Summary of changes

This revision reflects changes to the Development stream for libica version 3.0.

You can find the open source version of libica at:

<http://sourceforge.net/projects/opencryptoki/files/libica>

Updates for libica version 3.0

Edition SC34-2602-08

- The libica library is now enabled for FIPS 140-2 certification and therefore can run in the so-called FIPS mode. When running in FIPS mode, only cryptographic algorithms approved by the National Institute of Standards and Technology (NIST) can be used. FIPS mode can be disabled at compile time.
- The **icainfo** output now indicates whether libica has built-in FIPS support, whether it is running in FIPS mode, and whether it is in an error state.
- In Chapter 7, “Examples,” on page 99, you find three updated samples and two new AES samples, while all DES samples have been deleted.
- The following deprecated libica APIs are no longer available with libica version 3.0:

| | | | |
|----------------------|--------------------------|-----------------|---------------|
| icaAesDecrypt | icaAesEncrypt | icaCloseAdapter | icaDesDecrypt |
| icaDesEncrypt | icaDesMac | icaOpenAdapter | icaRsaCrt |
| icaRsaKeyGenerateCrt | icaRsaKeyGenerateModExpo | icaRsaModExpo | icaSha1 |
| icaSha224 | icaSha256 | icaSha384 | icaSha512 |
| icaTDesDecrypt | icaTDesEncrypt | icaTDesMac | |

Updates for libica version 2.6

Edition SC34-2602-07

- A new deterministic random bit generator (DRBG), which is compliant to the NIST SP800-90A specifications, has been added to libica.

Updates for libica version 2.5

Edition SC34-2602-07

- libica supports the CPACF MSA4 extension (AES GCM Mode) in accordance with the current PKCS #11 specification version 2.40.
- A new function is available that analyzes an RSA CRT key and checks if the components comply with the IBM[®] cryptographic architecture. If required, the function converts the key to a conform format that can be used for IBM cryptographic hardware acceleration.

About this document

This document describes how to install and use version 3.0 of the Library for IBM Cryptographic Architecture (libica).

libica is a library of cryptographic functions used to write cryptographic applications on IBM z Systems™, both with and without cryptographic hardware.

You can find the latest version of this document on the developerWorks® website at:

www.ibm.com/developerworks/linux/linux390/documentation_dev.html

and on the IBM Knowledge Center at:

http://www.ibm.com/support/knowledgecenter/linuxonibm/liaaf/lnz_r_ci.html

How this document is organized

The information is divided into topics that describe installing, configuring and using libica together with descriptions of the functions and example programs.

Chapter 1, “General information about libica,” on page 1 has general information about the current libica version.

Chapter 2, “Installing and using libica version 3.0,” on page 5 contains installation and set up instructions, and coexistence information for the current libica version.

Chapter 3, “libica version 3.0 application programming interfaces,” on page 9 describes the libica APIs.

Chapter 4, “Accessing libica functions through the PKCS #11 API (openCryptoki),” on page 75 describes how the cryptographic functions provided by libica can be accessed using the PKCS #11 API implemented by openCryptoki.

Chapter 5, “libica constants, type definitions, data structures, and return codes,” on page 89 lists the defines, typedefs, structs, and return codes for libica.

Chapter 6, “libica tools,” on page 95 contains tools to investigate the capabilities of your cryptographic hardware and how these capabilities are used by applications that use libica.

Chapter 7, “Examples,” on page 99 is a set of programming examples that use the libica APIs.

Who should read this document

This document is intended for C programmers that want to access IBM z Systems hardware support for cryptographic methods.

In particular, this publication addresses programmers who write hardware-specific plug-ins for cryptographic libraries such as OpenSSL and openCryptoki.

Distribution independence

This publication does not provide information that is specific to a particular Linux distribution.

The tools it describes are distribution independent.

Other publications for Linux on z Systems

You can find publications for Linux on z Systems™ on IBM Knowledge Center and on developerWorks.

These publications are available on IBM Knowledge Center at www.ibm.com/support/knowledgecenter/linuxonibm/liaaf/lnz_r_lib.html

www.ibm.com/developerworks/linux/linux390/documentation_ubuntu.html

Chapter 1. General information about libica

The libica library provides hardware support (and software fallbacks if the hardware is not available) for cryptographic functions. The information about libica version 2.6 presented in this document is valid for all libica versions 2.6.x., because the changes in version 2.6 later than 2.6.0 are not relevant for user documentation.

The cryptographic adapters are used for asymmetric encryption and decryption. The CPACF instructions are used for symmetric encryption and decryption, pseudo random number generation, message authentication, and secure hashing. For some of these functions, if the hardware is not available or failed, libica uses the low-level cryptographic functions of OpenSSL, if available.

This product includes software that is developed by the OpenSSL Project for use in the OpenSSL Toolkit (<http://www.openssl.org>). This product includes cryptographic software that is written by Eric Young (ey@cryptsoft.com).

The libica library is part of the openCryptoki project in SourceForge. It is primarily used by OpenSSL through the IBM OpenSSL CA engine or by openCryptoki through the ica_s390 token. A higher level of security can be achieved by using it through the PKCS #11 API implemented by openCryptoki.

The libica library is optimized to work on IBM z Systems hardware.

IBM reserves the right to change or modify this API at any time. However, an effort is made to keep the API compatible with later versions within a major release.

You can use the **icastats** utility to obtain statistics about cryptographic processes. The **icainfo** command shows whether libica is using cryptographic hardware or software fallback for each specific libica function. See “icastats - Show use of libica functions” on page 96 and “icainfo - Show available libica functions” on page 95 for more information.

You can find the open source version of libica at:

<http://sourceforge.net/projects/opencryptoki/files/libica>

In the extracted source package, you also find test cases for all APIs in directory `.../src/tests/`.

z Systems cryptographic hardware support

The information in this topic presents the different types of cryptographic hardware support that may be available on IBM z Systems, depending on the machine model.

Supported IBM CP Assist for Cryptographic Functions (CPACF):

Ciphers:

DES, TDES, AES128, AES192, and AES256 with the following modes of operation: ECB, CBC, OFB, CFB, CTR, CMAC, GCM, and XTS.

Hashes:

SHA-1, SHA224, SHA256, SHA384, SHA512, and GHASH.

Random:
PRNG

Cryptographic cards:

Accelerator: RSA (CRT, MOD-EXPO) with supported key sizes in the range 57 - 4096 bit.

CCA Co-processor: RSA (CRT, MOD-EXPO) with supported key sizes in the range 57 - 4096 bit, and RNG.

Check the prerequisites: cryptographic adapter and device driver

To exploit hardware support of asymmetric cryptographic operations, you need a loaded device driver and an installed IBM cryptographic adapter.

Loading the Linux zcrypt device driver

You also need an installed Linux kernel that includes the zcrypt device driver.

To check, enter the command:

```
$ lszcrypt
card06: CEX5A
```

If the following error message is displayed, load the zcrypt device driver main module:

```
error - cryptographic device driver zcrypt is not loaded!
```

The zcrypt device driver is no longer monolithic as in older distributions where the module was called z90crypt. The device driver is now loaded as separate modules, where the main module is called *ap*. There is, however, an alias name z90crypt that links to the *ap* main module.

To load the device driver *ap* main module, use the following command:

```
modprobe ap
```

See your Linux distribution documentation for how to load the module persistently.

Checking the cryptographic adapter availability

Check whether you have plugged in and enabled your IBM cryptographic adapter and validate your model and type configuration (accelerator or coprocessor). Use the **lszcrypt** command to retrieve basic status information.

To check, enter the command:

```
$ lszcrypt
card06: CEX5A
```

Use the **chzcrypt** command to enable (online state) or disable (offline state) the IBM crypto adapter:

```
$ chzcrypt -e 0x06 // set card06 online
$ chzcrypt -d 0x06 // set card06 offline
```

|
|
|
|
|
|

Use one of the following commands to display more detailed information about the adapters, for example, to see if the adapters are online:

```
lszcrypt -V
lszcrypt -VV
lszcrypt -VVV
```

For more information about the IBM crypto adapter with Linux on z Systems, see *Device Drivers, Features, and Commands*, SC33-8411 available at www.ibm.com/developerworks/linux/linux390/documentation_dev.html

Chapter 2. Installing and using libica version 3.0

View the contained subtopics for information about where to obtain the libica version 3.0 library, and how to install it.

Installing libica version 3.0 from the libica RPM

To make use of the libica hardware support for cryptographic functions, it is necessary to install the libica version 3.0 package. Obtain the current libica version 3.0 as an RPM package from your distribution provider for automated installation.

Procedure

The libica library is available as an RPM named `libica-<version>` within your distribution package. See your Linux distribution documentation for how to install an RPM. To check whether the libica library is installed, issue, for example:

```
# rpm -qa | grep -i libica
```

Installing libica version 3.0 from the source package

If you prefer, you can install libica from the source package manually.

Procedure

1. Download the latest libica version 3.0 sources from the SourceForge website:
<http://sourceforge.net/projects/opencryptoki/files/libica>
2. Extract the tar archive. There should be a new directory named `libica-3.x.x`.
3. Change to that directory and execute the following scripts and commands:

```
$ ./bootstrap  
$ ./configure  
$ make  
$ make install
```

where:

bootstrap

Initial setup, basic configurations

configure

Check configurations and build the makefile.

You can use the option `--enable-testcases` when running the **configure** command to enable the build environment to automatically compile the test-suite:

```
configure --enable-testcases
```

You can use the option `--enable-fips` when running the **configure** command to enable the build environment to compile with FIPS mode:

```
configure --enable-fips
```

make Compile and link

make install
Install the libraries

Using libica version 3.0

The function prototypes are provided in this header file: `include/ica_api.h`.

Applications using these functions must link libica and libcrypto. The libcrypto library is available from the OpenSSL package. You must have OpenSSL in order to run libica version 3.0 programs.

Using libica in FIPS mode

Starting with libica version 3.0, the library is enabled for FIPS 140-2 certification and therefore can run in the so-called FIPS mode. When running in FIPS mode, only cryptographic algorithms approved by the National Institute of Standards and Technology (NIST) can be used.

The NIST defines so called Federal Information Processing Standards (FIPS). One of their publications, the FIPS PUB 140-2 *Security Requirements For Cryptographic Modules* defines a standard for cryptography-based security systems (crypto modules) used by US Federal organizations to protect sensitive data. FIPS 140-2 certifications are done under the *Cryptographic Module Validation Program (CMVP)*.

The FIPS 140-2 standard specifies four levels of security. Each level corresponds to a set of requirements wherein a higher level is a strict superset of the lower levels. Software crypto modules can maximally reach a level 1 certification. In order to make the libica FIPS 140-2 level 1 conformant, the library has been extended by the following features:

- When running in FIPS mode, only NIST approved crypto algorithms can be used and various self-tests are conducted. Approved crypto algorithms are listed in *Annex A: Approved Security Functions for FIPS PUB 140-2*. However, it is possible to disable this feature at compile time. Non-approved algorithms (like for example, DES and PRNG) are disabled when running in FIPS mode.
For information on how to enable or disable the FIPS mode, see “Enabling libica for FIPS mode” on page 7.
- The software fallbacks and RSA key generation of libica is currently provided by OpenSSL. When running in FIPS mode, libica tries to load OpenSSL in FIPS mode. If the available OpenSSL build does not support this, libica consequently disables its fallbacks and RSA key generation. If loading OpenSSL in FIPS mode is successful, it allows only for the generation of RSA keys with FIPS approved parameters (moduli, exponents).
- Various self-tests required by FIPS 140-2 are implemented. If a self-test fails, libica enters an error state (FIPS error state) and does not perform any cryptographic operations. In this case, an error message is written to the *syslog*.
- The DRBG error state was changed to trigger the FIPS error state. In this case an error message is written to the *syslog*.
- New interfaces were added to enable the consuming application to trigger the self-tests on demand and to query the status (see “FIPS mode functions” on page 72). The status indicates, which self-tests were passed or failed and whether libica is running in FIPS mode.
- The **icainfo** output now indicates whether libica has built-in FIPS support, whether it is running in FIPS mode, and whether it is in an error state.

Algorithms that are not FIPS approved are marked as blocked when running in FIPS mode. All algorithms are marked as blocked when libica is in an error state.

For detailed information about the FIPS 140-2 standard, see *FIPS PUB 140-2*.

FIPS mode dependencies

Read about the dependencies on software and hardware that exist if you want to run libica in FIPS mode.

Dependencies on Open Source software (OpenSSL)

At startup, the library reads the kernel FIPS flag from the proc filesystem (see “Enabling the Linux kernel for FIPS mode”). If the flag is found to be 1, then the libica DRBG must be used for random number generation, because the libica PRNG is disabled with FIPS built. DRBG in turn has two options to obtain its seed material:

- Either from the `/dev/hwrng` device which is available via the CCA coprocessor adapter.
- If no `/dev/hwrng` device is available, the kernel `prng` module must be loaded to make the `/dev/prandom` device available for seed obtaining. This is, because the kernel `prng` like the libica DRBG is also FIPS compliant.

Dependencies on hardware

The pseudo random number generator (PRNG) provided by libica is disabled with FIPS built. So only the DRBG can be used for the generation of random data. However, the DRBG needs at least MSA 2 to work. This means that FIPS mode cannot be used if no MSA 2 (introduced with `z10™`) or higher is available.

Enabling libica for FIPS mode

To use libica in FIPS mode, the library itself and also the Linux kernel need to be enabled. That is, the FIPS-enabled libica library can run in FIPS mode when the kernel FIPS flag is set.

Enabling the Linux kernel for FIPS mode

A prerequisite for actually running the the FIPS-enabled libica in FIPS mode is to set the FIPS flag in the used Linux kernel configured for FIPS.

For all distributions, you need to enable the kernel FIPS mode at runtime by setting the kernel FIPS flag. To set this flag in `/proc/sys/crypto/fips_enabled`, boot or reboot with the kernel parameter `fips=1`.

For more information about setting and checking the kernel FIPS flag, refer to *Device Drivers, Features, and Commands*, SC33-8411. Or, for more distribution-specific information, refer to the publications provided by the specific distributor.

Enabling libica for FIPS mode

If you are using libica from a distribution, ensure that FIPS mode is supported, because a distribution may provide libica version 3.0 RPMs both with or without FIPS support.

If you want to install libica version 3.0 from the source package, as described in “Installing libica version 3.0 from the source package” on page 5, then refer to the INSTALL file for information on how to install, configure, and build the libica library. You can then enable the FIPS mode at compile time by running the configure script with the **enable-fips** option:

```
./configure --enable-fips
```

libica version 1, version 2, version 2.1.0, and up to version 3.0 coexistence

Some of the libica version 1 APIs are available in libica version 2, libica version 2.1.0, up to libica version 3.0.

Some of them, such as those APIs that work with an environment other than Linux on z Systems, were removed and are not present in libica version 2 or later versions. If your application program has calls to libica version 1 APIs, check to see whether these APIs are available in libica version 3.0. If they are, these API calls still work. However, we suggest that you convert your application to use the equivalent libica version 3.0. functions. See Chapter 3, “libica version 3.0 application programming interfaces,” on page 9.

libica key generation is restricted to the limits imposed by the OpenSSL implementation. Thus, the value of a public exponent passed to libica cannot be greater than the maximum value that would fit in an unsigned long integer.

Chapter 3. libica version 3.0 application programming interfaces

View a list of application programming interfaces (APIs) for the functions of libica version 3.0. All functions are included in `include/ica_api.h`.

Table 1. libica version 2.6 APIs

| Function | libica version 2.6 API name | Key length in bits | Supported on | CPACF function | SW fallback |
|--|--|--------------------|------------------------------|----------------|-------------|
| Open and close adapter functions | | | | | |
| Open adapter handle | "ica_open_adapter" on page 12 | N/A | z10, z196, zEC12, z13™, z13s | No | N/A |
| Close adapter handle | "ica_close_adapter" on page 13 | N/A | z10, z196, zEC12, z13, z13s | No | N/A |
| Secure hash operations | | | | | |
| Secure hash using the SHA-1 algorithm | "ica_sha1" on page 13 | N/A | z10, z196, zEC12, z13, z13s | Yes | Yes |
| Secure hash using the SHA-224 algorithm | "ica_sha224" on page 14 | N/A | z196, zEC12, z13, z13s | Yes | Yes |
| Secure hash using the SHA-256 algorithm | "ica_sha256" on page 16 | N/A | z196, zEC12, z13, z13s | Yes | Yes |
| Secure hash using the SHA-384 algorithm | "ica_sha384" on page 17 | N/A | z196, zEC12, z13, z13s | Yes | Yes |
| Secure hash using the SHA-512 algorithm | "ica_sha512" on page 18 | N/A | z196, zEC12, z13, z13s | Yes | Yes |
| Random number generation | | | | | |
| Generate a pseudo random number | "ica_random_number_generate" on page 20 | N/A | z10, z196, zEC12, z13, z13s | Yes | Yes |
| Generate pseudo random bits NIST compliant - instantiate | "ica_drbg_instantiate" on page 21 | N/A | z13, z13s | Yes | Yes |
| Generate pseudo random bits NIST compliant - reseed | "ica_drbg_reseed" on page 22 | N/A | z13, z13s | Yes | Yes |
| Generate pseudo random bits NIST compliant - generate | "ica_drbg_generate" on page 22 | N/A | z13, z13s | Yes | Yes |
| Generate pseudo random bits NIST compliant - unstantiate | "ica_drbg_unstantiate" on page 23 | N/A | z13, z13s | Yes | Yes |
| Generate pseudo random bits NIST compliant - health_test | "ica_drbg_health_test" on page 23 | N/A | z13, z13s | Yes | Yes |
| RSA key generation functions | | | | | |
| Generate RSA keys in modulus/exponent format | "ica_rsa_key_generate_mod_expo" on page 24 | N/A | z10, z196, zEC12, z13, z13s | No | SW only |

Table 1. libica version 2.6 APIs (continued)

| Function | libica version 2.6 API name | Key length in bits | Supported on | CPACF function | SW fallback |
|---|--|---|-----------------------------|----------------|-------------------------|
| Generate RSA keys in CRT format | "ica_rsa_key_generate_crt" on page 25 | N/A | z10, z196, zEC12, z13, z13s | No | SW only |

Open and close adapter functions

These functions open or close the crypto adapter. It is recommended to open the crypto adapter before using any of the libica crypto functions, and to close it after the last usage of the libica crypto functions. However, in this version of the libica only the RSA-related functions `ica_rsa_mod_expo` and `ica_rsa crt` require a valid adapter handle as input. A pointer to the value `DRIVER_NOT_LOADED` indicates an invalid adapter handle. The parameter `ica_adapter_handle_t` is a redefine of `int`.

These functions are included in: `include/ica_api.h`.

ica_open_adapter

Purpose

Opens an adapter.

Format

```
unsigned int ica_open_adapter(ica_adapter_handle_t *adapter_handle);
```

Parameters

ica_adapter_handle_t *adapter_handle

Pointer to the file descriptor for the adapter or to DRIVER_NOT_LOADED if opening the crypto adapter failed.

Opening an adapter succeeds if a cryptographic device is accessible for reading and writing. By default, cryptographic access must be available with the `/dev/z90crypt` path name for the adapter open request to succeed. If the environment variable LIBICA_CRYPT_DEVICE is set to a valid path name of an accessible cryptographic device, accessing the device with that path name takes precedence over the default path names.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_close_adapter

Purpose

Closes an adapter.

Comments

This API closes a device handle.

Format

```
unsigned int ica_close_adapter(ica_adapter_handle_t adapter_handle);
```

Parameters

ica_adapter_handle_t adapter_handle

Pointer to a previously opened device handle.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

Secure hash operations

These functions are included in: `include/ica_api.h`.

These functions perform secure hash on input data using the chosen algorithm of SHA-1, SHA-224, SHA-256, SHA-384, or SHA-512.

SHA context structs contain information about how much of the actual work was already performed. Also, it contains the part of the hash that is already produced. For the user, it is only interesting in cases where the message is not hashed at once, because the context is needed for further operations.

ica_sha1

Purpose

Performs a secure hash operation on the input data using the SHA-1 algorithm.

Format

```
unsigned int ica_sha1(unsigned int message_part,  
                    unsigned int input_length,  
                    unsigned char *input_data,  
                    sha_context_t *sha_context,  
                    unsigned char *output_data);
```

Required hardware support

KIMD-SHA-1, or KLMD-SHA-1

Parameters

unsigned int message_part

The message chaining state. This parameter must be one of the following values:

SHA_MSG_PART_ONLY

A single hash operation

SHA_MSG_PART_FIRST

The first part

SHA_MSG_PART_MIDDLE

The middle part

SHA_MSG_PART_FINAL

The last part

unsigned int input_length

Length in bytes of the input data to be hashed using the SHA-1 algorithm.

unsigned char *input_data

Pointer to the input data to be hashed. This pointer must not be zero. So even in case of zero size message data, it must be set to a valid value.

sha_context_t *sha_context

Pointer to the SHA-1 context structure used to store intermediate values needed when chaining is used. The contents are ignored for message part `SHA_MSG_PART_ONLY` and `SHA_MSG_PART_FIRST`. This structure must contain the returned value of the preceding call to `ica_sha1` for message part `SHA_MSG_PART_MIDDLE` and `SHA_MSG_PART_FINAL`. For message part `SHA_MSG_PART_FIRST` and `SHA_MSG_PART_FINAL`, the returned value can be used for a chained call of `ica_sha1`. Therefore, the application must not modify the contents of this structure in between chained calls.

unsigned char *output_data

Pointer to the buffer to contain the resulting hash data. The resulting output data has a length of `SHA_HASH_LENGTH`. Make sure that the buffer is at least this size.

Return codes

0 Success

For return codes indicating exceptions, see "Return codes" on page 93.

ica_sha224

Purpose

Performs a secure hash operation on the input data using the SHA-224 algorithm.

