Notices

For notices regarding this documentation, refer to [Help Directory > Notices](#) in the FileNet P8 online documentation.

Typographical Conventions

This document uses the conventions in the following table to distinguish elements of text.

Convention	Usage
UPPERCASE	Environment variables, status codes, utility names.
Bold	Paths and file names, program names, clickable user-interface elements (such as buttons), and selected terms such as command parameters or environment variables that require emphasis.
<i>Italic</i>	User-supplied variables and new terms introduced in text.
<i><italic></i>	User-supplied variables that replace everything between and including the angle bracket delimiters (< and >).
Monospace	Code samples, examples, display text, and error messages.

Introduction

This document provides detailed descriptions of each of the objects and features of the FileNet Business Activity Monitor. The specific topics include:

- [“Access Filters” on page 17](#) describes the filters that restrict the data a user sees without having to define a new view or cube for each user.
- [“Agents” on page 25](#) describes the objects that know how to receive or retrieve information from external sources.
- [“Alerts” on page 28](#) describes the notifications of exceptional events sent to users or external systems.
- [“Business Activities” on page 40](#) describes the container objects that collect the scenarios that identify exceptional business conditions.
- [“Context” on page 42](#) describes context data, how it flows into the system, and how to create it.
- [“Cubes” on page 48](#) describes multidimensional data cubes and how to create them.
- [“Data Types” on page 52](#) describes the supported SQL-99 data-types and their semantics.
- [“Dimensions” on page 65](#) describes dimensions and levels for use by cubes.
- [“Events” on page 70](#) describes event data, how it flows into the system, and how to create it.
- [“Flat Files” on page 73](#) describes how the system uses text files to source event data.
- [“Formulas” on page 89](#) describes how to construct formulas in the FileNet Business Activity Monitor.
- [“Functions” on page 95](#) describes C-SQL functions that may appear in commands and rule formulas.
- [“HTTP Post” on page 164](#) how to use HTTP to post events to an event stream.
- [“Java Messaging Service \(JMS\)” on page 171](#) describes how the system uses JMS to source event data.
- [“JDBC” on page 179](#) describes how the system uses JDBC interfaces to retrieve context data, receive event data, and to allow other Java applications to access the business views in memory.
- [“JDBC Access to View Data” on page 191](#) describes the application programming interface (API) that allows JDBC 2.0 applications to retrieve data from a view, and to retrieve the metadata that describes the views in the installation.
- [“Objects” on page 206](#) describes the details that all FileNet Business Activity Monitor objects have in common, including name, optional description, and status.
- [“Operators and Constants” on page 212](#) describes the supported operators and constants.
- [“Permissions” on page 216](#) describes the controls that identify which users may access, create, and edit FileNet Business Activity Monitor objects and user accounts.
- [“Processes” on page 223](#) describes how FileNet Business Activity Monitor uses and presents business process diagrams and statistics.
- [“Query Windows” on page 228](#) describes query windows, which are sets of rows used when making calculations regarding the current event window.
- [“Reportlets” on page 247](#) describes objects that provide information about an event that puts the event into context.

- [“Roles” on page 252](#) describes how to use roles to assign permissions to a set of users.
- [“Rules” on page 255](#) describes the objects that analyze business views looking for metrics that meet specific conditions.
- [“Scenarios” on page 261](#) describes the collections of rules, alerts, and reportlets that identify exceptional business conditions in a business view.
- [“SELECT” on page 264](#) describes C-SQL select statements that manage information in the FileNet Business Activity Monitor.
- [“TIBCO Rendezvous” on page 273](#) describes how the system uses TIBCO Rendezvous for event data.
- [“Users” on page 282](#) describes the accounts by which each user is *known* to the system.
- [“User-Defined Functions” on page 288](#) describes user-defined functions (UDFs) for use in formulas.
- [“Views” on page 291](#) describes the data models that provide a real-time picture of a business activity.
- [“Web services” on page 303](#) describes how the system uses Web services to retrieve context data.
- [“XML/XSD” on page 317](#) describes how to create FileNet Business Activity Monitor objects with XML.
- [“Glossary” on page 332](#) define common terms used throughout FileNet Business Activity Monitor.

Access Filters

Access filters allow different users to see different rows of the same view or cube depending on the criteria specified in the filter. These filters restrict the data a user sees without having to define a new view or cube for each user. For example, consider this view of total sales by region:

```
Total Sales Region
-----
 763000.00 West
 489500.00 Central
 522950.00 South
 650740.00 East
```

By defining an access filter that says something like “OrderTotals.Region=Employees.Region”, you can limit users to see only the rows that apply to their business region. As such, a user from the Central region looking at the view would see:

```
Total Sales Region
-----
 489500.00 Central
```

The filters are logical expressions similar to the Where clause of a view definition. See [“Access filter conditions” on page 18](#) for a complete description.

Access filters are defined on a view-by-view and cube-by-cube basis, and are applied to users and roles having Filtered/Read-Only permission on the view or cube. For details about how access filters work, see [“Access filter behavior and restrictions” on page 20](#).

Applying access filters to a view or cube requires that you first create the filter, and then assign it to users or roles, as described in these sections:

- [“Creating a view access filter” on page 21](#)
- [“Creating a cube access filter” on page 22](#)
- [“Assigning an access filter to users and roles” on page 23](#)

For detailed information about views, see [“Views” on page 291](#), for cubes, see [“Cubes” on page 48](#).

Access filter conditions

Access filter conditions are logical expressions that are applied to each row in the view, or dimension level in a cube. A user looking at the view or cube sees those rows where the expression evaluated to true. As a minimum each filter should contain some condition that evaluates data found in the view or cube. For example, this simple condition shows only the rows in OrderTotals that are in the *East* business region:

```
OrderTotals.Region='East'
```

Naming users

The filter above must be assigned to each user or role in the East region to limit their access. A more powerful expression is one that names the users. The CURRENT_USER() function returns the login name of the user looking at the view. You can include that function in the filter condition to apply the filter to specific users. For example, this condition also identifies two users, and as such, only these two users would see the results for the East region:

```
OrderTotals.Region='East' AND  
(CURRENT_USER()='Skyler' OR CURRENT_USER()='Nina')
```

NOTE: Access filters are logical expressions that can include Boolean operators (AND, OR, and NOT), and can use parentheses for grouping.

A limitation of the two examples above is that they have literal values hard-coded into the expressions: the region name and the user names. Using literals is problematic because it requires you to edit the filters whenever the names change. Further, you would need one for each region.

A more powerful expression is one that can be applied to all users by dynamically retrieving information about the user and applying it to the view.

Context filters

In addition to the current view, access filters can retrieve data from a context table. If you define a context table that contains information about the users, you can compare that information to the data in the view to create a dynamic context filter. Consider this filter that uses an Employees context table:

```
OrderTotals.Region=Employees.Region AND  
CURRENT_USER()=Employees.User_Name
```

Now you can apply the filter to many users and roles, and only those users assigned to the same business region as the data will see the data.

NOTE: To use dynamic look-ups you must provide the information in an external context table.

Users as context

Context tables usually support events by providing additional information about the event. When used in an access filter, a context table provides information that supports the filter: namely, information about the current user. As such, a “users” context table must have at least one column that contains the user name that matches the login name that the user uses to log in to FileNet Business Activity Monitor.

Be aware that `CURRENT_USER()` returns the user’s login name as defined in FileNet Business Activity Monitor, in the same character case, and as appears in the FileNet BAM Workbench. As such, it is important that the character case match exactly. (Note that some DBMS provide case-insensitive compares, so this might not be an issue to your installation.) To avoid mismatches, you might want to enter the names in the context table in a single case, and then use `UPPER()` or `LOWER()` in the filter expression, like this:

```
UPPER(CURRENT_USER())=Employees.User_Name
```

NOTE: You cannot use `UPPER()` or `LOWER()` on the reference to the Employees context table. See [“Context column limitations in queries” on page 45](#) for details.

Similarly, all text columns referenced in a filter need to be aware of case issues.

To use a context table in an access filter, add the table to the filter’s workset when defining the filter. See [“Creating a view access filter” on page 21](#) for details.

Summary

In summary, a “users” context table must include:

- One row for each user that will be assigned a Filtered/Read-Only access permission. If the user is not found in the context table, the filter will most likely fail to find any rows for that user.
- At least one text column that contains the user login name. If the DBMS provides case-sensitive matches, enter the names exactly as defined in FileNet Business Activity Monitor, or at least with the same characters in the one text-case if you plan to use `UPPER()` or `LOWER()` in your filters.
- One column for each reference in the filter, and the data types must match. For character values, the strings in the view must exactly match the strings in the context table.

Also be aware that if the context table data is cached, the filters can fail if the user data is not in the cache. In other words, if you add a user to the database, you might also want to invalidate the context table cache before the user attempts to look at filtered views or cubes. If the user is not found in the context, the filter returns false.

Access filter behavior and restrictions

Access filters are applied only when a user with Filtered/Read-Only permission on a view looks at or requests data from the view, or defines a new view on top of a such a view. The filters do not affect users or roles with Read-Only or Read-Write permission on the view, nor do they apply to users receiving reportlets sent as an attachment to alert notifications.

Specifically:

- The default access permission to the classes of View and Cube objects is No Access for all new users. Before any user can see the results, they must be assigned — directly or as a member of a role — Read-Only or Read-Write permission on the classes of View and Cube objects (all views and cubes), at least Filtered/Read-Only permission on the specific view.

- When a user is assigned multiple access filters to the same view or cube — perhaps as the result of being a member of multiple roles each with assigned filters — the user sees those rows where *any* of the filters is true for the row.

For example, one filter might restrict a user to see on “West” region data, but another might allow the user to see all results for a specific family of products. The result is that the user will see all results for the family, regardless of region.

- Reportlets always include all data from the view that they reference, regardless of any access filters associated with the view.

Users who receive reportlets as part of alert notifications always see the entire view referenced by the reportlet.

- When a user with filtered access to a view creates a new view on top of the filtered view, the new view inherits that user’s filtered results, but not the filter definition.

Subsequently, anyone else looking at the derived view sees the results as filtered for the creating user. For example, if Sklyer can see only Total Sales from the “West” region, and he creates a new view called WrapUp derived from the Total Sales view, anyone else with permission to look at WrapUp sees the data for the West region, regardless of their own access permission to Total Sales.

- Similarly, when a user with filtered access to a view creates a rule based on the view, the rule inherits that user’s filtered results.

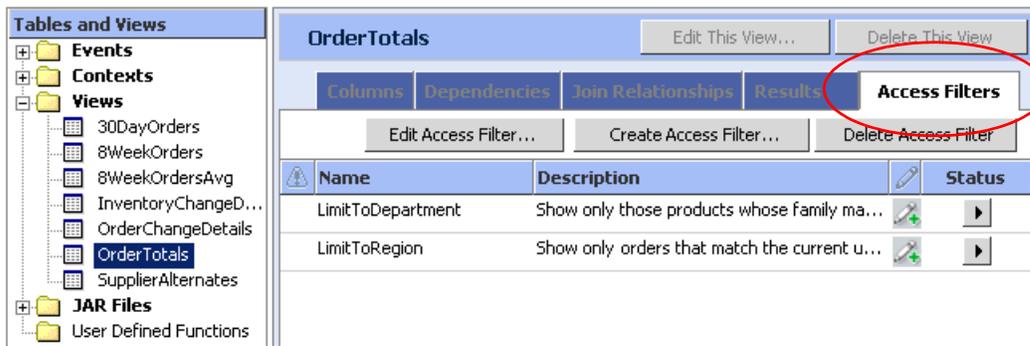

As such, that rule only sees events that match the users access filter condition, and any subscribers to the alert associated with the view only receive alerts for the filtered events.

Creating a view access filter

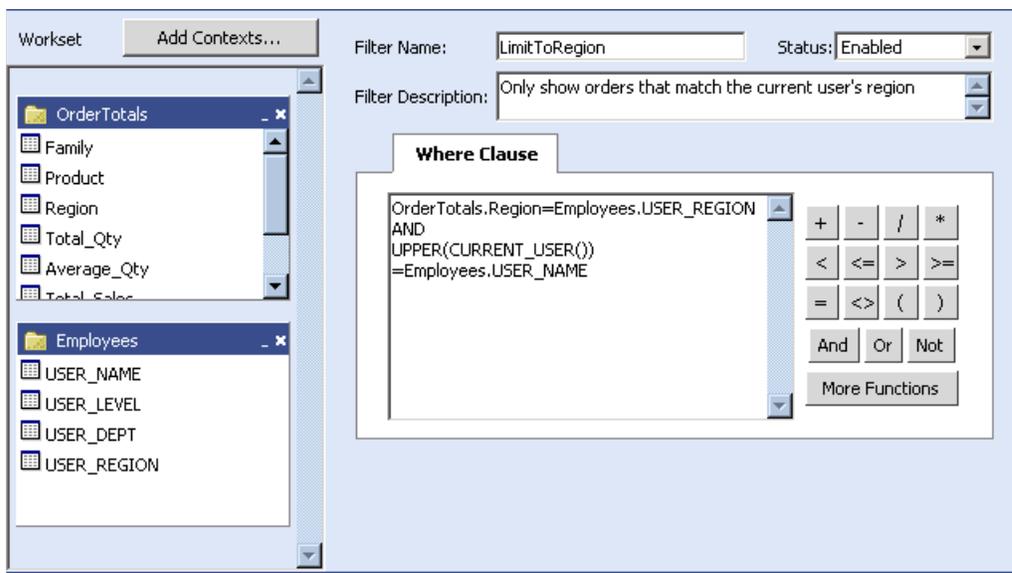

To create an access filter, you must have Read-Write permission on the view.

To create an access filter:

1. In the FileNet BAM Workbench, Workbench tab, Views list, select the view that will have the filter.
2. Select the Access Filters tab to see the list of filters currently associated with this view.

3. Click Create Access Filter to create the new filter.
4. Add a context table to the Workset by clicking Add Context. This example includes the Employees context table to retrieve information about the current user.
5. In the Edit Access Filter dialog, assign the filter's name and optionally provide a description. Define the filter condition following the instructions in ["Access filter conditions" on page 18](#).

6. Save the access filter.

You can now assign the filter to users having Read-Filtered access to the view.

Creating a cube access filter

You must have Read-Write permission on the cube.

To create an access filter:

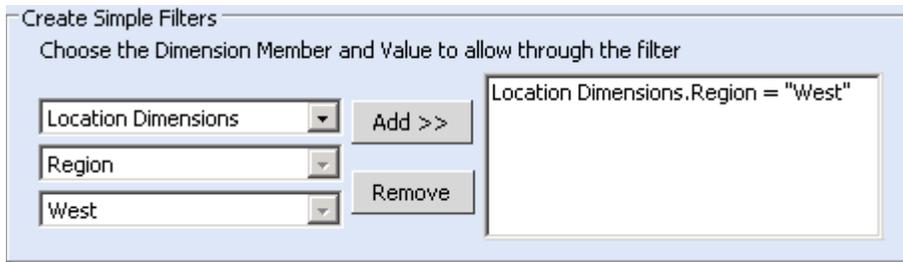

1. In the FileNet BAM Workbench, Workbench tab, Cubes list, select the cube that will have the filter.
2. Select the Access Filters tab to see the list of filters currently associated with this view.

3. Click Create Access Filter to create the new filter.
4. In the Configure Cube Filter dialog, assign the filter's name and optionally provide a description.
5. Define the filter condition per the details in ["Access filter conditions" on page 18](#).

To define a simple filter

- Choose the dimension, level, and value, as show here:

To define a context filter

1. Choose the Use Context Filters option.

2. Choose the context table and identify the column that contains the user's name and the column that maps to a dimension level, as show here.

NOTE: This filter is the same as the one shown in “Context filters” on page 18.

3. Save the access filter.

You can now assign the filter to users having Read-Filtered access to the view.

Assigning an access filter to users and roles

To perform this procedures:

- You must have Read-Write permission on the view or cube.
- The filters must already be defined. See “Creating a view access filter,” above, for details.

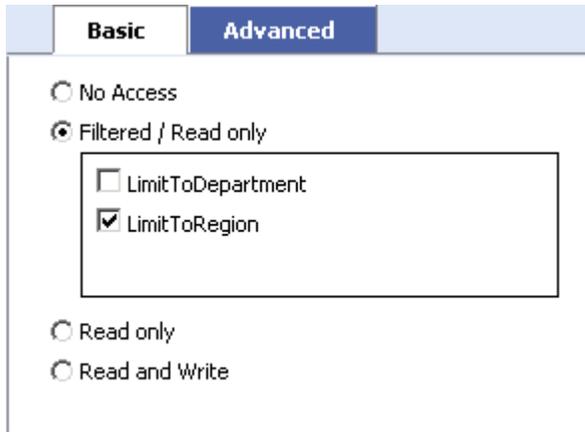

To assign an access filter to a user or role on a view:

1. In the FileNet BAM Workbench, Workbench tab, click the Views folder in the Workset to list all of the views.
2. Select the view to assign the filtered read permission, and click Permissions.

Views			
		Permissions...	Delete View(s)
Object Name	Description		Status
30DayOrders	Tracks orders for 30 days.		
8WeekOrders	Tracks orders totals for the previous 8 wee...		
8WeekOrdersAvg	Aggregate for 8 week orders.		
InventoryChangeDetails	Detailed information about a product quanti...		
OrderChangeDetails	Wrap-up of an order event and associated ...		
OrderTotals	Totals the sales totals		
SupplierAlternates	Shows a list of alternative suppliers for a pr...		

3. Select one or more users or roles who will have the filtered access, and click Change Permissions.
4. Choose the Filtered / Read only permission, and choose one or more access filters to use.

When multiple filters are assigned, the user see the rows that meet any of the conditions. For example, when one filter shows only rows that are in the user's department classification, and another shows rows applicable to their business region, the user sees the row if either condition is true.

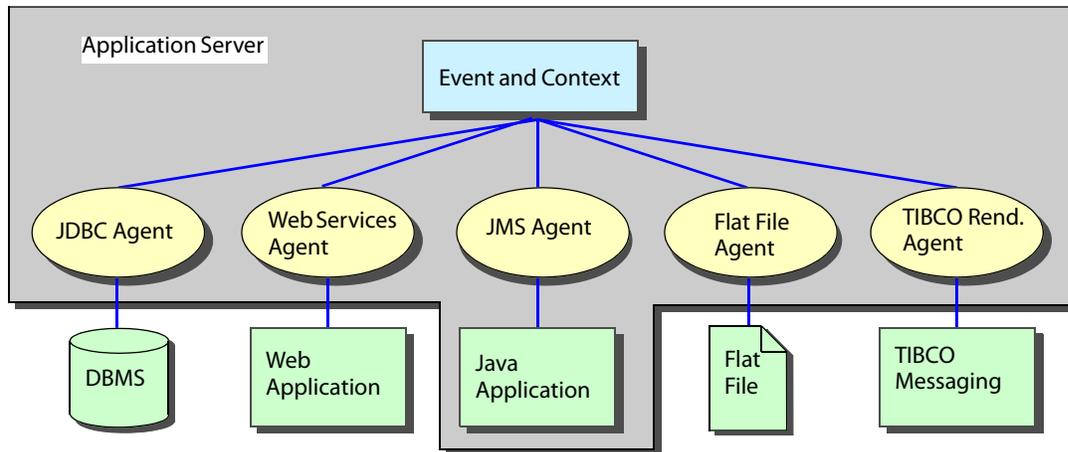

The image shows a configuration window with two tabs: 'Basic' and 'Advanced'. The 'Advanced' tab is selected. The window contains the following options:

- No Access
- Filtered / Read only
 - LimitToDepartment
 - LimitToRegion
- Read only
- Read and Write

Save the assignments and the permissions are immediately put into effect.

Agents

Agents are FileNet Business Activity Monitor processes that know how to receive or retrieve information from external sources. When an agent locates new event or context information, it passes that data to an Events and Context table for use by the Business Views.

NOTE: One agent may support multiple event or context tables.

While an agent knows *how* to communicate with an external source, event and context tables know *what* information is desired. As such, most of the event and context tables define the details that tell the agent what to look for.

External sources

FileNet Business Activity Monitor provides agents to several external context and event sources. Some events stream (are pushed) into the system as they happen. Other events are loaded (pulled) as the result

of a request, such as to a database or from a text file. Context data, however, are always pulled from the source. This table summarizes the available sources and identifies the source agent they support.

External source	Agent	Event push	Event pull	Context pull
Java Database Connectivity (JDBC), usually from a Relational database (RDBMS)	“JDBC” on page 179	No	Yes	Yes
Java Messaging Service (JMS) from a Java application.	“Java Messaging Service (JMS)” on page 171	Yes	No	No
Text file.	“Flat Files” on page 73	Yes	No	No
TIBCO Rendezvous (RV) from a business application using TIBCO message streams.	“TIBCO Rendezvous” on page 273	Yes	No	No
Web services from a Web application over an HTTP connection.	“Web services” on page 303	No	No	Yes

Creating agents

These steps summarize how to create an agent. For details about creating agents of specific types, see the descriptions of those types.

Before you create an agent, you must have create permission for agents (see [“Creating permission” on page 220](#) for details) and the connection specifications for the specific agent type.

To create an agent:

1. Open the Administration Console tab of the FileNet BAM Workbench.
2. Select Agents.
3. Click New Agent.
4. Choose the source type for the Agent (as described above in External sources.”).
5. Fill in the details for the specific source type. For details, see

Save the object as enabled and it will immediately be ready to receive events or context.

Editing agents

These steps summarize how to modify an existing an agent. For details about agents attributes, see the description of the specific source.

Before you create an agent, you must have Read and Write permission for the agent (see [“Accessing permissions” on page 218](#) for details).

To edit or alter an agent:

1. Open the Administration Console tab of the FileNet BAM Workbench.
2. Select Agents.
3. Double-click the agent to alter.
4. Fill in the details for the specific source type.

Save the object as enabled and it will immediately be ready to receive events or context.

Alerts

Alerts are the notifications of exceptional events sent to users or external systems. An alert may come in the form of a simple message indicating that an event has occurred, or it may more detailed, including information that indicates the cause and possible courses of action.

Each alert message is comprised of text that describes the exceptional incident to the subscriber. This is the text that appears in the FileNet BAM Workbench and in any other device identified by the subscriber's delivery profile. How the message is rendered depends on the device that displays it to the subscriber.

In this Chapter:

[“Creating alerts” on page 29](#)

[“Alert attributes” on page 30](#)

[“Message subject and body text” on page 31](#)

[“Alert subscribers” on page 32](#)

[“Managing alert notification messages” on page 33](#)

[“Alert states” on page 34](#)

[“Consolidating multiple messages” on page 35](#)

[“Alert reportlets” on page 35](#)

[“Reportlet filtering” on page 36](#)

Creating alerts

To create an alert you need these permissions:

- Create permission for business activities (see [“Creating permission” on page 220](#) for details)
- Read and Write permission on the business activity that will contain the alert
- Read Only permission on the view or cube that will feed the alert

There are three ways to create alerts with the FileNet BAM Workbench Scenario Modeler.

To create a stand-alone alert:

1. Select an existing Business Activity.
2. Select an existing scenario to contain the alert.
3. Select the Alerts folder.
4. Click the New Alert button.
5. Choose the data source that will feed the alert.
 - If the scenario has a “default view”, that one appears selected by default. Choose another source to monitor by clicking Select Data Source.
 - For a view, choose the view.
 - For a cube, choose the dimension level in a cube. Optionally you may also apply a filter that further restricts the data that the cube feeds to the alert.
 - If the source contains data, that data appears to provide a sample of what to expect. When the source is empty, the form displays just the column names and the message “No Data Available”.
6. Fill in the fields in the Alert Definition form.

To create an alert associated with a rule:

1. Follow the instructions for [“Creating rules” on page 256](#).
2. Fill in the fields in Step 2 of 2: the Alert Definition form.

To clone an existing alert:

Copy the definition of an existing alert to a new alert.

1. Edit the alert you want to clone.
2. Change the alert name, and change the other attributes that differ from the original alert.
3. Choose “Save as New Alert”.

Alert attributes

Every alert has the following attributes:

Attribute	Description
Alert Name	Identifies the alert object. The name can contain letters and numerals only. This name must be unique among alerts within the same scenario. See “Object namespace” on page 211 for details.
Status	Specifies if the rule is enabled (receiving new event information), or disabled. Note: When the containing scenario is disabled, you cannot make the alert enabled. The scenario must be enabled before the alert may be enabled.
Importance	A hint about how important a message is. Values are: HIGH, NORMAL (default), or LOW. Messages arriving in the FileNet BAM Dashboard are sorted into folders corresponding to the importance level. Further, e-mail messages are flagged accordingly with the “Importance” mail header field per mail standards.
Description	Optional description that may contain any text characters.
Data source	View or cube dimension level that defines the columns in the alert. Note that this should be the same source as the associated rule, or one derived from that source; otherwise, the generated alert might not contain valid information.
Subscribers	Users who receive the alert. See “Alert subscribers” on page 32 for details.
Subject	Text message that is the subject of the alert, similar to an e-mail subject line. Can contain column references to the underlying business view.
Body	Text message that is the body of the alert. Can contain column references to the underlying business view, and can contain acknowledgements and reportlets. For details about acknowledgements, see Acknowledgements, for reportlets, see “Reportlets” on page 247. ”

Message subject and body text

Each alert message is comprised of text that describes the exceptional incident to the subscriber. This is the text that appears in the FileNet BAM Workbench, FileNet BAM Dashboard and in any other device identified by the subscriber's delivery profile. How the message is rendered depends on the device that displays it to the subscriber.

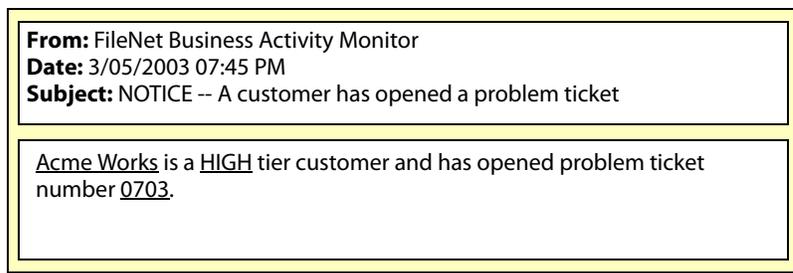

The Subject and Body alert attributes define the text of the message. Each attribute contains static text and fields. When the alert generates the message, it replaces the fields with the values from the columns of the same name in the business view row that caused the alert.

For example, consider this default message definition:

Subject: NOTICE -- A customer has opened a problem ticket.

Body: CUST_NAME is a TIER tier customer and has opened problem ticket number TICKET.

When the alert is activated, it generates a message similar to this e-mail:

NOTE: You can include any valid HTML code in the body of the message. If you reference an external object, such as a graphic, make the reference to a HTTP server; do not reference a local file because it will not be included in the message.

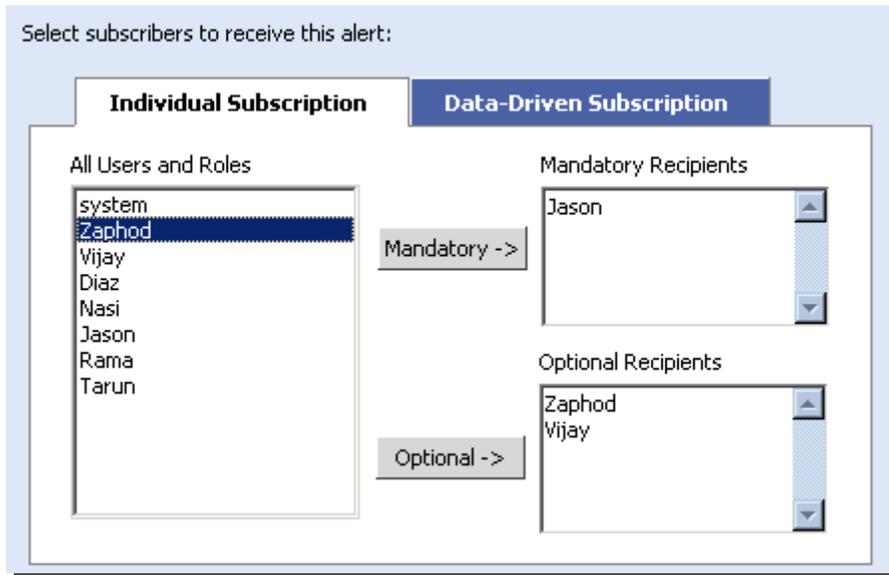

Alert subscribers

When you define an alert, you can also declare one or more Users to receive the alert notification. By clicking the Add/Remove button next to the subscribers list in the Alert editor, you can designate individual users and Roles to receive the alert, or identify columns in the alert's view that provide lists of users, roles, or e-mail addresses to receive the notification.

Subscribers:	Name	Subscriber Type	Subscription	Profile
	UserAddresses	User/Role List column	N/A	Default
	Vijay	User	Optional	User-specified
	Zaphod	User	Optional	User-specified
	Jason	User	Mandatory	User-specified

The Alert Subscribers dialog has two tabs:

- Individual Subscription tab is where you choose the users and roles to receive the notification.
 - Mandatory subscribers always receive the notification. These users or roles cannot voluntarily unsubscribe to the alert in the FileNet BAM Dashboard; rather, they must be removed from this dialog.
 - Optional subscribers receive notifications, but they may unsubscribe using the FileNet BAM Dashboard.

- Data-Driven Subscription tab is where you identify columns in the view that contain the names or addresses of users or roles to receive the notification. A column may contain either a list of users and

roles, or a list of e-mail addresses to receive the notifications. Each list of values in a column is separated by a comma or semi-colon, and each item may optionally be enclosed in quotes ("").

Select subscribers to receive this alert:

Individual Subscription **Data-Driven Subscription**

Columns in this alert's view may identify subscribers to receive this alert. A column may list email addresses, or it may list User names and groups of users (by Role) to receive this alert. Separate each value in the list with a comma or semicolon. Optionally enclose values in quotes ("").

Data-driven Recipients (User or Role):

Data-driven Recipients (Email Addresses):

NOTE: Data-driven subscriptions are mandatory: the users, roles, and e-mail addresses that receive them cannot “unsubscribe”. Further, users who receive these subscriptions as a result of an e-mail address list do not see them in the FileNet BAM Dashboard list of subscriptions.

When the column contains multiple instances of the same, exact e-mail address, only one message is sent. However, slight differences in the entries will generate one message for each instance. For example, these two variations of the same address myname@filenet.com and "Me" <myname@filenet.com> generate two messages.

Managing alert notification messages

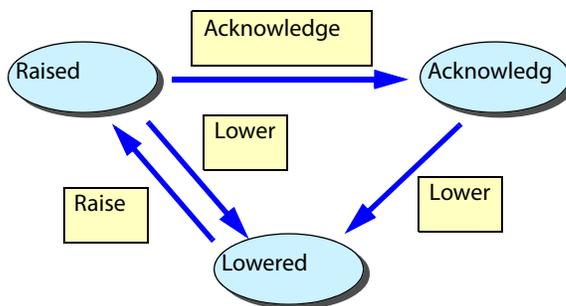

Users receive alert notifications the devices identified by their delivery profiles in the “[Delivery Profiles tab](#)” on page 284. For details about using the Alert Manager in the FileNet BAM Dashboard to view, subscribe and delete notifications, see Alert Messages.

Alerts remain in the Alert Manager list until deleted specifically by the user or automatically by the system. The system removes messages after a count of days specified by the system administrator in the Viewing user interface of the Working with system settings dialog.

Alert states

FileNet Business Activity Monitor provides two kinds of alerts:

- Stateless alerts are one-time notifications about the business condition when the condition happens. Stateless alerts are said to be fired when the rule condition is met. For example, a stateless alert might fire a notification to a warehouse manager when a product inventory count falls below a specific threshold. Note that every subsequent change in inventory levels for that product also sends a notification as long as the inventory count remains below the threshold.
- Stateful alerts have a status that is raised or acknowledged as long as the business condition exists, and which is lowered when the condition does not exist. With a stateful alert, warehouse managers receive the alert when the inventory falls below threshold, and do not receive another until the alert is lowered, presumably after inventory levels have been restored above the threshold. When multiple parties have interest in an alert, one may choose to handle the raise alert and *acknowledge* it. This is done by clicking the Acknowledge link in the message body. The alert's creator places the link in the message body when creating the alert. See Acknowledgements for details.

By combining a stateful alert with a Holds for time period, you can delay the notification. For example, only alert the warehouse manager when a product's inventory count has remained below a threshold for one day: "the alert condition *holds for 1 day*". This way the manager doesn't receive the notification if the inventory drops within a day of being restocked.

Alert escalation

You can monitor the alert's state and generate new alerts when conditions demand. For example, if an alert has not been handled in a timely manner, a new alert can be sent to more significant users, in effect escalating the original alert. To test for these states, use the IS_RAISED function. See Monitoring alerts for details.

Consolidating multiple messages

Events may contain multiple rows of information. When the event meets a rule condition, that rule generates one alert for each row of the event. Often it is desirable to send only one message describing all of the alerts. This is called a *consolidated alert*.

For example, consider a new purchase order entering the system (an event). If the quantity of items in-stock is insufficient to fulfill the order, an alert might note that condition. When multiple line items on the order have insufficient inventory, each generates a new alert. To send just one notification instead, use a consolidated alert.

To create a consolidated alert:

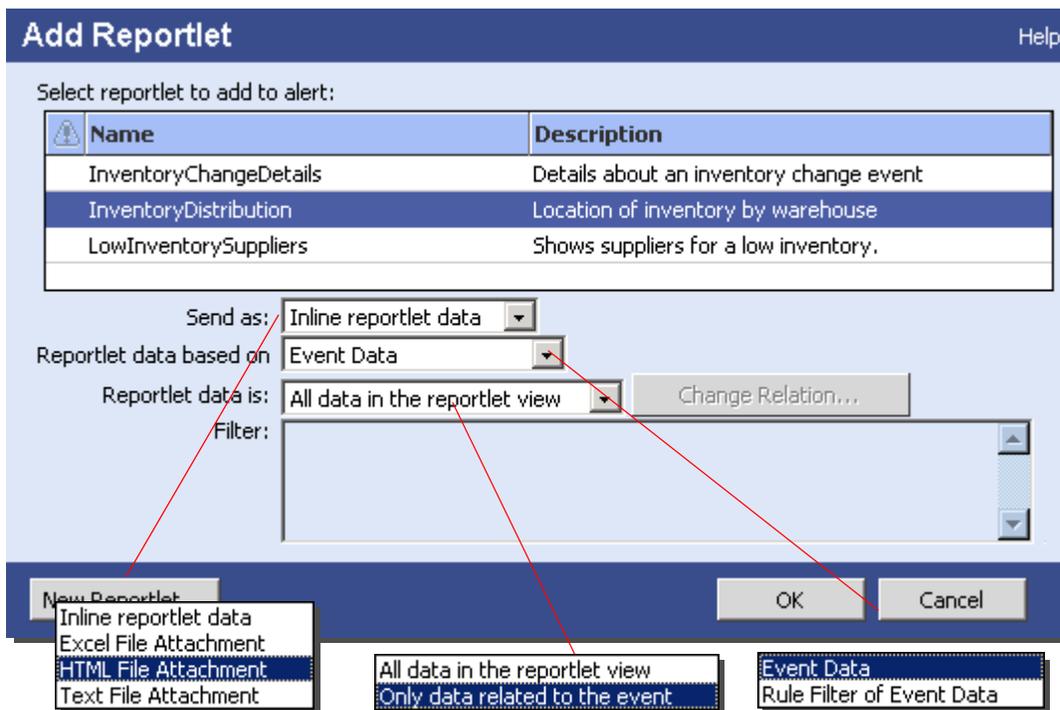

- On the Create Rule form, check the Consolidate multiple messages from same alert option.

Alert reportlets

Reportlets describe the contents of a view and present that information in a report that is attached to the alert message. Frequently reportlets provide information about an event that puts the event into context.

To include reportlets in the body of the alert notification:

1. Open the Add Reportlet dialog.
2. Select the reportlet from the list.
3. Choose OK to add it to the alert.

Send as

Alerts displayed in the FileNet BAM Dashboard embed the reportlet as an in-line, HTML table. The Send as option specifies the format of the reportlet to attach to the alert notification sent to user subscription profiles. The reportlet can be embedded in the body of the message, or included as an attachment in one of the available formats.

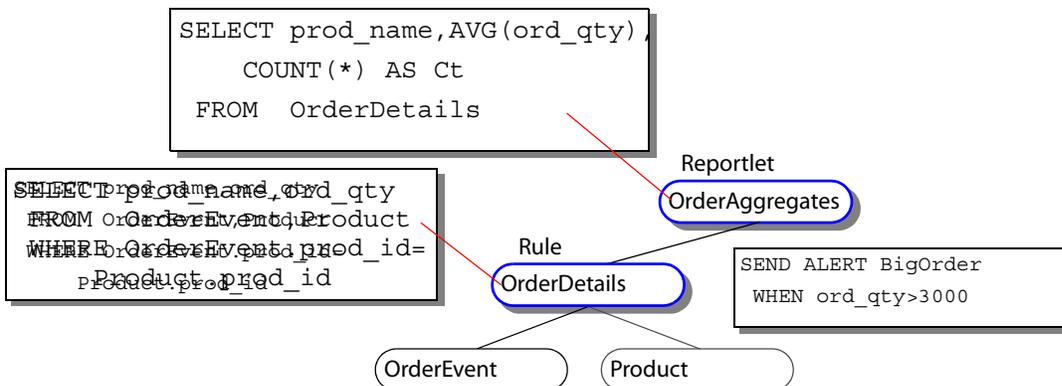

The next section, "Reportlet filtering", describes the Reportlet data base on and Reportlet data is options.

Reportlet filtering

When you create the reportlet, you identify the view or cube from which the reportlet draws its data. However, the data that appears in the reportlet depends on the type of the source (stateless or stateful), and how the rows of data are filtered as specified on the Add Reportlet dialog. In general,

- Reportlet data based on specifies whether a reportlet's stateful source should include data based on all events, or just those that have met the rule condition.
- Reportlet data is limits whether the rows in the reportlet's source include only those related to the event that activated the alert, or all previous event data also in the source.

To better understand how these settings affect the reportlet data, consider these two views that track and report on product orders. The *OrderDetails* stateless view is a summary of each order event, while the *OrderAggregates* stateful view tracks the average quantity for each product ordered.

Now consider these events:

prod_name	ord_qty
nails	1000
plywood	1000
nails	4000
nails	4000
plywood	5000

After the events have entered the stream, the *OrderAggregates* view has these values:

```
prod_name  AVG(ord_qty) Ct
-----  -
nails      3000    3
plywood    3000    2
```

By default, a reportlet using the *OrderAggregates* view shows the details for both products, regardless of which product event might have generated the alert. Further, even though only the last three events met the rule condition of ord_qty greater than 3,000, the reportlet shows the results from all events. Which might not be what you intended.

The two filtering options on the Add Report dialog alter the results by filtering the results that appear in the reportlet.

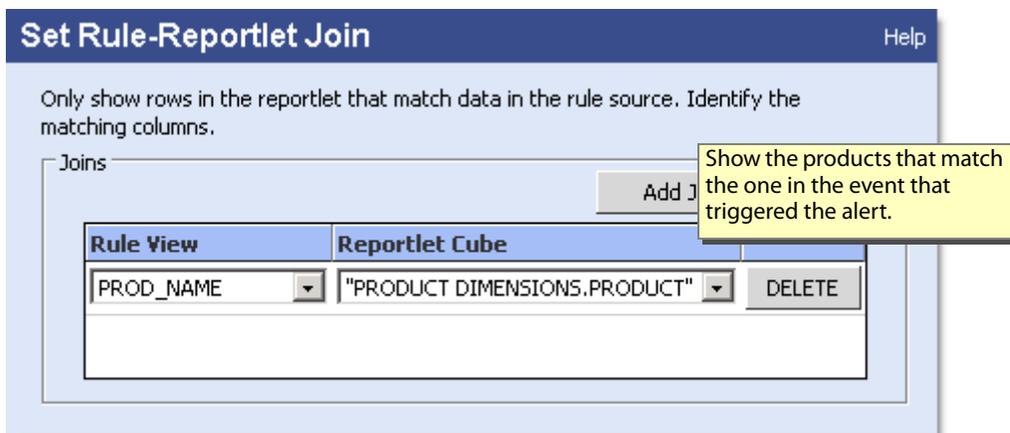

The Reportlet data is option causes the reportlet to show one of the following:

- All of the data in its view or cube face
- Only those data related to the event found by the rule

To show only the event-related data, you must define the relationship between the event and reportlet sources. For example, if you want the reportlet to only show the result for “products” in both views, define the relation by picking the prod_name column from both views. This tells the reportlet to show only those rows in the *OrderAggregates* view whose prod_name value matches the name in the *OrderDetails* view. Then, the reportlet shows the nails value only when the rule generates the alert.

```
prod_name  AVG(ord_qty) Ct
-----  -
nails      3000    3
```

Similarly, when working with cube face, you pick columns that best identify the event to the reportlet. For example, this illustration shows PROD_NAME in the rule view being joined to the PRODUCT dimension in the reportlet cube:

A variation would be to link the product family instead of the product name. In that case the reportlet shows all of the products in the same product-family as the one that triggered the event.

Reportlet data based on option

The Reportlet data based on option specifies whether a stateful view should include data based on all events, or just those that have met the rule condition. Following the example above, the *OrderAggregates* view AVG(ord_qty) column has a value of 3,000 for “nails” after both events have be processed. This is what happens when the setting for this option is Event Data. However, the rule condition says to generate an alert only when the order quantity is greater than 3,000. To track only events that have met the rule condition, change the setting for this option to Rule Filter of Event Data. Then the reportlet shows 4,000 as the average because 4,000 is the average of the two events greater than 3,000.

Example

These illustrations show the view results on the example data when you use the two reportlet filtering options. Notice that the first event does not pass the rule filter, and does not appear in those views.

Events		All data in the reportlet view	Only data related to the event (prod_name)
<pre>prod_name ord_qty ----- nails 1000</pre>	➔	<pre>prod_name ord_qty Ct ----- nails 1000 1</pre>	<pre>prod_name ord_qty Ct ----- nails 1000 1</pre>
	➔	<pre>prod_name ord_qty Ct ----- </pre> <p>Rule Filter of Event Data (ord_qty>3000)</p>	<pre>prod_name ord_qty Ct ----- </pre>

Similarly, the second event also does not pass the rule filter. Notice though that the view that shows event related data now only includes the plywood event.

Events		All data in the reportlet view	Only data related to the event (prod_name)
<pre>prod_name ord_qty ----- nails 1000 plywood 1000</pre>	➔	<pre>prod_name ord_qty Ct ----- nails 1000 1 plywood 1000 1</pre>	<pre>prod_name ord_qty Ct ----- plywood 1000 1</pre>
	➔	<pre>prod_name ord_qty Ct ----- </pre> <p>Rule Filter of Event Data (ord_qty>3000)</p>	<pre>prod_name ord_qty Ct ----- </pre>

The third event now passes the rule filter, and as such, appears in the bottom views. And once again, nails is the product in the event-related views.

Events	All data in the reportlet view	Only data related to the event (prod_name)																							
<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;">prod_name</th> <th style="text-align: left;">ord_qty</th> </tr> </thead> <tbody> <tr> <td>nails</td> <td>1000</td> </tr> <tr> <td>plywood</td> <td>1000</td> </tr> <tr> <td>nails</td> <td>4000</td> </tr> </tbody> </table>	prod_name	ord_qty	nails	1000	plywood	1000	nails	4000	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;">prod_name</th> <th style="text-align: left;">ord_qty</th> <th style="text-align: left;">Ct</th> </tr> </thead> <tbody> <tr> <td>nails</td> <td>2500</td> <td>2</td> </tr> <tr> <td>plywood</td> <td>1000</td> <td>1</td> </tr> </tbody> </table>	prod_name	ord_qty	Ct	nails	2500	2	plywood	1000	1	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;">prod_name</th> <th style="text-align: left;">ord_qty</th> <th style="text-align: left;">Ct</th> </tr> </thead> <tbody> <tr> <td>nails</td> <td>2500</td> <td>2</td> </tr> </tbody> </table>	prod_name	ord_qty	Ct	nails	2500	2

Business Activities

A *business activity* is a collection of possible scenarios that identify exceptional business conditions. Each scenario contains rules that identify specific possible conditions, and the alerts and reportlets to send to key personnel when the condition is found to exist.

You must have at least one business activity before creating any scenarios, rules, alerts, or reportlets.

Tips:

- Deleting a business activity deletes its contained scenarios, and all of the scenario's objects.
- Disabling a business activity disables its contained scenarios, rules, alerts, and reportlets.

The business activity topic discussions include:

- ["Creating business activities" on page 41](#)
- ["Business activity attributes" on page 41](#)
- ["Deleting business activities" on page 41](#)

Creating business activities

You need Create permission for business activities (see [“Creating permission” on page 220](#) for details).

To create a new business activity

1. Open the Scenario Modeler.
2. Click New Business Activity...
3. Fill in the fields of the New Business Activity dialog.

Business activity attributes

Every scenario has the following attributes:

Attribute	Description
Name	Identifies the business activity. The name can contain letters and numerals only. This name must be unique among business activities and users; you cannot have a user with the same name as a business activity. See “Object namespace” on page 211 for details.
Status	Specifies if the business activity is enabled (receiving new event information), or disabled. When an activity is disabled, all of the objects it contains are also disabled, including the rules, alerts, and reportlets.
Description	Optional description that may contain any text characters.

Deleting business activities

You need Read and Write permission on the business activity.

NOTE: Deleting a business activity deletes its contained scenarios, and all of the scenario's objects.

To delete a business activity:

1. Open the Scenario Modeler.
2. In the tree view, select the Business Activities folder.
3. In the list of business activities, select the activity to remove.
4. Click Delete Business Activity.

Context

Context support event processing by providing meaningful information about the event. Contexts are the business information stored in databases, data warehouses, or are provided by Web services. Context tables receive data from Agents that know how to communicate with information sources. When you define a context table, you also instruct the agent how to identify the information from the source.

In this Chapter:

[“How it works” on page 43](#)

[“Creating context tables” on page 44](#)

[“Editing context tables” on page 45](#)

[“Context column limitations in queries” on page 45](#)

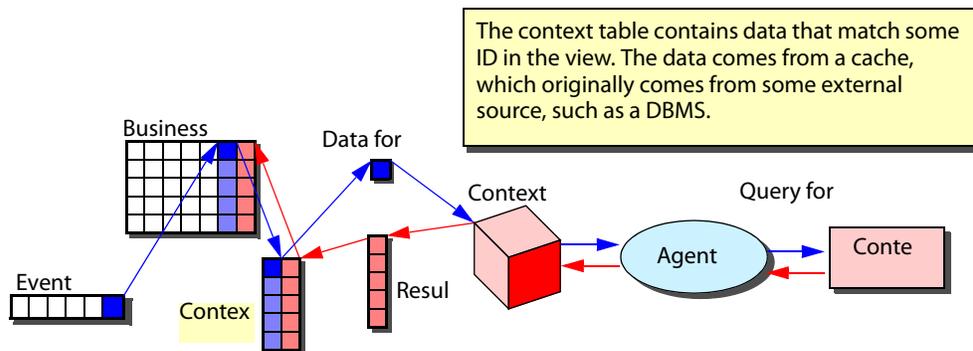

[“Caching context queries” on page 47](#)

How it works

When a business view requires context information, it does so based on some information already in the view. For example, a view that is processing a purchase order might have received a product identification number along with the event data. If the view also requires the suppliers of that product, it would retrieve the supplier names from a context table that contains the names that matches the ID. In the view definition, a WHERE clause would join the context table to the event, similar to this:

```
WHERE event.product_id = context.suppliers_of_product_id
```

When the view performs this join, it passes the ID from the event to the context table. If the matching supplier data are already in the context cache, the table uses that data and passes it to the business view. If the data are not already in memory, the ID is passed — either as an SQL query or by value for a stored procedure — to an agent, which sends data to the DBMS or Web service for processing. The result of the query is then loaded into the context table, and subsequently included in the business view.

The context source may be databases accessed via a JDBC, or business applications accessed via Web services. For details about these type of sources, see [“JDBC tables” on page 180](#), or [“Web service context” on page 306](#).

Creating context tables

Every context table has a name, description, status attribute, and agent.

Attribute	Description
Name	Identifies the table and is the name accessed by the Business Views that depend on this table. This name must be unique among views, events, context, and consolidated events. See “Object namespace” on page 211 for details.
Description	<i>(optional)</i> Description of the table.
Status	Whether or not the object is enabled (able to receive and pass data), or disabled (not receiving or passing data).
Agent	The agent that retrieves the context information, and passes the data to the event or context object. See “Agents” on page 25 for information about agent types.
Disable context after errors	Count of consecutive errors to receive before the system disables this context. Once disabled, a context must be re-enabled manually.

Before creating a context table, you must have Create permission for tables (see [“Creating permission” on page 220](#)), and Read Only access permission on the agent that will feed the table.

To create a context table:

1. Open the FileNet BAM Workbench WorkbenchWorkbench tab.
2. Click New Context...
3. Choose the source type, each type has its own specific attributes.

For details, see:

- [“JDBC” on page 179](#)
- [“Web services” on page 303](#)

4. Fill in the fields in the New Context form.

Save the table as enabled and it will immediately be ready to receive context.

Editing context tables

Editing the attributes of a context table causes the object to lose state, and possibly invalidates dependant views. For example, if you remove a column, any view or rule that references that column becomes invalid. (However, if you re-define the column in the table, the dependant views are automatically re-validated.)

Before editing a context table, you must have Read and Write permission for tables (see [“Accessing permissions” on page 218](#)), and Read Only access permission on the agent that feeds the table.

To edit a context table:

1. Open the FileNet BAM Workbench tab.
2. Select the event or context object.
3. Chose Edit This Context.
4. Change the definitions in the Edit Context form. Note that each type has its own specific attributes. For details, see
 - [“JDBC” on page 179](#)
 - [“Web services” on page 303](#)

Save the table as enabled and it will immediately be ready to receive events or context.

Context column limitations in queries

Context can be retrieved with *no limitations from a JDBC query source*. However, the following limitations apply when retrieving context from a JDBC stored procedure source or a Web service source:

- When the context column is referenced as part of a query, somewhere in the WHERE or FROM clause it *must* appear in an equality expression and then only as an atomic predicate (no other operators on the same side of the equal sign). For example, this is permitted:

```
WHERE context_column = 10*event_column
```

But the following is *not permitted* because the left-side predicate, which contains the context column, is an expression that includes an operator (*/*):

```
WHERE context_column/10 = event_column
```

- The required atomic reference *may not* appear in a disjunct (OR) expression. This fails:

```
WHERE (context_column = event_column OR A > B)
```

However, it *may* appear in a conjunct (AND) expression:

```
WHERE (context_column = event_column AND A > B)
```

- Once there is at least one equality reference in the query, you may use the column in any other way. For example, these two are permitted:

```
WHERE (context_column = event_column AND
       context_column/10 = other_event_column)
WHERE ((context_column = event_column AND
       context_column >= other_event_column) OR
       (A > B))
```

But the following *fails* because there is no equality reference in the query:

```
WHERE context_column >= event_column
```

- The required equality expression *may not* reference another context column in the same table. For example:

```
t1.context_column = t1.other_context_column
```

- However, the equality expression *may* reference a context column in another table, for example:

```
t1.context_column = t2.other_context_column
```

Sybase limitations

When making a query to a Sybase database, be aware of these limitations:

- All names, including tables and columns, are case-sensitive.
- All queries must be in the form `SELECT * FROM table` only; you cannot include any `SELECT` clauses. To filter the results, load them into a business view, and then filter that view.

Caching context queries

Caching allows you to store the results of context queries in memory. Subsequent requests for the same information are then retrieved from memory instead of impacting the DBMS with a redundant query. When caching is active and a view requests context, it searches the cache first. If the desired data are not in the cache, FileNet Business Activity Monitor issues a query to the database.

The context cache has these parameters:

- On Demand | Cache Data
Either don't cache or do cache context query results.
- Number of results to cache
Count of query results to cache in memory. Each set of results may contain one or more rows of context related to the event.
- Invalidation schedule
Identifies when to invalidate the cache and discard all information currently in the cache.

Description
On the 1st at 2:07 AM
Every Monday at 6:00 AM

The cache maintains results in on a least recently used (LRU) basis. It keeps track of when each result set was last requested. When the cache is full, it keeps the most recently accessed rows and discards those that have not been accessed in the longest period of time.

NOTE: Rows containing frequently requested data will remain in the cache the longest to reduce impact on the database. However, if details about the information can change often, define an invalidation schedule to account for the changes and thereby invalidate the cache.

When the context data are not rapidly changing, it is best to invalidate the cache less often. For example, if the context is fairly static, you might want to invalidate the cache weekly or monthly. However, if the context database is updated nightly, you might want to invalidate the cache nightly as well to ensure the latest data.

Cubes

A *cube* is a set of data organized by dimensions and measures for the purpose of aggregating different subsets of the larger set of data. When rendered as a Dashboard Object, cubes allow you to quickly choose categories that “filter” data to show the results that meet your selection. For example, a cube of “sales” data might provide aggregations of the same data by product, by time, or by sales region dimensions. Looking at the cube you might choose to view the total sales of a product (Nails) within a business region (West) during a fiscal quarter (Q1):

West	Q1	January	Hardware	Nails	120,000
West	Q1	March	Hardware	Nails	98,000
					218,000 Total

Further, by quickly removing the product dimension specification, you switch the classification to see all sales for that region and quarter:

West	Q1	January	Hardware	Nails	120,000
West	Q1	March	Hardware	Nails	98,000
West	Q1	March	Hardware	Screws	97,000
West	Q1	January	Lumber	Studs	137,000
					452,000 Total

Or for all sales during the month of March:

West	Q1	March	Hardware	Nails	98,000
West	Q1	March	Hardware	Screws	97,000
East	Q1	March	Lumber	Plywood	92,000
South	Q1	March	Hardware	Nails	98,000
					385,000 Total

Or for all West region sales of the Lumber family of products:

West	Q1	January	Lumber	Studs	137,000
					137,000 Total

NOTE: See *Cube charts* and *Cube tables* in the *Using Dashboard* documentation for details about viewing and working with cube data.

Measures

Measures are the central value that are aggregated and analyzed. In the examples above, *Total sales* is the aggregate value. In each example above, the Total is measuring the sum of all sales in the set. Measures are built with the C-SQL Set functions, including SUM, AVG, MIN, MAX, STD_DEVIATION, and VARIANCE. For more information about measures, see “[Measure columns](#)” on page 50.

Dimensions

A *dimension* is a ranked order of classifications that, from highest to lowest level each describe smaller, more distinct sets of related data. In the examples above, the business region is one level of a geographical dimension, the quarter and month columns are each levels of a time dimension, and the product family and product name are part of an inventory dimension. In the time dimension, months are

smaller sets of fiscal quarters, just as product name is a smaller set of the product family level. Here are some examples of dimensions:

Time	Geography	Inventory	Security	Taxonomy
year	continent	classification	type	kingdom
quarter	country	type	rating	phylum
month	region	manufacturer	company	class
week	state	model	cusip	order
day	county	configuration		family
hour	city			genus
minute	district			species

For information about dimensions, see [“Dimensions” on page 65](#).

NOTE: You can limit user access to data in the cube with an access filter. For details, see [“Access Filters” on page 17](#).

