor, you must choose how to record the data the event monitor collects. All event monitors can write their output to relational tables; however, depending on your specific purposes, there are different options that might be more appropriate.

2. Activate the event monitor.

To activate the event monitor, use the SET EVENT MONITOR STATE statement.

For example, for an event monitor called **capturestats**, use the following command:

```
SET EVENT MONITOR capturestats STATE 1
```

To turn off data collection by the event monitor, use the following statement:

```
SET EVENT MONITOR capturestats STATE 0
```

By default, some event monitors activate automatically upon database activation; others require that you activate them manually. However, an event monitor created with the AUTOSTART option will not automatically be activated until the next database activation. Use the SET EVENT MONITOR STATE statement to force a recently-created event monitor into the active state. To determine whether an event monitor starts automatically, refer to the reference information for the relevant CREATE EVENT MONITOR statement.

3. Enable the collection of data. (Only for LOCKING, ACTIVITIES, STATISTICS, UNIT OF WORK and PACKAGE CACHE event monitors)

Enabling data collection involves configuring the database manager to gather specific types of data to be recorded by event monitors.

Not all event monitors require data collection to be enabled; for those that do not, such as the TABLE event monitor, creating and activating them is sufficient to cause data to be collected. The threshold violations event monitor also starts data collection automatically; however, in this case, you must also define the thresholds for which you want data captured using the CREATE THRESHOLD statement.

For those event monitors that require data collection to be enabled, there are different options available to you. Depending on the type of event monitor you are working with, you might set a database configuration parameter to enable data collection across the entire database. Alternatively, you might choose to enable the collection of specific kinds of data for specific types of workload objects.

For example, to configure the collection of basic information for a unit of work event monitor when any unit of work in the system finishes, you can set the **mon\_uow\_data** parameter to BASE. Alternatively, to capture unit of work information only for a specific workload, you can specify the COLLECT UNIT OF WORK DATA BASE clause as part of the CREATE WORKLOAD or ALTER WORKLOAD statements.

4. Run your applications or queries.

After the event monitor has been created, and activated, and you have enabled data collection, run the applications or queries for which you want to collect data.

5. Optional: Deactivate the event monitor.

After you run the applications or queries for which you want data collected, you can deactivate the event monitor using the SET EVENT MONITOR STATE statement. (see step “2” on page 34). Deactivating the event monitor is not necessary before proceeding to the next step, however leaving the event monitor active will result in disk space being used for data that you might not be interested in looking at.

6. Examine the data collected by the event monitor.

Depending on the type of output the event monitor creates, there are different options for accessing the data collected. If the data is written directly to a relational table, you can use SQL to access the data contained in the table columns. On the other hand, if the event monitor writes to an unformatted event (UE) table, you must post-process the UE table using a command like **db2evmonfmt** or a procedure like **EVMON\_FORMAT\_UE\_TO\_TABLES** before you can view the event data.

7. Optional: Prune data that is no longer needed from the event monitor tables.

For event monitors that you use on a regular basis, you might want to prune unneeded data from the tables. For example, if you use a unit of work event monitor to generate daily accounting reports about the system resources used by different applications, you might want to delete the current day's data from the event monitor tables once the reports have been generated.

**Tip:** If you need to prune event monitor output regularly, consider using an unformatted event (UE) table to record event monitor output. UE tables can be pruned automatically after data is transferred to regular tables.

## Creating event monitors

You create different types of event monitors by using variations on the CREATE EVENT MONITOR statement. You can use the options for that statement to specify the type of data that event monitors collect and how the event monitors produce their output. The sections that follow describe the different output options and how to create event monitors that produce these types of output.

### Before you begin

Before creating an event monitor, it is important to understand the different options for the output that event monitors can produce. Most event monitors can produce output in at least two formats; some let you choose from up to four formats.

### Procedure

To create an event monitor:

1. Determine what kind of event monitor you need.
2. Decide what type of output you want from the event monitor. Do you want data to be written to a regular table, an unformatted event table, a file, or a pipe?
3. Issue a CREATE EVENT MONITOR statement.
4. If the type of event monitor that you created requires activation, activate it by issuing the SET EVENT MONITOR STATE statement.

### Output options for event monitors

Event monitors can report the data they collect in a number of ways. All event monitors can write the data they collect to tables; some write to unformatted event (UE) tables, which can help improve performance. Others can also write directly to a file or named pipe.

Depending on how you want to use the information collected by event monitors, and on the type of event monitor, you can choose to have the output that the event monitors collect produced in different ways. The output types available include:

## Regular tables

All event monitors can write to regular tables that can be queried directly using SQL. For a given event, each of the monitor elements or metrics collected for the event is written to its own column in the table. This makes it possible to use a SELECT statement query the output to examine the values for a specific monitor element.

To create an event monitor that writes to tables, specify the WRITE TO TABLE clause in the CREATE EVENT MONITOR statement. Depending on the event monitor, one or more tables are created to contain the output, each table containing monitor elements that belong to a single logical group. See [“Target tables, control tables, and event monitor table management” on page 109](#) for details about the specific table produced for each logical group.

Tables can be stored in a table space of your choosing; however the target table of a CREATE EVENT MONITOR statement must be a non-partitioned table.

**Note:** There are two types of event monitors that write to tables. The first type includes event monitors created in version 9.7 and later releases. These include the unit of work, package cache, locking and change history event monitor. As of Db2 version 10.1, the first three of these event monitors can write their output to regular tables as an alternative to UE tables. The change history event monitor writes only to regular tables.

The second type are the event monitors implemented before Db2 version 9.7. These include all other event monitors.

Generally, after an event monitor of either type has been created, they work in much the same way. That is, you can use SQL to directly access the data in the tables that they produce. However, the older event monitors in the second category have additional options that you can specify when creating the event monitor. In addition, only event monitors in the second category are capable of writing also to files and named pipes.

## Unformatted event (UE) tables

UE tables are relational tables; however, they have only a limited number of columns. Most of the data associated with each event is written to a column containing an inline binary (BLOB) object. Writing event data in binary format reduces the time it takes to write each record to the table. For this reason, UE tables are particularly useful where event monitor performance is important, which might be the case on highly I/O or CPU-bound systems.

However, because the event data is written in binary format, you cannot use SQL to extract legible data. You must perform post-processing on the UE table to extract the data stored in binary format. Another benefit of using UE tables is that you can have UE table data pruned automatically during post-processing. The EVMON\_FORMAT\_UE\_TO\_TABLES procedure has an option to delete data from the UE table after it has been successfully extracted.

To create an event monitor that writes to an unformatted event table, specify the WRITE TO UNFORMATTED EVENT TABLE clause in the CREATE EVENT MONITOR statement. Only one UE table is created per event monitor.

## Files

Some event monitors support sending their output directly to files maintained by the file system. This type of output is useful if you do not want the event monitor output to be subject to the additional processing time caused when being managed within the database, or if you want to look at the data while the database is offline. To create an event monitor that writes to files, specify the WRITE TO FILE clause in the CREATE EVENT MONITOR statement.

## Named pipes

If you want to have an application process event data as it is generated, you can use a named pipe event monitor. These types of event monitors send their output directly to a named pipe so that the data can be used by another application immediately. This might be useful if you need to manipulate event data in real time.

To create an event monitor that writes to a named pipe, specify the WRITE TO PIPE clause in the CREATE EVENT MONITOR statement.

Depending on your needs, one type of event monitor output might be more appropriate than another. Table 5 on page 37 provides an summary of when specific output types are particularly useful.

Output type	Scenarios where this output type is useful
Regular tables	<ul style="list-style-type: none"> <li>• When you want to examine monitoring data at a later point in time</li> <li>• In systems that are not approaching the maximum capacity for CPU, log file or disk storage</li> <li>• Where immediate access to data using SQL is desirable</li> </ul>
Unformatted event (UE) tables	<ul style="list-style-type: none"> <li>• When you want to examine monitoring data at a later point in time</li> <li>• In systems where event monitor performance is a priority, or where there are constraints on CPU, log file or disk usage</li> <li>• Where the added step of post-processing of data is not an issue</li> </ul>
Files	<ul style="list-style-type: none"> <li>• In systems where you do not want or need to manage monitor data as part of the database. (Eliminates the additional processing time of logging, inserts, maintaining consistency)</li> <li>• When you want to store the data outside of the database being monitored</li> <li>• When you want to examine the data offline at later point in time</li> </ul>
Pipes	<ul style="list-style-type: none"> <li>• Streaming event data to an application that processes it immediately.</li> <li>• When there is no need to access event data at a later point in time.</li> </ul>

Not all event monitors support all output types. For example, only the unit of work, package cache and locking event monitor can produce a UE table. Table 6 on page 37 shows what output options are available for different types of event monitors:

Event monitor type	Regular table	Unformatted event table	File	Named pipe
Activity	Yes		Yes	Yes
Buffer pool	Yes		Yes	Yes
Change history	Yes			
Connections	Yes		Yes	Yes
Database	Yes		Yes	Yes
Deadlocks*(all variations)	Yes		Yes	Yes
Locking	Yes	Yes		
Package cache	Yes	Yes		
Statement	Yes		Yes	Yes
Statistics	Yes		Yes	Yes
Table space	Yes		Yes	Yes
Table	Yes		Yes	Yes

Table 6. Output options for event monitors (continued)

Event monitor type	Regular table	Unformatted event table	File	Named pipe
Threshold violations	Yes		Yes	Yes
Transaction*	Yes		Yes	Yes
Unit of work	Yes	Yes		

\* Deprecated event monitor.

### Event monitors that write to tables

All event monitors can write output to regular tables that can be queried directly using SQL.

In addition, you can use the procedure `EVMON_UPGRADE_TABLES` to upgrade the tables produced by event monitors in earlier releases. This capability lets you more easily retain event monitor data that was recorded earlier.

#### Creating event monitors that write to tables

To create an event monitor, use the `CREATE EVENT MONITOR STATEMENT`. There are different forms of this statement that you use, depending on the type of events that you intend to monitor.

### Before you begin

- You need `SQLADM` or `DBADM` authority to create a table event monitor.
- The target table of a `CREATE EVENT MONITOR` statement - that is, the table to which the event monitor writes its output - must be a non-partitioned table.

### About this task

The various options for table event monitors are set in the `CREATE EVENT MONITOR` statement. For further assistance in generating `CREATE EVENT MONITOR` SQL statements for write-to-table event monitors, you can use the `db2evtb1` command. Simply provide the name of the event monitor and the required event type (or types), and the `CREATE EVENT MONITOR` statement is generated, complete with listings of all the target tables. You can then copy the generated statement, make modifications, and then execute the statement from the command line processor.

### Procedure

To create an event monitor that writes its output to a regular table, perform the following steps:

1. Formulate a `CREATE EVENT MONITOR` statement using the `WRITE TO TABLE` clause to indicate that event monitor data is to be collected in a table (or set of tables).

```
CREATE EVENT MONITOR evmon-name FOR eventtype
WRITE TO TABLE
```

Where `evmon-name` is the name of the event monitor, and `eventtype` is one of the following values:

- `ACTIVITIES`
- `BUFFERPOOLS`
- `CHANGE HISTORY`
- `CONNECTIONS`
- `DATABASE`
- `DEADLOCKS`
- `LOCKING`
- `PACKAGE CACHE`

- STATEMENTS
- STATISTICS
- TABLE
- TABLESPACE
- THRESHOLD VIOLATIONS
- TRANSACTIONS
- UNIT OF WORK

For example, to create a unit of work event monitor called `myevmon`, use a statement like the one that follows:

```
CREATE EVENT MONITOR myevmon FOR UNIT OF WORK
WRITE TO TABLE
```

The preceding statement creates a unit of work event monitor that uses defaults for the logical groups of monitor elements collected, the corresponding output table names, and the target table spaces for the tables. For more information on these defaults, refer to the documentation for the appropriate `CREATE EVENT MONITOR` statement.

2. Optional: Specify the logical groups for which you want data collected.

By default, event data is collected for all logical data groups for the event monitor type. (See [“Target tables, control tables, and event monitor table management”](#) on page 109 for details.) If you want only data for selected logical groups collected, you can specify the names of the logical groups to include in the `CREATE EVENT MONITOR` statement. For example, with a locking event monitor, you might want to collect only the information associated with the `LOCK` and `PARTICIPANT` logical groups. To include only these logical groups, you can use a statement like the one that follows:

```
CREATE EVENT MONITOR mylocks FOR LOCKING
WRITE TO TABLE
LOCK, PARTICIPANTS
```

3. Optional: Specify the table names to use for the output tables.

Unless you specify otherwise, default names are used for the tables for each logical group of monitor elements. The default name used is derived by concatenating the logical group name with the name of the event monitor. For example, for the locking event monitor created by the statement in the preceding step, the unqualified names for the tables produced are `LOCK_MYLOCKS` and `PARTICIPANTS_MYLOCKS`. To override the default names, include the table names to use when specifying the logical groups:

```
CREATE EVENT MONITOR mylocks FOR LOCKING
WRITE TO TABLE
LOCK(TABLE LOCKDATA), PARTICIPANTS(TABLE PARTICIP)
```

In the preceding example, the names used for the tables for the `LOCK` and `PARTICIPANTS` logical groups are `LOCKDATA_MYLOCKS` and `PARTICIP_MYLOCKS`.

You can also override the table space to be used for each table by including the name of the table space to use:

```
CREATE EVENT MONITOR mylocks FOR LOCKING
WRITE TO TABLE
LOCK(TABLE LOCKDATA IN EVMONSPACE), PARTICIPANTS(TABLE PARTICIP IN EVMONSPACE)
```

In the preceding example, the `EVMONSPACE` table space is used for both output tables.

### Additional options

Different event monitors provide different configuration options. For details on the options available for a specific type of event monitor, refer to the documentation for the `CREATE EVENT MONITOR` statement

for the type of event monitor you want to use. The examples that follow show some of the configuration options you can choose for different event monitors:

### Capturing multiple event types with a single event monitor

Some types<sup>3</sup> of event monitors can capture different types of events with a single event monitor. If you want to capture multiple types of events with this event monitor, specify additional values for event type, separated by a comma. For example, you might want to combine bufferpool and table space monitoring in a single event monitor:

```
CREATE EVENT MONITOR myevmon FOR BUFFERPOOLS, TABLESPACES
WRITE TO TABLE
```

This event monitor will monitor for the BUFFERPOOL and TABLESPACE event types. Assuming that the previously listed statement was issued by the user dbadmin, the derived names and table spaces of the target tables are as follows:

- DBADMIN.BUFFERPOOL\_MYEVMON
- DBADMIN.TABLESPACE\_MYEVMON
- DBADMIN.CONTROL\_MYEVMON

### Adjusting the size of event monitor output buffers

You can alter the size of the table event monitor buffers (in 4K pages) for some types<sup>3</sup> of event monitors by adjusting the BUFFERSIZE value. For example, in the following statement:

```
CREATE EVENT MONITOR myevmon FOR BUFFERPOOLS, TABLESPACES
WRITE TO TABLE BUFFERSIZE 8
```

8 is the combined capacity (in 4K pages) of the two event table buffers. This adds up to 32K of buffer space; 16K for each buffer.

The default size of each buffer is 4 pages (two 16K buffers are allocated). The minimum size is 1 page. The maximum size of the buffers is limited by the size of the monitor heap, because the buffers are allocated from that heap. For performance reasons, highly active event monitors should have larger buffers than relatively inactive event monitors.

### Controlling whether event monitor output is blocked or non-blocked

Some event monitors<sup>3</sup> let you control how to proceed when event monitor output buffers are full. For blocked event monitors, each agent that generates an event will wait for the event buffers to be written to table if they are full. This can degrade database performance, as the suspended agent and any dependent agents cannot run until the buffers are clear. Use the BLOCKED clause to ensure no losses of event data:

```
CREATE EVENT MONITOR myevmon FOR BUFFERPOOLS, TABLESPACES
WRITE TO TABLE BUFFERSIZE 8 BLOCKED
```

If database performance is of greater importance than collecting every single event record, use non-blocked event monitors. In this case, each agent that generates an event will not wait for the event buffers to be written to table if they are full. As a result, non-blocked event monitors are subject to data loss on highly active systems. Use the NONBLOCKED clause to minimize the additional processing time caused by event monitoring:

```
CREATE EVENT MONITOR myevmon FOR BUFFERPOOLS, TABLESPACES
WRITE TO TABLE BUFFERSIZE 8 NONBLOCKED
```

**Note:** See “Target tables, control tables, and event monitor table management” on page 109 and “Write-to-table and file event monitor buffering” on page 126 for additional information about how information about discarded events is written to the control table for the event monitor.

<sup>3</sup> Event monitors for BUFFERPOOLS, CONNECTIONS, DATABASE, DEADLOCKS, STATEMENTS, TABLES, and TABLESPACES support this option.

## Controlling what monitor elements for which data is collected

Which monitor elements to collect data for. If you are interested in only a few monitor elements, you can specify which ones you want to collect for some event monitors<sup>3</sup> by specifying the element name in the CREATE EVENT MONITOR statement:

```
CREATE EVENT MONITOR myevmon FOR DATABASE, BUFFERPOOLS, TABLESPACES
WRITE TO TABLE DB, DBMEMUSE,
BUFFERPOOL (EXCLUDES(db_path, files_closed)),
TABLESPACE (INCLUDES
(tablespace_name, direct_reads, direct_writes))
BUFFERSIZE 8 NONBLOCKED
```

All the monitor elements for the DB and DBMEMUSE logical data groups are captured (this is the default behavior). For BUFFERPOOL, all monitor elements except **db\_path** and **files\_closed** are captured. And finally, for TABLESPACE, **tablespace\_name**, **direct\_reads** and **direct\_writes** are the only monitor elements captured.

## Setting a threshold for deactivating an event monitor based on table space used

All event monitors provide the option to specify how full the table space can get before the event monitor automatically deactivates:

```
CREATE EVENT MONITOR myevmon FOR BUFFERPOOLS, TABLESPACES
PCTDEACTIVATE 90
```

When the table space reaches 90% capacity, the myevmon event monitor automatically shuts off. The PCTDEACTIVATE clause can only be used for DMS table spaces. If the target table space has auto-resize enabled, set the PCTDEACTIVATE clause to 100.

## What to do next

By default, event monitors that were introduced in version 9.7 or later are created as AUTOSTART event monitors. They are activated automatically when the database is next activated, and on subsequent database activations thereafter. If you want to activate the event monitor immediately, before the next database activation, use the SET EVENT MONITOR STATE statement to manually start the event monitor. In addition for each of the locking, unit of work and package cache event monitors, you must also enable data collection.

### *Event monitor logical data groups and monitor elements*

Monitor elements that are often useful to examine together are grouped in *logical data groups*. All event monitors use logical data groups in one way or another. For some event monitor types, you can specify what information you want to collect by specifying the logical data groups for which you want information recorded. Logical data groups are also used to group data together in the output event monitors generate; for example, event monitors that write to tables generally create one table for each logical data group of monitor elements.

The following table lists the logical data groupings and monitor elements that can be returned by event monitoring.

**Attention:** The addition of the coord\_time\_created, event\_timestamp, and application\_handle monitor elements to the following logical data groups is currently available in Db2 V11.5.2 and later releases:

[“partition\\_key - Partitioning key monitor element” on page 1137](#)

## **ddlstmexec logical data group**

[“ddl\\_classification - DDL classification ” on page 801](#)  
[“event\\_id - Event ID monitor element” on page 841](#)  
[“event\\_timestamp - Event timestamp monitor element” on page 843](#)  
[“event\\_type - Event Type monitor element” on page 843](#)  
[“global\\_transaction\\_id - Global transaction identifier monitor element” on page 921](#)  
[“local\\_transaction\\_id - Local transaction identifier monitor element” on page 1000](#)  
[“member - Database member monitor element” on page 1068](#)  
[“partition\\_key - Partitioning key monitor element” on page 1137](#)  
[“savepoint\\_id - Savepoint ID ” on page 1403](#)  
[“stmt\\_text - SQL statement text monitor element” on page 1490](#)  
[“uow\\_id - Unit of work ID monitor element” on page 1676](#)

## **dllock logical data group**

[“data\\_partition\\_id - Data partition identifier monitor element ” on page 784](#)  
[“lock\\_attributes - Lock attributes monitor element” on page 1001](#)  
[“lock\\_count - Lock count monitor element” on page 1002](#)  
[“lock\\_current\\_mode - Original lock mode before conversion monitor element” on page 1003](#)  
[“lock\\_escalation - Lock escalation monitor element” on page 1004](#)  
[“lock\\_hold\\_count - Lock hold count monitor element” on page 1012](#)  
[“lock\\_mode - Lock mode monitor element” on page 1013](#)  
[“lock\\_name - Lock name monitor element” on page 1016](#)  
[“lock\\_object\\_name - Lock Object Name ” on page 1017](#)  
[“lock\\_object\\_type - Lock object type waited on monitor element” on page 1017](#)  
[“lock\\_release\\_flags - Lock release flags monitor element” on page 1020](#)  
[“lock\\_status - Lock status monitor element” on page 1021](#)  
[“node\\_number - Node Number ” on page 1085](#)  
[“table\\_file\\_id - Table file ID monitor element” on page 1504](#)  
[“table\\_name - Table name monitor element” on page 1505](#)  
[“table\\_schema - Table schema name monitor element” on page 1507](#)  
[“tablespace\\_name - Table space name monitor element” on page 1515](#)

**Note:** The underlying implementation for this logical data group is the snapshot monitor LOCK logical data group. If you examine the output for this logical group in the self-describing stream used for the file and pipe output options, you can see that the LOCK group is used to generate the output.

## **event\_activity logical data group**

[“act\\_exec\\_time - Activity execution time monitor element” on page 593](#)

## **event\_histogrambin logical data group**

[“bin\\_id - Histogram bin identifier monitor element” on page 685](#)

[“bottom - Histogram bin bottom monitor element” on page 688](#)

[“histogram\\_type - Histogram type monitor element” on page 944](#)

[“mon\\_interval\\_id - Monitor interval identifier monitor element” on page 1081](#)

[“number\\_in\\_bin - Number in bin monitor element” on page 1102](#)

[“partition\\_key - Partitioning key monitor element” on page 1137](#)

[“partition\\_number - Partition Number ” on page 1138](#)

[“service\\_class\\_id - Service class ID monitor element” on page 1414](#)

[“statistics\\_timestamp - Statistics timestamp monitor element” on page 1476](#)

[“top - Histogram bin top monitor element” on page 1545](#)

[“work\\_action\\_set\\_id - Work action set ID monitor element” on page 1702](#)

[“work\\_class\\_id - Work class ID monitor element” on page 1703](#)

[“workload\\_id - Workload ID monitor element” on page 1704](#)

## **event\_log\_header logical data group**

[“byte\\_order - Byte Order of Event Data ” on page 693](#)

[“codepage\\_id - ID of Code Page Used by Application ” on page 719](#)

[“event\\_monitor\\_name - Event Monitor Name ” on page 842](#)

[“num\\_nodes\\_in\\_db2\\_instance - Number of Nodes in Partition ” on page 1098](#)

[“server\\_instance\\_name - Server Instance Name ” on page 1412](#)

[“server\\_prdid - Server Product/Version ID ” on page 1413](#)

[“territory\\_code - Database Territory Code ” on page 1538](#)

[“version - Version of Monitor Data ” on page 1696](#)

## **event\_overflow logical data group**

[“count - Number of Event Monitor Overflows ” on page 764](#)

[“first\\_overflow\\_time - Time of First Event Overflow ” on page 918](#)

[“last\\_overflow\\_time - Time of Last Event Overflow ” on page 990](#)

[“node\\_number - Node Number ” on page 1085](#)

## **event\_qstats logical data group**

[“last\\_wlm\\_reset - Time of last reset monitor element” on page 993](#)

[“mon\\_interval\\_id - Monitor interval identifier monitor element” on page 1081](#)

[“partition\\_key - Partitioning key monitor element” on page 1137](#)

[“partition\\_number - Partition Number ” on page 1138](#)

[“queue\\_assignments\\_total - Queue assignments total monitor element” on page 1354](#)

[“queue\\_size\\_top - Queue size top monitor element” on page 1354](#)

[“queue\\_time\\_total - Queue time total monitor element” on page 1355](#)

[“service\\_subclass\\_name - Service subclass name monitor element” on page 1417](#)

[“service\\_superclass\\_name - Service superclass name monitor element” on page 1418](#)

[“statistics\\_timestamp - Statistics timestamp monitor element” on page 1476](#)

[“threshold\\_domain - Threshold domain monitor element” on page 1540](#)

[“threshold\\_name - Threshold name monitor element” on page 1541](#)

[“threshold\\_predicate - Threshold predicate monitor element” on page 1541](#)

[“thresholdid - Threshold ID monitor element” on page 1543](#)

[“work\\_action\\_set\\_name - Work action set name monitor element” on page 1703](#)

[“work\\_class\\_name - Work class name monitor element” on page 1703](#)

## **event\_osmetrics logical data group**

[“cpu\\_configured - Number of configured CPUs monitor element” on page 764](#)

[“cpu\\_cores\\_per\\_socket - Number of CPU cores per socket monitor element” on page 765](#)

[“cpu\\_hmt\\_degree - Number of logical CPUs monitor element” on page 766](#)

[“cpu\\_idle - Processor idle time monitor element” on page 766](#)

[“cpu\\_iowait - IO Wait time monitor element” on page 767](#)

[“cpu\\_load\\_long - Processor load \(long timeframe\) monitor element” on page 768](#)

[“cpu\\_load\\_medium - Processor load \(medium timeframe\) monitor element” on page 768](#)

[“cpu\\_load\\_short - Processor load \(short timeframe\) monitor element” on page 769](#)

[“cpu\\_online - Number of CPUs online monitor element” on page 769](#)

[“cpu\\_speed - CPU clock speed monitor element” on page 770](#)

[“cpu\\_system - Kernel time monitor element” on page 770](#)

[“cpu\\_timebase - Frequency of timebase register increment monitor element” on page 771](#)

[“cpu\\_total - Number of CPUs monitor element” on page 772](#)

[“cpu\\_usage\\_total - Processor usage monitor element” on page 772](#)

[“cpu\\_user - Non-kernel processing time monitor element” on page 772](#)

[“last\\_wlm\\_reset - Time of last reset monitor element” on page 993](#)

[“member - Database member monitor element” on page 1068](#)

[“memory\\_free - Amount of free physical memory monitor element” on page 1074](#)

[“memory\\_swap\\_free - Total free swap space monitor element” on page 1078](#)

[“memory\\_swap\\_total - Total swap space monitor element” on page 1078](#)

[“memory\\_total - Total physical memory monitor element” on page 1079](#)

[“mon\\_interval\\_id - Monitor interval identifier monitor element” on page 1081](#)

[“partition\\_key - Partitioning key monitor element” on page 1137](#)

[“partition\\_number - Partition Number ” on page 1138](#)

[“statistics\\_timestamp - Statistics timestamp monitor element” on page 1476](#)

[“swap\\_page\\_size - Swap page size monitor element” on page 1501](#)

[“swap\\_pages\\_in - Pages swapped in from disk monitor element” on page 1500](#)

[“swap\\_pages\\_out - Pages swapped out to disk monitor element” on page 1501](#)

[“virtual\\_mem\\_free - Free virtual memory monitor element” on page 1696](#)

[“virtual\\_mem\\_reserved - Reserved virtual memory monitor element” on page 1697](#)

[“virtual\\_mem\\_total - Total virtual memory monitor element” on page 1697](#)

## **event\_scmetrics logical data group**

[“act\\_aborted\\_total - Total aborted activities monitor element” on page 590](#)

[“act\\_completed\\_total - Total completed activities monitor element” on page 591](#)

[“act\\_rejected\\_total - Total rejected activities monitor element” on page 594](#)

[“act\\_rqsts\\_total - Total activity requests monitor elements” on page 599](#)

[“agent\\_wait\\_time - Agent wait time monitor element” on page 641](#)

[“agent\\_waits\\_total - Total agent waits monitor element” on page 643](#)

[“app\\_act\\_aborted\\_total - Total failed external coordinator activities monitor element” on page 650](#)

[“app\\_act\\_completed\\_total - Total successful external coordinator activities monitor element” on page 651](#)

[“app\\_act\\_rejected\\_total - Total rejected external coordinator activities monitor element” on page 653](#)

[“app\\_rqsts\\_completed\\_total - Total application requests completed monitor element” on page 654](#)

[“appl\\_section\\_inserts - Section Inserts monitor element” on page 662](#)

[“appl\\_section\\_lookups - Section Lookups ” on page 663](#)

[“audit\\_events\\_total - Total audit events monitor element” on page 671](#)

[“audit\\_file\\_write\\_wait\\_time - Audit file write wait time monitor element” on page 673](#)

[“audit\\_file\\_writes\\_total - Total audit files written monitor element” on page 675](#)

[“audit\\_subsystem\\_wait\\_time - Audit subsystem wait time monitor element” on page 676](#)

[“audit\\_subsystem\\_waits\\_total - Total audit subsystem waits monitor element” on page 678](#)

[“binds\\_precompiles - Binds/Precompiles Attempted ” on page 685](#)

[“call\\_sql\\_stmts - CALL SQL statements executed monitor element” on page 694](#)

[“cat\\_cache\\_inserts - Catalog cache inserts monitor element” on page 696](#)

[“cat\\_cache\\_lookups - Catalog cache lookups monitor element” on page 697](#)

[“cf\\_wait\\_time - cluster caching facility wait time monitor element” on page 701](#)

[“cf\\_waits - Number of cluster caching facility waits monitor element” on page 703](#)

[“client\\_idle\\_wait\\_time - Client idle wait time monitor element” on page 712](#)

[“col\\_vector\\_consumer\\_overflows - Columnar vector consumer overflows monitor element” on page 723](#)

[“comm\\_exit\\_wait\\_time - Communication exit wait time monitor element” on page 724](#)

[“comm\\_exit\\_waits - Communication exit number of waits monitor element” on page 725](#)

[“ddl\\_sql\\_stmts - Data Definition Language \(DDL\) SQL Statements ” on page 801](#)

[“deadlocks - Deadlocks detected monitor element” on page 805](#)

[“diaglog\\_write\\_wait\\_time - Diagnostic log file write wait time monitor element” on page 810](#)

[“diaglog\\_writes\\_total - Total diagnostic log file writes monitor element” on page 812](#)

[“direct\\_read\\_reqs - Direct read requests monitor element” on page 813](#)

[“direct\\_read\\_time - Direct read time monitor element” on page 815](#)

[“direct\\_reads - Direct reads from database monitor element” on page 817](#)

[“direct\\_write\\_reqs - Direct write requests monitor element” on page 820](#)

[“direct\\_write\\_time - Direct write time monitor element” on page 822](#)

[“direct\\_writes - Direct writes to database monitor element” on page 824](#)

[“ disabled\\_peds - Disabled partial early distincts monitor element” on page 827](#)

[“dynamic\\_sql\\_stmts - Dynamic SQL Statements Attempted ” on page 830](#)

[“evmon\\_wait\\_time - Event monitor wait time monitor element” on page 846](#)

[“evmon\\_waits\\_total - Event monitor total waits monitor element” on page 848](#)

[“ext\\_table\\_read\\_volume - Total data read by external table readers monitor element” on page 854](#)

[“ext\\_table\\_rcv\\_volume - Total data received from external table readers monitor element” on page 855](#)

[“ext\\_table\\_rcv\\_wait\\_time - Total agent wait time for external table readers monitor element” on page 857](#)

[“ext\\_table\\_rcvs\\_total - Total row batches received from external table readers monitor element” on page 858](#)

[“ext\\_table\\_send\\_volume - Total data sent to external table writers monitor element” on page 860](#)

[“ext\\_table\\_send\\_wait\\_time - Total agent wait time for external table writers monitor element” on page 861](#)

[“ext\\_table\\_sends\\_total - Total row batches sent to external table writers monitor element” on page 863](#)

[“ext\\_table\\_write\\_volume - Total data written by external table writers monitor element” on page 864](#)

[“failed\\_sql\\_stmts - Failed Statement Operations ” on page 866](#)

[“fcm\\_message\\_rcv\\_volume - FCM message received volume monitor element” on page 868](#)

[“fcm\\_message\\_rcv\\_wait\\_time - FCM message received wait time monitor element” on page 869](#)

[“fcm\\_message\\_rcv\\_waits\\_total - Number of times spent waiting for FCM reply message monitor element” on page 871](#)

[“fcm\\_message\\_rcvs\\_total - Total FCM message receives monitor element” on page 873](#)

[“fcm\\_message\\_send\\_volume - FCM message send volume monitor element” on page 874](#)

[“fcm\\_message\\_send\\_wait\\_time - FCM message send wait time monitor element” on page 876](#)

[“fcm\\_message\\_send\\_waits\\_total - Number of times spent blocking on an FCM message send monitor element” on page 878](#)

[“fcm\\_message\\_sends\\_total - Total FCM message sends monitor element” on page 879](#)

[“fcm\\_rcv\\_volume - FCM received volume monitor element” on page 882](#)

[“fcm\\_rcv\\_wait\\_time - FCM received wait time monitor element” on page 884](#)

[“fcm\\_rcv\\_waits\\_total - Number of times spent waiting to receive data through FCM monitor element” on page 885](#)

[“fcm\\_rcvs\\_total - FCM receives total monitor element” on page 887](#)

[“fcm\\_send\\_volume - FCM send volume monitor element” on page 888](#)

[“fcm\\_send\\_wait\\_time - FCM send wait time monitor element” on page 890](#)

[“fcm\\_send\\_waits\\_total - Number of times spent blocking on an FCM send operation monitor element” on page 892](#)

[“fcm\\_sends\\_total - FCM sends total monitor element” on page 893](#)

[“fcm\\_tq\\_rcv\\_volume - FCM table queue received volume monitor element” on page 895](#)

[“fcm\\_tq\\_rcv\\_wait\\_time - FCM table queue received wait time monitor element” on page 897](#)

[“fcm\\_tq\\_rcv\\_waits\\_total - Number of times spent waiting to receive the next buffer monitor element” on page 898](#)

[“fcm\\_tq\\_rcvs\\_total - FCM table queue receives total monitor element” on page 900](#)

[“fcm\\_tq\\_send\\_volume - FCM table queue send volume monitor element” on page 901](#)

[“fcm\\_tq\\_send\\_wait\\_time - FCM table queue send wait time monitor element” on page 903](#)

[“fcm\\_tq\\_send\\_waits\\_total - Number of times spent waiting to send the next buffer monitor element” on page 905](#)

[“fcm\\_tq\\_sends\\_total - FCM table queue send total monitor element” on page 906](#)

[“fed\\_rows\\_deleted - Rows deleted by a federation system monitor element” on page 908](#)

[“fed\\_rows\\_inserted - Rows inserted by a federation system monitor element” on page 909](#)

[“fed\\_rows\\_read - Rows read by a federation system monitor element” on page 911](#)

[“fed\\_rows\\_updated - Rows updated by a federation system monitor element” on page 912](#)

[“fed\\_wait\\_time - Time spent by a federation server monitor element” on page 915](#)

[“fed\\_waits\\_total - Total number of execution times for a federation server monitor element” on page 914](#)

[“hash\\_join\\_overflows - Hash Join Overflows ” on page 938](#)

[“hash\\_join\\_small\\_overflows - Hash Join Small Overflows ” on page 940](#)

[“ida\\_rcv\\_volume - Total data volume received monitor element” on page 948](#)

[“ida\\_rcv\\_wait\\_time - Time spent waiting to receive data monitor element” on page 950](#)

[“ida\\_rcvs\\_total - Number of times data received monitor element” on page 952](#)

### *Target tables, control tables, and event monitor table management*

You can define an event monitor so that it stores its event records in SQL tables. To do this, use the CREATE EVENT MONITOR statement with the WRITE TO TABLE clause.

When you create a write-to-table event monitor, the event monitor creates target tables to store records for each of the logical data groups returning data. In each table, the column names match the monitor element names that they represent. By default, the event monitor creates the tables in the event monitor creator's schema and names the tables by concatenating their corresponding logical data group name to the event monitor name.

For example, consider the following statement, which creates an event monitor that captures STATEMENTS events:

```
CREATE EVENT MONITOR test FOR STATEMENTS WRITE TO TABLE
```

Event monitors using the STATEMENTS event type collect data from the event\_connheader, event\_stmt, and event\_subsection logical data groups. Tables representing logical data groups that are specific to individual event types are created, along with a control table for every write-to-table event monitor. For the event monitor test, created by user riihi, the database manager creates the following tables:

- `riihi.connheader_test`
- `riihi.stmt_test`
- `riihi.subsection_test`
- `riihi.control_test`

The first three tables correspond to each of the logical data groups `event_connheader`, `event_stmt`, and `event_subsection`. The last table, `riihi.control_test`, is the control table. The control table contains event monitor metadata, specifically, from the `event_start`, `event_dbheader` (`conn_time` monitor element only), and `event_overflow` logical data groups.

Monitor elements are written to the overflow group only for *non-blocked* event monitors. With non-blocked event monitors, agents that generate events do not wait for the event buffers to be written to the table if the buffers are full. Instead, they discard monitor data coming from agents when data is coming faster than the event monitor can write the data. In this case, the event monitor records information in the control table to indicate that an overflow has taken place. Included in this information is the monitor element **message**, which in the event of an overflow contains the text `OVERFLOW: n`, where *n* represents the number of event records that were discarded because the event buffers were full.

Whenever a write-to-table event monitor is activated, it acquires an IN or IX table lock on each target table to prevent the table from being modified while the event monitor is active. Table locks are maintained on all tables while the event monitor is active. If exclusive access is required on any of the target tables (for example, to run a utility), deactivate the event monitor to release the table locks before attempting such access.

Each column name in a target table matches an event monitor element identifier. Any event monitor element that does not have a corresponding target table column is ignored.

You must manually prune write-to-table event monitor target tables, including the unformatted event (UE) tables. On highly active systems, event monitors can quickly fill disk space because of the high volume of data that they record. Unlike defining event monitors that write to files or named pipes, you can define write-to-table event monitors to record information from only certain logical data groups or monitor elements. You can use this feature to collect only the data that is relevant to your purposes and reduce the volume of data that event monitors generate. For example, the following statement defines an event monitor that captures connection events only from the `event_conn` logical data group and includes only the **lock\_waits** monitor element:

```
CREATE EVENT MONITOR conn_monitor FOR CONNECTIONS WRITE TO TABLE
CONN(INCLUDES(lock_waits))
```

You might not want to have the target tables for an event monitor in the default schema, with default table names, in the default table space. If you anticipate high volumes of monitoring data, you might want the target tables to exist in their own table space. You can specify the schema, table, and table space names for the `CREATE EVENT MONITOR` statement. The schema name and table name form a derived name for the table. You can add the table space name after the table name by using the optional `IN` clause. Unlike the target tables, which the database manager automatically creates, a table space must exist if it you include it in an event monitor definition. If you do not specify a table space, a table space for which you have `USE` privileges is assigned.

A target table can be used by only a single event monitor. If you define a target table for another event monitor or if it cannot be created for any other reason, the `CREATE EVENT MONITOR` statement fails.

In a partitioned database environment, a write-to-table event monitor is active only on database partitions where the table space containing the event monitor table exists. If the target table space for an active event monitor does not exist on a particular database partition, the event monitor will be deactivated on that database partition, and an error is written to the **db2diag** command log file.

For increased performance in retrieving event monitor data, you can create indexes for the event tables. If you add table attributes such as triggers, relational integrity, and constraints, the event monitor ignores them.

For example, the following statement defines an event monitor that captures STATEMENTS events, using the `event_connheader`, `event_stmt`, and `event_subsection` logical data groups. Each of the three target tables has different schema, table and table space combinations:

```
CREATE EVENT MONITOR test FOR STATEMENTS
WRITE TO TABLE CONNHEADER,
STMT (TABLE mydept.statements),
SUBSECTION (TABLE subsections, IN mytablespace)
```

Assuming that the user `riihi` issued the previous statement, the derived names and table spaces of the target tables are as follows:

- CONNHEADER: `riihi.connheader_test` in the default table space
- STMT: `mydept.statements` in the default table space
- SUBSECTION: `riihi.subsections` in the `mytablespace` table space

If a target table does not exist when the event monitor activates, activation continues and data that would otherwise be inserted into the target table is ignored. Correspondingly, if a monitor element does not have a dedicated column in the target table, it is ignored.

For active write-to-table event monitors, there is a risk that the table spaces storing event records can reach their capacity. To control this risk for DMS table spaces, you can define the percentage of table space capacity at which the event monitor is deactivated. You can specify this value in the `PCTDEACTIVATE` clause for the `CREATE EVENT MONITOR` statement. For SMS table spaces, the value is set to 100. If you enabled the `autoresize` feature for the target table space, you should set the `PCTDEACTIVATE` value to 100.

In a non-partitioned database environment, all write-to-table event monitors are deactivated when the last application terminates (and the database has not been explicitly activated). In a partitioned database environment, write-to-table event monitors are deactivated when the catalog partition deactivates.

#### *Logical data groups and event monitor output tables*

Monitor elements that are frequently used together are grouped into *logical data groups*. Event monitors that write to tables generally produce one output table for each logical data group of monitor elements that they capture.

The following table presents the default target table names by event type.

Event type	Logical data group	Information in logical group	Name of table to which elements belonging to logical group are written
DEADLOCKS <sup>1</sup>	<a href="#">event_connheader</a>	Connection metadata.	<code>CONNHEADER_evmon-name</code>
	<a href="#">event_deadlock</a>	Deadlock data.	<code>DEADLOCK_evmon-name</code>
	<a href="#">event_dlconn</a>	Applications and locks that are involved in deadlock.	<code>DLCONN_evmon-name</code>
	CONTROL <sup>2</sup>	Event monitor metadata.	<code>CONTROL_evmon-name</code>
DEADLOCKS WITH DETAILS <sup>1</sup>	<a href="#">event_connheader</a>	Connection metadata.	<code>CONNHEADER_evmon-name</code>
	<a href="#">event_deadlock</a>	Deadlock data.	<code>DEADLOCK_evmon-name</code>
	<a href="#">event_detailed_dlconn</a>	Applications that are involved in deadlock.	<code>DLCONN_evmon-name</code>
	<a href="#">dllock</a>	Locks that are involved in deadlock.	<code>DLLOCK_evmon-name</code>
	CONTROL <sup>2</sup>	Event monitor metadata.	<code>CONTROL_evmon-name</code>

Table 7. Write-to-table event monitor logical data groups (continued)

Event type	Logical data group	Information in logical group	Name of table to which elements belonging to logical group are written
DEADLOCKS WITH DETAILS HISTORY <sup>1</sup>	<u>event_connheader</u>	Connection metadata.	CONNHEADER_evmon-name
	<u>event_deadlock</u>	Deadlock data.	DEADLOCK_evmon-name
	<u>event_detailed_dlconn</u>	Applications that are involved in deadlock.	DLCONN_evmon-name

	<a href="#">lock_participant_activities</a>	Activity data for each lock participant.	LOCK_PARTICIPANT_ACTIVITIES_ <i>evmon-name</i>
	<a href="#">lock_activity_values</a>	Details about the specific data being processed by a specific activity.	LOCK_ACTIVITY_VALUES_ <i>evmon-name</i>
	CONTROL <sup>2</sup>	Event monitor metadata.	CONTROL_ <i>evmon-name</i>

Table 7. Write-to-table event monitor logical data groups (continued)

Event type	Logical data group	Information in logical group	Name of table to which elements belonging to logical group are written
PACKAGE CACHE	<a href="#">pkgcache</a>	Summary package cache event information. This information includes detailed metrics in XML format in the METRICS column.	PKGCACHE_EVENT $evmon-name$
	<a href="#">pkgcache_metrics</a>	Table containing the same metrics that are included in the METRICS column of the PKGCACHE table.	PKGCACHE_METRICS_ $evmon-name$
	CONTROL <sup>2</sup>	Event monitor metadata.	CONTROL_ $evmon-name$
UNIT OF WORK	<a href="#">uow</a>	Summary unit of work event information. This information includes detailed metrics in XML format in the METRICS column.	UOW_EVENT $evmon-name$
	<a href="#">uow_metrics</a>	Table containing the same metrics that are included in the METRICS column of the PKGCACHE table.	UOW_METRICS_ $evmon-name$
	<a href="#">uow_package_list</a>	Package list detail information. <sup>4</sup>	UOW_PACKAGE_LIST_ $evmon-name$
	<a href="#">uow_executable_list</a>	Executable list information. <sup>4</sup>	UOW_EXECUTABLE_LIST_ $evmon-name$
	CONTROL <sup>2</sup>	Event monitor metadata.	CONTROL_ $evmon-name$
<b>1</b>	This option has been deprecated and might be removed in a future release. Use the CREATE EVENT MONITOR FOR LOCKING statement to monitor lock-related events, such as lock timeouts, lock waits, and deadlocks.		
<b>2</b>	The CONTROL logical group consists of selected elements from one or more of the <a href="#">event_dbheader</a> , <a href="#">event_start</a> and <a href="#">event_overflow</a> logical data groups.		
<b>3</b>	This option has been deprecated and might be removed in a future release. Use the CREATE EVENT MONITOR FOR UNIT OF WORK statement to monitor transaction events.		
<b>4</b>	Unless you explicitly specify which output tables to create for the unit of work event monitor, this table is included by default. If you do not set the configuration parameter for collecting the related information ( <b>mon_uow_pkglist</b> or <b>mon_uow_execlist</b> ) to ON, the table is created, but it contains no data.		

The following logical data groups are not collected for write-to-table event monitors:

- log\_stream\_header
- log\_header
- dbheader (only the **conn\_time** monitor element is collected)

The data type of each column in an event monitor table corresponds to the data type of the monitor element represented by the column. The following table contains a set of data type mappings that correspond the original system monitor data types of the monitor elements (found in `sqlmon.h` file) to the SQL data types of the table columns.

<i>Table 8. System Monitor Data Type Mappings</i>	
<b>System monitor data type</b>	<b>SQL data type</b>
SQLM_TYPE_DOUBLE	DOUBLE
SQLM_TYPE_STRING	CHAR[n], VARCHAR[n], CLOB[n]
SQLM_TYPE_U8BIT and SQLM_TYPE_8BIT	SMALLINT, INTEGER, or BIGINT
SQLM_TYPE_U16BIT and SQLM_TYPE_16BIT	SMALLINT, INTEGER, or BIGINT
SQLM_TYPE_U32BIT and SQLM_TYPE_32BIT	INTEGER or BIGINT
SQLM_TYPE_U64BIT and SQLM_TYPE_64BIT	BIGINT
SQLM_TIMESTAMP	TIMESTAMP
SQLM_TIME	BIGINT
SQLCA: SQLERRMC	VARCHAR[72]
SQLCA: SQLSTATE	CHAR[5]
SQLCA: SQLWARN	CHAR[11]
SQLCA: other fields	INTEGER or BIGINT
SQLM_TYPE_HANDLE	BLOB[n]

**Note:**

1. All columns are NOT NULL.
2. Because the performance of tables with CLOB columns is inferior to tables that have VARCHAR columns, consider using the TRUNC keyword when specifying the stmt evmGroup (or dlconn evmGroup, when using deadlocks with details).
3. SQLM\_TYPE\_HANDLE is used to represent the compilation environment handle object.

***Creating event monitors that write to unformatted event (UE) tables***

If the performance of event monitor data collection is particularly important, you might choose to have your event monitor write its output to an unformatted event (UE) table. Most of the data written to a UE table is written as inline binary data, which allows for faster I/O as data is collected.

Another advantage of UE tables over regular tables for event monitors is that you generally do not have to be concerned at event monitor creation time with different options such as what buffer size to use, whether the event monitor is blocked or unblocked, or what types of data (logical groups) must be collected. However, because most of the data collected is in binary format, you must post-process the UE table to be able to examine the event data.

**Note:** The following features related to the UE tables are available:

- You can use the procedure `EVMON_UPGRADE_TABLES` to upgrade the UE tables produced by event monitors in earlier releases. This capability lets you more easily retain event monitor data that was recorded earlier.
- All event monitors that can write their output to UE tables can also write to regular tables.
- You can prune unneeded data from UE tables using the option `PRUNE_UE_TABLE` of the procedure `EVMON_FORMAT_UE_TO_TABLES`.

## Before you begin

Keep the following considerations in mind when creating an event monitor that writes to an unformatted event table:

- You need SQLADM or DBADM authority to create an event monitor that writes to a UE table.
- Use a table space for your unformatted event tables that is optimized for performance. When you create the table space, keep the following guidelines in mind:
  - Specify a page size (PAGESIZE) as large as possible, up to 32KB. A large page size ensures that the BLOB containing the event data can be written inline with the table row. If the page size is too small to allow the BLOB to be inlined, performance of the event monitor might be diminished. The database manager attempts to inline the event\_data BLOB column in the unformatted event table, but this is not always possible. To check that the rows in the unformatted event table have been inlined, use the ADMIN\_IS\_INLINED function. If the rows have not been inlined, use the ADMIN\_EST\_INLINE\_LENGTH functions to determine how much space the rows need.
  - Specify the NO FILE CACHING SYSTEM option.
- In a partitioned database environment, consider on which partitions the table space exists. If a table space for a target unformatted event table does not exist on some database partition, data for that target unformatted event table is ignored. This behavior allows users to choose a subset of database partitions for monitoring to be chosen, by creating a table space that exists only on certain database partitions.

## About this task

The following event monitor types support the use of UE tables:

- Unit of work
- Package Cache
- Locking

**Note:** Despite their name, unformatted event tables are still relational tables. The main difference between a UE table produced by, say, a locking event monitor and a regular table produced by a locking event monitor is that most of the data in a UE table is written in binary format in the EVENT\_DATA column. See [“Unformatted event table column definitions”](#) on page 118 for more information about the structure of UE tables.

## Procedure

To create an event monitor that writes to a UE table:

- Formulate a CREATE EVENT MONITOR statement, using the WRITE TO UNFORMATTED EVENT TABLE clause.  
For example, to create a unit of work event monitor called uowmon, you might use a statement like the one that follows:

```
CREATE EVENT MONITOR uowmon FOR UNIT OF WORK
WRITE TO UNFORMATTED EVENT TABLE
```

By default, the name of the UE table that the event monitor creates is the same as the name of the event monitor.

- To specify an alternative to the default table name, use the TABLE clause.  
For example, if you want to have the UE table called myunitsofwork, construct the statement as follows:

```
CREATE EVENT MONITOR uowmon FOR UNIT OF WORK
WRITE TO UNFORMATTED EVENT TABLE
TABLE myunitsofwork
```

You can also specify the table space in which to store the UE table using the IN *tablespace-name* clause:

```
CREATE EVENT MONITOR uowmon FOR UNIT OF WORK
WRITE TO UNFORMATTED EVENT TABLE
TABLE myunitsofwork
IN mytablespace
```

or

```
CREATE EVENT MONITOR uowmon FOR UNIT OF WORK
WRITE TO UNFORMATTED EVENT TABLE
IN mytablespace
```

The first example places the UE table `myunitsofwork` in table space `mytablespace`; the second example places a UE table named `uowmon` (the default, as no table name is specified) in table space `mytablespace`.

- By default, any event monitor that writes to a UE table is created to activate automatically on database activation. You can override this behavior using the `MANUALSTART` clause:

```
CREATE EVENT MONITOR uowmon FOR UNIT OF WORK
WRITE TO UNFORMATTED EVENT TABLE
MANUALSTART
```

In the preceding example, the event monitor `uowmon` must always be activated manually, using the `SET EVENT MONITOR STATE` statement.

## What to do next

By default, event monitors that were introduced in version 9.7 or later are created as `AUTOSTART` event monitors. They are activated automatically when the database is next activated, and on subsequent database activations thereafter. If you want to activate the event monitor immediately, before the next database activation, use the `SET EVENT MONITOR STATE` statement to manually start the event monitor. In addition for each of the locking, unit of work and package cache event monitors, you must also enable data collection.

### *Unformatted event table column definitions*

An unformatted event table is created when you issue a `CREATE EVENT MONITOR` statement that includes the clause `WRITE TO UNFORMATTED EVENT TABLE`. The column definitions are useful when you want to extract data to analyze or prune a table of unneeded data.

The column definitions for the unformatted event table are useful when you want to extract data from an unformatted event table using one of the following routines:

- `EVMON_FORMAT_UE_TO_XML` - extracts data from an unformatted event table into an XML document.
- `EVMON_FORMAT_UE_TO_TABLES` - extracts data from an unformatted event table into a set of relational tables.

The call to these routines accepts a `SELECT` statement that specifies the rows that you want to extract. Use the unformatted event table column definitions to assist with composing your `SELECT` statement.

There is no automatic purging of the event data written to an unformatted event table. You must manually purge data from the table. The column definitions for the unformatted event table are useful when you want to purge a targeted set of records. Another option is to remove all the table rows using the `TRUNCATE TABLE` statement.

As part of the `CREATE EVENT MONITOR` statement, you can specify what to name the associated unformatted event table. If not specified, the name defaults to the same name as the event monitor. The `SYSCAT.EVENTTABLES` catalog view lists event monitors, their associated unformatted table, and other details.

The following table describes the columns in the unformatted event table. The key column is the `event_data` column. The other columns represent identifiers that you can use to locate events of interest. For further attributes of table columns, issue a `DESCRIBE` statement.

Table 9. Unformatted event table column definitions

Column name	Column data type	Column description
appl_id	VARCHAR	<a href="#">“appl_id - Application ID monitor element” on page 656</a>
appl_name	VARCHAR	<a href="#">“appl_name - Application name monitor element” on page 660</a>
event_correlation_id	BIT DATA	<p>An optional event correlation ID. A NULL value indicates that the event correlation ID was not available.</p> <p>The value is based on the event monitor type:</p> <ul style="list-style-type: none"> <li>• LOCKING - Reserved for future use</li> <li>• UOW- Reserved for future use</li> </ul>
event_data	BLOB	The entire event record data for an event captured by the event monitor, stored in its original binary form.
event_id	INTEGER	<a href="#">“event_id - Event ID monitor element” on page 841</a>
event_timestamp	TIMESTAMP	<a href="#">“event_timestamp - Event timestamp monitor element” on page 843</a>
event_type	VARCHAR	<a href="#">“event_type - Event Type monitor element” on page 843</a>
member	SMALLINT	<a href="#">“member - Database member monitor element” on page 1068</a>
partitioning_key	INTEGER	The partitioning key for the table, so that insert operations are performed locally on the database partition where the event monitor is running.
record_seq_num	INTEGER	The sequence number of the record that is stored within the event_data column.
record_type	INTEGER	The type of record that is stored within the event_data column.
service_subclass_name	VARCHAR	<a href="#">“service_subclass_name - Service subclass name monitor element” on page 1417</a>

Column name	Column data type	Column description
mon_interval_id	BIGINT	“mon_interval_id - Monitor interval identifier monitor element” on page 1081

#### *Differences between regular and UE table output*

Generally speaking, the event monitors that can write to both regular and unformatted event (UE) tables capture the same data. However, there are some minor differences to be aware of.

### Order of columns

The first difference pertains to the order of the columns of the tables. When the event monitor generates regular tables, compared to the output produced by running `EVMON_FORMAT_UE_TO_TABLES` against a UE table, columns are generally presented in alphabetical order, with two exceptions:

- If a `PARTITION_KEY` column is included in the output, it is the first column.
- For tables that report metrics, related columns are grouped together. For example, columns that report time spent in the system are grouped together.

### Columns returned

The other pertains to data types of columns. In most cases, the columns in write-to-table event monitors are the same as the columns produced by running `EVMON_FORMAT_UE_TO_TABLES` against a UE table. There are some differences however. These differences are summarized in [Table 10 on page 120](#).

Logical data group	Columns returned in regular tables	Columns returned from <code>EVMON_FORMAT_UE_TO_TABLES</code>
All groups	<code>PARTITION_KEY</code> column included	
<a href="#">uow</a>	<code>TYPE</code> column included	<code>TYPE</code> column excluded
<a href="#">uow_package_list</a>	<code>ROUTINE_ID</code> data type is <code>BIGINT</code>	<code>ROUTINE_ID</code> data type is <code>INTEGER</code>
<a href="#">pkgcache</a>	<code>XMLID</code> column excluded	<code>XMLID</code> column included
<a href="#">lock</a>	<code>DL_CONNS</code> data type is <code>BIGINT</code>	<code>DL_CONNS</code> data type is <code>INTEGER</code>
	<code>ROLLED_BACK_PARTICIPANT_NO</code> data type is <code>SMALLINT</code>	<code>ROLLED_BACK_PARTICIPANT_NO</code> data type is <code>INTEGER</code>
	<code>XMLID</code> column excluded	<code>XMLID</code> column included

Table 10. Summary of differences in returned columns (continued)

Logical data group	Columns returned in regular tables	Columns returned from EVMON_FORMAT_UE_TO_TABLES
<u>lock_participants</u>	AGENT_STATUS data type is BIGINT	AGENT_STATUS data type is INTEGER
	APPL_ID data type is VARCHAR(64)	APPL_ID data type is VARCHAR(128)
	APPL_NAME data type is VARCHAR(255)	APPL_NAME data type is VARCHAR(128)
	CLIENT_ACCTING data type is VARCHAR(200)	CLIENT_ACCTNG data type is VARCHAR(255)
	TABLESPACE_NAME data type is VARCHAR(18)	TABLESPACE_NAME data type is VARCHAR(128)
	XMLID column excluded	XMLID column included
	INTERNAL_DATA column included	Data contained in INTERNAL_DATA is not included.
<u>lock_participant_activities</u>	ACTIVITY_ID data type is BIGINT	ACTIVITY_ID data type is INTEGER
	Includes EVENT_ID, EVENT_TYPE and EVENT_TIMESTAMP rather than XMLID <sup>1</sup>	XMLID column included
	CONSISTENCY_TOKEN is CHAR(8)	CONSISTENCY_TOKEN is VARCHAR(8)
<u>lock_activity_values</u>	ACTIVITY_ID data type is BIGINT	ACTIVITY_ID data type is INTEGER
	PARTICIPANT_NO data type is SMALLINT	PARTICIPANT_NO data type is INTEGER
	Includes EVENT_ID, EVENT_TYPE and EVENT_TIMESTAMP instead of XMLID. <sup>1</sup>	XMLID column included
<p>1. The XMLID column represents a compound monitor element made up of the concatenation of the event_header, event_id, event_type, event_timestamp and partition monitor elements.</p>		

### Creating a file event monitor

When creating an event monitor you must determine where the information it collects is to be stored. File event monitors store event records in files. File event monitors and their options are defined by the CREATE EVENT MONITOR statement.

### Before you begin

You will need SQLADM or DBADM authority to create a file event monitor.

### About this task

A file event monitor streams event records to a series of 8-character numbered files with the extension "evt" (for example, 00000000.evt, 00000001.evt, and 00000002.evt). The data should be considered to be one logical file even though the data is broken up into smaller pieces (that is, the start of the data stream is the first byte in the file 00000000.evt; the end of the data stream is the last byte in the file nnnnnnnn.evt). An event monitor will never span a single event record across two files.

## Procedure

1. Indicate that event monitor data is to be collected in a file (or set of files), and provide a directory location where event files are to be stored.

```
CREATE EVENT MONITOR d1mon FOR eventtype
WRITE TO FILE '/tmp/d1events'
```

d1mon is the name of the event monitor.

/tmp/d1events is the name of the directory path (on UNIX systems) where the event monitor is to write the event files.

2. Specify the types of events to be monitored. You can monitor one or more event types with a single event monitor.

```
CREATE EVENT MONITOR d1mon FOR CONNECTIONS, DEADLOCKS WITH DETAILS
WRITE TO FILE '/tmp/d1events'
```

This event monitor will monitor for the CONNECTIONS and DEADLOCKS WITH DETAILS event types.

3. Specify the size of the file event monitor buffers (in 4K pages) by adjusting the BUFFERSIZE value:

```
CREATE EVENT MONITOR d1mon FOR CONNECTIONS, DEADLOCKS WITH DETAILS
WRITE TO FILE '/tmp/d1events' BUFFERSIZE 8
```

8 is the capacity in 4K pages of the two event file buffers.

The default size of each buffer is 4 pages (two 16K buffers are allocated). The minimum size is 1 page. The maximum size of the buffers is limited by the size of the monitor heap, because the buffers are allocated from that heap. For performance reasons, highly active event monitors should have larger buffers than relatively inactive event monitors.

4. Indicate if you need the event monitor to be blocked or non-blocked. For blocked event monitors, each agent that generates an event will wait for the event buffers to be written to file if they are full. This can degrade database performance, as the suspended agent and any dependent agents cannot run until the buffers are clear. Use the BLOCKED clause to ensure no losses of event data:

```
CREATE EVENT MONITOR d1mon FOR CONNECTIONS, DEADLOCKS WITH DETAILS
WRITE TO FILE '/tmp/d1events' BUFFERSIZE 8
BLOCKED
```

Event monitors are blocked by default. If database performance is of greater importance than collecting every single event record, use non-blocked event monitors. In this case, each agent that generates an event will not wait for the event buffers to be written to file if they are full. As a result, non-blocked event monitors are subject to data loss on highly active systems. Use the NONBLOCKED clause to minimize the additional processing time caused by event monitoring:

```
CREATE EVENT MONITOR d1mon FOR CONNECTIONS, DEADLOCKS WITH DETAILS
WRITE TO FILE '/tmp/d1events' BUFFERSIZE 8
NONBLOCKED
```

5. Specify the maximum number of event files that can be collected for an event monitor. If this limit is reached, the event monitor will deactivate itself.

```
CREATE EVENT MONITOR d1mon FOR CONNECTIONS, DEADLOCKS WITH DETAILS
WRITE TO FILE '/tmp/d1events' BUFFERSIZE 8
NONBLOCKED MAXFILES 5
```

5 is the maximum number of event files that will be created.

You can also specify that there is no limit to the number of event files that the event monitor can create:

```
CREATE EVENT MONITOR d1mon FOR CONNECTIONS, DEADLOCKS WITH DETAILS
WRITE TO FILE '/tmp/d1events' BUFFERSIZE 8
NONBLOCKED MAXFILES NONE
```

- Specify the maximum size (in 4K pages) for each event file created by an event monitor. If this limit is reached, a new file is created.

```
CREATE EVENT MONITOR dlmon FOR CONNECTIONS, DEADLOCKS WITH DETAILS
WRITE TO FILE '/tmp/dlevents' BUFFERSIZE 8
NONBLOCKED MAXFILES 5 MAXFILESIZE 32
```

32 is the maximum number of 4K pages that an event file can contain.

This value must be greater than the value specified by the `BUFFERSIZE` parameter. You can also specify that there is to be no limit on an event file's size:

```
CREATE EVENT MONITOR dlmon FOR CONNECTIONS, DEADLOCKS WITH DETAILS
WRITE TO FILE '/tmp/dlevents' BUFFERSIZE 8
NONBLOCKED MAXFILES NONE MAXFILESIZE NONE
```

- Specify if the event monitor is to be activated automatically each time the database starts. By default, event monitors (with the exception of the WLM event monitors) are not activated automatically when the database starts.

- To create an event monitor that starts automatically when the database starts, issue the following statement:

```
CREATE EVENT MONITOR dlmon FOR CONNECTIONS, DEADLOCKS WITH DETAILS
WRITE TO FILE '/tmp/dlevents' BUFFERSIZE 8
NONBLOCKED AUTOSTART
```

- To create an event monitor that does not start automatically when the database starts, issue the following statement:

```
CREATE EVENT MONITOR dlmon FOR CONNECTIONS, DEADLOCKS WITH DETAILS
WRITE TO FILE '/tmp/dlevents' BUFFERSIZE 8
NONBLOCKED MANUALSTART
```

- To activate or deactivate an event monitor, use the `SET EVENT MONITOR STATE` statement.

## Results

Once a file event monitor is created and activated, it will record monitoring data as its specified events occur.

### *Event monitor file management*

With some event monitors, you can have event data written to text files. You can configure some upper bounds on the number of files created, as well as their size with options on the `CREATE` or `ALTER EVENT MONITOR` statements.

A file event monitor enables the event monitor to store its event records in files. All the output of the event monitor goes in the directory supplied in the `FILE` parameter for the `CREATE EVENT MONITOR` statement. Before the monitor is activated, the directory must exist, or the `SET EVENT MONITOR` command will return an error; the directory will not be created by the database manager if it does not already exist.

**Important:** When a file event monitor is first activated, a control file named `db2event.ct1` is created in this directory. Do not remove or modify this file.

By default, an event monitor writes its trace to a single file, called `00000000.evt`. This file keeps growing as long as there is space on the file system. If you specified a file size limit with the **MAXFILESIZE** parameter of the `CREATE EVENT MONITOR` statement, then when a file is full, output is directed to a new file. The number that makes up the file name is increased by 1 each time a new file is created. Hence, the active file is the file with the highest number.

You can limit the maximum size of the entire event monitor trace by also using the **MAXFILES** parameter of the `CREATE EVENT MONITOR` statement. When the number of files reaches the maximum defined by

MAXFILES, the event monitor deactivates itself and the following message is written to the administration notification log.

```
DIA1601I Event Monitor monitor-name was deactivated when it reached
its preset MAXFILES and MAXFILESIZE limit.
```

If you receive this message, do not delete any of the event monitor files. If you do, you will not be able to view any of the event monitor information (even that contained in any remaining files) using the **db2evmon** command. Instead take one of the following actions:

- Recreate the event monitor without the **MAXFILES** and **MAXFILESIZE** limits.
- Leave the limits imposed by the **MAXFILES** and **MAXFILESIZE** parameters in place, but move all but the most recent \*.evt files in the directory to another directory or file system. You can then view the event monitor information from the files in the new directory. You can create a script to do this automatically if you want.

Either way, you must reactivate the event monitor using the statement **SET EVENT MONITOR event-monitor-name STATE 1** to start collecting information again after you receive the DIA1601I message.

When a file event monitor is restarted, it can either erase any existing data or append new data to it. This option is specified in the CREATE EVENT MONITOR statement, where either an APPEND monitor or a REPLACE monitor can be created. APPEND is the default option. An APPEND event monitor starts writing at the end of the file it was last using. If you have removed that file, the next file number in sequence is used. When an append event monitor is restarted, only a start\_event is generated. The event log header and database header are generated only for the first activation. A REPLACE event monitor always deletes existing event files and starts writing at 00000000.evt.

**Note:** If you did not use the REPLACE option for the event monitor, you can perform the following steps to force the event monitor to start collecting a new set of data:

1. Deactivate the event monitor using the **SET EVENT MONITOR event-monitor-name STATE 0** command.
2. Delete all files in the directory that was specified by the FILE option of the CREATE EVENT MONITOR statement.
3. Reactivate the event monitor using the **SET EVENT MONITOR event-monitor-name STATE 1** command.

If a file event monitor runs out of disk space, it shuts itself down after logging a system-error-level message in the administration notification log.

You might want to process monitor data while the event monitor is active. This is possible, and furthermore, when you are finished processing a file, you can delete it, freeing up space for further monitoring data. An event monitor cannot be forced to switch to the next file unless you stop and restart it. It must also be in APPEND mode. To track which events have been processed in the active file, you can create an application that simply tracks the file number and location of the last record processed. When processing the trace the next time around, the application can seek to that file location.

### ***Creating a pipe event monitor***

When creating an event monitor you must determine where the information it collects is to be stored. A pipe event monitor streams event records directly from the event monitor, to a named pipe.

### **Before you begin**

- You need SQLADM or DBADM authority to create a pipe event monitor.
- This task assumes the named pipe is already created. To create a named pipe on UNIX or Linux systems, use the **mkfifo** command provided on those systems.

## About this task

It is the responsibility of the monitoring application to promptly read the data from the pipe as the event monitor writes the event data. If the event monitor is unable to write data to the pipe (for example, if it is full), monitor data will be lost.

Pipe event monitors are defined with the `CREATE EVENT MONITOR` statement.

## Procedure

1. Indicate that event monitor data is to be directed to a named pipe.

```
CREATE EVENT MONITOR myevmon FOR eventtype
WRITE TO PIPE '/home/dbadmin/dlevents'
```

`myevmon` is the name of the event monitor.

`/home/dbadmin/dlevents` is the name of the named pipe (on UNIX) to where the event monitor will direct the event records. The `CREATE EVENT MONITOR` statement supports UNIX and Windows pipe naming syntax.

The named pipe specified in the `CREATE EVENT MONITOR` statement must be present and open when you activate the event monitor. If you specify that the event monitor is to start automatically, the named pipe must exist before the event monitor's creation.

2. Specify the types of events to be monitored. You can monitor one or more event types with a single event monitor.

```
CREATE EVENT MONITOR myevmon FOR BUFFERPOOLS, TABLESPACES
WRITE TO PIPE '/home/dbadmin/myevents'
```

This event monitor will monitor for the `BUFFERPOOLS` and `TABLESPACES` event types.

3. Specify if the event monitor is to be activated automatically each time the database starts. By default, event monitors are not activated automatically when the database starts.

- To create an event monitor that starts automatically when the database starts, issue the following statement:

```
CREATE EVENT MONITOR myevmon FOR BUFFERPOOLS, TABLESPACES
WRITE TO PIPE '/home/dbadmin/myevents'
AUTOSTART
```

- To create an event monitor that does not start automatically when the database starts, issue the following statement:

```
CREATE EVENT MONITOR myevmon FOR BUFFERPOOLS, TABLESPACES
WRITE TO PIPE '/home/dbadmin/myevents'
MANUALSTART
```

4. Start the client application that reads from the named pipe. For example, you can start the `db2evmon` tool to process the data as it is delivered to the pipe.
5. To activate or deactivate an event monitor, use the `SET EVENT MONITOR STATE` statement.

## Results

After a pipe event monitor is created and activated, it will record monitoring data as its specified events occur.

### *Event monitor named pipe management*

With some event monitors, you can have event data written to named pipes. What follows are some guidelines on how to use named pipe event monitors more effectively.

A pipe event monitor enables the processing of the event monitor data stream through a named pipe. Using a pipe event monitor is desirable if you need to process event records in real time. Another important advantage is that your application can ignore unwanted data as it is read off the pipe, giving the opportunity to considerably reduce storage requirements.

On AIX, you can create named pipes by using the `mkfifo` command. On Linux and other UNIX types use the `pipe()` routine. On Windows, you can create named pipes by using the `CreateNamedPipe()` routine.

When you direct data to a pipe, I/O is always blocked and the only buffering is that performed by the pipe. It is the responsibility of the monitoring application to promptly read the data from the pipe as the event monitor writes the event data. If the event monitor is unable to write the data to the pipe (for example, because the pipe is full), monitor data will be lost.

In addition, there must be enough space in the named pipe to handle incoming event records. If the application does not read the data from the named pipe fast enough, the pipe will fill up and overflow. The smaller the pipe buffer, the greater the chance of an overflow.

When a pipe overflow occurs, the monitor creates overflow event records indicating that an overflow has occurred. The event monitor is not turned off, but monitor data is lost. If there are outstanding overflow event records when the monitor is deactivated, a diagnostic message will be logged. Otherwise, the overflow event records will be written to the pipe when possible.

The amount of data that can be written to a pipe at any one time is determined by the underlying operating system. If your operating system allows you to define the size of the pipe buffer, use a pipe buffer of at least 32K. For high-volume event monitors, you should set the monitoring application's process priority equal to or higher than the agent process priority.

It is possible for the data stream coming from a single write operation of an activities or statistics event monitor to contain more data than can be written to the named pipe. In these situations, the data stream is split into blocks that can fit into the buffer, and each block is identified with a header: The first block is identified by a logical header with the element ID `SQLM_ELM_EVENT_STARTPIPEBLOCK`. The last block is identified by a logical header with element ID `SQLM_ELM_EVENT_ENDPIPEBLOCK`. All blocks in between are identified by logical headers with element ID `SQLM_ELM_EVENT_MIDPIPEBLOCK`. The monitoring application that is reading the pipe must be aware of these headers, and reassemble the blocks back into the complete data stream, stripping off the block headers as needed and reassembling the blocks to form a complete, valid data stream. The `db2evmon` tool provides this capability; it provides formatted output for all events generated by an event monitor that writes to a named pipe, reassembling the blocks as needed. If you want to process only selected events or monitor elements, you can write your own application to do so.

### ***Write-to-table and file event monitor buffering***

For some write-to-table and file event monitors, the event monitor stores output in a buffer before writing it to a file or table.

Table 11 on page 126 shows which event monitors use such output buffers.

<b>Event monitor type</b>	<b>Writes output to buffers before writing to disk?</b>
Activities	No
Bufferpools	Yes
Change history	No
Connections	Yes
Database	Yes
Deadlocks (all versions)	Yes
Locking	No
Package cache	No
Statements	Yes
Statistics	Yes

Table 11. Event monitors and output buffers (continued)

Event monitor type	Writes output to buffers before writing to disk?
Tablespaces	Yes
Tables	Yes
Transactions	Yes
Unit of work	No

Event monitors that do not use buffers use a newer, faster mechanism for writing output to disk, eliminating the need for buffers.

For those event monitors that use buffers, records are written to disk automatically when a buffer is full. Therefore, you can improve monitoring performance for event monitors with high amounts of throughput by specifying larger buffers to reduce the number of disk accesses. To force an event monitor to flush its buffers, you must either deactivate it or empty the buffers by using the FLUSH EVENT MONITOR statement.

Event monitors that use buffers let you specify whether the event monitor output is to be *blocked* or *non-blocked*. A blocked event monitor suspends the database process that is sending monitor data when both of its buffers are full. This is to ensure that no event records are discarded while the blocked event monitor is active. The suspended database process and consequently, any dependent database processes cannot run until a buffer has been written. This can introduce a significant performance consumption, depending on the type of workload and the speed of the I/O device. Event monitors are blocked by default.

A non-blocked event monitor discards monitor data coming from agents when data is coming faster than the event monitor can write the data. This prevents event monitoring from becoming a performance burden on other database activities.

An event monitor that has discarded event records generates an overflow event. It specifies the start and stop time during which the monitor was discarding events and the number of events that were discarded during that period. It is possible for an event monitor to terminate or be deactivated with a pending overflow to report. If this occurs, the following message is written to the admin log:

```
DIA2503I Event Monitor monitor-name had a pending overflow record
when it was deactivated.
```

Loss of event monitoring data can also occur for individual event records. If the length of an event record exceeds the event buffer size, the data that does not fit in the buffer is truncated. For example, this situation might occur if you are capturing the stmt\_text monitor element and applications attached to the database being monitored issue lengthy SQL statements. If you must capture all of the event record information, specify larger buffers. Keep in mind that larger buffers result in less frequent writes to file or table.

### Event monitor self-describing data stream

An event monitor that writes to a pipe or file produces a binary stream of logical data groupings that are identical for both pipe and file event monitors. You can format the data stream by using the **db2evmon** command or by developing a client application. This data stream is presented in a self-describing format.

Figure 4 on page 128 shows the structure of the data stream and Table 12 on page 128 provides some examples of the logical data groups and monitor elements that could be returned.

**Note:** In the examples and tables descriptive names are used for the identifiers. These names are prefixed by **SQLM\_ELM\_** in the actual data stream. For example, **db\_event** would appear as **SQLM\_ELM\_DB\_EVENT** in the event monitor output. Types are prefixed with **SQLM\_TYPE\_** in the actual data stream. For example, headers appear as **SQLM\_TYPE\_HEADER** in the data stream.

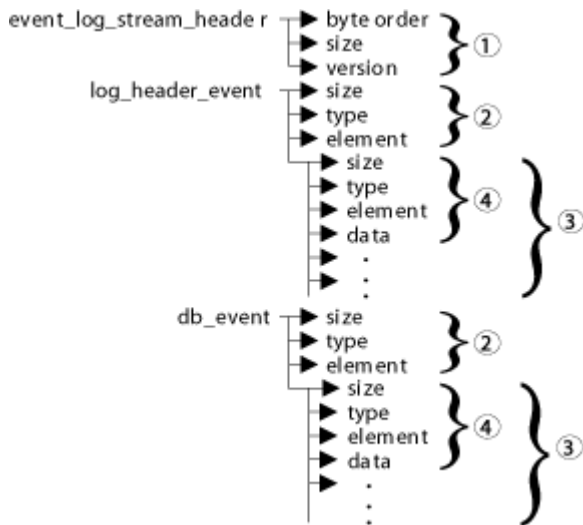

Figure 4. Pipe or File Event Monitor Data Stream

1. The structure of the `sqlm_event_log_data_stream_header` is different than the other headers in the data stream. The version field determines if the output can be processed as a self-describing data stream.

This header has the same size and type as pre-Version 6 event monitor streams. This allows applications to determine if the event monitor output is self-describing or is in the pre-Version 6 static format.

**Note:** This monitor element is extracted by reading `sizeof(sqlm_event_log_data_stream)` bytes from the data stream.

2. Each logical data group begins with a header that indicates its size and element name. This does not apply `event_log_stream_header`, as its size element contains a dummy value to maintain backwards compatibility.
3. The size element in the header indicates the size of all the data in that logical data group.
4. Monitor element information follows its logical data group header and is also self-describing.

Table 12. Sample event data stream

Logical Data Group	Data Stream	Description
event_log_stream_header	└─ sqlm_little_endian	Not used (for compatibility with previous releases).
	└─ 200	Not used (for compatibility with previous releases).
	└─ sqlm_dbmon_version9	The version of the database manager that returned the data. Event monitors write data in the self-describing format.

Table 12. Sample event data stream (continued)

Logical Data Group	Data Stream	Description
log_header_event	└─ 100	Size of the logical data group.
	└─ header	Indicates the start of a logical data group.
	└─ log_header	Name of the logical data group.
	└─ 4	Size of the data stored in this monitor element.
	└─ u32bit	Monitor element type - 32 bit numeric.
	└─ byte_order	The name of the monitor element collected.
	└─ little_endian	The collected value for this element.
	└─ 2	Size of the data stored in this monitor element.
	└─ u16bit	Monitor element type - unsigned 16 bit numeric.
	└─ codepage_id	The name of the monitor element collected.
db_event	└─ 850	The collected value for this element.
	└─ 100	Size of the logical data group.
	└─ header	Indicates the start of a logical data group.
	└─ db_event	Name of the logical data group.
	└─ 4	Size of the data stored in this monitor element
	└─ u32bit	Monitor element type - unsigned 32 bit numeric.
	└─ lock_waits	The name of the monitor element collected.
	└─ 2	The collected value for this element.

The event\_log\_stream\_header identifies the version of the database manager that returned the data. Event monitors write their data in the self-describing format. An event monitor, unlike a snapshot monitor, does not have a **size** element that returns the total size of the trace. The number present in event\_log\_stream\_header is a dummy value present for backwards compatibility. The total size of an event trace is not known when the event\_log\_stream\_header is written. You typically read an event monitor trace until you reach an end of file or pipe.

The log header describes the characteristics of the trace, containing information such as the memory model (for example little endian) of the server where the trace was collected, and the code page of the database. You might have to do byte swapping on numeric values, if the system where you read the trace has a different memory model than the server (for example, if you are reading a trace from a UNIX server on a Windows 2000 system). Code page translation might also need to be done if the database is configured in a different language than the machine from which you read the trace. When reading the trace, you can use the **size** element to skip a logical data group in the trace.

### Event type mappings to logical data groups

For file and pipe event monitors, event monitor output consists of an ordered series of logical data groupings. Regardless of the event monitor type, the output records always contain the same starting logical data groups. These frame the logical data groups whose presence varies depending on the event types recorded by the event monitor.

For file and pipe event monitors, event records may be generated for any connection and may therefore appear in mixed order in the stream. This means that you may get a transaction event for Connection 1, immediately followed by a connection event for Connection 2. However, records belonging to a single connection or a single event will appear in their logical order. For example, a statement record (end of statement) always precedes a transaction record (end of UOW), if any. Similarly, a deadlock event record

always precedes the deadlocked connection event records for each connection involved in the deadlock. The **application id** or **application handle (agent\_id)** can be used to match records with a connection.

Connection header events are normally written for each connection to the database. For deadlocks with details event monitors, they are only written when the deadlock occurs. In this case, connection header events are only written for participants in the deadlock and not for all connections to the database.

The logical data groupings are ordered according to four different levels: Monitor, Prolog, Contents, and Epilog. Following are detailed descriptions for each level, including the corresponding event types and logical data groups.

## Monitor

Information at the Monitor level is generated for all event monitors. It consists of event monitor metadata.

<i>Table 13. Event Monitor Data Stream: Monitor Section</i>		
<b>Event type</b>	<b>Logical data group</b>	<b>Available information</b>
Monitor Level	event_log_stream_header	Identifies the version level and byte order of the event monitor. Applications can use this header to determine whether they can handle the evmon output stream.

## Prolog

The Prolog information is generated when the event monitor is activated.

<i>Table 14. Event Monitor Data Stream: Prolog Section</i>		
<b>Event type</b>	<b>Logical data group</b>	<b>Available information</b>
Log Header	event_log_header	Characteristics of the trace, for example server type and memory layout.
Database Header	event_db_header	Database name, path and activation time.
Event Monitor Start	event_start	Time when the monitor was started or restarted.
Connection Header	event_connheader	One for each current connection, includes connection time and application name. Event connection headers are only generated for connection, statement, transaction, and deadlock event monitors. Deadlocks with details event monitors produce connection headers only when a deadlock occurs.

## Contents

Information specific to the event monitor's specified event types is presented in the Contents section.

Table 15. Event Monitor Data Stream: Contents Section

Event type	Logical data group	Available information
Statement Event	event_stmt	Statement level data, including text for dynamic statements. Statement event monitors do not log fetches.
Subsection Event	event_subsection	Subsection level data.
Transaction Event <sup>1</sup>	event_xact	Transaction level data.
Connection Event	event_conn	Connection level data.
Deadlock Event	event_deadlock	Deadlock level data.
Deadlocked Connection Event	event_dlconn	One for each connection involved in the deadlock, includes applications involved and locks in contention.
Deadlocked Connection Event with Details	event_detailed_dlconn, lock	One for each connection involved in the deadlock, includes applications involved, locks in contention, current statement information, and other locks held by the application contention.
Overflow	event_overflow	Number of records lost - generated when writer cannot keep up with a (non-blocked) event monitor.
Deadlocks with details history <sup>2</sup>	event_stmt_history	List of statements executed in any unit of work that was involved in a deadlock.
Deadlocks with details history values <sup>2</sup>	event_data_value	Parameter markers for a statement in the event_stmt_history list.
Activities	event_activity	List of activities that completed executing on the system or were captured before completion.
	event_activystmt	Information about the statement the activity was executing if the activity type was a statement.
	event_activityvals	The data values used as input variables for each activity that is an SQL statement. These data values do not include LOB data, long data, or structured type data.

Table 15. Event Monitor Data Stream: Contents Section (continued)

Event type	Logical data group	Available information
Statistics	event_scmetrics	Statistics computed from the activities that executed within each service class, work class, or workload in the system, as well as statistics computed from the threshold queues.
	event_scstats	
	event_superclassmetrics	
	event_superclasstats	
	event_wcstats	
	event_wlmetrics	
	event_wlstats	
	event_qstats	
event_histogrambin		
Threshold violations	event_thresholdviolations	Information identifying the threshold violated and the time of violation.

1

This option has been deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR FOR UNIT OF WORK statement to monitor transaction events.

2

This option has been deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR FOR LOCKING statement to monitor lock-related events, such as lock timeouts, lock waits, and deadlocks.

## Epilog

The Epilog information is generated during database deactivation (last application finished disconnecting):

Table 16. Event Monitor Data Stream: Epilog Section

Event type	Logical data group	Available information
Database Event	event_db	Database manager level data.
Buffer Pool Event	event_bufferpool	Buffer pool level data.
Table Space Event	event_tablespace	Table space level data.
Table Event	event_table	Table level data.

## Displaying a list of event monitors created in your database

You can see what event monitors are already defined in your database by using the catalog view SYSCAT.EVENTMONITORS.

### Procedure

- To view a list of the event monitors that you defined on your system, query the catalog view SYSCAT.EVENTMONITORS.  
For example, to see a list of event monitors that includes the event monitor name, the target output type (that is, a regular table, file, named pipe, or unformatted event table), and the owner, you can use a query such as the following one:

```
SELECT SUBSTR(EVMONNAME,1,20) AS EVMON_NAME, TARGET_TYPE, OWNER
FROM SYSCAT.EVENTMONITORS
```

The preceding query returns results similar to those that follow:

EVMON_NAME	TARGET_TYPE	OWNER
DB2DETAILDEADLOCK	F	DBADMIN1
CACHEEVMON	T	DBADMIN1
INVTLOCK	T	DBADMIN1
INVTUOW	T	DBADMIN1
INVTACT	T	DBADMIN1
INVTSTATS	T	DBADMIN1
INVTTHRESHOLD	T	DBADMIN1
TABLE_INVTTABLE	T	DBADMIN1
BUFFER_INVTT	T	DBADMIN1
TABLESPACES_INVTT	T	DBADMIN1
CONNECTIONS_INVTT	T	DBADMIN1
TRANSAC_INVTT	T	DBADMIN1
DEADLOCK_INVTT	T	DBADMIN1
QUINNJN_LOC_UNF	U	DBADMIN1
UNFORM	U	DBADMIN1
RM	U	DBADMIN1
UOWINVT	U	DBADMIN1
LOCK_UP_STAFF	U	DBADMIN1
INVTLOCK2	T	DBADMIN1
STAFF_UOW	T	DBADMIN1
STAFFSTATS	T	DBADMIN1

21 record(s) selected.

### Examples

You can also use a catalog view to see which event monitors exist for monitoring a specific type of event. The SYSCAT.EVENTS view returns a list of event monitors and the type of events for which they record data.

```
SELECT SUBSTR(TYPE,1,20) AS EVENT_TYPE,
SUBSTR(EVMONNAME,1,20) AS EVENT_MONITOR_NAME
FROM SYSCAT.EVENTS
ORDER BY TYPE
```

EVENT_TYPE	EVENT_MONITOR_NAME
ACTIVITIES	INVTACT
BUFFERPOOLS	BUFFER_INVTT
CONNECTIONS	CONNECTIONS_INVTT
DEADLOCKS	DEADLOCK_INVTT
DETAILDEADLOCKS	DB2DETAILDEADLOCK
LOCKING	INVTLOCK
LOCKING	QUINNJN_LOC_UNF
LOCKING	UNFORM
LOCKING	RM
LOCKING	LOCK_UP_STAFF
LOCKING	INVTLOCK2
PKGCACHEBASE	CACHEEVMON
STATISTICS	INVTSTATS
STATISTICS	STAFFSTATS
TABLES	TABLE_INVTTABLE
TABLESPACES	TABLESPACES_INVTT
THRESHOLDVIOLATIONS	INVTTHRESHOLD
TRANSACTIONS	TRANSAC_INVTT
UOW	INVTUOW
UOW	UOWINVT
UOW	STAFF_UOW

21 record(s) selected.

## Displaying a list of active event monitors in your database

You can see what event monitors are active in your database by using the catalog view SYSCAT.EVENTMONITORS.

### Procedure

- To view a list of active event monitors for your database, use the EVENT\_MON\_STATE scalar function to query the catalog view SYSCAT\_EVENTMONITORS.

```
SELECT substr(evmonname, 1, 30) as evmon_name FROM syscat.eventmonitors
WHERE event_mon_state(evmonname) = 1
```

The preceding query returns results similar to those that follow:

```
EVMON_NAME
-----
DB2DETAILDEADLOCK
MYACTEVMON
MYLOCKEVMON
CACHEEVMON

4 record(s) selected.
```

## Event monitors for partitioned databases and databases in a Db2 pureScale environment

Generally, event monitors on partitioned database systems or in a Db2 pureScale environment work similarly to event monitors that run on nonpartitioned, single-member databases. However, there are some differences to be aware of.

### Partitioned database environments

#### Event monitors that write to regular tables and unformatted event (UE) tables

You cannot create event monitors that write to regular tables and UE tables on a specific partition. Instead, for a partitioned database environment, an event monitor process runs on each of the partitions. More specifically, the event monitor process runs on the members for each partition that belong to the database partition groups in which the target tables exist.

Each partition where the event monitor process runs has the same set of target tables for a specific event monitor. The data in these tables is different from partition to partition because the data for a specific partition reflects only events that take place on that partition. For table event monitors, you can retrieve aggregate values from all the partitions by issuing SQL statements to collect data from event monitor tables from each partition. For UE table event monitors, you can aggregate data across partitions by using the SQL statement that you specify for the EVMON\_FORMAT\_UE\_TO\_TABLE stored procedure or by using the EVMON\_FORMAT\_UE\_TO\_XML table function.

The first column of each event monitor table is named PARTITION\_KEY and is used as the partitioning key for the table. The value of this column is chosen so that each event monitor process inserts data into the database partition on which the process is running. That is, insert operations are performed locally on the database partition where the event monitor process is running. On any database partition, the PARTITION\_KEY field contains the same value. As a result, if you drop a data partition and data redistribution is performed, all data on the dropped database partition goes to one other database partition instead of being evenly distributed. Therefore, before dropping a database partition, consider deleting all table rows on that database partition.

In addition, in partitioned database environments, a column named PARTITION\_NUMBER, or MEMBER is defined for each table. This column contains the number of the partition or member on which the data was inserted.

Events are written to the event monitor target tables on those partitions where the table space for the target tables exists. If the table space for the event monitor target tables does not exist on

any partition where the event monitor runs, no data is collected on those partitions, and no error is returned. Moreover, no log records for these events are written where the table space does not exist. This behavior means that you can choose a subset of partitions for monitoring by creating a table space that exists only on certain partitions.

During write-to-table event monitor activation, the CONTROL table rows for FIRST\_CONNECT and EVMON\_START are inserted on all database partitions where the table space for target tables exists.

If a partition is not yet active when an event monitor is activated, the event monitor is activated when that partition is next activated.

### Event monitors that write to files and named pipes

File and pipe event monitors, with one exception, capture only events that take place on the database partition on which they are running (the *monitor partition*). Such an event monitor is known as a *local event monitor*. The exception is the DEADLOCK event monitor; you can create it as a local or a *global* event monitor. When you create it as a global event monitor, deadlock information is collected on all database partitions and is reported to the specific database partition where the event monitor process runs.<sup>4</sup>

When you create a file or pipe event monitor in a partitioned database environment, you can specify the partition that you want it to run on as part of the CREATE EVENT MONITOR statement. If you omit the partition number, the event monitor runs on the database partition that was connected when you created the event monitor.

An event monitor can be activated only if the monitor partition is active. If you use the SET EVENT MONITOR statement to activate an event monitor but the monitor partition is not yet active, event monitor activation occurs when the monitor partition is next started. Furthermore, the event monitor is activated automatically until you explicitly deactivate the event monitor or the instance. For example, consider the following sequence of statements:

```
DB2 CONNECT TO PAYROLL
DB2 CREATE EVENT MONITOR ABC ... ON DBPARTITIONNUM 2
DB2 SET EVENT MONITOR ABC STATE 1
```

After these statements are run, event monitor ABC activates automatically whenever the database PAYROLL is activated on database partition 2. This automatic activation occurs until the statement DB2 SET EVENT MONITOR ABC STATE 0 is issued or partition 2 is stopped.

If you add database partitions, the existing global, table, or UE table event monitors do not automatically start collecting data for the newly created partitions. To collect and record data about the new partitions, you must take one of the following steps:

- For global event monitors (that is, a DEADLOCKS event monitor), restart the event monitors.
- For table or UE table event monitors, drop, re-create, and restart the event monitors.

### Db2 pureScale environments

In Db2 pureScale environments, there is effectively one data partition, with two or more members that process data. Thus, when you create an event monitor, event monitor processes run on all members, regardless of whether they write to a file, pipe, tables, or a UE table.

Event data is reported on a per-member basis. As a result, monitor elements or metrics that are associated with a member, such as the **total\_cpu\_time** monitor element, report data that is specific to that member. However, other monitor elements related to the data itself, such as the **tablespace\_total\_pages** monitor element, reflect the same values regardless of what member reports them.

---

<sup>4</sup> This event monitor is deprecated. The LOCKING event monitor is the preferred event monitor for capturing lock and deadlock event information.

## Examples

### Example 1: Creating a write-to-file event monitor in a partitioned database environment

The example that follows shows how to create an event monitor that runs and collects data for buffer pool-related events on partition 3, writing its output to a file:

```
CREATE EVENT MONITOR bpmon FOR BUFFERPOOLS
WRITE TO FILE '/tmp/dlevents'
ON DBPARTITION 3
```

### Example 2: Creating a table event monitor in a partitioned database environment

The example that follows shows how to create a table monitor that runs and collects data for activities-related events and writes its output to a table:

```
CREATE EVENT MONITOR myacts FOR ACTIVITIES
WRITE TO TABLE
```

In this example, because no logical data groups are specified for the event monitor, tables are created for all logical data groups associated with this type of event monitor. Each of these tables is created on each partition in the default table space if the default table space exists on each partition. The data that is collected in the tables on each database partition pertains to events that take place on that partition.

To view event monitor data from selected partitions, issue a SELECT statement that queries those partitions:

```
SELECT TOTAL_CPU_TIME FROM myacts WHERE PARTITION_NUMBER = 3
```

## Enabling event monitor data collection

Depending on the type of event monitor you are using, you might need to configure collection after you create the event monitor. By default, some event monitors collect certain data immediately when activated. Other event monitors require that you explicitly configure data collection independently of creating the event monitor. These types of event monitors are sometimes referred to as *passive* event monitors.

### Before you begin

All event monitors must be activated before any data is written its target output table or tables (regular or UE), file or pipe. Some event monitors are configured by default as AUTOSTART event monitors. This means they are activated automatically when the database is activated. Others are configured by default to required that you activate them manually. Either way, you can override the default startup options. However, to start an automatic event monitor after you create it, but before the next database activation, you must use the SET EVENT MONITOR STATE statement to activate it manually.

### About this task

Some event monitors support the use of a WHERE clause on the CREATE or ALTER EVENT MONITOR statement to capture event information selectively. The following event monitors, however, provide the ability to control what event data is collected independently of the event monitor definition:

- Activities
- Change history
- Locking
- Statistics
- Unit of work

Some of the event monitors listed collect certain types of data by default after the event monitor is activated; others require that you explicitly enable data collection. Either way, you can enable data collection in one of two ways, depending on the scope of activities for which you want data collected:

## All activities in the database

To have monitor data collected across all activities in the database, you modify the appropriate configuration parameter for the type of data you are interested in. For example, to have unit of work data collected for all units of work that run in the database, set `mon_uow_data` to `BASE`. In some cases, the default settings for configuration parameters are such that some type of data is always collected if there is an appropriate event monitor active to receive the data. For example, the default setting for `mon_req_metrics` is `BASE`; unless you override this setting, any active statistics or unit of work event monitor will record the values for the `BASE` set of request monitor elements.

**Remember:** Event monitors that support the use of the `WHERE` predicate collect only the data that satisfies the conditions specified in that predicate, regardless of the settings for any relevant configuration parameters.

## Selected activities

Some event monitors - in particular, the workload management event monitors (threshold violations, statistics and activities) - provide the ability to control data collection for specific workload management objects. For example, you might choose to collect activity information for activities running in a specific service superclass. Configuring collection at this level generally involves adding a `COLLECT` clause to the `CREATE` or `ALTER WORKLOAD` (or `SERVICE CLASS` or `WORK ACTION`) statements to specify what type of information to collect for activities running under the auspices of that WLM object. For example, to enable the collection of extended statistics information for the service class `urgent`, you might use the following statement:

```
ALTER SERVICE CLASS urgent
  COLLECT AGGREGATE ACTIVITY DATA EXTENDED
```

**Note:** If a `COLLECT` clause is specified in a WLM `CREATE` or `ALTER` statement, the settings specified in the clause take precedence for that WLM object over any database-wide setting configured using a configuration parameter. For example, if `mon_req_metrics` is set to `EXTENDED`, and if workload `payroll` was configured to collect `BASE` request metrics (for example, `CREATE WORKLOAD payroll COLLECT REQUEST METRICS BASE`), then extended request metrics are collected for all activities in the database *except* for the `payroll` workload.

## Procedure

To enable collection of data for one of the types of event monitors shown at the beginning of this section, perform the following steps:

1. Determine what, if any data is already collected by default. The data you are interested in might be collected without you having to change any settings.
2. Decide on the scope of activities for which you want to collect data. Do you want to collect data for the entire database, or only for specific workloads, service class or work actions?
3. Decide what types of monitor elements you want to collect. Some event monitors support the collection of different types of monitor data, such as request monitor elements, activity data, and so on.
4. For the different sets of monitor data collected, decide the scope of data to be collected within each set. You generally have the choice of collecting no data (`NONE`), basic data (`BASE`), or extended data (`EXTENDED`). See to determine what data is collected for each setting.
5. Based on the decisions made in the preceding steps, configure data collection using either a configuration parameter or a `COLLECT` clause.
  - a) To configure collection across the entire database, set the appropriate configuration parameter. For example, to enable the collection of lock wait information with history by the locking event monitor on the database `SALES`, run the following command.

```
UPDATE DATABASE CONFIGURATION for SALES USING mon_lockwait HISTORY
```

- b) To configure collection for a specific workload, create or modify the workload, including the appropriate `COLLECT` clause.

