Summary of changes

This revision reflects changes for SUSE Linux Enterprise Server 11 SP2.

Updates for SUSE Linux Enterprise Server 11 SP2

This revision (SC34-2598-01) contains changes related to SUSE Linux Enterprise Server 11 SP2.

New Information

- A new keyword, DELAY_MINUTES, has been introduced for the dumpconf configuration file to prevent potential panic-IPL-loops when using ON_PANIC with reipl and dump_reipl. See "Keywords for the configuration file" on page 39.
- Using the makedumpfile tool, to reduce the size of dump files to be transmitted for problem determination. See Chapter 7, “Handling large dumps,” on page 19.
- Using the snipl command, you can now remotely dump to SCSI disk. See "Triggering a dump remotely" on page 31.
- Support for installing the DASD or SCSI dump tool using Novell Yast has been added. See Appendix E, “Installing the DASD or SCSI dump tool with Novell Yast,” on page 45.

Changed Information

- The zgetdump command has been changed to support new options for mounting and unmounting a dump file and to export a dump in ELF format.

This revision also includes maintenance and editorial changes.

Deleted Information

- The support for multivolume tape dumps has been removed.
About this document

This book describes tools for obtaining dumps of Linux for IBM® System z® instances running SUSE Linux Enterprise Server 11 SP2. This book describes how to use DASD, tape, and SCSI dump devices, as well as how to use VMDUMP.

Unless stated otherwise, all z/VM® related information in this document assumes a current z/VM version, see [www.ibm.com/vm/techinfo/](http://www.ibm.com/vm/techinfo/).

In this document, System z is taken to include all IBM mainframe systems supported by SUSE Linux Enterprise Server 11 SP2 for System z.

Other relevant Linux on IBM System z publications

Several Linux on IBM System z publications for SUSE Linux Enterprise Server 11 SP2 are available on developerWorks.

You can find the latest versions of these publications at [www.ibm.com/developerworks/linux/linux390/documentation_novell_suse.html](http://www.ibm.com/developerworks/linux/linux390/documentation_novell_suse.html).

- Device Drivers, Features, and Commands on SUSE Linux Enterprise Server 11 SP2, SC34-2595
- Kernel Messages on SUSE Linux Enterprise Server 11 SP2, SC34-2600

For each of the following documents, the same web page points to the version that most closely reflects SUSE Linux Enterprise Server 11 SP2:

- How to use FC-attached SCSI devices with Linux on System z, SC33-8413
- How to Improve Performance with PAV, SC33-8414
- How to use Execute-In-Place Technology with Linux on z/VM, SC34-2594
- How to Set up a Terminal Server Environment on z/VM, SC34-2596
- libica Programmer's Reference, SC34-2602
Chapter 1. Introduction

Different tools can be used for obtaining dumps of Linux on IBM System z instances running SUSE Linux Enterprise Server 11 SP2. This chapter gives an overview of those tools.

You can use the dump analysis tool crash to analyze a dump. Depending on your service contract, you might also want to send a dump to IBM support to be analyzed.

Table 1 summarizes the available dump tools:

</tbody>
</table>

Note:
1. As of z/VM 5.4.
2. ECKD model 27, for example, provides 27 GB.
3. SCSI disks can be emulated as FBA disks. This dump method can, therefore, be used for SCSI-only z/VM installations.
4. IBM TotalStorage Enterprise Tape System 3592, 3590 and IBM 3490 Magnetic Tape Subsystem offer hardware compression.
5. The dump process kills a running operating system.

Note on device nodes

In all examples, the traditional device nodes for DASD, tape, and SCSI devices are used. You can also use the device nodes that udev creates for you.

Stand-alone tools

Four stand-alone dump tools are shipped in the s390-tools package as part of the zipl package:
- DASD dump tool for dumps on a single DASD device
- Multi-volume DASD dump tool for dumps on a set of ECKD DASD devices
- Tape dump tool for dumps on (channel-attached) tape devices
- SCSI disk dump tool for dumps on SCSI disks

You need to install these tools on the dump device. The dump device is the device you want to use for dumping the memory.

Typically, the system operator initiates a dump after a system crash, but you can initiate a dump at any time. To initiate a dump, you must IPL the dump device. This is destructive, that is, the running Linux operating system is killed. The IPL process writes the system memory to the IPL device (DASD and tape) or directly to a file on a SCSI disk.

You can configure a dump device that is automatically used when a kernel panic occurs. For more information, see "The dumpconf service" on page 39.

For more information on \texttt{zipl}, refer to the \texttt{zipl} man page and to the \texttt{zipl} description in \textit{Device Drivers, Features, and Commands on SUSE Linux Enterprise Server 11 SP2}, SC34-2595. You can find the latest version of this document on developerWorks at:

\url{www.ibm.com/developerworks/linux/linux390/documentation_novell_suse.html}

\section*{VMDUMP}

The VMDUMP tool is a part of z/VM and does not need to be installed separately. Dumping with VMDUMP is not destructive. If you dump an operating Linux instance, the instance continues running after the dump is completed.

VMDUMP can also create dumps for z/VM guests that use z/VM named saved systems (NSS).

Do not use VMDUMP to dump large z/VM guests; the dump process is very slow. Dumping 1 GB of storage can take up to 15 minutes depending on the used storage server and z/VM version.

For more information on VMDUMP see \textit{z/VM CP Commands and Utilities Reference}, SC24-6175.
Chapter 2. Using a DASD dump device

This chapter provides information on how to install the stand-alone DASD dump tool, how to use Novell Yast to perform the installation, how to perform the dump process, and how to copy the dump to a file in a Linux file system.

DASD dumps are written directly to a DASD partition that has not been formatted with a file system. The following DASD types are supported:

- ECKD DASDs
  - 3380
  - 3390
- FBA DASDs

Installing the DASD dump tool

Requirement: You need an unused DASD partition with enough space (memory size + 10 MB) to hold the system memory. If the system memory exceeds the capacity of a single DASD partition, you should use the multivolume dump tool, see Chapter 3, “Using DASD devices for multivolume dump,” on page 5.

This section describes how to install the DASD dump tool on an unused DASD partition. Dumps are written to this partition.

The examples in this section assume that /dev/dasdc is the dump device and that we want to dump to the first partition /dev/dasdc1.

The steps you need to perform for installing the DASD dump tool depend on your type of DASD, ECKD or FBA:

- If you are using an ECKD-type DASD, perform all three of the following steps:
- If you are using an FBA-type DASD, skip steps 1 and 2 and perform step 3 only:

1. Format your DASD with dasdfmt (ECKD only). A block size of 4 KB is recommended:

   Example:
   ```
   # dasdfmt -f /dev/dasdc -b 4096
   ```

2. Create a partition with fdasd (ECKD only). The partition must be sufficiently large (the memory size + 10 MB):

   Example:
   ```
   # fdasd /dev/dasdc
   ```

3. Install the dump tool using the zipl command. Specify the dump device on the command line:

   Example:
   ```
   # zipl -d /dev/dasdc1
   ```

Note: When using an ECKD-type DASD formatted with the traditional Linux disk layout ldl, the dump tool must be reinstalled using zipl after each dump.
### Initiating a DASD dump

To obtain a dump with the DASD dump tool, perform the following main steps:

1. Stop all CPUs.
2. Store status on the IPL CPU.
3. IPL the dump tool on the IPL CPU.

**Note:** Do not clear storage!

The dump process can take several minutes depending on the device type you are using and the amount of system memory. After the dump has completed, the IPL CPU should go into disabled wait.

The following PSW indicates that the dump process has completed successfully:

```
(64-bit) PSW: 00020000 80000000 00000000 00000000
```

Any other disabled wait PSW indicates an error.