Creating cubes

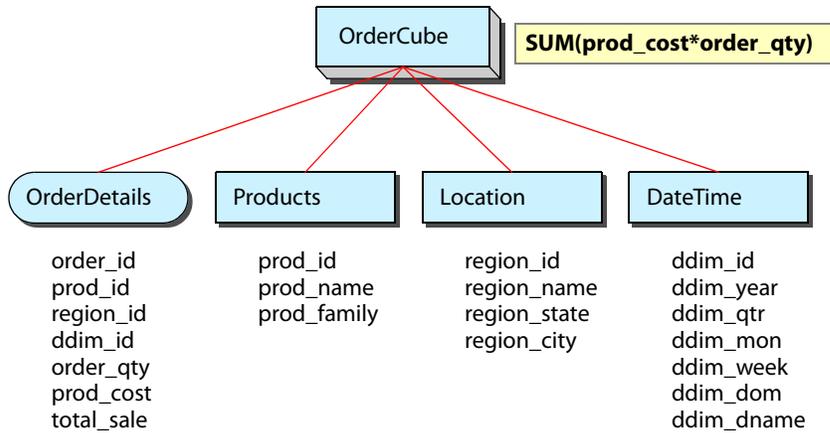

Cubes are similar to business views in that they aggregate event data, but they do so across different dimensions. The view that a cube aggregates is a *fact table*: a view or event table in an event stream that contains one or more columns to measure (aggregate), and which also contains columns that identify the dimensional elements associated with the event. For example, you could imagine a fact table containing an event similar to this:

```
Cost    Quantity Product State      Month
-----
200.00    1600 Nails   California January
```

However, in practice the dimensional elements are stored in Dimensions (special context tables) and referenced by IDs, like this:

```
Cost    Quantity prod_id region_id ddim_id
-----
200.00    1600    100         7        39
```

This illustration shows a cube built from the OrderDetails fact table and which measures total sales across various business regions, products, and time:

To define a cube:

1. Choose the fact table and columns to measure.
2. Specify how to measure them (aggregate formulas to use).
3. Choose one or more dimensions that classify the measurements.

Measure columns

Measure columns define the aggregations that the cube calculates. A cube must have at least one measure column, and may have more. Each measure column defines an expression that contains a C-SQL Set function that aggregates other columns from the fact table. For example, to determine the “total sales” from the OrderDetails fact table, a measure column might be defined as:

```
SUM(OrderDetails.prod_cost*OrderDetails.order_qty) AS TotalOrderSales
```

Dimension columns

Dimension columns categorize the measurements. A cube must have at least one dimension, and may have more. Further, the data in the fact table must be able to identify a unique element in each associated dimension. For a complete discussion, see “Dimensions” on page 65. (Note that while the mathematical term “cube” implies three dimensions; however, a database cube can have any number from one or more.)

Prerequisites

Before creating a cube, you need:

- Create permission for Views, Cubes, and Dimensions.
- At least Read-Only access to an existing fact table (business view).
- At least Read-Only access to the Dimensions to include. See “Creating dimensions” on page 69 for details.

Creation steps

To create a cube:

1. Open the Workbench tab of the FileNet BAM Workbench, select the Cubes folder, and click New Cube.
2. Identify a name, and optionally provide a description of the cube.
3. Choose the Fact Table that contains the data to measure, and which contains columns that identify the dimension elements.
4. Define one or more Measure columns.

- Click Add Measure Column to define a column.
- Name the column in the Measure Name field.
- Define the measure formula with a C-SQL Set function in the Aggregate Expression field. The function should reference a column from the fact table. For example, this SUM() expression totals the product of the cost and quantity columns):

```
SUM(OrderDetails.prod_cost*OrderDetails.order_qty)
```

For more information about C-SQL expressions, see [“Formulas” on page 89](#).

5. Define one or more Dimension columns.
 - Click Add Dimension to define a column.
 - Choose the dimension to include from the Dimension column drop-down list. This list includes all dimensions that you have at least Read-Only access to.

Dimension Column Information
Choose the columns on which this cube should be able to drill-down, and the dimension it is associated with.

Add Dimension

Dimension	Dimension Primary Key	Fact Column Foreign Key	
Location Dimensions	REGION_ID	REGION_ID	DELETE
Product Dimensions			
DateTime Dimensions			
Location Dimensions			

- Identify the key columns in the dimension and in the fact table. See [“Key columns” on page 67](#) for more details about the keys.

The data type for the key in the fact table must be the same for the key in the dimension (context table). You cannot, for example, mix integer and decimal types; both must be either integer or decimal.

6. Save the cube and you can immediately begin building Dashboard Objects on top of it.

Data Types

FileNet Business Activity Monitor and C-SQL supports the following SQL-99 data-types and their semantics, each of which is described in detail in the following sections of this documentation:

C-SQL Data Type	Data Type Category
BOOLEAN	Boolean
DECIMAL	Numeric
DOUBLE PRECISION	Numeric
INTEGER	Numeric
INTERVAL	Date-Time
TIMESTAMP	Date-Time
VARCHAR	String

C-SQL provides means for converting data of one type to another type. See [“Data type conversion” on page 53](#) for details.

Data type conversion

In FileNet Business Activity Monitor there are two ways to convert values from one data-type to another: *explicit casting* and *implicit casting*.

Explicit cast

Any C-SQL argument may contain CAST() to convert the data-type of a value. For example, you can cast a character string of numerals into a numeric value, and use the result as an argument to FLOOR():

```
FLOOR( CAST( '1234.56' AS DECIMAL) )
```

Implicit cast

C-SQL automatically attempts to convert a data-type to the correct type for the argument where the value is encountered. For example, if C-SQL encounters the VARCHAR '1234.56' in the FLOOR() argument, it automatically converts the value to a DOUBLE PRECISION numeric before truncating the decimal digits.

```
FLOOR( '1234.56' ) << Implicit cast to DOUBLE PRECISION.
```

Similarly, when a value of one data type is compared to a value of different type, C-SQL first converts one of the values to match the other. In this example, C-SQL converts the VARCHAR string to a BOOLEAN before evaluating the expression:

```
'true' = TRUE << Implicit cast to BOOLEAN.
```

Context also affects casting. For example, because the following arithmetic add operator expects numeric arguments, and even though both values are characters, the values are first cast to numeric:

```
'2' + '3' << Both cast to numeric to match operator data type.
```

NOTE: The value must be convertible to the required type or the expression will result in an *incorrect data-type* error.

Order of precedence

The following table shows which types are convertible, and the order of precedence assigned to each possible data type conversion, where zero (0) is the highest precedence and a million (1,000,000) is the lowest:

To \ From	VARCHA R	BOOLEA N	TIMESTAM P	DOUBLE PRECISIO N	DECIMA L	INTEGE R
VARCHAR	0	10	10	10	1,000,000	1,000,000
BOOLEAN	1	0	—	—	—	—
TIMESTAMP	2	—	0	—	—	—
DOUBLE PRECISION	3	—	—	0	1	3
DECIMAL	4	—	—	1	0	1
INTEGER	5	—	—	2	2	0

In the comparison example above, C-SQL converts the VARCHAR to a BOOLEAN because the precedence level for that conversion is 1, as opposed to 10 for converting the BOOLEAN to a VARCHAR. Similarly, in the FLOOR("1234.56") example C-SQL converts the string to a DOUBLE PRECISION because DOUBLE PRECISION has a higher precedence than DECIMAL, even though a decimal might seem to be more appropriate to the value.

See the descriptions of the individual C-SQL data types for the specific details about converting those types.

Numeric

C-SQL has three data types for numeric values.

Type	Description	Bits	Minimum value	Maximum value
INTEGER	Signed integer	32	-2,147,483,648	2,147,483,647
DECIMAL	Decimal	—	1 digits Total count of DECIMAL digits, both before and after the decimal separator is 256.	256 digits Total count of DECIMAL digits, both before and after the decimal separator is 256.
DOUBLE PRECISION	IEEE 754 floating point	64	+/-4.94065645841246544E-324	+/-1.79769313486231570E-308
Total count of DECIMAL digits, both before and after the decimal separator is 256.				
To express a DOUBLE PRECISION as a literal, use scientific notation, such as <i>1e24</i> .				

Third party data types

The C-SQL numerics map to these data types in other support systems:

C-SQL/JDBC	Java	Oracle	SQL-Server	Sybase
INTEGER	int	Number(<i>p</i> =38)	Int(32 bit)	Int(32 bit)
DECIMAL	BigDecimal	Number(<i>p</i> =38)	Decimal(<i>p</i> =38) Numeric(<i>p</i> =38) Money(64bit) SmallMoney(32bit)	Decimal(<i>p</i> =38) Numeric(<i>p</i> =38) Money(64bit) SmallMoney(32bit)
DOUBLE PRECISION	double	Number(<i>p</i> =38)	double real(4 bytes)	double real(4 bytes)
Where <i>p</i> is precision.				

Combining numeric types

When combining two different numeric types, the result is the type with higher precedence based on the [“Order of precedence” on page 53](#). For example, adding an INTEGER to a DECIMAL results in a DECIMAL sum.

Casting a fractional number to an integer silently truncates the fraction (rounds down) to fit the target. For example, forcing a DOUBLE PRECISION into an INTEGER truncates the fractional part of the value.

Casting numeric types

Casting numerics to types of different storage size is permissible provided that the target is large enough to hold the result; otherwise the conversion fails with a “Number out of range” error. For example, attempting to put a floating-point type of a larger storage size into a location of a smaller size results in an error.

To strings

When casting numerics to strings, be aware of the following:

- For DECIMAL numbers, the result is zero-padded in the decimal values to match the precision and scale defined for the column. So, for example, if a column is defined as precision 5 and scale 4, a value of 1.1 in the column is cast as `'1.1000'`.
- For DOUBLE PRECISION numbers, the 'e' is cast to upper case. So, for example, `+1e11` is converted to `'1.0E11'`.

Decimal precision results

All decimal numbers have two components:

- **Precision**
The count of digits, both to the left and right of the decimal point. The maximum is 256, and the minimum is 1.
- **Scale**
The count of digits of the fractional component, and is less than or equal to the precision. When no scale is specified the default is 2.

In instances where a value has greater scale or precision than the target storage, such as a database field with a smaller precision, FileNet Business Activity Monitor truncates decimals and rounds down the result to make it fit.

Casting

When casting a Decimal value, you can declare the precision and scale like this:

```
DECIMAL( precision, scale )
```

For example,

```
CAST( '4.012345', DECIMAL(5,4) ) --> 4.0123
```

When casting from a decimal formatted column to a string, the result is zero-padded on the decimals to match the scale. For example, when column is precision 5 and scale 4, implicitly casting a value of 1.1 in the column to a string results in '1.1000'.

Multiplication

In multiplication, the resulting precision is the sum of the precisions, and the scale is the sum of the scales.

```
PrecisionResult = MIN( PrecisionLeft+PrecisionRight, 256 )
```

```
ScaleResult = MIN( ScaleLeft+ScaleRight, 256)
```

For example, the result of (4.55*1.414) is precision **7** (3+4) and scale **5** (2+3).

Division

In division, the results are:

```
ScaleResult = MIN(MAX((ScaleLeft+PrecisionRight-ScaleRight+1),2), 256)
```

```
PrecisionResult = MIN((PrecisionLeft + ScaleRight + ScaleResult), 256)
```

For example, the result of (4.55/1.414) is scale **4** (2+4-1) and precision **10** (3+3+4).

Addition and subtraction

For addition and subtraction, the results are:

```
PrecisionResult = MIN( (MAX( PrecisionLeft - ScaleLeft,
                             PrecisionRight - ScaleRight) +
                        MAX( ScaleLeft, ScaleRight ) + 1), 256)
```

```
ScaleResult = MAX( ScaleLeft, ScaleRight )
```

All other functions

For other functions and operations, the result is determined by the value with the largest precision and the value with the largest scale — the results may be determined from the same value.

```
PrecisionResult = MIN( MAX( Precision[i] ), 256)
```

```
ScaleResult = MIN( MAX( Scale[i] ), 256)
```

String

The C-SQL VARCHAR data type maintains character string values.

Type	Description	Padding	Minimum Size	Maximum Size
VARCHAR	Variable length	No	1 character (default), may be null.	Infinite characters. Note that an error occurs if you attempt to store a value into a DBMS that is larger than the size of the column defined in the table.

String width

Though the maximum size limit for string values is infinite, try not to exceed 255 characters because that is the limit imposed on many DBM systems. However, to improve performance, assist data storage, and aid in string compares, it is good to declare an appropriate maximum width when defining a VARCHAR column. The width should be big enough to hold the maximum length of any string result inserted into the field. Text that is longer than the maximum width will be truncated when the string is stored.

Third party data types

The C-SQL string type maps to these data types in other support systems:

C-SQL/JDBC	Java	Oracle	SQL-Server	Sybase
VARCHAR	String	Char Varchar Varchar2(4k)	Varchar(8k)	Varchar(8k)

String concatenation

To concatenate two strings, use either CONCAT() or the || operator. See [“CONCAT” on page 103](#) for details.

String literal

To express a String as a literal, enclose the text in single quotes ('). To include a single quote, include two, for example:

```
'Couldn't'      Returns: Couldn't
```

Converting strings to other data types

When combining a string with another data type, or when expressing a string where another data type is expected, automatically converts the string to the new type based on the [“Order of precedence” on page 53](#). Additionally:

- All leading and trailing spaces are stripped.
- If the string contains an invalid character or invalid formatting, an error occurs. An invalid character is one that is inappropriate for the target data type. For example, 'hello' can't be converted to an INTEGER.
- Formatting that is not consistent with the definition of a literal data value of the target type is invalid. For example, for a string to implicitly convert successfully to a TIMESTAMP data type, the source string must contain be in the default C-SQL date format. See Date-Time for details about formatting strings for date-time types.

Date-Time

Date-time data types store date and time-of-day of that date as a single value (a number). There is no facility for directly accessing a date-time as its internal, numeric representation. Instead, to access date-time values in a meaningful way, C-SQL provides several functions for manipulating the values, and provides literal constructs for representing the values in expressions.

Function	Description
TIMESTAMP literal	A character string representation of a date-time value. Can be any combination of year, month, day-of-month, hour, minute, second, and fractional seconds.
INTERVAL literal	A character string representation of an interval: a span of time comprised of years and months, or of days, hours, minutes, and seconds.

NOTE: Date-time values are in the time-zone of the locale of the server running FileNet Business Activity Monitor.

Converting between date-time and strings

Convert a date-time to a character string (VARCHAR) with TO_CHAR(), and convert a string to a date-time with TO_DATE(). Both of those functions allow you to specify the format of the string.

Including a TIMESTAMP literal in a string an argument automatically converts the value to a string using the default date-time format, which is “yyyy-MM-dd hh:mm:ss.SSS”. For more information about converting between date-time and string values, see [“Data type conversion” on page 53](#).

Comparing date-time values

A date-time is stored internally as a number representing the date-time in milliseconds. As such, you need to be careful when comparing two date-time values. For example, this comparison is only true when both dates have exactly the same milliseconds:

```
first_date = second_date
```

If exact granularity is not important, consider first converting the date-time values to strings that represent just the date portion:

```
TO_CHAR(first_date, "yyyy-MM-dd") = TO_CHAR(second_date, "yyyy-MM-dd")
```

Note that according to the [“Order of precedence” on page 53](#), comparing a string to a date-time first casts the string to a date-time before the comparison occurs. Consider this example where `birth_date` is a date-time value. If `birth_date` has a time associated with it, the comparison will never be true:

```
'2003-02-18' = birth_date
```

A more exact comparison is to first cast `birth_date` to a string without a time:

```
'2003-02-18' = TO_CHAR( birth_date, "yyyy-MM-dd" )
```

Date-time arithmetic

The `DATE_ADD()` and `DATE_DIFF()` functions add and subtract intervals of years, months, days, hours, minutes, and seconds on date-time values. See the descriptions of those functions for details. Some query clauses, however, require a `INTERVAL` literal (described below).

Third party data types

The C-SQL date-time type maps to these data types in other support systems:

C-SQL/JDBC	Java	Oracle	SQL-Server	Sybase
Date-time	Date Time Timestamp	Date(YMDHMS)	Datetime(YMDHMS.xx) SmallDateTime (YMDHMS)	Datetime (YMDHMS.xx) SmallDateTime (YMDHMS)

TIMESTAMP literal

The `TIMESTAMP` literal represents a date-time value as a character string. To express as date-time as a literal value, prefix the data with the word `“TIMESTAMP”`, and enclose the entire data in single quotes (`'`), for example:

```
TIMESTAMP '2003-03-05 19:45:23.123'
```

The format of the string is `“yyyy-MM-dd hh:mm:ss.SSS”`, where S (the fractional seconds) are optional and may be from zero to nine digits of precision. See [“Date-Time formatting” on page 62](#) for details about the formatting characters.

INTERVAL literal

An INTERVAL literal identifies a span of time comprised of years and months (*year-month intervals*), or of days, hours, minutes, and seconds (*day-time intervals*). You cannot combine year-month and day-time in one interval declaration. Intervals are applied to date-time values to calculate the a span of time from that instance. Typically they are used in expressions to offset date-time columns and TIMESTAMP literals, such as when declaring the range from a date or time in Query Windows. For example, this query window totals of all events arriving in the last hour (implicitly applied to the arrival time of the latest event to arrive):

```
SUM(Qty) AS Total_Of_Qty OVER (RANGE INTERVAL '1' HOUR PRECEDING)
```

When applying an interval to a date-time, the interval is added to or subtracted from the value. For example, if the current date-time is 5 March 2003 at 7:45p.m., adding an interval of 1 year to that date results in 5 March 2004 at the exact same time. Note that calendar arithmetic follows Gregorian calendar rules—see DATE_DIFF() for details.

Year-Month intervals

A year-month INTERVAL uses either, or combines both, of the date-time fields YEAR or MONTH. The possible definitions are:

```
INTERVAL 'yy'    YEAR[(<precision>)]
INTERVAL 'mm'    MONTH[(<precision>)]
INTERVAL 'yy mm' YEAR[(<precision>)] TO MONTH[(<precision>)]
```

These examples define intervals of 3 years and of 10 months, respectively:

```
INTERVAL '3'    YEAR
INTERVAL '10'   MONTH
```

You can define a fraction year interval by expressing the result in total months, like 46 months, or by combining the field. For example, to identify an interval of 3 years and 10 months:

```
INTERVAL '3-10' YEAR TO MONTH
```

Note that you may specify a value of zero (0) for either field. These intervals are each 2 years:

```
INTERVAL '2-0'   YEAR TO MONTH
INTERVAL '1-12' YEAR TO MONTH
INTERVAL '0-24' YEAR TO MONTH
```

Precision

The <precision> argument is an ANSI standard that declares the maximum count of digits in the integer. By default, the <precision> is 2. As such, these two declarations of 100 month intervals each fail:

```
INTERVAL '100' MONTH(2) << ERROR, precision is less than value size.
INTERVAL '100' MONTH    << ERROR, default precision is 2.
```

To use more than 2 digits, declare a precision, like this:

```
INTERVAL '100' MONTH(3)
```

When using both fields, apply the precision on the YEAR field only; the MONTH field uses its default precision of 2. For example, the follow is erroneous because the month is greater than the default.

```
INTERVAL '100-123' YEAR(3) TO MONTH << ERROR, month is 3 digits
```

Day-Time Intervals

A day-time INTERVAL is comprised of a combination of days, hours, minutes and seconds. The possible definitions are:

```
INTERVAL 'dd' DAY
INTERVAL 'dd hh' DAY TO HOUR
INTERVAL 'dd hh:mm' DAY TO MINUTE
INTERVAL 'dd hh:mm:ss[.nn ]' DAY TO SECOND
INTERVAL 'hh' HOUR
INTERVAL 'hh:mm' HOUR TO MINUTE
INTERVAL 'hh:mm:ss[.nn ]' HOUR TO SECOND
INTERVAL 'mm' MINUTE
INTERVAL 'mm:ss[.nn ]' MINUTE TO SECOND
INTERVAL 'ss[.nn ]' SECOND
```

Where .nn is a fraction of a second.

Examples

Here are some examples of day-time intervals:

```
INTERVAL '27 23:59:59.999999999' DAY TO SECOND
INTERVAL '100 10:10' DAY(3) TO MINUTE
```

Precision

Each of the day-time fields also have a precision argument, such as:

```
MINUTE(<precision>)
```

The <precision> argument is an ANSI standard that declares the maximum count of digits in the integer. By default, the <precision> is 2 (except for fractional seconds whose default is 9, see below for details). As such, these two declarations of 100 hour intervals each fail:

```
INTERVAL '100' HOUR(2) << ERROR, precision is less than value size.
INTERVAL '100' HOUR << ERROR, default precision is 2.
```

To use more than 2 digits, declare a precision, like this:

```
INTERVAL '100' HOUR(3)
```

When declaring precision for SECOND with a fractional component, specify two precision values separated by a comma. Consider these examples:

```
INTERVAL '12.345' SECOND(2, 3)
INTERVAL '12.123456789' SECOND(2, 9)
INTERVAL '12.123456789' SECOND
```

Notice that the last two examples above have the same effect because the default is (2, 9) for SECOND.

When using multiple fields, expression the precision on the first field only; the remaining fields use their default. For example, the precision here applies to the minutes only and does not affect the fractional seconds:

```
INTERVAL '100:23.123456789' MINUTE(3) TO SECOND
```

Date-Time formatting

The TO_CHAR() and TO_DATE() functions both have arguments that define the format of the date-time string. The format date pattern string is identical to the one used by the Java SimpleDateFormat class, which uses these letters in pattern:

Letter	Date-time Component	Presentation	Examples
G	Era designator	Text	AD
y	Year	Year	1996; 96
M	Month in year	Month	July; Jul; 07
w	Week in year	Number	27
W	Week in month	Number	2
D	Day in year	Number	189
d	Day in month	Number	10
F	Day of week in month	Number	2
E	Day in week	Text	Tuesday; Tue
a	Am/pm marker	Text	PM
H	Hour in day (0-23)	Number	0
k	Hour in day (1-24)	Number	24
K	Hour in am/pm (0-11)	Number	0
h	Hour in am/pm (1-12)	Number	12
m	Minute in hour	Number	30
s	Second in minute	Number	55
S	Fraction of a second (one S always returns an integer of 0 to 9 digits)	Number	978
'	escape for text	Delimiter	
"	single quote	Literal	'

Some letters have multiple results, depending on the number of consecutive letters in the format. The result will be the value that best fits the pattern. For numbers, if the pattern is bigger than the value, the result is padded with leading zeros (0). See the examples below for details.

The following examples modified from the Java SimpleDateFormat class documentation show how date and time patterns are interpreted in the U.S. locale. The given date and time are 2001-08-04 12:08:56 local time in the U.S. Pacific Time time zone.

Date and Time Pattern	Result
'd M yy'	4 8 01
'dd MM yy'	04 08 01
'ddd MMM yy'	004 Aug 2001
'dddd MMMM yyyy'	0004 August 2001
"yyyy.MM.dd G 'at' HH:mm:ss z"	2001.08.04 AD at 12:08:56 PDT
"EEE, MMM d, 'yy"	Sat, Aug 4, '01
"h:mm a"	12:08 PM
"hh 'o'clock' a, zzzz"	12 o'clock PM, Pacific Daylight Time
"K:mm a, z"	0:08 PM, PDT
"yyyyy.MMMMM.dd GGG hh:mm aaa"	02001.August.04 AD 12:08 PM
"EEE, d MMM yyyy HH:mm:ss Z"	Sat, 4 Aug 2001 12:08:56 -0700
"yyMMddHHmmssZ"	010704120856-0700

Boolean

C-SQL follows the SQL-99 use of three-valued logic (TRUE, FALSE, and UNKNOWN) to support NULL value semantics. For example,

```
WHERE OnSale IS TRUE
```

```
WHERE (Age >= 21) IS UNKNOWN
```

When using Boolean operators to evaluate the truth of an expression, the values are evaluated as follows:

Truth table for NOT

NOT	TRUE	FALSE	UNKNOWN
	FALSE	TRUE	UNKNOWN

Truth table for AND

AND	TRUE	FALSE	UNKNOWN
TRUE	TRUE	FALSE	UNKNOWN
FALSE	FALSE	FALSE	FALSE
UNKNOWN	UNKNOWN	FALSE	UNKNOWN

Truth table for OR

OR	TRUE	FALSE	UNKNOWN
TRUE	TRUE	TRUE	TRUE
FALSE	TRUE	FALSE	UNKNOWN
UNKNOWN	TRUE	UNKNOWN	UNKNOWN

Truth table for IS

IS	TRUE	FALSE	UNKNOWN
TRUE	TRUE	FALSE	FALSE
FALSE	FALSE	TRUE	FALSE
UNKNOWN	FALSE	FALSE	TRUE

NOTE: TRUE is greater than FALSE in comparisons.

Dimensions

A *dimension* is a ranked order of classifications that, from highest to lowest level each describe decreasingly smaller sets of related data. Here are some examples of dimensions where the top level of each list contains the largest set of related items, while the bottom contains the smallest, most specific set:

Time	Geography	Inventory	Security	Taxonomy
year	continent	classification	type	kingdom
quarter	country	type	rating	phylum
month	region	manufacturer	company	class
week	state	model	cusip	order
day	county	configuration		family
hour	city			genus
minute	district			species

Cubes categorize measurements by dimensions, and within dimensions by levels and values. For example, a location dimension can filter the results to show the measurements for all cities in a state. This illustration shows several locations filtered by state name, which limits the measurements to just three cities:

The screenshot shows a software interface for filtering data. On the left is a panel titled "Add Dimension Filters:" with a dropdown menu for "Location Dimensions" set to "State". Below it, a "State" dropdown is set to "California", and an "Add Filter" button is visible. Underneath, the "Current Filters:" section shows a list with "State = 'California'" selected. At the bottom of the panel are "Delete Filter" and "Edit Filter" buttons. On the right is a data table with three columns: Region, State, and City. The table contains the following data:

East	New York	Rochester
East	Rhode Island	Tug Hollow
Central	Missouri	Parman
Central	Ohio	Toledo
Central	Texas	Austin
West	Nevada	Reno
West	California	Lodi
West	California	Ojai
West	California	Pasadena
South	Florida	Wallaby Ranch

A red box highlights the three rows where the State is California, and a red arrow points from the "Current Filters" section to this box.

Dimensions draw their values from context tables, where each dimension level is one column in the table, and each row is a unique dimension element. In the example above, the region names are in one column, states in another, and cities in a third. When you create a dimension, you identify the existing source context table and the columns to include, and arrange the columns into the level hierarchy.

Level hierarchy

The level hierarchy is what enables “roll-up” and “drill-down” in cubes. When a user is viewing data for one level, they can “roll-up” to see a higher level of measurements, or “drill-down” to see the data categorized at the next smaller level. For example, when looking at the results for a state, the user might choose to roll-up to see the measurement for all states in the region. Alternatively, the user might click on the results to see the results for each city in the state. The level hierarchy defines the levels in the dimension.

This picture shows four columns in the source file, but only three contain dimension level data. These three are selected and arranged in the containing hierarchy of largest to most-specific levels.

Available Fields:
Select fields for your hierarchy:

Column Name	Data Type
REGION_CITY	Varchar
REGION_ID	Integer
REGION_NAME	Varchar
REGION_STATE	Varchar

>>

Selected Fields:
Arrange fields to form a hierarchy from largest (top) to smallest contained subset (bottom):

Level	Column Name	Alias Name	Order By Col...
1	REGION_NAME	Region	REGION_NAI
2	REGION_STATE	State	REGION_STA
3	REGION_CITY	City	REGION_CIT

Up
Down
Remove

Alias names

After identifying the columns, you can optionally assign alias names that the users will see when they work with the cube. This illustration shows the filter level alias names as they appear in the Dashboard.

Level	Column Name	Alias Name
1	REGION_NAME	Region
2	REGION_STATE	State
3	REGION_CITY	City

Alias names that users see when choosing filter levels in the cube.

Select a Filter Level

- Select a Filter Level
- Region
- State
- City

Order by

In the FileNet BAM Dashboard, dimension values are presented in their sort order (as provided by the server). For example, a list of month names appears in alphabetical order starting with April and ending with September, rather than in the order they occur in a year. To specify another order, use the Order By Column field. This field identifies another column that contains the values to use for sorting. For example, instead of using the “month name” column, use the “month number” column, like this:

Level	Column Name	Alias Name	Order By Column
1	DDIM_YEAR	Year	DDIM_YEAR
2	DDIM_QTR_NAME	Quarter	DDIM_QTR_NAME
3	DDIM_MON_NAME	Month	DDIM_MON_NO
4	DDIM_WEEK	Select a Filter	DDIM_WEEK_NO

Key columns

To use the context as a dimension, your event data must identify the unique dimension element (row) that it belongs too. In the location context data, the most unique value in each element is the city name; however, while that name could be used for identification purposes, for performance reasons it is better to use a number. As such, the locations context data should have an integer ID, like this:

```

region_id  region_name  region_state  region_city
-----
1  West      Nevada      Reno
2  South     Texas       Austin
3  East      New York    Rochester
4  Central   Ohio        Toledo
5  West      California  Pasadena
...

```

Then the fact table that provides the value for the cube to measure also includes the key value to identify the associated dimension. For example, this order record is associated with Ojai, California, in the West region:

```
order_id region_id total_sales ...
-----
102341      7      120000 ...
```

NOTE: The data type for the key in the fact table must be the same for the key in the dimension (context table). You cannot, for example, mix integer and decimal types; both must be either integer or decimal.

When you define the dimension, identify one or more key fields that may be used to identify the specific level. You can choose any column that is not already a dimension level, because levels are automatically assumed to be potential keys. The illustration below shows one column, REGION_ID, because all the other columns in the dimension are assigned to levels. Later, when you define the cube, identify the key column in the dimension that maps to the key in the fact table. In this example they happen to have the same name; however, that is not a requirement. Further, you may assign an alias name to the column to make it easier to identify.

Select Key Fields: (Optional)

Column Name	Key Field	Alias Name
REGION_ID	<input checked="" type="checkbox"/>	REGION_ID

Identify keys in the Dimension editor.

Dimension Column Information
Choose the columns on which this cube should be able to drill-down, and the dimension it is associated with.

Dimension	Dimension Primary Key	Fact Column Foreign Key	
Product Dimensions	PROD_ID	prod_id	DELETE
Location Dimensions	REGION_ID	REGION_ID	
DateTime Dimensions	DDIM_ID	DDIM_ID	

Add Dimension

Map dimensions to facts in the Cube editor.

For information about defining cubes, see [“Creating cubes” on page 49](#).

Creating dimensions

Before creating a dimension, you need:

- Create permission for Views, Cubes, and Dimensions.
- At least Read-Only access to the Context table that provides the dimension elements.

NOTE: Turn on caching for the context table for optimum performance. When caching is off, performance for cubes can be slowed dramatically. See [“Caching context queries” on page 47](#) for information about controlling the cache.

To create a dimension:

1. Open the Workbench tab of the FileNet BAM Workbench, select the Dimensions folder, and click New Dimension.
2. Identify a name, and optionally provide a description of the dimension.
3. Choose the Context Table that contains the dimension elements.
4. Define the levels of the hierarchy:
 - Add fields to the hierarchy from the Available Fields list.
 - Order the levels from largest set (top) to smallest (bottom).
 - Identify one or more Key Columns to include.
 - Optionally assign Alias names to the levels.

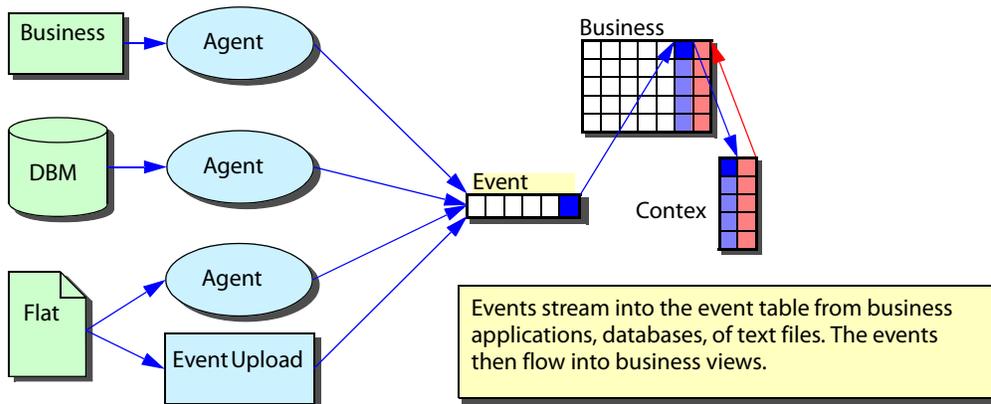

Save the dimension and you can immediately use it in Cubes.

Events

Events drive FileNet Business Activity Monitor internal processing. Events are data produced by external business applications that record transactions, identify changes in business state, and synthesize the details about the business activities. FileNet Business Activity Monitor receives events in *event tables*. Business views built on the tables then aggregate the event information and drive the Rules that look for exceptional business conditions.

How it works

Events come to FileNet Business Activity Monitor from business applications, databases, and text files. Usually Agents automatically receive or retrieve the event data and load it into an event table. Alternatively, you can manually load events from text files with the FileNet BAM Workbench. As events arrive they are processed and their data are passed to the business views. The views then aggregate the data and might they retrieve context data relative to the event.

NOTE: Events are processed in the order that they are received in the system. When one agent has received a large quantity of events, any new events received by other agents are queued behind the first set, and are not processed until the first set is completely processed.

External sources

FileNet Business Activity Monitor provides agents to access several external event sources. Some events stream (are pushed) into the system as they happen. Other events are loaded (pulled) as the result of a request, such as from a database or a text file. This table summarizes the available sources and identifies

the source agent they support. (See [“Agents” on page 25](#) for details about how they retrieve and receive event data.)

External source	Agent	Event push	Event pull
Java Messaging Service (JMS)	“Java Messaging Service (JMS)” on page 171	Yes	No
Text file (XML or flat)	“Flat Files” on page 73	No	Yes
TIBCO Rendezvous (RV)	“TIBCO Rendezvous” on page 273	Yes	No
HTTP Post action	“HTTP Post” on page 164	Yes	No
Web service	None. See “Web service events” on page 304	Yes	No

Event properties

Every event table has a name, description, and status attribute, and most have an agent.

Attribute	Description
Name	Identifies the table and is the name accessed by the Business Views that depend on this table. This name must be unique among views, events, context, and consolidated events. See “Object namespace” on page 211 for details.
Description	<i>(optional)</i> Description of the table.
Status	Whether or not the object is enabled (able to receive and pass data), or disabled (not receiving or passing data).
Agent	An agent that receives or retrieves the event information, and passes the data to the event table. See “Agents” on page 25 for information about agent types.
Log event data for recovery	When on, logs event data that arrived after the last checkpoint started. This “recovery” log is used to restore the state of the system in the event of an abnormal shutdown of the servers. See Working with checkpoint and recovery for complete details.
Process events in the order of arrival	Choose this option when events <i>must</i> be processed in the order received. When off, events may be processed out of order. Note: To join events in a view, the events must be processed in order: leave this option off to join the events.

Creating event tables

Before creating an event table, you must have Create permission for tables (see [“Creating permission” on page 220](#)), and Read only access permission on the agent that will feed the table.

To create an event table:

1. In the Workbench tab of the FileNet BAM Workbench, click New Event...
2. Choose the source type, each type has its own specific attributes. For details, see
 - [“Flat Files” on page 73](#)
 - [“HTTP Post” on page 164](#)
 - [“Java Messaging Service \(JMS\)” on page 171](#)
 - [“JDBC” on page 179](#)
 - [“TIBCO Rendezvous” on page 273](#)
3. Fill in the fields in the New Event or New Context form.

Save the object as enabled and it will immediately be ready to receive events or context.

Editing event tables

Editing the attributes of an event table causes the object to lose state, and possibly invalidates dependant views. For example, if you remove a column, any view or rule that references that column becomes invalid. (However, if you re-define the column in the table, the dependant views are automatically re-validated.)

Before editing an event table, you must have Read and write permission for tables (see [“Accessing permissions” on page 218](#)), and Read only access permission on the agent that feeds the table.

To edit an event table:

1. In the Workbench tab of the FileNet BAM Workbench, select the event or context object.
2. Chose Edit This Event or Edit This Context.
3. Change the definitions in the Edit Event form. Note that each type has its own specific attributes. For details, see
 - [“Flat Files” on page 73](#)
 - [“HTTP Post” on page 164](#)
 - [“Java Messaging Service \(JMS\)” on page 171](#)
 - [“JDBC” on page 179](#)
 - [“TIBCO Rendezvous” on page 273](#)

Save the object as enabled and it will immediately be ready to receive events or context.

Flat Files

A flat file is a text file that contains the information about one or more events. Each line in the file is usually one event record — one row in the event table — and the data in the row map into the columns in the event table. The rows may be formatted as fixed width, delimited, or XML files.

In this Chapter:

[“How it works” on page 74](#)

[“Flat file event tables” on page 74](#)

[“Flat file agents” on page 78](#)

[“Delimited files” on page 83](#)

[“Fixed-Width files” on page 84](#)

[“XML files” on page 85](#)

NOTE: Fixed-width and delimited files may contain multiple rows for the same event. See [“Multi-Row events” on page 77](#) for details.

How it works

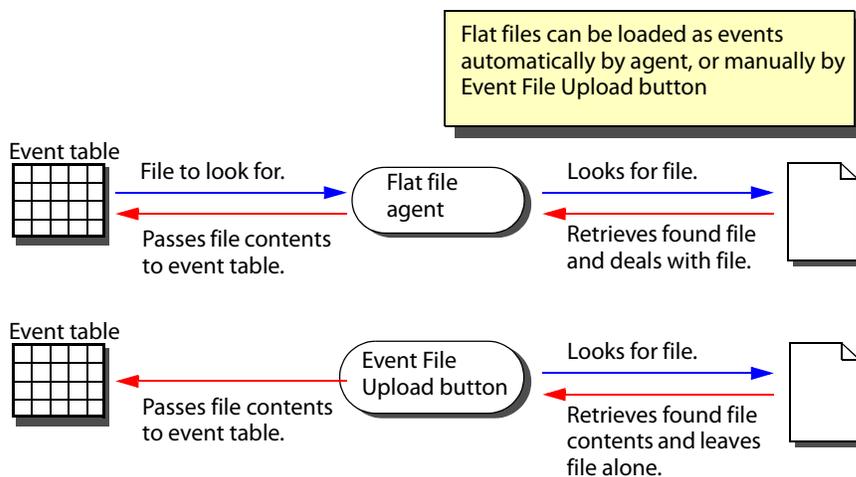

Flat file events are loaded in “batch” mode into the flat-file event table, though events are processed individually as they are loaded into the table. There are two ways to load flat-files into the event tables:

- Automatically

The Flat file agents periodically look to see if the associated file exists. When the file is found, the agent retrieves it and passes it to the event object for event processing.

- Manually

The Upload Event File button in the event-detail page in the FileNet BAM Workbench loads a manually selected file when chosen. See Upload Event File option for details.

Flat file event tables

Flat Files event tables receive event files from Flat file agents or from the Upload Event File option in the FileNet BAM Workbench of the FileNet BAM Workbench. The three flat-file formats are:

- “Delimited files” on page 83
- “Fixed-Width files” on page 84.
- “XML files” on page 85

Before creating an event to a flat-file event table, you need:

- Permissions — Create permission for tables (see “Creating permission” on page 220), and Read Only access permission on the agent that will feed the table.
- Fixed-width and delimited files — *(optional)* A sample file that contains data in the format of the actual events. Use the sample when you create the event to ensure that the fields map correctly into the event table. Note that this is optional; you can create the event without a source, but having it greatly assists you with event table creation.

- The schema of the XML files to load. Specifically, you need to know the names of the attributes that contain the event column information, and the XML path to the element that contains the columns for each event. See [“XPaths” on page 85](#) for details.

Attribute	Description
Name	Identifies the event object. This name must be unique among views, events, context, and consolidated events. See “Object namespace” on page 211 for details.
Description	Optional description that may contain any text characters.
Status	Whether or not the event object is enabled (monitoring for events), or disabled (not monitoring for events).
Log event data for recovery	<p>When on, logs event data that arrived after the last checkpoint started. This “recovery” log is used to restore the state of the system in the event of an abnormal shutdown of the servers. See Working with checkpoint and recovery for complete details.</p> <p>Note: To improve input/output performance, point the recovery log file directory to a disc different from the one that feeds this agent.</p>
Process events in the order of arrival	<p>Note: Choose this option when events must be processed in the order received. Otherwise, if events may be processed out of order, turn this on. To join events in a view, the events must be processed in order: leave this option off to join the events.</p>
File Agent	An existing file agent that retrieves events and context from a text file. Create an agent with the FileNet BAM Workbench Administration tab. See “Flat file agents” on page 78 for details.
Start import on row	For fixed-width and delimited files identifies the row of the text in the source file that contains the first data to import. Default is 1, the first row. Use this option if the text contains unnecessary introduction or header information.
Use this row for column names	For fixed-width and delimited files when using a sample, this option identifies a row in the sample that includes the column names. These names identify each column in the Column Information details. When this option is not specified, the default names are Field1, Field2, etc.
Skip rows	For fixed-width and delimited files identifies the rows to ignore in the source file before importing event data. For example, if the file contains some title and header information, the source might actually start on the third row of the file. In that example, specify 2 as the count of rows to skip.
Allow short rows	For delimited files only. See “Delimited files” on page 83 for details.
Delimiter	For delimited files only. See “Delimited files” on page 83 for details.
Escape character	For delimited files only. See “Delimited files” on page 83 for details.

Attribute	Description
Text qualifier	For delimited files only. See “Delimited files” on page 83 for details.
Number formats	Number formatting specifications. Default is comma (,) thousands separator and dot (.) decimal separator.
Column information	For fixed-width and delimited files details about each column in the table, including the name, data type, and formatting applicable to the type.
Event Key	For fixed-width and delimited files identifies key field columns for multi-row events. See “Multi-Row events” on page 77 for details.
Field information	For XML files identifies the source elements and how they map into the event table columns. See “XML field information” on page 86 for details.

Creating a flat-file source event

To create a flat-file source event:

1. Open the Workbench tab in the FileNet BAM Workbench.
2. Choose New Event and select Flat-file as the source type.
3. *(Optional for fixed-width and delimited files.)* Identify a sample file to assist in mapping the columns. This file is a sample of the real data file. Data from this file appears in the next step to assist you as you map the event data into the table.
4. For fixed-width files, define the positions of the data columns with the Set Field Widths dialog.
5. Identify the event Attribute.
6. Define the format-specific Column Information. For details about the source type, see:
 - [“Delimited files” on page 83](#)
 - [“Fixed-Width files” on page 84.](#)
 - [“XML files” on page 85](#)

Save the file source as enabled and it will immediately be ready to receive event messages.

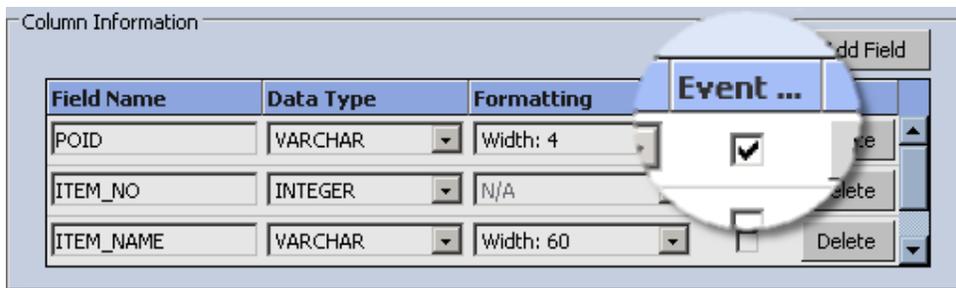

Multi-Row events

A fixed-width or delimited file may contain multiple rows for the same event. For example, a “purchase order” event might contain one row for each line-item in the order. When this event is loaded into the event table, each row is treated as part of the same event; the system does not treat each row as a new event.

To identify the rows as containing data for the same event, each row must have some identifying data that is unique to the event. For example, this sample data contains line items for 3 purchase orders where each order identified by the POID column. The first order has 3 items, the second has one, and the third has 2:

```
POID,ITEM_NO,ITEM_NAME,ITEM_QTY,ITEM_COST,ITEM_TOTAL
0697,1,Smoke Shifter,100,5.00,500.00
0697,2,Nano Webber,50,6.00,300.00
0697,3,Locking Rail Key,25,7.50,187.50
0698,1,Nano Webber,50,6.00,300.00
0699,1,Foo Bar Stool,100,60.00,6000.00
0699,2,Can of Levers,250,1.50,375.00
```

When defining the column information for this event, you identify the POID column as the key field by choosing Event Key. Each event may have one or more Event Key fields.

In the file, the rows for each event must appear together, and the data in the Event Key fields must be unique to the event. As soon as the data in one of the fields is not the same as the previous row, that field's row is a new event. For example, this sample is treated as three separate events, even though the last row has the same Event Key value as the first two rows:

```
POID,ITEM_NO,ITEM_NAME,ITEM_QTY,ITEM_COST,ITEM_TOTAL
0697,1,Smoke Shifter,100,5.00,500.00
0697,2,Nano Webber,50,6.00,300.00
0100,1,Foo Bar Stool,100,60.00,6000.00
0697,3,Locking Rail Key,25,7.50,187.50
```

NOTE: If any row contains invalid data, that row is discarded and does not affect subsequent rows. For example, the third row in this sample contains a character ('X') where an integer is expected. In this sample, the third row is discarded, and the fourth *is included* as the third row in the event:

```
POID,ITEM_NO,ITEM_NAME,ITEM_QTY,ITEM_COST,ITEM_TOTAL
0697,1,Smoke Shifter,100,5.00,500.00
0697,2,Nano Webber,50,6.00,300.00
0697,X,Foo Bar Stool,100,60.00,6000.00
0697,4,Locking Rail Key,25,7.50,187.50
```

Flat file agents

A flat file agent retrieves event messages from a text file.

NOTE: You *cannot* retrieve context from a file agent because there is no query logic.

Event push	Event pull	Context pull
Yes	No	No

File processing

The flat file agent searches for files in a specified location on a defined interval. The name of the files to search for may include * and ? wildcard characters. When the agent locates a file, it retrieves the events and then either deletes, moves, or renames the source file. When multiple files are located in the named location, the agent processes them in filename order.

Prerequisites

Before creating a flat file agent, you need:

- Create permission for agents (see [“Creating permission” on page 220](#) for details).
- A running File agent program (see [“Configuring the file agent program” on page 79](#))

A file agent has the following attributes:

Attribute	Description
Name	Identifies the agent and is the same name as defined by the agentName element in the agent's AgentProperties.xml configuration file. See “Configuring the file agent program” on page 79 for details.
Description	Optional description that may contain any text characters.
Status	Whether or not the agent is enabled (monitoring for events), or disabled (not monitoring for events).

Creating a flat file agent

This section shows you how to create a flat file agent.

To create a flat file agent:

1. Open the FileNet BAM Workbench Administration Console.
2. Click New Agent...
3. Choose Flat-file as the source type
4. Fill in the fields that define the agent's attributes.

Save the agent as enabled and it will immediately begin monitoring for events.

Configuring the file agent program

The File Agent is a stand-alone Java program that runs on a host, possibly different than the FileNet BAM Server host, gathering events from a text file. When it finds event data, it passes the data to the FileNet BAM Server for processing.

The agent has two XML configuration files:

- AgentProperties.xml (based on VCAGENT.xsd) defines the connection information, such as how to locate the FileNet BAM Server(s) and how those servers can locate the file agent.
- FileAgent.xml (based on FileAgent.xsd) identifies the text file and what to do with the file when finished uploading its data.

To start the agent, run the cqagent.jar file in Java and pass the AgentProperties.xml configuration file as an argument, like this:

```
java -jar ..\cqagent.jar AgentProperties.xml
```

Optionally, you can identify the logging configuration file directory and logging level by including logging properties. This example sets the logging level to all messages:

```
java "-Dcom.celequest.property.Logging Directory=C:\logs\agents"  
      "-Dcom.celequest.property.Detailed Log File Level=All"  
      -jar ..\cqagent.jar AgentProperties.xml
```

AgentProperties.xml

The AgentProperties.xml file has the following configuration attributes and elements:

Attribute	Description
serverPort (attribute)	(optional: default 80) HTTP port on the application server that is running the FileNet BAM Server, and which the agent uses to communicate to the server. This is the same port that users use to connect to the FileNet BAM Workbench.
pingInterval (attribute)	(optional: default 20 seconds) How often the agent test to see if the FileNet BAM Server is running. When the server is not running, the agent will not gather events.
agentName	(required) Identifies this agent and is the same Name to use when creating the agent in the Administration Console. This name must be unique among agents. See “Object namespace” on page 211 for details.
serverHost	(required) Name of the host machine running the FileNet BAM Server(s). If they are running on the same machine as the File Agent, specify localhost as the name.
agentImplClass	(required) Agent implementation class. Do not change this value; currently com.celequest.agent.FileAgent is required.
agentImplConfigFile	(required) Identifies the configuration file for the implementation (the text file component), usually FileAgent.xml.
agentPort	(required) Port used to communicate to the agent on the agent’s host. Used for communication by the server to the agent for disable and enable status changes. Use any valid port number, such as 5050.
pollingInterval	(required) How frequently (in seconds) to look for new events.
loggingDirectory	(optional: default is configuration file directory) Directory in which to log file information. The log filename is agentName.log.

Example

This example names the event agent as “orderStatusEvent”, identifies the implementation configuration file as FileAgent.xml, and sets the server port to 8080:

```
<?xml version="1.0" encoding="UTF-8"?>
<VCAgent
  xmlns="http://www.celequest.com"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

FileAgent.xml

This file configures the text file component (the *implementation*) of the File Agent. This file’s actual name and location are identified in the AgentProperties.xml file, and it is usually located in the same directory as that file. This configuration file has four configuration elements, though most configurations use the <filename> and <fileDisposal> elements only.

Elements

The FileAgent.xml file has the following configuration elements:

Element	Description
filename	<p>The name and location of the source text file that contains the events. The file is assumed to be in the same directory as the configuration file unless you identify another location in the filename. You may use relative or complete filepath specifications. And the filename may include * and ? wildcard characters.</p> <p>On UNIX systems use a slash to separate directory path names, such as events/file*.txt.</p> <p>On Windows systems use two backslashes to separate directory path names, such as events\\file*.txt.</p>
type	Identifies the source as a STREAM or FILE. Use FILE when the entire text file must be uploaded atomically (all or nothing), such as for an XML file. Otherwise, use STREAM to upload lines in batches defined by the buffersize element.
buffersize	(optional: default is 4,000+EOL) Count of characters to buffer or send in batch to the server. The actual size sent is the buffersize plus the remainder of the line of characters that span the limit. Use this setting to avoid uploading excessively large amounts of event text at one time.
fileDisposal	<p>(optional) What to do with the source file after uploading its data. Choices are:</p> <p>delete — (default) Deletes the file after upload.</p> <p>move — Moves the file to a directory specified by the target attribute.</p> <p>rename — Renames the file by adding the extension attribute to the filename.</p> <p>Both move and rename overwrite any existing files of the same name in the target location, without warning or error.</p>

Example

This example identifies the source text file as orderStatusData.txt in the events\ subdirectory on a Windows host, and moves the finished file into the ..\done\ sibling directory:

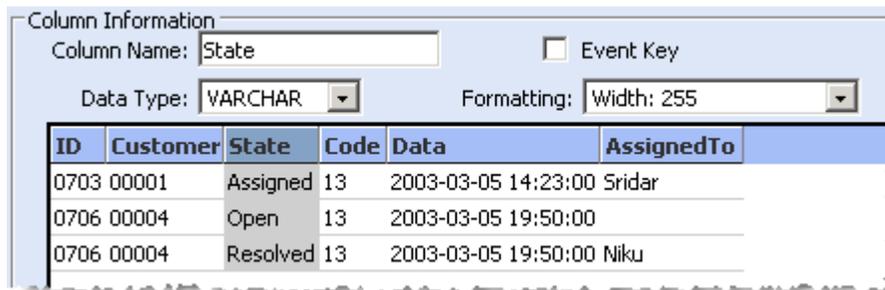

```
<?xml version="1.0" encoding="UTF-8"?>
<FileAgent
  xmlns="http://www.celequest.com"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.celequest.com FileAgent.xsd"
>
  <fileName>event\\orderStatusData.txt</fileName>
  <fileDisposal><move target="..\done\\"></move></fileDisposal>
</FileAgent>
```

Delimited files

In a delimited file, each field (column) is separated by a character, typically a comma. For example:

```
0703,00001,Assigned,13,2003-03-05 14:23:00,Sridar
0706,00004,Open,13,2003-03-05 19:50:00,
0706,00004,Resolved,13,2003-03-05 19:50:00,Niku
```

NOTE: Delimited files are also called comma separated value (CSV) files.

The field separator character, escape character, and text qualifier are each customizable.

- Separator character — Separates each field in the row; usually a comma character (,).
- Escape character — Precedes characters that are not to be used as a separator; usually a back slash character (\). For example, if the separator character is a comma, and the text contains a real comma, then the real comma is “escaped” with a preceding back slash. For example, the comma after “Altadena” is no a field separator:

```
123 Buena Loma Dr,Altadena\, CA,91001
```

- Text qualifier — Text strings are further bounded by this character, usually a double quote(""). Use this option when text strings are qualified to be different from other data types. For example, this event has text fields that contain numerals, but one of the fields (data value 13) is numeric:

```
"0706","00004","Open",13,2003-03-05 19:50:00,""
```

Source rows that do not contain enough data to fill the row generate an error. To permit the data without generating an error, turn on Allow Short Rows. For example, this text generates an error when the third row in imported unless short rows is allowed:

```
1,2,3,4,5,6
1,,,,,
1
```

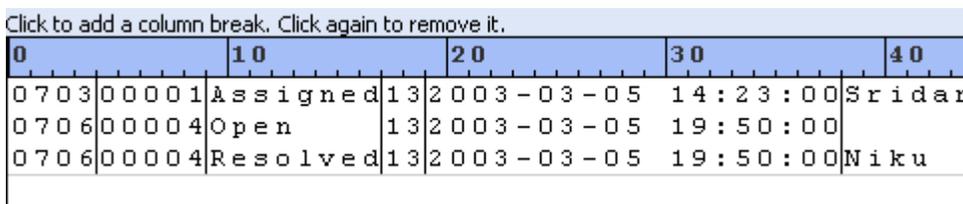

When the First row contains field names option is selected, the names in that row appear as the column names. Otherwise, assign the names manually. Additionally, for each column, assign a data type and optionally declare a data format.

Fixed-Width files

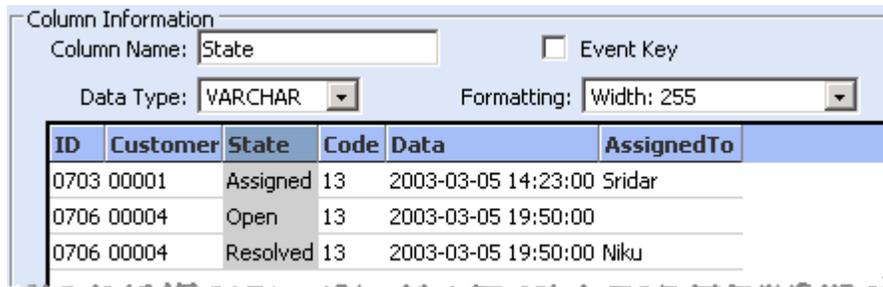

In fixed-width files, each field (column) is the same pre-defined width in each file row, similar to a spreadsheet table. For example:

```
070300001Assigned13 2003-03-05 14:23:00Sridar
070600004Open 13 2003-03-05 19:50:00
070600004Resolved13 2003-03-05 19:50:00Niku
```

To import a fixed-width file, you need to identify the column positions that begin each field of data with the Set Field Widths dialog. When you provide a sample, the sample data are shown and you click the columns to indicate the start of a field.

If you don't have a sample, you need to identify the starting position of each column in the text. Remember too that the first field starts at position zero (0).

Once the column positions have been defined, you can assign names and declare their data types and formats.

When the First row contains field names option is selected, the names in that row appear as the column names. Otherwise, assign the names manually. Additionally, for each column, assign a data type and optionally declare a data format.

XML files

In extensible markup language (XML) files, every event row is an XML element, and every column is an attribute or child element of the row. For example, this shows two problem ticket events.