Format

```
unsigned int ica_sha224(unsigned int message_part,  
    unsigned int input_length,  
    unsigned char *input_data,  
    sha256_context_t *sha256_context,  
    unsigned char *output_data);
```

Required hardware support

KIMD-SHA-256, or KLMD-SHA-256

Parameters

unsigned int message_part

The message chaining state. This parameter must be one of the following values:

SHA_MSG_PART_ONLY

A single hash operation

SHA_MSG_PART_FIRST

The first part

SHA_MSG_PART_MIDDLE

The middle part

SHA_MSG_PART_FINAL

The last part

unsigned int input_length

Length in bytes of the input data to be hashed using the SHA-224 algorithm.

unsigned char *input_data

Pointer to the input data to be hashed. This pointer must not be zero. So even in case of zero size message data, it must be set to a valid value.

sha256_context_t *sha256_context

Pointer to the SHA-256 context structure used to store intermediate values needed when chaining is used. The contents are ignored for message part `SHA_MSG_PART_ONLY` and `SHA_MSG_PART_FIRST`. This structure must contain the returned value of the preceding call to `ica_sha224` for message part `SHA_MSG_PART_MIDDLE` and `SHA_MSG_PART_FINAL`. For message part `SHA_MSG_PART_FIRST` and `SHA_MSG_PART_FINAL`, the returned value can be used for a chained call of `ica_sha224`. Therefore, the application must not modify the contents of this structure in between chained calls.

Note: Due to the algorithm used by SHA-224, a SHA-256 context must be used.

unsigned char *output_data

Pointer to the buffer to contain the resulting hash data. The resulting output data has a length of `SHA224_HASH_LENGTH`. Make sure that the buffer is at least this size.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_sha256

Purpose

Performs a secure hash on the input data using the SHA-256 algorithm.

Format

```
unsigned int ica_sha256(unsigned int message_part,  
    unsigned int input_length,  
    unsigned char *input_data,  
    sha256_context_t *sha256_context,  
    unsigned char *output_data);
```

Required hardware support

KIMD-SHA-256, or KLMD-SHA-256

Parameters

unsigned int message_part

The message chaining state. This parameter must be one of the following values:

SHA_MSG_PART_ONLY

A single hash operation

SHA_MSG_PART_FIRST

The first part

SHA_MSG_PART_MIDDLE

The middle part

SHA_MSG_PART_FINAL

The last part

unsigned int input_length

Length in bytes of the input data to be hashed using the SHA-256 algorithm.

unsigned char *input_data

Pointer to the input data to be hashed. This pointer must not be zero. So even in case of zero size message data, it must be set to a valid value.

sha256_context_t *sha256_context

Pointer to the SHA-256 context structure used to store intermediate values needed when chaining is used. The contents are ignored for message part `SHA_MSG_PART_ONLY` and `SHA_MSG_PART_FIRST`. This structure must contain the returned value of the preceding call to `ica_sha256` for message part `SHA_MSG_PART_MIDDLE` and `SHA_MSG_PART_FINAL`. For message part `SHA_MSG_PART_FIRST` and `SHA_MSG_PART_FINAL`, the returned value can be used for a chained call of `ica_sha256`. Therefore, the application must not modify the contents of this structure in between chained calls.

unsigned char *output_data

Pointer to the buffer to contain the resulting hash data. The resulting output data has a length of `SHA256_HASH_LENGTH`. Make sure that the buffer is at least this size.

Return codes

0 Success

For return codes indicating exceptions, see "Return codes" on page 93.

ica_sha384

Purpose

Performs a secure hash on the input data using the SHA-384 algorithm.

Format

```
unsigned int ica_sha384(unsigned int message_part,  
    uint64_t input_length,  
    unsigned char *input_data,  
    sha512_context_t *sha512_context,  
    unsigned char *output_data);
```

Required hardware support

KIMD-SHA-512, or KLMD-SHA-512

Parameters

unsigned int message_part

The message chaining state. This parameter must be one of the following values:

SHA_MSG_PART_ONLY

A single hash operation

SHA_MSG_PART_FIRST

The first part

SHA_MSG_PART_MIDDLE

The middle part

SHA_MSG_PART_FINAL

The last part

uint64_t input_length

Length in bytes of the input data to be hashed using the SHA-384 algorithm.

unsigned char *input_data

Pointer to the input data to be hashed. This pointer must not be zero. So even in case of zero size message data, it must be set to a valid value.

sha512_context_t *sha512_context

Pointer to the SHA-512 context structure used to store intermediate values needed when chaining is used. The contents are ignored for message part `SHA_MSG_PART_ONLY` and `SHA_MSG_PART_FIRST`. This structure must contain the returned value of the preceding call to `ica_sha384` for message part `SHA_MSG_PART_MIDDLE` and `SHA_MSG_PART_FINAL`. For message part `SHA_MSG_PART_FIRST` and `SHA_MSG_PART_FINAL`, the returned value can be used for a chained call of `ica_sha384`. Therefore, the application must not modify the contents of this structure in between chained calls.

Note: Due to the algorithm used by SHA-384, a SHA-512 context must be used.

unsigned char *output_data

Pointer to the buffer to contain the resulting hash data. The resulting output data has a length of `SHA384_HASH_LENGTH`. Make sure that the buffer is at least this size.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_sha512

Purpose

Performs a secure hash operation on input data using the SHA-512 algorithm.

Format

```
unsigned int ica_sha512(unsigned int message_part,  
    uint64_t input_length,  
    unsigned char *input_data,  
    sha512_context_t *sha512_context,  
    unsigned char *output_data);
```

Required hardware support

KIMD-SHA-512, or KLMD-SHA-512

Parameters

unsigned int message_part

The message chaining state. This parameter must be one of the following values:

SHA_MSG_PART_ONLY

A single hash operation

SHA_MSG_PART_FIRST

The first part

SHA_MSG_PART_MIDDLE

The middle part

SHA_MSG_PART_FINAL

The last part

uint64_t input_length

Length in bytes of the input data to be hashed using the SHA-512 algorithm.

unsigned char *input_data

Pointer to the input data to be hashed. This pointer must not be zero. So even in case of zero size message data, it must be set to a valid value.

sha512_context_t *sha512_context

Pointer to the SHA-512 context structure used to store intermediate values needed when chaining is used. The contents are ignored for message part `SHA_MSG_PART_ONLY` and `SHA_MSG_PART_FIRST`. This structure must contain the returned value of the preceding call to `ica_sha512` for message part `SHA_MSG_PART_MIDDLE` and `SHA_MSG_PART_FINAL`. For message part `SHA_MSG_PART_FIRST` and `SHA_MSG_PART_FINAL`, the returned value can be used for a chained call of `ica_sha512`. Therefore, the application must not modify the contents of this structure in between chained calls.

unsigned char *output_data

Pointer to the buffer to contain the resulting hash data. The resulting output data has a length of `SHA512_HASH_LENGTH`. Make sure that the buffer is at least this size.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

Pseudo random number generation functions

libica provides two methods of random number (random bit) generation:

- a conventional random number generator (“ica_random_number_generate” on page 20).
- a NIST SP800-90A compliant deterministic random bit generator. This generator is implemented by a combination of five separate functional APIs and is hereafter referred to as **ica_drbg** to denote the complete generator as a whole.

Conventional ica_random_number_generate function

libica initialization tries to seed the CPACF random generator. To get the seed, device /dev/hwrng is opened. Device /dev/hwrng provides true random data from crypto adapters over the crypto device driver (main module name is **ap**, with an alias name **z90crypt**, which is linking to **ap**). If that fails, the initialization mechanism uses device /dev/urandom. Within the initialization, a byte counter `s390_byte_count` is set to 0. If the CPACF pseudo random generator is available, after 4096 bytes of the pseudo random number are generated, the random number generator is seeded again. If the CPACF pseudo random generator is not available, random numbers are read from /dev/urandom.

Since libica version 2.6, this API internally invokes the NIST compliant **ica_drbg** functionality. The original code of this API is only processed if no MSA5, or at least no MSA2 support is available, which is the prerequisite of the **ica_drbg** API (see “NIST compliant ica_drbg functions”).

NIST compliant ica_drbg functions

The following APIs make up the complete **ica_drbg** functionality:

- “ica_drbg_instantiate” on page 21
- “ica_drbg_reseed” on page 22
- “ica_drbg_generate” on page 22
- “ica_drbg_uninstantiate” on page 23
- “ica_drbg_health_test” on page 23

The IBM zEnterprise® EC12 (zEC12) machines introduced an updated version 5 of the message security assist (MSA). If available, the **ica_drbg** function exploits this updated MSA5 version that provides full hardware support for random number generation based on SHA512 in accordance with NIST SP800-90A.

Note: If no MSA5 version is available, the **ica_drbg** software fallback exploits at least MSA2 support, which includes SHA512. This fallback also produces NIST SP800-90A compliant random numbers, however, without the mentioned high performance MSA5 hardware support. If no MSA2 or higher support is available, the **ica_drbg** mechanism cannot return any pseudorandom bytes to the requesting application. In such cases, you must use the **ica_random_number_generate** function.

The implementation is designed to be thread-safe such that different threads can share the same **ica_drbg** instantiation.

The **ica_drbg** functionality uses certain definitions and supports the following DRBG mechanisms as shown in Table 2 on page 20.

```
typedef struct ica_drbg_mech ica_drbg_mech_t;
extern ica_drbg_mech_t *const ICA_DRBG_SHA512;
```

Table 2. Supported DRBG mechanisms

| DRBG mechanism | supported security strengths (in bits) | max. byte length of pers/add parameters |
|----------------|--|---|
| DRBG_SHA512 | 112, 128, 196, 256 | 256 / 256 |

The following information list satisfies the NIST SP800-90A documentation requirements:

- Entropy input is read from `/dev/hwrng`. If `/dev/hwrng` is not available, the entropy input is read from `/dev/prandom`.
- `ica_drbg` provides the `ica_drbg_health_test` interface for validation and health testing. This function together with test parameters can be found in `libica/src/include/s390_drbg.h`. Nonce and entropy input can be injected via these parameters for the purpose of known answer testing.
- No further support functions other than health testing are supported.
- The only DRBG mechanism currently implemented is Hash_DRBG using SHA-512.
- `ica_drbg` supports 112, 128, 196, and 256 bits of security.
- `ica_drbg` supports prediction resistance.
- The generate function is tested every $2^{64} - 1$ calls. This interval size is chosen, because CPACF hardware failures should not happen frequently.
- The integrity of the health test can be determined by inspecting the checksum/hash of the package before install.

ica_random_number_generate

Purpose

This function generates a pseudo random number. Parameter `*output_data` is a pointer to a buffer of byte length `output_length`. `output_length` number of bytes of pseudo random data is placed in the buffer pointed to by `output_data`.

Format

```
unsigned int ica_random_number_generate(unsigned int output_length,
    unsigned char *output_data);
```

Required hardware support

KMC-PRNG

Parameters

unsigned int output_length

Length in bytes of the `output_data` buffer, and the length of the generated pseudo random number.

unsigned char *output_data

Pointer to the buffer to receive the generated pseudo random number.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_drbg_instantiate

Purpose

This function instantiates a NIST SP800-90A compliant deterministic random bit generator.

Format

```
int ica_drbg_instantiate(ica_drbg_t **sh,
                        int sec,
                        bool pr,
                        ica_drbg_mech_t *mech,
                        const unsigned char *pers,
                        size_t pers_len);
```

Parameters

ica_drbg_t **sh

State handle pointer. The (invalid) state handle is set to identify the new DRBG instantiation and thus becomes valid.

int sec

Requested security strength in bits of the new DRBG instantiation. The security strength is set to the lowest value supported by its DRBG mechanism that is greater than or equal to your selected **sec** value (see Table 2 on page 20). For example, if you request security strength 160 for your instance, it is actually set to 196.

bool pr

Prediction resistance flag. Indicates whether or not prediction resistance may be required by the consuming application during one or more requests for pseudo random bytes.

ica_drbg_mech_t *mech

Pointer to the mechanism type selected for the new DRBG instantiation. The new instantiation is then of this mechanism type. For available mechanisms, see Table 2 on page 20.

const unsigned char *pers

Pointer to a personalization string. This is optional input that provides personalization information. The personalization string should be unique for all instantiations of the same mechanism type. NULL indicates that no personalization string is used (not recommended).

size_t pers_len

Length in bytes of the string referenced by ***pers**.

Return codes

0 Success

ENOTSUP

Prediction resistance or the requested security strength is not supported.

EPERM

Failed to obtain a valid timestamp from clock.

ICA_DBRG_HEALTH_TEST_FAIL

Health test failed, see “ica_drbg_health_test” on page 23.

ICA_DBRG_ENTROPY_SOURCE_FAIL

Entropy source failed.

ica_drbg_reseed

Purpose

This function reseeds a NIST SP800-90A compliant DRBG instantiation from `ica_drbg_instantiate`.

Format

```
int ica_drbg_reseed(ica_drbg_t *sh,
                   bool pr,
                   const unsigned char *add,
                   size_t add_len);
```

Parameters

`ica_drbg_t *sh`

State handle pointer. Identifies the DRBG instantiation to be reseeded.

`bool pr`

Prediction resistance request. Indicates whether or not prediction resistance is required.

`const unsigned char *add`

Pointer to additional optional input. NULL indicates that no additional input is used.

`size_t add_len`

Length in bytes of parameter `add`.

Return codes

0 Success

ENOTSUP

Prediction resistance is not supported.

ICA_DBRG_HEALTH_TEST_FAIL

Health test failed, see “ica_drbg_health_test” on page 23.

ICA_DBRG_ENTROPY_SOURCE_FAIL

Entropy source failed.

ica_drbg_generate

Purpose

This function requests pseud random bytes from an `ica_drbg` instantiation created by the `ica_drbg_instantiate` function.

Format

```
int ica_drbg_generate(ica_drbg_t *sh,
                    int sec,
                    bool pr,
                    const unsigned char *add,
                    size_t add_len,
                    unsigned char *prnd,
                    size_t prnd_len);
```

Parameters

`ica_drbg_t *sh`

State handle pointer. Identifies the DRBG instantiation from which pseudorandom bytes are requested.

int sec

Requested security strength: Minimum bits of security that the generated pseudo random bytes shall offer.

bool pr

Prediction resistance request. Indicates whether or not prediction resistance is required.

const unsigned char *add

Pointer to additional optional input. NULL indicates that no additional input is used.

size_t add_len

Length in bytes of parameter **add**.

unsigned char *prnd

Pointer to the generated pseudo random bytes.

size_t prnd_len

Length in bytes of parameter **prnd**, which corresponds to the number of generated pseudo random bytes.

Return codes

0 Success

ENOTSUP

Prediction resistance or the requested security strength is not supported.

EPERM

Reseed required.

ICA_DBRG_HEALTH_TEST_FAIL

Health test failed, see “ica_drbg_health_test.”

ICA_DBRG_ENTROPY_SOURCE_FAIL

Entropy source failed.

For return codes indicating exceptions, see “Return codes” on page 93.

ica_drbg_uninstantiate

Purpose

This function destroys an existing **ica_drbg** instance.

Format

```
int ica_drbg_uninstantiate(ica_drbg_t **sh);
```

Parameters

ica_drbg_t **sh

State handle pointer. The corresponding DRBG instantiation is destroyed and the state handle is set to NULL (invalid).

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_drbg_health_test

Purpose

This function runs a health test for the complete **ica_drbg** function mechanism.

Format

```
int ica_drbg_health_test(void *func,
                        int sec,
                        bool pr,
                        ica_drbg_mech_t *mech);
```

Parameters

void *func

Pointer indicating which function should be tested. Options are:

ica_drbg_instantiate

ica_drbg_reseed

ica_drbg_generate

The ica_drbg_instantiate function is tested whenever other functions are tested.

int sec

Security strength. Argument for the call to the function denoted by parameter **func**.

bool pr

Prediction resistance. Argument for the call to the function denoted by parameter **func**.

ica_drbg_mech_t *mech

Pointer to the mechanism to be tested.

Return codes

0 Success

ICA_DBRG_HEALTH_TEST_FAIL

Health test failed.

ENOTSUP

Prediction resistance or the requested security strength is not supported.

ICA_DBRG_ENTROPY_SOURCE_FAIL

Entropy source failed.

For return codes indicating exceptions, see “Return codes” on page 93.

RSA key generation functions

These functions are included in: include/ica_api.h.

These functions generate an RSA public/private key pair. These functions are performed using software through OpenSSL. Hardware is not used.

ica_rsa_key_generate_mod_expo

Purpose

Generates RSA keys in modulus/exponent format.

Comments

For specific information about some of these parameters, see the considerations in “Data structures” on page 90.

Format

```
unsigned int ica_rsa_key_generate_mod_expo(ica_adapter_handle_t adapter_handle,  
    unsigned int modulus_bit_length,  
    ica_rsa_key_mod_expo_t *public_key,  
    ica_rsa_key_mod_expo_t *private_key);
```

Parameters

ica_adapter_handle_t adapter_handle

Pointer to a previously opened device handle.

unsigned int modulus_bit_length

Length in bits of the modulus. This value should comply with the length of the keys (in bytes), according to this calculation:

$$\text{key_length} = (\text{modulus_bits} + 7) / 8$$

ica_rsa_key_mod_expo_t *public_key

Pointer to where the generated public key is to be placed. If the *exponent* element in the public key is not set, it is randomly generated. A poorly chosen *exponent* could result in the program looping endlessly. Common public exponents are 3 and 65537.

ica_rsa_key_mod_expo_t *private_key

Pointer to where the generated private key in modulus/exponent format is to be placed. The length of both the private and public keys should be set in bytes. This value should comply with the length of the keys (in bytes), according to this calculation:

$$\text{key_length} = (\text{modulus_bits} + 7) / 8$$

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_rsa_key_generate_crt

Purpose

Generates RSA keys in Chinese-Remainder Theorem (CRT) format.

Comments

For specific information about some of these parameters, see the considerations in “Data structures” on page 90.

With libica version 2.5, this function has been extended to allow RSA key generation for any granularity in the range 57 - 4096 bits.

Format

```
unsigned int ica_rsa_key_generate_crt(ica_adapter_handle_t adapter_handle,  
    unsigned int modulus_bit_length,  
    ica_rsa_key_mod_expo_t *public_key,  
    ica_rsa_key_crt_t *private_key);
```

Parameters

ica_adapter_handle_t adapter_handle

Pointer to a previously opened device handle.

unsigned int modulus_bit_length

Length in bits of the modulus part of the key. This value should comply with the length of the keys (in bytes), according to this calculation:

$$\text{key_length} = (\text{modulus_bits} + 7) / 8$$
ica_rsa_key_mod_expo_t *public_key

Pointer to where the generated public key is to be placed. If the *exponent* element in the public key is not set, it is randomly generated. A poorly chosen *exponent* can result in the program looping endlessly. Common public exponents are 3 and 65537.

ica_rsa_key_crt_t *private_key

Pointer to where the generated private key in CRT format is to be placed. Length of both private and public keys should be set in bytes. This value should comply with the length of the keys (in bytes), according to this calculation

$$\text{key_length} = (\text{modulus_bits} + 7) / 8$$
Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_rsa_crt_key_check**Purpose**

Analyzes an RSA CRT key and check if the components are conform with the IBM cryptographic architecture. If necessary the key is converted to a conform format that can be used for IBM cryptographic hardware acceleration.

Checks if the RSA key credentials in CRT format are presented in privileged form, respectively whether prime **p** is greater than prime **q** ($p > q$) In case of $p < q$, key credentials **p** and **q** as well as **dp** and **dq** are swapped and **qInverse** is recalculated.

Format

```
unsigned int ica_rsa_crt_key_check(ica_rsa_key_crt_t *rsa_key);
```

Parameters**ica_rsa_key_crt_t *rsa_key**

Pointer to the key to be used in CRT format.

Return codes

0 All key credentials are in the correct format.

1 Key credentials were recalculated.

ENOMEM

Memory allocation fails.

For return codes indicating exceptions, see “Return codes” on page 93.

RSA encrypt and decrypt operations

These functions are included in: `include/ica_api.h`.

These functions perform a modulus/exponent operation using an RSA key whose type is either `ica_rsa_key_mod_expo_t` or `ica_rsa_key_crt_t`.

ica_rsa_mod_expo

Purpose

Performs an RSA encryption or decryption operation using a key in modulus/exponent format.

Comments

Make sure that your message is padded before using this function.

Format

```
unsigned int ica_rsa_mod_expo(ica_adapter_handle_t adapter_handle,  
    unsigned char *input_data,  
    ica_rsa_key_mod_expo_t *rsa_key,  
    unsigned char *output_data);
```

Parameters

ica_adapter_handle_t adapter_handle

Pointer to a previously opened device handle.

unsigned char *input_data

Pointer to the input data to be encrypted or decrypted. This data must be in big endian format. Make sure that the input data is not longer than the bit length of the key. The byte length for the input data and the key must be the same. Right align the input data inside the data block.

ica_rsa_key_mod_expo_t *rsa_key

Pointer to the key to be used, in modulus/exponent format.

unsigned char *output_data

Pointer to the location where the output results are to be placed. This buffer has to be at least the same size as *input_data* and therefore at least the same size as the size of the modulus.

Return codes

0 Success

For return codes indicating exceptions, see "Return codes" on page 93.

ica_rsa_crt

Purpose

Performs an RSA encryption or decryption operation using a key in CRT format.

Comments

Make sure that your message is padded before using this function.