After the dump tool is IPLed, messages that indicate the progress of the dump are written to the console:

```
Dumping 64 bit OS
00000032 / 00000256 MB
00000064 / 00000256 MB
00000096 / 00000256 MB
00000128 / 00000256 MB
00000160 / 00000256 MB
00000192 / 00000256 MB
00000224 / 00000256 MB
00000256 / 00000256 MB
Dump successful
```

4. You can IPL Linux again.

See [Appendix A, “Examples for initiating dumps,” on page 27](#) for more details.

### Copying the dump from DASD with zgetdump

This section describes how to copy a DASD dump to a file system using the `zgetdump` tool.

By default, the `zgetdump` tool takes the dump device as input and writes its contents to standard output. To write the dump to a file system, you must redirect the output to a file.

Assuming that the dump is on DASD device `/dev/dasdc1` and you want to copy it to a file named `dump_file`:

```
# zgetdump /dev/dasdc1 > dump_file
```

You can also use `zgetdump` to display information about the dump. See [Checking whether a DASD dump is valid and printing the dump header](#) for an example.

For general information about `zgetdump`, see [The zgetdump tool](#) or the man page.
Chapter 3. Using DASD devices for multivolume dump

This chapter describes how to prepare a set of ECKD DASD devices for a multivolume dump, how to install the stand-alone dump tool on each DASD device involved, how to perform the dump process, and how to copy the dump to a file in a Linux file system.

You can specify up to 32 partitions on ECKD DASD volumes for a multivolume dump. The dump tool is installed on each volume involved. The volumes must:

- Be in subchannel set 0.
- Be formatted with the compatible disk layout (cdl, the default option when using the `dasdfmt` command.)

You can use any block size, even mixed block sizes. However, to speed up the dump process and to reduce wasted disk space, use block size 4096.

For example, Figure 1 shows three DASD volumes, dasdb, dasdc, and dasdd, with four partitions selected to contain the dump. To earmark the partition for dump, a dump signature is written to each partition.

![Diagram of DASD volumes with partitions](image)

Figure 1. Three DASD volumes with four partitions for a multi-volume dump

The partitions need to be listed in a configuration file, for example:

```plaintext
/dev/dasdb2
/dev/dasdb1
/dev/dasdb3
/dev/dasdc1
/dev/dasdc2
/dev/dasdd1
/dev/dasdd2
/dev/dasdd3
```

You can define a maximum of three partitions on one DASD. All three volumes are prepared for IPL; regardless of which you use the result is the same.

The following sections will take you through the entire process of creating a multi-volume dump.
Installing the multivolume DASD dump tool

This example shows how to perform the dump process on two partitions, /dev/dasdc1 and /dev/dasdd1, which reside on ECKD volumes /dev/dasdc and /dev/dasdd.

Assume that the corresponding bus IDs (as displayed by lsdasd) are 0.0.4711 and 0.0.4712, so the respective device numbers are 4711 and 4712.

1. Format both dump volumes with dasdfmt. Specify cdl (compatible disk layout), which is the default. Preferably, use a block size of 4 KB:

```
# dasdfmt -f /dev/dasdc -b 4096
# dasdfmt -f /dev/dasdd -b 4096
```

2. Create the partitions with fdasd. The sum of the partition sizes must be sufficiently large (the memory size + 10 MB):

```
# fdasd /dev/dasdc
# fdasd /dev/dasdd
```

3. Create a file named mvdump.conf containing the device nodes of the two partitions, separated by one or more line feed characters (0x0a). The file's contents are as follows:

```
/dev/dasdc1
/dev/dasdd1
```

4. Prepare the volumes using the zipl command. Specify the dump list on the command line.

Command line example:

```
# zipl -M mvdump.conf
Dump target: 2 partitions with a total size of 1234 MB.
Warning: All information on the following partitions will be lost!
/dev/dasdc1
/dev/dasdd1
Do you want to continue creating multi-volume dump partitions (y/n)?
```

Now the two volumes /dev/dasdc and /dev/dasdd with device numbers 4711 and 4712 are prepared for a multivolume dump. Use the -device option of zgetdump to display information about these volumes:

```
# zgetdump -d /dev/dasdc
Dump device info:
   Dump tool..........: Multi-volume DASD dump tool
   Version...........: 2
   Architecture......: s390x (64 bit)
   Dump size limit...: none
   Force specified...: no

   Volume 0: 0.0.4711 (online/valid)
   Volume 1: 0.0.4712 (online/valid)
```

During zipl processing both partitions were earmarked for dump with a valid dump signature. The dump signature ceases to be valid when data other than dump data is written to the partition. For example, writing a file system to the partition overwrites the dump signature. Before writing memory to a partition the dump tool checks the partition's signature and exits if the signature is invalid. Thus any data inadvertently written to the partition is protected.
You can circumvent this protection, for example, if you want to use a swap space partition for dumping, by using the `zipl --force` option. The force option inhibits the dump signature check, and any data on the device is overwritten. Exercise great caution when using the force option!

The `zipl` command also takes a size specification, see Appendix B, “Obtaining a dump with limited size,” on page 33. For more details on `zipl`, see the description of the `zipl` command in Device Drivers, Features, and Commands on SUSE Linux Enterprise Server 11 SP2, SC34-2595.

---

## Initiating a multivolume DASD dump

To obtain a dump with the multivolume DASD dump tool, perform the following main steps:

1. Stop all CPUs.
2. Store status on the IPL CPU.
3. IPL the dump tool using one of the prepared volumes, either 4711 or 4712.

   **Note:** Do not clear storage!

   The dump process can take several minutes depending on each volume’s block size and the amount of system memory. After the dump has completed, the IPL CPU should go into disabled wait.

   The following PSW indicates that the dump process has completed successfully:

   ```
   (64-bit) PSW: 00020000 80000000 00000000 00000000
   ```

   Any other disabled wait PSW indicates an error.

   After the dump tool is IPLed, messages that indicate the progress of the dump are written to the console:

   ```
   Dumping 64 bit OS
   Dumping to: 4711
   00000128 / 00001024 MB
   00000256 / 00001024 MB
   00000384 / 00001024 MB
   00000512 / 00001024 MB
   Dumping to: 4712
   00000640 / 00001024 MB
   00000768 / 00001024 MB
   00000896 / 00001024 MB
   00001024 / 00001024 MB
   Dump successful
   ```

4. You can IPL Linux again.

---

## Copying a multivolume dump to a file

At this point the two volumes `/dev/dasdc` and `/dev/dasdd` (with device numbers 4711 and 4712) contain the dump. Dump data is spread along partitions `/dev/dasdc1` and `/dev/dasdd1`.

Use `zgetdump` without any options to copy the dump parts to a file:
# zgetdump /dev/dasdc > multi_volume_dump_file

Format Info:
Source: s390mv
Target: s390

Copying dump:
00000000 / 00001024 MB
00000171 / 00001024 MB
00000341 / 00001024 MB
00000512 / 00001024 MB
00000683 / 00001024 MB
00000853 / 00001024 MB
00001024 / 00001024 MB

Success: Dump has been copied

If you want to only check the validity of the multivolume dump rather than copying it to a file use the -info option with zgetdump. See "Checking whether a DASD dump is valid and printing the dump header" on page 38 for an example.
Chapter 4. Using a tape dump device

This chapter provides information on how to install the stand-alone tape dump tool, how to perform the dump process, and how to copy the dump to a file in a Linux file system.

The following tape devices are supported:

- 3480
- 3490
- 3590
- 3592

Installing the tape dump tool

Requirement: Have enough empty tapes ready to hold the system memory (memory size + 10 MB).

The examples in this section assume that /dev/ntibm0 is the tape device you want to dump to.