```
<problem_tickets>
  <ticket>
    <ticket_id>0703</ticket_id>
    <customer cust_id=00001>
      <customer_name>Big Trees</customer_name>
    </customer>
    <status>Assigned</status>
    <topic>13</topic>
    <when_opened>2003-03-05 14:23:00</when_opened>
    <assigned_to>Sridar</assigned_to>
  </ticket>
  <ticket>
    <ticket_id>0706</ticket_id>
    <customer cust_id=00004>
      <customer_name/>
    </customer>
    <status>Open</status>
    <topic>13</topic>
    <when_opened>2003-03-05 19:50:00</when_opened>
  </ticket>
</problem_tickets>
```

XPaths

When defining the event's Field Information, XPaths locate the rows and columns in the XML file as follows:

- Schema XPath identifies the event row element, such as <ticket> in the example above. A Schema XPath is an absolute path to the element in the XML structure, and as such always begins with a slash (/) followed by the root element and path to the row element. In the example above, the Schema XPath as "/problem_tickets/ticket".
- Relative XPath identifies a column element or attribute relative to the row element. When the column is a child element of the row element, the XPath is either just the element name, or it begins with "child:.". For example, these are valid Relative XPaths from the example:

```
ticket_id
child::status
customer/customer_name
child::customer/customer_name
```

To locate an attribute, put an at-symbol (@) before the attribute name, like this:

```
customer/@cust_id
```

NOTE: The XPath standard for locations defines additional XML node mappings not supported by FileNet Business Activity Monitor events.

XML field information

Each column in the event table is defined as a field in the XML event editor. Each field has the following attributes:

Attribute	Description
Field Name	Name of the column in the event table.
Relative XPath	Element in the XML file that contains this field's data. See "XPaths" above for details.
XML Data Type	Data type of the XML element. See below for details.
FileNet Business Activity Monitor Data Type	Data type of the column in the event table. See "Data Types" on page 52 for details.
Formatting	Formatting of the decimal, string, or date-time value.

XML data types

The XML data types map to FileNet Business Activity Monitor Data Types as follows.

XSD	Data Type
anyURI	Varchar
base64Binary	Varchar
Boolean	Boolean
byte	Integer
date	Timestamp (time portion zero'ed out)
dateTime	Timestamp Note the fractional part of a second is supported up to 9 significant digits
decimal	Decimal
double	Double
duration	Varchar (as a string)
ENTITIES	Varchar
ENTITY	Varchar
float	Double
gDay	Varchar (as a string) Defines a part of a date - the day (DD)
gMonth	Varchar (as a string) Defines a part of a date - the month (MM)

XSD	Data Type
gMonthDay	Varchar (as a string) Defines a part of a date - the month and day (MM-DD)
gYear	Varchar (as a string) Defines a part of a date - the year (CCYY)
gYearMonth	Varchar (as a string) Defines a part of a date - the year and month (CCYY-MM)
hexBinary	Varchar
ID	Varchar
IDREF	Varchar
IDREFS	Varchar
int	Integer
integer	Integer
language	Varchar
long	Decimal
Name	Varchar
NCName	Varchar
negativeInteger	Integer
NMTOKEN	Varchar
NMTOKENS	Varchar (as a single string)
nonNegativeInteger	Integer
nonPositiveInteger	Integer
normalizedString	Varchar
NOTATION	Varchar
positiveInteger	Integer
QName	Varchar
QName	Varchar
short	Integer
string	Varchar
time	Varchar

XSD	Data Type
token	Varchar
unsignedByte	Integer
unsignedInt	Decimal
unsignedLong	Decimal
unsignedShort	Integer

Formulas

All formulas in FileNet Business Activity Monitor are expressions in the C-SQL language, a derivative of ANSI SQL. Some of the formulas are simple expressions, such as field expressions that define the values in business view columns. Other expressions are more complex and represent entire components of the C-SQL query statement (SELECT), such as the WHERE, WINDOW, and JOIN clauses.

All formulas in FileNet Business Activity Monitor accept Operators and Constants that can manipulate the values, and they can accept most C-SQL Functions to further process results.

NOTE: For detailed descriptions of each of the C-SQL SELECT statement, operators, and functions, see [“SELECT” on page 264](#).

In this Chapter:

[“Functions” on page 90](#)

[“Function types” on page 90](#)

[“Function categories” on page 92](#)

Functions

Functions return values that are system information, such as the current time, manipulations of data, such as converting a string of characters to upper case, or are evaluations of sets of data, such as the total of all prices in a set of purchase orders.

C-SQL functions can be used in most formulas in FileNet Business Activity Monitor. However, some are limited by the operations allowed in the formula's context. Function types," below, describes the types of functions and tells where they are allowed.

If you are looking for a function for a specific task, see ["Function categories" on page 92](#) to see which tasks the functions can perform.

For a detailed description of each functions, see ["Functions" on page 95](#).

Function types

C-SQL has five types of functions: Scalar, Set, Rank, Moving set, and Tumbling set. The type distinctions determine where you may include the function in a formula.

Scalar

Scalar functions operates on a single item and provide a single result. For example, the ABS() function returns the absolute value of a (single) number. Scalar functions may appear in any C-SQL expression. The scalar functions are:

ABS	DISPLAY_MONEY	LPAD	SIGN
CAST	EXP	LTRIM	SQRT
CEIL	FLOOR	MOD	SUBSTRING
CHARACTER_LENGTH	GREATEST	POSITION	TIMESTAMP_DIFF
CONCAT	IS_RAISED	POWER	TO_CHAR
CURRENT_TIMESTAMP	LAST_DAY	PRIOR_VALUE	TO_DATE
CURRENT_USER	LEAST	ROUND	TRUNC
DATE_ADD	LOG	RPAD	UPPER
DATE_DIFF	LOWER	RTRIM	

Set

Set functions perform aggregations on sets of business view rows and produce a single results for the set. For example, SUM() provides the total of all the rows in a column in a view. A set function *may only be used* in the Select list of a SELECT statement: the field definitions of a view.

NOTE: A set function may reference another set function, but the results are the same as if only the referenced (inner) function was expressed alone. For example SUM(AVG(Order_Total)) has the same result as AVG(Order_Total).

AVG	MAX	PREV	STD_DEVIATION
COUNT	MIN	SUM	VARIANCE
CURRENT			

NOTE: NULL is ignored when computing set function, moving set function, and rank function values. For example, the average of (3, NULL, 3) is 3, not NULL and it is not 2.

Rank

Rank functions compute the scalar result for a column in each row in a set, *with respect to the entire set*. A rank function *may only be used* in the Select list of a SELECT statement.

NTILE	RANK	RATIO_TO_REPORT
-------	------	-----------------

Moving set

Moving set functions are special case set functions that performs calculations on a set of the *latest rows* in a view. The set of rows to include is determined only when a new event arrives. At that time, only the latest rows that meet the set criteria are included in the calculation. Moving set functions are defined by applying "MOV_" to an existing set function. For example, to calculate a moving average, use MOV_AVG(). A moving set can be determined by a count of events or as a duration of time. This example calculates the mean average of Order_Total for the last twelve hours. As new orders are inserted into the view they are included in the calculation; however, orders older than 12 hours are excluded.

```
SELECT MOV_AVG(Order_Total, HOUR, 12) FROM Purchase_Orders
```

NOTE: Moving set functions are a shorthand way to express a simple query window. See "[MOV_function](#)" on page 126 for a complete discussion.

MOV_AVG	MOV_MAX	MOV_SUM	MOV_VARIANCE
MOV_COUNT	MOV_MIN	MOV_STD_DEVIATION	

Tumbling set

Tumbling set functions are special case set functions that perform calculations on a windowed set of the rows in a view. The set of rows to include is determined when a new event arrives, and the set empties when full. Tumbling set functions are a shorthand way to express a tumbling window query. For more information, see [“Tumbling Windows” on page 242](#).

TUMBLE_AVG	TUMBLE_MIN	TUMBLE_STD_DEVIATION
C-SQL Function for a complete list of functions. TUMBLE_COUNT	TUMBLE_SUM	TUMBLE_VARIANCE
TUMBLE_MAX

Functions

C-SQL functions may appear in commands and rule formulas where an expression is accepted. For a general discussion of functions, a list of the Function categories, see [“Formulas” on page 89](#). This document describes each of the following C-SQL functions in detail.

C-SQL Function	Description
ABS	Returns the absolute value of a number.
AVG	Returns the average value (arithmetic mean) of a set of numeric values.
CAST	Converts a value from one FileNet Business Activity Monitor type to another FileNet Business Activity Monitor type.
CEIL	Returns the smallest integer, rounded up from zero, greater than or equal to a number.
CHARACTER_LENGTH	Returns the length of a string.
CONCAT	Returns a string that is the concatenation of two characters or strings.
concatList	Returns a string that is the concatenation of a list of characters or strings.
concatSet	Returns an alphabetically ordered set of strings.
COUNT	Returns the count of rows in a view or set.
CURRENT	Returns a value from the latest or last row in a set.
CURRENT_TIMESTAMP	Returns the current date and time in the server time zone.
CURRENT_USER	Returns the login name of the current user.
DATE_ADD	Adds a duration of time to a date-time value.
DATE_DIFF	Subtracts a duration from a date-time value.
DISPLAY_MONEY	Formats a number as a currency value.
EXP	Returns e raised to a specific power.
FLOOR	Returns largest integer less than or equal to an expression.
gammaDist	Returns the gamma distribution of a value.
GREATEST	Returns the greatest of a list of expression results.
IS_RAISED	Returns true when the specified alert is in a raised state.

C-SQL Function	Description
LAST_DAY	Returns the date of the last day of the month that contains a specified date.
LEAST	Returns the least value of a list of expressions.
LOG	Returns the logarithm of a number from a specific base.
logNormDist	Returns the cumulative lognormal distribution of a value.
LOWER	Converts all uppercase characters in a string to lower case.
LPAD	Inserts one or more instances of a string into the start of another string.
LTRIM	Removes characters from the start of a string.
MAX	Returns the maximum value from a set.
median	Returns the median (middle) number in a set.
MIN	Returns the minimum value from a set.
MOD	Returns the modulus (remainder) of a division.
mode	Returns the most frequently occurring number in a set.
MOV_function	Limits the rows used in a set function calculation to a set of the latest rows in the view.
MOV_AVG	Returns the moving average value (arithmetic mean) of a moving window set of numeric values.
MOV_COUNT	Returns the count of rows in a moving window set.
MOV_MAX	Returns the maximum value from a moving window set.
MOV_MIN	Returns the minimum value from a moving window set.
MOV_SUM	Returns the sum of a moving window set of numeric values.
MOV_STD_DEVIATION	Returns sample standard deviation of a moving window set of numbers.
MOV_VARIANCE	Returns the square of the sample standard deviation of a moving window set of numbers.
NTILE	Determines the tier rank of each value in a set with respect to the entire set.
POSITION	Returns the position of a character or string within a string.
POWER	Returns a value raised to a specific power.
PREV	Returns a value from the next to last row in a set.
PRIOR_VALUE	Returns the prior value of a column, alias, or expression.

C-SQL Function	Description
RANK	Determines the rank of each value in a set with respect to the entire set.
RATIO_TO_REPORT	Calculates the ratio of a value to the sum of the values for the entire set.
ROUND	Returns a number rounded up to a specified count of decimal places.
RPAD	Adds one or more instances of a string to the end of another string.
RTRIM	Removes characters from the end of a string.
SIGN	Identifies the arithmetic sign of a number.
SQRT	Returns the square root of a number.
SUBSTRING	Returns the portion of a string identified by position and length.
SUM	Returns the sum of a set of numeric values.
STD_DEVIATION	Returns sample standard deviation of a set of numbers.
TIMESTAMP_DIFF	Returns the interval of time between two timestamps.
TO_CHAR	Converts a date-time to a character string.
TO_DATE	Converts a character string to a date-time value.
TRUNC	Truncates a number to a specific count of decimal places.
TUMBLE_AVG	Returns the average value (arithmetic mean) of a tumbling window set.
C-SQL Function for a complete list of functions.TUMBLE_COUNT	Returns the count of rows in a tumbling window set.
TUMBLE_MAX	Returns the maximum value from a tumbling window set.
TUMBLE_MIN	Returns the minimum value from a tumbling window set.

C-SQL Function	Description
TUMBLE_SUM	Returns the sum of a tumbling window set of numeric values.
TUMBLE_STD_DEVIATION	Returns sample standard deviation of a tumbling window set of numbers.
TUMBLE_VARIANCE	Returns the square of the sample standard deviation of a tumbling window set of numbers.
UPPER	Converts all lowercase characters in a string to uppercase.
VARIANCE	Returns the square of the sample standard deviation of a set of numbers.

ABS

This scalar function returns the absolute value of a number.

Syntax

```
ABS( numeric )
```

Parameters

- numeric - An expression that evaluates to a numeric.

Return type

Numeric, same data-type as numeric argument.

Example

Return the difference in two persons ages, regardless of which is older.

```
SELECT ABS( father_age - mother_age ) AS "Difference of parents ages"  
FROM Family
```

SIGN() returns the arithmetic sign of a number.

AVG

This set function returns the average value (arithmetic mean) of a set of numeric values.

Syntax

```
AVG( numeric )
```

Parameters

- `numeric` - An expression that evaluates to a numeric and which cannot reference a rank function function. Typically the argument is a column in a view.

Return type

Numeric, same data-type as numeric argument.

Remarks

Calculates the average of numeric in all rows in the referenced view. When using a GROUP BY clause, the average applies to the numeric in each group.

```
SELECT AVG( pr_price ) "Average price" FROM Products
```

```
Average price
```

```
-----
```

```
49.96
```

Example

The following example uses moving averages to produce results *similar* to a Moving Average Convergence/Divergence (MACD) indicator. (This is not a true MACD because it does not use an exponential moving average.) In securities trading, the basic MACD trading rule is to sell when the MACD falls below its 9 day average and to buy when the MACD rises above the 9 day average. You can accomplish this by defining rules similar to this:

- Raise SELL when MACD > Nine_Day_MA
Lower SELL when MACD < Nine_Day_MA
- Raise BUY when MACD < Nine_Day_MA
Lower BUY when MACD > Nine_Day_MA

To get these values you need two views:

- **MACD_Base_View** tracks the moving averages for each security symbol in the event stream. Note that the **Nine_Day_MA** formula repeats the formulas for the other two averages. This is because you cannot reference an alias in another column of the same view.

```
SELECT
  StockQuotes.SYMBOL AS Symbol,
  MOV_AVG(StockQuotes_Event.CLOSE, Day, 26, StockQuotes.DATE)
    AS Twentysix_Day_MA,
  MOV_AVG(StockQuotes_Event.CLOSE, Day, 12, StockQuotes.DATE)
    AS Twelve_Day_MA,
  MOV_AVG((MOV_AVG(StockQuotes.CLOSE, Day, 12, StockQuotes.DATE) -
    MOV_AVG(StockQuotes.CLOSE, Day, 26, StockQuotes.DATE)),
    Day, 9, StockQuotes.DATE ) AS Nine_Day_MA
FROM StockQuotes
GROUP BY StockQuotes.SYMBOL
```

- **MACD_View** contains the last MACD values for each security stored in the base view:

```
SELECT MACD_Base_View.Symbol AS Symbol,
  MACD_Base_View.Nine_Day_MA AS Nine_Day_MA,
  (MACD_Base_View.Twentysix_Day_MA -
  MACD_Base_View.Twelve_Day_MA
  ) AS MACD
FROM MACD_Base_View
```

median() returns the median (middle) number in a set.

mode() returns the most frequently occurring number in a set.

MOV_AVG() returns the moving average for a set.

TUMBLE_AVG() returns the tumbling average for a set.

CAST

This scalar function converts a value from one FileNet Business Activity Monitor type to another FileNet Business Activity Monitor type.

Syntax

```
CAST( value AS vcDataType )
```

Parameters

- value - Value to convert.
- vcDataType - One of the C-SQL Data Types to convert to.
 - INTEGER
 - DECIMAL
 - DOUBLE PRECISION
 - VARCHAR
 - TIMESTAMP
 - BOOLEAN

Return type

Same as vcDataType argument.

Remarks

Types are cast according the Order of precedence table in [“Data type conversion” on page 53](#). CAST() returns an error if a type cannot be cast as specified in an expression. For example, the following is an error because C-SQL attempts to cast '4.5' to an INTEGER, but the decimal is an illegal character for INTEGER types:

```
3 < CAST( '4.5' AS INTEGER )
```

When casting from a decimal formatted column to a string, the result is zero-padded on the decimals to match the scale, just as when casting from a string to a decimal. For example,

```
CAST( '1.1' AS DECIMAL(5,4) ) --> 1.1000  
CAST( CAST( '1.1' AS DECIMAL(5,4) ) AS VARCHAR ) --> '1.1000'
```

Example

Cast a date string into a time-stamp:

```
SELECT CAST('1997-10-22' AS TIMESTAMP )  
FROM Foo;
```

[“Data type conversion” on page 53](#) provides details about converting types.

TO_CHAR() converts the timestamp to a character string of specified format.

TO_DATE() converts a character string to a date.

CEIL

This scalar function returns the smallest integer, rounded up from zero, greater than or equal to a number.

Syntax

```
CEIL( numeric )
```

Parameters

- numeric - Number to round.

Return type

Same data type are numeric result.

Example

```
CEIL(1234.56) returns 1235.00.
```

```
CEIL(-2.75) returns -2.00.
```

FLOOR() returns the largest value less than or equal to a number.

CHARACTER_LENGTH

This scalar function returns the length of a string.

Syntax

```
CHARACTER_LENGTH( string )
```

Parameters

- string - String or VARCHAR expression result whose length to evaluate.

Return type

INTEGER.

Remarks

Alternate spelling is:

```
CHAR_LENGTH( string )
```

Returns an integer that is the length of the string. Returns NULL if the string is NULL.

The length of a string is determined by its displayable characters, and not necessarily the storage length of the string. For example, a Unicode character requires 16-bits of storage — which might be considered as 2 characters of storage on some systems — but the actual character length is 1.

CONCAT

This scalar function returns a string that is the concatenation of two characters or strings.

Syntax

```
CONCAT( string1, string2 )
```

Parameters

- string - A character string value or VARCHAR expression result.

Return type

VARCHAR.

Remarks

Returns string2 appended to the end of string1. Returns NULL if either string is NULL.

The || operator ([“String operators” on page 213](#)) is identical to this function.

Examples

CONCAT('a', 'b') returns 'ab'.

'a' || 'b' returns 'ab'.

concatList() returns a string that is the concatenation of a list of characters or strings.

concatSet() returns an alphabetically ordered set of strings.

[“String operators” on page 213](#) describes the || operator.

concatList

This scalar function returns a string that is the concatenation of a list of characters or strings.

Syntax

```
concatList( string1, string2 [, ... stringN ] )
```

Parameters

- string - An expression that evaluates to a VARCHAR

Return type

VARCHAR.

Remarks

Returns string2 appended to the end of string1, string3 appended to string2, and so on.
Ignores NULL values unless all values are NULL, in which case returns an empty string.

Examples

`concatList('a', 'b', 'c')` returns 'abc'.

`CONCAT()` returns a string that is the concatenation of two characters or strings.

`concatSet()` returns an alphabetically ordered set of strings.

“[String operators](#)” on [page 213](#) describes the `||` operator.

concatSet

This set function returns an alphabetically ordered set of strings.

Syntax

```
concatSet( stringExp )
```

Parameters

- stringExp - An expression that evaluates to a VARCHAR. Typically the argument is a column in a view.

Return type

VARCHAR.

Remarks

Returns a string that is the ordered set of all the strings passed into the function.

Ignores NULL values unless all values are NULL, in which case returns an empty string.

Examples

Consider this statement:

```
SELECT concatSet(item) AS item_list FROM GroceryList
```

If the items in GroceryList are presented as follows in this order:

```
'banana'  
'egg'  
'apple'  
'donut'  
NULL  
'carrot'
```

The order in item_list in the new view is:

```
'apple,banana,carrot,donut,egg'
```

Subsequently, if 'bagel' is added to GroceryList, the new order in the new view is:

```
'apple,bagel,banana,carrot,donut,egg'
```

CONCAT() returns a string that is the concatenation of two characters or strings.

concatList() returns a string that is the concatenation of a list of characters or strings.

[“String operators” on page 213](#) describes the || operator.

COUNT

This set function returns the count of rows in a view or set.

Syntax

```
COUNT ( * )
```

Return type

INTEGER.

Remarks

Returns zero (0) if the view or set is empty.

This is also known as the “count star” function.

Rows that include NULLs are counted.

MOV_COUNT() returns the count of a moving set.

C-SQL Function for a complete list of functions. TUMBLE_COUNT() returns the count of a tumbling set.

CURRENT

This set function returns a value from the latest or last row in a set.

Syntax

```
CURRENT( columnName )
```

Parameters

- columnName - Column or alias to retrieve.

Return type

Same data-type as argument.

Remarks

Returns a value from the latest row in the set based on the event timestamp. When all rows in the set have the same timestamp, returns the value from the last row in the set.

Example

Gather all stock feed bids and group them by stock symbol. The “current” row will always be the last one received, and as such, will contain the current bid price:

```
SELECT symbol, CURRENT(bid) AS Bid, MAX(bid) AS High, MIN(bid) AS LOW
FROM Stock_feed
GROUP BY symbol
```

symbol	Bid	High	Low
K	31.25	31.28	30.72
IBM	80.79	80.04	82.55
VCLR	22.60	24.42	22.00

Moving set semantics

Cannot be used with a moving or tumbling set.

PREV() returns a value from the row previous to the current one.

CURRENT_TIMESTAMP

This scalar function returns the current date and time in the server time zone.

Syntax

```
CURRENT_TIMESTAMP()
```

Return type

Date-Time.

Example

LAST_DAY(CURRENT_TIMESTAMP()) returns the date of the last day of the current month.

TO_CHAR() converts a timestamp to a character string.

LAST_DAY() returns the date of the last day of a month.

DATE_ADD() adds a duration to a date-time.

DATE_DIFF() subtracts a duration from a date-time.

TIMESTAMP_DIFF() returns a time interval between two timestamps.

CURRENT_USER

This scalar function returns the login name of the current user.

Syntax

```
CURRENT_USER ( )
```

Return type

VARCHAR.

Remarks

Returns the user's login name as defined in FileNet Business Activity Monitor, in the same character case, and as it appears in the FileNet BAM Workbench. As such, when using in a comparison, be sure to match the character case exactly.

This function is primarily for use in access filters. See [“Access Filters” on page 17](#), especially the section [“Users as context” on page 19](#), for examples and uses.

DATE_ADD

This scalar function adds a duration of time to a date-time value.

Syntax

```
DATE_ADD( timestamp, [ durationType, ] duration )
```

Parameters

- timestamp - The date-time to adjust.
- durationType - Type of the duration value; one of these literals:
 - SECOND
 - MINUTE
 - HOUR
 - DAY (default)
 - MONTH
 - YEAR
- duration - Duration of time to add; a literal positive integer.

Return type

Date-Time.

Remarks

Uses Gregorian calendar addition rules.

Example

`DATE_ADD(CURRENT_TIMESTAMP(), 2)` returns a date-time two days in the future from now.

`DATE_ADD(aTimestamp, DAY, 14)` returns a value 2 weeks after the data.

`DATE_DIFF()` subtracts a duration from a date-time.

`CURRENT_TIMESTAMP()` returns the current date and time.

`TIMESTAMP_DIFF()` returns a time interval between two timestamps.

DATE_DIFF

This scalar function subtracts a duration from a date-time value.

Syntax

```
DATE_DIFF( timestamp, [ durationType, ] duration )
```

Parameters

- `timestamp` - The date-time from which to subtract some duration of time.
- `durationType` - Type of the duration value; one of these literals:
 - SECOND
 - MINUTE
 - HOUR
 - DAY (default)
 - MONTH
 - YEAR
- `duration` - Duration of time to subtract; a literal positive integer.

Return type

Date-Time.

Remarks

Uses Gregorian calendar subtraction rules.

Durations that span leap year days and seconds generally ignore the leap value. For example, subtracting 1 year from 3 March 1976 results in 3 March 1975 without being affected by the 29 February 1976 leap day. However, subtracting 1 year from 29 February results in a 28 February date.

Examples

`DATE_DIFF(CURRENT_TIMESTAMP(), 2)` returns a date-time two days ago from now.

`DATE_ADD()` adds a duration to a date-time.

`CURRENT_TIMESTAMP()` returns the current date and time.

TIMESTAMP_DIFF() returns a time interval between two timestamps.

DISPLAY_MONEY

This scalar function formats a number as a currency value.

Syntax

```
DISPLAY_MONEY( number [, languageCode, countryCode ] )
```

Parameters

- number - Number to format.
- languageCode - A two-letter ISO 639 language code. Helps determine the currency symbol to display.
- countryCode - A two-letter ISO 3166 country code. Specifies the thousands separator, decimal separator, and count of decimal digits to display based on what is appropriate for the country.

Return type

VARCHAR.

Remarks

Returns a the number formatted as a currency string.

Omitting the languageCode and countryCode uses the symbol and format appropriate for country that your computer is configured to use by default.

Some currency symbols require that the browser be configured to the correct code-page for the language.

Examples

Here are some examples that format the number 12345.678:

Language/country	Formula	Result
English/USA	DISPLAY_MONEY(12345.678, 'en', 'us')	\$12,345.68
Swedish/Sweden	DISPLAY_MONEY(12345.678, 'sv', 'se')	12 345,68 kr
German/Germany	DISPLAY_MONEY(12345.678, 'de', 'de')	12.345,68 dm

Common codes

Here are some common ISO 639 two-letter language codes:

Language	Code	Language	Code	Language	Code
Afrikaans	af	Fiji	fj	Dutch	nl
Arabic	ar	Faroese	fo	Norwegian	no
Catalan	ca	French	fr	Punjabi	pa
Corsican	co	Hebrew	he	Polish	pl
Czech	cs	Hindi	hi	Portuguese	pt
Danish	da	Croatian	hr	Russian	ru
German	de	Italian	it	Serbo-Croatian	sh
Greek	el	Inuktitut	iu	Swedish	sv
English	en	Japanese	ja	Turkish	tr
Spanish	es	Korean	ko	Urdu	ur
Persian	fa	Mongolian	mn	Yoruba	yo
Finnish	fi	Nepali	ne	Chinese	zh

Here are some of the common ISO 3166 two-letter country codes.

Country	Code	Country	Code
AUSTRALIA	AU	NEPAL	NP
AUSTRIA	AT	NETHERLANDS	NL
BRAZIL	BR	NEW ZEALAND	NZ
CANADA	CA	NORWAY	NO
CHINA	CN	OMAN	OM
CROATIA (local name: Hrvatska)	HR	PAKISTAN	PK
DENMARK	DK	PITCAIRN	PN
FIJI	FJ	POLAND	PL
FINLAND	FI	PORTUGAL	PT

Country	Code	Country	Code
FRANCE	FR	SAUDI ARABIA	SA
GERMANY	DE	SOUTH AFRICA	ZA
GREECE	GR	SPAIN	ES
HONG KONG	HK	SWEDEN	SE
INDIA	IN	SWITZERLAND	CH
IRAN (Islamic republic of)	IR	TAIWAN	TW
ISRAEL	IL	TURKEY	TR
ITALY	IT	UNITED ARAB EMIRATES	AE
JAPAN	JP	UNITED KINGDOM	GB
KOREA (Demo. people's republic of)	KP	UNITED STATES	US
MEXICO	MX	—	—

EXP

This scalar function returns e raised to a specific power.

Syntax

EXP (power)

Parameters

- power - The power (DOUBLE) to which to raise e .

Return type

DOUBLE PRECISION.

Remarks

Returns e raised to the n^{th} power, where $e = 2.71828183\dots$

Example

EXP (4) raises e to the 4th power and returns 54.59815.

LOG() returns the logarithm of a number from a specific base

POWER() raises a number to a specific power.

FLOOR

This scalar function returns largest integer less than or equal to an expression.

Syntax

```
FLOOR( numeric )
```

Parameter

- numeric - Number to floor.

Return type

Numeric, same data-type as numeric argument.

Example

`FLOOR('1234.56')` returns the integer 1234.00, after first implicitly casting the string literal to a DECIMAL.

`FLOOR(-2.75)` returns -3.00.

NOTE: This function behaves identical to the Microsoft Excel INT() function.

CEIL() returns smallest integer rounded up.

gammaDist

This scalar function returns the gamma distribution of a value.

Syntax

```
gammaDist( number, alphaNumber, betaNumber, isCumulative )
```

Parameter

- number - Positive number to evaluate, may be zero (0).
- alphaNumber - Alpha parameter (positive number, may be zero) to the gamma distribution equation.
- betaNumber - Beta parameter (positive number, may be zero) to the gamma distribution equation.
- isCumulative - Boolean that determines the form of the function of number based on alphaNumber and betaNumber:
 - TRUE uses the cumulative distribution function.
 - FALSE uses the probability mass function.

Return type

DOUBLE PRECISION.

Remarks

When alphaNumber is one (1), returns an *exponential distribution*.

When alphaNumber is a positive integer, the result is a *Erlang distribution*.

Example

Populate a view with the probability mass for a gamma distribution of alpha=9 and beta=2:

```

SELECT TimeToFail,
       gammaDist(TimeToFail, 9, 2, FALSE) AS GammaDist
FROM UnitTests
ORDER BY TimeToFail

```

logNormDist() returns the cumulative lognormal distribution of a value.

GREATEST

This scalar function returns the greatest of a list of expression results.

Syntax

```
GREATEST( value, value [, value ... ] )
```

Parameters

- value - A value to be used for the comparison. All values after the first are converted to the data type of the first.

Return type

Same data-type as argument.

Example

Selects the string with the greatest value:

```

SELECT Greatest (
    'SCHOLAR',
    'SKYLER',
    'SHUELLER')
FROM Foo;

```

Greatest

SKYLER

LEAST() determines the least value from a list.

MAX() returns the maximum value from a set.

["Function types" on page 90](#) discusses moving sets.

IS_RAISED

This scalar function returns true when the specified alert is in a raised state.

Syntax

```
IS_RAISED('alertName')
```

Parameters

- **alertName** - Fully qualified name of an alert: the name must include the containing business activity and scenario names, like this 'activityName.scenarioName.alertName'.

Return type

Boolean.

Remarks

Returns True if the alert exists and is in a raised state; otherwise, if the alert is in a lowered state or if it doesn't exist, returns False.

NOTE: Because this function returns False when the alert does not exist, there is no test to ensure that the name you entered is a valid alert in the system. As such, misspelling the name will cause the function to always return False.

Use this function in a rule condition to test the state of an alert, and to generate a new alert when the tested alert remains raised for a period of time.

When used in a view definition, the following conditions apply:

- this function can only appear in the WHERE clause
- the view definition cannot have a set function.

See [“Monitoring alerts” on page 259](#) for a detailed discussion of using this function.

Alert states.

Monitoring alerts.

LAST_DAY

This scalar function returns the date of the last day of the month that contains a specified date.

Syntax

```
LAST_DAY( dateTime )
```

Parameters

- `dateTime` - A valid date (TIMESTAMP).

Return type

Date-Time.

Example

`LAST_DAY(CURRENT_TIMESTAMP())` returns the date of the last day of the current month.

`CURRENT_TIMESTAMP()` returns the current date and time.

LEAST

This scalar function returns the least value of a list of expressions.

Syntax

```
LEAST( value, value [, value ... ] )
```

Parameters

- `value` - A value to be used for the comparison. All values after the first are converted to the data type of the first.

Return type

Same data-type as argument.

Example

```
SELECT Least (
    'SCHOLAR',
    'SKYLER',
    'SHUELLER')
FROM Foo;
```

```
Least
```

```
-----
```

```
SCHOLAR
```

`GREATEST()` determines the greatest value from a list.

`MIN()` returns the minimum value from a set.

[“Function types” on page 90](#) discusses moving sets.

LOG

This scalar function returns the logarithm of a number from a specific base.

Syntax

```
LOG( numeric [, base ] )
```

Parameters

- **numeric** - Number (DOUBLE) from which to retrieve the logarithm; must be greater than 1.
- **base** - Base (DOUBLE) of the logarithm; must be greater than zero (0). Omit this option to use the natural log of numeric.

Return type

DOUBLE PRECISION.

Remarks

This can be expressed mathematically as “ $\log_{\text{numeric}} \text{base}$ ”.

Example

LOG (8 , 64) returns 2.0.

LOG (2) returns 0.301029...

EXP() raise *e* to a specific power.

POWER() raises a value to a specific power.

logNormDist

This scalar function returns the cumulative lognormal distribution of a value.

Syntax

```
logNormDist( number, meanNumber, stdNumber )
```

Parameters

- number - Value to evaluate.
- meanNumber - Mean average of $\ln(\text{number})$.
- stdNumber - Standard deviation of $\ln(\text{number})$.

Return type

DOUBLE PRECISION.

Remarks

Returns the cumulative lognormal distribution of a value, where $\ln(\text{number})$ is normally distributed with mean and standard deviation.

gammaDist() returns gamma distribution of a value.

LOWER

This scalar function converts all uppercase characters in a string to lower case.

Syntax

```
LOWER( string )
```

Parameters

- string - String to convert.

Return type

VARCHAR.

Example

LOWER('Stage Right') returns 'stage right'.

UPPER() converts to all uppercase.

LPAD

This scalar function inserts one or more instances of a string into the start of another string.

Syntax

```
LPAD( string, length, [ padChar ] )
```

Parameters

- string - Character or string to alter.
- length - The display length of the returned string. Must be zero (0) or greater. When using multi-byte characters, the length is the count of characters that display or print, not the count of multi-bytes.
- padChar - Character or string to insert. Default is a single space or blank character (' ').

Return type

VARCHAR.

Remarks

Returns a string in the same character type as the string parameter.

When length is smaller than the length of string, returns the string truncated to length.

Examples

```
LPAD('ABC',6,'x') returns 'xxxABC'.
```

```
LPAD('ABC',6,'x0') returns 'xoxABC'.
```

```
LPAD('ABC',4) returns ' ABC'.
```

```
LPAD('ABC',2,'x') returns 'AB'.
```

RPAD() adds characters to the end of a string.

LTRIM

This scalar function removes characters from the start of a string.

Syntax

```
LTRIM( wholeString [, setString ] )
```

Parameters

- wholeString - String to trim.
- setString - Characters to remove; default is a single blank space (' ').

Return type

VARCHAR.

Remarks

Recursively removes all instances of setString from the start of wholeString until wholeString no longer starts with setString, and returns the result.

Examples

```
LTRIM(' ZZZ') returns 'ZZZ'.
```

```
LTRIM('aaaZZZ', 'a') returns 'ZZZ'.
```

```
LTRIM('ababaZZZ', 'ab') returns 'aZZZ'.
```

```
LTRIM('abcabaZZZ', 'abc') returns 'abaZZZ'.
```

RTRIM() removes characters from the end of a string.

MAX

This set function returns the maximum value from a set.

Syntax

```
MAX( expression )
```

Parameters

- `expression` - An expression that evaluates to any data type and which cannot reference a rank function function. Typically the argument is a column in a view.

Return type

Same data-type as expression argument.

Remarks

For Boolean, True is greater than False.

For String, 'z' is greater than 'A'.

Example

Return the maximum price from all the rows in Foo:

```
SELECT MAX( price ) FROM Foo;
```

```
PRICE  
-----  
770.00
```

Moving set semantics

When used as a `MOV_function()`, returns the maximum value for the moving set.

```
MOV_MAX( numeric, window, size [,timestampColumn] )
```

`MOV_MAX()` returns the maximum value from a moving window set.

`TUMBLE_MAX()` returns the maximum value from a tumbling window set.

`MIN()` returns the minimum value from a set.

`GREATEST()` returns the maximum value from a list.

median

This set function returns the median (middle) number in a set.

Syntax

```
median( numericExp )
```

Parameters

- `numericExp` - An expression that evaluates to numeric and which cannot reference a rank function function. Typically the argument is a column in a view.

Return type

INTEGER when all results of `numericExp` are integer; otherwise DOUBLE PRECISION when any of the results are decimal.

Remarks

This function sorts the values in the set and then returns the median of the ordered set.

When the count of values is odd, the median is the middle number of the set. For example, the median of 2,1,5 is 2: the middle value of the ordered set.

Otherwise, when the count is even, the median is the average value of the two middle numbers in the set. For example, the median of 2,1,5,4 is 3: the average of 2 and 4. Further, when the result of the average is a decimal value, the result is “floored” to the integer: the median of 2 and 3 is 2, which is $\text{floor}(2.5)$.

Ignores NULL values.

Examples

Consider this statement:

```
SELECT median(Value) AS MedianV FROM NumberList
```

The result is 1.5 (the average of 1.0 and 2.0 after ignoring the NULLs) when the items in `NumberList` are presented in this order:

```
3.0  
NULL  
0.0  
2.0  
1.0  
NULL  
NULL
```

The result is 1 if the set is

```
1  
2
```

Because the values are integers, the result must also be an integer. As such the average which is 1.5 is floored to 1.

`AVG()` returns the mean average value of a set.

`mode()` returns the most frequently occurring number in a set.

MIN

This set function returns the minimum value from a set.

Syntax

```
MIN( expression )
```

Parameters

- `expression` - An expression that evaluates to any data type and which cannot reference a rank function function. Typically the argument is a column in a view.

Return type

Same data-type as expression argument.

Remarks

For Boolean, True is greater than False.

For String, 'z' is greater than 'A'.

Example

Return the minimum price from all the rows in set Foo:

```
SELECT MIN( price ) FROM Foo;
```

```
PRICE  
-----  
100.00
```

Moving set semantics

When used as a `MOV_function()`, returns the minimum value for the moving set.

```
MOV_MIN( numeric, window, size [,timestampColumn] )
```

`MOV_MIN()` returns the minimum value from a moving window set.

`TUMBLE_MIN()` returns the minimum value from a tumbling window set.

`MAX()` returns the maximum value from a set.

`LEAST()` returns the smallest value from a list.

MOD

This scalar function returns the modulus (remainder) of a division.

Syntax

```
MOD( dividend, divisor )
```

Parameters

- `dividend` - Numeric to divide.

- divisor - Numeric to divide by.

Return type

INTEGER.

Remarks

When divisor is zero (0), returns dividend.

This function behaves differently from the classical mathematical modulus function when dividend is negative. The classical modulus can be expressed with this formula:

`dividend - divisor * FLOOR(dividend/divisor)`

This function uses this updated formula:

`SIGN(dividend) * (ABS(dividend) - ABS(divisor * FLOOR(ABS(dividend/divisor))))`

This table illustrates the difference between the MOD function and the classical modulus formula:

Dividend	Divisor	MOD (Dividend,Divisor)	Classical Modulus
11	4	3	3
11	-4	3	-1
-11	4	-3	1
-11	-4	-3	-3

Note: Most database management systems use the same formula as FileNet Business Activity Monitor, while spreadsheet applications like Microsoft Excel use the classical modulus.

Example

Return the remainder of dividend divided by divisor:

`SELECT MOD(11,4) "Modulus" FROM Foo;`

```
Modulus
-----
3
```

mode

This set function returns the most frequently occurring number in a set.

Syntax

```
mode( numericExp )
```

Parameters

- `numericExp` - An expression that evaluates to numeric and which cannot reference a rank function. Typically the argument is a column in a view.

Return type

Same type as `numericExp` result.

Remarks

When multiple different values occur with the same frequency, `mode()` returns the first one it encountered. See the example.

Ignores NULL values.

Examples

Consider this set of numbers, fed into `mode()` in this order:

```
1  
3  
4  
1  
3
```

The `mode()` function returns 1 because it occurs with the most frequency, and is encountered before 3, which occurs with the same frequency. Had the set been fed into `mode()` in reverse order, it would have returned 3.

For this set of numbers, `mode` returns 1.0:

```
1  
3  
NULL  
2.0  
NULL  
NULL  
1
```

The NULLs are ignored, and the 2.0 causes `mode()` to return a DOUBLE PRECISION value.

See also

`AVG()` returns the mean average number in a set.

`median()` returns the median (middle value) for a set.

[“C-SQL Function” on page 95](#) for a complete list of functions.

MOV_function

This scalar function limits the rows used in a set function calculation to a set of the latest rows in the view.

Moving set functions

The moving window set functions are:

Argument	Description
MOV_AVG	Returns the moving average value (arithmetic mean) of a moving window set of numeric values.
MOV_COUNT	Returns the count of rows in a moving window set.
MOV_MAX	Returns the maximum value from a moving window set.
MOV_MIN	Returns the minimum value from a moving window set.
MOV_SUM	Returns the sum of a moving window set of numeric values.
MOV_STD_DEVIATION	Returns sample standard deviation of a moving window set of numbers.
MOV_VARIANCE	Returns the square of the sample standard deviation of a moving window set of numbers.

NOTE: Moving set functions are shorthand for simple query windows. For a complete discussion, see [“Query Windows” on page 228](#).

Syntax

All moving set functions have this syntax:

```
mov_function( numeric, window, size [,timestampColumn] )
```

where functionName is an existing set function. The return type of the moving function is the same as that of the named function. The numeric is typically a column in the view, but may contain other functions and operators, though it cannot reference another set function, moving set function, or rank function.

The window and size arguments specify which rows are included in the set. The window argument determines if size is the count of rows in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR). For example a set of the last 6 events limits the set to no more than 6

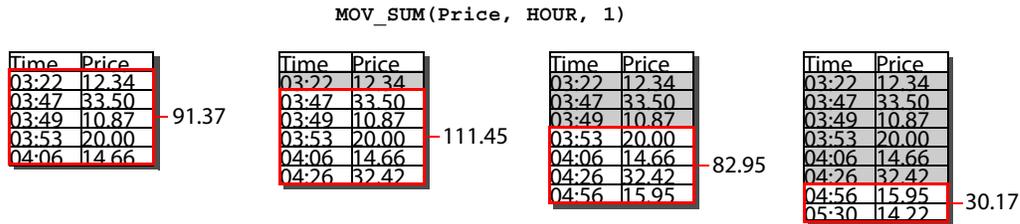

events (per group when using the GROUP BY clause). Note that some events generate multiple rows; do not confuse events with rows.

Complete window expression:

```
SUM(Price) OVER (EVENT '5' PRECEDING REFERENCE FRAME)
```

When using time-series span (instead of event span), the size of the set varies depending on when the events were recorded in the view. For example when using a time-series of 1 hour, only those rows that entered the view in the last hour are used in the calculation.

Complete window expression:

```
SUM(Price) OVER (RANGE '1' HOUR PRECEDING REFERENCE OPERATOR)
```

NOTE: It is possible, but highly unlikely, for an event to arrive in the system in time to be included in a view, but to be discarded because by the time it reaches the view, it is no longer in the view's time span. For example, if the event enters the event table a few milliseconds before it would be excluded from a derived view, it might be included or excluded depending on how long it takes to process and propagate the event in base views.

The optional timestampColumn argument instructs the system to use the value of a field in the view as the reference point for starting the time-series span. When you omit this option, the system calculates the time-series based on the system clock, such as the last hour from now. When you name a timestamp column

instead, the calculation is based on the time span from the value in the most recent value in the column from any row in the view.

`MOV_SUM(Price, HOUR, 1, Time)`

Events of the last hour from the most recent event based on its *Time* column value, not necessarily the order that the events entered the view.

Time	Price
03:47	33.50
03:22	12.34
04:06	14.66
03:53	20.00
05:30	14.22
04:26	32.42
04:56	15.95
03:49	10.87

30.17

Complete window expression:

```
SUM(Price) OVER (ORDER BY Time
                 RANGE '1' HOUR PRECEDING
                 REFERENCE OPERATOR)
```

Time-series spans

Time span calculations use the Gregorian calendar and are calculated to the second that the event was recorded in the system (recorded in the `vc_timestamp` column). For example, if the span is 1 day and an event arrives just before midnight, it excludes almost all events on the previous day; however, an event arriving just after midnight includes almost all of the events on the previous day. Here are some additional semantics:

- In locales where daylight savings time is observed, durations of days, months, and years are adjusted accordingly. As such, while 1 day is typically 24 hours long, it may be 23 or 25 hours depending on the time of year.
- Month calculations are based on the day of the month: a 1 month span on 5 April includes all dates after 5 March. When the day of the month does not exist at the start of the window, the end of the month is used. For example, a 1 month span on 31 May starts after 30 April.
- Similarly, year calculations are based on the day of the year, and adjust as necessary for leap years.
- For the purposes of parallel execution, you may choose to not process events in the order in which they are timestamped. In this case the order of the data within a group is arbitrary and will only produce approximate Moving Set values that may not be reproducible for the same input events during a subsequent evaluation of the same set.
- The set of events included in a moving window view are determined when a new event enters the view. Events that are filtered out of a view before they enter the view, such as when excluded by a `WHERE` clause, do not affect the view and do not cause the view to update.

View warning

Do not use a moving set function in a derived view to perform a calculation on a moving set function result in a base view. This is because the derived function will always return the current value in the base view, regardless of the span of the window. If you need such an aggregation, place the functions in the same view. See the example in [“AVG” on page 99](#) for details.

Interacting with GROUP BY

Using a moving set function on a view defined with a GROUP BY clause populates the groups as follows:

Time-series spans

Time-series spans apply to all events in all groups. Only events that fall within the time span are included in the groups. Events that do not meet time span definition are excluded. When all events have been removed from a group set, the group is empty. If no other columns retain the group, it is removed from the view. Consider this example where average prices are tracked in groups by product for the last hour. When a Product no longer has events in the last hour, that Product's group is removed.

```
SELECT MOV_AVG(Price,HOUR,1) AS Av_pr
FROM ...
GROUP BY Product
```

However, in this variation the presence of the SUM() function causes the view to retain every event group, but the average price for a group of the last hour may be empty. Querying an empty group returns NULL.

```
SELECT MOV_AVG(Price,HOUR,1) AS Av_pr,
SUM(Price) AS Total
FROM ...
GROUP BY Product
```

Event spans

Event spans apply their size to each group in the view; each group tracks a count of events determined by the size of the span. Groups are never removed from the view, and events are removed from the sets only when they are pushed out by a newer event. Consider the view in this example where MOV_AVG() tracks up to 3 events per group. When the fourth event whose Ix value is 100 is inserted, the first is dropped from the moving average calculation of the Ix=100 group. However, within this example, once the 200 group is created, its set remains constant with the one event:

For event spans that have events with multiple rows in the view, the entire event is treated as one item in the set based on the timestamp (vc_timestamp) and event ID (vc_event_id).

NOTE: All columnNames referred directly by a rank function or scalar function must appear in the set of columns listed in the GROUP BY list.

MOV_AVG

This moving set function returns the moving average value (arithmetic mean) of a moving window set of numeric values.

Syntax

```
MOV_AVG( numeric, window, size [,timestampColumn] )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view. See individual function descriptions for additional restrictions.
- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be an integer greater than zero (0).
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the most recent value in the column from any row in the view. Omit this option to use the system clock as the time basis.

Return type

Numeric, same data-type as numeric argument.

Remarks

Returns NULL if the group is empty.

Example

Return the average price of all the events that arrive within a 7 day interval:

```
MOV_AVG(price, DAY, 7, trade_time) AS Avg_7_day_price
```

“Function types” on page 90 discusses moving sets.

AVG() returns the mean average for a set.

TUMBLE_AVG() returns the tumbling average for a set.

MOV_COUNT

This moving set function returns the count of rows in a moving window set.

Syntax

```
MOV_COUNT( *, window, size [,timestampColumn] )
```

Parameters

- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be an integer greater than zero (0).
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the *most recent value in the column from any row in the view*. Omit this option to use the system clock as the time basis.

Return type

INTEGER.

Remarks

Returns zero (0) if the set is empty.

Rows that include NULLs are counted.

When used with a GROUP BY returns the count of rows in the group set. See the discussion and example in [“Interacting with GROUP BY” on page 129](#) for more information.

Example

Return the count of all the events that arrive within the current 8 hour interval:

```
MOV_COUNT(*, HOUR, 8, trade_time) AS Total
```

The above function is shorthand for this in-line window expression:

```
COUNT(*) AS Total OVER (ORDER BY trade_time '8' HOUR)
```

This expression is equivalent to the following after filling in all default values:

```
COUNT(*) AS Total OVER ( ORDER BY trade_time
    RANGE INTERVAL '8' HOUR PRECEDING
    REFERENCE OPERATOR)
```

NOTE: The eight-hour window begins when the first event arrives in the view. To begin the window at the top of the hour instead, include INITIALIZE '2003-03-05 00:00:00.000'.

[“Function types” on page 90](#) discusses moving sets.

COUNT() returns the count of a view or set.

C-SQL Function for a complete list of functions. TUMBLE_COUNT() returns the count of a tumbling window set.

MOV_MAX

This moving set function returns the maximum value from a moving window set.

Syntax

```
MOV_MAX( numeric, window, size [,timestampColumn] )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view. See individual function descriptions for additional restrictions.
- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be an integer greater than zero (0).
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the *most recent value in the column from any row in the view*. Omit this option to use the system clock as the time basis.

Return type

Same data-type as expression argument.

Remarks

For Boolean, True is greater than False.

For String, 'z' is greater than 'A'.

Example

Return the maximum price of all the events that arrive within a 7 day interval:

```
MOV_MAX(price, DAY, 7, trade_time) AS Max_7_day_price
```

MAX() returns the maximum value from a moving window set.

TUMBLE_MAX() returns the maximum value from a tumbling window set.

MIN() returns the minimum value from a set.

GREATEST() returns the maximum value from a list.

["Function types" on page 90](#) discusses moving sets.

MOV_MIN

This moving set function returns the minimum value from a moving window set.

Syntax

```
MOV_MIN( numeric, window, size [,timestampColumn] )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view. See individual function descriptions for additional restrictions.
- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be an integer greater than zero (0).
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the *most recent value in the column from any row in the view*. Omit this option to use the system clock as the time basis.

Return type

Same data-type as expression argument.

Remarks

For Boolean, True is greater than False.

For String, 'z' is greater than 'A'.

Example

Return the minimum price of all the events that arrive within a 7 day interval:

```
MOV_MIN(price, DAY, 7, trade_time) AS Min_7_day_price
```

MIN() returns the minimum value from a view or set.

TUMBLE_MIN() returns the minimum value from a tumbling window set.

MAX() returns the maximum value from a set.

LEAST() returns the smallest value from a list.

["Function types" on page 90](#) discusses moving sets.

MOV_SUM

This moving set function returns the sum of a moving window set of numeric values.

Syntax

```
MOV_SUM( numeric, window, size [,timestampColumn] )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view. See individual function descriptions for additional restrictions.
- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be an integer greater than zero (0).
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the *most recent value in the column from any row in the view*. Omit this option to use the system clock as the time basis.

Return type

Numeric, same data-type as numeric argument. Returns NULL if the set is empty.

Example

Total the price of all events that arrive in current hour:

```
MOV_SUM(Price, HOUR, 1)
```

Which is shorthand for this in-line window expression:

```
SUM(Price) OVER (RANGE '1' HOUR PRECEDING  
                REFERENCE OPERATOR)
```

SUM() returns the sum of a view or set.

TUMBLE_SUM() returns the sum of a tumbling window set.

[“Function types” on page 90](#) discusses moving sets.

MOV_STD_DEVIATION

This moving set function returns sample standard deviation of a moving window set of numbers.

Syntax

```
MOV_STD_DEVIATION( numeric, window, size [,timestampColumn] )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view. See individual function descriptions for additional restrictions.
- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be an integer greater than zero (0).
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the most recent value in the column from any row in the view. Omit this option to use the system clock as the time basis.

Return type

DOUBLE PRECISION.

Remarks

Returns 0 when there is only a single row of input. Returns NULL if the set is empty.

The result is computed using the formula $\sqrt{\sum \left[\frac{(X_i - X)^2}{n} \right]}$, where n is the number of elements in the sample and X is the sample mean.

Example

Return the standard deviation in salaries for the last year's worth of events:

```
SELECT MOV_STD_DEVIATION(salary, YEAR, 1) AS "Dev. for the last year"
FROM employees;
```

Which in turn is equivalent to the following after filling in all default values:

```
SELECT STD_DEVIATION(salary) AS "Dev. for the last year" OVER (
  RANGE INTERVAL '1' YEAR PRECEDING
  REFERENCE OPERATOR)
```

STD_DEVIATION() returns the standard deviation of a view or set.

TUMBLE_STD_DEVIATION() returns the standard deviation of a tumbling window set.

VARIANCE() returns the square of the standard deviation.

"Function types" on page 90 discusses moving sets.

MOV_VARIANCE

This moving set function returns the square of the sample standard deviation of a moving window set of numbers.