Format

```
unsigned int ica_rsa_crt(ica_adapter_handle_t adapter_handle,  
    unsigned char *input_data,  
    ica_rsa_key_crt_t *rsa_key,  
    unsigned char *output_data);
```

Parameters

ica_adapter_handle_t adapter_handle

Pointer to a previously opened device handle.

unsigned char *input_data

Pointer to the input data to be encrypted or decrypted. This data must be in big endian format. Make sure that the input data is not longer than the bit length of the key. The byte length for the input data and the key must be the same. Right align the input data inside the data block.

ica_rsa_keyCRT_t *rsa_key

Pointer to the key to be used, in CRT format.

unsigned char *output_data

Pointer to the location where the output results are to be placed. This buffer must be as large as the *input_data*, and as large as the length of the *modulus* specified in *rsa_key*.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

DES functions

These functions are included in: `include/ica_api.h`.

These functions perform encryption and decryption and computation or verification of message authentication codes using a DES (DEA) key. A DES key has a size of 8 bytes. Each byte of a DES key contains one parity bit, such that each 64-bit DES key contains only 56 security-relevant bits. The cipher block size for DES is 8 bytes.

To securely apply DES encryption to messages that are longer than the cipher block size, modes of operation can be used to chain multiple encryption, decryption, or authentication operations. Most modes of operation require an initialization vector as additional input. As long as the messages are encrypted or decrypted using such a mode of operation, and have a size that is a multiple of a particular block size (mostly the cipher block size), the functions encrypting or decrypting according to a mode of operation also compute an output vector. This output vector can be used as the initialization vector of a chained encryption or decryption operation in the same mode with the same block size and the same key.

When decrypting a cipher text, these values used for the decryption function must match the corresponding settings of the encryption function that transformed the plain text into the cipher text:

- The mode of operation
- The key
- The initialization vector (if applicable)
- For the `ica_des_cfb` function, the *lcfb* parameter

ica_des_cbc

Purpose

Encrypt or decrypt data with a DES key using Cipher Block Chaining (CBC) mode, as described in NIST Special Publication 800-38A Chapter 6.2.

Format

```
unsigned int ica_des_cbc(const unsigned char *in_data,
                        unsigned char *out_data,
                        unsigned long data_length,
                        const unsigned char *key,
                        unsigned char *iv,
                        unsigned int direction);
```

Required hardware support

KMC-DEA

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. This buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*. *data_length* must be a multiple of the cipher block size (a multiple of 8 bytes for DES).

const unsigned char *key

Pointer to a valid DES key of 8 bytes in length.

unsigned char *iv

Pointer to a valid initialization vector of cipher block size number of bytes (8 bytes for DES). This vector is overwritten by this function. The result value in *iv* can be used as the initialization vector for a chained **ica_des_cbc** or **ica_des_cbc_cs** call with the same key.

unsigned int direction

0 Use the decrypt function.
1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see "Return codes" on page 93.

ica_des_cbc_cs

Purpose

Encrypt or decrypt data with a DES key using Cipher Block Chaining with Ciphertext Stealing (CBC-CS) mode, as described in NIST Special Publication

800-38A, Chapter 6.2 and the Addendum to NIST Special Publication 800-38A on *Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode*.

`ica_des_cbc_cs` can be used to encrypt or decrypt the last chunk of a message consisting of multiple chunks, where all chunks except the last one are encrypted or decrypted by chained calls to `ica_des_cbc`. To do this, the resulting *iv* of the last call to `ica_des_cbc` is fed into the *iv* of the `ica_des_cbc_cs` call, provided that the chunk is greater than the cipher block size (8 bytes for DES).

Format

```
unsigned int ica_des_cbc_cs(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned char *iv,
    unsigned int direction,
    unsigned int variant);
```

Required hardware support

KMC-DEA

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as the *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. This buffer must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*. *data_length* must be greater than or equal to the cipher block size (8 bytes for DES).

const unsigned char *key

Pointer to a valid DES key of 8 bytes in length.

unsigned char *iv

Pointer to a valid initialization vector of cipher block size number of bytes. This vector is overwritten during the function. For *variant* equal to 1 or *variant* equal to 2, the result value in *iv* can be used as the initialization vector for a chained `ica_des_cbc` or `ica_des_cbc_cs` call with the same key, if *data_length* is a multiple of the cipher block size.

unsigned int direction

- 0 Use the decrypt function.
- 1 Use the encrypt function.

unsigned int variant

- 1 Use variant CBC-CS1 of the Addendum to NIST Special Publication 800-38A to encrypt or decrypt the message: always keep last two blocks in order.
- 2 Use variant CBC-CS2 of the Addendum to NIST Special Publication

- 800-38A to encrypt or decrypt the message: switch order of the last two blocks if *data_length* is not a multiple of the cipher block size (a multiple of 8 bytes for DES).
- 3 Use variant CBC-CS3 of the Addendum to NIST Special Publication 800-38A to encrypt or decrypt the message: always switch order of the last two blocks.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_des_cfb

Purpose

Encrypt or decrypt data with a DES key using Cipher Feedback (CFB) mode, as described in NIST Special Publication 800-38A Chapter 6.3.

Format

```
unsigned int ica_des_cfb(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned char *iv,
    unsigned int lcfb,
    unsigned int direction);
```

Required hardware support

KMF-DEA

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as the *data_length* parameter.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as the *data_length* parameter.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*.

const unsigned char *key

Pointer to a valid DES key of 8 bytes in length.

unsigned char *iv

Pointer to a valid initialization vector of cipher block size bytes (8 bytes for DES). This vector is overwritten during the function. The result value in *iv* can be used as the initialization vector for a chained **ica_des_cfb** call with the same key, if *data_length* in the preceding call is a multiple of the *lcfb* parameter.

unsigned int lcfb

Length in bytes of the cipher feedback, which is a value greater than or equal to 1 and less than or equal to the cipher block size (8 bytes for DES).

unsigned int direction
0 Use the decrypt function.
1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_des_cmac

Purpose

Authenticate data or verify the authenticity of data with a DES key using the Block Cipher Based Message Authentication Code (CMAC) mode, as described in NIST Special Publication 800-38B. `ica_des_cmac` can be used to authenticate or verify the authenticity of a complete message.

Format

```
unsigned int ica_des_cmac(const unsigned char *message,  
    unsigned long message_length,  
    unsigned char *mac,  
    unsigned int mac_length,  
    const unsigned char *key,  
    unsigned int direction);
```

Required hardware support

KMAC-DEA
PCC-Compute-Last_block-CMAC-Using-DEA

Parameters

const unsigned char *message

Pointer to a readable buffer of size greater than or equal to *message_length* bytes. This buffer contains a message to be authenticated or of which the authenticity is to be verified.

unsigned long message_length

Length in bytes of the message to be authenticated or verified.

unsigned char *mac

Pointer to a buffer of size greater than or equal to *mac_length* bytes. If *direction* is equal to 1, the buffer must be writable and a message authentication code for the message in *message* of size *mac_length* bytes is written to the buffer. If *direction* is equal to 0, the buffer must be readable and contain a message authentication code to be verified against the message in *message*.

unsigned int mac_length

Length in bytes of the message authentication code *mac*, which is less than or equal to the cipher block size (8 bytes for DES). It is recommended to use a *mac_length* of 8.

const unsigned char *key

Pointer to a valid DES key of 8 bytes in length.

unsigned int direction

0 Verify message authentication code.
1 Compute message authentication code for the message.

Return codes

0 Success

EFAULT

If *direction* is equal to 0 and the verification of the message authentication code fails.

For return codes indicating exceptions, see “Return codes” on page 93.

ica_des_cmac_intermediate

Purpose

Authenticate data or verify the authenticity of data with a DES key using the Block Cipher Based Message Authentication Code (CMAC) mode, as described in NIST Special Publication 800-38B. `ica_des_cmac_intermediate` and `ica_des_cmac_last` can be used when the message to be authenticated or to be verified using CMAC is supplied in multiple chunks. `ica_des_cmac_intermediate` is used to process all but the last chunk. All message chunks to be processed by `ica_des_cmac_intermediate` must have a size that is a multiple of the cipher block size (8 bytes for DES).

Note that `ica_des_cmac_intermediate` has no direction argument. This function can be used during authentication and during authenticity verification.

Format

```
unsigned int ica_des_cmac_intermediate(const unsigned char *message,
    unsigned long message_length,
    const unsigned char *key,
    unsigned char *iv);
```

Required hardware support

KMAC-DEA

Parameters

const unsigned char *message

Pointer to a readable buffer of size greater than or equal to *message_length* bytes. This buffer contains a non-final part of a message to be authenticated, or of which the authenticity is to be verified.

unsigned long message_length

Length in bytes of the message part in *message*. This value must be a multiple of the cipher block size.

const unsigned char *key

Pointer to a valid DES key of 8 bytes in length.

unsigned char *iv

Pointer to a valid initialization vector of cipher block size bytes (8 bytes for DES). For the first message part, this parameter must be set to a string of zeros. For processing the *n*-th message part, this parameter must be the resulting *iv* value of the `ica_des_cmac_intermediate` function applied to the (*n*-1)-th message part. This vector is overwritten during the function. The result value in *iv* can be used as the initialization vector for a chained call to `ica_des_cmac_initermediate`, or to `ica_des_cmac_last` with the same key.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_des_cmac_last

Purpose

Authenticate data or verify the authenticity of data with a DES key using the Block Cipher Based Message Authentication Code (CMAC) mode, as described in NIST Special Publication 800-38B. `ica_des_cmac_last` can be used to authenticate or verify the authenticity of a complete message or of the final part of a message for which all preceding parts were processed with `ica_des_cmac_intermediate`.

Format

```
unsigned int ica_des_cmac_last(const unsigned char *message,  
    unsigned long message_length,  
    unsigned char *mac,  
    unsigned int mac_length,  
    const unsigned char *key,  
    unsigned char *iv,  
    unsigned int direction);
```

Required hardware support

KMAC-DEA

PCC-Compute-Last_block-CMAC-Using-DEA

Parameters

const unsigned char *message

Pointer to a readable buffer of size greater than or equal to *message_length* bytes. This buffer contains a message or the final part of a message, to be either authenticated or of which the authenticity is to be verified.

unsigned long message_length

Length in bytes of the message to be authenticated or verified.

unsigned char *mac

Pointer to a buffer of size greater than or equal to *mac_length* bytes. If *direction* is equal to 1, the buffer must be writable and a message authentication code for the message in *message* of size *mac_length* bytes is written to the buffer. If *direction* is equal to 0, the buffer must be readable and contain a message authentication code that is verified against the message in *message*.

unsigned int mac_length

Length in bytes of the message authentication code *mac* that is less than or equal to the cipher block size (8 bytes for DES). It is recommended to use a *mac_length* of 8.

const unsigned char *key

Pointer to a valid DES key of 8 bytes in length.

unsigned char *iv

Pointer to a valid initialization vector of cipher block size number of bytes. If *iv* is NULL, *message* is assumed to be the complete message to be processed. Otherwise, *message* is the final part of a composite message to be processed and *iv* contains the output vector resulting from processing all previous parts with chained calls to `ica_des_cmac_intermediate` (the value returned in *iv* of the `ica_des_cmac_intermediate` call applied to the penultimate message part).

unsigned int direction

0 Verify message authentication code.

1 Compute message authentication code for the message.

Return codes

0 Success

EFAULT

If *direction* is equal to 0 and the verification of the message authentication code fails.

For return codes indicating exceptions, see “Return codes” on page 93.

ica_des_ctr

Purpose

Encrypt or decrypt data with a DES key using Counter (CTR) mode, as described in NIST Special Publication 800-38A Chapter 6.5. With the counter mode, each message block of the same size as the cipher block (8 bytes for DES) is combined with a counter value of the same size during encryption and decryption.

Starting with an initial counter value to be combined with the first message block, subsequent counter values to be combined with subsequent message blocks are derived from preceding counter values by an increment function. The increment function used in `ica_des_ctr` is an arithmetic increment without carry on the *M* least significant bytes in the counter, where *M* is a parameter to `ica_des_ctr`.

Format

```
unsigned int ica_des_ctr(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned char *ctr,
    unsigned int ctr_width,
    unsigned int direction);
```

Required hardware support

KMCTR-DEA

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*.

const unsigned char *key

Pointer to a valid DES key of 8 bytes in length.

unsigned char *ctr

Pointer to a readable and writable buffer of the same size as the cipher block in bytes. *ctr* contains an initialization value for a counter function, and it is replaced by a new value. That new value can be used as the initialization value for a counter function in a chained `ica_des_ctr` call with the same key, if the *data_length* used in the preceding call is a multiple of the cipher block size.

unsigned int ctr_width

A number M between 1 and the cipher block size. This value is used by the counter increment function, which increments a counter value by incrementing without carry the least significant M bytes of the counter value.

unsigned int direction

- 0 Use the decrypt function.
- 1 Use the encrypt function.

Return codes

- 0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_des_ctrlist**Purpose**

Encrypt or decrypt data with a DES key using Counter (CTR) mode, as described in NIST Special Publication 800-38A ,Chapter 6.5. With the counter mode, each message block of the same size as the cipher block is combined with a counter value of the same size during encryption and decryption.

The `ica_des_ctrlist` function assumes that a list n of precomputed counter values is provided, where n is the smallest integer that is less than or equal to the message size divided by the cipher block size. This function is used to optimally utilize IBM z Systems hardware support for non-standard counter functions.

Format

```
unsigned int ica_des_ctrlist(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    const unsigned char *ctrlist,
    unsigned int direction);
```

Required hardware support

KMCTR-DEA

Parameters**const unsigned char *in_data**

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is `data_length`. The size of this buffer must be at least as large as `data_length`.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as `data_length`.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of `in_data`.

Calls to `ica_des_ctrlist` with the same key can be chained if:

- With the possible exception of the last call in the chain the `data_length` used is a multiple of the cipher block size.
- The `ctrlist` argument of each chained call contains a list of counters that follows the counters used in the preceding call.

const unsigned char *key

Pointer to a valid DES key of 8 bytes in length.

const unsigned char *ctrlist

Pointer to a readable buffer of a size greater than or equal to *data_length*, and a multiple of the cipher block size (8 bytes for DES). *ctrlist* should contain a list of precomputed counter values, each of the same size as the cipher block.

unsigned int direction

0 Use the decrypt function.

1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_des_ecb

Purpose

Encrypt or decrypt data with a DES key using Electronic Code Book (ECB) mode, as described in NIST Special Publication 800-38A Chapter 6.1.

Format

```
unsigned int ica_des_ecb(const unsigned char *in_data,  
    unsigned char *out_data,  
    unsigned long data_length,  
    const unsigned char *key,  
    unsigned int direction);
```

Required hardware support

KM-DEA

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writeable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*. *data_length* must be a multiple of the cipher block size (8 bytes for DES).

const unsigned char *key

Pointer to a valid DES key of 8 bytes in length.

unsigned int direction

0 Use the decrypt function.

1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_des_ofb

Purpose

Encrypt or decrypt data with a DES key using Output Feedback (OFB) mode, as described in NIST Special Publication 800-38A Chapter 6.4.

Format

```
unsigned int ica_des_ofb(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned int key_length,
    unsigned char *iv,
    unsigned int direction);
```

Required hardware support

KMO-DEA

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer that contains the resulting encrypted or decrypted message. The size of this buffer must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*.

const unsigned char *key

Pointer to a valid DES key of 8 bytes in length.

unsigned char *iv

Pointer to a valid initialization vector of the same size as the cipher block in bytes (8 bytes for DES). This vector is overwritten during the function. If *data_length* is a multiple of the cipher block size (8 bytes for DES), the result value in *iv* can be used as the initialization vector for a chained **ica_des_ofb** call with the same key.

unsigned int direction

0 Use the decrypt function.

1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

Compatibility with earlier versions

In order to stay compatible with earlier versions of libica, the following DES interfaces remain supported:

```

unsigned int ica_des_encrypt(unsigned int mode,
    unsigned int data_length, unsigned char *input_data,
    ica_des_vector_t *iv, ica_des_key_single_t *des_key,
    unsigned char *output_data);

unsigned int ica_des_decrypt(unsigned int mode,
    unsigned int data_length, unsigned char *input_data,
    ica_des_vector_t *iv, ica_des_key_single_t *des_key,
    unsigned char *output_data);

```

Table 3 shows libica version 2.0 DES functions calls, and their corresponding libica version 2.4 DES function calls.

Table 3. Compatibility of libica version 2.0 DES functions calls to libica version 2.4 DES function calls

| Calling this libica version 2.0 DES function | Corresponds to calling this libica version 2.4 DES function |
|--|--|
| <code>ica_des_encrypt(MODE_ECB, data_length, in_data, NULL, key, out_data);</code> | <code>ica_des_ecb(in_data, out_data, (long) data_length, key, 1);</code> |
| <code>ica_des_encrypt(MODE_CBC, data_length, in_data, iv, key, out_data);</code> | <code>ica_des_cbc(in_data, out_data, (long) data_length, key, iv, 1);</code> |
| <code>ica_des_decrypt(MODE_ECB, data_length, in_data, NULL, key, out_data);</code> | <code>ica_des_ecb(in_data, out_data, (long) data_length, key, 0);</code> |
| <code>ica_des_decrypt(MODE_CBC, data_length, in_data, iv, key, out_data);</code> | <code>ica_des_cbc(in_data, out_data, (long) data_length, key, iv, 0);</code> |

The functions `ica_des_encrypt` and `ica_des_decrypt` remain supported, but their use is discouraged in favor of `ica_des_ecb` and `ica_des_cbc`.

For a detailed description of the earlier APIs, see *libica Programmers Reference* version 2.0.

TDES/3DES functions

These functions are included in: `include/ica_api.h`.

These functions perform encryption and decryption or computation and verification of message authentication codes using a triple-DES (3DES, TDES or TDEA) key. A 3DES key consists of a concatenation of three DES keys, each of which has a size of 8 bytes. Note that each byte of a DES key contains one parity bit, such that each 64-bit DES key contains only 56 security-relevant bits. The cipher block size for 3DES is 8 bytes.

3DES is known in two variants: a two key variant and a three key variant. This library implements only the three key variant. The two key variant can be derived from functions for the three key variant by using the same key as the first and third key.

To securely apply 3DES encryption to messages that are longer than the cipher block size, modes of operation can be used to chain multiple encryption, decryption, or authentication operations. Most modes of operation require an initialization vector as additional input. As long as the messages are encrypted or decrypted using such a mode of operation and have a size that is a multiple of a particular block size (mostly the cipher block size), the functions encrypting or decryption according to that mode of operation also compute an output vector that

can be used as the initialization vector of a chained encryption or decryption operation in the same mode with the same block size and the same key.

Note that when decrypting a cipher text, the mode of operation, the key, the initialization vector (if applicable), and for `ica_3des_cfb` the *lcb* value used for the decryption function must match the corresponding settings of the encryption function that was used to transform the plain text into the cipher text.

ica_3des_cbc

Purpose

Encrypt or decrypt data with an 3DES key using Cipher Block Chaining (CBC) mode, as described in NIST Special Publication 800-38A Chapter 6.2.

Format

```
unsigned int ica_3des_cbc(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned char *iv,
    unsigned int direction);
```

Required hardware support

KMC-TDEA-192

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*. *data_length* must be a multiple of the cipher block size (8 bytes for 3DES).

const unsigned char *key

Pointer to a valid 3DES key of 24 bytes in length.

unsigned char *iv

Pointer to a valid initialization vector of cipher block size number of bytes. This vector is overwritten during the function. The result value in *iv* can be used as the initialization vector for a chained `ica_3des_cbc` or `ica_3des_cbc_cs` call with the same key.

unsigned int direction

0 Use the decrypt function.
1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_3des_cbc_cs

Purpose

Encrypt or decrypt data with a 3DES key using Cipher Block Chaining with Ciphertext Stealing (CBC-CS) mode, as described in NIST Special Publication 800-38A Chapter 6.2 and the Addendum to NIST Special Publication 800-38A on *Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode*.

`ica_3des_cbc_cs` can be used to encrypt or decrypt the last chunk of a message consisting of multiple chunks, where all chunks except the last one are encrypted or decrypted by chained calls to `ica_3des_cbc`. To do this, the resulting *iv* of the last call to `ica_3des_cbc` is fed into the *iv* of the `ica_3des_cbc_cs` call, provided that the chunk is greater than the cipher block size (8 bytes for 3DES).

Format

```
unsigned int ica_3des_cbc_cs(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned char *iv,
    unsigned int direction,
    unsigned int variant);
```

Required hardware support

KMC-TDEA-192

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*. *data_length* must be greater than or equal to the cipher block size (8 bytes for 3DES).

const unsigned char *key

Pointer to a valid 3DES key of 24 bytes in length.

unsigned char *iv

Pointer to a valid initialization vector of the same size as the cipher block in bytes. This vector is overwritten during the function. For *variant* equal to 1 or *variant* equal to 2, the result value in *iv* can be used as the initialization vector for a chained `ica_3des_cbc` or `ica_3des_cbc_cs` call with the same key, if *data_length* is a multiple of the cipher block size.

unsigned int direction

0 Use the decrypt function.

1 Use the encrypt function.

unsigned int variant

- 1 Use variant CBC-CS1 of the Addendum to NIST Special Publication 800-38A to encrypt or decrypt the message: always keep last two blocks in order.
- 2 Use variant CBC-CS2 of the Addendum to NIST Special Publication 800-38A to encrypt or decrypt the message: switch order of the last two blocks if *data_length* is not a multiple of the cipher block size (a multiple of 8 bytes for 3DES).
- 3 Use variant CBC-CS3 of the Addendum to NIST Special Publication 800-38A to encrypt or decrypt the message: always switch order of the last two blocks.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_3des_cfb

Purpose

Encrypt or decrypt data with a 3DES key using Cipher Feedback (CFB) mode, as described in NIST Special Publication 800-38A Chapter 6.3.