Perform these steps to install the tape dump tool:
1. Insert an empty dump cartridge into your tape device.
2. Ensure that the tape is rewound.
3. Install the dump tool using the zipl command. You can specify the dump device on the command line.

Command line example:

```
# zipl -d /dev/ntibm0
```

Initiating a tape dump

To obtain a dump with the tape dump tool, perform the following main steps:
1. Ensure that the tape is rewound.
2. Stop all CPUs.
3. Store status on the IPL CPU.
4. IPL the dump tool on the IPL CPU.

Note: Do not clear storage!

The dump tool writes the number of dumped MB to the tape drive message display.

The dump process can take several minutes, depending on the device type that you are using and the amount of system memory available. When the dump is complete, the message dump=end is displayed and the IPL CPU should go into disabled wait.

The following PSW indicates that the dump was taken successfully:

(64-bit) PSW: 00020000 80000000 00000000 00000000

Any other disabled wait PSW indicates an error.

After the dump tool is IPLed, messages that indicate the progress of the dump are written to the console:
Dumping 64 bit OS
00000032 / 00000256 MB
00000064 / 00000256 MB
00000096 / 00000256 MB
00000128 / 00000256 MB
00000160 / 00000256 MB
00000192 / 00000256 MB
00000224 / 00000256 MB
00000256 / 00000256 MB
Dump successful

5. You can IPL Linux again.

See Appendix A, “Examples for initiating dumps,” on page 27 for more details.

Tape display messages

<table>
<thead>
<tr>
<th>number</th>
<th>The number of MB dumped.</th>

</thead>
<tbody>
<tr>
<td>dump*end</td>
<td>The dump process ended successfully.</td>
</tr>
</tbody>
</table>

Copying the dump from tape

This section describes how to copy a tape dump to a file system using the zgetdump tool.

Prerequisite: You must have installed the mt utility.

Preparing the dump tape

You need to rewind the tape, and find the correct position on the tape to start copying from. Use the mt tool to do this.

1. Rewind the tape.
   
   **Example:**
   ```
   # mt -f /dev/ntibm0 rewind
   ```

2. Skip the first file on the tape (this is the dump tool itself).
   
   **Example:**
   ```
   # mt -f /dev/ntibm0 fsf
   ```

Using the zgetdump tool

By default, the zgetdump tool takes the dump device as input and writes its contents to standard output. To write the dump to a file system you must redirect the output to a file.

**Example:** Assuming that the tape is in the correct position (see “Preparing the dump tape”) and is on tape device /dev/ntibm0, use the following command to copy the dump from tape to a file dump_file in the file system:

```
# zgetdump /dev/ntibm0 > dump_file
```

For general information on zgetdump, see “The zgetdump tool” on page 35 or the man page.
Checking whether a dump is valid, and printing the dump header

To check whether a dump is valid, use the -i option.

1. Ensure that the volume is loaded.
2. Skip the first file on the first tape (this is the dump tool itself):

   ```
   # mt -f /dev/ntibm0 fsf
   ```

3. Issue:

   ```
   # zgetdump -i /dev/ntibm0
   ```

   **zgetdump** goes through the dump until it reaches the end. See also "Using zgetdump to copy a tape dump" on page 37.
Chapter 5. Using a SCSI dump device

You can use SCSI disks that are accessed through the zfcp device driver as dump devices. SCSI disk dumps are written as files in an existing file system on the dump partition. No copying is necessary.

This section describes how to install the SCSI dump tool and how to initiate a SCSI dump.

Installing the SCSI disk dump tool

Requirement: The dump directory needs enough free space (memory size + 10 MB) to hold the system memory.

The SCSI dump tool (also referred to as the SCSI Linux System Dumper, or SD) is written to one partition, referred to here as the target partition. The dump can be written to a second partition, the dump partition, provided it is on the same physical disk. Only the target partition need be mounted when zipl is run. In a single-partition configuration, the target partition is also the dump partition.

SCSI dump tool parameters

When installing the SCSI disk dump tool, the following parameters can be specified using the -P option in the zipl command line.

**dump_dir=/<directory>**
Path to the directory (relative to the root of the dump partition) to which the dump file is to be written. This directory is specified with a leading slash. The directory must exist when the dump is initiated.

Example: If the dump partition is mounted as /dumps, and the parameter dump_dir=/mydumps is defined, the dump directory would be accessed as /dumps/mydumps.

The default is / (the root directory of the partition).

**dump_compress=gzip | none**
Dump compression option. Compression can be time-consuming on slower systems with a large amount of memory.

The default is none.

**dump_mode=interactive | auto**
Action taken if there is no room on the file system for the new dump file. interactive prompts the user to confirm that the dump with the lowest number is to be deleted. auto automatically deletes this file.

The default is interactive.

In rare cases, you might want to complement or overwrite the SCSI dump tool parameters that have been configured with zipl. For example, you might want to change the compression setting when you initiate the dump. How you specify such parameters depends on whether your Linux instance runs in LPAR mode or as a z/VM guest. For more information, see the SCSI examples in Appendix A, “Examples for initiating dumps,” on page 27.
Example: Combined dump and target partition

This example assumes that /dev/sda is a SCSI device that contains no data and is to be used exclusively as a dump device. Because no other data is to be stored on the device, a single partition is created that serves as both dump and target partition. The example also shows how to use the dump_compress parameter to generate the dump in gzip format.

1. Create a single partition with fdisk, using the PC-BIOS layout:

   Example:
   
   ```
   # fdisk /dev/sda
   ```

   The created partition is /dev/sda1.

2. Format this partition with either the ext2 or ext3 file system.

   Example:
   
   ```
   # mke2fs -j /dev/sda1
   ```

3. Mount the partition at a mount point of your choice and create a subdirectory to hold the dump files.

   Example:
   
   ```
   # mount /dev/sda1 /dumps
   # mkdir /dumps/mydumps
   ```

4. Install the dump tool using the zipl command. Specify the dump device on the command line:

   Example:
   
   ```
   # zipl -D /dev/sda1 -t /dumps -P "dump_dir=/mydumps"
   ```

5. Unmount the file system:

   ```
   # umount /dumps
   ```

When you IPL /dev/sda1 using boot program selector 1 or 0 (default), the dump is written to directory mydumps on partition 1 of /dev/sda. The boot program selector is located on the load panel, see Figure 4 on page 31 for an example.

Initiating a SCSI dump

To initiate the dump, IPL the dump tool using the SCSI dump load type. See Appendix A, “Examples for initiating dumps,” on page 27.

The dump process can take several minutes depending on the device type you are using and the amount of system memory. The dump progress and any error messages are reported on the operating system messages console.

The dump process creates a new dump file in the dump directory. All dumps are named dump.<n> where <n> is the dump number. A new dump receives the next highest dump number out of all dumps in the dump directory (see the dump_dir parameter under "SCSI dump tool parameters" on page 13).
Example: If there are already two dump files, “dump.0” and “dump.1”, in the dump directory, the new dump will be “dump.2”.

When the dump completes successfully, you can IPL Linux again.

See Appendix A, “Examples for initiating dumps,” on page 27 for more details.

You do not need to convert the dump or copy it to a different medium. To access the dumps, mount the dump partition.

Printing the dump header

To print the dump file header, use `zgetdump` with the `-i` option:

```
# zgetdump -i dump.0
General dump info:
  Dump format........: lkcd
  Version............: 8
  System arch........: s390x (64 bit)
  CPU count (online): 2
  CPU count (real)...: 2
  Dump memory range..: 1024 MB
  Memory map: 0000000000000000 -000000003fffffff (1024 MB)
```
Chapter 6. Using VMDUMP

Do not use VMDUMP to dump large z/VM guests; the dump process is very slow. Dumping 1 GB of storage can take up to 15 minutes depending on the used storage server and z/VM version.