Syntax

```
MOV_STD_DEVIATION( numeric, window, size [,timestampColumn] )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view. See individual function descriptions for additional restrictions.
- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be an integer greater than zero (0).
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the *most recent value in the column from any row in the view*. Omit this option to use the system clock as the time basis.

Return type

DOUBLE PRECISION.

Remarks

Returns zero (0) when the expression set contains only one element. Returns NULL if the set is empty.

The result is computed using the formula $\sum \left[\frac{(X_i - X)^2}{n} \right]$, where n is the number of elements in the sample and X is the sample mean.

Example

Return the variation in salaries for each calendar year:

```
SELECT MOV_STD_VARIATION(salary, YEAR, 1) AS "Variation for last year"
FROM employees;
```

Which in turn is equivalent to the following after filling in all default values:

```
SELECT VARIATION(salary) AS "Variation for last year" OVER (
  RANGE INTERVAL '1' YEAR PRECEDING
  REFERENCE OPERATOR)
```

VARIANCE() returns the variance of a view or set.

STD_DEVIATION() returns a standard deviation.

TUMBLE_VARIANCE() returns the variance of a tumbling window set.

["Function types" on page 90](#) discusses moving sets.

NTILE

This rank function determines the tier rank of each value in a set with respect to the entire set.

Syntax

```
NTILE( toRank, tiers )
```

Parameters

- toRank - A expression of any data type, and which typically references a column of values to rank.
- tiers - Count of tiers in which to partition the results; an integer greater than zero (0). When this value is greater than the count of items to rank, all items are given the same rank.

Return type

INTEGER.

Remarks

Returns an integer for each row in the set that represents the tier that the row belongs to, where one (1) is the highest tier holding the greatest value. When toRank results in NULL, that result is assigned to the lowest rank.

NOTE: This function *cannot* be used as an argument in a set function, moving set function, or rank function. For example, SUM(NTILE()) is illegal.

An *ntile* function ranks rows by attempting to evenly distribute them throughout a fixed set of tiers. For example, when there is a set of six expression results {D, B, E, C, A, and B} to rank into two tiers, NTILE() assigns each a rank of either 1 (for C, D, and E) or 2 (for A, B, and B). Results with the same value are always placed in the same tier.

When a set of values is not divisible by the tiers, the function evenly distributes any leftover rows into higher-level groups. For example, the following table demonstrates how the letter items are distributed into various counts of tiers:

tiers:	1	2	3	4	5	6	7
A	1	2	3	3	4	5	1
B	1	2	2	2	3	4	1
B	1	2	2	2	3	4	1
C	1	1	2	1	2	3	1
D	1	1	1	1	1	2	1
E	1	1	1	1	1	1	1

Example

The following query ranks sales of coffee and tea products into six tiers by their sales rankings. The ranking is in sixths, so each product name receives a value from 1 to 6. This example requires that there be just one unique entry for each product:

```
SELECT prod_name, NTILE( dollars, 6) AS sales_rank
FROM (lineitem INNER JOIN product
      ON lineitem.item_id=product.productid)
WHERE product.classkey IN (1, 2, 4, 5);
```

PROD_NAME	SALES_RANK
Demitasse M	1
Xalapa Lapa	1
Cafe Au Lait	2
Aroma Roma	2
Veracruzano	3
Colombiano	3
Darjeeling Special	4
Irish Breakfast	4
English Breakfast	5
Earl Grey	5
Gold Tips	6

RANK() ranks rows within the entire set.

“Function types” on page 90 discusses moving sets.

POSITION

This scalar function returns the position of a character or string within a string.

Syntax

```
POSITION( sourceForString , searchInString )
Alternate form: POSITION( sourceForString IN searchInString )
```

Parameters

- sourceForString - String to search for.
- sourceInString - String expression result in which to search.

Return type

INTEGER.

Remarks

Returns the position, starting from 1, of the 1st instance of sourceForString in the sourceInString result. When CHARACTER_LENGTH(sourceForString) is zero (0), returns 1. Returns NULL when either argument is NULL.

Examples

POSITION('a' IN 'banana') returns 2.

POSITION('ana' IN 'banana') returns 2.

POSITION('A' IN 'banana') returns 0.

POSITION('M' IN 'banana') returns 0.

POSITION('' IN 'banana') returns 1.

POSITION(NULL IN 'banana') returns NULL.

SUBSTRING() extracts a character or substring from a string.

POWER

This scalar function returns a value raised to a specific power.

Syntax

```
POWER( numeric, power )
```

Parameters

- numeric - Number to raise.
- power - Power to raise numeric. Must be an integer when numeric is negative.

Return type

Same data-type as numeric argument.

Remarks

This can be expressed mathematically as “number^{power}”.

Example

POWER(3, 5) returns 243.

EXP() raise e to a specific power.

LOG() returns the logarithm of a number from a specific base.

PREV

This set function returns a value from the next to last row in a set.

Syntax

```
PREV( columnName )
```

Parameters

- columnName - Column or alias of any data type to evaluate.

Return type

Same data-type as argument.

Remarks

Returns values from the row before the “current” row in a set, where the current row is the latest row in the set based on the event timestamp, or when all have the same timestamp, is last row in the set.

Example

Gather all stock feed closing prices and group them by stock symbol. The “current” row will always be the last one received, and as such, will contain the current closing price. The previous row will be the previous day’s close:

```
SELECT symbol, CURRENT(close) AS "Last Trade",  
       PREV(close) AS "Prev Cls",  
       (CURRENT(close) - PREV(close)) AS Change  
FROM Stock_feed  
GROUP BY symbol
```

symbol	Last Trade	Prev Cls	Change
K	31.25	31.28	-0.03
IBM	80.79	80.04	0.75
VCLR	24.42	22.60	1.82

Moving set semantics

Cannot be used with a moving or tumbling set.

CURRENT() returns the value from the latest or last row in a set.

PRIOR_VALUE() returns the prior value of a column, alias, or expression.

“Function types” on page 90 discusses moving sets.

PRIOR_VALUE

This scalar function returns the prior value of a column, alias, or expression.

Syntax

```
PRIOR_VALUE( columnName )
```

Parameters

- columnName - Column or alias of any data type to evaluate.

Return type

Same data-type as argument.

Remarks

Returns a NULL if there is no prior value — the first time the function is called on the columnName.

Use PRIOR_VALUE() when the data (events) enter the system grouped and ordered,

This function is not permitted in the WHERE clause of a view definition.

Example

Consider this query that identifies the how long a task took to complete — as a percentage of an hour — based on minutes since the previous task completed:

```
SELECT Task, CAST(
    (TIMESTAMP_DIFF(PRIOR_VALUE(Completed), Completed, MINUTE ) /60
    , DECIMAL(5,4)
    ) AS Hours
FROM Tasks_Completed
```

Task	Hours
-----	-----
Startup	
Initialize	0.0887
Begin job	0.1012
Finish job	4.3243
Clean up	0.2500
Shut down	0.1285
Have milk shake	0.6667

PREV() returns a value from the next to last row in a set.

RANK

This rank function determines the rank of each value in a set with respect to the entire set.

Syntax

```
RANK( expression )
```

Parameters

- expression - A expression of any data type, and which typically references a column.

Return type

INTEGER.

Remarks

Returns an integer for each row in the set that is the row's ranking within the entire set, where the greatest value is ranked 1. When expression results in NULL it is ranked last in the result list. For example, the ranking of (10, NULL, 20) ranks the 10 as 2, the 20 as 1, and NULL as 3.

When the values to be ranked are equal, they are assigned the same rank, and the next rank is skipped. For example values 4.5, 4.5, 1.0 will be assigned rank values of 1, 1, and 3 respectively.

NOTE: This function *cannot* be used as an argument in a set function, rank function, or moving set function. For example, SUM(RANK(...)) is illegal. Nor can RANK() be used on an stateless view.

When the set contains only one row, RANK() returns 1. For example, RANK(SUM(sales)) = 1.

Examples

Rank product sales by region:

```
SELECT RANK( SUM( sales ) ) AS R, SUM(sales) AS S, region
FROM product_orders
GROUP BY region
R   S      region
1   100000 north
2   50000  south
```

Rank product sales by product:

```
SELECT prod_name, SUM(dollars) AS prod_sales,
       RANK( SUM(dollars) ) AS prod_rank
FROM product, lineitem
WHERE lineitem.classkey = product.classkey
      AND lineitem.prodkey = product.prodkey
GROUP BY prod_name;
PROD_NAME      PROD_SALES  PROD_RANK
Demitasse Ms   656401.50   1
Xalapa Lapa    577450.00   2
Aroma Roma     479330.25   5
Verona         467234.00   6
NA Lite        557655.00   3
Lotta Latte    533454.50   4
```

NTILE() ranks rows and places them in a finite set of tiers.

“Function types” on page 90 discusses moving sets.

RATIO_TO_REPORT

This rank function calculates the ratio of a value to the sum of the values for the entire set.

Syntax

```
RATIO_TO_REPORT( numeric )
```

Parameters

- `numeric` - Any numeric data type expression, typically a reference a numeric column.

Return type

DOUBLE PRECISION.

Remarks

Returns an number for each row in the set that is the row's ratio to the sum of the entire set. When expression results in NULL, the function returns NULL. When the sum of the set is zero (0), the ratio is also zero.

NOTE: This function *cannot* be used as an argument in a set function, moving set function, or rank function. For example, `SUM(RATIO_TO_REPORT(...))` is illegal.

Example

Determine what percentage each product sales is to the total sales of all products, for the last 20 weeks:

```
SELECT prod_description DESC,
       SUM(dollars) as sales,
       RATIO_TO_REPORT( SUM( li_amount ) ) * 100 AS ratio_dollars
FROM lineitem, product
WHERE lineitem.li_prod_id = product.prod_id
GROUP BY prod_description;
```

DESC	SALES	RATIO_DOLLARS
Widget	896931.15	12.88
Basket	514830.00	7.39
Football	507022.35	7.28
Oil Drum	503493.10	7.23
Computer	437863.00	6.29
Chair	429637.75	6.17
Desk	424215.00	6.09
Mesh Bag	421205.75	6.05
Shoelace	417261.00	5.99
Powder	397102.50	5.70
Telephone	394086.50	5.66
Cord	392377.75	5.64
Mouse	389378.25	5.59
Monitor	305859.75	4.39
Case	294982.75	4.24
Cup	236772.75	3.40

ROUND

This scalar function returns a number rounded up to a specified count of decimal places.

Syntax

```
ROUND( number, [ places ] )
```

Parameters

- **number** - The numeric expression to round
- **places** - Count of decimal places to round to. A negative integer rounds to whole number digits. Default is zero (0) to remove any fractional components.

Return type

Numeric, same data-type as number argument.

Examples

```
ROUND(1294.5078) returns 1294.
```

```
ROUND(1294.5078, 0) returns 1294.
```

```
ROUND(1294.5078, 1) returns 1294.5.
```

```
ROUND(1294.5078, 2) returns 1294.51.
```

```
ROUND(1294.5078, -2) returns 1300.
```

TRUNC() removes digits from a number.

RPAD

This scalar function adds one or more instances of a string to the end of another string.

Syntax

```
RPAD( string, length, [ padChar ] )
```

Parameters

- **string** - Character or string to alter.
- **length** - The *display length* of the returned string. When using multi-byte characters, the length is the count of characters that display or print, not the count of multi-bytes.
- **padChar** - Character or string to append. Default is a single space or blank character (' ').

Return type

VARCHAR.

Remarks

When length is smaller than the length of string, returns the string truncated to length.

Examples

`RPAD('ABC', 6, 'x')` returns 'ABCxxx'.

`RPAD('ABC', 6, 'xo')` returns 'ABCxox'.

`RPAD('ABC', 4)` returns 'ABC '.

`RPAD('ABC', 2, 'x')` returns 'AB'.

`LPAD()` inserts characters to the start of a string.

RTRIM

This scalar function removes characters from the end of a string.

Syntax

```
RTRIM( sourceString [, setString ] )
```

Parameters

- `sourceString` - String to trim.
- `setString` - Characters to remove; default is a single blank space (' ').

Return type

VARCHAR.

Remarks

Recursively removes all instances of `setString` from the end of `sourceString` until `sourceString` no longer ends with `set`, and returns the result.

Examples

`RTRIM('ZZZ ')` returns 'ZZZ'.

`RTRIM('ZZZaaa', 'a')` returns 'ZZZ'.

`RTRIM('ZZZababab', 'ab')` returns 'ZZZ'.

`RTRIM('ZZZababc', 'abc')` returns 'ZZZab'.

`LTRIM()` removes characters from the start of a string.

SIGN

This scalar function identifies the arithmetic sign of a number.

Syntax

```
SIGN( number )
```

Parameters

- number - The numeric value to evaluate.

Return type

INTEGER.

Remarks

Returns 1 if the number is positive, 0 if the number is zero, and -1 if the number is negative.

Note that these expressions return identical results:

```
(number * SIGN(number) )
```

```
ABS(number)
```

ABS() returns the absolute value of a number.

SQRT

This scalar function returns the square root of a number.

Syntax

```
SQRT( number )
```

Parameters

- number - The number (DOUBLE) to evaluate. Must be greater than zero (0).

Return type

DOUBLE PRECISION.

Example

SQRT(42) returns 6.480...

SUBSTRING

This scalar function returns a substring of a specified string.

Syntax

```
SUBSTRING( string, position, [ length ] ).
```

Alternate forms:

```
SUBSTR( string, position, [ length ] )
```

```
SUBSTRING( string FROM position [ FOR length ] )
```

Parameters

- **string** - Character string to search.
- **position** - Starting position of the substring, where 1 is the first character at the start of the string, and -1 is the last character. Negative values count backwards from the end of the string. Using zero (0) is the same as using 1. A position not within string returns an empty string.
- **length** - Length of the substring to extract. Omitting length returns all characters from position through the end of the string. Specifying a value greater than the remainder of the string returns all characters from position through the end of the string, and pads the difference with space characters to achieve the specified length. A negative value or zero (0) returns an empty string.

Return type

VARCHAR.

Examples

```
SUBSTR('breakfast', 1) returns 'breakfast'.
```

```
SUBSTR('breakfast', 0) returns 'breakfast'.
```

```
SUBSTR('breakfast', 30) returns "" (empty string).
```

```
SUBSTR('breakfast', 1, 2) returns 'br'.
```

```
SUBSTR('breakfast', CHARACTER_LENGTH('breakfast'), 2) returns 't'.
```

```
SUBSTR('breakfast', 3, 4) returns 'eakf'.
```

```
SUBSTR('breakfast', 3, 8) returns 'eakfast'.
```

```
SUBSTR('breakfast', -5, 4) returns 'kfas'.
```

```
SUBSTR('breakfast', 1, -1) returns "" (empty string).
```

CHARACTER_LENGTH() returns the length of a character string.

POSITION() locates a character within a string.

SUM

This set function returns the sum of a set of numeric values.

Syntax

```
SUM( numeric )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view.

Return type

Numeric, same data-type as numeric argument. Returns NULL if the set is empty.

Example

Total the invOnHand column for all rows in the stock table:

```
SELECT SUM(invOnHand) "Total on hand"  
FROM stock;
```

```
Total on hand
```

```
-----
```

```
2
```

Moving set semantics

When used as a MOV_function(), returns the moving sum for the moving set.

```
MOV_SUM( numeric, windowwindow, size [,timestampColumn] )
```

Last value in the set

When the moving set size is a single event, MOV_SUM() maintains the sum of the last order prices for each customer, for all the customers that have placed an order since the system startup time.

```
SELECT os.os_cust_id, MOV_SUM(os.os_price, EVENT, 1)  
FROM order_status os  
GROUP BY os.os_cust_id
```

MOV_SUM() returns the sum of a moving window set.

TUMBLE_SUM() returns the sum of a tumbling window set.

STD_DEVIATION

This set function returns sample standard deviation of a set of numbers.

Syntax

```
STD_DEVIATION( number )
```

Parameters

- number - An expression that evaluates to a numeric and which cannot reference a rank function function. Typically the argument is a column in a view.

Return type

DOUBLE PRECISION.

Remarks

Returns 0 when there is only a single row of input. Returns NULL if the set is empty.

The result is computed using the formula $\sqrt{\sum \left[\frac{(X_i - X)^2}{n} \right]}$, where n is the number of elements in the sample and X is the sample mean.

Example

```
SELECT STD_DEVIATION(salary) "Deviation"  
FROM employees;
```

```
Deviation  
-----  
3909.36575
```

MOV_STD_DEVIATION() returns the standard deviation of a moving window set.

TUMBLE_STD_DEVIATION() returns the standard deviation of a tumbling window set.

VARIANCE() returns the square of the standard deviation.

TIMESTAMP_DIFF

This scalar function returns the interval of time between two timestamps.

Syntax

```
TIMESTAMP_DIFF( startTime, endTime, unit )
```

Parameters

- startTime - Start Date-Time.
- endTime - End Date-Time.
- unit - Type of the time interval to return; one of these literals:
 - SECOND
 - MINUTE
 - HOUR
 - DAY
 - MONTH (30 days)
 - YEAR (12 months or 360 days)

Return type

INTEGER.

Remarks

Uses absolute time difference rounded up to the nearest whole value; *does not use* Gregorian calendar arithmetic.

Rounds the result to the nearest integer. For example, the difference between 10:00 and 10:29 in HOUR units is zero (0), but 10:00 and 10:30 return one (1).

Returns a negative value when startTime is greater than endTime.

Returns NULL if either timestamp is NULL.

Example

Return the count of days from now until the end of the month.

```
TIMESTAMP_DIFF( CURRENT_TIMESTAMP(),  
                LAST_DAY( CURRENT_TIMESTAMP() ), DAY)
```

Return True when a problem ticket is open for more than 30 minutes:

```
TIMESTAMP_DIFF( ticket_opened, CURRENT_TIMESTAMP(), MINUTE) > 30
```

Return the number of days between two dates as a positive number, regardless of the which date is oldest:

```
ABS( TIMESTAMP_DIFF( father_birthdate, mother_birthdate, DAY) )
```

DATE_ADD() adds a duration to a date-time.

DATE_DIFF() subtracts a duration from a date-time.

CURRENT_TIMESTAMP() returns the current date and time.

TO_CHAR

This scalar function converts a date-time to a character string.

Syntax

```
TO_CHAR( date, [ format ] )
```

Parameters

- date - Date-Time value to convert.
- format - Date pattern of string identical to the one used by the Java SimpleDateFormat class, and is described in [“Date-Time formatting” on page 62](#). Omit this option to convert using the default format, which is “yyyy-MM-dd HH:mm:ss.SSSSSSSS”.

Return type

VARCHAR.

Remarks

See [“Converting between date-time and strings” on page 58](#) for a complete discussion about the conversion.

Examples

`TO_CHAR(CURRENT_TIMESTAMP(), 'd MMMM yy')` returns '5 March 03'.

`CAST()` converts one data type to another.

`TO_DATE()` converts a character string to a date.

`CURRENT_TIMESTAMP()` returns the current date and time.

TO_DATE

This scalar function converts a character string to a date-time value.

Syntax

```
TO_DATE( string, [ format ] )
```

Parameters

- string - Date string (VARCHAR) or literal to convert.
- format - Date pattern of string identical to the one used by the Java SimpleDateFormat class, and is described in [“Date-Time formatting” on page 62](#). Omit this option to convert using the default format, which is “yyyy-MM-dd HH:mm:ss.SSSSSSSS”.

Return type

Date-Time.

Remarks

Omitting the time values from the pattern zero-fills (0) the portion of the TIMESTAMP thereby setting the time to midnight.

Examples

`TO_DATE('2003-02-18')` is identical to `TO_DATE('2003-02-18', "yyyy-MM-dd")`.

`TO_DATE('2003-02-18 12:00:00', 'yyyy-MM-dd HH:mm:ss')` assigns noon as the time.

To strip the time portion off a TIMESTAMP, convert it to character and back to date:

```
TO_DATE( TO_CHAR( a_timestamp, 'yyyy-MM-dd' ) )
```

CAST() converts one data type to another.

TO_CHAR() converts a date to a character string.

CURRENT_TIMESTAMP() returns the current date and time.

TRUNC

This scalar function truncates a number to a specific count of decimal places.

Syntax

```
TRUNC( decimalNumber [, places ] )
```

Parameters

- decimalNumber - Number to truncate.
- places - Count of decimal places to truncate to. When omitted, truncates all decimals and returns an integer. When negative converts digits to zero.

Return type

Numeric, same data-type as decimalNumber argument.

Examples

TRUNC(1234.567) returns 1234.

TRUNC(1234.567, 1) returns 1234.5.

TRUNC(1234.567, -2) returns 1200.

ROUND() rounds the number up to a specified count of decimal places.

TUMBLE_AVG

This tumbling set function returns the average value (arithmetic mean) of a tumbling window set.

Syntax

```
TUMBLE_AVG( numeric, window, size [,timestampColumn] )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view. See individual function descriptions for additional restrictions.
- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be a positive integer.
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the *most recent value in the column from any row in the view*. Omit this option to use the system clock as the time basis.

Return type

Numeric, same data-type as numeric argument.

Remarks

Returns NULL if the group is empty.

Example

Return the average price of all the events that arrive within a 7 day interval:

```
TUMBLE_AVG(price, DAY, 7, trade_time) AS Avg_7_day_price
```

The above function is shorthand for this in-line window expression:

```
AVG(price) AS Avg_7_day_price OVER (  
    ORDER BY trade_time RANGE INTERVAL '7' DAY PRECEDING SLIDE)
```

To determine the average price of the previous 7 days, not including the current, use a window instead of a TUMBLE_AVG(), like this:

```
AVG(price) AS Avg_prev_7_day_price OVER (  
    ORDER BY trade_time  
    RANGE BETWEEN INTERVAL '8' DAY PRECEDING  
        AND INTERVAL '1' DAY PRECEDING  
    SLIDE INTERVAL '7' DAY  
    INITIALIZE TIMESTAMP '1963-02-18 00:00:00.000'  
    REFERENCE OPERATOR)
```

AVG() returns the mean average for a set.

MOV_AVG() returns the average for a moving window set.

Tumbling Windows discusses tumbling window sets.

TUMBLE_COUNT

This tumbling set function returns the count of rows in a tumbling window set.

Syntax

```
TUMBLE_COUNT( *, window, size [,timestampColumn] )
```

Parameters

- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be a positive integer.
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the *most recent value in the column from any row in the view*. Omit this option to use the system clock as the time basis.

Return type

INTEGER.

Remarks

Returns zero (0) if the set is empty.

When using an EVENT window, this function returns an integer less than or equal to the window value.

Rows that include NULLs are counted.

When used with a GROUP BY returns the count of rows in the group set.

Example

Return the count of all the events that arrive within an 8 hour interval:

```
TUMBLE_COUNT(*, HOUR, 8, trade_time) AS Total
```

The above function is shorthand for this in-line window expression:

```
COUNT(*) AS Total OVER (ORDER BY trade_time  
    RANGE INTERVAL '8' HOUR PRECEDING SLIDE)
```

Which in turn is equivalent to the following after filling in all default values:

```
COUNT(*) AS Total OVER ( ORDER BY trade_time  
    RANGE INTERVAL '8' HOUR PRECEDING  
    SLIDE INTERVAL '8' HOUR  
    REFERENCE OPERATOR)
```

Note: The eight-hour window begins when the first event arrives in the view. To begin the window at the top of the hour instead, include INITIALIZE '2003-03-05 00:00:00.000'.

COUNT() returns the count of a view or set.

MOV_COUNT() returns the count of a tumbling window set.

Tumbling Windows discusses tumbling window sets.

TUMBLE_MAX

This tumbling set function returns the maximum value from a tumbling window set.

Syntax

```
TUMBLE_MAX( numeric, window, size [,timestampColumn] )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view. See individual function descriptions for additional restrictions.
- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be a positive integer.
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the *most recent value in the column from any row in the view*. Omit this option to use the system clock as the time basis.

Return type

Same data-type as expression argument.

Remarks

For Boolean, True is greater than False.

For String, 'z' is greater than 'A'.

Example

Return the maximum price of all the events that arrive within a 1 hour interval:

```
TUMBLE_MAX(price, HOUR, 1, trade_time) AS Max_price
```

The above function is shorthand for this in-line window expression:

```
MAX(price) AS Max_price OVER (ORDER BY trade_time
    RANGE INTERVAL '1' HOUR PRECEDING SLIDE)
```

Which in turn is equivalent to the following after filling in all default values:

```
MAX(price) AS Max_price OVER ( ORDER BY trade_time
    RANGE INTERVAL '1' HOUR PRECEDING
    SLIDE INTERVAL '1' HOUR
    REFERENCE OPERATOR)
```

Note: The one-hour window begins when the first event arrives in the view. To begin the window at the top of the hour instead, include INITIALIZE TIMESTAMP '2003-03-05 00:00:00.000'.

Similarly, the function TUMBLE_MAX(price, EVENT, 5) is the shorthand for this complete window:

```
MAX(price) OVER ( ORDER BY trade_time
    EVENTS BETWEEN 4 PRECEDING AND CURRENT EVENT
    SLIDE 5
    REFERENCE OPERATOR)
```

MAX() returns the maximum value from a moving window set.

MOV_MAX() returns the maximum value from a tumbling window set.

MIN() returns the minimum value from a set.

GREATEST() returns the maximum value from a list.

Tumbling Windows discusses tumbling window sets.

TUMBLE_MIN

This tumbling set function returns the minimum value from a tumbling window set.

Syntax

```
TUMBLE_MIN( numeric, window, size [,timestampColumn] )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view. See individual function descriptions for additional restrictions.
- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be a positive integer.
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the *most recent value in the column from any row in the view*. Omit this option to use the system clock as the time basis.

Return type

Same data-type as expression argument.

Remarks

For Boolean, True is greater than False.

For String, 'z' is greater than 'A'.

Example

Return the minimum price of all the events that arrive within a 1 hour interval:

```
TUMBLE_MIN(price, HOUR, 1, trade_time) AS Min_price
```

The above function is shorthand for this in-line window expression:

```
MIN(price) AS Min_price OVER (ORDER BY trade_time
    RANGE INTERVAL '1' HOUR PRECEDING SLIDE)
```

Which in turn is equivalent to the following after filling in all default values:

```
MIN(price) AS Min_price OVER ( ORDER BY trade_time
    RANGE INTERVAL '1' HOUR PRECEDING
    SLIDE INTERVAL '1' HOUR
    REFERENCE OPERATOR)
```

Note: The one-hour window begins when the first event arrives in the view. To begin the window at the top of the hour instead, include INITIALIZE TIMESTAMP '2003-03-05 00:00:00.000'.

Similarly, the function TUMBLE_MIN(price, EVENT, 5) is the shorthand for this complete window:

```
MIN(price) OVER ( ORDER BY trade_time
  EVENTS BETWEEN 4 PRECEDING AND CURRENT EVENT
  SLIDE 5
  REFERENCE OPERATOR)
```

MIN() returns the minimum value from a moving window set.

MOV_MIN() returns the minimum value from a tumbling window set.

MAX() returns the maximum value from a set.

LEAST() returns the smallest value from a list.

Tumbling Windows discusses tumbling window sets.

TUMBLE_SUM

This tumbling set function returns the sum of a tumbling window set of numeric values.

Syntax

```
MOV_SUM( numeric, window, size [,timestampColumn] )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view. See individual function descriptions for additional restrictions.
- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be a positive integer.
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the *most recent value in the column from any row in the view*. Omit this option to use the first event in the view as the basis.

Return type

Numeric, same data-type as numeric argument. Returns NULL if the set is empty.

Example

This tumbling sum expression sums all the events that arrive within a 1 hour interval:

```
TUMBLE_SUM(price, HOUR, 1, trade_time) AS Total
```

The above function is shorthand for this in-line window expression:

```
SUM(price) AS Total OVER (ORDER BY trade_time
  RANGE INTERVAL '1' HOUR PRECEDING SLIDE)
```

Which in turn is equivalent to the following after filling in all default values:

```
SUM(price) AS Total OVER ( ORDER BY trade_time
    RANGE INTERVAL '1' HOUR PRECEDING
    SLIDE INTERVAL '1' HOUR
    REFERENCE OPERATOR)
```

Note: The one-hour window begins when the first event arrives in the view. To begin the window at the top of the hour instead, include INITIALIZE TIMESTAMP '2003-03-05 00:00:00.000'.

Similarly, the function TUMBLE_SUM(price, EVENT, 5) is the shorthand for this complete window:

```
SUM(price) OVER ( ORDER BY trade_time
    EVENTS BETWEEN 4 PRECEDING AND CURRENT EVENT
    SLIDE 5
    REFERENCE OPERATOR)
```

SUM() returns the sum of a view or set.

MOV_SUM() returns the sum of a moving window set.

Tumbling Windows discusses tumbling window sets.

TUMBLE_STD_DEVIATION

This tumbling set function returns sample standard deviation of a tumbling window set of numbers.

Syntax

```
TUMBLE_STD_DEVIATION( numeric, window, size [,timestampColumn] )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view. See individual function descriptions for additional restrictions.
- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be a positive integer.
- **timestampColumn** - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the *most recent value in the column from any row in the view*. Omit this option to use the system clock as the time basis.

Return type

DOUBLE PRECISION.

Remarks

Returns 0 when there is only a single row of input. Returns NULL if the set is empty.

The result is computed using the formula $\sqrt{\sum \left[\frac{(X_i - X)^2}{n} \right]}$, where n is the number of elements in the sample and X is the sample mean.

Example

Return the standard deviation in salaries for each calendar year:

```
SELECT TUMBLE_STD_DEVIATION(salary, YEAR, 1) AS "Deviation per year"
FROM employees;
```

Which in turn is equivalent to the following after filling in all default values:

```
SELECT STD_DEVIATION(salary) AS "Deviation per year" OVER (
  RANGE INTERVAL '1' YEAR PRECEDING
  SLIDE INTERVAL '1' YEAR
  REFERENCE OPERATOR)
```

Note that you can use INITIALIZE to declare a fiscal year. And consider using PARTITION BY to get the deviations for different pay grades. For example:

```
SELECT STD_DEVIATION(salary) AS "Deviation per year" OVER (
  PARTITION BY pay_grade
  RANGE INTERVAL '1' YEAR PRECEDING
  SLIDE INTERVAL '1' YEAR
  INITIALIZE '1963-07-01 00:00:00.000'
  REFERENCE OPERATOR)
```

STD_DEVIATION() returns the standard deviation of a view or set.

MOV_STD_DEVIATION() returns the standard deviation of a tumbling window set.

VARIANCE() returns the square of the standard deviation.

Tumbling Windows discusses tumbling window sets.

TUMBLE_VARIANCE

This tumbling set function returns the square of the sample standard deviation of a tumbling window set of numbers.

Syntax

```
TUMBLE_STD_DEVIATION( numeric, window, size [,timestampColumn] )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view. See individual function descriptions for additional restrictions.
- **window** - Determines if size is the count of events in the set (EVENT), or a duration of time (SECOND, MINUTE, HOUR, DAY, MONTH, or YEAR).
- **size** - Duration or count of window to use for determining the size of the set. Must be an integer greater than zero (0).

- `timestampColumn` - (optional) Use the value of the field as the starting point for the time-series span. The calculation is based on the time span from the *most recent value in the column from any row in the view*. Omit this option to use the system clock as the time basis.

Return type

DOUBLE PRECISION.

Remarks

Returns zero (0) when the expression set contains only one element. Returns NULL if the set is empty.

The result is computed using the formula $\sum \left[\frac{(X_i - X)^2}{n} \right]$, where n is the number of elements in the sample and X is the sample mean.

Examples

Return the variation in salaries for each calendar year:

```
SELECT TUMBLE_STD_VARIATION(salary, YEAR, 1)
       AS "Variation for last year"
FROM employees;
```

Which in turn is equivalent to the following after filling in all default values:

```
SELECT VARIANCE(price) AS "Variation for last year"
       OVER ( ORDER BY trade_time
              RANGE INTERVAL '1' YEAR PRECEDING
              SLIDE INTERVAL '1' YEAR
              REFERENCE OPERATOR)
FROM employees;
```

`MOV_VARIANCE()` returns the variance of a moving window set.

`STD_DEVIATION()` returns a standard deviation.

`VARIANCE()` returns the variance of a view or set.

“Function types” on page 90 discusses moving sets.

UPPER

This scalar function converts all lowercase characters in a string to uppercase.

Syntax

```
UPPER( string )
```

Parameters

- string - Character string (VARCHAR) to convert.

Return type

VARCHAR.

Example

UPPER('Volta') returns 'VOLTA'.

LOWER() converts to all lowercase.

VARIANCE

This set function returns the square of the sample standard deviation of a set of numbers.

Syntax

```
VARIANCE( numeric )
```

Parameters

- **numeric** - An expression that evaluates to a numeric and which cannot reference a rank function. Typically the argument is a column in a view.

Return type

DOUBLE PRECISION.

Remarks

Returns zero (0) when the expression set contains only one element. Returns NULL if the set is empty.

The result is computed using the formula $\sum \left[\frac{(X_i - X)^2}{n} \right]$, where n is the number of elements in the sample and X is the sample mean.

Example

```
SELECT VARIANCE(salary) "Variance"  
FROM employees;
```

```
Variance  
-----  
15283140.5
```

MOV_VARIANCE() returns the variance of a moving window set.

STD_DEVIATION() returns a standard deviation.

TUMBLE_VARIANCE() returns the variance of a tumbling window set.

HTTP Post

A HTTP Post event tables receive events from a HTTP Post action, either as the result of an HTML form sent from a browser or from data encoded in a URL that connects to the table.

In this Chapter:

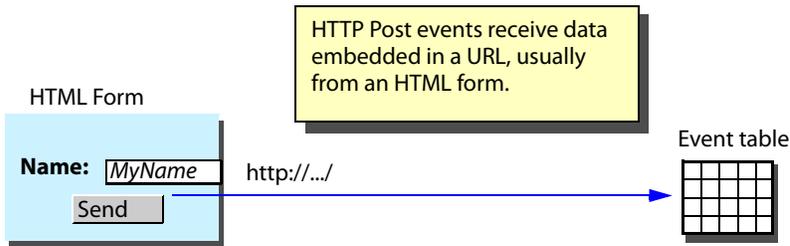

[“How it works” on page 165](#)

[“HTTP Post Event Tables” on page 165](#)

[“Posting to an HTTP post event” on page 168](#)

How it works

HTTP Post event data arrive embedded in a URL. The internal agent extracts the fields from the URL and puts them in the event table. The URL may be formed as the result of an HTML form containing <INPUT> fields, or it may be created by some other application that communicates in the HTTP protocol.

HTTP Post Event Tables

A HTTP Post event table receives new events from an HTTP Post action, which is usually the result of an HTML form sent from a browser. In an HTML form, each <INPUT> element maps to a column in the event table. Event data can also be published in the URL that passes the fields to the system. See [“Posting to an HTTP post event” on page 168](#) for examples.

Before creating an event to a HTTP Post, you must have Create permission for tables (see [“Creating permission” on page 220](#)).

Attribute	Description
Name	Event table name. This name must be unique among views, events, context, and consolidated events. See “Object namespace” on page 211 for details.
Description	Optional description that may contain any text characters.
Status	Whether or not the table is enabled (monitoring for events), or disabled (not monitoring for events).

Attribute	Description
Post To URL	URL in which to send the posted information. See “Posting to an HTTP post event” on page 168 for examples.
Log event data for recovery	When on, logs event data that arrived after the last checkpoint started. This “recovery” log is used to restore the state of the system in the event of an abnormal shutdown of the servers. See Working with checkpoint and recovery for complete details.
Process events in the order of arrival	Choose this option when events must be processed in the order received. Otherwise, if events may be processed out of order, turn this on. Note: To join events in a view, the events must be processed in order: leave this option off to join the events.
Disable event after this number of consecutive errors	Disables the event when a consecutive count of errors occur. For example, if set to 5, disables the event after 5 consecutive errors. However, if 4 errors occur, and then no errors followed by 2 errors, the event remains enabled. The default is <i>off</i> : do not disable.
Column Information	The Column Information fields define how to map the fields from the JMS message into columns in the event table. There is one column for every field in the event table. See “HTTP Post column information” on page 167 for details.

Creating an HTTP Post event table

This section shows you how to create an HTTP post event table.

To create a HTTP Post event table:

1. Open the FileNet BAM Workbench Administration Console.
2. Create a new single event.
3. Select HTTP Post as the source type.
4. Assign a name and define the columns of the event table in the Column Information fields.

Save the HTTP Post table as enabled and it will immediately be ready to receive event messages.

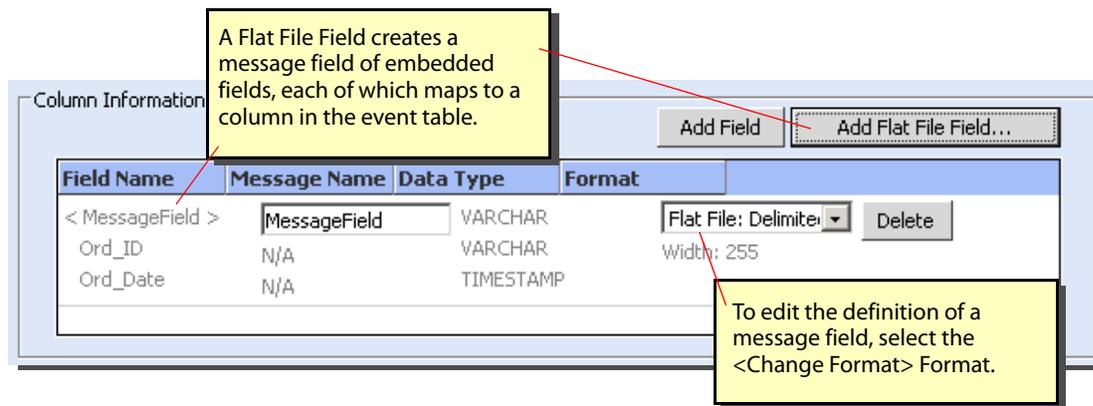

HTTP Post column information

The Column Information fields define how to map the fields from the HTTP Post message into columns in the event table. There is one field for every column in the event table, each with the following attributes:

Attribute	Description
Field Name	Name of the column in the event table.
Message Name	Name of the field in the message. On an HTML form, this is the NAME attribute assigned to each form element. See “Posting to an HTTP post event” on page 168 for examples. When mapping a Flat File field, the name for each embedded field is N/A and uneditable.
Data Type	Data type of the column in the event table.
Format	(optional) Format of the event column for VARCHAR (string) and DECIMAL values.

Each field in the message can be a simple field that maps directly into a event column, or it can be a complex field (a *flat file field*) that contains several fields that each map into columns in the table. Complex fields are treated as Flat Files in either delimited (CSV), fixed-width, or XML formats. See [“Flat Files” on page 73](#) for detailed descriptions of these file types.

NOTE: Message fields can contain more than one row of data; however, each row is part of the same event. This is different from flat file imports that treat each row in the file as a unique event.

To add a message field:

1. Click Add Flat File Field.
2. Choose the flat file type of the message field.

(Optional for fixed-width and delimited files.) Identify a sample file to assist in mapping the columns. This file is a sample of the real data file. Data from this file appears in the next step to assist you as you map the event data into the table.

3. For fixed-width files, define the positions of the data columns with the Set Field Widths dialog.
4. Identify the flat-file attributes. See [“Flat file event tables” on page 74](#) for details.
5. Define the format-specific Column Information. For details about the source type, see:
 - [“Fixed-Width files” on page 84](#).
 - [“Delimited files” on page 83](#)
 - [“XML files” on page 85](#)

See [“Multiple lines \(events\) of input” on page 170](#) for details about sending data to flat file fields.

6. Click Save Event to save the message field definition.

To edit the definition of a message field:

- In the field’s Format column, change the value from “Flat File: *file type*” to “<Change Formatting>”.

NOTE: When editing a message field, the sample file option for delimited and fixed-width file types is not available.

Posting to an HTTP post event

Most HTTP Post event are generated from an HTML form. When defining the event, define one column for each named <INPUT> element. For example, consider this HTML form:

```
<FORM action="http://.../filenetbam/postervlet?eventname=Example"
      method="post">
  <P>
    <LABEL for="name">Name: </LABEL>
      <INPUT type="text" name="name"><BR>

    <LABEL for="name">Date (yyyy-mm-dd): </LABEL>
      <INPUT type="text" name="date"><BR>

    <LABEL for="amt">Amount: </LABEL>
      <INPUT type="text" name="amt"><BR>

    <LABEL for="switch">Switch: </LABEL>
      <INPUT type="radio" name="switch" value="FALSE" checked >Off
      <INPUT type="radio" name="switch" value="TRUE">On<BR>

    <INPUT type="submit" value="Send">
    <INPUT type="reset">
  </P>
</FORM>
```

The four form fields map to these four columns in the event table:

Column Information				
Field Name	Message Name	Data Type	Format	
Name	name	VARCHAR	Width: 255	Delete
Date	date	VARCHAR	Width: 255	Delete
Amount	amt	DECIMAL	Precision: 28;	Delete
Switch	switch	BOOLEAN	N/A	Delete

Notice that the date field maps to a VARCHAR, not a TIMESTAMP. In the views that are derived from this event, *cast* the values to a date-time, similar to this:

```
CAST(httpEvent."Date" AS TIMESTAMP)
```

Posting to message fields

To pass data into a message field, you can either embed the information in the URL (as described below in Posting values in the URL”), or use an HTML <TEXTAREA> element and enter the flat-file data into that field. For example, your HTML form might have this declaration:

```
<LABEL for="flatfile">Flat file text: </LABEL>
  <TEXTAREA name="MessageField" rows="20" cols="80"></TEXTAREA>
```

In the browser, you can either enter the data manually or copy the data from a flat file and manually past it into the field. Remember that the data must be in the format of the declared Flat File Field, such as delimited.

Notes:

- When the event table contains more than just the Message Field column, you can enter only one row’s worth of data into the <TEXTAREA> field. If the Message Field is the only column, then you may enter multiple event row’s worth of data.
- Multiple rows passed through a <TEXTAREA> element are considered part of the same event, unlike a text file where each row is a unique event.

Posting values in the URL

When passing the field values directly in the URL, name and assign a value to each, and separate them with ampersands (&), like this:

```
...?eventname=Example&name="Skyler"&date=2003-03-05&amt=9.21&switch=TRUE
```

However, if passing the values to a delimited flat file field, just name the field and separate the values with the separator character (which is usually a comma), like this:

```
...?eventname=Example&msgFile="Skyler",2003-03-05,9.21,TRUE
```

Multiple lines (events) of input

To send multiple events to a flat file field, separate them with the %0D%0A (the MIME transmission for an end-of-line: "CR LF"), like this:

```
...="Skyler",2003-03-05,9.21,TRUE%0D%0A"Mike",1963-02-18,9.01,FALSE
```

Note that if you intend to send multiple lines, the Flat File field must be the only field in event column list. When the list includes other columns, only one "line" of input is permitted.

Java Messaging Service (JMS)

Java Messaging Service (JMS) provides access to messages produced by Java applications. The producer application publishes *topics* that the FileNet Business Activity Monitor agent *subscribes* to. Each new published topic message is mapped to a new event in the associated event table.

In this Chapter:

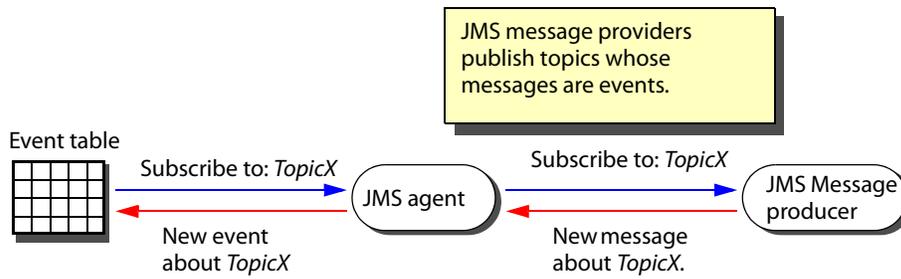

[“How it works” on page 172](#)

[“JMS event” on page 172](#)

[“JMS agents” on page 176](#)

How it works

FileNet Business Activity Monitor JMS agents communicate with JMS topic factories managed by Web application servers. When you define the agent, you tell it how to connect to the factory. When you define a JMS event table, you tell it to subscribe to a JMS topic managed by the factory that the agent talks to. Then when the topic publishes a new message, the agent receives it and passes it to the event table.

NOTE: FileNet Business Activity Monitor JMS agents support JMS *MapMessage* body type topic-message only. This type of message consists of name-value pairs, where the names are strings and the values are wrappers to Java types. See [“Mapping JMS data types” on page 176](#) for details.

JMS event

A Java Messaging Service (JMS) event receives new event data from a Java application that publishes messages to the topic that the table subscribes to. Each new topic message is a new event in the table.

Limitations

The JMS agent supports JMS *MapMessage* body types only. *MapMessage* consists of name-value pairs, where the names are strings and the values are wrappers to Java types. See [“Mapping JMS data types” on page 176](#) for details.

Prerequisites

Before creating an event to a JMS agent, you must:

- Create permission for tables (see [“Creating permission” on page 220](#)), and Read Only access permission on the agent that will feed the table.
- Obtain access to a JMS Topic as identified by the address factory’s JNDI location.
- A sample file (optional).

If the message contains a complex string that is CSV (delimited) or fixed-width text, it is helpful to have a sample file that contains data in the format of the actual event string. You can use this sample when

you create the event to ensure that the fields map correctly into the event table by seeing how the data lines up in the columns.

Attribute	Description
Name	Event table name. This name must be unique among views, events, context, and consolidated events. See “Object namespace” on page 211 for details.
Description	Optional description that may contain any text characters.
Status	Whether or not the table is enabled (monitoring for events), or disabled (not monitoring for events).
Log event data for recovery	When on, logs event data that arrived after the last checkpoint started. This “recovery” log is used to restore the state of the system in the event of an abnormal shutdown of the servers. See Working with checkpoint and recovery for complete details.
Process events in the order of arrival	Choose this option when events must be processed in the order received. Otherwise, if events may be processed out of order, turn this on. Note: To join events in a view, the events must be processed in order: leave this option off to join the events.
JMS Agent	An existing JMS agent that connects to the JMS message stream. Create an agent with the FileNet BAM Workbench Administration tab. See “JMS agents” on page 176 for details.
Topic	Identifies the <i>topic</i> on which the message is being sent, and defined by the message publisher. This is a JNDI address similar to this <code>com.celequest.myjmstopic</code> on BEA WebLogic, and this <code>topic/com.celequest.myjmstopic</code> on JBoss.
Message selector	A Boolean expression that puts a filter condition on the messages the publisher sends. The syntax of the condition is the same as that of the SELECT command’s WHERE clause. For example, this filter only accepts messages where the Supplier property contains one of three values: Supplier IN ('Xyz, Corp', 'Ink, Inc', 'Gizmos')
Column Information	The Column Information fields define how to map the fields from the JMS message into columns in the event table. There is one column for every field in the event table. See “JMS column information” on page 174 for details.

Creating a JMS event table

This section shows you how to create a JMS event table.

To create a JMS event table:

1. Open the FileNet BAM Workbench Administration Console.
2. Create a new event.
3. Select JMS as the source type.
4. Define the values of the event table's attributes.
5. Define the columns of the event table in the Column Information fields.

Save the JMS table as enabled and it will immediately be ready to receive event messages.

JMS column information

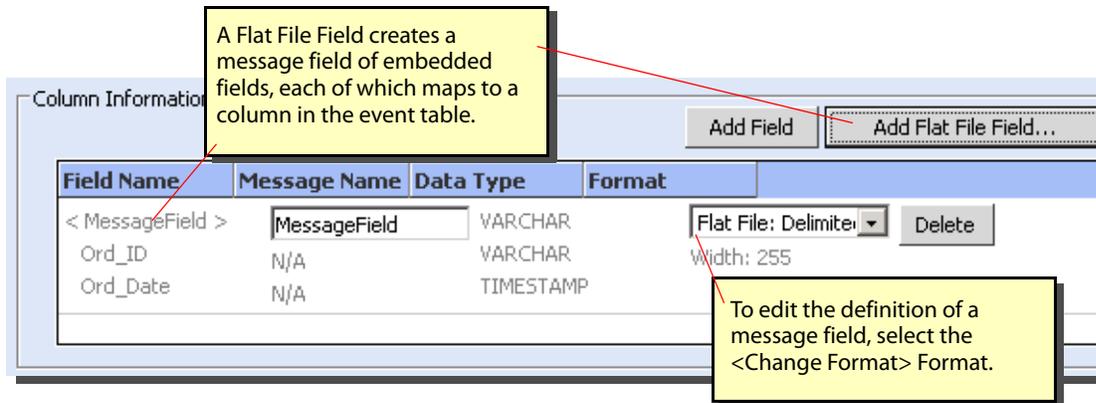

The Column Information fields define how to map the fields from the JMS message into columns in the event table. There is one field for every column in the event table.

Each field in the message can be a simple field that maps directly into a event column, or it can be a complex field (a *flat file field*) that contains several fields that each map into columns in the table. Complex fields are treated as Flat Files in either delimited (CSV), fixed-width, or XML formats. See [“Flat Files” on page 73](#) for detailed descriptions of these file types.

Each column in the event table has the following attributes:

Attribute	Description
Field Name	Name of the column in the event table.
Message Name	Name of the field in the message. When mapping a MessageField, the name for each embedded field is N/A and uneditable.
Data Type	Data type of the event column. See Mapping JMS data types,” below for details.
Format	(optional) Format of the event column for VARCHAR (string) and DECIMAL values.

Add columns by clicking Add Field or Add Flat File Field.

To add a message field:

1. Click Add Flat File Field.
2. Choose the flat file type of the message field.
 - (Optional for fixed-width and delimited files.) Identify a sample file to assist in mapping the columns. This file is a sample of the real data file. Data from this file appears in the next step to assist you as you map the event data into the table.
3. For fixed-width files, define the positions of the data columns with the Set Field Widths dialog.
4. Identify the flat-file attributes. See “Flat file event tables” on page 74 for details.
5. Define the format-specific Column Information. For details about the source type, see:
 - “Fixed-Width files” on page 84.
 - “Delimited files” on page 83
 - “XML files” on page 85
6. Click Save Event to save the message field definition.

To edit the definition of a message field:

- In the field’s Format column, change the value from “Flat File: *file type*” to “<Change Formatting>”.

NOTE: When editing a message field, the sample file option for delimited and fixed-width file types is not available.

Mapping JMS data types

The JMS mapped message data types map to FileNet Business Activity Monitor Data Types as follows.

Java Data Type	FileNet Business Activity Monitor Data Type
boolean	Boolean
byte	Integer
short	Integer
char	Varchar
int	Integer
long	Decimal
float	Double
double	Double
String	Varchar
byte[]	Not supported

JMS agents

A Java Messaging Service (JMS) agent communicates with a JMS message producer through a JMS topic running in the application server environment. The agent tells the producer which messages the JMS agents event table is interested in receiving. The producer then sends messages to the event table via the agent.

NOTE: JMS agents are asynchronous, they receive event messages as the events occur. You *cannot* retrieve context from a JMS agent.

Event push	Event pull	Context pull
Yes	No	No

Before creating a agent, you need:

- Create permission for agents (see [“Creating permission” on page 220](#) for details).
- The JNDI location of the topic factory in the application server that is publishing the topics.

A JMS agent has the following attributes:

Attribute	Description
Name	Identifies the agent. This name must be unique among agents. See “Object namespace” on page 211 for details.
Description	Optional description that may contain any text characters.
Status	Whether or not the agent is enabled (monitoring for events), or disabled (not monitoring for events).
Topic factory	<p>Identifies the J2EE connection factory that maintains the desired topics. This string identifies the factory by its JNDI lookup name. For example:</p> <p style="padding-left: 40px;">jms.ManufacturingTopic</p> <p>In a BEA WebLogic environment, the factory JNDI name is identified on the BEA WebLogic Console, Services > JMS > Connection Factories > <i>factoryName</i> > General tab.</p>
Acknowledge mode (Auto)	<p>Protocol to use when acknowledging receipt of the message.</p> <ul style="list-style-type: none"> • AUTO — (default) Provider acknowledges message when it is delivered. • CLIENT — Acknowledges the message when the agent receives it. • DUPS OK — Tells the publisher that it is OK to send a message more than once. Note that subsequent receipts of the same message are treated as new and unique events.
User name	User name to use to connect to the JMS factory.
Password	Password for the User name.
JNDI properties	<p>Optional and additional Java naming and directory interface (JNDI) properties necessary to make or maintain the agent to the JMS table. These name/value pairs allow you to specify JMS properties, and recognized by the JNDI.</p> <p>Note: When the JMS topic is running in a different namespace from the FileNet BAM Server), define the properties described below.</p>

JNDI properties for connecting to a remote namespace

When the JMS topic is running in a different namespace from the FileNet BAM Server, define these JNDI properties to make the connection:

```
java.naming.factory.initial  
java.naming.provider.url
```

Further, if you are using security, also define these properties:

```
java.naming.security.authentication  
java.naming.security.principal  
java.naming.security.credentials
```

Examples:

BEA WebLogic JNDI

```
java.naming.factory.initial=weblogic.jndi.WLInitialContextFactory  
java.naming.provider.url=t3://localhost:9180
```

IBM Websphere

```
java.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory  
java.naming.provider.url=iiop://localhost:9180
```

JBOSS

```
java.naming.factory.initial=org.jnp.interfaces.NamingContextFactory  
java.naming.provider.url=jnp://localhost:1099
```

Sun One Directory Server LDAP

```
java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory  
java.naming.provider.url=ldap://russell:59226/dc=viewceler,dc=com
```

Also, prefix the Topic factory parameter value with: cn=

Creating a JMS Agent

To create a JMS agent:

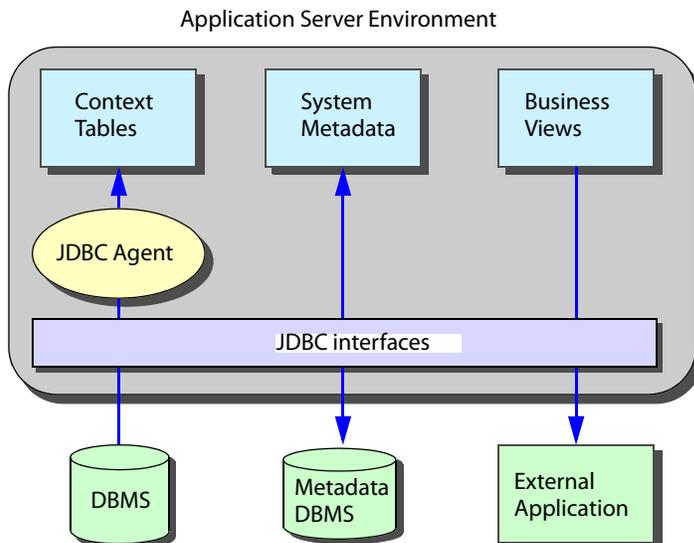

1. Open the Administration Console.
2. Click New Agent...
3. Choose JMS as the source type
4. Fill in the fields that define the agent's attributes.

Save the agent as enabled and it will immediately begin monitoring for events.

JDBC

JDBC (Java Database Connectivity) is a Java application programming interface for accessing standard SQL databases from Java programs. FileNet Business Activity Monitor (a Java application) uses JDBC to:

- Retrieve context data from a relational database (DBMS), as described in [“JDBC tables” on page 180](#) and [“JDBC agents” on page 187](#).
- Access the metadata database that FileNet Business Activity Monitor uses to store object and state definitions.
- Allow other Java applications to access the business view data in memory. See [“JDBC Access to View Data” on page 191](#) for details.

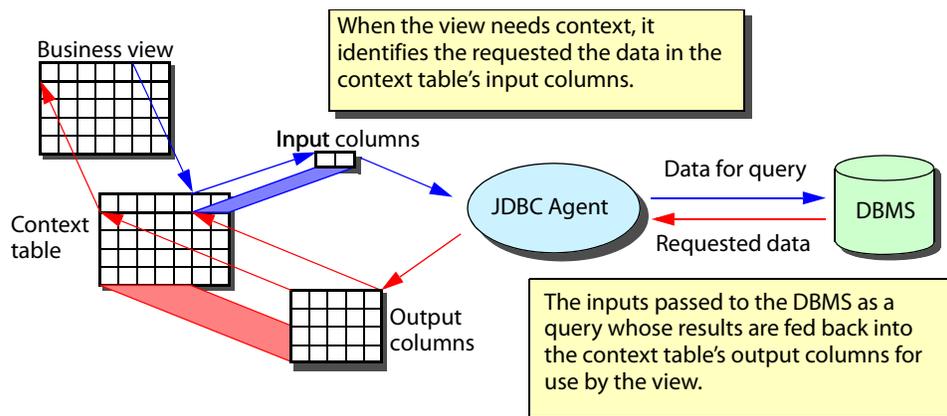

JDBC tables

Java database connectivity (JDBC) event and context tables receive their data from external relational database systems (DBMS). The data are retrieved by either making a query on the database or by calling a stored procedure in the DBMS.

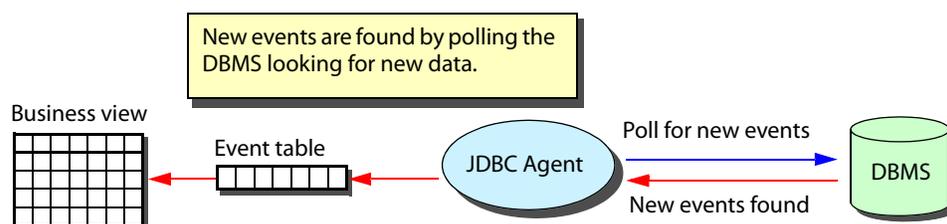

Context tables

For Context tables, new data is retrieved only when a new event requires it. Then the agent passes the query data to the DBMS, which then returns the result from DBMS.

Context tables

For event tables, the agent periodically polls the DBMS to see if new events are available, and then retrieves them for inclusion in the events table. Each event returned is processed individually, regardless of the count of events returned as a result of the polling query.

Before creating an event to a JDBC source table, you need:

- An agent — An existing JDBC agent defined with sufficient access rights to query the database, or call the stored procedure. Create an agent with the FileNet BAM Workbench Administration tab. See [“JDBC agents” on page 187](#) for details.
- For queries — The schemas of the tables to query.
- For query events — A column in the source table must be an incrementing value that identifies when new events are available. See [“Polling the JDBC source” on page 184](#).
- For stored procedures — To define the procedure in the RDBMS and provide a list of the input and (result set) output fields, and their data types. See [“Stored procedure source” on page 185](#), for details.

- Permissions — Create permission for tables (see [“Creating permission” on page 220](#)), and Read Only access permission on the agent that will feed the table.