For example, to configure the collection of lock wait data with statement history for locks waiting longer than 5 seconds in the MANAGERS workload, run a statement like the one that follows:

```
ALTER WORKLOAD MANAGERS
  COLLECT LOCK WAIT DATA FOR LOCKS WAITING MORE THAN 5 SECONDS
  WITH HISTORY
```

## What to do next

Now that the event monitor is created and active, and data collection is enabled, run your applications or workload.

## Methods for accessing event monitor information

Depending on the type of event monitor that you are using and the type of output it generates, there are different options for accessing and viewing event monitor data.

For example:

- Data produced by table event monitors can be queried directly using SQL.
- Data from event monitors that write to pipes can be viewed as it is produced.
- Data from file event monitors can be viewed by opening the output file after the event monitor is deactivated.
- Data from both file and pipe event monitors can also be formatted into a report using the **db2evmon** command.
- Data written to UE tables must be post-processed before it can be examined. UE event monitor data can be converted to tables or to XML, which makes it possible to query the data using SQL or XML query techniques. Alternatively, you can format the data in a UE table into a formatted report without going through a conversion process.

The sections that follow describe the different ways you can access information produced by event monitors.

### ***Accessing event monitor data in regular tables***

You can use SQL to directly access event monitor data that is written to regular relational tables.

### **Before you begin**

Before accessing data, you must perform the following tasks:

- Create and activate the event monitor
- Enable data collection if required for the type of event monitor that you are using and the type of data that you want to collect
- Run the workload or applications for which you want to collect monitoring data

Optionally, depending on how you are using the event monitor data, deactivate data collection before you start examining the event data. If the event monitor remains active, it continues to write data to the output tables. Therefore, the results from one query might differ from the results that you obtain by running the same query later on.

### **About this task**

Accessing event monitor data from relational tables involves using SQL to formulate queries to retrieve data from the tables produced by the event monitor.

### **Procedure**

To retrieve information from the tables that are produced by an event monitor that writes to tables:

1. Formulate a SELECT statement to display the monitor element data you want to see.

For example, to request lock data for the payroll workload from a locking event monitor named mylocks, you might use a query such as the following one:

```
SELECT DISTINCT CAST(STMT_TEXT AS VARCHAR(25)) STMT, LP.PARTICIPANT_NO,
    VARCHAR(LP.APPL_NAME,10) APPL_NAME, LP.LOCK_MODE_REQUESTED,
    LP.PARTICIPANT_TYPE
FROM LOCK_PARTICIPANT_ACTIVITIES_LOCK_MYLOCKS AS LPA
JOIN LOCK_PARTICIPANTS_LOCK_MYLOCKS AS LP
ON LPA.EVENT_ID = LP.EVENT_ID
WHERE LP.WORKLOAD_NAME = 'PAYROLL'
```

In this example, data from the LOCK\_PARTICIPANTS table from the event monitor mylocks is joined with information from the LOCK\_PARTICIPANTS\_ACTIVITIES table to return the following results.

2. Run the SQL statement.

## Results

STMT	PARTICIPANT_NO	APPL_NAME	LOCK_WAIT_VAL
select * from staff	2	db2bp	0
select * from staff	1	db2bp	1000

LOCK_MODE_REQUESTED	PARTICIPANT_TYPE
0	OWNER
1	REQUESTER

2 record(s) selected.

### Methods for accessing information in unformatted event tables

There are different ways to access the information in unformatted event (UE) tables. You can generate a text report intended to be read. Alternatively, you can extract the data into relational tables or XML; this approach lets you query the data using SQL or pureXML®.

Event monitors that write to UE tables write event data in a binary format. You can access this data using the db2evmonfmt command or routines provided for this purpose.

With the db2evmonfmt command you can:

- select events of interest based on the following attributes: event ID, event type, time period, application, workload, or service class.
- choose whether to receive the output in the form of a text report or a formatted XML document.
- completely control the output format by creating your own XSLT style sheets instead of using the ones provided with db2evmonfmt.

You can also extract data from an unformatted event table using the following routines:

- EVMON\_FORMAT\_UE\_TO\_XML - extracts data from an unformatted event table into an XML document.
- EVMON\_FORMAT\_UE\_TO\_TABLES - extracts data from an unformatted event table into a set of relational tables.

With these two routines, you can use a SELECT statement to specify the exact rows from the unformatted event table that you want to extract.

#### db2evmonfmt tool for reading event monitor data

The Java™-based, generic XML parser tool, **db2evmonfmt**, produces a readable flat-text output (text version) or a formatted XML output from the data generated by an event monitor that writes its output to a regular table or that uses the unformatted event table. Based on the parameters that you specify, the **db2evmonfmt** tool determines how to parse the event monitor data and the type of output to create.

The **db2evmonfmt** tool is provided as Java source code. You must setup and compile this tool, before you can use it, by performing the following steps:

1. Locate the source code in the sqllib/samples/java/jdbc directory

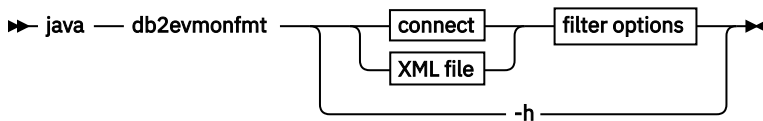

2. Follow the instructions embedded in the Java source file to setup and compile the tool

You can modify the source code to change the output to your liking.

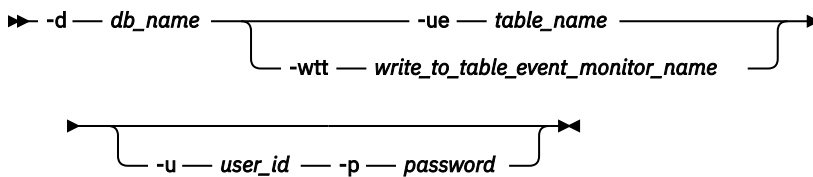

The tool uses XSLT style sheets to transform the event data into formatted text. You do not need to understand these style sheets. The tool will automatically load the correct style sheet, based on the event monitor type, and transform the event data. Each event monitor will provide default style sheets within the `sqllib/samples/xml/data` directory. The tool will also provide the following filtering options:

- Event ID
- Event timestamp
- Event type
- Workload name
- Service class name
- Application name

## Tool syntax

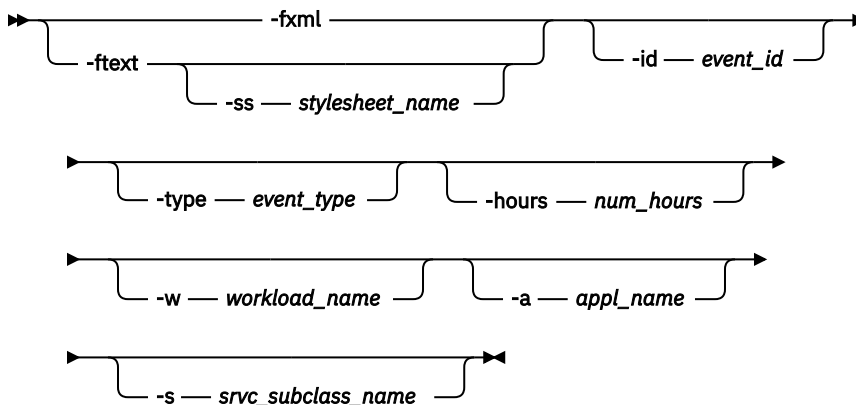

### connect

### XML file

### filter options

## Tool parameters

### java

To run the `db2evmonfmt` Java-based tool successfully, the `java` keyword must precede the tool name. The proper Java version to successfully run this tool is installed from the `sqllib/java/jdk64` directory during product installation.

### -d db\_name

Specifies the database name to which a connection is made

- ue *table\_name***  
Specifies the name of the unformatted event table
- wtt *write\_to\_table\_event\_monitor\_name***  
Specifies the name of an event monitor with a WRITE TO TABLE target. Only unit of work (UOW), package cache, locking and change history event monitors are supported.
- u *user\_id***  
Specifies the user ID
- p *password***  
Specifies the password
- f *xml\_filename***  
Specifies the name of the input XML file to format
- fxml**  
Produces a formatted XML document (pipe to stdout)
- ftext**  
Formats an XML document to a text document (pipe to stdout)
- ss *stylesheet\_name***  
Specifies the XSLT style sheet to use to transform the XML document
- id *event\_id***  
Displays all events matching the specified event ID. This option is only valid when the -ue option has been specified; it will be ignored otherwise.
- type *event\_type***  
Displays all events matching the specified event type. This option is only valid when the -ue option has been specified; it will be ignored otherwise.
- hours *num\_hours***  
Displays all events that have occurred within the specified last number of hours. This option is only valid when the -ue option has been specified; it will be ignored otherwise.
- w *workload\_name***  
Displays all events that are part of the specified workload. This option is only valid when the -ue option has been specified; it will be ignored otherwise.
- a *appl\_name***  
Displays all events that are part of the specified application. This option is only valid when the -ue option has been specified; it will be ignored otherwise.
- s *svrc\_subclass\_name***  
Displays all events that are part of the specified service subclass. This option is only valid when the -ue option has been specified; it will be ignored otherwise.

## XSLT style sheets

The database manager provides default XSLT style sheets (see Table 1) which can be found in the `sqllib/samples/java/jdbc` directory. You can change these style sheets to produce the required output.

<i>Table 17. Default XSLT style sheets for event monitors</i>	
<b>Event monitor</b>	<b>Default XSLT style sheet</b>
Locking	DB2EvmonLocking.xsl
Unit of work	DB2EvmonUOW.xsl
Package cache	DB2EvmonPkgCache.xsl

You can create your own XSLT style sheet to transform XML documents. You can pass these style sheets into the Java-based tool using the `-ss stylesheet_name` option.

## Examples

### Example 1

To obtain a formatted text output for all events that have occurred in the last 32 hours from the package cache unformatted event table PKG in database SAMPLE, issue the following command:

```
java db2evmonfmt -d sample -ue pkg -ftext -hours 32
```

### Example 2

To obtain a formatted text output for all events of type LOCKTIMEOUT that have occurred in the last 24 hours from unformatted event table LOCK in database SAMPLE, issue the following command:

```
java db2evmonfmt -d sample -ue LOCK -ftext -hours 24 -type locktimeout
```

### Example 3

To obtain a formatted text output from the XML source file LOCK.XML, extracting all events that match the event type LOCKWAIT in the last 5 hours, issue the following command:

```
java db2evmonfmt -f lock.xml -ftext -type lockwait -hours 5
```

### Example 4

To obtain a formatted text output using the created XSLT style sheet SUMMARY.XSL for all events in the unformatted event table UOW in database SAMPLE, issue the following command:

```
java db2evmonfmt -d sample -ue uow -ftext -ss summary.xsl
```

## Sample formatted flat-text output

The following sample of formatted flat-text output was generated from the locking event monitor XSLT style sheet:

```

## Usage notes

The **db2evmonfmt** utility is a Java-based tool which must be preceded by the **java** keyword in order to run successfully. The Java version required is that which is installed with the product from the `sqllib/java/jdk64` directory.

If connect parameters are supplied, the **db2evmonfmt** tool retrieves data directly from an event monitor. When the **db2evmonfmt** tool retrieves data directly from an event monitor, the command calls the `EVMON_FORMAT_UE_TO_XML` table function to build an XML document from the binary events in the event monitor. If you want details about partial events, you must modify the `EVMON_FORMAT_UE_TO_XML` call in the java-based tool to add the `LOG_PARTIAL_EVENTS` option. After you modify the `EVMON_FORMAT_UE_TO_XML` call, you must recompile the tool. For more information about partial events and the `LOG_PARTIAL_EVENTS` option, see [EVMON\\_FORMAT\\_UE\\_TO\\_XML table function - convert unformatted events to XML](#).

**Note:** You can also use the `EVMON_FORMAT_UE_TO_XML` table function directly to format the binary events, contained in the unformatted event table BLOB column, into an XML document.

### *Routines for extracting data from unformatted event tables*

If you want to perform queries on the data collected by an event monitor that writes to a unformatted event (UE) table, you must first extract the data from UE table using one of the two routines provided for this purpose. The `EVMON_FORMAT_UE_TO_TABLES` procedure extracts data from the UE table to create relational tables. The `EVMON_FORMAT_UE_TO_XML` table function creates an XML document.

### **EVMON\_FORMAT\_UE\_TO\_TABLES**

The `EVMON_FORMAT_UE_TO_TABLES` procedure examines the UE table produced by an event monitor, and extracts the data it contains into relational tables that you can query. The number of tables produced depends on the type of event monitor; and the logical data groups for which that event monitor collects data. Generally speaking, the data from each logical data group is written to a separate table. For example, the package cache event monitor collects event data from three logical data groups: `pkgcache` and `pkgcache_metrics`, and `pkgcache_stmt_args`. Thus, three tables are produced by `EVMON_FORMAT_UE_TO_TABLES`.

**Note:** `EVMON_FORMAT_UE_TO_TABLES` does not create a table for the control logical data group.

In addition to creating relational tables from UE tables, as of version 10.1 the `EVMON_FORMAT_UE_TO_TABLES` procedure provides the capability to prune data from UE tables. When you use the `PRUNE_UE_TABLES` option for `EVMON_FORMAT_UE_TO_TABLES`, data that is successfully inserted into relational tables is deleted from the unformatted event (UE) table.

### **EVMON\_FORMAT\_UE\_TO\_XML**

The `EVMON_FORMAT_UE_TO_XML` table function examines the UE table produced by an event monitor, and extracts the data it contains into an XML document. This document can then be queried as often as needed using pureXML.

#### **Notes:**

- This table function works similarly to the **db2evmonfmt** utility when that utility is used with the `-fxml` option. The differences between using `EVMON_FORMAT_UE_TO_XML` instead of **db2evmonfmt** are as follows:
  - `EVMON_FORMAT_UE_TO_XML` is a table function. As such, it is invoked as part of an SQL statement. **db2evmonfmt** runs as a separate utility.
  - `EVMON_FORMAT_UE_TO_XML` lets you specify a `SELECT` statement with a `WHERE` clause to filter events from the UE table. **db2evmonfmt** has only limited capabilities for filtering event data.

- The output XML document from `EVMON_FORMAT_UE_TO_XML` can be formatted by **db2evmonfmt** to create a flat text file.

With both routines, you must include a `SELECT` statement in the call to the routine to specify conditions for which data to extract.

#### *Pruning data from UE tables*

If you use the `EVMON_FORMAT_UE_TO_TABLES` procedure to extract data from UE tables, you can use the `PRUNE_UE_TABLE` option to remove data that you no longer need.

### **Before you begin**

Before you can extract data from a UE table, you must have created, activated, and enabled data collection for an event monitor that writes to a UE table.

### **About this task**

In addition to the performance advantages that UE tables offer, using UE tables as output for an event monitor lets you take advantage of the automatic pruning feature of the `EVMON_FORMAT_UE_TO_TABLES` procedure. When you use this procedure, any data that is extracted from the UE table and written to a regular table can be automatically removed from the UE table. This procedure makes it easier to manage a UE table. For example, assume that you want to use a unit of work event monitor to capture information to generate daily reports for accounting purposes, such as charging departments for CPU time that is used by an application or query. In that case, you might want to prune that data after producing the reports.

### **Procedure**

Issue an SQL statement that calls the `EVMON_FORMAT_UE_TO_TABLES` procedure with the `PRUNE_UE_TABLE` option to extract data into a regular table.

For example, if you have a unit of work event monitor called `TRACKWORK`, you might create a statement such as the one that follows:

```
CALL EVMON_FORMAT_UE_TO_TABLES
    ('UOW', NULL, NULL, NULL, NULL, NULL, 'PRUNE_UE_TABLE', -1,
     'SELECT * FROM TRACKWORK')
```

All event data is copied from the UE table to the `UOW_EVENT_TRACKWORK` and `UOW_METRICS_TRACKWORK` tables. In addition, all records that were copied are removed from the UE table.

### ***Formatting file or pipe event monitor output from a command line***

The output of a file or pipe event monitor is a binary stream of logical data groupings. You can format this data stream from a command line by using the **db2evmon** command. This productivity tool reads in event records from an event monitor's files or pipe, then writes them to the screen (standard output).

### **Before you begin**

No authorization is required unless you are connecting to the database, in which case one of the following authorities is required:

- SYSADM
- SYSCTRL
- SYSMAINT
- DBADM

### **About this task**

You can indicate which event monitor output to format by either providing the path of the event files, or providing the name of the database and the event monitor name.

## Procedure

To format event monitor output:

- Specify the directory containing the event monitor files:

```
db2evmon -path '/tmp/dlevents'
```

/tmp/dlevents represents a (UNIX) path.

- Specify the database and event monitor name:

```
db2evmon -db 'sample' -evm 'dlmon'
```

sample represents the database the event monitor belongs to.

dlmon represents an event monitor.

## Altering an event monitor

You cannot change an event monitor, with one exception: you can add one or more logical data groups to the set of logical data groups that the event monitor collects. You use the ALTER EVENT MONITOR statement to add logical groups.

### About this task

When you create an event monitor that writes to tables, by default, all logical data groups of monitor elements that are associated with that event monitor are captured. However, if you include the names of logical data groups in the CREATE EVENT MONITOR statement, only those groups are captured. For example, you might create an activities event monitor that captures data only from the event\_activity and event\_activity\_metrics logical data groups, as shown in the following example:

```
CREATE EVENT MONITOR myacts FOR ACTIVITIES  
WRITE TO TABLE  
event_activity, event_activity_metrics
```

The preceding DDL statement creates an event monitor that writes to two tables: ACTIVITY\_myacts and ACTIVITY\_METRICS\_myacts.

### Restrictions

You can use the ALTER EVENT MONITOR statement only to add logical data groups to an event monitor. You cannot remove a logical data group. You also cannot change the name, the target table space, or the value for PCTDEACTIVATE that is associated with the table that is used to capture the data in monitor elements that belong to a data group.

## Procedure

To add additional logical data groups to an event monitor:

1. Decide which logical data group you want to add.  
Using the preceding example of a locking event monitor where only two logical data groups are being captured, assume that you want to add the event\_activitystmt and event\_activityvals logical data groups.
2. Formulate an ALTER EVENT MONITOR statement to add these new logical data groups.

```
ALTER EVENT MONITOR mylacts  
ADD LOGICAL GROUP event_activitystmt  
ADD LOGICAL GROUP event_activityvals
```

3. Execute the statement.

## Results

When the ALTER EVENT MONITOR statement completes execution, two additional tables are created for the event monitor myacts:

ACTIVITYSTMT\_myacts  
ACTIVITYVALS\_myacts

The next time the event monitor is activated, these tables are populated with data from their corresponding logical data groups.

**Remember:** If you add new logical data groups to an event monitor, any data that existed for the logical data groups that were originally part of the table will not have any corresponding rows in the tables for the newly added logical group. Adjust your queries as needed, or consider pruning old data from the table after adding the logical groups.

### Example

A database administrator creates a locking event monitor called mylocks by using the following SQL statement:

```
CREATE EVENT MONITOR mylocks FOR LOCKING WRITE TO TABLE LOCK, LOCK_PARTICIPANTS
```

This statement collects information for monitor elements in the lock and lock\_participants logical data groups. The tables to which the monitor element data is written are created with the default table names LOCK\_MYLOCKS and LOCK\_PARTICIPANTS\_MYLOCKS.

Later on, the database administrator decides that she wants to collect information in the LOCK\_PARTICIPANT\_ACTIVITIES logical data group. She uses the following statement to modify the event monitor:

```
ALTER EVENT MONITOR mylocks ADD LOGICAL GROUP LOCK_PARTICIPANT_ACTIVITIES
```

This statement causes the monitor elements in the lock\_participant\_activities to be collected in addition to the other elements that already were collected. This new set of monitor elements are written to the table LOCK\_PARTICIPANT\_ACTIVITIES\_MYLOCKS.

Later, the database administrator decides that she also needs the data from the control logical data group. However, she wants this data to be written to a table with a name other than the default name, and to a table space other than the default table space. She uses the following statement:

```
ALTER EVENT MONITOR mylocks ADD LOGICAL GROUP CONTROL TABLE ctl_mylocks IN mytbsp3
```

This statement adds the control logical data group to the output of the event monitor. This statement adds the control logical data group to the output of the event monitor. The data is written to the CTL\_MYLOCKS table, and the table is written to the table space mytbsp3, instead of the default table space.

## Monitoring different types of events

### Lock and deadlock event monitoring

Diagnosing and correcting lock contention situations in large database environments can be complex and time-consuming. The locking event monitor designed to simplify this task by collecting locking data.

**Note:** The deadlocks event monitor has been deprecated, and the function it provided is included in the locking event monitor. In addition, the DB2DETAILDEADLOCK event monitor is also deprecated. See [“Deprecated lock monitoring functionality” on page 149](#) for important usage information about this event monitor.

The locking event monitor is used to capture descriptive information about lock events at the time that they occur. The information captured identifies the key applications involved in the lock contention that resulted in the lock event. Information is captured for both the lock requester (the application that received the deadlock or lock timeout error, or waited for a lock for more than the specified amount of time) and the current lock owner.

The information collected by the lock event monitor can be written in binary format to an unformatted event table in the database, in which case the captured data must be processed in a post-capture step. Alternatively, the lock event information can be written to a set of regular tables. See [“Output options](#)

for event monitors” on page 35 for more information about how to choose the most appropriate output format.

You can also directly access relational monitoring interfaces (table functions) to collect lock event information by using either dynamic or static SQL.

Determining if a deadlock or lock timeout has occurred is also simplified. Messages are written to the administration notification log when either of these events occurs; this supplements the SQL0911N (sqlcode -911) error returned to the application. In addition, a notification of lock escalations is also written to the administration notification log; this information can be useful in adjusting the size of the lock table and the amount of the table an application can use. There are also counters for lock timeouts (**lock\_timeouts**), lock waits (**lock\_waits**), and deadlocks (**deadlocks**) that can be checked.

The types of activities for which locking data can be captured are as follows:

- SQL statements, such as:
  - DML
  - DDL
  - CALL
- **LOAD** command
- **REORG** command
- **BACKUP DATABASE** command
- Utility requests

The lock event monitor replaces the deprecated deadlock event monitors (CREATE EVENT MONITOR FOR DEADLOCKS statement and DB2DETAILDEADLOCK) and the deprecated lock timeout reporting feature (DB2\_CAPTURE\_LOCKTIMEOUT registry variable) with a simplified and consistent interface for gathering locking event data, and adds the ability to capture data on lock waits.

## Functional overview

Two steps are required to enable the capturing of lock event data using the locking event monitor:

1. You must create a LOCK EVENT monitor using the CREATE EVENT MONITOR FOR LOCKING statement. You provide a name for the monitor and, if you are using UE tables as the output format, the name of an unformatted event table into which the lock event data is written.

**Note:** If you choose to use regular tables for event monitor output, default table names are assigned. You can override the defaults from the CREATE EVENT MONITOR statement, if you prefer.

2. You must specify the level for which you want lock event data captured by using one of the following methods:

- You can specify particular workloads by either altering an existing workload, or by creating a new workload using the CREATE or ALTER WORKLOAD statements. At the workload level you must specify the type of lock event data you want captured (deadlock, lock timeout or lock wait), and whether you want the SQL statement history and input values for the applications involved in the locking. For lock waits you must also specify the amount of time that an application will wait for a lock, after which data is captured for the lock wait.
- You can collect data at the database level and affect all database workloads by setting the appropriate database configuration parameter:

### **mon\_lockwait**

This parameter controls the generation of lock wait events

Best practice is to enable lock wait data collection at the workload level.

### **mon\_locktimeout**

This parameter controls the generation of lock timeout events

Best practice is to enable lock timeout data collection at the database level if they are unexpected by the application. Otherwise enable at workload level.

### **mon\_deadlock**

This parameter controls the generation of deadlock events

Best practice is to enable deadlock data collection at the database level.

### **mon\_lw\_thresh**

This parameter controls the amount of time spent in lock wait before an event for **mon\_lockwait** is generated

Capturing of SQL statement history and input values uses additional processor time, memory and storage, but this level of detail is often needed to successfully debug a locking problem.

After a locking event has occurred, you can view the event data in the output produced by the event monitor. If you used UE tables, the binary data in the unformatted event table can be transformed into an XML or a text document using a supplied Java-based application called **db2evmonfmt**. In addition, you can format the binary event data in the unformatted event table BLOB column into either an XML report document, using the `EVMON_FORMAT_UE_TO_XML` table function, or into a relational table, using the `EVMON_FORMAT_UE_TO_TABLES` procedure.

If you used regular tables as the output format, you can query the data directly using SQL.

To aid in the determination of what workloads should be monitored for locking events, the administration notification log can be reviewed. Each time a deadlock or lock timeout is encountered, a message is written to the log. These messages identify the workload in which the lock requester and lock owner or owners are running, and the type of locking event. There are also counters at the workload level for lock timeouts (**lock\_timeouts**), lock waits (**lock\_waits**), and deadlocks (**deadlocks**) that can be checked.

## **Information collected for a locking event**

Some of the information for lock events collected by the lock event monitor include the following:

- The lock that resulted in an event
- The application holding the lock that resulted in the lock event
- The applications that were waiting for or requesting the lock that result in the lock event
- What the applications were doing during the lock event

### **Note:**

- In Db2 pureScale environments, when the cluster caching facility (CF) is busy, a lock holder just released a lock, or due to other reasons, you might see the message "Unable to obtain Lock Holder information during the occurrence of the lock event", with no information about the lock holder.
- In Db2 pureScale environments, the deadlock event monitor does not always report the lock\_mode monitor element. You might see deadlock event monitor output with no information about the lock holder. This can happen even when the CF is not busy.

## **Deprecated lock monitoring functionality**

The deprecated detailed deadlock event monitor, `DB2DETAILDEADLOCK`, is created by default for each database and starts when the database is activated. If you use the locking event monitor to detect deadlocks, consider disabling the `DB2DETAILDEADLOCK` event monitor. If the `DB2DETAILDEADLOCK` event monitor remains active while the locking event monitor also collects deadlock information, both event monitors will be collecting data, which can significantly affect performance.

To remove the `DB2DETAILDEADLOCK` event monitor, issue the following SQL statements:

```
SET EVENT MONITOR DB2DETAILDEADLOCK state 0
DROP EVENT MONITOR DB2DETAILDEADLOCK
```

## Data generated by locking event monitors

Locking event monitors produce data about locks and deadlocks in the system. You can choose to have the output from a locking event monitor to regular tables, or to an unformatted event (UE) table. If data is written to a UE table, you must perform post-processing on it to view the data.

Regardless of the output format you choose, locking event data comes from one of four logical groups:

- [lock](#)
- [lock\\_participants](#)
- [lock\\_participant\\_activities](#)
- [lock\\_activity\\_values](#)

If you choose to have the locking event data written to regular tables, data from an additional group (CONTROL) is used to generate meta-data about the event monitor itself.

**Note:** By default, only deadlock information is generated for locking event monitors. To have other types of locking data generated, you must enable collection of that data explicitly.

### Information written to tables for a locking event monitor

Information written by the locking event monitor when the WRITE TO TABLE option is specified.

When you choose WRITE TO TABLE as the output type for the locking event monitor, by default, five tables are produced, each containing monitor elements from one or more logical data groups:

Default table name	Logical data groups reported
<a href="#">LOCK_evmon-name</a>	Refer to <a href="#">lock</a> in "Event monitor logical data groups and monitor elements"
<a href="#">LOCK_PARTICIPANTS_evmon-name</a>	Refer to <a href="#">lock_participants</a> in "Event monitor logical data groups and monitor elements"
<a href="#">LOCK_PARTICIPANT_ACTIVITIES_evmon-name</a>	Refer to <a href="#">lock_participant_activities</a> "Event monitor logical data groups and monitor elements"
<a href="#">LOCK_ACTIVITY_VALUES_evmon-name</a>	Refer to <a href="#">lock_activity_values</a> in "Event monitor logical data groups and monitor elements"
<a href="#">CONTROL_evmon-name</a>	The CONTROL logical group consists of selected elements from one or more of the <a href="#">event_dbheader</a> , <a href="#">event_start</a> and <a href="#">event_overflow</a> logical data groups.

**Important:** Even though all five tables are produced by default, you must still ensure that data collection is enabled for the kind of lock information that you want to gather. Otherwise, some of the columns contain null values.

To restrict the output of the event monitor to specific tables, specify the names of the logical groups for which you want tables produced for the CREATE EVENT MONITOR or ALTER EVENT MONITOR statement. Refer to the reference topics for those statements for details.

## Control table

Column name	Data type	Description
PARTITION_KEY	INTEGER	<a href="#">partition_key</a> - Partitioning key
EVENT_MONITOR_NAME	VARCHAR(128)	<a href="#">event_monitor_name</a> - Event monitor name

Table 19. Information returned for a locking event monitor: Default table name: CONTROL\_evmon-name (continued)

Column name	Data type	Description
MESSAGE	VARCHAR(128)	message - Control table message
MESSAGE_TIME	TIMESTAMP	message_time - Timestamp control table message
PARTITION_NUMBER	SMALLINT	partition_number - Partition number

Information written to relational tables by `EVMON_FORMAT_UE_TO_TABLES` for a locking event monitor  
 Information written for a locking event monitor from the `EVMON_FORMAT_UE_TO_TABLES` table function.  
 This is also documented in the `sqllib/misc/DB2EvmonLocking.xsd` file.

Table 20. Information returned for a locking event monitor: Table name: LOCK\_EVENT

Column Name	Data Type	Description
XMLID	VARCHAR(256 OCTETS) NOT NULL	"xmlid - XML ID monitor element" on page 1710
DEADLOCK_TYPE	VARCHAR(10 OCTETS)	"deadlock_type - Deadlock type monitor element" on page 804
EVENT_ID	BIGINT NOT NULL	"event_id - Event ID monitor element" on page 841

Information written to XML by EVMON\_FORMAT\_UE\_TO\_XML for a locking event monitor

Information written for a locking event monitor from the EVMON\_FORMAT\_UE\_TO\_XML table function. This is also documented in the `sqllib/misc/DB2EvmonLocking.xsd` file.

## db2\_lock\_event

The main schema that describes a lock timeout, lock wait or deadlock event in details.

**Element content:** ( ( [“db2\\_deadlock\\_graph” on page 155](#) {zero or one times (?)}, [“db2\\_participant” on page 155](#) {one or more (+)} ) | ( [“db2\\_message” on page 156](#) , [“db2\\_event\\_file” on page 156](#) ) )

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:long			required	
type			required		
timestamp	xs:dateTime			required	
member				required	
release	xs:long			required	
ANY attribute from ANY namespace					

## db2\_deadlock\_graph

Schema element represents the Db2 Deadlock Graph. The graph outlines all the participants involved in the deadlock.

**Contained by:** [“db2\\_lock\\_event” on page 155](#)

**Element content:** ( [“db2\\_participant” on page 165](#) {one or more (+)} )

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
dl_conns	xs:int			required	
rolled_back_participant_no	xs:int			required	
type			required		
ANY attribute from ANY namespace					

## db2\_participant

Schema element represents the application information of the all the participants involved in a lock event.

**Contained by:** [“db2\\_lock\\_event” on page 155](#) [“db2\\_deadlock\\_graph” on page 155](#)

**Element content:** (“db2\_object\_requested” on page 160 {zero or one times (?)}, “db2\_app\_details” on page 160 , “db2\_activity” on page 160 {zero or more (\*)})

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
no	xs:int			required	
type			required		
participant_no_holding_lk	xs:int			optional	
deadlock_member	xs:int			optional	
ANY attribute from ANY namespace					

**db2\_message**

Error message

**Contained by:** [“db2\\_lock\\_event” on page 155](#)

**db2\_event\_file**

Fully qualified path to file where event has been written.

**Contained by:** [“db2\\_lock\\_event” on page 155](#)

**application\_handle**

A system-wide unique ID for the application. See monitor element [“agent\\_id - Application handle \(agent ID\) monitor element” on page 634](#) for more details.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

**appl\_id**

This identifier is generated when the application connects to the database at the database manager. See monitor element [“appl\\_id - Application ID monitor element” on page 656](#) for more details.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

**appl\_name**

The name of the application running at the client, as known to the database. See monitor element [“appl\\_name - Application name monitor element” on page 660](#) for more details.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

**auth\_id**

The authorization ID of the user who invoked the application that is being monitored. See monitor element [“auth\\_id - Authorization ID ” on page 680](#) for more details.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## agent\_tid

The unique identifier for the engine dispatchable unit (EDU) for the agent. See monitor element [“agent\\_tid - Agent thread ID monitor element”](#) on page 640 for more details.

**Contained by:** [“db2\\_app\\_details”](#) on page 160

**Element content:**

Type	Facet
xs:long	

## coord\_agent\_tid

The engine dispatchable unit (EDU) identifier of the coordinator agent for the application. See monitor element [“coord\\_agent\\_tid - Coordinator agent engine dispatchable unit ID monitor element”](#) on page 760 for more details.

**Contained by:** [“db2\\_app\\_details”](#) on page 160

**Element content:**

Type	Facet
xs:long	

## agent\_status

The current status of the application. See monitor element [“appl\\_status - Application status monitor element”](#) on page 665 for more details.

**Contained by:** [“db2\\_app\\_details”](#) on page 160

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:int			optional	

## appl\_action

The action/request that the client application is performing

**Contained by:** [“db2\\_app\\_details”](#) on page 160

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:int			optional	

## lock\_timeout\_val

The database configuration parameter lock timeout. Value in seconds. See monitor element [“lock\\_timeout\\_val - Lock timeout value monitor element”](#) on page 1022 for more details.

**Contained by:** [“db2\\_app\\_details”](#) on page 160

**Element content:**

Type	Facet
xs:long	

## lock\_wait\_val

The lock wait parameter in effect during the lock event. This is either the database configuration parameter MON\_LKWAIT\_THRSH or the COLLECT LOCK WAIT DATA setting specified at the workload level. Value in milliseconds.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

**Element content:**

Type	Facet
xs:long	

## tentry\_state

TEntry state. Internal use only.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:int			optional	

## tentry\_flag1

TEntry flags1. Internal use only.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## tentry\_flag2

TEntry flags2. Internal use only.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## xid

XID - Global transaction identifier

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## workload\_id

ID of the workload to which this application belongs. See monitor element [“workload\\_id - Workload ID monitor element” on page 1704](#) for more details.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## workload\_name

Name of the workload to which this application belongs. See monitor element [“workload\\_name - Workload name monitor element” on page 1705](#) for more details.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## service\_class\_id

ID of the service subclass to which this application belongs. See monitor element [“service\\_class\\_id - Service class ID monitor element” on page 1414](#) for more details.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## **service\_subclass\_name**

Name of the service subclass to which this application belongs. See monitor element [“service\\_subclass\\_name - Service subclass name monitor element” on page 1417](#) for more details.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## **current\_request**

The operation currently being processed or most recently processed.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## **lock\_escalation**

Indicates whether a lock request was made as part of a lock escalation. See monitor element [“lock\\_escalation - Lock escalation monitor element” on page 1004](#) for more details. Possible values: Yes or No.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## **past\_activities\_wrapped**

Indicates whether the activities list has wrapped. The default limit on the number of past activities to be kept by any one application is 250. This default can be overridden using the registry variable DB2\_MAX\_INACT\_STMTS. Users may want to choose a different value for the limit to increase or reduce the amount of system monitor heap used for inactive statement information.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## **client\_userid**

The client user ID generated by a transaction manager and provided to the server. See monitor element [“client\\_userid - Client user ID monitor element” on page 717](#) for more details.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## **client\_wrkstname**

Identifies the client system or workstation, if the sqleseti API was issued in this connection. See monitor element [“client\\_wrkstname - Client workstation name monitor element” on page 718](#) for more details.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## **client\_applname**

Identifies the server transaction program performing the transaction, if the sqleseti API was issued in this connection. See monitor element [“client\\_applname - Client application name monitor element” on page 710](#) for more details.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## **client\_acctng**

The data passed to the target database for logging and diagnostic purposes, if the sqleseti API was issued in this connection. See monitor element [“client\\_acctng - Client accounting string monitor element” on page 709](#) for more details.

**Contained by:** [“db2\\_app\\_details” on page 160](#)

## utility\_invocation\_id

The utility invocation ID. See monitor element [“utility\\_invocation\\_id - Utility invocation ID ”](#) on page 1688 for more details.

**Contained by:** [“db2\\_app\\_details”](#) on page 160

## service\_superclass\_name

Name of the service superclass to which this application belongs. See monitor element [“service\\_superclass\\_name - Service superclass name monitor element”](#) on page 1418 for more details.

**Contained by:** [“db2\\_app\\_details”](#) on page 160

## db2\_object\_requested

Schema element represents the Db2 lock that the Requestor is attempting to acquire, which is being held by the Owner.

**Contained by:** [“db2\\_participant”](#) on page 155

**Element content:** ( [“lock\\_name”](#) on page 161 , [“lock\\_object\\_type”](#) on page 161 , [“lock\\_specifics”](#) on page 161 , [“lock\\_attributes”](#) on page 161 , [“lock\\_current\\_mode”](#) on page 161 , [“lock\\_mode\\_requested”](#) on page 161 , [“lock\\_mode”](#) on page 162 , [“lock\\_count”](#) on page 162 , [“lock\\_hold\\_count”](#) on page 162 , [“lock\\_rriid”](#) on page 162 , [“lock\\_status”](#) on page 162 , [“lock\\_release\\_flags”](#) on page 163 , [“tablespace\\_name”](#) on page 163 , [“table\\_name”](#) on page 163 , [“table\\_schema”](#) on page 163 , [“lock\\_object\\_type\\_id”](#) on page 163 , [“lock\\_wait\\_start\\_time”](#) on page 164 , [“lock\\_wait\\_end\\_time”](#) on page 164 , [“threshold\\_name”](#) on page 164 , [“threshold\\_id”](#) on page 164 , [“queue\\_start\\_time”](#) on page 164 {zero or one times (?)}, [“queued\\_agents”](#) on page 164 , ANY content ( skip ) {zero or more (\*)}

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
type			required		

## db2\_app\_details

Schema element represents the details regarding this participant.

**Contained by:** [“db2\\_participant”](#) on page 155

**Element content:** ( [“application\\_handle”](#) on page 156 , [“appl\\_id”](#) on page 156 , [“appl\\_name”](#) on page 156 , [“auth\\_id”](#) on page 156 , [“agent\\_tid”](#) on page 157 , [“coord\\_agent\\_tid”](#) on page 157 , [“agent\\_status”](#) on page 157 , [“appl\\_action”](#) on page 157 , [“lock\\_timeout\\_val”](#) on page 157 , [“lock\\_wait\\_val”](#) on page 158 , [“tentry\\_state”](#) on page 158 , [“tentry\\_flag1”](#) on page 158 , [“tentry\\_flag2”](#) on page 158 , [“xid”](#) on page 158 , [“workload\\_id”](#) on page 158 , [“workload\\_name”](#) on page 158 , [“service\\_class\\_id”](#) on page 158 , [“service\\_subclass\\_name”](#) on page 159 , [“current\\_request”](#) on page 159 , [“lock\\_escalation”](#) on page 159 , [“past\\_activities\\_wrapped”](#) on page 159 , [“client\\_userid”](#) on page 159 , [“client\\_wrkstnname”](#) on page 159 , [“client\\_applname”](#) on page 159 , [“client\\_acctng”](#) on page 159 , [“utility\\_invocation\\_id”](#) on page 160 , [“service\\_superclass\\_name”](#) on page 160 , ANY content ( skip ) {zero or more (\*)}

## db2\_activity

List of all Db2 activities the application is currently executing or has executed.

**Contained by:** [“db2\\_participant”](#) on page 155

**Element content:** ( [“db2\\_activity\\_details”](#) on page 169 , [“db2\\_input\\_variable”](#) on page 169 {zero or more (\*)}

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
type			required		
ANY attribute from ANY namespace					

### lock\_name

Internal binary lock name. This element serves as a unique identifier for locks. See monitor element [“lock\\_name - Lock name monitor element” on page 1016](#) for more details.

**Contained by:** [“db2\\_object\\_requested” on page 160](#)

### lock\_object\_type

The type of object the application is waiting to obtain a lock. See monitor element [“lock\\_object\\_type - Lock object type waited on monitor element” on page 1017](#) for more details.

**Contained by:** [“db2\\_object\\_requested” on page 160](#)

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:long			optional	

### lock\_specifics

Internal specifics about the lock. For information use only.

**Contained by:** [“db2\\_object\\_requested” on page 160](#)

### lock\_attributes

Lock attributes. See monitor element [“lock\\_attributes - Lock attributes monitor element” on page 1001](#) for more details.

**Contained by:** [“db2\\_object\\_requested” on page 160](#)

### lock\_current\_mode

Original lock before conversion. See monitor element [“lock\\_current\\_mode - Original lock mode before conversion monitor element” on page 1003](#) for more details.

**Contained by:** [“db2\\_object\\_requested” on page 160](#)

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:long			optional	
mode				optional	

### lock\_mode\_requested

The lock mode being requested by this participant. See monitor element [“lock\\_mode\\_requested - Lock mode requested monitor element” on page 1015](#) for more details.

**Contained by:** [“db2\\_object\\_requested” on page 160](#)

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:long			optional	
mode				optional	

### lock\_mode

The type of lock being held. See monitor element [“lock\\_mode - Lock mode monitor element”](#) on page 1013 for more details.

**Contained by:** [“db2\\_object\\_requested”](#) on page 160

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:long			optional	
mode				optional	

### lock\_count

The number of locks on the lock being held. See monitor element [“lock\\_count - Lock count monitor element”](#) on page 1002 for more details.

**Contained by:** [“db2\\_object\\_requested”](#) on page 160

**Element content:**

Type	Facet
xs:long	

### lock\_hold\_count

The number of holds placed on the lock. See monitor element [“lock\\_hold\\_count - Lock hold count monitor element”](#) on page 1012 for more details.

**Contained by:** [“db2\\_object\\_requested”](#) on page 160

**Element content:**

Type	Facet
xs:long	

### lock\_rriid

IID for Row locking. Internal use only.

**Contained by:** [“db2\\_object\\_requested”](#) on page 160

**Element content:**

Type	Facet
xs:long	

### lock\_status

Indicates the internal status of the lock. See monitor element [“lock\\_status - Lock status monitor element”](#) on page 1021 for more details.

**Contained by:** [“db2\\_object\\_requested” on page 160](#)

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:int			optional	

### lock\_release\_flags

Lock release flags. See monitor element [“lock\\_release\\_flags - Lock release flags monitor element” on page 1020](#) for more details.

**Contained by:** [“db2\\_object\\_requested” on page 160](#)

### tablespace\_name

The name of the table space where the lock is held. See monitor element [“tablespace\\_name - Table space name monitor element” on page 1515](#) for more details.

**Contained by:** [“db2\\_object\\_requested” on page 160](#)

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:long			optional	

### table\_name

The name of the table where the lock is held. See monitor element [“table\\_name - Table name monitor element” on page 1505](#) for more details.

**Contained by:** [“db2\\_object\\_requested” on page 160](#)

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:long			optional	
data_member_id				optional	The identifier of the data member for which information is returned.

### table\_schema

The schema of the table. See monitor element [“table\\_schema - Table schema name monitor element” on page 1507](#) for more details.

**Contained by:** [“db2\\_object\\_requested” on page 160](#)

### lock\_object\_type\_id

The type of object the application is waiting to obtain a lock. See monitor element [“lock\\_object\\_type - Lock object type waited on monitor element” on page 1017](#) for more details.

**Contained by:** [“db2\\_object\\_requested” on page 160](#)

## lock\_wait\_start\_time

The data and time the application started waiting to obtain a lock on the object that is currently locked by the lock owner. See monitor element [“lock\\_wait\\_start\\_time - Lock wait start timestamp monitor element”](#) on page 1027 for more details.

**Contained by:** [“db2\\_object\\_requested”](#) on page 160

**Element content:**

Type	Facet
xs:dateTime	

## lock\_wait\_end\_time

The data and time the application stopped waiting to obtain a lock on the object that is currently locked by the lock owner.

**Contained by:** [“db2\\_object\\_requested”](#) on page 160

**Element content:**

Type	Facet
xs:dateTime	

## threshold\_name

The name of the threshold queue.

**Contained by:** [“db2\\_object\\_requested”](#) on page 160

## threshold\_id

The ID of the threshold queue.

**Contained by:** [“db2\\_object\\_requested”](#) on page 160

## queue\_start\_time

The date and time the application started waiting in the queue to obtain a threshold ticket.

**Contained by:** [“db2\\_object\\_requested”](#) on page 160

**Element content:**

Type	Facet
xs:dateTime	

## queued\_agents

The total number of agents currently queued in the threshold.

**Contained by:** [“db2\\_object\\_requested”](#) on page 160

**Element content:**

Type	Facet
xs:long	

## db2\_participant

Schema element represents a single stack entry in a deadlock graph.

**Contained by:** [“db2\\_lock\\_event” on page 155](#) [“db2\\_deadlock\\_graph” on page 155](#)

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
no	xs:int			required	
deadlock_member				required	
participant_no_holding_lk	xs:int			required	
application_handle				required	
ANY attribute from ANY namespace					

## activity\_id

Counter which uniquely identifies an activity for an application within a given unit of work. See monitor element [“activity\\_id - Activity ID monitor element” on page 618](#) for more details.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

## uow\_id

The unit of work ID to which this activity record applies. See monitor element [“uow\\_id - Unit of work ID monitor element” on page 1676](#) for more details.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

## package\_name

The name of the package that contains the SQL statement currently executing. See monitor element [“package\\_name - Package name monitor element” on page 1126](#) for more details.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

## package\_schema

The schema name of the package associated with an SQL statement. See monitor element [“package\\_schema - Package schema monitor element” on page 1127](#) for more details.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

## package\_version\_id

The package version identifies the version identifier of the package that contains the SQL statement currently executing. See monitor element [“package\\_version\\_id - Package version monitor element” on page 1128](#) for more details.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

## consistency\_token

The package consistency token helps to identify the version of the package that contains the SQL statement currently executing. See monitor element [“consistency\\_token - Package consistency token monitor element”](#) on page 747 for more details.

**Contained by:** [“db2\\_activity\\_details”](#) on page 169

## section\_number

The internal section number in the package for the SQL statement currently processing or most recently processed. See monitor element [“section\\_number - Section number monitor element”](#) on page 1406 for more details.

**Contained by:** [“db2\\_activity\\_details”](#) on page 169

### Element content:

Type	Facet
xs:long	

## reopt

The REOPT bind option used to precompile this package. Possible values are: NONE, ONCE, and ALWAYS. See the REOPT bind options for more details.

**Contained by:** [“db2\\_activity\\_details”](#) on page 169

## incremental\_bind

The package was incrementally bound at execution time. Possible values: Yes or No.

**Contained by:** [“db2\\_activity\\_details”](#) on page 169

## effective\_isolation

The isolation value in effect for the SQL statement while it was being run. See monitor element [“effective\\_isolation - Effective isolation monitor element”](#) on page 834 for more details.

**Contained by:** [“db2\\_activity\\_details”](#) on page 169

### Attributes:

QName	Type	Fixed	Default	Use	Annotation
id	xs:long			optional	

## effective\_query\_degree

The degree value in effect for the SQL statement while it was being run. See monitor element [“effective\\_query\\_degree - Effective query degree monitor element”](#) on page 835 for more details.

**Contained by:** [“db2\\_activity\\_details”](#) on page 169

### Element content:

Type	Facet
xs:long	

## stmt\_unicode

The SQL statement unicode flag. Possible values: Yes or No.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

### stmt\_lock\_timeout

The locktimeout value in effect for the SQL statement while it was being run. See monitor element [stmt\\_lock\\_timeout](#) for more details

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

**Element content:**

Type	Facet
xs:int	

### stmt\_type

The type of SQL statement processed. Possible values: Dynamic or Static. See monitor element [“stmt\\_type - Statement type monitor element” on page 1491](#) for more details.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:long			optional	

### stmt\_operation

The SQL statement operation type. See monitor element [“stmt\\_operation/operation - Statement operation monitor element” on page 1484](#) for more details.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

### stmt\_query\_id

Internal query identifier given to any SQL statement. See monitor element [“stmt\\_query\\_id - Statement query identifier monitor element” on page 1487](#) for more details.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

**Element content:**

Type	Facet
xs:long	

### stmt\_nest\_level

This element shows the level of nesting or recursion in effect when the statement was run. See monitor element [“stmt\\_nest\\_level - Statement nesting level monitor element” on page 1484](#) for more details.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

**Element content:**

Type	Facet
xs:long	

### stmt\_invocation\_id

This element shows the identifier of the routine invocation in which the SQL statement was run. See monitor element [“stmt\\_invocation\\_id - Statement invocation identifier monitor element”](#) on page 1482 for more details.

**Contained by:** [“db2\\_activity\\_details”](#) on page 169

**Element content:**

Type	Facet
xs:long	

### stmt\_source\_id

This element shows the internal identifier given to the source of the the SQL statement that was run. See monitor element [“stmt\\_source\\_id - Statement source identifier ”](#) on page 1488 for more details.

**Contained by:** [“db2\\_activity\\_details”](#) on page 169

**Element content:**

Type	Facet
xs:long	

### stmt\_pkgcache\_id

**Contained by:** [“db2\\_activity\\_details”](#) on page 169

**Element content:**

Type	Facet
xs:long	

### stmt\_text

The text of the SQL statement. See monitor element [“stmt\\_text - SQL statement text monitor element”](#) on page 1490 for more details.

**Contained by:** [“db2\\_activity\\_details”](#) on page 169

### stmt\_first\_use\_time

This element shows the first time the statement entry was processed. For cursor operations, [“stmt\\_first\\_use\\_time - Statement first use timestamp monitor element”](#) on page 1481 shows when the cursor was opened. At application coordination nodes, this value reflects the application requests; at non-coordinator nodes, this value reflects when requests were received from the originating node. See monitor element [stmt\\_first\\_use\\_time](#) for more details.

**Contained by:** [“db2\\_activity\\_details”](#) on page 169

**Element content:**

Type	Facet
xs:dateTime	

## stmt\_last\_use\_time

This element shows the last time the statement entry was processed. For cursor operations, [“stmt\\_last\\_use\\_time - Statement last use timestamp monitor element” on page 1483](#) shows the time of the last action on the cursor where that action could be an open, fetch, or close. At application coordination nodes, this value reflects the application requests; at non-coordinator nodes, this value reflects when requests were received from the originating node. See monitor element [stmt\\_last\\_use\\_time](#) for more details.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

**Element content:**

Type	Facet
xs:dateTime	

## query\_actual\_degree

The actual runtime degree value for the SQL statement while it was being run. See monitor element [“query\\_actual\\_degree - Actual runtime degree of intrapartition parallelism monitor element” on page 1351](#) for more details.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

**Element content:**

Type	Facet
xs:int	

## stmtno

See monitor element [“stmtno - Statement number monitor element” on page 1497](#) for more details.

**Contained by:** [“db2\\_activity\\_details” on page 169](#)

**Element content:**

Type	Facet
xs:int	

## db2\_activity\_details

Schema represents the details regarding this activity

**Contained by:** [“db2\\_activity” on page 160](#)

**Element content:** ( [“activity\\_id” on page 165](#) , [“uow\\_id” on page 165](#) , [“package\\_name” on page 165](#) , [“package\\_schema” on page 165](#) , [“package\\_version\\_id” on page 165](#) , [“consistency\\_token” on page 166](#) , [“section\\_number” on page 166](#) , [“reopt” on page 166](#) , [“incremental\\_bind” on page 166](#) , [“effective\\_isolation” on page 166](#) , [“effective\\_query\\_degree” on page 166](#) , [“stmt\\_unicode” on page 166](#) , [“stmt\\_lock\\_timeout” on page 167](#) , [“stmt\\_type” on page 167](#) , [“stmt\\_operation” on page 167](#) , [“stmt\\_query\\_id” on page 167](#) , [“stmt\\_nest\\_level” on page 167](#) , [“stmt\\_invocation\\_id” on page 168](#) , [“stmt\\_source\\_id” on page 168](#) , [“stmt\\_pkgcache\\_id” on page 168](#) , [“stmt\\_text” on page 168](#) , [“stmt\\_first\\_use\\_time” on page 168](#) , [“stmt\\_last\\_use\\_time” on page 169](#) , [“query\\_actual\\_degree” on page 169](#) , [“stmtno” on page 169](#) , ANY content ( skip ) {zero or more (\*)}

## db2\_input\_variable

Schema element represents the list of input variables associated with the SQL statement.

**Contained by:** [“db2\\_activity” on page 160](#)

**Element content:** ( [“stmt\\_value\\_index”](#) on page 170 , [“stmt\\_value\\_isreopt”](#) on page 170 , [“stmt\\_value\\_isnull”](#) on page 170 , [“stmt\\_value\\_type”](#) on page 170 , [“stmt\\_value\\_data”](#) on page 170 , ANY content ( skip ) {zero or more (\*)}

### stmt\_value\_index

The element represents the position of the input parameter marker or host variable used in the SQL statement. See monitor element [“stmt\\_value\\_index - Value index ”](#) on page 1494 for more details.

**Contained by:** [“db2\\_input\\_variable”](#) on page 169

### stmt\_value\_isreopt

The element shows whether the variable was used during statement reoptimization. See monitor element [“stmt\\_value\\_isreopt - Variable used for statement reoptimization monitor element”](#) on page 1495 for more details.

**Contained by:** [“db2\\_input\\_variable”](#) on page 169

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:int			required	

### stmt\_value\_isnull

The element shows whether a data value associated with the SQL statement is the NULL value. See monitor element [“stmt\\_value\\_isnull - Value has null value monitor element”](#) on page 1494 for more details.

**Contained by:** [“db2\\_input\\_variable”](#) on page 169

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:int			required	

### stmt\_value\_type

The element contains a string representation of the type of data value associated with an SQL statement. See monitor element [“stmt\\_value\\_type - Value type monitor element”](#) on page 1496 for more details.

**Contained by:** [“db2\\_input\\_variable”](#) on page 169

### stmt\_value\_data

The element contains a string representation of a data value associated with an SQL statement. See monitor element [“stmt\\_value\\_data - Value data ”](#) on page 1493 for more details.

**Contained by:** [“db2\\_input\\_variable”](#) on page 169

### ***Collecting lock event data and generating reports***

You can use the lock event monitor to collect lock timeout, lock wait, and deadlock information to help identify and resolve locking problems. After the lock event data has been collected in an unreadable form in an unformatted event table, this task describes how to obtain a readable text report.

### **Before you begin**

To create the locking event monitor and collect lock event monitor data, you must have DBADM, or SQLADM authority.

## About this task

The lock event monitor collects relevant information that helps with the identification and resolution of locking problems. For example, some of the information the lock event monitor collects for a lock event is as follows:

- The lock that resulted in a lock event
- The applications requesting or holding the lock that resulted in a lock event
- What the applications were doing during the lock event

This task provides instructions for collecting lock event data for a given workload. You might want to collect lock event data under the following conditions:

- You notice that lock wait values are longer than usual when using the MON\_GET\_WORKLOAD table function.
- An application returns a -911 SQL return code with reason code 68 in the administration notification log, stating that "The transaction was rolled back due to a lock timeout." See also message SQL0911N for further details.
- You notice a deadlock event message in the administration notification log (-911 SQL return code with reason code 2, stating that "The transaction was rolled back due to a deadlock."). The log message indicates that the lock event occurred between two applications, for example, Application A and B, where A is part of workload FINANCE and B is part of workload PAYROLL. See also message SQL0911N for further details.

## Restrictions

To view data values, you need the EXECUTE privilege on the EVMON\_FORMAT\_UE\_\* routines, which the SQLADM and DBADM authorities hold implicitly. You also need SELECT privilege on the unformatted event table, which by default is held by users with the DATAACCESS authority and by the creator of the event monitor and the associated unformatted event table.

## Procedure

To collect detailed information regarding potential future lock events, perform the following steps:

1. Create a lock event monitor called `lockevmon` by using the CREATE EVENT MONITOR FOR LOCKING statement, as shown in the following example:

```
CREATE EVENT MONITOR lockevmon FOR LOCKING
WRITE TO UNFORMATTED EVENT TABLE
```

**Note:** The following lists important points to remember when creating an event monitor:

- You can create event monitors ahead of time and not worry about using up disk space since nothing is written until you activate the data collection at the database or workload level
  - In a partitioned database environment, ensure that the event monitors are placed in a partitioned table space across all nodes. Otherwise, lock events will be missed at partitions where the partitioned table space is not present.
  - Ensure that you set up a table space and bufferpool to minimize the interference on high performance work caused by ongoing work during accesses to the tables to obtain data.
2. Activate the lock event monitor called `lockevmon` by running the following statement:

```
SET EVENT MONITOR lockevmon STATE 1
```

3. To enable the lock event data collection at the workload level, issue the ALTER WORKLOAD statement with one of the following COLLECT clauses: COLLECT LOCK TIMEOUT DATA, COLLECT DEADLOCK

DATA, or COLLECT LOCK WAIT DATA. Specify the WITH HISTORY option on the COLLECT clause. Setting the database configuration parameter affects the lock event data collection at the database level and all workloads are affected.

#### For lock wait events

To collect lock wait data for any lock acquired after 5 seconds for the FINANCE application and to collect lock wait data for any lock acquired after 10 seconds for the PAYROLL application, issue the following statements:

```
ALTER WORKLOAD finance COLLECT LOCK WAIT DATA WITH HISTORY AND VALUES
FOR LOCKS WAITING MORE THAN 5 SECONDS
ALTER WORKLOAD payroll COLLECT LOCK WAIT DATA
FOR LOCKS WAITING MORE THAN 10 SECONDS WITH HISTORY
```

To set the **mon\_lockwait** database configuration parameter with HIST\_AND\_VALUES input data value for the SAMPLE database, and to set the **mon\_lw\_thresh** database configuration parameter for 10 seconds, issue the following commands:

```
db2 update db cfg for sample using mon_lockwait hist_and_values
db2 update db cfg for sample using mon_lw_thresh 10000000
```

#### For lock timeout events

To collect lock timeout data for the FINANCE and PAYROLL applications, issue the following statements:

```
ALTER WORKLOAD finance COLLECT LOCK TIMEOUT DATA WITH HISTORY
ALTER WORKLOAD payroll COLLECT LOCK TIMEOUT DATA WITH HISTORY
```

To set the **mon\_locktimeout** database configuration parameter with HIST\_AND\_VALUES input data value for the SAMPLE database, issue the following command:

```
db2 update db cfg for sample using mon_locktimeout hist_and_values
```

#### For deadlock events

To collect data for the FINANCE and PAYROLL applications, issue the following statements:

```
ALTER WORKLOAD finance COLLECT DEADLOCK DATA WITH HISTORY
ALTER WORKLOAD payroll COLLECT DEADLOCK DATA WITH HISTORY
```

To set the **mon\_deadlock** database configuration parameter with HIST\_AND\_VALUES input data value for the SAMPLE database, issue the following command:

```
db2 update db cfg for sample using mon_deadlock hist_and_values
```

4. Rerun the workload in order to receive another lock event notification.
5. Connect to the database.
6. Obtain the locking event report using one of the following approaches:
  - a) Use the XML parser tool, **db2evmonfmt**, to produce a flat-text report based on the event data collected in the unformatted event table and using the default stylesheet, for example:
7. Analyze the report to determine the reason for the lock event problem and resolve it.
8. Turn OFF lock data collection for both FINANCE and PAYROLL applications by running the following statements or resetting the database configuration parameters:

#### For lock wait events

```
ALTER WORKLOAD finance COLLECT LOCK WAIT DATA NONE
ALTER WORKLOAD payroll COLLECT LOCK WAIT DATA NONE
```

To reset the **mon\_lockwait** database configuration parameter with the default NONE input data value for the SAMPLE database, and to reset the **mon\_lw\_thresh** database configuration parameter back to its default value of 5 seconds, issue the following command:

```
db2 update db cfg for sample using mon_lockwait none
db2 update db cfg for sample using mon_lw_thresh 5000000
```

### For lock timeout events

```
ALTER WORKLOAD finance COLLECT LOCK TIMEOUT DATA NONE
ALTER WORKLOAD payroll COLLECT LOCK TIMEOUT DATA NONE
```

To reset the **mon\_locktimeout** database configuration parameter with the default NONE input data value for the SAMPLE database, issue the following command:

```
db2 update db cfg for sample using mon_locktimeout none
```

### For deadlock events

```
ALTER WORKLOAD finance COLLECT DEADLOCK DATA NONE
ALTER WORKLOAD payroll COLLECT DEADLOCK DATA NONE
```

To reset the **mon\_deadlock** database configuration parameter with the default WITHOUT\_HIST input data value for the SAMPLE database, issue the following command:

```
db2 update db cfg for sample using mon_deadlock without_hist
```

## What to do next

Rerun the application or applications to ensure that the locking problem has been eliminated.

## Unit of work event monitoring

The unit of work event monitor records an event whenever a unit of work is completed, that is, whenever there is a commit or a rollback. This historical information about individual units of work is useful for chargeback purposes (charging by CPU usage) and for monitoring compliance with response-time service-level objectives.

The unit of work event monitor is one way to perform system-perspective monitoring with request metrics. The most closely related alternatives or complements to the unit of work event monitor are the statistics event monitor and the MON\_GET\_UNIT\_OF\_WORK and MON\_GET\_UNIT\_OF\_WORK\_DETAILS table functions.

You can use the unit of work event monitor to collect a listing of packages used within a unit of work and the nesting level at which it was used. This information helps facilitate stored procedure troubleshooting. You can also generate a listing of the executable IDs and associated statement-level metrics for statements that ran within a unit of work.

To create the unit of work event monitor and collect unit of work event monitor data, you must have DBADM or SQLADM authority.

## Creating a unit of work event monitor

You have the choice of having the output for a unit of work event monitor output written to an unformatted event (UE) table, or a regular table. See [“Output options for event monitors” on page 35](#) for more information on how to choose the most appropriate output format.

Whichever type of table you use, when you create a unit of work event monitor, identify the table space where you plan to store the table or tables containing the output for your event monitor. The recommended practice is to have a table space that is dedicated and configured to store the table. However, when you create an event monitor, you can specify an existing table space. If you do not specify a table space, one is chosen for you.

To create a unit of work event monitor using defaults and best practices, use the CREATE EVENT MONITOR statement. The following sample statement uses defaults where possible and specifies that output will be stored in a UE table in the MY\_EVMON\_TABLESPACE table space:

```
CREATE EVENT MONITOR MY_UOW_EVMON
FOR UNIT OF WORK
WRITE TO UNFORMATTED EVENT TABLE (IN MY_EVMON_TABLESPACE)
```

## Configuring data collection

You can specify four different collection levels for unit of work data:

1. None
2. Basic unit of work data
  - a. Information about the packages that ran within the unit of work
  - b. A list of executable IDs for statements that ran within the unit of work.

You can use database configuration parameters to control the collection of unit of work data for all unit of work event monitors that are active in the database. Alternatively, to control the collection of information for specific workloads, service classes, or work actions, you can use the CREATE and ALTER statements for the appropriate workload objects.

To configure data collection at the database level, set the **mon\_uow\_data** database configuration parameter and, optionally, the **mon\_uow\_pkglist** and **mon\_uow\_execlist** database configuration parameters by using the **UPDATE DATABASE CONFIGURATION** command. Possible combinations of values for these parameters are shown in [Table 24 on page 174](#):

Data to collect	mon_uow_data	mon_uow_pkglist	mon_uow_execlist
Collect no unit of work data	NONE (default)	OFF(default)	OFF (default)
Collect only basic unit of work data	BASE	OFF (default)	OFF (default)
Collect package list information but not information about executable IDs	BASE	ON	OFF (default)
Collect information about executable IDs but not a list of packages	BASE	OFF (default)	ON
Collect basic unit of work data, package list information, and information about executable IDs	BASE	ON	ON

### Tips:

- If you do not set any of the configuration parameters, no unit of work data is collected unless you enable collection for specific workload objects. You can enable collection for specific workload objects by using either the CREATE or ALTER statement for the appropriate workload object type, for example, the CREATE SERVICE CLASS or ALTER WORKLOAD statement.
- To collect basic unit of work data but no package list or executable ID information, you can set the **mon\_uow\_data** configuration parameter to BASE and omit the **mon\_uow\_pkglist** and **mon\_uow\_execlist** configuration parameters. If you do not explicitly set them, the default value of OFF is used.

- To collect one or both of package list and executable ID information, you must also set the **mon\_uow\_data** configuration parameter to BASE. If you set the **mon\_uow\_data** configuration parameter to NONE, no information is collected, regardless of the settings of the **mon\_uow\_pkglist** and **mon\_uow\_execlist** configuration parameters.

To control the collection of data for specific workload objects, use the COLLECT UNIT OF WORK DATA clause of the CREATE or ALTER statement for the specific type of workload object that you are interested in. For example, to collect basic unit of work event data and package list information for the workload REPORTS, you might issue a statement such as this:

```
ALTER WORKLOAD REPORTS COLLECT UNIT OF WORK DATA BASE INCLUDE PACKAGE LIST
```

To collect both package list information and a list of the executable IDs for statements that are run in the unit of work, you might use this statement:

```
ALTER WORKLOAD REPORTS COLLECT UNIT OF WORK DATA BASE INCLUDE PACKAGE LIST,  
EXECUTABLE LIST
```

The settings that are shown in [Table 24 on page 174](#) apply to all workloads running in the system unless you override these settings for specific workloads by using the CREATE WORKLOAD or ALTER WORKLOAD statement. If you want to collect base-level information for all workloads but also want to collect package list information for selected workloads, set the **mon\_uow\_data** database configuration parameter to BASE. Then, use the CREATE WORKLOAD or ALTER WORKLOAD statement to set the level to BASE PACKAGE LIST for the workloads that you are interested in.

By default, applicable table functions and event monitors, including the unit of work event monitor, collect and report request metrics. You can change the default setting as follows:

- By using the **mon\_req\_metrics** database configuration parameter
- By using the COLLECT REQUEST METRICS clause of the CREATE SERVICE CLASS or ALTER SERVICE CLASS statement for a service superclass.

Changing the default setting affects any table function or event monitor that can report request metrics.

## Accessing event data that is captured by a unit of work event monitor

A unit of work event monitor can write data to a regular table or it can write data in binary format to an unformatted event (UE) table. You can access the data in regular tables by using SQL.

To access data in a UE table, use one of the following table functions:

### **EVMON\_FORMAT\_UE\_TO\_XML**

Extracts data from an unformatted event table into an XML document.

### **EVMON\_FORMAT\_UE\_TO\_TABLES**

Extracts data from an unformatted event table into a set of relational tables.

When you use one of these table functions, you can specify which data to extract by including a SELECT statement as one of the parameters to the function. You have full control over selection, ordering, and other aspects provided by the SELECT statement.

If you are generating package listing information, you can use the EVMON\_FORMAT\_UE\_TO\_XML table function to generate a single XML document that contains both the base unit of work event monitor data and the package listing. The EVMON\_FORMAT\_UE\_TO\_TABLES procedure produces two tables: one for the basic unit of work event monitor information and another for the package listing information. You can join the two tables by using the values in the MEMBER, APPLICATION\_ID, and UOW\_ID columns.

You can also use the **db2evmonfmt** command to help perform the following tasks:

- Select events of interest based on the following attributes: event ID, event type, time period, application, workload, or service class
- Choose whether to receive the output in the form of a text report or a formatted XML document
- Control the output format by creating your own XSLT style sheets instead of using the ones provided by the **db2evmonfmt** command

For example, the following command provides a unit of work report that selects unit of work events that occurred in the past 24 hours in the database SAMPLE. These event records are obtained from the unformatted event table called SAMPLE\_UOW\_EVENTS. The command creates formatted text output by using the MyUOW.xsl style sheet.

```
java db2evmonfmt -d SAMPLE -ue SAMPLE_UOW_EVENTS -ftext -ss MyUOW.xsl -hours 24
```

### **Data generated by unit of work event monitors**

Unit of work event monitors produce data about units of work (transactions) that run in the system. You can choose to have the output from a unit of work event monitor to regular tables, or to an unformatted event (UE) table. If data is written to a UE table, you must perform post-processing on it to view the data.

Regardless of the output format you choose, unit of work event data comes from one of four logical groups:

- [uow](#)
- [uow\\_metrics](#)
- [uow\\_package\\_list](#)
- [uow\\_exec\\_list](#)

If you choose to have the unit of work event data written to regular tables, data from an additional group (CONTROL) is used to generate meta-data about the event monitor itself.

**Note:** Unless you specify otherwise, the only monitor elements collected by a unit of work event monitor are request metrics. To enable the generation of basic unit of work event data, or for package or execution list data, you must enable data collection explicitly. See [“Enabling event monitor data collection”](#) on page 136 for more information.

#### *Information written to tables for a unit of work event monitor*

Information written by the unit of work event monitor when the WRITE TO TABLE option is specified.

When you choose WRITE TO TABLE as the output type for the unit of work event monitor, by default, five tables are produced, each containing monitor elements from one or more logical data groups:

<i>Table 25. Tables produced by UNIT OF WORK write-to-table event monitors.</i> The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by <i>evmon-name</i> in the table names shown in the following table) in the CREATE EVENT MONITOR statement.	
<b>Default table name</b>	<b>Logical data groups reported</b>
UOW_ <i>evmon-name</i>	Refer to <a href="#">uow</a> in "Event monitor logical data groups and monitor elements"
UOW_METRICS_ <i>evmon-name</i>	Refer to <a href="#">uow_metrics</a> in "Event monitor logical data groups and monitor elements"
UOW_PACKAGE_LIST_ <i>evmon-name</i>	Refer to <a href="#">uow_package_list</a> in "Event monitor logical data groups and monitor elements"
UOW_EXECUTABLE_LIST_ <i>evmon-name</i>	Refer to <a href="#">uow_executable_list</a> in "Event monitor logical data groups and monitor elements"
CONTROL_ <i>evmon-name</i>	The CONTROL logical group consists of selected elements from one or more of the <a href="#">event_dbheader</a> , <a href="#">event_start</a> and <a href="#">event_overflow</a> logical data groups.

**Note:** Even though all five tables are produced by default, you must still ensure data collection is enabled for the kind of lock information you want to gather, otherwise some of the columns will report null values.

To restrict the output of the event monitor to specific tables, specify the names of the logical groups for which you want tables produced in the CREATE EVENT MONITOR or ALTER EVENT MONITOR statements. Refer to the reference topics for those statements for details.

## Control table

*Table 26. Information returned for a unit of work event monitor: Default table name: CONTROL\_evmon-name*

Column name	Data type	Description
PARTITION_KEY	INTEGER	<a href="#">partition_key</a> - Partitioning key
EVENT_MONITOR_NAME	VARCHAR(128)	<a href="#">event_monitor_name</a> - Event monitor name
MESSAGE	VARCHAR(128)	<a href="#">message</a> - Control table message
MESSAGE_TIME	TIMESTAMP	<a href="#">message_time</a> - Timestamp control table message
PARTITION_NUMBER	SMALLINT	<a href="#">partition_number</a> - Partition number

*Information written to relational tables by EVMON\_FORMAT\_UE\_TO\_TABLES for a unit of work event monitor*

Information written for a unit of work event monitor from the EVMON\_FORMAT\_UE\_TO\_TABLES table function. This is also documented in the `sqllib/misc/DB2EvmonUOW.xsd` file.

*Table 27. Information returned for a locking event monitor: Table name: UOW\_EVENT*

Column Name	Data Type	Description

## executable\_list\_entries

**Contained by:** [“executable\\_list”](#) on page 204

**Element content:** ( [“executable\\_entry”](#) on page 199 {zero or more (\*)} )

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
ANY attribute from ANY namespace					

## completion\_status

The completion status of the unit of work. Possible values are: UNKNOWN, COMMIT, ROLLBACK, GLOBAL\_COMMIT, GLOBAL\_ROLLBACK, XA\_END, XA\_PREPARE

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

## start\_time

The start time of the unit of work. See monitor element [“uow\\_start\\_time - Unit of work start timestamp monitor element” on page 1679](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

**Element content:**

Type	Facet
xs:dateTime	

## stop\_time

The stop time of the unit of work. See monitor element [“uow\\_stop\\_time - Unit of work stop timestamp monitor element” on page 1680](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

**Element content:**

Type	Facet
xs:dateTime	

## connection\_time

The time the application connected to the database member. See monitor element [“conn\\_time - Time of database connection monitor element” on page 744](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

**Element content:**

Type	Facet
xs:dateTime	

## application\_name

The name of the application running at the client, as known to the database. See monitor element [“appl\\_name - Application name monitor element” on page 660](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

## application\_handle

A system-wide unique ID for the application. See monitor element [“agent\\_id - Application handle \(agent ID\) monitor element” on page 634](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

## application\_id

This identifier is generated when the application connects to the database at the database manager. See monitor element [“appl\\_id - Application ID monitor element” on page 656](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

### **uow\_id**

The unit of work ID to which this activity record applies. See monitor element [“uow\\_id - Unit of work ID monitor element” on page 1676](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

### **workload\_occurrence\_id**

The workload occurrence ID to which this activity record applies. See monitor element [“workload\\_occurrence\\_id - Workload occurrence identifier monitor element” on page 1707](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

### **coord\_member**

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

### **member\_activation\_time**

The time this database member was activated. See monitor element [“db\\_conn\\_time - Database activation timestamp monitor element” on page 790](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

#### **Element content:**

Type	Facet
xs:dateTime	

### **workload\_name**

The name of the workload under which the unit of work completed. See monitor element [“workload\\_name - Workload name monitor element” on page 1705](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

### **workload\_id**

The workload ID of the workload under which the unit of work completed. See monitor element [“workload\\_id - Workload ID monitor element” on page 1704](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

### **service\_superclass\_name**

The name of the service super class under which the unit of work completed. See monitor element [“service\\_superclass\\_name - Service superclass name monitor element” on page 1418](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

### **service\_subclass\_name**

The name of the service sub class under which the unit of work completed. See monitor element [“service\\_subclass\\_name - Service subclass name monitor element” on page 1417](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

## service\_class\_id

The service class ID of the service class under which the unit of work completed. See monitor element [“service\\_class\\_id - Service class ID monitor element”](#) on page 1414 for more details.

**Contained by:** [“db2\\_uow\\_event”](#) on page 194

## session\_authid

The session authorization ID of the user who invoked the application that is being monitored. See monitor element [“session\\_auth\\_id - Session authorization ID monitor element”](#) on page 1420 for more details.

**Contained by:** [“db2\\_uow\\_event”](#) on page 194

## system\_authid

The system authorization ID of the user who invoked the application that is being monitored. See monitor element [“system\\_auth\\_id - System authorization identifier monitor element”](#) on page 1503 for more details.

**Contained by:** [“db2\\_uow\\_event”](#) on page 194

## client\_pid

The process ID reported by the client. See monitor element [“client\\_pid - Client process ID monitor element”](#) on page 714 for more details.

**Contained by:** [“db2\\_uow\\_event”](#) on page 194

**Element content:**

## client\_product\_id

The product ID of the client. See monitor element [“client\\_prdid - Client product and version ID monitor element”](#) on page 716 for more details.

**Contained by:** [“db2\\_uow\\_event”](#) on page 194

## client\_platform

The platform of the client. See monitor element [“client\\_platform - Client operating platform monitor element”](#) on page 715 for more details.

**Contained by:** [“db2\\_uow\\_event”](#) on page 194

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:short			optional	

## client\_protocol

The product ID of the client. See monitor element [“client\\_protocol - Client communication protocol monitor element”](#) on page 717 for more details.

**Contained by:** [“db2\\_uow\\_event”](#) on page 194

## **client\_userid**

The client user ID generated by a transaction manager and provided to the server. See monitor element [“client\\_userid - Client user ID monitor element” on page 717](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

## **client\_wrkstname**

Identifies the client system or workstation, if the sqleseti API was issued in this connection. See monitor element [“client\\_wrkstname - Client workstation name monitor element” on page 718](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

## **client\_applname**

Identifies the server transaction program performing the transaction, if the sqleseti API was issued in this connection. See monitor element [“client\\_applname - Client application name monitor element” on page 710](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

## **client\_acctng**

The data passed to the target database for logging and diagnostic purposes, if the sqleseti API was issued in this connection. See monitor element [“client\\_acctng - Client accounting string monitor element” on page 709](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

## **local\_transaction\_id**

The local transaction id for the unit of work.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

## **global\_transaction\_id**

The global transaction id for the unit of work.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

## **system\_metrics**

The metrics for the unit of work.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

## **client\_hostname**

The hostname of the client. See monitor element [“client\\_hostname - Client hostname monitor element” on page 711](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

## **client\_port\_number**

The port number of the client. See monitor element [“client\\_port\\_number - Client port number monitor element” on page 715](#) for more details.

**Contained by:** [“db2\\_uow\\_event” on page 194](#)

*Unit of work event monitor package listing information*

The unit of work event monitor can collect a listing of packages used within a unit of work. This information can be used to determine which stored procedures within an application might be taking more time than expected to run.

You can have information about the packages used within units of work included in the data the event monitor collects. Depending on the output option you choose for the unit of work event monitor, this information is written to the unformatted event table or to the UOW\_PACKAGE\_LIST\_*evmon-name* table (where *evmon-name* is the name assigned to the event monitor) when the unit of work ends along with the rest of the information associated with the event.

There are two ways to control the capture of this information:

- The PACKAGE LIST option for the COLLECT UNIT OF WORK DATA clause of the CREATE or ALTER WORKLOAD statements controls the collection of this information for *specific* workloads. If this option is specified, information for the units of work that are executed under the workload identified in the CREATE or ALTER WORKLOAD statements, including package list information, is sent to any active unit of work event monitors.
- The **mon\_uow\_pkglist** configuration parameter can be set to ON so that package list information for *all* units of work executed on the data server is sent to any active unit of work event monitors.

**Note:** **mon\_uow\_data** must also be set to BASE for package list information to be collected.

The following data is collected for the package listing:

**Package ID (“package\_id - Package identifier monitor element” on page 1125)**

A unique ID that identifies a package.

**Nesting level (“nesting\_level - Nesting level monitor element” on page 1082)**

The level of nesting or recursion in effect when the statement was being run. Each level of nesting corresponds to nested or recursive invocation of a stored procedure or user-defined function (UDF).

**Routine ID (“routine\_id - Routine ID monitor element” on page 1386)**

A unique routine identifier. It returns zero if the activity is not part of a routine.

### **Invocation ID (“[invocation\\_id](#) - Invocation ID monitor element” on page 977)**

An identifier that distinguishes one invocation of a routine from others at the same nesting level within a unit of work. It is unique within a unit of work for a specific nesting level.

### **Package elapsed time (“[package\\_elapsed\\_time](#) - Package elapsed time monitor element” on page 1126)**

The elapsed time spent executing sections within the package.

As the list of information collected for the package listing suggests, information is captured not only for each package but also for each invocation of a routine within a package.

Elapsed time is also tracked. The time calculated for a given invocation starts from the first execution of a section within a package until the database manager switches to another package. See [“Examples” on page 210](#) to see more about how elapsed time is tracked.

## **How package lists are written to unformatted event tables**

When you enable the collection of package list information, the unit of work event monitor writes two records to the unformatted event (UE) table for each unit of work. The first record contains the basic unit of work event monitor data. The next record contains the package listing information.

Package list information is stored in the UE table in a BLOB column. A list with 32 entries can be stored as an inline BLOB when the page size for the table space is 4k (the default). The number of entries that can be written to the package list is controlled by the **mon\_pkglist\_sz** configuration parameter. The default for this parameter is 32, which means that up to 32 entries can be included in the package listing. If you want to increase the number of entries that can be included in the package list, ensure that the UE table used to store the event monitor output is created in a table space with a larger page size. Assume that every increase of 32 in the size of the package list requires an increase of 4k in the page size of the table space. So, for example, if you want to have up to 64 entries in the package list, ensure that the page size for the table space is at least 8k. If you increase **mon\_pkglist\_sz** without increasing the page size of the table space, the package list is still created, however the BLOB is not stored inline in the table, which might affect performance.

**Note:** You can use the `ADMIN_IS_INLINED` administrative function to determine whether the BLOB that contains the package list information is stored inline.

## **How package lists are written to regular tables**

When you use regular tables for event monitor output, package list information is captured as part of the [“`uow\_package\_list` logical data group” on page 108](#). As each unit of work completes, one or more rows are added to the `UOW_PACKAGE_LIST_evmon-name` table, with one column for each monitor element in the logical data group. The number of rows added to the table depends on how many packages ran as part of the unit of work. However, the upper limit to the number of rows that can be added to this table is controlled by the **mon\_pkglist\_sz** configuration parameter. The default for this parameter is 32, which means that up to 32 entries can be included in the package listing. If you want to increase the number of entries that can be included in the package list, increase **mon\_pkglist\_sz**.

## **Package listing output**

As stated earlier, when the event monitor writes to a UE table, the unit of work event monitor writes two records to the UE table when collecting package information. Each of the interfaces for displaying the data in a UE table provides a mechanism for viewing the information contained in the two UE table records.

For example, the **db2evmonfmt** tool combines the information in each record into a single report.

If you use the `EVMON_FORMAT_UE_TO_TABLES` procedure, it produces relational tables that you can join; the table `UOW_PACKAGE_LIST` contains the package list information. `EVMON_FORMAT_UE_TO_XML` produces a single XML document that contains the information from both records. For more information, see [“Accessing event data that is captured by a unit of work event monitor” on page 175](#).

When the event monitor writes to relational tables directly, the package list information is written to the table `UOW_PACKAGE_LIST_evmon-name`.

**Note:** In a partitioned database environment, the package list is only reported in the unit of work event generated by the *coordinator agent* and reflects the time spent in each package by that agent specifically; it does not reflect time spent in those packages by any other agent at any other partition.

Figure 5 on page 209 shows the information produced by the unit of work event monitor, as formatted by the **db2evmonfmt** tool.

```

**Note:** Some of the metrics in the "UOW Metrics" section have been excluded.

Figure 5. Sample output from the unit of work event monitor, with package listing information

The number of packages that appear in the package list for a given unit of work is reflected in the **package\_list\_count** monitor element ("Package List Size" in the preceding report), which is included with the base unit of work event monitor data. If the number of packages used with the unit of work exceeds the value specified in the **mon\_pkglist\_sz** configuration parameter, the additional packages are not included in the package listing. However, the **package\_list\_exceeded** monitor element indicates whether there were more packages than would fit into the package list. This monitor element is returned along with the base information for the unit of work event monitor ("Package List Exceeded"

in Figure 5 on page 209). If the value for this monitor element is YES, you can increase the value for `mon_pkglist_sz` to have a larger number of packages included in the package list.

## Examples

Each of the examples that follow show the information returned for the package listing as it would be displayed by the `db2evmonfmt` tool.

### Example 1: An application that executes one or more sections in a single package

In this example, one package with a package ID of 300 was run for this unit of work.

PACKAGE_ID	NESTING_LEVEL	ROUTINE_ID	INVOCATION_ID	ELAPSED_TIME
300	0	0	0	100

In this case, there is one entry on the package list, which reflects the execution of one or more sections in the package. All sections executed from the same package are considered to be part of the same package invocation.

### Example 2: An application calls a stored procedure in a package

In this example, the package with a package ID of 300 calls a stored procedure with an ID of 806. Three sections are executed within the stored procedure.

PACKAGE_ID	NESTING_LEVEL	ROUTINE_ID	INOVATION_ID	ELAPSED_TIME
300	0	0	0	21
300	1	806	1	100

This output shows two entries in the list. One entry is for the call to the stored procedure, and one for the execution of the three sections within the stored procedure. The `NESTING_LEVEL` for the second entry in the list reflects the fact that the stored procedure was called from another package.

### Example 3: An application executes sections in two different packages

In this example, an application executes sections from one package, then another package, and then back to the first package. No stored procedures are called. The pseudocode that follows is a representation of this unit of work:

```
Application
EXEC PACKAGEA
EXEC PACKAGEB
EXEC PACKAGEA
```

Assume also that the invocation of **PACKAGEA** requires 100 ms, the invocation of **PACKAGEB** requires 25 ms, and that the invocation of **PACKAGEC** requires 460 ms. The following output shows what the package listing would look like:

PACKAGE_ID	NESTING_LEVEL	ROUTINE_ID	INVOCATION_ID	ELAPSED_TIME
300	0	0	0	560
301	0	0	0	25

In this case, there are two entries in the list. Package A, with `PACKAGE_ID` 300 had sections that ran for 560 ms in total. Package B ran for 25 ms. Package A is represented by a single line because each invocation has the same `INVOCATION_ID` and `NESTING_LEVEL`. `INVOCATION_ID` and `NESTING_LEVEL` remain at 0, because no stored procedures were called in either package.

### Example 4: An application executes sections and stored procedures in multiple packages

In this example, there are 3 packages with IDs 100, 101, and 102. The application is in package 100. There are two stored procedures with IDs 201 and 202. The first stored procedure (SP1) is in package 101, and the second (SP2) is in package 102. The pseudocode that follows is a representation of this unit of work:

```
Application
CALL SP1 a
INSERT INTO T1 VALUES(7) b
```

```
CALL SP2 c
INSERT INTO T2 VALUES(8)
CALL SP2 d
INSERT INTO T2 VALUES(8)
```

The package listing for this unit of work would be as follows:

PACKAGE_ID	NESTING_LEVEL	ROUTINE_ID	INVOCATION_ID	ELAPSED_TIME
100	0	0	0	21
101	1 <b>1</b>	201	1	40
102	2 <b>2</b>	202	1 <b>3</b>	35
102	2	202	2 <b>3</b>	35

In the preceding output, there are four entries:

- The first corresponds to the execution of the call to SP1 within the first package, line **a** in the pseudocode that represents the unit of work.
- The second corresponds to the execution of the sections within the stored procedure with ID 201 in package 101. These sections include lines **b**, **c**, and **d**. The nesting level increases to 1, as shown by **1**.
- The third entry represents the execution of the first of the INSERT INTO T2 statements in SP2, as called from SP1. The nesting level increases again (**2**).
- The fourth entry in the list represents the execution of the second of the INSERT INTO T2 statements in SP2. The nesting level remains the same, because like the previous call to SP2, this stored procedure is called from SP1. However, because these two statements occur within separate invocations of the stored procedure, they each have separate invocation IDs (**3**). Thus, there are two separate entries in the package listing.

#### Executable list information

When collecting unit of work information, you have the option to also collect a list of the executable IDs of statements that run as part of each unit of work.

The information about the executable IDs is written to an unformatted event (UE) table or to a regular table. There are two ways to capture this information:

- Use the EXECUTABLE LIST option for the COLLECT UNIT OF WORK DATA clause of the CREATE WORKLOAD or ALTER WORKLOAD statement to collect information for specific workloads. Information for the units of work that are executed under the workload that you identify in the statement, including executable IDs, is sent to the active unit of work (UOW) event monitors.
- Use configuration parameters to have information about all units of work that are executed on the data server, including executable information, sent to active unit of work event monitors. To collect executable ID information, set the **mon\_uow\_data** configuration parameter to BASE, and set the **mon\_uow\_execlist** configuration parameter to ON.

The following data is collected for the executable listing:

#### Unit of Work Level

##### executable\_list\_size

The number of entries that are present within the executable ID listing for a particular unit of work.

##### executable\_list\_truncated

A YES or NO value indicating whether the list is truncated. The list can be truncated if there is insufficient memory available to store the entire executable list during processing.

#### Executable ID List

##### executable\_id (“executable\_id - Executable ID monitor element” on page 851)

An opaque binary token generated on the data server that uniquely identifies the SQL statement section that was executed.

##### num\_executions (“num\_executions - Statement executions monitor element” on page 1090)

The number of times that an SQL statement has been executed.

**rows\_read (“rows\_read - Rows read monitor element” on page 1393)**

The number of rows read from the table.

**total\_cpu\_time (“total\_cpu\_time - Total CPU time monitor element” on page 1584)**

The total amount of CPU time used while in the database. This represents total of both user and system CPU time. This value is in microseconds.

**total\_act\_time (“total\_act\_time - Total activity time monitor element” on page 1546)**

The total amount of time spent executing activities. This value is in milliseconds.

**total\_act\_wait\_time (“total\_act\_wait\_time - Total activity wait time monitor element” on page 1548)**

Total time spent waiting within the database server, while processing an activity. The value is in milliseconds.

**lock\_wait\_time (“lock\_wait\_time - Time waited on locks monitor element” on page 1027)**

The total elapsed time spent waiting for locks. The value is given in milliseconds.

**lock\_waits (“lock\_waits - Lock waits monitor element” on page 1032)**

The total number of times that applications or connections waited for locks.

**total\_sorts (“total\_sorts - Total sorts monitor element” on page 1648)**

The total number of sorts that have been executed.

**post\_threshold\_sorts (“post\_threshold\_sorts - Post threshold sorts monitor element” on page 1335)**

The number of sorts that have requested heaps after the sort heap threshold has been exceeded.

**post\_shrthreshold\_sorts (“post\_shrthreshold\_sorts - Post shared threshold sorts monitor element” on page 1323)**

The total number of sorts that were throttled back by the sort memory throttling algorithm. A throttled sort is a sort that was granted less memory than requested by the sort memory manager

**sort\_overflows (“sort\_overflows - Sort overflows monitor element” on page 1443)**

The total number of sorts that ran out of sort heap and may have required disk space for temporary storage.

## How execution lists are written to UE tables

At least two separate records can be written to the UE table when base data and executable ID list data is collected for an UOW event monitor. The first record contains information about the UOW event that contains the base UOW data. The second record is the UOW\_EXEC\_LIST event that contains the executable ID listing data. This second record might consist of multiple records because of the potentially large number of unique executable IDs for a single UOW. These records are written as separate rows to the UE table to ensure that each event is contained within the inlined LOB space available. You can use the interfaces for formatting the UE table to merge information for these events. When the executable ID list is not collected, an associated record is not created; the table does not contain any rows.

## How execution lists are written to regular tables

When you use regular tables for event monitor output, executable list information is captured as part of the [“uow\\_executable\\_list logical data group” on page 102](#). As each unit of work is completed, one or more rows are added to the table UOW\_EXECUTABLE\_LIST\_ *evmon\_name*, with one column for each monitor element in the logical data group. The number of rows that are added to the table depends on how many unique executable IDs ran as part of the unit of work.

## Executable listing output

When the event monitor writes to a UE table, the unit of work event monitor writes two records to the UE table when collecting execution information. Each of the interfaces for displaying the data in a UE table provides a mechanism for viewing the information contained in the two UE table records. The **db2evmonfmt** tool combines the information in each record into a single report. The EVMON\_FORMAT\_UE\_TO\_TABLES procedure produces relational tables that you can join; the table UOW\_EXECUTABLE\_LIST contains the executable list information. The EVMON\_FORMAT\_UE\_TO\_XML

table function produces a single XML document that contains the information from both records. For more information, see [“Accessing event data that is captured by a unit of work event monitor”](#) on page 175.

When the event monitor writes directly to relational tables, the executable list information is written to the table `UOW_EXECUTABLE_LIST_evmon_name`.

In a partitioned database environment, the executable ID list is generated per member, including per coordinator agent member and data member. In a Db2 pureScale environment, the list is generated from the coordinator member, which is similar to the situation in non-partitioned configurations.

## Examples

The following sample information was collected for an application that executes five different SQL statement sections within a UOW. This output provides a logical view with sample columns; the actual output depends on the tool or query that you run.

EXECUTABLE_ID	NUM_EXECUTIONS	ROWS_READ	TOTAL_CPU_TIME
x'01007A00000020020081126171554951791'	1	23456	76888
x'01007900000020020081126171533551120'	55	345	768
x'01007C00000020020081126171720728997'	234	67	232
x'01007B00000020020081126171657272914'	3456	347	1223
x'01007D00000020020081126172409987719'	22242	2244	432444

In this example, there are five entries in the executable ID list to correspond to the five different sections that were executed. The five sections were executed a different number of times, as illustrated by the `NUM_EXECUTIONS` column, but only one entry is provided for each unique section. The first row might indicate a problematic activity statement because it consumed excessive CPU time in just one execution.

## Collecting unit of work event data and generating reports

You can use the unit of work event monitor to collect data about transactions that you can use for chargeback purposes. The collected transaction event data is in an unreadable form in an unformatted event table. You can use this data to create a readable text report.

## Before you begin

To collect unit of work event monitor data, you must have `SYSADM` or `SYSCTRL` authority.

## About this task

This task provides instructions for collecting unit of work event data for a particular workload.

Package listing and execution list information is also collected if you set both the `mon_uow_pkglist` and `mon_uow_execlist` configuration parameters to `ON`. Alternatively, you can collect package listing and execution list information for a workload, regardless of the settings of the `mon_uow_pkglist` and `mon_uow_execlist` configuration parameters, by altering the `ALTER WORKLOAD` statement as follows:

- For package listing information, replace the `BASE` option with the `BASE INCLUDE PACKAGE LIST` option.
- For execution list information, replace the `BASE` option with the `BASE INCLUDE EXECUTABLE LIST` option.
- For package listing and execution list information, replace the `BASE` option with the `BASE INCLUDE PACKAGE LIST, EXECUTABLE LIST` option.

The unit of work event monitor collects information that identifies application transactions and the corresponding CPU usage. Examples of information that the unit of work event monitor collects for a transaction event are as follows:

- Total CPU usage time (`TOTAL_CPU_TIME` monitor element)
- Application handle (`APPLICATION_HANDLE` monitor element)

## Restrictions

Input data values are not viewable if you do not have SYSADM or SYSCTRL authority.

## Procedure

To collect detailed information regarding unit of work events:

1. Create a unit of work event monitor called UOWEVMON by issuing the CREATE EVENT MONITOR FOR UNIT OF WORK statement, as shown in the following example:

```
CREATE EVENT MONITOR UOWEVMON FOR UNIT OF WORK
WRITE TO UNFORMATTED EVENT TABLE
```

2. Activate the UOWEVMON unit of work event monitor by issuing the following statement:

```
SET EVENT MONITOR UOWEVMON STATE 1
```

3. Enable unit of work event data collection at the workload level by issuing the ALTER WORKLOAD statement with statement history.

For example, to collect unit of work data for the FINANCE and PAYROLL applications, issue the following statements:

```
ALTER WORKLOAD finance COLLECT UNIT OF WORK DATA BASE
ALTER WORKLOAD payroll COLLECT UNIT OF WORK DATA BASE
```

4. To collect unit of work transaction events, rerun the workload.
5. Connect to the database.
6. Produce a flat-text report that is based on the event data that is collected in the unformatted event table by using the XML parser tool, **db2evmonfmt**, as shown in the following example:

```
java db2evmonfmt -d db_name -ue table_name -ftext -u user_id -p password
```

7. Analyze the report to determine how much CPU time applications are using so that appropriate charges can be billed.
8. If you want to turn off unit of work data collection for both the FINANCE and PAYROLL applications, issue the following statements:

```
ALTER WORKLOAD finance COLLECT UNIT OF WORK DATA NONE
ALTER WORKLOAD payroll COLLECT UNIT OF WORK DATA NONE
```

## Example

The following example of a report was obtained by using the **db2evmonfmt** tool to convert the data that the unit of work event monitor collected in the unformatted event table:

```
-----
Event ID           : 1
Event Type        : UOW

### *Calculating the CPU time used by different applications or workloads with the unit of work event monitor*

This topic shows one way that you can use the unit of work event monitor in day-to-day database operations. In some business environments, departments are billed for the processing time their applications use. You can use the unit of work event to record the CPU time used by different application, workloads, or service classes. This information can, in turn, be used in accounting applications that perform billing for system resources.

## Before you begin

The CREATE EVENT MONITOR statement requires a table space with a page size of at least 8 K to store the unformatted event (UE) table produced by the event monitor. Unless a table space is explicitly named in the CREATE EVENT MONITOR statement, the default table space for the database is used.

## About this task

This task describes a basic scenario for "charge-back" accounting. In the example that follows, all work performed on the system is tracked. From the data gathered, reports are created that show the CPU time used by different applications.

Depending on how your organization is set up, tracking system time based on workload might be appropriate. Alternatively, you can also look at the CPU time used in different service super classes, by specific workloads, or even by different users. If the data is written to relational tables, as the example in this task shows, you can use SQL to query and present the data in almost limitless ways.

**Note:** Activities within a unit of work can run in different service subclasses. For this reason, it is not appropriate to aggregate unit of work information by service subclass. If you want to aggregate CPU time by service class, use the activity event monitor instead.

## Procedure

1. Create a unit of work event monitor to capture information about units of work as they finish. For example, to create an event monitor called TRACKWORK, you might could use the following SQL:

```
CREATE EVENT MONITOR TRACKWORK FOR UNIT OF WORK WRITE TO UNFORMATTED EVENT TABLE
```

This statement creates a unit of work event monitor that writes to an unformatted event (UE) table. The UE table has the same name as the event monitor itself, TRACKWORK, and it is stored in the default table space.

2. Tell the database manager that you want to collect event information for all units of work completed on the database by running the following command:

```
UPDATE DATABASE CONFIGURATION FOR dbname USING MON_UOW_DATA BASE
```

This command causes information about all units of work executed on the data server to be sent to the active unit of work event monitors when the units of work complete. See [“Configuring data collection” on page 174](#) for more information about controlling the scope of the unit of work data that is collected.

3. Next, activate the event monitor:

```
SET EVENT MONITOR TRACKWORK STATE 1
```

**Note:** By default, this event monitor starts automatically upon database activation, because the `AUTOSTART` option is applied by default. However, because this event monitor is being created in an already-active database, you must use the **SET EVENT MONITOR** command to start it manually.

From this point on, the unit of work event monitor captures information for each unit of work as it runs to completion. As each unit of work completes, the event monitor adds a record for the event to the UE table `TRACKWORK`.

4. When you are ready to collect data for reporting purposes, you must extract the records from the `TRACKWORK UE` table.

You can view this information in XML or relational format, using either the `EVMON_FORMAT_UE_TO_XML` or the `EVMON_FORMAT_UE_TO_TABLES` procedure to convert the data in the UE table. Alternatively, you can use the **db2evmonfmt** tool to create a text report of the information returned by the event monitor. This example shows the use of `EVMON_FORMAT_UE_TO_TABLES` to create relational tables that you can query in whatever way suits your needs.