This section describes how to create a dump with VMDUMP, how to transfer the dump to Linux, and how to convert the z/VM dump to a convenient format.

VMDUMP does not need to be installed separately.

Initiating a dump with VMDUMP

Issue the following command from the 3270 console of the z/VM guest virtual machine:

```
#CP VMDUMP
```

Result: z/VM CP temporarily stops the z/VM guest virtual machine and creates a dump file. The dump file is stored in the reader of the z/VM guest virtual machine. After the dump is complete, the Linux on z/VM instance continues operating.

You can use the “TO” option of the VMDUMP command to direct the dump to another guest virtual machine of the same z/VM system.

Example: To write the dump to the reader of z/VM guest virtual machine “linux02”, issue this command:

```
#CP VMDUMP TO LINUX02
```

For more information on VMDUMP refer to z/VM CP Commands and Utilities Reference, SC24-6175.

Copying the dump to Linux

You can use the vmur command under Linux or the DUMPLOAD command under CMS to copy the dump file.

Using the vmur command

1. Find the spool ID of the VMDUMP spool file in the output of the vmur li command:

````
# vmur li

ORIGINID FILE CLASS RECORDS CPY HOLD DATE TIME NAME TYPE DIST
T6360025 0463 V DMP 00020222 001 NONE 06/11 15:07:42 VMDUMP FILE T6360025
```

In the example above the required VMDUMP file spool ID is 463.

2. Copy the dump into your Linux file system using the vmur receive command. To convert the dump into a format that can be processed with the Linux dump analysis tool crash, convert the dump using the --convert option:
The created file, myvmdump, can then be used as input to crash.

**Using the DUMPLOAD command**

Alternatively you can use the DUMPLOAD command under CMS to access the dump. The DUMPLOAD command copies the dump from the z/VM reader to the CMS file system.

From the CMS file system, you can then transfer the dump to a Linux file system, for example with ftp.
Chapter 7. Handling large dumps

This topic describes how to handle dumps that are especially large (greater than 10 GB in size).

About this task

Large dumps present a challenge as they will:
- Take up a large amount of disk space
- Take a long time dumping
- Use considerable network bandwidth when being sent to the service organization.

Note: Sometimes you can recreate the problem on a test system with less memory, which makes the dump handling much easier. Take this option into account before creating a large dump.

Procedure

Complete these steps to prepare and process a large dump.

1. Choose a dump device. If you want to dump a system with a large memory footprint, you have to prepare a dump device that is large enough. You can use the following dump devices for large dumps:
   - **Single-volume DASD**
     - 3390 model 9 (up to 45 GB)
     - 3390 model A (up to 180 GB)
   - **Multivolume DASD**
     - Up to 32 DASDs are possible.
     - 32 x 3390 model 9 (up to 1.4 TB)
     - 32 x 3390 model A (up to 5.7 TB)
   - **z/VM FBA emulated SCSI dump disk**
     FBA disks can be defined with the CP command SET EDEVICE. These disks can be used as single-volume DASD dump disks. The SCSI disk size depends on your storage server setup.
   - **SCSI dump**
     The SCSI disk size depends on your storage server setup. The ext2 and ext3 file system dump size limit with block size 4 KB is 2 TB. For the ext4 file system, the limit is 16 TB.

     Note: SCSI dump compression (the dump_compress option) creates smaller dumps, but due to CPU consumption it slows down the dump speed significantly. Therefore, use this option on large systems only if dump speed is not important for your scenario.
   - **Dump on 3592 channel-attached tape drive**
     Cartridges with up to 300 GB capacity.

     Do not use VMDUMP for large systems, because this dump method is very slow.

2. Estimate the dump time. The dump speed depends on your environment, for example your SAN setup and your storage server. With a dump speed of
approximately 100 MB per second on DASDs or SCSI disks, and a system with 50 GB memory, the dump takes approximately 8 minutes. Do a test dump on your system to determine the dump speed for it. Then you will have an indication of how long a dump will take in case of emergency.

3. Send the dump. For transferring dumps in a short amount of time to a service organization, it is often useful to reduce the dump size or split the dump into several parts for easier and faster transmission. In this step, two different mechanisms: 'Use makedumpfile' and 'Use gzip and split' are described. Choose one of these methods.

a. Use makedumpfile

The makedumpfile tool can be used to compress s390 dumps and exclude memory pages that are not needed for analysis. Compression substantially reduces the size of dump files and the amount of time needed to transmit them from one location to another. For SUSE Linux Enterprise Server 11, the makedumpfile tool is included in the makedumpfile RPM that you can install with Yast. Because makedumpfile expects as input dump files in ELF format, you first have to transform your s390 format dump to ELF format. The transform is best done by mounting the dump with the zgetdump command.

1) Mount the dump in ELF format by performing one of these steps:

- To mount a DASD dump from the partition /dev/dasdb1 to /mnt
  
  ```
  # zgetdump -m -f elf /dev/dasdb1 /mnt
  ```

- To mount a SCSI dump from file dump.0 to /mnt
  
  ```
  # zgetdump -m -f elf dump.0 /mnt
  ```

2) After mounting the dump in ELF format with zgetdump, the dump is available in the file named /mnt/dump.elf. In order to use makedumpfile with dump level greater than one, you also need the vmlinux file that contains necessary debug information. You find this file in the kernel debuginfo RPM. To find the location of the vmlinux file in the debuginfo RPM, issue the following commands. The xx in the example must be replaced by the appropriate kernel version that caused the dump.

```
rpm -qlf kernel-default-debuginfo-3.0.xx-xx.s390x.rpm | grep vmlinux
```

3) To extract the vmlinux file to ./usr/lib/debug/boot/, issue the following command:

```
# rpm2cpio kernel-default-debuginfo-3.0.4-0.11.1.s390x.rpm | cpio -idv | vmlinux
```

4) Use the -d (dump level) option of makedumpfile to specify which pages to exclude from the dump. See the man page for makedumpfile for a description of the dump level and other options of makedumpfile.

This example compresses the dump file named /mnt/dump.elf (-c option) and excludes pages that are typically not needed to analyze a kernel problem. Excluded pages are: pages containing only zeroes, pages used to cache file contents (cache, cache private), pages belonging to user spaces processes, and free pages (maximum dump level 31):
5) The newly created file, named dump.kdump should be much smaller than the original file, named dump.elf. Until your kernel problem is resolved, it is recommended to keep the original dump file. If pages that had been excluded are needed for problem determination, you can obtain them from the original dump file by reducing the dump level.

6) For initial problem analysis, you can also extract the kernel log with `makedumpfile`, and send it to your service organization:

   ```bash
   # makedumpfile --dump-dmesg -x vmlinux /mnt/dump.elf kernel.log
   ```

7) After you have used `makedumpfile`, you can unmount the dump:

   ```bash
   # zgetdump -u /mnt
   ```

b. Use `gzip` and `split`

1) Compress the dump and split it into parts of 1 GB with the `gzip` and `split` commands.

   **For a DASD dump:**
   ```bash
   # zgetdump /dev/dasdd1 | gzip | split -b 1G
   ```

   **For a tape dump:**
   ```bash
   # mt -f /dev/ntibm0 rewind
   # mt -f /dev/ntibm0 fsf
   # zgetdump /dev/ntibm0 | gzip | split -b 1G
   ```

   **For a SCSI dump:**
   ```bash
   # cat /mnt/dump.0 | gzip | split -b 1G
   ```

   This command creates several compressed files in your current directory:
   ```bash
   # ls
   # xaa xab xac xad xae
   ```

2) Create md5 sums of parts:

   ```bash
   # md5sum * > dump.md5
   ```

3) Upload the parts together with the MD5 information to the service organization.