Format

```
unsigned int ica_3des_cfb(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned char *iv,
    unsigned int lcfb,
    unsigned int direction);
```

Required hardware support

KMF-TDEA-192

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*.

const unsigned char *key

Pointer to a valid 3DES key of 24 bytes in length.

unsigned char *iv

Pointer to a valid initialization vector of cipher block size number of bytes (8 bytes for 3DES). This vector is overwritten during the function. The result value in *iv* can be used as the initialization vector for a chained **ica_3des_cfb** call with the same key, if the *data_length* in the preceding call is a multiple of *lcfb*.

unsigned int lcfb

Length in bytes of the cipher feedback, which is a value greater than or equal to 1 and less than or equal to the cipher block size (8 bytes for 3DES).

unsigned int direction

- 0 Use the decrypt function.
- 1 Use the encrypt function.

Return codes

- 0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_3des_cmac

Purpose

Authenticate data or verify the authenticity of data with an 3DES key using the Block Cipher Based Message Authentication Code (CMAC) mode, as described in NIST Special Publication 800-38B. `ica_3des_cmac` can be used to authenticate or verify the authenticity of a complete message.

Format

```
unsigned int ica_3des_cmac(const unsigned char *message,
    unsigned long message_length,
    unsigned char *mac,
    unsigned int mac_length,
    const unsigned char *key,
    unsigned int direction);
```

Required hardware support

- KMAC-TDEA-192
- PCC-Compute-Last_block-CMAC-Using-TDEA-192

Parameters**const unsigned char *message**

Pointer to a readable buffer of size greater than or equal to *message_length* bytes. This buffer contains a message to be authenticated, or of which the authenticity is to be verified.

unsigned long message_length

Length in bytes of the message to be authenticated or verified.

unsigned char *mac

Pointer to a buffer of size greater than or equal to *mac_length* bytes. If *direction* is equal to 1, the buffer must be writable and a message authentication code for the message in *message* of size *mac_length* bytes is written to the buffer. If *direction* is equal to 0, the buffer must be readable and contain a message authentication code to be verified against the message in *message*.

unsigned int mac_length

Length in bytes of the message authentication code *mac*, which is less than or equal to the cipher block size (8 bytes for 3DES). It is recommended to use a *mac_length* of 8.

const unsigned char *key

Pointer to a valid 3DES key of 24 bytes in length.

unsigned int direction

- 0 Verify message authentication code.

- 1 Compute message authentication code for the message.

Return codes

0 Success

EFAULT

If *direction* is equal to 0 and the verification of the message authentication code fails.

For return codes indicating exceptions, see “Return codes” on page 93.

ica_3des_cmac_intermediate

Purpose

Authenticate data or verify the authenticity of data with an 3DES key using the Block Cipher Based Message Authentication Code (CMAC) mode, as described in NIST Special Publication 800-38B. `ica_3des_cmac_intermediate` and `ica_3des_cmac_last` can be used when the message to be authenticated or to be verified using CMAC is supplied in multiple chunks. `ica_3des_cmac_intermediate` is used to process all but the last chunk. All message chunks to be processed by `ica_3des_cmac_intermediate` must have a size that is a multiple of the cipher block size (a multiple of 8 bytes for 3DES).

Note that `ica_3des_cmac_intermediate` has no direction argument. This function can be used during authentication and during authenticity verification.

Format

```
unsigned int ica_3des_cmac_intermediate(const unsigned char *message,
                                       unsigned long message_length,
                                       const unsigned char *key,
                                       unsigned char *iv);
```

Required hardware support

KMAC-TDEA-192

Parameters

const unsigned char *message

Pointer to a readable buffer of size greater than or equal to *message_length* bytes. This buffer contains a non-final part of a message to be authenticated, or of which the authenticity is to be verified.

unsigned long message_length

Length in bytes of the message part in *message*. This value must be a multiple of the cipher block size.

const unsigned char *key

Pointer to a valid 3DES key of 24 bytes in length.

unsigned char *iv

Pointer to a valid initialization vector of size cipher block size (8 bytes for 3DES). For the first message part, this parameter must be set to a string of zeros. For processing the *n*-th message part, this parameter must be the resulting *iv* value of the `ica_3des_cmac_intermediate` applied to the (*n*-1)-th message part. This vector is overwritten during the function. The result value in *iv* can be used as the initialization vector for a chained call to `ica_3des_cmac_initermediate` or to `ica_3des_cmac_last` with the same key.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_3des_cmac_last

Purpose

Authenticate data or verify the authenticity of data with an 3DES key using the Block Cipher Based Message Authentication Code (CMAC) mode, as described in NIST Special Publication 800-38B. `ica_3des_cmac_last` can be used to authenticate or verify the authenticity of a complete message or of the final part of a message, for which all preceding parts were processed with `ica_3des_cmac_intermediate`.

Format

```
unsigned int ica_3des_cmac_last(const unsigned char *message,
    unsigned long message_length,
    unsigned char *mac,
    unsigned int mac_length,
    const unsigned char *key,
    unsigned char *iv,
    unsigned int direction);
```

Required hardware support

KMAC-TDEA,-192

PCC-Compute-Last_block-CMAC-Using-TDEA-192

Parameters

const unsigned char *message

Pointer to a readable buffer of size greater than or equal to *message_length* bytes. It contains a message or the final part of a message to be authenticated, or of which the authenticity is to be verified.

unsigned long message_length

Length in bytes of the message to be authenticated or verified.

unsigned char *mac

Pointer to a buffer of size greater than or equal to *mac_length* bytes. If *direction* is equal to 1, the buffer must be writable and a message authentication code for the message in *message* of size *mac_length* bytes is written to the buffer. If *direction* is equal to 0, the buffer must be readable and contain a message authentication code that is to be verified against the message in *message*.

unsigned int mac_length

Length in bytes of the message authentication code *mac* in bytes that is less than or equal to the cipher block size (8 bytes for 3DES). It is recommended to use a *mac_length* of 8.

const unsigned char *key

Pointer to a valid 3DES key of 24 bytes in length.

unsigned char *iv

Pointer to a valid initialization vector of cipher block size number of bytes. If *iv* is NULL, *message* is assumed to be the complete message to be processed. Otherwise, *message* is the final part of a composite message to be processed and *iv* contains the output vector resulting from processing all previous parts with chained calls to `ica_des_cmac_intermediate` (the value returned in *iv* of the `ica_des_cmac_intermediate` call applied to the penultimate message part.

unsigned int direction

- 0 Verify message authentication code.
- 1 Compute message authentication code for the message.

Return codes

0 Success

EFAULT

If *direction* is equal to 0 and the verification of the message authentication code fails.

For return codes indicating exceptions, see “Return codes” on page 93.

ica_3des_ctr

Purpose

Encrypt or decrypt data with a triple-length DES key using Counter (CTR) mode, as described in NIST Special Publication 800-38A Chapter 6.5. With the counter mode, each message block of size cipher block size (8 bytes for 3DES) is combined with a counter value of the same size during encryption and decryption.

Starting with an initial counter value to be combined with the first message block, subsequent counter values to be combined with subsequent message blocks are derived from preceding counter values by an increment function. The increment function used in `ica_3des_ctr` is an arithmetic increment without carry on the *M* least significant bytes in the counter, where *M* is a parameter to `ica_3des_ctr`.

Format

```
unsigned int ica_3des_ctr(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned char *ctr,
    unsigned int ctr_width,
    unsigned int direction);
```

Required hardware support

KMCTR-TDEA-192

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*.

const unsigned char *key

Pointer to a valid 3DES key of 24 bytes in length.

unsigned char *ctr

Pointer to a readable and writable buffer of the same size as the cipher block

in bytes. *ctr* contains an initialization value for a counter function that is replaced by a new value. The new value can be used as an initialization value for a counter function in a chained `ica_3des_ctr` call with the same key, if the *data_length* used in the preceding call is a multiple of the cipher block size.

unsigned int ctr_width

A number *M* between 1 and the cipher block size. The value is used by the counter increment function, which increments a counter value by incrementing without carry the least significant *M* bytes of the counter value.

unsigned int direction

- 0 Use the decrypt function.
- 1 Use the encrypt function.

Return codes

- 0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_3des_ctrlist

Purpose

Encrypt or decrypt data with an 3DES key using Counter (CTR) mode, as described in NIST Special Publication 800-38A ,Chapter 6.5. With the counter mode, each message block of the same size as the cipher block is combined with a counter value of the same size during encryption and decryption.

The `ica_3des_ctrlist` function assumes that a list *n* of precomputed counter values is provided where *n* is the smallest integer that is less than or equal to the message size divided by the cipher block size. This function is used to optimally utilize IBM z Systems hardware support for non-standard counter functions.

Format

```
unsigned int ica_3des_ctrlist(const unsigned char *in_data,  
    unsigned char *out_data,  
    unsigned long data_length,  
    const unsigned char *key,  
    const unsigned char *ctrlist,  
    unsigned int direction);
```

Required hardware support

KMCTR-TDEA-192

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*.

Calls to `ica_3des_ctrlist` with the same key can be chained if:

- With the possible exception of the last call in the chain the `data_length` used is a multiple of the cipher block size.
- The `ctrlist` argument of each chained call contains a list of counters that follows the counters used in the preceding call.

const unsigned char *key

Pointer to a valid 3DES key of 24 bytes in length.

const unsigned char *ctrlist

Pointer to a readable buffer that is both of size greater than or equal to `data_length`, and a multiple of the cipher block size (8 bytes for 3DES). `ctrlist` should contain a list of precomputed counter values, each of the same size as the cipher block.

unsigned int direction

0 Use the decrypt function.

1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_3des_ecb

Purpose

Encrypt or decrypt data with an 3DES key using Electronic Code Book (ECB) mode, as described in NIST Special Publication 800-38A Chapter 6.1.

Format

```
unsigned int ica_3des_ecb(const unsigned char *in_data,  
    unsigned char *out_data,  
    unsigned long data_length,  
    const unsigned char *key,  
    unsigned int direction);
```

Required hardware support

KM-DEA-192

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is `data_length`. The size of this buffer must be at least as large as `data_length`.

unsigned char *out_data

Pointer to a writeable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as `data_length`.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of `in_data`. `data_length` must be a multiple of the cipher block size (8 bytes for 3DES).

const unsigned char *key

Pointer to a valid 3DES key of 24 bytes in length.

unsigned int direction
0 Use the decrypt function.
1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_3des_ofb

Purpose

Encrypt or decrypt data with an 3DES key using Output Feedback (OFB) mode, as described in NIST Special Publication 800-38A Chapter 6.4.

Format

```
unsigned int ica_3des_ofb(const unsigned char *in_data,  
    unsigned char *out_data,  
    unsigned long data_length,  
    const unsigned char *key,  
    unsigned int key_length,  
    unsigned char *iv,  
    unsigned int direction);
```

Required hardware support

KMO-TDEA-192

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer that contains the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*.

const unsigned char *key

Pointer to a valid 3DES key of 24 bytes in length.

unsigned char *iv

Pointer to a valid initialization vector of the same size as the cipher block in bytes (8 bytes for 3DES). This vector is overwritten during the function. If *data_length* is a multiple of the cipher block size (a multiple of 8 for 3DES), the result value in *iv* can be used as the initialization vector for a chained **ica_3des_ofb** call with the same key.

unsigned int direction

0 Use the decrypt function.
1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

Compatibility with earlier versions

In order to stay compatible with earlier versions of libica, the following 3DES interfaces remain supported:

```
unsigned int ica_3des_encrypt(unsigned int mode,
    unsigned int data_length, unsigned char *input_data,
    ica_des_vector_t *iv, ica_des_key_triple_t *des_key,
    unsigned char *output_data);
unsigned int ica_3des_decrypt(unsigned int mode,
    unsigned int data_length, unsigned char *input_data,
    ica_des_vector_t *iv, ica_des_key_triple_t *des_key,
    unsigned char *output_data);
```

Table 4 shows libica version 2.0 TDES functions calls, and their corresponding libica version 2.4 TDES function calls.

Table 4. Compatibility of libica version 2.0 TDES functions calls to libica version 2.4 TDES function calls

| Calling this libica version 2.0 TDES function | Corresponds to calling this libica version 2.4 TDES function |
|---|---|
| <code>ica_3des_encrypt(MODE_ECB, data_length, in_data, NULL, key, out_data);</code> | <code>ica_3des_ecb(in_data, out_data, (long) data_length, key, 1);</code> |
| <code>ica_3des_encrypt(MODE_CBC, data_length, in_data, iv, key, out_data);</code> | <code>ica_3des_cbc(in_data, out_data, (long) data_length, key, iv, 1);</code> |
| <code>ica_3des_decrypt(MODE_ECB, data_length, in_data, NULL, key, out_data);</code> | <code>ica_3des_ecb(in_data, out_data, (long) data_length, key, 0);</code> |
| <code>ica_3des_decrypt(MODE_CBC, data_length, in_data, iv, key, out_data);</code> | <code>ica_3des_cbc(in_data, out_data, (long) data_length, key, iv, 0);</code> |

The functions `ica_3des_encrypt` and `ica_3des_decrypt` remain supported, but their use is discouraged in favor of `ica_3des_ecb` and `ica_3des_cbc`.

For a detailed description of the earlier APIs, see *libica Programmers Reference* version 2.0.

AES functions

These functions are included in: `include/ica_api.h`.

These functions perform encryption and decryption or computation or verification of message authentication codes using an AES key. Supported key lengths are 16, 24 or 32 bytes for AES-128, AES-192 and AES-256 respectively. The cipher block size for AES is 16 bytes.

To securely apply AES encryption to messages that are longer than the cipher block size, modes of operation can be used to chain multiple encryption, decryption, or authentication operations. Most modes of operation require an initialization vector as additional input.

As long as the messages are encrypted or decrypted using such a mode of operation, have a size that is a multiple of a particular block size (mostly the cipher block size), the functions encrypting or decryption according to a mode of operation also compute an output vector. The output vector can be used as the

initialization vector of a chained encryption or decryption operation in the same mode with the same block size and the same key.

Note that when decrypting a cipher text the mode of operation, the key, the initialization vector (if applicable), and for `ica_aes_cfb` the `lcfb` value used for the decryption function must match the corresponding settings of the encryption function that transformed the plain text into the cipher text.

ica_aes_cbc

Purpose

Encrypt or decrypt data with an AES key using Cipher Block Chaining (CBC) mode, as described in NIST Special Publication 800-38A Chapter 6.2.

Format

```
unsigned int ica_aes_cbc(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned int key_length,
    unsigned char *iv,
    unsigned int direction);
```

Required hardware support

KMC-AES-128, KMC-AES-192, or KMC-AES-256

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*. *data_length* must be a multiple of the cipher block size (a multiple of 16 for AES).

const unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32, for AES-128, AES-192, and AES-256 respectively. Therefore, you can use the definitions: `AES_KEY_LEN128`, `AES_KEY_LEN192`, and `AES_KEY_LEN256`.

unsigned char *iv

Pointer to a valid initialization vector of the same size as the cipher block in bytes. This vector is overwritten during the function. The result value in *iv* can be used as the initialization vector for a chained `ica_aes_cbc` or `ica_aes_cbc_cs` call with the same key.

unsigned int direction

0 Use the decrypt function.
1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_cbc_cs

Purpose

Encrypt or decrypt data with an AES key using Cipher Block Chaining with Ciphertext Stealing (CBC-CS) mode, as described in NIST Special Publication 800-38A Chapter 6.2, and the Addendum to NIST Special Publication 800-38A on *Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode*.

`ica_aes_cbc_cs` can be used to encrypt or decrypt the last chunk of a message consisting of multiple chunks, where all chunks except the last one are encrypted or decrypted by chained calls to `ica_aes_cbc`. To do this, the resulting *iv* of the last call to `ica_aes_cbc` is fed into the *iv* of the `ica_aes_cbc_cs` call, provided that the chunk is greater than the cipher block size (greater than 16 bytes for AES).

Format

```
unsigned int ica_aes_cbc_cs(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned int key_length,
    unsigned char *iv,
    unsigned int direction,
    unsigned int variant);
```

Required hardware support

KMC-AES-128, KMC-AES-192 or KMC-AES-256

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*. *data_length* must be greater than or equal to the cipher block size (16 bytes for AES).

const unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32, for AES-128, AES-192, and AES-256 respectively. . Therefore, you can use the definitions: `AES_KEY_LEN128`, `AES_KEY_LEN192`, and `AES_KEY_LEN256`.

unsigned char *iv

Pointer to a valid initialization vector of cipher block size number of bytes. This vector is overwritten during the function. For *variant* equal to 1 or *variant* equal to 2, the result value in *iv* can be used as the initialization vector for a chained `ica_aes_cbc` or `ica_aes_cbc_cs` call with the same key, if *data_length* is a multiple of the cipher block size.

unsigned int direction

- 0 Use the decrypt function.
- 1 Use the encrypt function.

unsigned int variant

- 1 Use variant CBC-CS1 of the Addendum to NIST Special Publication 800-38A to encrypt or decrypt the message: always keep last two blocks in order.
- 2 Use variant CBC-CS2 of the Addendum to NIST Special Publication 800-38A to encrypt or decrypt the message: switch order of the last two blocks if *data_length* is not a multiple of the cipher block size (a multiple of 16 bytes for AES).
- 3 Use variant CBC-CS3 of the Addendum to NIST Special Publication 800-38A to encrypt or decrypt the message: always switch order of the last two blocks.

Return codes

- 0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_ccm**Purpose**

Encrypt and authenticate or decrypt data and check authenticity of data with an AES key using Counter with Cipher Block Chaining Message Authentication Code (CCM) mode, as described in NIST Special Publication 800-38C. Formatting and counter functions are implemented according to NIST 800-38C Appendix A.

Format

```
unsigned int ica_aes_ccm(unsigned char *payload,
    unsigned long payload_length,
    unsigned char *ciphertext_n_mac,
    unsigned int mac_length,
    const unsigned char *assoc_data,
    unsigned long assoc_data_length,
    const unsigned char *nonce,
    unsigned int nonce_length,
    const unsigned char *key,
    unsigned int key_length,
    unsigned int direction);
```

Required hardware support

KMCTR-AES-128, KMCTR-AES-192, or KMCTR-AES-256
 KMAC-AES-128, KMAC-AES-192, or KMAC-AES-256

Parameters**unsigned char *payload**

Pointer to a buffer of size greater than or equal to *payload_length* bytes. If *direction* is equal to 1, the payload buffer must be readable and contain a

payload message of size *payload_length* to be encrypted. If *direction* is equal to 0, the payload buffer must be writable. If the authentication verification succeeds, the decrypted message in the most significant *payload_length* bytes of *ciphertext_n_mac* is written to this buffer. Otherwise, the contents of this buffer is undefined.

unsigned long payload_length

Length in bytes of the message to be encrypted or decrypted. This value can be 0 unless *assoc_data_length* is equal to 0.

unsigned char *ciphertext_n_mac

Pointer to a buffer of size greater than or equal to *payload_length* plus *mac_length* bytes. If *direction* is equal to 1, the buffer must be writable and the encrypted message from *payload* followed by the message authentication code for the nonce, the payload, and associated data are written to that buffer. If *direction* is equal to 0, then the buffer is readable and contains an encrypted message of length *payload_length* followed by a message authentication code of length *mac_length*.

unsigned int mac_length

Length in bytes of the message authentication code. Valid values are: 4, 6, 8, 10, 12, and 16.

const unsigned char *assoc_data

Pointer to a readable buffer of size greater than or equal to *assoc_data_length* bytes. The associated data in the most significant *assoc_data_length* bytes is subject to the authentication code computation, but is not encrypted.

unsigned long assoc_data_length

Length of the associated data in *assoc_data*. This value can be 0 unless *payload_length* is equal to 0.

const unsigned char *nonce

Pointer to readable buffer of size greater than or equal to *nonce_length* bytes, which contains a nonce (number used once) of size *nonce_length* bytes.

unsigned int nonce_length

Length of the *nonce* in bytes. Valid values are greater than 6 and less than 14.

const unsigned char *key

Specifies a pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32 for AES-128, AES-192 and AES-256 respectively. Therefore, you can use the definitions: **AES_KEY_LEN128**, **AES_KEY_LEN192**, and **AES_KEY_LEN256**.

unsigned int direction

0 Use the decrypt function.
1 Use the encrypt function.

Return codes

0 Success

EFAULT

If *direction* is equal to 0 and the verification of the message authentication code fails.

For return codes indicating exceptions, see "Return codes" on page 93.

ica_aes_cfb

Purpose

Encrypt or decrypt data with an AES key using Cipher Feedback (CFB) mode, as described in NIST Special Publication 800-38A Chapter 6.3.

Format

```
unsigned int ica_aes_cfb(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned int key_length,
    unsigned char *iv,
    unsigned int lcfb,
    unsigned int direction);
```

Required hardware support

KMF-AES-128, KMF-AES-192, or KMF-AES-256

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*.

const unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32, for AES-128, AES-192, and AES-256 respectively. Therefore, you can use the definitions: **AES_KEY_LEN128**, **AES_KEY_LEN192**, and **AES_KEY_LEN256**.

unsigned char *iv

Pointer to a valid initialization vector of the same size as the cipher block in bytes (16 bytes for AES). This vector is overwritten during the function. The result value in *iv* can be used as the initialization vector for a chained **ica_aes_cfb** call with the same key, if the *data_length* in the preceding call is a multiple of *lcfb*.

unsigned int lcfb

Length in bytes of the cipher feedback, which is a value greater than or equal to 1 and less than or equal to the cipher block size (16 bytes for AES).

unsigned int direction

0 Use the decrypt function.
1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_cmac

Purpose

Authenticate data or verify the authenticity of data with an AES key using the Block Cipher Based Message Authentication Code (CMAC) mode, as described in NIST Special Publication 800-38B. `ica_aes_cmac` can be used to authenticate or verify the authenticity of a complete message.