A JDBC tables has the following attributes:

Attributes	Description
Name	Identifies the table. This name must be unique among views, events, context, and consolidated events. See “Object namespace” on page 211 for details.
Description	Optional description that may contain any text characters.
Status	Whether or not the event object is enabled (monitoring for events), or disabled (not monitoring for events).
Log event data for recovery	When on, logs event data that arrived after the last checkpoint started. This “recovery” log is used to restore the state of the system in the event of an abnormal shutdown of the FileNet BAM Server(s). See Working with checkpoint and recovery for complete details.
Process events in the order of arrival	Choose this option when events must be processed in the order received. Otherwise, if events may be processed out of order, turn this on. Note: To join events in a view, the events must be processed in order: leave this option off to join the events.
JDBC Agent	An existing JDBC source agent that accesses an RDBMS. Create an agent with the FileNet BAM Workbench Administration tab. See “JDBC agents” on page 187 for details.
JDBC Query	SELECT statement made against the database <i>in the native database language</i> . For details about the SELECT command, see the reference documentation for the DBMS. If you change the query, click Resubmit Query to validate it; you cannot save this form with an invalid query.

Attributes	Description
Disable context after errors	Count of consecutive errors to receive before the system disables this context. Once disabled, a context must be re-enabled manually.
Field Information	Columns to populate in the event or context table. The Field Names are derived from the JDBC Query result. When the system validates the query, it populates this field list and identifies the JDBC Data Type of each return value. You specify the associated Data Type of the column in the table. The field names are the same as defined in the DBMS schema unless you alias them with the AS operator in the SELECT statement's select list.
Event Key (event only)	For fixed-width and delimited files identifies key field columns for multi-row events. See "Multi-Row events" on page 77 for details.
Caching (context only)	Stores query results in memory and future requests retrieve data from memory, thereby lessening the impact on the DBMS by reducing the number of queries. See "Caching context queries" on page 47 for details about this feature.
Polling (event only)	How frequently to call the stored procedure or to query the DBMS for new events. See Polling the JDBC source," below , for details.

Creating a JDBC source event or context table

This section shows how to create JDBC source event or context table.

To create a JDBC source event or context table:

1. Open the FileNet BAM Workbench tab.
2. Click **New Event** or **New Context**.
3. Choose JDBC tables as the Source type.
4. Select the Agent source.
5. Choose either Query source or Stored Procedure source.
 - Stored Procedure source calls a stored procedure in the DBMS to locate the data. See ["Stored procedure source" on page 185](#), for details about this source.
 - Query source makes a SELECT SQL query on the database *in the native database language*. Enter the the SELECT statement in the query field. See [Query source," below](#), for details about this source. When you click Continue, the FileNet BAM Workbench issues the query to validate the query and determine the return columns.
6. Save the JDBC source as enabled.

The source will immediately be ready to receive events or context.

Query source

A query source makes a SELECT query on the database in the source DBMS. Queries are used for both context and events, and are in native syntax used by the DBMS. For specific syntax information, see the DBMS documentation.

Sybase limitations

When making a query to a Sybase database, be aware of these limitations:

- All names, including tables and columns, are case-sensitive.
- All queries must be in the form SELECT * FROM table only; you cannot include any SELECT clauses. To filter the results, load them into a business view, and then filter that view.

Example of context

Consider a view that joins an event table with a context table as follows:

```
SELECT Event.ID, Context.Name, Context.BDate AS Birth_Date
      FROM Event, Context      WHERE Event.ID = Context.ID
```

The context Output for this view might look like this:

Field Name	JDBC Data Type	Data Type
Name	STRING	Varchar
Birth_Date	DATE	Timestamp

Example of event using a polling query

Consider this query of the an Events table:

```
SELECT * FROM Events
```

The resulting field information might look like this:

Field Name	JDBC Data Type	Data Type
Event_ID	TINYINT	Integer
Product_ID	TINYINT	Integer
Product_Name	STRING	Varchar

Note that the polling Incrementing field is most likely Event_ID. See Polling the JDBC source, for details.

Polling the JDBC source

Polling tells the object how frequently to call the stored procedure or to query the DBMS for new events.

Parameter	Description
Polling interval	How often to call the procedure or issue the query.
Persist state across reboots	<p>After a restart, continue polling using the state of the polling prior to stopping the system. At run-time the object keeps track of values returned from the last call or query, and uses them to determine the starting point of the next call or query. When the option is checked, that information is saved at every check point and when the system is shutdown. See Working with checkpoint and recovery for more information.</p> <p>Otherwise, when the option is not checked, polling restarts with the initial values defined for this object.</p>
Disable after errors	Disables the object (stops polling) after consecutive errors occur. By default, the polling stops after five consecutive errors. To re-enable the object, change its Object status to enabled. Set this option to zero (0) to never disable automatically.
Incrementing field (event query only)	Identifies the column in the source table that contains a value that increments for every event. For example, if the table being queried contains unique, ascending ID values, that field is the one used by the query using the logic <i>"where ID greater than maximum ID from last query"</i> .
Initial value (event query only)	Value to use the first time the object queries the DBMS for events. For example, you might specify ID values starting with 500. For subsequent queries, the value must be greater than the Incrementing field value returned from the last query.

Stored procedure source

The JDBC stored procedure source requires the following attributes:

Attribute	Description
Procedure name	<p>Name of the stored procedure in the DBMS.</p> <ul style="list-style-type: none"> JDBC events do not support <i>multiple result-set</i> or <i>stored procedure output parameters</i>. For Oracle this means that only Oracle functions are supported because only they return a single result.
Outputs	<p>Columns in the event or context table, their data types, and optional formatting. The procedure returns a result set whose values map to the columns in the order they appear in this list. The data type identifies the type of the column in the table, and will automatically be converted from the JDBC type as defined in Mapping JDBC data types," described below.</p>
Inputs	<p><i>(optional for events)</i> Parameters passed to the stored procedure, and their data types. The parameters contain values to look up in the DBMS table. Inputs are passed as arguments to the procedure in the order they appear in the list.</p> <p>The data type identifies FileNet Business Activity Monitor data type of the value being passed to the procedure. See Mapping JDBC data types," below for details. Further,</p> <p>For events, the procedure usually queries the DBMS looking for events inserted since the last time the procedure was called. This is done by identifying fields in the table that contain some incrementing or increasing values. For example, if the table being queried contains unique, ascending ID values, that field is the one used by the procedure using the logic "<i>where ID greater that maximum ID from last query</i>".</p> <p>For events, the Initial Polling Value specifies the value to use the first time the procedure queries the DBMS for events. For example, you might specify ID values starting with 500. For subsequent queries, the Subsequent Polling Value identifies a field that contains the maximum value from the last query. This value is an Output field from the previous result.</p>
Polling	<p>How often to call the stored procedure. See Polling the JDBC source," below, for details.</p>

NOTE: When making a query to a Sybase database, be aware that the names, including tables and columns, are case-sensitive.

Example of receiving context using a stored procedure

Consider a view that joins an event table with a context table as follows:

```
SELECT Event.ID, Context.Name
      FROM Event, Context
      WHERE Event.ID = Context.ID
```

The context Output for this view is the Name column, and the Input to the procedure is the ID column.

Output Field Name	Data Type
Name	Varchar

Input Field Name	Data Type
ID	Integer

Example of receiving events using a stored procedure

Consider an event with the following fields. Note that Event_Timestamp is the field with the unique and increasing value: each event record has a timestamp assigned by the DBMS.

Output Field Name	Data Type
Ticket_ID	Varchar
Cust_ID	Varchar
Status	Varchar
Topic	Integer
When_Opened	Timestamp
Assigned_To	Varchar
Event_Timestamp	Timestamp

The event input identifies a parameter that passes the value to query. The name of the input must be unique to the list, but is otherwise insignificant. In this example, the field name is "IN1".

Input Field Name	Initial Polling Value	Subsequent Polling Value
IN1	2003-03-05 19:45:00	Event_Timestamp

The first time the stored procedure queries the DBMS, it issues one semantically similar to this:

```
SELECT * FROM events
      WHERE event_time >= "2003-03-05 19:45:00"
```

Subsequent queries use the results from the previous query as the starting point for new events.

Mapping JDBC data types

The data types of the DBMS columns are displayed as JDBC data types, and map to FileNet Business Activity Monitor Data Types as follows.

JDBC data type	Character	Integer	Double	Decimal	Timestamp	Boolean
CHAR	yes	—	—	—	—	as literal
VARCHAR	yes	—	—	—	—	as literal
LONGVARCHAR	yes	—	—	—	—	as literal
NUMERIC	—	yes	yes	yes	—	yes
DECIMAL	—	yes	yes	yes	—	yes
BIT	—	yes	yes	yes	—	yes
TINYINT	—	yes	yes	yes	—	yes
SMALLINT	—	yes	yes	yes	—	yes
INTEGER	—	yes	yes	yes	—	yes
BIGINT	—	yes	yes	yes	—	yes
REAL	—	yes	yes	yes	—	yes
FLOAT	—	yes	yes	yes	—	yes
DOUBLE	—	yes	yes	yes	—	yes
BINARY	—	—	—	—	—	—
VARBINARY	—	—	—	—	—	—
DATE	—	—	—	—	yes	—
TIME	—	—	—	—	yes	—
TIMESTAMP	—	—	—	—	yes	—

NOTE: Do not use FileNet Business Activity Monitor Boolean data type in a WHERE predicate passed to the JDBC source. Boolean values may be included in the Select list.

JDBC agents

A Java database connectivity (JDBC) agent communicates with a relational database (DBMS) by either making a query on the database, or calling a stored procedure in the DBMS. The DBMS then returns one or more rows of data, which the agent passes on to the requesting event or context JDBC tables.

NOTE: JDBC agents are synchronous, they retrieve event messages and context data as the result of a specific request. For context, the agents access the DBMS when a new event requires context data. For

events, the agent periodically polls the DBMS to see if new events are available, and then retrieves them for inclusion in the events table. Each event returned is processed individually, regardless of the count of events returned as a result of the polling query.

Event push	Event pull	Context pull
No	Yes	Yes

Before creating a JDBC agent, you need:

- Create permission for agents (see [“Creating permission” on page 220](#) for details).
- A JDBC data source defined and managed by the application server, preferably one that pools connections. Note, configure the connection pool as documented in your application server’s documentation. Additionally, in the pool’s definition:
 - Set the maximum number of open connections to the database to be at least 200.
 - Set a refresh rate to be greater than 0, preferably to 1 or 2 minutes. This allows the database to go down and come back up with loosing the connection from the pool. Further, you should set the pool to test for the existence of a physical table in the database.

Attributes

A JDBC agent has the following attributes:

Attribute	Description
Name	Identifies the agent. This name must be unique among agents. See “Object namespace” on page 211 for details.
Description	Optional description that may contain any text characters.
Status	Whether or not the agent is enabled (monitoring for events), or disabled (not monitoring for events).
Database type	Identifies the DBMS vendor as Oracle, Sybase, SQL Server, or DB2.
User name	User name to use to connect to the DBMS. Must have <i>query</i> access rights.
Password	Password for the User name. If you omit this option, the agent uses the password specified in the JDBC Source configuration definition in the application server.
Max rows per query	Maximum count of rows to return as the query result. Useful to keep users from returning exceptionally large results that impact the DBMS.

Attribute	Description
Type of JDBC connection	<p>How to connect to the JDBC in the application server.</p> <ul style="list-style-type: none"> • Datasource-based: Connects to a JDBC database pool via a JNDI connection. Do not use for IBM Websphere. • URL-based: Connects to a JDBC source via a URL.
JNDI name for JDBC Source (Datasource only)	<p>Name of the data source to use as a connection to the database. The name is in JNDI form, such as "com.celequest.products.ProductSource".</p> <p>A source gets its connection from a pool of connections maintained by the application server. That server keeps the connections open to reduce delays when establishing a connection.</p> <p>Note: The connection pool must be configured as a non-transactional pool; non-TxT on WebLogic.</p>
JNDI properties (Datasource only)	<p>Optional and additional Java naming and directory interface (JNDI) properties necessary to make or maintain the agent to the JDBC source. These name/value pairs allow you to specify JDBC properties. The names are either one of the short cuts listed below, or a JNDI recognized property.</p> <p>The agent recognizes the following names as short cuts to JNDI properties:</p> <ul style="list-style-type: none"> • factory maps to INITIAL_CONTEXT_FACTORY. • provider maps to PROVIDER_URL. • security_credentials maps to SECURITY_CREDENTIALS. • security_principal maps to SECURITY_PRINCIPAL.
JDBC URL (URL only)	<p>URL that maps to the JDBC connection configured in the application server running FileNet Business Activity Monitor. For example, a URL might look like this: jdbc:oracle:thin:some_context/context@v480:1521:symbols</p>
JDBC driver class (URL only)	<p>JDBC driver to use. This driver must reside in the classpath of the application server running FileNet Business Activity Monitor. Include the complete classname, such as: oracle.jdbc.driver.OracleDriver</p>

Creating a JDBC agent

The following procedures show you how to create a JDBC agent.

To create a JDBC agent:

1. Open the FileNet BAM Workbench Administration Console.
2. Click **New Agent**.
3. Choose JDBC as the source type
4. Fill in the fields that define the agent's attributes.

Save the agent as enabled and it will immediately be ready to retrieve data.

JDBC Access to View Data

FileNet Business Activity Monitor provides an application programming interface (API) that allows JDBC 2.0 applications to retrieve data from a view, and to retrieve the metadata that describes the views in the installation. The data that you can retrieve are:

- View data from the recent view. Note that if the view contains a (moving set) window, the window data is returned.
- Event identifier (VC_EVENT_ID always included) which identifies the event that produced the most recent row included in the view.
- Latest event identifier (VC_LATEST_EVENT_ID always included) which identifies the last event that caused the view to update, though data from that event might not be included in the view.
- Event timestamp (VC_TIMESTAMP always included) which identifies when the last event was included in the view.

NOTE: This is the same information that is written to a database when persisting views. See [“Persisting views to a database” on page 301](#) for more information.

Classpath

The classpath to FileNet Business Activity Monitor JDBC driver (cqjdbcclient.jar) needs to be added to the client JDBC application. The client application should also link in the application server (such as weblogic.jar) to have access to the JNDI naming service. For example, when running a program (e.g., Test) from a command line, the java call might look like this one on a BEA WebLogic server:

```
java -classpath .;c:\bea\weblogic700\server\lib\weblogic.jar;  
c:\cq\cqjdbcclient\cqjdbcclient.jar JDBCAccessor
```

The rest of this document describes the JDBC view interfaces, and provides [“JDBC accessor examples” on page 198](#).

JDBC view interfaces

JDBC 2.0 defines interfaces for accessing data. FileNet Business Activity Monitor implements the following interfaces for accessing its data. For complete details about the interfaces, see the JDBC documentation at <http://java.sun.com/j2se/1.3/docs/api/java/sql/package-summary.html>.

NOTE: All methods return data that meet the JDBC 1.0 standard. Further, methods defined in the JDBC class but which not supported in FileNet Business Activity Monitor API, throw an SQLException.

These are the interfaces that FileNet Business Activity Monitor supports:

Class	Member	Description
Driver		The JDBC SQL database driver. See “Example: Establishing a connection to the FileNet BAM Server” on page 199 for an example. The class name is: <code>com.celequest.jdbc.driver.Driver</code>
	<code>connect</code>	Attempts to make a database connection to the URL.
	<code>acceptsURL</code>	Returns true if this driver understands the specified subprotocol.
	<code>getMajorVersion</code>	Returns the driver’s major revision number.
	<code>getMinorVersion</code>	Returns the driver’s minor revision number.
	<code>jdbcCompliant</code>	Returns false.
Connection		A connection to a specific database. See “Example: Establishing a connection to the FileNet BAM Server” on page 199 for an example of using this interface.
	<code>createStatement</code>	Returns a newly-created Statement object
	<code>close</code>	Releases a Connection object’s JDBC resources immediately.
	<code>getMetaData</code>	Returns a newly created DatabaseMetaData object.
	<code>isClosed</code>	Returns true if the calling Connection object is closed; otherwise, returns false when it is still open.
Statement		An SQL statement to pass to the database. See “Example: Querying the contents of a view” on page 201 for an example of using this interface.

Class	Member	Description
	executeQuery	Executes a FileNet Business Activity Monitor C-SQL select query, returns a single ResultSet, and closes the calling Statement object's current ResultSet, if any. The query statement involves a single table only, and may contain WHERE, GROUP BY, and ORDER clauses. The viewname references in the query are case insensitive and may be quoted (using the double quote character).
	close	Releases a Statements object's JDBC resources.
DatabaseMetaData		Provides information about the view definitions defined in FileNet Business Activity Monitor installation.
	getTables	Returns view definitions. See "Example: Querying View Metadata" on page 204 for an example of using this method.
	getColumns	Returns the column information for a given view. See "Example: Querying Column Metadata" on page 203 for an example of using this method. See getColumns() column summary," below, for a summary listing of the columns:
ResultSet		A table of data representing a database result set, which is usually generated by executing a statement that queries the database.
	next	Moves the cursor to the next row in the set and fixes the current row.
	close	Immediately releases a ResultSet's JDBC resources.
	wasNull	Returns true if the last value read was SQL NULL.
	getString	Returns the value of a column as a Java String.
	getBoolean	Returns the value of a column as a Java Boolean.
	getInt	Returns the value of a column as a Java int.
	getDouble	Returns the value of a column as a Java double.
	getObject	Returns the value of a column as a Java object (as defined in the default type mapping).
	getBigDecimal	Returns the value of a column as a java.math.BigDecimal object.
	getTimestamp	Returns the value of a column as a Java Timestamp.
	getMetaData	Returns the number, types, and properties of a ResultSet object's columns as a ResultSetMetaData object.

Class	Member	Description
ResultSetMetaData		Provides information about the types and properties of the columns in a ResultSet object.
	getColumnCount	Returns the count of columns in the ResultSet object.
	getPrecision	
	getScale	Returns the count of digits to the right of the decimal separator.
	getTableName	Returns the table name from which the ResultSet was derived.
	getColumnName	Returns the name of a column.
	getColumnType	Returns the JDBC type for the value stored in a column. See "Data type mappings," below, for a summary of the mappings.
	getColumnTypeName	Returns the FileNet Business Activity Monitor type name for the a column.

Data type mappings

The "get" functions in this class return values from FileNet Business Activity Monitor columns. This matrix indicates which functions should be used for the various FileNet Business Activity Monitor data types.

	getBoolean	getInt	getDouble	getBigDecimal	getString	getTimestamp
Boolean	X	o	o	o	o	—
Integer	o	X	o	o	o	—
Double	o	o	X	o	o	—
Decimal	o	o	o	X	o	—
Varchar	o	o	o	o	X	x
Timestamp	—	—	—	—	x	X
<p>X indicates that the function returns a value compatible with FileNet Business Activity Monitor data type.</p> <p>o indicates data types that might be compatible, but whose conversion is not recommended.</p>						

getColumns() column summary

This table is a summary of the Java documentation for DatabaseMetaData.getColumns(). See the Java documentation for a complete list.

Column	Type	Description
TABLE_CAT	String	Table catalog (may be null)
TABLE_SCHEM	String	Table schema (may be null)
TABLE_NAME	String	Table name
COLUMN_NAME	String	Column name
DATA_TYPE	int	SQL type from java.sql.Types. See DATA_TYPE return values," below, for a summary.
TYPE_NAME	String	Data source dependent type name, for a UDT the type name is fully qualified
COLUMN_SIZE	int	Column size. For char or date types this is the maximum number of characters, for numeric or decimal types this is precision.
BUFFER_LENGTH	String	Not used.
DECIMAL_DIGITS	int	Count of fractional digits
NUM_PREC_RADIX	int	Radix (typically either 10 or 2)
NULLABLE	int	Is NULL allowed. <ul style="list-style-type: none"> columnNoNulls - might not allow NULL values columnNullable - definitely allows NULL values columnNullableUnknown - nullability unknown
REMARKS	String	Comment describing column (may be null)
COLUMN_DEF	String	Default value (may be null)
SQL_DATA_TYPE	int	Not used.
SQL_DATETIME_SUB	int	Not used.
CHAR_OCTET_LENGTH	int	For char types the maximum number of bytes in the column.
ORDINAL_POSITION	int	Index of column in table (starting at 1)
IS_NULLABLE	String	"NO" means column definitely does not allow NULL values; "YES" means the column might allow NULL values. An empty string means nobody knows.

DATA_TYPE return values

The DATA_TYPE column returns an int value that identifies the Java data type. See the java.sql.Types file for details. This table summarizes those values.

Type	Value
BIT	-7
TINYINT	-6
BIGINT	-5
LONGVARBINARY	-4
VARBINARY	-3
BINARY	-2
LONGVARCHAR	-1
NULL	0
CHAR	1
NUMERIC	2
DECIMAL	3
INTEGER	4
SMALLINT	5
FLOAT	6
REAL	7
DOUBLE	8
VARCHAR	12
DATE	91
TIME	92
TIMESTAMP	93
OTHER	1111
JAVA_OBJECT	2000
DISTINCT	2001

Type	Value
STRUCT	2002
ARRAY	2003
BLOB	2004
CLOB	2005
REF	2006

JDBC accessor examples

The examples in this section demonstrate how to connect to the FileNet BAM Server and query view data, metadata, and metadata about the views and columns defined in the installation. The examples, include:

- [“Example: Establishing a connection to the FileNet BAM Server” on page 199](#)
- [“Example: Querying the contents of a view” on page 201](#)
- [“Example: Querying a view’s column specifications” on page 201](#)
- [“Example: Querying Column Metadata” on page 203](#)
- [“Example: Querying View Metadata” on page 204](#)

Java

Access to the JDBC driver depends on the `java.sql.*` classes. As such, be sure to include the following import in your applications;

```
import java.sql.*;
```

Complete Sample

Included on the product CD-ROM is a sample application that contains the complete code for the snippets listed in these examples. See the `\samples\JDBC\` directory for the files. That directory has two files:

- `readme.txt` describes how to compile and run the application.
- `JDBCAccessor.java` is the application.

Briefly, to compile the application:

```
javac -classpath . JDBCAccessor.java
```

To run the program, load it into the application server, similar to this:

BEA WebLogic:

```
java -classpath .;c:\bea\weblogic700\server\lib\weblogic.jar;  
c:\cq\cqjdbcclient\cqjdbcclient.jar JDBCAccessor
```

JBoss:

```
java -classpath .;C:\jboss\3.2.3\client\jnet.jar;  
C:\jboss\3.2.3\client\jboss-net-client.jar;  
C:\jboss\3.2.3\client\jnp-client.jar;  
C:\jboss\3.2.3\client\jboss-common-client.jar;  
c:\cq\cqjdbcclient\cqjdbcclient.jar JDBCAccessor
```

The results from the examples print to the standard output, with errors going to standard error.

Example: Establishing a connection to the FileNet BAM Server

This example shows how to establish a connection to the FileNet BAM Server's JDBC driver.

Establish the connection by creating a Connection object, similar to this:

```
Connection connection = null;
connection = DriverManager.getConnection(url, userName, password);
```

The `userName` and `password` parameters identify a FileNet Business Activity Monitor account. When querying a specific object (like a view), the user account must have at least Read Only access permission. Otherwise, if the account has No Access to the view, the query fails as if the view does not exist.

The `url` parameter identifies the factory in the application server that establishes the connection to FileNet Business Activity Monitor JDBC driver. This URL specifies the type of connection, host and port to connect to, and the factory in the application server. Further properties vary among application servers. The sample application names the common properties in variables that you can customize for your installation:

```
String userName    = "system";
String password    = "manager";
```

The sample application that builds the `url` parameter from the properties specific to the application server, like this:

BEA WebLogic connection properties

```
String hostAndPort = "localhost:80";
String factory     = "weblogic.jndi.WLInitialContextFactory";
String url         = "jdbc:celequest:wl:factory="+factory+
                    ";provider=t3://" + hostAndPort + ";;";
```

JBoss connection properties

```
String hostAndPort = "localhost:1099";
String factory     = "org.jnp.interfaces.NamingContextFactory";
String url         = "jdbc:celequest:wl:java.naming.factory.url.pkgs="+
                    "org.jboss.naming:org.jnp.interfaces;" +
                    "factory="+factory+";provider=jnp://" + hostAndPort + ";;";
```

Following is a more detailed example. However, to see the complete listing, examine the `JDBCAccessor.main()` member.

```
// Common connection properties
String userName    = "system";
String password    = "manager";

// JBoss connection properties
String hostAndPort = "localhost:1099";
String factory     = "org.jnp.interfaces.NamingContextFactory";
String url         = "jdbc:celequest:wl:java.naming.factory.url.pkgs="+
                    "org.jboss.naming:org.jnp.interfaces;" +
                    "factory="+factory+";provider=jnp://" + hostAndPort + ";";

// Verify the JDBC driver in the application o
try {
    Class.forName("com.celequest.jdbc.driver.Driver");
} catch (ClassNotFoundException e) {
    handleError("Could not find the JDBC driver class.", e);
    return;
}

// Establish the connection to the JDBC driver
Connection connection = null;

try {
    connection = DriverManager.getConnection(url, userName, password);
} catch (SQLException e) {
    handleError("Could not connect to the JDBC driver.", e);
    return;
}
```

Example: Querying the contents of a view

This snippet shows how to query the entire contents of a view. The `executeQuery()` call passes the query to the driver, which returns the view contents in a `ResultSet` object. All columns, including the internal system columns like `VC_TIMESTAMP` are included in this list. Additionally, metadata about the view is retrieved in a `ResultSetMetaData` object to determine the count of columns in the view.

NOTE: See the `JDBCAccessor.PrintViewContents()` sample for a complete code listing.

```
/* Query all contents of a view.
 * Connection has already been established, and view name defined.
 */
String queryString = "SELECT * FROM " + VIEW_NAME ;
ResultSet rs;           // Table to hold the query results.
ResultSetMetaData rmd;  // Metadata about the result set.

// Query the view, and get its data and metadata.
Statement stmt = connection.createStatement();
rs = stmt.executeQuery( queryString );
rmd = rs.getMetaData();

// Print the contents of the entire view, row by row.
int columnCount = rmd.getColumnCount();
boolean isEmpty = true;
while (rs.next()) {
    isEmpty = false;
    System.out.print(" Row: ");
    for (int i=0;i<columnCount;i++) {
        // Show the column value, or "NULL"
        String ts = rs.getString(i+1);
        System.out.print( (rs.isNull() ? "NULL " : ts + " "));
    }
    System.out.println(); // Line break
}
if (isEmpty) {
    System.out.println("\n *** The view is empty ***");
}
```

The result might look like this:

```
Contents of view [OrderProductTotals]:
Row: Hinges 132300.00 49 130000.00 28 2004-08-17 11:22:06.818 28
Row: Lag bolts 16400.00 41 65000.00 21 2004-08-17 11:22:06.818 28
Row: Nails 129600.00 48 150000.00 26 2004-08-17 11:22:06.818 28
Row: Nuts 337875.00 159 280000.00 27 2004-08-17 11:22:06.818 28
Row: Screws 60000.00 30 80000.00 20 2004-08-17 11:22:06.818 28
Row: Washers 122400.00 72 170000.00 23 2004-08-17 11:22:06.818 28
Row: Chip board 277200.00 126 250000.00 18 2004-08-17 11:22:06.818 28
Row: Plywood 304800.00 127 250000.00 10 2004-08-17 11:22:06.818 28
```

Example: Querying a view's column specifications

This snippet shows how to query the user-defined specifications about the columns in a view. First it shows all of the metadata available for column specifications, and then it shows the interesting specifications

about each column in the view, including the internal system columns. Note that the results appear *in the order that the columns appear in the view*, followed by the internal columns.

NOTE: See the JDBCAccessor.PrintColumns() sample for a complete code listing.

```
/* Query a view's column specifications.
 * Connection has already been established, and view name defined.
 */
// Query the table to identify the columns to report on. Because the
// view contents are irrelevant here, omit them by declaring
// 'WHERE false' as the query condition.
String queryString = "SELECT * FROM " + VIEW_NAME + " WHERE false";

ResultSet rs;                // Table to hold the query results.
ResultSetMetaData rmd;       // Metadata about the result set.

// Query the view, and then get its metadata.
Statement stmt = connection.createStatement();
rs = stmt.executeQuery( queryString );
rmd = rs.getMetaData();

// Print the metadata about the columns in the view.
System.out.println("Column details for view [" +
    rmd.getTableName(1) + "]:");

// Walk through and show the interesting metadata available for
// each column in the view. Include labels to identify what we see
// in the result.
for (int i=0;i<rmd.getColumnCount();i++) {
    System.out.println(
        " " + Integer.toString(i+1) +
        ". Name [" + rmd.getColumnName(i+1) +
        "] Type [" + Integer.toString(rmd.getColumnType(i+1)) +
        "] Precision [" + Integer.toString(rmd.getPrecision(i+1)) +
        "] Scale [" + Integer.toString(rmd.getScale(i+1))+"]");
}
```

The results might look like this:

```
View: [ORDERPRODUCTTOTALS]
Column details for view [ORDERPRODUCTTOTALS]:
1. Name [FAMILY] Type [12] Precision [20] Scale [0]
2. Name [PRODUCT] Type [12] Precision [50] Scale [0]
3. Name [SALES] Type [3] Precision [25] Scale [2]
4. Name [QTY] Type [4] Precision [10] Scale [0]
5. Name [TARGET] Type [3] Precision [15] Scale [2]
6. Name [TARGET MIN] Type [3] Precision [15] Scale [2]
7. Name [TARGET MAX] Type [3] Precision [15] Scale [2]
8. Name [VC_EVENT_ID] Type [4] Precision [10] Scale [0]
9. Name [VC_TIMESTAMP] Type [93] Precision [0] Scale [9]
10. Name [VC_LATEST_EVENT_ID] Type [4] Precision [10] Scale [0]
```

Example: Querying Column Metadata

These snippets show how to retrieve metadata about the columns view. (To retrieve the column specifications instead, see [“Example: Querying a view’s column specifications” on page 201.](#))

NOTE: See the `JDBCAccessor.PrintColumnMeta()` sample for a complete code listing.

```
/* Retrieve the metadata about the columns of a defined view.
 */
// NOTE: Specify 'null' instead of 'VIEW_NAME' to get the metadata
//       for ALL columns in the installation.
rs = meta.getColumns(null,null,VIEW_NAME,null);
rmd = rs.getMetaData();

// Show the metadata available for view columns.
int columnCount = rmd.getColumnCount();
for (int i=0;i<columnCount;i++) {
    System.out.print(rmd.getColumnName(i+1) +
        ((i+1)==columnCount ? "" : ", "));
}
}
```

The results first lists the metadata column names (see [“getColumns\(\) column summary” on page 195](#) for a description of the columns):

```
Getting column metadata for [OrderProductTotals]
TABLE_CAT, TABLE_SCHEM, TABLE_NAME, COLUMN_NAME, DATA_TYPE, TYPE_NAME,
COLUMN_SIZE, BUFFER_LENGTH, DECIMAL_DIGITS, NUM_PREC_RADIX, NULLABLE,
REMARKS, COLUMN_DEF, SQL_DATA_TYPE, SQL_DATETIME_SUB, CHAR_OCTET_LENGTH,
ORDINAL_POSITION, IS_NULLABLE
```

Next, show all of the metadata about the columns in a specific view. Note that columns *do not* appear in the order that they appear in the view.

```
// Show the metadata values for the columns in the view.
boolean isEmpty = true;
while (rs.next()) {
    isEmpty = false;
    for (int i=0;i<columnCount;i++) {
        String ts = rs.getString(i+1); // Metadata value
        if (rs.isNull())
            System.out.print(",");
        else
            System.out.print(ts +
                ((i+1)==columnCount ? "" : ", "));
    }
    System.out.println();
}
if (isEmpty) {
    System.out.println("\n *** Either there are no columns defined "+
        "for this view (unlikely), or the view is not "+
        "defined (probably).");
}
}
```

Here is a sample listing of the metadata for the OrderProductTotals view. (See [“Data type mappings” on page 194](#) for a mapping of the data types from Java). Again, the columns *do not* appear in any particular order.

```
,,OrderProductTotals,VC_EVENT_ID,4,VCInteger,10,,0,10,1,,,,,1,YES
,,OrderProductTotals,VC_TIMESTAMP,93,VCTimestamp,9,,0,10,1,,,,,3,YES
,,OrderProductTotals,Target_max,3,VCDecimal,15,,2,10,1,,,,,4,YES
,,OrderProductTotals,VC_LATEST_EVENT_ID,4,VCInteger,10,,0,10,1,,,,,5,YES
,,OrderProductTotals,Family,12,VCVarchar,20,,0,10,1,,,,,6,YES
,,OrderProductTotals,Target_min,3,VCDecimal,15,,2,10,1,,,,,7,YES
,,OrderProductTotals,Qty,4,VCInteger,10,,0,10,1,,,,,9,YES
,,OrderProductTotals,Product,12,VCVarchar,50,,0,10,1,,,,,10,YES
,,OrderProductTotals,Target,3,VCDecimal,15,,2,10,1,,,,,11,YES
,,OrderProductTotals,Sales,3,VCDecimal,25,,2,10,1,,,,,12,YES
```

Example: Querying View Metadata

These snippets show how to query view metadata. First it shows the metadata available for views, and then it shows how to find all of the views defined in the system.

NOTE: See the `JDBCAccessor.PrintAllViewsMeta()` sample for a complete code listing.

```
/* Retrieve metadata about views.
 */
ResultSet rs;
ResultSetMetaData rmd;
DatabaseMetaData meta = connection.getMetaData();

// Use 'null' for the 3rd parameter to retrieve information about all
// of the views in the system, instead of just one.
rs = meta.getTables(null,null,null,null);
rmd = rs.getMetaData();
for (int i=0;i<rmd.getColumnCount();i++) {
    System.out.println(
        " ["+ rmd.getColumnName(i+1) +
        "] Type ["      + Integer.toString(rmd.getColumnType(i+1)) +
        "] Precision ["  + Integer.toString(rmd.getPrecision(i+1)) +
        "] Scale ["      + Integer.toString(rmd.getScale(i+1))+"]");
}
}
```

The results first describe the metadata that is available:

This metadata is available for views.

```
[TABLE_CAT] Type [12] Precision [255] Scale [0]
[TABLE_SCHEM] Type [12] Precision [255] Scale [0]
[TABLE_NAME] Type [12] Precision [255] Scale [0]
[TABLE_TYPE] Type [12] Precision [255] Scale [0]
[REMARKS] Type [12] Precision [255] Scale [0]
```

Next, list the views (table names) defined in the system:

```
// Use the metadata to list all of the views in the system.
final int GT_TABLE_NAME = 3; // View name
boolean isEmpty = true;
while (rs.next()) {
    isEmpty = false;
    System.out.println(" " + rs.getString(GT_TABLE_NAME) );
}
if (isEmpty) {
    System.out.println(" *** There are no views defined. ***");
}
```

The results look similar to this:

```
OrderChangeDetails
OrderTotals
8WeekOrders
8WeekOrdersAvg
OrderProductTotals
OrderSalesGrandTotal
30DayOrders
InventoryChangeDetails
SupplierAlternates
```

Objects

Objects manage data in FileNet Business Activity Monitor. Every object has a name, optional description, and a status that determines if it is able to work with its intended data. Further, each object has additional information that you define that tells the object what data to manage, and how to manage it.

In this Chapter:

[“Object status” on page 207](#)

[“Object names” on page 208](#)

[“Object namespace” on page 211](#)

Object status

Every object has one of three statuses that determine its ability to operate:

Icon	Description
	Enabled — The object is accepting new data and processing them. You can only enable valid objects that do not depend on disabled objects. When you enable a disabled object, you have the choice of enabling just that object, or that object and all objects that depend on that object (<i>cascade enable</i>). Further, all of the dependant objects must be capable of being enabled — none may be invalid — or the entire operation fails and no objects are enabled.
	Disabled — The object is not accepting new data. Disabling an object does not affect the definition or existence of that object; rather, it just keeps new data from flowing into the object and to all objects that depend on the object. For example, disabling a view also disables all rules that monitor the view, and thereby also disables all associated alerts and reportlets.
	Disabled dependant— The object is not accepting new data because an object that this one depends on is disabled. Enabling the referenced object will also enable this object.
	Invalid — The object that has a reference to another object which cannot be satisfied, such as one view that references a column in another view, but that column no longer exists in the referenced view. An object can be invalid because a referenced object does not exist or because some attribute of the object does not match the requirements of the dependent (such as a data type mismatch or a missing column name). Invalidating an object also invalidates all objects that depend on the object. This usually happens when you delete an object that has dependencies, or change an object's definition.

When you view a list of objects, you can see each object's valid/invalid state, and the enabled/disabled status. You can click on an enabled indicator in the Status column to disable it, or click on a disabled indicator to enable it.

 Name	Description		Status
 Customer_Aggregate	This is the customer_ag...		 Click to enable.
Customer_Order	This is the customer_or...		 Click to disable.
OrdersPerCustomerCou...	This is the orderspercu...		

Object names

All object names must be either a *regular identifier* or a *delimited identifier*.

- **Regular Identifier** — The first character of a regular identifier must begin with a letter from ‘a’-‘z’ or ‘A’-‘Z’, and all subsequent characters can be from ‘a’-‘z’, ‘A’-‘Z’, ‘0’-‘9’, or ‘_’.
- **Delimited Identifier** — A delimited identifier must start and end with a double quote ("). The body of a delimited identifier must be non-empty and can contain any SQL language characters including: the Regular Identifier characters, underscore ('_'), space(' '), percent('%'), ampersand('&'), single quote, left parenthesis ('('), right parenthesis (')'), asterisk('*'), plus sign('+'), comma(','), minus sign('-'), slash('/'), colon(':'), semicolon(';'), equals operator('='), question mark('?'), vertical bar('|') or double quote (") (escaped with another double quote).

NOTE: Names may not contain periods ('.'), less than ('<'), or greater than ('>') characters.

All names must be unique within their class (such as view or agents; see [“Object namespace” on page 211](#) for details), and may not be identical to reserved words. For example, you cannot have a view named by the regular identifier select, though you can have a delimited one named "select".

Reserved words

All identifiers beginning with “VC_” are reserved system names and may not be used. Further, all reserved words in the SQL-99 standard are reserved in C-SQL. Following are FileNet Business Activity Monitor reserved words:

Reserved Words			
abs	delete	local	rollback
absolute	desc	log	round
acked	describe	lower	rows
action	descriptor	lowered	rpad
add	diagnostics	lpad	rtrim
all	disconnect	ltrim	schema
allocate	distinct	match	scroll
alter	domain	max	second
and	double	min	section
any	drop	minute	select
are	else	mod	session
as	end	module	session_user
asc	end-exec	month	set
assertion	escape	mov_avg	sign
at	event	mov_count	size

Reserved Words			
authorization	except	mov_max	smallint
avg	exception	mov_min	some
begin	exec	mov_ntile	space
between	execute	mov_rank	sql
bit	exists	mov_ratio_to_report	sqlcode
bit_length	exp	mov_std_deviation	sqlerror
boolean	external	mov_sum	sqlstate
both	extract	mov_variance	sqrt
by	false	names	std_deviation
cascade	fetch	national	substr
cascaded	first	natural	substring
case	float	nchar	sum
cast	floor	next	system_user
catalog	for	no	table
ceil	foreign	not	temporary
char	found	ntile	then
char_length	from	null	time

Object namespace

The namespace controls how objects are named within FileNet Business Activity Monitor. Generally, object names must be unique among other objects of the same type, within the same container. However, here are some exceptions:

- Alerts, rules, and reportlets *can* share the same name within the containing scenario; you can use the same name for one alert, one rule, and one reportlet within a scenario. Further, each object within a scenario may share the same name as an object of the same type in another scenario.
- Profiles must be unique within a single user; multiple users may share profile names.
- Users and business activities cannot share the same name; they must be unique within the “containers” class. See the summary below for details.
- Views, events, context, etc., cannot share the same name; they must be unique within the “tables” class. See the summary below for details.
- Agents must be unique within the “agents” class.

This outline summarizes the namespace constraints:

```

/containers
  /Business activities      Unique among /containers
    /Scenarios
      /Alerts
      /Rules
      /Reportlets
  /Users and Roles         Unique among /containers
    /E-mail profiles       Unique within a user
    /RTD (Excel) profiles  Unique within a user
/tables
  /Events                  Unique among /tables
  /Context                 Unique among /tables
  /Consolidated events     Unique among /tables
  /Cube                    Unique among /tables
  /Dimensions              Unique among /tables
  /Views                   Unique among /tables
/agents
  /Flat (text) files       Unique among /agents
  /SOAP (Web services)     Unique among /agents
  /JMS                     Unique among /agents
  /JDBC                    Unique among /agents
  /Rendezvous (TIBCO)     Unique among /agents
/Excel templates
/External actions (processes)
/Join relationships

```

Operators and Constants

This chapter describes the operators and constants that FileNet Business Activity Monitor and C-SQL support in expressions and arguments.

In this Chapter:

[“Numeric operators” on page 213](#)

[“String operators” on page 213](#)

[“Comparison operators” on page 214](#)

[“Logical operators” on page 215](#)

[“Constants” on page 215](#)

Numeric operators

There are two classes of numeric operators:

Prefix operators

Control the arithmetical sign of numeric values.

Prefix Operator	Description
+	Unary plus
-	Unary minus

Infix operators

Numeric operators perform arithmetical operations on numeric values:

Numeric Operator	Description	Example
+	Addition	11 + 3 returns 14
-	Subtraction	11 - 3 returns 8
*	Multiplication	11 * 3 returns 33
/	Division	11 / 3 returns 3

To perform arithmetic operations on date-time values, use DATE_ADD() and DATE_DIFF().

String operators

Concatenation (||) is the only string operator and it appends the right-side string to the end of the left-side string. For example 'a' || 'b' returns 'ab'. The behavior is identical to the CONCAT() function.

Comparison operators

Comparison operators compare two or more values of the same data type and return a Boolean:

Operator	Description	Example
=	Equal	1=1 returns TRUE
<>	Not equal	'A'<>'a' returns TRUE
>	Greater than	CURRENT_DATE()>TO_DATE('02/28/1963') returns TRUE
<	Less than	Age<21 returns UNKNOWN when Age is NULL
>=	Greater than or equal	TRUE>=FALSE returns TRUE
<=	Less than or equal	NULL<=NULL returns NULL
IN	Is a member of a list	Symbol IN ('IBM', 'MSFT', 'VCLR') or Count NOT IN (5, 10, 15, 20)
BETWEEN/AND	Is within a range	SalePrice BETWEEN 50.0 AND (90.0) or NOT BETWEEN 'M' AND 'O'
LIKE	Pattern matching. See below for details.	Title LIKE 'MR_'

LIKE operator

The LIKE operator matches a pattern of characters. A percent sign (%) in the pattern is a wildcard for zero or more characters, and an underscore (_) is a wildcard for exactly one character.

```
WHERE Title LIKE 'MR_'  
WHERE E_Mail NOT LIKE '%.edu'
```

To include either '%' or '_' in the search string, use the keyword ESCAPE to designate an escape character. A '%' or '_' following an escape character is treated as a literal. Note that the escape character may not be used elsewhere in the search string. This example looks for "10%" anywhere in Discount:

```
WHERE Discount LIKE '%10$%' ESCAPE '$'
```

NOTE: An escape character prefixing anything other than an escape or special character is ignored.

Be careful about using LIKE when comparing against numeric types. LIKE is a string operator and as such, searching a numeric first performs an implicit cast of the numeric value to a string. When casting numerics to strings, be aware of the following:

- For DECIMAL numbers, casting to string zero-pads the decimal values to match the precision and scale defined for the column. So, for example, if a column is defined as precision 5 and scale 4, a value of 1.1 in the column is cast as '1.1000', and so searches for single digit decimals must be done as LIKE '._000'.
- For DOUBLE PRECISION numbers, the 'e' is cast to upper case. So, for example, +1e11 is converted to '1.0E11'.

Logical operators

Logical operators compare Boolean values, such as the result of a comparison operation.

Logical Operator	Description	Example
AND	Both true	(SalesPrice>500) AND (OnSale)
OR	One must be true	(ZipCode = '90210') OR (City = 'Lodi')
NOT	Inverse	NOT OnSale
IS	Test of Boolean	IS OnSale or IS NOT OnSale

The truth table for the equal sign (=) operator is equivalent to IS. See [“Truth table for IS” on page 64](#) for details.

Constants

The C-SQL Boolean constants are TRUE, FALSE, and UNKNOWN. See [“Boolean” on page 64](#) for details about these constants.

Constants	Description
TRUE	True.
FALSE	Not true.
NULL	No data.
UNKNOWN	Test for Boolean value that is NULL, or where a comparison cannot be determined such as when comparing null to null.

NOTE: NULL is ignored when computing set function, moving set function, and rank function values. For example, the average of (3, NULL, 3) is 3, not NULL and it is not 2.

NULL is a null value. Any non-Boolean column which does not have an entry is considered NULL.

WHERE SalesPrice = NULL Returns TRUE

WHERE SalesPrice = UNKNOWN **Error**, cannot cast Numeric to Boolean

However, testing a Boolean column returns UNKNOWN when the column is empty.

WHERE OnSale = NULL Returns UNKNOWN (null = null)

WHERE OnSale = UNKNOWN Returns UNKNOWN (null = unknown)

WHERE OnSale IS NULL Returns TRUE

WHERE OnSale IS UNKNOWN Returns TRU

Permissions

Permissions control which users may see, create, and edit FileNet Business Activity Monitor objects and user accounts.

In this Chapter:

[“Accessing permissions” on page 218](#)

[“Granting permissions” on page 221](#)

[“Creating permission” on page 220](#)

Application of permissions

Permissions can be applied in two places:

- On a specific object from the Permissions button after selecting the object in a list. When you assign a permission a specific object, it is the *maximum* permission that the user has to *that object*. You cannot set a user's permission to a specific object lower than that user's permission to the class of objects.
- At the class level from the Administration Console>Edit User dialog>Access Permissions tab. When you assign a class level permission, it is the *minimum* permission that the user has to *all objects of this type*. You can also assign class level permissions to a role from the Edit Role dialog>Access Permissions tab. Roles define permissions for set of users over sets of objects.

When a user belong to one or more roles, the highest level of access between the roles and the user's assigned permissions is the one that applies. For detailed information about roles, see ["Roles" on page 252](#).

By default, every new user has No Access permissions for everything (except user accounts, to which they have Read Only permission). However, even with this minimal set of permissions, a user may receive and view alert notifications and reportlets generated as the result of mandatory subscriptions.

NOTE: A System user always has full permissions to every object in the installation. For information about the System user, see ["Users" on page 282](#).

The rest of this discussion describes the permissions in detail:

- ["Permission restrictions" on page 221](#) details the rules for when you are allowed to change permissions.
- ["Permission inheritance and dependencies" on page 222](#) describes the permissions you need to create and edit classes, and how some objects affect access to others.

Accessing permissions

Access permissions specify the level of access a user has to an object. Permissions can be assigned to an entire class of object or to a specific object. The access permissions are:

Permission	On the class	On a specific object
No Access	Cannot see any objects of this class, unless granted “read” on specific objects.	—
Filtered/Read-Only	—	Limits the rows in a view that the user can see based on an access filter. See “Access Filters” on page 17 for details.
Read-Only	Can see all objects of the class.	Can see the object.
Read-Write	Can see and edit all objects of the class.	Can see and edit the object.

NOTE: You cannot assign a permission to a specific object that is more restrictive than the user’s permission on the class. For example, you cannot assign Read Only when a user has Read-Write on the object’s class. Further, you cannot assign a permission to an object that is greater than your own for the same object.

Class level access permissions

All class level permissions are assigned to a user or role. To see or change a class level permission, you must first edit the user’s account or role definition.

NOTE: When viewing the list of user or roles, *do not use* the Permissions button. That button defines which users and roles may access the specific user accounts or role definitions in the list. See [“Specific Object Access Permissions,”](#) below, for details of this button.

To change a user’s permissions for a class of objects:

1. In the Administration Console, select the Users folder, and double-click on the user’s account in the list. This edit’s the user’s account.
2. On the Edit User dialog, click the Access Permissions tab.
3. Click Edit next to the permission to change. The permission dialog has three fields:
 - Role-Granted Permissions shows the permission assigned by the roles that the user is a member of. When the user belongs to multiple roles, the greatest level of access among them is applied.
 - Additional User-Specific Permission is the permission that you are assigning for the user for the class. While you can assign a permission lower than the role permissions, doing so does not lower the users permission.
 - Effective Permissions is the greatest level of permission assigned by the other two fields, and is *the permission assigned* to the user for this class of objects.

For more information about this dialog, see [“User Permissions tab” on page 286](#).

4. Save the changes to immediately apply them to the user.

To change a role’s permissions for a class of objects:

1. In the Administration Console, select the Roles folder, and double-click on the role in the list. This edit’s the role’s definition
2. Click the Access Permissions tab.
3. Click Edit next to the permission to change. Set the permission to the class for this role.
4. Save the changes to immediately apply them to the role.

Specific Object Access Permissions

You access the permissions to specific objects by selecting the object in the list of objects, and clicking the Permissions button above the list. Note that this applies to the Users and Roles lists as well. You can assign access permissions to specific user accounts and roles in the same way you assign access to specific views or agents.

To see user permissions for one or more specific objects:

- Select the objects in a list (such as a specific view in the Views list) and click Permissions. Your permissions to the object are shown at the top of the dialog, and the permissions that each user has to the object are listed below your permissions.

To change user permissions for one or more specific objects:

1. Select one or more objects and click Permissions. (Note that Filtered/Read-Only permission can only be assigned to one view at a time.)
2. Select the users whose access permissions you want to change and click Change Permissions.

You cannot change the permissions for users that do not meet the criteria listed in “[Permission restrictions](#)” on page 221. For example, this picture lists each user’s access permissions to the current object, shows that three users have higher permission than the current user (because their permissions cannot be changed), and shows that two users who are about to have their permissions changed.

You cannot change the permissions of this users.

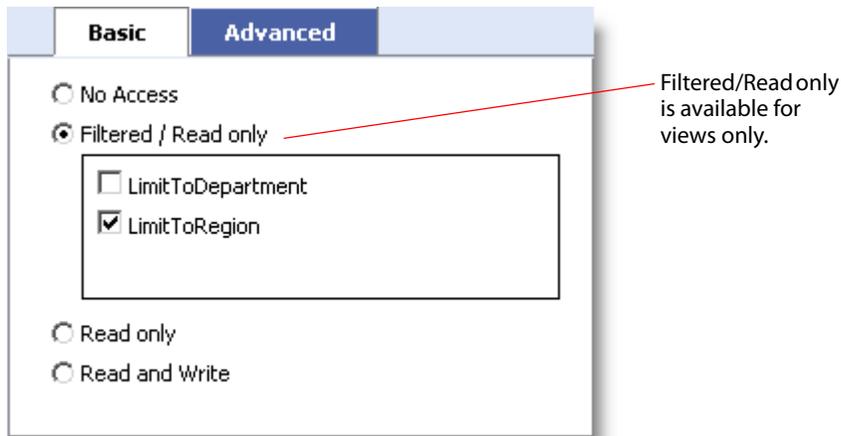

These two selected users are about to have their permissions changed.

Your permissions:

Set business activity permissions for these users or roles:

<input type="checkbox"/>	Name	Type	Permissions	Change Permissions...
<input type="checkbox"/>	Diaz	User	Read/write with gra...	
<input type="checkbox"/>	InventoryManagers	Role	No access	
<input checked="" type="checkbox"/>	Jason	User	Read-only access	
<input type="checkbox"/>	Nasi	User	Read/write access	
<input checked="" type="checkbox"/>	Rama	User	Read-only with gran...	
<input type="checkbox"/>	SalesExecutives	Role	No access	
<input type="checkbox"/>	SalesManagers	Role	No access	
<input type="checkbox"/>	Skyler	User	Read with grant, re...	
<input type="checkbox"/>	Tarun	User	Read/write access	
<input checked="" type="checkbox"/>	Vijay	User	No access	
<input type="checkbox"/>	Zaphod	User	Read/write access	

3. Set the permissions on the Basic tab. Note that when you assign permissions to a view, you have the option of choosing a Filtered/Read-Only permission, as shown in the illustration. See [“Access Filters” on page 17](#) for information about this permission.

Save the permissions and they are immediately applied to the objects.

Creating permission

The Create permissions specifies which classes of objects a user may create.

When you create an object, you have Read and Write, and Grant Access permissions to that object. This allows you to grant any Access or Grant permissions to any other users for that object.

NOTE: Once you have created an object, any other user with Grant permissions on the object can re-assign permissions, in effect overriding any permissions you assigned.

When you create a user, the user has No Access to everything. You may assign permissions to that user for an entire class of objects on the user's User Permissions tab.

To see which types of objects you may create:

- Click Account Settings and view the User Permissions tab for you account.

Granting permissions

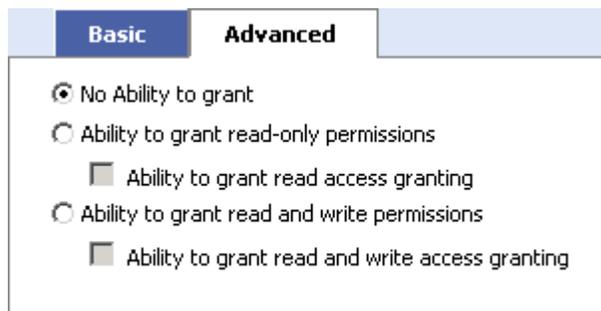

The Grant permissions allow you to assign permissions to other users. The Grant permissions are:

Permission	Description
Grant Read Only	May grant Read Only permission.
Grant Read and Write	May grant Read and Write permission.
Grant Create	May grant Create permission.
Grant ability to grant Read Only	May grant ability to grant Read Only permission.
Grant ability to grant Read and Write	May grant ability to grant Read and Write permission.
Grant ability to grant Create	May grant ability to grant Create permission.

NOTE: The System user is the only user that is always guaranteed to have full permissions on all objects.

To grant permissions to other users:

1. Select the objects and click Permissions.
2. Select the users to modify and click Change Permissions and choose the Grant permissions on the Advanced tab.

Permission restrictions

When granting permissions, be aware of these restrictions:

- You cannot lower another user's permission on an object for which they have higher permission than you.
- You cannot raise another user's permission on an object to be higher than your own permission on that object. You will usually encounter this restriction when attempting to assign permissions on multiple objects are once, where your permission on one of the objects is less than your permission for the others.

Permission inheritance and dependencies

Objects that track permissions control access to the object, and to objects they may contain. Other objects inherit their permissions from the object that they are contained in. The objects that control permissions are:

- Agents
- Business Activities (controls access to contained scenarios, rules, alerts, and reportlets)
- Microsoft Excel templates (active reports)
- Roles
- Tables, includes Events, Contexts, and consolidated events
- Users (controls access to user accounts).
- Views

NOTE: Regardless of what permissions a user has to an alert or reportlet, the user can always see the information in alert notifications and reportlets sent to the user.

Dependencies

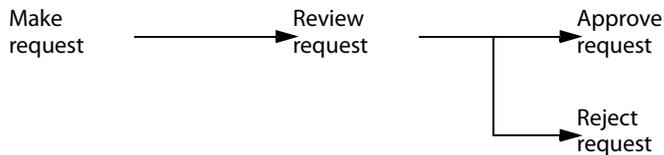

When you create or edit objects, you are limited by the permissions of any dependant objects, and by the permissions of any containing object. Here are the objects that have dependant requirements for create or edit:

- Table — You must have Read permission to the agent that feeds the table.
- View — You must have Read permission to the event table or base view, and any context tables that feed the view.
- Business activity — To see the definitions of any objects contained in a business activity, you need Read permission on that business activity. Further, for contained scenarios, rules, alerts, and reportlets:
 - To see the definition of the object you need Read permission on the underlying view.
 - To create a contained object, you need Read and Write permission on the business activity, *and* Read permission on the underlying view.

NOTE: Permissions on one object can affect a user's access to another, especially for restrictions on views. For example, you might be able to edit an alert but not the alert's reportlet when the reportlet's view is No Access but the alert's view is Read Only.