4) The receiver (the service organization) must do the following:

   a) Verify md5 sums:

      ```bash
      # cd dumpdir
      # md5sum -c dump.md5
      xaa: OK
      xab: OK
      ...
      ```

   b) Merge parts and uncompress the dump:
# cat x* | gunzip -c > dump
Chapter 8. Sharing dump devices

The ideal dump device setup is that each Linux instance has its own dump device. With this setup, every system can be dumped independently at any time, and the dump space is always sufficient. However, if you have many systems you might want to share dump devices due to economical considerations. This chapter describes how you can set up your system for sharing dump devices between Linux instances.

Serialization and device locking

If you share devices, some type of serialization is needed to prevent two systems from dumping at the same time, and thus corrupting the dumps. Either the involved operators must prevent concurrent dumps manually, or, in some cases, available system mechanisms can be used to prevent concurrent dumping.

It is possible in many cases to use a pool of devices for sharing. For the sake of simplicity, most of the following examples use only one dump device.

Possible serialization mechanisms:

External
Operators must find an external way to ensure serialization manually.

Link
Exclusive write for minidisk is used as a locking mechanism (see "Sharing DASD devices under z/VM" on page 24).

Attach
Attach and detach is used as locking mechanism (see "Using attach and detach as locking mechanism under z/VM" on page 24).

vmcmd
Use the vmcmd panic action (see "DASD (vmcmd panic action)" on page 25).

Alternatively, use no serialization and take the risk that dumps are overwritten, see "DASD (dump or dump_reipl panic action)" on page 25.

Table 2 shows the serialization methods available for different system configurations.

Table 2. Serialization of dump devices overview

<table>

<td>overwrite</td>
</tr>
</tbody>
</table>

Sharing devices when dumping manually

In the following sections, it is assumed that you start the dump process manually, without using automatic dump on panic.
Sharing DASD devices on LPARs

Configure your IOCDS so that all LPARs that want to share the dump device can access the DASD device. There is no system mechanism available for serialization. Exclusive access must be ensured manually by the involved system operators.

Sharing DASD devices under z/VM

Under z/VM, DASD devices can be shared if they are defined as sharable minidisks for a NOLOG user. Exclusive access can be guaranteed with the CP LINK command and the exclusive write mode option. With this mode, only one DASD can be linked to one z/VM guest virtual machine at the same time. Therefore, the dump device is excluded from other systems until it is detached.

To create a dump after a system crash, do the following:

1. To link the dump device, issue a command of the form:
   
   ```
   #cp link <disk owner> <vdev1> <vdev2> EW
   ```

   where
   - `<disk owner>` is the user ID in the system directory whose entry is to be searched for device `<vdev1>`.
   - `<vdev1>` is the virtual device number of the specified user.
   - `<vdev2>` is the virtual device number that is to be assigned to the device for your virtual machine configuration.

2. Create the dump with device `<vdev2>`

3. Reboot your Linux system.

4. On your Linux system, set dump device `<vdev2>` online.

5. On your Linux system, copy the dump with the zgetdump command.

6. On your Linux system, set dump device `<vdev2>` offline.

7. Detach the dump device:

   ```
   #cp detach <vdev2>
   ```

Afterwards, the dump DASD is free again and can be used by other systems.

Sharing SCSI devices

In order to share FCP attached SCSI disks for dump, they must be accessible through your SAN on all Linux systems that are to use the dump device. The involved operators must ensure manually that two dumps are not taking place at the same time. Otherwise, if multiple Linux systems write to the shared dump device at the same time, you may not only corrupt the dump file but also the file system on the dump device.

Using attach and detach as locking mechanism under z/VM

When the z/VM guest virtual machines that use the shared dump device have the permission to attach devices (that is, class B guest virtual machines), device attachment can also be used as a locking mechanism. Only one guest can attach a device at the same time. If you use one single FCP adapter for dumps on all systems, attach and detach can be used as locking mechanism for SCSI dump.
Sharing devices when dumping automatically

You can configure a dump to be taken automatically if a kernel panic occurs. The automatic dump on panic can be configured in `/etc/sysconfig/dumpconf` (see “The dumpconf service” on page 39).

DASD (dump or dump_reipl panic action)

Technically, it is possible to share DASD devices for automatic dump on panic. However, there is no serialization mechanism available, which means that if two systems are dumping at the same time, your dumps might be corrupted.

Normally, system crashes are rare, and therefore the chance of producing corrupted dumps is low. However, you must consider carefully if this risk is acceptable. Such a dump setup is a trade-off between reliability and resource expenses. You have to consider the likelihood of two concurrent system crashes and the business impact of losing a dump.

To share DASDs under z/VM, you must use minidisks linked in access mode multiple-write (MW) to all systems where you want to configure dump on panic.

DASD (vmcmd panic action)

With z/VM, when using the panic action `vmcmd` in `/etc/sysconfig/dumpconf`, it is possible to specify up to five CP commands that are executed in the event of a kernel panic. You can use this mechanism to implement locking through the exclusive link or attach method.

Example:

In this example, assume that we want to link either 4e1 or 4e2 as device number 5000 and then create the dump with device 5000. The first free DASD is linked. If both devices are already linked to other z/VM guest virtual machines, the system stops without creating a dump.

**Before you begin:** Define minidisks 4e1 and 4e2 with disk owner user `SHARDISK` and prepare them as dump DASDs.

The corresponding configuration for `/etc/sysconfig/dumpconf` looks like this output:

```
ON_PANIC=vmcmd
VMCMD_1="LINK SHARDISK 4E1 5000 EW"
VMCMD_2="LINK SHARDISK 4E2 5000 EW"
VMCMD_3="STORE STATUS"
VMCMD_4="IPL 5000"
```

After the dump process has finished, you must perform an IPL on the Linux system manually, copy the dump, and detach the disk 5000.

Compared to “DASD (dump or dump_reipl panic action),” this option has the advantage that you cannot get corrupted dumps, and you can use more than one dump device. It has the disadvantage that automatic re-IPL is not possible.

FCP-attached SCSI devices

For automatic dump on a FCP-attached SCSI device, device sharing should not be used. Otherwise, if multiple Linux systems write to the shared dump device at the same time, you might not only corrupt the dump file, but also the file system on the dump device.
Sharing dump devices between different versions of Linux

Do not share dump devices between Linux installations with different major releases. For example, do not share dump devices between SUSE Linux Enterprise Server 10 and SUSE Linux Enterprise Server 11.

You can share dump devices between Linux installations with different service levels. Prepare the dump device with the zipl tool from the lowest service level. For example, if you have systems with SUSE Linux Enterprise Server 11 SP1 and SP2, prepare your dump device with the zipl tool from the SP1 system. Newer tools such as zgetdump or dump analysis tools such as crash can always process dumps that have been created with older zipl versions. The other way around might work, but it is not guaranteed to work.

Sharing dump resources with VMDUMP

With z/VM, VMDUMP can be run concurrently on different guest virtual machines. The dump speed is slow, and therefore is best for very small systems. The shared resource here is the z/VM spool. You have to ensure that it has enough space to hold multiple VMDumpS.
Appendix A. Examples for initiating dumps

The following sections describe how to initiate a dump from different control points.

z/VM

The following examples assume the 64-bit mode. Corresponding 31-bit examples would have a different PSW but be the same otherwise.

Using DASD

If 193 is the dump device:

```
#cp cpu all stop
#cp store status
#cp i 193
```

On z/VM, a three-processor machine in this example, you will see messages about the disabled wait:

```
01: The virtual machine is placed in CP mode due to a SIGP stop from CPU 00.
02: The virtual machine is placed in CP mode due to a SIGP stop from CPU 00.
"CP entered; disabled wait PSW 00020000 80000000 00000000 00000000"
```

You can now IPL your Linux instance and resume operations.