```
CALL EVMON_FORMAT_UE_TO_TABLES  
( 'UOW', NULL, NULL, NULL, NULL, NULL, -1, 'SELECT * FROM TRACKWORK' )
```

The `EVMON_FORMAT_UE_TO_TABLES` procedure examines the UE table `TRACKWORK` produced by the event monitor; it selects each of the records from the UE table, and from them, creates rows containing the data collected by the unit of work event monitor in two relational tables:

- `UOW_EVENT`
- `UOW_METRICS`

The first table contains the most frequently used monitor elements and metrics associated with each event captured. The second contains detailed metrics for each event.

**Notes:**

- If you specify `PKGLIST` rather than `BASE` for the **MON\_UOW\_DATA** configuration parameter in step “2” on page 216, the `EVMON_FORMAT_UE_TO_TABLES` procedure creates a third table called `UOW_PACKAGE_LIST`. This table contains package list information related to the units of work. However, in this example, because only basic monitor elements are collected (see step “2” on page 216), this table will not contain any data. (See [“Unit of work event monitor package listing information” on page 207](#) for more information about how the package list information can be used.)
  - The values in the columns of `UOW_METRICS` can also be found in the XML document contained in the `METRICS` column of the `UOW_EVENT` table. They are provided in the `UOW_METRICS` table for more convenient, column-oriented access.
5. Query the tables produced in the previous step to see how CPU time was used by applications. The statement that follows returns a breakdown of total CPU time used by different users on the system since the unit of work event monitor was initialized. (This example assumes that client applications have identified themselves to the database using the `sqlseti` API, or through whatever application development environment you might be using, such as IBM® Rational® Application Developer for WebSphere® Software.

```

SELECT SUBSTR(E.CLIENT_USERID,1,10) AS CLIENT_ID,
       SUBSTR(E.CLIENT_APPLNAME,1,80) AS CLIENT_APP,
       SUBSTR(E.CLIENT_WRKSTNNAME,1,10) AS WKSTN,
       SUM(M.TOTAL_CPU_TIME) AS CPU_TIME
FROM UOW_EVENT E, UOW_METRICS M
WHERE M.APPLICATION_ID = E.APPLICATION_ID
      AND M.UOW_ID = E.UOW_ID
      AND M.MEMBER = E.MEMBER
GROUP BY E.CLIENT_USERID, E.CLIENT_APPLNAME, E.CLIENT_WRKSTNNAME
ORDER BY CPU_TIME DESC;

```

The preceding query returns the following results:

```

6. At this point, the unit of work event monitor TRACKWORK is still collecting information. Depending on how you want to track CPU time used by different applications, users or workloads, you can choose to take one of the following courses of action:

- If you want to calculate CPU usage on a daily basis, you can leave this unit of work event monitor active. Each day, run the EVMON\_FORMAT\_UE\_TO\_TABLES procedure to retrieve just the time-spent metrics for the preceding day:

```

CALL EVMON_FORMAT_UE_TO_TABLES
  ('UOW', NULL, NULL, NULL, NULL, NULL, -1,
  'SELECT * FROM TRACKWORK
   WHERE (DATE(EVENT_TIMESTAMP)=(CURRENT DATE - 1 DAY))'
  )

```

With this approach, the three relational tables produced by the EVMON\_FORMAT\_UE\_TO\_TABLES procedure continue to grow, providing a history of CPU usage over time. The query in step “5” on [page 216](#) returns the cumulative totals for CPU time since the tables were first created with the EVMON\_FORMAT\_UE\_TO\_TABLES procedure. You can modify that query to show only the results from the previous day as follows:

```

SELECT SUBSTR(E.CLIENT_USERID,1,10) AS CLIENT_ID,
       SUBSTR(E.CLIENT_APPLNAME,1,80) AS CLIENT_APP,
       SUBSTR(E.CLIENT_WRKSTNNAME,1,10) AS WKSTN,
       SUM(M.TOTAL_CPU_TIME) AS CPU_TIME
FROM UOW_EVENT E, UOW_METRICS M
WHERE M.APPLICATION_ID = E.APPLICATION_ID
      AND M.UOW_ID = E.UOW_ID
      AND M.MEMBER = E.MEMBER
      AND (DATE(E.EVENT_TIMESTAMP)=(CURRENT DATE - 1 DAY))
GROUP BY E.CLIENT_USERID, E.CLIENT_APPLNAME, E.CLIENT_WRKSTNNAME
ORDER BY CPU_TIME DESC;

```

**Tip:** If you want to track CPU usage on a daily basis, but also want to manage how much data you collect on your system, remove data you no longer need from the UE table after you have updated the relational tables. For example, to delete the data collected on the previous day from the UE table TRACKWORK, use a DELETE statement similar to the one that follows:

```

DELETE FROM TRACKWORK WHERE (DATE(EVENT_TIMESTAMP)=(CURRENT DATE - 1 DAY))

```

While an event monitor is active, it holds an intention exclusive (IX) table lock on any tables to which it writes information to prevent those tables from being dropped while it is using them. When a large number of rows is being deleted, the DELETE statement acquires a large number of row locks. In this situation, lock escalation might occur, as row locks might be converted to a table lock. This request for table lock can cause the DELETE statement to hang, since the event monitor already has a lock on the table.

To avoid this situation, consider setting a lock timeout before issuing the DELETE statement:

```
SET CURRENT LOCK TIMEOUT 60
```

If increasing the lock timeout period does not resolve the problem, try deleting smaller subsets of the data, such as the records for smaller time periods (for example, 6 or 12 hours). This approach requires fewer locks, which will reduce the chance of lock escalation happening.

You can also prune the relational tables produced by EVMON\_FORMAT\_UE\_TO\_TABLES as needed to balance storage requirements with the need to view historical data.

- If you are finished calculating CPU time, you can stop the collection of event monitor information, and drop the event monitor and its related tables by performing the following steps:
  - a. Disable the collection of unit of work for this event monitor information using the **SET EVENT MONITOR TRACKWORK STATE 0** command.
  - b. Drop the event monitor itself using the DROP EVENT MONITOR statement.
  - c. Drop the tables related to the event monitor using a DROP TABLE statement. In this case, there are four tables in total to drop:
    - TRACKWORK, the UE table used to collect information from the event monitor
    - UOW\_EVENT
    - UOW\_METRICS
    - UOW\_PACKAGE\_LIST
  - d. Optional: If there are no remaining active event monitors, you might want to update the database configuration such that no unit of work event information is collected using the following command:

```
UPDATE DATABASE CONFIGURATION FOR dbname USING MON_UOW_DATA NONE
```

### Variation: Collecting metrics for specific workloads

The previous example illustrates how you can capture unit of work metrics for all work done on the system. Setting the scope of data collected using the **UPDATE DATABASE CONFIGURATION** command might cause more information to be collected than you need. You might, for example, want to track only work done by specific workloads. In this case, rather than enable collection of unit of work information across the whole database as shown in step “2” on page 216, you can specify the COLLECT UNIT OF WORK DATA clause with the CREATE or ALTER WORKLOAD statements. This clause causes only data for the workload specified to be collected by the event monitor. For example, to collect unit of work data for the workload named PAYROLL, use the following statement:

```
ALTER WORKLOAD PAYROLL COLLECT UNIT OF WORK DATA BASE
```

You can collect data for multiple workloads by running an ALTER WORKLOAD statement for each.

The remaining steps are the same, except for step “5” on page 216, where you would change the query to resemble the one that follows:

```
SELECT E.WORKLOAD_NAME,  
       SUM(M.TOTAL_CPU_TIME) AS CPU_TIME  
FROM UOW_EVENT E, UOW_METRICS M  
WHERE M.APPLICATION_ID = E.APPLICATION_ID  
      AND M.UOW_ID = E.UOW_ID  
      AND M.MEMBER = E.MEMBER
```

```
GROUP BY E.WORKLOAD_NAME
ORDER BY CPU_TIME DESC
```

The preceding statement reports the CPU time for each workload for which metrics collection is enabled:

WORKLOAD	CPU_TIME
PAYROLL	2143292042
MARKETING	492784916

2 record(s) selected.

## Package cache statement eviction event monitoring

The package cache event monitor captures data related to statement entries that have been flushed from the database package cache. This event monitor provides the history of the contents of the package cache which can help with SQL query performance and problem determination issues.

### Overview

The package cache event monitor collects the same information as the MON\_GET\_PKG\_CACHE\_STMT table function, including the full set of available activity metrics and the executable section information of an entry.

Starting in version 10.1, you can get information about input arguments related to the longest-running statement. This statement is the one associated with the monitor element **max\_coord\_stmt\_exec\_time**. The input arguments associated with this statement are recorded as part of the pkgcache\_stmt\_args logical data group.

Two control mechanisms on the CREATE EVENT MONITOR statement help limit the volume of data that can be captured. The two control mechanisms provide the following capabilities:

1. Filter entries with the WHERE clause based on one or more of the following conditions:
  - Whether the last update of the metrics for an entry occurs after a specific time before it is evicted (UPDATED\_SINCE\_BOUNDARY\_TIME). An entry will only be collected if the time that the metrics were last updated is more recent than boundary time defined for the event monitor. The boundary time for an event monitor can be set using the MON\_GET\_PKG\_CACHE\_STMT table function. If no boundary time has been set for the event monitor, the UPDATED\_SINCE\_BOUNDARY\_TIME clause will have no effect.
  - The number of times the section of an entry was executed (NUM\_EXECUTIONS)
  - The total aggregated amount of time spent executing the statement (STMT\_EXEC\_TIME)
2. COLLECT DATA clause options:
  - COLLECT BASE DATA  
Same information collected as the MON\_GET\_PKG\_CACHE\_STMT table function, as well as the full set of available activity metrics
  - COLLECT DETAILED DATA  
Collects the same information gathered with the COLLECT BASE DATA clause and includes the executable section of the entry

When you need to investigate the individual execution of an SQL statement, you can use the MON\_GET\_PKG\_CACHE\_STMT table function (if the entries are still in the package cache) to compare the behavior of a cached entry relative to others. The execution metrics, compilation environment, and detailed descriptions for a cached entry are available for diagnostic purposes.

If an entry has already been flushed from the package cache, you can use the package cache event monitor to review the history of the cached entries which were flushed from the package cache. The history data contains the same information that the MON\_GET\_PKG\_CACHE\_STMT table function provides. In addition, the event monitor also provides the executable section of the statement. All of this applies to both dynamic and static SQL statements.

## Creating a package cache event monitor

To create a package cache event monitor and collect package cache event monitor data, you must have DBADM or SQLADM authority.

A package cache event monitor can write its output to either a regular table or an unformatted event table.

Before you create a package cache event monitor, identify the table space where you plan to store the output for your event monitor. The CREATE EVENT MONITOR statement will assume a default table space if you do not specify one. However, the recommended practice is to have a table space dedicated and configured to store the output table or tables associated with any event monitor. If you are using an unformatted event table, create package cache event monitors in table spaces with at least an 8K pagesize to ensure that event data is contained within the inlined BLOB column of the UE table. If the BLOB column is not inlined, then the performance of writing and reading the events to the unformatted event table might not be efficient.

To setup a package cache event monitor using defaults and best practices, complete the following steps:

- Create the event monitor by issuing the CREATE EVENT MONITOR statement. The following example uses defaults where possible and specifies to store the unformatted event table in an existing table space MY\_EVMON\_TABLESPACE:

```
CREATE EVENT MONITOR MY_PKGCACHE_EVMON
FOR PACKAGE CACHE
WRITE TO UNFORMATTED EVENT TABLE (IN MY_EVMON_TABLESPACE)
```

## Enabling data collection

To enable data collection, you must activate the event monitor using the SET EVENT MONITOR STATE statement. The package cache event monitor is not a *passive* event monitor; following activation, it automatically starts collecting data whenever a statement is flushed from the package cache and meets the filter criteria set at the time of creation of the package cache event monitor.

## Accessing event data captured by a package cache event monitor

A unit of work event monitor can write data to a regular table or it can write data in binary format to an unformatted event (UE) table. You can access the data in regular tables by using SQL.

To access data in a UE table, use one of the following table functions:

### **EVMON\_FORMAT\_UE\_TO\_XML**

Extracts data from an unformatted event table into an XML document.

### **EVMON\_FORMAT\_UE\_TO\_TABLES**

Extracts data from an unformatted event table into a set of relational tables.

When you use one of these table functions, you can specify which data to extract by including a SELECT statement as one of the parameters to the function. You have full control over selection, ordering, and other aspects provided by the SELECT statement.

The schema file `~/sql1lib/misc/DB2EvmonPkgCache.xsd` is used to document the expected output of the package cache event monitor report in an XML document. The schema file will reference a common monitor schema file (`DB2MonCommon.xsd`) to avoid duplicating the common contents.

An XML stylesheet is provided in `~/sql1lib/samples/jdbc/DB2EvmonPkgCache.xsl`.

Use these table functions to specify the data to extract using a SELECT statement. You have full control over selection, ordering, and other aspects provided by the SELECT statement.

You can also use the **db2evmonfmt** command to perform the following tasks:

- Select events of interest based on the following attributes: executable ID, section type, query cost estimate, statement package cache ID, and flush time.
- Choose whether to receive the output in the form of a text report or a formatted XML document.

- Control the output format by creating your own XSLT style sheets instead of using the ones provided by the **db2evmonfmt** command.

For example, the following command provides a package cache report that:

1. Selects package cache events that have occurred in the past 24 hours in the database SAMPLE. These event records are obtained from the unformatted event table called SAMPLE\_PKG\_CACHE\_EVENTS.
2. Provides formatted text output using the DB2EvmonPkgCache.xsl style sheet.

```
java db2evmonfmt -d SAMPLE -ue SAMPLE_PKG_CACHE_EVENTS -ftext -ss DB2EvmonPkgCache.xsl -hours 24
```

### **Data generated by package cache event monitors**

Package cache event monitors produce data about packages evicted from the package cache. You can choose to have the output from a package cache event monitor to regular tables, or to an unformatted event (UE) table. If data is written to a UE table, you must perform post-processing on it to view the data.

Regardless of the output format you choose, all package cache event data comes from one of three logical groups:

- [pkgcache](#)
- [pkgcache\\_metrics](#)
- [pkgcache\\_stmt\\_args](#)

If you choose to have the package cache event data written to regular tables, data from an additional group (CONTROL) is used to generate metadata about the event monitor itself.

**Note:** Unlike the locking and unit of work event monitors, you do not need to enable the generation of package cache event data after you create a package cache event monitor; data collection begins as soon as the event monitor is activated.

#### *Information written to tables for a package cache event monitor*

Information written by a package cache event monitor when the WRITE TO TABLE option is specified.

When you choose WRITE TO TABLE as the output type for a package cache event monitor, by default, three tables are produced, each containing monitor elements from one or more logical data groups.

*Table 31. Tables produced by package cache write-to-table event monitors.* The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by *evmon-name* in the table names shown in the following table) in the CREATE EVENT MONITOR statement.

<b>Default table name</b>	<b>Logical data groups reported</b>
PKG_CACHE_ <i>evmon-name</i>	Refer to <a href="#">pkgcache</a> in "Event monitor logical data groups and monitor elements"
PKG_CACHE_METRICS_ <i>evmon-name</i>	Refer to <a href="#">pkgcache_metrics</a> in "Event monitor logical data groups and monitor elements"
PKG_CACHE_STMT_ARGS_ <i>evmon-name</i> <sup>1</sup>	Refer to " <a href="#">pkgcache_stmt_args</a> logical data group" on page 100 in "Event monitor logical data groups and monitor elements"
CONTROL_ <i>evmon-name</i>	The CONTROL logical group consists of selected elements from one or more of the <a href="#">event_dbheader</a> , <a href="#">event_start</a> and <a href="#">event_overflow</a> logical data groups.

1. This table records entries for the following data types; however, the actual values of the arguments are not recorded in the STMT\_VALUE\_DATA element: BLOB, CLOB, REF, BOOLEAN, Structured data types, DATALINK, LONG VARGRAPHIC, LONG VARCHAR, XML types, DBCLOB, ARRAY types, ROW types, ROWID, CURSOR variables

To restrict the output of the event monitor to specific tables, specify the names of the logical groups for which you want tables produced in the CREATE EVENT MONITOR or ALTER EVENT MONITOR statement. Refer to the reference topics for those statements for details.

## Control table

*Table 32. Information returned for a package cache event monitor: Default table name: CONTROL\_evmon-name*

Column name	Data type	Description
PARTITION_KEY	INTEGER	<a href="#">partition_key</a> - Partitioning key
EVENT_MONITOR_NAME	VARCHAR(128)	<a href="#">event_monitor_name</a> - Event monitor name
MESSAGE	VARCHAR(128)	<a href="#">message</a> - Control table message
MESSAGE_TIME	TIMESTAMP	<a href="#">message_time</a> - Timestamp control table message
PARTITION_NUMBER	SMALLINT	<a href="#">partition_number</a> - Partition number

*Information written to relational tables by EVMON\_FORMAT\_UE\_TO\_TABLES for a package cache event monitor*

Information written for a package cache event monitor from the EVMON\_FORMAT\_UE\_TO\_TABLES table function. This is also documented in the DB2EvmonPkgCache .xsd file.

*Table 33. Information returned for a locking event monitor: Table name: PKGCACHE\_EVENT*

Column Name	Data Type	Description
XMLID	VARCHAR(256 OCTETS) NOT NULL	<a href="#">"xmlid - XML ID monitor element"</a> on page 1710
EVENT_ID	BIGINT NOT NULL	<a href="#">"event_id - Event ID monitor element"</a> on page 841
EVENT_TYPE	VARCHAR(128 OCTETS) NOT NULL	<a href="#">"event_type - Event Type monitor element"</a> on page 843
EVENT_TIMESTAMP	TIMESTAMP NOT NULL	<a href="#">"event_timestamp - Event timestamp monitor element"</a> on page 843
MEMBER	SMALLINT NOT NULL	<a href="#">"member - Database member monitor element"</a> on page 1068
SECTION_TYPE	CHAR(1 OCTETS)	<a href="#">"section_type - Section type indicator monitor element"</a> on page 1407
INSERT_TIMESTAMP	TIMESTAMP	<a href="#">"insert_timestamp - Insert timestamp monitor element"</a> on page 965
EXECUTABLE_ID	VARCHAR(32 OCTETS) FOR BIT DATA	<a href="#">"executable_id - Executable ID monitor element"</a> on page 851
PACKAGE_SCHEMA	VARCHAR(128 OCTETS)	<a href="#">"package_schema - Package schema monitor element"</a> on page 1127
PACKAGE_NAME	VARCHAR(128 OCTETS)	<a href="#">"package_name - Package name monitor element"</a> on page 1126
PACKAGE_VERSION_ID	VARCHAR(64 OCTETS)	<a href="#">"package_version_id - Package version monitor element"</a> on page 1128
SECTION_NUMBER	BIGINT	<a href="#">"section_number - Section number monitor element"</a> on page 1406
EFFECTIVE_ISOLATION	CHAR(2 OCTETS)	<a href="#">"effective_isolation - Effective isolation monitor element"</a> on page 834
NUM_EXECUTIONS	BIGINT	<a href="#">"num_executions - Statement executions monitor element"</a> on page 1090
NUM_EXEC_WITH_METRICS	BIGINT	<a href="#">"num_exec_with_metrics - Number of executions with metrics collected monitor element"</a> on page 1089

Table 33. Information returned for a locking event monitor: Table name: PKGCACHE\_EVENT (continued)

Column Name	Data Type	Description
PREP_TIME	BIGINT	"prep_time - Preparation time monitor element" on page 1340
LAST_METRICS_UPDATE	TIMESTAMP	"last_metrics_update - Metrics last update timestamp monitor element" on page 990
NUM_COORD_EXEC	BIGINT	"num_coord_exec - Number of executions by coordinator agent monitor element" on page 1088
NUM_COORD_EXEC_WITH_METRICS	BIGINT	"num_coord_exec_with_metrics - Number of executions by coordinator agent with metrics monitor element" on page 1088
STMT_TYPE_ID	VARCHAR(32 OCTETS)	"stmt_type_id - Statement type identifier monitor element" on page 1492
QUERY_COST_ESTIMATE	BIGINT	"query_cost_estimate - Query cost estimate monitor element" on page 1352
STMT_PKG_CACHE_ID	BIGINT	"stmt_pkg_cache_id - Statement package cache identifier monitor element" on page 1486
STMT_TEXT	CLOB(2M OCTETS)	"stmt_text - SQL statement text monitor element" on page 1490
COMP_ENV_DESC	BLOB(10K)	"comp_env_desc - Compilation environment monitor element" on page 727
METRICS	BLOB(1M)	XML document containing metrics-related monitor elements. The metrics in this document are the same as those described in the PKGCACHE_METRICS table that appears later in this topic. See "Interfaces that return monitor data in XML documents" on page 15 for more information.
SECTION_ENV	BLOB(150M)	"section_env - Section environment monitor element" on page 1405
ROUTINE_ID	BIGINT	"routine_id - Routine ID monitor element" on page 1386
QUERY_DATA_TAG_LIST	VARCHAR(32 OCTETS)	"query_data_tag_list - Estimated query data tag list monitor element" on page 1353
TOTAL_STATS_FABRICATION_TIME	BIGINT	"total_stats_fabrication_time - Total statistics fabrication time monitor element" on page 1651

TOTAL_COL_SYNOPSIS_TIME	BIGINT	

Table 34. Information returned for a package cache event monitor: Table name: PKGCACHE\_METRICS. The metrics in this table are the same as those returned in the METRICS monitor element in the PKGCACHE\_EVENT table (continued)

Column Name	Data Type	Description
TOTAL_COL_SYNOPSIS_PROC_TIME	BIGINT	
TOTAL_COL_SYNOPSIS_EXECUTIONS	BIGINT	
COL_SYNOPSIS_ROWS_INSERTED	BIGINT) ORGANIZE BY ROW	

Table 35. Information returned for a locking event monitor: Table name: PKGCACHE\_STMT\_ARGS

Column Name	Data Type	Description
XMLID	VARCHAR(256 OCTETS) NOT NULL	<a href="#">“xmlid - XML ID monitor element” on page 1710</a>
STMT_VALUE_INDEX	INTEGER NOT NULL	<a href="#">“stmt_value_index - Value index ” on page 1494</a>
STMT_VALUE_ISREOPT	INTEGER	<a href="#">“stmt_value_isreopt - Variable used for statement reoptimization monitor element” on page 1495</a>
STMT_VALUE_ISNULL	INTEGER	<a href="#">“stmt_value_isnull - Value has null value monitor element” on page 1494</a>
STMT_VALUE_TYPE	CHAR(16 OCTETS)	<a href="#">“stmt_value_type - Value type monitor element” on page 1496</a>
STMT_VALUE_DATA	CLOB(32K OCTETS)) ORGANIZE BY ROW	<a href="#">“stmt_value_data - Value data ” on page 1493</a>

Entries for the following data types are recorded in the preceding table, however, the actual values of the arguments are not recorded in the STMT\_VALUE\_DATA element:

- BLOB
- CLOB
- REF
- BOOLEAN
- Structured data types
- DATALINK
- LONG VARGRAPHIC
- LONG VARCHAR
- XML types
- DBCLOB
- ARRAY types
- ROW types
- ROWID
- CURSOR variables

Input arguments are recorded beginning with the one that appears first in the statement, and continuing with each one in succession. The number of input parameters that can be recorded in this table is constrained only by the upper limit on the size of the BLOB document that the UE event monitor uses to capture event information. In practical terms, it is unlikely the number input arguments captured would ever cause this limit to be reached.

Information written to XML for a package cache event monitor

Information written for a package cache event monitor from the EVMON\_FORMAT\_UE\_TO\_XML table function. This is also documented in the DB2EvmonPkgCache.xsd file.

## db2\_pkgcache\_event

The main schema that describes a package cache event in details.

**Element content:** ( [“section\\_type”](#) on page 237 , [“insert\\_timestamp”](#) on page 237 , [“executable\\_id”](#) on page 238 , [“package\\_schema”](#) on page 238 , [“package\\_name”](#) on page 238 , [“package\\_version\\_id”](#) on page 238 , [“section\\_number”](#) on page 238 {zero or one times (?)}, [“effective\\_isolation”](#) on page 238 , [“num\\_executions”](#) on page 239 , [“num\\_exec\\_with\\_metrics”](#) on page 239 , [“prep\\_time”](#) on page 239 , [“last\\_metrics\\_update”](#) on page 239 , [“num\\_coord\\_exec”](#) on page 239 , [“num\\_coord\\_exec\\_with\\_metrics”](#) on page 240 , [“stmt\\_type\\_id”](#) on page 240 , [“query\\_cost\\_estimate”](#) on page 240 , [“stmt\\_pkg\\_cache\\_id”](#) on page 240 , [“stmt\\_text”](#) on page 240 , [“comp\\_env\\_desc”](#) on page 241 , [“section\\_env”](#) on page 241 , [“activity\\_metrics”](#) on page 241 , [“routine\\_id”](#) on page 241 , [“query\\_data\\_tag\\_list”](#) on page 241 , [“total\\_stats\\_fabrication\\_time”](#) on page 241 , [“total\\_stats\\_fabrications”](#) on page 241 , [“total\\_sync\\_runstats\\_time”](#) on page 242 , [“total\\_sync\\_runstats”](#) on page 242 , [“max\\_coord\\_stmt\\_exec\\_timestamp”](#) on page 242 {zero or one times (?)}, [“max\\_coord\\_stmt\\_exec\\_time\\_arg”](#) on page 242 {zero or more (\*)}, [“max\\_coord\\_stmt\\_exec\\_time”](#) on page 242 , [“stmtno”](#) on page 243 , [“num\\_routines”](#) on page 243 , [“stmtid”](#) on page 243 , [“planid”](#) on page 243 , [“prep\\_warning”](#) on page 243 , [“prep\\_warning\\_reason”](#) on page 244 , [“semantic\\_env\\_id”](#) on page 244 , [“active\\_hash\\_grpbys\\_top”](#) on page 244 , [“active\\_hash\\_joins\\_top”](#) on page 244 , [“active\\_olap\\_funcs\\_top”](#) on page 244 , [“active\\_peas\\_top”](#) on page 245 , [“active\\_peds\\_top”](#) on page 245 , [“active\\_sort\\_consumers\\_top”](#) on page 245 , [“active\\_sorts\\_top”](#) on page 245 , [“active\\_col\\_vector\\_consumers\\_top”](#) on page 245 , [“sort\\_consumer\\_heap\\_top”](#) on page 246 , [“sort\\_consumer\\_shrheap\\_top”](#) on page 246 , [“sort\\_heap\\_top”](#) on page 246 , [“sort\\_shrheap\\_top”](#) on page 246 , ANY content ( skip ) {zero or more (\*)} )

### Attributes:

QName	Type	Fixed	Default	Use	Annotation
id	xs:long			required	
type			required		
timestamp	xs:dateTime			required	
member				required	
release	xs:long			required	
ANY attribute from ANY namespace					

### section\_type

The type of SQL statement processed. Possible values: D:Dynamic or S:Static. See monitor element [“section\\_type - Section type indicator monitor element”](#) on page 1407 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

### insert\_timestamp

The time when the variation or section was inserted into the cache. See monitor element [“insert\\_timestamp - Insert timestamp monitor element”](#) on page 965 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

### Element content:

Type	Facet
xs:dateTime	

### executable\_id

A binary token generated on the data server that uniquely identifies the SQL statement section that was executed. See monitor element [“executable\\_id - Executable ID monitor element”](#) on page 851 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

### package\_schema

The schema name of the package associated with an SQL statement. See monitor element [“package\\_schema - Package schema monitor element”](#) on page 1127 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

### package\_name

The name of the package that contains the SQL statement currently executing. See monitor element [“package\\_name - Package name monitor element”](#) on page 1126 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

### package\_version\_id

The package version identifies the version identifier of the package that contains the SQL statement currently executing. See monitor element [“package\\_version\\_id - Package version monitor element”](#) on page 1128 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

### section\_number

The internal section number in the package for the SQL statement currently processing or most recently processed. See monitor element [“section\\_number - Section number monitor element”](#) on page 1406 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

#### Element content:

Type	Facet
xs:long	

### effective\_isolation

The isolation value in effect for the SQL statement while it was being run. See monitor element [“effective\\_isolation - Effective isolation monitor element”](#) on page 834 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

#### Attributes:

QName	Type	Fixed	Default	Use	Annotation
id	xs:long			optional	

## num\_executions

The number times the SQL statement has been executed. See monitor element [“num\\_executions - Statement executions monitor element”](#) on page 1090 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:long	

## num\_exec\_with\_metrics

The number times the SQL statement has been executed with the metrics collected. See monitor element [“num\\_exec\\_with\\_metrics - Number of executions with metrics collected monitor element”](#) on page 1089 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:long	

## prep\_time

Time in milliseconds required to prepare an SQL statement if the activity is an SQL statement. See monitor element [“prep\\_time - Preparation time monitor element”](#) on page 1340 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:long	

## last\_metrics\_update

Timestamp reflecting the last time metrics were updated for this cache entry. See monitor element [“last\\_metrics\\_update - Metrics last update timestamp monitor element”](#) on page 990 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:dateTime	

## num\_coord\_exec

The number of times this section was executed by a coordinator agent. See monitor element [“num\\_coord\\_exec - Number of executions by coordinator agent monitor element”](#) on page 1088 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:long	

### num\_coord\_exec\_with\_metrics

The number of times this section was executed by a coordinator agent and monitoring metrics were being captured. See monitor element [“num\\_coord\\_exec\\_with\\_metrics - Number of executions by coordinator agent with metrics monitor element”](#) on page 1088 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:long	

### stmt\_type\_id

Statement type identifier. See monitor element [“stmt\\_type\\_id - Statement type identifier monitor element”](#) on page 1492 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:long			optional	

### query\_cost\_estimate

Estimated cost for a query, as determined by the SQL compiler. See monitor element [“query\\_cost\\_estimate - Query cost estimate monitor element”](#) on page 1352 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:long	

### stmt\_pkg\_cache\_id

This element shows the internal package cache identifier for a dynamic SQL statement. See monitor element [“stmt\\_pkg\\_cache\\_id - Statement package cache identifier monitor element”](#) on page 1486 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:long	

### stmt\_text

The text of the SQL statement. See monitor element [“stmt\\_text - SQL statement text monitor element”](#) on page 1490 for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

### **comp\_env\_desc**

The element stores information about the compilation environment used when compiling the SQL statement. See monitor element [“comp\\_env\\_desc - Compilation environment monitor element” on page 727](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

### **section\_env**

A BLOB that contains the section for an SQL statement. See monitor element [“section\\_env - Section environment monitor element” on page 1405](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

### **activity\_metrics**

The activity metrics for this cache entry.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

### **routine\_id**

For CALL statements this element stores the routine identifier associated with the stored procedure invoked. See monitor element [“routine\\_id - Routine ID monitor element” on page 1386](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:**

Type	Facet
xs:long	

### **query\_data\_tag\_list**

The data tag list for this cache entry. See monitor element [“query\\_data\\_tag\\_list - Estimated query data tag list monitor element” on page 1353](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

### **total\_stats\_fabrication\_time**

Total time spent, in milliseconds, on statistics fabrications by real-time statistics gathering. See monitor element [“total\\_stats\\_fabrication\\_time - Total statistics fabrication time monitor element” on page 1651](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:**

Type	Facet
xs:long	

### **total\_stats\_fabrications**

Total number of statistics fabrications performed by real-time statistics during query compilation. See monitor element [“total\\_stats\\_fabrications - Total statistics fabrications monitor elements” on page 1653](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:**

Type	Facet
xs:long	

### **total\_sync\_runstats\_time**

Total time spent, in milliseconds, on synchronous RUNSTATS activities triggered by real-time statistics gathering. See monitor element [“total\\_sync\\_runstats\\_time - Total synchronous RUNSTATS time monitor elements” on page 1654](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:**

Type	Facet
xs:long	

### **total\_sync\_runstats**

Total number of synchronous RUNSTATS activities triggered by real-time statistics gathering. See monitor element [“total\\_sync\\_runstats - Total synchronous RUNSTATS activities monitor element” on page 1657](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:**

Type	Facet
xs:long	

### **max\_coord\_stmt\_exec\_timestamp**

See monitor element [“max\\_coord\\_stmt\\_exec\\_timestamp - Maximum coordinator statement execution timestamp monitor element” on page 1055](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:**

Type	Facet
xs:dateTime	

### **max\_coord\_stmt\_exec\_time\_arg**

Describes an input variable to this statement which produced the max\_coord\_stmt\_exec\_time.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:** ( [“stmt\\_value\\_index” on page 246](#) , [“stmt\\_value\\_isreopt” on page 247](#) , [“stmt\\_value\\_isnull” on page 247](#) , [“stmt\\_value\\_type” on page 247](#) , [“stmt\\_value\\_data” on page 247](#) , ANY content ( skip ) {zero or more (\*)}

### **max\_coord\_stmt\_exec\_time**

See monitor element [“max\\_coord\\_stmt\\_exec\\_time - Maximum coordinator statement execution time monitor element” on page 1052](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:**

Type	Facet
xs:long	

### **stmtno**

See monitor element [“stmtno - Statement number monitor element” on page 1497](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:**

Type	Facet
xs:int	

### **num\_routines**

See monitor element [“num\\_routines - Number of routines monitor element” on page 1099](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:**

Type	Facet
xs:int	

### **stmtid**

See monitor element [“stmtid - Query statement ID monitor element” on page 1496](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:**

Type	Facet
xs:long	

### **planid**

See monitor element [“planid - Query plan ID monitor element” on page 1147](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:**

Type	Facet
xs:long	

### **prep\_warning**

See monitor element [“prep\\_warning - Prepare warning SQLCODE monitor element” on page 1342](#) for more details.

**Contained by:** [“db2\\_pkgcache\\_event” on page 237](#)

**Element content:**

Type	Facet
xs:int	

### prep\_warning\_reason

See monitor element [“prep\\_warning\\_reason - Prepare warning SQLCODE reason identifier monitor element”](#) on page 1342 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:int	

### semantic\_env\_id

See monitor element [“semantic\\_env\\_id - Query semantic compilation environment ID monitor element”](#) on page 1410 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:long	

### active\_hash\_grpbys\_top

See monitor element [“active\\_hash\\_grpbys\\_top - Active hash GROUP BY operations high watermark monitor element”](#) on page 605 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:long	

### active\_hash\_joins\_top

See monitor element [“active\\_hash\\_joins\\_top - Active hash join operations high watermark monitor element”](#) on page 607 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:long	

### active\_olap\_funcs\_top

See monitor element [“active\\_olap\\_funcs\\_top - Active OLAP function operations high watermark monitor element”](#) on page 609 for more details.

**Contained by:** [“db2\\_pkgcache\\_event”](#) on page 237

**Element content:**

Type	Facet
xs:long	

### active\_peas\_top

See monitor element “[active\\_peas\\_top - Active partial early aggregation operations high watermark monitor element](#)” on page 611 for more details.

**Contained by:** “[db2\\_pkgcache\\_event](#)” on page 237

**Element content:**

Type	Facet
xs:long	

### active\_peds\_top

See monitor element “[active\\_peds\\_top - Active partial early distinct operations high watermark monitor element](#)” on page 613 for more details.

**Contained by:** “[db2\\_pkgcache\\_event](#)” on page 237

**Element content:**

Type	Facet
xs:long	

### active\_sort\_consumers\_top

See monitor element “[active\\_sort\\_consumers\\_top - Active sort memory consumers high watermark monitor element](#)” on page 615 for more details.

**Contained by:** “[db2\\_pkgcache\\_event](#)” on page 237

**Element content:**

Type	Facet
xs:long	

### active\_sorts\_top

See monitor element “[active\\_sorts\\_top - Active sorts high watermark monitor element](#)” on page 617 for more details.

**Contained by:** “[db2\\_pkgcache\\_event](#)” on page 237

**Element content:**

Type	Facet
xs:long	

### active\_col\_vector\_consumers\_top

See monitor element “[active\\_col\\_vector\\_consumers\\_top - Active columnar vector memory consumers high watermark monitor element](#)” on page 603 for more details.

**Contained by:** “[db2\\_pkgcache\\_event](#)” on page 237

**Element content:**

Type	Facet
xs:long	

### sort\_consumer\_heap\_top

See monitor element “[sort\\_consumer\\_heap\\_top - Individual private sort heap consumer high watermark monitor element](#)” on page 1438 for more details.

**Contained by:** “[db2\\_pkgcache\\_event](#)” on page 237

**Element content:**

Type	Facet
xs:long	

### sort\_consumer\_shrheap\_top

See monitor element “[sort\\_consumer\\_shrheap\\_top - Individual shared sort heap consumer high watermark monitor element](#)” on page 1439 for more details.

**Contained by:** “[db2\\_pkgcache\\_event](#)” on page 237

**Element content:**

Type	Facet
xs:long	

### sort\_heap\_top

See monitor element “[sort\\_heap\\_top - Sort private heap high watermark](#)” on page 1442 for more details.

**Contained by:** “[db2\\_pkgcache\\_event](#)” on page 237

**Element content:**

Type	Facet
xs:long	

### sort\_shrheap\_top

See monitor element “[sort\\_shrheap\\_top - Sort share heap high watermark](#)” on page 1448 for more details.

**Contained by:** “[db2\\_pkgcache\\_event](#)” on page 237

**Element content:**

Type	Facet
xs:long	

### stmt\_value\_index

The element represents the position of the input parameter marker or host variable used in the SQL statement. See monitor element “[stmt\\_value\\_index - Value index](#)” on page 1494 for more details.

**Contained by:** “[max\\_coord\\_stmt\\_exec\\_time\\_arg](#)” on page 242

## stmt\_value\_isreopt

The element shows whether the variable was used during statement reoptimization. See monitor element [“stmt\\_value\\_isreopt - Variable used for statement reoptimization monitor element”](#) on page 1495 for more details.

**Contained by:** [“max\\_coord\\_stmt\\_exec\\_time\\_arg”](#) on page 242

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:int			required	

## stmt\_value\_isnull

The element shows whether a data value associated with the SQL statement is the NULL value. See monitor element [“stmt\\_value\\_isnull - Value has null value monitor element”](#) on page 1494 for more details.

**Contained by:** [“max\\_coord\\_stmt\\_exec\\_time\\_arg”](#) on page 242

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:int			required	

## stmt\_value\_type

The element contains a string representation of the type of data value associated with an SQL statement. See monitor element [“stmt\\_value\\_type - Value type monitor element”](#) on page 1496 for more details.

**Contained by:** [“max\\_coord\\_stmt\\_exec\\_time\\_arg”](#) on page 242

## stmt\_value\_data

The element contains a string representation of a data value associated with an SQL statement. See monitor element [“stmt\\_value\\_data - Value data ”](#) on page 1493 for more details.

**Contained by:** [“max\\_coord\\_stmt\\_exec\\_time\\_arg”](#) on page 242

## ***Collecting package cache event data and generating reports***

You can use the package cache event monitor to collect data about statement entries that were flushed from the database package cache. After the package cache event data has been collected in an unformatted event table, follow the directions in this task to obtain a text report.

## **Before you begin**

To collect package cache event monitor data, you must have DBADM or SQLADM authority.

## **About this task**

The package cache event monitor collects relevant history information about what was in the package cache to help with query performance and problem determination issues related to SQL statements. For example, some of the information the package cache event monitor collects from the database package cache is as follows:

- Executable ID (EXECUTABLE\_ID)
- The estimated cost of the query (QUERY\_COST\_ESTIMATE)
- The time that the entry was flushed from the package cache (Event Timestamp)

This task provides instructions for collecting package cache event data.

### Restrictions

Input data values are not viewable if you do not have DBADM or SQLADM authority.

### Procedure

To collect detailed information regarding package cache events, perform the following steps:

1. Create a package cache event monitor called `cachestmtevmon` by using the CREATE EVENT MONITOR FOR PACKAGE CACHE statement, as shown in the following example:

```
CREATE EVENT MONITOR cachestmtevmon FOR PACKAGE CACHE
WRITE TO UNFORMATTED EVENT TABLE
```

2. Activate the package cache event monitor called `cachestmtevmon` by running the following statement:

```
SET EVENT MONITOR cachestmtevmon STATE 1
```

3. Unlike the locking and the unit of work event monitors, the package cache event monitor automatically starts collecting data after the event monitor is activated.
4. Connect to the database.

5. Run the application, workload or SQL statements for which you want to collect event monitor information.

6. If you want to turn OFF package cache data collection, deactivate the event monitor by running the following command:

```
SET EVENT MONITOR cachestmtevmon STATE 0
```

7. Obtain the package cache event report using the XML parser tool, **db2evmonfmt**, to produce a flat-text report based on the event data collected in the unformatted event table, for example:

```
java db2evmonfmt -d db_name -ue table_name -ftext -u user_id -p password
```

8. Analyze the report.

### Example

The following is an example of a report obtained by using the **db2evmonfmt** Java-based report tool to convert data in the unformatted event table collected by the package cache event monitor:

```

### *Using package cache information to identify statements that are candidates for performance tuning*

You can use the package cache event monitor along with in-memory metrics to identify which statements from the package cache are costly to run. Once you know which statements take a long time to run, you can do performance tuning on them.

## Before you begin

The CREATE EVENT MONITOR statement requires a table space with a page size of at least 8 K to store the unformatted event (UE) table produced by the event monitor. Unless a table space is explicitly named in the CREATE EVENT MONITOR statement, the default table space for the database is used.

## About this task

This task shows how you can examine all work done on the system between two points in time to find the costliest statements in terms of total CPU time. Using the package cache event monitor together with package cache information reflected in in-memory monitor elements (as returned by the MON\_GET\_PKG\_CACHE\_STMT or MON\_GET\_PKG\_CACHE\_STMT\_DETAILS table functions) is useful because you can see both statements in the cache as well as statements that have been evicted from the cache. Once the costly statements have been identified, you can then do performance tuning on these statements.

**Note:** You can choose from a number of monitor elements to use when determining which statements are costly to run. In this example, CPU time is used (“total\_cpu\_time - Total CPU time monitor element” on page 1584). This measurement shows actual CPU resources consumed; it does not reflect things like lock wait time or other time spent during statement execution. You might instead choose to use statement execution time (“stmt\_exec\_time - Statement execution time monitor element” on page 1481), which includes the time spent by all agents in the section, and includes wait times, among other things. You can also choose from many of the other time-spent elements returned by the package cache event monitor. See “Information written to relational tables by EVMON\_FORMAT\_UE\_TO\_TABLES for a package cache event monitor” on page 223 or “Information written to XML for a package cache event monitor” on page 237 for more information about which monitor elements you can choose from.

## Restrictions

In this particular example, the length of the analyzed statements is limited to 3000 characters. This limitation is due to the use of the GROUP BY clause used in the statement, which cannot be used with LOB values, such as the **stmt\_text** monitor element.

## Procedure

1. Create a package cache event monitor to capture statements as they are removed (evicted) from the package cache.

For example, to create an event monitor called EXPENSIVESTMTS, you could use the following SQL:

```
CREATE EVENT MONITOR EXPENSIVESTMTS FOR PACKAGE CACHE WRITE TO UNFORMATTED EVENT TABLE
```

This statement creates a package cache event monitor that writes to a UE table with the same name as the event monitor, EXPENSIVESTMTS, in the default table space for the database. You can override the default name for the UE table using the TABLE *table-name* clause. You can also override the table space used for the UE table by using the **IN** *tablespace-name* clause.

By default, all statements evicted from the package cache are captured by the package cache event monitor. To limit the amount of information collected, you can specify options as part of the CREATE EVENT MONITOR statement that restrict the information collected. See the documentation for the CREATE EVENT MONITOR (package cache) statement for more information.

- Next, activate the event monitor:

```
SET EVENT MONITOR EXPENSIVESTMTS STATE 1
```

**Note:** By default, this event monitor starts automatically upon database activation, because the AUTOSTART option is applied by default. However, because this event monitor is being created in an already-active database, you must use the **SET EVENT MONITOR** command to start it manually.

- Connect to the database and run whichever statements, workload, or applications for which you are interested in doing performance analysis. You can collect as much information as you like. However, this type of performance tuning works best when you have applications or workloads that run on a regular basis; otherwise adjustments you make for previously executed statements might not have any impact on statements that run in the future.
- When you are finished collecting data, deactivate the event monitor:

```
SET EVENT MONITOR EXPENSIVESTMTS STATE 0
```

- Extract the data from the UE table that was populated by the event monitor using the EVMON\_FORMAT\_UE\_TO\_TABLES procedure.

```
CALL EVMON_FORMAT_UE_TO_TABLES ('PKG_CACHE', NULL, NULL, NULL, NULL, NULL, NULL, -1, 'SELECT * FROM EXPENSIVESTMTS')
```

This procedure examines the UE table TRACKSTMTS produced by the event monitor. It selects all of the records from the UE table, and from them, creates two relational tables from the data collected by the package cache event monitor:

- PKG\_CACHE\_EVENT
- PKG\_CACHE\_METRICS

The first table contains the most frequently used monitor elements and metrics associated with each event captured. The second contains detailed metrics for each event.

**Note:** The values in the columns of PKG\_CACHE\_METRICS can also be found in the XML document contained in the METRICS column of the PKG\_CACHE\_EVENT table. They are provided in the PKG\_CACHE\_METRICS table for more convenient, column-oriented access.

- Query the output from the event monitor to determine which statements took the longest time to run. In this example, total CPU time (“total\_cpu\_time - Total CPU time monitor element” on page 1584) is the time-spent monitor element used to determine overall cost:

```
WITH STMTS AS
(
  1 [ SELECT SUM(TOTAL_CPU_TIME) AS TOTAL_CPU_TIME, EXECUTABLE_ID, VARCHAR(STMT_TEXT, 3000) AS STMT_TEXT
        FROM TABLE(MON_GET_PKG_CACHE_STMT(NULL, NULL, NULL, -2)) AS T
        GROUP BY EXECUTABLE_ID, VARCHAR(STMT_TEXT, 3000)
        UNION ALL
        2 [ SELECT SUM(TOTAL_CPU_TIME) AS TOTAL_CPU_TIME, EXECUTABLE_ID, VARCHAR(STMT_TEXT, 3000) AS STMT_TEXT
            FROM PKG_CACHE_EVENT E, PKG_CACHE_METRICS M WHERE E.XMLID = M.XMLID
            GROUP BY EXECUTABLE_ID, VARCHAR(STMT_TEXT, 3000)
        ]
)
SELECT SUM(TOTAL_CPU_TIME) AS TOTAL_CPU_TIME, STMT_TEXT, EXECUTABLE_ID
FROM STMTS
GROUP BY EXECUTABLE_ID, STMT_TEXT
ORDER BY TOTAL_EXEC_TIME DESC
FETCH FIRST 10 ROWS ONLY;
```

In the preceding example, both the data returned from by the MON\_GET\_PKG\_CACHE\_STMT table function (see **1**) and the package cache event monitor (see **2**) are retrieved. Looking at both data sets lets you see data for statements that still exist in the package cache, as well as data for statements that have been evicted from the package cache. Doing so assures that when you evaluate which statements are costly to run that all the statements run between two points in time are considered.

The preceding query returns the following results:

**Note:** For the purposes of printing, the font size of the characters that comprise the sample output that follows has been reduced. This output might be easier to read from the online version of the topic "Using package cache information to identify statements that are candidates for performance tuning" in the online Knowledge Center.

## What to do next

Use the output from the query shown in step “6” on page 251 to determine which statements to tune.

*Using package cache information and db2advis to look for performance improvement opportunities*

The Design Advisor can analyze SQL statements to make recommendations for how to improve database performance. You can use statements from the package cache (including statements captured by the package cache event monitor) as input to the Design Advisor to identify changes you can make to improve the performance for a given workload, or even for all statements run between two points in time.

## Before you begin

- The CREATE EVENT MONITOR statement requires a table space with a page size of at least 8 K to store the unformatted event (UE) table produced by the event monitor. Unless a table space is explicitly named in the CREATE EVENT MONITOR statement, the default table space for the database is used.
- You must have created the explain tables required by the Design Advisor.

## About this task

This task shows how you can use the package cache event monitor to track all work done on the system between two points in time, and then use the **db2advis** command to analyze high-cost statements that were run during that period. The output of the db2advis command suggests adjustments or changes you can make to your database to improve its performance, based on the statements run while the package cache event monitor was active. Using the package cache event monitor to capture these statements is useful if the statements in question are no longer in the package cache.

### Restrictions

In this particular example, the length of the analyzed statements is limited to 3000 characters. This limitation is due to the use of the GROUP BY clause used in the statement, which cannot be used with LOB values, such as the **stmt\_text** monitor element.

## Procedure

1. Create a package cache event monitor to capture statements as they are removed (evicted) from the package cache.  
For example, to create an event monitor called TRACKSTMTS, you could use the following SQL:

```
CREATE EVENT MONITOR TRACKSTMTS FOR PACKAGE CACHE WRITE TO UNFORMATTED EVENT TABLE
```

This statement creates a package cache event monitor that writes to a UE table with the same name as the event monitor, TRACKSTMTS.

2. Next, activate the event monitor:

```
SET EVENT MONITOR TRACKSTMTS STATE 1
```

3. Connect to the database and run whichever statements, workload or applications for which you are interested in doing performance analysis. You can collect as much information as you like. However, this type of performance tuning works best when you have applications or workloads that run on a regular basis; otherwise adjustments you make for previously executed statements might not have any impact on statements that run in the future.

4. When you are finished collecting data, deactivate the event monitor:

```
SET EVENT MONITOR TRACKSTMTS STATE 0
```

5. Extract the data from the UE table that was populated by the event monitor using the `EVMON_FORMAT_UE_TO_TABLES` procedure.

```
CALL EVMON_FORMAT_UE_TO_TABLES
('PKGCACHE', NULL, NULL, NULL, NULL, NULL, -1,
'SELECT * FROM TRACKSTMTS')
```

This procedure creates two relational tables from the data collected by the package cache event monitor:

- PKGCACHE\_EVENT
- PCKCACHE\_METRICS

The first table contains the most frequently used monitor elements and metrics associated with each event captured. The second contains detailed metrics for each event.

**Note:** The values in the columns of PKGCACHE\_METRICS can also be found in the XML document contained in the METRICS column of the PKGCACHE\_EVENT table. They are provided in the PKGCACHE\_METRICS table for more convenient, column-oriented access.

6. Query the output from the event monitor to determine which statements took the longest time to run. In this example, statement execution time (“`stmt_exec_time - Statement execution time monitor element`” on page 1481) is the time-spent monitor element used to determine overall cost. This monitor element is summed across all database partitions.

**Tip:** Save the output from the query into a text file. You will use this file in the next step.

```
WITH STMTS AS
(
  SELECT SUM(TOTAL_STMT_EXEC_TIME)/SUM(TOTAL_NUM_COORD_EXEC_WITH_METRICS) AS AVG_TIME_PER_EXEC,
         STMT_TEXT, SUM(NUM_EXECUTIONS) AS NUM_EXECUTIONS, STMT_TYPE_ID
  FROM (
    (
      SELECT      SUM(STMT_EXEC_TIME) AS TOTAL_STMT_EXEC_TIME,
                  SUM(NUM_COORD_EXEC_WITH_METRICS) AS TOTAL_NUM_COORD_EXEC_WITH_METRICS,
                  SUM(NUM_COORD_EXEC) AS NUM_EXECUTIONS,
                  VARCHAR(STMT_TEXT, 3000) AS STMT_TEXT,
                  STMT_TYPE_ID
      FROM        PKGCACHE_EVENT AS E, PKGCACHE_METRICS AS M
      WHERE       E.XMLID = M.XMLID
      AND        NUM_COORD_EXEC_WITH_METRICS > 0
      GROUP BY   VARCHAR(STMT_TEXT, 3000), STMT_TYPE_ID
      ORDER BY   TOTAL_NUM_COORD_EXEC_WITH_METRICS DESC
      FETCH FIRST 50 ROWS ONLY
    )
  )
  UNION ALL
  (
    SELECT      SUM(STMT_EXEC_TIME) AS TOTAL_STMT_EXEC_TIME,
                  SUM(NUM_COORD_EXEC_WITH_METRICS) AS TOTAL_NUM_COORD_EXEC_WITH_METRICS,
                  SUM(NUM_COORD_EXEC) AS NUM_EXECUTIONS,
```

```

        VARCHAR(STMT_TEXT, 3000) AS STMT_TEXT,
        STMT_TYPE_ID
    FROM      TABLE(MON_GET_PKG_CACHE_STMT(NULL,NULL,NULL,-2)) AS T
    WHERE     NUM_COORD_EXEC_WITH_METRICS > 0
    GROUP BY  VARCHAR(STMT_TEXT, 3000),STMT_TYPE_ID
    ORDER BY  TOTAL_NUM_COORD_EXEC_WITH_METRICS DESC
    FETCH FIRST 50 ROWS ONLY
)
) AS Q_UA
GROUP BY STMT_TEXT, STMT_TYPE_ID
)
SELECT      '--# SET FREQUENCY ' || NUM_EXECUTIONS || X'0A' || STMT_TEXT || ';'
FROM        STMTS WHERE STMT_TYPE_ID LIKE 'DML, Select%' OR STMT_TYPE_ID LIKE 'DML, Insert%' 1
ORDER BY    AVG_TIME_PER_EXEC DESC
FETCH FIRST 50 ROWS ONLY;

```

In the preceding sample statement, both the data from the package cache event monitor and the in-memory information from the MON\_GET\_PKG\_CACHE\_STMT table function are retrieved. Looking at both data sets lets you see data for statements evicted from the package cache, as well as statements that still exist in the package cache. Doing so assures that when you evaluate which statements are costly to run that you also include statements not yet evicted from the cache. In each case, the query retrieves the top 50 statements from both the active package cache, and the package cache event monitor, based on the number of times the statements ran. Then, from these statements, the top 50 SELECT or INSERT statements are chosen **1** based on the average length of time the statements ran for.

**Note:** You can choose from a number of monitor elements to use when determining which statements are costly to run. In this example, statement execution time is used. This measurement includes shows the amount of time spent in execution by all members and agents executing this section, and includes things like wait time. You might instead choose to use CPU time (“total\_cpu\_time - Total CPU time monitor element” on page 1584), which reports only the time spent by the CPU processing the statement. You could also choose from many of the other time-spent elements returned by the package cache event monitor. See “Information written to relational tables by EVMON\_FORMAT\_UE\_TO\_TABLES for a package cache event monitor” on page 223 or “Information written to XML for a package cache event monitor” on page 237 for more information about which monitor elements you can choose from.

In addition, the query presents the output in the --# SET FREQUENCY format the Design Advisor uses for its analysis.

The preceding query returns results like the ones that follow:

```

-----
--# SET FREQUENCY 1
WITH STMTS AS ( SELECT SUM(TOTAL_STMT_EXEC_TIME)/SUM(TOTAL_NUM_COORD_EXEC_WITH_METRICS) AS AVG_TIME_PER_EXEC, STMT
--# SET FREQUENCY 2

47 record(s) selected

```

**Note:** The lines in the preceding sample output have been truncated for presentation purposes.

7. Create an input file for the **db2adviz** command using the statements returned by the query in step “6” on page 253. (For more information about creating input files for the **db2adviz** command, refer to the reference documentation for that command.)
8. Run the **db2adviz** command using the input file created in step “7” on page 255. For example, if the input file you create is called `pkgcache_stmts.txt`, run a command similar to this:

```
db2adviz -d customer -i pkgcache_stmts.txt -m MICP
```

where

- **-d CUSTOMER** identifies the name of the database for which you are getting recommendations
- **-i pkgcache\_stmts.txt** identifies the name of the input file for **db2adviz**
- **-m MICP** is a directive to the **db2adviz** command to produce the following recommendations to improve performance:

#### **M**

Recommends to create new materialized query tables (MQTs) and indexes on the MQTs. In partitioned database environments, partitioning on MQTs is also recommended.

#### **I**

Recommends new indexes. This is the default.

#### **C**

Recommends either to convert standard tables to multidimensional clustering (MDC) tables or to create a clustering index on the tables.

#### **P**

Recommends to repartition existing tables.

## Results

The Design Advisor returns recommendations like ones that follow:

```

execution started at timestamp 2010-03-16-14.25.57.562000
Using the default table space name USERSPACE1
found [47] SQL statements from the input file
excluding statement [0] from the workload.
excluding statement [1] from the workload.
excluding statement [19] from the workload.
excluding statement [39] from the workload.

## What to do next

Use the output from the Design Advisor to help when deciding what changes to make to your database to improve performance.

## Activity event monitoring

The activity event monitor captures data that is related to activities that run on the system. You can use this event monitor to gather data to help you better understand the performance and behavior of statements and of the load on your system in general. The activity event monitor records information after the completion of each activity in the system. By contrast, the unit of work event monitor records data at the completion of each transaction. Using the activity event monitor, you can examine monitor elements related to the execution of individual statements.

The data that the activity event monitor returns complements the data that the following table functions return:

- MON\_GET\_ACTIVITY\_DETAILS
- MON\_GET\_PKG\_CACHE\_STMT
- MON\_GET\_PKG\_CACHE\_STMT\_DETAILS

Whereas the event monitor returns historical information about activities that ran on the system, the table functions provide information about activities that have run or have recently run on the system.

## Uses of the activity event monitor

### Use with other event monitors

The activity event monitor is particularly useful in conjunction with other event monitors. For example, you might want to capture information about the execution of a statement that violates a threshold that you define. In this case, you perform the following steps:

1. Define the threshold by using the CREATE THRESHOLD statement. As part of defining the threshold, specify the COLLECT ACTIVITY DATA clause to have activity data recorded by any active activity event monitors.
2. Create a threshold violations event monitor to capture details about when the threshold was violated, along with other data about what was happening in the system at that time.
3. Create an activity event monitor that captures the activity information that the threshold violation generates.
4. Run your application or workload.
5. Query the event monitor output to view information about what was happening when the threshold was violated. You might perform a join of data from the threshold violations event monitor with the data from the activity event monitor to pinpoint the statement that was running when the violation occurred.

This process is described in more detail in [“Example: Capturing activity information related to the execution of a statement”](#) on page 263.

Other applications of the activity event monitor include the following ones:

- Capturing information about long-running queries. In this case, you run the WLM\_CAPTURE\_ACTIVITY\_IN\_PROGRESS procedure to force the collection of information about an activity before the activity is finished. Running this procedure is useful if you want to terminate a long-running statement but also want to capture information about it.
- Seeing what statements the applications in a specific workload are running.

### Input to commands, procedures, or tools

The data produced by the activity event monitor can be used as input for various tools and stored procedures, including:

#### db2adviz - Design Advisor command

The **db2adviz** command can use the output of the activity event monitor to produce recommendations about the following items and activities:

- Materialized query tables (MQTs)
- Indexes

- Repartitioning of tables
- Conversion to multidimensional clustering (MDC) tables
- Deletion of unused objects

### **db2exp1n - SQL and XQuery Explain command**

The **db2exp1n** command can use section information from the activity event monitor to describe the access plan for statements related to a section.

### **EXPLAIN\_FROM\_ACTIVITY stored procedure**

The EXPLAIN\_FROM\_ACTIVITY stored procedure explains a specific execution of a statement by using the contents of the section that the procedure obtains from an activity event monitor. The Explain output is placed in the Explain tables for processing using Explain tools (for example, the **db2exfmt** command). The Explain output contains, if available, both the access plan and section actuals (runtime statistics for operators in the access plan).

### **Workload management historical analysis tools**

The `wlmhist.pl` and `wlmhistrep.pl` Perl scripts perform historical analysis by using information that the activities event monitor captures.

### **Section actuals**

Another use of the activity event monitor is to capture section actuals. You can use this data to compare the actual values that an activity event monitor captures with the estimated costs in an access plan. Doing this comparison can let you see whether the access plan is still valid.

### ***Creating an activity event monitor***

To create an event monitor that captures activity events, use the CREATE EVENT MONITOR FOR ACTIVITIES statement.

### **Before you begin**

You must have either DBADM or SQLADM authority to create an activity event monitor.

### **Procedure**

To create an activities event monitor:

1. Formulate a CREATE EVENT MONITOR FOR ACTIVITIES statement.

For example, to create an event monitor called `myactevmon`, you might use a statement such as the one that follows:

```
CREATE EVENT MONITOR myactevmon FOR ACTIVITIES
WRITE TO TABLE
```

2. Run the statement.

This example creates an activities event monitor called `myactevmon` with the following characteristics:

- Monitor elements for all logical data groups that are applicable to activity event monitors are collected.
- Output is written to relational tables. Default table names are assigned to each table.
- The event monitor is configured to start automatically when the database is first activated.
- 

These results are due to using the default settings for activity event monitors. You can override the defaults if necessary.

3. Activate the event monitor.

Although the event monitor is configured to start automatically, it will not do so until the first database activation subsequent to the creation of the event monitor. To force the event monitor to start collecting data immediately, use the SET EVENT MONITOR STATE statement, as shown in the following example:

## What to do next

Configure the event monitor to collect the data that you want.

### **Configuring data collection for an activity event monitor**

Before you can collect event data related to activities, you must configure data collection. The configuration options that you can use depend on your purpose for collecting data.

### **About this task**

There are two ways to configure data collection for an activity event monitor:

- You can have activity event data generated whenever a threshold that you created by using the CREATE THRESHOLD statement is violated.
- You can specify the COLLECT ACTIVITY METRICS clause for the CREATE or ALTER statement for WLM objects.

### **Procedure**

To collect event data that is related to activities:

1. Determine the activities for which you want to collect data.

The table that follows outlines the options:

<b>For which activities is data to be collected?</b>	<b>Configuration controlled by:</b>
<b>Activities related to a threshold violation</b>	<p>For activities that are related to a threshold violation, issue the CREATE THRESHOLD or ALTER THRESHOLD statement, specifying the COLLECT ACTIVITY DATA clause. When you specify the COLLECT ACTIVITY DATA clause, activity data is sent to any active activities event monitors whenever the threshold is violated. Optionally, specify one of the following additional clauses: WITH DETAILS; WITH DETAILS, SECTION; or AND VALUES.</p> <p><b>Tip:</b> Consider changing the value of the <code>mon_act_metrics</code> configuration parameter to NONE. Doing so restricts the activities for which event data that is collected to just those activities that are related to threshold violations.</p>
<b>Activities related to specific workload management objects</b>	<p>For activities related to workload management, issue one of the following statements, specifying the COLLECT ACTIVITY DATA clause. Optionally, specify one of the following additional clauses: WITH DETAILS; WITH DETAILS, SECTION; WITH SECTION INCLUDE ACTUALS BASE; or AND VALUES:</p> <ul style="list-style-type: none"> <li>• CREATE WORKLOAD</li> <li>• ALTER WORKLOAD</li> <li>• CREATE WORK ACTION SET</li> <li>• ALTER WORK ACTION SET</li> <li>• CREATE SERVICE CLASS</li> <li>• ALTER SERVICE CLASS</li> </ul> <p>When you specify a COLLECT ACTIVITY DATA clause for any of these statements, activity data for the workload objects that are referenced in the statement is sent to any active activity event monitor.</p> <p>For example, to collect activity event data for the PAYROLL workload, you can alter the workload by issuing this statement:</p>

For which activities is data to be collected?	Configuration controlled by:
	<pre>ALTER WORKLOAD PAYROLL COLLECT ACTIVITY DATA WITH SECTION INCLUDE ACTUALS BASE</pre> <p>In this example, activity data is collected along with data for section actuals.</p>

2. Set the collection level using one of the configuration options described in the previous step. For example, to collect activity event data for the PAYROLL workload, you can alter the workload with this statement:

```
ALTER WORKLOAD PAYROLL COLLECT ACTIVITY DATA WITH SECTION INCLUDE ACTUALS BASE
```

In this last example, activity data is collected, along with data for section actuals.

## Results

Data collection is configured.

### Collecting activity data for the default user workload

If you want to collect activity event data for activities that do not map to a specific workload, you can collect data for the default user workload by issuing a statement such as the one that follows:

```
ALTER WORKLOAD SYSDEFAULTUSERWORKLOAD COLLECT ACTIVITY DATA ON COORDINATOR
WITH DETAILS
```

This statement causes detailed activity data to be collected for any activity that is not associated with a user-defined workload object. By default, all database connections are associated with the SYSDEFAULTUSERWORKLOAD workload if there are no user-defined workload objects.

### What to do next

Run your application or workload. As activities that satisfy the collection criteria are run, event data is sent to any active activity event monitors.

### Data generated by activities event monitors

You can choose to have the output from a activities event monitor written to regular tables, files or named pipes.

Regardless of the output format you choose, all data captured by activities event monitors comes from one of four logical data groups:

- [event\\_activity](#)
- [event\\_activitymetrics](#)
- [event\\_activitystmt](#)
- [event\\_activityvals](#)

If you choose to have the statistics event monitor data written to regular tables, data from an additional group (CONTROL) is used to generate metadata about the event monitor itself.

#### Information written to tables for an activities event monitor

Information written by an activities event monitor when the WRITE TO TABLE option is specified.

When you choose WRITE TO TABLE as the output type for an activities event monitor, by default, five tables are produced, each containing monitor elements from one or more logical data groups:

Table 36. Tables produced by ACTIVITIES write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by *evmon-name* in the table names shown in the following table) in the CREATE EVENT MONITOR statement.

Default table name	Logical data groups reported
ACTIVITY_ <i>evmon-name</i>	Refer to <u>event_activity</u> in "Event monitor logical data groups and monitor elements"
ACTIVITYSTMT_ <i>evmon-name</i>	Refer to <u>event_activitystmt</u> in "Event monitor logical data groups and monitor elements"
ACTIVITYVALS_ <i>evmon-name</i>	Refer to <u>event_activityvals</u> in "Event monitor logical data groups and monitor elements"
ACTIVITYMETRICS_ <i>evmon-name</i>	Refer to <u>event_activitymetrics</u> in "Event monitor logical data groups and monitor elements"
<u>CONTROL_<i>evmon-name</i></u>	The CONTROL logical group consists of selected elements from one or more of the <u>event_dbheader</u> , <u>event_start</u> and <u>event_overflow</u> logical data groups.

To restrict the output of the event monitor to specific tables, specify the names of the logical groups for which you want tables produced in the CREATE EVENT MONITOR or ALTER EVENT MONITOR statements. Refer to the reference topics for those statements for details.

## Control table

Table 37. Information returned for an activities event monitor: Default table name: CONTROL\_*evmon-name*

Column Name	Data Type	Description
PARTITION_KEY	INTEGER	<u>partition_key</u> - Partitioning key
EVENT_MONITOR_NAME	VARCHAR(128)	<u>event_monitor_name</u> - Event monitor name
MESSAGE	VARCHAR(128)	<u>message</u> - Control table message
MESSAGE_TIME	TIMESTAMP	<u>message_time</u> - Timestamp control table message
PARTITION_NUMBER	SMALLINT	<u>partition_number</u> - Partition number

### Accessing event information written by an activity event monitor to a table

Activity event monitors can write their output to tables, files, and pipes. For more information about using data written to files and pipes, see [“Event monitor self-describing data stream” on page 127](#).

<sup>5</sup> Some columns returned in the ACTIVITY\_*evmon-name* are dependent on the snapshot monitoring infrastructure. The snapshot statement switch must be enabled (using the DBM parameter DFT\_MON\_STMT) to return activity information for them. The metrics returned in these columns do not always align strictly with activity boundaries. To get more accurate activity metrics, use the corresponding columns with the same names that are returned in the ACTIVITYMETRICS\_*evmon-name* table, except for ROWS\_READ, now called ROWS\_FETCHED, and USER\_CPU\_TIME and SYSTEM\_CPU\_TIME, which are now combined into TOTAL\_CPU\_TIME.

## Before you begin

You must have created and activated an activity event monitor and enabled data collection.

## About this task

The tables that an activity event monitor produces are described in [“Target tables, control tables, and event monitor table management”](#) on page 109.

## Procedure

To access the data produced by an activity event monitor:

1. Formulate a query that returns the columns that you want to see.  
For example, if you are interested in information about the text of the statements that are associated with a specific unit of work, you might formulate a query such as the one that follows:

```
SELECT UOW_ID, SUBSTR(STMT_TEXT, 1,70) AS STMT_TEXT FROM ACTIVITYSTMT_ACTEVMON
WHERE UOW_ID=11
```

In this case, the event monitor is named `actevmon`.

2. Run the query.

The preceding query might return results similar to the ones that follow:

```
UOW_ID  STMT_TEXT
-----
11 select * from gosaleshr.employee_expense_detail order by expense_date
1 record(s) selected.
```

## Results

### Example

If you want to access the data in the `DETAILS_XML` column of the `ACTIVITY` table, you can use any of the interfaces that are provided for this purpose. For example, to see metrics information that an activity event monitor collects for a unit of work, you might use a statement such as the one that follows:

```
SELECT SUBSTR(B.METRIC_NAME, 1, 20) METRIC_NAME, B.VALUE
FROM ACTIVITY_ACTEVMON AS A,
TABLE(MON_FORMAT_XML_METRICS_BY_ROW(A.DETAILS_XML)) AS B
WHERE UOW_ID=23
ORDER BY B.VALUE DESC
```

This statement returns all of the activity metrics collected for the unit of work with the `UOW_ID` of 23:

```
METRIC_NAME          VALUE
-----
TOTAL_CPU_TIME      140625
ROWS_READ           977
TOTAL_ACT_TIME      880
STMT_EXEC_TIME      880
COORD_STMT_EXEC_TIME 880
TOTAL_SECTION_PROC_T 880
TOTAL_SECTION_TIME  880
:                   :
FCM_TO_SEND_WAITS_TO 0
FCM_MESSAGE_SEND_WAI 0
FCM_SEND_WAITS_TOTAL 0
FCM_RECV_WAITS_TOTAL 0
92 record(s) selected.
```

For more information about working with XML data returned by event monitors, see [“Interfaces that return monitor data in XML documents”](#) on page 15.

### **Example: Capturing activity information related to the execution of a statement**

If you identify a statement that is taking a long time to execute, you can define a threshold that causes an activity event monitor to capture information about the execution of that statement when the threshold is exceeded. You can then correlate statement execution information with information collected by the activity event monitor to view activity metrics that can help you understand what might be causing the slowdown.

### **Before you begin**

Before capturing activity information, you must identify the statement in question; for example, a user or application developer might complain that a specific statement runs longer than expected. Or, you might identify a statement that is taking longer to run by using the package cache event monitor.

### **About this task**

In this example, the query that is being investigated runs as part of an application. The query is as follows:

```
SELECT DISTINCT PARTS_BIN FROM STOCK WHERE PART_NUMBER = ?
```

One possible reason for a slowdown might be unfavorable data distribution. For example, if the STOCK table has only a few rows for most part numbers, but has several thousand for one particular part number, it takes longer to run this SELECT statement. The example that follows shows how you can retrieve the actual values that are processed for the parameter marker ("?") by the activity associated with the preceding query.

### **Procedure**

To test the hypothesis that unfavorable data distribution is the cause of the slow-running query, you can create a threshold for the statement in question. Then you can use the threshold and activity event monitors to capture information about the execution of that particular statement. From this information, you can determine the actual value that was processed by the query that ran for longer than expected.

1. Create a threshold for the statement in question, specifying that a threshold violation event occurs when the statement runs for longer than 10 seconds:

```
CREATE THRESHOLD TH1
  FOR STATEMENT TEXT 'SELECT DISTINCT PARTS_BIN
  FROM STOCK WHERE PART_NUMBER = ?' ACTIVITIES
  ENFORCEMENT DATABASE
  WHEN ACTIVITYTOTALTIME > 10 SECONDS
  COLLECT ACTIVITY DATA WITH DETAILS, SECTION AND VALUES
  CONTINUE
```

2. Create a threshold event monitor to record threshold violations:

```
CREATE EVENT MONITOR STMT_THRESH_VIOLATIONS
  FOR THRESHOLD VIOLATIONS
  WRITE TO TABLE
  AUTOSTART
```

3. Create an activity event monitor to record detailed activity information:

```
CREATE EVENT MONITOR ACTIVITIES
  FOR ACTIVITIES
  WRITE TO TABLE
```

4. Enable the new event monitors:

```
SET EVENT MONITOR ACTIVITIES STATE 1
SET EVENT MONITOR STMT_THRESH_VIOLATIONS STATE 1
```

5. Run the application that executes the statement. If a threshold violation occurs, the threshold violations event monitor STMT\_THRESH\_VIOLATIONS records information about the threshold violation; information about the activity associated with the threshold violation is recorded by the activity event monitor ACTIVITIES.

- To determine whether a threshold violation occurred, query the number of violations recorded by the threshold event monitor for the threshold TH1 defined in step “1” on page 263. To perform this query, join the view SYSCAT.THRESHOLDS with the table that was produced by the thresholds event monitor that contains the threshold violation information. This join is necessary because the threshold name TH1 is maintained in SYSCAT.THRESHOLDS:

```
SELECT COUNT(1) NUM_VIOLATIONS
FROM THRESHOLDVIOLATIONS_DB2THRESHOLDVIOLATIONS T
JOIN SYSCAT.THRESHOLDS S ON T.THRESHOLDID = S.THRESHOLDID
WHERE S.THRESHOLDNAME = 'TH1';
```

```
NUM_VIOLATIONS
-----
1

1 record(s) selected.
```

In this case, there was one threshold violation; one execution of the statement identified in step “1” on page 263 ran for longer than 10 seconds.

- Examine the data (the part number) that is represented by the parameter marker (“?”) in the statement that you identified in “1” on page 263.

In the following example, the SELECT statement retrieves the value for the parameter marker (represented by STMT\_VALUE\_DATA in the SQL that follows) from one of the ACTIVITYVALS tables that the activity event monitor produces:

```
SELECT SUBSTR(V.STMT_VALUE_DATA, 1, 80) PARAM_MARKER_VALUE
FROM ACTIVITYVALS_ACTIVITIES V
JOIN THRESHOLDVIOLATIONS_STMT_THRESH_VIOLATIONS T
ON T.APPL_ID = V.APPL_ID
AND T.UOW_ID = V.UOW_ID
AND T.ACTIVITY_ID = V.ACTIVITY_ID
JOIN SYSCAT.THRESHOLDS S
ON T.THRESHOLDID = S.THRESHOLDID
WHERE S.THRESHOLDNAME = 'TH1';
```

In the preceding example, the select statement retrieves the value for the parameter marker (STMT\_VALUE\_DATA) from the one of the tables produced by the activity event monitor.

```
PARAM_MARKER_VALUE
-----
475299
```

- Now that you know the value for the PART\_NUMBER associated with the long-running statement, you can examine the STOCK table to see if there is anything about the occurrences of that part number in the table that might lead to longer query times. For example, many rows that contain 475299 as the value for the PART\_NUMBMER (as compared to the number of rows for other part numbers) might be a reason that the query runs longer when this value is encountered.

### Variation: Defining a threshold for a statement by using the executable ID

In the preceding example, the threshold is identified in step “1” on page 263 explicitly, by using the actual text of the statement. You can also define the threshold indirectly, identifying the executable ID for a statement contained in the package cache. For example, you can define the threshold as follows:

```
CREATE THRESHOLD TH1
FOR STATEMENT REFERENCE
x'010000000000000000000000200000000000000000000000000000020020100304162158584850' ACTIVITIES
ENFORCEMENT DATABASE
WHEN ACTIVITYTOTALTIME > 10 SECONDS
COLLECT ACTIVITY DATA WITH DETAILS, SECTION AND VALUES
CONTINUE;
```

In this example, the executable ID that follows the keywords STATEMENT REFERENCE is used to look up the corresponding statement text in the package cache. The executable ID for a statement can be determined by examining the package cache. For more information about how to view information

contained in the package cache, including the executable ID for a statement, see [“Using package cache information to identify statements that are candidates for performance tuning”](#) on page 250 .

If the executable ID is found in the package cache, the associated statement text is retrieved from the package cache and is used for defining the statement threshold. For statements in static SQL sections, if the executable ID is not in the package cache, the statement text is retrieved from the system catalogs. For statements in dynamic SQL sections, consider using the PREPARE statement to create a prepared statement from the statement string. If the executable ID cannot be found in the package cache or the system catalogs, an error (SQL4721N) is returned.

## Statistics event monitoring

The statistics event monitor captures data that can be used to measure different aspects of system operation.

You can use the statistics event monitor to collect two types of information:

### Metrics

Metrics are request monitor elements that capture measurement information about the system.

These metrics include time-spent monitor elements like the time waited on locks and counter monitor elements like the number of deadlocks that occurred. Collection of these metrics can be configured for the entire database with the **mon\_req\_metrics** database configuration parameter, or for specific service classes through the COLLECT REQUEST METRICS clause of CREATE or ALTER SERVICE CLASS statements. Some system metrics are collected as part of the **details\_xml** and **metrics** monitor elements in the EVENT\_SCSTATS, EVENT\_SUPERCLASSSTATS and EVENT\_WLSTATS logical data groups. Both these monitor elements are XML documents.

### Statistics

Statistics are maintained for workload manager objects. Workload manager objects include service classes, work classes, workloads, and threshold queues. These statistics include high watermark monitor elements like temporary table space usage and calculated monitor elements like estimated cost averages. The statistics reside in memory and can be viewed in real time by using workload manager statistics table functions. Alternatively, or the statistics can be collected and sent to a statistics event monitor where they can be viewed later for historical analysis. By default, a minimal set of statistics is collected for each workload manager object. You can modify the scope of statistics collection by using the clauses in the CREATE or ALTER statements for the various workload manager objects.

The XML documents in the **details\_xml** and **metrics** monitor elements contain the same metrics with one important difference. The metrics in **details\_xml** generally start at 0 and continue to accumulate until the next database activation, while the metrics in **metrics** are calculated to show the change in value for the metric since the last time statistics were collected. The schema for the XML documents returned is available in the file `sql1lib/misc/DB2MonCommon.xsd`. The top-level element is **system\_metrics**.

In addition to viewing system metrics from the XML document in the **metrics** monitor element, you can also view the individual metrics directly from the output associated with the EVENT\_SCMETRICS, EVENT\_SUPERCLASSMETRICS and EVENT\_WLMETRICS logical data groups.

**Important:** Starting with Version 10.1 Fix Pack 1, the XML document in **details\_xml** is deprecated for the statistics event monitor and might be removed in a future release. If you use the XML metrics data returned in **details\_xml**, start by using the **metrics** document instead. Alternatively, you can include the EVENT\_SCMETRICS, EVENT\_SUPERCLASSMETRICS and EVENT\_WLMETRICS logical data groups in the information collected by the event monitor, and then you can access the metrics monitor elements directly.

The metrics collected by the statistics event monitor are the same set of metrics that are reported by the MON\_GET\_SERVICE\_SUBCLASS\_DETAILS, MON\_GET\_SERVICE\_SUPERCLASS\_DETAILS and MON\_GET\_WORKLOAD\_DETAILS table functions. The XML document in the DETAILS column of the tables returned by these two table functions contain many other monitor elements in addition to the system metrics monitor elements.

Note that the metrics from background **EDUs** such as **prefetchers** and page cleaners are not rolled up to workloads or service classes.

System metrics monitor elements are only collected for a request if the request is processed by an agent in a service subclass whose parent service superclass has request monitor element collection enabled, or if system metrics collection is enabled for the entire database. If system metrics collection is disabled at the database level, as well as for a service superclass, the metrics reported in the **details\_xml** document stop increasing (or remain at 0 if request metrics were disabled at database activation time).

### **Data generated by statistics event monitors**

Statistics event monitors record statistics events that occur when using the database. The definition of the statistics event monitor specifies where the database records the events. You can choose to have the output from a statistics event monitor written to regular tables, files, or named pipes.

Regardless of the output format you choose, all data captured by statistics event monitors is written to one of the following logical data groups: The statistics event monitor can write captured data for the following logical data groups to tables, files, or named pipes:

- [EVENT\\_SCSTATS](#)
- [EVENT\\_WCSTATS](#)
- [EVENT\\_WLSTATS](#)
- [EVENT\\_QSTATS](#)
- [EVENT\\_HISTOGRAMBIN](#)

If you choose to have the statistics event monitor data written to regular tables, then the following three additional logical data groups are available:

- [EVENT\\_SCMETRICS](#)
- [EVENT\\_WLMETRICS](#)
- The CONTROL logical data group is used to generate metadata about the event monitor itself

#### *Information written to tables for a statistics event monitor*

When you choose WRITE TO TABLE as the output type for a statistics event monitor, a number of tables are produced. Each table contains monitor elements from one or more logical data groups.

The following table contains a list of the logical data groups and associated tables used by the statistics event monitor. The default table name for each logical data group is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor when it was created by using the CREATE EVENT MONITOR statement. The table names shown are the default table names when a name is not specified as part of the CREATE EVENT MONITOR statement.

<b>Default table name</b>	<b>Logical data groups reported</b>
<i>QSTATS_evmon-name</i>	Refer to “ <a href="#">event_qstats logical data group</a> ” on page 61 in “Event monitor logical data groups and monitor elements”
<i>SCSTATS_evmon-name</i>	Refer to “ <a href="#">event_scstats logical data group</a> ” on page 69 in “Event monitor logical data groups and monitor elements”
<i>SUPERCLASSMETRICS_evmon-name</i>	Refer to “ <a href="#">event_superclassmetrics logical data group</a> ” on page 72 in “Event monitor logical data groups and monitor elements”
<i>SUPERCLASSTATS_evmon-name</i>	Refer to “ <a href="#">event_superclasstats logical data group</a> ” on page 79 in “Event monitor logical data groups and monitor elements”

Table 38. Tables produced by STATISTICS write-to-table event monitors (continued)

Default table name	Logical data groups reported
HISTOGRAMBIN_evmon-name	Refer to “event_histogrambin logical data group” on page 61 in “Event monitor logical data groups and monitor elements”
WCSTATS_evmon-name	Refer to “event_wcstats logical data group” on page 83 in “Event monitor logical data groups and monitor elements”
WLSTATS_evmon-name	Refer to “event_wlstats logical data group” on page 90 in “Event monitor logical data groups and monitor elements”
SCMETRICS_evmon-name	Refer to “event_scmetrics logical data group” on page 62 in “Event monitor logical data groups and monitor elements”
WLMETRICS_evmon-name	Refer to “event_wlmetrics logical data group” on page 83 in “Event monitor logical data groups and monitor elements”
OSMETRICS_evmon-name	Refer to “event_osmetrics logical data group” on page 62 in “Event monitor logical data groups and monitor elements”
CONTROL_evmon-name	The CONTROL logical group consists of selected elements from one or more of the event_dbheader, event_start and event_overflow logical data groups.

To restrict the output of the event monitor to specific tables, specify the names of the logical groups for which you want tables produced in the CREATE EVENT MONITOR or ALTER EVENT MONITOR statements. You can refer to the reference topics for those statements for details.

## Control table

Table 39. Information returned for a statistics event monitor: Default table name: CONTROL\_evmon-name

Column name	Data type	Description
PARTITION_KEY	INTEGER	partition_key - Partitioning key
EVENT_MONITOR_NAME	VARCHAR(128)	event_monitor_name - Event monitor name
MESSAGE	VARCHAR(128)	message - Control table message
MESSAGE_TIME	TIMESTAMP	message_time - Timestamp control table message
PARTITION_NUMBER	SMALLINT	partition_number - Partition number

Information written to XML for system\_metrics and activity\_metrics monitor elements

The **activity\_metrics** monitor element is reported in the MON\_GET\_ACTIVITY\_DETAILS table function, the MON\_GET\_PKG\_CACHE\_STMT\_DETAILS table function, and the activity event monitor. The **system\_metrics** monitor element is reported in the MON\_GET\_CONNECTION\_DETAILS, MON\_GET\_UNIT\_OF\_WORK\_DETAILS, MON\_GET\_SERVICE\_SUBCLASS\_DETAILS, MON\_GET\_WORKLOAD\_DETAILS table functions, and the statistics event monitor. This is also documented in the sqllib/misc/DB2MonCommon.xsd file.

## system\_metrics

System level metrics.

**Element content:** ([“wlm\\_queue\\_time\\_total”](#) on page 290, [“wlm\\_queue\\_assignments\\_total”](#) on page 290, [“fcm\\_tq\\_recv\\_wait\\_time”](#) on page 290, **Attributes:**

QName	Type	Fixed	Default	Use	Annotation
release	xs:long			required	
ANY attribute from ANY namespace					

**stmt\_value\_index**

The element represents the position of the input parameter marker or host variable used in the SQL statement. See monitor element [“stmt\\_value\\_index - Value index” on page 1494](#) for more details.

**Contained by:**

**Element content:**

Type	Facet
xs:int	

## stmt\_value\_isnull

The element shows whether a data value associated with the SQL statement is the NULL value. See monitor element [“stmt\\_value\\_isnull - Value has null value monitor element”](#) on page 1494 for more details.

**Contained by:**

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:int			required	

## stmt\_value\_isreopt

The element shows whether the variable was used during statement reoptimization. See monitor element [“stmt\\_value\\_isreopt - Variable used for statement reoptimization monitor element”](#) on page 1495 for more details.

**Contained by:**

**Attributes:**

QName	Type	Fixed	Default	Use	Annotation
id	xs:int			required	

## stmt\_value\_type

The element contains a string representation of the type of data value associated with an SQL statement. See monitor element [“stmt\\_value\\_type - Value type monitor element”](#) on page 1496 for more details.

**Contained by:**

**Element content:**

Type	Facet
xs:string	Max length: 16

## stmt\_value\_data

The element contains a string representation of a data value associated with an SQL statement. See monitor element [“stmt\\_value\\_data - Value data ”](#) on page 1493 for more details.

**Contained by:**

**Element content:**

Type	Facet
xs:string	Max length: 32768

## agent\_wait\_time

See monitor element [“agent\\_wait\\_time - Agent wait time monitor element”](#) on page 641 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## agent\_waits\_total

See monitor element [“agent\\_waits\\_total - Total agent waits monitor element”](#) on page 643 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long

## act\_rqsts\_total

See monitor element [“act\\_rqsts\\_total - Total activity requests monitor elements”](#) on page 599 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## total\_stats\_fabrication\_proc\_time

See monitor element [“total\\_stats\\_fabrication\\_proc\\_time - Total statistics fabrication processing time monitor element”](#) on page 1650 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## total\_stats\_fabrication\_time

See monitor element [“total\\_stats\\_fabrication\\_time - Total statistics fabrication time monitor element”](#) on page 1651 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## total\_stats\_fabrications

See monitor element [“total\\_stats\\_fabrications - Total statistics fabrications monitor elements”](#) on page 1653 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### **total\_sync\_runstats\_proc\_time**

See monitor element [“total\\_sync\\_runstats\\_proc\\_time - Total synchronous RUNSTATS processing time monitor element”](#) on page 1655 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### **total\_sync\_runstats\_time**

See monitor element [“total\\_sync\\_runstats\\_time - Total synchronous RUNSTATS time monitor elements”](#) on page 1654 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### **total\_sync\_runstats**

See monitor element [“total\\_sync\\_runstats - Total synchronous RUNSTATS activities monitor element”](#) on page 1657 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### **app\_act\_completed\_total**

See monitor element [“app\\_act\\_completed\\_total - Total successful external coordinator activities monitor element”](#) on page 651 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### **app\_act\_aborted\_total**

See monitor element [“app\\_act\\_aborted\\_total - Total failed external coordinator activities monitor element”](#) on page 650 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## app\_act\_rejected\_total

See monitor element [“app\\_act\\_rejected\\_total - Total rejected external coordinator activities monitor element”](#) on page 653 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## total\_connect\_request\_proc\_time

See monitor element [“total\\_connect\\_request\\_proc\\_time - Total connection or switch user request processing time monitor element”](#) on page 1580 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## total\_connect\_request\_time

See monitor element [“total\\_connect\\_request\\_time - Total connection or switch user request time monitor element”](#) on page 1582 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## total\_connect\_requests

See monitor element [“total\\_connect\\_requests - Connection or switch user requests monitor element”](#) on page 1581 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## total\_connect\_authentication\_proc\_time

See monitor element [“total\\_connect\\_authentication\\_proc\\_time - Total connection authentication processing time monitor element”](#) on page 1576 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### **total\_connect\_authentication\_time**

See monitor element [“total\\_connect\\_authentication\\_time - Total connection or switch user authentication request time monitor element”](#) on page 1579 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### **total\_connect\_authentications**

See monitor element [“total\\_connect\\_authentications - Connections or switch user authentications performed monitor element”](#) on page 1578 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### **uow\_client\_idle\_wait\_time**

See monitor element [“uow\\_client\\_idle\\_wait\\_time - Client idle time within a unit of work monitor element”](#) on page 1674 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### **dynamic\_sql\_stmts**

See monitor element [“dynamic\\_sql\\_stmts - Dynamic SQL Statements Attempted ”](#) on page 830 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### **static\_sql\_stmts**

See monitor element [“static\\_sql\\_stmts - Static SQL Statements Attempted ”](#) on page 1475 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## failed\_sql\_stmts

See monitor element [“failed\\_sql\\_stmts - Failed Statement Operations ”](#) on page 866 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## select\_sql\_stmts

See monitor element [“select\\_sql\\_stmts - Select SQL Statements Executed ”](#) on page 1408 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## uid\_sql\_stmts

See monitor element [“uid\\_sql\\_stmts - Update/Insert/Merge/Delete SQL Statements Executed ”](#) on page 1671 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## ddl\_sql\_stmts

See monitor element [“ddl\\_sql\\_stmts - Data Definition Language \(DDL\) SQL Statements ”](#) on page 801 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## merge\_sql\_stmts

See monitor element [“merge\\_sql\\_stmts - Merge SQL statements executed monitor element”](#) on page 1079 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### xquery\_stmts

See monitor element [“xquery\\_stmts - XQuery Statements Attempted”](#) on page 1710 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### implicit\_rebinds

See monitor element [“implicit\\_rebinds - number of implicit rebinds monitor element”](#) on page 959 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### binds\_precompiles

See monitor element [“binds\\_precompiles - Binds/Precompiles Attempted ”](#) on page 685 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### call\_sql\_stmts

See monitor element [“call\\_sql\\_stmts - CALL SQL statements executed monitor element”](#) on page 694 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

### total\_backup\_proc\_time

See monitor element [“total\\_backup\\_proc\\_time - Total non-wait time for online backups monitor element”](#) on page 1556 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## total\_backup\_time

See monitor element [“total\\_backup\\_time - Total elapsed time for doing online backups monitor element”](#) on page 1557 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## total\_backups

See monitor element [“total\\_backups - Total online backups monitor element”](#) on page 1558 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268

**Element content:**

Type	Facet
xs:long	

## wlm\_queue\_time\_total

See monitor element [“wlm\\_queue\\_time\\_total - Workload manager total queue time monitor element”](#) on page 1700 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268 [“activity\\_metrics”](#) on page 270

**Element content:**

Type	Facet
xs:long	

## wlm\_queue\_assignments\_total

See monitor element [“wlm\\_queue\\_assignments\\_total - Workload manager total queue assignments monitor element”](#) on page 1699 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268 [“activity\\_metrics”](#) on page 270

**Element content:**

Type	Facet
xs:long	

## fcm\_tq\_recv\_wait\_time

See monitor element [“fcm\\_tq\\_recv\\_wait\\_time - FCM table queue received wait time monitor element”](#) on page 897 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268 [“activity\\_metrics”](#) on page 270

**Element content:**

Type	Facet
xs:long	

### **fcm\_message\_rcv\_wait\_time**

See monitor element [“fcm\\_message\\_rcv\\_wait\\_time - FCM message received wait time monitor element”](#) on page 869 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268 [“activity\\_metrics”](#) on page 270

**Element content:**

Type	Facet
xs:long	

### **fcm\_tq\_send\_wait\_time**

See monitor element [“fcm\\_tq\\_send\\_wait\\_time - FCM table queue send wait time monitor element”](#) on page 903 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268 [“activity\\_metrics”](#) on page 270

**Element content:**

Type	Facet
xs:long	

### **fcm\_message\_send\_wait\_time**

See monitor element [“fcm\\_message\\_send\\_wait\\_time - FCM message send wait time monitor element”](#) on page 876 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268 [“activity\\_metrics”](#) on page 270

**Element content:**

Type	Facet
xs:long	

### **lock\_wait\_time**

See monitor element [“lock\\_wait\\_time - Time waited on locks monitor element”](#) on page 1027 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268 [“activity\\_metrics”](#) on page 270

**Element content:**

Type	Facet
xs:long	

### **lock\_waits**

See monitor element [“lock\\_waits - Lock waits monitor element”](#) on page 1032 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268 [“activity\\_metrics”](#) on page 270

**Element content:**

Type	Facet
xs:long	

## direct\_read\_time

See monitor element [“direct\\_read\\_time - Direct read time monitor element”](#) on page 815 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268 [“activity\\_metrics”](#) on page 270

**Element content:**

Type	Facet
xs:long	

## direct\_read\_reqs

See monitor element [“direct\\_read\\_reqs - Direct read requests monitor element”](#) on page 813 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268 [“activity\\_metrics”](#) on page 270

**Element content:**

Type	Facet
xs:long	

## direct\_write\_time

See monitor element [“direct\\_write\\_time - Direct write time monitor element”](#) on page 822 for more details.

**Contained by:** [“system\\_metrics”](#) on page 268 [“activity\\_metrics”](#) on page 270

**Element content:**

Type	Facet
xs:long	

## direct\_write\_reqs

See monitor element [“direct\\_write\\_reqs - Direct write requests monitor element”](#) on page 820 for more details.

## Database event monitoring

### **Data generated by database event monitors**

Database event monitors produce data about database-level counters. You can choose to have the output from a database event monitor to regular tables, files or pipes.

Regardless of the output format you choose, all database event data comes from one of two logical groups:

- [“event\\_db logical data group” on page 56](#)
- [“event\\_dbmemuse logical data group” on page 58](#)

In addition, if you choose to have the database event data written to tables, data from an additional group (CONTROL) is used to generate metadata about the event monitor itself.

#### *Information written to tables for a database event monitor*

Information written by an database event monitor when the WRITE TO TABLE option is specified.

When you choose WRITE TO TABLE as the output type for the database event monitor, by default, three tables are produced, each containing monitor elements from one or more logical data groups:

<i>Table 40. Tables produced by DATABASE write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by <i>evmon-name</i> in the table names shown in the following table) in the CREATE EVENT MONITOR statement.</i>	
Default table name	Logical data groups reported
DB_ <i>evmon-name</i>	Refer to <a href="#">event_db</a> in "Event monitor logical data groups and monitor elements"
DBMEMUSE_ <i>evmon-name</i>	Refer to <a href="#">event_dbmemuse</a> in "Event monitor logical data groups and monitor elements"
CONTROL_ <i>evmon-name</i>	The CONTROL logical group consists of selected elements from one or more of the <a href="#">event_dbheader</a> , <a href="#">event_start</a> and <a href="#">event_overflow</a> logical data groups.

To restrict the output of the event monitor to specific tables, specify the names of the logical groups for which you want tables produced in the CREATE EVENT MONITOR or ALTER EVENT MONITOR statements. Refer to the reference topics for those statements for details.

For information about the output returned when the event monitor writes to a file or named pipe, see [“Event monitor self-describing data stream” on page 127](#).

### Control table

<i>Table 41. Information returned for a database event monitor: Default table name: CONTROL_<i>evmon-name</i></i>		
Column name	Data type	Description
EVENT_MONITOR_NAME	VARCHAR(128)	<a href="#">event_monitor_name</a> - Event monitor name

Table 41. Information returned for a database event monitor: Default table name: CONTROL\_evmon-name (continued)

Column name	Data type	Description
MESSAGE	VARCHAR(128)	message - Control table message
MESSAGE_TIME	TIMESTAMP	message_time - Timestamp control table message

## Threshold violation event monitoring

### Data generated by threshold violation event monitors

Threshold violation event monitors produce data about threshold violations. You can choose to have the output from a database event monitor to regular tables, files or pipes.

Regardless of the output format you choose, all threshold violation event data comes from the event\_thresholdviolations logical data group. In addition, if you choose to have the event data written to tables, data from an additional group (CONTROL) is used to generate metadata about the event monitor itself.

#### Information written to tables for a threshold violation event monitor

Information written by a threshold violations event monitor when the WRITE TO TABLE option is specified.

The sections that follows illustrates the output of a threshold violations event monitor when the WRITE TO TABLE option is used on the CREATE EVENT MONITOR statement. For information about the output returned when the event monitor writes to a file or named pipe, see “Event monitor self-describing data stream” on page 127.