Format

```
unsigned int ica_aes_cmac(const unsigned char *message,  
    unsigned long message_length,  
    unsigned char *mac,  
    unsigned int mac_length,  
    const unsigned char *key,  
    unsigned int key_length,  
    unsigned int direction);
```

Required hardware support

KMAC-AES-128, KMAC-AES-192 or KMAC-AES-256
PCC-Compute-Last_block-CMAC-Using-AES-128, PCC-Compute-Last_block-
CMAC-Using-AES-192, or PCC-Compute-Last_block-CMAC-Using-AES-256

Parameters

const unsigned char *message

Pointer to a readable buffer of size greater than or equal to *message_length* bytes. This buffer contains a message to be authenticated, or of which the authenticity is to be verified.

unsigned long message_length

Length in bytes of the message to be authenticated or verified.

unsigned char *mac

Pointer to a buffer of size greater than or equal to *mac_length* bytes. If *direction* is equal to 1, the buffer must be writable and a message authentication code for the message in *message* of size *mac_length* bytes is written to this buffer. If *direction* is equal to 0, this buffer must be readable and contain a message authentication code to be verified against the message in *message*.

unsigned int mac_length

Length in bytes of the message authentication code *mac* in bytes, which is less than or equal to the cipher block size (16 bytes for AES). It is recommended to use values greater than or equal to 8.

const unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32 for AES-128, AES-192, and AES-256 respectively. Therefore, you can use the definitions: `AES_KEY_LEN128`, `AES_KEY_LEN192`, and `AES_KEY_LEN256`.

unsigned int direction

0 Verify message authentication code.
1 Compute message authentication code for the message.

Return codes

0 Success

EFAULT

If *direction* is equal to 0 and the verification of the message authentication code fails.

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_cmac_intermediate

Purpose

Authenticate data or verify the authenticity of data with an AES key using the Block Cipher Based Message Authentication Code (CMAC) mode, as described in NIST Special Publication 800-38B. **ica_aes_cmac_intermediate** and **ica_aes_cmac_last** can be used when the message to be authenticated or to be verified using CMAC is supplied in multiple chunks. **ica_aes_cmac_intermediate** is used to process all but the last chunk. All message chunks to be processed by **ica_aes_cmac_intermediate** must have a size that is a multiple of the cipher block size (a multiple of 16 bytes for AES).

Note that **ica_aes_cmac_intermediate** has no *direction* argument. This function can be used during authentication and during authenticity verification.

Format

```
unsigned int ica_aes_cmac_intermediate(const unsigned char *message,
    unsigned long message_length,
    const unsigned char *key,
    unsigned int key_length,
    unsigned char *iv);
```

Required hardware support

KMAC-AES-128, KMAC-AES-192, or KMAC-AES-256

Parameters

const unsigned char *message

Pointer to a readable buffer of size greater than or equal to *message_length* bytes. This buffer contains a non-final part of a message, to be authenticated or of which the authenticity is to be verified.

unsigned long message_length

Length in bytes of the message part in *message*. This value must be a multiple of the cipher block size.

const unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32 for AES-128, AES-192, and AES-256 respectively. Therefore, you can use the definitions: **AES_KEY_LEN128**, **AES_KEY_LEN192**, and **AES_KEY_LEN256**.

unsigned char *iv

Pointer to a valid initialization vector of cipher block size number of bytes (16 bytes for AES). For the first message part, this parameter must be set to a string of zeros. For processing the *n*-th message part, this parameter must be the resulting *iv* value of the **ica_aes_cmac_intermediate** function applied to the (*n-1*)-th message part. This vector is overwritten during the function. The result

value in *iv* can be used as the initialization vector for a chained call to `ica_aes_cmac_intermediate` or to `ica_aes_cmac_last` with the same key.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_cmac_last

Purpose

Authenticate data or verify the authenticity of data with an AES key using the Block Cipher Based Message Authentication Code (CMAC) mode, as described in NIST Special Publication 800-38B. `ica_aes_cmac_last` can be used to authenticate or verify the authenticity of a complete message, or of the final part of a message for which all preceding parts were processed with `ica_aes_cmac_intermediate`.

Format

```
unsigned int ica_aes_cmac_last(const unsigned char *message,
    unsigned long message_length,
    unsigned char *mac,
    unsigned int mac_length,
    const unsigned char *key,
    unsigned int key_length,
    unsigned char *iv,
    unsigned int direction);
```

Required hardware support

KMAC-AES-128, KMAC-AES-192 or KMAC-AES-256
PCC-Compute-Last_block-CMAC-Using-AES-128, PCC-Compute-Last_block-CMAC-Using-AES-192, or PCC-Compute-Last_block-CMAC-Using-AES-256

Parameters

const unsigned char *message

Pointer to a readable buffer of size greater than or equal to *message_length* bytes. This buffer contains a message or the final part of a message to be authenticated, or of which the authenticity is to be verified.

unsigned long message_length

Length in bytes of the message to be authenticated or verified.

unsigned char *mac

Pointer to a buffer of size greater than or equal to *mac_length* bytes. If *direction* is equal to 1, the buffer must be writable and a message authentication code for the message in *message* of size *mac_length* bytes is written to the buffer. If *direction* is equal to 0, the buffer must be readable and contain a message authentication code that is verified against the message in *message*.

unsigned int mac_length

Length in bytes of the message authentication code *mac* in bytes, which is less than or equal to the cipher block size (16 bytes for AES). It is recommended to use values greater than or equal to 8.

const unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32 for AES-128,

AES-192, and AES-256 respectively. Therefore, you can use the definitions: `AES_KEY_LEN128`, `AES_KEY_LEN192`, and `AES_KEY_LEN256`.

unsigned char *iv

Pointer to a valid initialization vector of cipher block size number of bytes. If *iv* is NULL, *message* is assumed to be the complete message to be processed. Otherwise, *message* is the final part of a composite message to be processed, and *iv* contains the output vector resulting from processing all previous parts with chained calls to `ica_aes_cmac_intermediate` (the value returned in *iv* of the `ica_aes_cmac_intermediate` call applied to the penultimate message part).

unsigned int direction

- 0 Verify message authentication code.
- 1 Compute message authentication code for the message.

Return codes

0 Success

EFAULT

If *direction* is equal to 0 and the verification of the message authentication code fails.

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_ctr

Purpose

Encrypt or decrypt data with an AES key using Counter (CTR) mode, as described in NIST Special Publication 800-38A Chapter 6.5. With the counter mode, each message block of size cipher block size (16 bytes for AES) is combined with a counter value of the same size during encryption and decryption.

Starting with an initial counter value to be combined with the first message block, subsequent counter values to be combined with subsequent message blocks are derived from preceding counter values by an increment function. The increment function used in `ica_aes_ctr` is an arithmetic increment without carry on the *M* least significant bytes in the counter where *M* is a parameter to `ica_aes_ctr`.

Format

```
unsigned int ica_aes_ctr(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned int key_length,
    unsigned char *ctr,
    unsigned int ctr_width,
    unsigned int direction);
```

Required hardware support

KMCTR-AES-128, KMCTR-AES-192, or KMCTR-AES-256

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*.

const unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32 for AES-128, AES-192, and AES-256 respectively. Therefore, you can use the definitions: **AES_KEY_LEN128**, **AES_KEY_LEN192**, and **AES_KEY_LEN256**.

unsigned char *ctr

Pointer to a readable and writable buffer of the same size as the cipher block in bytes. *ctr* contains an initialization value for a counter function, and it is replaced by a new value. That new value can be used as an initialization value for a counter function in a chained **ica_aes_ctr** call with the same key, if the *data_length* used in the preceding call is a multiple of the cipher block size.

unsigned int ctr_width

A number M between 1 and the cipher block size. The value is used by the counter increment function, which increments a counter value by incrementing without carry the least significant M bytes of the counter value.

unsigned int direction

0 Use the decrypt function.
1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see "Return codes" on page 93.

ica_aes_ctrlist**Purpose**

Encrypt or decrypt data with an AES key using Counter (CTR) mode, as described in NIST Special Publication 800-38A ,Chapter 6.5. With the counter mode, each message block of the same size as the cipher block in bytes is combined with a counter value of the same size during encryption and decryption.

The **ica_aes_ctrlist** function assumes that a list n of precomputed counter values is provided, where n is the smallest integer that is less than or equal to the message size divided by the cipher block size. This function optimally uses IBM z Systems hardware support for non-standard counter functions.

Format

```
unsigned int ica_aes_ctrlist(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned int key_length,
    const unsigned char *ctrlist,
    unsigned int direction);
```

Required hardware support

KMCTR-DEAKMCTR-AES-128, KMCTR-AES-192, or KMCTR-AES-256

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*.

Calls to **ica_aes_ctrlist** with the same key can be chained if:

- With the possible exception of the last call in the chain the *data_length* used is a multiple of the cipher block size.
- The *ctrlist* argument of each chained call contains a list of counters that follows the counters used in the preceding call.

const unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32 for AES-128, AES-192, and AES-256 respectively. Therefore, you can use the definitions: **AES_KEY_LEN128**, **AES_KEY_LEN192**, and **AES_KEY_LEN256**.

const unsigned char *ctrlist

Pointer to a readable buffer that is both of a size greater than or equal to *data_length*, and a multiple of the cipher block size (16 bytes for AES). *ctrlist* should contain a list of precomputed counter values, each of the same size as the cipher block.

unsigned int direction

- 0 Use the decrypt function.
- 1 Use the encrypt function.

Return codes

- 0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_ecb

Purpose

Encrypt or decrypt data with an AES key using Electronic Code Book (ECB) mode, as described in NIST Special Publication 800-38A Chapter 6.1.

Format

```
unsigned int ica_aes_ecb(const unsigned char *in_data,
    unsigned char *output,
    unsigned int data_length,
    const unsigned char *key,
    unsigned int key_length,
    unsigned int direction);
```

Required hardware support

KM-AES-128, KM-AES-192, or KM-AES-256

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*. *data_length* must be a multiple of the cipher block size (a multiple of 16 for AES).

const unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32 for AES-128, AES-192, and AES-256 respectively. Therefore, you can use the definitions: **AES_KEY_LEN128**, **AES_KEY_LEN192**, and **AES_KEY_LEN256**.

unsigned int direction

0 Use the decrypt function.
1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_gcm

Purpose

Encrypt data and authenticate data or decrypt data and check authenticity of data with an AES key using the Galois/Counter Mode (GCM), as described in NIST Special Publication 800-38D. If no message needs to be encrypted or decrypted and only authentication or authentication checks are requested, then this method implements the GMAC mode.

Format

```
unsigned int ica_aes_gcm(unsigned char *plaintext,
    unsigned long plaintext_length,
    unsigned char *ciphertext,
    const unsigned char *iv,
    unsigned int iv_length,
```

```
const unsigned char *aad,  
unsigned long aad_length,  
unsigned char *tag,  
unsigned int tag_length,  
const unsigned char *key,  
unsigned int key_length,  
unsigned int direction);
```

Required hardware support

KM-AES-128, KM-AES-192 or KM-AES-256

KIMD-GHASH

KMCTR-AES-128, KMCTR_AES-192 or KMCTR-AES-256

Parameters

unsigned char *plaintext

Pointer to a buffer of size greater than or equal to *plaintext_length* bytes. If *direction* is equal to 1, the *plaintext* buffer must be readable and contain a payload message of size *plaintext_length* to be encrypted. If *direction* is equal to 0, the *plaintext* buffer must be writable and if the authentication verification succeeds, the decrypted message in the most significant *plaintext_length* bytes of *ciphertext* is written to the buffer. Otherwise, the contents of the buffer are undefined.

unsigned long plaintext_length

Length in bytes of the message to be encrypted or decrypted. This value can be 0 unless *aad_length* is equal to 0. The value must be greater than or equal to 0 and less than $(2^{**36}) - 32$.

unsigned char *ciphertext

Pointer to a buffer of size greater than or equal to *plaintext_length* bytes. If *direction* is equal to 1, then this buffer must be writable and the encrypted message from *plaintext* is written to that buffer. If *direction* is equal to 0, then this buffer is readable and contains an encrypted message of length *plaintext_length*.

const unsigned char *iv

Pointer to a readable buffer of size greater than or equal to *iv_length* bytes, which contains an initialization vector of size *iv_length*.

unsigned int iv_length

Length in bytes of the initialization vector in *iv*. The value must be greater than 0 and less than 2^{**61} . A length of 12 is recommended.

const unsigned char *aad

Pointer to a readable buffer of size greater than or equal to *aad_length* bytes. The additional authenticated data in the most significant *aad_length* bytes is subject to the message authentication code computation, but is not encrypted.

unsigned int aad_length

Length in bytes of the additional authenticated data in *aad*. The value must be greater than or equal to 0 and less than 2^{**61} .

unsigned char *tag

Pointer to a buffer of size greater than or equal to *tag_length* bytes. If *direction* is equal to 1, this buffer must be writable, and a message authentication code for the additional authenticated data in *aad* and the plain text in *plaintext* of size *tag_length* bytes is written to this buffer. If *direction* is equal to 0, this buffer must be readable and contain a message authentication code to be verified against the additional authenticated data in *aad* and the decrypted cipher text from *ciphertext*.

unsigned int tag_length

Length in bytes of the message authentication code tag. Valid values are 4, 8, 12, 13, 14, 15, and 16.

const unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32 for AES-128, AES-192, and AES-256 respectively. Therefore, you can use the definitions: `AES_KEY_LEN128`, `AES_KEY_LEN192`, and `AES_KEY_LEN256`.

unsigned int direction

- 0 Verify message authentication code and decrypt encrypted payload.
- 1 Encrypt payload and compute message authentication code for the additional authenticated data and the payload.

Return codes

0 Success

EFAULT

If *direction* is equal to 0 and the verification of the message authentication code fails.

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_gcm_initialize

Purpose

Start and initialize a new session of AES-GCM for stream cipher requests.

Format

```
unsigned int ica_aes_gcm_initialize(const unsigned char *iv,
                                   unsigned int iv_length,
                                   unsigned char *key,
                                   unsigned int key_length,
                                   unsigned char *icb,
                                   unsigned char *ucb,
                                   unsigned char *subkey,
                                   unsigned int direction);
```

Required hardware support

KM-AES-128, KM-AES-192 or KM-AES-256

KIMD-GHASH

KMCTR-AES-128, KMCTR_AES-192 or KMCTR-AES-256

Parameters**unsigned char *iv**

Pointer to a readable buffer of size greater than or equal to **iv_length** bytes, that contains an initialization vector of size **iv_length**.

unsigned int iv_length

Length in bytes of the initialization vector in **iv**. It must be greater than 0 and less than $2^{*}61$. A length of 12 is recommended.

unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32 for AES-128,

AES-192 and AES-256 respectively. Therefore, you can use the macros: AES_KEY_LEN128, AES_KEY_LEN192, and AES_KEY_LEN256.

unsigned char *icb

Pointer to the initial counter block, which is a writable buffer that is created during `ica_aes_gcm_initialize()` and is used in `ica_aes_gcm_last()` for the final tag computation. The length of this counter block is **AES_BLOCK_SIZE** (16 bytes).

unsigned char *ucb

Pointer to the usage counter block, which is a writable buffer that is created during `ica_aes_gcm_initialize()` and is updated (increased) during the intermediate update operations. The length of this counter block is **AES_BLOCK_SIZE** (16 bytes).

unsigned char *subkey

Pointer to a writable buffer generated in `ica_aes_gcm_initialize()` and used in `ica_aes_gcm_intermediate()` and `ica_aes_gcm_last()`. The length of this subkey block is **AES_BLOCK_SIZE** (16 bytes).

unsigned int direction

- 0 Verify message authentication code and decrypt encrypted payload.
- 1 Encrypt payload and compute message authentication code for the additional authenticated data and the payload.

Return codes

- 0 Success
- EIO If the operation fails.
- EFAULT
 If **direction** equals 0 and the verification of the message authentication code fails.

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_gcm_intermediate

Purpose

Authenticate data or verify the authenticity of data with an AES key using the Galois/Counter Mode (GCM), as described in NIST Special Publication 800-38D. `ica_aes_gcm_intermediate()` and `ica_aes_gcm_last()` can be used when the message to be authenticated or to be verified using GCM is supplied in multiple chunks. `ica_aes_gcm_intermediate()` is used to process all data chunks. Be aware that all chunks, with the possible exception of the last one, must be a multiple of **AES_BLOCK_SIZE** (16 bytes). The last data chunk might be any size. In any cases the `ica_aes_gcm_last()` must be called at the end to calculate the final authentication tag.

Format

```
unsigned int ica_aes_gcm_intermediate(unsigned char *plaintext,
                                     unsigned long plaintext_length,
                                     unsigned char *ciphertext,
                                     unsigned char *ucb,
                                     unsigned char *aad,
                                     unsigned long aad_length,
                                     unsigned char *tag,
                                     unsigned int tag_length,
                                     unsigned char *key,
                                     unsigned int key_length,
                                     unsigned char *subkey,
                                     unsigned int direction);
```

Required hardware support

KIMD-GHASH

KMCTR-AES-128, KMCTR_AES-192 or KMCTR-AES-256

Parameters

unsigned char *plaintext

Pointer to a buffer of size greater than or equal to **plaintext_length** bytes.

If **direction** equals 1, the **plaintext** buffer must be readable and contain a payload message of size **plaintext_length** that is encrypted. If **direction** equals 0 the **plaintext** buffer must be writable.

If the authentication verification succeeds, the decrypted message in the most significant **plaintext_length** bytes of **ciphertext** is written to the buffer. Otherwise the contents of the buffer is undefined.

unsigned long plaintext_length

Length in bytes of the message to be encrypted or decrypted. It must be equal or greater than 0 and less than $(2^{**36})-32$. With the exception of the call followed by a call to `ica_aes_gcm_last()`, the value must be a multiple of **AES_BLOCK_SIZE**. Only in the call followed by `ica_aes_gm_last()`, the value does not have to be a multiple of **AES_BLOCK_SIZE**. Padding is done automatically.

unsigned char *ciphertext

Pointer to a buffer of a size which is a multiple of **AES_BLOCK_SIZE** and which is greater than or equal to **plaintext_length** bytes.

If **direction** equals 1, then the buffer must be writable and the encrypted message from **plaintext** is written to that buffer. If **direction** equals 0, then the buffer is readable and contains an encrypted message of a length which is equal to the least multiple of **AES_BLOCK_SIZE** that is greater than or equal to **plaintext_length**.

unsigned char *ucb

Pointer to the usage counter block, which is a writable buffer that is created during `ica_aes_gcm_initialize()` and is updated (increased) during the intermediate update operations. The length of this counter block is **AES_BLOCK_SIZE** (16 bytes). It is assumed that with the call to `ica_aes_gcm_intermediate()` the contents of the usage counter block was returned in the **ucb** parameter of a preceding call to `ica_aes_gcm_init()` or `ica_aes_gcm_intermediate()`.

unsigned char *aad

Pointer to a readable buffer of size greater than or equal to **aad_length** bytes. The additional authenticated data in the most significant **aad_length** bytes is subject to the authentication code computation, but is not encrypted.

unsigned long aad_length

Length in bytes of the additional authenticated data in **aad**. It must be equal to or greater than 0 and less than 2^{**61} , and the following constraints must apply:

- If the **aad_length** is not a multiple of **AES_BLOCK_SIZE** or 0, then in all subsequent calls to `ica_aes_gcm_intermediate()` that belong to the same AES GCM computation, the **aad_length** must be 0 which implies that only the last **aad** chunk can have a length that is not a multiple of **AES_BLOCK_SIZE**.
- If in a preceding call to `ica_aes_gcm_intermediate()` belonging to the same AES GCM computation, the **plaintext_length** was greater than 0, then **aad_length** must be 0, which implies that plaintext or ciphertext can only be supplied when all additional authenticated data is supplied.

unsigned char *tag

Contains the temporary hash/tag value.

unsigned int tag_length

This parameter is currently not used.

unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32 for AES-128, AES-192, and AES-256 respectively. Therefore, you can use the macros: AES_KEY_LEN128, AES_KEY_LEN192, and AES_KEY_LEN256.

unsigned char *subkey

Pointer to a writable buffer, generated in `ica_aes_gcm_initialize()` and used in `ica_aes_gcm_intermediate()` and `ica_aes_gcm_last()`. The length of this buffer is **AES_BLOCK_SIZE** (16 bytes).

unsigned int direction

- 0 Verify message authentication code and decrypt encrypted payload.
- 1 Encrypt payload and compute message authentication code for the additional authenticated data and the payload.

Return codes

- 0 Success
- EIO If the operation fails.
- EFAULT

If *direction* is equal to 0 and the verification of the message authentication code fails.

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_gcm_last

Purpose

Authenticate data or verify the authenticity of data with an AES key using the Galois/Counter Mode (GCM), as described in NIST Special Publication 800-38D. `ica_aes_gcm_last()` must be used to authenticate or verify the authenticity of a message for which all preceding parts were processed with `ica_aes_gcm_intermediate()`.

Format

```
unsigned int ica_aes_gcm_last(unsigned char *icb,
                             unsigned long aad_length,
                             unsigned long ciph_length,
                             unsigned char *tag,
                             unsigned char *final_tag,
                             unsigned int final_tag_length,
                             unsigned char *key,
                             unsigned int key_length,
                             unsigned char *subkey,
                             unsigned int direction);
```

Required hardware support

KIMD-GHASH
KMCTR-AES-128, KMCTR-AES-192 or KMCTR-AES-256

Parameters

unsigned char *icb

Pointer to the initial counter block, which is a writable buffer that is created during `ica_aes_gcm_initialize()` and is used in `ica_aes_gcm_last()` for the final tag computation. The length of this counter block is **AES_BLOCK_SIZE** (16 bytes).

unsigned long aad_length

Overall length of authentication data, cumulated over all intermediate operations.

unsigned long ciph_length

Length in bytes of the overall ciphertext, cumulated over all intermediate operations.

unsigned char *tag

Contains the temporary hash/tag value computed during preceding `ica_aes_gcm_initialize()` and `ica_aes_gcm_intermediate()` calls.

unsigned char *final_tag

Pointer to a readable buffer of size greater than or equal to **final_tag_length** bytes. If **direction** is 1, the buffer is not used. If **direction** is 0, this message authentication code (tag) is verified with the message authentication code computed over the intermediate update operations.

unsigned int final_tag_length

Length in bytes of the final message authentication code (tag). Valid values are 4, 8, 12, 13, 14, 15, and 16.

unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32 for AES-128, AES-192 and AES-256 respectively. Therefore, you can use the macros: **AES_KEY_LEN128**, **AES_KEY_LEN192**, and **AES_KEY_LEN256**.

unsigned char *subkey

Pointer to a writable buffer generated in `ica_aes_gcm_initialize()` and used in `ica_aes_gcm_intermediate()` and `ica_aes_gcm_last()`. The length of this subkey block is **AES_BLOCK_SIZE** (16 bytes).

unsigned int direction

- 0** Verify message authentication code and decrypt encrypted payload.
- 1** Encrypt payload and compute message authentication code for the additional authenticated data and the payload.