Using tape

If 193 is the tape device:

```
#cp rewind 193
#cp cpu all stop
#cp store status
#cp i 193
```

On z/VM, a three-processor machine in this example, you will see messages about the disabled wait:

```
01: The virtual machine is placed in CP mode due to a SIGP stop from CPU 00.
02: The virtual machine is placed in CP mode due to a SIGP stop from CPU 00.
"CP entered; disabled wait PSW 00020000 80000000 00000000 00000000"
```

You can now IPL your Linux instance and resume operations.

Using SCSI

**Prerequisite:** SCSI dump from z/VM is supported as of z/VM 5.4.

Assume your SCSI dump disk has the following parameters:

- WWPN: 4712076300ce93a7
- LUN: 4712000000000000
- FCP adapter device number: 4711
- Boot program selector: 0

To initiate the dump process, follow these steps:
#cp set dumpdev portname 47120763 00ce93a7 lun 47120000 00000000 bootprog 0
#cp ipl 4711 dump

Messages on the operating system console will show when the dump process is finished.

You can now IPL your Linux instance and resume operations.

In rare cases, you might want to overwrite or complement the existing SCSI dump tools parameters that have been configured with `zpl`. For example, you might want to change the dump mode setting. You can use a command of this form to specify SCSI dump tools parameters to be concatenated to the existing parameters:

```bash
#cp set dumpdev scpdata '<parameters>'
```

Enter this command before entering the IPL command.

In contrast to SCSI IPL configurations, where you can use a leading equal sign to replace all kernel parameters you cannot use a leading equal sign to replace all SCSI dump tool parameters. Specifying the parameters with a leading equal sign causes the dump to fail.

**Using VMDUMP**

To initialize a dump with VMDUMP, issue this command from the 3270 console of your z/VM guest virtual machine:

```bash
#cp vmdump
```

Dumping does not force you to IPL. If the Linux instance ran as required before dumping, it will continue running when the dump is completed.

**HMC or SE**

You can initiate a dump process on an LPAR from an HMC (Hardware Management Console) or SE (Support Element). The following description refers to an HMC, but the steps also apply to an SE.

The steps are similar for DASD, tape, and SCSI. Differences are noted where applicable. You cannot initiate a dump with VMDUMP from the HMC or SE.

To initiate the dump:

1. In the left navigation pane of the HMC expand Systems Management and Servers and select the mainframe system you want to work with. A table of LPARs is displayed in the upper content area on the right.
2. Select the LPAR for which you want to initiate the dump.
3. In the Tasks area, expand Recovery. Proceed according to your dump device:
   - If you are dumping to DASD or tape, click Stop all in the Recovery list to stop all CPUs. Confirm when you are prompted to do so.
   - If you are dumping to a SCSI disk, skip this step and proceed with step 4 on page 29.
Figure 2 shows an example of an HMC with a selected mainframe system and LPAR. The **Load** and **Stop all** tasks can be seen in the expanded **Recovery** list.

**Figure 2. HMC with the **Load** and **Stop all** tasks**

4. Click **Load** in the **Recovery** list to display the Load panel.

   **For a dump to DASD or tape:**
   a. Select **Load type** “Normal”.
   b. Select the **Store status** check box.
   c. Type the device number of the dump device into the **Load address** field.

   **Figure 3 on page 30** shows a Load panel with all entries and selections required to start the dump process for a DASD or tape dump device.
For a dump to SCSI disk:

a. Select Load type "SCSI dump".

b. Type the device number of the FCP adapter for the SCSI disk into the Load address field.

c. Type the World Wide Port name of the SCSI disk into the World wide port name field.

d. Type the Logical Unit Number of the SCSI disk into the Logical unit number field.

e. Type the configuration number of the dump IPL configuration in the Boot program selector field.

The 'configuration number' defines the IPL or dump configuration which is to be IPLed. The numbering starts with 1 and is related to the menu of IPL/dump entries in the zipl configuration file for the SCSI disk.

Configuration number 0 specifies the default configuration. If you do not use a zipl menu, specify number 0 here.

f. Accept the defaults for the remaining fields.

In rare cases, you might want to overwrite or complement the existing SCSI dump tools parameters that have been configured with zipl. For example, you might want to change the dump mode setting. In the Operating system specific load parameters field, you can specify SCSI dump tools parameters to be concatenated to the existing parameters.

In contrast to SCSI IPL configurations, where you can use a leading equal sign to replace all kernel parameters you cannot use a leading equal sign to replace all SCSI dump tool parameters. Specifying the parameters with a leading equal sign causes the dump to fail.
Figure 4 shows a Load panel with all entries and selections required to start the SCSI dump process.

5. Click OK to start the dump process.
6. Wait until the dump process completes. Click the Operating System Messages icon for progress and error information.

When the dump has completed successfully, you can IPL Linux again.

**Triggering a dump remotely**

You can trigger HMC or SE activities remotely by using the **snipl** command. As of snipl version 2.1.9 the **snipl** command can be used for dump handling. The required setup for **snipl** usage and further details are described in *Device Drivers, Features, and Commands on SUSE Linux Enterprise Server 11 SP2, SC34-2595*.

You can dump to a DASD device or a SCSI device.

**Before you begin**

For example, assume that you have a **snipl** configuration file `/etc/snipl.conf` containing the following:

```
snipl

server=myse9.example.com
image=LPARLNX1
image=LPARLNX2

server=myse5.example.com
image=LPRLNX05
```

Further assume that you have prepared a dump DASD (in this example with device number 5199) with the **zipl** tool.
Procedure

Then use the following snipl commands to write a memory dump of LPARLNX1 to the prepared DASD:

1. Stop the CPUs:

```
# snipl LPARLNX1 --stop
Server myse9.example.com from config file /etc/snipl.conf is used
processing......
LPARLNX1: acknowledged.
```

2. IPL the dump tool on DASD 5199, prepared with the dump tool:

```
# snipl LPARLNX1 --load -A 5199 --storestatus
Server myse9.example.com from config file /etc/snipl.conf is used
processing......
LPARLNX1: acknowledged.
```

3. Monitor the dump progress:

```
# snipl LPARLNX1 --dialog
LPARLNX1: acknowledged.
Starting operating system messages interaction for
partition LPARLNX1 (Ctrl-D to abort):
00000128 / 00001024 MB
... 00000896 / 00001024 MB
00001024 / 00001024 MB
Dump successful
```

Example

The corresponding snipl command to write a memory dump to a SCSI disk with WWPN 500507630303c562, LUN 4010404900000000, and FCP adapter 5000 is:

```
# snipl LPRNLNX05 --scsidump -A 5000 --wwpn_scsiload 500507630303c562 --lun_scsiload 4010404900000000
Server myse5.example.com from config file /etc/snipl.conf is used
processing......
LPRNLNX05: acknowledged.
```
Appendix B. Obtaining a dump with limited size

The “mem” kernel parameter can make Linux use less memory than is available to it. A dump of a Linux system like this does not need to include the unused memory. You can use the `zipl` “size” option to limit the amount of memory that is dumped.

The “size” option is available for all `zipl` based dumps: DASD, tape, and SCSI, in command line mode or in configuration file mode. The “size” option is appended to the dump device specification, with a comma as separator.

The value is a decimal number that can optionally be suffixed with K for kilobytes, M for megabytes, or G for gigabytes. Values specified in byte or kilobyte are rounded to the next megabyte boundary.

Be sure not to limit the dump size below the amount of memory actually used by the system to be dumped. Limiting the size to below the amount of used memory results in an incomplete dump.

**Example:** The following command prepares a DASD dump device for a dump that is limited to 100 megabyte:

```
# zipl -d /dev/dasdc1,100M
```
Appendix C. Command summary

This chapter describes tools to work with dumps. The descriptions of the commands contain only the relevant options and parameters, for a full description refer to the man pages.