Table 42. Tables produced by THRESHOLD write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by evmon-name in the table names shown in the following table) in the CREATE EVENT MONITOR statement.

Default table name	Logical data groups reported
THRESHOLDVIOLATIONS_evmon-name	Refer to event_thresholdviolations in "Event monitor logical data groups and monitor elements"
CONTROL_evmon-name	The CONTROL logical group consists of selected elements from one or more of the event_dbheader, event_start and event_overflow logical data groups.

To restrict the output of the event monitor to specific tables, specify the names of the logical groups for which you want tables produced in the CREATE EVENT MONITOR or ALTER EVENT MONITOR statements. Refer to the reference topics for those statements for details.

### Control table

Table 43. Information returned for a threshold violations event monitor: Table name: CONTROL\_evmon-name

Column Name	Data Type	Description
PARTITION_KEY	INTEGER	“partition_key - Partitioning key monitor element” on page 1137
EVENT_MONITOR_NAME	VARCHAR(128 )	event_monitor_name - Event monitor name

Table 43. Information returned for a threshold violations event monitor: Table name: CONTROL\_evmon-name (continued)

Column Name	Data Type	Description
MESSAGE	VARCHAR(128)	<a href="#">message</a> - Control table message
MESSAGE_TIME	TIMESTAMP	<a href="#">message_time</a> - Timestamp control table message
PARTITION_NUMBER	SMALLINT	<a href="#">partition_number</a> - Partition number

## Statement event monitoring

### Data generated by statement event monitors

Statement event monitors produce data about statements that run on the system. You can choose to have the output from a database event monitor to regular tables, files or pipes.

Regardless of the output format you choose, all statement event data comes from one of three logical groups:

- [“event\\_stmt logical data group” on page 71](#)
- [“event\\_connheader logical data group” on page 55](#)
- [“event\\_subsection logical data group” on page 72](#)

In addition, if you choose to have statement event data written to tables, data from an additional group (CONTROL) is used to generate metadata about the event monitor itself.

### Information written to tables for a statement event monitor

Information written by a statement event monitor when the WRITE TO TABLE option is specified.

The sections that follows illustrates the output of a statement event monitor when the WRITE TO TABLE option is used on the CREATE EVENT MONITOR statement. For information about the output returned when the event monitor writes to a file or named pipe, see [“Event monitor self-describing data stream” on page 127](#).

Table 44. Tables produced by STATEMENT write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by evmon-name in the table names shown in the following table) in the CREATE EVENT MONITOR statement.

Default table name	Logical data groups reported
STMT_evmon-name	Refer to <a href="#">“event_stmt logical data group” on page 71</a> in "Event monitor logical data groups and monitor elements".
CONNHEADER_evmon-name	Refer to <a href="#">“event_connheader logical data group” on page 55</a> in "Event monitor logical data groups and monitor elements".
CONNHEADER_evmon-name	Refer to <a href="#">“event_connheader logical data group” on page 55</a> in "Event monitor logical data groups and monitor elements"
SUBSECTION_evmon-name	Refer to <a href="#">“event_subsection logical data group” on page 72</a> in "Event monitor logical data groups and monitor elements".  <b>Note:</b> This logical data group is generated only in partitioned database environments.

*Table 44. Tables produced by STATEMENT write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by *evmon-name* in the table names shown in the following table) in the CREATE EVENT MONITOR statement. (continued)*

Default table name	Logical data groups reported
<u>CONTROL_</u> <i>evmon-name</i>	The CONTROL logical group consists of selected elements from one or more of the <u>event_dbheader</u> , <u>event_start</u> and <u>event_overflow</u> logical data groups.

To restrict the output of the event monitor to specific tables, specify the names of the logical groups for which you want tables produced in the CREATE EVENT MONITOR or ALTER EVENT MONITOR statements. Refer to the reference topics for those statements for details.

## Control table

*Table 45. Information returned for a statement event monitor: Default table name: CONTROL\_**evmon-name*

Column name	Data type	Description
EVENT_MONITOR_NAME	VARCHAR(128)	<u>event_monitor_name</u> - Event monitor name
MESSAGE	VARCHAR(128)	<u>message</u> - Control table message
MESSAGE_TIME	TIMESTAMP	<u>message_time</u> - Timestamp control table message

## Table event monitoring

### Data generated by table event monitors

Table event monitors produce aggregate metrics for tables in the database. You can choose to have the output from a database event monitor to regular tables, files or pipes.

**Note:** If you want more detailed usage information for a specific table object, consider creating a usage list for that object.

Regardless of the output format you choose, all table event data comes from the event\_table logical data group. In addition, if you choose to have statement event data written to tables, data from an additional group (CONTROL) is used to generate metadata about the event monitor itself.

### Information written to tables for a table event monitor

Information written by an table event monitor when the WRITE TO TABLE option is specified.

The sections that follows illustrates the output of a table event monitor when the WRITE TO TABLE option is used on the CREATE EVENT MONITOR statement. For information about the output returned when the event monitor writes to a file or named pipe, see [“Event monitor self-describing data stream”](#) on page 127.

*Table 46. Tables produced by TABLE write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by *evmon-name* in the table names shown in the following table) in the CREATE EVENT MONITOR statement.*

Default table name	Logical data groups reported
TABLE_	Refer to <u>event_table</u> in "Event monitor logical data groups and monitor elements"

*Table 46. Tables produced by TABLE write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by *evmon-name* in the table names shown in the following table) in the CREATE EVENT MONITOR statement. (continued)*

Default table name	Logical data groups reported
<u>CONTROL_</u> <i>evmon-name</i>	The CONTROL logical group consists of selected elements from one or more of the <u>event_dbheader</u> , <u>event_start</u> and <u>event_overflow</u> logical data groups.

To restrict the output of the event monitor to specific tables, specify the names of the logical groups for which you want tables produced in the CREATE EVENT MONITOR or ALTER EVENT MONITOR statements. Refer to the reference topics for those statements for details.

## Control table

*Table 47. Information returned for a table event monitor: Default table name: CONTROL\_**evmon-name*

Column name	Data type	Description
EVENT_MONITOR_NAME	VARCHAR(128)	<u>event_monitor_name</u> - Event monitor name
MESSAGE	VARCHAR(128)	<u>message</u> - Control table message
MESSAGE_TIME	TIMESTAMP	<u>message_time</u> - Timestamp control table message

## Buffer pool event monitoring

### ***Data generated by buffer pool event monitors***

Buffer pool event monitors produce aggregate metrics about buffer pool activity. You can choose to have the output from a database event monitor to regular tables, files or pipes.

Regardless of the output format you choose, all buffer pool event data comes from the event\_bufferpool logical data group. In addition, if you choose to have statement event data written to tables, data from an additional group (CONTROL) is used to generate metadata about the event monitor itself.

### *Information written to tables for a buffer pool event monitor*

Information written by a buffer pool event monitor when the WRITE TO TABLE option is specified.

The sections that follows illustrates the output of a buffer pool event monitor when the WRITE TO TABLE option is used on the CREATE EVENT MONITOR statement. For information about the output returned when the event monitor writes to a file or named pipe, see [“Event monitor self-describing data stream”](#) on page 127.

*Table 48. Tables produced by BUFFERPOOL write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by *evmon-name* in the table names shown in the following table) in the CREATE EVENT MONITOR statement.*

Default table name	Logical data groups reported
<u>BUFFERPOOL_</u> <i>evmon-name</i>	Refer to <u>event_bufferpool</u> in "Event monitor logical data groups and monitor elements"

*Table 48. Tables produced by BUFFERPOOL write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by *evmon-name* in the table names shown in the following table) in the CREATE EVENT MONITOR statement. (continued)*

Default table name	Logical data groups reported
<u>CONTROL_</u> <i>evmon-name</i>	The CONTROL logical group consists of selected elements from one or more of the <u>event_dbheader</u> , <u>event_start</u> and <u>event_overflow</u> logical data groups.

To restrict the output of the event monitor to specific tables, specify the names of the logical groups for which you want tables produced in the CREATE EVENT MONITOR or ALTER EVENT MONITOR statements. Refer to the reference topics for those statements for details.

## Control table

*Table 49. Information returned for a buffer pool event monitor: Default table name: CONTROL\_**evmon-name*

Column Name	Data Type	Description
EVENT_MONITOR_NAME	VARCHAR(128) )	<u>event_monitor_name</u> - Event monitor name
MESSAGE	VARCHAR(128) )	<u>message</u> - Control table message
MESSAGE_TIME	TIMESTAMP	<u>message_time</u> - Timestamp control table message

## Table space event monitoring

### **Data generated by table space event monitors**

Table space event monitors produce aggregate metrics for table spaces in the database. You can choose to have the output from a database event monitor to regular tables, files or pipes.

Regardless of the output format you choose, all table space event data comes from the event\_tablespace logical data group. In addition, if you choose to have statement event data written to tables, data from an additional group (CONTROL) is used to generate metadata about the event monitor itself.

### *Information written to tables for a table space event monitor*

Information written by a table space event monitor when the WRITE TO TABLE option is specified.

The sections that follows illustrates the output of a table space event monitor when the WRITE TO TABLE option is used on the CREATE EVENT MONITOR statement. For information about the output returned when the event monitor writes to a file or named pipe, see [“Event monitor self-describing data stream”](#) on page 127.

*Table 50. Tables produced by TABLESPACE write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by *evmon-name* in the table names shown in the following table) in the CREATE EVENT MONITOR statement.*

Default table name	Logical data groups reported
<u>TABLESPACE_</u> <i>evmon-name</i>	Refer to <u>event_tablespace</u> in "Event monitor logical data groups and monitor elements"

*Table 50. Tables produced by TABLESPACE write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by *evmon-name* in the table names shown in the following table) in the CREATE EVENT MONITOR statement. (continued)*

Default table name	Logical data groups reported
<u>CONTROL_</u> <i>evmon-name</i>	The CONTROL logical group consists of selected elements from one or more of the <u>event_dbheader</u> , <u>event_start</u> and <u>event_overflow</u> logical data groups.

To restrict the output of the event monitor to specific tables, specify the names of the logical groups for which you want tables produced in the CREATE EVENT MONITOR or ALTER EVENT MONITOR statements. Refer to the reference topics for those statements for details.

## Control table

*Table 51. Information returned for a table space event monitor: Default table name: CONTROL\_**evmon-name*

Column name	Data type	Description
EVENT_MONITOR_NAME	VARCHAR(128)	<u>event_monitor_name</u> - Event monitor name
MESSAGE	VARCHAR(128)	<u>message</u> - Control table message
MESSAGE_TIME	TIMESTAMP	<u>message_time</u> - Timestamp control table message

## Connection event monitoring

### ***Data generated by connections event monitors***

Connections event monitors capture metrics and other monitor elements for each connection to the database by an application. You can choose to have the output written to files, named pipes or regular tables.

Regardless of the output format you choose, all connections event data comes from one of three logical groups:

- event\_connheader
- event\_conn
- event\_connmemuse

In addition, if you choose to have the connections event data written to tables, data from an additional group (CONTROL) is used to generate metadata about the event monitor itself.

### *Information written to tables for a connections event monitor*

Information written by a connections event monitor when the WRITE TO TABLE option is specified.

When you choose WRITE TO TABLE as the output type for the connections event monitor, by default, four tables are produced, each containing monitor elements from one or more logical data groups:

Table 52. Tables produced by CONNECTIONS write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by *evmon-name* in the table names shown in the following table) in the CREATE EVENT MONITOR statement.

Default table name	Logical data groups reported
CONNHEADER_ <i>evmon-name</i>	Refer to <a href="#">event_connheader</a> in "Event monitor logical data groups and monitor elements"
CONN_ <i>evmon-name</i>	Refer to <a href="#">event_conn</a> in "Event monitor logical data groups and monitor elements"
CONMEMUSE_ <i>evmon-name</i>	Refer to <a href="#">event_connmemuse</a> in "Event monitor logical data groups and monitor elements"
CONTROL_ <i>evmon-name</i>	The CONTROL logical group consists of selected elements from one or more of the <a href="#">event_dbheader</a> , <a href="#">event_start</a> and <a href="#">event_overflow</a> logical data groups.

To restrict the output of the event monitor to specific tables, specify the names of the logical groups for which you want tables produced in the CREATE EVENT MONITOR or ALTER EVENT MONITOR statements. Refer to the reference topics for those statements for details.

For information about the output returned when the event monitor writes to a file or named pipe, see "Event monitor self-describing data stream" on page 127.

## Control table

Table 53. Information returned for a connections event monitor: Default table name: CONTROL\_*evmon-name*

Column Name	Data Type	Description
APPL_ID	VARCHAR(64)	<a href="#">appl_id</a> - Application ID
EVMON_FLUSHES	BIGINT	<a href="#">evmon_flushes</a> - Number of event monitor flushes
POOL_CUR_SIZE	BIGINT	<a href="#">pool_cur_size</a> - Current size of memory pool
POOL_ID	BIGINT	<a href="#">pool_id</a> - Memory pool identifier
POOL_LIST_ID	BIGINT	
POOL_MAX_SIZE	BIGINT	
POOL_WATERMARK	BIGINT	<a href="#">pool_watermark</a> - Memory pool watermark

## Transaction event monitoring

### Data generated by transaction event monitors

Transaction event monitors record information about database transactions.

**Note:** This event monitor has been deprecated. Its use is no longer recommended and it might be removed in a future release. Use the unit of work event monitor to monitor units of work instead.

Regardless of the output format you choose, all transaction event data comes from two logical groups:

- "[event\\_xact logical data group](#)" on page 91
- "[event\\_connheader logical data group](#)" on page 55

In addition, if you choose to have the transaction event data written to tables, data from an additional group (CONTROL) is used to generate metadata about the event monitor itself.

### Information written to tables for a transaction event monitor

Information written by a transaction event monitor when the WRITE TO TABLE option is specified.

The sections that follows illustrates the output of a transaction event monitor when the WRITE TO TABLE option is used on the CREATE EVENT MONITOR statement. For information about the output returned when the event monitor writes to a file or named pipe, see [“Event monitor self-describing data stream”](#) on page 127.

Default table name	Logical data groups reported
XACT_ <i>evmon-name</i>	Refer to <a href="#">“event_xact logical data group”</a> on page 91 in <a href="#">“Event monitor logical data groups and monitor elements”</a>
CONNHEADER_ <i>evmon-name</i>	Refer to <a href="#">“event_connheader logical data group”</a> on page 55 in <a href="#">“Event monitor logical data groups and monitor elements”</a>
CONTROL_ <i>evmon-name</i>	The CONTROL logical group consists of selected elements from one or more of the <a href="#">event_dbheader</a> , <a href="#">event_start</a> and <a href="#">event_overflow</a> logical data groups.

### Control table

Column name	Data type	Description
EVENT_MONITOR_NAME	VARCHAR(128)	<a href="#">event_monitor_name</a> - Event monitor name
MESSAGE	VARCHAR(128)	<a href="#">message</a> - Control table message
MESSAGE_TIME	TIMESTAMP	<a href="#">message_time</a> - Timestamp control table message

## Deadlock event monitoring

### Data generated by deadlock event monitors

Deadlock event monitors record information about deadlock conditions.

**Note:** This event monitor has been deprecated. It is no longer recommended and might be removed in a future release. Use the locking event monitor to monitor deadlocks instead.

Regardless of the output format you choose, all deadlock event data comes from three logical groups:

- [“event\\_connheader logical data group”](#) on page 55
- [“event\\_deadlock logical data group”](#) on page 59
- [“event\\_dlconn logical data group”](#) on page 60

In addition, if you choose to have the transaction event data written to tables, data from an additional group (CONTROL) is used to generate metadata about the event monitor itself.

*Information written to tables for a deadlock event monitor*

Information written by a deadlock event monitor when the WRITE TO TABLE option is specified.

The sections that follows illustrates the output of a deadlock event monitor when the WRITE TO TABLE option is used on the CREATE EVENT MONITOR statement. For information about the output returned when the event monitor writes to a file or named pipe, see [“Event monitor self-describing data stream”](#) on page 127.

<i>Table 56. Tables produced by DEADLOCK write-to-table event monitors. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor (as represented by <i>evmon-name</i> in the table names shown in the following table) in the CREATE EVENT MONITOR statement.</i>	
<b>Default table name</b>	<b>Logical data groups reported</b>
<i>CONNHEADER_</i> <u><i>evmon-name</i></u>	Refer to <a href="#">“event_connheader logical data group”</a> on page 55 in "Event monitor logical data groups and monitor elements"
<i>DEADLOCK_</i> <u><i>evmon-name</i></u>	Refer to <a href="#">“event_deadlock logical data group”</a> on page 59 in "Event monitor logical data groups and monitor elements"
<i>DLCONN_</i> <u><i>evmon-name</i></u>	Refer to <a href="#">“event_dlconn logical data group”</a> on page 60 in "Event monitor logical data groups and monitor elements"
<i>CONTROL_</i> <u><i>evmon-name</i></u>	The CONTROL logical group consists of selected elements from one or more of the <a href="#">event_dbheader</a> , <a href="#">event_start</a> and <a href="#">event_overflow</a> logical data groups.

**Control table**

<i>Table 57. Information returned for a deadlock event monitor: Default table name: CONTROL_</i> <u><i>evmon-name</i></u>		
<b>Column Name</b>	<b>Data Type</b>	<b>Description</b>
AGENT_ID	BIGINT	<a href="#">agent_id</a> - Application handle (agent ID) monitor element
APPL_ID	VARCHAR(64)	<a href="#">appl_id</a> - Application ID monitor element
APPL_ID_HOLDING_LK	VARCHAR(64)	<a href="#">appl_id_holding_lk</a> - Application ID Holding Lock monitor element
DATA_PARTITION_ID	INTEGER	<a href="#">data_partition_id</a> - Data partition identifier monitor element
DEADLOCK_ID	BIGINT	<a href="#">deadlock_id</a> - Deadlock Event Identifier monitor element
EVMON_ACTIVATES	BIGINT	<a href="#">evmon_activates</a> - Number of Event Monitor Activations monitor element
LOCK_ATTRIBUTES	BIGINT	<a href="#">lock_attributes</a> - Lock attributes monitor element
LOCK_COUNT	BIGINT	<a href="#">lock_count</a> - Lock count monitor element
LOCK_CURRENT_MODE	BIGINT	<a href="#">lock_current_mode</a> - Original lock mode before conversion monitor element

## Change history event monitoring

The change history event monitor captures information about events on the database server that might impact the running of your regular database workload. You can use the data captured by this event monitor to understand changes in the behavior, performance, or stability of your databases and database management system.

When your regular workload experiences a degradation in performance or unexpected behavior is observed, you can correlate the change in workload behavior with events captured by the change history event monitor. The following changes can have a negative impact on your database system.

- The unexpected creation or dropping of an index
- The failure of scheduled maintenance to run

- The changing of a database configuration parameter or database registry variable

Changes can be explicitly caused by a user. For example, an administrator might run a DDL statement that drops an index. Or, changes might occur implicitly or automatically without any user interaction. For example, the self-tuning memory manager (STMM) might change a configuration parameter, or automatic table reorganization might reorganize a table.

Manually tracking changes to the database server can be a difficult task. Historically, the information for different types of changes has been captured through different interfaces. For example, configuration updates are written to the diagnostic log files (for example, the db2diag log files), while utility progress is captured in the database history file. The change history event monitor provides you with a single interface that captures the events that change the behavior and performance characteristics of your database system. Using the event monitor tables, you can investigate any change events that are of interest.

The change history event monitor can capture change-related events for a number of actions and operations, including:

- Database and database manager configuration parameter changes
- Registry variable changes
- Execution of DDL statements
- Change history event monitor startup
- Execution of the following database utilities and commands:
  - LOAD
  - ADMIN\_MOVE\_TABLE procedure invocations
  - BACKUP DATABASE (ONLINE option only)
  - RESTORE DATABASE (ONLINE option only)
  - ROLLFORWARD DATABASE (ONLINE option only)
  - REDISTRIBUTE DATABASE PARTITION GROUP
  - REORG
  - RUNSTATS

Generally, information related to events that occur while the change history event monitor is inactive or the database is offline are not captured. However, the change history event monitor can be configured to capture the registry variable values that are in effect when the an event monitor is activated. Similarly, database and database manager configuration parameter values can be captured when a change history event monitor is activated. When capturing configuration parameter values, the event monitor can detect if any configuration parameters were changed while the event monitor was inactive, and so the event monitor captures configuration parameter values only if changes occur.

### ***Data generated by change history event monitors***

Change history event monitors capture information about activities that might impact the performance, behavior, and stability of databases and database management systems. The output from a change history event monitor is written to logical data groups, where each logical data group has an associated event monitor table.

A change-related action can generate one or more events in the change history event monitor. For example, a database configuration update generates a single event, while the execution of the REORG utility generates two events that mark the beginning and end of the REORG operation. There is a one-to-many mapping between an event and a logical data group. An event can write information to more than one logical data group and can write more than one entry (row) to the table associated with a given logical data group. Each change-related event is uniquely identified by the following three key fields:

#### **Event timestamp**

The time that the event occurred.

#### **Event ID**

A numeric token that ensures uniqueness in cases where the event timestamp is common.

## Member

The database manager process where the event occurred.

All logical groups contain these three fields and all records or rows corresponding to the same event contain the same values for these fields. These common values facilitate the joining of information across different logical data groups. Utility operations and configuration parameter updates on different members are captured as different events and result in different values for these key fields.

The change history event monitor only supports the TABLE target for event monitor logical data groups. The change history event monitor does not support UNFORMATTED EVENT TABLE, FILE, and PIPE targets.

The following table contains a list of the logical data groups and associated tables used by the change history event monitor. The default table name for each logical data group is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor when it was created using the CREATE EVENT MONITOR statement. The table names shown are the default table names when a name is not specified as part of the CREATE EVENT MONITOR statement.

Default table name	Logical data group
CHANGESUMMARY_evmon-name (see “CHANGESUMMARY logical data group” on page 352)	<u>CHANGESUMMARY</u>
DBDBMCFG_evmon-name (see “DBDBMCFG logical data group” on page 352)	<u>DBDBMCFG</u>
REGVAR_evmon-name (see “REGVAR logical data group” on page 352)	<u>REGVAR</u>
DDLSTMTEXEC_evmon-name (see “DDLSTMTEXEC logical data group” on page 352)	<u>DDLSTMTEXEC</u>
TXNCOMPLETION_evmon-name (see “TXNCOMPLETION logical data group” on page 353)	<u>TXNCOMPLETION</u>
EVMONSTART_evmon-name (see “EVMONSTART logical data group” on page 353)	<u>EVMONSTART</u>
UTILSTART_evmon-name (see “UTILSTART logical data group” on page 353)	<u>UTILSTART</u>
UTILLOCATION_evmon-name (see “UTILLOCATION logical data group” on page 353)	<u>UTILLOCATION</u>
UTILSTOP_evmon-name (see “UTILSTOP logical data group” on page 353)	<u>UTILSTOP</u>
UTILPHASE_evmon-name (see “UTILPHASE logical data group” on page 354)	<u>UTILPHASE</u>

The change history event monitor can capture a wide range of events. Not all events are of interest to all users. You can control which event types are captured by the change history event monitor by using the WHERE EVENT IN clause in the CREATE EVENT MONITOR statement when you create the event monitor.

The following table shows the actions on the database server that generate events available for capture by the change history event monitor. It also indicates which control options specified in the WHERE EVENT IN clause results in the capture of these events and which logical data groups are populated when the event is generated.

Table 59. Events generated by actions

Action	Event type	WHERE EVENT IN clause	Logical data group	Details
Changing a database configuration parameter	DBCFCG		CHANGESUMMARY DBDBMCFG	1 record written to CHANGESUMMARY 1 record written to DBDBMCFG for each changed parameter
Capturing all database configuration parameter values at event monitor startup if a database configuration parameter was changed while the event monitor was inactive	DBCFCGVALUES		CHANGESUMMARY DBDBMCFG	1 record written to CHANGESUMMARY 1 record written to DBDBMCFG for each parameter
Changing a database manager configuration parameter	DBMCFG		CHANGESUMMARY DBDBMCFG	1 record written to CHANGESUMMARY 1 record written to DBDBMCFG for each changed parameter
Capturing all database manager configuration parameter values at event monitor startup if a database manager configuration parameter was changed while the event monitor was inactive	DBMCFGVALUES		CHANGESUMMARY DBDBMCFG	1 record written to CHANGESUMMARY 1 record written to DBDBMCFG for each parameter
Changing a registry variable. Only immediate updates (registry variable changes that use the -immediate flag on the <b>db2set</b> command) generate events.	REGVAR		CHANGESUMMARY REGVAR	1 record written to CHANGESUMMARY 1 record written to REGVAR for each changed variable. Only registry variables that are set explicitly are captured. No records are written for variables that are implicitly set through an aggregate registry variable.

Table 59. Events generated by actions (continued)

Action	Event type	WHERE EVENT IN clause	Logical data group	Details
Capturing registry variable values at event monitor startup	REGVARVALUES		CHANGESUMMARY REGVAR	1 record written to CHANGESUMMARY 1 record written to REGVAR for each explicitly set variable
Executing a DDL statement successfully	DDLSTMTEEXEC		CHANGESUMMARY DDLSTMTEEXEC	1 record written to CHANGESUMMARY 1 record written to DDLSTMTEEXEC
Commit or rollback of a transaction containing a successfully executed DDL statement or the rollback to a savepoint containing a successfully executed DDL statement	TXNCOMPLETION		CHANGESUMMARY TXNCOMPLETION	1 record written to CHANGESUMMARY 1 record written to TXNCOMPLETION
Starting or stopping the event monitor	EVMONSTART		CHANGESUMMARY EVMONSTART	1 record written to CHANGESUMMARY 1 record written to EVMONSTART
Starting utility execution or resuming execution after being paused. This event is only generated on the coordinator member	UTILSTART		CHANGESUMMARY UTILSTART UTILLOCATION	1 record written to CHANGESUMMARY 1 record written to UTILSTART 0 or more records written to UTILLOCATION; 1 record for each file associated with a utility start.
Completing utility execution or pausing execution. This event is only generated on the coordinator member	UTILSTOP		CHANGESUMMARY UTILSTOP	1 record written to CHANGESUMMARY 1 record written to UTILSTOP
Processing of a utility starts on a member. This event is only generated in a multi-member environment	UTILSTARTPROC		CHANGESUMMARY UTILSTART	1 record written to CHANGESUMMARY 1 record written to UTILSTART

Table 59. Events generated by actions (continued)

Action	Event type	WHERE EVENT IN clause	Logical data group	Details
Processing of a utility stops on a member. This event is only generated in a multi-member environment	UTILSTOPPROC		CHANGESUMMARY UTILSTOP	1 record written to CHANGESUMMARY 1 record written to UTILSTOP
Starting the execution of a specific processing phase of a utility on a member	UTILPHASESTART		CHANGESUMMARY UTILPHASE	1 record written to CHANGESUMMARY 1 record written to UTILPHASE
Stopping the execution of a specific processing phase of a utility on a member	UTILPHASESTOP		CHANGESUMMARY UTILPHASE	1 record written to CHANGESUMMARY 1 record written to UTILPHASE

*CHANGESUMMARY logical data group*

The table for the CHANGESUMMARY logical data group is produced by the change history event monitor, where each row represents a unique change history event that occurred.

For information returned by a change history event monitor for the CHANGESUMMARY logical data group, refer to [CHANGESUMMARY](#) in "Event monitor logical data groups and monitor elements".

*DBDBMCFG logical data group*

The table for the DBDBMCFG logical data group is produced by the change history event monitor, where each row represents a configuration parameter that was updated as part of a DBCFG or DBMCFG event, or captured at event monitor startup as part of a DBCFGVALUES or DBMCFGVALUES event. The CFG\_COLLECTION\_TYPE monitor element identifies whether the record describes a configuration parameter update, or an initial value recorded at event monitor startup.

For information returned by a change history event monitor for the DBDBMCFG logical data group, refer to [DBDBMCFG](#) in "Event monitor logical data groups and monitor elements".

*REGVAR logical data group*

The table for the REGVAR logical data group is produced by the change history event monitor, where each row represents a registry variable that was updated as part of a REGVAR event, or captured at event monitor startup as part of a RERVARVALUES event. The REGVAR\_COLLECTION\_TYPE monitor element identifies whether the record describes an immediate registry variable update (*U*) or an initial value recorded at event monitor startup (*I*).

For information returned by a change history event monitor for the REGVAR logical data group, refer to [REGVAR](#) in "Event monitor logical data groups and monitor elements".

*DDLSTMTEEXEC logical data group*

The table for the DDLSTMTEEXEC logical data group is produced by the change history event monitor, where each row represents an executed DDL statement event. In a partitioned database environment, rows are captured on the coordinator partition for the DDL execution.

Whenever a row is written to the DDLSTMTEEXEC\_evmon-name table, a row is written to the TXNCOMPLETION\_evmon-name table for each associated transaction state change (commit, rollback, or rollback to savepoint) performed in the same unit of work following the DDL statement. You can then use the GLOBAL\_TRANSACTION\_ID, LOCAL\_TRANSACTION\_ID, and SAVEPOINT\_ID columns

in the DDLSTMTEEXEC\_evmon-name table to locate the corresponding state change operation in the TXNCOMPLETION\_evmon-name table and determine whether the DDL was committed or not.

For information returned by a change history event monitor for the DDLSTMTEEXEC logical data group, refer to [DDLSTMTEEXEC](#) in "Event monitor logical data groups and monitor elements".

#### *TXNCOMPLETION logical data group*

The table for the TXNCOMPLETION logical data group is produced by the change history event monitor, where each row represents a completed transaction event. Rows are written whenever a commit, rollback, or rollback to savepoint occurs in the same unit of work as a corresponding DDLSTMTEEXEC\_evmon-name table event.

Use the information in TXNCOMPLETION\_evmon-name table to determine whether the DDL statements in the transaction were committed. You can then use the GLOBAL\_TRANSACTION\_ID, LOCAL\_TRANSACTION\_ID, and SAVEPOINT\_ID columns in the TXNCOMPLETION\_evmon-name table to find the DDL statements in the DDLSTMTEEXEC\_evmon-name table that were affected by a transaction completion event.

For information returned by a change history event monitor for the TXNCOMPLETION logical data group, refer to [TXNCOMPLETION](#) in "Event monitor logical data groups and monitor elements".

#### *EVMONSTART logical data group*

The table for the EVMONSTART logical data group is produced by the change history event monitor, where each row represents a starting of the change history event monitor. Though event monitor startup is not directly related to system performance, this information provides context for other information captured by the monitor.

Event monitor startup events can help you understand when changes started to take effect. For example, activation timestamps help you track when any deferred database or database manager configuration parameter updates took effect. Knowing when the event monitor was activated also helps you understand the completeness of the information captured in the event monitor tables. Any events that occurred while the event monitor is deactivated, either explicitly or implicitly, are not captured. If the database is not activated, then the event monitor is implicitly inactive.

For information returned by a change history event monitor for the EVMONSTART logical data group, refer to [EVMONSTART](#) in "Event monitor logical data groups and monitor elements".

#### *UTILSTART logical data group*

The table for the UTILSTART logical data group is produced by the change history event monitor, where each row represents a utility that was started.

For information returned by a change history event monitor for the UTILSTART logical data group, refer to [UTILSTART](#) in "Event monitor logical data groups and monitor elements".

#### *UTILLOCATION logical data group*

The table for the UTILLOCATION logical data group is produced by the change history event monitor, where each row represents each file or path associated with the start of a utility.

For information returned by a change history event monitor for the UTILLOCATION logical data group, refer to [UTILLOCATION](#) in "Event monitor logical data groups and monitor elements".

#### *UTILSTOP logical data group*

The table for the UTILSTOP logical data group is produced by the change history event monitor, where each row represents a utility that has been stopped.

For information returned by a change history event monitor for the UTILSTOP logical data group, refer to [UTILSTOP](#) in "Event monitor logical data groups and monitor elements".

### *UTILPHASE logical data group*

The table for the UTILPHASE logical data group is produced by the change history event monitor, where each row contains information about the phase of the utility being started or stopped.

Utility execution is divided into phases or processing stages. Currently the change history event monitor only captures the starting and stopping phases of table space backups.

For information returned by a change history event monitor for the UTILPHASE logical data group, refer to [UTILPHASE](#) in "Event monitor logical data groups and monitor elements".

### **Monitoring utility history using the change history event monitor**

The change history event monitor can capture a number of events related to the execution of utilities. These events can be used to monitor the history of utility execution on the database server. This event history is written to logical data groups, where each logical data group has an associated event monitor table.

The execution of a utility can generate one or more events in the change history event monitor. For example, the execution of the REORG utility generates two events that mark the beginning and end of the REORG operation. There is a one-to-many mapping between an event and a logical data group. An event can write information to more than one logical data group and can write more than one entry (row) to the table associated with a given logical data group. Each event corresponding to a particular invocation of a utility is identified by the *utility\_invocation\_id* element. The *utility\_invocation\_id* is a binary token that uniquely identifies a given invocation of a utility. The *utility\_invocation\_id* is the same on each member where the utility is executing. The *utility\_invocation\_id* will retain its uniqueness across database deactivation, reactivation, and member shutdown, allowing quick identification of all event monitor records corresponding to a given invocation of a utility. There is no need to join with other fields or worry about duplicate identifiers.

Using the *utility\_invocation\_id* you can identify all events describing a particular invocation of a utility. For example, when the REORG command is issued on a table, a UTILSTART event is generated when the utility starts execution and a UTILSTOP event is generated when the utility completes execution. Both the UTILSTART and UTILSTOP events will have the same *utility\_invocation\_id*, because they describe the same invocation of the REORG command. The *utility\_invocation\_id* can be used to join these events to compute the elapsed time for the utility.

The change history event monitor can monitor the execution of the following utility types:

- BACKUP
- LOAD
- MOVETABLE
- ONLINERECOVERY
- REDISTRIBUTE
- REORG
- RESTORE
- ROLLFORWARD
- RUNSTATS

The change history event monitor will not capture the execution of an offline backup, restore, or rollforward operation. Online recovery operations will only be captured if they perform an asynchronous backward phase. Note that utility events are only be captured if the change history event monitor is active during the execution of the utility. If the event monitor is deactivated before the utility executes, no events are captured for the execution of that utility. For example, if the utility needs exclusive access to the table space where the event monitor target tables reside.

The following table lists the change history event monitor logical data groups and associated tables are associated with utility execution events. The table name is derived by concatenating the name of the logical data group used to populate the table with the name given to the event monitor when it was created using the CREATE EVENT MONITOR statement. The table names shown are the default table names when a name is not specified as part of the CREATE EVENT MONITOR statement.

Table 60. Logical data groups populated during utility executions

Logical data group	Default table name	Contains
<u>CHANGESUMMARY</u>	CHANGESUMMARY_evmon-name (see “CHANGESUMMARY logical data group” on page 352)	Summary of all events captured by the change history event monitor
<u>UTILSTART</u>	UTILSTART_evmon-name (see “UTILSTART logical data group” on page 353)	Utility startup information
<u>UTILLOCATION</u>	UTILLOCATION_evmon-name (see “UTILLOCATION logical data group” on page 353)	Utility path or file information
<u>UTILSTOP</u>	UTILSTOP_evmon-name (see “UTILSTOP logical data group” on page 353)	Utility stop information
<u>UTILPHASE</u>	UTILPHASE_evmon-name (see “UTILPHASE logical data group” on page 354)	Utility phase information

The WHERE EVENT IN clause of the CREATE EVENT MONITOR (change history) statement controls which utilities are monitored by the change history event monitor. The following list indicates which controls enable the capture of which utilities:

**UTILALL**

Capture execution of the load, move table, online backup, online recovery, online restore, online rollforward, redistribute, reorg and runstats utilities.

**BACKUP**

Capture execution of the online backup utility.

**LOAD**

Capture execution of the load utility.

**MOVETABLE**

Capture execution of the table move utility (invocations of the ADMIN\_MOVE\_TABLE stored procedure).

**ONLINERECOVERY**

Capture execution of a crash recovery operation which utilized an asynchronous backward phase that allowed for database connectivity during the operation. (This includes the implicit crash recovery performed during an HADR TAKEOVER).

**REDISTRIBUTE**

Capture execution of the redistribute partition group utility.

**REORG**

Capture execution of the reorg utility.

**RESTORE**

Capture execution of the online restore utility.

**ROLLFORWARD**

Capture execution of the online rollforward utility.

**RUNSTATS**

Capture execution of the runstats utility.

## ***Collecting change history event data***

You can use the change history event monitor to collect information about activities that might impact the performance, behavior, and stability of your databases and database management systems.

### **Before you begin**

To create a change history event monitor and collect change history event monitor data, you must have DBADM, or SQLADM authority.

### **About this task**

The change history event monitor captures changes that might impact the running of your regular database workload. When your regular workload experiences a degradation in performance or you observe unexpected behavior, you must determine what changes occurred that might be causing the problem. Each change-related event is uniquely identified by the following three key fields:

#### **Event timestamp**

The time that the event occurred.

#### **Event ID**

A numeric token that ensures uniqueness in cases where the event timestamp is common.

#### **Member**

The database manager process where the event occurred. Member ensures global uniqueness because event timestamp and event ID are only unique per member.

All logical groups contain these three fields and all records or rows corresponding to the same event contain the same values for these fields. These common values facilitate the joining of information across different logical data groups. Utility operations and configuration parameter updates on different members are captured as different events and result in different values for these key fields.

### **Restrictions**

Change history event monitor data can be written only to tables associated with logical data groups. The change history event monitor does not write to unformatted event tables, files, or named pipes.

### **Procedure**

To collect detailed information about activities that might be impacting database performance, behavior, or stability, perform the following steps:

1. Decide which change history events are of interest. The change history event monitor is capable of capturing events describing the following:
  - Configuration parameter changes
  - Registry variable changes
  - DDL execution
  - Occurrence of a commit, rollback, or rollback to savepoint
  - Event monitor startup information
  - Utility startup information
  - Utility path or file information
  - Utility stop information
  - Utility phase information
2. Create a change history event monitor called `whats_changed` by using the `CREATE EVENT MONITOR FOR CHANGE HISTORY` statement. Use the `WHERE EVENT IN` clause to specify the change history events that should be captured. The following example shows how to create a change history event monitor that captures all event types:

```
CREATE EVENT MONITOR whats_changed
FOR CHANGE HISTORY WHERE EVENT IN (ALL)
WRITE TO TABLE
```

3. Activate the change history event monitor called `whats_changed` by running the following statement:

```
SET EVENT MONITOR whats_changed STATE 1
```

## Results

Whenever a change history event takes place while the change history event monitor is active (for example a database configuration update), information about the event will be captured in the change history event monitor tables. Only events identified in the `WHERE EVENT IN` clause of the event monitor will be captured by the change history event monitor.

## Example

*Example: Investigating an increase in lock escalations using the change history event monitor*

You can use the change history event monitor to detect what changes might have led to a database performance degradation.

## Scenario

In this example, users are reporting a decline in database performance. The database administrator (DBA) notices an abnormally high number of lock escalations occurred in the last 24 hours. The DBA also notices a corresponding increase in application lock wait times over the same period.

The DBA has been monitoring configuration changes, index changes, and LOAD operations with a change history event monitor. The event monitor was created with the following statement:

```
CREATE EVENT MONITOR CFGHIST
FOR CHANGE HISTORY WHERE EVENT IN (DBCFCG, DBMCFG, DBCFGVALUES,
DBMCFGVALUES, REGVAR, REGVARVALUES, DDLDATA, LOAD)
WRITE TO TABLE
```

The event monitor was activated with the following statement:

```
SET EVENT MONITOR CFGHIST STATE=1
```

The following table shows some sample event monitor data that the `CFGHIST` change history event monitor might write to the `CHANGESUMMARY_CFGHIST` table. All change history event monitors write to the `CHANGESUMMARY` logical data group. As described in "[CHANGESUMMARY logical data group](#)", the `CHANGESUMMARY` logical data group returns a number of event monitor elements that summarize the events captured, only a subset of those elements are shown in the following output. The table name is derived by concatenating the name of the logical data group used to populate the table (`CHANGESUMMARY`) with the name given to the event monitor in the `CREATE EVENT MONITOR` statement (`CFGHIST`).

```
APPL_ID          APPL_NAME  .... EVENT_ID  EVENT_TIMESTAMP
-----
*LOCAL.tripathy.111028110756 db2bp      .... 1      28/10/2011 07:12:02

EVENT_TYPE MEMBER ....
-----
EVMONSTART 0      ....
```

Since performance was not previously a problem, the DBA suspects that some recent change might be causing the problem and performs the following steps:

1. Check the `CHANGESUMMARY` logical data group for any changes made in the last 24 hours. For this example, assume that the current time is `31/10/2011 06:00:00`.

```
SELECT EVENT_TYPE FROM CHANGESUMMARY_CFGHIST
WHERE EVENT_TIMESTAMP > CURRENT_TIMESTAMP - 24 HOURS
```

The query returns the following result:

```
EVENT_TYPE
-----
DBCFCG
DBCFCG
```

The output indicates that there were two database configuration updates in the last 24 hours.

2. Query the DBDBMCFG logical data group to get the details of the configuration changes.

```
3. SELECT EVENT_TIMESTAMP, CFG_NAME, CFG_VALUE, CFG_OLD_VALUE, DB_DEFERRED
FROM DBDBMCFG_CHGHIST
```

The query returns the following result:

EVENT_TIMESTAMP	CFG_NAME	CFG_VALUE	CFG_OLD_VALUE	DB_DEFERRED
30/10/2011 08:41:39	LOCKLIST	1024	2048	N
30/10/2011 08:42:35	LOCKTIMEOUT	0	-1	Y

The output indicates that locking changes were made during the time period when performance declined.

The DBA notices that the LOCKTIMEOUT change was deferred and issues a query to check whether the database was activated after this configuration change. This check determines whether the configuration change was picked up by the database. If the change was not picked up, then it is unlikely that it is causing the performance problem. The database activation time is recorded in the EVMONSTART logical data group. All change history event monitors write to the EVMONSTART logical data group by default.

```
SELECT COUNT (*) as POST_CFG_ACTIVATIONS FROM EVMONSTART_CHGHIST
WHERE DB_CONN_TIME > TIMESTAMP(2011-10-30-08:42:35)
```

The query returns a nonzero value.

```
POST_CFG_ACTIVATIONS
-----
1
```

This nonzero value confirms that the database was activated after the LOCKTIMEOUT configuration parameter was changed, meaning that the new value is in effect. The DBA now understands what changed on the system and can try adjusting the lock-related configuration parameters back to their original values to see whether this resolves the issue.

**Note:** If the change history event monitor was inactive when the configuration parameters were changed, then the event monitor would not capture the DBCFCG events. Instead the change history event monitor would capture a DBCFCGVALUES event when the event monitor was started. In the DBDBMCFG logical data group each row represents a configuration parameter that was updated as part of a DBCFCG or DBMCFG event, or captured at event monitor startup as part of a DBCFCGVALUES or DBMCFGVALUES event. The CFG\_COLLECTION\_TYPE monitor element identifies whether the record describes a configuration parameter update, or an initial value recorded at event monitor startup. The DBA would need to compare the values captured at the start of the current change history event monitor with the values of the previous capture to look for changed values that might be causing the problem. Examining the diagnostic log would also be helpful.

*Example: Identifying configuration changes and utility executions using the change history event monitor*

You can use the change history event monitor to determine if there have been any recent configuration changes or the recent execution of utilities.

### Scenario

In this example, the database administrator (DBA) notices a change in database performance over the last 24 hours. The DBA previously created a change history event monitor called HIST, that he has been using to understand changes in the behavior, performance, or stability of the databases and database management system.

The DBA issues the following query against the CHANGESUMMARY logical data group in order to summarize any change events or utility executions that occurred in the last 24 hours.

```
SELECT EVENT_TIMESTAMP,
       EVENT_TYPE,
       UTILITY_TYPE,
       COORD_MEMBER,
       MEMBER
FROM CHANGESUMMARY_HIST
WHERE EVENT_TIMESTAMP > CURRENT_TIMESTAMP - 24 HOURS
ORDER BY BY EVENT_TIMESTAMP ASC
```

The query might return output similar to the following:

EVENT_TIMESTAMP	EVENT_TYPE	UTILITY_TYPE	COORD_MEMBER	MEMBER
2010-10-31-17.29.04.545210	DBCFG			0 0
2010-10-31-18.29.04.545210	UTILSTART	LOAD		0 0
2010-10-31-18.40.04.545210	UTILSTARTPROC	LOAD		0 0
2010-10-31-18.50.04.545210	UTILSTOPPROC	LOAD		0 0
2010-10-31-18.40.04.545210	UTILSTARTPROC	LOAD		0 1
2010-10-31-18.50.04.545210	UTILSTOPPROC	LOAD		0 1
2010-10-31-19.29.04.545210	UTILSTOP	LOAD		0 0
2010-10-31-19.56.04.545210	UTILSTART	BACKUP		0 0

9 record(s) selected.

From this output, the DBA determines that there have been configuration changes and utility executions in the last 24 hours. He can now query the other change history event monitor logical data groups and obtain more information about the events returned in the CHANGESUMMARY logical data group. For example, for more information about the UTILSTART events, the DBA can query the UTILSTART logical data group to understand which objects are being acted on by the utilities and what options were used when the utilities were started.

*Example: Listing LOAD operations using the change history event monitor*

You can use the change history event monitor to track all LOAD operations performed on a database.

### Scenario

In this example, the database administrator (DBA) wants to capture and list the history of all load utility executions on a database. To track LOAD utility events.

1. Create a change history event monitor that tracks LOAD events. For example:

```
CREATE EVENT MONITOR MON_LOAD
FOR CHANGE HISTORY WHERE EVENT IN (LOAD)
WRITE TO TABLE
  CHANGESUMMARY (TABLE UTIL_COMMON),
  UTILSTART (TABLE LOAD_START),
  UTILSTOP (TABLE LOAD_STOP),
  UTILLOCATION (TABLE LOAD_INPUT_FILES),
  UTILPHASE (TABLE LOAD_PHASES);
```

2. Activate the event monitor.

```
SET EVENT MONITOR MON_LOAD STATE=1
```

- Query the logical data groups for information about LOAD operations executed on the database. For example, the following query lists the start and stop time of all executed load utilities. The query shows only the coordinator start and stop times. It ignores pause and resume records in order to show the full elapsed time of utility execution.

```
SELECT A.APPL_ID,
       A.COORD_MEMBER,
       A.EVENT_TIMESTAMP AS START_TIME,
       B.EVENT_TIMESTAMP AS STOP_TIME,
       A.TABLE_SCHEMA,
       A.TABLE_NAME,
       SQLCODE,
       VARCHAR(A.UTILITY_DETAIL, 200) AS DETAIL
FROM   LOAD_START AS A
       LOAD_STOP AS B
       UTIL_COMMON AS C
WHERE  A.UTILITY_INVOCATION_ID = B.UTILITY_INVOCATION_ID AND
       A.UTILITY_START_TYPE = 'START' AND
       B.UTILITY_STOP_TYPE = 'STOP' AND
       A.MEMBER = B.MEMBER AND
       A.MEMBER = A.COORD_MEMBER
ORDER BY A.EVENT_TIMESTAMP ASC
```

The result of the query shows that two load utilities were executed and provides details on their start and stop times, the target (table name) of the load, and details about the loads that were executed.

APPL_ID	START_TIME	STOP_TIME
*LOCAL.test.110131213809	2010-10-31-17.29.04.545210	2010-10-31-17.29.04.545210
*LOCAL.test.110131213809	2010-10-31-17.29.04.545210	2010-10-31-17.29.04.545210

TABLES_SCHEMA	TABLE_NAME	SQLCODE	DETAIL
TEST	T1	0	LOAD CURSOR..
TEST	T3	0	LOAD DEL...

*Example: Reporting the history of utility execution using the change history event monitor*

You can use the change history event monitor to track utility operations performed on a database.

## Scenario

In this example, the database administrator (DBA) wants to capture and list the utility event executions on a database. To report utility events:

- Create a change history event monitor that tracks utility events. For example:

```
CREATE EVENT MONITOR MON_UTIL
FOR CHANGE HISTORY WHERE EVENT IN (UTILALL)
WRITE TO TABLE
  CHANGESUMMARY (TABLE UTIL_COMMON),
  UTILSTART (TABLE UTIL_START),
  UTILSTOP (TABLE UTIL_STOP),
  UTILLOCATION (TABLE UTIL_LOCATION),
  UTILPHASE (TABLE UTIL_PHASES) AUTOSTART
```

- Enable the event monitor.

```
SET EVENT MONITOR MON_UTIL STATE=1
```

- Query the logical data groups for information about utility operations executed on the database. For example, the following query lists the history of each utility invocation per member.

```
WITH UTIL_HIST(TIMESTAMP, UTIL_TYPE, ACTION, PHASE_TYPE, UTILITY_INVOCATION_ID,
              MEMBER, SQLCODE) AS
(SELECT A.EVENT_TIMESTAMP,
       A.UTILITY_TYPE,
       CAST('START' AS VARCHAR(32)),
```

```

        CAST(NULL AS VARCHAR(16)),
        A.UTILITY_INVOCATION_ID,
        A.MEMBER,
        CAST(NULL as INTEGER)
FROM UTIL_START AS A
UNION ALL
    SELECT B.EVENT_TIMESTAMP,
           B.UTILITY_TYPE,
           CASE WHEN EVENT_TYPE IN ('UTILPHASESTART') THEN
                CAST('PHASE START' AS VARCHAR(32))
           ELSE
                CAST('PHASE STOP' AS VARCHAR(32))
           END CASE,
           CAST(UTILITY_PHASE_TYPE AS VARCHAR(16)),
           B.UTILITY_INVOCATION_ID,
           B.MEMBER,
           CAST(NULL as INTEGER)
FROM UTIL_PHASES AS B
UNION ALL
    SELECT C.EVENT_TIMESTAMP,
           C.UTILITY_TYPE,
           CAST('STOP' AS VARCHAR(32)),
           CAST(NULL AS VARCHAR(16)),
           C.UTILITY_INVOCATION_ID,
           C.MEMBER,
           C.SQLCODE
FROM UTIL_STOP AS C)
SELECT * FROM UTIL_HIST
ORDER BY UTILITY_INVOCATION_ID, MEMBER, TIMESTAMP ASC

```

The resulting report of utility events can be used to:

- Identify any utilities that are overlapping. For example, a utility starts on a partition before another utility has stopped on that same partition.
- Determine where a utility is spending its time. For example, how much time was spent in each phase. Note: In 11.5 this is only available for the table space backup phase of online backups.

TIMESTAMP	UTIL_TYPE	ACTION	PHASE_TYPE	UTILITY_INVOCATION_ID	MEMBER	SQLCODE
2010-10-31-17.29.04.545210	LOAD	START	-	x'18A901F...621'	0	-
2010-10-31-17.50.04.344230	LOAD	STOP	-	x'18A901F...621'	0	0

2010-10-31-17.51.04.545214	BACKUP	PHASE STOP	BACKUPTS	x'18A901F...645'	0	-
2010-10-31-17.52.04.344218	BACKUP	STOP	-	x'18A901F...645'	0	0

8 record(s) selected.

*Example: Listing all committed DDL statements using the change history event monitor*

You can use the change history event monitor to quickly list all committed DDL statements executed to determine if any changes made might be impacting your workload.

## Scenario

In this example, the database administrator (DBA) notices a degradation in the performance of a number of queries has occurred in the last 24 hours. The DBA uses the change history event monitor to quickly examine the DDL executed during that time period, in order to determine if any changes were made that might be having a significant impact on the workload (for example, indexes that were dropped). The DBA previously created a change history event monitor called CHGHIST, that is being used to track DDL statements. The DBA issues the following statement to list all committed DDL statements captured by the change history event monitor in the last 24 hours. The issued statement excludes statements that were rolled back, either via a ROLLBACK statement or ROLLBACK TO SAVEPOINT statement.

Note that the change history event monitor records DDL events when the DDL is executed. Whether the DDL causes any change in the database depends on the DDL being committed.

```

WITH savepoint_rollback (global_tran_id, local_tran_id, savepoint_id) AS
(SELECT DISTINCT T.global_transaction_id, T.local_transaction_id, T.savepoint_id
 FROM DDLSMTXEXE_C as D, TXNCOMPLETION_C as T
 WHERE T.txn_completion_status='S' AND
        D.savepoint_id >= T.savepoint_id AND
        D.event_timestamp <= T.event_timestamp)

```

```

SELECT VARCHAR(D.STMT_TEXT, 70) AS STMT_TEXT FROM DDLSTMTEXEC_CHGHIST as D,
TXNCOMPLETION_CHGHIST as T
WHERE D.global_transaction_id = T.global_transaction_id AND
D.local_transaction_id = T.local_transaction_id AND
T.txn_completion_status = 'C' AND
(D.global_transaction_id, D.local_transaction_id, D.savepoint_id)
NOT IN (SELECT * FROM savepoint_rollbacks) AND
D.EVENT_TIMESTAMP > CURRENT_TIMESTAMP - 24 HOURS;

```

STMT\_TEXT

-----  
CREATE INDEX I1 ON T1 (ONE)

1 record(s) selected.

*Example: Listing changes performed by the STMM using the change history event monitor*

You can use the change history event monitor to list changes performed by the self tuning memory manager (STMM).

### Scenario

In this example, the database administrator (DBA) wants to monitor any changes performed by the STMM. Since the STMM can modify configuration parameters and buffer pool sizes, the DBA has created an event monitor called HIST to capture configuration and DDL changes.

Changes initiated by the STMM can be found by querying the event monitor for records containing one of the following information:

- The application name (appl\_name) is db2stmm.
- The DDL statement text (stmt\_text) contains a comment with the keyword db2stmm. Note that some DDL changes are performed on behalf of the STMM by other applications.

```

SELECT A.EVENT_TIMESTAMP,
VARCHAR(A.EVENT_TYPE, 20) AS EVENT_TYPE, A.MEMBER
FROM CHANGESUMMARY_HIST A LEFT OUTER JOIN
DDLSTMTEXEC_HIST B
ON A.EVENT_TIMESTAMP = B.EVENT_TIMESTAMP AND
A.MEMBER = B.MEMBER AND
A.EVENT_ID = B.EVENT_ID
WHERE (A.APPL_NAME = 'db2stmm' OR
B.STMT_TEXT LIKE '%db2stmm%');

```

The query might return output similar to the following example:

EVENT_TIMESTAMP	EVENT_TYPE	MEMBER
2011-04-22-12.12.17.832316	DBCFCG	0
2011-04-22-12.22.35.227550	DBCFCG	0
2011-04-22-12.12.17.530274	DBCFCG	0
2011-04-22-12.12.17.721403	DBCFCG	0
2011-04-22-12.12.17.776889	DBCFCG	0
2011-04-22-12.22.35.172119	DBCFCG	0
2011-04-22-12.12.17.665098	DBCFCG	0
2011-04-22-12.22.35.116343	DBCFCG	0
2011-04-22-12.29.47.092822	DBCFCG	0
2011-04-22-12.29.47.037709	DBCFCG	0
2011-04-22-12.12.17.600511	DBCFCG	0
2011-04-22-12.22.35.283320	DBCFCG	0
2011-04-22-12.29.46.752477	DBCFCG	0
2011-04-22-12.29.47.148562	DBCFCG	0

14 record(s) selected.

## Event monitor data retention from release to release

You can upgrade event monitor output tables after you upgrade the database product. This capability lets you retain any data that might exist in event monitor tables that you had before you upgraded.

As new capabilities are introduced in Db2, the output for an event monitor type can change when a product update or upgrade is applied. The output tables for existing event monitors do not automatically change to reflect these new fields. Whenever new output is available, you can upgrade existing event

monitor output tables using the `EVMON_UPGRADE_TABLES` stored procedure. Running the stored procedure captures the latest output and retains existing data in those event monitor tables.

In previous versions of Db2, if the `EVMON_UPGRADE_TABLES` stored procedure wasn't used, manual changes might have been required to update tables. For example, if you had existing event monitors that wrote to tables containing data that you wanted to retain, and you wanted to collect the data in some newly-added columns. In this case, you would need to manually alter the columns after upgrading to the new release. This alteration involved adding any of the new columns that you might want to use. If you did not add the new columns, the event monitor would work as it had in the previous release, capturing only the data supported by that the event monitor in that release.

Unformatted event tables that had changed could not be upgraded at all; you were required to drop them and then re-create them.

The `EVMON_UPGRADE_TABLES` stored procedure upgrades the definitions of existing event monitor tables to match those produced by the current level of the Db2 product. This feature lets you keep any existing tables that you might have, along with all the data they contain, eliminating the need to manually alter, or to drop and re-create tables.

**Note:** Starting in 10.1, you can also use the `ALTER EVENT MONITOR` statement to add new logical groups to an event monitor. You can use this approach as an alternative to `EVMON_UPGRADE_TABLES` to add logical data groups added in a new release. However, you cannot use `ALTER EVENT MONITOR` to modify logical groups that are already associated with the event monitor; if a logical data group already associated with the event monitor has changed, the only way to modify the event monitor is using the `EVMON_UPGRADE_TABLES` procedure.

The `EVMON_UPGRADE_TABLES` procedure works with both regular and UE tables. For regular tables, the procedure adds any new columns needed, drops old columns that are no longer required, and alters any columns as needed. For UE tables, the procedure adds new columns and modifies existing columns as needed to allow the UE table to be processed by the `db2evmonfmt` tool, or the `EVMON_FORMAT_UE_TO_TABLES` or `EVMON_FORMAT_UE_TO_XML` routines.

**Important:** Any active event monitors must be deactivated for the upgrade process to work properly. The `EVMON_UPGRADE_TABLES` procedure automatically deactivates any active event monitors before it begins upgrading tables. Do not reactivate any event monitors with tables being processed by `EVMON_UPGRADE_TABLES`, or the upgrade process will fail. Any event monitors that were active before the upgrade are activated again after the upgrade has completed.

## Implications of not upgrading event monitor tables

As in past releases, you can choose to not upgrade your event monitor tables. However, any new columns that have been added to the event monitor in the new release will not be populated with data, and will not be available for queries. Also, the values for any monitor elements that previously existed in the old release and that increased in size in the new release might be truncated. For example, if a monitor element increases in size from `VARCHAR(20)` to `VARCHAR(128)` in the new release, and you do not upgrade the previously-existing tables, the column that contains the monitor element values will continue to store only 20 characters of data, even though the system may be sending 128-bytes of data for that monitor element to the event monitor.

## Upgrading tables produced by `EVMON_FORMAT_UE_TO_TABLES`

When used with UE tables, the `EVMON_UPGRADE_TABLES` procedure upgrades the UE table itself; it has no effect on any regular tables that you might have created using the `EVMON_FORMAT_UE_TO_TABLES` procedure. After you use `EVMON_UPGRADE_TABLES` to upgrade a UE table, you can also upgrade the output tables produced by `EVMON_FORMAT_UE_TO_TABLES`. When you run the `EVMON_FORMAT_UE_TO_TABLES` procedure with the `UPGRADE_TABLES` option, any existing tables produced by the procedure are altered so that the table columns match the output produced by the new version of `EVMON_FORMAT_UE_TO_TABLES` procedure.

## Other monitoring interfaces

### Reports generated using the MONREPORT module

The MONREPORT module generates text reports of monitoring data that you can use to troubleshoot SQL performance problems.

You can generate the following reports using the MONREPORT module:

*Table 61. List of reports generated using the MONREPORT module*

Report Name	Procedure to create report	Main data source / table functions
Summary report	MONREPORT.DBSUMMARY	MON_GET_SERVICE_SUBCLASS and selected details from MON_GET_CONNECTION and MON_GET_WORKLOAD
Connection report	MONREPORT.CONNECTION	MON_GET_CONNECTION
Current Applications report	MONREPORT.CURRENTAPPS	Includes fields from MON_GET_CONNECTION, MON_GET_UNIT_OF_WORK, WLM_GET_SERVICE_CLASS_AGENTS, WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES
Current SQL report	MONREPORT.CURRENTSQL	MON_GET_PKG_CACHE_STMT (For the <b>executable_id</b> obtained from the WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function.)
Package Cache report	MONREPORT.PKGCACHE	MON_GET_PKG_CACHE_STMT
Current Lock Wait report	MONREPORT.LOCKWAIT	Most data from MON_GET_APPL_LOCKWAIT; additional data from MON_GET_CONNECTION, WLM_GET_SERVICE_CLASS_AGENTS, WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES, MON_GET_PKG_CACHE_STMT, MON_GET_TABLE

Most reports start with a summary section that provides one line of key information for each item in the report. For example, the Connection report contains a one-line summary of each connection. The main body of the report consists of a detailed section for each item in the summary.

Each metric in the report is labeled with the underlying monitor element name (for example: CLIENT\_IDLE\_WAIT\_TIME = 44). To determine what the metric represents, search the Information Center for the monitor element name.

### Reports for initial diagnosis

An important use of these reports is to troubleshoot SQL performance slowdowns. Each report is designed to answer certain diagnosis questions. Some reports support initial diagnosis, while others support subsequent detailed diagnosis of particular types of problems.

Initial diagnosis involves:

- Determining the problem category, by narrowing the problem down to the aspect or stage of processing that has slowed down.
- Identifying the SQL statements involved in the problem and collecting information about the SQL statements for further analysis.

*Table 62. MONREPORT module reports suitable for initial diagnosis*

Procedure name	Information provided and usage
MONREPORT.DBSUMMARY Part 1: System Performance	<p>Part 1 of the Summary report provides monitor data for most aspects of processing aggregated across the entire database.</p> <p>This information is useful for answering questions about the aspect or stage of processing that has slowed down. For example:</p> <ul style="list-style-type: none"> <li>• Is the problem inside or outside the data server?</li> <li>• Is there a computing resource bottleneck?</li> <li>• Are requests in a wait state? If so, for what resource?</li> <li>• Is the slowdown located in a particular data server processing component?</li> </ul>

Table 62. MONREPORT module reports suitable for initial diagnosis (continued)

Procedure name	Information provided and usage
<p>MONREPORT.DBSUMMARY Part 2: Application Performance</p>	<p>Part 2 of the Summary report provides key performance indicators for each connection, workload, and service class.</p> <p>This information is useful for answering questions about the scope of application requests involved in the slowdown. For example:</p> <ul style="list-style-type: none"> <li>• Is this slowdown a general system slowdown that affects much or all the workload?</li> <li>• Is this slowdown limited to SQL statements issued from a particular source such as particular connections, database workloads or database service classes?</li> </ul>
<p>MONREPORT.DBSUMMARY Part 3: Member level information</p>	<p>Part 3 of the Summary report provides key performance indicators for each member.</p> <p>This information is useful for determining whether the slowdown is isolated to one or a few members.</p>
<p>MONREPORT.CURRENTSQL</p>	<p>The current SQL report provides information about statements that are currently running, in the form of several lists of the top <i>N</i> activities. The statements are ranked by different metrics: processing resource, rows processed, direct reads and direct writes.</p> <p>This information is useful for determining whether the slowdown is isolated to one or a few SQL statements. If the slowdown is isolated to one or a few SQL statements, those statements are likely to appear in this report of top statements.</p>
<p>MONREPORT.PKGCACHE</p>	<p>The package cache report provides information about statements that have run recently and are stored in the package cache. This report shows several summaries, each listing the top <i>N</i> activities. The activities are ranked by the following monitor elements:</p> <ul style="list-style-type: none"> <li>• CPU</li> <li>• wait time</li> <li>• rows processed</li> <li>• <u>num_coord_exec_with_metrics</u> - Number of executions by coordinator agent with metrics monitor element (if no member was specified) or <u>num_exec_with_metrics</u> - Number of executions with metrics collected monitor element (if a member was specified)</li> <li>• I/O wait time</li> </ul> <p>This report contains a summary for each of these metrics as well as a report for each execution.</p> <p>This information is useful for determining whether the slowdown is isolated to one or a few SQL statements. If so, those statements are likely to appear at the top in this report. The information per execution can help identify the most costly statements while the information summed across executions can help identify statements with the most impact on the system cumulatively considering both the statement cost and frequency of execution.</p>

Table 62. MONREPORT module reports suitable for initial diagnosis (continued)

Procedure name	Information provided and usage
MONREPORT.CURRENTAPPS	<p>The current applications report show the current processing state for units of work, agents, and activities. The report starts with a summary section showing the number of current connections and activities, as well as a series of summaries, such as the summary of current units of work by workload occurrence state. The body of the report consists of one section for each connection that provides the details of the connection.</p> <p>This information is useful for viewing all the work currently running on the system. This allows you to check for patterns that might identify the problem category.</p>

## Reports for detailed diagnosis

After completing the initial diagnosis, you might need to pursue a specialized or detailed set of troubleshooting analyses for the problem category you identified during the initial diagnosis phase.

Table 63. MONREPORT module reports suitable for detailed diagnosis

Procedure name	Information provided and usage
MONREPORT.CONNECTION	<p>If the MONREPORT.DBSUMMARY report showed that the slowdown is limited to SQL statements issued from a particular connection, then you can view detailed information about the affected connection.</p> <p>This report contains the same metrics as Part 1 of the MONREPORT.DBSUMMARY report, but it presents this information for each connection.</p>
MONREPORT.LOCKWAIT	<p>If the reports viewed during the initial diagnosis suggest there is a lock wait problem, then you can view detailed information about each lock wait currently in progress.</p> <p>This information includes lock holder and lock requester details, as well as characteristics of the lock held and the lock requested.</p>

## Snapshot monitor

You can use the snapshot monitor to capture information about the database and any connected applications at a specific time. Snapshots are useful for determining the status of a database system. Taken at regular intervals, they are also useful for observing trends and foreseeing potential problems. Some of the data from the snapshot monitor is obtained from the system monitor. The data available from the system monitor is determined by system monitor switches.

The system monitor accumulates information for a database only while it is active. If all applications disconnect from a database and the database deactivates, then the system monitor data for that database is no longer available. You can keep the database active until your final snapshot has been taken, either by starting the database with the ACTIVATE DATABASE command, or by maintaining a permanent connection to the database.

Snapshot monitoring requires an instance attachment. If there is not an attachment to an instance, then a default instance attachment is created. An instance attachment is usually done implicitly to the instance specified by the DB2INSTANCE environment variable when the first database system monitor API is invoked by the application. It can also be done explicitly, using the ATTACH TO command. Once

an application is attached, all system monitor requests that it invokes are directed to that instance. This allows a client to monitor a remote server by simply attaching to the instance on it.

In partitioned database environments, snapshots can be taken at any partition of the instance, or globally using a single instance connection. A global snapshot aggregates the data collected at each partition and returns a single set of values.

In Db2 pureScale environments, snapshots can be taken at any member or globally. A global snapshot aggregates the data collected at each member and returns a single set of values.

**Note:** The snapshot monitor is deprecated in Db2 pureScale environments since it only shows lock information for the member it is run on. For proper lock monitoring, see [Lock monitoring in a Db2 pureScale environment overview](#).

You can capture a snapshot from the CLP, from SQL table functions, or by using the snapshot monitor APIs in a C or C++ application. A number of different snapshot request types are available, each returning a specific type of monitoring data. For example, you can capture a snapshot that returns only buffer pool information, or a snapshot that returns database manager information. Before capturing a snapshot, consider if you need information from monitor elements that are under monitor switch control. If a particular monitor switch is off, the monitor elements under its control will not be collected.

### **Related information**

Technical article: [Db2 monitoring: Migrate from snapshot monitor interfaces to in-memory metrics monitor interfaces](#)

## **Access to system monitor data: SYSMON authority**

Users that are part of the SYSMON database manager level group have the authority to gain access to database system monitor data. System monitor data is accessed using the snapshot monitor APIs, CLP commands, or SQL table functions.

The SYSMON authority group provides the means to enable users without system administration or system control authorities to access database system monitor data.

Aside from SYSMON authority, the only way to access system monitor data using the snapshot monitor is with system administration or system control authority.

Any user that is part of the SYSMON group or has system administration or system control authority can perform the following snapshot monitor functions:

- CLP Commands:
  - GET DATABASE MANAGER MONITOR SWITCHES
  - GET MONITOR SWITCHES
  - GET SNAPSHOT
  - LIST ACTIVE DATABASES
  - LIST APPLICATIONS
  - LIST DCS APPLICATIONS
  - LIST UTILITIES
  - RESET MONITOR
  - UPDATE MONITOR SWITCHES
- APIs:
  - db2GetSnapshot - Get Snapshot
  - db2GetSnapshotSize - Estimate Size Required for db2GetSnapshot ( ) Output Buffer
  - db2MonitorSwitches - Get/Update Monitor Switches
  - db2ResetMonitor - Reset Monitor
- Snapshot SQL table functions without previously running SYSPROC.SNAP\_WRITE\_FILE

**Important:** The SYSPROC.SNAP\_WRITE\_FILE procedure is deprecated and might be removed in a future release. For more information, see "SNAP\_WRITE\_FILE procedure" in *Administrative Routines and Views*.

## Capturing a database snapshot from the CLP

You can capture database snapshots from the CLP using the GET SNAPSHOT command. A number of different snapshot request types are available, which can be accessed by specifying certain parameters for the GET SNAPSHOT command.

### Before you begin

You must have SYSADM, SYSCTRL, SYSMaint, or SYSMON authority to capture a database snapshot.

You must have an instance attachment to capture a database snapshot. If there is not an attachment to an instance, then a default instance attachment is created. To obtain a snapshot of a remote instance, you must first attach to that instance.

### Procedure

- Optional: [Set and check the status of the monitor switches](#).
- From the CLP, issue the GET SNAPSHOT command with the required parameters. In the following example, the snapshot captures information for all databases:

```
db2 get snapshot for all databases
```

To capture a database snapshot for a specific database, use the following command:

```
db2 get snapshot for database on db-name
```

where *db-name* is the name of the database you are interested in.

- The following example captures database manager level information:

```
db2 get snapshot for dbm
```

- For partitioned database systems, you can capture a database snapshot specifically for a certain partition, or globally for all partitions. To capture a database snapshot for all applications on a specific partition (for example, partition number 2), issue the following command:

```
db2 get snapshot for all applications at dbpartitionnum 2
```

- To capture a database snapshot for all applications on all partitions, issue the following command:

```
db2 get snapshot for all applications global
```

For global snapshots on partitioned databases, the monitor data from all the partitions is aggregated.

## Snapshot monitor CLP commands

You can control the snapshot monitor through the command line prompt. For CLP commands, information about the monitor level is returned only if the associated monitor switch is set to ON. You must check the monitor elements that you want to use to determine if the element is under monitor switch control.

The following table lists all the supported snapshot request types.

Table 64. Snapshot Monitor CLP Commands

Monitor level	CLP command	Information returned
Connections list	<code>list applications [show detail]</code>	Application identification information for all applications currently connected to a database that is managed by the database instance on the partition where snapshot is taken.
Connections list	<code>list applications for database <i>dbname</i> [show detail]</code>	Application identification information for each application currently connected to the specified database.
Connections list	<code>list dcs applications</code>	Application identification information for all DCS applications currently connected to a database that is managed by the database instance on the partition where snapshot is taken.
Database manager	<code>get snapshot for dbm</code>	Database manager level information, including instance-level monitor switch settings.
Database manager	<code>get dbm monitor switches</code>	Instance-level monitor switch settings.
Database	<code>get snapshot for database on <i>dbname</i></code>	Database level information and counters for a database. Information is returned only if there is at least one application connected to the database.
Database	<code>get snapshot for all databases</code>	Database level information and counters for each database active on the partition. Information is returned only if there is at least one application connected to the database.
Database	<code>list active databases</code>	The number of connections to each active database. Includes databases that were started using the <code>ACTIVATE DATABASE</code> command, but have no connections.
Database	<code>get snapshot for dcs database on <i>dbname</i></code>	Database level information and counters for a specific DCS database. Information is returned only if there is at least one application connected to the database.
Database	<code>get snapshot for remote database on <i>dbname</i></code>	Database level information and counters for a specific federated system database. Information is returned only if there is at least one application connected to the database.
Database	<code>get snapshot for all remote databases</code>	Database level information and counters for each active federated system database on the partition. Information is returned only if there is at least one application connected to the database.
Application	<code>get snapshot for application <i>applid</i> <i>appl-id</i></code>	Application level information, including cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	<code>get snapshot for application <i>agentid</i> <i>appl-handle</i></code>	Application level information, includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).

Table 64. Snapshot Monitor CLP Commands (continued)

Monitor level	CLP command	Information returned
Application	get snapshot for applications on <i>dbname</i>	Application level information for each application that is connected to the database on the partition. This includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	get snapshot for all applications	Application level information for each application that is active on the partition. This includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	get snapshot for dcs application applid <i>appl-id</i>	Application level information, including cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	get snapshot for all dcs applications	Application level information for each DCS application that is active on the partition. This includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	get snapshot for dcs application agentid <i>appl-handle</i>	Application level information, including cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	get snapshot for dcs applications on <i>dbname</i>	Application level information for each DCS application that is connected to the database on the partition. This includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	get snapshot for remote applications on <i>dbname</i>	Application level information, includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	get snapshot for all remote applications	Application level information for each federated system application that is active on the partition. This includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Table	get snapshot for tables on <i>dbname</i>	Table activity information at the database and application level for each application connected to the database. Table activity information at the table level for each table that <b>was accessed</b> by an application connected to the database. Requires the table switch.
Lock	get snapshot for locks for application applid <i>appl-id</i>	List of locks held by the application. Lock wait information requires the lock switch.
Lock	get snapshot for locks for application agentid <i>appl-handle</i>	List of locks held by the application. Lock wait information requires the lock switch.

Table 64. Snapshot Monitor CLP Commands (continued)

Monitor level	CLP command	Information returned
Lock	get snapshot for locks on <i>dbname</i>	Lock information at the database level, and application level for each application connected to the database. Requires the lock switch.
Table space	get snapshot for tablespaces on <i>dbname</i>	Information about table space activity for a database. Requires the buffer pool switch. Also included is information about containers, quiescers, and ranges. This information is not under switch control.
Buffer pool	get snapshot for all bufferpools	Buffer pool activity counters. Requires the buffer pool switch.
Buffer pool	get snapshot for bufferpools on <i>dbname</i>	Buffer pool activity counters for the specified database. Requires the buffer pool switch.
Dynamic SQL	get snapshot for dynamic sql on <i>dbname</i>	Point-in-time statement information from the SQL statement cache for the database. The information can also be from a remote data source.

## Capturing a database snapshot from a client application

You can capture database snapshots using the snapshot monitor API in a C, C++, or a COBOL application. In C and C++ a number of different snapshot request types can be accessed by specifying certain parameters in `db2GetSnapshot()`.

### Before you begin

You must have SYSADM, SYSCTRL, SYSMAINT, or SYSMON authority to use the `db2MonitorSwitches` API.

You must have an instance attachment to capture a database snapshot. If there is not an attachment to an instance, then a default instance attachment is created. To obtain a snapshot of a remote instance, you must first attach to that instance.

### Procedure

1. Optional: [Set and check the status of the monitor switches.](#)
2. Include the database libraries `sqlmon.h` and `db2ApiDf.h`, which are located in the `include` subdirectory under `sqllib`.

```
#include <db2ApiDf.h>
#include <sqlmon.h>
```

3. Set snapshot buffer unit size to 100 KB.

```
#define SNAPSHOT_BUFFER_UNIT_SZ 102400
```

4. Declare the `sqlca`, `sqlma`, `db2GetSnapshotData`, and `sqlm_collected` structures. Also, initialize a pointer to contain the snapshot buffer, and establish the buffer's size.

```
struct sqlma *pRequestedDataGroups;
struct sqlca sqlca;
memset (&sqlca, '\0', sizeof(struct sqlca));
struct sqlm_collected collectedData;
memset (&collectedData, '\0', sizeof(collectedData));
db2GetSnapshotData getSnapshotParam;
memset (&getSnapshotParam, '\0', sizeof(getSnapshotParam));

static sqluint32 snapshotBufferSize = SNAPSHOT_BUFFER_UNIT_SZ;
sqluint32 outputFormat;
char *snapshotBuffer;
```

5. Initialize the sqlma structure and specify that the snapshot to be captured is of database manager level information.

```
pRequestedDataGroups = (struct sqlma *)malloc(SQLMASIZE(1));
memset(pRequestedDataGroups, '\\0', SQLMASIZE(1));
pRequestedDataGroups->obj_num = 1;
pRequestedDataGroups->obj_var[0].obj_type = SQLMA_DB2;
```

6. Initialize the buffer which is to hold the snapshot output.

```
snapshotBuffer = (char *)malloc(snapshotBufferSize);
memset(snapshotBuffer, '\\0', snapshotBufferSize);
```

7. Populate the db2GetSnapshotData structure with the snapshot request type (from the sqlma structure), buffer information, and other information required to capture a snapshot.

```
getSnapshotParam.piSqlmaData = pRequestedDataGroups;
getSnapshotParam.poCollectedData = &collectedData;
getSnapshotParam.poBuffer = snapshotBuffer;
getSnapshotParam.iVersion = SQLM_DBMON_VERSION9_5;
getSnapshotParam.iBufferSize = snapshotBufferSize;
getSnapshotParam.iStoreResult = 0;
getSnapshotParam.iNodeNumber = SQLM_CURRENT_NODE;
getSnapshotParam.poOutputFormat = &outputFormat;
getSnapshotParam.iSnapshotClass = SQLM_CLASS_DEFAULT;
```

8. Capture the snapshot. Pass the db2GetSnapshotData structure, which contains the information necessary to capture a snapshot, as well as a reference to the buffer, where snapshot output is to be directed.

```
db2GetSnapshot(db2Version810, &getSnapshotParam, &sqlca);
```

9. Verify that the snapshot was successfully taken. If the db2GetSnapshotData API returns a negative sqlcode or a nonzero return code, then the snapshot failed. Check the user response for the error and take the appropriate corrective action.
10. Include logic to handle buffer overflow. After a snapshot is taken, the sqlcode is checked for a buffer overflow. If a buffer overflow occurred the buffer is cleared and reinitialized, and the snapshot is taken again.

```
while (sqlca.sqlcode == 1606)
{
    free(snapshotBuffer);
    snapshotBufferSize = snapshotBufferSize +
        SNAPSHOT_BUFFER_UNIT_SZ;
    snapshotBuffer = (char *)malloc(snapshotBufferSize);
    if (snapshotBuffer == NULL)
    {
        printf("\\nMemory allocation error.\\n");
        return 1;
    }
    getSnapshotParam.iBufferSize = snapshotBufferSize;
    getSnapshotParam.poBuffer = snapshotBuffer;
    db2GetSnapshot(db2Version810, &getSnapshotParam, &sqlca);
}
```

11. Process the snapshot monitor data stream.
12. Clear the buffer.

```
free(snapshotBuffer);
free(pRequestedDataGroups);
```

## Snapshot monitor API request types

For API request types, information about the monitor level is returned if the associated monitor switch is ON. You must check the monitor elements that you want to use to determine if the monitor element is under monitor switch control.

The following table lists all the supported snapshot request types.

Table 65. Snapshot Monitor API Request Types

Monitor level	API request type	Information returned
Connections list	SQLMA_APPLINFO_ALL	Application identification information for all applications currently connected to a database that is managed by the database instance on the partition where snapshot is taken.
Connections list	SQLMA_DBASE_APPLINFO	Application identification information for each application currently connected to the specified database.
Connections list	SQLMA_DCS_APPLINFO_ALL	Application identification information for all DCS applications currently connected to a database that is managed by the database instance on the partition where snapshot is taken.
Database manager	SQLMA_DB2	Database manager level information, including instance-level monitor switch settings.
Database	SQLMA_DBASE	Database level information and counters for a database. Information is returned only if there is at least one application connected to the database.
Database	SQLMA_DBASE_ALL	Database level information and counters for each database active on the partition. The number of connections to each active database. Includes databases that were started using the ACTIVATE DATABASE command, but have no connections. Information is returned only if there is at least one application connected to the database.
Database	SQLMA_DCS_DBASE	Database level information and counters for a specific DCS database. Information is returned only if there is at least one application connected to the database.
Database	SQLMA_DCS_DBASE_ALL	Database level information and counters for each DCS database active on the partition. Information is returned only if there is at least one application connected to the database.
Database	SQLMA_DBASE_REMOTE	Database level information and counters for a specific federated system database. Information is returned only if there is at least one application connected to the database.
Database	SQLMA_DBASE_REMOTE_ALL	Database level information and counters for each active federated system database on the partition. Information is returned only if there is at least one application connected to the database.
Application	SQLMA_APPL	Application level information, including cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).

Table 65. Snapshot Monitor API Request Types (continued)

Monitor level	API request type	Information returned
Application	SQLMA_AGENT_ID	Application level information, includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	SQLMA_DBASE_APPLS	Application level information for each application that is connected to the database on the partition. This includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	SQLMA_APPL_ALL	Application level information for each application that is active on the partition. This includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	SQLMA_DCS_APPL	Application level information, including cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	SQLMA_DCS_APPL_ALL	Application level information for each DCS application that is active on the partition. This includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	SQLMA_DCS_APPL_HANDLE	Application level information, including cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	SQLMA_DCS_DBASE_APPLS	Application level information for each DCS application that is connected to the database on the partition. This includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	SQLMA_DBASE_APPLS_REM OTE	Application level information, includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).
Application	SQLMA_APPL_REMOTE_ALL	Application level information for each federated system application that is active on the partition. This includes cumulative counters, status information, and most recent SQL statement executed (if statement switch is set).

Table 65. Snapshot Monitor API Request Types (continued)

Monitor level	API request type	Information returned
Table	SQLMA_DBASE_TABLES	Table activity information at the database and application level for each application connected to the database. Table activity information at the table level for each table that <b>was accessed</b> by an application connected to the database. Requires the table switch.
Lock	SQLMA_APPL_LOCKS	List of locks held by the application. Lock wait information requires the lock switch.
Lock	SQLMA_APPL_LOCKS_AGENT_ID	List of locks held by the application. Lock wait information requires the lock switch.
Lock	SQLMA_DBASE_LOCKS	Lock information at the database level, and application level for each application connected to the database. Requires the lock switch.
Table space	SQLMA_DBASE_TABLESPACES	Information about table space activity at the database level, the application level for each application connected to the database, and the table space level for each table space that has been accessed by an application connected to the database. Requires the buffer pool switch.
Buffer pool	SQLMA_BUFFERPOOLS_ALL	Buffer pool activity counters. Requires the buffer pool switch.
Buffer pool	SQLMA_DBASE_BUFFERPOOLS	Buffer pool activity counters for the specified database. Requires the buffer pool switch.
Dynamic SQL	SQLMA_DYNAMIC_SQL	Point-in-time statement information from the SQL statement cache for the database.

## Snapshot monitor sample output

You can use the snapshot monitor to capture information about your database and applications that are connected to your database at a specific time. Information collected in a snapshot include the database name, the number of locks held by the database, and application handles.

To illustrate the nature of the snapshot monitor, here is an example of a snapshot being taken using the CLP, along with its corresponding output. The objective in this example is to obtain a list of the locks held by applications connected to the SAMPLE database. The steps taken are as follows:

1. Connect to the sample database:

```
db2 connect to sample
```

2. Turn on the LOCK switch with the UPDATE MONITOR SWITCHES command, so that the time spent waiting for locks is collected:

```
db2 update monitor switches using LOCK on
```

3. Issue a command or statement that will require locks on the database catalogs. In this case, we will declare, open, and fetch a cursor:

```
db2 -c- declare c1 cursor for
      select * from staff where job='Sales' for update
```

```
db2 -c- open c1
db2 -c- fetch c1
```

4. Take the database lock snapshot, using the GET SNAPSHOT command:

```
db2 get snapshot for locks on sample
```

After the GET SNAPSHOT command is issued from the CLP, the snapshot output is directed to the screen.

```
Database Lock Snapshot

Database name           = SAMPLE
Database path          = C:\DB2\NODE0000\SQL00001\
Input database alias   = SAMPLE
Locks held              = 5
Applications currently connected = 1
Agents currently waiting on locks = 0
Snapshot timestamp     = 06-05-2002 17:08:25.048027

Application handle     = 8
Application ID         = *LOCAL.DB2.0098C5210749
Sequence number       = 0001
Application name       = db2bp.exe
CONNECT Authorization ID = DB2ADMIN
Application status     = UOW Waiting
Status change time    = Not Collected
Application code page  = 1252
Locks held             = 5
Total wait time (ms)  = 0

List Of Locks

Lock Name              = 0x020003000500000000000000052
Lock Attributes        = 0x00000000
Release Flags          = 0x00000001
Lock Count             = 1
Hold Count             = 0
Lock Object Name      = 5
Object Type            = Row
Tablespace Name       = USERSPACE1
Table Schema          = DB2ADMIN
Table Name             = STAFF
Mode                   = U

Lock Name              = 0x020003000000000000000000054
Lock Attributes        = 0x00000000
Release Flags          = 0x00000001
Lock Count             = 1
Hold Count             = 0
Lock Object Name      = 3
Object Type            = Table
Tablespace Name       = USERSPACE1
Table Schema          = DB2ADMIN
Table Name             = STAFF
Mode                   = IX

Lock Name              = 0x01000000010000000100810056
Lock Attributes        = 0x00000000
Release Flags          = 0x40000000
Lock Count             = 1
Hold Count             = 0
Lock Object Name      = 0
Object Type            = Internal Variation Lock
Mode                   = S

Lock Name              = 0x4141414141414A48520000000041
Lock Attributes        = 0x00000000
Release Flags          = 0x40000000
Lock Count             = 1
Hold Count             = 0
Lock Object Name      = 0
Object Type            = Internal Plan Lock
Mode                   = S

Lock Name              = 0x434F4E544F4B4E310000000041
Lock Attributes        = 0x00000000
Release Flags          = 0x40000000
Lock Count             = 1
Hold Count             = 0
Lock Object Name      = 0
```

```
Object Type          = Internal Plan Lock
Mode                 = S
```

From this snapshot, you can see that there is currently one application connected to the SAMPLE database, and it is holding five locks.

```
Locks held           = 5
Applications currently connected = 1
```

Note that the time (Status change time) when the Application status became UOW Waiting is returned as Not Collected. This is because the UOW switch is OFF.

The lock snapshot also returns the total time spent so far in waiting for locks, by applications connected to this database.

```
Total wait time (ms) = 0
```

## Subsection snapshots

On systems that use interpartition parallelism, the SQL compiler partitions the access plan for an SQL statement into subsections. Each subsection is executed by a different database agent (or agents for SMP).

The access plan for an SQL statement generated by the database code generator during compilation can be obtained using the db2expln command. As an example, selecting all the rows from a table that is partitioned across several partitions might result in an access plan having two subsections:

1. Subsection 0, the coordinator subsection, whose role is to collect rows fetched by the other database agents (subagents) and return them to the application.
2. Subsection 1, whose role is to perform a table scan and return the rows to the coordinating agent.

In this simple example, subsection 1 would be distributed across all the database partitions. There would be a subagent executing this subsection on each physical partition of the database partition group to which this table belongs.

The database system monitor allows you to correlate runtime information with the access plan, which is compile time information. With interpartition parallelism, the monitor breaks information down to the subsection level. For example, when the statement monitor switch is ON, a GET SNAPSHOT FOR APPLICATION will return information for each subsection executing on this partition, as well as totals for the statement.

The subsection information returned for an application snapshot includes:

- the number of table rows read/written
- CPU consumption
- elapsed time
- the number of table queue rows sent and received from other agents working on this statement. This allows you to track the execution of a long running query by taking a series of snapshots.
- subsection status. If the subsection is in a WAIT state, because it is waiting for another agent to send or receive data, then the information also identifies the partition or partitions preventing the subsection from progressing in its execution. You may then take a snapshot on these partitions to investigate the situation.

The information logged by a statement event monitor for each subsection after it has finished executing includes: CPU consumption, total execution, time, and several other counters.

## Global snapshots on partitioned database systems

On a partitioned database system, you can use the snapshot monitor to take a snapshot of the current partition, a specified partition, or all partitions. When taking a global snapshot across all the partitions of a partitioned database, data is aggregated before the results are returned.

Data is aggregated for the different element types as follows:

- **Counters, Time, and Gauges**

Contains the sum of all like values collected from each partition in the instance. For example, GET SNAPSHOT FOR DATABASE XYZ ON TEST GLOBAL would return the number of rows read (rows\_read) from the database for all partitions in the partitioned database instance.

- **Watermarks**

Returns the highest (for high water) or lowest (for low water) value found for any partition in the partitioned database system. If the value returned is of concern, then snapshots for individual partitions can be taken to determine if a particular partition is over utilized, or if the problem is instance-wide.

- **Timestamp**

Set to the timestamp value for the partition where the snapshot monitor instance agent is attached. Note that all timestamp values are under control of the timestamp monitor switch.

- **Information**

Returns the most significant information for a partition that may be impeding work. For example, for the element appl\_status, if the status on one partition was UOW Executing, and on another partition Lock Wait, Lock Wait would be returned, since it is the state that's holding up execution of the application.

You can also reset counters, set monitor switches, and retrieve monitor switch settings for individual partitions or all partitions in your partitioned database.

**Note:** When taking a global snapshot, if one or more partitions encounter an error, then data is collected from the partitions where the snapshot was successful and a warning (sqlcode 1629) is also returned. If a global get or update of monitor switches, or a counter reset fails on one or more partitions, then those partitions will not have their switches set, or data reset.

## Using snapshot monitor data to monitor the reorganization of a partitioned table

The following information describes some of the most useful methods of monitoring the global status of a table reorganization.

### About this task

There is no separate data group indicating the overall table reorganization status for a partitioned table. A partitioned table uses a data organization scheme in which table data is divided across multiple storage objects, called data partitions or ranges, according to values in one or more table partitioning key columns of the table. However, you can deduce the global status of a table reorganization from the values of elements in the individual data partition data group being reorganized. The following information describes some of the most useful methods of monitoring the global status of a table reorganization.

#### Determining the number of data partitions being reorganized

You can determine the total number of data partitions being reorganized on a table by counting the number of monitor data blocks for table data that have the same table name and schema name. This value indicates the number of data partitions on which reorganization has started. Examples 1 and 2 indicate that three data partitions are being reorganized.

#### Identifying the data partition being reorganized

You can deduce the current data partition being reorganized from the phase start time (reorg\_phase\_start). During the SORT/BUILD/REPLACE phase, the monitor data corresponding to the data partition that is being reorganized shows the most recent phase start time. During the INDEX\_RECREATE phase, the phase start time is the same for all the data partitions. In Examples

1 and 2, the INDEX\_RECREATE phase is indicated, so the start time is the same for all the data partitions.

### Identifying an index rebuild requirement

You can determine if an index rebuild is required by obtaining the value of the maximum reorganize phase element (reorg\_max\_phase), corresponding to any one of the data partitions being reorganized. If reorg\_max\_phase has a value of 3 or 4, then an Index Rebuild is required. Examples 1 and 2 report a reorg\_max\_phase value of 3, indicating an index rebuild is required.

### Examples

The following sample output is from a three-node server that contains a table with three data partitions:

```
CREATE TABLE sales (c1 INT, c2 INT, c3 INT)
PARTITION BY RANGE (c1)
(PART P1 STARTING FROM (1) ENDING AT (10) IN parttbs,
PART P2 STARTING FROM (11) ENDING AT (20) IN parttbs,
PART P3 STARTING FROM (21) ENDING AT (30) IN parttbs)
DISTRIBUTE BY (c2)
```

Statement executed:

```
REORG TABLE sales ALLOW NO ACCESS ON ALL DBPARTITIONNUMS
```

#### Example 1:

```
GET SNAPSHOT FOR TABLES ON DPARTDB GLOBAL
```

The output is modified to include table information for the relevant table only.

```
Table Snapshot

**Example 6:**

The Table Reorg Information includes information about reclaiming extents as part of a reorganization operation. The example that follows shows the relevant output.