Return codes

0 Success

EIO If the operation fails.

EFAULT

If *direction* is equal to 0 and the verification of the message authentication code fails.

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_ofb

Purpose

Encrypt or decrypt data with an AES key using Output Feedback (OFB) mode, as described in NIST Special Publication 800-38A Chapter 6.4.

Format

```
unsigned int ica_aes_ofb(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key,
    unsigned int key_length,
    unsigned char *iv,
    unsigned int direction);
```

Required hardware support

KMO-AES-128, KMO-AES-192, or KMO-AES-256

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer that to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*.

const unsigned char *key

Pointer to a valid AES key.

unsigned int key_length

Length in bytes of the AES key. Supported sizes are 16, 24, and 32 for AES-128, AES-192, and AES-256 respectively. Therefore, you can use the definitions: **AES_KEY_LEN128**, **AES_KEY_LEN192**, and **AES_KEY_LEN256**.

unsigned char *iv

Pointer to a valid initialization vector of the same size as the cipher block, in bytes (16 bytes for AES). This vector is overwritten during the function. If *data_length* is a multiple of the cipher block size (16 bytes for AES), the result value in *iv* can be used as the initialization vector for a chained **ica_aes_ofb** call with the same key.

unsigned int direction

0 Use the decrypt function.
1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_aes_xts

Purpose

Encrypt or decrypt data with an AES key using the XEX Tweakable Bloc Cipher with Ciphertext Stealing (XTS) mode, as described in NIST Special Publication 800-38E and IEEE standard 1619-2007.

Format

```
unsigned int ica_aes_xts(const unsigned char *in_data,
    unsigned char *out_data,
    unsigned long data_length,
    const unsigned char *key1,
    const unsigned char *key2,
    unsigned int key_length,
    unsigned char *tweak,
    unsigned int direction);
```

Required hardware support

KM-XTS-AES-128, or KM-XTS-AES-256

PCC-Compute-XTS-Parameter-Using-AES-128, or PCC-Compute-XTS-Parameter-Using-AES-256

Parameters

const unsigned char *in_data

Pointer to a readable buffer that contains the message to be encrypted or decrypted. The size of the message in bytes is *data_length*. The size of this buffer must be at least as large as *data_length*.

unsigned char *out_data

Pointer to a writable buffer to contain the resulting encrypted or decrypted message. The size of this buffer in bytes must be at least as large as *data_length*.

unsigned long data_length

Length in bytes of the message to be encrypted or decrypted, which resides at the beginning of *in_data*. The minimal value of *data_length* is 16.

const unsigned char *key1

Pointer to a buffer containing a valid AES key. *key1* is used for the actual encryption of the message buffer, combined with some vector computed from the *tweak* value (Key1 in IEEE Std 1619-2007).

const unsigned char *key2

Pointer to a buffer containing a valid AES key *key2* is used to encrypt the tweak (Key2 in IEEE Std 1619-2007).

unsigned int key_length

The length in bytes of the AES key. XTS supported AES key sizes are 16 and 32, for AES-128 and AES-256 respectively. Therefore, you can use:

`2 * AES_KEY_LEN128` and `2 * AES_KEY_LEN256`.

unsigned char *tweak

Pointer to a valid 16-byte tweak value (as in IEEE standard 1619-2007). This tweak is overwritten during the function. If *data_length* is a multiple of the cipher block size (a multiple of 16 for AES), the result value in *tweak* can be used as the *tweak* value for a chained `ica_aes_xts` call with the same key pair.

unsigned int direction

0 Use the decrypt function.
1 Use the encrypt function.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

Compatibility with earlier versions

In order to stay compatible with earlier versions of libica, the following AES interfaces remain supported:

```
unsigned int ica_aes_encrypt(unsigned int mode,
    unsigned int data_length, unsigned char *input_data,
    ica_aes_vector_t *iv, unsigned int key_length, unsigned char *aes_key,
    unsigned char *output_data);
```

```
unsigned int ica_aes_decrypt(unsigned int mode,
    unsigned int data_length, unsigned char *input_data,
    ica_aes_vector_t *iv, unsigned int key_length, unsigned char *aes_key,
    unsigned char *output_data);
```

Table 5 shows libica version 2.0 AES functions calls, and their corresponding libica version 2.4 AES function calls.

Table 5. Compatibility of libica version 2.0 AES functions calls to libica version 2.4 AES function calls

| Calling this libica version 2.0 AES function | Corresponds to calling this libica version 2.4 AES function |
|--|--|
| <code>ica_aes_encrypt(MODE_ECB, data_length, in_data, NULL, key_length, key, out_data);</code> | <code>ica_aes_ecb(in_data, out_data, (long) data_length, key, key_length, 1);</code> |
| <code>ica_aes_encrypt(MODE_CBC, data_length, in_data, iv, key_length, key, out_data);</code> | <code>ica_des_cbc(in_data, out_data, (long) data_length, key, key_length, iv, 1);</code> |
| <code>ica_aes_decrypt(MODE_ECB, data_length, in_data, NULL, key_length, key, out_data);</code> | <code>ica_aes_ecb(in_data, out_data, (long) data_length, key, key_length, 0);</code> |
| <code>ica_aes_decrypt(MODE_CBC, data_length, in_data, iv, key_length, key, out_data);</code> | <code>ica_aes_cbc(in_data, out_data, (long) data_length, key, key_length, iv, 0);</code> |

The functions `ica_aes_encrypt` and `ica_aes_decrypt` remain supported, but their use is discouraged in favor of `ica_aes_ecb` and `ica_aes_cbc`.

For a detailed description of the earlier APIs, see *libica Programmers Reference* version 2.0.

Information retrieval functions

These functions are included in: `include/ica_api.h`.

`ica_get_version`

Purpose

Return libica version information.

Format

```
unsigned int ica_get_version(libica_version_info *version_info);
```

Parameters

libica_version_info *version_info

Pointer to a *libica_version_info* structure. The structure is filled with the current libica version information.

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_get_functionlist

Purpose

Returns a list of crypto mechanisms supported by libica.

Format

```
unsigned int ica_get_functionlist(libica_func_list_element *mech_list,  
unsigned int *mech_list_len);
```

Parameters

libica_func_list_element *mech_list

Null or pointer to an array of at least as many *libica_func_list_element* structures as denoted in the **mech_list_len* argument. If the value in the **mech_list_len* argument is equal to or greater than the number of mechanisms available in libica then the *libica_func_list_element* structures in **mech_list* are filled (in the order of the array indices) with information for the supported otherwise the **mech_list* argument remains unchanged.

unsigned int *mech_list_len

Pointer to an integer which contain the actual number of array elements (number of structures). If **mech_list* was NULL the contents of **mech_list_len* will be replaced by the number of mechanisms available in libica.

Return codes

0 Success

EINVAL

The value in **mech_list* is too small

For return codes indicating exceptions, see “Return codes” on page 93.

Recommended usage

First call **ica_get_functionlist** with a NULL mechanism list, then allocate the mechanism list according to number of mechanisms in libica returned by that function, and then call **ica_get_functionlist** with the allocated mechanism list.

| FIPS mode functions

| These functions are included in: include/ica_api.h.

ica_fips_status

Purpose

Queries and returns a FIPS status that indicates, which self-tests were passed or failed, and whether libica is running in FIPS mode.

The output is an integer, which is interpreted as a series of 32 bits, where each bit is a flag. Each flag, if set, corresponds to one of the defined constants as described in “FIPS mode constants” on page 89. Each constant, in return indicates either a status, or whether a certain test has passed (flag or constant is not set) or failed (flag or constant is set).

For example, look at the following returned integer as a bitmap, where only the 12 rightmost bits are considered:

```
... 0001 0000 1000
      |      |
      2^8=256 2^3=8
```

In this example, we see that bits with values 8 and 256 are set, which means, that ICA_FIPS_CRITICALFUNC 8 and ICA_FIPS_BYPASS 256 are set. This in turn means, that the *Critical functions test* and the *Bypass test* failed.

Format

```
int ica_fips_status(void);
```

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

ica_fips_powerup_tests

Purpose

Triggers the implemented self-tests. Use the `int ica_fips_status(void);` function to see which tests passed or failed (see “ica_fips_status”).

Format

```
void ica_fips_powerup_tests(void);
```

Return codes

0 Success

For return codes indicating exceptions, see “Return codes” on page 93.

Chapter 4. Accessing libica functions through the PKCS #11 API (openCryptoki)

Learn how the cryptographic functions provided by libica can be accessed using the PKCS #11 API implemented by openCryptoki.

For a description of the current PKCS #11 standard, see PKCS #11 Cryptographic Token Interface Standard.

openCryptoki overview

openCryptoki consists of an implementation of the PKCS #11 API, a slot manager, an API for slot token dynamic link libraries (STDLLs), and a set of STDLLs (or tokens). The libica token is such a STDLL introduced into openCryptoki.

The openCryptoki base library (`libopencryptoki.so`) supports the generic PKCS #11 API as outlined in the PKCS #11 specification. Currently, openCryptoki 3.6 conforms to PKCS #11 version 2.40. openCryptoki also loads token-specific modules (STDLLs) that provide the token specific implementation of the PKCS #11 API and cryptographic functions (for example, session management, object management, and crypto algorithms). So, openCryptoki 3.6 conforming to PKCS #11 2.40 requires libica version 2.5 or later. The current libica version 3.0 can be used with openCryptoki 3.4, 3.5 or later versions.

A global configuration file (`/etc/opencryptoki/opencryptoki.conf`) is provided which describes the available tokens. This configuration file can be customized for the individual tokens. The openCryptoki package contains man pages that describe the format of the configuration files. For more information, see “Adjusting the openCryptoki configuration file” on page 79.

The libica token is a plug-in into the openCryptoki token library, providing support for several cryptographic algorithms.

Slot manager

The slot manager (`pkcsslotd`) runs as a daemon. Upon start-up, it creates a shared memory segment and reads the openCryptoki configuration file to acquire the available token and slot information. The openCryptoki API attaches to this memory segment to retrieve token information. Thus, the slot manager provides the openCryptoki API with the token information when required. An application in turn links to or loads the openCryptoki API.

Slot token dynamic link libraries (STDLLs)

The libica token is an example of an STDLL within openCryptoki. STDLLs are plug-in modules to the openCryptoki (main) API. They provide token-specific functions that implement the interfaces. Specific devices can be supported by building an appropriate STDLL. Figure 1 on page 77 illustrates the stack and the process flow in a z Systems environment.

The STDLLs require local disk space to store persistent data, such as token information, personal identification numbers (PINs) and token objects. This information is stored in a separate directory for each token (for example in

/var/lib/opencryptoki/lite for the libica token). Within each of these directories there is a sub-directory TOK_OBJ that contains the token objects (token key store). Each private token object is represented by an encrypted file. Most of these directories are created during installation of openCryptoki.

The pkcsconf command line program

openCryptoki provides a command line program (/usr/sbin/pkcsconf) to configure and administer tokens that are supported within the system. The pkcsconf capabilities include token initialization, and security officer (SO) PIN and user PIN initialization and maintenance.

pkcsconf operations that address a specific token must specify the slot that contains the token with the **-c** option. You can view the list of tokens present within the system by specifying the **-t** option (without **-c** option). For example, the following code shows the options for the pkcsconf command and displays slot information for the system:

```
# pkcsconf ?  
usage: pkcsconf [-itsmIupPh] [-c slotnumber -U user-PIN -S SO-PIN -n new PIN]
```

The available options have the following meanings:

- i** display PKCS11 info
- t** display token info
- s** display slot info
- m** display mechanism list
- l** display slot description
- I** initialize token
- u** initialize user PIN
- p** set the user PIN
- P** set the SO PIN
- h | --help | ?** show pkcsconf help information
- c** specify the token slot for the operation
- U** the current user PIN (for use when changing the user pin with **-u** and **-p** options); if not specified, user will be prompted
- S** the current Security Officer (SO) pin (for use when changing the SO pin with **-P** option); if not specified, user will be prompted
- n** the new pin (for use when changing either the user pin or the SO pin with **-u**, **-p** or **-P** options); if not specified, user will be prompted

For more information about the pkcsconf command, see the pkcsconf man page.

Figure 1 on page 77 illustrates the stack and the process flow:

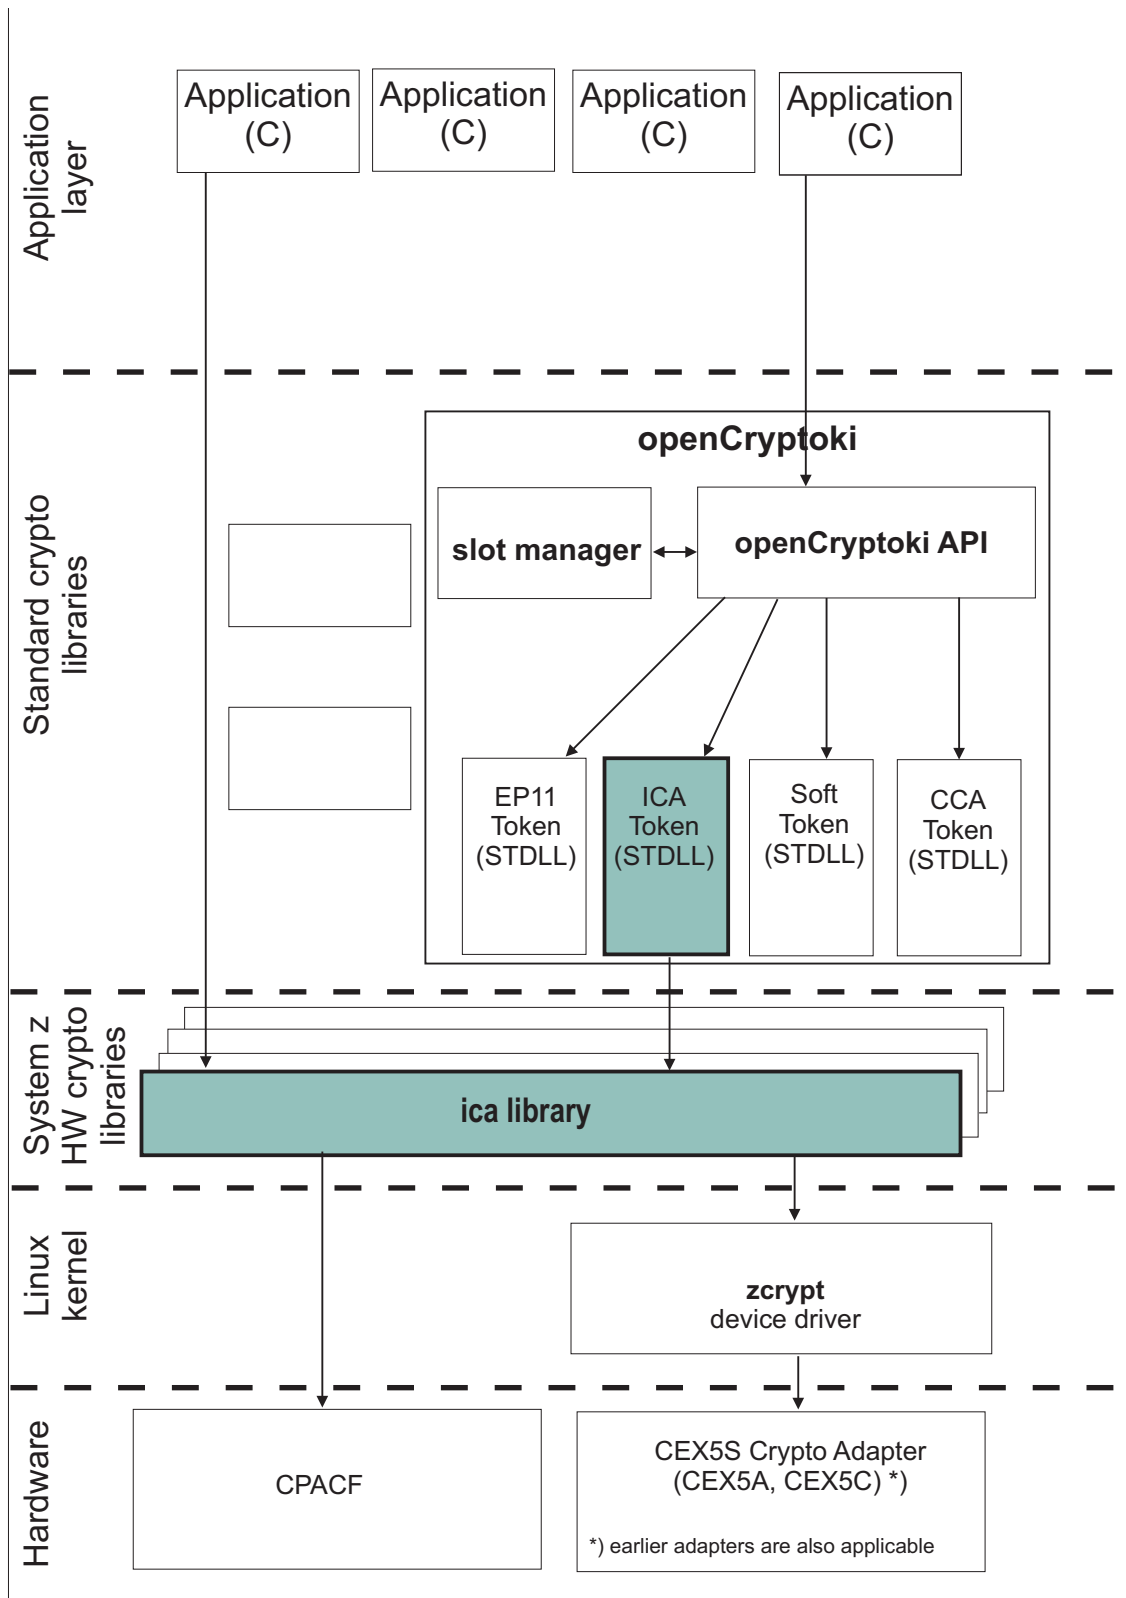

Figure 1. Stack and process flow

Functions provided by openCryptoki with the ICA token

The PKCS #11 functions that manage tokens, slots, and sessions are described in the PKCS #11 standard.

For an overview of the algorithms supported by the ica token, see “Supported mechanisms for the ICA token” on page 84.

The PKCS #11 standard describes the exact API for the mentioned mechanisms. For more information, see PKCS #11 Cryptographic Token Interface Standard

For more details about how to use openCryptoki, see “Using the ICA token” on page 84.

Installing openCryptoki

openCryptoki is shipped with the Linux on z Systems distributions. Follow the instructions in this section to install openCryptoki.

Check whether you have already installed openCryptoki in your current environment:

```
$ rpm -qa | grep -i opencryptoki
```

Note: This command example is distribution dependent. `opencryptoki` must in certain distribution be specified as `openCryptoki` (case-sensitive).

You should see all installed openCryptoki packages. If required packages are missing, use the installation tool of your Linux distribution to install the appropriate openCryptoki RPM.

Note: You must remove any previous package of openCryptoki before you install a new package.

Installing from the RPM

The current distributions already provide the openCryptoki binary RPMs.

Customers can install these openCryptoki RPM packages by using the installation tool of their selected distribution.

If you received openCryptoki as an *RPM* package, follow the *RPM* installation process that is described in the *RPM* man page. This process is the preferred installation method.

Installing from the source package

If you prefer, you can install openCryptoki from the source package.

As an alternative, for example for development purposes, you can get the latest openCryptoki version (inclusive latest patches) from the SourceForge repository (sourceforge.net/projects/opencryptoki) and build it yourself. But this version is not serviced. It is suitable for non-production systems and early feature testing, but you should not use it for production.

1. Download the latest version of the openCryptoki sources from:
<http://sourceforge.net/projects/opencryptoki/files/opencryptoki/>

2. Decompress and extract the compressed tape archive (TGZ file). There is a new directory named `opencryptoki`.
3. Change to that directory and issue the following scripts and commands:

```
$ ./bootstrap
$ ./configure
$ make
$ make install
```

The scripts or commands perform the following functions:

bootstrap

Initial setup, basic configurations

configure

Check configurations and build the makefile

make Compile and link

make install

Install the libraries

Note: When installing `openCryptoki` from the source package, the location of some installed files will differ from the location of files installed from an RPM.

Configuring `openCryptoki`

After a successful installation of `openCryptoki`, you need to perform certain configuration and customization tasks to enable the exploitation of the `libica` functions from applications. Especially, you need to set up tokens and daemons and then initialize the tokens.

`openCryptoki`, and in particular the slot manager, can handle several tokens, which can have different support for different hardware devices or software solutions. As shown in Figure 1 on page 77, `libica` interacts with the `libica` library host part. `libica` can operate with all Crypto Express adapters in accelerator or coprocessor mode, up to CEX5S (CEX5A and CEX5C), for asymmetric cryptographic functions. Furthermore it can operate with CPACF for symmetric cryptographic functions.