- The zgetdump tool
- The dumpconf service
- The crash tool
- The vmconvert tool
- The vmur tool

The zgetdump tool

The zgetdump tool reads or converts a dump. The dump can be located either on a dump device or on a file system. The dump content is written to standard output, unless you redirect it to a specific file. You can also mount the dump content, print dump information, or check whether a DASD device contains a valid dump tool.

Before you begin: Mounting is implemented with "fuse" (file system in user space). Therefore the fuse kernel module must to be loaded before you can use the --mount option.

zgetdump syntax

```
$zgetdump <dump> [-f s390] [-f elf] > <dump_file>
```

Where:

- `<dump>` is the file, DASD device or partition, or tape device node where the dump is located:
  - Regular dump file (for example /testdir/dump.0)
  - DASD partition device node (for example /dev/dasdc1)
  - DASD device node for multivolume dump (for example /dev/dasdc)
  - Tape device node (for example /dev/ntibm0)

Note: For a DASD multivolume dump it is sufficient to specify only one of the multivolume DASDs as `<dump>`. 

© Copyright IBM Corp. 2004, 2011
<dump_file>

Is the file to which the output is redirected. The default is standard output.

<dumpdevice>

Specifies the dump device for the -d option. The device node of the DASD device, for example /dev/dasdb.

-m <dump> <dir> or --mount <dump> <dir>

Mounts the <dump> to mount point <dir> and generates a virtual target dump file instead of writing the content to standard output. The virtual dump file is named dump.FMT, where FMT is the name of the specified dump format (see the --fmt option).

-u <dir> or --umount <dir>

Unmounts the dump that is mounted at mount point <dir>. You can specify the dump itself instead of the directory, for example /dev/dasdd1. This option is a wrapper for fusermount -u.

-i <dump> or --info <dump>

Displays the dump header information from the dump and performs a validity check.

-d <dumpdevice> or --device <dumpdevice>

Checks whether the specified ECKD or FBA device contains a valid dump tool and prints information about it.

-f <format> or --fmt <format>

Uses the specified target dump format <format> when writing or mounting the dump. The following target dump formats are supported:

elf      Executable and Linking Format core dump (64 bit only)

s390    S/390® dump (default)

-h or --help

Displays the help information for the command.

-v or --version

Displays the version information for the command.

Examples

Using zgetdump to copy a dump

Assuming that the dump is on DASD partition /dev/dasdb1 and that you want to copy it to a file named dump_file:

```bash
# zgetdump /dev/dasdb1 > dump_file
```

Using zgetdump to transfer a dump with ssh

Assuming that the dump is on DASD partition /dev/dasdd1 and that you want to transfer it to a file on another system with ssh:

```bash
# zgetdump /dev/dasdd1 | ssh user@host "cat > dump_file_on_target_host"
```

Using zgetdump to transfer a dump with FTP

Follow these steps to transfer a dump with FTP:

1. Establish an FTP session with the target host and log in.
2. To transfer a file in binary mode, enter the FTP **binary** command:

```
ftp> binary
```

3. To send the dump file to the host issue a command of the following form:

```
ftp> put |"zgetdump /dev/dasdb1" <dump_file_on_target_host>
```

**Using zgetdump to copy a multi-volume dump**

Assuming that the dump is on DASD devices `/dev/dasdc` and `/dev/dasdd` spread along partitions `/dev/dasdc1` and `/dev/dasdd1`, and that you want to copy it to a file named `multi_volume_dump_file`:

```
# zgetdump /dev/dasdc > multi_volume_dump_file
```

For an example of the output from this command, see Chapter 3, “Using DASD devices for multivolume dump,” on page 5.

**Using zgetdump to copy a tape dump**

Assuming that the tape device is `/dev/ntibm0`:

```
# zgetdump /dev/ntibm0 > dump_file
Format Info:
Source: s390tape
Target: s390

Copying dump:
00000000 / 00001024 MB
00000171 / 00001024 MB
00000341 / 00001024 MB
00000512 / 00001024 MB
00000683 / 00001024 MB
00000853 / 00001024 MB
00001024 / 00001024 MB

Success: Dump has been copied
```

**Checking whether a tape dump is valid, and printing the dump header**

Assuming that the tape device is `/dev/ntibm0`:

```
# zgetdump -i /dev/ntibm0
Checking tape, this can take a while...
General dump info:
Dump format.........: s390tape
Version...............: 5
Dump created.........: Mon, 10 May 2010 17:26:46 +0200
Dump ended...........: Mon, 10 May 2010 17:27:58 +0200
Dump CPU ID..........: ff00012320948000
Build arch...........: s390x (64 bit)
System arch..........: s390x (64 bit)
CPU count (online)..: 2
CPU count (real)...: 2
Dump memory range...: 1024 MB
Real memory range...: 1024 MB

Memory map:
0000000000000000 - 000000003fffffff (1024 MB)
```
Checking whether a DASD dump is valid and printing the dump header

Assuming that the dump is on a partition, part1, of a DASD device /dev/dasdb1:

```
# zgetdump -i /dev/dasdb1
General dump info:
    Dump format........: s390
    Version............: 5
    Dump created.......: Mon, 10 May 2010 17:32:36 +0200
    Dump ended.........: Mon, 10 May 2010 17:32:48 +0200
    Dump CPU ID........: ff00012320948000
    Build arch.........: s390x (64 bit)
    System arch........: s390x (64 bit)
    CPU count (online): 2
    CPU count (real) ..: 2
    Dump memory range..: 1024 MB
    Real memory range ..: 1024 MB
Memory map:
    0000000000000000 - 000000003fffffff (1024 MB)
```

Checking whether a device contains a valid dump record

Checking DASD device /dev/dasda, which is a valid dump device:

```
# zgetdump -d /dev/dasdb
Dump device info:
    Dump tool.........: Single-volume DASD dump tool
    Version...........: 2
    Architecture......: s390x (64 bit)
    DASD type.........: ECKD
    Dump size limit...: none
```

Checking DASD device /dev/dasdc, which is not a valid dump device:

```
# zgetdump -d /dev/dasdc
zgetdump: No dump tool found on "/dev/dasdc"
```

Using the mount option

Mounting is useful for multivolume DASD dumps. After a multivolume dump has been mounted, it is shown as a single dump file that can be accessed directly with dump processing tools such as crash.

The following example mounts a multivolume DASD dump as an ELF dump, processes it with crash, and unmounts it with zgetdump:

```
# zgetdump -m -f elf /dev/dasdx /dumps
# crash vmlinux /dumps/dump.elf
# zgetdump -u /dumps
```

Mounting can also be useful when you want to process the dump with a tool that cannot read the original dump format. To do this, mount the dump and specify the required target dump format with the --fmt option.
The dumpconf service

The dumpconf service configures the action to be taken if a kernel panic occurs. The service is installed as a script under /etc/init.d/dumpconf and reads the configuration file /etc/sysconfig/dumpconf.

To enable the dumpconf service, issue:

```
# chkconfig --add dumpconf
```

Before you start: You need root permissions.

dumpconf service syntax

```
dumpconf start stop status
```

Where:

- `start` Enable configuration defined in /etc/sysconfig/dumpconf.
- `stop` Disable the dumpconf service.
- `status` Show current configuration status of the dumpconf service.
- `-h` or `--help` Display short usage text on console. To view the man page, enter `man dumpconf`.
- `-v` or `--version` Display version number on console, and exit.

Keywords for the configuration file

**ON_PANIC**

Shutdown action to be taken if a kernel panic occurs. Possible values are:

- `dump` Dump Linux and stop system.
- `reipl` Reboot Linux.
- `dump_reipl` Dump Linux and reboot system. Note that `dump_reipl` is only available on LPAR with z9® machines and later, and on z/VM with version 5.3 and later.
- `vmcmd` Execute specified CP commands and stop system.
- `stop` Stop Linux (default).