Processes

A *process* is the set of steps (actions) that accomplish a task, such as the example below which is a four-step process for making a request for approval. Further, a real transaction through a process is a *process instance*, such as a specific request for approval.

Business process management (BPM) systems create and manage business processes and instances. When a BPM is managing a process instance, it sends details about each step of the transaction to FileNet Business Activity Monitor, which then develops statistics about the entire process. For example, the system might determine how long, on average, it takes to complete the entire process, is the process getting faster over time, what percentage of requests are rejected, or how long just the review step takes.

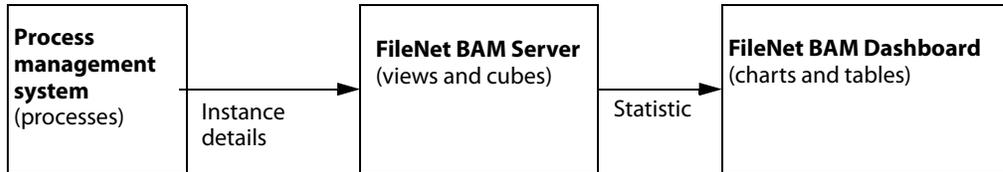

In this Chapter:

[“How it works” on page 224](#)

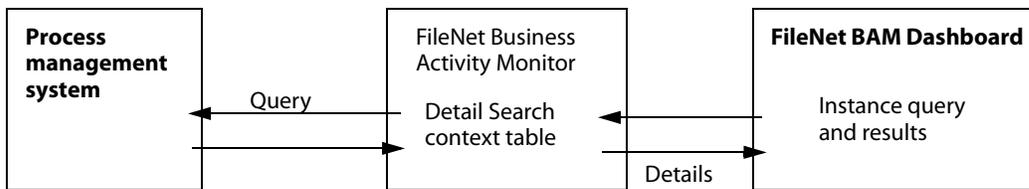

[“Creating and using processes” on page 225](#)

How it works

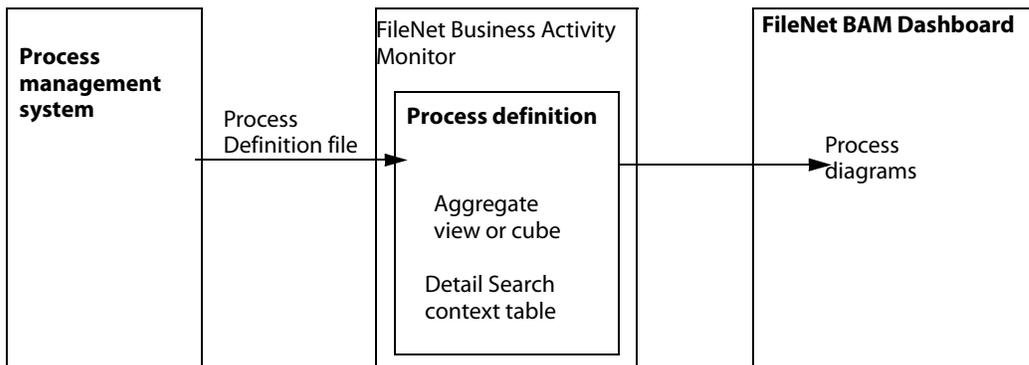

Process instance details arrive in FileNet Business Activity Monitor as events. The FileNet BAM Server aggregates the details in views or cubes to generate the statistics. The FileNet BAM Dashboard then presents the process as a diagram, and includes the statistics in a table. Other objects can display other metrics, such as charts that present statistics over times.

The FileNet BAM Dashboard also provides an optional ad-hoc query to the BPM to get the details about a specific process instance, such as where is it in the process. When a user makes such a request, the FileNet BAM Dashboard queries a context table in the FileNet BAM Server, and that table queries the BPM for the specific instance details. The results are then returned to the FileNet BAM Dashboard for display.

The process management system generates a *process definition file* that describes the process in XML. A *process definition* in the FileNet BAM Workbench then associates that definition file with an aggregate view or cube, and optionally with a search context table. The FileNet BAM Dashboard uses that object as the source for a process chart, and to identify the associated aggregate view or cube and search context table.

Creating and using processes

To create and use processes in FileNet Business Activity Monitor, the external business process system must:

- Generate a process definition file in an XML format recognized by FileNet Business Activity Monitor.
- Publish process step statistics as event data into the FileNet BAM Server.
- Optionally provide an interface for the process instance queries from FileNet Business Activity Monitor context tables.

The general steps for creating process diagrams are:

1. Create an agent (if necessary) and event table to receive the process events from the BPM.
2. Create one view or cube per process.
3. (Optional) Create a context table to query the BPM.
4. Create a process definition object.
5. Create a process diagram.

Event streams

The event streams receive and aggregate the process instance statistics. Event data are received in an event table, usually arrive through an agent. And the aggregate views are based on the event table. For detailed information about these components, see the following topics:

- [“Agents” on page 25](#)
- [“Events” on page 70](#)
- [“Views” on page 291](#)
- [“Cubes” on page 48](#)

The following requirements also apply:

- There should be only one agent and event table per BPM.
- There should be one view or cube per process. Use a Where clause to distinguish the process events from other processes in the event table, such as "Process Name"='Request Approval'. See Working with process definitions for details.

Context search table

The context table generates a query to the BPM whenever a FileNet BAM Dashboard user makes an ad hoc query about a specific process instance. For details about context tables, see [“Context” on page 42](#).

When the context receives a query from the FileNet BAM Dashboard, it first looks for the details in the context cache. If the instance is not in the cache, the table then queries the BPM for the details. Be sure to define a reasonable invalidation schedule for your business, or disable the cache if the queries need to return the most up-to-date information about the process instance.

Process definitions

See [Working with process definitions](#) for details about this task.

Before creating a process definition, you need:

- Read Only access permission on the view or cube that aggregates the process events.
- (Optional) Read Only access permission on the context search table.

To create a process definition in the FileNet BAM Workbench:

1. Open the Process Definitions folder in the FileNet BAM Workbench and choose New Process Definition.
2. Name the object and upload the process definition file generated by the BPM.
3. Choose the aggregate view or cube, and choose the column that identifies the steps in the process.
4. (Optional) Choose the detail search context table, choose the column to search, and optionally provide descriptive text to appear in the FileNet BAM Dashboard.

Detail Search (Optional)
Context table to query the process management system about a specific process instance. Choose the column to query and provide a descriptive name for it.

Context Table:

Search Column:

Descriptive Name:

Process

Request number:

Result:

--	--

5. Save the process definition.

You can now create process diagrams based on this definition.

Process Diagrams

See Process Diagrams for details about this task.

Before creating a process diagram, you need:

- Read Only access permission on the aggregate view or cube that provides the statistics.

To create a process diagram in the FileNet BAM Dashboard:

1. Open the Process Diagrams manager and choose Create Diagram.
2. Select the process definition (as defined in the FileNet BAM Workbench).
3. Select the source columns to present as statistics.
4. Name the process diagram and save it.

The FileNet BAM Dashboard immediately presents the process diagram. The statistics update as events arrive for the specific process.

Query Windows

A *query window* specifies a set of rows that are used in calculations with respect to the current row (event) under examination in a view constructed with a C-SQL SELECT statement. (Business views created in the FileNet BAM Workbench construct views via a well-formed SELECT statement passed to the servers.)

In this Chapter:

The rest of this discussion describes how to define and use windows.

[“Overview” on page 229](#)

[“Window declarations and references” on page 230](#)

[“Event-Series windows” on page 232](#)

[“Time-Series windows” on page 233](#)

[“Window partitions” on page 238](#)

[“Window advancement” on page 241](#)

[“Window update reference” on page 245](#)

[“Window Initialization” on page 246](#)

Overview

The calculation using a window may be for computing a moving set function, a join, or expiring rows from a view. All such calculations use a window; however, in the default cases for these operations, you do not need to define the window semantics. For example, in C-SQL, *set functions* perform calculations on sets of rows in a view. The default set of rows for each function is *all events since the view was initiated* (an “unbounded” set). Consider this view which calculates the total value of column named Qty for all events that were ever included in the view:

```
SELECT SUM(Qty) AS Total_Qty FROM Orders
```

However, another way to express the SUM() to get the same result is the following, which says to *sum over the set of all previous events*:

```
SELECT SUM(Qty) OVER (EVENTS UNBOUNDED PRECEDING) AS Total_Qty  
FROM Orders
```

The OVER clause defines a window that identifies the set of rows to include. With a window you can limit the set to a specific count of event rows, or to those events that occurred within a specific time-span. For example, *to total just the current and last five events*, define a window like this:

```
SUM(Qty) OVER (EVENTS 5 PRECEDING) AS Total_Qty
```

And, to total *just the current month's events*, use a time-series window, like this:

```
SUM(Qty) (RANGE INTERVAL '1' MONTH PRECEDING) AS Total_Qty OVER
```

Window types

All windows are identified by either the EVENTS or RANGE clause, and include an *extent* definition that defines the size of the window.

```
{ RANGE | EVENTS } <window frame extent>
```

The extent syntax is unique to the window type and is described in detail in [“Event-Series windows” on page 232](#) and [“Time-Series windows” on page 233](#). Other clauses (not shown) control how the window behaves as new events enter the window, which items to include, and how and when the window updates to include new events and discard old ones.

Window declarations and references

There are two ways to define windows and associate them with functions:

In-line

In-line defines the window parameters immediately following the function reference, similar to this:

```
SELECT PartName, SUM(Qty) OVER (EVENTS 4 PRECEDING) AS Total_Qty,  
       FROM Orders  
       GROUP BY PartName
```

This format is useful when you have only one window per query, though you can also use it with multiple windows. Note that you cannot share these window definitions among functions in the same query.

Reference by name

Reference by name to use a window defined with the WINDOW clause, similar to this:

```
SELECT PartName,  
       SUM(Qty) OVER Previous4 AS Total_Qty,  
       AVG(Qty) OVER Previous4 AS Average_Qty  
FROM Orders  
GROUP BY PartName  
WINDOW Previous4 AS (EVENTS 4 PRECEDING)
```

This format is useful when you have multiple simple window definitions because you can define them all in one place: in the same WINDOW clause definition. This form also allows you to share the definition over multiple functions in the same query (as shown above), and allows you to use windows that extend another window's definition (see "Extending one window definition with another", below).

NOTE: Functions in the select list associated with a window must have alias names defined with the AS operator, such as AS Total_Qty in the examples above.

Multiple windows per query

The WINDOW clause defines windows that can be shared throughout the query, and which may be extended by other windows. This example defines two windows, each used by a different function in the query:

```
SELECT PartName,  
       SUM(Qty) OVER Previous4 AS Total_Qty_4,  
       AVG(Qty) OVER Previous10 AS Average_Qty_10  
FROM Orders  
GROUP BY PartName  
WINDOW Previous4 AS (EVENTS 4 PRECEDING),  
       Previous10 AS (EVENTS 10 PRECEDING)
```

Extending one window definition with another

When windows share common traits, you can define those traits in one window definition, and then extend (inherit) that definition with other, unique aspects in different windows. For example, this definition defines one window named `Common` with the `PARTITION BY` clause, and then defines additional windows that extend the common traits with the range required for the unique windows:

```
SELECT PartName,  
       SUM(Qty) OVER Events4 AS Total_Of_Qty_4,  
       AVG(Qty) OVER Events10 AS Average_Of_Qty_10  
FROM Orders  
WINDOW Common AS (PARTITION BY PartName),  
       Events4 AS (Common EVENTS 4 PRECEDING),  
       Events10 AS (Common EVENTS 10 PRECEDING)
```

The `WINDOW` definition above is the same as this:

```
Events4 AS (PARTITION BY PartName EVENTS 4 PRECEDING),  
Events10 AS (PARTITION BY PartName EVENTS 10 PRECEDING)
```

Restrictions

Window extension definitions may not include properties defined in the base window. For example, you cannot define an `ORDER BY` in both the base and extension windows. Further:

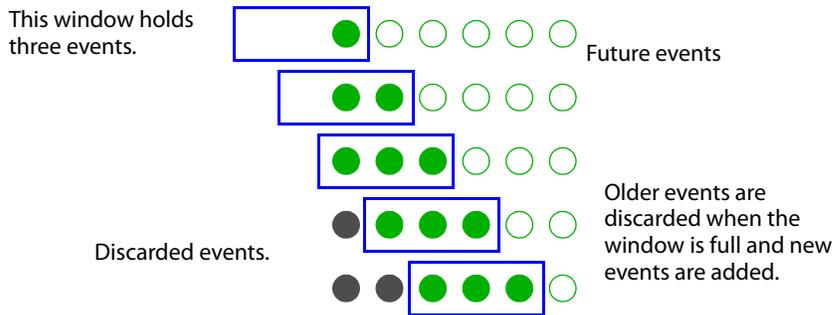

- A `PARTITION BY` clause can appear *in the base window definition only*; it cannot appear in an extensions.
- These clauses can appear *in extension definitions only*; they cannot appear in the base window:

```
BETWEEN/AND  
CURRENT EVENT  
EVENTS  
INITIALIZE  
RANGE  
REFERENCE  
SLIDE  
UNBOUNDED  
<window start integer> without an EVENTS or RANGE clause
```

- A window may only extend another window defined in the same query; a window in a derived view cannot extend a window in a base view.

Event-Series windows

Event-series windows contain a maximum fixed-set of events. Initially the window is empty, but fills with new events until it reaches its defined capacity. After that, the oldest events are discarded one-for-one as the newest events are included.

EVENTS clause

Event-series windows are identified by the EVENTS clause. Spans of events are expressed with the BETWEEN and AND clauses. Omit the span arguments to include just the latest events, starting with the current event. PRECEDING is optional and provided for ANSI compatibility, it clarifies that the event rows precede the current one.

```
([PARTITION BY <column>]
EVENTS [BETWEEN] {<oldestEvent> | UNBOUNDED} PRECEDING
      [AND { <newestEvent> [PRECEDING] | CURRENT EVENT } ]
[SLIDE <distance>]
[REFERENCE {FRAME | OPERATOR} ]
```

- PARTITION BY creates one window frame for each <column> of events, similar to a GROUP BY window. See [“Window partitions” on page 238](#) for details.
- SLIDE identifies how to advance the window when new events arrive in the view. See [“Window advancement” on page 241](#) for a detailed description of this option.
- REFERENCE tells the window when to determine if rows have expired from the window set. The default value is FRAME: expire rows only when new rows enter the window. The OPERATOR form is useful only when the view has multiple PARTITION BY or GROUP BY windows. See [“Window update reference” on page 245](#) for a detailed description of this option.

Examples

This window contains rows limited by a count of consecutive events in the view, such as the last 5 events,

```
SUM(Qty) OVER (EVENTS 4 PRECEDING) AS Total_Qty
```

or the 10 events starting 12 events ago.

```
SUM(Qty) OVER (EVENTS BETWEEN 11 PRECEDING AND 2 PRECEDING)
      AS Total_Qty
```

Notice that the size of the window frame is (<oldestEvent>--<newestEvent>+1). For example, the frame above contains 10 events (11–2+1).

To include all of the previous events, including the current one, with the UNBOUNDED option, like this:

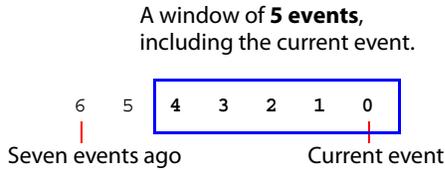

```
SUM(Qty) OVER (EVENTS UNBOUNDED PRECEDING) AS Total_Qty
```

Which is the same behavior as if no window was defined:

```
SUM(Qty) AS Total_Qty
```

Current event

In the examples above notice that the starting event is numbered 1 less than the desired starting event. This is because the counting is zero-based: *event zero (0) is the current event*.

Another way to express the last 5 events is:

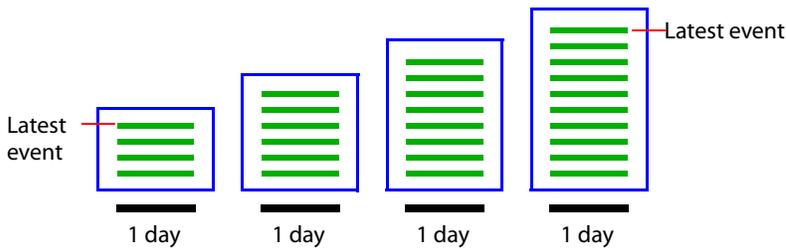

```
OVER (EVENTS BETWEEN 4 PRECEDING AND 0 PRECEDING)
```

Yet another way to express the range of events is to use the CURRENT EVENT literal, like this:

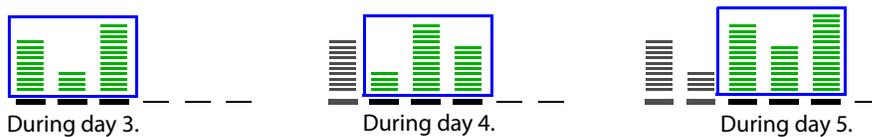

```
OVER (EVENTS BETWEEN 4 PRECEDING AND CURRENT EVENT )
```

Time-Series windows

Time-series windows grow to include all of the events that occur within an interval of time. Such as this 1-day window that grows as new events arrive during the day.

Similarly, a 3-day window includes all of the events within the current 3-day window.

RANGE clause

Time-series windows are identified by the RANGE clause. These windows contain rows that are limited to a time range in combinations of years, months, days, hours, minutes, or seconds. A span of time is expressed with the BETWEEN and AND clauses. Omit the span clauses to include the latest event (the current event). PRECEDING clarifies that the event rows precede the current one.

```
([PARTITION BY <column>]
 [ORDER BY {<date-time column> | <integer column>} [ ASC | DESC ] ]
 RANGE [BETWEEN]
       {INTERVAL <oldestTime> | <oldestInt> | UNBOUNDED} [PRECEDING]
       [AND {INTERVAL <newestTime> | <oldestInt>} [PRECEDING] ]
 [SLIDE INTERVAL <distance>]
 [REFERENCE {FRAME | OPERATOR} ]
 [INITIALIZE <initTimestamp>]
)
```

Further,

- The order-by, “oldest”, and “newest” columns are usually date-time data types. However, you can also use an integer that represents a time-series. See [“Integer Time-Series” on page 237](#) for details.
- PARTITION creates one window for each <column> of events, similar to a GROUP BY window. See [“Window partitions” on page 238](#) for details.
- ORDER BY identifies the column used to calculate the time of the event. See [ORDER BY Clause,](#) below for details.
- SLIDE identifies how to advance the window when new events arrive in the view. See [“Window advancement” on page 241](#) for a detailed description of this option.
- INITIALIZE specifies a common date-time to which to initialize all associated windows in a view. When you use a time-series window it is best to initialize the start time to be midnight for day, month, and year windows; to the first day of the month for month and year windows, and to the first day of the desired range for year windows. See [“Window Initialization” on page 246](#).
- REFERENCE tells the window when to determine if rows have expired from the window set. The default value is FRAME: expire rows only when new rows enter the window. The OPERATOR form is useful only when the view has multiple PARTION or GROUP BY windows. See [“Window update reference” on page 245](#) for a detailed description of this option.

Examples

This window totals the Qty column for the current month’s worth of events:

```
SUM(Qty) OVER (RANGE INTERVAL '1' MONTH PRECEDING) AS Total_Qty
```

You can also identify very specific ranges, such as this one which starts 18 hours and 15 minutes ago, and stops 45 seconds ago: See [“Date-Time” on page 58](#) for detail about the date-time specifications.

```
OVER (RANGE BETWEEN INTERVAL '18:15' HOUR TO MINUTE PRECEDING
      AND INTERVAL '45' SECOND PRECEDING
)
```

Which Events are Included

The events to include in a time-series window are determined when a new event enters the window or view (see [“Window update reference” on page 245](#) for more details). However, it is important to note that interval are inclusive of events that are exactly the size of the range interval from the current event. For example, consider a window with a one day interval:

```
SUM(order_qty) OVER ( RANGE INTERVAL '1' DAY PRECEDING ) AS TotalQty
```

When two events have *exactly* one day between them, they are both included in the window. Notice the value of TotalQty after the two events:

```
order_qty TotalQty EventTime
-----
1          1 2003-12-01 09:00:00.0
1          2 2003-12-02 09:00:00.0
```

When using the BETWEEN clause the <oldestTime> is included, while <newestTime> is excluded. For example, to have two windows, one of the current week and one for the week before that, use these definitions:

```
ThisWeek: RANGE INTERVAL '7' DAY PRECEDING
LastWeek: RANGE BETWEEN INTERVAL '14' DAY PRECEDING
           AND INTERVAL '7' DAY PRECEDING
```

Notice that both ranges use '7' as a bounding value. The current week includes everything from now back seven days inclusive, while the previous week includes the seven days *before* seven days ago. Another way to define the windows above is to use '0' as the current time, like this:

```
ThisWeek: RANGE INTERVAL '7' DAY PRECEDING
           AND INTERVAL '0' DAY PRECEDING
LastWeek: RANGE BETWEEN INTERVAL '14' DAY PRECEDING
           AND INTERVAL '7' DAY PRECEDING
```

ORDER BY Clause

Unless defined otherwise, all times are calculated based on each event's internal event arrival timestamp. For example, this window contains events of the last hour in the order that they arrived in the system.

```
OVER (RANGE INTERVAL '1' HOUR PRECEDING)
```

You can designate any date-time column in the event as key. For example, you might want to use the time that an order was placed:

```
OVER (ORDER BY order.order_timestamp RANGE '4' DAY PRECEDING)
```

The ORDER BY argument is a *single column name reference*; you cannot use integers to represent the ordinal position of the column in the SELECT list. Further the default sort order is ascending (ASC); though descending (DESC) is available too, see [“Descending” on page 236](#) for details.

```
ORDER BY <columnNameReference> { ASC | DESC }
```

Out-of-Order Arrival

When the event stream is not in the expected order, the query engine attempts to insert the out-of-order event into its correct location in the window frame, and updates all aggregations accordingly. The query engine always uses the latest time of all the events received prior to the out-of-order event to determine if it should be included. If the event is not within the latest window frame, it is omitted.

For example, consider a window of 1-hour that receives the following events in the order listed. Here the second event is the latest, and as such, only events received after 08:10 (09:10 minus 1 hour) are included in the window. The fourth event, therefore, is rejected because its timestamp is 08:04.

```
OVER (ORDER BY Time RANGE INTERVAL '1' HOUR PRECEDING)
```

Arrival

Sequence	Time	Amount	
1	08:45	242.69	
2	09:10	103.76	<< Latest timestamp sets the window
3	08:50	90.20	<< Out-of-order, accepted
4	08:04	188.88	<< Out-of-order, rejected

After the four events above have been processed, the view that contains them looks like this:

Arrival

Sequence	Time	Amount	
1	08:45	242.69	
3	08:50	90.20	<< Reordered
2	09:10	103.76	

Descending

By default, order is assumed to be ascending: oldest events are processed first. However, you may specify DESC for descending sort order. When events arrive and they are not already in descending order, they are processed the same as noted above in Out-of-Order Arrival.”

```
OVER (ORDER BY Time DESC RANGE INTERVAL '1' HOUR PRECEDING)
```

Arrival

Sequence	Time	Amount	
1	08:45	242.69	
2	09:10	103.76	<< Out-of-order, expires after fourth event
3	08:50	90.20	<< Out-of-order, accepted
4	08:04	188.88	

After the four events above have been processed, the view that contains them looks like this:

Arrival

Sequence	Time	Amount
4	08:04	188.88
1	08:45	242.69
3	08:50	90.20

NULL Value Timestamps

When the referenced column contains a NULL value for the timestamp, the event is rejected *unless* the range is UNBOUNDED. When the window frame is unbounded, all events are included, including the NULL timestamps; though the NULL values are placed last in the set, in the order they arrived. For example:

```
Arrival
Sequence  Time    Amount
-----  -
1         08:04  188.88
2         08:45  242.69
3                 103.76 << First NULL time
4         08:50   90.20
5                 157.11 << Second NULL time
```

When the above events are processed in ascending order by Time column, the resulting view looks like this:

```
Arrival
Sequence  Time    Amount
-----  -
1         08:04  188.88
2         08:45  242.69
4         08:50   90.20
5                 157.11 << Second NULL time
3                 103.76 << First NULL time
```

Integer Time-Series

A time-series range is usually expressed as a range of date-time or date interval values. However, you can also use an integer that represents a time-series. For example, consider this series of date-time values and matching integer values:

```
Date_time_value      Date_time_int
-----
2003-12-01 09:00:00    3795637500
2003-12-01 13:00:00    3795654167
2003-12-02 09:00:00    3795737500
2003-12-03 09:01:00    3795837569
2003-12-04 09:00:00    3795937500
```

The “time” that the integers represent is entirely arbitrary and not a factor in how FileNet Business Activity Monitor processes the values. Rather, it is up to you to understand what the values mean. For example, in the series above, 100,000 represents one day. As such, a window of the previous two days for this data is defined as:

```
ORDER BY Date_time_int
RANGE 200000 PRECEDING
```

Or to see just the previous day:

```
ORDER BY Date_time_int
RANGE BETWEEN 200000 PRECEDING AND 100000 PRECEDING
```

When using an integer time-series, always use the ORDER BY clause and identify the integer column as the series order.

Window partitions

All events in a view are included in a single set (window) unless defined otherwise by the GROUP BY or the PARTITION BY clause. These clauses sort events into windows based on a key value, such as a common name or ID. Use partitioned windows to aggregate the events specific to the window. For example, to collect the total volume for all transactions by security, the view definition might look like this:

```
SELECT Trades.symbol, SUM(Trades.volume) OVER Symbols AS Total_volume
FROM Trades
WINDOW Symbols AS ( PARTITION BY Trades.symbol )
```

This is similar to a view defined with the GROUP BY clause like this:

```
SELECT Trades.symbol, SUM(Trades.volume) AS Total_volume
FROM Trades
GROUP BY Trades.symbol
```

NOTE: Querying the two views above produces very different results. The grouped view returns one row for each group. While, the partitioned view, by default, returns just one row containing the result of the last event that entered the view (though the information for each partition is maintained internally). To see more rows from a partitioned view, set the view's Maintain in view setting to a size greater than 1. For more information, see [“Historical results from partitioned views” on page 240](#).

PARTITION BY Clause

The PARTITION BY clause defines one or more columns that contain the values that identify a partition window.

```
PARTITION BY <column> [, <column> ... ]
```

Where <column> is either the name of a column in the SELECT list, or is an ordinal integer that represents the position of a column listed in the SELECT list of columns (the first reference is 1). When you declare a list of columns, one partition is created for each unique value of the set. For example, this declaration creates partitions for individuals based on unique lastname+firstname combinations:

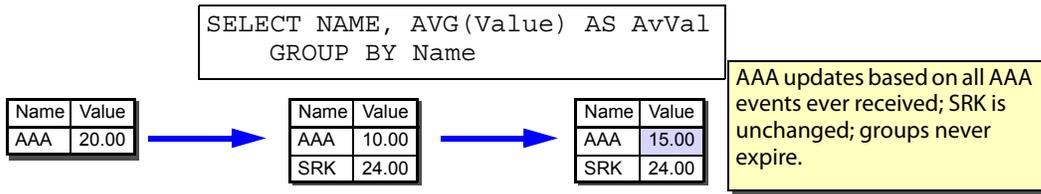

```
PARTITION BY last_name,first_name
```

Advantage of partitions over groups

The main advantage of partitions is that you can control when to expire (remove from memory) time-series windows using the REFERENCE OPERATOR clause (see [“Window update reference” on page 245](#) for details). Also, you can have multiple partitions based on different columns in the same view; while GROUP BY applies solely to the entire view. Consider these illustrations that show what happens when a new event arrives that is significantly newer than the most recent event already in the view:

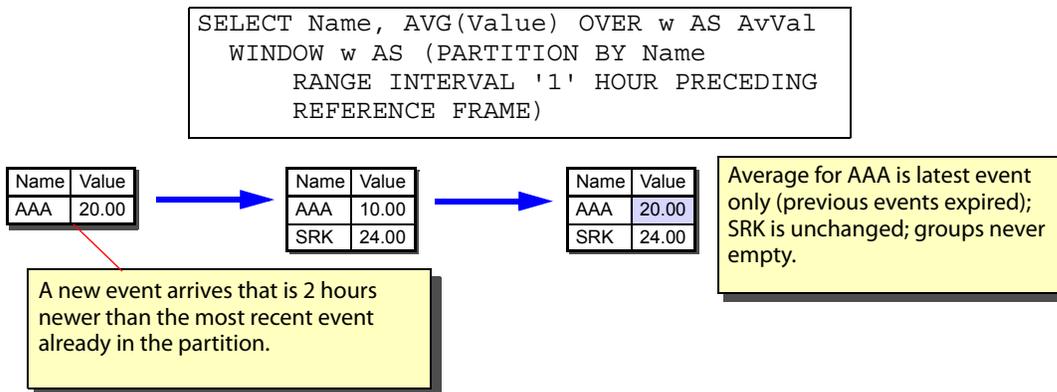

View update for a simple GROUP BY

When an event arrives in a view with a simple GROUP BY clause, the new event is applied to the associated group. In this case, the new event is applied to the average for all AAA events ever received:

View update for a partition with frame reference

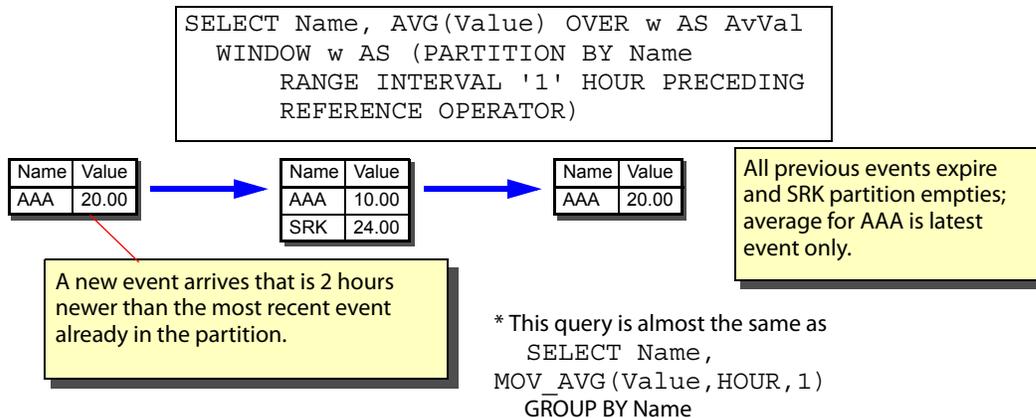

Now consider the same event entering a view partitioned by Name, and where only the partition window frame that identifies the event updates. In this example, the AAA event is 2 hours newer than the last AAA event. As such, all previous values for the partition expire and are discarded, and only the new event is used. Notice that the other partition is no affected.

View update for a partition with operator reference

Finally consider the same event entering a partitioned view that updates based on REFERENCE OPERATOR. The reference tells all partitions to update when an new event enters the window. Here,

because none of the events tracked by the existing partitions are within the range of the last hour, all existing partitions expire and a new one is created for the new event.

Using windows to expire GROUP BY

One disadvantage of windows is that you cannot look at the view to see the contents of the partitions; unlike a view with GROUP BY where you can view the results of all groups in the FileNet BAM Dashboard or in the Results tab of the FileNet BAM Workbench. A GROUP BY maintains results for each group as long as there are data in the group. In the illustration above, if you use the view constructed with the GROUP BY expression instead of the PARTION, you will be able to view the contents, and groups will expire when they have had no events in the last hour.

Historical results from partitioned views

When you query a partitioned view, by default, the result is a view with one row containing the result of the last event that entered the view (though the information for each partition is maintained internally). For example, if you track the average price of securities, partitioned by symbol, querying SELECT * on the view would return a result similar to this:

```
SELECT * FROM AveragePricesView
```

```
Symbol  AvgPrice  Date
-----  -
JMH      164.35    2003-07-14
```

In the results above, the last event that the *AveragePricesView* received was for the JMH symbol.

To see more rows, set the partitioned view's Maintain in view setting to a size greater than 1. If you have many aggregate events, set the value to a large number, such as 500. Then, querying the view returns up to that many rows:

Symbol	AvgPrice	Date
-----	-----	-----
AAA	24.35	2003-03-05
SRKH	102.07	2003-03-05
JMH	90.22	2003-03-05
SRKH	106.88	2003-03-06
AAA	25.66	2003-03-06
JMH	94.11	2003-03-06
...		

The results appear in the order that the view produced them: the order of the events that last entered each partition.

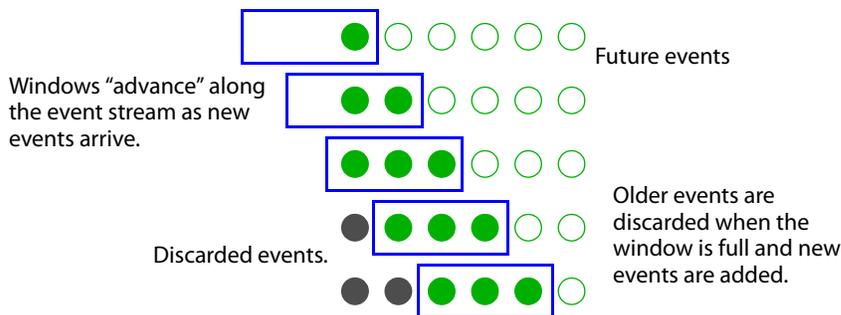

To get meaningful historical results, order the new view, such as on Symbol and Date.

```
SELECT * FROM AveragePricesView ORDER BY Symbol, "Date"
```

Symbol	AvgPrice	Date
-----	-----	-----
AAA	24.35	2003-03-05
AAA	25.66	2003-03-06
AAA	25.25	2003-03-07
AAA	24.92	2003-03-08
...		

Window advancement

When a new event enters a window, the window determines which events to keep and which to discard when the window is full. A window frame is full if the next row causes an existing row in the frame to expire out of the window. When viewed in the context of future and past events in the event stream, the window can be seen to *advance* or *slide* along the event stream as it adds and discards events.

SLIDE clause

The window advance clause (SLIDE) specifies the distance to advance when the window is full. By default, when SLIDE is omitted, event-series windows slide one event along the stream for each new event, while time-series windows advance to include the latest event and all events within the interval defined in the RANGE clause remain; the rest are discarded.

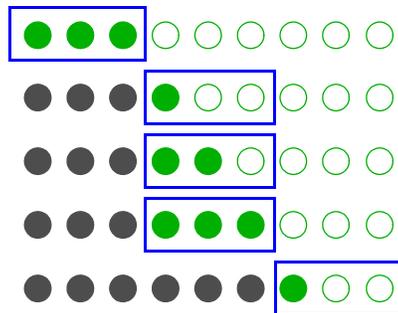

Including a SLIDE clause advances the window either the entire size of the window (when you omit the argument), or advances the event distance or time interval specified by the argument.

`SLIDE [<interval> | <distance>]`

For example, consider an event-series window whose size is 3 events. Declaring SLIDE with no arguments is the same effect as declaring SLIDE 3.

This window slides 3 events when advancing after being full.

`EVENTS '2' PRECEDING
 SLIDE 3`

After advancing, the window contains only the new event. Future events are added until the window again becomes full.

When a window advances more than one event, it is *tumbling*, as described next. Further, the TUMBLE_ functions are shorthand for complete window expressions that use this sliding behavior. See [“Tumble Functions” on page 243](#) for information.

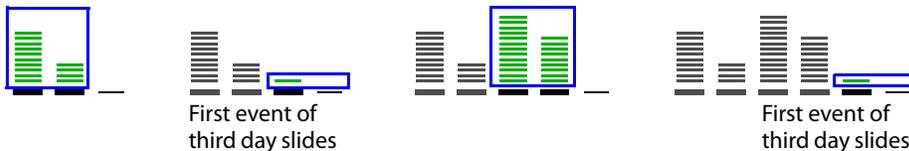

NOTE: Omitting the SLIDE clause always advances 1 interval/distance. To “tumble” a window, include a SLIDE value greater than one (1).

Tumbling Windows

A *tumbling window* empties its contents when it advances to include the newest event. For example, a tumbling time-series window continues to grow until a new event enters that causes older events to be discarded. When the SLIDE interval is the same as the window size, the window dumps all existing events when a new one arrives and the window is full.

This 2-day window also slides 2 days after becoming full.

`RANGE '2' DAY PRECEDING
 SLIDE 2`

First event of third day slides

First event of third day slides

This functionality is useful for tracking a full interval’s worth of events during the interval. For example, if you start an interval on a Sunday and declare a slide interval of 7 days, the window will empty and advance

every Sunday. Use the INITIALIZE clause to set the starting time appropriately. See [“Window Initialization” on page 246](#) for details.

Trailing tumbling windows

A *trailing tumbling window* empties and begins re-filling after it slides. However, it is important to understand that the items that enter the view must fall within the window as identified by the last event. For example, consider this 7-day window that includes values from the previous week, and which empties every 7 days:

```
RANGE BETWEEN INTERVAL '14' DAY PRECEDING
        AND INTERVAL '7' DAY PRECEDING
SLIDE INTERVAL '7' DAY
```

This window only accepts values that are older 7 days preceding the last event. Even though there might be a full week’s worth of events, the window only contains those that are 7 days older than the last. For example, when these events are fed into the window, only the first event is included in the window because it is more than 7 days older than the last event:

```
Event_Time
-----
2003-12-01 09:00:00  << Only event included in the window
2003-12-01 10:00:00
2003-12-02 08:45:00
2003-12-08 09:10:00  << Last event
```

Each of the first three events is included only after receiving an event after 08:45 on the 12-09.

Tumble Functions

Most of the set functions have associated “tumble_” functions which are shorthand for complete sliding window expressions. For example, consider this tumbling SUM() expression which sums all the events that arrive within a 1 hour interval:

```
TUMBLE_SUM(price, HOUR, 1, trade_time) AS T_Sum
```

The above function is shorthand for this in-line window expression:

```
SUM(price) OVER (ORDER BY trade_time
        RANGE INTERVAL '1' HOUR PRECEDING SLIDE) AS T_Sum
```

Which in turn is equivalent to the following after filling in all default values:

```
SUM(price) OVER ( ORDER BY trade_time
        RANGE INTERVAL '1' HOUR PRECEDING
        SLIDE INTERVAL '1' HOUR
        REFERENCE OPERATOR) AS T_Sum
```

Similarly, the function TUMBLE_SUM(price, EVENT, 5) is the shorthand for this complete window:

```
SUM(price) OVER (
        EVENTS BETWEEN 4 PRECEDING AND CURRENT EVENT
        SLIDE 5
        REFERENCE FRAME) AS T_Sum
```

See the descriptions of the individual tumble functions for details about their behavior. For descriptions of tumbling windows and inheritance, see [“Tumbling and moving windows using window inheritance” on page 244](#).

Tumbling and moving windows using window inheritance

The window definition inheritance feature also applies to the `tumble_` and `mov_` functions. (See [“Tumbling Windows” on page 242](#) for more information.) For example, all of the following queries are equivalent.

Tumbling sum over a referenced window

```
SELECT c1, TUMBLE_SUM(price,HOUR,1) OVER w AS sum_price
FROM trades
WINDOW w AS
(PARTITION BY c1
 INITIALIZE TIMESTAMP '1999-10-10 0:0:0'
 REFERENCE FRAME)
```

Tumbling sum over an in-line window

```
SELECT c1, TUMBLE_SUM(price,HOUR,1)
OVER (PARTITION BY c1
 INITIALIZE TIMESTAMP '1999-10-10 0:0:0'
 REFERENCE FRAME)
AS sum_price
FROM trades
```

Sum over a window over a tumbling window

```
SELECT c1, SUM(price) OVER w2 AS sum_price
FROM trades
WINDOW w AS (PARTITION BY c1
 INITIALIZE TIMESTAMP '1999-10-10 0:0:0'
 REFERENCE FRAME),
w2 AS (w RANGE INTERVAL '1' HOUR PRECEDING SLIDE)
```

Sum over a tumbling window

```
SELECT c1,
SUM(price) OVER (w RANGE INTERVAL '1' HOUR PRECEDING
 SLIDE INTERVAL '1' HOUR
 REFERENCE FRAME
 INITIALIZE TIMESTAMP '1999-10-10 0:0:0') AS sum_price
FROM trades
WINDOW w AS
(PARTITION BY c1 ORDER BY "Date")
```

Window update reference

When a view receives a new event, one or more of the view's windows may update to reflect the new information. Depending each window's *reference* and definition, it is possible for all events in a window to expire and be removed from the window, or to not be affected by the update.

NOTE: Events that are filtered out before they enter the view, such as when excluded by a WHERE clause, do not affect the view's windows and do not cause the windows to update, regardless of the reference point.

REFERENCE clause

A reference determines when to evaluate the set of events included in a window. The references are:

OPERATOR — the window updates whenever a new event enters the view, whether or not the event is included in the window. For example, if a view tracks securities traded in the last hour, and partitions each security into its own window, each window evaluates its set whenever a new trade enters the view. If a security has not been traded in the last hour, its window becomes empty. All other windows include only those securities traded in the last hour; older trades are removed from their windows.

```
SELECT Trades.symbol,  
       AVG(Trades.price)  
         OVER (RANGE INTERVAL '1' HOUR PRECEDING REFERENCE OPERATOR)  
         AS av_price_last_hour  
GROUP BY symbol  
FROM Trades
```

This mode is desirable — and the default — when using time-series aggregations and you want all windows to include events referenced from the same time: the time of the last event that arrived in the view. This mode is also useful for views where you want event-series windows to expire and thereby reduce memory consumption by the view.

FRAME — the window updates only when a new event enters the window. For example, if the view tracks the last 10 trades for each security, only the window that receives the new trade updates. All other (security) windows retain their 10 event's worth of events.

```
SELECT Trades.symbol,  
       AVG(Trades.price) OVER (EVENTS 9 PRECEDING REFERENCE FRAME)  
         AS av_price_last_10_trades  
GROUP BY symbol  
FROM Trades
```

This mode is desirable when you want windows to retain a set of events, regardless of when they arrived, such as for event-based moving aggregates.

NOTE: The FRAME reference is also useful for reclaiming server memory.

Window Initialization

When using a time-series window, the beginning time for the window frame is set by the first event that arrives in the window. When a view has several group or partition frames, each might have a different starting time. Consider these two events, which are the first to arrive in the view:

```
Symbol  Time
IBM     09:00:00.875
CQST    09:23:02.111
```

If the view that receives these events places them in different group-by frames, each will start at each event's Time, and continue to reset based on that initialization time.

```
SELECT Trades.Symbol, Trades.Time,
       AVG(Trades.Price) OVER An_Hour AS Avg_Price_One_Hour_Tumble
GROUP BY Trades.Symbol, Trades.Time
FROM Trades
WINDOW An_Hour AS (ORDER BY Trades.Time
                  RANGE INTERVAL '1' HOUR PRECEDING SLIDE)
```

With this view definition, an event arriving at 09:10 will cause the initial IBM event to expire, but the CQST will remain in its window for at least another 13:02 minutes: the time remaining since it entered the view.

INITIALIZE clause

To have all windows begin at the same time, use the INITIALIZE clause. This clause defines the initialization point for all frames based on the window definition. For example, to have all windows begin at the same time, initialize them to a date-time *older than the first event likely to arrive in the view*.

```
WINDOW An_Hour AS (ORDER BY Trades.Time
                  RANGE INTERVAL '1' HOUR PRECEDING SLIDE
                  INITIALIZE TIMESTAMP '2003-03-05 00:00:00.000')
```

With this definition, all windows initialize at the same time: midnight. As such, each frame expires at the top of the hour (when minutes is 00:00.000). Because the window includes the SLIDE clause, all previous trades are discarded when the frame expires and only new events arriving during the current hour are accepted.

NOTE: This clause acts as a filter in that it excludes all events before the initialization time.

The initialization time is a date-time literal value — a TIMESTAMP literal. Further, the initialization value is static: it cannot change after the view is created.

Another example

This initialization definition defines the current fiscal year, which begins on 1 July of the calendar year:

```
(RANGE INTERVAL '1' YEAR PRECEDING SLIDE
 INITIALIZE TIMESTAMP '1963-07-01 00:00:00')
```

Reportlets

Reportlets describe the contents of a view and present that information in a report that is either attached to an alert message, or presented by an external system. Frequently reportlets provide information about an event that puts the event into context. For example, when an inventory is low for a product and a restock shipment is overdue, an alert might notify purchasing managers of that state and a reportlet attached to the alert might list the alternative suppliers for that product. Reportlets are attached to all subscribers of the associated alert.

There are two types of reportlets:

- Internal reportlets are the visual representation of the information in a view when the alert generated the reportlet. The presentation is a table formatted in either text, HTML, or a Microsoft Excel worksheet, and contains all of the information that was in the view.
- External (3rd-party) reportlets are produced by external reporting systems such as Business Objects or Cognos. External reportlets present a report based on view data passed to them when the user clicks a link to the external system. That system is responsible for generating and presenting the report.

In this Chapter:

[“Creating reportlets” on page 248](#)

[“Reportlet attributes” on page 249](#)

[“External reportlet attributes” on page 250](#)

[“Reportlet views” on page 251](#)

Creating reportlets

To create a reportlet you must have:

- Create permission for business activities (see [“Creating permission” on page 220](#) for details)
- Read and Write permission on the business activity that will contain the reportlet
- Read Only permission on the view that will feed the reportlet.

To create a reportlet:

1. Open the FileNet BAM Workbench Scenario Modeler.
2. Open an existing scenario that will contain the reportlet.
3. Select the Reportlets tab.
4. Chose New Reportlet.
5. Select the type of reportlet to create.

Reportlets are formatted as HTML tables or Microsoft Excel spreadsheets.

External (3rd-party) reportlets are defined and produced by external reporting systems based on the data passed to them.

NOTE: The External reportlets option is only available when an external links have been defined. See [Working with external links](#) for more information.

6. Fill in the attribute fields on the Create Reportlet dialog.

NOTE: For details, see [“Reportlet attributes” on page 249](#), or [“External reportlet attributes” on page 250](#).

Save the reportlet as enabled and it will immediately be ready for use.

You can also create a reportlet when creating or editing an alert. Doing so there automatically attaches the reportlet to that alert.

Reportlet attributes

Reportlets are formatted as HTML tables or Microsoft Excel spreadsheets. Each reportlet has the following attributes:

Attribute	Description	
Name	Identifies the reportlet. The name can contain letters and numerals only. This name must be unique among reportlets within the same scenario. See “Object namespace” on page 211 for details.	
Description	Optional description that may contain any text characters.	
Status	Whether or not the reportlet is enabled, or disabled. Note: When the containing scenario is disabled, you cannot make the reportlet enabled. The scenario must be enabled before the reportlet may be enabled.	
View	Business view from which the report draws its data.	
Excel format	(optional) Specifies how to format Excel-type reportlets: Leave this setting as <an empty spreadsheet> to produce an HTML formatted reportlet.	
	Template	Identifies a worksheet template for formatting the reportlet. Options are: Select an existing template — One that has already been created and uploaded to the FileNet BAM Server. New Template — Opens the Add Template dialog where you identify an existing Microsoft Excel template on your computer. Saving and closing this dialog uploads the template from your machine to the server. An empty spreadsheet — Uses the Microsoft Excel default worksheet format.
	Sheet name	Name of the worksheet to contain the reportlet. Default is “Sheet1”.
	Sheet address	Location on the worksheet to present the reportlet. Default is “A1”.

External reportlet attributes

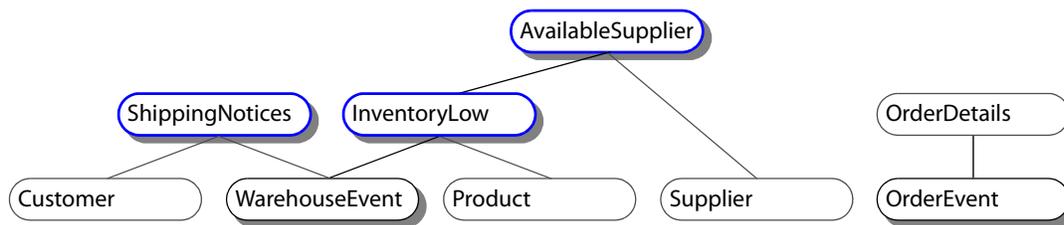

External reportlets present reports based on view data passed to them when the user clicks a link to the external (3rd-party) reporting system. That system is responsible for generating and presenting the report. The external reportlet definition identifies the external link, and the view information to pass to the external system that that system then uses to identify the report to present. For example, an external report might present a PDF that contains the complete description of a product identified in an alert.

Attribute	Description
Reportlet Name	Identifies the reportlet. The name can contain letters and numerals only. This name must be unique among reportlets within the same scenario. See “Object namespace” on page 211 for details.
Status	Whether or not the reportlet is enabled, or disabled. Note: When the containing scenario is disabled, you cannot make the reportlet enabled. The scenario must be enabled before the reportlet may be enabled.
Description	Optional description that may contain any text characters.
Data from View	Business view from which the report draws its data. Contains the column data to send to the external report.
Report Name	Name of the report in the external system. This is the DocName element in the URL that communicates with the external report system: <code>http://localhost.com?DocName=<Report Name></code>
Report Parameters	Parameters to pass to the external system. Each parameter corresponds to a column in the view. The reportlet substitutes the value of each named column into the URL. For example, the URL is defined like this: <code>...?DocName=<Report Name>&Parameter1=PROD_ID&...</code> It looks similar to this when sent to the external system: <code>...?DocName=<Report Name>&product="product_id"&...</code>
Display Link	Shows the complete, qualified URL that will appear in the alert message and is the link to the external report system.

The URLs used to communicate with the external report system begin with the string defined for the report in the External Links list on the FileNet BAM Workbench tab in the FileNet BAM Workbench. See [Working with external links](#) for more information about these locators.

Reportlet views

Reportlets retrieve their information from the business view that the alert is based on, or from *any* view derived from the same event source (in the same event stream). For example, consider a rule that generated the customer alert is based on the view *InventoryLow*. Another view, *AvailableSuppliers* adds context by indicating alternative suppliers. The reportlet attached to the alert may draw information from either of these views. Further, because *ShippingNotices* is derived from the same event source, you could also retrieve information from it. However, you cannot retrieve information from *OrderDetails* because it is on a different event stream.

For more details about the information that appears in the reportlet view, see [“Reportlet filtering” on page 36](#).

Note that the reportlet view may not be a synchronized join. See [“Synchronized joins” on page 294](#) for details.

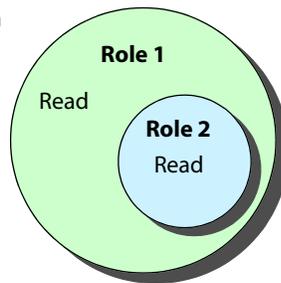

Roles

Roles define the minimum sets of Permissions associated with Users. Roles provide a way to quickly assign *the same permissions* to an object or class of objects, for groups of users without having to set those permissions for each individual user of the group. For example, an “operator” role might provide full permissions to agents, but not to events or business activity objects. While a “application developer” role might have full permissions on all objects except agents.

Users may belong to none, one, or more roles. To see which roles a user belongs to edit the user account and view the User Details tab. To see which roles you belong to, click Account Settings and view the tab.

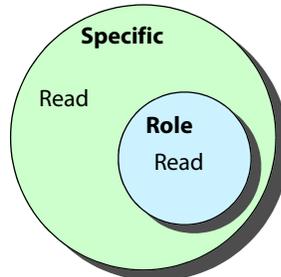

A user’s permission for a particular operation is the *maximum* of all the permissions associated with that user’s roles, and with any individual permissions assigned to the user for the object. Consider a user with two roles: one has Read-only access to the views class, and the other has read and write access. The maximum permission on views for this user is Read and Write, and as such, this user can edit views.

When a user has multiple roles with overlapping permissions on an object, the greatest permission is used. This user has Read and Write access.

Similarly, if a user has one role and that role is limited to Read only for all views, but has been individually assigned Read and Write to a particular view, that user may edit that view.

When a user's specific permission overlaps with a role, greatest permission is used. This user has Read and Write access.

NOTE: For details about specific access levels, see [“Permissions” on page 216](#). Any unusual interactions between object permissions and roles are described in the discussions of the object.

Roles are objects maintain lists of users and associated permissions. And like all other FileNet Business Activity Monitor objects, roles are protected by permissions. Only users with specific permissions on a role — or on all roles — can perform that action on the role. For example, to add users to a role, you need Read and Write permission on that role.

To see the roles defined in the installation, look at the Roles list in the Administration Console of the FileNet BAM Workbench.

The rest of this discussion describes:

- [“Creating roles” on page 254](#)
- [“Role attributes” on page 254](#)

Creating roles

To create roles, you need Create permission for roles. For each object class, you can assign up to the greatest permission that you have for that class. For example, if you have Create permission for a class, you can assign any of No Access, Read only, Read and Write, or Create for that class.

To create a role:

1. Open the Administration Console.
2. Click Roles to see the list of all currently defined roles.
3. Click New Role.
4. Fill in the role attributes, assign access permissions, and identify the members of the role.

Save the role to begin using it.

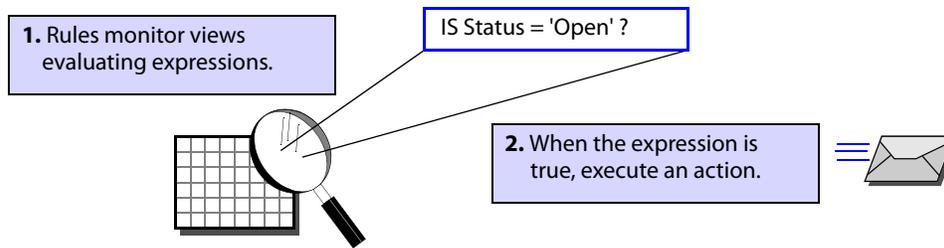

Role attributes

Each role object has the following attributes:

Attribute	Description
Name	Identifies the role object. The name can contain letters and numerals only. This name must be unique among roles. See “Object namespace” on page 211 for details.
Description	Optional description that may contain any text characters.
Access Permissions	Permissions for each class of objects assigned to this role. These are the <i>minimum</i> permissions. A user may have a greater permissions assigned individually to the class (see “User Permissions tab” on page 286) or to a specific object.
Members	Users associated with this role.

Rules

Rules monitor business activities by analyzing business views looking for metrics that meet specific conditions. Rule conditions are spreadsheet-like formulas that evaluate the changing business metrics looking for exceptional conditions. When a condition is found to exist, an alert of that incident is sent to key personnel.

```
WHEN [ Status = 'Open' ] FIRE [ myAlert ]
```

You can create rules that send alerts every time the condition is found to exist (fire), create rules that send alerts once and ignore subsequent events until the initial condition is resolved (raise), or create rules that reset (lower) previously raised rules.

NOTE: Prior to Version 3.2, the rule could only monitor views derived from the scenario “default” view. This restriction no longer applies.

In this Chapter:

[“Creating rules” on page 256](#)

[“Rule attributes” on page 257](#)

[“Rule condition” on page 258](#)

[“Rule action” on page 258](#)

[“Monitoring alerts” on page 259](#)

[“Monitoring the system log” on page 260](#)

Creating rules

You can create rules from scratch or clone and modify existing rules. Both require the user to have Create permission for business activities (see [“Creating permission” on page 220](#) for details), Read and Write permission on the business activity that will contain the rule, and Read Only permission on the view that will feed the rule.

To create a new rule:

1. Open the Scenario Modeler.
2. Open an existing business activity.
3. Open an existing scenario.
4. Click the New Rule button.
5. Fill in the rule attributes (described below) in Step 1 of the Rule Definition form. Additionally:
 - Choose the data source that the rule will monitor.
 - If the scenario has a “default view”, that one appears selected by default. Choose another source to monitor by clicking Select Data Source.
 - For a view, choose the view.
 - For a cube, choose the dimension level in a cube. Optionally you may also apply a filter that further restricts the data that the rule monitors.