For a complete configuration of `openCryptoki`, finish the tasks as described in the contained subtopics:

- “Adjusting the `openCryptoki` configuration file”
- “Configuring the ICA token” on page 82
- “Initializing the ICA token” on page 82
- “How to recognize the ICA token” on page 83

Finally, to control your configuration results, follow the instructions provided in “How to recognize the ICA token” on page 83.

Adjusting the `openCryptoki` configuration file

A preconfigured list of all available tokens that are ready to register to the `openCryptoki` slot daemon is required before the `openCryptoki` daemon can start. This list is provided by the global configuration file. Read this topic for information on how to adapt this file according to your installation.

Table 6 provides an overview of supported libraries (tokens) that may be in place after you have successfully installed openCryptoki. The list may vary for different distributions and is dependent from the installed RPM packages.

Also, Linux on z Systems does not support the TPM token library.

A token is only available, if the token library is installed, and the appropriate software and hardware support pertaining to the stack of the token is also installed.

A token needs not be available, even if the corresponding token library is installed. Display the list of available tokens by using the command:

```
$ pkcsconf -t
```

Table 6. openCryptoki libraries

| Library | Explanation |
|---|---------------------------|
| /usr/lib64/opencryptoki/libopencryptoki.so | openCryptoki base library |
| /usr/lib64/opencryptoki/stdll/libpkcs11_ica.so | ICA token library |
| /usr/lib64/opencryptoki/stdll/libpkcs11_sw.so | software token library |
| /usr/lib64/opencryptoki/stdll/libpkcs11_tpm.so | TPM token library |
| /usr/lib64/opencryptoki/stdll/libpkcs11_cca.so | CCA token library |
| /usr/lib64/opencryptoki/stdll/libpkcs11_ep11.so | EP11 token library |
| /usr/lib64/opencryptoki/stdll/libpkcs11_icsf.so | ICSF token library |

Note: An analogous set of libraries is available for 32 bit compatibility mode.

Sample configuration file:

```

----- content of opencryptoki.conf -----
version opencryptoki-3.4

# The following defaults are defined:
#   hwversion = 0.0
#   firmwareversion = 0.0
#   description = Linux
#   manufacturer = IBM
#
# The slot definitions below may be overridden and/or customized.
# For example:
#   slot 0
#   {
#       stdll = libpkcs11_cca.so
#       description = "OCC CCA Token"
#       manufacturer = "MyCompany Inc."
#       hwversion = 2.32
#       firmwareversion = 1.0
#   }
# See man(5) opencryptoki.conf for further information.
#
slot 0
{
stdll = libpkcs11_tpm.so
}

slot 1
{
stdll = libpkcs11_ica.so
description = "ICA Token"
manufacturer = "IBM"
hwversion = 1.0
firmwareversion = 1.0
}

slot 2
{
stdll = libpkcs11_cca.so
}

slot 3
{
stdll = libpkcs11_sw.so
}

slot 4
{
stdll = libpkcs11_ep11.so
confname = ep11tok.conf
}
----- end -----

```

Note:

- The standard path for slot token dynamic link libraries (STDLLs) is:
/usr/lib64/opencryptoki/stdll/.

Use one of the following command to start the slot-daemon, which reads out the configuration information and sets up the tokens:

```

$ pkcsslotd start
$ service pkcsslotd start
$ systemctl start pkcsslotd.service

```

For a permanent solution, for example, for an automatic start-up of the slot-daemon, refer to the distribution documentation.

Configuring the ICA token

You need to connect the libica library to the ICA token. For this purpose, you should check the slot entry definition in the openCryptoki configuration file.

Each token has its own token directory, which is used by openCryptoki to store token-specific information (like for example, key objects, user PIN, or SO PIN). The ICA token directory is `/var/lib/opencryptoki/lite/`.

Note: This configuration is token-based. It applies to all applications that use this ICA token.

Defining the slot entry for the ICA token in openCryptoki

Normally, the default openCryptoki configuration file `opencryptoki.conf` already provides a slot entry for the ICA token. It is preconfigured to slot #1. Check this default entry to find out whether you can use it as is. If it is missing, then define a slot entry that sets the `stdll` attribute to `libpkcs11_ica.so`.

Initializing the ICA token

Once the configuration files of openCryptoki and the ICA token are set up, and the `pkcs10td` daemon is started, the ICA token must be initialized.

Note: PKCS #11 defines two users for each token: a security officer (SO) whose responsibility is the administration of the token, and a standard user (User) who wants to use the token to perform cryptographic operations. openCryptoki requires that for both the SO and the User a log-in PIN is defined as part of the token initialization.

The following command provides some useful slot information:

```
# pkcsconf -s

Slot #0 Info
  Description: EP11 Token
  Manufacturer: IBM
  Flags: 0x1 (TOKEN_PRESENT)
  Hardware Version: 1.2
  Firmware Version: 1.0

Slot #1 Info
  Description: ICA Token
  Manufacturer: IBM
  Flags: 0x1 (TOKEN_PRESENT)
  Hardware Version: 2.32
  Firmware Version: 1.0
```

Find your preferred token in the details list and select the correct slot number. This number is used in the next initialization steps to identify your token:

```
$ pkcsconf -I -c <slot> // Initialize the Token and setup a Token Label
$ pkcsconf -P -c <slot> // change the SO PIN (recommended)
$ pkcsconf -u -c <slot> // Initialize the User PIN (SO PIN required)
$ pkcsconf -p -c <slot> // change the User PIN (optional)
```

pkcsconf -I

During token initialization, you are asked for a token label. Provide a meaningful name, because you might need this reference for identification purposes.

pkcsconf -P

For security reasons, openCryptoki requires that you change the default SO PIN (87654321) to a different value. Use the `pkcsconf -P` option to change the SO PIN.

pkcsconf -u

When you enter the user PIN initialization you are asked for the newly set SO PIN. The length of the user PIN must be 4 - 8 characters.

pkcsconf -p

You must at least once change the user PIN with `pkcsconf -p` option. After you completed the PIN setup, the token is prepared and ready for use.

Note: An initialization (`pkcsconf -u` option) with 12345678 will work without any issues. However, this is not recommended, because this pattern is checked internally and marked as default PIN. Therefore, change to a user PIN that is different from 12345678.

How to recognize the ICA token

You can use the `pkcsconf -t` command to display a table that shows all available tokens. You can check the slot and token information, and the PIN status at any time.

The following information provided by the `pkcsconf -t` command about the ICA token is returned in the *Token Info* section, where, for example, *Token #1 Info* displays information about the token plugged into slot number 1.

```
$ pkcsconf -t
Token #0 Info:
Label: IBM ICA PKCS #11
Manufacturer: IBM Corp.
Model: IBM ICA
Serial Number: 123
Flags: 0x880045 (RNG|LOGIN_REQUIRED|CLOCK_ON_TOKEN|USER_PIN_TO_BE_CHANGED|SO_PIN_TO_BE_CHANGED)
Sessions: 0/18446744073709551614
R/W Sessions: 18446744073709551615/18446744073709551614
PIN Length: 4-8
Public Memory: 0xFFFFFFFFFFFFFFFF/0xFFFFFFFFFFFFFFFF
Private Memory: 0xFFFFFFFFFFFFFFFF/0xFFFFFFFFFFFFFFFF
Hardware Version: 1.0
Firmware Version: 1.0
Time: 14:48:30
```

Figure 2. Token info before initialization

The most important information is as follows:

- The token **Label** you assigned at the initialization phase (IBM ICA PKCS #11, in the example). You can initialize or change a token label by using the `pkcsconf -I` command. In the output from Figure 3 on page 84 you see the label changed to `icatest`.
- The **Model** name is unique and designates the token that is in use.
- The **Flags** provide information about the token initialization status, the PIN status, and features such as *Random Number Generator* (RNG). They also

provide information about requirements, such as *Login required*, which means that there is at least one mechanism that requires a session log-in to use that cryptographic function.

The flag `USER_PIN_TO_BE_CHANGED` indicates that the user PIN must be changed before the token can be used. The flag `SO_PIN_TO_BE_CHANGED` indicates that the SO PIN must be changed before administration commands can be used.

For more information about the flags provided in this output, see the description of the `TOKEN_INFO` structure and the Token Information Flags in the PKCS #11 Cryptographic Token Interface Standard.

- The **PIN length** range declared for this token.

```
Token #0 Info:
Label: icatest
Manufacturer: IBM Corp.
Model: IBM ICA
Serial Number: 123
Flags: 0x44D (RNG|LOGIN_REQUIRED|USER_PIN_INITIALIZED|CLOCK_ON_TOKEN|TOKEN_INITIALIZED)
Sessions: 0/18446744073709551614
R/W Sessions: 18446744073709551615/18446744073709551614
PIN Length: 4-8
Public Memory: 0xFFFFFFFFFFFFFFFF/0xFFFFFFFFFFFFFFFF
Private Memory: 0xFFFFFFFFFFFFFFFF/0xFFFFFFFFFFFFFFFF
Hardware Version: 1.0
Firmware Version: 1.0
Time: 14:56:24
```

Figure 3. Token info after initialization

Figure 2 on page 83 shows the information for an uninitialized token, and Figure 3 shows the information for an initialized one.

Using the ICA token

Applications that are designed to work with openCryptoki can take advantage of the libica library functions by using the openCryptoki standard interface (PKCS #11 standard C API).

Applications that are designed to work with openCryptoki are also able to use the functions provided by the ICA token.

For a list of code samples, refer to “openCryptoki code samples” on page 154.

Supported mechanisms for the ICA token

View a list of the supported mechanisms for the ICA token in the openCryptoki implementation.

Use the following command to retrieve a complete list of algorithms (or mechanisms) that are supported by the token:

```

$ pkcsconf -m -c <slot>
Mechanism #2
  Mechanism: 0x131 (CKM_DES3_KEY_GEN)
  Key Size: 24-24
  Flags: 0x8001 (CKF_HW|CKF_GENERATE)
...
Mechanism #10
  Mechanism: 0x132 (CKM_DES3_ECB)
  Key Size: 24-24
  Flags: 0x60301 (CKF_HW|CKF_ENCRYPT|CKF_DECRYPT|CKF_WRAP|CKF_UNWRAP)
...
Mechanism #11
  Mechanism: 0x133 (CKM_DES3_CBC)
  Key Size: 24-24
  Flags: 0x60301 (CKF_HW|CKF_ENCRYPT|CKF_DECRYPT|CKF_WRAP|CKF_UNWRAP)
...

```

The list displays all mechanisms supported by this token. The mechanism ID and name corresponds to the PKCS #11 specification. Each mechanism provides its supported key size and some further properties such as hardware support and mechanism information flags. These flags provide information about the PKCS #11 functions that may use the mechanism. Typical functions are for example, *encrypt*, *decrypt*, *wrap key*, *unwrap key*, *sign*, or *verify*.

Table 7. Supported mechanism list for the ica token

| Mechanisms | ica token | supported with openCryptoki version |
|----------------------------|-----------|-------------------------------------|
| CKM_GENERIC_SECRET_KEY_GEN | x | 3.4 |
| CKM_RSA_PKCS_KEY_PAIR_GEN | x | 2.4 |
| CKM_RSA_PKCS | x | 2.4 |
| CKM_RSA_X_509 | x | 2.4 |

| CKM_AES_CBC_PAD | x | 2.4 |
| CKM_AES_CTR | x | 2.4 |
| CKM_AES_GCM | x | 3.4 |

Chapter 5. libica constants, type definitions, data structures, and return codes

Use these constants, type definitions, data structures, and return codes when you program with the libica APIs.

The APIs are described in Chapter 3, “libica version 3.0 application programming interfaces,” on page 9. To use them, include `ica_api.h` in your programs.

libica constants

The constants listed in this topic are provided and valid for the current libica version.

Use these constants instead of the equivalent libica version 1 constants. There is no difference in their values.

```
#define ICA_ENCRYPT 1
#define ICA_DECRYPT 0
#define ICA_DRBG_NEW_STATE_HANDLE NULL
```

FIPS mode constants

```
/* 'FIPS mode active'-flag */
#define ICA_FIPS_MODE 1
```

Powerup-test-failed flags

```
/* Cryptographic algorithm test (KAT or pair-wise consistency test) */
#define ICA_FIPS_CRYPTOALG 2
```

```
/* Critical functions test (N/A) */
#define ICA_FIPS_CRITICALFUNC 8
```

Conditional-test-failed flags

```
/* Pair-wise consistency test for public & private keys (N/A) */
#define ICA_FIPS_CONSISTENCY 16
```

```
/* Software/Firmware load test (N/A) */
#define ICA_FIPS_LOAD 32
```

```
/* Manual key entry test (N/A) */
#define ICA_FIPS_KEYENTRY 64
```

```
/* Continuous random number generator test */
#define ICA_FIPS_RNG 128
```

```
/* Bypass test (N/A) */
#define ICA_FIPS_BYPASS 256
```

Type definitions

These type definitions are available to ensure compatibility with libica version 1 types.

```
typedef ica_des_vector_t ICA_DES_VECTOR;
typedef ica_des_key_single_t ICA_KEY_DES_SINGLE;
typedef ica_des_key_triple_t ICA_KEY_DES_TRIPLE;
typedef ica_aes_vector_t ICA_AES_VECTOR;
typedef ica_aes_key_single_t ICA_KEY_AES_SINGLE;
typedef ica_aes_key_len_128_t ICA_KEY_AES_LEN128;
typedef ica_aes_key_len_192_t ICA_KEY_AES_LEN192;
typedef ica_aes_key_len_256_t ICA_KEY_AES_LEN256;
typedef sha_context_t SHA_CONTEXT;
typedef sha256_context_t SHA256_CONTEXT;
typedef sha512_context_t SHA512_CONTEXT;
typedef unsigned char ica_des_vector_t[8];
typedef unsigned char ica_des_key_single_t[8];
typedef unsigned char ica_key_t[8];
typedef unsigned char ica_aes_vector_t[16];
typedef unsigned char ica_aes_key_single_t[8];
typedef unsigned char ica_aes_key_len_128_t[16];
typedef unsigned char ica_aes_key_len_192_t[24];
typedef unsigned char ica_aes_key_len_256_t[32];
typedef struct ica_drbg_mech ica_drbg_mech_t;
typedef struct ica_drbg ica_drbg_t;
```

Data structures

These structures are used in the API of the current libica version.

For the definitions of older functions, see previous versions of this book. The older functions are no longer recommended for use, but they are supported.

```
typedef struct {
    unsigned int key_length;
    unsigned char* modulus;
    unsigned char* exponent;
} ica_rsa_key_mod_expo_t;

typedef struct {
    unsigned int key_length;
    unsigned char* p;
    unsigned char* q;
    unsigned char* dp;
    unsigned char* dq;
    unsigned char* qInverse;
} ica_rsa_key_crt_t;

typedef struct {
    unsigned int mech_mode_id;
    unsigned int flags;
    unsigned int property;
} libica_func_list_element;
```

* mech_mode_id: Unique mechanism ID for each mechanism implemented in libica

```

#define SHA1 1
#define SHA224 2
#define SHA256 3
#define SHA384 4
#define SHA512 5
#define DES_ECB 20
#define DES_CBC 21
#define DES_CBC_CS 22
#define DES_OFB 23
#define DES_CFB 24
#define DES_CTR 25
#define DES_CTRLST 26
#define DES_CBC_MAC 27
#define DES_CMAC 28
#define DES3_ECB 41
#define DES3_CBC 42
#define DES3_CBC_CS 43
#define DES3_OFB 44
#define DES3_CFB 45
#define DES3_CTR 46
#define DES3_CTRLST 47
#define DES3_CBC_MAC 48
#define DES3_CMAC 49
#define AES_ECB 60
#define AES_CBC 61
#define AES_CBC_CS 62
#define AES_OFB 63
#define AES_CFB 64
#define AES_CTR 65
#define AES_CTRLST 66
#define AES_CBC_MAC 67
#define AES_CMAC 68
#define AES_CCM 69
#define AES_GCM 70
#define AES_XTS 71
#define P_RNG 80
#define RSA_ME 90
#define RSA_CRT 91
#define RSA_KEY_GEN_ME 92
#define RSA_KEY_GEN_CRT 93

```

For more details regarding these mechanisms, refer to the openCryptoki version 2.20 specification.

*** flags**

This flag represents the type of hardware/software support for each mechanism.

#define ICA_FLAG_SHW 4

Static hardware support (operations on CPACF). Hardware support will be available unless a hardware error occurs.

#define ICA_FLAG_DHW 2

Dynamic hardware support (operations on crypto cards). Hardware support will be available unless the hardware is reconfigured.

#define ICA_FLAG_SW 1

Software support. If both static and dynamic hardware support as well as software support are available, then software support is used as fall back if hardware support fails.

*** property**

This property field is optional depending on the mechanism. It is used to declare mechanism specific parameters, such as key sizes for RSA and AES.

For RSA mechanisms:

- **bit 0**
512 bit key size support
- **bit 1**
1024 bit key size support
- **bit 2**
2048 bit key size support
- **bit 3**
4096 bit key size support

For AES mechanisms:

- **bit 0**
128 bit key size support
- **bit 1**
192 bit key size support
- **bit 2**
256 bit key size support

For all non-RSA/AES mechanisms this field is empty.

Take note of these considerations:

- The buffers pointed to by members of type *unsigned char ** must be manually allocated and deallocated by the user.
- Key parts must always be right-aligned in their fields.
- All buffers pointed to by members *modulus* and *exponent* in struct *ica_rsa_key_mod_expo_t* must be of length *key_length*.
- All buffers pointed to by members *p*, *q*, *dp*, *dq*, and *qInverse* in struct *ica_rsa_key_crt_t* must be of size *key_length / 2* or larger.
- In the struct *ica_rsa_key_crt_t*, the buffers *p*, *dp*, and *qInverse* must contain 8 bytes of zero padding in front of the actual values.
- If an exponent is set in struct *ica_rsa_key_mod_expo_t* as part of a public key for key generation, be aware that due to a restriction in OpenSSL, the public exponent cannot be larger than a size of unsigned long. Therefore, you must have zeros left-padded in the buffer pointed to by *exponent* in the struct *ica_rsa_key_mod_expo_t* struct. Be aware that this buffer also must be of size *key_length*.
- This *key_length* value should be calculated from the length of the modulus in bits, according to this calculation:

$$\text{key_length} = (\text{modulus_bits} + 7) / 8$$

```
typedef struct {
    uint64_t runningLength;
    unsigned char shaHash[LENGTH_SHA_HASH];
} sha_context_t;
typedef struct {
    uint64_t runningLength;
    unsigned char sha256Hash[LENGTH_SHA256_HASH];
} sha256_context_t;
typedef struct {
    uint64_t runningLengthHigh;
    uint64_t runningLengthLow;
    unsigned char sha512Hash[LENGTH_SHA512_HASH];
} sha512_context_t;
```

```
typedef struct {
    unsigned int major_version;
    unsigned int minor_version;
    unsigned int fixpack_version;
} libica_version_info;
```

Return codes

The current libica functions use the standard Linux return codes listed in this topic.

0 Success

EFAULT

The message authentication failed.

EINVAL

Incorrect parameter

EIO I/O error

EPERM

Operation not permitted by Hardware (CPACF).

ENODEV

No such device

ENOMEM

Not enough memory

errno When libica calls **open**, **close**, **begin_sigill_section**, or OpenSSL function **RSA_generate_key_ex()**, the error codes of these programs are returned.

Chapter 6. libica tools

The libica package includes tools to investigate the capabilities of your cryptographic hardware and how these capabilities are used by applications that use libica.

icainfo - Show available libica functions

Use the **icainfo** command to find out which libica functions are available on your Linux system.

The **icainfo** output also indicates, whether the libica library has built-in FIPS support, whether it is running in FIPS mode, and whether it is in an error state. Algorithms that are not FIPS approved are marked as blocked in both table columns when running in FIPS mode. All algorithms are marked as blocked when libica is in an error state.

Format

icainfo syntax

Where:

-v or --version

Displays the version number of **icainfo**, then exits.

-h or --help

Displays help information for the command.

Examples

To obtain an overview of the supported algorithms with modes of operations and how they are implemented on your Linux system (hardware, software, or both), enter:

```
# icainfo
```

View the output produced by this command. A no in column software indicates, that no software fallback for this function is implemented in libica.

The following CP Assist for Cryptographic Function (CPACF) operations are supported by libica on this system:

```
      Cryptographic algorithm support
-----+-----+-----
function | hardware | software
-----+-----+-----
      SHA-1 |      yes  |      yes
```

| | | |
|--------------|---------|---------|
| SHA-224 | yes | yes |
| SHA-256 | yes | yes |
| SHA-384 | yes | yes |
| SHA-512 | yes | yes |
| GHASH | yes | no |
| P_RNG | blocked | blocked |
| DRBG-SHA-512 | yes | yes |
| RSA ME | no | yes |
| RSA CRT | no | yes |
| DES ECB | blocked | blocked |
| DES CBC | blocked | blocked |
| DES OFB | blocked | blocked |
| DES CFB | blocked | blocked |
| DES CTR | blocked | blocked |
| DES CMAC | blocked | blocked |
| 3DES ECB | yes | yes |
| 3DES CBC | yes | yes |
| 3DES OFB | yes | no |
| 3DES CFB | yes | no |
| 3DES CTR | yes | no |
| 3DES CMAC | yes | no |
| AES ECB | yes | yes |
| AES CBC | yes | yes |
| AES OFB | yes | no |
| AES CFB | yes | no |
| AES CTR | yes | no |
| AES CMAC | yes | no |
| AES XTS | yes | no |

 Built-in FIPS support: FIPS mode active.

icastats - Show use of libica functions

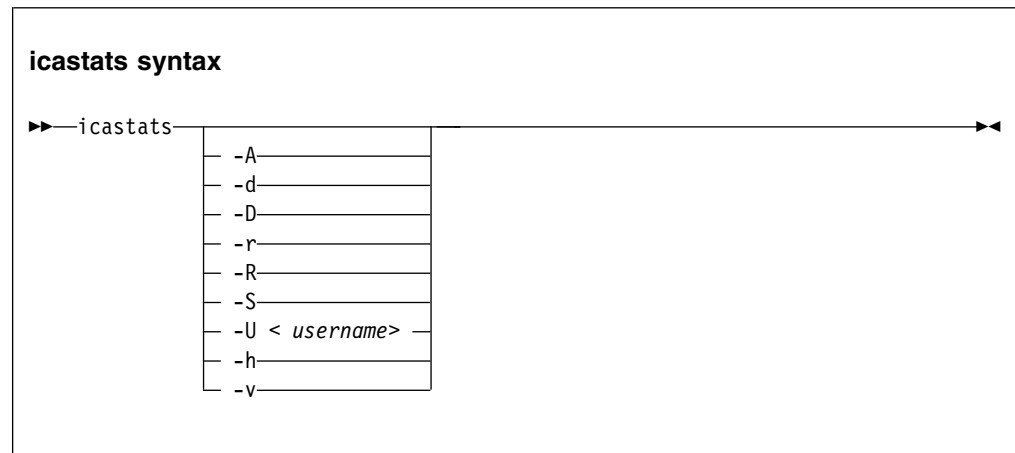

Use the **icastats** utility to find out whether libica uses hardware acceleration features or works with software fallbacks. **icastats** collects the statistical data per user and not per system.