**DELAY_MINUTES**

The number of minutes that the activation of the dumpconf service is to be delayed. The default is zero.

Using `reipl` or `dump_reipl` actions with `ON_PANIC` can lead to the system looping with alternating IPLs and crashes. Use `DELAY_MINUTES` to prevent such a loop. `DELAY_MINUTES` delays activating the specified panic action for a newly started system. When the specified time has elapsed, the dumpconf service activates the specified panic action. This
action is taken should the system subsequently crash. If the system crashes before the time has elapsed, the previously defined action is taken. If no previous action has been defined, the default action (STOP) is performed.

**VMCMD_<X>**
Specifies a CP command, <X> is a number from one to five. You can specify up to five CP commands that are executed in case of a kernel panic. Note that CP commands, device addresses, and names of z/VM guest virtual machines must be uppercase.

**DUMP_TYPE**
Type of dump device. Possible values are **ccw** and **fcp**.

**DEVICE**
Device number of dump device.

**WWPN**
WWPN for SCSI dump device.

**LUN**
LUN for SCSI dump device.

**BOOTPROG**
Boot program selector

**BR_LBA**
Boot record logical block address.

### Examples

**Example configuration files for the dumpconf service**

- Example configuration for a CCW dump device (DASD) using **reipl** after dump and **DELAY_MINUTES**:  

```sh
ON_PANIC=dump_reipl  
DUMP_TYPE=ccw  
DEVICE=0.0.4714  
DELAY_MINUTES=5
```

- Example configuration for FCP dump device (SCSI disk):

```sh
ON_PANIC=dump  
DUMP_TYPE=fcp  
DEVICE=0.0.4711  
WWPN=0x5005076303004712  
LUN=0x4713000000000000  
BOOTPROG=0  
BR_LBA=0
```

- Example configuration for re-IPL if a kernel panic occurs:

```sh
ON_PANIC=reipl
```

- Example of sending a message to the z/VM guest virtual machine "MASTER", executing a **CP VMDUMP** command, and rebooting from device 4711 if a kernel panic occurs:

```sh
ON_PANIC=vmcmd  
VMCMD_1="MSG MASTER Starting VMDUMP"  
VMCMD_2="VMDUMP"  
VMCMD_3="IPL 4711"
```
Note that CP commands, device addresses, and names of z/VM guest virtual machines must be uppercase.

**Examples of dumpconf service use**

Use the `dumpconf` service to enable and disable the configuration.

- **To enable the configuration:**
  
  ```bash
  # service dumpconf start
  ccw dump device configured. "dump" on panic configured.
  ```

- **To display the status:**
  
  ```bash
  # service dumpconf status
  type....: ccw
  device..: 0.0.4714
  on_panic: dump
  ```

- **To disable dump on panic:**
  
  ```bash
  # service dumpconf stop
  Dump on panic is disabled now
  ```

- **To display the status again and check that the status is now stopped.**
  
  ```bash
  # service dumpconf status
  on_panic: stop
  ```

---

**The crash tool**

The `crash` tool is a GPL-licensed tool maintained by Red Hat. For more details see the tool online help.

**The vmconvert tool**

The `vmconvert` tool converts a dump that was created with VMDUMP into a file that can be analyzed with `crash`.

**vmconvert syntax**

```
vmconvert -f <vmdump_file> [-o <output_file> -v -h]
```

Where:

- `<vmdump_file>` or `-f <vmdump_file>` or `--file <vmdump_file>` specifies the VMDUMP created dump file to be converted.
<output_file> or -o <output_file> or --output <output_file>
specifies the name of the dump file to be created. The default is dump.lkcd.

-v or --version
displays the tool version.

-h or --help
displays the help information for the command.

Example

To convert a VMDUMP-created dump file “vmdump1” into a dump file “dump1.lkcd” that can be processed with crash issue:

```
# vmconvert -f vmdump1 -o dump1.lkcd
```

You can also use positional parameters:

```
# vmconvert vm.dump lkcd.dump
vmdump information:
architecture: 32 bit
date.........: Fri Feb 18 11:06:45 2005
storage.....: 16 MB
cpus........: 6
16 of 16 |##################################################| 100%
'lkcd.dump' has been written successfully.
```

The vmur tool

The vmur command can receive a VMDUMP file from the z/VM reader and convert it into a file that can be analyzed with crash. Issue a command of the following form:

```
# vmur receive -c <spool ID> <dump file name>
```

Where:

<spool ID>
  specifies the VMDUMP file spool ID.

<dump file name>
  specifies the name of the output file to receive the reader spool file's data.

For more details, see the vmur man page and Device Drivers, Features, and Commands on SUSE Linux Enterprise Server 11 SP2, SC34-2595.

Example

To receive and convert a VMDUMP spool file with spool ID 463 to a file called dump_file on the Linux file system in the current working directory:

```
# vmur rec -c 463 dump_file
```
Appendix D. Preparing for analyzing a dump

To analyze your dump with crash, additional files are required. If you need to send your dump for analysis, it might be good to include these additional files with the dump file. Your distribution typically provides the additional files in RPMs.

If the dump is to be analyzed with crash, include:

- vmlinux (text): Contains addresses of kernel symbols
- vmlinux (debug): Contains datatype debug information

SLES debug files

The SLES debug files are:

<table>
<thead>
<tr>
<th>Debug file</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>System.map</td>
<td>/boot/System.map-3.0.xx-xx-default</td>
</tr>
<tr>
<td>Kerntypes</td>
<td>/boot/Kerntypes-3.0.xx-xx-default</td>
</tr>
<tr>
<td>vmlinux (text)</td>
<td>/boot/vmlinux-3.0.xx-xx-default.gz</td>
</tr>
<tr>
<td>vmlinux (debug)</td>
<td>/usr/lib/debug/boot/vmlinux-3.0.xx-xx-default.debug</td>
</tr>
</tbody>
</table>

The RPMs that contain the debuginfo files are:

<table>
<thead>
<tr>
<th>SLES version</th>
<th>RPM</th>
</tr>
</thead>
</table>
| SLES 11      | • kernel-default-base-3.0.xx-xx.rpm  
|              | • kernel-default-debuginfo-3.0.xx-xx.rpm |
Appendix E. Installing the DASD or SCSI dump tool with Novell Yast

It is possible to prepare multivolume ECKD DASD and SCSI dump devices with the Novell Yast tool. Complete the following steps:

1. Start Yast:
   
   ```
   # yast
   ```

2. Ensure that the dump DASDs or SCSI devices (LUNs) are activated:
   a. Enter menu: **Hardware > DASD** or **Hardware > Zfcp**.
   b. Activate the correct DASDs or SCSI disks, if not already activated.

3. Prepare the DASDs or SCSI device for dump use:
   a. Enter menu: **Hardware > Dump Devices**.
   b. Select the dump DASDs or SCSI device.
   c. Click **Create** to prepare the DASDs or SCSI disk.

4. A message is displayed when your dump device has been prepared.

After a dump device has been prepared it is possible to configure the **dumpconf** service for automatic dump on panic:

1. Enter menu: **Hardware > On Panic**.
2. Configure settings according to chapter “The dumpconf service” on page 39.

**Note:** The Yast dialogues can also be entered directly with these commands:

- `yast dasd`
- `yast zfcp`
- `yast dump`
- `yast onpanic`
Accessibility

Accessibility features help users who have a disability, such as restricted mobility or limited vision, to use information technology products successfully.

Documentation accessibility

The Linux on System z publications are in Adobe Portable Document Format (PDF) and should be compliant with accessibility standards.