```
db2 -v "get snapshot for tables on wsdb"

Table Reorg Information:
  Reorg Type           =
  Reclaim Extents     =
  Allow Write Access  =
  Reorg Index         = 0
  Reorg Tablespace    = 0
  Start Time          = 10/22/2008 15:49:35.477532
  Reorg Phase         = 12 - Release
  Max Phase           = 3
```

**Note:** Any snapshot requests from a monitor version before SQLM\_DBMON\_VERSION9\_7 will not return any Reclaim Reorg status to the requesting client.

### Snapshot monitor self-describing data stream

After you capture a snapshot with the db2GetSnapshot API, the API returns the snapshot output as a self-describing data stream. Self-describing data includes data attributes such as element names and sizes.

Figure 6 on page 385 shows the structure of the data stream and Table 66 on page 386 provides some examples of the logical data groups and monitor elements that might be returned.

**Note:** Descriptive names are used for the identifiers in the examples and tables. These names are prefixed by **SQLM\_ELM\_** in the actual data stream. For example, collected would appear as SQLM\_ELM\_COLLECTED in the snapshot monitor output. Types are prefixed with **SQLM\_TYPE\_** in the actual data stream. For example, headers appear as SQLM\_TYPE\_HEADER in the data stream.

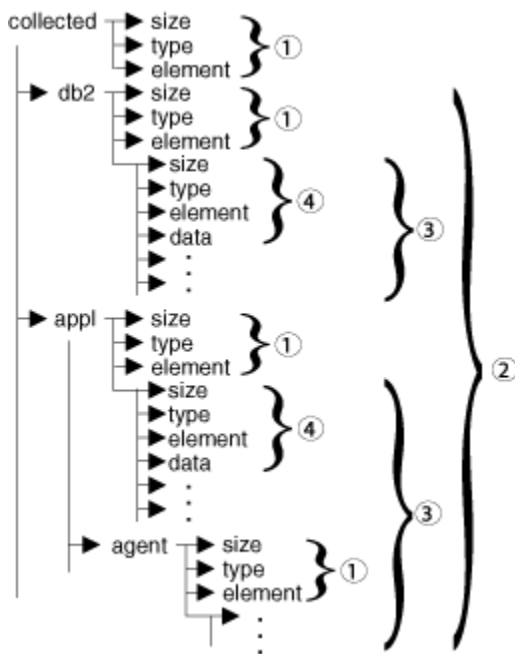

Figure 6. Snapshot Monitor Data Stream

1. Each logical data group begins with a header that indicates its size and name. This size does not include the volume of data taken up by the header itself.
2. Size in the collected header returns the total size of the snapshot.
3. The size element in other headers indicates the size of all the data in that logical data group, including any subordinate groupings.
4. Monitor element information follows its logical data group header and is also self-describing.

*Table 66. Sample Snapshot Data Stream*

<b>Logical Data Group</b>	<b>Data Stream</b>	<b>Description</b>
collected	1000 header collected	Size of snapshot data (in bytes). Indicates the start of a logical data group. Name of the logical data group.
	4 u32bit server_db2_type sqlf_nt_server	Size of the data stored in this monitor element. Monitor element type - unsigned 32 bit numeric. The name of the monitor element collected. The collected value for this element.
	2 u16bit node_number 3	Size of the data stored in this monitor element. Monitor element type - unsigned 16 bit numeric. The name of the monitor element collected. The collected value for this element.
	...	...
	...	...
	...	...
db2	200 header db2	Size of the level portion of data in the snapshot. Indicates the start of a logical data group. Name of the logical data group.
	4 u32bit sort_heap_allocated 16	Size of the data stored in this monitor element. Monitor element type - unsigned 32 bit numeric. The name of the monitor element collected. The collected value for this element.
	4 u32bit local_cons 3	Size of the data stored in this monitor element. Monitor element type - unsigned 32 bit numeric. The name of the monitor element collected. The collected value for this element.
	...	...
	...	...
	...	...
appl	100 header appl	Size of the appl element data in the snapshot. Indicates the start of a logical data group. Name of the logical data group.
	4 u32bit locks_held 3	Size of the data stored in this monitor element. Monitor element type - unsigned 32 bit numeric. The name of the monitor element collected. The collected value for this element.
	...	...
	...	...
	...	...
	...	...

Table 66. Sample Snapshot Data Stream (continued)

Logical Data Group	Data Stream	Description
agent	50	Size of the agent portion of the appl structure.
	header	Indicates the start of a logical data group.
	agent	Name of the logical data group.
	4	Size of the data stored in this monitor element.
	u32bit	Monitor element type - 32 bit numeric.
	agent_pid	The name of the monitor element collected.
	12	The collected value for this element.
	...	...

The db2GetSnapshot() routine returns the self-describing snapshot data in the user-supplied buffer. Data is returned in the logical data groupings associated with the type of snapshot being captured.

Each item returned by a snapshot request contains fields that specify its size and type. The size can be used to parse through the returned data. A field's size can also be used to skip over a logical data group. For example, to skip over the database record you need to determine the number of bytes in the data stream. Use the following formula to calculate the number of bytes to skip:

```
size of the db2 logical data grouping + sizeof(sqlm_header_info)
```

## Progress monitoring of the rollback process

If you obtain an application snapshot while a transaction is rolling back, you will see rollback monitor elements in the output. This information can be used to monitor the progress of the rollback operation.

The information provided in the application snapshot includes the start time of the rollback, the total work to be done, and completed work. The work metric is bytes.

The following is an example of output from the **GET SNAPSHOT FOR ALL APPLICATIONS** command:

```

Application Snapshot
Application handle      = 6
Application status     = Rollback Active
  Start Time           = 02/20/2004 12:49:27.713720
  Completed Work       = 1024000 bytes
  Total Work           = 4084000 bytes

Application Snapshot
Application handle      = 10
Application status     = Rollback to Savepoint
  Start Time           = 02/20/2004 12:49:32.832410
  Completed Work       = 102400 bytes
  Total Work           = 2048000 bytes

```

The value in the application status monitor element implies which type of rollback event is occurring:

### Rollback Active

This is a unit of work rollback: an explicit (user invoked) or implicit (forced) rollback of the entire transaction.

### Savepoint rollback

This is a partial rollback to a statement or application level savepoint. Nested savepoints are considered a single unit, using the outermost savepoint.

Completed Work units shows the relative position in the log stream that has been rolled back. Updates to Completed Work are made after every log record is processed. Updates are not performed evenly because log records vary in size.

Total Work units is an estimate based on the range of log records in the log stream that need to be rolled back for the transaction or savepoint. It does not indicate the exact number of log record bytes that need to be processed.

## Monitoring with db2top in interactive mode commands

The **db2top** monitoring utility quickly and efficiently monitors a complex database environment. It combines snapshot information from all database partitions and provides a dynamic, real-time view of a running database system using a text-based user interface.

### About this task

**Important:** The **db2top** command has been deprecated and might not appear in future releases.

When you run **db2top** in interactive mode, you can issue the following commands:

#### A

Monitor either the primary or the secondary database in a HADR cluster.

#### a

Goto application details for agent (or restrict on agent on statement screen). The **db2top** command will prompt for the agent-id.

#### B

Display the main consumer of critical server resources (Bottleneck Analysis).

#### c

This option allows to change the order of the columns displayed on the screen. The syntax is in the form: 1,2,3,... where 1,2,3 correspond to the 1st, 2nd and 3rd columns displayed. These are the column numbers to use when specifying a sort criteria.

When you use the **c** switch key, a screen is shown specifying the order of the columns displayed on screen. The left part of the screen displays the default order and column numbers; the right part of the screen displays the current ordering. To change the order of the columns, enter the new column order in the text field at the bottom of the screen. Next, enter the relative column positions as displayed on the left, separated by commas. Not all columns need to be specified. This column ordering can be saved in *\$DB2TOPRC* for subsequent **db2top** monitoring sessions by selecting **w**. You can sort and select in which order the columns are displayed on the screen. Valid keywords for column ordering in the *.db2toprc* file are:

- sessions=
- tables=
- tablespaces=
- bufferpools=
- dynsql=
- statements=
- locks=
- utilities=
- federation=

#### b

Goto buffer pool screen.

#### C

Toggle snapshot data collector on/off.

#### d

Goto database screen.

#### D

Goto the dynamic SQL screen.

- f** Freeze screen.
- F** Monitor federated queries on the primary server.
- G** Toggle graph on/off.
- h** Go to Help screen
- H** Goto the history screen
- i** Toggle idle sessions on/off.
- k** Toggle actual vs delta values.
- l** Goto sessions screen.
- L** Allows displaying the complete query text from the SQL screen. Regular explain can then be run using e or X options.
- m** Display memory pools.
- o** Display session setup.
- p** Goto the partitions screen.
- P** Select db partition on which to issue snapshot.
- q** Quit db2top.
- R** Reset snapshot data.
- s** Goto the statements screen.
- S** Run native snapshot.
- t** Goto table spaces screen.
- T** Goto tables screen
- u** Display active utilities and aggregate them across database partitions.
- U** Goto the locks screen.
- V** Set default explains schema.
- w** Write session settings to .db2toprc.

**W**

Watch mode for agent\_id, os\_user, db\_user, application or netname. Statements returned by the session snapshot (option l) will be written to agent.sql, os\_user-agent.sql, db\_user-agent.sql, application-agent.sql or netname-agent.sql. When issued from the dynamic SQL screen (option D), statements will be written to db2adv.sql in a format compatible with db2advvis.

**X**

Toggle extended mode on/off.

**z|Z**

Sort on ascending or descending order.

**/**

Enter expression to filter data. Expression must conform to regular expression. Each function (screen) can be filtered differently. The regexp check is applied to the whole row.

**<|>**

Move to left or right of screen.

The following switches apply to the applications screen only:

**r**

Return to previous function.

**R**

Toggle automatic refresh.

**g**

Toggle graph on/off.

**X**

Toggle extended mode on/off.

**d**

Display agents.

To start **db2top in interactive mode**, issue the following command:

```
db2top -d <database name>
```

When you type

```
db2top -d sample
```

the following output is displayed:

```
[\\]11:57:10,refresh=2secs(0.000) Inactive,part=[1/1],<instanceName>:sample
[d=Y,a=N,e=N,p=ALL] [qp=off]
```

[/]: When rotating, it means that db2top is waiting between two snapshots, otherwise, it means db2top is waiting

from an answer from Db2

11:57:10: current time

refresh=2secs: time interval

refresh=!secs: Exclamation mark means the time to process the snapshot by Db2 is longer than the refresh interval.

In this case, db2top will increase the interval by 50%. If this occurs too often because the system is too busy,

you can either increase the snapshot interval (option I), monitor a single database partition (option P), or turn

off extended display mode (option x)

0.000 : time spent inside Db2 to process the snapshot

d=Y/N : delta or cumulative snapshot indicator (command option -k or option k).

a=Y/N : Active only or all objects indicator (-a command option set or i)

e=Y/N : Extended display indicator

p=ALL : All database partitions

p=CUR: Current database partition (-P command option with no partition number specified)

p=3 : target database partition number: say 3

Inactive: : Shows inactive if Db2 is not running, otherwise displays the platform on which Db2 is running

part=[1/1] : active database partition number vs total database partition number. For example,

part=[2,3] means one

database partition out of 3 is down (2 active, 3 total)

```
<instanceName> : instance name
sample : database name
```

## Example

The following example demonstrates running the **db2top** monitoring utility in interactive mode in a partitioned database environment:

```
db2top -d TEST -n mynode -u user -p passwd -V skm4 -B -i 1
The command parameters are as follows:
-d TEST      # database name
-n mynode    # node name
-u user      # user id
-p passwd    # password
-V skm4      # Schema name
-B           # Bold enabled
-i 1         # Screen update interval: 1 second
```

## **.db2toprc configuration file**

The **.db2toprc** configuration file is a user generated file used to set parameters at initialization time for the **db2top** monitoring utility.

The **db2top** utility will search for the location of the **.db2toprc** file using the user-defined variable **\$db2topRC**. If the variable is not set, **db2top** will first search for the **.db2toprc** file in the current directory and then in the home directory. The **.db2toprc** file is user generated.

## Environment variables

You can set the following environment variables:

- **DB2TOPRC**

A user defined environment variable that stores the location of the **.db2toprc** file. For example, on Linux, you can define **DB2TOPRC** as: `export db2topRC=~/.db2top`.

If the variable is not set by the user, **db2top** will first search for the **.db2toprc** file in the current directory and then in the home directory.

- **DB2DBDFT**

This variable specifies the database alias name of the database to be used for implicit connects. It is used when no database name is specified on the command line or in the **.db2toprc** configuration file.

- **EDITOR**

This system environment variable specifies the command used to start the text editor used to display the results of explain or native snapshots.

If this variable is not set, **vi** is used.

## Structure

Some of the entries in the **.db2toprc** file are described here.

### **cpu=command**

Use this entry to display the results of CPU activity on the second line at the right of the screen output. For example:

```
cpu=vmstat 2 2 | tail -1 | awk '{printf("%d(usr+sys)", $14+$15);}'
```

displays `Cpu=2(usr+sys)` on the right of the screen.

### **io=command**

Use this entry to specify a command and display the result on the second line at the left of the screen output. For example:

```
io=vmstat 2 2 | tail -1 | awk '{printf("%d(bi+bo)", $10+$11);}'
```

displays Disk=76 (bi+bo) on the left of the screen.

Both commands run as background processes and the fields on the screen are updated asynchronously.

#### shell alias=command

Use this shell entry to specify a user defined command, for example: shell M=top spawns top from a **db2top** session when entering M. It returns to the current screen upon exit.

#### function alias=command

Use this entry to specify a user defined command, for example: function N=netstat creates a new function called N that repeatedly displays the output of **netstat**. There can be multiple function entries. They must be placed on separate lines. For example:

```
function Q=netstat
function N=df -k
```

#### sort=command

Use this entry to specify a sort order, for example: sort=command creates a default sort order for this function, where command is the column number. It can be either ascending or descending. Sort is valid for sessions, tables, tablespaces, bufferpool, dynsql, statements, locks, utilities and federation.

### Sample .db2toprc file

There is no default .db2toprc configuration file. However, you can press "W" to create a .db2toprc for the current setup. Use the following sample **.db2toprc** file as a reference. Comments have been added to all entries.

```
# db2top configuration file
# On UNIX, should be located in $HOME/.db2toprc
# File generated by db2top-1.0a
#
node= # [-n] nodename
database=sample # [-d] databasename
user= # [-u] database user
password= # [-p] user password (crypted)
schema= # [-V] default schema for explains
interval=2 # [-i] sampling interval
active=OFF # [-a] display active sessions only (on/off)
reset=OFF # [-R] Reset snapshot at startup (on/off)
delta=ON # [-k] Toggle display of delta/cumulative values (on/off)
gauge=ON # display graph on sessions list (on/off)
colors=ON
# True if terminal supports colors. Informs GE_WRS if it can display information with colors
graphic=ON # True if terminal supports semi graphical characters (on/off).
port= # Port for network collection
streamsize=size # Max collection size per hour (eg. 1024 or 1K : K, M or G)
# Command to get cpu usage information from OS
cpu=vmstat 2 2 | tail -1 | awk '{printf("%d(usr+sys)", $14+$15);}'
# Command to get IO usage information from OS
io=vmstat 2 2 | tail -1 | awk '{printf("%d(bi+bo)", $10+$11);}'
# Ordering of information in sessions screen
# Column order for the session screen (option l)
sessions=0,1,18,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,19,20,21,22,23
# Column order for the tables screen (option T)
tables=0,1,2,4,3,5,6,7
# Column order for the tablespaces screen (option t).
# The display will be sorted in ascending order on column #22
tablespaces=0,1,18,2,3,4,5,6,7,8, sort=22a
# Column order for the bufferpool screen (option b)
bufferpools=0,1,18,2,3,4,5,6,7,8,9,10
# Column order for the Dynamic SQL screen (option D)
dynsql=0,1,18,2,3,4,5,6,7,8,9
statements=0,1
locks=0,1
utilities=0 # contains the default column and sort order for the utility screen
federation=0,2,4 # contains the default column and sort order for the federation screen

# User defined commands
shell P=top
function N=date && netstat -t tcp
```

## Switch-based monitoring concepts

### System monitor switches

System monitor switches control how snapshot monitors and some event monitors collect data.

**Note:** These system monitor switches do not affect the unit of work event monitor and locking event monitor.

The snapshot monitor and some event monitors report data collected by the system monitor. Collecting system monitor data introduces extra processing for the database manager. For example, in order to calculate the execution time of SQL statements, the database manager must make calls to the operating system to obtain timestamps before and after the execution of every statement. These types of system calls are generally expensive. The system monitor also increases memory consumption. For every monitor element tracked by the system monitor, the database manager uses its memory to store the collected data.

In order to minimize the additional processor time involved in maintaining monitoring information, monitor switches control the collection of potentially expensive data by the database manager. Each switch has only two settings: ON or OFF. If a monitor switch is OFF, the monitor elements under that switch's control do not collect any information. There is a considerable amount of basic monitoring data that is not under switch control, and will always be collected regardless of switch settings.

Each monitoring application has its own logical view of the monitor switches (and the system monitor data). Upon startup each application inherits its monitor switch settings from the `dft_monswitches` parameters in the database manager configuration file (at the instance level). A monitoring application can alter its monitor switch settings with the `UPDATE MONITOR SWITCHES USING MONSWITCH OFF/ON` command. The `MONSWITCH` parameter holds values found in the Monitor Switch column in the Snapshot Monitor Switches table shown in the next section. Changes to the switch settings at the application level only affect the application from where the switch was changed.

Instance-level monitor switches can be changed without stopping the database management system. To do this use the `UPDATE DBM CFG USING DBMSWITCH OFF/ON` command. The `DBMSWITCH` parameter holds values from the DBM Parameter column in the Snapshot Monitor Switches table shown in the next section. This dynamic updating of switches requires that the application performing the update be explicitly attached to the instance for the updates to dynamically take effect. Other existing snapshot applications will not be affected by a dynamic update. New monitoring applications will inherit the updated instance-level monitor switch settings. For an existing monitoring application to inherit the new default monitor switch values, it must terminate and re-establish its attachment. Updating the switches in the database manager configuration file will update the switches for all partitions in a partitioned database.

The database manager keeps track of all the snapshot monitoring applications and their switch settings. If a switch is set to ON in one application's configuration, then the database manager always collects that monitor data. If the same switch is then set to OFF in the application's configuration, then the database manager will still collect data as long as there is at least one application with this switch turned ON.

The collection of time and timestamp elements is controlled by the `TIMESTAMP` switch. Turning this switch OFF (it is ON by default) instructs the database manager to skip any timestamp operating system calls when determining time or timestamp-related monitor elements. Turning this switch OFF becomes important as CPU utilization approaches 100%. When this occurs, the performance degradation caused by issuing timestamps increases dramatically. For monitor elements that can be controlled by the `TIMESTAMP` switch and another switch, if either of the switches is turned OFF, data is not collected. Therefore, if the `TIMESTAMP` switch is turned OFF, the overall cost of data under the control of other monitor switches is greatly reduced.

Event monitors are not affected by monitor switches in the same way as snapshot monitoring applications. When an event monitor is defined, it automatically turns ON the instance level monitor switches required by the specified event types. For example, a deadlock event monitor will automatically turn ON the `LOCK` monitor switch. The required monitor switches are turned ON when the event monitor is activated. When the event monitor is deactivated, the monitor switches are turned OFF.

The **TIMESTAMP** monitor switch is not set automatically by event monitors. It is the only monitor switch that controls the collection of any monitor elements belonging to event monitor logical data groupings. If the **TIMESTAMP** switch is **OFF**, most of the timestamp and time monitor elements collected by event monitors will not be collected. These elements are still written to the specified table, file, or pipe, but with a value of zero.

<i>Table 67. Snapshot Monitor Switches</i>		
<b>Monitor Switch</b>	<b>DBM Parameter</b>	<b>Information Provided</b>
BUFFERPOOL	DFT_MON_BUFPOOL	Number of reads and writes, time taken
LOCK	DFT_MON_LOCK	Lock wait times, deadlocks
SORT	DFT_MON_SORT	Number of heaps used, sort performance
STATEMENT	DFT_MON_STMT	Start/stop time, statement identification
TABLE	DFT_MON_TABLE	Measure of activity (rows read/written)
UOW	DFT_MON_UOW	Start/end times, completion status
TIMESTAMP	DFT_MON_TIMESTAMP	Timestamps

Before capturing a snapshot or using an event monitor, you must determine what data you need the database manager to gather. If you want any of the following special types of data to be collected in a snapshot, you will need to set the appropriate monitor switches.

- Buffer pool activity information
- Lock, lock wait, and time related lock information
- Sorting information
- SQL statement information
- Table activity information
- Times and timestamp information
- Unit of work information

The switches corresponding to the previously listed information types are all **OFF** by default, except for the switch corresponding to times and timestamp information, which is **ON** by default.

Event monitors are only affected by the time and timestamp information switch. All other switch settings have no effect on the data collected by event monitors.

### ***Setting system monitor switches from the CLP***

System monitor switches control the collection of data by the system monitor. By setting certain monitor switches to **ON**, you can collect specific types of monitor data.

### **Before you begin**

The application performing any monitor switch updates must have an instance attachment. You must have one of **SYSADM**, **SYSCTRL**, **SYSMAINT**, or **SYSMON** authority to use the following commands:

- **UPDATE MONITOR SWITCHES**
- **GET MONITOR SWITCHES**
- **GET DATABASE MANAGER MONITOR SWITCHES**

You must have **SYSADM** authority to use the **UPDATE DBM CFG** command.

## About this task

### Procedure

- To activate any of the local monitor switches, use the UPDATE MONITOR SWITCHES command. The switches will remain active until the application (CLP) detaches, or until they are deactivated with another UPDATE MONITOR SWITCHES command. The following example updates all of the local monitor switches to be ON:

```
db2 update monitor switches using BUFFERPOOL on LOCK on SORT on STATEMENT on TIMESTAMP on
TABLE on UOW on
```

- To deactivate any of the local monitor switches, use the UPDATE MONITOR SWITCHES command. The following example updates all of the local monitor switches to be OFF:

```
db2 update monitor switches using BUFFERPOOL off LOCK off SORT off STATEMENT off TIMESTAMP
off TABLE off UOW off
```

The following is an example of the output you would expect to see after issuing the previously shown UPDATE MONITOR SWITCH command:

```
Monitor Recording Switches

Switch list for db partition number 1
Buffer Pool Activity Information (BUFFERPOOL) = OFF
Lock Information (LOCK) = OFF
Sorting Information (SORT) = OFF
SQL Statement Information (STATEMENT) = OFF
Table Activity Information (TABLE) = OFF
Unit of Work Information (UOW) = OFF
Get timestamp information (TIMESTAMP) = OFF
```

- It is also possible to manipulate the monitor switches at the database manager level. This involves changing the dft\_monswitches parameters in the database manager configuration file, using the UPDATE DBM CFG command. In the following example, only lock switch controlled information is to be collected in addition to the basic information.

```
db2 update dbm cfg using DFT_MON_LOCK on
```

Whenever a monitoring application is started, it inherits its monitor switch settings from the database manager. Any changes to the database manager's monitor switch settings will not impact any running monitoring applications. Monitoring applications must reattach themselves to the instance to pick up any changes to monitor switch settings.

- For partitioned database systems, you can set monitor switches specifically for a certain partition, or globally for all partitions.
  - a) To set a monitor switch (for example, BUFFERPOOL) for a specific partition (for example, partition number 3), issue the following command:

```
db2 update monitor switches using BUFFERPOOL on
at dbpartitionnum 3
```

- b) To set a monitor switch (for example, SORT) for all partitions, issue the following command:

```
db2 update monitor switches using SORT on global
```

- To check the status of the local monitor switches use the GET MONITOR SWITCHES command.

```
db2 get monitor switches
```

- For partitioned database systems, you can view the monitor switch settings specifically for a certain partition, or globally for all partitions.
  - a) To view the monitor switch settings for a specific partition (for example, partition number 2), issue the following command:

```
db2 get monitor switches at dbpartitionnum 2
```

b) To view the monitor switch settings for all partitions, issue the following command:

```
db2 get monitor switches global
```

- To check the status of the monitor switches at the database manager level (or instance level) use the GET DATABASE MANAGER MONITOR SWITCHES command. This command will show the overall switch settings for the instance being monitored.

```
db2 get database manager monitor switches
```

The following is an example of the output you should expect to see after issuing the previously shown command:

```
DBM System Monitor Information Collected
Switch list for db partition number 1
Buffer Pool Activity Information (BUFFERPOOL) = OFF
Lock Information (LOCK) = ON 10-25-2001 16:04:39
Sorting Information (SORT) = OFF
SQL Statement Information (STATEMENT) = OFF
Table Activity Information (TABLE) = OFF
Unit of Work Information (UOW) = OFF
Get timestamp information (TIMESTAMP) = OFF
```

## Results

Now that you have set the required monitor switches and confirmed the switch settings, you are ready to capture and collect monitor data.

## Setting system monitor switches from a client application

System monitor switches control the collection of data by the system monitor. By setting certain monitor switches to ON, you can collect specific types of monitor data.

## Before you begin

The application performing any monitor switch updates must have an instance attachment. You must have SYSADM, SYSCTRL, SYSMANT, or SYSMON authority to use the db2MonitorSwitches API.

## Procedure

1. Include the database libraries sqlutil.h and db2ApiDf.h, which are located in the include subdirectory under sqllib.

```
#include <sqlutil.h>
#include <db2ApiDf.h>
#include <string.h>
#include <sqlmon.h>
```

2. Set switch lists buffer unit size to 1 KB.

```
#define SWITCHES_BUFFER_UNIT_SZ 1024
```

3. Initialize the sqlca, db2MonitorSwitches, and sqlm\_recording\_group structures. Also, initialize a pointer to contain the switch lists buffer, and establish the buffer's size.

```
struct sqlca sqlca;
memset (&sqlca, '\0', sizeof(struct sqlca));
db2MonitorSwitchesData switchesData;
memset (&switchesData, '\0', sizeof(switchesData));
struct sqlm_recording_group switchesList[SQLM_NUM_GROUPS];
memset(switchesList, '\0', sizeof(switchesList));
sqluint32 outputFormat;
static sqluint32 switchesBufferSize = SWITCHES_BUFFER_UNIT_SZ;
char *switchesBuffer;
```

4. Initialize the buffer, which is to hold the switch list output.

```
switchesBuffer = (char *)malloc(switchesBufferSize);
memset(switchesBuffer, '\\0', switchesBufferSize);
```

5. To alter the state of the local monitor switches, alter the elements in the `sqlm_recording_group` structure (named `switchesList` as indicated in the previous step). For a monitor switch to be turned on, the parameter `input_state` is to be set to `SQLM_ON`. For a monitor switch to be turned off, the parameter `input_state` must be set to `SQLM_OFF`.

```
switchesList[SQLM_UOW_SW].input_state = SQLM_ON;
switchesList[SQLM_STATEMENT_SW].input_state = SQLM_ON;
switchesList[SQLM_TABLE_SW].input_state = SQLM_ON;
switchesList[SQLM_BUFFER_POOL_SW].input_state = SQLM_OFF;
switchesList[SQLM_LOCK_SW].input_state = SQLM_OFF;
switchesList[SQLM_SORT_SW].input_state = SQLM_OFF;
switchesList[SQLM_TIMESTAMP_SW].input_state = SQLM_OFF;
switchesData.piGroupStates = switchesList;
switchesData.poBuffer = switchesBuffer;
switchesData.iVersion = SQLM_DBMON_VERSION9_5;
switchesData.iBufferSize = switchesBufferSize;
switchesData.iReturnData = 0;
switchesData.iNodeNumber = SQLM_CURRENT_NODE;
switchesData.poOutputFormat = &outputFormat;
```

**Note:** `SQLM_TIMESTAMP_SW` is unavailable if `iVersion` is less than `SQLM_DBMON_VERSION8`.

6. To submit the changes to switch settings, call the `db2MonitorSwitches()` function. Pass the `db2MonitorSwitchesData` structure (named `switchesData` in this example) as a parameter to the `db2MonitorSwitches` API. The `switchesData` contains the `sqlm_recording_group` structure as a parameter.

```
db2MonitorSwitches(db2Version810, &switchesData, &sqlca);
```

7. Process the switch list data stream from the switch list buffer.
8. Clear the switch list buffer.

```
free(switchesBuffer);
free(pRequestedDataGroups);
```

## Results

Now that you have set the required monitor switches and confirmed the switch settings, you are ready to capture and collect monitor data.

### ***System monitor switches self-describing data stream***

After you update or view the switch settings of the current system monitor with the `db2MonitorSwitches` API, the API returns the switch settings as a self-describing data stream. Self-describing data includes data attributes such as element names and sizes.

Figure 7 on page 398 shows the structure of the switch list information that may be returned for a partitioned database environment.

#### **Note:**

1. Descriptive names are used for the identifiers in the examples and tables. These names are prefixed by **SQLM\_ELM\_** in the actual data stream. For example, `db_event` would appear as `SQLM_ELM_DB_EVENT` in the event monitor output. Types are prefixed with **SQLM\_TYPE\_** in the actual data stream. For example, headers appear as `SQLM_TYPE_HEADER` in the data stream.
2. For global switch requests the partition order of the returned information can be different in each switch request. In this case, a partition id is included in the data stream.

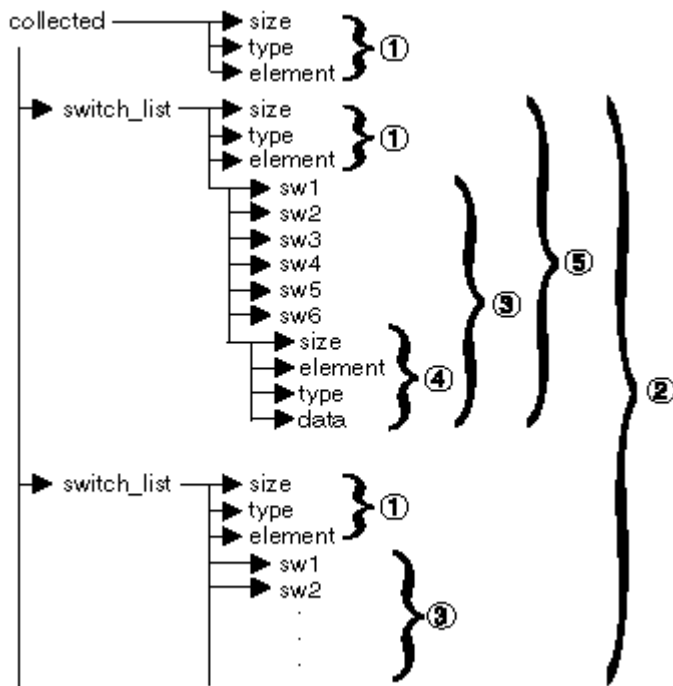

Figure 7. Switch List Monitor Data Stream

1. Each logical data group begins with a header that indicates its size and name. This size does not include the volume of data taken up by the header itself.
2. Size in the collected header returns the total size of all monitor switch lists for all partitions.
3. The size element in switch list header indicates the size of switch data for that partition.
4. Switch information is self-describing.
5. For a non-partitioned database, the switch settings for the stand alone partition are returned. That is, only one switch list is returned.

## Database system monitor data organization

The system monitor collects and stores information that you can access using interfaces to the snapshot monitor and some event monitors. The database system monitor stores information it collects in entities called *monitor elements* (these were previously known as data elements). Each monitor element stores information regarding one specific aspect of the state of the database system. In addition, monitor elements are identified by unique names and store a certain type of information.

The following element types are available for the system monitor to store data:

### Counter

Counts the number of times an activity occurs. Counter values increase during monitoring. Most counter elements can be reset.

### Gauge

Indicates the current value for an item. Gauge values can go up and down depending on database activity (for example, the number of locks held). Gauge elements can not be reset.

### Watermark

Indicates the highest (maximum) or lowest (minimum) value an element has reached since monitoring was started. Watermark elements can not be reset.

### Information

Provides reference-type details of your monitoring activities. This can include items such as partition names, aliases, and path details. Information elements can not be reset.

## Timestamp

Indicates the date and time that an activity took place by providing the number of seconds and microseconds that have elapsed since January 1, 1970. For the snapshot monitor and event monitors, the collection of timestamp elements is controlled by the `TIMESTAMP` monitor switch. While this switch is on by default, you should turn it off for performance reasons if CPU utilization on the database instance approaches 100%. Timestamp elements can not be reset.

A value of 0 for the timestamp element means "not available". If you attempt to import this data, such a value will generate an out of range error (SQL0181). To avoid this error, update the value to any valid timestamp value before exporting the data.

## Time

Returns the number of seconds and microseconds spent on an activity. For the snapshot monitor and event monitors, the collection of most time elements is controlled by the `TIMESTAMP` monitor switch. While this switch is on by default, you should turn it off for performance reasons if CPU utilization on the database instance approaches 100%. Some time elements can be reset.

Monitor elements collect data for one or more logical data groups. A logical data group is a collection of monitor elements that gather database system monitoring information for a specific scope of database activity. Monitor elements are sorted in logical data groups based on the levels of information they provide. For example, while snapshot monitoring, the Total Sort Time monitor element returns database (dbase), application (appl), and statement (stmt) information; hence, it appears in each of the logical data groups listed in parentheses.

Although many monitor elements are used by both the snapshot monitor and event monitors, they each use a distinct set of logical data groups. This is because the scopes of database activity for which you can capture a snapshot differ from those for which you can collect event data. Practically speaking, the overall set of monitor elements accessible from the snapshot monitor is different from those accessible from event monitors.

## Counter status and visibility

Among the monitor elements collected by the system monitor are several accumulating counters. These counters are incremented during the operation of the database or database manager, for example, every time an application commits a transaction.

Counters are initialized when their applicable object becomes active. For instance, the number of buffer pool pages read for a database (a basic monitor element) is set to zero when the database is activated.

Some counters that can be collected by the system monitor are controlled by monitor switches. If a particular monitor switch is off, the monitor elements under its control do not collect data. When a monitor switch is turned on, all the associated counters are reset to zero.

Counters returned by event monitors are reset to zero when the event monitor is activated.

Event monitor counting represents a count since one of the following starting points:

- Event monitor startup, for database, table space, and tables.
- Event monitor startup, for existing connections.
- Application connection, for connections made after the monitor was started.
- Start of the next transaction (unit of work) or statement after the monitor was started.
- Occurrence of a deadlock after the monitor was started.

Each event monitor and any monitoring application (an application using the snapshot monitor APIs) has its own logical view of the system monitor data. This means that when counters are reset or initialized, it only affects the event monitor or application that reset or initialized them. Event monitor counters cannot be reset, except by turning the event monitor off, and then on again. An application taking snapshots can reset its view of the counters at any time by using the `RESET MONITOR` command.

If you start a statement event monitor after a statement starts, the monitor will start collecting information when the next SQL statement starts. As a result, the event monitor will not return information

about statements that the database manager is executing when the monitor was started. This is also true for transaction information.

## System monitor output: the self-describing data stream

Aside from presenting system monitor data on screen or storing it in SQL tables, you can develop a client application to process it. The system monitor returns monitor data via a self-describing data stream for both the snapshot monitor and event monitor. In a snapshot monitoring application you can call the snapshot APIs to capture a snapshot and then directly process the data stream.

Processing event monitor data is different, in that the event data is sent to the application at the pace database events occur. For a pipe event monitor, the application waits for event data to arrive, and then processes it when it does. For a file event monitor, the application parses event files, thus processing event records in batches.

This self-describing data stream allows you to parse through the returned data one element at a time. This opens up numerous monitoring possibilities, including looking for information regarding a particular application or a specific database state.

The returned monitor data is in the following format:

### size

The size (in bytes) of the data stored in the monitor element or logical data grouping. In the case of a logical data grouping, this is the size of all data in the logical group. For example, the database logical grouping (*db*) contains individual monitor elements (such as *total\_log\_used*) along with other logical data groupings, such as rollforward information (*rollforward*). This does not include the size taken up by the 'size', 'type', and 'element' information.

### type

The type of element stored in the data (for example, variable length string or signed 32 bit numeric value). An element type of *header* refers to a logical data grouping for an element.

### element id

The identifier for the monitor element that was captured by the monitor. In the case of a logical data grouping, this is the identifier for the group (for example, *collected*, *dbase*, or *event\_db*).

### data

The value collected by a monitor for a monitor element. In the case of a logical data grouping, the data is composed of the monitor elements belonging to it.

All timestamps in monitor elements are returned in two unsigned 4 byte monitor elements (seconds and microseconds). These represent the number of seconds since January 1, 1970 in GMT time.

The size element of strings in monitor elements represents the actual size of data for the string element. This size does not include a null terminator, as the strings are not null terminated.

## Memory requirements for monitor data

The memory required for monitor data is allocated from the monitor heap. Monitor heap size is controlled by the **mon\_heap\_sz** database configuration parameter. This parameter has a default value of AUTOMATIC, meaning that the monitor heap can increase as needed until the **instance\_memory** limit is reached.

If you configure the **mon\_heap\_sz** parameter manually, consider the following factors:

- The number of monitoring applications
- The number and nature of event monitors
- The monitor switches set
- The level of database activity

Consider increasing the value for the **mon\_heap\_sz** parameter if monitor commands fail with an SQLCODE of -973.

The amount of monitor heap being used can be seen using the **MON\_GET\_MEMORY\_POOL** table function:

```
SELECT *
  FROM TABLE(MON_GET_MEMORY_POOL('DBMS', NULL, -1))MEM
 WHERE MEMORY_POOL_TYPE = 'MONITOR'
```

There are many situations where monitor heap is used:

- All active event monitors consume monitor heap. Every fast writer (db2fw) thread and event monitor (db2evm) thread uses monitor heap.
- Active ACTIVITIES, LOCKING, PACKAGE CACHE, UNIT OF WORK, STATISTICS, THRESHOLD VIOLATIONS and CHANGE HISTORY event monitors allocate **event records** from monitor heap. The number of allocated records is included in the **Queue Manager Info** portion of the output of db2pd -gfw. On busy systems where you expect a heavy volume to be recorded by these event monitors, the **Current Number of Records** increases quickly. On less busy systems, it increases more slowly depending on the expected amount of work.
- Each application's past activities (those completed in the current unit of work) are allocated from monitor heap. This occurs in the following situations:
  - When a LOCKING event monitor is active and HISTORY collection is enabled
  - When a DEADLOCKS WITH DETAILS HISTORY event monitor is active
- Routine data is stored in monitor heap when MON\_RTN\_DATA is enabled.
- Executable list data is stored in monitor heap when MON\_UOW\_EXECLIST is enabled.
- Monitor usage list data is stored in monitor heap.
- Any monitor switch that is turned ON consumes monitor heap.
- Each monitor application using SNAPSHOT, SWITCH and RESET interfaces consumes monitor heap. In these situations, monitor heap is used to hold switch and resettable data until the monitor application detaches from the instance.
- Each database connection consumes monitor heap when the STATEMENT switch is turned on. In these situations, monitor heap is used to hold monitoring data for currently running statements.
- An application's client information, set through the sqlseti() api or through the WLM\_SET\_CLIENT\_INFO procedure, is stored using monitor heap.
- On a Db2 Connect gateway, database and application information is stored in monitor heap. If the statement switch is ON, currently running statements store information in monitor heap.

## Monitoring buffer pool activity

The database server reads and updates all data from a buffer pool. Data is copied from a disk to a buffer pool as it is required by applications.

Pages are placed in a buffer pool:

- by the agent. This is synchronous I/O.
- by the I/O servers (prefetchers). This is asynchronous I/O.

Pages are written to disk from a buffer pool:

- by the agent, synchronously
- by page cleaners, asynchronously

If the server needs to read a page of data, and that page is already in the buffer pool, then the ability to access that page is much faster than if the page had to be read from disk. It is desirable to hit as many pages as possible in the buffer pool. Avoiding disk I/O is an important factor in database performance, therefore proper configuration of the buffer pools is one of the most important considerations for performance tuning.

The buffer pool *hit ratio* indicates the percentage of time that the database manager did not need to load a page from disk in order to service a page request because the page was already in the buffer pool. The greater the buffer pool hit ratio, the lower the frequency of disk I/O.

**Note:** The information that follows discusses buffer pools in environments other than Db2 pureScale environments. Buffer pools work differently in Db2 pureScale environments. For more information, see "[Buffer pool monitoring in a Db2 pureScale environment](#)", in the *Database Monitoring Guide and Reference*.

For example, the overall buffer pool hit ratio can be calculated as follows:

```
((pool_data_lbp_pages_found
+ pool_index_lbp_pages_found
+ pool_xda_lbp_pages_found
+ pool_col_lbp_pages_found
- pool_async_data_lbp_pages_found
- pool_async_index_lbp_pages_found - pool_async_xda_lbp_pages_found
- pool_async_col_lbp_pages_found)
/ (pool_data_l_reads
+ pool_index_l_reads + pool_xda_l_reads + pool_col_l_reads + pool_temp_data_l_reads
+ pool_temp_xda_l_reads + pool_temp_index_l_reads + pool_temp_col_l_reads))
× 100
```

This calculation takes into account all of the pages (index and data) that are cached by the buffer pool.

You can also use the MON\_BP\_UTILIZATION administrative view as a convenient method of monitoring the hit ratio for your buffer pools.

For a large database, increasing the buffer pool size may have minimal effect on the buffer pool hit ratio. Its number of data pages may be so large, that the statistical chances of a hit are not improved by increasing its size. Instead, you might find that tuning the index buffer pool hit ratio achieves the required result. This can be achieved using two methods:

1. Split the data and indexes into two different buffer pools and tune them separately.
2. Use one buffer pool, but increase its size until the index hit ratio stops increasing. The index buffer pool hit ratio can be calculated as follows:

```
((pool_index_lbp_pages_found
- pool_async_index_lbp_pages_found )
/ (pool_index_l_reads
+ pool_temp_index_l_reads)) × 100
```

The first method is often more effective, but because it requires indexes and data to reside in different table spaces, it may not be an option for existing databases. It also requires tuning two buffer pools instead of one, which can be a more difficult task, particularly when memory is constrained.

You should also consider the impact that prefetchers may be having on the hit ratio. Prefetchers read data pages into the buffer pool anticipating their need by an application (asynchronously). In most situations, these pages are read just before they are needed (the required case). However, prefetchers can cause unnecessary I/O by reading pages into the buffer pool that will not be used. For example, an application starts reading through a table. This is detected and prefetching starts, but the application fills an application buffer and stops reading. Meanwhile, prefetching has been done for a number of additional pages. I/O has occurred for pages that will not be used and the buffer pool is partially taken up with those pages.

Page cleaners monitor the buffer pool and asynchronously write pages to disk. Their goals are:

- Ensure that agents will always find free pages in the buffer pool. If an agent does not find free pages in the buffer pool, it must clean them itself, and the associated application will have a poorer response.
- Speed database recovery, if a system crash occurs. The more pages that have been written to disk, the smaller the number of log file records that must be processed to recover the database.

Although dirty pages are written out to disk, the pages are not removed from the buffer pool right away, unless the space is needed to read in new pages.

**Note:** Buffer pool information is typically gathered at a table space level, but the facilities of the database system monitor can roll this information up to the buffer pool and database levels. Depending on your type of analysis, you may need to examine this data at any or all of these levels.

## Snapshot system monitor interfaces

There are a number of system monitor tools that you can use to control the collection of monitor data and review the results.

The following tables show the APIs, CLP commands, and SQL statements available for snapshot system monitor.

Monitoring task	API
Capturing a snapshot	db2GetSnapshot
Converting the self-describing data stream	db2ConvMonStream
Displaying the database system monitor switches	db2MonitorSwitches
Estimating the size of a snapshot	db2GetSnapshotSize
Get/update monitor switches	db2MonitorSwitches
Resetting monitor counters	db2ResetMonitor
Updating the database system monitor switches	db2MonitorSwitches

Monitoring task	CLP Command
Capturing a snapshot	GET SNAPSHOT
Displaying the database manager monitor switches	GET DATABASE MANAGER MONITOR SWITCHES
Displaying the monitoring application's monitor switches	GET MONITOR SWITCHES
Formatting the event monitor trace	db2evmon
Generating sample SQL for write-to-table CREATE EVENT MONITOR statements	db2evtbl
Listing the active databases	LIST ACTIVE DATABASES
Listing the applications connected to a database	LIST APPLICATIONS
Listing the DCS applications	LIST DCS APPLICATIONS
Resetting monitor counters	RESET MONITOR
Updating the database system monitor switches	UPDATE MONITOR SWITCHES

Monitoring task	SQL Statement
Activating an event monitor	SET EVENT MONITOR STATE
Creating an event monitor	CREATE EVENT MONITOR
Deactivating an event monitor	SET EVENT MONITOR STATE
Removing an event monitor	DROP

Monitoring task	SQL Statement
Writing event monitor values	FLUSH EVENT MONITOR

## Determining the date a database object was last used

The last date that an object was used is indicated by the last referenced date (also referred to as the last used date). The last referenced date is available for indexes, packages, tables, table data partitions, and materialized query tables (MQTs). You can use the last referenced date to identify objects which have not been used for an extended period of time and which might be considered as candidates for removal.

The last referenced date is stored in the LASTUSED column of the corresponding catalog table for the object and accessible through the catalog view on the table. Usage information in the catalogs is updated by an engine dispatchable unit (EDU), called **db2lused** (the LASTUSED daemon), that runs on the database catalog partition. Every 15 minutes, the LASTUSED daemon gathers usage information for all objects across all partitions and updates the LASTUSED column in the corresponding catalog tables to write the information to disk. At most, the catalog entry for a given object is updated once per day, which means the same object will not be checked again until a 24 hour interval has passed. The 15 minute interval was chosen to minimally affect performance on the database server and is not user configurable. The updates to the last referenced date are performed asynchronously and, therefore, object access is not immediately recorded in the catalogs.

**Note:** If the corresponding row in a catalog table is locked, an update of usage information might be deferred until the next 15 minute collection interval. Also, when a database is deactivated, any usage information that was not gathered by the LASTUSED daemon before deactivation (for example, any objects accessed for the first time since the last poll was done by the daemon) cannot be written to disk. Explicitly activate the database for this feature to behave as expected.

The last referenced date is of interest when an object has not been used for an extended period of time (for example, several months). The last referenced date is useful in the following cases:

- Tables and table data partitions: can help to identify opportunities to reclaim unused space
- Indexes: can help to identify opportunities to reclaim unused space, avoid unnecessary inserts and maintenance, and can improve compile time by reducing the number of choices for an index to consider
- Packages: can help to detect unused package versions which can be freed
- MQTs: can help to detect unused MQTs, to reclaim unused space, or help to investigate and understand why an MQT is not being used

The following examples describe some specific scenarios in which the last referenced date can be useful:

- To identify opportunities to save space and maintenance time, you can examine last used information for indexes every year by checking the LASTUSED column in the SYSCAT.INDEXES catalog view. If an index has not been used in the last year, the index can be considered as a candidate for being dropped. The final decision to drop an index remains under your control because there might be circumstances in which dropping an index is not required. For example, you might have a table which is known to be accessed only under emergency or infrequent cases where fast access is critical, or the index for a table might be unique and used to enforce the uniqueness constraint even though it is never explicitly used. The last used date information can be used as an aid in making decisions to remove indexes.
- Your company has internal applications that were deployed on the database and were either replaced or are no longer in use after a period of months or years. The retired applications have been identified as opportunities to save space. The last used date information can be used to identify database objects that are no longer in use and were not cleaned up after an application was retired. For example, these database objects might be tables storing values used to populate a GUI. The last used date for these tables can be found in the LASTUSED column of the SYSCAT.TABLES catalog view and this date can be used as a starting point in the investigation of table objects that can be removed to reclaim space.

For additional information about the LASTUSED column of the catalog view for a specific database object, particularly which operations result in an update, see the following topics:

- SYSCAT.DATAPARTITIONS catalog view

- SYSCAT.INDEXES catalog view
- SYSCAT.PACKAGES catalog view
- SYSCAT.TABLES catalog view

## Deprecated monitoring tools

The health monitor and Windows Management Instrumentation (WMI) are deprecated and might be removed in a future release.

Start to use IBM InfoSphere Optim tools. IBM InfoSphere Optim Performance Manager provides a Web interface that you can use to isolate and analyze typical database performance problems. You can also view a summary of the health of your databases and drill down. For more details, see *Monitoring with Optim Performance Manager* at [http://publib.boulder.ibm.com/infocenter/idm/docv3/topic/com.ibm.datatools.perfmgmt.monitor.doc/p\\_monitor.html](http://publib.boulder.ibm.com/infocenter/idm/docv3/topic/com.ibm.datatools.perfmgmt.monitor.doc/p_monitor.html).

## Deprecated built-in routines

### Capturing database system snapshot information to a file using the SNAP\_WRITE\_FILE stored procedure

With the SNAP\_WRITE\_FILE stored procedure you can capture snapshots of monitor data and save this information to files on the database server and allow access to the data by users who do not have SYSADM, SYSCTRL, SYSMAINT, or SYSMON authority.

Any user can then issue a query with a snapshot table function to access the snapshot information in these files. In providing open access to snapshot monitor data, sensitive information (such as the list of connected users and the SQL statements they have submitted to the database) is available to all users who have the execution privilege for the snapshot table functions. The privilege to execute the snapshot table functions is granted to PUBLIC by default. (Note, however, that no actual data from tables or user passwords can be exposed using the snapshot monitor table functions.)

**Important:** The SYSPROC.SNAP\_WRITE\_FILE procedure is deprecated and might be removed in a future release. For more information, see "SNAP\_WRITE\_FILE procedure" in *Administrative Routines and Views*.

#### Before you begin

You must have SYSADM, SYSCTRL, SYSMAINT, or SYSMON authority to capture a database snapshot with the SNAP\_WRITE\_FILE stored procedure.

#### About this task

When issuing a call to the SNAP\_WRITE\_FILE stored procedure, in addition to identifying the database and partition to be monitored, you need to specify a *snapshot request type*. Each snapshot request type determines the scope of monitor data that is collected. Choose the snapshot request types based on the snapshot table functions users will need to run. The following table lists the snapshot table functions and their corresponding request types.

Table 68. Snapshot request types

Snapshot table function	Snapshot request type
SNAP_GET_AGENT	APPL_ALL
SNAP_GET_AGENT_MEMORY_POOL	APPL_ALL
SNAP_GET_APPL	APPL_ALL
SNAP_GET_APPL_INFO	APPL_ALL
SNAP_GET_STMT	APPL_ALL
SNAP_GET_SUBSECTION	APPL_ALL

Table 68. Snapshot request types (continued)

Snapshot table function	Snapshot request type
SNAP_GET_BP_PART	BUFFERPOOLS_ALL
SNAP_GET_BP	BUFFERPOOLS_ALL
SNAP_GET_DB	DBASE_ALL
SNAP_GET_DETAILLOG	DBASE_ALL
SNAP_GET_DB_MEMORY_POOL	DBASE_ALL
SNAP_GET_HADR	DBASE_ALL
SNAP_GET_STORAGE_PATHS	DBASE_ALL
SNAP_GET_DBM	DB2
SNAP_GET_DBM_MEMORY_POOL	DB2
SNAP_GET_FCM	DB2
SNAP_GET_FCM_PART	DB2
SNAP_GET_SWITCHES	DB2
SNAP_GET_DYN_SQL	DYNAMIC_SQL
SNAP_GET_LOCK	DBASE_LOCKS
SNAP_GET_LOCKWAIT	APPL_ALL
SNAP_GET_TAB	DBASE_TABLES
SNAP_GET_TAB_REORG	DBASE_TABLES
SNAP_GET_TBSP	DBASE_TABLESPACES
SNAP_GET_TBSP_PART	DBASE_TABLESPACES
SNAP_GET_CONTAINER	DBASE_TABLESPACES
SNAP_GET_UTIL	DB2
SNAP_GET_UTIL_PROGRESS	DB2

## Procedure

1. Connect to a database. This can be any database in the instance you need to monitor. To be able to call a stored procedure, you must be connected to a database.
2. Determine the snapshot request type, and the database and partition you need to monitor.
3. Call the SNAP\_WRITE\_FILE stored procedure with the appropriate parameter settings for the snapshot request type, database, and partition. For example, here is a call that will capture a snapshot of application information about the SAMPLE database for the current connected partition:

```
CALL SNAP_WRITE_FILE('APPL_ALL', 'SAMPLE', -1)
```

The SNAP\_WRITE\_FILE stored procedure has three input parameters:

- a snapshot request type (see Table 68 on page 405, which provides a cross-reference of the snapshot table functions and their corresponding request types)
- a VARCHAR (128) for the database name. If you enter NULL, the name of the currently connected database is used.

**Note:** This parameter does not apply to the database manager level snapshot table functions; they only have parameters for request type and partition number.

- a SMALLINT for the partition number (a value between 0 and 999). For the partition number parameter, enter the integer corresponding to partition number you want to monitor. To capture a snapshot for the currently connected partition, enter a value of -1 or a NULL. To capture a global snapshot, enter a value of -2.

## Results

Once the snapshot data has been saved to a file, all users can issue queries with the corresponding snapshot table functions, specifying (NULL, NULL) as input values for database-level table functions, and (NULL) for database manager level table functions. The monitor data they receive is pulled from the files generated by the SNAP\_WRITE\_FILE stored procedure.

**Note:** While this provides a means to limit user access to sensitive monitor data, this approach does have some limitations:

- The snapshot monitor data available from the SNAP\_WRITE\_FILE files is only as recent as the last time the SNAP\_WRITE\_FILE stored procedure was called. You can ensure that recent snapshot monitor data is available by making calls to the SNAP\_WRITE\_FILE stored procedure at regular intervals. For instance, on UNIX systems you can set a cron job to do this.
- Users issuing queries with the snapshot table functions cannot identify a database or partition to monitor. The database name and partition number identified by the user issuing the SNAP\_WRITE\_FILE calls determine the contents of the files accessible by the snapshot table functions.
- If a user issues an SQL query containing a snapshot table function for which a corresponding SNAP\_WRITE\_FILE request type has not been run, a direct snapshot is attempted for the currently connected database and partition. This operation is successful only if the user has SYSADM, SYSCTRL, SYSMOINT, or SYSMON authority.

## Accessing database system snapshots using snapshot table functions in SQL queries (with file access)

For every request type that authorized users have called the SNAP\_WRITE\_FILE stored procedure, any user can issue queries with the corresponding snapshot table functions. The monitor data they receive will be retrieved from the files generated by the SNAP\_WRITE\_FILE stored procedure.

**Important:** The SYSPROC.SNAP\_WRITE\_FILE procedure is deprecated and might be removed in a future release. For more information, see "SNAP\_WRITE\_FILE procedure" in *Administrative Routines and Views*.

### Before you begin

For every snapshot table function with which you intend to access SNAP\_WRITE\_FILE files, an authorized user must have issued a SNAP\_WRITE\_FILE stored procedure call with the corresponding snapshot request types. If you issue an SQL query containing a snapshot table function for which a corresponding SNAP\_WRITE\_FILE request type has not been run, a direct snapshot is attempted for the currently connected database and partition. This operation is successful only if the user has SYSADM, SYSCTRL, SYSMOINT, or SYSMON authority.

### About this task

Users who access snapshot data from SNAP\_WRITE\_FILE files with snapshot table functions cannot identify a database or partition to monitor. The database name and partition number identified by the user issuing the SNAP\_WRITE\_FILE calls determine the contents of the SNAP\_WRITE\_FILE files. The snapshot monitor data available from the SNAP\_WRITE\_FILE files is only as recent as the last time the SNAP\_WRITE\_FILE stored procedure captured snapshots.

### Procedure

1. Connect to a database. This can be any database in the instance you need to monitor. To issue an SQL query with a snapshot table function, you must be connected to a database.

2. Determine the type of snapshot you need to capture.
3. Issue a query with the appropriate snapshot table function. For example, here is a query that will capture a snapshot of table space information:

```
SELECT * FROM TABLE(SNAP_GET_TBSP(CAST(NULL AS VARCHAR(1)),
                                  CAST(NULL AS INTEGER))) AS SNAP_GET_TBSP
```

**Note:** You must enter NULL values for the database name and partition number parameters. The database name and partition for the snapshot are determined in the call of the SNAP\_WRITE\_FILE stored procedure. Also, the database name parameter does not apply to the database manager level snapshot table functions; they only have a parameter for partition number.

Each snapshot table function returns a table with one or more rows, with each column representing a monitor element. Accordingly, the monitor element column names correlate to the monitor element names.

4. You can also select individual monitor elements from the returned table. For example, the following statement will return only the **agent\_id** monitor element:

```
SELECT agent_id FROM TABLE(
    SNAP_GET_APPL(CAST(NULL AS VARCHAR(1)),
                 CAST(NULL AS INTEGER))
    as SNAP_GET_APPL
```

## Introduction to the health monitor

The health monitor is a server-side tool that adds a management-by-exception capability by constantly monitoring the health of an instance and active databases. The health monitor can also alert a database administrator (DBA) of potential system health issues.

The health monitor proactively detects issues that might lead to hardware failure, or to unacceptable system performance or capability. The proactive nature of the health monitor enables users to address an issue before it becomes a problem that affects system performance.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

The health monitor checks the state of your system using health indicators to determine whether an alert should be issued. Preconfigured actions can be taken in response to alerts. The health monitor can also log alerts in the administration notification log and send notifications by email or pager. This management-by-exception model frees up valuable DBA resources by generating alerts to potential system health issues without requiring active monitoring.

The health monitor periodically gathers information about the health of the system with a minimal impact to overall performance. It does not turn on any snapshot monitor switches to collect information.

## Health indicators

The health monitor uses health indicators to evaluate the health of specific aspects of database manager performance or database performance. A health indicator measures the health of some aspect of a particular class of database objects, such as table spaces. Criteria are applied to the measurement to determine healthiness. The criteria applied depends on the type of health indicator. A determination of unhealthiness is based on the criteria generates an alert.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

Three types of health indicators are returned by the health monitor:

- **Threshold-based** indicators are measurements that represent a statistic (on a continuous range of values) of the behavior of the object. Warning and alarm threshold values define boundaries or zones for normal, warning, and alarm ranges. Threshold-based health indicators have three valid states: Normal, Warning, or Alarm.
- **State-based** indicators are measurements that represent a finite set of two or more distinct states of an object that defines whether the database object or resource is operating normally. One of the states is normal and all others are considered non-normal. State-based health indicators have two valid states: Normal, Attention.
- **Collection state-based** indicators are database-level measurements that represent an aggregate state or one or more objects within the database. Data is captured for each object in the collection and the highest severity of conditions among those objects is represented in the aggregated state. If one or more objects in the collection are in a state requiring an alert, the health indicator shows Attention state. Collection state-based health indicators have two valid states: Normal, Attention.

Health indicators exist at the instance, database, table space, and table space container level.

You can access health monitor information through the CLP, or APIs. You can configure health indicators through these same tools.

An alert is generated in response to either a change from a normal to a non-normal state or a change in the health indicator value to a warning or alarm zone that is based on defined threshold boundaries. There are three types of alerts: attention, warning, and alarm.

- For health indicators measuring distinct states, an attention alert is issued if a non-normal state is registered.
- For health indicators measuring a continuous range of values, threshold values define boundaries or zones for normal, warning and alarm states. For example, if the value enters the threshold range of values that defines an alarm zone, an alarm alert is issued to indicate that the problem needs immediate attention.

The health monitor will only send notification and run an action on the first occurrence of a particular alert condition for a given health indicator. If the health indicator stays in a particular alert condition, no further notification will be sent and no further actions will be run. If the health indicator changes alert conditions, or goes back to normal state and re-enters the alert condition, notification will be sent anew and actions will be run.

The following table shows an example of a health indicator at different refresh intervals and the health monitor response to the health indicator state. This example uses the default warning of 80% and alarm thresholds of 90%.

<i>Table 69. Health indicator conditions at different refresh intervals</i>			
<b>Refresh interval</b>	<b>Value of ts.ts_util (Table space utilization) health indicator</b>	<b>State of ts.ts_util health indicator</b>	<b>Health monitor response</b>
1	80	warning	notification of warning is sent, actions for a warning alert condition are run
2	81	warning	no notification is sent, no actions are run
3	75	normal	no notification is sent, no actions are run
4	85	warning	notification of warning is sent, actions for a warning alert condition are run

Table 69. Health indicator conditions at different refresh intervals (continued)

<b>Refresh interval</b>	<b>Value of ts.ts_util (Table space utilization) health indicator</b>	<b>State of ts.ts_util health indicator</b>	<b>Health monitor response</b>
5	90	alarm	notification of alarm is sent, actions for an alarm condition are run

### ***Health indicator process cycle***

The following diagram illustrates the evaluation process for health indicators. The set of steps runs every time the refresh interval for the specific health indicator elapses.

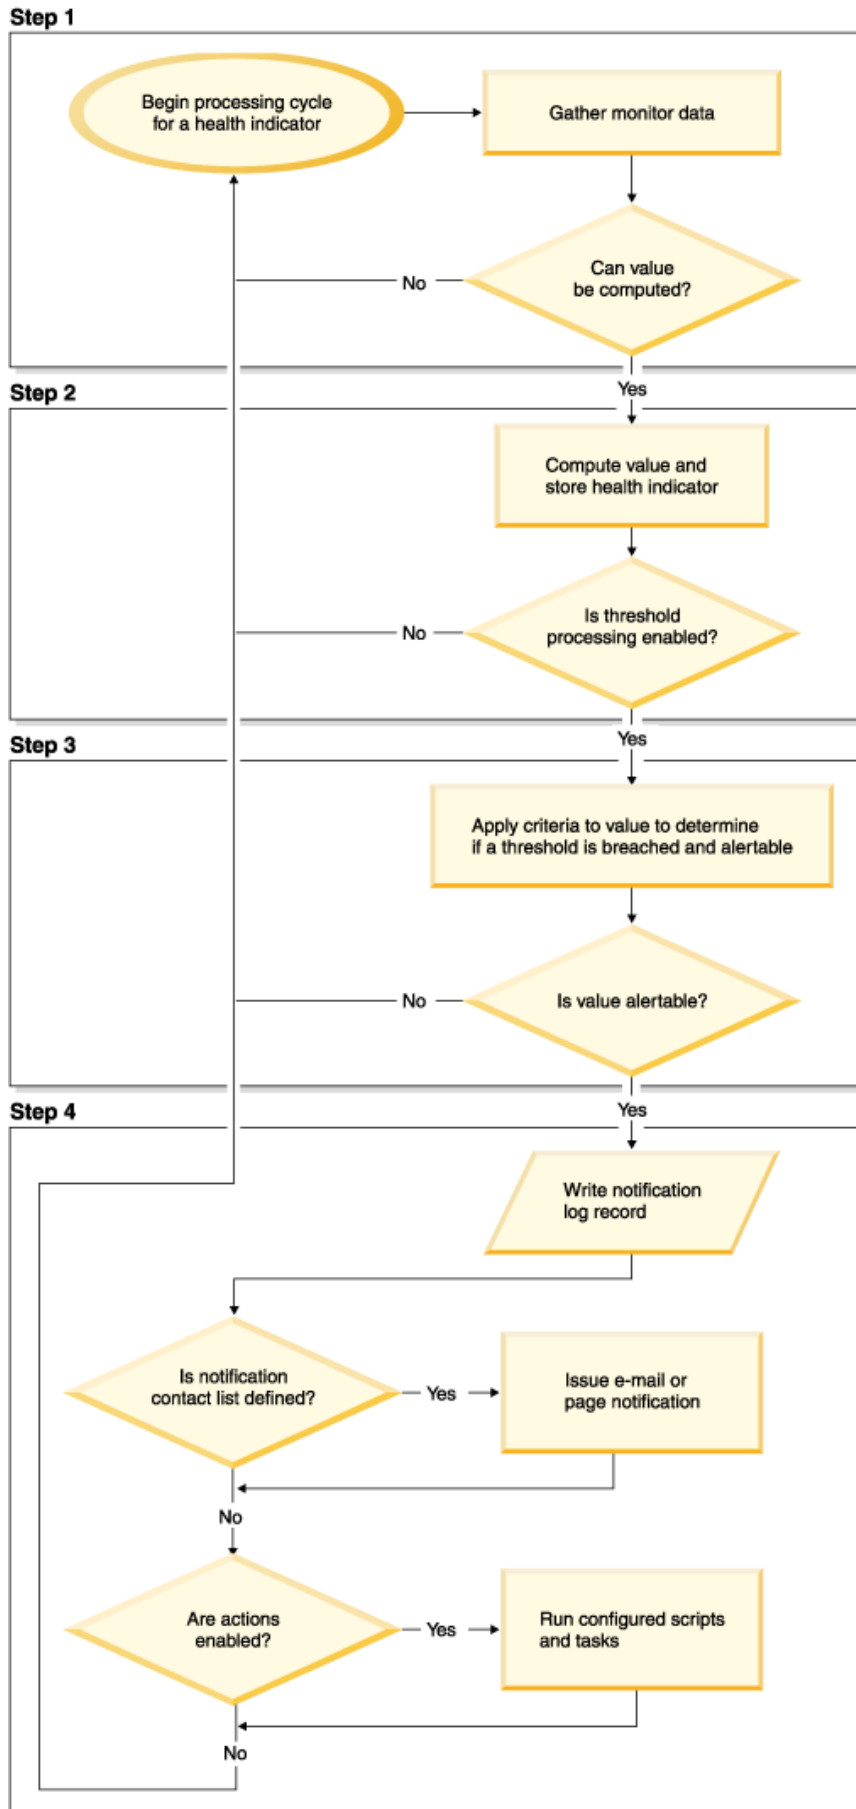

Figure 8. Health indicator process cycle

**Note:**

1. The NOTIFYLEVEL database manager configuration parameter controls whether alert notifications are sent to the database administration notification log and to any defined contacts. A minimum severity level of 2 is required for alarm notifications. A minimum severity level of 3 is required for warnings and attention alerts to be sent.

**Health indicator format**

A description of the data collected by the health indicator.

The documentation for health indicators is described in a standard format as follows:

**Identifier**

The name of the health indicator. This identifier is used for configuration from the CLP.

**Health monitor level**

The level at which the health indicator is captured by the health monitor.

**Category**

The category for the health indicator.

**Type**

The type of the health indicator. There are four possible values for type:

- Upper-bounded threshold-based, where the progression to an alert is: Normal, Warning, Alarm
- Lower-bounded threshold-based
- State-based, where one state is normal and all others are non-normal
- Collection state-based, where the state is based on the aggregation of states from objects in the collection

**Unit**

The unit of the data measured in the health indicator, such as percentage. This is not applicable for state-based or collection state-based health indicators.

**Health indicators summary**

You use health indicators to monitor your database performance. Health indicators include automatic storage utilization, table space utilization, High Availability Disaster Recovery (HADR) monitors, and application concurrency monitors.

The following tables list all health indicators, grouped by category.

<i>Table 70. Database automatic storage utilization health indicators</i>		
<b>Name</b>	<b>Identifier</b>	<b>Additional Information</b>
Database Automatic Storage Utilization	db.auto_storage_util	<a href="#">“db.auto_storage_util - Database automatic storage utilization health indicator” on page 417</a>

*Table space storage health indicators*

*Health indicators for DMS table spaces*

You can determine the health indicators that are relevant for a DMS table space based on the characteristics of the table space.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

This table describes which table space health indicators are relevant for a DMS table space based on the characteristics of the table space:

Table 82. Relevant table space health indicators for a DMS table space

Table space characteristics	Maximum table space size defined	Maximum table space size undefined
Automatic resize enabled = Yes	<p>ts.ts_util_auto_resize - Tracks percentage of table space used relative to the maximum defined by you. An alert indicates that the table space will soon be full and requires intervention by you. As long as the maximum size has been set to a reasonable value (that is, the amount of space specified by the maximum size does exist), this is the most important health indicator for this configuration.</p> <p>ts.ts_util - Tracks usage of currently allocated table space storage. An alert may not require intervention by you to resolve any problems since the table space will attempt to increase in size when it is full.</p> <p>ts.ts_auto_resize_status - Tracks health of resize attempts. An alert indicates that the table space failed to resize (that is, the table space is full).</p>	<p>ts.ts_util_auto_resize - Not applicable. No upper bound specified for the table space size.</p> <p>ts.ts_util - Tracks usage of currently allocated table space storage. An alert may not require intervention by you to resolve any problems since the table space will attempt to increase in size.</p> <p>ts.ts_auto_resize_status - Tracks health of resize attempts. An alert indicates that the table space failed to resize (that is, the table space is full).</p> <p><b>Note:</b> If a DMS table space is defined using automatic storage and there is no maximum size specified, you should also pay attention to the db.auto_storage_util health indicator. This health indicator tracks utilization of the space associated with the database storage paths. When this space fills up, the table space is unable to grow. This may result in a table space full condition.</p>
Automatic resize enabled = No	<p>Not a valid configuration. Maximum table space size is only valid for table spaces that have automatic resize enabled.</p>	<p>ts.ts_util_auto_resize - Not applicable. Table space will not attempt to resize.</p> <p>ts.ts_util - Tracks usage of currently allocated table space storage. An alert indicates a table space full condition and requires immediate intervention by you. The table space will not attempt to resize itself.</p> <p>ts.ts_auto_resize_status - Not applicable. Table space will not attempt to resize.</p>

*db.auto\_storage\_util* - Database automatic storage utilization health indicator  
 Indicates the consumption of storage for the defined database storage paths.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.auto\_storage\_util

**Health monitor level**

Database

**Category**

Database

**Type**

Upper-bounded threshold-based

**Unit**

Percentage

When automatic storage table spaces are created, containers are allocated automatically for these table spaces on the database storage paths. If there is no more space on any of the file systems on which the database storage paths are defined, automatic storage table spaces will be unable to increase in size and may become full.

The indicator is calculated using the formula:

```
(db.auto_storage_used / db.auto_storage_total) * 100
```

where

- *db.auto\_storage\_used* is the sum of used space across all physical file systems identified in the list of database storage paths
- *db.auto\_storage\_total* is the sum of total space across all physical file systems identified in the list of database storage paths

Database automatic storage path utilization is measured as a percentage of the space consumed on the database storage path file systems, where a high percentage indicates less than optimal function for this indicator.

The "Time to fullness" in the Additional Information line returned for this health indicator is a prediction of how much time is remaining until the maximum size for the table space has been reached.

**Usage note**

If you use storage groups, this health indicator indicates the consumption of storage for the defined database storage paths in the default storage group only.

*ts.ts\_auto\_resize\_status - Table space automatic resize status health indicator*

This health indicator identifies whether table space resize operations are succeeding for DMS table spaces which have automatic resize enabled.

When a DMS table space with automatic resize enabled fails to increase in size, it is effectively full. This condition may be due to lack of free space on the file systems on which the table space containers are defined, or a result of the table space automatic resize settings. For example, the defined maximum size may have been reached, or the increase amount may be set too high to be accommodated by the remaining free space.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

ts.ts\_auto\_resize\_status

**Health monitor level**

Table Space

**Category**

Table Space Storage

**Type**

State-based

**Unit**

Not applicable

*ts.ts\_util\_auto\_resize - Automatic resize table space utilization health indicator*

This health indicator tracks the consumption of storage for each automatic resize DMS table space on which a maximum size has been defined. The DMS table space is considered full when the maximum size has been reached.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

ts.ts\_util\_auto\_resize

**Health monitor level**

Table Space

**Category**

Table Space Storage

**Type**

Upper-bounded threshold-based

**Unit**

Percentage

The indicator is calculated using the formula:

$$((ts.used * ts.page\_size) / ts.max\_size) * 100$$

where

- *ts.used* is the value of "[tablespace\\_used\\_pages - Used pages in table space monitor element](#)" on page [1524](#)
- *ts.page\_size* is the value of "[tablespace\\_page\\_size - Table space page size monitor element](#)" on page [1518](#)
- *ts.max\_size* is the value of "[tablespace\\_max\\_size - Maximum table space size](#)" on page [1514](#)

Automatic resize DMS table space utilization is measured as a percentage of the maximum table space storage consumed. A high percentage indicates the table space is approaching fullness. The short term and long term growth rates, included in the additional information for this indicator, can be used to determine if the current rate of growth is a short term aberration, or consistent with long term growth.

The "Time to fullness" in the Additional Information line returned for this health indicator is a prediction of how much time is remaining until the maximum size for the table space has been reached.

*ts.ts\_util - Table Space Utilization*

This health indicator tracks the consumption of storage for each DMS table space.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

ts.ts\_util

**Health monitor level**

Table Space

**Category**

Table Space Storage

**Type**

Upper-bounded threshold-based

**Unit**

Percentage

The DMS table space is considered full when all containers are full.

If automatic resize is enabled on the table space, this health indicator will not be evaluated. Instead, the database automatic storage utilization **db.auto\_storage\_util** and table space automatic resize status (**ts.ts\_auto\_resize\_status**) health indicators are relevant for table space storage monitoring. The automatic resize table space utilization (**ts.ts\_util\_auto\_resize**) health indicator will also be available if a maximum size was defined on this table space. The table space utilization percentage can still be retrieved from column TBSP\_UTILIZATION\_PERCENT of the TBSP\_UTILIZATION administrative view if it is required.

The indicator is calculated using the formula:

```
(ts.used / ts.usable) * 100
```

where

- *ts.used* is the value of “[tablespace\\_used\\_pages - Used pages in table space monitor element](#)” on page 1524
- *ts.usable* is the value of “[tablespace\\_usable\\_pages - Usable pages in table space monitor element](#)” on page 1523

Table space utilization is measured as the percentage of space consumed, where a high percentage indicates less than optimal function for this indicator.

The short term and long term growth rates, included in the additional information for this indicator, can be used to determine if current rate of growth is a short term aberration or consistent with longer term growth.

The "Time to fullness" in the Additional Information line returned for this health indicator is a prediction of how much time is remaining until the maximum size for the table space has been reached.

***tsc.tscont\_util - Table Space Container Utilization***

This health indicator tracks the consumption of storage for each SMS table space that is not using automatic storage.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

tsc.tscont\_util

**Health monitor level**

Table Space Container

**Category**

Table Space Storage

**Type**

Upper-bounded threshold-based

**Unit**

Percentage

An SMS table space is considered full if there is no more space on any of the file systems for which containers are defined.

If free space is not available on the file system to expand an SMS container, the associated table space becomes full.

An alert may be issued for each container defined on the file system that is running out of free space.

The indicator is calculated using the formula:

$$(\text{fs.used} / \text{fs.total}) * 100$$

where *fs* is the file system in which the container resides.

SMS table space utilization is measured as the percentage of space consumed, where a high percentage indicates less than optimal function for this indicator.

The short term and long term growth rates, included in the additional information for this indicator, can be used to determine if current rate of growth is a short term aberration or consistent with longer term growth.

The "Time to fullness" in the Additional Information line returned for this health indicator is a prediction of how much time is remaining until the maximum size for the table space has been reached.

#### *ts.ts\_op\_status - Table Space Operational State*

The state of a table space can restrict activity or tasks that can be performed. A change from normal to another state may generate an Attention alert.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

#### **Identifier**

#### **Health monitor level**

Table Space

#### **Category**

Table Space Storage

#### **Type**

State-based

#### **Unit**

Not applicable

#### *tsc.tscont\_op\_status - Table Space Container Operational State*

This health indicator tracks the accessibility of the table space container. The accessibility of the container can restrict activity or tasks that can be performed. If the container is not accessible, an Attention alert may be generated.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

*Sorting health indicators**db2.sort\_privmem\_util - Private Sort Memory Utilization*

This indicator tracks the utilization of the private sort memory. If `db2.sort_heap_allocated` (system monitor element)  $\geq$  `sheapthres` (DBM configuration parameter), sorts may not be getting full sort heap as defined by the `sortheap` parameter and an alert may be generated.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

`db2.sort_privmem_util`

**Health monitor level**

Database

**Category**

Sorting

**Type**

Upper-bounded threshold-based

**Unit**

Percentage

Sorting is considered healthy if there is sufficient heap space in which to perform sorting and sorts do not overflow unnecessarily.

The indicator is calculated using the formula:

$$(db2.sort\_heap\_allocated / sheapthres) * 100$$

The Post Threshold Sorts snapshot monitor element measures the number of sorts that have requested heaps after the sort heap threshold has been exceeded. The value of this indicator, shown in the Additional Details, indicates the degree of severity of the problem for this health indicator.

The Maximum Private Sort Memory Used snapshot monitor element maintains a private sort memory high watermark for the instance. The value of this indicator, shown in the Additional Information, indicates the maximum amount of private sort memory that has been in use at any one point in time since the instance was last recycled. This value can be used to help determine an appropriate value for `sheapthres`.

*db.sort\_shrmem\_util - Shared Sort Memory Utilization*

This indicator tracks the utilization of the shared sort memory. The `sheapthres_shr` database configuration parameter is a hard limit. If the allocation is close to the limit, an alert might be generated.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

`db.sort_shrmem_util`

**Health monitor level**

Database

**Category**

Sorting

**Type**

Upper-bounded threshold-based

**Unit**

Percentage

Sorting is considered healthy if there is sufficient heap space in which to perform sorting and sorts do not overflow unnecessarily.

The indicator is calculated using the formula:

$$(db.sort\_shrheap\_allocated / sheapthres\_shr) * 100$$

Note that if *sheapthres\_shr* is set to 0, then *sheapthres* serves as the shared sortheap threshold.

The Maximum Shared Sort Memory Used snapshot monitor element maintains a shared sort memory high watermark for the database. The value of this indicator, shown in the Additional Information, indicates the maximum amount of shared sort memory that has been in use at any one point in time since the database has been active. This value can be used to help determine an appropriate value for the shared sort memory threshold.

Consider using the self-tuning memory feature to have sort memory resources automatically allocated as required by the current workload. If you have the self tuning memory feature enabled for the sort memory area, you should configure this health indicator to disable threshold checking.

*db.spilled\_sorts - Percentage of Sorts That Overflowed*

Sorts that overflow to disk can cause significant performance degradation. If this occurs, an alert may be generated.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.spilled\_sorts

**Health monitor level**

Database

**Category**

Sorting

**Type**

Upper-bounded threshold-based

**Unit**

Percentage

Sorting is considered healthy if there is sufficient heap space in which to perform sorting and sorts do not overflow unnecessarily.

The indicator is calculated using the formula:

$$\frac{(db.sort\_overflows_t - db.sort\_overflows_{t-1})}{(db.total\_sorts_t - db.total\_sorts_{t-1}) * 100}$$

where *t* is the current snapshot and *t-1* is a snapshot 1 hour ago. The system monitor element *db.sort\_overflows* (based on the *sort\_overflows* monitor element) is the total number of sorts that ran out of sort heap and may have required disk space for temporary storage. The element *db.total\_sorts* (based on the *total\_sorts* monitor element) is the total number of sorts that have been executed.

Consider using the self-tuning memory feature to have sort memory resources automatically allocated as required by the current workload. If you have the self tuning memory feature enabled for the sort memory area, you should configure this health indicator to disable threshold checking.

### *db.max\_sort\_shrmem\_util - Long Term Shared Sort Memory Utilization*

This indicator tracks an over-configured shared sort heap, looking to see if there are resources that can be freed for use somewhere else in the database system.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.max\_sort\_shrmem\_util

**Health monitor level**

Database

**Category**

Sorting

**Type**

Lower-bounded threshold-based

**Unit**

Percentage

Sorting is considered healthy if there is sufficient heap space in which to perform sorting and if sorts do not overflow unnecessarily.

An alert might be generated when the percentage usage is low.

The indicator is calculated using the formula:

```
(db.max_shr_sort_mem / sheaphres_shr)*100
```

The system monitor element db.max\_shr\_sort\_mem (based on the sort\_shrheap\_top monitor element) is the high watermark for shared sort memory usage.

Consider using the self-tuning memory feature to have sort memory resources automatically allocated as required by the current workload. If you have the self-tuning memory feature enabled for the sort memory area, you should configure this health indicator to disable threshold checking.

### *Database manager (DBMS) health indicators*

#### *db2.db2\_op\_status - Instance Operational State*

An instance is considered healthy if the instance state does not restrict activity or tasks being performed.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db2.db2\_op\_status

**Health monitor level**

Instance

**Category**

DBMS

**Type**

State-based

**Unit**

Not applicable

The state can be one of the following values: Active, Quiesce pending, Quiesced, or Down. A non-Active state may generate an Attention alert.

The health monitor is unable to execute actions for the db2.db2\_op\_status health indicator if the indicator enters the down state. This state can arise, for example, when an instance that the indicator is monitoring becomes inactive because of an explicit stop request or an abnormal termination. If you want to have the instance restart automatically after any abnormal termination, you can configure the fault monitor (**db2fm**) to keep the instance highly available.

#### *Instance Highest Severity Alert State*

This indicator represents the rolled-up alert state of an instance being monitored. The alert state of an instance is the highest alert state of the instance and its databases, and database objects being monitored.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

#### **Identifier**

Not applicable. This health indicator does not have configuration or recommendations support.

Instance

#### **Category**

DBMS

#### **Type**

State-based

#### **Unit**

Not applicable

The order of the alert states is as follows:

- Alarm
- Warning
- Attention
- Normal

The alert state of the instance determines the overall health of the database system.

#### *Database health indicators*

#### *db.db\_op\_status - Database Operational State*

The state of the database can restrict activity or tasks that can be performed. The state can be one of the following values: Active, Quiesce pending, Quiesced, or Rollforward. A change from Active to another state may generate an Attention alert.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

### *Database Highest Severity Alert State*

This indicator represents the rolled-up alert state of the database being monitored. The alert state of a database is the highest alert state of the database and its objects.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

The order of the alert states is as follows:

- Alarm
- Warning
- Attention
- Normal

### *Maintenance health indicators*

#### *db.tb\_reorg\_req - Reorganization Required*

This health indicator tracks the need to reorganize tables or indexes within a database. Tables or all indexes defined on a table require reorganization to eliminate fragmented data. The reorganization is accomplished by compacting the information and reconstructing the rows or index data. The result might yield an improved performance and freed space in the table or indexes.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

#### **Identifier**

db.tb\_reorg\_req

#### **Health monitor level**

Database

#### **Category**

Database Maintenance

#### **Type**

Collection state-based

#### **Unit**

Not applicable

You can filter the set of tables evaluated by this health indicator by specifying in your automatic maintenance policy the names of the tables to be evaluated. This can be done using the Automatic Maintenance wizard.

An attention alert might be generated to indicate that reorganization is required. Reorganization can be automated by setting the AUTO\_REORG database configuration parameter to ON. If automatic reorganization is enabled, the attention alert indicates either that one or more automatic reorganizations

could not complete successfully or that there are tables which require reorganization, but automatic reorganization is not being performed because the size of the table per database partition exceeds the maximum size criteria for tables that should be considered for offline reorganization. Refer to the collection details of this health indicator for the list of objects that need attention.

*db.tb\_runstats\_req - Statistics Collection Required*

This health indicator tracks the need to collect statistics for tables and their indexes within a database. Tables and all indexes defined on a table require statistics to improve query execution time.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.tb\_runstats\_req

**Health monitor level**

Database

**Category**

Database Maintenance

**Type**

Collection state-based

**Unit**

Not applicable

The tables considered by this health indicator can be limited using an SQL query. The scope in the additional information displays the subselect clause on system tables for this query.

An attention alert may be generated to indicate that statistics collection is required. Statistics can be automatically collected by setting the AUTO\_RUNSTATS database configuration parameter to ON. If automatic statistics collection is enabled, the attention alert indicates that one or more automatic statistics collection actions did not complete successfully.

*db.db\_backup\_req - Database Backup Required*

This health indicator tracks the need for a backup on the database. Backups should be taken regularly as part of a recovery strategy to protect your data against the possibility of loss in the event of a hardware or software failure.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.db\_backup\_req

**Health monitor level**

Database

**Category**

Database Maintenance

**Type**

State-based

**Unit**

Not applicable

This health indicator determines when a database backup is required based on the time elapsed and amount of data changed since the last backup.

An attention alert might be generated to indicate that a database backup is required. Database backups can be automated by setting the AUTO\_DB\_BACKUP database configuration parameter to ON.

If automatic database backups are enabled, the attention alert indicates that one or more automatic database backups did not complete successfully.

#### *High availability disaster recovery (HADR) health indicators*

##### *db.hadr\_op\_status - HADR Operational Status*

This health indicator tracks the high availability disaster recovery (HADR) operational state of the database. The state between primary and standby servers can be one of the following values: Connected, Congested or Disconnected. A change from Connected to another state might generate an Attention alert.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.hadr\_op\_status

**Health monitor level**

Database

**Category**

High availability disaster recovery

**Type**

State-based

**Unit**

Not applicable

##### *db.hadr\_delay - HADR Log Delay*

This health indicator tracks the current average delay (in minutes) between the data changes on the primary database and the replication of those changes on the standby database.

With a large delay value, data loss can occur when failing over to the standby database after a failure on the primary database. A large delay value can also mean longer downtime when takeover is required, because the primary database is ahead of the standby database.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.hadr\_delay

**Health monitor level**

Database

**Category**

High availability disaster recovery

**Type**

Upper-bounded threshold-based

**Unit**

Minutes

#### *Logging health indicators*

##### *db.log\_util - Log Utilization*

This indicator tracks the total amount of active log space used in bytes in the database.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.log\_util

**Health monitor level**

Database

**Category**

Logging

**Type**

Upper-bounded threshold-based

**Unit**

Percentage

Log utilization is measured as the percentage of space consumed, where a high percentage may generate an alert.

The indicator is calculated using the formula:

```
(db.total_log_used / (db.total_log_used + db.total_log_available)) * 100
```

The values for the log-related database configuration parameters, shown in the additional information, display the current allocations for logs. The additional information also includes the application id for the application which has the oldest active transaction. This application can be forced to free up log space.

*db.log\_fs\_util - Log File System Utilization*

Log File System Utilization tracks the fullness of the file system on which the transaction logs reside.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.log\_fs\_util

**Health monitor level**

Database

**Category**

Logging

**Type**

Upper-bounded threshold-based

**Unit**

Percentage

The database system may not be able to create a new log file if there is no room on the file system.

Log utilization is measured as the percentage of space consumed. If the amount of free space in the file system is minimal (that is, there is a high percentage for utilization), an alert may be generated.

The indicator is calculated using the formula:  $(fs.log\_fs\_used / fs.log\_fs\_total) * 100$  where fs is the file system on which the log resides.

The values for the log-related database configuration parameters, shown in the additional information, display the current allocations for logs. The additional details also shows if user exit is enabled.

If Block on Log Disk Full, shown in the additional details, is set to yes and utilization is at 100%, you should resolve any alerts as soon as possible to limit the impact to applications which cannot commit transactions until the log file is successfully created.

## Application concurrency health indicators

### *db.deadlock\_rate* - Deadlock Rate

Deadlock rate tracks the rate at which deadlocks are occurring in the database and the degree to which applications are experiencing contention problems.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

#### Identifier

db.deadlock\_rate

#### Health monitor level

Database

#### Category

Application Concurrency

#### Type

Upper-bounded threshold-based

#### Unit

Deadlocks per hour

Deadlocks may be caused by the following situations:

- Lock escalations are occurring for the database
- An application may be locking tables explicitly when system-generated row locks may be sufficient
- An application may be using an inappropriate isolation level when binding
- Catalog tables are locked for repeatable read
- Applications are getting the same locks in different orders, resulting in deadlock.

The indicator is calculated using the formula:

$$(db.deadlocks_t - db.deadlocks_{t-1})$$

where  $t$  is the current snapshot and  $t-1$  is the last snapshot, taken 60 minutes before the current snapshot.

The higher the rate of deadlocks, the greater the degree of contention which may generate an alert.

### *db.locklist\_util* - Lock List Utilization

This indicator tracks the amount of lock list memory that is being used.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

#### Identifier

db.locklist\_util

#### Health monitor level

Database

#### Category

Application Concurrency

#### Type

Upper-bounded threshold-based

#### Unit

Percentage

There is one lock list per database and it contains the locks held by all applications concurrently connected to the database. There is a set limit on lock list memory. Once the limit is reached, performance degrades because of the following situations:

- Lock escalation converts row locks to table locks, thereby reducing concurrency on shared objects in the database.
- More deadlocks between applications can occur since applications are waiting for a limited number of table locks. As a result, transactions are rolled back.

An error is returned to the application when the maximum number of lock requests has reached the limit set for the database.

The indicator is calculated using the formula:

```
(db.lock_list_in_use / (locklist * 4096)) * 100
```

Utilization is measured as a percentage of memory consumed, where a high percentage represents an unhealthy condition.

Consider using the self-tuning memory feature to have lock memory resources automatically allocated as required by the current workload. If you have the self-tuning memory feature enabled for the lock memory area, you should configure this health indicator to disable threshold checking.

#### *db.lock\_escal\_rate* - Lock Escalation Rate

This indicator tracks the rate at which locks have been escalated from row locks to a table lock thereby impacting transaction concurrency.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

#### **Identifier**

db.lock\_escal\_rate

#### **Health monitor level**

Database

#### **Category**

Application Concurrency

#### **Type**

Upper-bounded threshold-based

#### **Unit**

Lock escalations per hour

A lock is escalated when the total number of locks held by an application reaches the maximum amount of lock list space available to the application, or the lock list space consumed by all applications is approaching the total lock list space. The amount of lock list space available is determined by the *maxlocks* and *locklist* database configuration parameters.

When an application reaches the maximum number of locks allowed and there are no more locks to escalate, the application uses the space in the lock list allocated for other applications. There is one lock list per database and it contains the locks held by all applications concurrently connected to the database. When the entire lock list is full, an error occurs.

The indicator is calculated using the formula:

```
(db.lock_escalst - db.lock_escalst-1)
```

where 't' is the current snapshot and 't-1' is the last snapshot, taken 60 minutes before the current snapshot.

The higher the rate of deadlocks, the greater the degree of contention which may generate an alert.

Consider using the self-tuning memory feature to have lock memory resources automatically allocated as required by the current workload. If you have the self-tuning memory feature enabled for the lock memory area, you should configure this health indicator to disable threshold checking.

*db.apps\_waiting\_locks - Percentage of Applications Waiting on Locks*

This indicator measures the percentage of all currently executing applications that are waiting on locks.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.apps\_waiting\_locks

**Health monitor level**

Database

**Category**

Application Concurrency

**Type**

Upper-bounded threshold-based

**Unit**

Percentage

A high percentage can indicate that applications are experiencing concurrency problems which can negatively affect performance.

The indicator is calculated using the formula:

```
(db.locks_waiting / db.appls_cur_cons) *100
```

*Package cache, catalog cache, and workspace health indicators*

*db.catcache\_hitratio - Catalog Cache Hit Ratio*

The hit ratio is a percentage indicating how well the catalog cache is helping to avoid actual accesses to the catalog on disk. A high ratio indicates it is successful in avoiding actual disk I/O accesses.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.catcache\_hitratio

**Health monitor level**

Database

**Category**

Package and Catalog Caches, and Workspaces

**Type**

Lower-bounded threshold-based

**Unit**

Percentage

The indicator is calculated using the formula:

```
(1 - (db.cat_cache_inserts/db.cat_cache_lookups)) *100
```

### *db.pkgcache\_hitratio* - Package Cache Hit Ratio

The hit ratio is a percentage indicating how well the package cache is helping to avoid reloading packages and sections for static SQL from the system catalogs as well as helping to avoid recompiling dynamic SQL statements. A high ratio indicates it is successful in avoiding these activities.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

#### **Identifier**

db.pkgcache\_hitratio

#### **Health monitor level**

Database

#### **Category**

Package and Catalog Caches, and Workspaces

#### **Type**

Lower-bounded threshold-based

#### **Unit**

Percentage

The indicator is calculated using the formula:

```
(1-(db.pkg_cache_inserts/db.pkg_cache_lookups))*100
```

Consider using the self-tuning memory feature to have package cache memory resources automatically allocated as required by the current workload. If you have the self-tuning memory feature enabled for the package cache memory area, you should configure this health indicator to disable threshold checking.

### *db.shrworkspace\_hitratio* - Shared Workspace Hit Ratio

The hit ratio is a percentage indicating how well the shared SQL workspace is helping to avoid having to initialize sections for SQL statements that are about to be executed. A high ratio indicates it is successful in avoiding this action.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Note:** The **db.shrworkspace\_hitratio** health indicator is deprecated. Using this health indicator will not generate an error. However, it does not return a valid value and might be removed in a future release.

#### **Identifier**

db.shrworkspace\_hitratio

#### **Health monitor level**

Database

#### **Category**

Package and Catalog Caches, and Workspaces

#### **Type**

Lower-bounded threshold-based

#### **Unit**

Percentage

The indicator is calculated using the formula:

```
(1-(db.shr_workspace_section_inserts/db.shr_workspace_section_lookups))*100
```

## Memory health indicators

### *db2.mon\_heap\_util - Monitor Heap Utilization*

This indicator tracks the consumption of the monitor heap memory, based on the memory pool with the ID SQLM\_HEAP\_MONITOR.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db2.mon\_heap\_util

**Health monitor level**

Instance

**Category**

Memory

**Type**

Upper-bounded threshold-based

**Unit**

Percentage

The utilization is calculated using the formula:

```
(db2.pool_cur_size / db2.pool_config_size) * 100
```

for the Memory Pool Identifier SQLM\_HEAP\_MONITOR.

Once this percentage reaches the maximum, 100%, monitor operations may fail.

### *db.db\_heap\_util - Database Heap Utilization*

This indicator tracks the consumption of the monitor heap memory, based on the memory pool with the ID SQLM\_HEAP\_DATABASE.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.db\_heap\_util

**Health monitor level**

Database

**Category**

Memory

**Type**

Upper-bounded threshold-based

**Unit**

Percentage

The utilization is calculated using the formula

```
(db.pool_cur_size / db.pool_config_size) * 100
```

for the Memory Pool Identifier SQLM\_HEAP\_DATABASE.

Once this percentage reaches the maximum, 100%, queries and operations may fail because there is no heap available.

## *Federated health indicators*

### *db.fed\_nicknames\_op\_status - Nickname Status*

This health indicator checks all of the nicknames defined in a federated database to determine if there are any invalid nicknames. A nickname may be invalid if the data source object was dropped or changed, or if the user mapping is incorrect.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.fed\_nicknames\_op\_status

**Health monitor level**

Database

**Category**

Federated

**Type**

Collection state-based

**Unit**

Not applicable

An attention alert might be generated if any nicknames defined in the federated database are invalid. Refer to the collection details of this health indicator for the list of objects that need attention.

The FEDERATED database manager parameter must be set to YES for this health indicator to check nicknames status.

### *db.fed\_servers\_op\_status - Data Source Server Status*

This health indicator checks all of the data source servers defined in a federated database to determine if any are unavailable. A data source server might be unavailable if the data source server was stopped, no longer exists, or was incorrectly configured.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

**Identifier**

db.fed\_servers\_op\_status

**Health monitor level**

Database

**Category**

Federated

**Type**

Collection state-based

**Unit**

Not applicable

An attention alert might be generated if any nicknames defined in the federated database are not valid. Refer to the collection details of this health indicator for the list of objects that need attention.

The FEDERATED database manager parameter must be set to YES for this health indicator to check data source server status.

## Health monitor interfaces

There are a number of different health monitor interfaces. The interface you chose depends on your database configuration and current state.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

The following table lists the health monitor interfaces for APIs:

Table 83. Health monitor interfaces: APIs

Monitoring task	API
Capturing a health snapshot	db2GetSnapshot - Get Snapshot with snapshot class SQLM_CLASS_HEALTH
Capturing a health snapshot with the full list of collection objects	db2GetSnapshot - Get Snapshot with snapshot class SQLM_CLASS_HEALTH and SQLM_HMON_OPT_COLL_FULL for agent_id
Capturing a health snapshot with formula, additional information, and history	db2GetSnapshot - Get Snapshot with snapshot class SQLM_CLASS_HEALTH_WITH_DETAIL
Capturing a health snapshot with formula, additional information, history, and the full list of collection objects	db2GetSnapshot - Get Snapshot with snapshot class SQLM_CLASS_HEALTH_WITH_DETAIL and SQLM_HMON_OPT_COLL_FULL for agent_id
Converting the self-describing data stream	db2ConvMonStream - Convert Monitor stream
Estimating the size of a health snapshot	db2GetSnapshotSize - Estimate Size Required for db2GetSnapshot Output Buffer

The **GET HEALTH SNAPSHOT** command is part of the health monitor components that have been deprecated.

The following table lists the health monitor interfaces for CLP commands:

Table 84. Health monitor interfaces: CLP commands

Monitoring task	CLP command
Capturing a health snapshot	GET HEALTH SNAPSHOT Command
Capturing a health snapshot with formula, additional information, and history	GET HEALTH SNAPSHOT WITH DETAILS Command

The health monitor SQL functions are part of the health monitor components that have been deprecated.

The following table lists the health monitor interfaces for SQL functions:

Table 85. Health monitor interfaces: SQL functions

Monitoring task	SQL Function
Database manager level health information snapshot	HEALTH_DBM_INFO
Database manager level health indicator snapshot	HEALTH_DBM_HI
Database manager level health indicator history snapshot	HEALTH_DBM_HI_HIS
Database level health information snapshot	HEALTH_DB_INFO
Database level health indicator snapshot	HEALTH_DB_HI

Table 85. Health monitor interfaces: SQL functions (continued)

Monitoring task	SQL Function
Database level health indicator history snapshot	HEALTH_DB_HI_HIS
Database level health indicator collection snapshot	HEALTH_DB_HIC
Database level health indicator collection history snapshot	HEALTH_DB_HIC_HIS
Table space level health information snapshot	HEALTH_TBS_INFO
Table space level health indicator snapshot	HEALTH_TBS_HI
Table space level health indicator history snapshot	HEALTH_TBS_HI_HIS
Table space container level health information snapshot	HEALTH_CONT_INFO
Table space container level health indicator snapshot	HEALTH_CONT_HI
Table space container level health indicator history snapshot	HEALTH_CONT_HI_HIS

*Health monitor SQL table functions*

You can use SQL table functions to capture snapshots of your database. The snapshots that you create are used by the health monitor to assess the current state of your database. The health monitor SQL table functions have been deprecated.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

The following table lists all of the snapshot table functions. Each table function corresponds to a health snapshot request type.

Table 86. Snapshot monitor SQL table functions

Monitor level	SQL table function	Information returned
Database manager	HEALTH_DBM_INFO	Basic information about the health snapshot from the database manager level
Database manager	HEALTH_DBM_HI	Health indicator information from the database manager level
Database manager	HEALTH_DBM_HI_HIS	Health indicator history information from the database manager level
Database	HEALTH_DB_INFO	Basic information about the health snapshot from a database
Database	HEALTH_DB_HI	Health indicator information from a database
Database	HEALTH_DB_HI_HIS	Health indicator history information from a database
Database	HEALTH_DB_HIC	Collection information for collection health indicators for a database
Database	HEALTH_DB_HIC_HIS	Collection history information for collection health indicators for a database

Table 86. Snapshot monitor SQL table functions (continued)

Monitor level	SQL table function	Information returned
Table space	HEALTH_TBS_INFO	Basic information about the health snapshot for the table spaces for a database
Table space	HEALTH_TBS_HI	Health indicator information about the table spaces for a database
Table space	HEALTH_TBS_HI_HIS	Health indicator history information about the table spaces for a database
Table space	HEALTH_CONT_INFO	Basic information about the health snapshot for the containers for a database
Table space	HEALTH_CONT_HI	Health indicator information about the containers for a database
Table space	HEALTH_CONT_HI_HIS	Health indicator history information about the containers for a database

#### Health monitor CLP commands

You can get health status information for the database manager and its databases by issuing health monitor commands. The information returned represents a snapshot of the health state at the time the command was issued.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

The following table lists all the supported snapshot request types.

Table 87. Snapshot monitor CLP commands

Monitor level	CLP command	Information returned
Database manager	get health snapshot for dbm	Database manager level information.
Database	get health snapshot for all databases	Database level information. Information is returned only if the database is activated.
Database	get health snapshot for database on <i>database-alias</i>	Database level information. Information is returned only if the database is activated.
Database	get health snapshot for all on <i>database-alias</i>	Database, table space, and table space container information. Information is returned only if the database is activated.
Table space	get snapshot for tablespaces on <i>database-alias</i>	Table space level information for each table space that was accessed by an application connected to the database. Also includes health information for each table space container within the table space.

#### Health monitor API request types

You can use database APIs to capture snapshots of your database. The snapshots that you create are used by the health monitor to assess the current state of your database.

The following table lists all the supported snapshot request types.

Table 88. Snapshot Monitor API Request Types

Monitor level	API request type	Information returned
Database manager	SQLMA_DB2	Database manager level information.
Database	SQLMA_DBASE_ALL	Database level information. Information is returned only if the database is activated.
Database	SQLMA_DBASE	Database level information. Information is returned only if the database is activated.
Table space	SQLMA_DBASE_TABLESPACES	Table space level information for each table space that has been accessed by an application connected to the database. Also includes health information for each table space container within the table space.

### Health monitor interface mappings to logical data groups

You can collect health monitor data by using the command line, SQL table functions, or APIs. The method that you choose does not affect the type or amount of data that is available.

The following table lists all the supported health snapshot request types.

Table 89. Health monitor interface mappings to logical data groups

API request type	CLP command	SQL table function	Logical data groups
SQLMA_DB2	get health snapshot for dbm	HEALTH_DBM_INFO	db2
		HEALTH_DBM_HI	health_indicator
SQLMA_DBASE	get health snapshot for dbm show detail	HEALTH_DBM_HI_HIS	health_indicator_history
	get health snapshot for database on <i>dbname</i>	HEALTH_DB_INFO	dbase
SQLMA_DBASE with SQLM_HMON_OPT_COLL_FULL in the agent_id	get health snapshot for database on <i>dbname</i> show detail	HEALTH_DB_HI	health_indicator
	get health snapshot for database on <i>dbname</i> show detail	HEALTH_DB_HI_HI_S	health_indicator_history
SQLMA_DBASE with SQLM_HMON_OPT_COLL_FULL in the agent_id	get health snapshot for database on <i>dbname</i> with full collection	HEALTH_DB_HIC	health_indicator, hi_obj_list
	get health snapshot for database on <i>dbname</i> show detail with full collection	HEALTH_DB_HIC_HIST	health_indicator_history, hi_obj_list
SQLMA_DBASE_ALL	get health snapshot for all databases	HEALTH_DB_INFO	dbase
		HEALTH_DB_HI	health_indicator
	get health snapshot for all databases show detail	HEALTH_DB_HI_HI_S	health_indicator_history

Table 89. Health monitor interface mappings to logical data groups (continued)

API request type	CLP command	SQL table function	Logical data groups
SQLMA_DBASE_TABLESPACES	get health snapshot for tablespaces on <i>dbname</i>	HEALTH_TS_INFO	tablespace
		HEALTH_TS_HI	health_indicator
		HEALTH_CONT_INF0	tablespace_container
		HEALTH_CONT_HI	health_indicator
	get health snapshot for tablespaces on <i>dbname</i> show detail	HEALTH_TS_HI_HI S	health_indicator_history
		HEALTH_CONT_HI_HIS	health_indicator_history

The following figure shows the order that logical data groupings can appear in a health snapshot data stream.

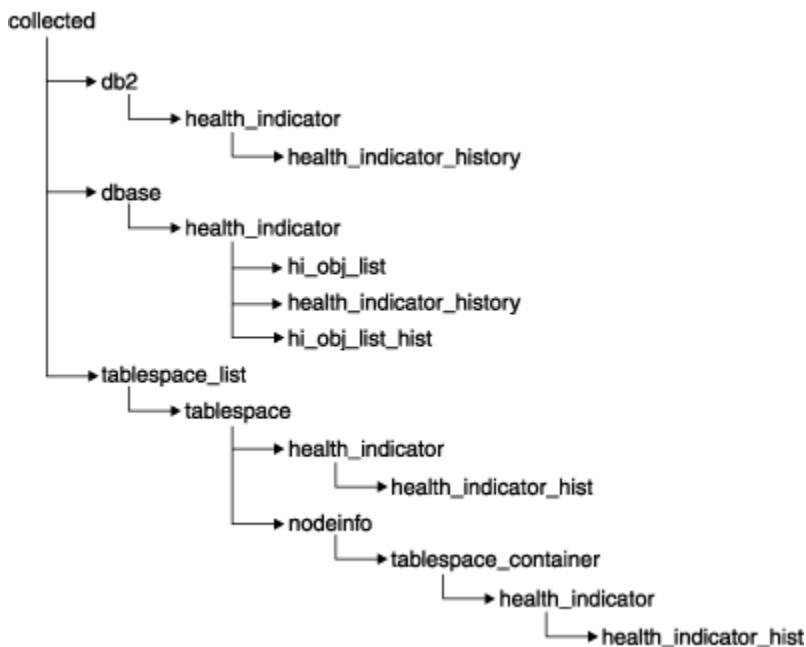

Figure 9. Health snapshot logical data groupings

## Enabling health alert notification

To enable email or pager notification when an alert is generated, you must set configuration parameters and specify contact information.

### Before you begin

The Database Administration Server (DAS) must be running on the system where the contact list is located. For example, if the CONTACT\_HOST configuration parameter is set to a remote system, the DAS must be running on the remote system in order for contacts to be notified of alerts.

### About this task

To enable health alert notification:

### Procedure

1. Specify the SMTP\_SERVER parameter.

The DAS configuration parameter, SMTP\_SERVER, specifies the location of the mail server to use when sending both email and pager notification messages. Omit this step if the system on which the database is installed is enabled as an unauthenticated SMTP server.

2. Specify the CONTACT\_HOST parameter.

The DAS configuration parameter, CONTACT\_HOST, specifies the remote location of the contact list for all instances on the local system. By setting this parameter, a single contact list can be shared between multiple systems. Omit this step if you want to keep the contact list on the local system where the database is installed.

3. Specify the default contact for health monitor notification. To enable email or pager notification from the health monitor when an alert is generated, a default administration contact must be specified. If you choose not to provide this information, notification messages cannot be sent for alert conditions. You can provide the default administration contact information during installation, or you can defer the task until after installation is complete.

If you choose to defer the task or want to add more contacts or groups to the notification list, you can specify contacts through the CLP, or C APIs:

- **To specify contacts using the CLP:**

To define an email contact as the default for health monitor notification, issue the following commands:

```
DB2 ADD CONTACT contact_name TYPE EMAIL ADDRESS
      email_address DESCRIPTION 'Default Contact'

DB2 UPDATE NOTIFICATION LIST ADD CONTACT contact_name
```

For complete syntax details, see the Command Reference.

- **To specify contacts using C APIs:**

The following C code excerpt illustrates how to define health notification contacts:

```
...
#include <db2ApiDf.h>

SQL_API_RC rc = 0;
struct db2AddContactData addContactData;
struct sqlca sqlca;

char* userid = "myuser";
char* password = "pwd";
char* contact = "DBA1";
char* email = "dba1@mail.com";
char* desc = "Default contact";

memset(&addContactData, '\0', sizeof(addContactData));
memset(&sqlca, '\0', sizeof(struct sqlca));

addContactData.piUserId = userid;
addContactData.piPassword = password;
addContactData.piName = contact;
addContactData.iType = DB2CONTACT_EMAIL;
addContactData.piAddress = email;
addContactData.iMaxPageLength = 0;
addContactData.piDescription = desc;

rc = db2AddContact(db2Version810, &addContactData, &sqlca);

if (rc == 0) {
    db2HealthNotificationListUpdate update;
    db2UpdateHealthNotificationListData data;
    db2ContactTypeData contact;

    contact.pName = contact;
    contact.contactType = DB2CONTACT_EMAIL;

    update.iUpdateType = DB2HEALTHNOTIFICATIONLIST_ADD;
    update.piContact = &contact;

    data.iNumUpdates = 1;
    data.piUpdates = &update;

    rc = db2UpdateHealthNotificationList (db2Version810, &data, &ca);
}
```

```
}  
...
```

## Health monitor

The health monitor captures information about the database manager, database, table space, and table space containers.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

The health monitor calculates health indicators based on data retrieved from database system monitor elements, the operating system, and database. The health monitor can only evaluate health indicators on a database and its objects when the database is active. You can keep the database active either by starting it with the **ACTIVATE DATABASE** command or by maintaining a permanent connection to the database.

The health monitor retains a maximum of 10 history records for each health indicator. This history is stored in the *instance\_path*\hmonCache directory and is removed when the health monitor is stopped. The health monitor automatically prunes obsolete history records when the maximum number of records is reached.

Health monitor data is accessible through health snapshots. Each health snapshot reports the status for each health indicator based on its most recent refresh interval. The snapshots are useful for detecting existing database health problems and predicting potential poor health of the database environment. You can capture a health snapshot from the CLP, by using APIs in a C or C++ application, or by using the graphical administration tools.

Health monitoring requires an instance attachment. If an attachment to an instance was not established using the **ATTACH TO** command, then a default instance attachment to the local instance is created.

In partitioned database environments, snapshots can be taken at any partition of the instance, or globally using a single instance connection. A global snapshot aggregates the data collected at each partition and returns a single set of values.

## Usage notes

The health monitor is supported on all editions of the database.

On Windows, the service for the database instance needs to run under an account with SYSADM authority. You can use the **-u** option on the **db2icrt** command, or use the Services folder on Windows and edit the Log On properties to use an account with administrator privilege.

The health monitor process runs as a fenced mode process. These processes appear as DB2FMP on Windows. On other platforms, the health monitor process appears as DB2ACD.

The Administration server must be running on the system where the health monitor resides for notifications to be sent and alert actions to be run. If remote scripts, tasks, or contact lists are used, the Administration server on the remote system must also be started.

The tools catalog database is required only for creating tasks. If you do not use alert task actions for any health indicator, the tools catalog database is not required by the health monitor.

## Health indicator data

The health monitor records a set of data for each health indicator on each database partition.

This data includes:

- Health indicator name
- Value

- Evaluation timestamp
- Alert state
- Formula, if applicable
- Additional information, if applicable
- History of up to ten of the most recent health indicator evaluations. Each history entry captures the following health indicator evaluations leading up to the current health indicator output:
  - Value
  - Formula (if applicable)
  - Alert state
  - Timestamp

The health monitor also tracks the highest severity alert state at the instance, database, and table space levels. At each level, this health indicator represents the highest severity alert existing for health indicators at that level, or any of the levels below it. For example, the highest severity alert state for an instance includes health indicators on the instance, any of its database, and any of the table spaces and table space containers for each of the databases.

### ***Capturing database health snapshots***

#### *Capturing a database health snapshot using SQL table functions*

You can capture database health snapshots using SQL table functions. Each available health snapshot table function corresponds to a health snapshot request type.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

### **About this task**

To capture a database health snapshots using SQL table functions:

### **Procedure**

1. Identify the SQL table function you plan to use.

SQL table functions have two input parameters:

- A VARCHAR(255) for the database name
- An INT for the partition number (a value between 0 and 999). Enter the integer corresponding to the partition number you want to monitor. To capture a snapshot for the currently connected partition, enter a value of -1. To capture a global snapshot, enter a value of -2.

**Note:** The database manager snapshot SQL table functions are the only exception to this rule because they have only one parameter. The single parameter is for partition number. If you enter NULL for the database name parameter, the monitor uses the database defined by the connection through which the table function has been called.

2. Issue the SQL statement.

The following example captures a basic health snapshot for the currently connected partition, and on the database defined by the connection from which this table function call is made:

```
SELECT * FROM TABLE( HEALTH_DB_INFO( cast (NULL as VARCHAR(1)), -1))
as HEALTH_DB_INFO
```

You can also select individual monitor elements from the returned table. Each column in the returned table corresponds to a monitor element. Accordingly, the monitor element column names correspond directly to the monitor element names. The following statement returns only the db path and server platform monitor elements:

```
SELECT db_path, server_platform
FROM TABLE( HEALTH_DB_INFO( cast (NULL as VARCHAR(1)), -1 ) )
as HEALTH_DB_INFO
```

### *Capturing a database health snapshot using the CLP*

You can capture health snapshots using the GET HEALTH SNAPSHOT command from the CLP. The command syntax supports retrieval of health snapshot information for the different object types monitored by the health monitor.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

## Before you begin

You must have an instance attachment to capture a health snapshot. If there is not an attachment to an instance, then a default instance attachment is created. To obtain a snapshot of a remote instance, you must first attach to that instance.

## About this task

To capture a database health snapshot using the CLP

## Procedure

1. From the CLP, issue the GET HEALTH SNAPSHOT command with the required parameters.

In the following example, a database manager level health snapshot is captured immediately after starting the database manager.