The command also shows which specific functions of libica are used. For a standard user, **icastats** shows a statistics table with all crypto operations that are used by the user's processes. For the root user, **icastats** provides statistics for all users, or processes, on the system.

The shared memory segment that holds the statistic data is created when a user starts **icastats** or when a program is started, that performs cryptographic operations using libica. Once the shared memory segment exists, it can only be removed by one of the delete options (**-d** or **-D**) provided with the **icastats** utility. Thus, this function collects crypto statistics independently from the process context for continuing availability of data. All cryptographic operations using libica are counted into the statistics.

Note: Before deleting the shared memory segment, ensure that there are no running applications that are using this memory segment.

Format

Where:

-A or --all

Shows the statistic tables from all users (for root users only).

-d or --delete

Removes the user specific shared memory segment.

-D or --delete-all

Removes all shared memory segments (for root users only).

-r or --reset

Resets the user statistic data table.

-R or --reset-all

Resets all statistic data tables from all users (for root users only).

-S or --summary

Shows accumulated statistics from all users (for root users only).

-U <username> or --user <username>

Shows statistic data for a dedicated user (for root users only).

-h or --help

Displays help information for the command.

-v or --version

Displays the version number of **icastats**, then exits.

Examples

To display the current use of libica functions issue:

```
# icastats
```

View an excerpt of a sample output produced by this command:

| function | # hardware | | | # software | | |
|----------|------------|-------|-----|------------|-------|-----|
| | ENC | CRYPT | DEC | ENC | CRYPT | DEC |
| SHA-1 | | 0 | | | 0 | |
| SHA-224 | | 0 | | | 0 | |
| SHA-256 | | 0 | | | 0 | |

| | | | | |
|-----------|-----|---|---|---|
| SHA-384 | 0 | | | 0 |
| SHA-512 | 0 | | | 0 |
| GHASH | 0 | | | 0 |
| P_RNG | 55 | | | 0 |
| RSA-ME | 351 | | | 1 |
| RSA-CRT | 64 | | | 0 |
| DES ECB | 0 | 0 | 0 | 0 |
| DES CBC | 0 | 0 | 0 | 0 |
| DES OFB | 0 | 0 | 0 | 0 |

| 3DES CBC | 0 | 0 | 0 | 0 |
| 3DES OFB | 0 | 0 | 0 | 0 |
| 3DES CFB | 0 | 0 | 0 | 0 |
| 3DES CTR | 0 | 0 | 0 | 0 |
| 3DES CMAC | 0 | 0 | 0 | 0 |
| AES ECB | 0 | 0 | 0 | 0 |
| AES CBC | 0 | 0 | 0 | 0 |
| AES OFB | 0 | 0 | 0 | 0 |
| AES CFB | 0 | 0 | 0 | 0 |
| AES CTR | 0 | 0 | 0 | 0 |
| AES CMAC | 0 | 0 | 0 | 0 |
| AES XTS | 0 | 0 | 0 | 0 |

Logging and error handling

Access failures to the shared memory segments that are used by the **icastats** utility, are logged once via the syslog interface. After a failed attempt to access the shared memory segment, the library no longer collects any statistic data for this application (related to application lifetime and user).

Example of syslog message:

```
<date> <machine> <application>: failed to create or access shared memory segment.
```

The **icastats** utility prints an error messages if it cannot create, access, or remove the shared memory segment.

Note: The log message may indicate a permission problem with the shared memory segment. An administrator can remove the defect memory segment. The next call of **icastats** should create a new memory segment automatically.

Chapter 7. Examples

These sample program segments illustrate the use of the libica APIs.

These examples are released under the Common Public License - V1.0, which is stated in full at the end of this chapter. See “Common Public License - V1.0” on page 165.

In the extracted source package, you also find test cases for all APIs in directory `.../src/tests/`. You can have the source of these test cases compiled using the `--enable-testcases` option with the **configure** command as described in “Installing libica version 3.0 from the source package” on page 5.

View a list of examples for libica, and the makefile used to create the library.

```

openCryptoki code samples

This section provides coding samples in C for dynamic library calls as well as for direct access with static shared linked libraries.

- “Dynamic library call” on page 155
- “Shared linked library” on page 155

Coding samples (C)

To develop an application that uses openCryptoki, you need to access the library.

There are two ways to access the library:

- Load shared objects using dynamic library calls (dlopen)
- Link the library (statically) to your application during built time

For a list of supported mechanisms for the ICA token, refer to “Supported mechanisms for the ICA token” on page 84.

Dynamic library call

View some openCryptoki code samples for a dynamic library call.

```
#include <stdlib.h>
#include <errno.h>
#include <stdio.h>
#include <dlfcn.h>
#include <pkcs11types.h>

CK_RV init();
CK_RV cleanup();
CK_RV rc; /* return code */
void *dllPtr, (*symPtr)(); /* pointer to the ock library */
CK_FUNCTION_LIST_PTR FunctionPtr = NULL; /* pointer to function list */

int main(int argc, char *argv[]){
    init("/usr/lib64/opencryptoki/libopencryptoki.so"); /* opencryptoki initialization */
    /* ... other opencryptoki commands... */
    cleanup(); /* cleanup/close shared library */
    return 0;
}

CK_RV init(char *libPath){

    dllPtr = dlopen(libPath, RTLD_NOW); /* open the PKCS11 library */
    if (!dllPtr) {
        printf("Error loading PKCS#11 library \n");
        return errno;
    }
    symPtr = (void (*)())dlsym(dllPtr, "C_GetFunctionList"); /* Get ock function list */
    if (!symPtr) {
        printf("Error getting function list \n");
        return errno;
    }
    symPtr(&FunctionPtr);
    rc = FunctionPtr->C_Initialize(NULL); /* initialize opencryptoki/tokens */
    if (rc != CKR_OK) {
        printf("Error initializing the opencryptoki library: 0x%X\n", rc);
        cleanup();
    }
    printf("Opencryptoki initialized.\n");
    return CKR_OK;
}

CK_RV cleanup(void) {
    rc = FunctionPtr->C_Finalize(NULL);
    if (dllPtr)
        dlclose(dllPtr);
    return rc;
}
```

To compile your sample code you need to provide the path of the source/include files. Issue a command of the form:

```
gcc sample_dynamic.c -g -O0 -o sample_dynamic -I <include filepath>
```

The exact location of the include files depends on your Linux distribution.

Shared linked library

When you use your sample code with a static linked library you can access the APIs directly.

At the compile time you need to specify the openCryptoki library:

```
gcc sample_shared.c -g -O0 -o sample_shared /usr/lib64/opencryptoki/libopencryptoki.so
-I /usr/<include filepath>
```

The exact location of the include files depend on your Linux distribution.

The following code samples that interact with the openCryptoki API are based on the shared linked openCryptoki library.

Base procedures:

View some openCryptoki code samples for base procedures, such as main program, initialization, slot and token, mechanism, and finalize information.

The following code sample provides an insight into how to deal with the openCryptoki API's. After describing some basic functions such as initialization, session and login handling, the sample shows how to retrieve data, such as get slot and token information and also detailed mechanism information. It also provides an introduction about how to create key objects and process symmetric encryption/decryption (DES). The last section shows RSA key generation with RSA encrypt and decrypt operations.

Main program

```
#include <stdlib.h>
#include <errno.h>
#include <stdio.h>
#include <dlopen.h>
#include <pkcs11types.h>
#include <defs.h>

Common Public License - V1.0

Common Public License - V1.0

THE ACCOMPANYING PROGRAM IS PROVIDED UNDER THE TERMS OF THIS COMMON PUBLIC LICENSE ("AGREEMENT"). ANY USE, REPRODUCTION OR DISTRIBUTION OF THE PROGRAM CONSTITUTES RECIPIENT'S ACCEPTANCE OF THIS AGREEMENT.

1. DEFINITIONS

"Contribution" means:

1. in the case of the initial Contributor, the initial code and documentation distributed under this Agreement, and
2. in the case of each subsequent Contributor:
 1. changes to the Program, and
 2. additions to the Program;

where such changes and/or additions to the Program originate from and are distributed by that particular Contributor. A Contribution 'originates' from a Contributor if it was added to the Program by such Contributor itself or anyone acting on such Contributor's behalf. Contributions do not include additions to the Program which: (i) are separate modules of software distributed in conjunction with the Program under their own license agreement, and (ii) are not derivative works of the Program.

"Contributor" means any person or entity that distributes the Program.

"Licensed Patents " mean patent claims licensable by a Contributor which are necessarily infringed by the use or sale of its Contribution alone or when combined with the Program.

"Program" means the Contributions distributed in accordance with this Agreement.

"Recipient" means anyone who receives the Program under this Agreement, including all Contributors.

2. GRANT OF RIGHTS

1. Subject to the terms of this Agreement, each Contributor hereby grants Recipient a non-exclusive, worldwide, royalty-free copyright license to reproduce, prepare derivative works of, publicly display, publicly perform, distribute and sublicense the Contribution of such Contributor, if any, and such derivative works, in source code and object code form.

2. Subject to the terms of this Agreement, each Contributor hereby grants Recipient a non-exclusive, worldwide, royalty-free patent license under Licensed Patents to make, use, sell, offer to sell, import and otherwise transfer the Contribution of such Contributor, if any, in source code and object code form. This patent license shall apply to the combination of the Contribution and the Program if, at the time

the Contribution is added by the Contributor, such addition of the Contribution causes such combination to be covered by the Licensed Patents. The patent license shall not apply to any other combinations which include the Contribution. No hardware per se is licensed hereunder.

3. Recipient understands that although each Contributor grants the licenses to its Contributions set forth herein, no assurances are provided by any Contributor that the Program does not infringe the patent or other intellectual property rights of any other entity. Each Contributor disclaims any liability to Recipient for claims brought by any other entity based on infringement of intellectual property rights or otherwise. As a condition to exercising the rights and licenses granted hereunder, each Recipient hereby assumes sole responsibility to secure any other intellectual property rights needed, if any. For example, if a third party patent license is required to allow Recipient to distribute the Program, it is Recipient's responsibility to acquire that license before distributing the Program.

4. Each Contributor represents that to its knowledge it has sufficient copyright rights in its Contribution, if any, to grant the copyright license set forth in this Agreement.

3. REQUIREMENTS

A Contributor may choose to distribute the Program in object code form under its own license agreement, provided that:

1. it complies with the terms and conditions of this Agreement; and
2. its license agreement:
 1. effectively disclaims on behalf of all Contributors all warranties and conditions, express and implied, including warranties or conditions of title and non-infringement, and implied warranties or conditions of merchantability and fitness for a particular purpose;
 2. effectively excludes on behalf of all Contributors all liability for damages, including direct, indirect, special, incidental and consequential damages, such as lost profits;
 3. states that any provisions which differ from this Agreement are offered by that Contributor alone and not by any other party; and
 4. states that source code for the Program is available from such Contributor, and informs licensees how to obtain it in a reasonable manner on or through a medium customarily used for software exchange.

When the Program is made available in source code form:

1. it must be made available under this Agreement; and
2. a copy of this Agreement must be included with each copy of the Program.

Contributors may not remove or alter any copyright notices contained within the Program.

Each Contributor must identify itself as the originator of its Contribution, if any, in a manner that reasonably allows subsequent Recipients to identify the originator of the Contribution.

4. COMMERCIAL DISTRIBUTION

Commercial distributors of software may accept certain responsibilities with respect to end users, business partners and the like. While this license is intended to facilitate the commercial use of the Program, the Contributor who includes the Program in a commercial product offering should do so in a manner which does not create potential liability for other Contributors. Therefore, if a Contributor includes the Program in a commercial product offering, such Contributor ("Commercial Contributor") hereby agrees to defend and indemnify every other Contributor ("Indemnified Contributor") against any losses, damages and costs (collectively "Losses") arising from claims, lawsuits and other legal actions brought by a third party against the Indemnified Contributor to the extent caused by the acts or omissions of such Commercial Contributor in connection with its distribution of the Program in a commercial product offering. The obligations in this section do not apply to any claims or Losses relating to any actual or alleged intellectual property infringement. In order to qualify, an Indemnified Contributor must: a) promptly notify the Commercial Contributor in writing of such claim, and b) allow the Commercial Contributor to control, and cooperate with the Commercial Contributor in, the defense and any related settlement negotiations. The Indemnified Contributor may participate in any such claim at its own expense.

For example, a Contributor might include the Program in a commercial product offering, Product X. That Contributor is then a Commercial Contributor. If that Commercial Contributor then makes performance claims, or offers warranties related to Product X, those performance claims and warranties are such Commercial Contributor's responsibility alone. Under this section, the Commercial Contributor would have to defend claims against the other Contributors related to those performance claims and warranties, and if a court requires any other Contributor to pay any damages as a result, the Commercial Contributor must pay those damages.

5. NO WARRANTY

EXCEPT AS EXPRESSLY SET FORTH IN THIS AGREEMENT, THE PROGRAM IS PROVIDED ON AN "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, EITHER EXPRESS OR IMPLIED INCLUDING, WITHOUT LIMITATION, ANY WARRANTIES OR CONDITIONS OF TITLE, NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Each Recipient is solely responsible for determining the appropriateness of using and distributing the Program and assumes all risks associated with its exercise of rights under this Agreement, including but not limited to the risks and costs of program errors, compliance with applicable laws, damage to or loss of data, programs or equipment, and unavailability or interruption of operations.

6. DISCLAIMER OF LIABILITY

EXCEPT AS EXPRESSLY SET FORTH IN THIS AGREEMENT, NEITHER RECIPIENT NOR ANY CONTRIBUTORS SHALL HAVE ANY LIABILITY FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING WITHOUT LIMITATION LOST PROFITS), HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OR DISTRIBUTION OF THE PROGRAM OR THE EXERCISE OF ANY RIGHTS GRANTED HEREUNDER, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

7. GENERAL

If any provision of this Agreement is invalid or unenforceable under applicable law, it shall not affect the validity or enforceability of the remainder of the terms of this Agreement, and without further action by the parties hereto, such provision shall be reformed to the minimum extent necessary to make such provision valid and enforceable.

If Recipient institutes patent litigation against a Contributor with respect to a patent applicable to software (including a cross-claim or counterclaim in a lawsuit), then any patent licenses granted by that Contributor to such Recipient under this Agreement shall terminate as of the date such litigation is filed. In addition, if Recipient institutes patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Program itself (excluding combinations of the Program with other software or hardware) infringes such Recipient's patent(s), then such Recipient's rights granted under Section 2(b) shall terminate as of the date such litigation is filed.

All Recipient's rights under this Agreement shall terminate if it fails to comply with any of the material terms or conditions of this Agreement and does not cure such failure in a reasonable period of time after becoming aware of such noncompliance. If all Recipient's rights under this Agreement terminate, Recipient agrees to cease use and distribution of the Program as soon as reasonably practicable. However, Recipient's obligations under this Agreement and any licenses granted by Recipient relating to the Program shall continue and survive.

Everyone is permitted to copy and distribute copies of this Agreement, but in order to avoid inconsistency the Agreement is copyrighted and may only be modified in the following manner. The Agreement Steward reserves the right to publish new versions (including revisions) of this Agreement from time to time. No one other than the Agreement Steward has the right to modify this Agreement. IBM is the initial Agreement Steward. IBM may assign the responsibility to serve as the Agreement Steward to a suitable separate entity. Each new version of the Agreement will be given a distinguishing version number. The Program (including Contributions) may always be distributed subject to the version of the Agreement under which it was received. In addition, after a new version of the Agreement is published, Contributor may elect to distribute the Program (including its Contributions) under the new version. Except as expressly stated in Sections 2(a) and 2(b) above, Recipient receives no rights or licenses to the intellectual property of any Contributor under this Agreement, whether expressly, by implication, estoppel or otherwise. All rights in the Program not expressly granted under this Agreement are reserved.

This Agreement is governed by the laws of the State of New York and the intellectual property laws of the United States of America. No party to this Agreement will bring a legal action under this Agreement more than one year after the cause of action arose. Each party waives its rights to a jury trial in any resulting litigation.

Accessibility

Accessibility features help users who have a disability, such as restricted mobility or limited vision, to use information technology products successfully.

Documentation accessibility

The Linux on z Systems publications are in Adobe Portable Document Format (PDF) and should be compliant with accessibility standards. If you experience difficulties when you use the PDF file and want to request a Web-based format for this publication, use the Readers' Comments form in the back of this publication, send an email to eservdoc@de.ibm.com, or write to:

IBM Deutschland Research & Development GmbH
Information Development
Department 3282
Schoenaicher Strasse 220
71032 Boeblingen
Germany

In the request, be sure to include the publication number and title.

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute the information in any way it believes appropriate without incurring any obligation to you.

IBM and accessibility

Glossary

Advanced Encryption Standard (AES)

A data encryption technique that improved upon and officially replaced the Data Encryption Standard (DES). AES is sometimes referred to as Rijndael, which is the algorithm on which the standard is based.

asymmetric cryptography

Synonym for public key cryptography..

Central Processor Assist for Cryptographic Function (CPACF)

Hardware that provides support for symmetric ciphers and secure hash algorithms (SHA) on every central processor. Hence the potential encryption/decryption throughput scales with the number of central processors in the system.

Chinese-Remainder Theorem (CRT)

A mathematical problem described by Sun Tsu Suan-Ching using the remainder from a division operation.

Cipher Block Chaining (CBC)

A method of reducing repetitive patterns in cipher-text by performing an exclusive-OR operation on each 8-byte block of data with the previously encrypted 8-byte block before it is encrypted.

Cipher block length

The length of a block that can be encrypted or decrypted by a symmetric cipher. Each symmetric cipher has a specific cipher block length.

clear key

Any type of encryption key not protected by encryption under another key.

CPACF instructions

Instruction set for the CPACF hardware. CPACF functions for DES, TDES and SHA1 functions can be invoked by five new instructions as described in *z/Architecture Principles of Operation*. As a group, these instructions are known as the Message Security Assist (MSA).

Crypto Express4S (CEX4S)

Successor to the Crypto Express3 feature. The PCIe adapter on a CEX4S feature can be configured in three ways: Either as cryptographic accelerator (CEX4A), or as CCA coprocessor (CEX4C) for secure key encrypted transactions, or in EP11 coprocessor mode (CEX4P) for exploiting Enterprise PKCS #11 functionality.

A CEX4P only supports secure key encrypted transactions.

electronic code book mode (ECB mode)

A method of enciphering and deciphering data in address spaces or data spaces. Each 64-bit block of plain-text is separately enciphered and each block of the cipher-text is separately deciphered.

Federal Information Processing Standards (FIPS)

A standard published by the US National Institute of Science and Technology.

FIPS see *Federal Information Processing Standards*

libica Library for IBM Cryptographic Architecture.

master key (MK)

In computer security, the top-level key in a hierarchy of key-encrypting keys.

MSA Message Security Assist. See *CPACF instructions*.

Mode of operation

A schema describing how to apply a symmetric cipher to encrypt or decrypt a message that is longer than the cipher block length. The goal of most modes of operation is to keep the security level of the cipher by avoiding the situation where blocks that occur more than once will always be translated to the same value. Some modes of operations allow handling messages of arbitrary lengths.

modulus-exponent (Mod-Expo)

A type of exponentiation performed using a modulus.

National Institute of Standards and Technology (NIST)

A measurement standards laboratory and a non-regulatory agency of the United States Department of Commerce. It is the federal technology agency that works with industry to develop and apply technology, measurements, and standards.

NIST see *National Institute of Standards and Technology*

public key cryptography

In computer security, cryptography in which a public key is used for encryption and a private key is used for decryption. Synonymous with asymmetric cryptography.

Rivest-Shamir-Adleman (RSA)

An algorithm used in public key cryptography. These are the surnames of the three researchers responsible for creating this asymmetric or public/private key algorithm.

Secure Hash Algorithm (SHA)

A standardized cryptographic hash function to compute a unique (message) digest from a message in a way that is mathematically impossible to reverse. Different data can possibly produce the same hash value, but there is no way to use the hash value to determine the original data.

secure key

A key that is encrypted under a master key. When using a secure key, it is passed to a cryptographic coprocessor where the coprocessor decrypts the key and performs the function. The secure key never appears in the clear outside of the cryptographic coprocessor.

symmetric cryptogrphy

An encryption method that uses the same key for encryption and decryption. Keys of symmetric ciphers are private keys.

zcrypt device driver

Kernel device driver to access Crypto Express adapters. Formerly, a monolithic module called **z90crypt**. Today, it consists of multiple modules that are implicitly loaded when loading the **ap** main module of the device driver.