If the source contains data, that data appears to provide a sample of what to expect. When the source is empty, the form displays just the column names and the message “No Data Available”.

- For the Action Taken, identify the alert to activate when the rule condition is met. Do one of the following:
 - Select an existing alert by clicking this alert in the Rule effect field, or
 - Click Next to access the Alert Definition form, and define or review the alert. See [“Alert attributes” on page 30](#) for details about the fields on this form.
6. Finish creating the rule.

If the rule was saved enabled, it will immediately begin monitoring the view for events.

To clone an existing rule:

1. Edit the rule you want to clone.
2. Change the rule name, and change the other attributes that differ from the original rule.
3. Choose “Save as New Rule”.

Rule attributes

Every rule has the following attributes:

Attribute	Description
Data source	Identifies the business view or cube that the rule monitors.
Name	Identifies the rule object. The name can contain letters and numerals only. This name must be unique among rules within the same scenario. See “Object namespace” on page 211 for details.
Status	Specifies if the rule is enabled (receiving new event information), or disabled. Note: When the containing scenario is disabled, you cannot make the rule enabled. The scenario must be enabled before the rule may be enabled.
Description	Optional description that may contain any text characters.
Rule condition	The spreadsheet-like, true or false formula that is evaluated against the associated business view. When the formula evaluates to True, the condition is said to exist and the system then sends the alert. See Rule condition, below, for details.
Holds for	Sends the alert only when the condition holds true for an entire specified length of time. No alert is sent if the condition becomes false at any time during the wait. When you omit the duration the system sends the alert as soon as the condition exists. You can specify a value using one of the following methods: <ul style="list-style-type: none"> Specify a number to indicate the length or time or count of events to wait. Specify the name of a column in the view that contains the number. When you use this option, the rule takes the value from the event in the view. <p>When specifying a count of events, the alert is sent only when the rule condition is true for each new event entering the view, and only until the specified count have been inserted.</p> <p>Note that in locales where daylight savings time is observed, durations of days, months, and years are adjusted accordingly. As such, while 1 day is typically 24 hours long, it may be 23 or 25 hours depending on the time of year.</p>
Action taken	What to do when the condition exists. Rules can send alerts every time the condition is found to exist (<i>fire</i>), send alerts once and ignore subsequent events until the initial condition is resolved (<i>raise</i>), or reset (<i>lower</i>) previously raised rules. See Rule action, below, for details.

Rule condition

A rule condition is a formula that tests the row in the associated business view looking for a specific condition. When the condition exists the rule action activates an alert. Formulas can be simple tests for a value in a column in the view, like `Status='Resolved'`, or that can be complex Boolean expressions with functions, operators, and parenthesis groupings, like this `(Status='Resolved' OR Status='Assigned') AND UPPER(cust_tier)='HIGH'`.

A rule condition formula contains any number of column references, operators, and functions. However, the formula must:

- The formula result must be Boolean: return True or False.
- All column references must be in the associated business view.
- Only scalar functions (functions that apply to a single row in a view) may be used. To see which functions are available, click More Functions when entering the rule condition. See [“Functions” on page 95](#) for detailed descriptions of the functions.

Rule action

Rules can have one of three effects:

- Send alerts every time the condition is found to exist (*fire*). A fire action sends an alert every time a rule identifies an exceptional condition. For example, consider a customer support center that tracks customer problems as ticket events, an alert might be fired every time a new ticket is opened.
- Send alerts once and ignore subsequent events until the initial condition is resolved (*raise*). A raise action sends an alert message when the rule’s condition applies, but ignores subsequent events until after the initial condition is resolved. A raise action is useful when you don’t want multiple alerts for situations where the rule condition is true for multiple, related events. For example, if an open customer problem ticket is edited, you don’t want another alert for the edit event, even though the status of second event is still “open.”

The “for a specific occurrence” option allows you to send alerts once for each specific occurrence of the named column. For example, to send an alert every time a new problem ticket is opened you might identify Ticket as the specific occurrence column. That way, one alert is sent for each ticket’s “open” event, but ignored for all subsequent events to that ticket while its status remains “open.”

- Reset (*lower*) previously raised rules to allow them to send alerts.

Specific occurrences

When a Raise rule activates an alert, the alert does not activate again — subsequent Raise rules for the alert are ignored — until a Lower rule first resets it. For example, when a rule condition is “Status=Open”, the first event below activates the alert, but the subsequent ones are ignored unless the alert’s state is first lowered.

```
Ticket Status
-----
0703 Open << Raise
0706 Open << Ignore
0704 Open << Ignore
0705 Open << Ignore
```

In this example it is more likely that you would want an alert for each Open event. To do that, you can use a “For a specific” condition which activates an instance of the alert for each unique occurrence of the values in the specified columns.

```
Raise someAlert when Status = 'Open' for unique occurrences of Ticket.
```

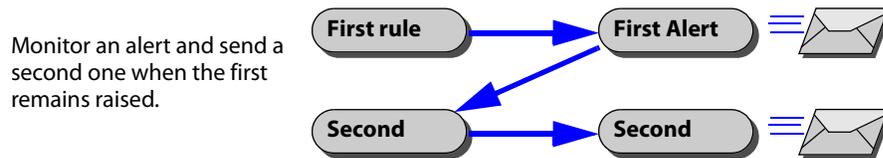

By identifying Ticket as the specific column, an alert instance will be activated, and a message sent, every time for each Open event that does not already have an instance for the specific ticket number. Similarly, you can reset each alert instance individually with specific Lower rules.

```
Lower someAlert when Status = 'Open' for unique occurrences of Ticket.
```

NOTE: If you ignore the specific fields in the Lower rule, the rule will reset all instances of the alert that have been raised.

Monitoring alerts

Rules typically analyze Business Views looking for metrics that meet specific conditions. However, rules can also monitor generated alerts looking for conditions that require further attention with the IS_RAISED() function.

For example, if an alert was sent 4 hours earlier and is still in a raised state, another rule might notice that fact and generate a new, escalated alert. Consider these rule descriptions where *EscalateAlert* is raised only when *OpenAlert* remains raised for at least 4 hours.

```
Raise OpenAlert when Status = 'Open'
Reset OpenAlert when Status <> 'Open'
Raise EscalateAlert when IS_RAISED('OpenAlert') holds for 4 HOUR.
Reset EscalateAlert when NOT IS_RAISED('OpenAlert')
```

Specific alerts

When an alert is generated for unique occurrences of fields, the system tracks each alert by those field values. For example, this rule raises alerts and tracks the open ones by the unique values of the Ticket field:

```
Raise OpenAlert when Status = 'Open' for unique occurrences of Ticket
```

To properly track this alert, the rule with the `IS_RAISED()` needs the same specific condition:

```
Raise EscalateAlert when IS_RAISED('OpenAlert') holds for 4 HOUR  
    for unique occurrences of Ticket
```

If you were to omit the specific field condition, the *EscalateAlert* would be raised for the first *OpenAlert* only. Similarly, you must reset the alerts with rule conditions specific to the same fields, or you will reset all of the raised alerts.

```
Reset OpenAlert when Status <> 'Open' for unique occurrences of Ticket  
Reset EscalateAlert when NOT IS_RAISED('OpenAlert')  
    for unique occurrences of Ticket
```

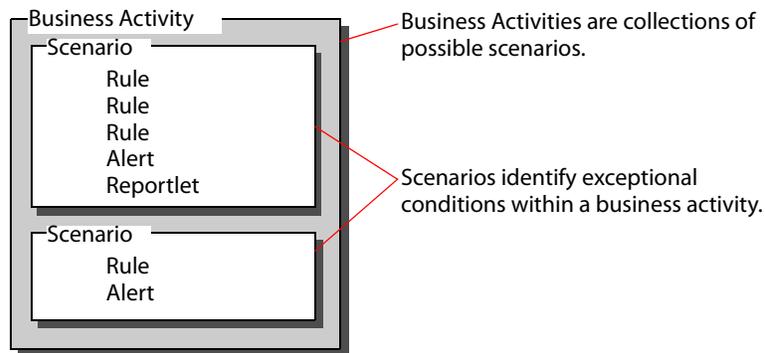

Monitoring the system log

FileNet Business Activity Monitor generates messages that facilitate software service and maintenance by producing reports suitable for analysis by end users, system administrators, support engineers, and software development teams. See *Understanding logging* for details about the logging system.

You can build a rule that monitors the messages looking for high priority error conditions, and then report them to key administrators. To do that, follow the steps in *Monitoring the logs*.

Scenarios

A scenario is a collection of rules, alerts, and reportlets that identify exceptional business conditions. The rules in the scenario are the tests that determine when the exceptional condition exists, or when it no longer exists.

Tips:

- Deleting a scenario deletes its contained rules, alerts, and reportlets.
- Disabling a scenario disables its contained rules, alerts, and reportlets.

In this Chapter:

[“Creating scenarios” on page 262](#)

[“Scenario attributes” on page 262](#)

[“Deleting scenarios” on page 263](#)

Creating scenarios

To create a scenario, you must have the following:

- Create permission for business activities (see [“Creating permission” on page 220](#) for details)
- Read and Write permission on the business activity that will contain the scenario
- (Optional) Read Only permission on the default view for the scenario.

To create a new scenario:

1. Open the Scenario Modeler.
2. Select a Business Activity to contain the scenario
3. Click New Scenario
4. Fill in the fields of the New Scenario dialog.

Scenario attributes

Every scenario has the following attributes:

Attribute	Description
Folder Status	Specifies if the rule is enabled (receiving new event information), or disabled. When an scenario is disabled, all of its rules, alerts, and reportlets are also disabled. Note: When the containing business activity is disabled, you cannot make the scenario enabled. The business activity must be enabled before the scenario may be enabled.
Scenario Name	Identifies the scenario object. The name can contain letters and numerals only. This name must be unique among scenarios. See “Object namespace” on page 211 for details.
Description	Optional description of the scenario that may contain any text characters.
View	Identifies the default business view that the rules of this scenario monitor, and reportlets report on. “No default view” requires that you pick a view for rules and reportlets when you create them.
View Description	Displays the description of the selected View.

Deleting scenarios

Deleting a scenario deletes its contained rules, alerts, and reportlets. Once deleted, they cannot be restored.

To delete a scenario:

1. Open the Scenario Modeler.
2. Select the business activity that contains the scenario.
3. Select the scenario to remove.
4. Click Delete Scenario.

SELECT

C-SQL SELECT statements define the views that manage information in FileNet Business Activity Monitor. FileNet BAM Workbench constructs SELECT statements based on the views you define in its graphical user interface, and then passes them to the FileNet BAM Server(s) for instantiation. You can see the complete SELECT statement that defines a view in the FileNet BAM Workbench by clicking the Displaying SQL expressions option when creating or editing a view.

Some of the advanced features of the SELECT command cannot be expressed by the options in the FileNet BAM Workbench. For example, complex join conditions, query windows, and table expressions must be entered manually in fields in the user interface.

This topic describes the syntax and features of the C-SQL SELECT command in detail.

NOTE: The C-SQL SELECT command is a subset and extension of ANSI SQL-99, a query language standard. The C-SQL implementation supports outer joins using the ANSI outer join (left outer join and right outer join) syntax, and aggregation functions in the select clause. Further, each individual statement is treated as a transaction and is committed as soon as it executes.

Syntax

The operators that define the SELECT specifications are:

```
SELECT selectList
      FROM joinClauses
      [ WHERE searchCondition ]
      [ GROUP BY groupClause ]
      [ WINDOW windowClause ]
      [ ORDER BY orderClause ]
```

The operators are applied in the following order:

5. FROM clause — specifies the base tables or views that provide data to this view.
6. WHERE clause (optional) — filters the input to match specified criteria.
7. GROUP BY clause (optional) — groups the resulting table on one or more columns.
8. Select list — defines the columns to appear in the resulting table.
9. WINDOW clause (optional) — defines windows used by aggregate functions in the Select list. This clause is described in the separate topic: [“Query Windows” on page 228](#).
10. (optional) — orders (sorts) the resulting table.

Select list

Defines the columns to appear in the resulting virtual table.

The select list immediately follows the SELECT keyword and has two forms:

- Just an asterisk (*) to choose all columns that are part of the source table.

```
SELECT * ...
```

The resulting view contains the columns of each of the input tables or views, in the order that they occur in the source, and in the order listed in the FROM clause. For Outer joins, resulting columns that do not exist in both references are assigned NULL values.

- A list of unique column names or derived columns.

```
SELECT columnNameList
```

Where each columnName is separated by a comma (,) and is defined as

```
columnName [[AS] aliasName [ OVER (windowClause) ] ]
```

The AS option assigns a new name to the associated column. The literal “AS” is optional.

The OVER option defines an in-line window. See [“Query Windows” on page 228](#) for details.

Where each columnName is one of the following:

- simple column reference — the column name

```
current_rental_price
```

- qualified column reference — one prefaced by the table name

```
movie_titles.current_rental_price
```

To select all columns from one table while selecting some columns from other tables, use a qualified column reference and specify an asterisk (*) for the column name. For example, this selects all *movie_title* columns, and two columns from the *media* table:

```
movie_titles.*, media.media_type, media.name
```

- derived column — an expression (possibly a case expression, see below for details):

```
MAX((movie_titles.current_rental_price/2)) AS Half_Price
```

For derived columns the aliasName is required.

CASE expression

A CASE expression returns the result of an expression that corresponds to a matching true condition. Optionally, each condition may return NULL instead. If no condition is found to be true, the expression returns the result of the ELSE condition, or NULL when ELSE is omitted.

There are two forms of CASE expressions:

- **Simple condition** — Evaluates the *caseExpression* and compares it against the result of each *equalsExpression* until one matches, then returns the corresponding *resultExpression* result. Each of the *equalsExpression* must of a type comparable to the *caseExpression*.

```
CASE caseExpression
  [ { WHEN equalsExpression THEN { resultExpression | NULL } }...]
  [ ELSE { resultExpression | NULL } ]
END
```

- **Search condition** — Evaluates each *searchCondition* until one is found to be true, then returns the corresponding *resultExpression* result.

```
CASE WHEN searchExpression THEN { resultExpression | NULL }
  [ { WHEN searchExpression THEN { resultExpression | NULL } }...]
  [ ELSE { resultExpression | NULL } ]
END
```

These CASE expressions have the same result:

```
SELECT Tier AS
  CASE WHEN Tier = 'High' THEN 'Priority customer'
  ...
```

```
SELECT Tier AS
  CASE Tier WHEN 'High' THEN 'Priority customer'
  ...
```

Here is an example that generates running totals for each ticket status at each tier level:

```
CREATE VIEW vTotal_Tickets AS
  SELECT Tier,
    SUM(CASE Status WHEN Open THEN 1 ELSE 0 END) AS Opens,
    SUM(CASE Status WHEN Reopen THEN 1 ELSE 0 END) AS Reopens,
    SUM(CASE Status WHEN Resolved THEN 1 ELSE 0 END) AS Closes,
    ( Opens+Reopens-Closes) AS Pending
  FROM VCustomerTickets
  GROUP BY Tier
```

Tier	Opens	Reopens	Closes	Pending
High	2	0	0	2
Medium	1	2	3	0
Low	1	1	1	1

FROM clause

Specifies the tables and views from which to build the new view.

```
FROM reference [[ AS ] aliasName ]  
  [, reference [[ AS ] aliasName ] ... ]
```

Where a reference is:

- Simple reference:

```
tableOrView
```

- Join operation (see “Join operations” below, for details):

```
( reference [ {LEFT | RIGHT} [ OUTER ] | INNER ]  
  JOIN reference ON searchCondition )
```

- Table expression (see “Table expressions” on page 269 for details):

```
( SELECT selectList FROM joinClauses [ WHERE searchCondition ]  
  [ GROUP BY groupClause ] [ WINDOW windowClause ] )
```

Specifying a single, simple reference creates a view that is a snapshot view of the source table or view. Including more than one reference specifies a *join* operation.

View constraints

Views have these constraints of the sources to the FROM clause:

- A view may be derived from an event table or another view.
- A view may join an event table or view, and one or more context tables.
- A view may *not* join two or more event streams, or views based on different event streams. (A *Consolidated Event* is a special-case join of event streams.)
- A view may *not* be derived from context tables only.

Join operations

The C-SQL SELECT supports these join operations:

- Cross joins
- Inner joins
- Outer joins
- Nested joins

Including more than one reference causes a *join* operation. The resulting view is *cross join* unless you either use the JOIN operator to specify another type of join condition, or include a WHERE clause that specifies a join condition

Cross joins

If you omit the JOIN operator, you define a a view that is a cross join of the input views (also know as a *cartesian product*), such as this join of the *Product* and *Manufacturer* views:

```
FROM Product AS P, Manufacturer AS M
```

NOTE: DO NOT create a cross join unless you are sure that is what you want. A cross join creates a view whose count of rows is the equal to the count of rows in the first view times the count in the second view ($\text{rows}^{\text{join}} = \text{rows}^{\text{view1}} * \text{rows}^{\text{view2}}$). This severely impacts the system and does not usually produce the view you desire.

Instead of creating a cross join, you should specify another type of join with the JOIN clause:

```
reference [ joinType ] JOIN reference ON searchCondition
```

Inner joins

The JOIN clause performs an inner join unless you specify a joinType. An inner join is one where the rows in the result table are the rows from the first table that meet the specified criteria, combined with the corresponding rows from the second table that meet the specified criteria.

```
FROM (Product AS P INNER JOIN Manufacturer AS M  
      ON P.productName = M.ProductName)
```

NOTE: Inner joins are sometimes called *equi-joins*.

Outer joins

An outer join is where the rows in the result table are the rows that would have resulted from an inner join plus the rows from the first table (LEFT OUTER JOIN) or the second table (RIGHT OUTER JOIN) that had no matches in the other table. For example:

```
FROM (Product AS P LEFT OUTER JOIN Manufacturer AS M  
      ON P.productName = M.ProductName)
```

NOTE: The first table in a LEFT OUTER JOIN and the second table in a RIGHT OUTER JOIN must be an event table or a view; it cannot be a context table.

Resulting columns that do not exist in both references are assigned NULL values.

Nested joins

Joins can be nested and there is no practical limit on the maximum level of nesting. For example:

```
FROM (Product AS P LEFT OUTER JOIN Manufacturer AS M  
      ON P.productName = M.ProductName)  
      AS Temp, inventoryContext AS INVvt
```

Table expressions

A *table expression*, also called an *in-line view*, is a sub-query that creates a view that can be referenced by the containing query. It is essentially a SELECT statement, bounded by parenthesis, and appearing in the FROM clause. For example, here is a table expression contained in a query:

```
SELECT *
  FROM Warehouse AS wh,
       (SELECT *
        FROM WarehouseQtyChange AS wqc,
         Product AS pr
        WHERE wqc.wprod_id = pr.pprod_id) AS sv,
  WHERE sv.warehouse_id = wh.wh_region_id
```

The example above has the same result as *WHRegionView* in this example:

SummaryView:

```
SELECT *
  FROM WarehouseQtyChange AS wqc,
       Product AS pr
  WHERE wqc.wprod_id = pr.pprod_id
```

WHRegionView:

```
SELECT *
  FROM Warehouse AS wh,
       SummaryView AS sv
  WHERE sv.warehouse_id = wh.wh_region_id
```

Syntax

A table expression is a limited SELECT statement, enclosed in parenthesis, and with restrictions.

```
( SELECT selectList FROM joinClauses
  [ WHERE searchCondition ]
  [ GROUP BY groupClause ]
  [ WINDOW windowClause ] ) AS aliasName
```

Restrictions

In-line views have the same semantic restrictions as standard views. For example, a derived column in an in-line view cannot have the same name or alias as a column in the containing selectList list. Additionally, they have these restrictions and limitations:

- Must be enclosed in parenthesis.
- Must be in the same event stream (have the same base event table) as the other views and tables in the containing query.
- Must be defined in the FROM clause only.

“HAVING” example

Some SQL implementations include a HAVING clause that allows you to filter the aggregate results of a view; C-SQL does not include HAVING. However, you can construct a HAVING by using a WHERE clause to filter the results of an in-line view. Essentially:

```
SELECT * FROM (inlineView) WHERE filterCondition
```

For example, to create a view that filters the result of an aggregation, you first need to perform the aggregation in an in-line view, and then filter the results with the containing view. This in-line view sums the total sales for each product line, and then the containing view displays — in descending order — only those results greater than \$1,000,000.

```
SELECT FamilyTotals.family AS "Product Line",
       FamilyTotals.sales_for_family AS "Total Sales"
FROM (SELECT family,
            SUM(total_price) AS sales_for_family
      FROM OrdQtyDemand
      GROUP BY Family
     ) AS FamilyTotals
WHERE "Total Sales" > 1000000
ORDER BY "Total Sales" DESC;
```

In the example above, as new events enter the *OrdQtyDemand* view, the totals are updated and the order of product families can change. In fact, new families can enter the view as their sales totals exceed a million.

WHERE clause

Examines each row in the input and accepts only those that match the specified condition.

WHERE *searchCondition*

A *searchCondition* is a combination of Boolean predicates that together make a test. Only those input row that pass the test are inserted into the new view. Rows that do not meet the condition are discarded, not tracked, and not included in the calculations of a set function, moving set function, or rank function.

NOTE: All dependant views update and their functions recalculate, regardless of whether or not the input met the condition. See [“Updating views through event propagation” on page 298](#) for more information.

Predicates

A *predicate* is an Boolean expression that asserts a fact about values. Each expression may be stated alone or compared to one of the Boolean test values. For example, these expressions are equivalent

```
WHERE (Age >= 21)
WHERE (Age >= 21) IS TRUE
```

The predicates that the WHERE clause supports are listed in [“Operators and Constants” on page 212](#).

Predicates may include functions, but functions that reference columns may only reference event columns.

Aliases

C-SQL extends the ANSI standard to permit alias references in the WHERE clause. For example:

```
SELECT user_age AS Age
FROM user_list
WHERE (Age >= 21)
```

GROUP BY clause

Groups the resulting virtual table one or more columns.

```
GROUP BY [tableName.]columnName [ , [tableName.]columnName ... ]
```

Where `tableName` is a source table or view. All `columnNames` in the Select list that are not referred directly by a rank function or scalar function, must appear in the GROUP BY list.

NOTE: Another, and more powerful way to group data is with the windows PARTITION clause. See [“Window partitions” on page 238](#) for details.

The Group by option produces summary information for groups of rows whose values in the selected fields are the same. Consider this set of data:

Name	Quantity
Nano Webber	10
Fizzy Lifter	700
Nano Webber	50
Nano Webber	20
Nano Webber	15
Smoke Shifter	310

If you create a view that groups by Name and determines the sum of the quantity for each group, it would look like this:

```
SELECT product.name AS Name, SUM(product.quantity) AS Qsum
FROM product
GROUP BY product.name
```

Name	Qsum
Nano Webber	95
Fizzy Lifter	700
Smoke Shifter	310

You can also group on multiple fields, like this:

```
SELECT product.name AS Name, product.location AS Locale,
SUM(product.quantity) AS Qsum
FROM product
GROUP BY product.name, product.location
```

Name	Location	Qsum
Nano Webber	West	10
Fizzy Lifter	East	700
Nano Webber	East	85
Smoke Shifter	West	310

When the Select list includes a Moving set function, each group contains a result for the moving set.

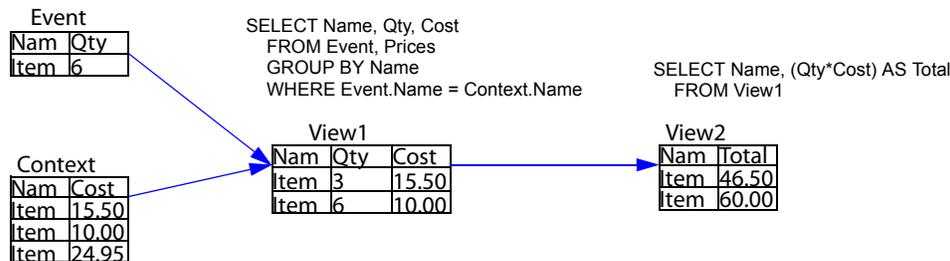

Aliases

C-SQL extends the ANSI standard to permit alias references in the GROUP BY clause. For example:

```
SELECT product.name AS Name, product.location AS Locale,
SUM(product.quantity) AS Qsum
FROM product
GROUP BY Name, Locale
```

Derived views

When a view is defined with a GROUP BY clause, any view derived from that view has an implicit GROUP BY clause. This is known as *view merging* or *view expansion*. For example, even though the SELECT statement for View2 does not include a GROUP BY clause, its results include the same groups as View1.

Stateful view semantics

When a view contains a GROUP BY clause, that view is a stateful view: it maintains information from previous events, not just the most recent event. [See Stateless and stateful views” for details.] As such, View2 in the example above is stateful even though its SELECT definition does not contain a set function or an explicit GROUP BY clause; rather it is stateful because it is derived from a stateful view.

ORDER BY clause

Orders (sorts) the resulting view based on column names or on expression results.

```
ORDER BY columnName [{ASC|DESC}] [ , [columnName [{ASC|DESC}] ] ...
```

Without this clause there is no guarantee that the same query will produce rows in the same order on subsequent queries.

NOTE: Any sort key mentioned in the ORDER BY must refer to a column name in the Select list.

By default, the view is ordered in ascending order (ASC). To order in descending order, specify the DESC option.

Here’s an example that orders the view first by supplier name in ascending order, and the by price in descending order within each supplier:

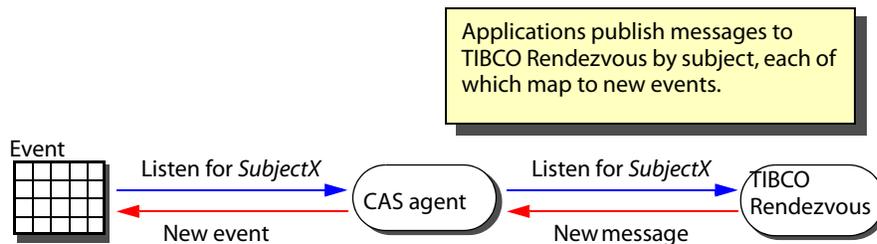

```
SELECT Product.prod_id AS ProductID,  
       orderStatusEvent.OS_PRICE AS Price,  
       Supplier.supp_name AS SupplierName  
FROM orderStatusEvent, Product, Supplier  
WHERE orderStatusEvent.OS_PROD_ID = Product.prod_id AND  
       Product.prod_supp_id = Supplier.supp_id  
ORDER BY Supplier.supp_name ASC, orderStatusEvent.OS_PRICE DESC
```

TIBCO Rendezvous

TIBCO Rendezvous is a messaging system for business applications. Business applications *publish* messages to the stream managed by TIBCO Rendezvous transport servers. Each message has a name that identifies the *subject* of the message. Other applications monitor the stream looking for messages that, when found, are provided to other applications, such as FileNet Business Activity Monitor TIBCO Rendezvous agents.

How it works

FileNet Business Activity Monitor event tables receive TIBCO Rendezvous messages as events. Each event table corresponds to a single message subject. The tables identify the message subjects to a listening daemon application via the agent. When the daemon locates a new message of the requested subject, it passes the message to the table via the agent. The table definition then maps the message into the table as a new event.

In this Chapter:

[“TIBCO Rendezvous tables” on page 274](#)

[“Creating a TIBCO Rendezvous event table” on page 276](#)

[“TIBCO Rendezvous agents” on page 280](#)

TIBCO Rendezvous tables

A TIBCO Rendezvous event table receives messages from a business application via a TIBCO Rendezvous message stream. Each message is identified by subject, and each new message for a subject is a new event. When the table receives a new message, it first maps the message data into the event table data types.

Limitations

All messages for an event subject must be in the same form: every message must have the same fields, though a field may be empty. Further:

- FileNet Business Activity Monitor does not support nested messages.
- Some TIBCO Rendezvous data types are not supported and cannot be mapped into a FileNet Business Activity Monitor event. See [Mapping TIBCO Rendezvous Data types](#), below, for details.

Prerequisites

Before creating a TIBCO Rendezvous event, you need:

- **Permission** — Create permission for tables (see [“Creating permission” on page 220](#)), and Read Only access permission on the agent that will feed the table.
- **An agent** — An existing TIBCO Rendezvous agent that connects to the TIBCO Rendezvous message stream. Create an agent with the FileNet BAM Workbench Administration tab. See [“TIBCO Rendezvous agents” on page 280](#) for details.
- **The subject name** — Each TIBCO Rendezvous message has a subject name that identifies the event source. You identify the subject name and the agent will monitor the message stream looking for the messages. When it finds one, it passes the message information to the event table. Subject names consist of one or more elements separated by dot characters (periods), such as: SUPPORT.TICKETS
- **The format of the message** — Each TIBCO Rendezvous message contains fields of information. You tell the event object what fields to extract from the message, and how they map into FileNet Business Activity Monitor data types.
- **A sample file** — (*optional*) If the message contains a complex string, it is helpful to have a sample file that contains data in the format of the actual event string. You can use this sample when you create the event to ensure that the fields map correctly into the event table by seeing how the data lines up in the columns.

For the details of the subject name and message format, consult the IT specialist who maintains your TIBCO Rendezvous system.

Attribute	Description
Name	Identifies the event object. This name must be unique among views, events, context, and consolidated events. See “Object namespace” on page 211 for details.
Description	Optional description that may contain any text characters.
Status	Whether or not the table is enabled (monitoring for events), or disabled (not monitoring for events).
Log event data for recovery	When on, logs event data that arrived after the last checkpoint started. This “recovery” log is used to restore the state of the system in the event of an abnormal shutdown of the servers. See Working with checkpoint and recovery for complete details.
Process events in the order of arrival	Choose this option when events must be processed in the order received. Otherwise, if events may be processed out of order, turn this on. Note: To join events in a view, the events must be processed in order: leave this option off to join the events.
TIBCO Rendezvous agent	An existing agent that connects to the TIBCO Rendezvous message stream. Create an agent with the FileNet BAM Workbench Administration tab. See “TIBCO Rendezvous agents” on page 280 for details.
Subscription	Identifies the <i>subject</i> on which the message is being sent, and defined by the message publisher. Typically this string looks similar to this: com.celequest.mytibcotopic.
Column Information	The Column Information fields define how to map the fields from the TIBCO Rendezvous message into columns in the event table. There is one column for every field in the event table. See “TIBCO column information” on page 276 for details.

Creating a TIBCO Rendezvous event table

This section shows you how to create a TIBCO Rendezvous event table.

To create a TIBCO Rendezvous event table:

1. Open the FileNet BAM Workbench Administration Console.
2. Create a new event.
3. Select TIBCO Rendezvous as the agent type.
4. Identify the Subject of the message events to collect. See Prerequisites above, for details.
5. Select an existing TIBCO Rendezvous agent.
6. Identify the fields in the message, and how they map to FileNet Business Activity Monitor data types. See TIBCO column information for details.

Save the TIBCO Rendezvous table as enabled and it will immediately be ready to receive event messages.

TIBCO column information

The Column Information fields define how to map the fields from the TIBCO Rendezvous message into columns in the event table. There is one column for every field in the event table.

Each field in the message can be a simple field that maps directly into a event column, or it can be a complex field (a *flat file field*) that contains several fields that each map into columns in the table. Complex fields are treated as Flat Files in either delimited (CSV), fixed-width, or XML formats. See [“Flat Files” on page 73](#) for detailed descriptions of these file types.

Each column in the event table has the following attributes:

Attribute	Description
Field Name	Name of the column in the event table.
Message Name	Name of the field in the message. When mapping a MessageField, the name for each embedded field is N/A and uneditable.
Data Type	Data type of the event column. See Mapping TIBCO Rendezvous Data types,” below for details.
Format	(optional) Format of the event column for VARCHAR (string) and DECIMAL values.

Add columns by clicking Add Field or Add Flat File Field.

A Flat File Field creates a message field of embedded fields, each of which maps to a column in the event table.

Field Name	Message Name	Data Type	Format
< MessageField >	MessageField	VARCHAR	Flat File: Delimited
Ord_ID	N/A	VARCHAR	Width: 255
Ord_Date	N/A	TIMESTAMP	

To edit the definition of a message field, select the <Change Format> Format.

To add a message field:

1. Click Add Flat File Field.
2. Choose the flat file type of the message field.
 - (Optional for fixed-width and delimited files.) Identify a sample file to assist in mapping the columns. This file is a sample of the real data file. Data from this file appears in the next step to assist you as you map the event data into the table.
3. For fixed-width files, define the positions of the data columns with the Set Field Widths dialog.
4. Identify the flat-file attributes. See [“Flat file event tables” on page 74](#) for details.
5. Define the format-specific Column Information. For details about the source type, see:
 - [“Fixed-Width files” on page 84.](#)
 - [“Delimited files” on page 83](#)
 - [“XML files” on page 85](#)
6. Click Save Event to save the message field definition.

To edit the definition of a message field:

- In the field’s Format column, change the value from “Flat File: *file type*” to “<Change Formatting>”.

NOTE: When editing a message field, the sample file option for delimited and fixed-width file types is not available.

Mapping TIBCO Rendezvous Data types

Each message is a set of fields that each contain one data item of a specific data type. You identify each field by its defined name, and specify the field’s associated FileNet Business Activity Monitor data type.

The TIBCO Rendezvous data types map to FileNet Business Activity Monitor Data Types as follows.

TIBCO Rendezvous Type	FileNet Business Activity Monitor Type
Custom Data Types	Not Supported
BOOL	Boolean
DATETIME	Timestamp
F32	Double
F32ARRAY	Not Supported
F64	Double
F64ARRAY	Not Supported
I16	Integer
I16ARRAY	Not Supported

TIBCO Rendezvous Type	FileNet Business Activity Monitor Type
I32	Integer
I32ARRAY	Not Supported
I64	Decimal
I64ARRAY	Not Supported
I8	Integer
I8ARRAY	Not Supported
IPADDR32	Not Supported
IPPORT16	Not Supported
MSG	Not Supported
OPAQUE	Not Supported
STRING (see note below)	Varchar
U16	Integer
U16ARRAY	Not Supported
U32	Decimal
U32ARRAY	Not Supported
U64	Decimal
U64ARRAY	Not Supported
U8	Integer
U8ARRAY	Not Supported
XML	Varchar

TIBCO Rendezvous agents

A TIBCO Rendezvous agent communicates with a TIBCO Rendezvous daemon running in the application server environment. The daemon listens for messages on a TIBCO Rendezvous message stream. When the daemon finds a message requested by one of the TIBCO Rendezvous tables, it retrieves the message data and passes it to the table via the agent.

NOTE: TIBCO Rendezvous agents are asynchronous, they receive event messages as the events occur. You *cannot* retrieve context from a TIBCO Rendezvous agent.

Event push	Event pull	Context pull
Yes	No	No

Prerequisites

Before creating a agent, you need to:

- Create permission for agents (see [“Creating permission” on page 220](#) for details).
- Connect to the TIBCO Rendezvous listener daemon.

NOTE: To connect, you need the Service, Network, and Daemon names. Consult the IT specialist who maintains your TIBCO Rendezvous system for specific values.

Attributes

A TIBCO Rendezvous agent has the following attributes:

Attribute	Description
Name	Identifies the agent. This name must be unique among agents. See “Object namespace” on page 211 for details.
Description	Optional description that may contain any text characters.
Service	TIBCO Rendezvous service port. Leave this blank to use the default port 7500. Change this value only if your TIBCO Rendezvous administrator gives you another port.
Network	Identifies the network interface to use when the host is connected to more than one network, or when the host supports multi-casting (in which case the address will look something like ;222.1.2.3). Change this value only when the host machine is not on the default network, and then use the IP address provided by your TIBCO Rendezvous administrator.
Daemon	Port of the routing daemon on the TIBCO Rendezvous host found on the network identified by the Network attribute. Leave this blank to use the default port 7500. Change this value only if your TIBCO Rendezvous administrator gives you another port.
Status	Whether or not the agent is enabled (monitoring for events), or disabled (not monitoring for events).

Creating a TIBCO Rendezvous Agent

This section shows you how to create a TIBCO Rendezvous agent.

To create a TIBCO Rendezvous agent:

1. Open the FileNet BAM Workbench Administration Console.
2. Click New Agent...
3. Choose TIBCO Rendezvous as the source type
4. Fill in the fields that define the agent's attributes.ef

Save the agent as enabled and it will immediately begin monitoring for events.

Users

Each user that interacts with FileNet Business Activity Monitor is known to the system by their user account information. When administrators create or edit accounts, or when users views their Account Settings, they access specific account information from these tabs:

- “[User Details tab](#)” on page 283, details the attributes that describe a user.
- “[Delivery Profiles tab](#)” on page 284 specifies how and where a user may receive alerts.
- “[User Preferences tab](#)” on page 286 describes the settings that the user sets to affect the FileNet BAM Workbench.
- “[User Permissions tab](#)” on page 286 provides access to the permissions assigned to the user.

To edit you own account information:

- Click Account Settings at any time.

To create, edit, or delete a user account:

1. Open the Administration Console.
2. Click Users to see a list of all users currently defined in the system. To
 - Create a new user account, click New User and specify the user’s User Details tab and Delivery Profiles tab. Optionally, you can specify User Permissions tab as well.
 - Edit an existing user’s account information by double-clicking the name in the list.
 - Delete an existing user by selecting one or more users in the list and clicking Delete Users. Note that you cannot delete the *system* user or yourself.

System user

Every installation has a default *system* user who is identified during installation and who has all permissions. That user creates other users and assigns permissions. Among the permissions that system user may grant is the ability to create users. See the Release Notes or contact FileNet Corporation to learn your installation’s default system user username and password.

User Details tab

User details identify a user with the following attributes:

Attribute	Description
Username	Login name of the user. The name can contain letters and numerals only. This name must be unique among business activities and users; you cannot have a user with the same name as a business activity. See “Object namespace” on page 211 for details.
Password	User password. Any combination of letters, numerals, or characters.
Default profile	Default profile used to deliver alerts to this user. See Delivery Profiles tab,” below, for details.
Roles	Roles that this user may belong too, and which ones the user does belong to. See “Roles” on page 252 for details.

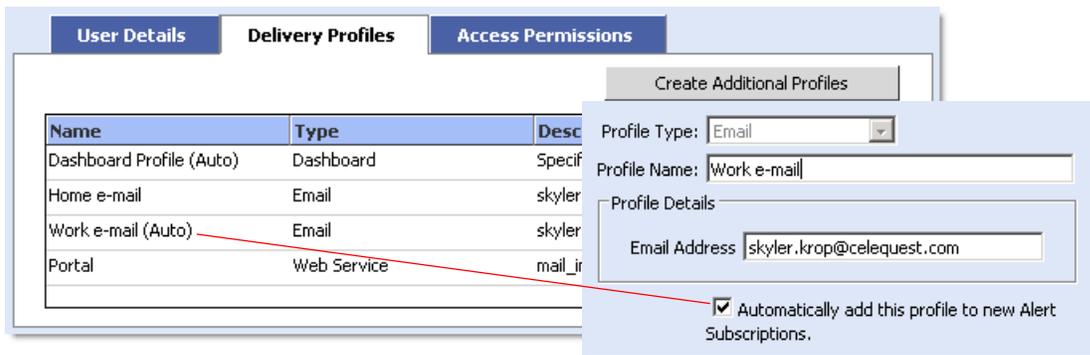

The screenshot shows a software interface with three tabs: **User Details**, **Delivery Profiles**, and **Access Permissions**. The **User Details** tab is active. The form contains the following fields:

- User Name:
- Password:
- Confirm Password:
- Default Profile: (dropdown menu)
- Roles: SalesManagers, InventoryManagers, SalesExecutives

Delivery Profiles tab

Delivery profiles specify where and how to deliver alerts and data feeds to the user. Users may have multiple profiles, and in the Alert Manager in the FileNet BAM Dashboard, they can identify which profiles receive which alerts. Further, every user has at least one profile: Dashboard Profile sends notifications to the Alert Manager in the FileNet BAM Dashboard.

At least one of the profiles must be designated as the one to use when subscribing to an alert. All profile flagged as Auto are automatically added to new alert subscriptions.

The profile types are the possible delivery mechanisms available in the installation, and they include:

- Dashboard Profile — The Alert Manager in FileNet BAM Dashboard. You cannot delete this profile.
- E-mail — An e-mail account to receive the generated alert message.
- RTD (real-time data) — A server that updates a Microsoft Excel spreadsheet as the alert’s status and context changes.
- Web Service — A Web services method that receives the alert notification and attached reportlet as XML data.

E-mail

An address where the user receives e-mail messages.

Attribute	Description
Profile Name	Identifies this profile. The name can contain letters and numerals only.
E-mail address	E-mail address to use.

RTD

RTD metrics appear in the FileNet BAM Dashboard (see FileNet Business Activity Monitor generates metrics about your business' activities. Metrics are measurements taken over time that monitor, assess, and communicate vital information about an activity, and are presented in a spreadsheet. The Excel Dashboard tab in FileNet BAM Workbench is where you view and pick the metrics you wish to receive, and specify how the metrics get populated in the spreadsheet. for details). The profile identifies the RTD server that provides data feeds.

Attribute	Description
Profile Name	Identifies this profile. The name can contain letters and numerals only.
RTD Host	Host machine that serves the RTD to the clients.
RTD Port	Port number (Integer) on the host that receives the data feed.

Web Service

Web Service to receives the alert notification and any attached reportlets as XML data.

Attribute	Description
Web service URL	HTTP location of the application providing the DOC (SOAP) service. Note that RPC style messages are not supported.
Method	Method of the Web service to use.
Username	(optional) Account name to use when connecting to the service.
Password	(optional) Password for the account.

To use a Web Service, your administrator will need to reference the `WebServicesAlert.xsd` file which is the Web service definition language file (WSDL) that describes the subscription service, the data it provides, and how to exchange data with the service. Note that this service publishes a SOAP doc-style message, not an RPC style message.

Your administrator can locate the file on FileNet Business Activity Monitor CD-ROM at this location:

`FileNet Business Activity Monitor/Server/config/wsalert/WebServicesAlert.xsd`

For more information about FileNet Business Activity Monitor use of Web Services, see ["Web services" on page 303](#).

User Preferences tab

User preferences are settings that the user may specify that affect the FileNet BAM Workbench.

Dashboard polling

Dashboard polling tells the FileNet BAM Dashboard how frequently to update the list of alerts received.

Attribute	Description
Offline	Do not poll the servers looking for new alerts.
Polling Interval	How frequently to poll the server looking for new alerts.

NOTE: Clicking on the **FileNet BAM Dashboard** tab or the Alerts tab in the FileNet BAM Dashboard always polls the server before displaying the list of active alerts.

User Permissions tab

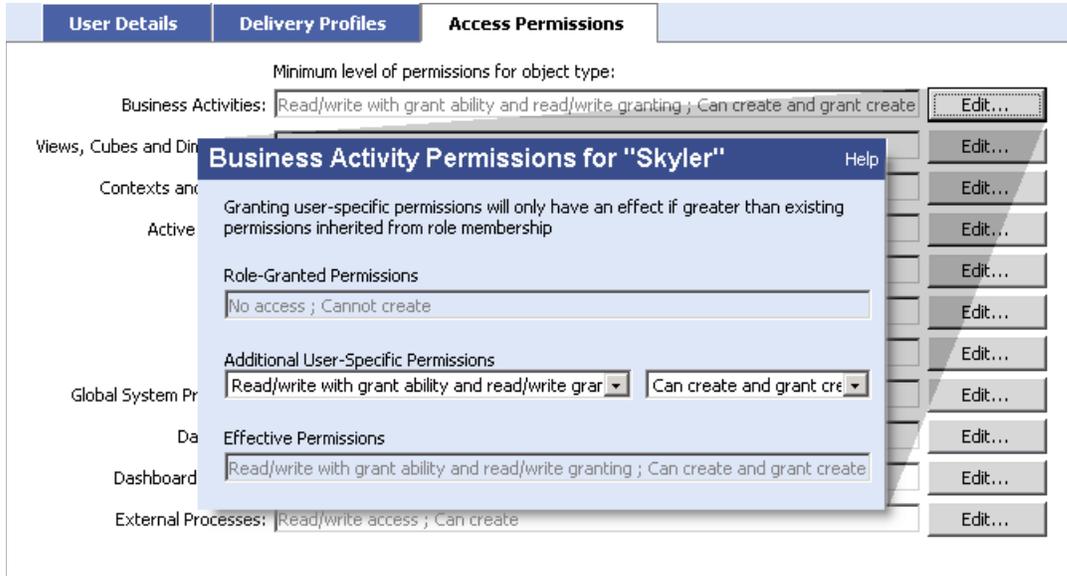

User permissions are the global permissions that a user may have. From this tab the user can see what Create permissions they have, and administrators can assign the user’s permissions to classes of objects. For a detailed discussion about permissions, see [“Permissions” on page 216](#).

NOTE: Every new user has No Access permissions for everything. This allows the user to receive and view alerts and reportlets as the result of mandatory subscriptions, but they may not subscribe to any.

When a user views their own permissions, they see which classes of objects that they may create.

Object Type	Permission Level	Action
Minimum level of permissions for object type:		
Business Activities:	Read/write with grant ability and read/write granting ; Can create and grant create	Edit...
Views, Cubes and Dimensions:	Read/write with grant ability ; Can create and grant create	Edit...
Contexts and Events:	Read/write access ; Cannot create	Edit...
Active Reports:	Read-only with grant ability and read-only granting ; Cannot create	Edit...
Users:	Read-only access ; Cannot create	Edit...
Roles:	Read-only access ; Cannot create	Edit...
Agents:	Read/write access ; Cannot create	Edit...
Global System Properties:	Read-only access	Edit...
Dashboard:	Read-only access ; Cannot create	Edit...
Dashboard Objects:	Read-only access ; Cannot create	Edit...
External Processes:	Read/write access ; Can create	Edit...

When an administrator creates or edits permissions, they can specify which objects a user may create and assign permissions to all existing objects.

For a detailed discussion about assigning permissions, see ["Permissions"](#) on page 216.

User-Defined Functions

User-defined functions (UDFs) provide a mechanism for extending C-SQL by defining your own functions for use in queries, views, and rules. With this feature you can define a scalar function or set function by implementing the appropriate FileNet Business Activity Monitor Java interfaces.

UDFs are Java programs that take arguments and return a value, just like the internal FileNet Business Activity Monitor functions. For example, you might have a UDF that takes a set of values and concatenates them alphabetically while ignoring NULL values. You would use that UDF in an expression like this:

```
ConcatSet (Product .Name)
```

After compiling the Java program, you deploy (load) it into FileNet Business Activity Monitor where it is then available to all users who can create or edit queries, views, and rules.

For information about creating user-defined functions, see “Creating and using a UDF,” below. Further, for details about the interfaces, see “com.celequest.api.function” in the Javadoc documentation. You can access the Javadoc documentation with a Web browser directly from FileNet Business Activity Monitor CD-ROM by pointing your browser to: <cd>/helpdocs/javadoc/index.htm.

UDF restrictions

User-defined functions have these restrictions:

- Scalar and set functions only; no rank functions.
UDFs can define Scalar functions by implementing the IUDScalarFunction interface, or Set functions by implementing the IUDAggregateFunction and IUDAggregateState interfaces. See “com.celequest.api.function” in the Javadoc documentation for details.
- UDFs are not exposed to the FileNet BAM Workbench.
The formula editor does not recognize UDFs. As such, you are responsible to keeping track of which UDFs are registered with the system.
- All users have access to all UDFs.
You cannot apply access permissions to a UDF. Similarly, multiple users may define different UDFs with the same name. In that case, the system uses the first one it finds.
- Set functions must implement object serialization and maintain backward compatibility.
Failure to implement meaningful serialization/deserialization routines may result in unpredictable behavior in many areas including checkpoint and recovery, and parallel execution.
- UDFs are never pushed as predicates to a remote source.
Essentially, UDFs are never sent to a DBMS for evaluation. See [“Context column limitations in queries” on page 45](#) for more details.

Creating and using a UDF

These instructions use the ConcatSet sample UDF included on the product CD-ROM in the /samples/udf/ directory. To follow along using the sample, first copy the contents of that directory to a location on your local machine. See the README.txt file in that directory for more information about the sample.

To create and use a UDF:

1. Implement the interfaces.
2. Create your UDF by implementing the appropriate `com.celequest.api.function` interfaces.

NOTE: See the Javadoc documentation for details about the interfaces.

3. Compile your implementation.

When you compile your UDF implementation, include the `celequestAPI.jar` file. (The file is on the product CD-ROM in the `/FileNet Business Activity Monitor/CelequestAPI/` directory.) For example:

```
javac -classpath <CD-ROM>/FileNet Business Activity Monitor/CelequestAPI/celequestAPI.jar src/
samples/udf/concatset/*.java src/samples/udf/concatlist/*.java src/samples/udf/util/*.java -d
jar
```

4. Create a manifest for the UDF JAR file.

A manifest is an XML file that describes the UDF JAR file to FileNet Business Activity Monitor. For a description of the file and a sample listing, see [“Manifest files” on page 290](#).

5. Create the UDF JAR:

- Create a JAR file containing your class(es) (such as `ConcatSet.class`) and the manifest (`manifest.xml`). The manifest must appear under `com/celequest/manifest` in the jar. For example:

```
jar -cvf udf.jar samples/* com/celequest/manifest/manifest.xml
```

6. Upload the JAR to the FileNet Business Activity Monitor server.

- Open the Workbench tab in the FileNet BAM Workbench, select the JAR Files folder, and choose New Jar.
- Assign a meaningful name to the JAR, and optionally provide a description.
- Locate the JAR file in the Path.
- Choose Upload JAR File.

7. Add the UDF to the list of available UDFs.

- Select the User Defined Functions folder and choose New User Defined Function.
- Identify the source by choosing the existing JAR file that you just uploaded, and choose Continue.
- Select the functions to add, and optionally assign new names to them.
- Choose Finish to add the UDFs to the list.

8. Use the UDF in formulas. Once the UDF is deployed, you can use it in formulas, similar to this:

```
ConcatSet (Product.Name)
```

This completes the steps for creating and using a UDF.

To alter an existing UDF:

1. Change the implementation and create an updated JAR file.
2. Upload the JAR over the existing one.
3. Re-add the UDFs to the list of User Defined Functions.

Manifest files

A manifest is an XML file that describes the contents of the UDF JAR to FileNet Business Activity Monitor. For every function in your jar file, define <UDF> and <name> elements. Further, for every data-type that the function can return, define a <UDFDescriptor> element. Finally, if subsequent calls to the same function with the same argument values can return different values, set the <isVariant> element to true. For example, the CURRENT_TIMESTAMP() internal function takes no arguments, but returns a different result each time it is called. That function is "variant".

Here is a sample manifest for the ConcatSet() function. This listing is adapted from the file in the samples directory at /samples/udf/jar/com/celequest/manifest.xml.