```
db2 get health snapshot for dbm
```

2. For partitioned database systems, you can capture a database snapshot specifically for a certain partition or globally for all partitions. To capture a health snapshot for a database on a specific partition (for example, partition number 2), issue the following command:

```
db2 get health snapshot for db on sample at dbpartitionnum 2
```

To capture a database snapshot for all applications on all partitions, issue the following command:

```
db2 get health snapshot for db on sample global
```

The following command captures a health snapshot with additional detail, including the formula, additional information, and health indicator history:

```
db2 get health snapshot for db on sample show detail
```

3. For collection state-based health indicators, you can capture a database snapshot for all collection objects, regardless of state. The regular GET HEALTH SNAPSHOT FOR DB command returns all collection objects requiring an alert for all collection state-based health indicators.

To capture a health snapshot for a database with all collection objects listed, issue the following command:

```
db2 get health snapshot for db on sample with full collection
```

### *Capturing a database health snapshot from a client application*

You can capture health snapshots using the snapshot monitor API in a C or C++ application. A number of different health snapshot request types can be accessed by specifying parameters in the db2GetSnapshot API.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

## Before you begin

You must be attached to an instance to capture a health snapshot. If there is not an attachment to an instance, then a default instance attachment is created. To obtain a snapshot of a remote instance, you must first attach to that instance.

## Procedure

1. Include the sqlmon.h and db2ApiDf.h libraries in your code. These libraries are located in the sqlllib\include directory.

```
#include <db2ApiDf.h>
#include <sqlmon.h>
```

2. Set the snapshot buffer unit size to 50 KB.

```
#define SNAPSHOT_BUFFER_UNIT_SZ 51200
```

3. Declare the sqlma, sqlca, sqlm\_collected, and db2GetSnapshotData structures.

```
struct sqlma *pRequestedDataGroups;
struct sqlca sqlca;
memset (&sqlca, '\0', sizeof(struct sqlca));
struct sqlm_collected collectedData;
memset (&sqlm_collected, '\0', sizeof(struct sqlm_collected));
db2GetSnapshotData getSnapshotParam;
memset (&db2GetSnapshotData, '\0', sizeof(db2GetSnapshotData));
```

4. Initialize a pointer to contain the snapshot buffer, and to establish the buffer's size.

```
static sqluint32 snapshotBufferSize = SNAPSHOT_BUFFER_UNIT_SZ;
sqluint32 outputFormat;
char *snapshotBuffer;
```

5. Initialize the sqlma structure and specify that the snapshot you are capturing is of database manager level information.

```
pRequestedDataGroups = (struct sqlma *)malloc(SQLMASIZE(1));
memset (&pRequestedDataGroups, '\0', sizeof(struct pRequestedDataGroups));
pRequestedDataGroups->obj_num = 1;
pRequestedDataGroups->obj_var[0].obj_type = SQLMA_DB2;
```

6. Initialize the buffer, which will hold the snapshot output.

```
snapshotBuffer = (char *)malloc(snapshotBufferSize);
memset (&snapshotBuffer, '\0', sizeof(snapshotBuffer));
```

7. Populate the db2GetSnapshotData structure with the snapshot request type (from the sqlma structure), buffer information, and other information required to capture a snapshot.

```
getSnapshotParam.piSqlmaData = pRequestedDataGroups;
getSnapshotParam.poCollectedData = &collectedData;
getSnapshotParam.poBuffer = snapshotBuffer;
getSnapshotParam.iVersion = SQLM_DBMON_VERSION9_5;
getSnapshotParam.iBufferSize = snapshotBufferSize;
getSnapshotParam.iStoreResult = 0;
getSnapshotParam.iNodeNumber = SQLM_CURRENT_NODE;
```

```

getSnapshotParam.poOutputFormat = &outputFormat;
getSnapshotParam.iSnapshotClass = SQLM_CLASS_HEALTH;

```

8. Capture the health snapshot. Pass the following parameters:

- db2GetSnapshotData structure, which contains the information necessary to capture a snapshot
- A reference to the buffer where snapshot output is directed.

```

db2GetSnapshot(db2Version810, &getSnapshotParam, &sqlca);

```

9. Include logic to handle buffer overflow. After a snapshot is taken, the sqlcode is checked for a buffer overflow. If a buffer overflow occurs, the buffer is cleared, reinitialized, and the snapshot is taken again.

```

while (sqlca.sqlcode == 1606)
{
    free(snapshotBuffer);
    snapshotBufferSize += SNAPSHOT_BUFFER_UNIT_SZ;
    snapshotBuffer = (char *)malloc(snapshotBufferSize);
    if (snapshotBuffer == NULL)
    {
        printf("\nMemory allocation error.\n");
        return;
    }

    getSnapshotParam.iBufferSize = snapshotBufferSize;
    getSnapshotParam.poBuffer = snapshotBuffer;
    db2GetSnapshot(db2Version810, &getSnapshotParam, &sqlca);
}

```

10. Process the snapshot monitor data stream. Refer to the figure following these steps to see the snapshot monitor data stream.

11. Clear the buffer.

```

free(snapshotBuffer);
free(pRequestedDataGroups);

```

## Results

After you capture a health snapshot with the db2GetSnapshot API, the API returns the health snapshot output as a self-describing data stream.

The following example shows the data stream structure:

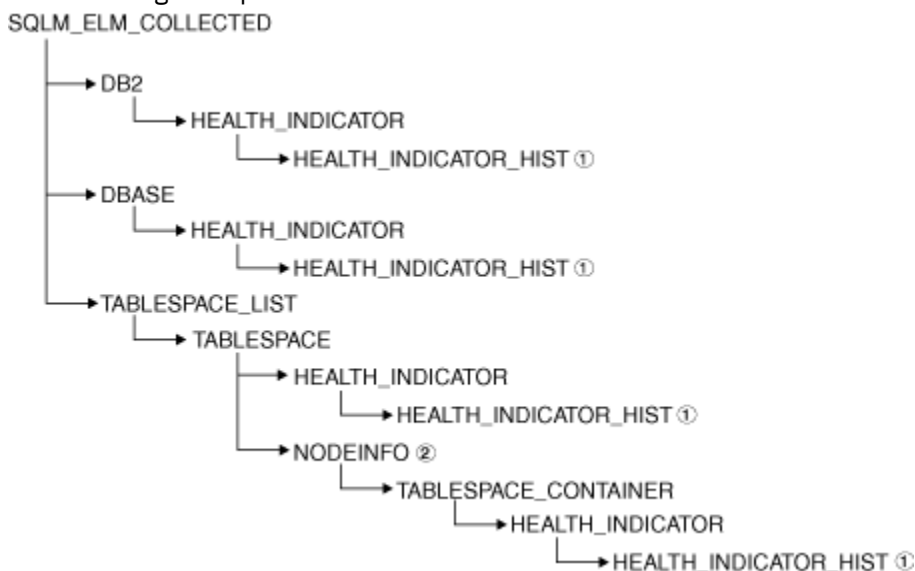

Figure 10. Health snapshot self-describing data stream

### Legend:

1. Available only when the SQLM\_CLASS\_HEALTH\_WITH\_DETAIL snapshot class is used.
2. Available only in Db2 Enterprise Server Edition. Otherwise, table space container stream follows.

The following hierarchies display the specific elements in the health snapshot self-describing data stream.

The hierarchy of elements under SQLM\_ELM\_HI:

```
SQLM_ELM_HI
  SQLM_ELM_HI_ID
  SQLM_ELM_HI_VALUE
    SQLM_ELM_HI_TIMESTAMP
      SQLM_ELM_SECONDS
      SQLM_ELM_MICROSEC
  SQLM_ELM_HI_ALERT_STATE
```

The hierarchy of elements under SQLM\_ELM\_HI\_HIST, available only with the SQLM\_CLASS\_HEALTH\_WITH\_DETAIL snapshot class:

```
SQLM_ELM_HI_HIST
  SQLM_ELM_HI_FORMULA
  SQLM_ELM_HI_ADDITIONAL_INFO
    SQLM_ELM_HEALTH_INDICATOR_HIST
      SQLM_ELM_HI_ID
      SQLM_ELM_HI_VALUE
        SQLM_ELM_HI_TIMESTAMP
          SQLM_ELM_SECONDS
          SQLM_ELM_MICROSEC
      SQLM_ELM_HI_ALERT_STATE
      SQLM_ELM_HI_FORMULA
      SQLM_ELM_HI_ADDITIONAL_INFO
```

The hierarchy of elements under SQLM\_ELM\_OBJ\_LIST:

```
SQLM_ELM_HI_OBJ_LIST
  SQLM_ELM_HI_OBJ_NAME
  SQLM_ELM_HI_OBJ_DETAIL
  SQLM_ELM_HI_OBJ_STATE
    SQLM_ELM_HI_TIMESTAMP
      SQLM_ELM_SECONDS
      SQLM_ELM_MICROSEC
```

The hierarchy of elements under SQLM\_ELM\_OBJ\_LIST\_HIST, available only with the SQLM\_CLASS\_HEALTH\_WITH\_DETAIL snapshot class:

```
SQLM_ELM_HI_OBJ_LIST_HIST
  SQLM_ELM_HI_OBJ_NAME
  SQLM_ELM_HI_OBJ_STATE
    SQLM_ELM_HI_TIMESTAMP
      SQLM_ELM_SECONDS
      SQLM_ELM_MICROSEC
```

### ***Health monitor sample output***

Use the health monitor to determine if there are any potential database health issues, such as hardware failure or poor system performance. You can gather data for the health monitor by capturing snapshots through the command line, SQL table functions, and APIs.

The following examples show health snapshots taken using the CLP, and their corresponding output, and illustrate the nature of the health monitor. The objective in the examples is to check the overall health status immediately after starting the database manager.

1. Take the database manager snapshot, using the GET HEALTH SNAPSHOT command:

```
db2 get health snapshot for dbm
```

After the GET HEALTH SNAPSHOT command is issued from the CLP, the snapshot output is directed to the screen.

```

Node name                =
Node type                = Database Server with local
                        and remote clients
Instance name            = Db2
Snapshot timestamp       = 11-07-2002 12:43:23.613425

Number of database partitions in Db2 instance = 1
Start Database Manager timestamp = 11-07-2002 12:43:18.000108
Instance highest severity alert state = Not yet evaluated

Health Indicators:

    Not yet evaluated

```

- Analyze the output. From this health snapshot, you can see that the instance highest severity alert state is "Not yet evaluated". The instance is in this state because the health monitor has just started and has not yet evaluated any health indicators.

Should the instance highest severity alert state not change:

- Check the value of the HEALTH\_MON database manager configuration parameter to determine if the health monitor is on.
- If HEALTH\_MON=OFF, then the health monitor is not started. To start the health monitor, issue the UPDATE DBM CFG USING HEALTH\_MON ON command.
- If HEALTH\_MON=ON, attach to the instance to activate the health monitor. If an instance attachment exists, it is possible that the health monitor could not be loaded into memory.

Here is another example of taking a database health snapshot using the CLP.

- Before you begin, ensure that a database connection exists, and that the database is quiesced.
- Take the database manager snapshot, using the GET HEALTH SNAPSHOT command:

```
db2 get health snapshot for db on sample
```

- After the GET HEALTH SNAPSHOT command is issued from the CLP, the snapshot output is directed to the screen.

```

                Database Health Snapshot

Snapshot timestamp           = 12-09-2002 11:44:37.793184

Database name                = SAMPLE
Database path                = E:\DB2\NODE0000\SQL00002\
Input database alias         = SAMPLE
Operating system running at database server= NT
Location of the database     = Local
Database highest severity alert state = Attention

Health Indicators:

...
Indicator Name              = db.log_util
Value                       = 60
Unit                        = %
Evaluation timestamp        = 12-09-2002 11:44:00.095000
Alert state                  = Normal

Indicator Name              = db.db_op_status
Value                       = 2
Evaluation timestamp        = 12-09-2002 11:44:00.095000
Alert state                  = Attention

```

- Analyze the output.

This health snapshot reveals that there is an attention alert on the *db.db\_op\_status* health indicator. The value of 2 indicates that the database is in quiesced state.

## Global health snapshots

On a partitioned database system you can take a health snapshot of the current partition, a specified partition, or all partitions. When taking a global health snapshot across all the partitions of a partitioned database, data is aggregated, where possible, before the results are returned.

The aggregated alert state for the health indicator is equivalent to the highest severity alert state across all the database partitions. Additional information and history data cannot be aggregated across the database partitions, and therefore are not available. The remaining data for the health indicator is aggregated as detailed in the following table.

Table 90. Aggregation of health indicator value, timestamp, and formula data

Health indicator	Aggregation details
<ul style="list-style-type: none"><li>• db2.db2_op_status</li><li>• db2.sort_privmem_util</li><li>• db2.mon_heap_util</li><li>• db.db_op_status</li><li>• db.sort_shrmem_util</li><li>• db.spilled_sorts</li><li>• db.log_util</li><li>• db.log_fs_util</li><li>• db.locklist_util</li><li>• db.apps_waiting_locks</li><li>• db.db_heap_util</li><li>• db.db_backup_req</li><li>• ts.ts_util</li></ul>	<p>The health indicator value is obtained from the partition that contains the highest value.</p> <p>The evaluation timestamp and formula are obtained from the same partition.</p>
<ul style="list-style-type: none"><li>• db.max_sort_shrmem_util</li><li>• db.pkgcache_hitratio</li><li>• db.catcache_hitratio</li><li>• db.shrworkspace_hitratio</li></ul>	<p>The health indicator value is obtained from the partition that contains the lowest value.</p> <p>The evaluation timestamp and formula are obtained from the same partition.</p>
<ul style="list-style-type: none"><li>• db.deadlock_rate</li><li>• db.lock_escal_rate</li></ul>	<p>The health indicator value is the sum of the values across all the database partitions.</p> <p>The evaluation timestamp and formula cannot be aggregated and are not available.</p>
<ul style="list-style-type: none"><li>• ts.ts_op_status</li><li>• tsc.tscont_op_status</li><li>• tsc.tscont_util</li></ul>	<p>These health indicators is not aggregated.</p>
<ul style="list-style-type: none"><li>• db.hadr_op_status</li><li>• db.hadr_log_delay</li></ul>	<p>These health indicators are not supported in a multiple partition database.</p>
<ul style="list-style-type: none"><li>• db.tb_reorg_req</li><li>• db.tb_runstats_req</li><li>• db.fed_nicknames_op_status</li><li>• db.fed_servers_op_status</li></ul>	<p>This health indicator is evaluated only on one partition, so no aggregation is required. The data is returned from the partition which is evaluating the health indicator.</p>

**Note:** When taking a global snapshot on a single partition object, the output includes all the attributes because there are no partitions to aggregate.

## **Retrieving health recommendations**

### *Health recommendation queries with SQL*

Recommendations can be queried with SQL using the SYSPROC.HEALTH\_HI\_REC stored procedure.

When using the SYSPROC.HEALTH\_HI\_REC stored procedure, recommendations are returned in an XML document that is:

- Formatted according to the health recommendations XML schema DB2RecommendationSchema.xsd located in the sqllib\misc directory.
- Encoded in UTF-8 and contains text in the client language.
- Organized as a collection of recommendation sets, where each recommendation set describes a problem (health indicator) being resolved and contains one or more recommendations to resolve that health indicator. Refer to the schema definition for specific details about information that can be retrieved from the document.

All information available through the CLP is also available in the XML recommendation document that is returned when you query with SQL.

The SYSPROC.HEALTH\_HI\_REC stored procedure takes the following arguments:

- A health indicator
- A definition of the object on which the health indicator has entered an alert state

The output recommendation document is returned as a BLOB. Therefore, it is not helpful to work with this stored procedure from the command line, since the CLP will limit the amount of output displayed. It is recommended that this stored procedure be invoked using a high level language (such as C or Java) that allows the returned XML document to be properly parsed to retrieve any required elements and attributes.

### *Retrieving health recommendations using the command line processor*

Recommendations can be retrieved using the GET RECOMMENDATIONS command from the command line processor (CLP). The command syntax supports querying recommendations to resolve a specific health alert, such as a health indicator that entered an alert state on a particular object.

## **Before you begin**

You must have an instance attachment to retrieve recommendations from the health monitor. If there is not an attachment to an instance, a default instance attachment is created. To obtain recommendations from a health monitor on a remote instance, you must first attach to that instance. No special authority is required to retrieve recommendations from the health monitor.

## **About this task**

The command syntax also supports retrieval of the complete set of recommendations for a specific health indicator, which does not have to be in an alert state when the command is executed. Recommendations for resolving an alert on a specific health indicator can be queried at either a single partition level or a global level.

When querying recommendations on a health alert on a specific object, the health monitor is solving a specific alert and is able to provide details on the alert that is being resolved in the problem section of the output.

The health monitor is also able to provide a ranking for the recommendations and, in some cases, it might be able to generate scripts that can be executed to resolve the alert. Additionally, the health monitor might reject and not display some recommendations if they are not applicable to the particular problem situation. Alternatively, if recommendations are queried by health indicator name only, as in the first example shown, the total set of possible recommendations is always returned. In such cases, the CLP

command is simply providing information about actions that you should consider undertaking if they see an alert.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

## Procedure

Retrieve the recommendations using the GET RECOMMENDATIONS command:

- You might want to issue the following command to see the total set of actions that could be recommended to resolve an alert on the **db.db\_op\_status** health indicator.

```
db2 get recommendations for health indicator db.db_op_status
```

In this example, the full set of recommendations for the **db.db\_op\_status** health indicator is returned. The health indicator does not have to be in an alert state to issue this command.

This output shows that there are two possible recommendations for this health indicator: unquiesce the database or investigate rollforward progress on the database. Because the command is being used to query all possible recommendations, rather than to ask how to resolve a specific alert, the health monitor cannot identify the best recommendation in this case. As a result, the full set of recommendations is returned.

```
Recommendations:
```

```
Recommendation: Investigate rollforward progress.
```

```
A rollforward is in progress on the database due to an explicit request from the administrator. You have to wait for the rollforward to complete for the instance to return to active state.
```

```
From the Command Line Processor, issue the commands shown in the following example to view the progress of the rollforward utility:
```

```
LIST UTILITIES SHOW DETAIL
```

```
Recommendation: Unquiesce the database.
```

```
The database has been put into QUIESCE PENDING or QUIESCE state by an explicit request from the administrator. If you have QUIESCE_CONNECT authority, or are DBADM or SYSADM, you will still have access to the database and will be able to use it normally. For all other users, new connections to the database are not permitted and new units of work cannot be started. Also, depending on the quiesce request, active units of work will be allowed to complete or will be rolled back immediately. You can issue an unquiesce to return to active state.
```

```
From the Command Line Processor, issue the commands shown in the following example:
```

```
CONNECT TO DATABASE database-alias
UNQUIESCE DATABASE
```

- Suppose you observe that the health indicator **db.db\_heap\_util** entered an alert state for the database SAMPLE, and you want to determine how to resolve the alert. In this case, you want to resolve a specific problem, therefore you could issue the GET RECOMMENDATIONS command in the following way:

```
db2 get recommendations for health indicator db.db_heap_util
    for database on sample
```

This output shows a summary of the problem and a set of recommendations to resolve the problem. The health monitor ranked the recommendations in its order of preference. Each recommendation contains a description and a set of actions that indicate how to perform the recommended action.

Problem:

Indicator Name	= db.db_heap_util
Value	= 42
Evaluation timestamp	= 11/25/2003 19:04:54
Alert state	= Alarm
Additional information	=

Recommendations:

Recommendation: Increase the database heap size.  
Rank: 1

Increase the database configuration parameter dbheap sufficiently to move utilization to normal operating levels. To increase the value, set the new value of dbheap to be equal to  $(\text{pool\_cur\_size} / (4096 * U))$  where U is the desired utilization rate. For example, if your desired utilization rate is 60% of the warning threshold level, which you have set at 75%, then  $U = 0.6 * 0.75 = 0.45$  (or 45%).

Execute the following commands at the Db2 server (this can be done using the EXEC\_DB2\_CMD stored procedure):

```
CONNECT TO DATABASE SAMPLE;  
UPDATE DB CFG USING DBHEAP 149333;  
CONNECT_RESET;
```

Recommendation: Investigate memory usage of database heap.  
Rank: 2

There is one database heap per database and the database manager uses it on behalf of all applications connected to the database. The data area is expanded as needed up to the maximum specified by dbheap.

For more information on the database heap, refer to the Db2 documentation.

Investigate the amount of memory that was used for the database heap over time to determine the most appropriate value for the database heap configuration parameter. The database system monitor tracks the highest amount of memory that was used for the database heap.

- For partitioned database systems, you can query recommendations for a health indicator that entered an alert state on a certain partition, or globally for all partitions. When recommendations are queried globally, a set of recommendations is returned that applies to the health indicator on all partitions. For example, if the health indicator is in an alert state on partitions 1 and 3, a collection of two scripts might be returned where each script is to be applied to a different partition.

The following example shows how to query recommendations for a health indicator on a specific partition (in this example, partition number 2):

```
db2 get recommendations for health indicator db.db_heap_util  
for database on sample at dbpartitionnum 2
```

The following example shows how to retrieve a set of recommendations to resolve a health indicator that is in an alert state on several partitions:

```
db2 get recommendations for health indicator db.db_heap_util  
for database on sample global
```

## Retrieving health recommendations using a client application

Recommendations can be queried using the `db2GetRecommendations` API in a C or C++ application.

### Before you begin

You must have an instance attachment to capture a health snapshot. If there is not an attachment to an instance, then a default instance attachment is created. To query recommendations on a remote instance, you must first attach to that instance.

### About this task

When using the `db2GetRecommendations` API, recommendations are returned in an XML document that is:

- Formatted according to the health recommendations XML schema `DB2RecommendationSchema.xsd` located in the `MISC` subdirectory within the `SQLLIB` directory.
- Encoded in UTF-8 and contains text in the client language.
- Organized as a collection of recommendation sets, where each recommendation set describes a problem (health indicator) being resolved and contains one or more recommendations to resolve that health indicator. Refer to the schema definition for specific details about what information that can be retrieved from the document.

All information available through the CLP is also available in the XML recommendation document that is returned.

To retrieve health recommendations using a client application:

### Procedure

1. Include the `sqlmon.h` and `db2ApiDf.h` header files. These are located in the `sqllib\include` directory.

```
#include <db2ApiDf.h>
#include <sqlmon.h>
```

2. Declare the `sqlca`, and the `db2GetRecommendationsData` structure.

```
struct sqlca sqlca ;
db2GetRecommendationsData recData ;

memset( &sqlca, '\0', sizeof( struct sqlca ) ) ;
memset( &recData, '\0', sizeof( db2GetRecommendationsData ) ) ;
```

3. Populate the `db2GetRecommendationsData` structure with information about the alert for which you want to retrieve recommendations. In the code excerpt that follows, recommendations are being queried for the **db2.db\_heap\_util** health indicator on the Sample database.

```
recData.iSchemaVersion = DB2HEALTH_RECSCHEMA_VERSION8_2 ;
recData.iNodeNumber = SQLM_CURRENT_NODE ;
recData.iIndicatorID = SQLM_HI_DATABASE_HEAP_UTILIZATION ;
recData.iObjType = DB2HEALTH_OBJTYPE_DATABASE ;
recData.piDbName = "SAMPLE" ;
```

4. Invoke the `db2GetRecommendations` API to retrieve recommendations for an alert on this health indicator on the specified database.

```
db2GetRecommendations( db2Version820, &recData, &sqlca ) ;
```

5. Check the `sqlcode` returned in the `sqlca` for any errors that occurred. If the API call was successful, process the recommendation XML document that is returned in the `poRecommendation` field of the `db2GetRecommendationsData` structure. Use your choice of XML parser to extract the required elements or attributes. Refer to the `DB2RecommendationSchema.xsd` XML schema in the `sqllib\misc` directory for details about the information that can be retrieved from the XML document.

- Free any memory allocated by the db2GetRecommendations API. This will free the recommendation document returned in the poRecommendation field of the db2GetRecommendationsData structure.

```
db2GetRecommendationsFree( db2Version820, &recData, &sqlca );
```

## Results

Typically you would combine the preceding code with a call to the snapshot APIs to take a health snapshot because recommendations are generally queried when you detect a health indicator has entered an alert state.

### Health indicator configuration

A default health monitor configuration is provided during installation. This configuration ensures that the health monitor can evaluate the health of the database environment as soon as the database system is started. However, the health monitor's behavior in evaluating health indicators and reacting to alert states can be fine-tuned through configuration for a specific user's environment.

The health monitor SQL table functions have been deprecated.

**Important:** The health monitor, health indicators, and related components have been deprecated and might be removed in a future release. Health monitor is not supported in Db2 pureScale environments. For more information, see the "Health monitor has been deprecated" topic at [http://www.ibm.com/support/knowledgecenter/SSEPGG\\_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html](http://www.ibm.com/support/knowledgecenter/SSEPGG_9.7.0/com.ibm.db2.luw.wn.doc/doc/i0055045.html).

There are different levels at which the configuration can be defined. A default configuration of factory settings is provided for each health indicator when the database system is installed. When the health monitor starts for the first time, a copy of the factory settings provides the defaults for the instance and global settings.

Instance settings apply to the instance. Global settings apply to objects such as databases, table spaces, and table space containers in the instance that do not have customized settings defined.

Updating health indicator settings for a specific database, table space, or table space container creates object settings for the updated health indicators. The default for object settings is the global settings.

The health monitor checks the object settings when it processes a health indicator for a particular database, table space, or table space container. If the settings for a particular health indicator have never been updated, the default global settings are used to process the health indicator. The instance settings are used when the health monitor processes a health indicator for the instance.

You can alter health monitor behavior by using a number of attributes that can be configured for each health indicator. The first set of parameters (evaluation flag, thresholds, sensitivity) defines when the health monitor will generate an alert for a health indicator. The second set of parameters (action flag, actions) defines what the health monitor does upon generating the alert.

### Evaluation flag

Each health indicator has an evaluation flag to enable or disable evaluation of alert state.

### Warning and alarm thresholds

Threshold-based health indicators have settings defining the warning and alarm regions for the health indicator value. These warning and alarm threshold values can be modified for your particular database environment.

### Sensitivity parameter

The sensitivity parameter defines the minimum amount of time, in seconds, that the health indicator value has to be in an alert state before the alert is generated. The wait time associated with the sensitivity value starts on the first refresh interval during which the health indicator value enters an alert state. You can use this value to eliminate erroneous alerts generated due to temporary spikes in resource usage.

Consider an example using the Log Utilization (*db.log\_util*) health indicator. Suppose that you review the database notify log on a weekly basis. In the first week, an entry for *db.log\_util* is in alarm state. You recall having received notification for this situation, but on checking for the alert situation from the CLP, the health indicator was back in normal state. After a second week, you notice a second

alarm notification entry for the same health indicator at the same time of the week. You investigate activity in your database environment on the two occasions that alerts were generated, and you discover that an application that takes a long time to commit is run weekly. This application causes the log utilization to spike for a short time, approximately eight to nine minutes, until the application commits. You can see from the history entries in the alarm notification record in the notification log, that the *db.log\_util* health indicator is evaluated every 10 minutes. Because the alert is being generated, the application time must be spanning that refresh interval. You set the sensitivity for the *db.log\_util* parameter to ten minutes. Now every time the value of *db.log\_util* first enters the warning or alarm threshold regions, the value must remain in that region for at least ten minutes before the alert is generated. No further notification entries are recorded in the notification log for this situation because the application only lasts eight to nine minutes.

### Action flag

The running of actions on alert generation is controlled by the action flag. Only when the action flag is enabled are the configured alert actions run.

### Actions

Script or task actions can be configured to run on alert occurrence. For threshold-based health indicators, actions can be configured to run on warning or alarm thresholds. For state-based health indicators, actions can be configured to run on any of the possible non-normal conditions. The database administration server must be running for actions to run.

The following input parameters are passed to every operating system command script:

- <health indicator shortname>
- <object name>
- <value | state>
- <alert type>

Script actions use the default interpreter on the operating system. If you want to use a non-default interpreter, create a task using the ADMIN\_TASK\_ADD procedure with the script content. In a multipartitioned environment, the script defined in the script action must be accessible by all partitions.

The refresh interval at which the health monitor checks each health indicator cannot be configured. The recommendation actions considered by the health monitor cannot be configured.

The health monitor configuration is stored in a binary file, HealthRules.reg:

- On Windows, HealthRules.reg is stored in x:\<SQLLIB\_PATH>\<INSTANCE\_NAME>. For example, d:\sqllib\DB2.
- On UNIX, HealthRules.reg is stored in ~/<SQLLIB\_PATH>/cfg. For example, ~/home/sqllib/cfg.

It is possible to replicate a health monitor configuration to other database instances on a Linux, UNIX, or Windows server. You can accomplish this replication by copying the binary configuration file to the appropriate directory location on the target instance.

### *Retrieving health indicator configuration using the CLP*

The GET ALERT CONFIGURATION command allows you to view the factory settings and the instance, global, and object settings.

## Procedure

1. To view the global settings for database-level health indicators, which apply to all databases without customized settings for the health indicator, issue the following command:

```
DB2 GET ALERT CONFIGURATION FOR DATABASES
```

2. To view the global settings for database-level health indicators, which apply to all databases without customized settings for the health indicator, issue the following command:

```
DB2 GET ALERT CONFIGURATION FOR DATABASES
```

The output of each health indicator's settings indicates whether it has been changed from its default. In the following output, the global settings have not been updated; therefore, they are the same as the default factory settings. To view factory settings for database-level health indicators, issue the same command as in the preceding example with the `DEFAULT` keyword.

```

Alert Configuration

Indicator Name           = db.db_op_status
Default                 = Yes
Type                   = State-based
Sensitivity             = 0
Formula                = db.db_status;
Actions                = Disabled
Threshold or State checking = Enabled

Indicator Name           = db.sort_shrmem_util
Default                 = Yes
Type                   = Threshold-based
Warning                = 70
Alarm                  = 85
Unit                   = %
Sensitivity             = 0
Formula                = ((db.sort_shrheap_allocated/sheapthres_shr)
                        *100);
Actions                = Disabled
Threshold or State checking = Enabled

...

```

3. To view the custom settings for the `SAMPLE` database, issue the following command:

```
DB2 GET ALERT CONFIGURATION FOR DATABASE ON SAMPLE
```

If there are no specific settings for a particular health indicator on the object specified, the global settings for all databases are displayed. To view the settings for a particular health indicator, add the `USING health-indicator-name` clause to any of the preceding examples.

#### *Health indicator configuration updates using the CLP*

You can update the health indicator configuration for a particular object. You can make updates to the global settings or to the object settings for a particular object.

The `UPDATE ALERT CONFIGURATION` command has four sub-clauses that cover the different update options. Only one sub-clause can be used in each `UPDATE ALERT CONFIGURATION` command. To use more than one of the options, multiple `UPDATE ALERT CONFIGURATION` commands must be issued.

The first sub-clause, `SET parameter-name value`, provides support to update:

- The evaluation flag
- The warning and alarm thresholds (if applicable)
- The sensitivity flag
- The action flag

The corresponding parameter names for these settings are:

- `THRESHOLDSCHECKED`
- `WARNING` and `ALARM`
- `SENSITIVITY`
- `ACTIONSENABLED`

The other three sub-clauses provide support to add, to update, and to delete script or task actions.

The following commands update a threshold-based health indicator configuration for the `db.spilled_sorts` health indicator on the `SAMPLE` database. The update changes the warning threshold to 25, to enable actions, and to add a script action:

```

DB2 UPDATE ALERT CONFIGURATION FOR DATABASE ON SAMPLE USING DB.SPILLED_SORTS
SET WARNING 25, ACTIONSENABLED YES
DB2 UPDATE ALERT CONFIGURATION FOR DATABASE ON SAMPLE USING DB.SPILLED_SORTS

```

```
ADD ACTION SCRIPT c:\myscript TYPE OS COMMAND LINE PARAMETERS 'space'  
WORKING DIRECTORY c:\ ON ALARM USER dba1 PASSWORD dba1
```

The following commands update a state-based health indicator configuration for the *ts.ts\_util* health indicator for the global settings. The update defines an action to run when any table space is in backup pending state.

```
DB2 UPDATE ALERT CONFIGURATION FOR TABLESPACES USING TS.TS_UTIL  
SET ACTIONSENABLED YES  
DB2 UPDATE ALERT CONFIGURATION FOR TABLESPACES USING TS.TS_UTIL  
ADD ACTION TASK 0.1 ON ATTENTION 32 ON localhost USER dba1 PASSWORD dba1
```

This update will apply to all table spaces for the instance that do not have customized settings for this health indicator.

When adding actions to a health indication configuration, the options for the ON *condition* clause are based on the type of health indicator:

- For a threshold-based health indicator, WARNING and ALARM are valid conditions.
- For a state-based health indicator, the ON ATTENTION *state* option must be used. A valid numeric state, as defined for the health indicator, should be used. The database manager and database operational state values can be found in `sqllib\include\sqlmon.h`. The table space and table space container operational values are listed in `sqllib\include\sqlutil.h`. Note that actions cannot be executed for the database manager down state. Refer to the description of the `db2.db2_op_status` health indicator for details.

#### *Resetting health indicator configuration using the CLP*

The CLP provides support for the global settings to be reset to the factory settings. The object settings for a particular object can also be reset to the custom settings for that object type.

## Procedure

- To reset the object settings for the SAMPLE database to the current global settings for databases:

```
DB2 RESET ALERT CONFIGURATION FOR DATABASE ON SAMPLE
```

- Issue the following command to reset the global settings for databases to the factory settings:

```
DB2 RESET ALERT CONFIGURATION FOR DATABASES
```

- To reset the configuration for a particular health indicator, add the USING *health-indicator-name* clause to any of the preceding examples.

#### *Configuring health indicators using a client application*

Health monitor configuration is accessible through the `db2GetAlertCfg`, `db2UpdateAlertCfg`, and `db2ResetAlertCfg` APIs in a C or C++ application. Each of these APIs can access the factory, instance, global, and object settings.

## Before you begin

You must have an instance attachment to access the health monitor configuration. If there is not an attachment to an instance, then a default instance attachment is created. To access the health monitor configuration of a remote instance, you must first attach to that instance.

## About this task

Combinations of the **objType** and **defaultType** parameters in the `db2GetAlertCfgData` structure allow access to the various levels of health indicator configuration.

Table 91. Settings for objType and defaultType to access configuration levels

Setting	objType and defaultType
Factory settings	objType = DB2ALERTCFG_OBJTYPE_{DBM   DATABASES   TABLESPACES   CONTAINERS} and defaultType = DB2ALERTCFG_DEFAULT
Global settings	objType = DB2ALERTCFG_OBJTYPE_{DBM   DATABASES   TABLESPACES   CONTAINERS} and defaultType = DB2ALERTCFG_NOT_DEFAULT  or  objType = DB2ALERTCFG_OBJTYPE_{DATABASE   TABLESPACE   CONTAINER} and defaultType = DB2ALERTCFG_DEFAULT
Object settings	objType = DB2ALERTCFG_OBJTYPE_{DATABASE   TABLESPACE   CONTAINER} and defaultType = DB2ALERTCFG_NOT_DEFAULT

## Procedure

- To get the specific object setting for health indicators on the SAMPLE database:

- Include the db2ApiDf.h header file, which is located in the sqlllib\include directory.

```
#include <db2ApiDf.h>
```

- Declare and initialize the sqlca and db2GetAlertCfgData structures.

```
struct sqlca ca;
memset (&sqlca, '\0', sizeof(struct sqlca));

char* objName = NULL;
char* dbName = "SAMPLE";
db2Uint32 objType = DB2ALERTCFG_OBJTYPE_DATABASE;
db2Uint32 defaultType = DB2ALERTCFG_NOT_DEFAULT;

db2GetAlertCfgData data = {objType, objName, defaultType, dbName, 0, NULL} ;
```

- Call the db2GetAlertCfg API.

```
rc = db2GetAlertCfg (db2Version810, &data, &ca);
```

- Process the returned configuration and free the buffer allotted by the API.

```
if (rc >= SQL0_OK) {
    if ((data.ioNumIndicators > 0) && (data.pioIndicators != NULL)) {
        db2GetAlertCfgInd *pIndicators = data.pioIndicators;

        for (db2Uint32 i=0; i < data.ioNumIndicators; i++) {
            //process the entry as necessary using fields defined in db2ApiDf.h
        }
    }

    db2GetAlertCfgFree (db2Version810, &data, &ca);
}
```

- The following steps detail the procedure to update the alert configuration of the **db.sort\_shrmem\_util** health indicator for the global settings for database objects, setting warning threshold to 80 and adding task action 1.1:

- Include the db2ApiDf.h header file, which is located in the sqlllib\include directory.

```
#include <db2ApiDf.h>
```

b) Declare and initialize the sqlca and db2AlertTaskAction structures.

```
struct sqlca ca;
memset (&sqlca, '\0', sizeof(struct sqlca));

db2Uuint32 objType = DB2ALERTCFG_OBJTYPE_DATABASES;

db2Uuint32 taskCondition = DB2ALERTCFG_CONDITION_WARNING;
char* taskname = "1.1";
char* hostname = NULL;
char* userid = "nobody";
char* password = "nothing";

db2AlertTaskAction newTask={taskname,taskCondition,userid,password,hostname};
```

c) Declare and initialize the db2UpdateAlertCfgData structure.

```
struct db2UpdateAlertCfgData setData;

setData.iObjType = objType;
setData.piObjName = NULL;
setData.piDbName = NULL;

setData.iIndicatorID = 1002;

setData.iNumIndAttribUpdates = 1;
setData.piIndAttribUpdates[0].iAttribID = DB2ALERTCFG_WARNING;
setData.piIndAttribUpdates[0].piAttribValue == 80;

setData.iNumActionUpdates = 0;
setData.piActionUpdates = NULL;

setData.iNumActionDeletes = 0;
setData.piActionDeletes = NULL;

setData.iNumNewActions = 1;
setData.piNewActions[0].iActionType = DB2ALERTCFG_ACTIONTYPE_TASK;
setData.piNewActions[0].piScriptAttribs = NULL;
setData.piNewActions[0].piTaskAttribs = &newTask;
```

d) Call the db2UpdateAlertCfg API.

```
rc = db2UpdateAlertCfg(db2Version810, &setData, &ca);
```

3. The following steps detail the procedure to RESET the custom settings for the MYTS table space in the SAMPLE database.

a) Include the db2ApiDf.h header file, which is located in the sqlllib\include directory.

```
#include <db2ApiDf.h>
```

b) Declare and initialize the sqlca and db2ResetAlertCfgData structures.

```
struct sqlca ca;
memset (&sqlca, '\0', sizeof(struct sqlca));

char* objName = "MYTS";
char* dbName = "SAMPLE";
db2Uuint32 objType = DB2ALERTCFG_OBJTYPE_TABLESPACE;

db2ResetAlertCfgData data = {objType, objName, dbName};
```

c) Call the db2ResetAlertCfg API.

```
rc = db2ResetAlertCfg (db2Version810, &data, &ca);
```

#### *Health monitor alert actions on combined states*

Alert actions are tasks or scripts that are run when a health indicator goes into an alert state.

The health monitor alert actions defined for the health indicator **ts.ts\_op\_status** on a single alert state are executed whenever this state is set for the table space, irrespective of the other combined

states. This makes it possible to run alert actions on a specific table space state even when it is set in conjunction with other states.

In the following example, an alert action script1 defined on attention state QUIESCED:share will run, even if the table space state is QUIESCED:share and QUIESCE:update at the same time.

```
db2 call SYSPROC.ADMCMD('update alert cfg for tablespaces using ts.ts_op_status
set actionsenabled yes')
```

```
db2 call SYSPROC.ADMCMD('update alert cfg for tablespaces using ts.ts_op_status
add action script /home/guest001/script1 type operating system command line
parameters userParam working directory /home/guest001/
on attention QUIESCED_SHARE on aix1 user guest001 using passw0rd')
```

In the following example, an alert action defined using a combination of states ( QUIESCED:share + QUIESCED:update = 3 ) is executed if and only if the table space state is both QUIESCED:share and QUIESCED:update.

```
db2 call SYSPROC.ADMCMD('update alert cfg for tablespaces using ts.ts_op_status
set actionsenabled yes')
```

```
db2 call SYSPROC.ADMCMD('update alert cfg for tablespaces using ts.ts_op_status
add action script /home/guest001/script1 type operating system command line
parameters userParam working directory /home/guest001/
on attention 3 on aix1 user guest001 using passw0rd')
```

Health monitor alert actions defined on an object with the same action attributes (name, working directory, command line parameters, host, user and password) run only once, even if it was defined on multiple alert states.

In the following example, the same action is defined on two different alert states. The action is only executed once for a given table space, even if the table space state is in both QUIESCED:share and QUIESCED:update.

```
db2 call SYSPROC.ADMCMD('update alert cfg for tablespaces using ts.ts_op_status
add action script /home/guest001/script1 type operating system command line
parameters userParam working directory /home/guest001/
on attention QUIESCED_SHARE on aix1 user guest001 using passw0rd')
```

```
db2 call SYSPROC.ADMCMD('update alert cfg for tablespaces using ts.ts_op_status
add action script /home/guest001/script1 type operating system command line
parameters userParam working directory /home/guest001/
on attention QUIESCED_UPDATE on aix1 user guest001 using passw0rd')
```

## Introduction to Windows Management Instrumentation (WMI)

There is an industry initiative that establishes management infrastructure standards and provides a way to combine information from various hardware and software management systems. This initiative is called Web-Based Enterprise Management (WBEM). WBEM is based on the Common Information Model (CIM) schema, which is an industry standard driven by the Desktop Management Task Force (DMTF).

Microsoft Windows Management Instrumentation (WMI) is an implementation of the WBEM initiative for supported Windows platforms. WMI is useful in a Windows enterprise network where it reduces the maintenance and cost of managing enterprise network components. WMI provides:

- A consistent model of Windows operation, configuration, and status.
- A COM API to allow access to management information.
- The ability to operate with other Windows management services.
- A flexible and extensible architecture allowing vendors a means of writing other WMI providers to support new devices, applications, and other enhancements.
- The WMI Query Language (WQL) to create detailed queries of the information.

- An API for management application developers to write Visual Basic or Windows Scripting Host (WSH) scripts.

The WMI architecture has two parts:

1. A management infrastructure that includes the CIM Object Manager (CIMOM) and a central storage area for management data called the CIMOM object repository. CIMOM allows applications to have a uniform way to access management data.
2. WMI providers. WMI providers are the intermediaries between CIMOM and managed objects. Using WMI APIs, WMI providers supply CIMOM with data from managed objects, handle requests on behalf of management applications, and generate event notifications.

Windows Management Instrumentation (WMI) providers are standard COM or DCOM servers that function as mediators between managed objects and the CIM Object Manager (CIMOM). If the CIMOM receives a request from a management application for data that is not available from the CIMOM object repository, or for events, the CIMOM forwards the request to the WMI providers. WMI providers supply data, and event notifications, for managed objects that are specific to their particular domain.

## Database system integration with Windows Management Instrumentation

The snapshot monitors can be accessed by Windows Management Instrumentation (WMI) by means of performance counters and using the built-in PerfMon provider.

The profile registry variables can be accessed by WMI by using the built-in Registry provider.

The WMI Software Development Kit (WMI SDK) includes several built-in providers:

- PerfMon provider
- Registry event provider
- Registry provider
- Windows event log provider
- Win32 provider
- WDM provider

Database errors in the Event Logs can be accessed by WMI by using the built-in Windows Event Log provider.

The database system has a WMI Administration provider, and sample WMI script files, to access the following managed objects:

1. Instances of the database server including those instances that are distributed. The following operations can be done:
  - Enumerate instances
  - Configure database manager parameters
  - Start/stop/query the status of the database server service
  - Setup or establish communication
2. Databases. The following operations can be done:
  - Enumerate databases
  - Configure database parameters
  - Create/drop databases
  - Backup/restore/roll forward databases

You will need to register the WMI provider with the system before running WMI applications. Registration is done by entering the following commands:

- `mofcomp %DB2PATH%\bin\db2wmi.mof`

This command loads the definition of the database WMI schema into the system.

- `regsvr %DB2PATH%\bin\db2wmi.dll`

This command registers the database WMI provider COM DLL with Windows.

In both commands, %DB2PATH% is the path where the database is installed, and db2wmi.mof is the .MOF file that contains the WMI schema definition.

There are several benefits to integrating with the WMI infrastructure:

1. You are able to easily write scripts to manage database servers in a Windows-based environment using the WMI provided tool. Sample Visual Basic scripts are provided to carry out simple tasks such as listing instances, creating and dropping databases, and updating configuration parameters. These sample scripts are included in the Db2 Application Development for Windows product.
2. You can create powerful management applications that perform many tasks using WMI. The tasks could include:
  - Displaying system information
  - Monitoring database performance
  - Monitoring database system resource consumption

By monitoring both system events and database events through this type of management application, you can manage the database better.

3. You can use existing COM and Visual Basic programming knowledge and skills. By providing a COM or Visual Basic interface, your programmers can save time when developing enterprise management applications.

## Performance monitoring on Windows platforms

When working with Db2 database manager for Windows, there are tools that can be used to monitor performance.

**Important:** The Windows Performance Monitor has been deprecated and may be discontinued in a future release. In version 10.1 the IBM InfoSphere Optim Performance Manager should be used instead.

### • Windows Performance Monitor

The Windows Performance Monitor enables you to monitor both database and system performance, retrieving information from any of the performance data providers registered with the system. Windows also provides performance information data on all aspects of computer operation including:

- CPU usage
- Memory utilization
- Disk activity
- Network activity

### ***Registering the database system with the Windows performance monitor***

The setup program automatically registers the database system with the Windows Performance Monitor for you. To make database and Db2 Connect performance information accessible to the Windows Performance Monitor, you must register the DLL for the Db2 Performance Counters.

### **About this task**

This process also enables any other Windows application using the Win32 performance APIs to get performance data. To install and register the Db2 Performance Counters DLL (DB2Perf.DLL) with the Windows Performance Monitor, type:

```
db2perfi -i
```

Registering the DLL also creates a new key in the services option of the registry. One entry gives the name of the DLL, which provides the counter support. Three other entries give names of functions provided within that DLL. These functions include:

**Open**

Called when the DLL is first loaded by the system in a process.

**Collect**

Called to request performance information from the DLL.

**Close**

Called when the DLL is unloaded.

***Enabling remote access to database performance information***

To see Windows performance objects for a database that runs on a different computer, you must register an administrator username and password with the Db2 database manager. The default Windows Performance Monitor username, SYSTEM, is reserved and cannot be used.

**About this task**

If your workstation is networked to other Windows computers, you can use the feature described in this section.

To register the name, type:

```
db2perftr -r username password
```

**Note:** The username used must conform to the database naming rules.

The username and password data is held in a key in the registry, with security that allows access only by administrators and the SYSTEM account. The data is encoded to prevent security concerns about storing an administrator password in the registry.

**Note:**

1. Once a username and password combination has been registered with the database system, even local instances of the Performance Monitor will explicitly log on using that username and password. This means that if the username information registered with the database system does not match, local sessions of the Performance Monitor will not show database performance information.
2. The username and password combination must be maintained to match the username and password values stored in the Windows Security database. If the username or password is changed in the Windows Security database, the username and password combination used for remote performance monitoring must be reset.
3. To deregister, type:

```
db2perftr -u <username> <password>
```

***Displaying database and Db2 Connect performance values***

While you are conducting maintenance, or if you are trying to improve overall database performance, it is good to review the current performance values to determine if you have to perform database maintenance or tuning.

**About this task**

To display database and Db2 Connect performance values using the Performance Monitor:

**Procedure**

1. Choose the performance counters whose values you want displayed from the **Add to** box. This box displays a list of performance objects providing performance data.
2. Select an object to see a list of the counters it supplies. A performance object can have multiple instances. For example, the LogicalDisk object provides counters such as "% Disk Read Time" and "Disk Bytes/sec"; it also has an instance for each logical drive in the computer, including "C:" and "D:".

## ***Windows performance objects***

You use performance objects to monitor and view database information about a database instance or application, or a DCS database or application.

Windows provides the following performance objects:

- **Database Manager**

This object provides general information for a single Windows instance. The database instance being monitored appears as the object instance.

For practical and performance reasons, you can only get performance information from one database instance at a time. The database instance that the Performance Monitor shows is governed by the `db2instance` registry variable in the Performance Monitor process. If you have multiple database instances running simultaneously and want to see performance information from more than one, you must start a separate session of the Performance Monitor, with `db2instance` set to the relevant value for each database instance to be monitored.

If you are running a partitioned database environment, you can only get performance information from one database partition server at a time. By default, the performance information for the default database partition (that is, the database partition that has logical port 0) is displayed. To see performance information of another database partition, you must start a separate session of the Performance Monitor with the `DB2NODE` environment variable set to the database partition number of the database partition to be monitored.

- **Databases**

This object provides information for a particular database. Information is available for each currently active database.

- **Database Applications**

This object provides information for a particular database application. Information is available for each currently active database application.

- **DCS Databases**

This object provides information for a particular DCS database. Information is available for each currently active database.

- **DCS Applications**

This object provides information for a particular DCS application. Information is available for each currently active DCS application.

Which of these objects will be listed by the Windows Performance Monitor depends on what is installed on your Windows computer and what applications are active. For example, if the database manager is installed has been started, the Database Manager object will be listed. If there are also some databases and applications that are currently active on that computer, the Databases and Database Applications objects are listed as well. If you are using your Windows system as a Db2 Connect gateway and if DCS databases and DCS applications are currently active, the DCS Databases and DCS Applications objects are listed.

## ***Accessing remote database performance information***

If the database is in a remote location, you might prefer to access and analyze performance information from a different location.

### **About this task**

Enabling remote access to database performance information was discussed earlier. In the **Add to** box, select another computer to monitor. This brings up a list of all the available performance objects on that computer.

In order to be able to monitor a database performance object on a remote computer, the level of the database or Db2 Connect code installed on that computer must be Version 6 or higher.

## Resetting database performance values

You should reset the database performance values if you are testing your database environment or performing maintenance. Resetting performance values allows you to collect specific data from controlled database loads.

### About this task

When an application calls the Db2 Connect monitor APIs, the information returned is normally the cumulative values since the database server was started. However, it is often useful to:

- Reset performance values.
- Run a test.
- Reset the values again.
- Re-run the test.

To reset database performance values, use the **db2perf** program. Type:

```
db2perf
```

By default, this resets performance values for all active databases. However, you can also specify a list of databases to reset. You can also use the **-d** option to specify that performance values for DCS databases should be reset. For example:

```
db2perf
db2perf dbalias1 dbalias2 ... dbaliasn

db2perf -d
db2perf -d dbalias1 dbalias2 ... dbaliasn
```

The first example resets performance values for all active databases. The second example resets values for specific databases. The third example resets performance values for all active DCS databases. The last example resets values for specific DCS databases.

The **db2perf** program resets the values for ALL programs currently accessing database performance information for the relevant database server instance (that is, the one held in DB2INSTANCE in the session in which you run **db2perf**).

Invoking **db2perf** also resets the values seen by anyone remotely accessing database performance information when the **db2perf** command is executed.

**Note:** There is a database API, **sqlmrset**, that allows an application to reset the values it sees locally, not globally, for particular databases.

---

## Chapter 2. Monitor elements

Monitor elements are data structures used to store information about a particular aspect of the database system status. For example, the monitor element **direct\_reads** reflects the number of read operations that take place that are performed directly from disk, rather than from any buffer pool.

Each monitor element reflects one of the following types of data:

### Counter

Counters track the number of times something happens. For example, the **deadlocks** monitor element records the total number of deadlocks that have occurred. Other examples of counters include **commit\_sql\_stmts** (**commit statements attempted**), **rows\_deleted** and **total\_sorts**.

### Gauge

Gauges reflect a measurement of how much of something is happening or is used. For example, time-spent monitor elements, such as **total\_section\_proc\_time** or **total\_sort\_time** are measures of how much time is used in different phases of processing. Other examples of gauges include: **locks\_held**, **num\_extent\_moved**, and **sort\_heap\_allocated**. Compared to counters, which can only increase over time, the values in gauges might go up or down, depending on what is happening in the database.

### Watermark

Watermarks reflect the highest value reached for a given measurement. For example, **uow\_total\_time\_top** shows the lifetime of the longest-running unit of work since the database was activated. Other examples of watermarks include: **pkg\_cache\_size\_top**, and **sort\_heap\_top**.

### Text

Many monitor elements report text values. For example, **stmt\_text** contains the text of an SQL statement. Other examples of text monitor elements include: **table\_name**, **tablespace\_type**, and **db\_storage\_path\_state**.

### Timestamp

Timestamp monitor elements show the time that something happened. For example, **conn\_time** shows the time that a connection was made to a database. Other examples of timestamp monitor elements include: **lock\_wait\_start\_time**, **stmt\_first\_use\_time**, and **uow\_stop\_time**. Compared to gauges that measure elapsed time, timestamps measure the exact point in time that something begins or ends.

You can examine monitor elements by using monitoring interfaces such as table functions or event monitors.

---

## Request monitor elements

Request monitor elements, also known as *request metrics*, measure the volume of work or effort expended by the database server to process different types of requests, including overall system processing, requests related to a specific type of processing, and requests related to a specific data server environment. Use request monitor elements to monitor the database system, specifically the volume of work and the effort expended by the data server to process application requests.

A *request* is a directive to a database agent to perform some work that expends database resources. Sources of the request can include:

- A directive issued directly by an external application, such as an OPEN or EXECUTE directive. These are referred to as application requests.
- A directive issued by a coordinator agent to a subagent at the same or a different database member.
- A directive issued by an agent at a different database member.

Some representative monitor elements for measuring overall system processing information:

- The **rqsts\_completed\_total** monitor element measures the number of completed by the system.
- The **total\_rqst\_time** monitor element measures the time spent by requests in the data server, including wait time and processing time
- The **total\_wait\_time** monitor element measures the overall wait time.
- The **total\_cpu\_time** monitor element measures the CPU usage time.

Some representative monitor elements for measuring client-server processing information:

- The **client\_idle\_wait\_time** monitor element measures the time spent waiting for the next request from an open connection.
- The **tcpip\_recv\_volume** monitor element measures the volume of data received by the data server from clients over TCP/IP.

Some representative monitor elements for measuring common data server processing operations:

- **pool\_data\_l\_reads** is one of the monitor elements providing information about buffer pool resource usage.
- **pool\_read\_time** is one of the monitor elements providing information about I/O processing.
- **lock\_wait\_time** is one of the monitor elements providing information about locks and locking.
- **total\_section\_sorts** is one of the monitor elements providing information about sorts.

Some representative monitor elements for monitoring processing relevant to selected types of data server environments:

- **fcml\_recv\_wait\_time** is one of the monitor elements measuring fast communications manager (FCM) processing.
- **wlm\_queue\_time\_total** is one of the monitor elements measuring workload management control actions.

## Accessing request metrics using table functions

You can use the following table functions to access the request metrics:

- MON\_GET\_SERVICE\_SUBCLASS and MON\_GET\_SERVICE\_SUBCLASS\_DETAILS
- MON\_GET\_WORKLOAD and MON\_GET\_WORKLOAD\_DETAILS
- MON\_GET\_CONNECTION and MON\_GET\_CONNECTION\_DETAILS
- MON\_GET\_UNIT\_OF\_WORK and MON\_GET\_UNIT\_OF\_WORK\_DETAILS

Each table function in this set of monitor table functions has two forms, one of which has a name ending with "DETAILS." The function that does not end with "DETAILS" provides an SQL relational interface that returns the most commonly needed data. The other function provides XML-based access to the monitor data and returns a more comprehensive set of data.

This set of table functions enables you to focus on request metrics at a particular level of aggregation. You can choose the table function that enables you to focus on subset (or aggregation) of the system workload you are interested in a given situation. All of these table functions include a common set of request metric monitor elements. Each table function may return a few additional details not common with all the table functions.

In a database with no user-defined workloads or service classes, all of the user work performed by the database manager occurs in the default user workload and user service class. The table functions that return data for each service class (or workload) return data for a single service class (or workload) that represents the processing for the user workload for the entire database.

In a database with user-defined workloads and service classes, table functions that return data for each service class (or workload) enable you to compare processing per service class (or workload). Using SQL, you can sum the values across service classes (or workloads) to obtain the value of a monitor element that represents the processing for the user workload for the entire database.

## Accessing request metrics using event monitors

Request metrics are reported by the following event monitors:

- Statistics event monitor - Request metrics are one of several types of information reported by this event monitor.
- UoW event monitor - This event monitor reports similar or identical fields as the `MON_GET_UNIT_OF_WORK` table function

## Activity monitor elements

Activity monitor elements, also known as *activity metrics*, are a subset of request monitor elements. Use activity metrics to monitor the subset of data server processing related to executing activities, especially processing done to execute SQL statement sections.

Request monitor elements monitor the complete volume of work and effort expended by the data server to process application requests. Activity monitor elements monitor the work done to execute SQL statement sections, including locking, sorting, and row processing.

To access the current values for activity monitor elements, use the following table functions:

### **MON\_GET\_ACTIVITY\_DETAILS**

Returns details about one or more activities in progress. Specify the activities of interest in the input parameters. Data returned includes activity metric monitor elements, many other monitor elements, and statement text. Data is returned in XML format.

### **MON\_GET\_PKG\_CACHE\_STMT**

Returns details for some or all SQL statement sections in the database package cache, which includes both static and dynamic SQL statements. Data returned includes activity metric monitor elements aggregated over all executions of the section since it was added to the package cache. Data is returned in a relational form.

Use the activity event monitor to access historical data about activities. This monitor captures data for each execution of each activity. The activity event monitor captures the same activity monitor elements as the `MON_GET_ACTIVITY_DETAILS` table function. It also captures some additional information.

## Data object monitor elements

---

Data object monitor elements provide information about operations performed on particular data objects, including tables, indexes, buffer pools, table spaces, and containers.

Every data object type has a set of monitor elements that can be monitored. For example, buffer pools have elements that can be used to calculate buffer pool hit ratios.

Use the following table functions to access current values for data object monitor elements. These monitor table functions return data in a relational form:

- `MON_GET_BUFFERPOOL`
- `MON_GET_TABLESPACE`
- `MON_GET_CONTAINER`
- `MON_GET_TABLE`
- `MON_GET_INDEX`

## Monitor element collection levels

---

The *monitor element collection level* for a monitor element refers to what, if any settings must be active for data to be collected for that element. For many monitor elements, data collection is controlled by configuration parameters, clauses in the DDL used to define workload management objects, or a combination of both.

## Collection level settings

Setting collection levels using database configuration parameters sets the default collection level for a specific class of monitor elements for the entire database. For example, setting the configuration parameter **mon\_req\_metrics** to BASE causes request metrics to be collected for all agents running in the database. For request and activity metrics, and for section actuals monitor elements, you can also specify a collection level for specific WLM objects that is different from the level used for the database as a whole. In this way, the *effective collection level* for a given monitor element is determined by applying the broadest (highest) collection level specified for that element for the scope in which it is collected. See the section titled “Examples” on page 471 for examples of how the different collection scopes work together.

Collection levels are used in the topics that describe most monitor elements. (Monitor elements returned by snapshot interfaces use monitor switches rather than collection levels.) For example, Table 92 on page 470 shows the table that describes the interfaces that return the monitor element **skipped\_prefetch\_data\_p\_reads**, along with the monitor element collection level that must be active for data to be collected for this element.

Most topics include such a table to show what interfaces return the monitor element, and what the minimum collection level must be for data to be collect for the monitor element described in the topic.

Table 92. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_BUFFERPOOL table function - Get buffer pool metrics	DATA OBJECT METRICS BASE
MON_GET_DATABASE table function - Get database level information	DATA OBJECT METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	DATA OBJECT METRICS BASE
MON_GET_TABLESPACE table function - Get table space metrics	DATA OBJECT METRICS BASE

The collection levels used in monitor element reference topics are as follows:

### Always collected

Data for this monitor element is always collected. There are no configuration parameters, or SQL statement options to control collection of this information.

### DATA OBJECT METRICS BASE, DATA OBJECT METRICS EXTENDED

Monitor elements with this collection level are collected if the database configuration parameter **mon\_obj\_metrics** is set to BASE or EXTENDED. If **mon\_obj\_metrics** is set to NONE, no data is collected.

### REQUEST METRICS BASE, REQUEST METRICS EXTENDED

Monitor elements with this collection level are collected if the effective collection level set to BASE or EXTENDED. The effective collection level for request metrics is determined by examining the current setting for the database configuration parameter **mon\_req\_metrics** and the settings specified for the COLLECT REQUEST METRICS clause for WLM service superclasses.

### ACTIVITY METRICS BASE, ACTIVITY METRICS EXTENDED

Monitor elements with this collection level are collected if the effective collection level set to BASE or EXTENDED. The effective collection level for activity metrics is determined by examining the current setting for the database configuration parameter **mon\_act\_metrics** and the settings specified for the COLLECT ACTIVITY METRICS clause for WLM workloads.

### SECTION ACTUALS BASE

Monitor elements with this collection level are collected if the effective collection level set to BASE. The effective collection level for section actuals is determined by examining the current setting for the database configuration parameter **section\_actuals** along with the settings for the following items:

- The INCLUDE ACTUALS clause as part of the CREATE or ALTER WORKLOAD, CREATE or ALTER WORK ACTION SET, or CREATE or ALTER SERVICE CLASS statements.
- The <collectsectionactuals> setting on the WLM\_SET\_CONN\_ENV routine.

### **COLLECT AGGREGATE ACTIVITY DATA, COLLECT AGGREGATE REQUEST DATA**

Monitor elements with this collection level are collected if the clause COLLECT AGGREGATE ACTIVITY DATA or COLLECT AGGREGATE REQUEST DATA is included as part of the CREATE or ALTER statement for specific types of WLM objects.

Some elements are marked as "Not applicable; reports whichever elements are in the XML document that is provided as input to the formatting function." In these cases, the element is returned by a function that merely formats the output of event data already collected.

### **Examples**

#### **Example 1: Default collection level of NONE for the database as a whole, EXTENDED for a specific service super class.**

This example shows how you can specific a collection level of NONE for, in this case, request metrics monitor elements for the database as a whole, but still collect EXTENDED metrics for agents running in a service super class.

To disable the collection of request metrics for agents running in the database in general, but collect extended metrics for a specific service super class, then perform the following steps:

1. Set the collection level for request metrics for the database as whole to NONE by issuing the following command:

```
DB2 UPDATE DB CFG FOR database-name USING MON_REQ_METRICS NONE
```

2. Alter the service super class for which you want to collect request metrics by executing the following statement:

```
ALTER SERVICE CLASS service-class-name COLLECT REQUEST METRICS EXTENDED
```

Results: Request metrics are collected for all agents that run in the service super class with the name *service-class-name*. Request metrics are not collected for agents that run outside of that service super class.

#### **Example 2: Default collection level of EXTENDED for the database as a whole.**

This example shows how the broadest collection level is applied for collecting monitor element data, perhaps with unintended consequences.

- Specify that activity metrics are to be captured for all activities running in the database using the following command:

```
DB2 UPDATE DB CFG FOR database-name USING MON_ACT_METRICS EXTENDED
```

- Modify a WLM workload so that activity metrics are not collected:

```
ALTER WORKLOAD workload-name COLLECT ACTIVITY METRICS NONE
```

Results: Activity metrics are collected for all agents running in the database, including those running as part of the workload *workload-name*. In this case, the effective collection level is determined by the broader collection level (EXTENDED) specified for the database as a whole through the **mon\_act\_metrics** configuration parameter.

## Time-spent monitor elements

Time-spent monitor elements track how time is spent in the system. You can query them to see where time is spent waiting, or performing different types of processing. You can also view the elapsed time spent in a particular system component.

Figure 11 on page 472 shows an example of one way that you can view the relative time spent in waits and processing times for a request.

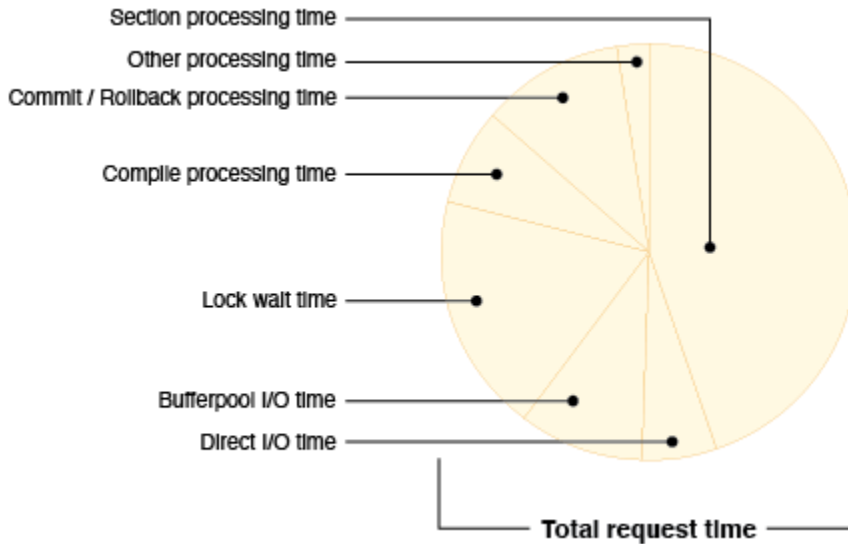

Figure 11. How time-spent metrics can provide an overall view of where time is spent in the system

There are three ways that the database manager monitors time spent in the system:

- Wait times
- Component processing times
- Component elapsed times.

### Wait times

Wait-time monitor elements reflect the time that the database manager spends waiting on something before it can proceed with processing. Some examples include time spent waiting for the following services:

- Incoming client requests
- Locks on objects to be released
- Writing to the diagnostic log
- Reading from or writing to the buffer pool.

Examples of monitor elements that track wait time include **lock\_wait\_time** and **pool\_read\_time**.

### Component processing times

These times represent the time spent doing actual processing within a specific logical component of the database. Some examples include time spent doing the following services:

- Committing or rolling back transactions
- Performing database reorganizations
- Compiling SQL
- Loading data
- Performing runstats operations.

Examples of monitor elements that track component processing time include **total\_compile\_proc\_time** and **total\_commit\_proc\_time**.

### Component elapsed times

Component elapsed times reflect the total amount of elapsed time spent within a logical component of the database. They include *both* processing time and various types of wait times that might be incurred during that overall stage of processing. For example, the overall time spent doing a commit includes actual commit processing and might also include various types of wait times, such as time incurred waiting for I/O operations or log file operations to complete.

**Note:** Elapsed time is not the same as elapsed time as measured on a clock; if the overall time spent was split among multiple threads, the time spent in each thread is represented in this number.

Some examples of how you can use component times include:

- Learning where relatively costly processing is taking place for a given workload (for example SQL compilation, as compared to query execution)
- Determining whether the cost of a specific component area can be attributed to actual processing, or whether wait time plays a significant role in reducing throughput
- Understanding the cost of a particular component area (for example, rollback processing) in the context of the overall time spent in the system.

Examples of monitor elements that track overall component times include **total\_compile\_time** and **total\_commit\_time**

You can query component processing times and wait times to get a breakdown of specific wait times relative to processing times. [Figure 11 on page 472](#) is an example of how these two types of time-spent metrics can be viewed relative to one another.

While component elapsed times cannot be used to obtain a breakdown of specific types of wait times (for example, lock waits, I/O-related waits), they do provide an alternative view that you can use to view processing times relative to the overall time spent in a given logical database component. An example would be examining the ratio of actual processing time for table or index reorganizations (**total\_reorg\_proc\_time**), to the overall elapsed time spent performing reorgs (**total\_reorg\_time**), which could include time spent on a variety of miscellaneous processing and waits not directly related to the reorg itself.

## Time-spent monitor element hierarchy

The information in many time-spent monitor elements is rolled up in more general monitor elements.

For example, individual wait time elements, such as that for the time spent waiting to receive the information in the next buffer from a table queue (**fcm\_tq\_recv\_wait\_time**) and time spent waiting for an FCM reply message (**fcm\_message\_recv\_wait\_time**) are both included in overall **fcm\_recv\_wait\_time** element. The hierarchical organization of time-spent monitor element makes it possible to choose the element with the most appropriate level of specificity for your needs.

### Dimensions and perspectives for viewing time-spent monitor elements

There are different ways that you can look at the hierarchies of time-spent monitor elements. One way is to look at them from the viewpoint of the system as a whole; you can also look at them in the context of specific activities within the system.

The system-level view or system *dimension* includes elements that you can use to see what the system is doing as a whole. You can also use elements in the system dimension to view time-spent information for specific workloads.

The activity-level view or activity dimension includes elements that you can use to see which specific activities the system is spending time on, such as the execution of SQL statements. All monitor elements in the activity dimension are included in the higher-level system dimension.

Within each of these two dimensions are two different *perspectives* that you can use to look at time-spent monitor elements:

- Component processing times as compared to wait times
- Component elapsed times as compared to component processing times

In the first perspective, the values for wait-time elements are independent of and complementary to the values for component processing time elements. If you add the sum of all of the reported wait times to the sum of all component processing times, the resulting value is very close to the value that is reported by the **total\_rqst\_time** monitor element. Any minor difference between the two values is the result of a small amount of miscellaneous component processing time that is not tracked by any monitor element.

In the second perspective, component elapsed times are a superset of component processing times. For example, for a logical component of the database such as that component that performs commits, the total amount of commit processing time, as reported by the **total\_commit\_proc\_time** monitor element, is included in the overall elapsed time for the commit, as reported by the **total\_commit\_time** monitor element. The difference between the total elapsed time and the total processing time is made up of miscellaneous wait or processing times that are not individually tracked by the component elapsed time monitor element.

Viewing component elapsed times relative to wait times is not meaningful, because component elapsed times already include wait times that are incurred as part of the elapsed time in that part of the system. If you created a pie chart consisting of both component elapsed times and wait times, it would not be an accurate representation of the time that is spent in your system because you would be double-counting the various types of wait times.

The sections that follow describe the various dimensions (system and activity) and perspectives (component processing, wait times and component elapsed, and component processing times) from which you can view the information in time-spent monitor elements.

**Tip:** Not all information from time-spent elements is reported through all interfaces. For example, the **client\_idle\_wait\_time** monitor element is applicable only to system-level interfaces such as the MON\_GET\_SERVICE\_SUBCLASS table function. See the reference topic for each monitor element for a list of the interfaces that report the element.

- *Other monitor elements*<sup>3</sup>
- *Other monitor elements*<sup>4</sup>

<sup>1</sup>These FCM-related wait times do not yield meaningful information when aggregated across members. For more information, see "Wait times for FCM communications for more information".

<sup>2</sup>When reported by the **MON\_GET\_DATABASE** interface or the **MON\_GET\_DATABASE\_DETAILS** interface, **pool\_read\_time** includes asynchronous read time and **pool\_write\_time** includes asynchronous write time.

<sup>3</sup>These processing time elements include miscellaneous processing and wait times that are not specifically related to this component. For example, the time that the **total\_section\_proc\_time** element reports includes the time that the **total\_section\_proc\_sort\_time** element reports. The **total\_section\_sort\_proc\_time** element reports the time that is spent performing activities such as table and index scans or joins.

<sup>4</sup> These monitor elements include a small number of miscellaneous types of time spent (processing and wait times) that are not currently monitored.

## System dimension: Component time-spent monitor elements

The following list shows a detailed view of the monitor elements for the time that is spent in various component areas. Each component time is represented by two different monitor elements:

- One that reports the total amount of processing time in a component or stage of processing
- One that reports the overall elapsed time that is spent in the component. This overall time includes the processing time for the component and any other processing or wait times that might be involved.

The values for indented monitor elements are included in the element that precedes those elements in the next-highest level of the hierarchy.

- [“total\\_index\\_build\\_proc\\_time - Total non-wait time spent building indexes due to index creation or re-creation monitor element” on page 1601](#)
- *Other monitor elements*<sup>4</sup>

<sup>1</sup>This monitor element does not include any wait time that is incurred by nested (child) activities that the statement executes.

<sup>2</sup>These FCM-related wait times do not yield meaningful information when aggregated across members. For more information, see "Wait times for FCM communications".

<sup>3</sup>Includes miscellaneous processing times that are not specifically related to this component.

<sup>4</sup>Includes a small number of miscellaneous types of time spent (processing and wait times) that are not currently monitored. In addition, this time includes any processing and wait times that child activities incur.

## Activity dimension: Component elapsed and component processing times

The following list shows the monitor elements that you can view for activities from the perspective of component elapsed times, which include component processing times.

The values for indented monitor elements are included in the element that precedes those elements in the next-highest level of the hierarchy.

- [“stmt\\_exec\\_time - Statement execution time monitor element” on page 1481](#)
- [“total\\_section\\_time - Total section time monitor element” on page 1645](#)
- [“total\\_section\\_sort\\_time - Total section sort time monitor element” on page 1642](#)

- [“total\\_index\\_build\\_proc\\_time - Total non-wait time spent building indexes due to index creation or re-creation monitor element” on page 1601](#)

<sup>1</sup>These monitor elements include one or more different types of wait times.

<sup>2</sup>These processing time elements include miscellaneous processing and wait times that are not specifically related to this component.

## Wait times for FCM communications

In a multi-partition database, or in an environment where there is intrapartition parallelism, the Fast Communications Manager (FCM) manages communication between different agents working on the same statement, whether those agents are on the same or on different members. All FCM communications involve the potential for wait times as one agent waits for work to be done by another, or for data to be transferred from one to another.

FCM-related wait times do not necessarily indicate that processing is blocked across members; for a given statement, work might be proceeding in parallel or serially on sub-agents across members. The FCM-related wait times show the time that an agent is blocked on a single member waiting for another; however, work might very well be proceeding on the other member.

For example, Agent A on member 0 might be blocked waiting for Agent B on member 1 to read the data being sent to it. If Agent B is busy and does not receive the data from the table queue immediately, Agent A will only be allowed to send a limited amount of data before being forced to wait for an acknowledgement from Agent B before sending the remaining data. This wait time is counted as **fcm\_tq\_send\_wait\_time** by Agent A.

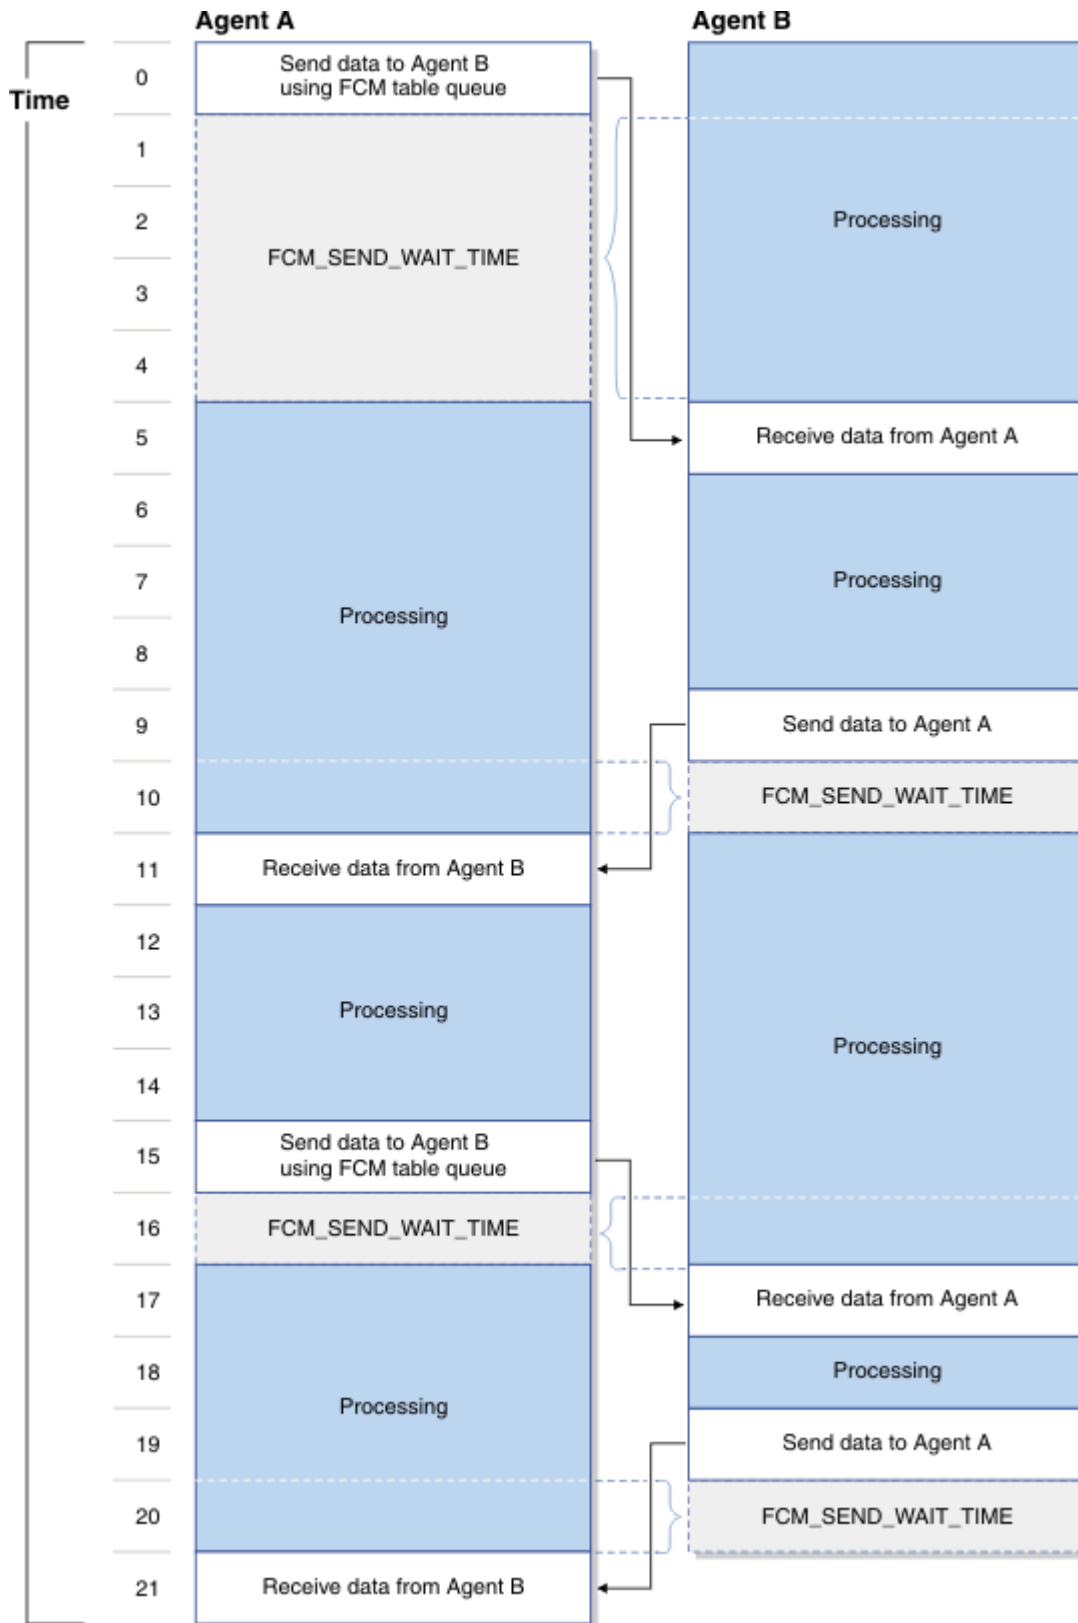

Figure 12. Wait times in FCM communications

Another scenario might involve an agent on one member dispatching a request to an agent on another member. `fcm_message_rcv_wait_time` will be incurred if one of the following situations takes place:

- Agent A sends a lengthy request to agent B, and agent B is forced to wait for the full request to be received. In this case, agent B incurs **fcm\_message\_rcv\_wait\_time**.
- Agent A sends a request to agent B, and awaits a reply from agent B. In this case, agent A incurs **fcm\_message\_rcv\_wait\_time**.

**fcm\_message\_send\_wait\_time** will be incurred if one of the following situations takes place:

- Agent A sends a lengthy request to agent B, and is blocked for some reason. For example, Agent A might need to wait while the first portion of the request being sent is processed by the local FCM daemon. In this case, agent A incurs **fcm\_message\_send\_wait\_time**.
- Agent B sends a reply to a request from agent A. If agent B is for some reason blocked before the entire message can be sent, then agent B incurs **fcm\_message\_send\_wait\_time**.

Depending on what it is that you want to measure, it might be appropriate to subtract FCM wait times from the total time spent if you are aggregating metrics for time spent across multiple partitions.

## Retrieving and working with time-spent monitor element data

Time-spent monitor element data can be used in almost unlimited ways. For example, you can automate the production of charts that show, at a glance, how time is spent in the system. Or you could use the data to track certain types of wait times in the system over a period of time.

The topics that follow provide some basic examples of how to use the time-spent monitor elements, as well as the table functions that you use to access the data they contain.

### Seeing where time is spent across the system

You can use the time-spent monitor elements to get a view of where time is being spent in the system. Time spent monitor elements can be used to report on specific units of work, service subclasses, workloads or connections.

#### About this task

Once you retrieve the various monitor elements that report where time is being spent in the system, you can view them in several ways. At the most basic level, you can view the reported values as a list. You might want to use the values to create ratios, for example the ratio of lock wait time to total request time. Or you could use the values retrieved to create charts to help you visualize time spent monitor elements relative to another.

#### Notes:

- The values shown in the output for queries are for illustrative purposes only, and should not be construed as representative of what you might see in your own system.
- This task shows you how to retrieve specific time-spent monitor elements. You can also use new formatting functions introduced in version 9.7 Fix Pack 1 to retrieve time spent monitor elements that meet specific criteria, such as those with non-zero values, those within a certain range of values that you specify, or the top *n* monitor element (for example, the top five wait times). [Example 4](#) illustrates how these functions work.

#### Procedure

1. First, determine what time-spent elements you are interested in.  
For example, you might want to look at total wait time as compared to the total request time for all connections in your system.
2. Formulate an SQL query that uses one of the monitoring table functions that retrieve the elements you are interested in.  
In this case, you can retrieve the **total\_request\_time** and the **total\_wait\_time** monitor elements for a connection using the MON\_GET\_CONNECTION table function:

```
SELECT APPLICATION_HANDLE,
       TOTAL_WAIT_TIME,
```

```
TOTAL_RQST_TIME
FROM TABLE(MON_GET_CONNECTION(NULL, NULL))
```

The preceding query will return the following output (times are reported in milliseconds):

APPLICATION_HANDLE	TOTAL_WAIT_TIME	TOTAL_RQST_TIME
39	179	269
78	0	0
51	207	316
77	0	21
50	1014	1408
40	109	351
79	89	167

7 record(s) selected.

3. In this case, there are 7 application connections; you could use the results from the second and third columns to determine the percentage of time spent waiting for each application. For example, for application 50, compared to the total request time, the wait time spent by that application is  $(1014 \div 1408) \times 100 \approx 72\%$ .

### Example

#### **Example 1: Determining the average across all connections of the time spent waiting relative to overall request time.**

This example is similar to the preceding one, except that the calculation of the average percentage wait time is done within the SQL:

```
WITH PCTWAIT AS (
  SELECT SUM(TOTAL_WAIT_TIME) AS WAIT_TIME,
         SUM(TOTAL_RQST_TIME) AS RQST_TIME
  FROM TABLE(MON_GET_CONNECTION(NULL, NULL)) AS METRICS)
SELECT WAIT_TIME,
       RQST_TIME,
       CASE WHEN RQST_TIME > 0
            THEN DEC((FLOAT(WAIT_TIME))/FLOAT(RQST_TIME) * 100, 5, 2)
            ELSE NULL END AS WAIT_PCT FROM PCTWAIT
```

The results of running the preceding query would look something like this:

WAIT_TIME	RQST_TIME	WAIT_PCT
1515	2439	62.11

1 record(s) selected.

#### **Example 2: Comparing total wait time against selected component processing times for a specific service subclass**

This example shows how you can compare time spent in specific types of component processing with the time spent waiting:

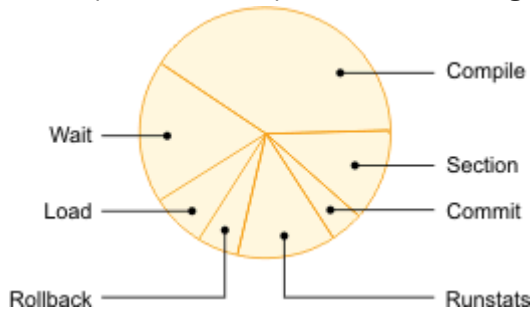

```
SELECT SUM(TOTAL_WAIT_TIME) AS WAIT,
       SUM(TOTAL_COMPILE_PROC_TIME) AS COMPILE,
       SUM(TOTAL_IMPLICIT_COMPILE_PROC_TIME) AS IMP_COMPILE,
       SUM(TOTAL_SECTION_PROC_TIME) AS SECTION,
       SUM(TOTAL_COMMIT_PROC_TIME) AS COMMIT,
       SUM(TOTAL_REORG_PROC_TIME) AS REORG,
       SUM(TOTAL_RUNSTATS_PROC_TIME) AS RUNSTATS,
       SUM(TOTAL_ROLLBACK_PROC_TIME) AS ROLLBACK,
       SUM(TOTAL_LOAD_PROC_TIME) AS LOAD
FROM TABLE(MON_GET_SERVICE_SUBCLASS('SYSDEFAULTUSERCLASS', 'SYSDEFAULTSUBCLASS', NULL))
```

The results of the preceding query would look something like this (the output rows from the query have been split for presentation purposes):

WAIT	COMPILE	IMP_COMPILE	SECTION	COMMIT	
	611	1931	0	395	15
REORG	RUNSTATS	ROLLBACK	LOAD		
	0	432	18	0	

1 record(s) selected.

The numbers reported could be used to construct a pie chart to show the relative time spent waiting as compared to time spent in different stages of processing (component times of 0 are not included):

**Example 3: View the ratio of total time spent as compared to processing time in different components**

This example shows you how you can get an overview of the time spent doing work in different stages of processing (components), relative to the total time spent in that component. The following query computes the ratio (expressed as a percentage) of the time spent in actual processing as compared to the total elapsed time spent in a specific component.

```
WITH PCTPROC AS (
  SELECT SUM(TOTAL_SECTION_TIME) AS SECT_TIME, SUM(TOTAL_SECTION_PROC_TIME) AS SECT_PROC_TIME,
         SUM(TOTAL_COMPILE_TIME) AS COMP_TIME, SUM(TOTAL_COMPILE_PROC_TIME) AS COMP_PROC_TIME,
         SUM(TOTAL_IMPLICIT_COMPILE_TIME) AS IMP_C_TIME, SUM(TOTAL_IMPLICIT_COMPILE_PROC_TIME) AS
  IMP_C_PROC_TIME,
         SUM(TOTAL_COMMIT_TIME) AS COMMIT_TIME, SUM(TOTAL_COMMIT_PROC_TIME) AS COMMIT_PROC_TIME,
         SUM(TOTAL_ROLLBACK_TIME) AS ROLLBACK_TIME, SUM(TOTAL_ROLLBACK_PROC_TIME) AS ROLLBACK_PROC_TIME,
         SUM(TOTAL_RUNSTATS_TIME) AS RUNSTATS_TIME, SUM(TOTAL_RUNSTATS_PROC_TIME) AS RUNSTATS_PROC_TIME,
         SUM(TOTAL_REORG_TIME) AS REORG_TIME, SUM(TOTAL_REORG_PROC_TIME) AS REORG_PROC_TIME,
         SUM(TOTAL_LOAD_TIME) AS LOAD_TIME, SUM(TOTAL_LOAD_PROC_TIME) AS LOAD_PROC_TIME
  FROM TABLE(MON_GET_CONNECTION(NULL, -2)) AS METRICS)
SELECT CASE WHEN SECT_TIME > 0
  THEN DEC((FLOAT(SECT_PROC_TIME) / FLOAT(SECT_TIME)) * 100,5,1)
  ELSE NULL END AS SECT_PROC_PCT,
  CASE WHEN COMP_TIME > 0
  THEN DEC((FLOAT(COMP_PROC_TIME) / FLOAT(COMP_TIME)) * 100,5,1)
  ELSE NULL END AS COMP_PROC_PCT,
  CASE WHEN IMP_C_TIME > 0
  THEN DEC((FLOAT(IMP_C_PROC_TIME) / FLOAT(IMP_C_TIME)) * 100,5,1)
  ELSE NULL END AS IMPL_COMPILE_PROC_PCT,
  CASE WHEN ROLLBACK_TIME > 0
  THEN DEC((FLOAT(ROLLBACK_PROC_TIME) / FLOAT(ROLLBACK_TIME)) * 100,5,1)
  ELSE NULL END AS ROLLBACK_PROC_PCT,
  CASE WHEN COMMIT_TIME > 0
  THEN DEC((FLOAT(COMMIT_PROC_TIME) / FLOAT(COMMIT_TIME)) * 100,5,1)
  ELSE NULL END AS COMMIT_PROC_PCT,
  CASE WHEN RUNSTATS_TIME > 0
  THEN DEC((FLOAT(RUNSTATS_PROC_TIME) / FLOAT(RUNSTATS_TIME)) * 100,5,1)
  ELSE NULL END AS RUNSTATS_PROC_PCT,
  CASE WHEN REORG_TIME > 0
  THEN DEC((FLOAT(REORG_PROC_TIME) / FLOAT(REORG_TIME)) * 100,5,1)
  ELSE NULL END AS REORG_PROC_PCT,
  CASE WHEN LOAD_TIME > 0
  THEN DEC((FLOAT(LOAD_PROC_TIME) / FLOAT(LOAD_TIME)) * 100,5,1)
  ELSE NULL END AS LOAD_PROC_PCT
FROM PCTPROC
```

The query produces the following output:

SECT_PROC_PCT	COMPILE_PROC_PCT	IMPL_COMPILE_PROC_PCT	ROLLBACK_PROC_PCT	COMMIT_PROC_PCT	RUNSTATS_PROC_PCT	REORG_PROC_PCT	LOAD_PROC_PCT
71.1	57.6	84.6	0.1	-	96.9	95.6	0.0

1 record(s) selected.

A graphical representation of this data might look something like what is shown in [Figure 13 on page 485](#):

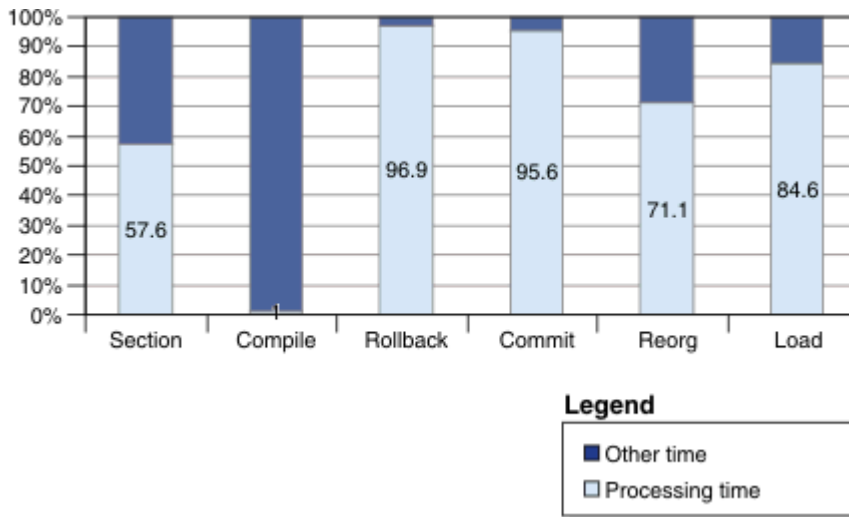

Figure 13. Component processing times as a percentage of overall time spent

#### Example 4: Ranking time-spent monitor elements

In the preceding examples, all monitor elements that are displayed are specified explicitly in the SQL for the query; each appears in its own column in the query results. However, there might be times when you do not know which time spent monitor elements you want to examine, such as if you want to see the top ten wait-time monitor elements, or only the non-zero time-spent monitor elements.

Several table functions enable you to display monitor elements in a row-oriented format, where each element appears in a row by itself. The table functions you can use to do this have names of the form `MON_FORMAT_XML*_BY_ROW`. These functions extract metrics from XML documents returned by certain monitoring interfaces. (See “Interfaces that return monitor data in XML documents” on page 15 for more information.)

The `MON_FORMAT_XML*_BY_ROW` functions are useful when you do not know which elements you want to view. For example, you might want to see the top 10 wait-time monitor elements for the workload named `CLPWORKLOAD`. To collect this information, you can create a statistics event monitor called `DBSTATS` (event `wlstats` logical data group). Assuming you set up this event monitor to write to a table, it records metrics in a column called `DETAILS_XML` in the table called `WLSTATS_DBSTATS` by default. Once the output table from the event monitor is populated with monitor data, you can construct a query that uses the `MON_FORMAT_XML_WAIT_TIMES_BY_ROW` function to extract the monitor elements you want to see:

```
SELECT SUBSTR(STATS.WORKLOAD_NAME,1,15) AS WORKLOAD_NAME,
       SUBSTR(METRICS.METRIC_NAME,1,30) AS METRIC_NAME,
       SUM(METRICS.TOTAL_TIME_VALUE) AS TOTAL_TIME_VALUE
FROM   WLSTATS_DBSTATS AS STATS,
       TABLE(MON_FORMAT_XML_WAIT_TIMES_BY_ROW(STATS.DETAILS_XML)) AS METRICS
WHERE  WORKLOAD_NAME='CLPWORKLOAD' AND (PARENT_METRIC_NAME='TOTAL_WAIT_TIME')
GROUP BY WORKLOAD_NAME,METRIC_NAME
ORDER BY TOTAL_TIME_VALUE DESC
FETCH FIRST 10 ROWS ONLY
```

**Remember:** Time spent monitor elements are organized into hierarchies. In this example, to avoid double-counting wait times, only the monitor elements that roll-up to **total\_wait\_time** are included (see the `WHERE` clause in the preceding SQL statement). Otherwise, **total\_wait\_time** itself would be included in the results, which includes several individual wait times.

The output that follows shows what the results of the preceding query might look like:

WORKLOAD_NAME	METRIC_NAME	TOTAL_TIME_VALUE
CLPWORKLOAD	LOCK_WAIT_TIME	15138541
CLPWORKLOAD	DIRECT_READ_TIME	6116231
CLPWORKLOAD	POOL_READ_TIME	6079458
CLPWORKLOAD	DIRECT_WRITE_TIME	452627
CLPWORKLOAD	POOL_WRITE_TIME	386208
CLPWORKLOAD	IPC_SEND_WAIT_TIME	283172

CLPWORKLOAD	LOG_DISK_WAIT_TIME	103888
CLPWORKLOAD	DIAGLOG_WRITE_WAIT_TIME	78198
CLPWORKLOAD	IPC_RECV_WAIT_TIME	15612
CLPWORKLOAD	TCPIP_SEND_WAIT_TIME	3291

10 record(s) selected.

## Determining where time is spent during SQL statement execution

One example of retrieving time-spent information at the activity level is viewing time spent monitor elements for specific SQL statements. You can use the MON\_GET\_PKG\_CACHE\_STMT table function to retrieve this information.

### About this task

This task shows an example of how to retrieve selected time-spent details for SQL statements in the package cache.

**Note:**

- The time-spent metrics reported for a given statement in the package cache are aggregates of the time-spent metrics for all executions of that statement.
- The values shown in the output for queries are for illustrative purposes only, and should not be construed as representative of what you might see in your own system.

### Procedure

- Formulate an SQL statement that uses the MON\_GET\_PKG\_CACHE\_STMT table function to retrieve information about statements in the package cache.

For example, assume that you want to determine the total wait time relative to the total statement execution time. A query to retrieve this might look like this:

```
SELECT SUM(STMT_EXEC_TIME) AS TOTAL_EXEC_TIME,
       SUM(TOTAL_ACT_WAIT_TIME) AS TOTAL_WAIT_TIME,
       EXECUTABLE_ID
FROM TABLE(MON_GET_PKG_CACHE_STMT ( NULL, NULL, NULL, -2)) AS T
WHERE STMT_EXEC_TIME <> 0
GROUP BY EXECUTABLE_ID
ORDER BY TOTAL_EXEC_TIME DESC
```

- Run the query.

The results might look like the following output:

TOTAL_EXEC_TIME	TOTAL_WAIT_TIME	EXECUTABLE_ID
9021	3017	9021 x '01000000000000003200000000000000000000000000000020020091111120320140000'

1	1	0 x '010000000000000001700000000000000000000000000002002009111115442750000'
1	1	0 x '010000000000000001600000000000000000000000000002002009111115442734000'
1	1	0 x '010000000000000002800000000000000000000000000002002009111115937000001'
1	1	0 x '010000000000000002A00000000000000000000000000002002009111115943984000'

30 record(s) selected.

## Results

At this point, you could use the MON\_GET\_PKG\_CACHE\_STMT table function again to retrieve the statement text for any statement you are particularly interested in. For example, the statement with the highest wait time previously shown could be determined using the following query:

```
SELECT VARCHAR(STMT_TEXT, 80) AS STMT_TEXT
FROM
TABLE(MON_GET_PKG_CACHE_STMT(NULL,x'0100000000000000320000000000000000000000000020020091111120320140000',NULL,-2))
AS T
```

The output of the preceding query would look something like this:

```
STMT_TEXT
-----
UPDATE EMPLOYEE SET BONUS=10000 WHERE PERF_RATING=1
1 record(s) selected.
```

## Logical data groups overview

When examining monitor element data, it is frequently useful to look at multiple related elements at the same time. *Logical data groups* are groupings of elements that complement each other. For example, the uow logical data group includes elements like **appl\_id** (application ID) and **appl\_name** (application name), which are two elements that you can easily imagine wanting to see together.

Logical data groups are used by snapshot monitoring interfaces, and in particular, by event monitors. The database system has over one thousand monitor elements. When examining monitor elements, it would be very tiresome to always have to think about and specify exactly which elements you want to see. For example, if you are creating an event monitor, thinking about and specifying what elements to capture data for might be very tedious. Instead, the database system associates a default set of logical data groups with each event monitor. This means that you do not need to specify anything in the CREATE EVENT MONITOR statement to capture a useful set of monitor elements; only monitor elements relevant to the events being captured are included. For event monitors that write to regular tables, you have the added flexibility of being able to specify the logical data groups for which you want monitor element data captured.

Event monitors that write to unformatted event (UE) tables capture also capture a default set of monitor elements; when you use the EVMON\_FORMAT\_UE\_TO\_TABLES procedure to generate relational tables, logical data groups are used to group related elements together in separate tables. For example, the lock logical data group contains the elements used in the LOCK\_EVENT table; the participant logical data group contains the elements used in the LOCK\_PARTICIPANT table.

## Event monitor logical data groups and monitor elements

Monitor elements that are often useful to examine together are grouped in *logical data groups*. All event monitors use logical data groups in one way or another. For some event monitor types, you can specify what information you want to collect by specifying the logical data groups for which you want information recorded. Logical data groups are also used to group data together in the output event monitors generate; for example, event monitors that write to tables generally create one table for each logical data group of monitor elements.

The following table lists the logical data groupings and monitor elements that can be returned by event monitoring.

**Attention:** The addition of the coord\_time\_created, event\_timestamp, and application\_handle monitor elements to the following logical data groups is currently available in Db2 V11.5.2 and later releases:

[“stmt\\_text - SQL statement text monitor element” on page 1490](#)  
[“uow\\_id - Unit of work ID monitor element” on page 1676](#)

## **dllock logical data group**

[“data\\_partition\\_id - Data partition identifier monitor element ” on page 784](#)  
[“lock\\_attributes - Lock attributes monitor element” on page 1001](#)  
[“lock\\_count - Lock count monitor element” on page 1002](#)  
[“lock\\_current\\_mode - Original lock mode before conversion monitor element” on page 1003](#)  
[“lock\\_escalation - Lock escalation monitor element” on page 1004](#)  
[“lock\\_hold\\_count - Lock hold count monitor element” on page 1012](#)  
[“lock\\_mode - Lock mode monitor element” on page 1013](#)  
[“lock\\_name - Lock name monitor element” on page 1016](#)  
[“lock\\_object\\_name - Lock Object Name ” on page 1017](#)  
[“lock\\_object\\_type - Lock object type waited on monitor element” on page 1017](#)  
[“lock\\_release\\_flags - Lock release flags monitor element” on page 1020](#)  
[“lock\\_status - Lock status monitor element” on page 1021](#)  
[“node\\_number - Node Number ” on page 1085](#)  
[“table\\_file\\_id - Table file ID monitor element” on page 1504](#)  
[“table\\_name - Table name monitor element” on page 1505](#)  
[“table\\_schema - Table schema name monitor element” on page 1507](#)  
[“tablespace\\_name - Table space name monitor element” on page 1515](#)

**Note:** The underlying implementation for this logical data group is the snapshot monitor LOCK logical data group. If you examine the output for this logical group in the self-describing stream used for the file and pipe output options, you can see that the LOCK group is used to generate the output.

## **event\_activity logical data group**

[“act\\_exec\\_time - Activity execution time monitor element” on page 593](#)  
[act\\_sortmem\\_limit\\_pages - Activity sort memory limit \(4k pages\) monitor element](#)  
[“activate\\_timestamp - Activate timestamp monitor element” on page 602](#)  
[“active\\_col\\_vector\\_consumers\\_top - Active columnar vector memory consumers high watermark monitor element” on page 603](#)

[“active\\_hash\\_grpbys\\_top - Active hash GROUP BY operations high watermark monitor element” on page 605](#)

[“active\\_hash\\_joins\\_top - Active hash join operations high watermark monitor element” on page 607](#)

[“active\\_olap\\_funcs\\_top - Active OLAP function operations high watermark monitor element” on page 609](#)

[“active\\_peas\\_top - Active partial early aggregation operations high watermark monitor element” on page 611](#)

[“active\\_peds\\_top - Active partial early distinct operations high watermark monitor element” on page 613](#)

[“active\\_sort\\_consumers\\_top - Active sort memory consumers high watermark monitor element” on page 615](#)

[“active\\_sorts\\_top - Active sorts high watermark monitor element” on page 617](#)

[“activity\\_id - Activity ID monitor element” on page 618](#)

[“activity\\_secondary\\_id - Activity secondary ID monitor element” on page 619](#)

[“activity\\_type - Activity type monitor element” on page 621](#)

[act\\_sortmem\\_limit\\_pct - Activity sort memory limit \(percentage\) monitor element](#)

[“address - IP address from which the connection was initiated” on page 626](#)

[adm\\_bypassed - Admission control bypassed monitor element](#)

[“agent\\_id - Application handle \(agent ID\) monitor element” on page 634](#)

[“agents\\_top - Number of Agents Created ” on page 646](#)

[“appl\\_id - Application ID monitor element” on page 656](#)

[“appl\\_name - Application name monitor element” on page 660](#)

[“application\\_handle - Application handle monitor element” on page 667](#)

[“arm\\_correlator - Application response measurement correlator monitor element” on page 670](#)

[“coord\\_partition\\_num - Coordinator partition number monitor element” on page 761](#)

[“coord\\_time\\_created - Time of execution on member monitor element” on page 763](#)

[“db\\_work\\_action\\_set\\_id - Database work action set ID monitor element” on page 795](#)

[“db\\_work\\_class\\_id - Database work class ID monitor element” on page 796](#)

[“details\\_xml - Details XML monitor element” on page 809](#)

## Event type mappings to logical data groups

For file and pipe event monitors, event monitor output consists of an ordered series of logical data groupings. Regardless of the event monitor type, the output records always contain the same starting logical data groups. These frame the logical data groups whose presence varies depending on the event types recorded by the event monitor.

For file and pipe event monitors, event records may be generated for any connection and may therefore appear in mixed order in the stream. This means that you may get a transaction event for Connection 1, immediately followed by a connection event for Connection 2. However, records belonging to a single connection or a single event will appear in their logical order. For example, a statement record (end of statement) always precedes a transaction record (end of UOW), if any. Similarly, a deadlock event record always precedes the deadlocked connection event records for each connection involved in the deadlock. The **application id** or **application handle (agent\_id)** can be used to match records with a connection.

Connection header events are normally written for each connection to the database. For deadlocks with details event monitors, they are only written when the deadlock occurs. In this case, connection header events are only written for participants in the deadlock and not for all connections to the database.

The logical data groupings are ordered according to four different levels: Monitor, Prolog, Contents, and Epilog. Following are detailed descriptions for each level, including the corresponding event types and logical data groups.

## Monitor

Information at the Monitor level is generated for all event monitors. It consists of event monitor metadata.

Event type	Logical data group	Available information
Monitor Level	event_log_stream_header	Identifies the version level and byte order of the event monitor. Applications can use this header to determine whether they can handle the evmon output stream.

## Prolog

The Prolog information is generated when the event monitor is activated.

Event type	Logical data group	Available information
Log Header	event_log_header	Characteristics of the trace, for example server type and memory layout.
Database Header	event_db_header	Database name, path and activation time.
Event Monitor Start	event_start	Time when the monitor was started or restarted.
Connection Header	event_connheader	One for each current connection, includes connection time and application name. Event connection headers are only generated for connection, statement, transaction, and deadlock event monitors. Deadlocks with details event monitors produce connection headers only when a deadlock occurs.

## Contents

Information specific to the event monitor's specified event types is presented in the Contents section.

Event type	Logical data group	Available information
Statement Event	event_stmt	Statement level data, including text for dynamic statements. Statement event monitors do not log fetches.
Subsection Event	event_subsection	Subsection level data.
Transaction Event <sup>1</sup>	event_xact	Transaction level data.
Connection Event	event_conn	Connection level data.
Deadlock Event	event_deadlock	Deadlock level data.
Deadlocked Connection Event	event_dlconn	One for each connection involved in the deadlock, includes applications involved and locks in contention.

Table 95. Event Monitor Data Stream: Contents Section (continued)

Event type	Logical data group	Available information
Deadlocked Connection Event with Details	event_detailed_dlconn, lock	One for each connection involved in the deadlock, includes applications involved, locks in contention, current statement information, and other locks held by the application contention.
Overflow	event_overflow	Number of records lost - generated when writer cannot keep up with a (non-blocked) event monitor.
Deadlocks with details history <sup>2</sup>	event_stmt_history	List of statements executed in any unit of work that was involved in a deadlock.
Deadlocks with details history values <sup>2</sup>	event_data_value	Parameter markers for a statement in the event_stmt_history list.
Activities	event_activity	List of activities that completed executing on the system or were captured before completion.
	event_activystmt	Information about the statement the activity was executing if the activity type was a statement.
	event_activityvals	The data values used as input variables for each activity that is an SQL statement. These data values do not include LOB data, long data, or structured type data.
Statistics	event_scmetrics	Statistics computed from the activities that executed within each service class, work class, or workload in the system, as well as statistics computed from the threshold queues.
	event_scstats	
	event_superclassmetrics	
	event_superclassstats	
	event_wcstats	
	event_wlmetrics	
	event_wlstats	
	event_qstats	
event_histogrambin		
Threshold violations	event_thresholdviolations	Information identifying the threshold violated and the time of violation.

1

This option has been deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR FOR UNIT OF WORK statement to monitor transaction events.

2

This option has been deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR FOR LOCKING statement to monitor lock-related events, such as lock timeouts, lock waits, and deadlocks.

## Epilog

The Epilog information is generated during database deactivation (last application finished disconnecting):

Event type	Logical data group	Available information
Database Event	event_db	Database manager level data.
Buffer Pool Event	event_bufferpool	Buffer pool level data.
Table Space Event	event_tablespace	Table space level data.
Table Event	event_table	Table level data.

## Logical data groups affected by COLLECT ACTIVITY DATA settings

The following table shows what logical data groups are collected when different COLLECT ACTIVITY DATA options are specified all types of WLM objects, including Service Subclass, Workload, Work Class (via a Work Action), and Threshold.

Setting for COLLECT ACTIVITY DATA	Logical data groups collected
NONE	none
WITHOUT DETAILS	event_activity event_activitymetrics
WITH DETAILS	event_activity event_activitymetrics event_activystmt
WITH DETAILS AND VALUES	event_activity event_activitymetrics event_activystmt event_activityvals

## Snapshot monitor interface mappings to logical data groups

Each individual API request type and CLP command only captures monitor data from a subset of all the logical data groups.

The following table lists several ways of accessing snapshot monitor data. All snapshot monitor data is stored in monitor elements, which are categorized by logical data groups. Each individual API request type and CLP command listed in this table returns monitor elements from the logical data groups listed in the right-most column. Some monitor elements are returned only if the associated monitor switch is set ON. See the individual monitor elements to determine if a required element is under switch control.

db2GetSnapshot API request type	CLP command	Logical data groups
SQLMA_APPLINFO_ALL	list applications [show detail]	appl_info
SQLMA_DBASE_APPLINFO	list applications for database <i>dbname</i> [show detail]	appl_info

Table 98. Snapshot Monitor Interface Mappings to Logical Data Groups (continued)

<b>db2GetSnapshot API request type</b>	<b>CLP command</b>	<b>Logical data groups</b>
SQLMA_DCS_APPLINFO_ALL	list dcs applications [show detail]	dc_s_appl_info
SQLMA_DB2	get snapshot for dbm	db2 fcm fcm_node utility_info progress, progress_info memory_pool
	get dbm monitor switches	switch_list
SQLMA_DBASE	get snapshot for database on <i>dbname</i>	dbase detail_log db_storage_group rollforward db_sto_path_info tablespace memory_pool
SQLMA_DBASE_ALL	get snapshot for all databases	dbase db_storage_group rollforward db_sto_path_info tablespace memory_pool
	list active databases	dbase
SQLMA_DCS_DBASE	get snapshot for dcs database on <i>dbname</i>	dc_s_dbase, stmt_transmissions
SQLMA_DCS_DBASE_ALL	get snapshot for all dcs databases	dc_s_dbase, stmt_transmissions
SQLMA_DBASE_REMOTE	get snapshot for remote database on <i>dbname</i>	dbase_remote
SQLMA_DBASE_REMOTE_ALL	get snapshot for all remote databases	dbase_remote

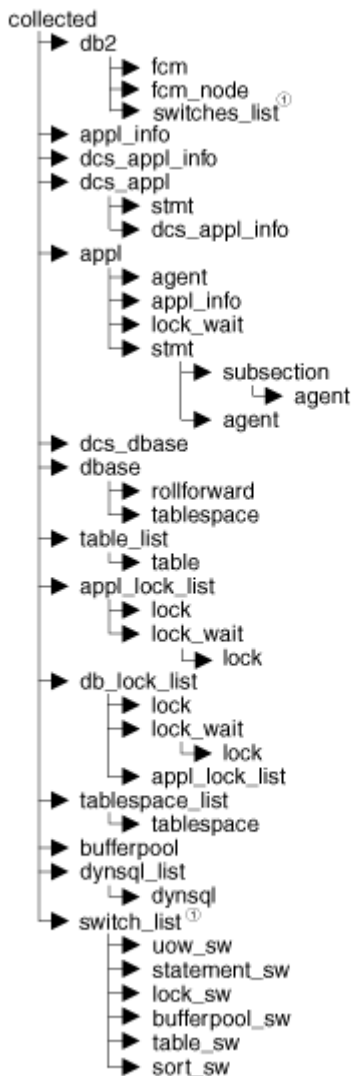

Table 98. Snapshot Monitor Interface Mappings to Logical Data Groups (continued)

<b>db2GetSnapshot API request type</b>	<b>CLP command</b>	<b>Logical data groups</b>
SQLMA_APPL	get snapshot for application applid <i>appl-id</i>	appl agent appl_info lock_wait stmt subsection memory_pool
SQLMA_AGENT_ID	get snapshot for application agentid <i>appl-handle</i>	appl agent appl_info lock_wait stmt subsection memory pool

SQLMA_DCS_APPL_ALL	get snapshot for all dcs applications	dcsl_appl, dcs_stmt, dcs_appl_info, stmt_transmissions
SQLMA_DCS_APPL_HANDLE	get snapshot for dcs application agentid <i>appl-handle</i>	dcsl_appl, dcs_stmt, dcs_appl_info, stmt_transmissions

Table 98. Snapshot Monitor Interface Mappings to Logical Data Groups (continued)

<b>db2GetSnapshot API request type</b>	<b>CLP command</b>	<b>Logical data groups</b>
SQLMA_DCS_DBASE_APPLS	get snapshot for dcs applications on <i>dbname</i>	dcs_appl, dcs_stmt, dcs_appl_info, stmt_transmissions
SQLMA_DBASE_APPLS_REMOTE	get snapshot for remote applications on <i>dbname</i>	dbase_appl
SQLMA_APPL_REMOTE_ALL	get snapshot for all remote applications	dbase_appl
SQLMA_DBASE_TABLES	get snapshot for tables on <i>dbname</i>	table table_reorg table_list
SQLMA_APPL_LOCKS	get snapshot for locks for application <i>applid</i> <i>appl-id</i>	appl_lock_list, lock_wait, lock
SQLMA_APPL_LOCKS_AGENT_ID	get snapshot for locks for application <i>agentid</i> <i>appl-handle</i>	appl_lock_list, lock_wait, lock
SQLMA_DBASE_LOCKS	get snapshot for locks on <i>dbname</i>	appl_lock_list, lock db_lock_list, lock_wait
SQLMA_DBASE_TABLESPACES	get snapshot for tablespaces on <i>dbname</i>	tablespace tablespace, tablespace_nodeinfo tablespace_quiescer, tablespace_nodeinfo tablespace_container, tablespace_nodeinfo tablespace_ranges, tablespace_nodeinfo tablespace_list, tablespace_nodeinfo
SQLMA_BUFFERPOOLS_ALL	get snapshot for all bufferpools	bufferpool
SQLMA_DBASE_BUFFERPOOLS	get snapshot for bufferpools on <i>dbname</i>	bufferpool
SQLMA_DYNAMIC_SQL	get snapshot for dynamic sql on <i>dbname</i>	dynsql dynsql_list

The following figure shows the order that logical data groupings may appear in a snapshot data stream.

<sup>①</sup>Similar structures (lower level\_sw items are returned by db2, but are not shown in the figure)

Figure 14. Data Stream Hierarchy

**Note:** Times may be returned as part of any logical data grouping.

## Snapshot monitor logical data groups and monitor elements

The following sections list the logical data groupings and monitor elements that can be returned by snapshot monitoring.

- [“agent logical data group” on page 564](#)
- [“appl logical data group” on page 564](#)
- [“appl\\_id\\_info logical data group” on page 566](#)
- [“appl\\_info logical data group” on page 567](#)
- [“appl\\_lock\\_list logical data group” on page 567](#)
- [“appl\\_remote logical data group” on page 568](#)
- [“bufferpool logical data group” on page 568](#)
- [“bufferpool\\_nodeinfo logical data group” on page 569](#)
- [“collected logical data group” on page 570](#)

### **agent logical data group**

- [“agent\\_pid - Engine dispatchable unit \(EDU\) identifier monitor element” on page 639](#)
- [“lock\\_timeout\\_val - Lock timeout value monitor element” on page 1022](#)

### **appl logical data group**

- [“acc\\_curs\\_blk - Accepted Block Cursor Requests ” on page 589](#)
- [“agent\\_sys\\_cpu\\_time - System CPU Time used by Agent ” on page 640](#)
- [“agent\\_usr\\_cpu\\_time - User CPU Time used by Agent ” on page 641](#)
- [“agents\\_stolen - Stolen Agents ” on page 646](#)
- [“appl\\_con\\_time - Connection Request Start Timestamp ” on page 655](#)

[“appl\\_idle\\_time - Application Idle Time ” on page 659](#)  
[“appl\\_priority - Application Agent Priority ” on page 661](#)  
[“appl\\_priority\\_type - Application Priority Type ” on page 662](#)  
[“associated\\_agents\\_top - Maximum Number of Associated Agents ” on page 670](#)  
[“authority\\_bitmap - User authorization level monitor element” on page 682](#)  
[“authority\\_lvl - User authorization level monitor element” on page 683](#)  
[“binds\\_precompiles - Binds/Precompiles Attempted ” on page 685](#)  
[“cat\\_cache\\_inserts - Catalog cache inserts monitor element” on page 696](#)  
[“cat\\_cache\\_lookups - Catalog cache lookups monitor element” on page 697](#)  
[“cat\\_cache\\_overflows - Catalog Cache Overflows ” on page 699](#)  
[“commit\\_sql\\_stmts - Commit Statements Attempted ” on page 727](#)  
[“conn\\_complete\\_time - Connection Request Completion Timestamp ” on page 744](#)  
[“ddl\\_sql\\_stmts - Data Definition Language \(DDL\) SQL Statements ” on page 801](#)  
[“deadlocks - Deadlocks detected monitor element” on page 805](#)  
[“direct\\_read\\_reqs - Direct read requests monitor element” on page 813](#)  
[“direct\\_read\\_time - Direct read time monitor element” on page 815](#)  
[“direct\\_reads - Direct reads from database monitor element” on page 817](#)  
[“direct\\_write\\_reqs - Direct write requests monitor element” on page 820](#)  
[“direct\\_write\\_time - Direct write time monitor element” on page 822](#)  
[“direct\\_writes - Direct writes to database monitor element” on page 824](#)  
[“dynamic\\_sql\\_stmts - Dynamic SQL Statements Attempted ” on page 830](#)  
[“failed\\_sql\\_stmts - Failed Statement Operations ” on page 866](#)  
[“hash\\_join\\_overflows - Hash Join Overflows ” on page 938](#)  
[“hash\\_join\\_small\\_overflows - Hash Join Small Overflows ” on page 940](#)  
[“inbound\\_comm\\_address - Inbound Communication Address ” on page 961](#)  
[“int\\_auto\\_rebinds - Internal Automatic Rebinds ” on page 966](#)  
[“int\\_commits - Internal commits monitor element” on page 967](#)  
[“int\\_deadlock\\_rollbacks - Internal Rollbacks Due To Deadlock ” on page 969](#)  
[“int\\_rollbacks - Internal rollbacks monitor element” on page 969](#)  
[“int\\_rows\\_deleted - Internal Rows Deleted ” on page 971](#)  
[“int\\_rows\\_inserted - Internal Rows Inserted ” on page 973](#)  
[“int\\_rows\\_updated - Internal Rows Updated ” on page 975](#)  
[“last\\_reset - Last Reset Timestamp ” on page 992](#)  
[“lock\\_escalation - Lock escalation monitor element” on page 1004](#)  
[“lock\\_timeout\\_val - Lock timeout value monitor element” on page 1022](#)  
[“lock\\_timeouts - Number of lock timeouts monitor element” on page 1022](#)  
[“lock\\_wait\\_time - Time waited on locks monitor element” on page 1027](#)  
[“lock\\_waits - Lock waits monitor element” on page 1032](#)  
[“locks\\_held - Locks held monitor element” on page 1036](#)  
[“locks\\_waiting - Current agents waiting on locks monitor element” on page 1037](#)  
[“num\\_agents - Number of Agents Working on a Statement ” on page 1086](#)  
[“olap\\_func\\_overflows - OLAP Function Overflows monitor element” on page 1116](#)  
[“open\\_loc\\_curs - Open Local Cursors ” on page 1118](#)  
[“open\\_loc\\_curs\\_blk - Open Local Cursors with Blocking ” on page 1118](#)  
[“open\\_rem\\_curs - Open Remote Cursors ” on page 1119](#)  
[“open\\_rem\\_curs\\_blk - Open Remote Cursors with Blocking ” on page 1119](#)  
[“pkg\\_cache\\_inserts - Package cache inserts monitor element” on page 1142](#)  
[“pkg\\_cache\\_lookups - Package cache lookups monitor element” on page 1143](#)  
[“pool\\_data\\_l\\_reads - Buffer pool data logical reads monitor element” on page 1194](#)  
[“pool\\_data\\_p\\_reads - Buffer pool data physical reads monitor element” on page 1197](#)  
[“pool\\_data\\_writes - Buffer pool data writes monitor element” on page 1199](#)

[“pool\\_index\\_l\\_reads - Buffer pool index logical reads monitor element” on page 1235](#)  
[“pool\\_index\\_p\\_reads - Buffer pool index physical reads monitor element” on page 1238](#)  
[“pool\\_index\\_writes - Buffer pool index writes monitor element” on page 1240](#)  
[“pool\\_read\\_time - Total buffer pool physical read time monitor element” on page 1281](#)  
[“pool\\_temp\\_data\\_l\\_reads - Buffer pool temporary data logical reads monitor element” on page 1288](#)  
[“pool\\_temp\\_data\\_p\\_reads - Buffer pool temporary data physical reads monitor element” on page 1290](#)  
[“pool\\_temp\\_index\\_l\\_reads - Buffer pool temporary index logical reads monitor element” on page 1292](#)  
[“pool\\_temp\\_index\\_p\\_reads - Buffer pool temporary index physical reads monitor element” on page 1294](#)  
[“pool\\_temp\\_xda\\_l\\_reads - Buffer pool temporary XDA data logical reads monitor element” on page 1297](#)  
[“pool\\_temp\\_xda\\_p\\_reads - Buffer pool temporary XDA data physical reads monitor element” on page 1299](#)  
[“pool\\_write\\_time - Total buffer pool physical write time monitor element” on page 1302](#)  
[“pool\\_xda\\_l\\_reads - Buffer pool XDA data logical reads monitor element” on page 1312](#)  
[“pool\\_xda\\_p\\_reads - Buffer pool XDA data physical reads monitor element” on page 1316](#)  
[“pool\\_xda\\_writes - Buffer pool XDA data writes monitor element” on page 1319](#)  
[“prefetch\\_wait\\_time - Time waited for prefetch monitor element” on page 1337](#)  
[“prev\\_uow\\_stop\\_time - Previous Unit of Work Completion Timestamp ” on page 1342](#)  
[“rej\\_curs\\_blk - Rejected Block Cursor Requests ” on page 1371](#)  
[“rollback\\_sql\\_stmts - Rollback Statements Attempted ” on page 1383](#)  
[“rows\\_deleted - Rows deleted monitor element” on page 1388](#)  
[“rows\\_inserted - Rows inserted monitor element” on page 1390](#)  
[“rows\\_read - Rows read monitor element” on page 1393](#)  
[“rows\\_selected - Rows Selected ” on page 1398](#)  
[“rows\\_updated - Rows updated monitor element” on page 1399](#)  
[“rows\\_written - Rows Written ” on page 1400](#)  
[“select\\_sql\\_stmts - Select SQL Statements Executed ” on page 1408](#)  
[“sort\\_overflows - Sort overflows monitor element” on page 1443](#)  
[“sql\\_reqs\\_since\\_commit - SQL Requests Since Last Commit ” on page 1458](#)  
[“static\\_sql\\_stmts - Static SQL Statements Attempted ” on page 1475](#)  
[“total\\_hash\\_joins - Total Hash Joins ” on page 1594](#)  
[“total\\_hash\\_loops - Total Hash Loops ” on page 1596](#)  
[“total\\_olap\\_funcs - Total OLAP Functions monitor element” on page 1612](#)  
[“total\\_sort\\_time - Total sort time monitor element” on page 1647](#)  
[“total\\_sorts - Total sorts monitor element” on page 1648](#)  
[“uid\\_sql\\_stmts - Update/Insert/Merge/Delete SQL Statements Executed ” on page 1671](#)  
[“unread\\_prefetch\\_pages - Unread prefetch pages monitor element” on page 1673](#)  
[“uow\\_comp\\_status - Unit of Work Completion Status ” on page 1674](#)  
[“uow\\_elapsed\\_time - Most Recent Unit of Work Elapsed Time ” on page 1675](#)  
[“uow\\_lock\\_wait\\_time - Total time unit of work waited on locks monitor element” on page 1678](#)  
[“uow\\_log\\_space\\_used - Unit of work log space used monitor element” on page 1678](#)  
[“uow\\_start\\_time - Unit of work start timestamp monitor element” on page 1679](#)  
[“uow\\_stop\\_time - Unit of work stop timestamp monitor element” on page 1680](#)  
[“x\\_lock\\_escals - Exclusive lock escalations monitor element” on page 1708](#)  
[“xquery\\_stmts - XQuery Statements Attempted” on page 1710](#)

## **appl\_id\_info logical data group**

[“agent\\_id - Application handle \(agent ID\) monitor element” on page 634](#)

[“appl\\_id - Application ID monitor element” on page 656](#)  
[“appl\\_name - Application name monitor element” on page 660](#)  
[“appl\\_status - Application status monitor element” on page 665](#)  
[“auth\\_id - Authorization ID ” on page 680](#)  
[“client\\_db\\_alias - Database Alias Used by Application ” on page 711](#)  
[“client\\_prdid - Client product and version ID monitor element” on page 716](#)  
[“codepage\\_id - ID of Code Page Used by Application ” on page 719](#)  
[“db\\_name - Database name monitor element” on page 791](#)  
[“db\\_path - Database Path ” on page 792](#)  
[“input\\_db\\_alias - Input Database Alias ” on page 964](#)  
[“sequence\\_no - Sequence number monitor element” on page 1411](#)  
[“status\\_change\\_time - Application Status Change Time ” on page 1479](#)

## **appl\_info logical data group**

[“agent\\_id - Application handle \(agent ID\) monitor element” on page 634](#)  
[“appl\\_id - Application ID monitor element” on page 656](#)  
[“appl\\_name - Application name monitor element” on page 660](#)  
[“appl\\_section\\_inserts - Section Inserts monitor element” on page 662](#)  
[“appl\\_section\\_lookups - Section Lookups ” on page 663](#)  
[“appl\\_status - Application status monitor element” on page 665](#)  
[“auth\\_id - Authorization ID ” on page 680](#)  
[“authority\\_bitmap - User authorization level monitor element” on page 682](#)  
[“authority\\_lvl - User authorization level monitor element” on page 683](#)  
[“client\\_db\\_alias - Database Alias Used by Application ” on page 711](#)  
[“client\\_pid - Client process ID monitor element” on page 714](#)  
[“client\\_platform - Client operating platform monitor element” on page 715](#)  
[“client\\_prdid - Client product and version ID monitor element” on page 716](#)  
[“client\\_protocol - Client communication protocol monitor element” on page 717](#)  
[“codepage\\_id - ID of Code Page Used by Application ” on page 719](#)  
[“coord\\_agent\\_pid - Coordinator agent identifier monitor element” on page 759](#)  
[“coord\\_node - Coordinating Node ” on page 761](#)  
[“corr\\_token - DRDA Correlation Token ” on page 763](#)  
[“db\\_name - Database name monitor element” on page 791](#)  
[“db\\_path - Database Path ” on page 792](#)  
[“execution\\_id - User Login ID ” on page 853](#)  
[“input\\_db\\_alias - Input Database Alias ” on page 964](#)  
[“is\\_system\\_appl - Is System Application monitor element” on page 985](#)  
[“num\\_assoc\\_agents - Number of Associated Agents ” on page 1086](#)  
[“sequence\\_no - Sequence number monitor element” on page 1411](#)  
[“session\\_auth\\_id - Session authorization ID monitor element” on page 1420](#)  
[“status\\_change\\_time - Application Status Change Time ” on page 1479](#)  
[“territory\\_code - Database Territory Code ” on page 1538](#)  
[“tpmon\\_acc\\_str - TP monitor client accounting string monitor element” on page 1660](#)  
[“tpmon\\_client\\_app - TP monitor client application name monitor element” on page 1661](#)  
[“tpmon\\_client\\_userid - TP monitor client user ID monitor element” on page 1661](#)  
[“tpmon\\_client\\_wkstn - TP monitor client workstation name monitor element” on page 1662](#)  
[“workload\\_id - Workload ID monitor element” on page 1704](#)

## **appl\_lock\_list logical data group**

[“agent\\_id - Application handle \(agent ID\) monitor element” on page 634](#)

[“appl\\_id - Application ID monitor element” on page 656](#)  
[“appl\\_name - Application name monitor element” on page 660](#)  
[“appl\\_status - Application status monitor element” on page 665](#)  
[“auth\\_id - Authorization ID ” on page 680](#)  
[“client\\_db\\_alias - Database Alias Used by Application ” on page 711](#)  
[“codepage\\_id - ID of Code Page Used by Application ” on page 719](#)  
[“lock\\_wait\\_time - Time waited on locks monitor element” on page 1027](#)  
[“locks\\_held - Locks held monitor element” on page 1036](#)  
[“locks\\_waiting - Current agents waiting on locks monitor element” on page 1037](#)  
[“sequence\\_no - Sequence number monitor element” on page 1411](#)  
[“session\\_auth\\_id - Session authorization ID monitor element” on page 1420](#)  
[“status\\_change\\_time - Application Status Change Time ” on page 1479](#)

## **appl\_remote logical data group**

[“commit\\_sql\\_stmts - Commit Statements Attempted ” on page 727](#)  
[“create\\_nickname - Create Nicknames ” on page 777](#)  
[“create\\_nickname\\_time - Create Nickname Response Time ” on page 778](#)  
[“datasource\\_name - Data Source Name ” on page 787](#)  
[“db\\_name - Database name monitor element” on page 791](#)  
[“delete\\_sql\\_stmts - Deletes ” on page 807](#)  
[“delete\\_time - Delete Response Time ” on page 808](#)  
[“failed\\_sql\\_stmts - Failed Statement Operations ” on page 866](#)  
[“insert\\_sql\\_stmts - Inserts ” on page 964](#)  
[“insert\\_time - Insert Response Time ” on page 965](#)  
[“passthru\\_time - Pass-Through Time ” on page 1138](#)  
[“passthru - Pass-Through ” on page 1139](#)  
[“remote\\_lock\\_time - Remote Lock Time ” on page 1372](#)  
[“remote\\_locks - Remote Locks ” on page 1372](#)  
[“rollback\\_sql\\_stmts - Rollback Statements Attempted ” on page 1383](#)  
[“rows\\_deleted - Rows deleted monitor element” on page 1388](#)  
[“rows\\_inserted - Rows inserted monitor element” on page 1390](#)  
[“rows\\_selected - Rows Selected ” on page 1398](#)  
[“rows\\_updated - Rows updated monitor element” on page 1399](#)  
[“select\\_sql\\_stmts - Select SQL Statements Executed ” on page 1408](#)  
[“select\\_time - Query Response Time ” on page 1409](#)  
[“sp\\_rows\\_selected - Rows Returned by Stored Procedures ” on page 1453](#)  
[“stored\\_proc\\_time - Stored Procedure Time ” on page 1499](#)  
[“stored\\_procs - Stored Procedures ” on page 1499](#)  
[“update\\_sql\\_stmts - Updates ” on page 1682](#)  
[“update\\_time - Update Response Time ” on page 1683](#)

## **bufferpool logical data group**

[“block\\_ios - Number of block I/O requests monitor element” on page 687](#)  
[“bp\\_id - Buffer pool identifier monitor element” on page 689](#)  
[“bp\\_name - Buffer pool name monitor element” on page 689](#)  
[“db\\_name - Database name monitor element” on page 791](#)  
[“db\\_path - Database Path ” on page 792](#)  
[“direct\\_read\\_reqs - Direct read requests monitor element” on page 813](#)  
[“direct\\_read\\_time - Direct read time monitor element” on page 815](#)  
[“direct\\_reads - Direct reads from database monitor element” on page 817](#)

[“direct\\_write\\_reqs - Direct write requests monitor element” on page 820](#)  
[“direct\\_write\\_time - Direct write time monitor element” on page 822](#)  
[“direct\\_writes - Direct writes to database monitor element” on page 824](#)  
[“files\\_closed - Database files closed monitor element” on page 917](#)  
[“input\\_db\\_alias - Input Database Alias ” on page 964](#)  
[“pages\\_from\\_block\\_ios - Total number of pages read by block I/O monitor element” on page 1132](#)  
[“pages\\_from\\_vectored\\_ios - Total number of pages read by vectored I/O monitor element” on page 1132](#)  
[“pool\\_async\\_data\\_read\\_reqs - Buffer pool asynchronous read requests monitor element” on page 1154](#)  
[“pool\\_async\\_data\\_reads - Buffer pool asynchronous data reads monitor element” on page 1155](#)

- [“utility\\_state - Utility State ” on page 1693](#)
- [“utility\\_type - Utility Type ” on page 1694](#)

## Monitor element reference

---

A description of the data collected by the monitor element.

The monitor elements returned by the system monitor fall into the following categories:

- **Identification** for the database manager, an application, or a database connection being monitored.
- Data primarily intended to help you to **configure** the system.
- Database **activity** at various levels including database, application, table, or statement. This information can be used for activity monitoring, problem determination, and performance analysis. It can also be used for configuration.
- information about **Db2 Connect** applications. Including information about DCS applications running at the gateway, SQL statements being executed, and database connections.
- information about **Federated Database Systems**. This includes information about the total access to a data source by applications running in a federated system and information about access to a data source by a given application running in a federated server instance.

Monitor elements are described in a standard format as follows:

### Element identifier

The name of the element. If parsing the data stream directly, the element identifier is uppercase and prefixed with SQLM\_ELM\_.

### Element type

The type of information the monitor element returns. For example, the db2start\_time monitor element returns a timestamp.

### Table function monitoring information

If a monitor element is returned by a table function, a table with the following fields is shown.

- *Table Function*: The name of the table function that returns the monitor element.
- *Monitor Element Collection Level*: For more information about monitor element collection levels, see [“Monitor element collection levels” on page 469](#).

## Snapshot monitoring information

If a monitor element returns snapshot monitoring information, a table with the following fields is shown.

- *Snapshot level*: The level of information that can be captured by the snapshot monitor. For example, the `appl_status` monitor element returns information at the Application level and at the Lock level.
- *Logical data grouping*: The logical data group where captured snapshot information is returned. If parsing the data stream directly, the logical data group identifier is uppercase and prefixed with `SQLM_ELM_`. For example, the `appl_status` monitor element returns information for the `appl_id_info` grouping and for the `appl_lock_list` grouping.
- *Monitor switch*: The system monitor switch that must be set to obtain this information. If the switch is Basic, data will always be collected for the monitor element.

## Event monitoring information

If a monitor element is collected by event monitors, a table with the following fields is shown.

- *Event type*: The level of information that can be collected by the event monitor. The event monitor must be created with this event type to collect this information. For example, the `appl_status` monitor element is collected for `CONNECTIONS` event monitors.
- *Logical data grouping*: The logical data group where captured event information is returned. If parsing the data stream directly, the logical data group identifier is uppercase and prefixed with `SQLM_ELM_`. For example, the `appl_status` monitor element returns information for the `event_conn` grouping.
- *Monitor switch*: The system monitor switch that must be set to obtain this information. For event monitors, the `TIMESTAMP` switch is the only monitor switch that can restrict the collection of event data. If there is a dash shown for this field, data will always be collected for the monitor element.

## Usage

information about how you can use the information collected by the monitor element when monitoring your database system.

# A

## acc\_curs\_blk - Accepted Block Cursor Requests

The number of times that a request for an I/O block was accepted.

### Element identifier

`acc_curs_blk`

### Element type

counter

Table 99. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl	Basic

Table 100. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Connection	event_conn	Always collected

## Usage

You can use this element in conjunction with `rej_curs_blk` to calculate the percentage of blocking requests that are accepted, rejected, or both.

See `rej_curs_blk` for suggestions on how to use this information to tune your configuration parameters.

## act\_aborted\_total - Total aborted activities monitor element

The total number of coordinator activities at any nesting level that completed with errors. For service classes, if an activity is remapped to a different service subclass with a REMAP ACTIVITY action before it aborts, then this activity counts only toward the total of the subclass it aborts in.

Table 101. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get service subclass metrics as an XML document	Always collected
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics (reported in DETAILS XML document)	REQUEST METRICS BASE

Table 102. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats (reported in the details_xml document)	REQUEST METRICS BASE

Table 102. Event Monitoring Information (continued)

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_superclasstats (reported in the details_xml document)	REQUEST METRICS BASE
Statistics	event_wlstats (reported in the details_xml document)	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE

## Usage

Use this element to understand if activities on the system are completing successfully. Activities may be aborted due to cancellation, errors, or reactive thresholds.

### act\_completed\_total - Total completed activities monitor element

The total number of coordinator activities at any nesting level that completed successfully. For service classes, if an activity is remapped to a different subclass with a REMAP ACTIVITY action before it completes, then this activity counts only toward the total of the subclass it completes in.

Table 103. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get service subclass metrics as an XML document	Always collected
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE

Table 103. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_SAMPLE_SERVICE_CLASS_METRICS - Get sample service class metrics	REQUEST METRICS BASE
MON_SAMPLE_WORKLOAD_METRICS - Get sample	REQUEST METRICS BASE

Table 104. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats (reported in the details_xml document)	REQUEST METRICS BASE
Statistics	event_superclassstats (reported in the details_xml document)	REQUEST METRICS BASE
Statistics	event_wlstats (reported in the details_xml document)	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	-

## Usage

Use this element to determine the throughput of activities in the system.

### act\_cpu\_time\_top - Activity CPU time top monitor element

The high watermark for processor time used by activities at all nesting levels in a service class, workload, or work class. This value is reported in microseconds.

The monitor element returns -1 when COLLECT AGGREGATE ACTIVITY DATA for the service class or workload in which the activity runs is set to NONE. Activities contribute toward this high watermark only when request metrics are enabled. If the collection of activity metrics is not enabled, a value of 0 is returned.

For service classes, when you remap activities between service subclasses with a REMAP ACTIVITY action, only the act\_cpu\_time\_top high watermark of the service subclass where an activity completes is updated, provided that a new high watermark is reached. The act\_cpu\_time\_top high watermarks of other service subclasses an activity is mapped to but does not complete in are unaffected.

Table 105. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 106. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected
Statistics	event_wcstats	Always collected
Statistics	event_wlstats	Always collected

## Usage

Use this element to determine the highest amount of processor time used by an activity on a member for a service class, workload, or work class during the time interval collected.

## act\_estimated\_sort\_shrheap\_top - Activity estimated shared sort memory high watermark monitor element

The **act\_estimated\_sort\_shrheap\_top** monitor element reports the high watermark for estimated shared sort memory usage by an individual activity in a workload, service superclass or subclass. The value is reported in 4K pages. The monitor element can help users identify which service classes contain activities with high sort memory estimates. These service classes are may be candidates for applying a sort memory limit.

Table 107. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
<u>WLM_GET_WORKLOAD_STATS</u> table function	Always collected
	Always collected
	Always collected
	Always collected
	Always collected
	Always collected

Table 108. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	EVENT_WLSTATS	Always collected
Statistics	EVENT_SCSTATS	Always collected
Statistics	EVENT_SUPERCLASSTATS	Always collected

## act\_exec\_time - Activity execution time monitor element

The **act\_exec\_time** element stores the time spent executing at this member, in microseconds. For cursors, the execution time is the combined time for the open, the fetches, and the close. The time when the cursor is idle is not counted toward execution time. For routines, execution time is the start to end of routine invocation. The lifetimes of any cursors left open by routine (to return a result set) after the routine finishes are not counted toward the routine execution time. For all other activities, execution time is the difference between start time and stop time. In all cases, execution time does not include time spent initializing or queued.

Table 109. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activities	event_activity	Always collected

## Usage

This element can be used alone to know the time spent by the database manager to execute the activity on each member. This element can also be used together with **time\_started** and **time\_completed** monitor elements on the coordinator member to compute the idle time for cursor activities. You can use the following formula:

```
Cursor idle time = (time_completed - time_started) - act_exec_time
```

## act\_rejected\_total - Total rejected activities monitor element

The total number of coordinator activities at any nesting level that were rejected instead of being allowed to execute.

Table 110. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get service subclass metrics as an XML document	Always collected
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE

Table 110. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics (reported in DETAILS XML document)	REQUEST METRICS BASE

Table 111. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats (reported in the details_xml document)	REQUEST METRICS BASE
	event_superclassstats (reported in the details_xml document)	REQUEST METRICS BASE
Statistics	event_wlstats (reported in the details_xml document)	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	-

## Usage

Use this element to help determine whether predictive thresholds and work actions that prevent execution are effective and whether they are too restrictive.

## act\_remapped\_in - Activities remapped in monitor element

Count of the number of activities to be remapped into this service subclass since the last reset.

Table 112. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected

Table 113. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	-

## Usage

Use this count to determine whether the remapping of activities into the service subclass is occurring as desired.

## act\_remapped\_out - Activities remapped out monitor element

Count of the number of activities to be remapped out of this service subclass since the last reset.

Table 114. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected

Table 115. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	-

### Usage

Use this count to determine whether the remapping of activities out of the service subclass is occurring as desired.

## act\_rows\_read\_top - Activity rows read top monitor element

The high watermark for the number of rows read by activities at all nesting levels in a service class, workload, or work class.

The monitor element returns -1 when COLLECT AGGREGATE ACTIVITY DATA for the service class or workload in which the activity runs is set to NONE. Activities contribute toward this high watermark only when request metrics are enabled. If the collection of activity metrics is not enabled, a value of 0 is returned.

For service classes, when you remap activities between service subclasses with a REMAP ACTIVITY action only the act\_rows\_read\_top high watermark of the service subclass where an activity completes is updated, provided that a new high watermark is reached. The act\_rows\_read\_top high watermarks of service subclasses an activity is mapped to but does not complete in are unaffected.

Table 116. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 117. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wcstats	Always collected
Statistics	event_wlstats	Always collected

### Usage

Use this element to determine the highest number of rows read by an activity on a member for a service class, workload, or work class during the time interval collected.

## act\_sort\_shrheap\_top - Activity shared sort memory high watermark monitor element

The **act\_sort\_shrheap\_top** monitor element reports the high watermark for actual shared sort memory usage by an individual activity in a workload, service superclass or subclass. The value is reported in 4K pages. The monitor element can help you identify which service classes contain activities with high sort memory requirements. These service classes are may be candidates for applying a sort memory limit.

Table 118. Table Function Monitoring Information

Statistics	EVENT_WLSTATS	Always collected
Statistics	EVENT_SCSTATS	Always collected
Statistics	EVENT_SUPERCLASSTATS	Always collected

## act\_sortmem\_limit\_pages - Activity sort memory limit monitor element (4k pages)

A sort memory limit specifies a maximum percentage of **sheapthres\_shr** that an activity is allowed to consume. This monitor element reports the sort memory limit applied to an activity. The **act\_sortmem\_limit\_pages** monitor element reports the sort memory limit applied to an activity as an absolute number of 4K pages (the value obtained from applying the sort memory limit percentage to **sheapthres\_shr**). If no sort memory limit is applied to an activity, the value is NULL. This monitor element can be used to understand whether a sort memory limit was applied to a query at runtime.

Table 120. Table Function Monitoring Information

MON_GET_ACTIVITY table function	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function	Always collected
	Always collected

Table 121. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
ACTIVITY	EVENT_ACTIVITY	Always collected

## act\_sortmem\_limit\_pct - Activity sort memory limit (percentage) monitor element

A sort memory limit specifies a maximum percentage of **sheapthres\_shr** that an activity is allowed to consume. The **act\_sortmem\_limit\_pct** monitor element reports the sort memory limit applied to an activity. If no sort memory limit is applied to an activity, the value is NULL. This element can be used to understand if a sort memory limit was applied to a query at runtime.

Table 122. Table Function Monitoring Information

MON_GET_ACTIVITY table function	Always collected
	Always collected
	Always collected

Table 123. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
ACTIVITY	EVENT_ACTIVITY	Always collected

## act\_sort\_shrheap\_top - Activity shared sort memory high watermark monitor element

The **act\_sort\_shrheap\_top** monitor element reports the high watermark for actual shared sort memory usage by an individual activity in a workload, service superclass or subclass. The value is reported in 4K pages. The monitor element can help you identify which service classes contain activities with high sort memory requirements. These service classes are may be candidates for applying a sort memory limit.

Event Type	Logical Data Grouping	Monitor Switch
Statistics	EVENT_WLSTATS	Always collected
Statistics	EVENT_SCSTATS	Always collected
Statistics	EVENT_SUPERCLASSSTATS	Always collected

## act\_rqsts\_total - Total activity requests monitor elements

The number of individual coordinator and subagent requests completed as part of an activity. For example, a fetch on a cursor activity.

*Table 126. Table Function Monitoring Information*

<b>Table Function</b>	<b>Monitor Element Collection Level</b>
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get service subclass metrics as an XML document	Always collected
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics (reported in DETAILS XML document)	REQUEST METRICS BASE

*Table 127. Event Monitoring Information*

Table 127. Event Monitoring Information (continued)

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_wlstats (reported in the metrics document)	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE

## act\_throughput - Activity throughput monitor element

The rate at which coordinator activities are completed at any nesting level. Measured in coordinator activities per second.

Table 128. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_SAMPLE_SERVICE_CLASS_METRICS - Get sample service class metrics	REQUEST METRICS BASE
MON_SAMPLE_WORKLOAD_METRICS - Get sample workload metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
WLM_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
WLM_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected

Table 129. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats (reported in the metrics document)	Always collected
Statistics	event_superclasstats (reported in the metrics document)	Always collected
Statistics	event_wlstats (reported in the metrics document)	Always collected

## Usage

When returned by the WLM\_GET\_SERVICE\_SUBCLASS\_STATS or the WLM\_GET\_WORKLOAD\_STATS function, this monitor element represents the activity throughput since the last reset of the statistics.

When returned by the MON\_SAMPLE\_SERVICE\_CLASS\_METRICS or the MON\_SAMPLE\_WORKLOAD\_METRICS function, this monitor element represents the activity throughput since the function was executed.

## ACT\_TOP - The peak activity count monitor element

The high watermark for the concurrently executing activities in this service subclass, superclass, or workload (at any nesting level).

Table 130. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 131. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected

## act\_sortmem\_limit - Activity sort memory limit

This parameter specifies the individual query sort memory limit for the database.

### Configuration type

Database

### Parameter type

Configurable online

### Default [range]

NONE [NONE, 10-100]

### Usage notes

Specifies the maximum percentage of the configured shared sort memory (**SHEAPTHRES\_SHR**) that individual queries executing in the database can consume. If sort memory limits are set at the service class, the most constrained value will take precedence. The value NONE and 100 are synonyms and indicate that no limit exists for a query.

The activity sort memory limit will only be enforced for queries that are managed by the adaptive workload manager. If the adaptive workload manager is disabled (**WLM\_ADMISSION\_CTRL** database config parameter is set to NO) or a query bypasses the adaptive workload manager, no sort memory limit will be applied to the query regardless of the service class it runs in.

**Note:** Setting an activity sort memory limit too low may result in reduced performance for queries.

## act\_total - Activities total monitor element

Total number of activities at any nesting level that had work actions corresponding to the specified work class applied to them since the last reset.

Table 132. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_WORK_ACTION_SET_STATS table function - Return work action set statistics	Always collected
WLM_GET_WORK_ACTION_SET_STATS table function - Return work action set statistics	Always collected

Table 133. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_wcstats	Always collected

## Usage

Every time an activity has one or more work actions associated with a work class applied to it, a counter for the work class is updated. This counter is exposed using the **act\_total** monitor element. The counter can be used to judge the effectiveness of the work action set (for example, how many activities have a actions applied). It can also be used to understand the different types of activities on the system.

## activate\_timestamp - Activate timestamp monitor element

The time when an event monitor was activated.

Table 134. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activity	event_activity	-
Activity	event_activitystmt	-
Activity	event_activityvals	-
Threshold Violations	event_thresholdviolations	-

## Usage

Use this element to correlate information returned by the previously mentioned event types.

## active\_col\_vector\_consumers - Active columnar vector memory consumers monitor element

The number of columnar vector memory consumers that are active.

Table 135. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected

Table 135. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_CONNECTION_DETAILS table function - Get connection metrics as an XML document	Always collected
MON_GET_DATABASE table function - get database information metrics	Always collected
MON_GET_DATABASE_DETAILS table function - get database information metrics as an XML document	Always collected
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get service subclass metrics as an XML document	Always collected
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get unit of work metrics as an XML document	Always collected
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	Always collected
MON_GET_WORKLOAD_DETAILS table function - Get workload metrics as an XML document	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### **active\_col\_vector\_consumers\_top - Active columnar vector memory consumers high watermark monitor element**

The high watermark for the number of columnar vector memory consumers that were active at any one time.

Table 136. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected

Table 136. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_DATABASE table function - get database information metrics	Always collected
MON_GET_DATABASE_DETAILS table function - get database information metrics as an XML document	Always collected
MON_GET_PKG_CACHE_STMT table function - get package cache statement metrics	Always collected
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	Always collected
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 137. Event monitoring information

Event type	Logical data grouping	Monitor switch
Activities	event_activity	Always collected
Package Cache	pkgcache	Always collected
Statistics	event_scstats	Always collected
Statistics	event_superclassstats	Always collected
Statistics	event_wlstats	Always collected
Unit of Work	uow	Always collected

### **active\_hash\_grpbys - Active hash GROUP BY operations monitor element**

The number of GROUP BY operations using hashing as their grouping method that are currently running and consuming sort heap memory.

Table 138. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get connection metrics as an XML document	Always collected

Table 138. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_DATABASE table function - Get database level information	Always collected
MON_GET_DATABASE_DETAILS table function - Get database information metrics	Always collected
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get service subclass metrics as an XML document	Always collected
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get unit of work metrics as an XML document	Always collected
MON_GET_WORKLOAD table function - Get workload metrics	Always collected
MON_GET_WORKLOAD_DETAILS table function - Get workload metrics as an XML document	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### **active\_hash\_grpbys\_top - Active hash GROUP BY operations high watermark monitor element**

The high watermark for the number of hash GROUP BY operations that were active at any one time.

Table 139. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_DATABASE table function - get database information metrics	Always collected
MON_GET_DATABASE_DETAILS table function - get database information metrics as an XML document	Always collected
MON_GET_PKG_CACHE_STMT table function - get package cache statement metrics	Always collected

Table 139. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	Always collected
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 140. Event monitoring information

Event type	Logical data grouping	Monitor switch
Activities	event_activity	Always collected
Package Cache	pkgcache	Always collected
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected
Unit of Work	uow	Always collected

## active\_hash\_joins - Active hash joins

The total number of hash joins that are currently running and consuming memory.

Table 141. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get connection metrics as an XML document	Always collected
MON_GET_DATABASE table function - Get database level information	Always collected
MON_GET_DATABASE_DETAILS table function - Get database information metrics	Always collected
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected

Table 141. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get service subclass metrics as an XML document	Always collected
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get unit of work metrics as an XML document	Always collected
MON_GET_WORKLOAD table function - Get workload metrics	Always collected
MON_GET_WORKLOAD_DETAILS table function - Get workload metrics as an XML document	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 142. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	-

### active\_hash\_joins\_top - Active hash join operations high watermark monitor element

The high watermark for the number of hash join operations that were active at any one time.

Table 143. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_DATABASE table function - get database information metrics	Always collected
MON_GET_DATABASE_DETAILS table function - get database information metrics as an XML document	Always collected
MON_GET_PKG_CACHE_STMT table function - get package cache statement metrics	Always collected
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	Always collected

Table 143. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 144. Event monitoring information

Event type	Logical data grouping	Monitor switch
Activities	event_activity	Always collected
Package Cache	pkgcache	Always collected
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected
Unit of Work	uow	Always collected

### active\_olap\_funcs - Active OLAP Functions monitor element

The total number of OLAP functions that are currently running and consuming sort heap memory.

Table 145. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get connection metrics as an XML document	Always collected
MON_GET_DATABASE table function - Get database level information	Always collected
MON_GET_DATABASE_DETAILS table function - Get database information metrics	Always collected
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get service subclass metrics as an XML document	Always collected

Table 145. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get unit of work metrics as an XML document	Always collected
MON_GET_WORKLOAD table function - Get workload metrics	Always collected
MON_GET_WORKLOAD_DETAILS table function - Get workload metrics as an XML document	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 146. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	-

For snapshot monitoring, this counter can be reset.

### **active\_olap\_funcs\_top - Active OLAP function operations high watermark monitor element**

The high watermark for the number of OLAP function operations that were active at any one time.

Table 147. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_DATABASE table function - get database information metrics	Always collected
MON_GET_DATABASE_DETAILS table function - get database information metrics as an XML document	Always collected
MON_GET_PKG_CACHE_STMT table function - get package cache statement metrics	Always collected
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	Always collected

Table 147. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 148. Event monitoring information

Event type	Logical data grouping	Monitor switch
Activities	event_activity	Always collected
Package Cache	pkgcache	Always collected
Statistics	event_scstats	Always collected
	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected
Unit of Work	uow	Always collected

### active\_peas - Active partial early aggregation operations monitor element

The number of partial early aggregation operations that are active.

Table 149. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get connection metrics as an XML document	Always collected
MON_GET_DATABASE table function - get database information metrics	Always collected
MON_GET_DATABASE_DETAILS table function - get database information metrics as an XML document	Always collected
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get service subclass metrics as an XML document	Always collected

Table 149. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get unit of work metrics as an XML document	Always collected
MON_GET_WORKLOAD table function - Get workload metrics	Always collected
MON_GET_WORKLOAD_DETAILS table function - Get workload metrics as an XML document	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### **active\_peas\_top - Active partial early aggregation operations high watermark monitor element**

The high watermark for the number of partial early aggregation operations that were active at any one time.

Table 150. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_DATABASE table function - get database information metrics	Always collected
MON_GET_DATABASE_DETAILS table function - get database information metrics as an XML document	Always collected
MON_GET_PKG_CACHE_STMT table function - get package cache statement metrics	Always collected
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	Always collected
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected

Table 150. Table function monitoring information (continued)

Table function	Monitor element collection level
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 151. Event monitoring information

Event type	Logical data grouping	Monitor switch
Activities	event_activity	Always collected
Package Cache	pkgcache	Always collected
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected
Unit of Work	uow	Always collected

### active\_peds - Active partial early distinct operations monitor element

The number of partial early distinct operations that are active.

Table 152. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get connection metrics as an XML document	Always collected
MON_GET_DATABASE table function - get database information metrics	Always collected
MON_GET_DATABASE_DETAILS table function - get database information metrics as an XML document	Always collected
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get service subclass metrics as an XML document	Always collected
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected

Table 152. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_UNIT_OF_WORK_DETAILS table function - Get unit of work metrics as an XML document	Always collected
MON_GET_WORKLOAD table function - Get workload metrics	Always collected
MON_GET_WORKLOAD_DETAILS table function - Get workload metrics as an XML document	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### **active\_peds\_top - Active partial early distinct operations high watermark monitor element**

The high watermark for the number of partial early distinct operations that were active at any one time.

Table 153. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_DATABASE table function - get database information metrics	Always collected
MON_GET_DATABASE_DETAILS table function - get database information metrics as an XML document	Always collected
MON_GET_PKG_CACHE_STMT table function - get package cache statement metrics	Always collected
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	Always collected
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected

Table 154. Event monitoring information

Event type	Logical data grouping	Monitor switch
Activities	event_activity	Always collected
Package Cache	pkgcache	Always collected
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected

Table 154. Event monitoring information (continued)

Event type	Logical data grouping	Monitor switch
Statistics	event_wlstats	Always collected
Unit of Work	uow	Always collected

### active\_sort\_consumers - Active sort memory consumers monitor element

The total number of currently active sort memory consumers.

Table 155. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get connection metrics as an XML document	Always collected
MON_GET_DATABASE table function - get database information metrics	Always collected
MON_GET_DATABASE_DETAILS table function - get database information metrics as an XML document	Always collected
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get service subclass metrics as an XML document	Always collected
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get unit of work metrics as an XML document	Always collected
MON_GET_WORKLOAD table function - Get workload metrics	Always collected
MON_GET_WORKLOAD_DETAILS table function - Get workload metrics as an XML document	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

## Usage

You can use the **active\_sort\_consumers** and **active\_sort\_consumers\_top** monitor elements to help tune the use of sort heap memory and workload concurrency. For example, you can use the **MON\_GET\_DATABASE** table function to retrieve the monitor element values for all database members. Knowing the number of concurrently active sort consumers and the high watermark over a period of time can help you adjust the value of the **sheapthres\_shr** configuration parameter to better accommodate the concurrent sort activities.

### **active\_sort\_consumers\_top - Active sort memory consumers high watermark monitor element**

The high watermark for the number of active sort memory consumers.

*Table 156. Table function monitoring information*

<b>Table function</b>	<b>Monitor element collection level</b>
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_DATABASE table function - get database information metrics	Always collected
MON_GET_DATABASE_DETAILS table function - get database information metrics as an XML document	Always collected
MON_GET_PKG_CACHE_STMT table function - get package cache statement metrics	Always collected
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	Always collected
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

*Table 157. Event monitoring information*

<b>Event type</b>	<b>Logical data grouping</b>	<b>Monitor switch</b>
Activities	event_activity	Always collected
Package Cache	pkgcache	Always collected
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected
Unit of Work	uow	Always collected

## Usage

You can use the **active\_sort\_consumers** and **active\_sort\_consumers\_top** monitor elements to help tune the use of sort heap memory and workload concurrency. For example, you can use the **MON\_GET\_DATABASE** table function to retrieve the monitor element values for all database members. Knowing the number of concurrently active sort consumers and the high watermark over a period of time can help you adjust the value of the **sheapthres\_shr** configuration parameter to better accommodate the concurrent sort activity.

## active\_sorts - Active Sorts

The number of sorts in the database that currently have a sort heap allocated.

Table 158. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get connection metrics as an XML document	Always collected
MON_GET_DATABASE table function - Get database level information	Always collected
MON_GET_DATABASE_DETAILS table function - Get database information metrics	Always collected
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get service subclass metrics as an XML document	Always collected
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get unit of work metrics as an XML document	Always collected
MON_GET_WORKLOAD table function - Get workload metrics	Always collected
MON_GET_WORKLOAD_DETAILS table function - Get workload metrics as an XML document	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 159. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic

**Usage**

Use this value in conjunction with *sort\_heap\_allocated* to determine the average sort heap space used by each sort. If the *sortheap* configuration parameter is substantially larger than the average sort heap used, you may be able to lower the value of this parameter.

This value includes heaps for sorts of temporary tables that were created during relational operations.

**active\_sorts\_top - Active sorts high watermark monitor element**

The high watermark for the number of sort operations that were active at any one time.

Table 160. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - return information about an activity as an XML document	Always collected
MON_GET_DATABASE table function - get database information metrics	Always collected
MON_GET_DATABASE_DETAILS table function - get database information metrics as an XML document	Always collected
MON_GET_PKG_CACHE_STMT table function - get package cache statement metrics	Always collected
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	Always collected
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 161. Event monitoring information

Event type	Logical data grouping	Monitor switch
Activities	event_activity	Always collected
Package Cache	pkgcache	Always collected
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected

Table 161. Event monitoring information (continued)

Event type	Logical data grouping	Monitor switch
Unit of Work	uow	Always collected

### activity\_collected - Activity collected monitor element

This element indicates whether or not activity event monitor records are to be collected for a violated threshold.

Table 162. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Threshold violations	event_thresholdviolations	-

### Usage

Use this element to determine whether to expect an activity event for the activity that violated the threshold to be written to the activity event monitor.

When an activity finishes or aborts and the activity event monitor is active at the time, if the value of this monitor element is 'Y', the activity that violated this threshold will be collected. If the value of this monitor element is 'N', it will not be collected.

### activity\_id - Activity ID monitor element

Counter which uniquely identifies an activity for an application within a given unit of work.

Table 163. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
MON_GET_AGENT table function - List agents, fenced mode processes, and system entities for the database	Always collected
MON_GET_WLM_ADMISSION_QUEUE table function - Return a list of queued activities	Always Collected
WLM_GET_SERVICE_CLASS_AGENTS table function - list agents running in a service class	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 164. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Locking	-	Always collected
Activities	event_activity	Always collected
Activities	event_activitystmt	Always collected

Table 164. Event Monitoring Information (continued)

Event Type	Logical Data Grouping	Monitor Switch
Activities	event_activityvals	Always collected
Activities	event_activitymetrics	Always collected
Threshold violations	event_thresholdviolations	Always collected

## Usage

Use this element in conjunction with other activity history elements for analysis of the behavior of an activity.

To uniquely identify an activity outside its unit of work, use the combination of **activity\_id** and **uow\_id** plus one of the following monitor elements: **appl\_id** or **agent\_id**.

## activity\_secondary\_id - Activity secondary ID monitor element

The value for this element is incremented each time an activity record is written for the same activity. For example, if an activity record is written once as a result of having called the WLM\_CAPTURE\_ACTIVITY\_IN\_PROGRESS procedure and a second time when the activity ends, the element would have a value of 0 for the first record and 1 for the second record.

Table 165. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activities	event_activity	-
Activities	event_activitystmt	-
Activities	event_activityvals	-
Activities	event_activitymetrics	ACTIVITY METRICS BASE

## Usage

Use this element with **activity\_id**, **uow\_id**, and **appl\_id** monitor elements to uniquely identify activity records when information about the same activity has been written to the activities event monitor multiple times.

For example, information about an activity would be sent to the activities event monitor twice in the following case:

- the WLM\_CAPTURE\_ACTIVITY\_IN\_PROGRESS stored procedure was used to capture information about the activity while it was running
- information about the activity was collected when the activity completed, because the COLLECT ACTIVITY DATA clause was specified on the service class with which the activity is associated

## activity\_state - Activity state monitor element

The current state of the activity.

Table 166. Table Function Monitoring Information

Table Function	Monitor Element Collection Command and Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected

Table 166. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Command and Level
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

## Usage

Use this monitor element to understand what the activity is currently doing (for example, is the activity stuck in a queue or waiting for input from the client). Possible values include:

Activity State	Description
CANCEL_PENDING	Activity was cancelled when there was no agent actively working on a request for the activity. The next time a request is submitted as part of the activity, the activity will be cancelled and the user who submitted the activity will receive an SQL4725N error.
EXECUTING	Agents are actively working on a request for the activity.
IDLE	There is no agent actively processing a request for the activity.
INITIALIZING	Activity has been submitted, but has not yet started executing. During the initializing state, predictive thresholds are applied to the activity to determine whether or not the activity will be allowed to execute.
QP_CANCEL_PENDING	Same as the CANCEL_PENDING state, but the activity was cancelled by query patroller rather than by the WLM_CANCEL_ACTIVITY procedure.
QP_QUEUED	Activity is queued by Query Patroller.
QUEUED	<p>The activity is queued by the adaptive workload manager or by a workload management concurrency threshold.</p> <p>When the adaptive workload manager is enabled, whether a query is allowed to run depends on its resource requirements and the resources that are currently available. If a query is submitted to the database server but there are insufficient resources available to run the query, it will be queued. When resources become available, the query will be admitted for execution.</p> <p>When a workload management concurrency threshold is active, activities can be queued if the number of concurrently executing activities exceeds the concurrency limit.</p> <p>In a partitioned database environment, this state might mean that the coordinator agent has made an RPC to the catalog partition to determine whether or not it is allowed to be executed and has not yet received a response. Seeing this state might indicate that the activity has been queued by the workload manager or, over very short periods of time, can just indicate that the activity is in the process of obtaining permission to execute.</p> <p>To obtain a more accurate picture of whether or not the activity is really being queued by the adaptive workload manager or a concurrency threshold, one can determine which agent is working on the activity and find out whether this agent's EVENT_OBJECT at the catalog partition has a value of WLM_QUEUE.</p>

Activity State	Description
TERMINATING	Activity has completed execution and is being removed from the system.

## activity\_type - Activity type monitor element

The type of the activity.

Table 167. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 168. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activities	event_activity	Always collected

## Usage

The possible values are:

- LOAD
- READ\_DML
- WRITE\_DML
- DDL
- CALL
- OTHER

**Attention:** Starting in Version 11.5 Mod Pack 1, READ\_WRITE\_DML will be available as a possible value.

The value OTHER is returned for SET statements that do not perform SQL (for example, SET special register, or SET EVENT MONITOR STATE) and the LOCK TABLE statement.

## activitytotalruntime\_threshold\_id - Activity total runtime threshold ID monitor element

The ID of the ACTIVITYTOTALRUNTIME threshold that was applied to the activity.

Table 169. Table Function Monitoring Information

Table Function	Monitor Element Collection Command and Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected

Table 169. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Command and Level
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### **activitytotalruntime\_threshold\_value - Activity total runtime threshold value monitor element**

A timestamp that is computed by adding the ACTIVITYTOTALRUNTIME threshold duration to the activity execution start time. If the activity is still executing when this timestamp is reached, the threshold will be violated.

Table 170. Table Function Monitoring Information

Table Function	Monitor Element Collection Command and Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### **activitytotalruntime\_threshold\_violated - Activity total runtime threshold violated monitor element**

This monitor element returns '1' (Yes) to indicate that the activity violated the ACTIVITYTOTALRUNTIME threshold. '0' (No) indicates that the activity has not yet violated the threshold.

Table 171. Table Function Monitoring Information

Table Function	Monitor Element Collection Command and Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### **activitytotalruntimeinallsc\_threshold\_id - Activity total runtime in all service classes threshold ID monitor element**

The ID of the ACTIVITYTOTALRUNTIMEINALLSC threshold that was applied to the activity.

Table 172. Table Function Monitoring Information

Table Function	Monitor Element Collection Command and Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected

Table 172. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Command and Level
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### **activitytotalruntimeinallsc\_threshold\_value - Activity total runtime in all service classes threshold value monitor element**

A timestamp that is computed by adding the ACTIVITYTOTALRUNTIMEINALLSC threshold duration to the activity execution start time. If the activity is still executing when this timestamp is reached, the threshold will be violated.

Table 173. Table Function Monitoring Information

Table Function	Monitor Element Collection Command and Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### **activitytotalruntimeinallsc\_threshold\_violated - Activity total runtime in all service classes threshold violated monitor element**

This monitor element returns '1' (Yes) to indicate that the activity violated the ACTIVITYTOTALRUNTIMEINALLSC threshold. '0' (No) indicates that the activity has not yet violated the threshold.

Table 174. Table Function Monitoring Information

Table Function	Monitor Element Collection Command and Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### **activitytotaltime\_threshold\_id - Activity total time threshold ID monitor element**

The ID of the ACTIVITYTOTALTIME threshold that was applied to the activity.

Table 175. Table Function Monitoring Information

Table Function	Monitor Element Collection Command and Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### Usage

Use this element to understand which ACTIVITYTOTALTIME threshold, if any, was applied to the activity.

### **activitytotaltime\_threshold\_value - Activity total time threshold value monitor element**

A timestamp that is computed by adding the ACTIVITYTOTALTIME threshold duration to the activity entry time. If the activity is still executing when this timestamp is reached, the threshold will be violated.

Table 176. Table Function Monitoring Information

Table Function	Monitor Element Collection Command and Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### Usage

Use this element to understand the value of the ACTIVITYTOTALTIME threshold applied to the activity, if any.

### **ACTUAL\_PARALLELISM - The actual parallelism monitor element**

The total actual degree across all activities in this service subclass, superclass, or workload

Table 177. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_WORKLOAD table function - Get workload metrics	Always collected
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service superclass metrics	REQUEST METRICS BASE

Table 178. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected

### ACTUAL\_PARALLELISM\_AVG - The average parallelism monitor element

The average query\_actual\_degree for all activities in this service subclass, superclass, or workload.

Table 179. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 180. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected

### ACTUAL\_PARALLELISM\_TOP - The peak parallelism monitor element

The peak query\_actual\_degree for an individual activity across all activities in this service subclass, superclass, or workload.

Table 181. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 182. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected

Table 182. Event Monitoring Information (continued)

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_superclasstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected

### adapter\_name - Adapter name monitor element

Name of the network adapter on this host.

Table 183. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
ENV_GET_NETWORK_RESOURCES table function - Return network adapter information	Always collected

### address - IP address from which the connection was initiated

The IP address from which the activity connection was initiated.

Table 184. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
WLM_GET_SERVICE_CLASS_WORKLOAD_OCCURRENCES table function - list workload occurrences	Always collected

Table 185. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activities	event_activity	Always collected

### Usage

Use this to identify the IP address from which the activity connection was initiated. Secure domain names are shown converted to an IP address.

### adm\_resource\_actuals - Query uses WLM admission control resource actuals

Whether the activity that was admitted by WLM admission control uses estimates generated from a previous execution.

This monitor element returns 'Y' or 'N':

- 'Y' indicates that the activity was admitted by WLM admission control using resource actuals, that is, using estimates that were generated from a previous execution.
- 'N' indicates that the activity was admitted by WLM admission control, but that the estimates used for workload management are not based on resource actuals.

Table 186. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected

Table 186. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 187. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activity	event_activity	Always collected

### adm\_resource\_actuals - admission control resource actuals monitor element

Indicates if the estimated resource usage and runtime is based on actual observed values from prior runs of the same query.

**Note:** This monitor element is available in Db2version 11.5.4 and later.

Table 188. Table function monitoring information

Table function	Monitor element collection level
MON_GET_WLM_ADMISSION_QUEUE table function - Return a list of queued activities	Always Collected

Table 189. Event monitoring information

Event type	Logical data grouping	Monitor switch
Activity	event_activity	Always collected
Package cache	pkgcache	Always collected

### adm\_bypassed - Admission control bypassed monitor element

Indicates whether the activity bypassed admission control.

- A value of 0 indicates that the activity did not bypass admission control.
- A value of 1 indicates that the activity bypassed admission control.
- A null value indicates that records were returned from non-coordinating members in a partitioned database environment.

Table 190. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY table function - Return a list of activities	Always collected

Table 191. Event monitoring information

Event type	Logical data grouping	Monitor switch
Activity	event_activity	Always collected

### **adm\_bypass\_act\_total - Number of times admission control was bypassed monitor element**

Count of activities that bypass adaptive admission control. This includes DDL statements, CALL statements, and DML statements with an estimated runtime of less than 1 second.

Table 192. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - Return a list of activities	ACTIVITY METRICS BASE
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details	ACTIVITY METRICS BASE
MON_GET_BUFFERPOOL table function - Get buffer pool metrics	REQUEST METRICS BASE
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_PKG_CACHE_STMT table function - Get SQL statement activity metrics in the package cache	ACTIVITY METRICS BASE
MON_GET_PKG_CACHE_STMT_DETAILS - Get detailed metrics for package cache entries	ACTIVITY METRICS BASE
MON_GET_ROUTINE table function - get aggregated execution metrics for routines	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS table function - get aggregated execution metric details for routines	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_TABLE table function - get table metrics	REQUEST METRICS BASE

Table 192. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_TABLESPACE table function - Get table space metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics	REQUEST METRICS BASE
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	ACTIVITY METRICS BASE

Table 193. Event monitoring information

Activity	event_activitymetrics	ACTIVITY METRICS BASE
Package Cache	pkgcache_metrics	ACTIVITY METRICS BASE
Statistics	event_wlmetrics	REQUEST METRICS BASE
Unit of Work	uow_metrics	REQUEST METRICS BASE

### ADM\_BYPASSED\_ACT\_LOAD - Load of activities that bypass the adaptive workload manager monitor element

Ratio of the total time activities are not controlled by the adaptive workload manager spent running versus the interval of measurement.

Table 194. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 195. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_stats (reported in the details_xml document)	Always collected
Statistics	event_superclasstats (reported in the details_xml document)	Always collected

## ADM\_BYPASSED\_ACT\_TIME - Total time spent running activities that bypass adaptive workload manager monitor element

The total time activities not controlled by the adaptive workload manager spent running in the interval of measurement. This value is in microseconds.

Table 196. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 197. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_stats (reported in the details_xml document)	Always collected
Statistics	event_superclasstats (reported in the details_xml document)	Always collected

## adm\_overflows - Number of times an activity fit as an overflow monitor element

Number of times that Workload Manager adaptive admission control allowed an activity to exceed hard resource entitlement of a service class.

Table 198. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - Return a list of activities	ACTIVITY METRICS BASE
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details	ACTIVITY METRICS BASE
MON_GET_BUFFERPOOL table function - Get buffer pool metrics	REQUEST METRICS BASE
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_PKG_CACHE_STMT table function - Get SQL statement activity metrics in the package cache	ACTIVITY METRICS BASE
MON_GET_PKG_CACHE_STMT_DETAILS - Get detailed metrics for package cache entries	ACTIVITY METRICS BASE

Table 198. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_ROUTINE table function - get aggregated execution metrics for routines	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS table function - get aggregated execution metric details for routines	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_TABLE table function - get table metrics	REQUEST METRICS BASE
MON_GET_TABLESPACE table function - Get table space metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics	REQUEST METRICS BASE
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	ACTIVITY METRICS BASE

Table 199. Event monitoring information

Event type	Logical data grouping	Monitor switch
Activity	event_activitymetrics	ACTIVITY METRICS BASE
Package Cache	pkgcache_metrics	ACTIVITY METRICS BASE
Statistics	event_wlmetrics	REQUEST METRICS BASE
Unit of Work	uow_metrics	REQUEST METRICS BASE

### adm\_queue\_position - Admission queue position monitor element

The position of the activity in the workload manager (WLM) admission queue. The activity with position 1 is at the head of the queue.

**Note:** This monitor element is available in Db2version 11.5.4 and later.

<i>Table 200. Table function monitoring information</i>	
<b>Table function</b>	<b>Monitor element collection level</b>
<a href="#">MON_GET_WLM_ADMISSION_QUEUE table function - Return a list of queued activities</a>	Always Collected

*Table 201. Event monitoring information*

<b>Event type</b>	<b>Logical data grouping</b>	<b>Monitor switch</b>
Activity	event_activity	Always collected
Package cache	pkgcache	Always collected

### **adm\_queue\_entry\_time - Admission queue entry time monitor element**

The time when the activity entered the workload manager (WLM) admission queue.

**Note:** This monitor element is available in Db2version 11.5.4 and later.

<i>Table 202. Table function monitoring information</i>	
<b>Table function</b>	<b>Monitor element collection level</b>
<a href="#">MON_GET_WLM_ADMISSION_QUEUE table function - Return a list of queued activities</a>	Always Collected

*Table 203. Event monitoring information*

<b>Event type</b>	<b>Logical data grouping</b>	<b>Monitor switch</b>
Activity	event_activity	Always collected
Package cache	pkgcache	Always collected

### **ADM\_QUEUED\_ACT\_LOAD - Load of queued activities controlled by adaptive workload management monitor element**

Ratio of the total time activities controlled by the adaptive workload manager spent queued vs. the interval of measurement.

*Table 204. Table Function Monitoring Information*

<b>Table Function</b>	<b>Monitor Element Collection Level</b>
<a href="#">MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses</a>	Always collected
<a href="#">MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses</a>	Always collected

*Table 205. Event Monitoring Information*

<b>Event Type</b>	<b>Logical Data Grouping</b>	<b>Monitor Switch</b>
Statistics	event_stats (reported in the details_xml document)	Always collected
Statistics	event_superclassstats (reported in the details_xml document)	Always collected

## ADM\_QUEUED\_ACT\_TIME - Total time spent queued activities controlled by adaptive workload manager monitor element

The total time activities controlled by the adaptive workload manager spent running in the interval of measurement. This value is in microseconds.

Table 206. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 207. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_stats (reported in the details_xml document)	Always collected
Statistics	event_superclasstats (reported in the details_xml document)	Always collected

## ADM\_RUNNING\_ACT\_LOAD - Load of running activities controlled by adaptive workload management monitor element

Ratio of the total time activities controlled by the adaptive workload manager spent running vs. the interval of measurement.

Table 208. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 209. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_stats (reported in the details_xml document)	Always collected
Statistics	event_superclasstats (reported in the details_xml document)	Always collected

## ADM\_RUNNING\_ACT\_TIME - Total time spent running activities controlled by the adaptive workload manager monitor element

The total time activities controlled by the adaptive workload manager are spent running in the interval of measurement. This value is in microseconds.

Table 210. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 211. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_stats (reported in the details_xml document)	Always collected
Statistics	event_superclasstats (reported in the details_xml document)	Always collected

## agent\_id - Application handle (agent ID) monitor element

A system-wide unique ID for the application. In a single-member database configuration, this identifier consists of a 16-bit counter. In a multi-member configuration, this identifier consists of the coordinating member number concatenated with a 16-bit counter. In addition, this identifier is the same on every member where the application may make a secondary connection.

**Attention:** As of the release of Db2 version 11.5.2, the *agent\_id* monitor element for the Activities Event Type is deprecated and might be removed in a future release. Instead use the [application\\_handle](#) monitor element

Table 212. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected
MON_GET_LOCKS table function - list all locks in the currently connected database	Always collected
MON_GET_MEMORY_POOL table function - Get memory pool information	Always collected
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	Always collected

Table 213. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl_id_info	Basic
Lock	appl_lock_list	Basic
DCS Application	dcs_appl_info	Basic
Transaction	event_xact	-

Table 214. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Locking	-	Always collected
Unit of work	-	Always collected
Connections	event_connheader	Always collected
Statements	event_stmt	Always collected
Statements	event_subsection	Always collected
Deadlocks <sup>1</sup>	event_dlconn	Always collected
Deadlocks with Details <sup>1</sup>	event_detailed_dlconn	Always collected
Threshold violations	event_thresholdviolations	Always collected
Activities <sup>2</sup>	event_activity	Always collected
Change history	changesummary	Always collected

**1**

This event monitor has been deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR for locking statement to monitor lock-related events, such as lock timeouts, lock waits, and deadlocks.

**2**

As of the release of Db2 version 11.5.2, this element is deprecated in this event monitor. Its use is no longer recommended and might be removed in a future release. Use the element `application_handle` instead.>

## Usage

The application handle, also known as the agent ID, can be used to uniquely identify an active application.

**Note:** The `agent_id` monitor element has different behavior depending on your version of Db2. When taking snapshots from Db2 with version `SQLM_DBMON_VERSION1` or `SQLM_DBMON_VERSION2` to a Db2 (Version 5 or greater) database, the `agent_id` returned is not usable as an application identifier, rather it is the `agent_pid` of the agent serving the application. In these cases an `agent_id` is still returned for compatibility with earlier releases, but internally the Db2 database server will not recognize the value as an `agent_id`.

This value can be used as input to GET SNAPSHOT commands that require an agent ID or to the monitor table functions that require an application handle.

When reading event traces, it can be used to match event records with a given application.

It can also be used as input to the FORCE APPLICATION command or API. On multi-node systems this command can be issued from any node where the application has a connection. Its effect is global.

## agent\_id\_holding\_lock - Agent ID Holding Lock

The application handle of the agent holding a lock for which this application is waiting. The lock monitor group must be turned on to obtain this information.

Table 215. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl	Lock
Lock	appl_lock_list	Lock
Lock	lock_wait	Lock

### Usage

This element can help you determine which applications are in contention for resources.

If this element is 0 (zero) and the application is waiting for a lock, this indicates that the lock is held by an indoubt transaction. You can use either `appl_id_holding_lk` or the command line processor `LIST INDOUBT TRANSACTIONS` command (which displays the application ID of the CICS agent that was processing the transaction when it became indoubt) to determine the indoubt transaction, and then either commit it or roll it back.

Note that more than one application can hold a shared lock on an object for which this application is waiting. See `lock_mode` for information about the type of lock that the application holds. If you are taking an application snapshot, only one of the agent IDs holding a lock on the object will be returned. If you are taking a lock snapshot, all of the agent IDs holding a lock on the object will be identified.

## AGENT\_LOAD\_TRGT\_DEMAND - Estimated agent load target demand monitor element

The estimated demand for agent load resources from the activities currently executing within the service class. This value represents the aggregate resource demand if all executing activities reach their peak consumption at the same time. This value is a percentage.

Table 216. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	Always collected
MON_GET_SERVICE_SUPERCLASS table function - Get service superclass metrics	Always collected

Table 217. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_stats (reported in the details_xml document)	Always collected
Statistics	event_superclasstats (reported in the details_xml document)	Always collected

## AGENT\_LOAD\_TRGT\_DEMAND\_AVG – Average estimated agent load target demand monitor element

The average estimated demand for agent load resources from the activities currently executing within the service class. This value is a percentage.

Table 218. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 219. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_stats (reported in the details_xml document)	Always collected
Statistics	event_superclasstats (reported in the details_xml document)	Always collected

## AGENT\_LOAD\_TRGT\_DEMAND\_TOP - Peak estimated agent load target demand monitor element

The high watermark estimated demand for agent load resources from the activities currently executing within the service class. This value is a percentage.

Table 220. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 221. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_stats (reported in the details_xml document)	Always collected
Statistics	event_superclasstats (reported in the details_xml document)	Always collected

## AGENT\_LOAD\_TRGT\_UTILIZATION\_AVG - The average load utilization monitor element

The average usage of the agent load target for this service subclass, superclass, or workload, expressed as a percentage.

Table 222. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 223. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected

## AGENT\_LOAD\_TRGT\_UTILIZATION\_TOP - The peak load utilization monitor element

The peak usage of the agent load target for this service subclass, superclass, or workload, expressed as a percentage.

Table 224. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 225. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected

## AGENT\_LOAD\_TRGT\_UTILIZATION - The agent load utilization monitor element

The percentage of total effective degree, divided by the agent load per core, and multiplied by the number of cores in this service subclass, superclass, or workload.

Table 226. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_WORKLOAD table function - Get workload metrics	Always collected
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service superclass metrics	REQUEST METRICS BASE

Table 227. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_wlstats	Always collected

## agent\_pid - Engine dispatchable unit (EDU) identifier monitor element

The unique identifier for the engine dispatchable unit (EDU) for the agent. Except on the Linux operating system, the EDU ID is mapped to the thread ID. On the Linux operating system, the EDU ID is a unique identifier that is generated by the database system.

Table 228. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	agent	Statement

Table 229. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Locking	-	-

### Usage

You can use this element to link database system monitor information to other sources of diagnostic information, such as system traces. You can also use it to monitor how agents working for a database application use system resources.

## agent\_status - DCS Application Agents

In a connection concentrator environment, this value shows which applications currently have associated agents.

### Element identifier

agent\_status

**Element type**  
information

*Table 230. Snapshot Monitoring Information*

Snapshot Level	Logical Data Grouping	Monitor Switch
DCS Application	dcs_appl_info	Basic

**Usage**

Values are:

- `SQLM_AGENT_ASSOCIATED` (numeric value 1)  
The agent working on behalf of this application is associated with it.
- `SQLM_AGENT_NOT_ASSOCIATED` (numeric value 2)  
The agent that was working on behalf of this application is no longer associated with it and is being used by another application. The next time work is done for this application without an associated agent, an agent will be re-associated.

### **agent\_sys\_cpu\_time - System CPU Time used by Agent**

The total *system* CPU time (in seconds and microseconds) used by the database manager agent process.

**Element identifier**

agent\_sys\_cpu\_time

**Element type**

time

*Table 231. Snapshot Monitoring Information*

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl	Timestamp

For snapshot monitoring at the application level, this counter can be reset. This counter cannot be reset at other levels.

**Usage**

This element along with the other related CPU-time elements can help you understand the level of activity within an application, and may help you identify applications that could benefit from additional tuning.

This element includes CPU time for both SQL and non-SQL statements, as well as CPU time for any unfenced user-defined functions (UDFs)

System CPU represents the time spent in system calls. User CPU represents time spent executing database manager code.

**Note:** If this information is not available for your operating system, this element will be set to 0.

### **agent\_tid - Agent thread ID monitor element**

The thread ID of the agent or system entity. If this ID is unavailable, the value of the column is null.

*Table 232. Table Function Monitoring Information*

Table Function	Monitor Element Collection Level
ENV_GET_DB2_EDU_SYSTEM_RESOURCES - return database engine dispatchable units system information	Always collected

Table 232. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_AGENT table function - List agents, fenced mode processes, and system entities for the database	Always collected
MON_GET_APPL_LOCKWAIT table function - Get information about locks for which an application is waiting	Always collected
WLM_GET_SERVICE_CLASS_AGENTS table function - list agents running in a service class	Always collected

Table 233. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Locking	lock_participants	

## agent\_usr\_cpu\_time - User CPU Time used by Agent

The total CPU time (in seconds and microseconds) used by database manager agent process.

### Element identifier

agent\_usr\_cpu\_time

### Element type

time

Table 234. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl	Timestamp

For snapshot monitoring, this counter can be reset.

### Usage

This element along with the other CPU-time related elements can help you identify applications or queries that consume large amounts of CPU.

This counter includes time spent on both SQL and non-SQL statements, as well as any unfenced user-defined functions (UDFs) or stored procedures executed by the application.

System CPU represents the time spent in system calls. User CPU represents time spent executing database manager code.

**Note:** If this information is not available for your operating system, this element will be returned as 0.

## agent\_wait\_time - Agent wait time monitor element

Time spent by an application queued to wait for an agent under concentrator configurations. The value is given in milliseconds.

Table 235. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE

Table 235. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics (reported in DETAILS XML document)	REQUEST METRICS BASE

Table 236. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_superclasstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_wlstats (reported in the metrics document)	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE

## Usage

The **agent\_wait\_time** monitor element can be used to help evaluate how efficiently your system is running in a concentrator environment. A high agent wait relative to the **total\_request\_time** monitor element value indicates that requests are spending a lot of time queued waiting for agents, which may be indicative of one or more of the following events:

- The **max\_coordagents** configuration parameter has been configured too small for your workload. You may need to increase the value of **max\_coordagents** configuration parameter, or the ratio of **max\_coordagents** configuration parameter to **max\_connections** configuration parameter if you are running with both parameters set to AUTOMATIC, to ensure that enough coordinator agents are available to service your application requests in a timely manner.
- Your workload is not committing frequently enough. For the concentrator to work efficiently, applications should issue commits relatively frequently to ensure that their agents can be freed up to serve requests on other applications. If your applications do not do frequent commits you may need to configure a proportionally higher number of coordinator agents to reduce the time spent waiting for agents to become available.

## agent\_waits\_total - Total agent waits monitor element

Number of times an application had to wait for an agent to be assigned under concentrator configurations.

*Table 237. Table Function Monitoring Information*

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics (reported in DETAILS XML document)	REQUEST METRICS BASE

Table 238. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats (reported in the details_xml document)	REQUEST METRICS BASE
Statistics	event_superclasstats (reported in the details_xml document)	REQUEST METRICS BASE
Statistics	event_wlstats (reported in the details_xml document)	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE

## Usage

Use this element in conjunction with the **agent\_wait\_time** monitor element to determine the average amount of time an application request spends waiting for an agent in a concentrator environment.

## agents\_created\_empty\_pool - Agents Created Due to Empty Agent Pool

The number of agents created because the agent pool was empty. It includes the number of agents started at **db2start** time. (*num\_initagents*).

Table 239. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_INSTANCE table function - Get instance level information	Always collected

Table 240. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	db2	Basic

## Usage

In conjunction with `agents_from_pool`, you can calculate the ratio of

$$\text{Agents Created Due to Empty Agent Pool} / \text{Agents Assigned From Pool}$$

See `agents_from_pool` for information about using this element.

## agents\_from\_pool - Agents Assigned From Pool

The number of agents assigned from the agent pool.

Table 241. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_INSTANCE table function - Get instance level information	Always collected

Table 242. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	db2	Basic

## Usage

This element can be used with the **agents\_created\_empty\_pool** monitor element to determine how often an agent must be created because the pool is empty.

The following ratio

Agents Created Due to Empty Agent Pool / Agents Assigned From Pool

can be used to help set an appropriate value for the **num\_poolagents** configuration parameter.

For most users, the default value of 100 with AUTOMATIC will ensure optimal performance.

This ratio may fluctuate somewhat with the workload. At times of low activity on the system, additional agent creation and termination may occur. At times of high activity on the system, more agent reuse will occur. A low ratio indicates that there is a high amount of agent reuse, which is expected on systems with high activity. A high ratio indicates a higher amount of agent creation than reuse is occurring. If this is a concern, increase the value for the **num\_poolagents** configuration parameter to lower the ratio. However, this will cause additional resources consumption on the system.

## agents\_registered - Agents Registered

The number of agents registered in the database manager instance that is being monitored (coordinator agents and subagents).

Table 243. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_INSTANCE table function - Get instance level information	Always collected

Table 244. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	db2	Basic

## Usage

Use this element to help evaluate your settings for the **max\_coordagents** and **max\_connections** configuration parameters, as well as the intraquery parallelism settings.

## agents\_registered\_top - Maximum Number of Agents Registered

The maximum number of agents that the database manager has ever registered, at the same time, since it was started (coordinator agents and subagents).

Table 245. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_INSTANCE table function - Get instance level information	Always collected

Table 246. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	db2	Basic

## Usage

You may use this element to help you evaluate your settings for the **max\_coordagents** and **max\_connections** configuration parameters, as well as the intraquery parallelism settings.

The number of agents registered at the time the snapshot was taken is recorded by the `agents_registered` monitor element.

## agents\_stolen - Stolen Agents

At the database manager snapshot level, this monitor element represents the number of idle agents associated with an application which get reassigned to work on a different application. At the application snapshot level, this monitor element represents the number of idle agents associated with a different application which get reassigned to work on this application.

Table 247. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_INSTANCE table function - Get instance level information	Always collected

Table 248. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	db2	Basic
Application	appl	Basic

For snapshot monitoring, this counter can be reset.

## Usage

The **num\_poolagents** configuration parameter is set to `AUTOMATIC` by default. This means that the database system automatically manages the pooling of idle agents, which includes assigning work to idle agents associated with another application.

## agents\_top - Number of Agents Created

At the activity level, this is the maximum number of agents that were used when executing the statement. At the database level, it is the maximum number of agents for all applications.

Table 249. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details	Always collected
MON_GET_DATABASE table function - Get database level information	Always collected
MON_GET_DATABASE_DETAILS table function - Get database information metrics	Always collected
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	Always collected

Table 249. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_PKG_CACHE_STMT table function - Get package cache statement metrics	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 250. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Statement
Application	stmt	Statement

Table 251. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activity	event_activity	Always collected
Package Cache	pkgcache	Always collected

#### Usage

An indicator how well intra-query parallelism was realized.

### agents\_waiting\_on\_token - Agents Waiting for a Token

The number of agents waiting for a token so they can execute a transaction in the database manager.

**Note:** The **agents\_waiting\_on\_token** monitor element is deprecated. Using this monitor element will not generate an error. However, it does not return a valid value and might be removed in a future release.

Table 252. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	db2	Basic

#### Usage

You can use this element to help evaluate your setting for the **maxcagents** configuration parameter.

Each application has a dedicated coordinator agent to process database requests within the database manager. Each agent has to get a token before it can execute a transaction. The maximum number of agents that can execute database manager transactions is limited by the configuration parameter **maxcagents**.

### agents\_waiting\_top - Maximum Number of Agents Waiting monitor element

The maximum number of agents that have ever been waiting for a token, at the same time, since the database manager was started.

**Note:** The **agents\_waiting\_top** monitor element is deprecated. Using this monitor element will not generate an error. However, it does not return a valid value and might be removed in a future release.

Table 253. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	db2	Basic

## Usage

Use this element to help you evaluate your setting of the **maxcagents** configuration parameter.

The number of agents waiting for a token at the time the snapshot was taken is recorded by the **agents\_waiting\_on\_token** monitor element.

If the **maxcagents** parameter is set to its default value (-1), no agents should wait for a token and the value of this monitor element should be zero.

## agg\_temp\_tablespace\_top - Aggregate temporary table space top monitor element

The **agg\_temp\_tablespace\_top** monitor element stores the high watermark, in KB, for the aggregate temporary table space usage of DML activities at all nesting levels in a service class.

The aggregate is computed by summing the temporary table space usage across all activities in the service subclass or superclass, and this high watermark represents the highest value reached by this aggregate since the last reset. The monitor element returns -1 when COLLECT AGGREGATE ACTIVITY DATA for the service class is set to NONE. An AGGSQLTEMPSPACE threshold must be defined and enabled for at least one service subclass in the same superclass as the subclass to which this record belongs. Otherwise a value of zero (0) is returned.

For a service superclass, an AGGSQLTEMPSPACE threshold must be defined and enabled for at least one service subclass under the superclass to which the record belongs. Otherwise, a value of zero (0) is returned.

---

*Table 254. Table Function Monitoring Information*

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

---

*Table 255. Event Monitoring Information*

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected

## Usage

Use this element to determine the highest aggregate DML activity system temporary table space usage reached on a member for a service subclass or superclass in the time interval collected.

## aggsqltempespace\_threshold\_id - Aggregate SQL temporary space threshold ID monitor element

The numeric ID of the AGGSQLTEMPSPACE threshold that was applied to the activity.

---

*Table 256. Table Function Monitoring Information*

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected

Table 256. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### Usage

Use this element to understand which AGGSQLTEMPSPACE threshold, if any, was applied to the activity.

### **aggsqltempespace\_threshold\_value - AggSQL temporary space threshold value monitor element**

The upper bound of the AGGSQLTEMPSPACE threshold that was applied to the activity.

Table 257. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### Usage

Use this element to understand the value of the AGGSQLTEMPSPACE threshold applied to the activity, if any.

### **aggsqltempespace\_threshold\_violated - AggSQL temporary space threshold violated monitor element**

The optional monitor element when set to '1' (Yes) indicates that the activity violated the AGGSQLTEMPSPACE threshold that was applied to it. '0' (No) indicates that the activity has not yet violated the threshold.

Table 258. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

## Usage

Use this element to determine if the activity violated the AGGSQLTEMPSPACE threshold that was applied to the activity.

### **app\_act\_aborted\_total - Total failed external coordinator activities monitor element**

The total number of external, non-nested coordinator activities that completed with errors. For service classes, if an activity is remapped to a different service subclass with a REMAP ACTIVITY action before it aborts, the activity counts only toward the total of the subclass in which it aborts.

*Table 259. Table Function Monitoring Information*

<b>Table Function</b>	<b>Monitor Element Collection Level</b>

Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE

## Usage

Use this monitor element to understand how many requests are being submitted into the system from applications.

## appl\_action - Application action monitor element

The action or request that the client application is performing.

Table 267. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Locking	lock_participants	

## appl\_con\_time - Connection Request Start Timestamp

The date and time that an application started a connection request.

### Element identifier

appl\_con\_time

### Element type

timestamp

Table 268. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl	Timestamp

## Usage

Use this element to determine when the application started its connection request to the database.

## appl\_id - Application ID monitor element

This identifier is generated when the application connects to the database at the database manager or when Db2 Connect receives a request to connect to a DRDA database.

Table 269. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_AGENT table function - List agents, fenced mode processes, and system entities for the database	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	Always collected
MON_GET_UTILITY table function - Get utilities running on the database	Always collected
PD_GET_DIAG_HIST table function - Return records from a given facility	Always collected
PDLOGMSGs_LAST24HOURS administrative view and PD_GET_LOG_MSGS table function - Retrieve problem determination messages	Always collected
WLM_GET_SERVICE_CLASS_AGENTS table function - list agents running in a service class	Always collected
WLM_GET_SERVICE_CLASS_WORKLOAD_OCCURRENCES table function - list workload occurrences	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

1. For this event monitor, this monitor element is returned in the column APPLICATION\_ID.

2. This event monitor has been deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR FOR UNIT OF WORK statement to monitor transaction events.

3. This event monitor has been deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR FOR LOCKING statement to monitor lock-related events, such as lock timeouts, lock waits, and deadlocks.

## Usage

This ID is known on both the client and server, so you can use it to correlate the client and server parts of the application. For Db2 Connect applications, you will also need to use **outbound\_app1\_id** monitor element to correlate the client and server parts of the application.

This identifier is unique across the network. There are different formats for the application ID, which are dependent on the communication protocol between the client and the server machine on which the database manager, Db2 Connect, or both are running. Each of the formats consists of three parts separated by periods.

### 1. TCP/IP

#### Format

IPAddr.Port.Timestamp

#### IPv4

#### Example

9.26.120.63.43538.090924175700

#### Details

In IPv4, a TCP/IP-generated application ID is composed of three sections. The first section is the IP address. It is represented as four decimal numbers of the form a . b . c . d. The second section is the port number, which is represented as 5 decimal characters. The third section is the approximate timestamp, represented as 12 decimal characters.

## IPv6

### Example