Sample manifest.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<jarManifest
  xmlns="http://www.celequest.com"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.celequest.com jarManifest.xsd"
>
  <jarManifestXSDVersion>1</jarManifestXSDVersion>
  <author>Celequest Corporation</author>
  <UserDefinedFunctions>
    <UDF>
      <name>ConcatSet</name>
      <description><![CDATA [
        Function which concatenates a set of values
        alphabetically into a large string. Null values
        are ignored.
      ]]></description>
      <implementor>samples.udf.concatset.ConcatSet</implementor>

        </UDFDescriptor>
      </UDFDescriptors>
      <isVariant>false</isVariant>
    </UDF>
  </UserDefinedFunctions>
</jarManifest>
```

Views

Business views are data models that provide a real-time picture of a business activity. Records of changes and transactions in your business enter FileNet Business Activity Monitor as events. Each new event drives an immediate update of the views — the business models — derived from that event, thereby providing a real-time picture of the business metrics. Further, after a view has been updated, the system evaluates the rules associated with the view looking for exceptional business conditions that require attention.

A business view is a virtual table that resides in memory and whose contents come from one or more sources as defined by an C-SQL SELECT query statement. You define views with the graphical user interface in the FileNet BAM Workbench. That system then constructs a well-formed SELECT statement before passing it to the FileNet Business Activity Monitor servers for execution and maintenance. For details about the SELECT statement and its syntax and usage, see [“SELECT” on page 264](#).

In this Chapter:

[“Creating views” on page 292](#)

[“View attributes” on page 293](#)

[“View constraints” on page 294](#)

[“Synchronized joins” on page 294](#)

[“Consolidated events” on page 296](#)

[“Aggregate views” on page 297](#)

[“Updating views through event propagation” on page 298](#)

[“Stateless and stateful views” on page 298](#)

[“View initialization” on page 299](#)

[“Maintaining events in stateless views” on page 300](#)

[“Persisting views to a database” on page 301](#)

You can limit the rows that a user sees by associating an access filter to the view, and applying the filter to users or roles that see the view. See [“Access Filters” on page 17](#) for complete details.

NOTE: The data in the context views are static or slowly changing. As such, the query engine does not update the view due to changes in the context tables. Changes in the context table are, however, reflected in the view when the context table is joined with the next event row.

Creating views

You need Create permission for views (see [“Creating permission” on page 220](#)), and Read Only access permission on the table (and optional views) that will feed the new view.

To create views with the FileNet BAM Workbench:

1. Click the New View button.
2. Select the existing event, view, or views on which to build your view.
3. Fill in the fields in the Create View form.

To create views for a specific events with the FileNet BAM Workbench:

1. Select the existing event, view, or views on which to build your view.
2. Click the New View For This Event button.
3. Fill in the fields in the Create View form.

Copying a view

You can also copy the definition of an existing view to a new view.

To clone an existing view:

1. Edit the view you want to copy.
2. Change the view name, and change the other attributes that differ from the original view.
3. Choose “Save as New View”.

View attributes

Every view has the following attributes:

Attribute	Description
Name	Identifies the view object. The name can contain letters and numerals only. This name must be unique among views, events, context, and consolidated events. See “Object namespace” on page 211 for details.
Status	Specifies if the view is enabled (receiving new event information), or disabled. When an view is disabled, all objects that depend on the view are also disabled, including rules, alerts, and reportlets.
Description	Optional description that may contain any text characters.
Workset	Event table and or views on which the view is derived.
Field list	Columns to include in the view, including columns whose values are derived from formulas. This is the Select list in the underlying SELECT statement. The Group By option identifies columns on which to group the results. This is the GROUP BY clause in the underlying SELECT statement.
Maintain in view	Allows tracking of past event information for stateless views. See “Maintaining events in stateless views” for details.
From clause	How to join the information from multiple tables and views in the Workset. This is the FROM clause in the underlying SELECT statement.
Where clause	Identifies which source information to include in the new view. Events which do not meet the specification are not included in the view. This is the WHERE clause in the underlying SELECT statement. Note that even though an event’s information might be discarded, derived views will still update, though they too will not contain the event information. See “Updating views through event propagation” for details.
Window clause	Defines windows for aggregating sets of rows in the view. See “Query Windows” on page 228 for details.
Order by clause	Sorts the resulting view based on column names or on expression results. This is the in the underlying SELECT statement.
View Persistence	Save view data to a database for later analysis. See “Persisting views to a database” for details.

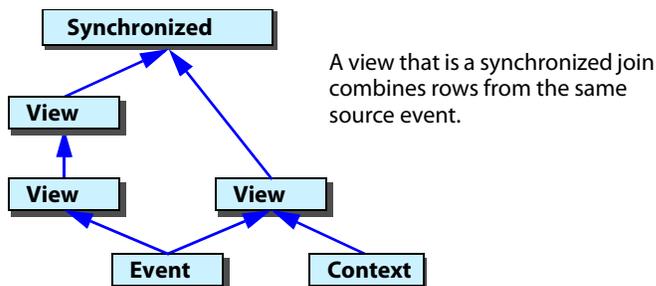

View constraints

FileNet Business Activity Monitor views have these constraints:

- A view may be derived from an event table or another view.
- A view may *not* join different event streams. (Though a *Consolidated Event* is a union of two identical event streams; see “Consolidated events” for details.)
- A view may join two views of the same event stream. (A *synchronized join* is a view derived from multiple views based on the same event stream; see “Synchronized joins” for details)
- A view may join an event table and one or more context tables.
- A view may join a view and one or more context tables.
- A view may *not* be derived from context tables only.

Synchronized joins

A *synchronized join* is a view derived from two views based on the same originating event stream. In a synchronized join, the resulting view contains rows that are the combination of the *same events* in the source views.

Synchronized joins are always based on the event’s internal ID; there is an implicit join condition on the internal event column. However, you still should define a WHERE clause or join condition in the FROM clause to avoid a possible cross join result (see “[Cross joins](#)” on page 268 for details).

NOTE: A synchronized join stream always results in a stateless view.

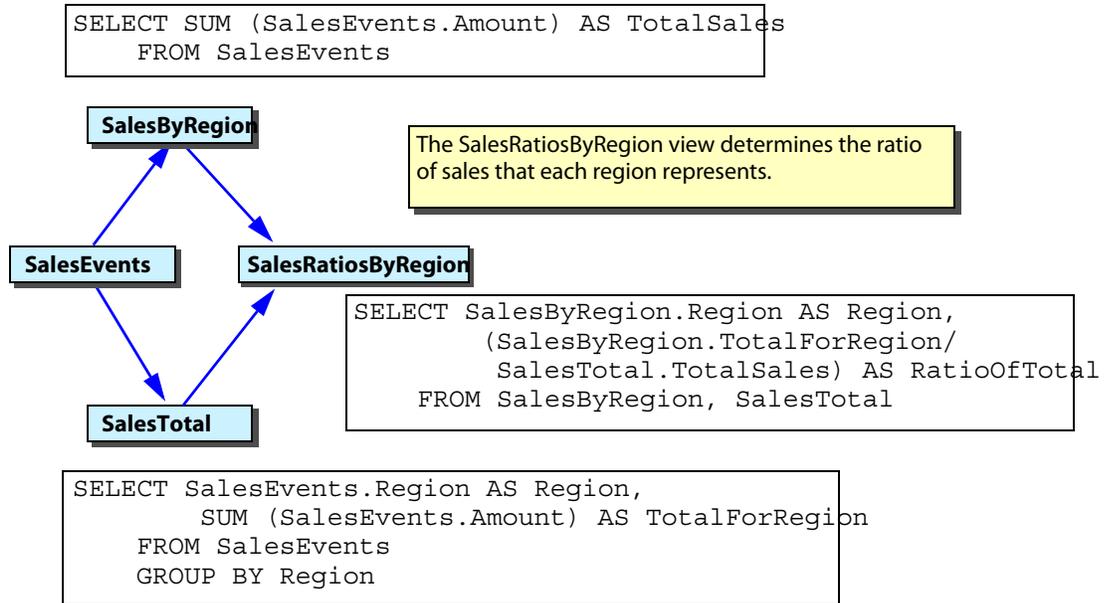

Restriction

A synchronized join requires that events be processed in the order that they arrive. As such, the source event object must have Process events in the order of arrival turned on.

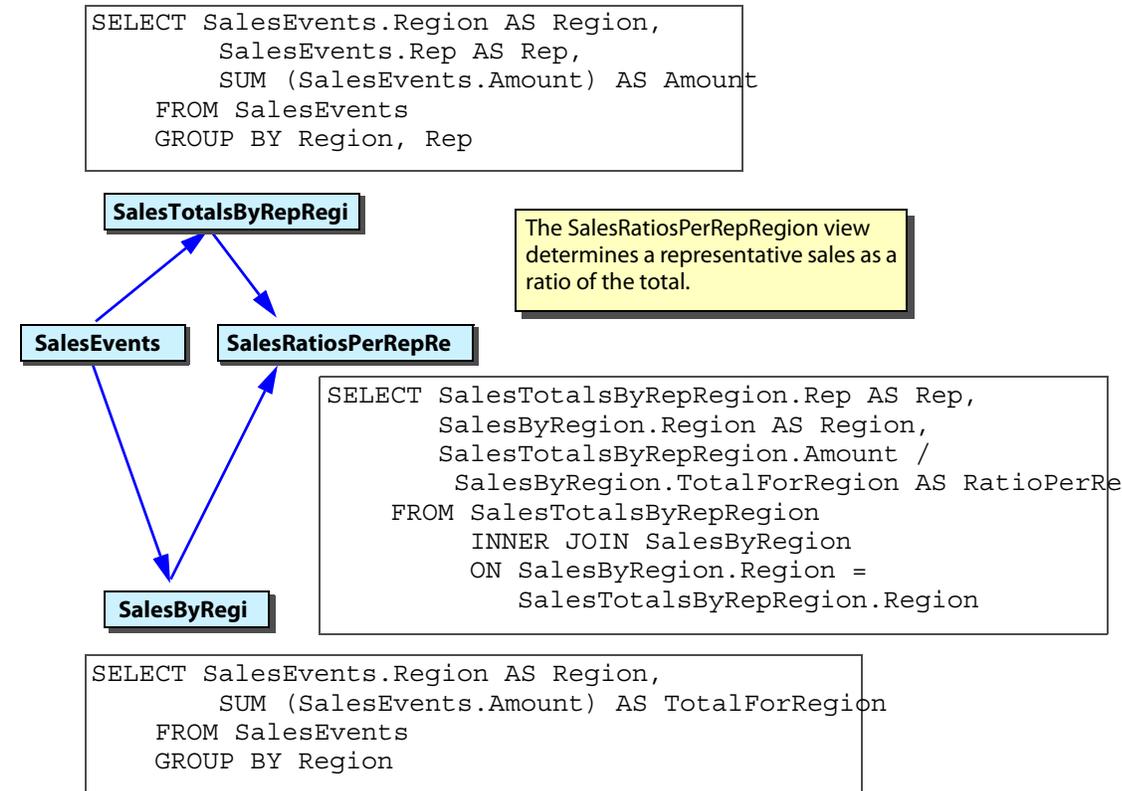

Example

One example, of a synchronized join is this one which determines the ratio of total sales by region. One view (*SalesTotal*) determine the total sales for all events, while the other (*SalesByRegion*) determines the

totals for each region. Finally, the synchronized join (*SalesRatiosByRegion*) determines the percentage of each region by joining the two “total” views and dividing the region totals into the grand total.

Note that the above synchronized join is a cross join, which in this case is acceptable. However, consider this example that determines each sales representatives ratio relative to the total sales:

In the above illustration, you do not want a cross join because it creates one row for each sales representative in every region, including the regions that the representatives do not belong too. Instead, the SalesRatiosPerRepRegion view declares an inner join to limit the results by region.

Consolidated events

Consolidated events are special views that accept events from two different event streams. See Working with consolidated events for a detailed discussion.

Aggregate views

A key power of business views is the ability to aggregate event and context information; to extract, analyze, and combine the information into meaningful business metrics. Aggregate views have at least one field definition that includes an aggregation or GROUP BY clause.

For example, consider this simple view that tracks the total count of events that arrived in the last hour. Every time a new event arrives the MOV_COUNT() function recalculates the count of all events in the view, thereby providing a real-time metric about the event stream:

```
SELECT MOV_COUNT( *, HOUR, 1) AS "Events in the last hour"
      FROM Events
```

You can make the example a little more complex by limiting the events that the view sees. For example, to count only those events whose *Status* value is Open:

```
SELECT MOV_COUNT( *, HOUR, 1) AS "Opens in the last hour"
      FROM Events
      WHERE Status='Open'
```

By combining the aggregate information with other context, you can generate more meaningful metrics. For example, this view reports the count of events whose *Status* value is Open, and groups them by *Feature*:

```
SELECT Context.Topic AS Topic,
      MOV_COUNT( *, HOUR, 3) AS "Opens in 3 hours"
      FROM Events INNER JOIN Context ON Event.Feature = Context.Feature
      WHERE (Status='Open')
      GROUP BY Feature
```

```
Feature          Opens in 3 hours
-----
Configuration    12
Install           3
Servers           6
```

For detailed information about aggregate and moving set functions, see [Function types](#).

Updating views through event propagation

When a view receives a new event, it attempts to update itself with the new information, and if the update occurred the view then notifies all dependant views to also update. However, these exceptions can keep the view from updating:

- If a view is empty when it receives an event, and it remains empty after processing the event, it never notifies the dependant views.
- If a stateful view becomes empty as a result of a deletion, such as when an existing event is discarded from a moving set function set, all dependant views are notified to update as well.
- An update may cause a stateless view to become empty, and any dependant views will also be empty. If subsequent event also results in an empty view, the view will appear to have not updated, though it had.
- If the new event is discarded because it does not meet some criteria, the stateful view is not updated. However, it still publishes a snapshot of itself to all dependant views which can cause dependant moving set functions to update their views.

If an error occurs when processing an event while updating a view, all rows related to the entire event are discarded, and the view remains valid and enabled.

Stateless and stateful views

All views in FileNet Business Activity Monitor are either *stateless* or *stateful*:

Stateful views contain the results of aggregations derived from past events in a single row. A view is stateful if it

- contains an set function, or moving set function in the SELECT clause, or
- contains a GROUP BY clause (in which case each group contains only one row), or
- is derived from a stateful view.

Stateless views are any views that are not stateful.

Generally, a stateless view shows the information about a single event, such as a single purchase order. A stateful view, on the other hand, shows the aggregate information about multiple events, such as the average price of multiple purchase order events.

View initialization

Each view maintains two snapshots of the data it contains:

- **Current view** — This is the data currently in the view. For a stateful view, the snapshot shows all rows in the view. For a stateless view, it shows all the rows corresponding to the last event, which after aggregation might be an empty set.
- **Recent view** — A snapshot of the last *non-empty* current view. When the view has a moving set window, the recent view contains the last non-empty rows in the window. For example, if the window is 2 days, the recent view contains the last 2-day set that was not empty, even if the current view is empty. A recent view is what appears in the FileNet BAM Workbench when editing an object that displays view results, and what is used by derived views during view initialization.

When you create or enable a view, it is initialized to a state based on the data in the base view as follows. When a view is derived from a

- **stateful view**, the new view is initialized with the data in the base view's *current view* snapshot. For example, consider a stateful base view which tracks sales by region:

```
SELECT region, SUM(sales) AS region_sales GROUP BY region
```

When you derive a new view from *sales_by_region*, the new view is immediately populated with the data in *sales_by_region*'s current view.

```
SELECT SUM(region_sales) AS total_sales FROM sales_by_region
```

- **stateless view**, the new view is initialized with the data in the base view's *recent view* snapshot. For example, consider this stateless view. This view's current snapshot is empty when no sales are greater than 1,000,000.

```
SELECT region, sales WHERE sales > 1000000
```

However, a view derived from this view will be initialized with the data in the view's recent view snapshot

- **event table**, the new view is empty; event tables do not maintain snapshots.

Maintaining events in stateless views

By default, a stateless view contains only rows representing the last event and which satisfied the view condition; rows from previous events are discarded. If the event did not meet the condition, the view will be empty. With the Maintaining events in a stateless view option you can specify a set of recent *non-empty* event information to maintain in the view.

Use this option to include the recent events in

- The FileNet BAM Workbench when displaying a the view's contents on the Results tab. This tab displays the current rows in the view.
- External applications that receive the view as a real-time data feed. This allows the external application to perform trend or historical analysis.

To maintain events in a stateless view:

1. Open the View Editor on a view to persist.
 - On an existing view choose Edit View, or
 - When creating a new view...
2. Check Maintain in view.
3. Enter either the count or time-span of events to retain.
 - An event count is the maximum number of *non-empty* events to maintain. The view discards the oldest event rows that do not fit in the specified size.
 - A time interval defines a set of the most recent events. The count of events in the view varies depending on the number of events in the interval when the view was updated. For example, if an event arrived that did not meet the view criteria, it is excluded from the view, but the view recalculates the interval that time.

NOTE: The set of events is determined *when the last event was inserted*, not at the current time. For example, an interval of one hour shows all the events that arrived in the view for the hour previous to the last update. If no events were inserted in the last day, the view might still show an hour's worth of events from the previous day. However, as soon as new event arrives at the view, all those events are discarded.

See also "[Moving set functions](#)" on page 126 for a means of performing aggregations on sets of recent events.

Persisting views to a database

FileNet Business Activity Monitor can persist business view data to an external DBMS for future reporting by third party tools. The information in the table is sufficient for the reporting tools to recreate a complete snapshot of the view. When persisting, the view information is written to a table in the DBMS at a rate following a policy that you define.

NOTE: FileNet Business Activity Monitor can create the table automatically, or you can pre-define the table in the DBMS. See the View persistence attributes,” table below for details.

To activate view persistence:

1. An application specialist must have first define a JDBC Agent to the RDBMS that will store the view data. See [“JDBC agents” on page 187](#) for details about creating this agent.
2. Open the View Editor on a view to persist.
 - On an existing view choose Edit View, or
 - When creating a new view...
3. Check Persist data from view to a database.
4. Choose Define Database Connection...
5. Fill in the fields in the Define Database Connection dialog.

The view begins persisting data as soon as it is enabled.

View persistence attributes

The database connection attributes include:

Attribute	Description
JDBC Agent	Agent to the RDBMS defined in 1 above.
Table	<p>Target table in the RDBMS to receive the persisted data. If you omit this name, the table will have the same name as the business view.</p> <p>The columns in the target table must have the same names as the columns in the view, appear in the same order as in the view, and they must be at least the same width as the columns in the view. When a column width in the target is smaller, the RDBMS either silently truncates the data to fit or generates an error. Similarly, the target table must support row lengths at least as long as the rows in business view.</p>
Create this table if it isn't there	Indicates that the application specialist or database administrator has not already created the named table. If this option is selected, FileNet Business Activity Monitor attempts to create the target table using a CREATE TABLE command in the JDBC user's default table space.
Persistence policy	Defines when to write the view data to the target table. The system caches the rows of data and writes them to the target after exceeding either a count of rows, or an interval of time.
Stop logging after	<p>Specifies how many consecutive errors to write to the error log before suspending error logging of the messages. Use this option to avoid rapidly filling the error log.</p> <p>Note, the system continues persisting view snapshots as long as the view is enabled, even when errors occur in the target, such as in "Out of space" conditions.</p>

View columns to persist

The database receives all of the columns and rows currently in the view. Additionally, each row contains these additional internal columns:

Column	Description
VC_EVENT_ID	Event identifier identifies the event that produced the most recent row included in the view.
VC_LATEST_EVENT_ID	Latest event identifier identifies the last event that caused the view to update, though data from that event might not be included in the view.
VC_TIMESTAMP	Event timestamp identifies when the last event was included in the view.

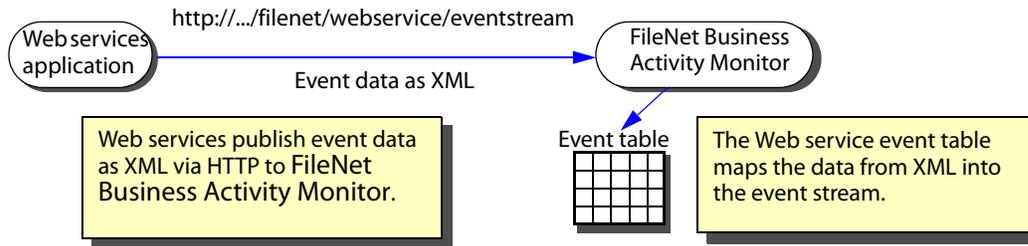

Web services

A Web service is an interface to an application running on a Web application server. The service can be a simple database lookup script, or a complex enterprise application integration (EAI) product, like those provided by Siebel or SAP. FileNet Business Activity Monitor connects to Web services to do the following:

- Receive events, (as describe in [“Web service events” on page 304](#)),
- Retrieve context (as described in [“Web service context” on page 306](#)),
- Publish alert messages as follows:
 - to a subscriber’s delivery profile, (see [“Delivery Profiles tab” on page 284](#) for details)
 - on an individual basis as initiated by a user viewing the message in the FileNet BAM Dashboard ([“Web service external processes” on page 313](#) for details).

Web service events

Web services publish event data as XML via HTTP directly to the FileNet Business Activity Monitor servers. All Web service publishers use the same URL. As such, encoded in XML with the event data is the name of the event to receive the data, and the FileNet Business Activity Monitor account that has access to the event table. When the servers receive the event data, they parse the XML, decode the data, and insert it into the identified event stream.

Web service event attributes

Each Web service event table has the following attributes:

Attribute	Description
Name	Identifies the table and is the name accessed by the Business Views that depend on this table. This name must be unique among views, events, context, and consolidated events. See “Object namespace” on page 211 for details.
Description	<i>(optional)</i> Description of the table.

Attribute	Description
Status	Whether or not the object is enabled (able to receive and pass data), or disabled (not receiving or passing data).
Log event data for recovery	When on, logs event data that arrived after the last checkpoint started. This "recovery" log is used to restore the state of the system in the event of an abnormal shutdown of the servers. See Working with checkpoint and recovery for complete details.
Process events in the order of arrival	Choose this option when events must be processed in the order received. Otherwise, if events may be processed out of order, turn this on. Note: To join events in a view, the events must be processed in order: leave this option off to join the events.
Disable event after this number of consecutive errors	Disables the event when a consecutive count of errors occur. For example, if set to 5, disables the event after 5 consecutive errors. However, if 4 errors occur, and then no errors followed by 2 errors, the event remains enabled. The default is <i>off</i> : do not disable.
Column Information	The Column Information fields define the columns in the event table, and are the same name as the fields in the XML message, as described in the WSDL for the event.

Creating a Web Service Event

Before creating a Web service event table, you need to create permission for tables (see ["Creating permission" on page 220](#)).

To publish event from a Web service:

1. Create and the event in the FileNet BAM Workbench.
2. (Optional) Create a FileNet Business Activity Monitor user account for the Web service to use when publishing the event. The account must have at least Read-Write on the event table to publish to the event stream.
3. Retrieve the event WSDL definition using HTTP.

```
http://<host:port>/filenetbam/wsdl/eventstream.wsdl
```

The eventstream.wsdl file describes all defined FileNet Business Activity Monitor Web service events streams. See the documentation in the WSDL for descriptions of the XML elements and attributes.

4. Create the Web service publisher and define the XML event data to conform to the WSDL.

This example of XML carries data to the *OrderWSEvent* event stream.

- The account used to access the event stream (*WSInputAccount*)
- there are four columns of data defined in the <OrderWSEventData> element

```
<?xml version="1.0" encoding="UTF-8"?>
<soapenv:Envelope
  xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
```

```

xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body>
  <OrderWSEvent_input xmlns="http://www.celequest.com">
    <cqesi>
      <eventname>OrderWSEvent</eventname>
      <username>WSInputAccount</username>
      <password>wspwd</password>
    </cqesi>
    <OrderWSEventData>
      <ProdName>Plywood</ProdName>
      <OrderQuantity>150</OrderQuantity>
      <OrderTotal>987.34</OrderTotal>
      <IsBackordered>true</IsBackordered>
    </OrderWSEventData>
  </OrderWSEvent_input>
</soapenv:Body>
</soapenv:Envelope>

```

5. Publish events to the URL identified in the eventstream.wsdl file, similar to this:

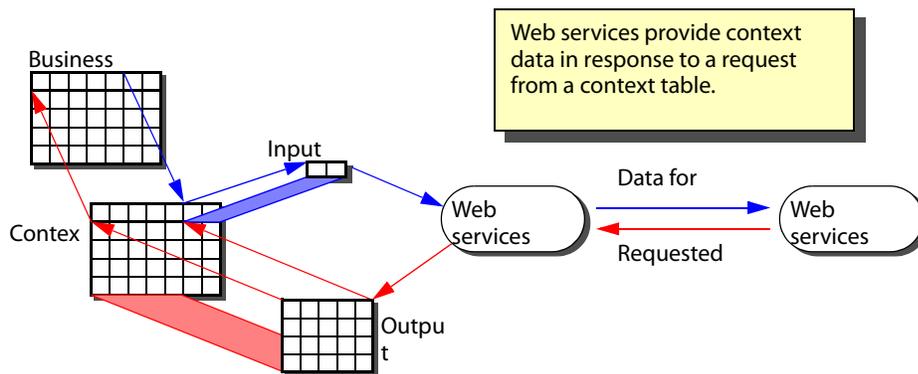

`http://<host:port>/filenetbam/webservice/eventstream.wsdl`

If you later change the machine that hosts the FileNet Business Activity Monitor servers, be sure to re-query the WSDL file to determine the correct URL.

This completes the steps for creating and using a Web service event.

Web service context

Business views request rows from a context table that match one or more input values, such as a list of suppliers that supply an item, where the item ID is the input. That input is then passed to the Web service application via the agent as XML. The application then returns one or more rows of data as XML, which are then mapped into the context table. The table then passes the requested data to the requesting business view.

FileNet Business Activity Monitor Web service agents are synchronous: they retrieve context data as the result of a specific request. When requesting data, the agent uses Simple Object Access Protocol (SOAP binding) to communicate with the application via an HTTP connection. The application then returns one or

more rows of data in XML following the Web service definition language (WSDL) format, Doc-type format. (Note that WSDL RPC-style is *not* supported.)

NOTE: For details about context agents, see [“Web service agents” on page 312](#)

Before creating a Web service context table, you must:

- Create permission for tables (see [“Creating permission” on page 220](#))
- Have a Web service agent that will feed the table (see [“Web service agents” on page 312](#) for details)
- Read Only access permission on the agent.

A Web services table has the following attributes:

Attribute	Description
Name	Context table name. This name must be unique among views, events, context, and consolidated events. See “Object namespace” on page 211 for details.
Description	Optional description that may contain any text characters.
Status	Whether or not the table is enabled (monitoring for events), or disabled (not monitoring for events).
Web Service Agent	An existing Web service agent that connects to a Web service application. Create an agent with the FileNet BAM Workbench Administration tab. See “Web service agents” on page 312 for details. This value cannot be changed.
Method	Method of the Web service to use. When the service provides multiple methods, you need to choose which one to use. This value cannot be changed in this release.
XPath Root	Identifies the XPath root of the repeating elements in the output, typically / Envelope/Body. This path is prepended to all paths in the Output Field Name list.
Disable context after errors	Count of consecutive errors to receive before the system disables this context. Once disabled, a context must be re-enabled manually.
Outputs	Columns that receive the information from the Web service. See “Output columns” on page 309 for details.
Inputs	Columns that contain the data which identify what to look up in the query. See “Input columns” on page 310 for details.
Caching	See “Caching context queries” on page 47 for details about this feature.

Creating a Web Service Context Table

This section describes how to create a Web service context table.

To create a Web service context table:

1. In the FileNet BAM Workbench, Workbench tab, create a New context and choose Web service as the table type.
2. Select an existing **Web service** agent.
3. Select the service method to use. Each Web service provides one or more methods for accessing the data it provides according its WSDL file definition (the URL location of which you specified when creating the Web service agent). Choose the method that performs the query your context needs.
4. Define columns that receive information from the Web service — the Output columns. By default, the editor defines one column for each element returned by the method. See Output columns,” below for details of defining these columns.
5. Define the columns that contain the data that identify what to look up in the query — the Input columns. By default, the editor defines one column for each element returned by the method. See Input columns,” below for details.
6. Specify how many results to cache, if any. See [“Caching context queries” on page 47](#) for details about this feature.

Save the Web services table as enabled and it will immediately be ready to receive context.

Output columns

The Output columns receive the information from the Web service and define the table to receive the data. The editor automatically defines one column for each element returned by the method. Further, each column has the following attributes:

Attribute	Description
Column Name	Name of the table column that contains the result returned by the Web service. By default, the name is the same as the element in the Output Field Name. You may assign any valid name.
Output Field Name	<i>(Cannot be changed.)</i> Identifies the element in the XML returned by the service. Note that you can view the entire path to the element by opening the Hide/Show dialog.
XSD Data Type	<i>(Cannot be changed.)</i> Identifies the data type of the element in the XML. Note that only the basic data types are supported: numbers, strings, dates, and boolean. Complex types like ANY and ARRAY, and mime types are <i>not</i> supported.
FileNet Business Activity Monitor Data Type	Data type of the column in the table. Choose a data type appropriate to the data returned.
Formatting	Formats the String, Date-Time, or DECIMAL value returned. This option is not available for other data types. See "Data Types" on page 52 for details.

To exclude columns from the result, open the Hide/Show dialog and deselect the fields to exclude.

Input columns

The Input columns pass information to the Web service to identify the information to return (the Outputs). The editor automatically defines one column for each element identified by the method. Each column has the following attributes:

Attribute	Description
Column Name	Name of the column that contains the information passed to the Web service query. For example, it might contain an ID that identifies a product to look up. This column is populated by the business view that requires the context information. By default, the name is the same as the element in the Input Field Name. You may assign any valid name.
Input Field Name	<i>(Cannot be changed.)</i> Identifies the element in the XML passed to the service. Note that you can view the entire path to the element by opening the Hide/Show dialog.
String Replacement Text	A string to pass to the service which contains values inserted by the business view requesting the information. See "String replacement templates," below for details.
XSD Data Type	<i>(Cannot be changed.)</i> Identifies the data type of the element in the XML. Note that only the basic data types are supported: numbers, strings, dates, and boolean. Complex types like ANY and ARRAY, and mime types are <i>not</i> supported.
FileNet Business Activity Monitor Data Type	Data type of the Column Name attribute. Choose a data type appropriate to the data to pass.
Formatting	Formats the String, Date-Time, or DECIMAL value returned. This option is not available for other data types. See "Data Types" on page 52 for details.

To exclude unnecessary columns from the query, open the **Hide/Show** dialog and deselect the fields to exclude.

String replacement templates

Use a String Replacement Template when the Web service requires a string with embedded lookup data. For example, some services require an expression that is the query to issue to the data source. This illustration contains returns context where Part_ID and Qty_On_Hand values are provided by the business view requiring the information. Here each Column Name (Alias) is a column in the context table. When the Web service is queried, the values in those columns are inserted in the string passed to the service.

Inputs

Column Name	Input Field Na...	String Replace...	XSD Data Type	Celequest Da
po_part_id	/Envelope/Body/...	Part_ID= ?	string	VARCHAR
po_order_qty		AND Qty_On_Hand >= ?		

Template expression (mark replacement fields with "?"):
 To include an actual question mark proceed the character with a "\". (example: "\?")

Part_ID= ? AND Qty_On_Hand >= ?

Replacement fields:

- po_part_id
- po_order_qty

Template Preview:

Part_ID= **po_part_id** AND Qty_On_Hand >= **po_order_qty**

To use string replacement templates:

1. Click on the (...) to open the template editor.
2. Type the template expression and enter a question mark (?) for each piece of information to retrieve from a column. Each question mark corresponds to one replacement field. The fields are the column names in the context table and appear in the order that the question marks appear in the expression.

Save the template to update the Inputs column display.

Web service agents

A Web service agent communicates with an application running on a Web application server for the purpose of retrieving context data. The agent connects to the application via an HTTP connection using Simple Object Access Protocol (SOAP).

NOTE: Web service agents are synchronous, they retrieve context data as the result of a specific request.

Event push	Event pull	Context pull
No	No	Yes

Before creating a Web services agent, you need:

- To create permission for agents (see [“Creating permission” on page 220](#) for details).
- To know the HTTP location of the WSDL file that defines the service to use. Note that the service must publish its data in SOAP binding; RPC binding is not supported.

Web service agent attributes

A Web service agent has the following attributes:

Attribute	Description
Name	Identifies the agent. This name must be unique among agents. See “Object namespace” on page 211 for details.
Description	Optional description that may contain any text characters.
Status	Whether or not the agent is enabled (monitoring for events), or disabled (not monitoring for events).
URL	HTTP location of the Web service definition language file (WSDL) that describes the service, the data it provides, and how to exchange data with the service. Note that returned data must be a SOAP doc-style message; RPC binding is not supported.
User name	(optional) User name to use when connecting to the service. This parameter is passed to the server when the server requires a user name.
Password	(optional) User password to use when connecting to the service. This parameter is passed to the server when the server requires a password.

Creating a web service agent

To create a Web service agent:

1. In the FileNet BAM Workbench, Administration Console, click New Agent...
2. Choose Web Service as the source type.
3. Fill in the fields that define the agent's attributes.

Save the agent as enabled and it will immediately be ready to retrieve data.

Web service external processes

External Web service processes are methods that receive XML documents that describe the alert message or dashboard object that a FileNet BAM Dashboard user is viewing, and which was sent to the service by the user. The XML document describes all of the data in the item that the user was viewing.

How it works

To publish an item to an external Web service:

1. Define the external process to receive the message in the FileNet BAM Workbench. See [Creating an External Process](#).
2. Send the item from the FileNet BAM Dashboard. When viewing an alert message or dashboard object, select **Take Action > Initiate Process** and select the process.
3. The external service receives the item as an XML document and processes it. See ["Implementing the external service" on page 314](#) for details about the document.

External process attributes

Each external process has the following attributes:

Attribute	Description
Name	External process name to appear in the Initiate Process dialog in the FileNet BAM Dashboard. This name must be unique among external processes. See "Object namespace" on page 211 for details.
Description	Optional description that may contain any text characters. This description appears in the Initiate Process dialog in the FileNet BAM Dashboard.
Status	Whether or not the process is enabled (sending XML documents), or disabled (not sending documents).
Web Service URL	HTTP location of the application providing the RPC (SOAP binding) service. Note that DOC style messages are not supported.
Method	Method of the Web service to use.
Username	(Optional) Account to use when connecting to the service.
Password	(Optional) Password for the account.

Creating an External Process

Define an external process in the Administration Console of the FileNet BAM Workbench.

Before creating a Web services external process, you need:

- An already defined, external Web service method to receive the published method. You will need to know the URL for connecting to the service, the name of the method that will receive the message, and any user or account name and password required by the service. See [Implementing the external service](#) for additional details.
- Create permission for external processes (see [“Creating permission” on page 220](#) for details).

To create an external process

1. In the FileNet BAM Workbench, open Administration Console > External Processes list, and click New Process.
2. Define the attributes for the process.
3. Save the process and it is immediately available to all users with access to it.

To use the process, in the FileNet BAM Dashboard, choose Take Action > Initiate Process and select the process.

NOTE: To see and use a process from the FileNet BAM Dashboard, users will need Read permission for that process. You can assign permissions for the new object by clicking Permissions in the External Processes list, or an administrator can grant Read access to the class of external processes for the users. See [“Accessing permissions” on page 218](#) for details.

Implementing the external service

To implement the external Web service,

- define it to receive a SOAP binding message with the fields in the external action XSD, and
- create a WSDL (definition file) following FileNet Business Activity Monitor target and import requirements.

Message fields

The XML message fields are defined in the `invokeExternalAction.xsd` definition file. Find this (and all XSD files) in the `/api/metadata` directory on the product CD-ROM file. For more information about XML and XSD files in FileNet Business Activity Monitor, see [“XML/XSD” on page 317](#).

NOTE: You will also need the `common.xsd` located in the same directory.

Every message contains at least these fields:

- `description` — Description of the external process defined in the FileNet BAM Workbench
- `actionName` — Name of the external process defined in the FileNet BAM Workbench.
- `severity` — Severity either of the original alert message, or as chosen by the user that initiated the message.

Other fields are included as necessary based on the object that the user was viewing in the FileNet BAM Dashboard when they initiated the action, such as the subject of an alert message, or the row set of the data in the view on which a chart was presenting. See the XSD file for details.

Web service WSDL

When implementing the Web service, define it to receive a SOAP message and with the following attributes:

Attribute	Value	Comment
style	rpc	Do not use "document".
target namespace (tns)	http://www.celequest.com	—
encoding (soap:body)	encoded	Do not use "literal".
import namespace	http://www.celequest.com/2	Defines FileNet Business Activity Monitor data types. Alternatively, you can define the types in the WSDL, but that is beyond the scope of this document.
import location	<i>Installation-specific</i>	Location of invokeExternalAction.xsd in your installation.

Here's an example WSDL that handles the `invokeExternalAction` message on a machine and port named `host:80`. Note that it imports the `invokeExternalAction.xsd` definition file.

```
<?xml version="1.0" encoding="utf-8" ?>
<definitions
  xmlns:http="http://schemas.xmlsoap.org/wsdl/http/"
  xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:soapenc="http://schemas.xmlsoap.org/soap/encoding/"
  xmlns:tm="http://microsoft.com/wsdl/mime/textMatching/"
  xmlns:mime="http://schemas.xmlsoap.org/wsdl/mime/"
  xmlns:impl="http://www.celequest.com/2"
  xmlns:tns="http://www.celequest.com"
  targetNamespace="http://www.celequest.com"
  xmlns="http://schemas.xmlsoap.org/wsdl/">

  <import namespace="http://www.celequest.com/2"
    location="/celequest/api/metadata/invokeExternalAction.xsd"/>

  <message name="invokeExternalActionRequest">
    <part name="request" element="impl:invokeExternalAction" />
  </message>

  <portType name="invokeExternalActionPortType">
    <operation name="invokeExternalActionOperation">
      <documentation>Receives a Celequest external action.
      </documentation>
      <input message="tns:invokeExternalActionRequest"/>
    </operation>
  </portType>

  <binding name="invokeExternalActionBinding"
    type="tns:invokeExternalActionPortType">
    <soap:binding transport="http://schemas.xmlsoap.org/soap/http"
      style="rpc" />
    <operation name="invokeExternalActionOperation">
      <soap:operation soapAction="" />
      <input>
        <soap:body
          encodingStyle="http://schemas.xmlsoap.org/soap/encoding/"
          namespace="http://www.celequest.com" use="encoded" />
        </input>
      </operation>
    </binding>

  <service name="invokeExternalActionService">
    <port name="invokeExternalActionService"
      binding="tns:invokeExternalActionBinding">
      <soap:address
        location="http://host:80/axis/services/invokeExternalActionService" />
      </port>
    </service>
</definitions>
```

XML/XSD

All FileNet Business Activity Monitor Objects and many system operations can be expressed in XML format and uploaded into the system. The XML must be properly formatted as defined by XML schema files (XSD). For a complete list of the objects define and operations you can perform, see [“FileNet Business Activity Monitor XSD files” on page 327](#).

NOTE: Details about XML and XSD are beyond the scope of this documentation. For information about XML and XSD, see www.xml.org.

In this Chapter:

[“About XML and XSD files in FileNet Business Activity Monitor” on page 318](#)

[“Uploading XML files” on page 319](#)

[“Defining an object with XML” on page 321](#)

[“Defining multiple objects with XML” on page 322](#)

[“Altering an existing object with XML” on page 324](#)

[“Issuing commands with XML” on page 325](#)

[“FileNet Business Activity Monitor XSD files” on page 327](#)

About XML and XSD files in FileNet Business Activity Monitor

All XML files in FileNet Business Activity Monitor have schema files that define the structure of the XML. The XSD files and sample XML files, are provided on the product CD-ROM.

```
/api/metadata      XSD files
/samples/metadata  Sample XML files
```

In addition to the samples, another way to see properly defined XML files is to first create objects in the FileNet BAM Workbench or FileNet BAM Dashboard, and then use the Administration Console to export the entire set. All exported objects are written as XML files to the export directory on the server. See [Importing/exporting metadata](#) for more information about this procedure.

Dependencies

Most of the objects in the system depend on other objects. When you define a new object, all of its dependencies must be defined first. Do that by defining and uploading base objects in the order of dependency, or by defining them in batch as described in [“Defining multiple objects with XML” on page 322](#).

White space

When an XML element value contains multiple, contiguous white space characters that must be retained, direct the system to keep the spaces with `xml:space="preserve"`. Otherwise, the XML specification says to remove extra spaces. For example, without the preservation directive, this description would be trimmed of the trailing spaces and would have only one space between the words:

```
<description xml:space="preserve">A note </description>
```

Escape characters

The characters “<” and “&” are illegal in XML. Some other characters are legal, but can cause confusion when looking at them. For these characters, use these XML escape entities instead.

Sequence		Result
<	<	Less than
>	>	Greater than
&	&	Ampersand
'	'	Apostrophe
"	"	Quotation mark

For example, when expressing a query that contains a less-than symbol, use `<` instead, like this:

```
<query>SELECT c1, c2 FROM event1 WHERE c3&lt;=100 AND c2=&apos;CQST&apos;</query>
```

Character data

Instead of using escape characters, another way to express special characters is to use a CDATA tag. This tag tells the parser to ignore all special characters and treat them as literals. For example:

```
<query><![CDATA[SELECT c1, c2 FROM event1  
WHERE c3<=100 AND c2='CQST']]></query>
```

Uploading XML files

There are two ways to upload XML files into FileNet Business Activity Monitor:

- From a command line with the cqupload.jar utility.
- From a Web Browser with the fileupload.jsp script.

Both methods require that the FileNet Business Activity Monitor server be running. Also, each method uses a FileNet Business Activity Monitor user account to log in to the server and perform the action. In each case, the account must have create rights to the class of objects to create, or administration rights to the operations to perform. See [“Users” on page 282](#) for information about user accounts.

From a command line

From a command line use the cqupload.jar utility to upload files. You can find it on the product CD-ROM in the /FileNet Business Activity Monitor/CQUpload/ directory.

This utility has three options:

Option	Description
-s applicationURL	A URL that locates FileNet Business Activity Monitor
-u userName	(Optional) User account to use. Omit this option to use the default system administrator account.
-p password	Password for the user account. Required if you include -u.

For example, to upload an XML using the default system administrator account:

```
java -jar <CD-ROM>/FileNet Business Activity Monitor/CQUpload/cqupload.jar -s http://  
<applicationServer>/filenet createUserSkyler.xml
```

To include a username or password:

```
java -jar cqupload.jar -u skyler -p roo -s ...
```

A successful operation occurs silently; however, if the operation fails, the utility returns an error message to the command window. Review the error message to identify the problem. For example, this message indicates an error in the XML:

```
Error uploading file: createUserSkyler.xml
-----
java.io.IOException: Error parsing an XML document.  Ensure that the
XML conforms exactly to the XML schema definition.  The XML that
cannot be parsed is:
```

Further down the message you can find the actual cause: an invalid element:

```
Caused by:
javax.xml.bind.UnmarshalException: Unexpected element
{http://www.celequest.com/2}:nome
```

From a Web Browser

The fileupload.jsp script presents a form where you identify the XML file to upload. It includes a file picker where you to identify the XML file to load, and displays a message with the results of the upload.

To upload from a Web browser:

1. Run the fileupload.jsp script. Use an address similar to the following URL. Use the localhost only if you are running the browser on the same host as FileNet Business Activity Monitor servers; otherwise, use the same location that you use to run the FileNet BAM Workbench.

```
http://localhost/filenet/jsp/fileupload.jsp
```

2. Identify the user name and password of the FileNet Business Activity Monitor account to use.
3. Identify the XML file to upload.
4. Choose **Upload** to perform the action.

The results page displays the name of the XML file uploaded and its result. If the Status is Failed, review the exception to see what went wrong and correct the problem. For example, this message reveals that the operation failed because the user object *Rolf* did not exist.

```
Exception Encountered
com.celequest.exception.VCException: Cannot alter the [User]
named [Rolf] because that object does not exist.
```

Defining an object with XML

This discussion describes how to define and upload a single XML definition. To upload multiple XML files — especially objects with dependencies — follow the instructions in the next section, [“Defining multiple objects with XML” on page 322](#).

To define an object with XML:

1. Create XML definition. Use the associated XSD file to determine the valid elements of the XML file. See [“Example: Create user” on page 321](#), below, for an example of a complete XML file.
2. Ensure that FileNet Business Activity Monitor is running.
3. Upload the XML file.

Use either of the methods described in [“Uploading XML files” on page 319](#). To upload the file from the command line with the `cqupload.jar` utility:

```
java -jar <CD-ROM>/FileNet Business Activity Monitor/CQUpload/cqupload.jar -s http://  
<applicationServer>/filenetbam createUserSkyler.xml
```

This completes the steps for creating a new object.

Example: Create user

```
<?xml version="1.0" encoding="UTF-8"?>  
<createUser  
  xsi:schemaLocation="http://www.celequest.com/2  
    ../../api/metadata/createUser.xsd"  
  xmlns="http://www.celequest.com/2 "  
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"  
>  
  <name>Skyler</name>  
  <description xml:space="preserve">A power user</description>  
  <Password>roo</Password>  
</createUser>
```

Defining multiple objects with XML

When defining multiple objects — especially objects with dependencies — use `commandBatch.xsd`: the “batch mode” XML definition object. When you use the batch mode, include all of the XML in a single file, and then upload that file. All of the operations must be valid or none of them are accepted. To define and upload a single XML object, follow the instructions in [“Defining an object with XML” on page 321](#).

To define multiple objects with XML:

1. Create an XML batch file. Use `commandBatch.xsd` as the definition. Within the file, nest each definition within a `<command>` element, and place them all in a single `<commands>` element, in the order that they objects must be defined.

NOTE: See [“Example: Batch command” on page 323](#),” below for a listing that defines multiple, dependant objects.

2. Ensure that FileNet Business Activity Monitor is running.
3. Upload the batch XML file. Use the `cqupload.jar` utility to upload the XML file the application server running FileNet Business Activity Monitor. For example, to upload the example batch file:

```
java -jar <CD-ROM>/FileNet Business Activity Monitor/CQUpload/cqupload.jar -s http://  
<applicationServer>/filenetbam commandBatchSkyler.xml
```

This completes the steps for defining multiple objects.

Example: Batch command

This batch command defines a user account, two delivery profiles for the user, a user preference, and assigns one permission to the user.

```
<?xml version="1.0" encoding="UTF-8"?>
<commandBatch
  xsi:schemaLocation="http://www.celequest.com/2
    ../../api/metadata/commandBatch.xsd"
  xmlns="http://www.celequest.com/2"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
>
  <commands>
    <command>
      <createUser>
        <name>Skyler</name>
        <description xml:space="preserve">A power user</description>
        <Password>roo</Password>
      </createUser>
    </command>
    <command>
      <createUserProfile>
        <name xml:space="preserve">Work e-mail</name>
        <UserName>Skyler</UserName>
        <isDefault>true</isDefault>
        <EmailProfile><typeName/>
          <emailAddress>skyler@celequest.com</emailAddress>
        </EmailProfile>
      </createUserProfile>
    </command>
    <command>
      <createUserProfile>
        <name xml:space="preserve">Second profile</name>
        <UserName>Skyler</UserName>
        <isDefault>false</isDefault>
        <EmailProfile><typeName/>
          <emailAddress>skyler@viewceler.com</emailAddress>
        </EmailProfile>
      </createUserProfile>
    </command>
    <command>
      <setUserPreferences>
        <userName>Skyler</userName>
        <userPreference>
          <operation>set</operation>
          <name>polling_interval</name>
          <value>5</value>
        </userPreference>
      </setUserPreferences>
    </command>
    <command>
      <setPrivilege>
        <operation>GRANT</operation>
      </setPrivilege>
    </command>
  </commands>
</commandBatch>
```

```

    <privilegeTuple>
      <objectType>VIEW</objectType>
      <privilege>UPDATE</privilege>
      <accessorType>USER</accessorType>
      <accessorName>Skylar</accessorName>
    </privilegeTuple>
    <withGrant>>false</withGrant>
  </setPrivilege>
</command>
</commands>
</commandBatch>

```

Altering an existing object with XML

To alter an existing object's definition, use the same XML and schema as when creating the object, but include an `<alterInformation>` element to identify the alter operation. (The `<alterInformation>` element is defined in `common.xsd`.) For example, this definition renames a view from *OldName* to *NewName*; note that it uses the `createView.xsd` schema:

```

<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<createView xsi:schemaLocation="http://www.celequest.com/2
  /api/metadata/createView.xsd"
  xmlns="http://www.celequest.com/2"      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
>
  <alterInformation>
    <previousName>OldName</previousName>
  </alterInformation>
  <name>newName</name>
  <description>My test view</description>
  <query>SELECT c1, c2 FROM event1 WHERE c3<=100</query>
</createView>

```

No matter what change you are implementing, you must use `<previousName>`. If you are not changing the object's name, use the same name for both `<previousName>` and `<name>` elements, like this:

```

...
<alterInformation>
  <previousName>OldName</previousName>
</alterInformation>
<name>OldName</name>
<description>New description</description>
<query>SELECT c1, c2 FROM event1 WHERE c3<=555</query>
...

```

By default, an alter operation fails if the existing object does not exist. However, you can force the object to be created regardless of the existence of the existing object by including a `<createIfNotFound>` element, like this:

```

...
<alterInformation>
  <previousName>OldName</previousName>
  <createIfNotFound>true</createIfNotFound>
</alterInformation>
...

```

Dependencies

When you alter an existing object all other objects that depend on the altered object are evaluated and made “invalid” if their definition is broken as a result of the change. You will have to alter the invalid objects and correct their definitions before they can be re-enabled.

Issuing commands with XML

Many system operations can be performed with XML commands. Here are some of the common operations:

Operation	Schema
Enable an object	enableObject.xsd
Disable an object	disableObject.xsd
Drop (delete) an object	dropObject.xsd
Set a system property	setProperty.xsd
Import or export the system metadata	performImportExport.xsd
Stop or restart the system	systemCommand.xsd
Perform a “checkpoint”	systemCommand.xsd

Following are two example operations.

Example: Enabling an object and its dependencies

To enable an object and all of its dependencies, use the `enableObject.xsd` schema. You must identify the name of the object and its object type. (The valid `<type>` values are defined in `common.xsd` by the `<VCEnableObjectType>` element.)

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<enableObject xsi:schemaLocation="http://www.celequest.com/2
  /api/metadata/enableObject.xsd"
  xmlns="http://www.celequest.com/2"      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
>
  <name>MyView</name>
  <type>VIEW</type>
  <cascade>true</cascade>
</enableObject>
```

This example enables all dependent objects because `<cascade>` is set to `true`. Omit this element, or set it to `false` to enable just the named object.

Example: Restarting the system

To shutdown and restart the FileNet Business Activity Monitor servers, use the `<stop>` element from the `systemCommand.xsd` schema, and declare `<restart>` to be *true* (*false* stops without restart)

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<systemCommand xsi:schemaLocation="http://www.celequest.com/2
  /api/metadata/systemCommand.xsd"
  xmlns="http://www.celequest.com/2"      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
>
  <stop>
    <restart>true</restart>
  </stop>
</systemCommand>
```

FileNet Business Activity Monitor XSD files

These are FileNet Business Activity Monitor XML schema files, arranged by category:

- [“Users, Profiles, and Roles” on page 327](#) (below)
- [“Dashboard” on page 328](#)
- [“Rules, Alerts, and Reportlets” on page 328](#)
- [“Events, context, cubes, and views” on page 329](#)
- [“Scenarios and business activities” on page 330](#)
- [“Agents” on page 330](#)
- [“System administration” on page 330](#)
- [“Object management” on page 331](#)
- [“Miscellaneous files” on page 331](#)

The files are located on the product CD-ROM in this directory: /api/metadata

Users, Profiles, and Roles	
Schema	Description
addMembersToRole.xsd	Adds one or more existing users to an existing role.
addMemberToRole.xsd	Adds an existing user to an existing role.
createRole.xsd	Creates a user role object.
createSecurityFilter.xsd	Creates an access filter
createUser.xsd	Creates a user object.
createUserProfile.xsd	Creates a user delivery profile object.
setPrivilege.xsd	Sets a user’s or role’s permission on an object or class of objects.
setUserPreferences.xsd	Set a user’s preferences.

Dashboard	
Schema	Description
createBookmarks.xsd	Creates a dashboard bookmark
createDashboard.xsd	Creates a dashboard
createPlan.xsd	Creates dashboard references and plans
createPortlet.xsd	Creates a dashboard object
createTask.xsd	Creates a dashboard task
createTaskMessage.xsd	Creates a dashboard task message

Rules, Alerts, and Reportlets	
Schema	Description
alertCommon.xsd	Common alert XSD definitions.
alertMessage.xsd	Alert message to be delivered to a Web Service.
alterAlertState.xsd	Alters the state of an existing alert.
alterRule.xsd	Alters an existing rule object.
createAlert.xsd	Creates an alert object.
createExcelTemplate.xsd	Creates a Excel Template object that describes the template that a reportlet might use.
createReportlet.xsd	Creates a reportlet object.
createRule.xsd	Creates a rule object.
createRuleBundle.xsd	Specifies the values associated with parameters in a rule template, and generates the rules, alerts and reportlets based on the template definition.
createRuleTemplate.xsd	Creates a template of parameterized definitions of a set of rules, the alert used by the rules, and the reportlets associated with the alert.
ruleCommon.xsd	Contains common rule XSD definitions.

Events, context, cubes, and views	
Schema	Description
createConsolidatedEventView.xsd	Creates a consolidated event view based on an existing event stream and one or more additional event streams or views.
createContext.xsd	Creates a context object based on an existing source.
createCube.xsd	Creates a cube object.
createDimension.xsd	Creates a cube dimension
createEventStream.xsd	Creates an event (stream) object based on an existing source.
createView.xsd	Creates a view object based on an existing source table (event stream) and other, optional (joined) tables (event or context).
createViewPersistence.xsd	Creates a view persistence definition.
ffsourceType.xsd	A flat-file event object.
jdbcSource.xsd	A JDBC context object.
messageSource.xsd	A message object passed from an agent to an event or context, used by JMS, TIBCO RV, log4j, and HTTP.
queryCube.xsd	Issues a query on a cube against measures in dimensions.
queryInformation.xsd	Contains the elements of a query (SELECT statement).
sourceDefinition.xsd	Source types (agent types) supported by the system.
sourceDefinition.xsd	Contains common source definitions for event and context object XSD definitions.
tableDefinition.xsd	Supports event source definition.
webServiceSource.xsd	A Web Service event object.

Scenarios and business activities	
Schema	Description
createBusinessActivity.xsd	Creates a business activity object.
createScenario.xsd	Creates a scenario object in an existing business view and linked to an existing view.

Agents	
Schema	Description
FFConnection.xsd	A flat-file agent.
jdbcConnection.xsd	A JDBC agent.
JMSTopicConnection.xsd	A JMS agent.
log4jConnection.xsd	A log4j messaging agent (used internally for logging).
procSource.xsd	Stored procedure definitions.
RVConnection.xsd	A TIBCO RV agent.
SOAPConnection.xsd	A Web Service connection.
xmlBuffer.xsd	An XML buffer, holds part of a message.

System administration	
Schema	Description
propertyTypeDefinition.xsd	Describes a system property.
setLogLevel.xsd	Sets the logging level in a system logger (logging module).
setProperty.xsd	Command to set a system property.
systemCommand.xsd	Performs a checkpoint, shutdown, or restart.

Object management	
Schema	Description
createKeyRelationship.xsd	Creates a relationship between two objects.
disableObject.xsd	Disables an object.
dropObject.xsd	Deletes an object
enableObject.xsd	Enables an object.
setObjectRelation.xsd	Relates two objects.

Miscellaneous files	
Schema	Description
commandBatch.xsd	Defines multiple objects to be loaded (defined) in batch. All definitions must be valid or no objects are defined.
common.xsd	Contains common XSD definitions used by most XSD schemas.
createJar.xsd	Creates a JAR object.
createUDF.xsd	Creates a UDF object.
invokeExternalAction.xsd	Describes an external action message sent to a Web service. For more information about this file, see “Web service external processes” on page 313 .
jarManifest.xsd	Defines the manifest in a JAR.
performImportExport.xsd	Command to the system to perform an import or export
schedule.xsd	Contains common schedule and schedule interval definitions used by XSD definitions.

Glossary

business data modeling

A technique for describing the events, context, views, and rules that depict how your business functions.

cascade

A operation that propagates the exact same operation to all dependant objects.

consolidated event

An event table that captures events from different, but similar event sources and combines them into a single event stream. See [Working with consolidated events](#) for details.

current view

A snapshot of the data currently in a view. For a stateful view, the snapshot shows all rows in the view. For a stateless view, it shows all the rows corresponding to the last event, and might be an empty set. See [“View initialization” on page 299](#) for details.

delivery profile

Specifies where and how to deliver alerts and data feeds to the user. See [“Delivery Profiles tab” on page 284](#) for details.

enabled

An object that is accepting new data and is processing them. All objects are created *enabled*. See [“Object status” on page 207](#) for details.

disabled

An object that is not accepting new data. Disabling an object does not affect the definition or existence of that object; rather, it just keeps new data from flowing into the object and to all objects that rely on the target object. See [“Object status” on page 207](#) for details.

inner join

A join where the rows in the resulting view are the rows from the first table or view that meet the specified criteria, combined with the corresponding rows from the second view that meet the specified criteria. Inner joins are sometimes called *equi-joins*.

invalid

An object that has a reference to another object which cannot be satisfied. A reference can be invalid because an object does not exist or because some attribute of an object does not match the requirements of the dependent (such as a data type mismatch), not because the dependent is disabled. Note that all objects that depend on an invalid object are also invalid. See [“Object status” on page 207](#) for details.

invalid and disabled

An object that is both disabled and invalid; it cannot receive data and it has no state. See [“Object status” on page 207](#) for details.

metrics

Measurements taken over time that monitor, assess, and communicate vital information about the results of a program or activity. See [Understanding active reports](#) for details.

moving set function

A function that performs calculations on a set of the *latest rows* in a view. The set of rows to include is determined only when a new event arrives. For more information, see [“Moving set” on page 91](#).

outer join

A join where the rows in the result table are the rows that would have resulted from an inner join and the rows from the first table (LEFT OUTER JOIN) or the second table (RIGHT OUTER JOIN) that had no matches in the other table.

query window

Specifies a set of rows that are used in calculations with respect to the current row (event) under examination. The calculation may be for computing a moving set function, a join, or expiring rows from a view. See [“Query Windows” on page 228](#) for details.

rank function

A function that computes the scalar result for each value in a set, with respect to the entire set. A rank function may only be used in the selection list of a SELECT statement. For more information, see [“Rank” on page 91](#).

recent view

A snapshot of the last non-empty current view. A recent view is what appears in the FileNet BAM Workbench when editing an object that displays view results. See [“View initialization” on page 299](#) for details.

scenarios

Test business data models for expected or possible outcomes, and to identify exceptional business conditions. See [“Scenarios” on page 261](#) for detailed information.

scalar expression

An expression without a set function.

scalar function

A function operates within the bounds of a single event and provides a single result for each row, such as the absolute value of a number or concatenation of two strings. These functions may appear in any C-SQL expression. For more information, see [“Scalar” on page 90](#).

set function

A function performs calculations on a column in a set of rows in a view, such as the average value of the cost of some similar product orders. A set function may only be used in the selection list of a SELECT statement. For more information, see [“Set” on page 91](#).

snapshot view

A view that is a replica of a view at the time the query executed; constructed with `SELECT *`. Note that the view might not reflect those events which have arrived in the system but which have not yet been processed at the time of the query.

stateful view

A view that contains the results of aggregations derived from past events in a single row. A view is stateful if it contains an set function or moving set function in the `SELECT` clause, or contains a `GROUP BY` clause (in which case there is one row for each group), or is derived from a stateful view. See [“Stateless and stateful views” on page 298](#) for details.

stateless view

A view that is not a stateful view. See [“Stateless and stateful views” on page 298](#) for details.

terminal set function

a set function that has only scalar arguments.

terminal rank function

A rank function that has only scalar arguments.

tumbling set function

A function that performs calculations on a windowed set of the rows in a view. The set of rows to include is determined when a new event arrives, and the set empties when full. For more information, see [“Tumbling Windows” on page 242](#).

user-defined functions

(UDFs) provide a mechanism for extending C-SQL by defining and your own functions for use in formulas, including queries, field expressions, and rules. See [“User-Defined Functions” on page 288](#) for detailed information.

virtual table

A table or view where the rows are derived as they are required in memory.

window

See query window.