```
2002:91a:519:13:20d:60ff:feef:cc64.5309.090924175700
```

### Details

In IPv6, a TCP/IP-generated application ID is composed of three sections. The first section contains the IPv6 address of the form a:b:c:d:e:f:g:h, where each of a-h is up to 4 hexadecimal digits. The second section is the port number. The third section is the approximate timestamp identifier for the instance of this application.

## 2. Local Applications

### Format

```
*LOCAL.DB2 instance.Application instance
```

### Example

```
*LOCAL.DB2INST1.930131235945
```

### Details

The application ID generated for a local application is made up by concatenating the string \*LOCAL, the name of the database instance, and a unique identifier for the instance of this application.

For multiple database partition instances, LOCAL is replaced with Nx, where x is the partition number from which the client connected to the database. For example, \*N2.DB2INST1.0B5A12222841.

Use the **client\_protocol** monitor element to determine which communications protocol the connection is using and, as a result, the format of the **appl\_id** monitor element.

## appl\_id\_holding\_lk - Application ID Holding Lock

The application ID of the application that is holding a lock on the object that this application is waiting to obtain.

### Element identifier

```
appl_id_holding_lk
```

### Element type

```
information
```

Table 272. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl	Lock
Lock	appl_lock_list	Lock
Lock	lock_wait	Lock

Table 273. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Deadlocks	event_dlconn	Always collected
Deadlocks with Details	event_detailed_dlconn	Always collected

### Usage

This element can help you determine which applications are in contention for resources. Specifically, it can help you identify the application handle (agent ID) and table ID that are holding the lock. Note that you may use the LIST APPLICATIONS command to obtain information to relate the application ID with an agent ID. However, it is a good idea to collect this type of information when you take the

snapshot, as it could be unavailable if the application ends before you run the LIST APPLICATIONS command.

Note that more than one application can hold a shared lock on an object for which this application is waiting to obtain a lock. See lock\_mode for information about the type of lock that the application holds. If you are taking an application snapshot, only one of the application IDs holding a lock on the object will be returned. If you are taking a lock snapshot, all of the application IDs holding a lock on the object will be returned.

## appl\_id\_oldest\_xact - Application with Oldest Transaction

The application ID (which corresponds to the agent\_id value from the application snapshot) of the application that has the oldest transaction.

### Element identifier

appl\_id\_oldest\_xact

### Element type

information

Table 274. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic

### Usage

This element can help you determine which application has the oldest active transaction. This application can be forced to free up log space. If it is taking up a great deal of log space, you should examine the application to determine if it can be modified to commit more frequently.

There are times when there is not a transaction holding up logging, or the oldest transaction does not have an application ID (for example, indoubt transaction or inactive transaction). In these cases, this application's ID is not returned in the data stream.

## appl\_idle\_time - Application Idle Time

Number of seconds since an application has issued any requests to the server. This includes applications that have not terminated a transaction, for example not issued a commit or rollback.

### Element identifier

appl\_idle\_time

### Element type

information

Table 275. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl	Statement
DCS Application	dcs_appl	Statement

### Usage

This information can be used to implement applications that force users that have been idle for a specified number of seconds.

## appl\_name - Application name monitor element

The name of the application running at the client, as known to the database or Db2 Connect server.

Table 276. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
ADMINTEMPCOLUMNS administrative view and ADMIN_GET_TEMP_COLUMNS table function - Retrieve column information for temporary tables	Always collected
ADMINTEMPTABLES administrative view and ADMIN_GET_TEMP_TABLES table function - Retrieve information for temporary tables	Always collected
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Return information about an activity as an XML document	Always collected
MON_GET_AGENT table function - List agents, fenced mode processes, and system entities for the database	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	Always collected
MON_GET_UTILITY table function - Get utilities running on the database	Always collected
WLM_GET_SERVICE_CLASS_AGENTS table function - list agents running in a service class	Always collected
WLM_GET_SERVICE_CLASS_WORKLOAD_OCCURRENCES table function - list workload occurrences	Always collected

Table 277. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl_id_info	Basic
Lock	appl_lock_list	Basic
DCS Application	dcsl_appl_info	Basic

Table 278. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Locking	-	Always collected
Unit of work	-	Always collected
Connections	event_connheader	Always collected
Activities	event_activity	Always collected
Threshold violations	event_thresholdviolations	Always collected
Change history	changesummary	Always collected

## Usage

This element can be used with **appl\_id** to relate data items with your application.

In a client-server environment, this name is passed from the client to the server when establishing the database connection. Any non-English characters in the application name will be removed. A CLI application can set the SQL\_ATTR\_INFO\_PROGRAMNAME attribute with a call to SQLSetConnectAttr. When SQL\_ATTR\_INFO\_PROGRAMNAME is set before the connection to the server is established, the value specified overrides the actual client application name and will be the value that is displayed in the **appl\_name** monitor element.

In situations where the client application code page is different from the code page under which the database system monitor is running, you can use **codepage\_id** to help translate **appl\_name**.

## appl\_priority - Application Agent Priority

The priority of the agents working for this application.

### Element identifier

appl\_priority

### Element type

information

Table 279. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl	Basic

Table 280. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Connection	event_conn	Always collected

## Usage

Use this element to check whether applications are running with the expected priorities. Application priorities can be set by an administrator. They can be changed by the governor utility (**db2gov**).

The governor is used by the database system to monitor and change the behavior of applications running against a database. This information is used to schedule applications and balance system resources.

A governor daemon collects statistics about the applications by taking snapshots. It checks these statistics against the rules governing applications running on that database. If the governor detects a rule violation, it takes the appropriate action. These rules and actions were specified by you in the governor configuration file.

If the action associated with a rule is to change an application's priority, the governor changes the priority of the agents in the partition where the violation was detected.

## appl\_priority\_type - Application Priority Type

Operating system priority type for the agent working on behalf of the application.

### Element identifier

appl\_priority\_type

### Element type

information

*Table 281. Snapshot Monitoring Information*

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl	Basic

*Table 282. Event Monitoring Information*

Event Type	Logical Data Grouping	Monitor Switch
Connection	event_conn	Always collected

### Usage

Dynamic priority is recalculated by the operating system based on usage. Static priority does not change.

## appl\_section\_inserts - Section Inserts monitor element

Inserts of SQL sections by an application from its shared SQL workspace.

The working copy of any executable section is stored in a shared SQL workspace. This is a count of when a copy was not available and had to be inserted.

*Table 283. Table function monitoring information*

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics	REQUEST METRICS BASE

Table 283. Table function monitoring information (continued)

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics	REQUEST METRICS BASE

Table 284. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Connection	event_conn	Always collected
Database	event_db	Always collected
Statistics	event_scmetrics	REQUEST METRICS BASE
Statistics	event_superclassmetrics	REQUEST METRICS BASE
Statistics	event_wlmetrics	REQUEST METRICS BASE
Unit of Work	uow_metrics	REQUEST METRICS BASE

Table 285. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic
Application	appl	Basic

## appl\_section\_lookups - Section Lookups

Lookups of SQL sections by an application from its shared SQL workspace.

Each agent has access to a shared SQL workspace where the working copy of any executable section is kept. This counter indicates how many times the SQL work area was accessed by agents for an application.

Table 286. Table function monitoring information

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics	REQUEST METRICS BASE

Table 286. Table function monitoring information (continued)

Table Function	Monitor Element Collection Level
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics	REQUEST METRICS BASE

Table 287. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Connection	event_conn	Always collected
Database	event_db	Always collected
Statistics	event_scmetrics	REQUEST METRICS BASE
Statistics	event_superclassmetrics	REQUEST METRICS BASE
Statistics	event_wlmetrics	REQUEST METRICS BASE
Unit of Work	uow_metrics	REQUEST METRICS BASE

Table 288. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic
Application	appl	Basic

For snapshot monitoring, this counter can be reset.

## appl\_status - Application status monitor element

The current status of the application.

Table 289. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl_id_info	Basic
Lock	appl_lock_list	Basic

Table 290. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Locking	-	Always collected
Connection	event_conn	Always collected

### Usage

For a locking event monitor's lock wait, lock timeout, or deadlock event, the lock requester reports the appl\_status value that was in effect before entering lock wait status rather than the current lock wait status.

With the APPLICATIONS and SNAPAPPL\_INFO Administrative views deprecated, information that is returned from the appl\_status monitor element can be obtained by examining the WORKLOAD\_OCCURRENCE\_STATE monitor element from the MON\_GET\_CONNECTION interface along with the EVENT\_STATE, EVENT\_TYPE and EVENT\_OBJECT monitor elements from the MON\_GET\_AGENT interface. For example, to monitor the SQLM\_LOCKWAIT application status, the EVENT\_STATE, EVENT\_TYPE and EVENT\_OBJECT columns in the MON\_GET\_AGENT interface can be used to determine which agents are waiting on locks.

This element can help you diagnose potential application problems. Values for this field are listed in the following table.

API Constant	Description
SQLM_AUTONOMOUS_WAIT	<b>Autonomous Wait:</b> The application is waiting for an autonomous routine to complete.
SQLM_BACKUP	<b>Backing Up Database:</b> The application is performing a backup of the database.
SQLM_COMMIT_ACT	<b>Commit Active:</b> The unit of work is committing its database changes.
SQLM_COMP	<b>Compiling:</b> The database manager is compiling an SQL statement or precompiling a plan on behalf of the application.
SQLM_CONNECTED	<b>Database Connect Completed:</b> The application has initiated a database connection and the request has completed.
SQLM_CONNECTPEND	<b>Database Connect Pending:</b> The application has initiated a database connection but the request has not yet completed.
SQLM_CREATE_DB	<b>Creating Database:</b> The agent has initiated a request to create a database and that request has not yet completed.

API Constant	Description
SQLM_DECOUPLED	<b>Decoupled from Agent:</b> There are no agents currently associated with the application. This is a normal state. When the Connection Concentrator is enabled, there is no dedicated coordinator agent, so an application can be decoupled on the coordinator partition. In non-concentrator environments, an application cannot be decoupled on the coordinator partition as there will always be a dedicated coordinator agent .
SQLM_DISCONNECTPEND	<b>Database Disconnect Pending:</b> The application has initiated a database disconnect but the command has not yet completed executing. The application may not have explicitly executed the database disconnect command. The database manager will disconnect from a database if the application ends without disconnecting.
SQLM_INTR	<b>Request Interrupted:</b> An interrupt of a request is in progress.
SQLM_IOERROR_WAIT	<b>Wait to Disable Table space:</b> The application has detected an I/O error and is attempting to disable a particular table space. The application has to wait for all other active transactions on the table space to complete before it can disable the table space.
SQLM_LOAD	<b>Data Fast Load:</b> The application is performing a "fast load" of data into the database.
SQLM_LOCKWAIT	<b>Lock Wait:</b> The unit of work is waiting for a lock. After the lock is granted, the status is restored to its previous value.
SQLM QUIESCE_TABLESPACE	<b>Quiescing a Table space:</b> The application is performing a quiesce table space request.
SQLM_RECOMP	<b>Recompiling:</b> The database manager is recompiling (that is, rebinding) a plan on behalf of the application.
SQLM_REMOTE_RQST	<b>Federated request pending:</b> The application is waiting for results from a federated data source.
SQLM_RESTART	<b>Restarting Database:</b> The application is restarting a database in order to perform crash recovery.
SQLM_RESTORE	<b>Restoring Database:</b> The application is restoring a backup image to the database.
SQLM_ROLLBACK_ACT	<b>Rollback Active:</b> The unit of work is rolling back its database changes.
SQLM_ROLLBACK_TO_SAVEPOINT	<b>Rollback to savepoint:</b> The application is rolling back to a savepoint.
SQLM_TEND	<b>Transaction Ended:</b> The unit of work is part of a global transaction that has ended but has not yet entered the prepared phase of the two-phase commit protocol.
SQLM_THABRT	<b>Transaction Heuristically Rolled Back:</b> The unit of work is part of a global transaction that has been heuristically rolled-back.

API Constant	Description
SQLM_THCOMT	<b>Transaction Heuristically Committed:</b> The unit of work is part of a global transaction that has been heuristically committed.
SQLM_TPREP	<b>Transaction Prepared:</b> The unit of work is part of a global transaction that has entered the prepared phase of the two-phase commit protocol.
SQLM_UNLOAD	<b>Data Fast Unload:</b> The application is performing a "fast unload" of data from the database.
SQLM_UOWEXEC	<b>UOW Executing:</b> The database manager is executing requests on behalf of the unit of work.
SQLM_UOWQUEUED	<b>UOW Queued:</b> The unit of work is queued, waiting for another activity to complete execution. The unit of work is queued because a wlm concurrency threshold has been defined and the concurrency limit has been reached or the adaptive workload manager is enabled and the currently executing queries have exhausted all available resources.
SQLM_UOWWAIT	<b>UOW Waiting:</b> The database manager is waiting on behalf of the unit of work in the application. This status typically means that the system is executing in the application's code.
SQLM_WAITFOR_REMOTE	<b>Pending remote request:</b> The application is waiting for a response from a remote partition in a partitioned database instance.

## application\_handle - Application handle monitor element

A system-wide unique ID for the application. In a single-member database configuration, this identifier consists of a 16-bit counter. In a multi-member configuration, this identifier consists of the coordinating member number concatenated with a 16-bit counter. In addition, this identifier is the same on every member where the application may make a secondary connection.

Table 291. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
MON_GET_AGENT table function - List agents, fenced mode processes, and system entities for the database	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected
MON_GET_LATCH table function - List all latches in the current member	Always collected

Table 291. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_LOCKS table function - list all locks in the currently connected database	Always collected
MON_GET_MEMORY_POOL table function - Get memory pool information	Always collected
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	Always collected
MON_GET_UTILITY table function - Get utilities running on the database	Always collected
MON_GET_WLM_ADMISSION_QUEUE table function - Return a list of queued activities	Always Collected
WLM_GET_CONN_ENV - get settings for activity data collection for a connection	Always collected
WLM_GET_SERVICE_CLASS_WORKLOAD_OCCURRENCES table function - list workload occurrences	Always collected

Table 292. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl_id_info	Basic
Lock	appl_lock_list	Basic
DCS Application	dcs_appl_info	Basic
Transaction	event_xact	-

Table 293. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Locking	-	Always collected
Unit of work	-	Always collected
Connections	event_connheader	Always collected
Statements	event_stmt	Always collected
Statements	event_subsection	Always collected
Deadlocks <sup>1</sup>	event_dlconn	Always collected
Deadlocks with Details <sup>1</sup>	event_detailed_dlconn	Always collected
Threshold violations	event_thresholdviolations	Always collected

Table 293. Event Monitoring Information (continued)

Event Type	Logical Data Grouping	Monitor Element Collection Level
Activity	<ul style="list-style-type: none"> <li>• event_activity</li> <li>• event_activitystmt</li> <li>• event_activityvals</li> <li>• event_activitymetrics</li> </ul>	Always collected
Change history	changesummary	Always collected

**1**

This event monitor has been deprecated. Its use is no longer recommended and might be removed in a future release. Use the CREATE EVENT MONITOR FOR LOCKING statement to monitor lock-related events, such as lock timeouts, lock waits, and deadlocks.

**Usage**

This monitor element is an alias of the **agent\_id** monitor element.

When returned by MON\_GET\_MEMORY\_POOL, this monitor element is NULL except when the memory pool being described is one of the following types:

- APPLICATION
- STATISTICS
- STATEMENT
- SORT\_PRIVATE.

**appls\_cur\_cons - Applications Connected Currently**

Indicates the number of applications that are currently connected to the database.

Table 294. Table function monitoring information

Table function	Monitor element collection level
MON_GET_DATABASE table function - Get database level information	Always collected
MON_GET_DATABASE_DETAILS table function - Get database information metrics	Always collected

Table 295. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic
Lock	db_lock_list	Basic

**Usage**

You may use this element to help you understand the level of activity within a database and the amount of system resource being used.

It can help you adjust the setting of the *maxappls* and *max\_coordagents* configuration parameters. For example, its value is always the same as *maxappls*, you may want to increase the value of *maxappls*. See the *rem\_cons\_in* and the *local\_cons* monitor elements for more information.

## appls\_in\_db2 - Applications Executing in the Database Currently

Indicates the number of applications that are currently connected to the database, and for which the database manager is currently processing a request.

Table 296. Table function monitoring information

Table function	Monitor element collection level
MON_GET_DATABASE table function - Get database level information	Always collected
MON_GET_DATABASE_DETAILS table function - Get database information metrics	Always collected

Table 297. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic

## arm\_correlator - Application response measurement correlator monitor element

Identifier of a transaction in the Application Response Measurement (ARM) standard.

Table 298. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activities	event_activity	-

### Usage

This element can be used to link an activity collected by the activities event monitor to the applications associated with the activity, if such applications also support the Application Response Measurement (ARM) standard.

## associated\_agents\_top - Maximum Number of Associated Agents

The maximum number of subagents associated with this application.

Table 299. Table function monitoring information

Table function	Monitor element collection level
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics	Always collected

Table 300. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl	Basic

## async\_runstats - Total number of asynchronous RUNSTATS requests monitor element

The total number of successful asynchronous RUNSTATS activities performed by real-time statistics gathering for all the applications in the database. Values reported by all the database partitions are aggregated together.

**Important:** The SQL administrative views and table functions that return this monitor element are deprecated. For SQL access to this information, see the **total\_async\_runstats** monitor element.

Table 301. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Statement

For snapshot monitoring, this counter can be reset.

Table 302. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Database	event_db	Always collected

### Usage

Use this element to determine how many successful asynchronous RUNSTATS activities have been performed by real-time statistics gathering. This value changes frequently. In order to get a better view of the system usage, take a snapshot at specific intervals over an extended period of time. When used in conjunction with **sync\_runstats** and **stats\_fabrications** monitor elements, this element can help you to track the different types of statistics collection activities related to real-time statistics gathering and analyze their performance impact.

This monitor element is an alias for the **total\_async\_runstats** monitor element.

## audit\_events\_total - Total audit events monitor element

The total number of audit events generated.

Table 303. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	ACTIVITY METRICS BASE
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	ACTIVITY METRICS BASE

Package cache	Reported in the activity_metrics document.	ACTIVITY METRICS BASE

## Usage

Use this monitor element to determine the amount of time an agent spends waiting to open and write an audit event synchronously to disk.

In a typical scenario, only one agent attempts to open the audit log file at a time, as the other agents wait for access to the audit common subsystem before opening the file. Therefore, the wait time usually represents the time spent waiting to write the file to disk by the operating system. Audit utilities might lock the audit log file during execution, which causes a longer than normal wait time for agents to open and write to the audit log file. If asynchronous auditing is enabled, audit events that are larger than the asynchronous audit buffer are written directly to disk, instead of to the buffer, and contribute to the wait time.

Outside of the special audit utility scenario, the wait time depends on the speed of the disks and how quickly the operating system can write the data to them. In order to reduce this wait time for a given application and audit configuration, you might tune the operating system or use faster disks.

## audit\_file\_writes\_total - Total audit files written monitor element

The total number of times an agent has had to wait to write an audit event directly to disk.

Table 307. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	ACTIVITY METRICS BASE
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	ACTIVITY METRICS BASE
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_PKG_CACHE_STMT table function - Get SQL statement activity metrics in the package cache	ACTIVITY METRICS BASE
MON_GET_PKG_CACHE_STMT_DETAILS table function - get detailed metrics for package cache entries	ACTIVITY METRICS BASE

Table Function	Monitor Element Collection Level
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	ACTIVITY METRICS BASE

Table 308. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activities	event_activity (reported in the details_xml document)	ACTIVITY METRICS BASE
Activities	event_activitymetrics	ACTIVITY METRICS BASE
Statistics	event_scstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_superclassstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_wlstats (reported in the metrics document)	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE
Package cache	Reported in the activity_metrics document.	ACTIVITY METRICS BASE

## Usage

Use this monitor element in conjunction with the **audit\_file\_write\_wait\_time** monitor element to determine the average time an application request spends waiting to open and write an audit event synchronously to disk.

### **audit\_subsystem\_wait\_time - Audit subsystem wait time monitor element**

Time spent waiting for space in audit buffer. Waiting occurs when audit buffer is full and agent must wait for audit daemon to write buffer to disk. The value is given in milliseconds.

Table 309. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	ACTIVITY METRICS BASE
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	ACTIVITY METRICS BASE
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE

Table 309. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_PKG_CACHE_STMT table function - Get SQL statement activity metrics in the package cache	ACTIVITY METRICS BASE
MON_GET_PKG_CACHE_STMT_DETAILS table function - get detailed metrics for package cache entries	ACTIVITY METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE

Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE
Package cache	Reported in the activity_metrics document.	ACTIVITY METRICS BASE

## Usage

Use this monitor element to determine the amount of time an agent spends waiting to access the audit common subsystem, while the audit common subsystem is busy handling events for other agents.

Certain common portions of the audit subsystem can only be accessed by a single agent at a time. The value of this monitor element indicates the amount of time that an agent must wait to access the audit common subsystem. This includes time spent by an agent that has filled the current asynchronous buffer waiting for the audit daemon to finish writing out a previous asynchronous buffer to disk. Other agents that are waiting while writing to the audit log file or waiting to make a request of the audit daemon have also accessed the audit common subsystem and wait times there will be reflected in this value.

To reduce this wait time, you might change the value of the **audit\_buf\_sz** configuration parameter if asynchronous auditing is in use. You can increase the value of the **audit\_buf\_sz** configuration parameter until further increases no longer show any reductions in the audit common subsystem wait time. At this point, the asynchronous buffers are large enough such that the daemon is able to write one full buffer to disk before the next buffer is full, and then the daemon is no longer a bottleneck. If the value of the **audit\_buf\_sz** configuration parameter must be increased to such an extent that too many audit records could be lost if a system failure were to occur, then you might reduce the wait time by tuning the operating system or using faster disks. If further reduction in the wait time is necessary, then use audit policies to reduce the number of audit events generated.

## **audit\_subsystem\_waits\_total** - Total audit subsystem waits monitor element

Number of times audit has waited for a buffer write.

Table 311. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	ACTIVITY METRICS BASE
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	ACTIVITY METRICS BASE
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE

Table 311. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE

Activities	event_activity (reported in the details_xml document)	ACTIVITY METRICS BASE
Activities	event_activitymetrics	ACTIVITY METRICS BASE
Statistics	event_scstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_superclassstats (reported in the metrics document)	REQUEST METRICS BASE

Table 312. Event Monitoring Information (continued)

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_wlstats (reported in the metrics document)	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE
Package cache	Reported in the activity_metrics document.	ACTIVITY METRICS BASE

## Usage

Use this monitor element to determine the total number of times an agent has had to access the audit common subsystem. The generation of one audit event may need to access the audit common subsystem none, one, or more times to record the event. Use the **audit\_events\_total** monitor element to determine the exact number of audit events generated.

## auth\_id - Authorization ID

The authorization ID of the user who invoked the application that is being monitored. On a Db2 Connect gateway node, this is the user's authorization ID on the host.

Table 313. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
PD_GET_DIAG_HIST table function - Return records from a given facility	Always collected

Table 314. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl_id_info	Basic
Lock	appl_lock_list	Basic
DCS Application	dcs_appl_info	Basic

Table 315. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Locking	-	Always collected
Unit of work	-	Always collected
Connections	event_connheader	Always collected

## Usage

In an explicit trusted connection, the **auth\_id** value does not change immediately when you switch users. Rather, the **auth\_id** is updated the first time you access the database after switching users. This is because the switch user operation is always chained to the subsequent operation.

You can use this element to determine who invoked the application.

## **authn\_cache\_expired\_evictions - Authentication cache expired evictions monitor element**

Number of times the system evicted expired entries from the cache.

*Table 316. Table function monitoring information*

<b>Table function</b>	<b>Monitor element collection level</b>
MON_GET_DATABASE table function - Get database level information	ALWAYS COLLECTED
MON_GET_DATABASE_DETAILS table function - Get database information metrics	ALWAYS COLLECTED

## **authn\_cache\_group\_inserts - Authentication cache group inserts monitor element**

Number of times the system inserted new group information into the cache.

*Table 317. Table function monitoring information*

<b>Table function</b>	<b>Monitor element collection level</b>
MON_GET_DATABASE table function - Get database level information	ALWAYS COLLECTED
MON_GET_DATABASE_DETAILS table function - Get database information metrics	ALWAYS COLLECTED

## **authn\_cache\_hits - Authentication cache hits monitor element**

Number of times the system found a valid, non-expired entry in the cache that can be used to authenticate the incoming connection.

*Table 318. Table function monitoring information*

<b>Table function</b>	<b>Monitor element collection level</b>
MON_GET_DATABASE table function - Get database level information	ALWAYS COLLECTED
MON_GET_DATABASE_DETAILS table function - Get database information metrics	ALWAYS COLLECTED

## **authn\_cache\_inserts - Authentication cache inserts monitor element**

The number of times that the system inserted new authentication information into the authentication cache.

*Table 319. Table function monitoring information*

<b>Table function</b>	<b>Monitor element collection level</b>
MON_GET_DATABASE table function - Get database level information	ALWAYS COLLECTED
MON_GET_DATABASE_DETAILS table function - Get database information metrics	ALWAYS COLLECTED

## authn\_cache\_lookups - Authentication cache lookups monitor element

The number of times that the authentication cache was referenced to look for matching cached authentication information.

Table 320. Table function monitoring information

Table function	Monitor element collection level
MON_GET_DATABASE table function - Get database level information	ALWAYS COLLECTED
MON_GET_DATABASE_DETAILS table function - Get database information metrics	ALWAYS COLLECTED

## authn\_cache\_memory\_usage - Authentication cache memory usage monitor element

Amount of memory in bytes that the authentication cache is using to store user and group information.

Table 321. Table function monitoring information

Table function	Monitor element collection level
MON_GET_DATABASE table function - Get database level information	ALWAYS COLLECTED
MON_GET_DATABASE_DETAILS table function - Get database information metrics	ALWAYS COLLECTED

## authn\_cache\_valid\_evictions - Authentication cache valid evictions monitor element

Number of times the system evicted valid entries from the cache.

Table 322. Table function monitoring information

Table function	Monitor element collection level
MON_GET_DATABASE table function - Get database level information	ALWAYS COLLECTED
MON_GET_DATABASE_DETAILS table function - Get database information metrics	ALWAYS COLLECTED

## authority\_bitmap - User authorization level monitor element

The authorities granted to the user and to the groups to which the user belongs. These include authorities granted to roles that are granted to the user and to the groups to which the user belongs. Authorities granted to a user or to roles granted to the user are considered user authorities. Authorities granted to a group to which the user belongs or to roles granted to the group to which the user belongs are considered group authorities.

Table 323. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl	Basic
Application	appl_info	Basic

Table 324. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Connection	event_conn	Always collected

## Usage

The `authority_bitmap` monitor element has the format of an array. Each array element is a single character that represents whether or not the user ID has been granted a specific authority and how the user has received that authority.

Individual array elements are indexed through an index value defined in the `sql.h` file. The value of an index in the `authority_bitmap` array is called an *authority index*. For example, `SQL_DBAUTH_SYSADM` is the index to determine if the user has `SYSADM` authority.

The value of one element in the `authority_bitmap` array identified by an authority index represents whether the authority is held by an authorization ID. To determine how the authorization ID is held, for each array element identified by the authority index, use the following defines from `sql.h`:

### SQL\_AUTH\_ORIGIN\_USER

If this bit is on, then the authorization ID has the authority granted to the user or to a role granted to the user.

### SQL\_AUTH\_ORIGIN\_GROUP

If this bit is on, then the authorization ID has the authority granted to the group or to a role granted to the group.

For example, to determine if a user holds `DBADM` authority, verify the following value:

```
authority_bitmap[SQL_DBAUTH_DBADM]
```

To determine if the `DBADM` authority is held directly by the user, verify the following:

```
authority_bitmap[SQL_DBAUTH_DBADM] & SQL_AUTH_ORIGIN_USER
```

## authority\_lvl - User authorization level monitor element

The highest authority level granted to an application.

**Note:** The `authority_lvl` monitor element is deprecated. Use the `authority_bitmap` monitor element instead. See “[authority\\_bitmap - User authorization level monitor element](#)” on page 682.

Table 325. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl	Basic
Application	appl_info	Basic

Table 326. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Connection	event_conn	Always collected

## Usage

The operations allowed by an application are granted either directly or indirectly.

The following defines from `sql.h` may be used to determine the authorizations granted explicitly to a user:

- `SQL_SYSADM`

- SQL\_DBADM
- SQL\_CREATETAB
- SQL\_BINDADD
- SQL\_CONNECT
- SQL\_CREATE\_EXT\_RT
- SQL\_CREATE\_NOT\_FENC
- SQL\_SYSCTRL
- SQL\_SYSMANT

The following defines from sql.h may be used to determine indirect authorizations inherited from group or public:

- SQL\_SYSADM\_GRP
- SQL\_DBADM\_GRP
- SQL\_CREATETAB\_GRP
- SQL\_BINDADD\_GRP
- SQL\_CONNECT\_GRP
- SQL\_CREATE\_EXT\_RT\_GRP
- SQL\_CREATE\_NOT\_FENC\_GRP
- SQL\_SYSCTRL\_GRP
- SQL\_SYSMANT\_GRP

## auto\_storage\_hybrid - Hybrid automatic storage table space indicator monitor element

If the table space is an automatic storage table space with some non-automatic storage containers, this monitor element returns a value of 1. Otherwise, it returns a value of 0.

*Table 327. Table Function Monitoring Information*

Table Function	Monitor Element Collection Level
MON_GET_TABLESPACE table function - Get table space metrics	Always collected

### Usage

A hybrid automatic storage table space is a table space that has been converted to be managed by automatic storage using the ALTER TABLESPACE command, but has not yet been rebalanced. This table space still has non-automatic storage containers. After the table space is rebalanced, it contains only automatic storage containers, and is no longer considered a hybrid table space.

## automatic - Buffer pool automatic monitor element

Indicates whether a particular buffer pool has self-tuning enabled. This element is set to 1 if self-tuning is enabled for the buffer pool; and 0 otherwise.

*Table 328. Table Function Monitoring Information*

Table Function	Monitor Element Collection Command and Level
MON_GET_BUFFERPOOL table function - Get buffer pool metrics	DATA OBJECT METRICS BASE

## B

### backup\_timestamp - Backup timestamp

Timestamp of the backup image.

Table 329. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Change History	changesummary	Always collected

#### Usage

For the change history event monitor:

- If UTILITY\_TYPE is BACKUP and EVENT\_TYPE is UTILSTART, the BACKUP\_TIMESTAMP value is the timestamp of the backup image. If UTILITY\_TYPE is RESTORE and EVENT\_TYPE is UTILSTOP, the BACKUP\_TIMESTAMP value is the timestamp of the backup image. For all other cases, the BACKUP\_TIMESTAMP is an empty string.
- For RESTORE, the image timestamp is not always known at the start time of the utility.

A BACKUP\_TIMESTAMP can be correlated with information stored in the database history file (for example, Lookup sequence information) using the SYSIBMADM.DB\_HISTORY administration view

### bin\_id - Histogram bin identifier monitor element

The identifier of a histogram bin. The **bin\_id** is unique within a histogram.

Table 330. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_histogrambin	-

#### Usage

Use this element to distinguish bins within the same histogram.

### binds\_precompiles - Binds/Precompiles Attempted

The number of binds and pre-compiles attempted.

Table 331. Table function monitoring information

Table function	Monitor element collection level
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE

Table 331. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_ROUTINE table function - get aggregated execution metrics for routines	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS table function - get aggregated execution metric details for routines	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics	REQUEST METRICS BASE

Table 332. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic
Application	appl	Basic

For snapshot monitoring, this counter can be reset.

Table 333. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Connection	event_conn	Always collected
Database	event_db	Always collected
Statistics	event_scmetrics	REQUEST METRICS BASE
Statistics	event_superclassmetrics	REQUEST METRICS BASE
Statistics	event_wlmetrics	REQUEST METRICS BASE
Unit of work	uow_metrics	REQUEST METRICS BASE

### Usage

You can use this element to gain insight into the current level of activity within the database manager.

This value does not include the count of *int\_auto\_rebinds*, but it does include binds that occur as a result of the REBIND PACKAGE command.

## block\_ios - Number of block I/O requests monitor element

The number of block I/O requests. More specifically, the number of times the database performs sequential prefetching of pages into the block area of the buffer pool.

Table 334. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_BUFFERPOOL table function - Get buffer pool metrics	DATA OBJECT METRICS BASE
MON_GET_CONTAINER table function - Get table space container metrics	DATA OBJECT METRICS BASE
MON_GET_DATABASE table function - Get database level information	DATA OBJECT METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	DATA OBJECT METRICS BASE
MON_GET_TABLESPACE table function - Get table space metrics	DATA OBJECT METRICS BASE

Table 335. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Buffer Pool	bufferpool	Buffer Pool

## Usage

If block-based buffer pool is enabled, this monitor element will report how often block I/O is being done. Otherwise, this monitor element will return 0. The number of block I/O requests is monitored only during sequential prefetching when using block-based buffer pools.

If block-based buffer pool is enabled and this number is very low, or close to the number of vectored I/Os (the value of the **vectored\_ios** monitor element), consider changing the block size. This state can be an indication of the following occurrences:

- The extent size of one or more table spaces bound to the buffer pool is smaller than the block size specified for the buffer pool.
- Some pages requested in the prefetch request are already present in the page area of the buffer pool.

The prefetcher allows some wasted pages in each buffer pool block, but if too many pages are wasted, then the prefetcher will decide to perform vectored I/O into the page area of the buffer pool.

To take full advantage of the sequential prefetch performance improvements that block-based buffer pools provide, it is essential to choose an appropriate value for the block size. This can, however, be difficult because multiple table spaces with different extent sizes can be bound to the same block-based buffer pool. For optimal performance, it is recommended that you bind table spaces with the same extent size to a block-based buffer pool with a block size equal to the extent size. Good performance can be achieved when the extent size of the table spaces are greater than the block size, but not when the extent size is smaller than the block size.

For example, if the extent size is 2 and the block size is 8, vectored I/O would be used instead of block I/O (block I/O would have wasted 6 pages). A reduction of the block size to 2 would solve this problem.

## blocking\_cursor - Blocking Cursor

This element indicates if the statement being executed is using a blocking cursor.

### Element identifier

blocking\_cursor

### Element type

information

Table 336. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	stmt	Statement
DCS Statement	dcx_stmt	Statement

Table 337. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Deadlocks with Details	event_detailed_dlconn	Always collected
Statements	event_stmt	Always collected

### Usage

Using blocking for data transfer for a query can improve its performance. The SQL used for a query can affect the use of blocking and might require some modification.

## blocks\_pending\_cleanup - Pending cleanup rolled-out blocks monitor element

The total number of MDC table blocks in the database that are pending asynchronous cleanup following a roll out delete.

Table 338. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
ADMINTABINFO administrative view and ADMIN_GET_TAB_INFO table function - retrieve table size and state information	Always collected

Table 339. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	-
Database	event_db	-

### Usage

Use this element to determine the number of MDC table blocks that, following the deletion of a defer cleanup roll out, have not been released back to the system as available storage.

## bottom - Histogram bin bottom monitor element

The exclusive bottom end of the range of a histogram bin. The value of this monitor element is also the top inclusive end of the range of the previous histogram bin, if there is one.

Table 340. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_histogrambin	-

## Usage

Use this element with the corresponding **top** element to determine the range of a bin within a histogram.

## boundary\_leaf\_node\_splits - Boundary leaf node splits monitor element

A boundary leaf node split is when a leaf node split is triggered by the insertion of a new highest or new lowest key into an index. The **boundary\_leaf\_node\_splits** monitor element returns the number of times a boundary leaf node was split during an insert operation.

Table 341. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_INDEX table function - Get index metrics	Always collected

## bp\_cur\_bufsz - Current Size of Buffer Pool

The current buffer pool size, in pages.

Table 342. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_BUFFERPOOL table function - Get buffer pool metrics	Always collected

Table 343. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Buffer Pool	bufferpool_nodeinfo	Buffer Pool

## bp\_id - Buffer pool identifier monitor element

This element contains the buffer pool identifier for the buffer pool that is being monitored.

Table 344. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Buffer Pool	bufferpool	Basic

## bp\_name - Buffer pool name monitor element

The name of the buffer pool.

Table 345. Table Function Monitoring Information

Table Function	Monitor Element Collection Command and Level
MON_GET_BUFFERPOOL table function - Get buffer pool metrics	Always collected

Table 346. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Buffer Pool	bufferpool	Basic

### Usage

Each database requires at least one buffer pool. Depending on your needs, you may choose to create several buffer pools, each of a different size, for a single database. The CREATE, ALTER, and DROP BUFFERPOOL statements allow you to create, change, or remove a buffer pool.

When a database is created, it has a default buffer pool called IBMDEFAULTBP with a size determined by the platform. It also has a set of system buffer pools, each corresponding to a different page size:

- IBMSYSTEMBP4K
- IBMSYSTEMBP8K
- IBMSYSTEMBP16K
- IBMSYSTEMBP32K

These system buffer pools cannot be altered.

### bp\_new\_buffsz - New Buffer Pool Size

The size the buffer pool will be changed to once the database is restarted. When the ALTER BUFFERPOOL statement is executed as DEFERRED, the buffer pool size is not changed until the database is stopped and restarted.

Table 347. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Buffer Pool	bufferpool_nodeinfo	Buffer Pool

### bp\_pages\_left\_to\_remove - Number of Pages Left to Remove

The number of pages left to remove from the buffer pool before the buffer pool resize is completed. This applies only to buffer pool resize operations invoked by ALTER BUFFERPOOL statements executed as IMMEDIATE.

Table 348. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_BUFFERPOOL table function - Get buffer pool metrics	Always collected

Table 349. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Buffer Pool	bufferpool_nodeinfo	Buffer Pool

### bp\_tbsp\_use\_count - Number of Table Spaces Mapped to Buffer Pool

The number of table spaces using this buffer pool.

Table 350. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_BUFFERPOOL table function - Get buffer pool metrics	Always collected

Table 351. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Buffer Pool	bufferpool_nodeinfo	Buffer Pool

## buff\_auto\_tuning - FCM buffer auto-tuning indicator monitor element

Indicates whether the number of fast communication manager (FCM) buffers is set and tuned automatically. A value of 1 means "Yes"; a value of 0 means "No".

Table 352. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_FCM - Get FCM metrics	Always collected

### Usage

FCM buffer auto-tuning is enabled by setting the **fcm\_num\_buffers** configuration parameter to AUTOMATIC.

## buff\_free - FCM Buffers Currently Free

This element indicates the number of FCM buffers currently free.

### Element identifier

buff\_free

### Element type

gauge

Table 353. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_FCM - Get FCM metrics	Always collected

Table 354. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	fcm	Basic

### Usage

To calculate the percentage of free FCM buffers, use the following formula:

$$(\text{buff\_free}/\text{buff\_total}) * 100$$

If the percentage of free FCM buffers falls below 20% and if the FCM buffer auto-tuning is enabled, then the database manager will adjust the FCM buffer numbers.

If the percentage of free FCM buffers falls below 20% and if the FCM buffer auto-tuning is not enabled, then you need to tune the **fcm\_num\_buffers** configuration parameter.

## buff\_free\_bottom - Minimum FCM Buffers Free

The lowest number of free FCM buffers reached during processing.

Table 355. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_FCM - Get FCM metrics	Always collected

Table 356. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	fcm	Basic

### Usage

Use this element along with the **fcm\_num\_buffers** configuration parameter to determine the maximum FCM buffer pool utilization. If the value of the **buff\_free\_bottom** monitor element is low, increase the value of the **fcm\_num\_buffers** configuration parameter to ensure that operations do not run out of FCM buffers. If the value of the **buff\_free\_bottom** monitor element is high, decrease the value of the **fcm\_num\_buffers** configuration parameter to conserve system resources.

## buff\_max - Maximum possible number of FCM buffers monitor element

Maximum number of fast communication manager (FCM) buffers that can be allocated, based on the amount of virtual memory reserved when the instance was started.

Table 357. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_FCM - Get FCM metrics	Always collected

Table 358. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	fcm	Basic

### Usage

This internal monitor element is used by IBM Support only.

## buff\_total - Number of currently allocated FCM buffers monitor element

Number of fast communication manager (FCM) buffers currently allocated. This number includes both in-use buffers and free buffers.

Table 359. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_FCM - Get FCM metrics	Always collected

Table 360. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	fcm	Basic

## Usage

If the **buff\_auto\_tuning** monitor element indicates that FCM is being tuned automatically, then the value of the **buff\_total** monitor element is adjusted based on the demand for FCM buffers.

To determine the number of FCM buffers currently in use, use the following formula:

```
buff_total - buff_free
```

To calculate the percentage of free FCM buffers, use the following formula:

```
(buff_free/buff_total) * 100
```

If the percentage of free FCM buffers falls below 20% and if the FCM buffer auto-tuning is enabled, then the database manager will adjust the FCM buffer numbers.

If the percentage of free FCM buffers falls below 20% and if the FCM buffer auto-tuning is not enabled, then you need to tune the **fcnum\_buffers** configuration parameter.

## byte\_order - Byte Order of Event Data

The byte ordering of numeric data, specifically whether the event data stream was generated on a "big endian" server (for example, a RS/6000) or "little endian" server (for example, an Intel-based PC running Windows 2000).

Table 361. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Event Log Header	event_log_header	Always collected

## Usage

This information is needed to allow you to interpret numeric data in the data stream, since the byte order of integers on a "big endian" server is the reverse of the byte order on a "little endian" server.

If the application that processes the data recognizes that it is running on one type of computer hardware (for example, a big endian computer), while the event data was produced on the other type of computer hardware (for example, a little endian computer), then the monitoring application will have to reverse the bytes of numeric data fields before interpreting them. Otherwise, byte reordering is not required.

This element can be set to one of the following API constants:

- SQLM\_BIG\_ENDIAN
- SQLM\_LITTLE\_ENDIAN

## bytes\_total - Total number of bytes monitor element

Total number of bytes completed by the utility.

Table 362. Event monitoring information

Event type	Logical data grouping	Monitor switch
Change History	UTILSTOP	Always collected

## Usage

Bytes\_total is used only by the BACKUP change history event monitor. This element contains the actual size of the backup image, which is determined at the end of a backup process. In other words, the total number of bytes written by all the backup media sessions combined. This number varies according to the various backup options used; the counter is smaller for a compressed backup image, assuming that compression has already taken place.

## C

### cached\_timestamp - Cached timestamp monitor element

The time when the server list was cached.

*Table 363. Table Function Monitoring Information*

Table Function	Monitor Element Collection Level
MON_GET_SERVERLIST table function - get member priority details	Always collected

### call\_sql\_stmts - CALL SQL statements executed monitor element

The number of CALL statements that were executed.

*Table 364. Table function monitoring information*

Table function	Monitor element collection level
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_ROUTINE table function - get aggregated execution metrics for routines	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS table function - get aggregated execution metric details for routines	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics	REQUEST METRICS BASE

Table 365. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scmetrics	REQUEST METRICS BASE
Statistics	event_superclassmetrics	REQUEST METRICS BASE
Statistics	event_wlmmetrics	REQUEST METRICS BASE
Unit of work	uow_metrics	REQUEST METRICS BASE

### call\_stmt\_routine\_id - Call statement routine identifier monitor element

For CALL statements, this is the routine ID of the procedure being invoked.

The element returns NULL if the row does not correspond to a CALL statement.

Table 366. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ROUTINE_EXEC_LIST table function - get list of statements executed by routine	Always collected

### Usage

This element can be used to recreate the hierarchy of embedded and recursive routine calls.

### call\_stmt\_subroutine\_id - Call statement subroutine identifier monitor element

For CALL statements to a subroutine, this is the subroutine ID of the procedure being invoked.

Table 367. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ROUTINE_EXEC_LIST table function - get list of statements executed by routine	Always collected

### Usage

This element can be used to recreate the hierarchy of embedded and recursive routine calls.

### cat\_cache\_heap\_full - Catalog cache heap full monitor element monitor element

The number of times that an insert into the catalog cache failed due to a heap-full condition in the database heap.

Table 368. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Connections	event_conn	Always collected

## Usage

The catalog cache draws its storage dynamically from the database heap and even if the cache storage has not reached its limit, inserts into the catalog cache may fail due to a lack of space in the database heap. If the catalog cache heap full count is not zero, then this insert failure condition can be corrected by increasing the database heap size or reducing the catalog cache size.

### cat\_cache\_inserts - Catalog cache inserts monitor element

The number of times that the system tried to insert table descriptor or authorization information into the catalog cache.

*Table 369. Table Function Monitoring Information*

<b>Table Function</b>	<b>Monitor Element Collection Level</b>
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics (reported in DETAILS XML document)	REQUEST METRICS BASE

Table 370. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic
Application	appl	Basic

For snapshot monitoring, this counter can be reset.

Table 371. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Database	event_db	Always collected
Connection	event_conn	Always collected
Statistics	event_scstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_superclassstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_wlstats (reported in the metrics document)	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE

## Usage

In conjunction with "Catalog Cache Lookups", you can calculate the catalog cache hit ratio using the following formula:

$$1 - (\text{Catalog Cache Inserts} / \text{Catalog Cache Lookups})$$

See the **cat\_cache\_lookups** monitor element for more information about using this element.

## cat\_cache\_lookups - Catalog cache lookups monitor element

The number of times that the catalog cache was referenced to obtain table descriptor information or authorization information.

Table 372. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE

Table 372. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics (reported in DETAILS XML document)	REQUEST METRICS BASE

Table 373. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic
Application	appl	Basic

For snapshot monitoring, this counter can be reset.

Table 374. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Database	event_db	Always collected
Connection	event_conn	Always collected
Statistics	event_scstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_superclasstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_wlstats (reported in the metrics document)	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE

## Usage

This element includes both successful and unsuccessful accesses to the catalog cache. The catalog cache is referenced whenever:

- a table, view, or alias name is processed during the compilation of an SQL statement
- database authorization information is accessed
- a routine is processed during the compilation of an SQL statement

To calculate the catalog cache hit ratio use the following formula:

$$(1 - (\text{cat\_cache\_inserts} / \text{cat\_cache\_lookups}))$$

indicates how well the catalog cache is avoiding catalog accesses. If the ratio is high (more than 0.8), then the cache is performing well. A smaller ratio might suggest that the **catalogcache\_sz** configuration parameter should be increased. You should expect a large ratio immediately following the first connection to the database.

The execution of Data Definition Language (DDL) SQL statements involving a table, view, or alias will evict the table descriptor information for that object from the catalog cache causing it to be re-inserted on the next reference. In addition, GRANT and REVOKE statements for database authorization and execute privilege of routines will evict the subject authorization information from the catalog cache. Therefore, the heavy use of DDL statements and GRANT/REVOKE statements may also increase the ratio.

## cat\_cache\_overflows - Catalog Cache Overflows

The number of times that the catalog cache overflowed the bounds of its allocated memory.

Table 375. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_DATABASE table function - Get database level information	Always collected
MON_GET_DATABASE_DETAILS table function - Get database information metrics	Always collected

Table 376. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic
Application	appl	Basic

For snapshot monitoring, this counter can be reset.

Table 377. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Database	event_db	Always collected
Connection	event_conn	Always collected

## Usage

Use this element with the **cat\_cache\_size\_top** monitor element to determine whether the size of the catalog cache needs to be increased to avoid overflowing.

Catalog cache space is reclaimed by evicting table descriptor information for tables, views, or aliases, or authorization information that is not currently in use by any transaction.

If the value of the **cat\_cache\_overflows** monitor element is large, the catalog cache may be too small for the workload. Enlarging the catalog cache may improve its performance. If the workload includes transactions which compile a large number of SQL statements referencing many tables, views, aliases, user-defined functions, or stored procedures in a single unit of work, then compiling fewer SQL statements in a single transaction may improve the performance of the catalog cache. Or if the workload includes binding of packages containing many SQL statements referencing many tables, views, aliases, user-defined functions, or stored procedures, you can try splitting packages so that they include fewer SQL statements to improve performance.

## cat\_cache\_size\_top - Catalog cache high watermark monitor element

The largest logical size reached by the catalog cache.

Table 378. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic

Table 379. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Database	event_db	Always collected

### Usage

This element indicates the maximum number of bytes the catalog cache required logically for the workload run against the database since it was activated.

The catalog cache is managed by logical size, which does not include memory management usage. The **pool\_watermark** element in the database snapshot provides the physical high water mark value for memory used by the catalog cache. The logical size rather than physical size should be used for catalog cache monitoring and tuning efforts.

If the catalog cache overflowed, then this element contains the largest size reached by the catalog cache during the overflow. Check the **cat\_cache\_overflows** monitor element to determine if such a condition occurred.

You can determine the minimum size of the catalog cache required by your workload by:

```
maximum catalog cache size / 4096
```

Rounding the result up to a whole number, indicates the minimum number of 4K pages required by the catalog cache to avoid overflow.

## catalog\_node - Catalog Node Number

The node number of the node where the database catalog tables are stored.

Table 380. Table function monitoring information

Table function	Monitor element collection level
MON_GET_DATABASE table function - Get database level information	Always collected
MON_GET_DATABASE_DETAILS table function - Get database information metrics	Always collected

Table 381. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic

Table 382. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Database	event_db	Always collected

#### Usage

The catalog node is the node where all system catalog tables are stored. All access to system catalog tables must go through this node.

### catalog\_node\_name - Catalog Node Network Name

The network name of the catalog node.

#### Element identifier

catalog\_node\_name

#### Element type

information

Table 383. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic

Table 384. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Database	event_db	Always collected

#### Usage

Use this element to determine the location of a database.

### cf\_wait\_time - cluster caching facility wait time monitor element

The cf\_wait\_time monitor element stores the amount of time spent communicating with the cluster caching facility. This time does not include time spent performing any of the processing that may have been requested by, or that may occur as a result of the communications, such as granting locks or performing page reclaims. The unit of measurement is milliseconds.

Table 385. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	ACTIVITY METRICS BASE
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	ACTIVITY METRICS BASE
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE

Table 385. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_PKG_CACHE_STMT table function - Get SQL statement activity metrics in the package cache	ACTIVITY METRICS BASE
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	ACTIVITY METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	Not applicable; reports whichever elements are in the XML document that is provided as input to the formatting function.
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics	REQUEST METRICS BASE
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	ACTIVITY METRICS BASE

Table 386. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activities	event_activity (reported in the details_xml document)	ACTIVITY METRICS BASE
Statistics	event_scstats (reported in the metrics document)	REQUEST METRICS BASE

Table 386. Event Monitoring Information (continued)

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_superclasstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_wlstats (reported in the metrics document)	REQUEST METRICS BASE
Unit of work	-	REQUEST METRICS BASE
Package cache	-	ACTIVITY METRICS BASE

## Usage

This value is an indicator of the amount of time the database system spent waiting while it was communicating with the cluster caching facility.

## cf\_waits - Number of cluster caching facility waits monitor element

The number of times that the database system waited while it communicated with a cluster caching facility.

Table 387. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	ACTIVITY METRICS BASE
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	ACTIVITY METRICS BASE
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_PKG_CACHE_STMT table function - Get SQL statement activity metrics in the package cache	ACTIVITY METRICS BASE
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	ACTIVITY METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE

Table 387. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics	REQUEST METRICS BASE
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	ACTIVITY METRICS BASE

Table 388. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activities	event_activity (reported in the details_xml document)	ACTIVITY METRICS BASE
Statistics	event_scstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_superclassstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_wlstats (reported in the metrics document)	REQUEST METRICS BASE
Unit of work	-	REQUEST METRICS BASE
Package cache	-	ACTIVITY METRICS BASE

### cfg\_collection\_type - Configuration collection type

Indicates when the configuration parameter value was collected:

Table 389. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Change History	DBDBMCFG	Always collected

### Usage

The change history event monitor collected this value as:

**I**

The initial value that was captured when the event monitor was activated.

**U**

Updated value

**cfg\_name - Configuration name**

Name of the configuration parameter.

*Table 390. Event Monitoring Information*

Event Type	Logical Data Grouping	Monitor Switch
Change History	DBDBMCFG	Always collected

**Usage**

For the change history event monitor, this element identifies the configuration parameter that was updated as part of a DBCFG or DBMCFG event, or captured at event monitor startup as part of a DBCFGVALUES or DBMCFGVALUES event. These events represent the following occurrences:

**DBCFG**

Changing a database configuration parameter

**DBMCFG**

Changing a database manager configuration parameter

**DBCFGVALUES**

Capturing database configuration parameter values at event monitor startup, if a database configuration parameter was changed while the event monitor was inactive

**DBMCFGVALUES**

Capturing database manager configuration parameter values at event monitor startup, if a database manager configuration parameter was changed while the event monitor was inactive

**cfg\_old\_value - Configuration old value**

The old value for the configuration parameter or the in memory configuration parameter value.

*Table 391. Event Monitoring Information*

Event Type	Logical Data Grouping	Monitor Switch
Change History	DBDBMCFG	Always collected

**Usage**

For the change history event monitor:

- If the event is a change to a database configuration parameter (DBCFG) or a database manager configuration parameter (DBMCFG), this is the old configuration parameter value.
- If the event is a capture of database configuration parameter values (DBCFGVALUES) or database manager configuration parameter values (DBMCFGVALUES) that changed while the event monitor was inactive, this is the current in-memory configuration parameter value. This is the configuration parameter value currently in use.

## cfg\_old\_value\_flags - Configuration old value flags

This flag indicates how the old configuration parameter value was determined.

Table 392. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Change History	DBDBMCFG	Always collected

### Usage

For the change history event monitor, this element indicates how the old configuration parameter value was determined:

- AUTOMATIC
- COMPUTED
- NONE

If the event is a capture of database configuration parameter values (DBCFGVALUES) or database manager configuration parameter values (DBMCFGVALUES) that changed while the event monitor was inactive, the flags represent the current in-memory value for the configuration parameter.

## cfg\_value - Configuration value

The new value for the configuration parameter or the on-disk configuration parameter value.

Table 393. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Change History	DBDBMCFG	Always collected

### Usage

For the change history event monitor:

- If the event is a change to a database configuration parameter (DBCFG) or a database manager configuration parameter (DBMCFG), this is the new value for the configuration parameter.
- If the event is a capture of database configuration parameter values (DBCFGVALUES) or database manager configuration parameter values (DBMCFGVALUES) that changed while the event monitor was inactive, this is the on-disk configuration parameter value. The on-disk configuration parameter value is the most current value and might not be in effect yet.

## cfg\_value\_flags - Configuration value flags

This flag indicates how the new configuration parameter value was determined.

Table 394. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Change History	DBDBMCFG	Always collected

### Usage

For the change history event monitor, this element indicates how the new configuration parameter value was determined:

- AUTOMATIC
- COMPUTED
- NONE

If the event is a capture of database configuration parameter values (DBCFGVALUES) or database manager configuration parameter values (DBMCFGVALUES) that changed while the event monitor was inactive, the flags represent the current on-disk value for the configuration parameter.

## ch\_auto\_tuning - FCM channel auto-tuning indicator monitor element

Indicates whether the number of fast communication manager (FCM) channels is set and tuned automatically. A value of 1 means "Yes"; a value of 0 means "No".

Table 395. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_FCM - Get FCM metrics	Always collected

### Usage

FCM channel auto-tuning is enabled by setting the **fcm\_num\_channels** configuration parameter to AUTOMATIC.

## ch\_free - Channels Currently Free

This element indicates the number of FCM communication channels that are currently free.

Table 396. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_FCM - Get FCM metrics	Always collected

Table 397. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	fcm	Basic

### Usage

To calculate the percentage of free FCM channels, use the following formula:

$$(ch\_free/ch\_total) * 100$$

If the percentage of free FCM channels falls below 20% and if the FCM channel auto-tuning is enabled, then the database manager will adjust the FCM channel numbers.

If the percentage of free FCM channels falls below 20% and if the FCM channel auto-tuning is not enabled, then you need to tune the **fcm\_num\_channels** configuration parameter.

## ch\_free\_bottom - Minimum Channels Free

The lowest number of free FCM communication channels reached during processing.

Table 398. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_FCM - Get FCM metrics	Always collected

Table 399. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	fcm	Basic

## Usage

Use this monitor element in conjunction with the **fcm\_num\_channels** configuration parameter to determine the maximum connection entry utilization.

## ch\_max - Maximum possible number of FCM channels monitor element

Maximum number of fast communication manager (FCM) channels that can be allocated based on the amount of virtual memory reserved when the instance was started.

Table 400. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_FCM - Get FCM metrics	Always collected

Table 401. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	fcm	Basic

## Usage

This internal monitor element is used by IBM Support only.

## ch\_total - Number of currently allocated FCM channels monitor element

Number of fast communication manager (FCM) channels currently allocated. This number includes both in-use channels and free channels.

Table 402. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_FCM - Get FCM metrics	Always collected

Table 403. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	fcm	Basic

## Usage

If the **ch\_auto\_tuning** monitor element indicates that FCM is being tuned automatically, then the value of the **ch\_total** monitor element is adjusted based on the demand for FCM channels.

To determine the number of FCM channels currently in use, use the following formula:

```
ch_total - ch_free
```

To calculate the percentage of free FCM channels, use the following formula:

```
(ch_free/ch_total) * 100
```

If the percentage of free FCM channels falls below 20% and if the FCM channel auto-tuning is enabled, then the database manager will adjust the FCM channel numbers.

If the percentage of free FCM channels falls below 20% and if the FCM channel auto-tuning is not enabled, then you need to tune the **fcm\_num\_channels** configuration parameter.

## client\_acctng - Client accounting string monitor element

The data passed to the target database for logging and diagnostic purposes, if the `sqlseti` API was issued in this connection. The current value of the CLIENT\_ACCTNG special register for this connection, unit of work, or activity.

**Note:** This element is reported for the coordinating member only. On remote members, the value reported is a string with a length of 0.

This monitor element is synonymous to the **tpmon\_acc\_str** monitor element. The **client\_acctng** monitor element is used for monitoring table functions and event monitors that write to unformatted tables. The **tpmon\_acc\_str** monitor element is used for snapshot monitors and event monitors that write to tables, files, and pipes.

Table 404. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	Always collected
MON_GET_UTILITY table function - Get utilities running on the database	Always collected
WLM_GET_SERVICE_CLASS_WORKLOAD_OCCURRENCES table function - list workload occurrences	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 405. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Locking	-	Always collected
Unit of work	-	Always collected
Threshold violations	event_thresholdviolations	Always collected

Table 405. Event Monitoring Information (continued)

Event Type	Logical Data Grouping	Monitor Element Collection Level
Change history	changesummary	Always collected

## Usage

Use this element for problem determination and accounting purposes.

### client\_applname - Client application name monitor element

Identifies the server transaction program performing the transaction, if the `sqlseti` API was issued in this connection. The current value of the CLIENT\_APPLNAME special register for this connection, unit of work, or activity.

**Note:** This element is reported for the coordinating member only. On remote members, the value reported is a string with a length of 0.

This monitor element is synonymous to the `tpmon_client_app` monitor element. The `client_applname` monitor element is used for monitoring table functions and event monitors that write to unformatted tables. The `tpmon_client_app` monitor element is used for snapshot monitors and event monitors that write to tables, files, and pipes.

Table 406. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	Always collected
MON_GET_UTILITY table function - Get utilities running on the database	Always collected
WLM_GET_SERVICE_CLASS_WORKLOAD_OCCURRENCES table function - list workload occurrences	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 407. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Locking	-	Always collected
Unit of work	-	Always collected
Threshold violations	event_thresholdviolations	Always collected
Change history	changesummary	Always collected

## Usage

Use this element for problem determination and accounting purposes.

## client\_db\_alias - Database Alias Used by Application

The alias of the database provided by the application to connect to the database.

### Element identifier

client\_db\_alias

### Element type

information

Table 408. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl_id_info	Basic
Lock	appl_lock_list	Basic

Table 409. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Connections	event_connheader	Always collected

## Usage

This element can be used to identify the actual database that the application is accessing. The mapping between this name and *db\_name* could be done by using the database directories at the client node and the database manager server node.

This is the alias defined within the database manager where the database connection request originated.

This element can also be used to help you determine the authentication type, since different database aliases can have different authentication types.

## client\_hostname - Client hostname monitor element

The hostname of the machine the client application is connecting from.

Table 410. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	Always collected

Table 410. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	Always collected

Table 411. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Unit of work	-	Always collected
Threshold violations	event_thresholdviolations	Always collected
Change history	changesummary	Always collected

## client\_idle\_wait\_time - Client idle wait time monitor element

This monitor element records time spent waiting for the client to send its next request. The value is given in milliseconds.

Table 412. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE

Table 412. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics (reported in DETAILS XML document)	REQUEST METRICS BASE

Table 413. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_superclassstats (reported in the metrics document)	REQUEST METRICS BASE
Statistics	event_wlstats (reported in the metrics document)	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE

## Usage

Use this monitor element to determine the amount of time spent waiting for requests from a client, as opposed to working on requests. A high client idle time may indicate performance issues that need to be addressed on the client rather than the server.

## client\_ipaddr - Client IP address monitor element

Contains the IP address of the current client as returned by the operating system. If the client did not connect using the TCP/IP or SSL protocols, the NULL value is returned.

Table 414. Table function monitoring information

Table function	Monitor element collection level
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics	Always collected
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics	Always collected

## client\_name - Client name monitor element

This monitor element is deprecated. The value returned is not a valid value.

Table 415. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Transaction	event_connheader	
Statement	event_connheader	
Deadlock	event_connheader	
Connections	event_connheader	

## client\_pid - Client process ID monitor element

The process ID of the client application that made the connection to the database.

Table 416. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_AGENT table function - List agents, fenced mode processes, and system entities for the database	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected
WLM_GET_SERVICE_CLASS_AGENTS table function - list agents running in a service class	Always collected

Table 417. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl_info	Basic
Application	appl	Basic
DCS Application	dcs_appl_info	Basic

Table 418. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Unit of work	-	Always collected
Connections	event_connheader	Always collected
Threshold violations	event_thresholdviolations	Always collected
Change history	changesummary	Always collected

## Usage

You can use this element to correlate monitor information such as CPU and I/O time to your client application.

In the case of a DRDA AS connection, this element will be set to 0.

## client\_platform - Client operating platform monitor element

The operating system on which the client application is running.

Table 419. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected

Table 420. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl_info	Basic
Application	appl	Basic
DCS Application	dcx_appl_info	Basic

Table 421. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Unit of work	-	Always collected
Connections	event_connheader	Always collected
Threshold violations	event_thresholdviolations	Always collected
Change history	changesummary	Always collected

## Usage

This element can be used for problem determination for remote applications. Values for this field can be found in the header file `sqlmon.h`.

## client\_port\_number - Client port number monitor element

For TCP/IP connections, the port number on the client machine the application is using to communicate with the database server.

Table 422. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected

Table 422. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	Always collected

Table 423. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Unit of work	-	Always collected
Threshold violations	event_thresholdviolations	Always collected
Change history	changesummary	Always collected

### client\_prdid - Client product and version ID monitor element

The product and version that is running on the client. This monitor element is a synonym for the client\_product\_id monitor element.

Table 424. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected

Table 425. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl_id_info	Basic
DCS Application	dcs_appl_info	Basic

Table 426. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Unit of work	-	Always collected
Connections	event_connheader	Always collected
Threshold violations	event_thresholdviolations	Always collected

### Usage

Use this element to identify the product and code version of the data server client. It is in the form PPPVRRM, where:

- PPP identifies the product. This is "SQL" for IBM relational database products.
- VV identifies a 2-digit version number.
- RR identifies a 2-digit release number.
- M identifies a 1-character modification level (0-9 or A-Z).

## client\_protocol - Client communication protocol monitor element

The communication protocol that the client application is using to communicate with the server.

Table 427. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected

Table 428. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl_info	Basic
Application	appl	Basic
DCS Application	dcs_appl_info	Basic

Table 429. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Unit of work	-	Always collected
Connections	event_connheader	Always collected
Threshold violations	event_thresholdviolations	Always collected
Change history	changesummary	Always collected

### Usage

This element can be used for problem determination for remote applications. Values for this field are:

#### LOCAL

The client is running on the same node as the server and no communication protocol is in use.

#### TCPIP4

TCP/IPv4

#### TCPIP6

TCP/IPv6

#### SSL4

SSL over TCP/IPv4

#### SSL6

SSL over TCP/IPv6

## client\_userid - Client user ID monitor element

The client user ID generated by a transaction manager and provided to the server, if the `sqlseti` API is used. The current value of the CLIENT\_USERID special register for this connection, unit of work, or activity.

**Note:** This element is reported for the coordinating member only. On remote members, the value reported is a string with a length of 0.

This monitor element is synonymous to the **tpmon\_client\_userid** monitor element. The **client\_userid** monitor element is used for monitoring table functions and event monitors that write to unformatted tables. The **tpmon\_client\_userid** monitor element is used for snapshot monitors and event monitors that write to tables, files, and pipes.

Table 430. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	Always collected
MON_GET_UTILITY table function - Get utilities running on the database	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 431. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Locking	-	Always collected
Unit of work	-	Always collected
Threshold violations	event_thresholdviolations	Always collected
Change history	changesummary	Always collected

## Usage

Use this element in application server or Transaction Processing monitor environments to identify the end-user for whom the transaction is being executed.

## client\_wrkstname - Client workstation name monitor element

Identifies the client's system or workstation (for example CICS EITERMID), if the `sqlseti` API was issued in this connection. The current value of the CLIENT\_WRKSTNNAME special register for this connection, unit of work, or activity.

**Note:** This element is reported for the coordinating member only. On remote members, the value reported is a string with a length of 0.

This monitor element is synonymous to the **tpmon\_client\_wkstn** monitor element. The **client\_wrkstnname** monitor element is used for monitoring table functions and event monitors that write to unformatted tables. The **tpmon\_client\_wkstn** monitor element is used for snapshot monitors and event monitors that write to tables, files, and pipes.

Table 432. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
MON_GET_CONNECTION table function - Get connection metrics	Always collected
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics (reported in DETAILS XML document)	Always collected
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	Always collected
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics (reported in DETAILS XML document)	Always collected
MON_GET_UTILITY table function - Get utilities running on the database	Always collected
WLM_GET_SERVICE_CLASS_WORKLOAD_OCCURRENCES table function - list workload occurrences	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

Table 433. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Element Collection Level
Locking	-	Always collected
Unit of work	-	Always collected
Threshold violations	event_thresholdviolations	Always collected
Change history	changesummary	Always collected

## Usage

Use this element to identify the user's machine by node ID, terminal ID, or similar identifiers.

### **codepage\_id - ID of Code Page Used by Application**

The code page identifier.

Table 434. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Application	appl_id_info	Basic
Lock	appl_lock_list	Basic
DCS Application	dc_s_appl_info	Basic

Table 435. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Event Log Header	event_log_header	Always collected
Connections	event_connheader	Always collected

### Usage

For snapshot monitor data, this is the code page at the partition where the monitored application started. This identifier may be used for problem determination for remote applications. You may use this information to ensure that data conversion is supported between the application code page and the database code page (or for DRDA host databases, the host CCSID). For information about supported code pages, see the *Administration Guide*.

For event monitor data, this is the code page of the database for which event data is collected. You can use this element to determine whether your event monitor application is running under a different code page from that used by the database. Data written by the event monitor uses the database code page. If your event monitor application uses a different code page, you may need to perform some character conversion to make the data readable.

## col\_object\_l\_pages - Column-organized logical pages monitor element

The number of logical pages used on disk by column-organized data contained in this table.

Table 436. Table function monitoring information

Table function	Monitor element collection level
MON_GET_TABLE table function - get table metrics	Always collected

### Usage

This value might be:

- More than the amount of space allocated for the object. This can happen when you use the RECLAIM EXTENTS ONLY option with the REORG TABLE command. In this case, reclaimed extents are included in the logical number of pages returned by MON\_GET\_TABLE.
- Less than the amount of space physically allocated for the object. This can happen when you use the REUSE STORAGE option of the TRUNCATE statement. This option causes storage allocated for the table to continue to be allocated, although the storage will be considered empty. In addition, the value for this monitor element might be less than the amount of space logically allocated for the object, because the total space logically allocated includes a small amount of additional meta data.

## col\_object\_l\_size - Column-organized data object logical size monitor element

Amount of disk space logically allocated for the column-organized data in the table, reported in kilobytes.

Table 437. Table function monitoring information

Table function	Monitor element collection level
ADMIN_GET_TAB_INFO table function - retrieve table size and state information	Always collected

### Usage

This size represents the logical size of the base column-organized table data only.

## col\_object\_p\_size - Column-organized data object physical size monitor element

Amount of disk space physically allocated for the column-organized data in the table, reported in kilobytes.

Table 438. Table function monitoring information

Table function	Monitor element collection level
ADMIN_GET_TAB_INFO table function - retrieve table size and state information	Always collected

### Usage

The size returned takes into account full extents allocated for the table and includes the EMP extents for objects created in DMS table spaces. This size represents the physical size of the base columnar data only. Space consumed by LOB data, Long Data, Indexes and XML objects are reported by other columns.

## col\_synopsis\_rows\_inserted - Column-organized synopsis table rows inserted monitor element

The number of column-organized synopsis table row insertions that were attempted.

Table 439. Table function monitoring information

Table function	Monitor element collection level
MON_GET_ACTIVITY table function - Return a list of activities	ACTIVITY METRICS BASE
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details	ACTIVITY METRICS BASE
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE

Table 439. Table function monitoring information (continued)

Table function	Monitor element collection level
MON_GET_PKG_CACHE_STMT table function - Get SQL statement activity metrics in the package cache	ACTIVITY METRICS BASE
MON_GET_PKG_CACHE_STMT_DETAILS - Get detailed metrics for package cache entries	ACTIVITY METRICS BASE
MON_GET_ROUTINE table function - get aggregated execution metrics for routines	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS table function - get aggregated execution metric details for routines	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics	REQUEST METRICS BASE
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	ACTIVITY METRICS BASE

Table 440. Event monitoring information

Event Type	Logical Data Grouping	Monitor Switch
Activities	event_activitymetrics	ACTIVITY METRICS BASE
Package cache	pkgcache_metrics	ACTIVITY METRICS BASE
Statistics	event_scmetrics	REQUEST METRICS BASE
Statistics	event_wlmetrics	REQUEST METRICS BASE
Unit of work	uow_metrics	REQUEST METRICS BASE

## col\_vector\_consumer\_overflows - Columnar vector consumer overflows monitor element

The number of columnar vector consumers that exceeded the available sort heap space.

Table 441. Table function monitoring information

Table function	Monitor element collection level
MON_FORMAT_XML_METRICS_BY_ROW	REQUEST METRICS BASE
MON_GET_ACTIVITY	ACTIVITY METRICS BASE
MON_GET_ACTIVITY_DETAILS	ACTIVITY METRICS BASE
MON_GET_CONNECTION	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS	REQUEST METRICS BASE
MON_GET_DATABASE	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS	REQUEST METRICS BASE
MON_GET_PKG_CACHE_STMT	ACTIVITY METRICS BASE
MON_GET_PKG_CACHE_STMT_DETAILS	ACTIVITY METRICS BASE
MON_GET_ROUTINE	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS	REQUEST METRICS BASE
MON_GET_WORKLOAD	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS	REQUEST METRICS BASE
WLM_GET_WORKLOAD_OCCURENCE_ACTIVITIES	ACTIVITY METRICS BASE

Table 442. Event monitoring information

Event type	Logical data grouping	Monitor switch
Activities	event_activitymetrics	ACTIVITY METRICS BASE
Package cache	pkgcache_metrics	ACTIVITY METRICS BASE
Statistics	event_scmetrics	REQUEST METRICS BASE
Statistics	event_superclassmetrics	REQUEST METRICS BASE
Statistics	event_wlmmetrics	REQUEST METRICS BASE
Unit of work	uow_metrics	REQUEST METRICS BASE

## comm\_exit\_wait\_time - Communication exit wait time monitor element

Time spent waiting for the return from a communication exit library API function. The value is given in milliseconds.

Table 443. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	ACTIVITY METRICS BASE
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	ACTIVITY METRICS BASE
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_PKG_CACHE_STMT table function - Get SQL statement activity metrics in the package cache	ACTIVITY METRICS BASE
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	ACTIVITY METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics	REQUEST METRICS BASE

Table 443. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	ACTIVITY METRICS BASE

Table 444. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activities	event_activitymetrics	ACTIVITY METRICS BASE
Package Cache	pkgcache_metrics	ACTIVITY METRICS BASE
Statistics	Event_scstats (reported in the details_xml document).	REQUEST METRICS BASE
Statistics	Event_wlstats (reported in the details_xml document).	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE

### **comm\_exit\_waits - Communication exit number of waits monitor element**

The number of times a communication exit library API function is called.

Table 445. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	ACTIVITY METRICS BASE
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	ACTIVITY METRICS BASE
MON_GET_CONNECTION table function - Get connection metrics	REQUEST METRICS BASE
MON_GET_CONNECTION_DETAILS table function - Get detailed connection metrics	REQUEST METRICS BASE
MON_GET_DATABASE table function - Get database level information	REQUEST METRICS BASE
MON_GET_DATABASE_DETAILS table function - Get database information metrics	REQUEST METRICS BASE
MON_GET_PKG_CACHE_STMT table function - Get SQL statement activity metrics in the package cache	ACTIVITY METRICS BASE
MON_GET_PKG_CACHE_STMT_DETAILS table function - Get package cache statement metrics as an XML document	ACTIVITY METRICS BASE
MON_GET_ROUTINE - get aggregated execution metrics for routines table function	REQUEST METRICS BASE
MON_GET_ROUTINE_DETAILS - get aggregated execution metric details for routines table function	REQUEST METRICS BASE

Table 445. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUBCLASS_DETAILS table function - Get detailed service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS table function - Get service subclass metrics	REQUEST METRICS BASE
MON_GET_SERVICE_SUPERCLASS_DETAILS table function - Get detailed service subclass metrics (reported in DETAILS XML document)	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK table function - Get unit of work metrics	REQUEST METRICS BASE
MON_GET_UNIT_OF_WORK_DETAILS table function - Get detailed unit of work metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD table function - Get workload metrics	REQUEST METRICS BASE
MON_GET_WORKLOAD_DETAILS table function - Get detailed workload metrics	REQUEST METRICS BASE
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	ACTIVITY METRICS BASE

Table 446. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Activities	event_activitymetrics	ACTIVITY METRICS BASE
Package Cache	pkgcache_metrics	ACTIVITY METRICS BASE
Statistics	Event_scstats (reported in the details_xml document).	REQUEST METRICS BASE
Statistics	Event_wlstats (reported in the details_xml document).	REQUEST METRICS BASE
Unit of work	Reported in the system_metrics document.	REQUEST METRICS BASE

## comm\_private\_mem - Committed Private Memory

The amount of private memory that the instance of the database manager has currently committed at the time of the snapshot. The comm\_private\_mem value returned is only relevant on Windows operating systems.

Table 447. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	db2	Basic

## commit\_sql\_stmts - Commit Statements Attempted

The total number of SQL COMMIT statements that have been attempted.

Table 448. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
Database	dbase	Basic
Database	dbase_remote	Basic
Application	appl	Basic
Application	appl_remote	Basic
DCS Database	dcс_dbase	Basic
DCS Application	dcс_appl	Basic

For snapshot monitoring, this counter can be reset.

Table 449. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Database	event_db	Always collected
Connection	event_conn	Always collected

### Usage

A small rate of change in this counter during the monitor period may indicate that applications are not doing frequent commits, which may lead to problems with logging and data concurrency.

You can also use this element to calculate the total number of units of work using the following expression:

```
commit_sql_stmts
+ int_commits
+ rollback_sql_stmts
+ int_rollbacks
```

**Note:** The units of work calculated will only include those since the later of:

- The connection to the database (for database-level information, this is the time of the first connection)
- The last reset of the database monitor counters.

This calculation can be done at a database or application level.

## comp\_env\_desc - Compilation environment monitor element

This element stores information about the compilation environment used when compiling the SQL statement.

Table 450. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_PKG_CACHE_STMT table function - Get SQL statement activity metrics in the package cache	Always collected

Table 450. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_PKG_CACHE_STMT_DETAILS table function - get detailed metrics for package cache entries	Always collected

Table 451. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Deadlocks with Details History Values	event_stmt_history	Always collected
Deadlocks with Details History	event_stmt_history	Always collected
Activities	event_activitystmt	Always collected
Package cache	-	Always collected

## Usage

This monitor element stores the compilation environment description in a binary large object. To view this information in readable form, use the COMPILATION\_ENV table function.

You can provide this element as input to the COMPILATION\_ENV table function, or to the SET COMPILATION ENVIRONMENT SQL statement.

## completion\_status - Completion status monitor element

The status of the unit of work.

Table 452. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Unit of work	-	Always collected

## Usage

Use this element to determine if the unit of work ended due to a deadlock or abnormal termination. The possible values are listed in the sqllib/misc/DB2EvmonUOW.xsd file:

- UNKNOWN
- COMMIT
- ROLLBACK
- GLOBAL\_COMMIT
- GLOBAL\_ROLLBACK
- XA\_END
- XA\_PREPARE

## CONCURRENT\_CONNECTION\_TOP - The concurrent connection peak monitor element

High watermark for concurrent coordinator connections in this service subclass or superclass since the last reset.

Table 453. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 454. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected
Statistics	event_superclasstats	Always collected

## con\_elapsed\_time - Most Recent Connection Elapsed Time

The elapsed time that the DCS application that most recently disconnected from this host database was connected.

### Element identifier

con\_elapsed\_time

### Element type

time

Table 455. Snapshot Monitoring Information

Snapshot Level	Logical Data Grouping	Monitor Switch
DCS Database	dcs_dbase	Timestamp

## Usage

Use this element as an indicator of the length of time that applications are maintaining connections to a host database.

This element is composed of two subelements that report time spent as seconds and microseconds (one millionth of a second). The names of the subelements can be derived by adding "\_s" and "\_ms" to the name of this monitor element. To retrieve the total time spent for this monitor element, the values of the two subelements must be added together. For example, if the "\_s" subelement value is 3 and the "\_ms" subelement value is 20, then the total time spent for the monitor element is 3.00002 seconds.

## con\_local\_dbases - Local Databases with Current Connects

The number of local databases that have applications connected.

---

Table 456. Table Function Monitoring Information

---

Table Function	Monitor Element Collection Level
MON_GET_INSTANCE table function - Get instance level information	Always collected

---

Table 457. Snapshot Monitoring Information

---

Snapshot Level	Logical Data Grouping	Monitor Switch
Database Manager	db2	Basic

---

### Usage

This value gives an indication of how many database information records you can expect when gathering data at the database level.

The applications can be running locally or remotely, and may or may not be executing a unit of work within the database manager

## con\_response\_time - Most Recent Response Time for Connect

The elapsed time between the start of connection processing and actual establishment of a connection, for the most recent DCS application that connected to this database.

### Element identifier

con\_response\_time

### Element type

time

---

Table 458. Snapshot Monitoring Information

---

Snapshot Level	Logical Data Grouping	Monitor Switch
DCS Database	dcs_dbase	Timestamp

---

### Usage

Use this element as an indicator of the time it currently takes applications to connect to a particular host database.

This element is composed of two subelements that report time spent as seconds and microseconds (one millionth of a second). The names of the subelements can be derived by adding "\_s" and "\_ms" to the name of this monitor element. To retrieve the total time spent for this monitor element, the values of the two subelements must be added together. For example, if the "\_s" subelement value is 3 and the "\_ms" subelement value is 20, then the total time spent for the monitor element is 3.00002 seconds.

## concurrent\_act\_top - Concurrent activity top monitor element

The high watermark for the concurrent activities (at any nesting level) in a service subclass since the last reset.

**Note:** This element monitors the highest concurrent execution of all activities, including those activities that do not participate in the CONCURRENTDBCOORDACTIVITIES threshold. For example, although CALL statements do not count toward the concurrency that is enforced by the CONCURRENTDBCOORDACTIVITIES threshold, they are included in the concurrent activity high watermark measurement.

Table 459. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
WLM_GET_SERVICE_CLASS_WORKLOAD_OCCURRENCES table function - list workload occurrences	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected
WLM_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected

Table 460. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected

## Usage

Use this element to know the highest concurrency of activities (including nested activities) reached on a member for a service subclass in the time interval collected.

### **concurrent\_connection\_top - Concurrent connection top monitor element**

High watermark for concurrent coordinator connections in this service class since the last reset. This field has the same value in every subclass of the same superclass.

Table 461. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected
WLM_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected

Table 462. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected

## Usage

This element may be useful in determining where to place thresholds on connection concurrency by showing where the current high watermark is. It is also useful for verifying that such a threshold is configured correctly and doing its job.

## concurrent\_wlo\_act\_top - Concurrent WLO activity top monitor element

High watermark for concurrent activities (at any nesting level) of any occurrence of this workload since the last reset.

Table 463. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
WLM_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected

Table 464. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_wlstats	Always collected

### Usage

Use this element to know the highest number of concurrent activities reached on a member for any occurrence of this workload in the time interval collected.

## concurrent\_wlo\_top - Concurrent workload occurrences top monitor element

The high watermark for the concurrent occurrences of a workload since the last reset.

Table 465. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
MON_GET_SERVICE_SUPERCLASS_STATS table function - Return statistics of service superclasses	Always collected
MON_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected
WLM_GET_SERVICE_SUBCLASS_STATS table function - Return statistics of service subclasses	Always collected
WLM_GET_WORKLOAD_STATS table function - Return workload statistics	Always collected

Table 466. Event Monitoring Information

Event Type	Logical Data Grouping	Monitor Switch
Statistics	event_wlstats	Always collected
Statistics	event_scstats	Always collected
Statistics	event_superclasstats	Always collected

## Usage

Use this element to know the highest concurrency of workload occurrences reached on a member for a workload in the time interval collected.

### **concurrentdbcoordactivities\_db\_threshold\_id - Concurrent database coordinator activities database threshold ID monitor element**

The ID of the CONCURRENTDBCOORDACTIVITIES database threshold that was applied to the activity.

Table 467. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

## Usage

Use this element to understand which CONCURRENTDBCOORDACTIVITIES database threshold, if any, was applied to the activity.

### **concurrentdbcoordactivities\_db\_threshold\_queued - Concurrent database coordinator activities database threshold queued monitor element**

This monitor element returns '1' (Yes) to indicate that the activity was queued by the CONCURRENTDBCOORDACTIVITIES database threshold. A value of '0' (No) indicates that the activity was not queued.

Table 468. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

## Usage

Use this element to understand if the activity was queued by the CONCURRENTDBCOORDACTIVITIES database threshold applied to the activity.

### **concurrentdbcoordactivities\_db\_threshold\_value - Concurrent database coordinator activities database threshold value monitor element**

This monitor element returns the upper bound of the CONCURRENTDBCOORDACTIVITIES database threshold that was applied to the activity.

Table 469. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### Usage

Use this element to understand the value of the CONCURRENTDBCOORDACTIVITIES database threshold applied to the activity, if any.

### **concurrentdbcoordactivities\_db\_threshold\_violated - Concurrent database coordinator activities database threshold violated monitor element**

This monitor element returns '1' (Yes) to indicate that the activity violated the CONCURRENTDBCOORDACTIVITIES database threshold. A value of '0' (No) indicates that the activity has not yet violated the threshold.

Table 470. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### Usage

Use this element to determine if the activity violated the CONCURRENTDBCOORDACTIVITIES database threshold that was applied to the activity.

### **concurrentdbcoordactivities\_subclass\_threshold\_id - Concurrent database coordinator activities service subclass threshold ID monitor element**

This monitor element returns the ID of the CONCURRENTDBCOORDACTIVITIES service subclass threshold that was applied to the activity.

Table 471. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected

---

Table 471. Table Function Monitoring Information (continued)

---

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

---

### Usage

Use this element to understand which CONCURRENTDBCOORDACTIVITIES service subclass threshold, if any, was applied to the activity.

### **concurrentdbcoordactivities\_subclass\_threshold\_queued - Concurrent database coordinator activities service subclass threshold queued monitor element**

This monitor element returns '1' (Yes) to indicate that the activity was queued by the CONCURRENTDBCOORDACTIVITIES service subclass threshold. A value of '0' (No) indicates that the activity was not queued.

---

Table 472. Table Function Monitoring Information

---

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

---

### Usage

Use this element to understand if the activity was queued by the CONCURRENTDBCOORDACTIVITIES service subclass threshold applied to the activity.

### **concurrentdbcoordactivities\_subclass\_threshold\_value - Concurrent database coordinator activities service subclass threshold value monitor element**

This monitor element returns the upper bound of the CONCURRENTDBCOORDACTIVITIES service subclass threshold that was applied to the activity.

---

Table 473. Table Function Monitoring Information

---

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected

---

Table 473. Table Function Monitoring Information (continued)

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### Usage

Use this element to understand the value of the CONCURRENTDBCOORDACTIVITIES service subclass threshold applied to the activity, if any.

### **concurrentdbcoordactivities\_subclass\_threshold\_violated - Concurrent database coordinator activities service subclass threshold violated monitor element**

This monitor element returns '1' (Yes) to indicate that the activity violated the CONCURRENTDBCOORDACTIVITIES service subclass threshold. A value of '0' (No) indicates that the activity has not yet violated the threshold.

Table 474. Table Function Monitoring Information

Table Function	Monitor Element Collection Level
MON_GET_ACTIVITY table function - Return a list of activities	Always collected
MON_GET_ACTIVITY_DETAILS table function - Get complete activity details (reported in DETAILS XML document)	Always collected
WLM_GET_WORKLOAD_OCCURRENCE_ACTIVITIES table function - Return a list of activities	Always collected

### Usage

Use this element to determine if the activity violated the CONCURRENTDBCOORDACTIVITIES service subclass threshold that was applied to the activity.

### **concurrentdbcoordactivities\_superclass\_threshold\_id - Concurrent database coordinator activities service superclass threshold ID monitor element**

The ID of the CONCURRENTDBCOORDACTIVITIES\_SUPERCLASS threshold that was applied to the activity.
